Discovery of new angiotensin converting enzyme (ACE) inhibitors from medicinal plants to treat hypertension using an *in vitro* assay

Niusha Sharifi¹, Effat Souiri¹, Seyed Ali Ziai², Gholamreza Amin³ and Massoud Amanlou^{1,4*}

Abstract

Background and purpose of the study: Angiotensin converting enzyme (ACE) inhibitors plays a critical role in treating hypertension. The purpose of the present investigation was to evaluate ACE inhibition activity of 50 Iranian medicinal plants using an *in vitro* assay.

Methods: The ACE activity was evaluated by determining the hydrolysis rate of substrate, hippuryl-L-histidyl-L-leucine (HHL), using reverse phase high performance liquid chromatography (RP-HPLC). Total phenolic content and antioxidant activity were determined by Folin-Ciocalteu colorimetric method and DPPH radical scavenging assay respectively.

Results: Six extracts revealed > 50% ACE inhibition activity at 330 µg/ml concentration. They were *Berberis integrerrima* Bunge. (Berberidaceae) ($88.2 \pm 1.7\%$), *Crataegus microphylla* C. Koch (Rosaceae) ($80.9 \pm 1.3\%$), *Nymphaea alba* L. (Nymphaeaceae) ($66.3 \pm 1.2\%$), *Onopordon acanthium* L. (Asteraceae) ($80.2 \pm 2.0\%$), *Quercus infectoria* G. Olivier. (Fagaceae) ($93.9 \pm 2.5\%$) and *Rubus* sp. (Rosaceae) ($51.3 \pm 1.0\%$). *Q. infectoria* possessed the highest total phenolic content with 7410 ± 101 mg gallic acid/100 g dry plant. Antioxidant activity of *Q. infectoria* (IC₅₀ value 1.7 ± 0.03 µg/ml) was more than that of BHT (IC₅₀ value of 10.3 ± 0.15 µg/ml) and Trolox (IC₅₀ value of 3.2 ± 0.06 µg/ml) as the positive controls.

Conclusions: In this study, we introduced six medicinal plants with ACE inhibition activity. Despite the high ACE inhibition and antioxidant activity of *Q. infectoria*, due to its tannin content (tannins interfere in ACE activity), another plant, *O. acanthium*, which also had high ACE inhibition and antioxidant activity, but contained no tannin, could be utilized in further studies for isolation of active compounds.

Introduction

In 2000, 26.4% of the world's population suffered hypertension and it is predicted that this rate would increase by 60% in 2025 [1]. Since the proportion of hypertensive people will increase rapidly, new therapeutic approaches for management of hypertension are essential. High blood pressure is a silent killer, causing several serious diseases such as heart failure, kidney failure and stroke. There are a number of choices for the treatment of hypertension. Some treatments include diuretics, β -blockers, calcium channel blockers and angiotensin II

receptor blockers, the most common of which is angiotensin converting enzyme inhibitors.

Angiotensin converting enzyme, EC 3.4.15.1, is a zinc metalloproteinase that converts the angiotensin I (inactive decapeptide) to angiotensin II (a potent vasoconstrictor), and bradykinin (a hypotensive peptide) to inactive components [2]. High ACE activity leads to increased concentration of angiotensin II and hypertension. Therefore, development of agents that inhibit the conversion of angiotensin I to angiotensin II, and bradykinin to inactive components began as a therapeutic strategy to treat hypertension. ACE inhibitors such as captopril and lisinopril play key roles in treating hypertension and maintaining the electrolyte balance [3]. They are commonly used as they are safe and well tolerated with few side effects.

Tannins are plant polyphenolic compounds that precipitate proteins and interfere in the functions of many macromolecules including ACE. Therefore, plants with $\geq 50\%$ ACE inhibition activity would be further tested for the presence of tannins in order to eliminate false positives [4].

Furthermore, reactive oxygen species (ROS) play a significant role in cardiovascular diseases such as hypertension and congestive heart failure. In hypertensive patients, angiotensin II increases chronically and nicotinamide adenine dinucleotide phosphate (NADPH) oxidase is activated, which causes a rise in ROS. As a result, it is more beneficial for an antihypertensive drug to have antioxidant effect [5]. Phenolic compounds have antioxidant activity and are effective agents to prevent oxidative stress.

Natural products could be important sources of ACE inhibitors such as captopril, a synthetic antihypertensive drug, which is developed by changing and optimizing the structure of the venom of the Brazilian viper. Active substances derived from medicinal plants can also be a source of new ACE inhibitors. Moreover, some plants contain a great amount of phenolic compounds, so consequently, they have antioxidant activity.

