STRELITZIA

This series has replaced *Memoirs of the Botanical Survey of South Africa* and *Annals of the Kirstenbosch Botanic Gardens,* which SANBI inherited from its predecessor organisations.

The plant genus *Strelitzia* occurs naturally in the eastern parts of southern Africa. It comprises three arborescent species, known as wild bananas, and two acaulescent species, known as crane flowers or bird-of-paradise flowers. The logo of the South African National Biodiversity Institute is partly based on the striking inflorescence of *Strelitzia reginae*, a native of the Eastern Cape and KwaZulu-Natal that has become a garden favourite worldwide. It symbolises the commitment of the Institute to champion the exploration, conservation, sustainable use, appreciation and enjoyment of South Africa's exceptionally rich biodiversity for all people.

Preface

This significant work is the first complete account of the Iridaceae in southern Africa to have appeared for over a century, and consolidates our knowledge of this diverse and important family. It comprises a full taxonomic account of the Iridaceae for all of southern Africa, including South Africa, Botswana, Lesotho, Namibia and Eswatini. It is presented in a formal botanical way, with a description of the family, plus identification keys and descriptions of the four subfamilies that occur in southern Africa. Subfamily Aristeoideae comprises only the African and Madagascan genus *Aristea*; Nivenioideae includes the three shrubby genera *Klattia, Nivenia* and *Witsenia*, all endemic to the Western Cape, South Africa; Crocoideae, with 28 genera, is the most diverse; and Iridoideae includes just four genera. We provide identification keys and descriptions to the genera (including subgenera, sections and series) in each subfamily and keys to the species and infraspecific taxa. The bulk of the treatment is devoted to accounts of the species, including brief narratives about relationships. Geographic ranges and ecology are described, supplemented by distribution maps. Full nomenclature and synonymy for all names applying to southern African taxa are provided.

Iridaceae include an estimated 70 genera and perhaps 2 160 species worldwide. Southern Africa, with 36 genera and 1 210 species, or slightly more than half the family, is a major centre of diversity for Iridaceae. Most of the southern African species are restricted to the subcontinent, with by far the greatest number found in the winter-rainfall belt in the southwest of the region but with an important secondary centre along the Drakensberg Escarpment of KwaZulu-Natal and Lesotho.

Moraea, with 209 species in southern Africa out of a total of 230, is the largest genus in the region, followed by *Gladiolus*, with 169 species in southern Africa out of a total of 272 species. This is nearly as many as *Iris*, the largest genus of Iridaceae, with an estimated 275 species. The southern African Iridaceae include several more unusually large genera, notably *Geissorhiza* with 104 species, *Ixia* with 100 species, *Babiana* with 93 species and *Hesperantha* with 87 species. At the opposite pole are the monospecific genera *Afrocrocus*, *Devia*, *Duthiastrum*, *Melasphaerula*, *Pillansia* and *Schizorhiza*.

The taxonomy presented here is the result of revisionary and pollination studies begun in 1970 and continued until 2016, at which time all the southern African genera had been reviewed or fully revised, often in light of molecular phylogenetic research. Major changes to traditional generic circumscriptions that were implemented during this period include the reduction of *Anomalesia* and *Homoglossum* in *Gladiolus* in 1989, and the inclusion of *Galaxia, Gynandriris, Hexaglottis* and *Homeria* in *Moraea* in 2000. The genus *Lapeirousia*, in contrast, has recently been restricted in its circumscription, with the remaining species segregated among the genera *Afrosolen*, *Codonorhiza* and *Schizorhiza*. We also include a refined, phylogeny-based classification for Crocoideae.

The publication of this work represents the culmination of well over two and a half centuries of taxonomic study of this remarkable plant family in southern Africa. The taxonomic paradigms under which the accounts of the genera and species were produced have changed markedly over that time. The advent of cladistic methods represented a watershed in our interpretation of morphological characters, and the development of DNA-based phylogenetic study has introduced an era of unprecedented understanding of evolutionary relationhsips. These advances are reflected in the taxonomy that we present here, representing the first unified treatment for the family in southern Africa in over a century.

Acknowledgements

We are indebted to Nicole Meyer for her meticulous editing of the manuscript, and to Hannelie Snyman for developing and generating the distribution maps for the species. We also thank many of our colleagues who helped us with field work, library resources and often complex nomenclatural questions: in particular we are grateful to Roy Gereau, Anne-Lise Fourie, Ingrid Nänni, Lendon Porter, Mary Stiffler and Jan Vlok. Most of the field work was funded through grants awarded to us from the US National Science Foundation and the National Geographic Society. We are especially indebted to Peter Raven for his endless encouragement, and to Elizabeth Parker and the Mapula Trust for their ongoing and unstinting support. Thanks are due also to Yolande Steenkamp for the final editing, and Elizma Fouché for her inspired design and layout.

