JAROLÍMEK I. & ZALIBEROVÁ M. (1995): Ruderal plant communities of north-eastern Slovakia II. *Chenopodietea*, *Plantaginetea*. - Thaiszia - J. Bot., Košice, 5: 61-79. - ISSN 1210-0420.

Abstract: The second part of the results of phytocoenological study of ruderal vegetation in the north-eastern Slovakia is presented. 15 associations and communities of classes *Chenopodietea* and *Plantaginetea* are briefly characterized from the point of view of floristic composition, ecological conditions, and distribution in the territory studied. Phytocoenological tables of these syntaxa are added.

Keywords: ruderal plant communities, *Chenopodietea*, *Plantaginetea*, north-eastern Slovakia

This paper follows up the foregoing article (ZALIBEROVÁ & JAROLÍMEK 1995, Thaiszia - J. Bot. 5: 31-59.). The chapters Introduction, and Material and methods are brought in that article.

Description of plant communities

Matricario-Anthemitetum cotulae (Tab.14)

Species rich plant community of low aromatic therophyte herbs with optimum of development in late summer. In this time the most abundant species *Anthemis cotula* is in flower. Stands of the community regularly contain *Chamomilla suaveolens* and the group of trampled species such as *Plantago major*, *Poa annua*, *Polygonum arenastrum*, and *Potentilla anserina*. They often play role of subdominants. The community occurs in villages on moister poultry pastures and along foot-paths. Soils are enriched with nutrient from poultry mutes. *Matricario-Anthemitetum* is relatively frequent in the territory studied though it is rare in the other parts of Slovakia. Phytocoenological relevés were made mainly in Ondavská vrchovina highlands and Busov Mts. The community seldom occurs in some other orographic units.

Malvetum neglectae (Tab.14)

Low therophyte herbs prevail in the plant community medium rich in species. Beside dominant species *Malva neglecta* the nitrophilous species *Lamium album*, *Urtica dioica*, *U. urens*, and trampling tolerant species *Polygonum arenastrum* and *Plantago major* are frequent. *Malvetum neglectae* is typical rustic archeophyte plant community occurring on small areas in sunny to semishaded moist habitats enriched by liquid rubbish and poultry mutes. In comparison with the other regions of Slovakia the community is more frequent in the territory studied thanks to traditional way of life. Phytocoenological relevés were made in Beskydské predhorie foothills, Laborecká vrchovina and Ondavská vrchovina highlands and Spišsko-šarišské medzihorie basin.

Atriplex patula-community (Tab.15)

Rare, species rich plant community of tall therophyte herbs. Abundantly branched species *Atriplex patula* dominates the stands. *Chenopodium strictum* and *Matricaria perforata* play the role of subdominants. The community prefers habitats on recent

ruins and dumps of building material rests or nitrogen rich places near dung-heaps. Phytocoenological relevés were made in Ondavská vrchovina highlands.

Sisymbrietum sophiae (Tab.15)

Species poor plant community of therophyte herbs with dominant species *Descurainia sophia*. It was registered on two localities: 1. new bank near city fortification in Bardejov (Ondavská vrchovina highlands); 2. humus wastage from the farm in Nová Ľubovňa (Spišsko-šarišské medzihorie basin). The community belongs to rare plant communities in the territory studied like the majority of communities of alliance *Atriplici-Sisymbrium*. Its stands are short of winter therophyte grasses.

Chenopodietum stricti (Tab.15)

Species rich plant community of tall therophyte herbs with dominant species *Chenopodium strictum*. Only one relevé was made in the village Zborov in Ondavská vrchovina highlands on recent dump of building material rests. Probably it occurs in other orographic units.

Matricaria perforata-comm. (Tab.15)

Species poor plant community of middle tall therophyte herbs with optimum of development at the beginning of summer, when the dominant species *Matricaria perforata* is in flower. In recent years the community spreads on bank substratum of various composition over all Slovakia, mainly in warmer regions. In the territory studied it is not abundant till this time. Phytocoenological relevés were made only in Spišsko-šarišské medzihorie basin.

Lolietum perennis (Tab.16)

Mostly dense closed trampled lawns abundant in perennial grasses and herbs. Physiognomy of stands with height 15-25 cm mainly determines dominant species *Lolium perenne* together with the most frequent species, such as *Plantago major*, *Trifolium repens*, *Taraxacum officinale* agg., and *Poa annua*. The community occurs on trampled habitats of medium intensity of trampling on playgrounds, cemeteries and courtyards, and along roads and paths. *Lolietum perennis* is the most common trampled plant community in the region studied.