In this study, some medicinal plants that are used to manage different diseases were screened to discover possible new ACE inhibition activity using an *in vitro* ACE inhibition assay. Among the plants tested, the most active ones were examined for total phenolic content and antioxidant activity.

Material and methods

Chemicals

Angiotensin converting enzyme (ACE) from rabbit lung, hippuryl-L-histidyl-L-leucine (HHL), 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid (HEPES) buffer, hippuric acid (HA) and captopril were purchased from Sigma-Aldrich Co. (England). HCl, KH_2PO_4 , methanol (HPLC grade), 2,2-diphenyl-1-picrylhydrazyl (DPPH), Folin-Ciocalteu reagent, Na_2CO_3 , gallic acid, butylated hydroxyl toluene (BHT), 6-hydroxy-2,5,7,8-tetramethylchroman-2-carboxylic acid (Trolox), FeCl_3 , NaCl, NaOH and dimethyl sulfoxide (DMSO) were purchased from Merck Co. (Germany). Ultrapure water was applied to prepare all of the aqueous solutions.

Apparatus

Enzymatic incubation was performed in a thermomixer eppendorf comfort (Germany). HPLC analysis was carried out by a Knauer liquid chromatograph, with an ODS Eurospher column (250×4.6 mm, 100–5; C18), protected by a C18 precolumn (Perfectsil Target, ODS-3 (5 μm)) and a 20 μl injection loop. A smartline Photodiode Array (PDA) detector 2850 (Knauer, Germany) was used to

detect analytes, and a Chromgate software version 3.3, was used for data processing. A Cecil UV/Vis spectrophotometer (series 9000) was utilized to measure the absorbances.

Plant materials

Some of the studied plants (41 plants) were purchased from a local herbal store located in Tehran, Iran (June 2011). *Rubus* sp. was collected from north of Iran, Mazandaran province (June 2012), and 8 other plants were collected from Herburatum of Faculty of Pharmacy, Tehran University of Medical Sciences (June 2011). All of the mentioned plants were identified by Prof. G. Amin. Voucher specimens of the collected plants were deposited in the Herbarium of Tehran University of Medical Sciences.

Preparation of crude extracts

Dried plant materials (1 g) were extracted with 20 ml methanol:water (80:20, v/v) at room temperature for 24 h and then over 2 h in an ultrasonic bath [6]. The extracts were filtered and concentrated under reduced pressure, using a rotary evaporator at room temperature and then they were lyophilized.

ACE inhibition assay

In this study, the assay method is based on the hydrolysis of the substrate HHL by ACE, and measuring the amount of HA using RP-HPLC [6-9]. HEPES buffer solution used in this assay was prepared by dissolving 50 mM HEPES and 300 mM NaCl in 1000 ml water and adjusting the solution to pH 8.3 by 1 M NaOH solution. The substrate solution (9 mM) was prepared by dissolving HHL (19.74 mg) in 5 ml of HEPES buffer. Herbal extract (1 mg) was dissolved in 1 ml of solvent containing buffer/DMSO (90:10, v/v) to provide 330 $\mu\text{g}/\text{ml}$ concentration (a comparable scale all over the world) [10].

First, ACE solution (25 μl) (80 mU/ml) was added to 25 μl of inhibitor solution (or solvent as negative control). After 3 min preincubation at 37°C , 25 μl substrate solution was added and the mixture was incubated at 37°C for 30 min with shaking at 300 rpm in an Eppendorf thermomixer. After 30 min, the reaction was stopped by addition of 50 μl of 1 M HCl and then the reaction mixture was subjected to RP-HPLC. The mobile phase was an isocratic system consisting of a mixture of 10 mM KH_2PO_4 (adjusted to pH 3 with H_3PO_4) and methanol (50:50, v/v). The flow rate was 1 ml/min and the injection volume was 20 μl . Analytes were detected by a PDA detector at the wavelength of 228 nm.

ACE inhibition measurement

ACE inhibition calculation was based on the ratio of the area under curve (AUC) of HA peak in an inhibitor

Table 1 Angiotensin converting enzyme (ACE) inhibition activity of the 50 studied plants*

Scientific name and plant family	Common name in Persian	Part used	Collection site	Medicinal use	Voucher No	Inhibition%

sample to that of negative control sample as it is expressed by equation 1:

$$\text{ACE inhibition (\%)} = \left[1 - \left(\frac{\text{AUC}_{\text{inhibitor}}}{\text{AUC}_{\text{control}}} \right) \right] \times 100$$

AUC_{inhibitor} : AUC of the HA peak with inhibitor

AUC_{control} : AUC of the HA peak of control sample without inhibitor

(1)

Gelatin salt block test (eliminating false positive results)

In order to detect tannins, extracts with ≥ 50% ACE inhibition activity were tested under gelatin salt block test.