Abstract

This is the first complete taxonomic treatment for Iridaceae in southern Africa (including Botswana, Lesotho, Namibia, South Africa and Eswatini) since the publication of J.G. Baker's account in *Flora capensis* (1896). It treats a total of 1 210 species in 36 genera, classified in the four subfamilies **Aristeoideae** (*Aristea* 46 spp.), **Nivenioideae** (*Nivenia* 11 spp., *Klattia* 3 spp. and *Witsenia* 1 sp.), **Crocoideae** tribe Tritoniopsideae (*Tritoniopsis* 23 spp.), tribe Watsonieae (*Watsonia* 53 spp., *Pillansia* 1 sp., *Thereianthus* 11 spp., *Micranthus* 7 spp., *Codonorhiza* 7 spp., *Schizorhiza* 1 sp., *Lapeirousia* 27 spp. and *Afrosolen* 11 spp.) and tribe Ixieae subtribes Gladiolinae (*Gladiolus* 169 spp.), Melasphaerulinae (*Melasphaerula* 1 sp.), Freesiinae (*Xenoscapa* 3 spp., *Freesia* 16 spp., *Crocosmia* 7 spp. and *Devia* 1 sp.), Hesperanthinae (*Geissorhiza* 104 spp. and *Hesperantha* 87 spp.), Tritoniinae (*Babiana* 93 spp., *Chasmanthe* 3 spp., *Sparaxis* 16 spp., *Duthiastrum* 1 sp., *Dierama* 37 spp., *Tritonia* 30 spp. and *Ixia* 100 spp.), subtribe Radinosiphoninae (*Radinosiphon* 2 spp.) and Crocinae (*Romulea* 84 spp., *Afrocrocus* 1 sp. and *Syringodea* 7 spp.), and **Iridoideae** (*Dietes* 5 spp., *Bobartia* 17 spp., *Ferraria* 15 spp. and *Moraea* 209 spp.). A revised, phylogeny-based tribal and subtribal classification is presented here for Crocoideae, correlating with corm ontogeny and seed characteristics. Keys are provided to subfamilies, tribes and genera (and in the case of larger genera to subgenera or sections) as well as to species and infraspececific taxa. Each species is fully described with complete nomenclature, geographic range and a distribution map. Genera are illustrated with line drawings, and nearly half of the species are illustrated with colour photographs. Four new species are described, **Bobartia vlokii** *Goldblatt & J.C.Manning,* **Geissorhiza adriaanii** *Goldblatt & J.C.Manning,* **Hesperantha mtamvunae** *Goldblatt & J.C.Manning* and **Romulea fuscomontana** *J.C.Manning & Goldblatt*, and a number of names are synonymised.

Keywords: classification; Flora; new species; nomenclature; synonymy; taxonomy

Introduction

The family Iridaceae is almost worldwide in distribution, and numbers some 2 250–2 300 species divided among six subfamilies. Southern Africa, comprising the subcontinent south of the Cunene–Limpopo axis (i.e. Botswana, Lesotho, Namibia, South Africa and Eswatini), is a major centre of radiation, accounting for slightly more than half the family, or 1 210 species in 36 genera. This represents nearly a threefold increase in the number of species that were recognised in the last comprehensive treatment of the family in southern Africa by Baker (1896), in which 428 species were listed. The circumscription of several genera has also altered substantially since then, with just 22 of the 32 genera accepted by Baker (1896) still recognised. This is largely a result of the realisation of the influence that pollination systems have on floral morphology (Goldblatt & Manning 2006), and of the role that cladistic and phylogenetic techniques have played in improving our understanding of relationships among the species and genera (Goldblatt & Manning 2008).

Almost all of the southern African species and most of the genera are endemic to the subcontinent, with just a few shared with adjacent tropical Africa and Madagascar. Crocoideae, with 866 species in the region, is the largest subfamily. Centred in the winter-rainfall area in the southwest, it includes 32 genera, of which *Gladiolus* L. and *Romulea* Maratti are shared with western Eurasia while a third, *Crocus* L., is restricted to North Africa and Eurasia. Iridoideae, with 246 southern African species in four genera, also occurs in Eurasia and the Americas, and includes the Eurasian and North American genus *Iris* L., as well as the largely African genus *Moraea* Miller. Aristeoideae, comprising only the single genus *Aristea* Aiton, is likewise centred in southern Africa, where 46 species are recorded, a few of them shared with tropical Africa, while several more occur in Madagascar. Subfamily Nivenioideae, with three genera and 15 species, is restricted to the Cape Floristic Region of South Africa and includes the shrubby members of the family, representing a remarkable growth form for Iridaceae.

All Crocoideae and most Iridoideae are seasonal geophytes with underground storage organs, termed corms, formed by modified, highly contracted stems. The corms of Crocoideae differ in anatomy and ontogeny from those of Iridoideae, and the two types have evolved independently from ancestors with rhizomatous rootstocks. *Dietes* Salisb. ex Klatt and *Bobartia* L. (Iridoideae) and *Aristea* (Aristeoideae) are evergreen herbs, as are a few species of *Watsonia* Miller and *Tritoniopsis* L.Bolus (Crocoideae). The remaining species of Crocoideae and Iridoideae are deciduous herbs that retreat underground in the dry season. In contrast, species of Nivenioideae are evergreen shrubs with multiple branches produced from a large, woody, fire-restistant underground stem termed a caudex.