Prunello-Ranunculetum repentis (Tab.17)

Moderately trampled, medium rich in species plant community of hemicryptophyte herbs and grasses. Stands of the community are characterized by group of species, such as *Prunella vulgaris*, *Plantago major*, *Ranunculus repens*, *Bellis perennis*, *Agrostis stolonifera* and *Juncus tenuis*. They occur on semishaded to sunny habitats on forest roads. They occur less in villages on moderately shaded habitats along walls and houses. Soils are fresh moist, clayey, in villages with admixture of anthropogenic skeleton. Phytocoenological relevés were made in Čergov Mts., Busov Mts., Ondavská vrchovina highlands, and Spišsko-šarišské medzihorie basin, but we assume the community is common on suitable habitats in all studied territory.

Matricario-Polygonetum arenastrum (Tab.18)

Community with dominant species *Polygonum arenastrum* builds up carpet stands with small or bigger gaps on the most intensively trampled open and sunny habitats in cities and villages. Soils are clay-and-sand, often loose and quickly drying with high content of anthropogenic skeleton, such as gravel and slag. The community occurs more rare in the studied territory than in the other, especially south regions of Slovakia. It was found in Ondavská and Laborecká vrchovina highlands, Beskydské predhorie foothills and in Spišská Magura Mts.

Herniarietum glabrae (Tab.17)

Medium rich to rich in species, two layer plant community. Spread and creeping herbs such as *Herniaria glabra*, *Medicago lupulina*, *Trifolium repens*, and *Potentilla argentea* dominate the stands of the community. In the gaps among them species *Arenaria serpyllifolia*, *Acinos arvensis*, *Cerastium holosteoides*, and some species of class *Plantaginetea majoris* grow. Habitats of the community are sunny and warm. Soils are dry, light, sandy with high content of skeleton. The stands were found on gravel terraces near streams, on field roads on dams along streams, seldom on fine gravel covered public grounds. The community is rare in the territory studied. It was found only in Spišsko-šarišské medzihorie basin and in Ondavská vrchovina highlands.

Poa annua-community (Tab.19)

Therophyte grass *Poa annua* dominates fresh green carpet trampled low and thin lawns. Besides it the species *Plantago major*, *Trifolium repens* and *Taraxacum officinale* agg. were found with highest constancy in the stands. The community occurs on trampled places near family houses, on courtyards, on public grounds, and near roads mainly in villages, less in cities. Habitats are semishaded, scarcely ever sunny. Fresh moist clayey to clay-and-sand soils seldom contain admixture of slag or fine gravel. *Poa annua*-community belongs to the most common ruderal plant communities in north-east part of Slovakia. Phytocoenological relevés were made almost in all orographic units of the territory studied.

Chamomilla suaveolens-community (Tab.20)

Low therophyte herbs and grasses build up a thin stands on trampled habitats on periphery of playgrounds, along field roads, on farm courtyards and on public places mainly in villages. Soils are fresh moist to dry, clayey, sometimes with admixture of gravel. Dominant species *Chamomilla suaveolens* determines a physiognomy of stands. Some species are present with high constancy such as *Capsella bursa-pastoris*, *Plantago major*, and *Taraxacum officinale* agg. The community occurs in the territory studied, in comparison with southern part of Slovakia, rather frequently. Phytocoenological relevés were made in Spišsko-šarišské medzihorie basin and Ondavská vrchovina highlands.

Chamomilla recutita-community (Tab.17)

Seldom seen plant community with dominant species *Chamomilla recutita*. Its stands occur on trampled habitats on moist to dry soils, sometimes with admixture of sand and gravel. They are tolerant to pasture of poultry. The community is limited to villages. It

was found on two localities in Ondavská vrchovina highlands and in Spišsko-šarišské medzihorie basin. Occurrence on other places inside closed courtyards is probable.

Potentilla anserina-community (Tab.21)

Species medium rich plant community of low (3-10 cm) perennial herbs and grasses forms usually compact, dense silver-green carpet stands. *Potentilla anserina* determines their appearance. *Plantago major*, *Taraxacum officinale* agg., *Trifolium repens*, and *Rumex obtusifolius* occur in the stands with lower cover and high constancy. They are optimally developed on goose pastures. Soils are saturated with nutrient from poultry mutes. Stands are selectively affected by pasture of poultry. They are less frequent in moister trampled habitats in microdepressions or along roads and lawns. The community is typical in villages. In towns it occurs seldom in periphery. Phytocoenological relevés were made in Ondavská and Laborecká vrchovina highlands and in Spišsko-šarišské medzihorie basin.