Active extracts (200 mg) were dissolved in 4 ml water (50°C) and allowed to reach room temperature. To remove non-tannin compounds, a few drops of an aqueous 10% NaCl solution was added to the extracts. After filtration, the filtrate (1 ml) was added to four test tubes. Tube 1 contained 4–5 drops of 1% gelatin solution. Tube 2 contained 4–5 drops of 1% gelatin + 10% NaCl solution. Tube 3 contained 3–4 drops of 10% ferric chloride solution, and tube 4, was a control sample containing no reagent. Tube 1 and 2 were observed for the formation of precipitate, while tube 3 was observed for color [4].

The presence of greenish-blue or greenish-black color following the addition of ferric chloride indicates the presence of condensed tannins, and bluish-black color

accounts for the presence of pyrogallol type tannins (assuming that precipitation is the result of gelatin salt block test). The presence of greenish-black or bluish-black color after the addition of ferric chloride with negative gelatin salt block test indicated no tannins in that extract.

Total phenolic content (TP)

Folin-Ciocalteu colorimetric method [11] was used to determine the total phenolic content of extracts. First, Folin-Ciocalteu reagent (0.5 ml) was added to 0.5 ml of methanol extract solution (100 mg/ml). Then Na₂CO₃ (0.5 ml) (100 mg/ml) was added to the mixture. The absorbance was measured at 760 nm, after 60 min incubation at room temperature. Calibration curve of gallic acid in different concentrations (1, 10, 100, 500 and 1000 µg/ml) was prepared using the same method. Total phenolic content of each extract was calculated from calibration curve of gallic acid and reported as mg of gallic acid equivalent in 100 g dry of plant [12].

DPPH radical scavenging activity

The DPPH radical scavenging activity assay is a method for determining the ability of extracts to trap free radicals [13]. First, DPPH methanol solution (2.0 ml) (0.16 mM) was added to 2.0 ml of extract methanol solutions in different concentrations. Next the same sample was prepared with 2.0 ml methanol replacing extract methanol solution as control. After that the mixtures were vortexed for 1 min and left at room temperature for 30 min. Later the absorbance (Abs) were read at 517 nm. For calculating radical scavenging activity (RSA), the equation 2 was used:

$$\text{RSA (\%)} = [1 - (\text{Abs}_{\text{extract}} / \text{Abs}_{\text{control}})] \times 100$$

Abs_{extract} : Absorbance of the extract sample
Abs_{control} : Absorbance of the control sample

(2)

Radical scavenging activity of extracts was compared with those of BHT and Trolox as the positive controls.

Establishing the sensitivity of the ACE assay system

The half maximal inhibitory concentration (IC₅₀) value of captopril was determined from concentration - response curve by nonlinear regression, using GraphPad Prism software version 5, and it was compared with the value in the literature. The IC₅₀ value for captopril determined in this study was 25 ± 2.6 nM, which was close to the value (23 nM) in the literature [14].

Results

ACE inhibition activity

Table 1 illustrates scientific names, plant families, common names in Persian, parts used, collection sites, collection times, medicinal uses, voucher numbers and ACE inhibition activities of herbal extracts. Of a total of fifty herbal extracts, six extracts have shown inhibition activity more than 50% at 330 µg/ml concentration (Table 2). They were *B. integerrima* (88.2 ± 1.7%), *C. microphylla* (80.9 ± 1.3%), *N. alba* (66.3 ± 1.2%), *O. acanthium* (80.2 ± 2.0%), *Q. infectoria* (93.9 ± 2.5%) and *Rubus* sp. (51.3 ± 1.0%).

Tannin test

Out of six active extracts investigated in this study, only the extract of *Q. infectoria* produced a positive gelatin salt block test (Table 3). The presence of greenish-black

or bluish-black color after the addition of ferric chloride with negative gelatin salt block test indicated no tannins in other extracts.

Total phenolic content and radical scavenging activity

Oxidative stress plays a critical role in cardiovascular disease [15]. Phenolic compounds are responsible for antioxidant activity due to their ability for scavenging free radicals. Therefore, total phenolic content and radical scavenging activities of these six medicinal plants were determined (Table 4). Most of these six extracts had a large phenolic content. In DPPH radical scavenging assay, IC_{50} values of six plant extracts were determined and compared with those of BHT and Trolox as the positive controls (Table 4). *Q. infectoria* possessed more antioxidant activity (IC_{50} value of $1.7 \pm 0.03 \mu\text{g/ml}$), compared to that

of BHT (IC_{50} value of $10.3 \pm 0.15 \mu\text{g/ml}$) and Trolox (IC_{50} value of $3.2 \pm 0.06 \mu\text{g/ml}$).