Leaves of most Iridaceae are oriented fan-wise in a single plane with the blades usually upright and unifacial (isobilateral), i.e. with both sides anatomically and morphologically identical. The margins of these leaves sometimes show marked anatomical developments, often thickened but sometimes raised into broad wings, and the midveins may also be strongly raised, rendering the leaf cross-shaped in section. These elaborations are most common in some of the winter-rainfall lineages, especially *Geissorhiza* Ker Gawl., *Gladiolus* and *Tritonia* Ker Gawl. In contrast, the leaves of *Crocus, Moraea* and *Syringodea* Hook.f. are secondarily bifacial and often channelled, with the upper and lower faces dissimilar. The ecophysiological aspects of these various foliar elaborations remain to be explored.

Flowers of Iridaceae are often their most striking feature, and have largely informed previous understandings of relationships within the family. Floral morphology varies greatly, often within a single genus, and we have only recently appreciated that much of this variation represents adaptations for a wide range of insect and bird pollinators. Indeed, the majority of species of Iridaceae are specialised for pollination by one or a few classes of pollinators, some of which are unusually well developed in southern Africa. The pollination biology of the family in the subcontinent is relatively well studied, and recorded pollinators include female pollen-collecting bees, large-bodied, long-tongued apid and anthophorine bees, short-tongued oil-collecting bees, long-proboscid flies, short-proboscid dung, game and muscid flies, settling and hovering moths, butterflies, hopliine beetles, and sunbirds. Some important insights have emerged through combining our understanding of evolutionary relationships among species with our knowledge of their pollination biology. These include evidence that the evolution of the zygomorphic flower in Crocoideae represents a key innovation that has accellerated the variety of pollination systems that such flowers can exploit compared with radially symmetrical forms (Goldblatt & Manning, 2006).

IRIDACEAE Jussieu

Perennial evergreen or deciduous herbs, rarely annuals or shrubs with anomalous secondary growth. *Rootstock* a rhizome, bulb, corm, or a woody caudex when shrubs. *Leaves* basal and cauline, sometimes lower 2 or 3 without blades, sheathing base of stem and reaching shortly above ground (thus cataphylls), mostly in two opposed ranks, bases usually overlapping and clasping the one above, sheaths of foliage leaves open or closed, usually contemporary with flowers, occasionally produced later, rarely already dry at flowering, occasionally leaves of flowering stem with reduced to entirely sheathing blades, then foliage leaves sometimes produced from separate shoots; blades either unifacial and oriented edgewise to stem, parallel-veined, with or without distinct central vein, plane or pleated or occasionally oval to round in section; or bifacial and oriented with adaxial surface facing stem, then channelled to flat and usually without median vein; margins plane or sometimes undulate to crisped, sometimes thickened and fibrotic or raised into wings at right angles to surface. *Flowering stems* aerial or subterranean, simple or branched, round in section or compressed, then often angled or winged. *Inflorescence* either composed of umbellate monochasial cymes (rhipidia) enclosed in opposed leafy to dry bracts (spathes) with flowers usually pedicellate, sometimes sessile, each flower within a rhipidium subtended by one bract; or flowers sessile, subtended by a pair of opposed bracts and arranged in a spike, or solitary. *Flowers* bisexual, with a petaloid perianth of 2 whorls of 3 tepals each, rarely inner whorl reduced or lacking, radially or bilaterally symmetric and then usually bilabiate, variously coloured, often with contrasting markings; fugacious or long-lasting; scented or unscented; tepals usually large and showy, free or united below in a tube, whorls equal or unequal, when zygomorphic the posterior tepal usually largest and inclined to hooded, lower 3 often smallest and with contrasting markings (nectar guides); tube when present straight or curved, cylindric or funnel- to trumpet-shaped. *Stamens* 3 (2 in Australian *Diplarrena*), opposite outer tepals, arising at base of outer tepals or within floral tube, symmetrically disposed or unilateral and arcuate or sometimes declinate; filaments filiform, free or partly to completely united; anthers 2-thecous, usually extrorse and splitting longitudinally, occasionally splitting laterally or at apex or base. *Ovary* inferior (superior in Australian *Isophysis*), 3-locular with axile placentation (rarely 1-locular with parietal placentation); ovules anatropous or campylotropous, many to few, in 2 rows (rarely 1 row) per locule; style filiform, 3-branched or 3-lobed, style branches either filiform (sometimes very short) to distally expanded, sometimes each divided in upper half and stigmatic towards apices, or branches thickened or flattened and petaloid, stigmas then abaxial below apices. *Fruit* a loculicidal capsule, rarely indehiscent, firm to cartilaginous, occasionally woody, xerochastic or rarely hygrochastic. *Seeds* globose to angular or discoid, sometimes broadly winged, usually dry, rarely seed coat fleshy or an aril present, rugulose or smooth, shiny or matte; endosperm hard, with reserves of hemicellulose, oil and protein; embryo small. *Pollen grains* monosulcate, trisulcate, disulculate, zonasulculate, dizonasulculate, spiraperturate or inaperturate, operculate or not, exine reticulate to areolate, micropunctate, or perforate-scabrate.