Potentilla reptans-community (Tab.17)

Moderately trampled, species poor plant community with dominant species *Potentilla reptans* was found on semishaded moist habitats along walls and brooks on two localities in Spišsko-šarišské medzihorie basin and Ondavská vrchovina highlands. Syntaxonomic classification is makeshift and it needs next study.

Discussion

The list of communities and their characteristics show that the ruderal vegetation is relatively diversified in north-eastern Slovakia. 38 associations and communities belonging to five classes were found. Trampled communities of the order *Plantaginealia* (e.g. *Lolietum perennis*, *Poa annua*-community, *Potentilla anserina*-community) unambiguously prevail during the whole vegetation season (cf. ZALIBEROVÁ 1994). In spring and early summer tall-herb plant communities of the order *Lamio albi-Chenopodietalia boni-henrici* (e.g. *Chaerophylletum aromatici*, *Anthriscus sylvestris*-community, *Urtico-Aegopodietum*) stand out. In the summer the communities of *Onopordetalia* have their symphenological optimum (e.g. *Arctietum lappae*, *Tanacetum-Artemisietum*). In late summer and autumn the *Polygono-Bidentetum* (*Bidentetalia*) and the *Aegopodio-Geranium pratense* (*Lamio albi-Chenopodietalia boni-henrici*) dominate.

On the base of phytocoenological relevés we can intimate that thermophilous plant communities of the order *Onopordetalia*, especially of alliances *Onopordion acanthii* and *Dauco-Melilotion pterum* out in the territory studied (*Onopordetum acanthii*, *Potentilla argenteae-Artemisietum absinthii*, *Echio-Melilotetum*). Moister climate and prevailing of clayey soils cause that the communities lack xerothermophilous species of winter grasses such as *Bromus tectorum*, *B. sterilis*, *Hordeum murinum*. The species *Reseda lutea* is also missing. Species composition of *Sisymbrietum sophiae* (order *Sisymbrietalia*) was changed similarly. Low presence and abundance of *Arction*- and *Onopordetalia*- species and higher occurrence of *Galio-Urticetea*- species such as *Urtica dioica*, *Glechoma hederacea*, *Lamium album* and *Heracleum sphondylium* in

the *Tanaceto-Artemisietum* complicates the classification of the association into higher syntaxa.

Climatic conditions and traditional way of life of inhabitants allow the development and relatively frequent occurrence of communities which are rare or absent in other regions of Slovakia, such as *Matricario-Anthemitetum cotulae* and *Malvetum neglectae* from the alliance *Malvion neglectae* and *Herniarietum glabrae* and *Chamomilla recutita*-community from alliance *Polygonion avicularis*.

Communities *Urtico urentis-Chenopodietum boni-henrici* (*Arction*), *Alliario-Chaerophylletum temuli* (*Galio-Alliarion*), *Sisymbrietum strictissimi* (*Aegopodion podagrariae*), *Bidentetum cernui* (*Bidention tripartiti*) were found rarely in north-eastern Slovakia. They are rare or in retreat throughout Slovakia. The association *Catabroso-Polygonetum hydropipers* is the most interesting one of the last mentioned alliance. It is very rare in the warmest regions of southern and eastern Slovakia (OŤAHELOVÁ & al., 1984). In the territory studied it occurs more frequently. Following the recent knowledge we assume that community is related just to flysh region of north-eastern Slovakia.

We registered only two taxa included into the Red list of ferns and flowering plants of Slovakia (MAGLOCKÝ & FERÁKOVÁ 1993) among all species building ruderal plant communities. *Geum aleppicum* (category vulnerable) occurs in the stands of *Chelidonium majus*-community and *Poa annua*-community in the villages Bodružal, Jakubany, and Stará Ľubovňa. *Lythrum hyssopifolia* (category indeterminate) was registered in the stand of association *Polygono-Bidentetum* in the village Dlhé nad Cirochou.

Acknowledgements

Authors are indebted to Dr. T. KRIPPELOVÁ, CSc. for providing unpublished phytocoenological relevés, to Dr. S. KVARTEKOVÁ and Dr. J. ZLINSKÁ, CSc. for help in the field, and to K. KRAJČOVIČOVÁ and B. WOLFOVÁ for technical assistance. The study has been supported by Slovak Academy of Sciences, Grant no. 1178.