Discussion

Hypertension, a worldwide illness, is a major factor in cardiovascular diseases that affects a large population of adults. One of the most effective medications for the treatment of hypertension is angiotensin converting enzyme inhibitors. Meanwhile, medicinal plants have been used for treating illnesses. Therefore, they can be important resources to develop new drug candidates [16].

As illustrated in Table 1 six extracts showed inhibition activity more than 50%, nineteen extracts showed inhibition activity less than 50% and 25 of them showed no inhibition activity at $330 \mu\text{g/ml}$ concentration. Among these active medicinal plants, three ones (*C. microphylla*,

Figure 2 The correlation between total phenolic content and DPPH radical scavenging activity for six plant extracts.

O. acanthium and *Rubus* sp.) are utilized for the treatment of hypertension in traditional medicine and this research revealed that the mechanism of action of the three mentioned plants in treatment of hypertension could be done through ACE inhibition.

In addition, Antihypertensive activity is reported in traditional medicine for similar species of the above mentioned plants including *Crataegus oxyacantha* [17], *Onopordon leptolepis* and *Onopordon carmanicum* [18].

Flavonoids [19], flavanols [20], flavonols [21], anthocyanins [22], isoflavones [23], flavones [24] and other phenolic compounds have proved to be effective in decreasing the ACE activity. Therefore, the above mentioned secondary metabolites could be responsible for ACE inhibition activity in these 6 active extracts.

On the other hand, such ACE inhibitors with antioxidant activity might be useful to treat other diseases which are caused as a result of a rise in ROS production [25].

The highest ACE inhibition activity ($93.9 \pm 2.5\%$) was observed at 330 $\mu\text{g/ml}$ concentration in *Q. infectoria*. It is clear that tannins are phenolic natural products that interfere in enzymatic activity. Consequently, we checked for its presence in our active extracts (extracts with $\geq 50\%$ ACE inhibition activity). Unfortunately, greenish-black color after the addition of ferric chloride with positive gelatin salt block test indicated the presence of condensed tannins in *Q. infectoria* extract. Therefore, in spite of high ACE inhibition and antioxidant activity, it is not the plant of choice for further studies to isolate the active compounds.

Among other active medicinal plants, three ones including *B. integerrima*, *C. microphylla* and *O. acanthium* possessed $> 80\%$ ACE inhibition activity. Out of the three mentioned plants, *O. acanthium* possessed more antioxidant activity (IC_{50} value of $7 \pm 0.09 \mu\text{g/ml}$), compared to that of *B. integerrima* (IC_{50} value of $15.3 \pm 0.2 \mu\text{g/ml}$) and *C. microphylla* (IC_{50} value of $13.1 \pm 0.2 \mu\text{g/ml}$). Therefore, because of high ACE inhibition and antioxidant activity, *O. acanthium* is a valuable medicinal plant for isolation of active compounds.

Furthermore, *N. alba* and *Rubus* sp. are moderate ACE inhibitors and after the above three mentioned plants, are valuable plants for isolation of active compounds in further studies.

Conclusions

Medicinal plants presented in Table 2 are potential sources for developing new ACE inhibitors (Figure 1) [26-31]. There was a linear relationship between total phenolic content and radical scavenging activity with equation formula, $y = 83.53x - 823.4$; $R^2 = 0.714$ (Figure 2). As shown in Tables 2, 3 and 4, in spite of possessing the highest ACE inhibition and antioxidant activity, *Q. infectoria* had tannin content. On the other hand, *O.*

acanthium, which also had high ACE inhibition and antioxidant activity containing no tannin, and could be used in further studies for isolation of active compounds.

Competing interests

The authors have no conflict of interests to declare.

Authors' contributions

NS: Performed the experimental work including plant extraction, biological tests, data interpretation, and manuscript preparation. ES: Was responsible for HPLC analysis. SAZ: Was involved in designing the experiments. GHA: Identified all plants. MA: Was responsible for the study registration, financial and administrative support, and also gave final approval of the version to be published. All authors read and approved the final manuscript.

Submit your next manuscript to BioMed Central and take full advantage of:

- Convenient online submission
- Thorough peer review
- No space constraints or color figure charges
- Immediate publication on acceptance
- Inclusion in PubMed, CAS, Scopus and Google Scholar
- Research which is freely available for redistribution

Submit your manuscript at