Key to subfamilies

1a Plants evergreen shrubs with woody aerial stems; rootstock a woody caudex; individual flowers sessile, the tepals united in a well-developed tube; flowers lasting at least two days . . . . . 2. NIVENIOIDEAE

1b Plants perennial, either with herbaceous aerial stems or acaulescent, sometimes evergreen; rootstock a rhizome or corm; individual flowers stalked or sessile, the tepals free, basally connate, or united in a tube; flowers variously long-lived or lasting < 1 day and deliquescing on fading:

2a Flowers sessile and subtended by a pair of opposed bracts, usually arranged in a spike or solitary on branches; tepals always united in a tube below; flowers lasting at least 2 days; style dividing into filiform branches, rarely simple; rootstock a corm producing roots from the base; pollen grains usually with perforate scabrate exine, rarely exine reticulate, aperture usually with operculum unless zonasulculate; nectaries present, septal. 3. CROCOIDEAE

2b Flowers usually pedicellate or sometimes sessile, in umbellate clusters (rhipidia) enclosed by a pair of opposed leafy bracts (spathes), rarely solitary on the peduncles or plants acaulescent but then style either dividing below the anthers into tangentially compressed, petal-like branches or dividing below or above the base of the anthers and obscurely 3-lobed apically, the lobes entire or fringed; tepals free to basally connate, or united in an extended tube; flowers lasting < 1 day or 2 or more days; rootstock a rhizome or a corm rooting from the apical bud; pollen grains usually with reticulate or microreticulate exine, rarely rugulate or areolate, aperture usually without an operculum; nectaries septal or perigonal or oil glands present:

3a Rhipidia (at least the terminal) united in pairs (binate); style notched or divided apically into 3 lobes, occasionally forming filiform branches; nectaries rarely present, then perigonal . . . . . 1. ARISTEOIDEAE

3b Rhipidia never united in pairs; style dividing below level of anthers into 3 branches, these either filiform and extending between the stamens, or thickened or flattened and lying opposite the stamens, each usually terminating in paired appendages (style crests); nectaries or oil glands when present perigonal. . . . . 4. IRIDOIDEAE

1. Subfamily **ARISTEOIDEAE**

Aristeoideae *Vines*, A student's text-book of botany: 569 (1895). Type: *Aristea* Aiton

Evergreen perennials with a creeping or ± erect rhizome. *Leaves* unifacial, without a midrib, several, basal and cauline. *Inflorescence units* binate rhipidia enclosed in paired, opposed leafy or dry spathes, often many units per flowering stem. *Flowers* fugaceous, lasting single day, radially symmetric, without nectaries or with perigonal nectaries (only *Aristea spiralis*); tepals united basally, spreading. *Stamens* with the filaments free; anthers loculicidal and extrorse or porose (Madagascan species); pollen grains variable, most commonly monosulcate, zonasulculate, or dizonasulculate, exine reticulate, microreticulate, or rugulate, exine masses covering apertures in subg. *Eucapsulares*. *Ovary* inferior; style slender, dividing into 3 entire or fringed lobes or apically 3-notched. *Capsules* ± woody, ovoid, prismatic and 3-lobed, or oblong with locules compressed into narrow radial wings. *Seeds* angular, triangular-columnar, or lamellate. *Basic chromosome number x* = 16.

Genera 1, species ± 58: sub-Saharan Africa and Madagascar, 46 in southern Africa.

1. **Aristea**

Aristea *Aiton*, Hortus kewensis: 67 (1789), conserved name; Weimarck: 1–140 (1940). Type: *A. africana* (L.f.) Hoffmanns.

Cleanthe Salisb. ex Benth. & Hook.f.: 684, 701 (1883). Type: *C. melaleuca* [Thunb.] Salisb. ex Pax = *Aristea lugens* (L.f.) Steud.

Revisionary accounts: Weimarck (1940); Goldblatt & Manning: 137–144 (1997a), 357–365 (1997b).

From the Greek, *arista*, an awn, a dry, acute-tipped bract-like structure, as in the dry, fringed spathes and bracts of the type species, *Aristea africana*.

Evergreen herbs with short to long rhizomes or aerial stolons (*A. singularis*). *Stems* rounded to compressed and 2-angled or 2-winged, simple or few- to many-branched. *Leaves* sword-shaped to linear or terete, in two ranks, crowded basally, usually with a few progressively smaller leaves above; without marginal vein or subepidermal sclerenchyma, marginal epidermal cells thickened, columnar. *Inflorescence* simple or compound, composed of one or more binate rhipidia (flower-clusters in 2 series, unless reduced to 1 flower); lateral clusters stalked or sessile; spathes enclosing flowers green, rust-coloured, or partly to entirely membranous or dry and papery, margins entire, irregularly torn, or fringed; floral bracts (within spathes) similar but usually smaller, forked apically, often 2-keeled. *Flowers* actinomorphic, upright or half to fully nodding, mostly fugaceous, lasting a single day (rarely 2 days), pedicellate or often subsessile, perianth twisting spirally on fading, persisting on ovary, usually dark blue, sometimes pale blue, white, mauve, or pink, occasionally with contrasting markings, scentless; with nectar from perigonal nectaries only in *A. spiralis*; tepals basally connate for 0.5–2.0(3.0) mm, subequal, or outer tepals shorter, always narrower than inner, oblanceolate to obovate, usually spreading horizontally, sometimes ascending. *Stamens* free; filaments filiform (unequal in *A. inaequalis*); anthers oblong to linear. *Ovary* top-shaped, triangular-columnar or oblong, with ovules opposite in 2 rows or alternating, forming a single row; style filiform, eccentric, either minutely 3-notched or divided into spreading, ± subentire or deeply fringed stigmatic lobes. *Capsules* ovoid to oblong or cylindric, rounded in section or shallowly to deeply 3-lobed, or broadly 3-winged, subsessile or stalked, remains of perianth persisting on developing capsule. *Seeds* rounded to angular (prismatic), shortly cylindric, triangular-columnar, or radially compressed and lamellate, with foveate sculpturing or smooth, many per locule or only 1 or 2. *Pollen grains* monosulcate, trisulcate, disulculate, zonasulculate or spiraperturate, sometimes exine covering aperture, exine reticulate to microreticulate or rugose. *Basic chromosome number x* = 16.

Species ± 58: 46 in southern Africa and most diverse there; extending through tropical Africa to Senegal and Ethiopia in the north, 8 in Madagascar; most frequent in well-watered highlands in grassland, rocky outcrops, or marshes; in the southern African winter-rainfall zone often montane and in rocky sandstone habitats, frequently flowering in mass after fires.

ARISTEA. A. ecklonii: A, flowering plant. ***A. torulosa***: B, inflorescence; C, flower; D, stigma. ***A. abyssinica***: E, fruiting plant.

Displaying relatively modest variation in floral structure, species of *Aristea* vary remarkably in their pollen grains and in their fruit and seed morphology. Pollen grains in subg. *Eucapsulares* are mostly inaperturate or have exine covering the apertures rendering them difficult to identify, and the exine is usually rugose to rugulose; in subg. *Aristea* pollen grains are either monosulcate (rarely zonasulculate) or spiraperturate; in subg. *Pseudaristea* pollen grains are dizonasulculate with reticulate exine. Capsules and seeds vary from ovoid-ellipsoid to cylindric-3-lobed (subg. *Eucapsulares*) to broadly radially winged (sect. *Racemosae*). Seeds are prismatic to subglobose in many members of subg. *Eucapsulares*, cylindric or cylindric-triangular in subg. *Pseudaristea,* and flattened and lamellate in most members of subg. *Aristea.* The variation in fruit and seed structure is largely congruous with pollen variation and forms the basis for the current infrageneric taxonomy, which recognises three subgenera. This corresponds broadly with preliminary molecular data.

Floral morphology in *Aristea* is conservative, most species having blue flowers with the tepals united only basally, and yellow anthers. The flowers last a single morning, deliquescing after midday. No nectar is produced and pollination is by pollen-collecting female bees. Only species of subg. *Pseudaristea* depart from this pattern, having blue to white or pink flowers, often with dark markings or sometimes dark brown to almost black outer tepals, as in *A. lugens*. Pollination of most these species is by hopliine beetles that use the flowers for assembly and mating. Flowers of *A. spiralis* are unique in the genus in secreting nectar from perigonal nectaries and are recorded as being pollinated by long-proboscid flies.

Key to subgenera

Note: only well developed basal leaves should be examined; the cauline leaves are usually smaller and grade into bracts subtending branches. Measure leaf width at about the middle of a leaf. A hand lens is essential for examining spathe and bract characters, as well as seed features, including presence of marginal papillae and surface sculpturing. Individual inflorescence units (binate rhipidia) are referred to simply as flower clusters.

1a Capsules elongate, leathery to ± woody when dry, 20–70 mm long, tardily dehiscent; ovary on pedicels 5–18(–25) mm long, cylindric-trigonous or cylindric-triangular, 8–17(–22) mm long; style dividing into three spreading lobes, each deeply fringed; pollen grains with 2 ring-like apertures (dizonasulculate) . . . . . subg. 2. *Pseudaristea*

1b Capsules not as above, dehiscent in upper half, 3.5–50.0 mm long; ovary subsessile or on short pedicels, usually < 4 mm long, obovoid, often shallowly 3-lobed; style either minutely 3-notched at apex or dividing into three spreading, entire or shallowly fringed lobes; pollen grains various, not dizonasulculate (except some *A. zeyheri*):

2a Capsules short to relatively long, 8–15(–25) mm, with 3 radial, usually narrow wings; seeds compressed radially, flattened and lamellate (except *A. singularis*); style either minutely 3-notched at apex or dividing into three spreading, entire or shallowly fringed lobes . . . . . subg. 3. *Aristea*

2b Capsules short to elongate, usually 4–35(–50) mm, shallowly to deeply 3-lobed but lobes not forming wings; seeds columnar with flattened ends, rounded or angular; style dividing into three spreading, entire or shallowly fringed lobes . . . . . subg. 1. *Eucapsulares*

Keys to species

1. Subg. *Eucapsulares*

1a Plants robust with leaves 15–25 mm wide; stems mostly 800–1 200 mm high; plants of southwestern Western Cape . . . . . 1. *A. latifolia*

1b Plants small to relatively robust with leaves 1.5–15.0 mm wide; stems variously 150–1 200 mm high; plants of eastern southern Africa:

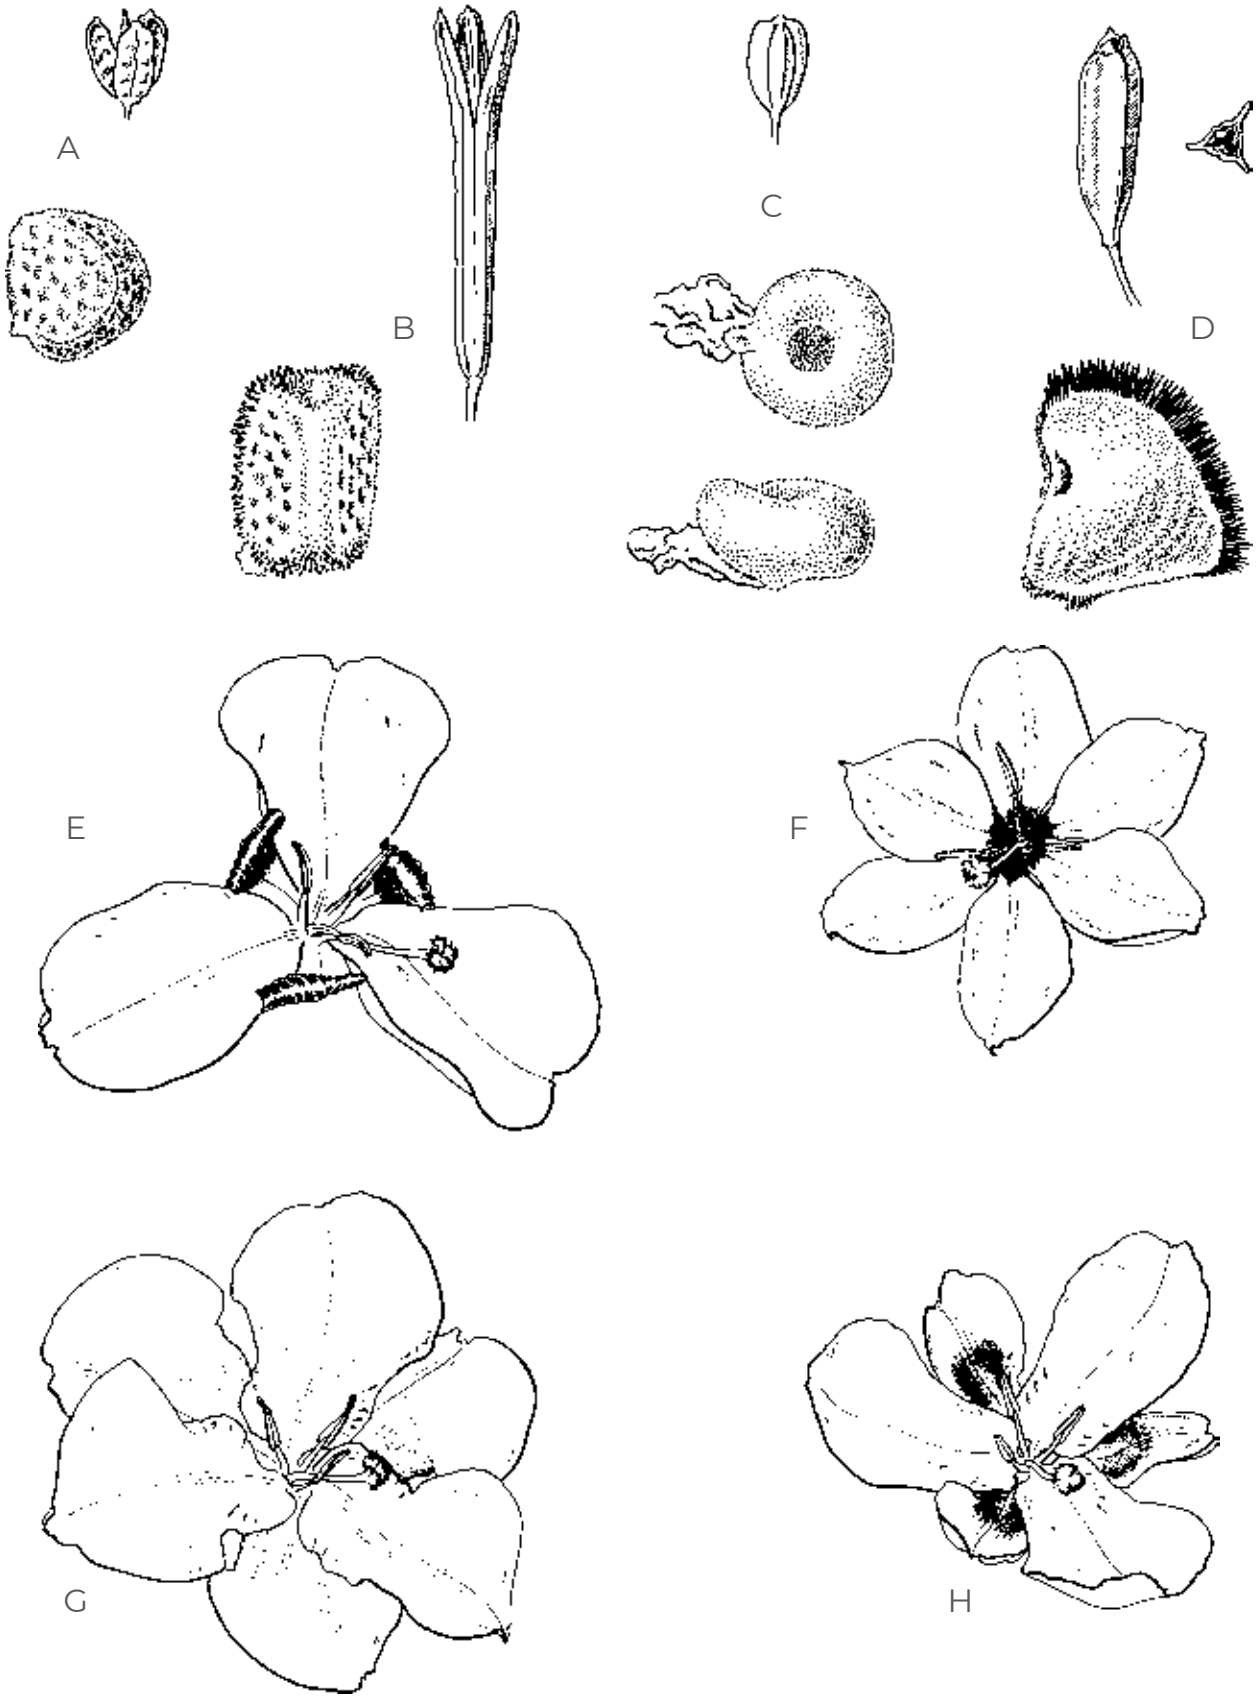
2a Plants with flowering stem of 1 extended internode without leaves or with a short subterminal leaf below uppermost flower cluster:

3a Plants small, 80–150(–250) mm high, and flowering stem leafless; pedicels 10–15 mm long in flower, up to 20 mm long in fruit. . . . . 18. *A. nana*

3b Plants small to moderate in size, (80–)120–300 mm high, and flowering stem always with subterminal leaf; pedicels vestigial or up to 2 mm long in flower, up to 2 mm long in fruit:

4a Spathes rust-brown, 15–22 mm long; capsules 8–12 mm long . . . . . 17. *A. anceps*

4b Spathes green to ± dry and dull-translucent, 6–11 mm long; capsules 4–8 mm long. . . . . 16. *A. abyssinica*



2b Plants not as above, with flowering stem of at least 2 internodes and bearing one or more cauline leaves but lacking a foliage leaf below the first flower cluster:

5a Ovary conspicuously papillose; capsules warty, usually wider than long, 3.5–4.0 × 4.0–4.5 mm; stems flattened and broadly 2-winged . . . . . 11. *A. platycaulis*

5b Ovary smooth; capsules smooth, usually ± as wide as long or longer than wide; stems rounded to elliptic in section or flattened and winged:

6a Capsules elongate, at least 12 mm and up to 50 mm long:

7a Capsules 35–50 mm long, indehiscent . . . . . 15. *A. ensifolia*

ARISTEA. A. anceps: A, dehisced capsule and seed. ***A. cistiflora***: B, dehisced capsule and seed. ***A. singularis***: C, capsule and seed top view and side view. ***A. rigidifolia***: D, capsule and seed. ***A. lugens***: E, flower. ***A. cantharophila***: F, flower. ***A. biflora***: G, flower. ***A. teretifolia***: H, flower.

7b Capsules 12–30 mm long, splitting from apex:
8a Flower clusters several, > 6; tepals 8–10 mm long . . . . . 12. *A. ecklonii*
8a Flower clusters few, mostly 1–4(5); tepals 9–18 mm long:
9a Tepals 16–18 mm long . . . . . 13. *A. elliptica*
9b Tepals 9–11 mm long . . . . . 14. *A. pusilla*
6b Capsules relatively short, 4–10 mm long:
10a Flowers small, with tepals ± 6 mm long; capsules globose and 3-lobed, ± 4 mm long . . . . . 4. *A. parviflora*
10b Flowers medium-sized, tepals 8–14 mm long; capsules ovoid to oblong in outline and often 3-lobed, mostly 5–9 mm long:
11a Stem compressed and winged, 5–10 mm wide; several-branched . . . . . 2. *A. compressa*
11b Stem compressed and elliptic in section, with or without narrow wings (rarely ± terete); simple to several-branched:
12a Stems mostly 3- to several-branched in upper half with branching subdivaricate; plants turning black with age or when dry; spathes with solid dark centre and broad translucent margins broad:
13a Plants 700–1 200 mm high; branches often bearing at least one lateral flower cluster; flowers large, with inner tepals 9–12 mm long . . . . . 10. *A. flexicaulis*
13b Plants up to 500 mm high; branches mostly each bearing a single terminal flower cluster; flowers relatively small with inner tepals 9–10 mm long . . . . . 9. *A. majubensis*
12b Stems simple or 1- to few-branched with branches ascending to suberect; spathes green below, membranous distally with broad, translucent margins feathered dark in centre and not drying black:
14a Flower clusters with 8 or more flowers; sessile lateral flower clusters each usually subtended by a prominent green bract, becoming dry brown from the tips:
15a Leaves 10–16 mm wide; plants 700–950 mm high . . . . . 8. *A. grandis*
15b Leaves 4–9 mm wide; plants 200–650 mm high. . . . . 7. *A. galpinii*
14b Flower clusters with (2)4(6) flowers; sessile lateral flower clusters small, sometimes subtended by a prominent bract:
16a Spathes when alive green below and dry-membranous distally, becoming dry and rust-brown entirely . . . . . 6. *A. schizolaena*
16a Spathes when alive green to grey-green with broad membranous margins:
17a Flower clusters mostly 2 to 6 per stem, the lowermost sometimes shortly stalked; stem 120–300 mm high, strongly compressed, 2(3)-angled below first flower cluster. . . . . 5. *A. montana*
17b Flower clusters at least 3 and usually many per stem; stem usually 300–700 mm high, weakly compressed and angled below first flower cluster . . . . . 3. *A. torulosa*

Subg. 2. *Pseudaristea*

1a Stems broadly winged above first flower cluster (or uppermost leaf if lateral flower clusters lacking); filaments short, 8–10 mm long, or much longer than anthers and 24–26 mm long; flowers nodding (facing to side) . . . 21. *A. spiralis*
1b Stems not broadly winged above first flower cluster or uppermost leaf; filaments short, as long as or not much longer than anthers, 3.0–6.5 mm long; flowers either nodding (facing to side) or upright:
2a Outer tepals differentiated from inner, smaller in size and each either with dark basal or distal marking or with a pair of large transparent windows in lower half:
3a Outer tepals dark brown or ± black in upper half and nearly symmetric about the midline; inner tepals ± twice as long as outer . . . . . 27. *A. lugens*
3b Outer tepals concolorous with inner tepals in upper half and asymmetric about midline; inner tepals slightly longer than outer, not twice as long:
4a Outer tepals not darkly coloured below, with paired translucent windows of membranous tissue above base; leaves linear, (2–)3–6 mm wide. . . . . 25. *A. biflora*
4b Outer tepals each with small to large, dark bronze-brown mark near base:
5a Leaves terete or linear, 1–2 mm diam. . . . . 24. *A. teretifolia*
5b Leaves linear, mostly 2.5–3.0 mm wide . . . . . 23. *A. cistiflora*
2b Outer tepals ± same size or slightly smaller than inner and similarly coloured:
6a Tepals white to cream-coloured or lilac to light mauve:
7a Tepals dark purple or greenish black at base, flower thus with dark central eye. . . . . 22. *A. cantharophila*
7b Tepals uniformly white or pale blue but outer tepals blackish outside . . . . . 26. *A. nigrescens*
6b Tepals light to dark blue, pale greenish yellow at base:
8a Flowers upright, dark blue, darker at base of tepals; leaves oval in section, with rounded, undifferentiated margins; capsule lobes strongly angular. . . . . 19. *A. pauciflora*
8b Flowers suberect or nodding (facing to side), pale or deep blue; leaves narrowly elliptic in section, with acute, translucent margins; capsule lobes rounded. . . . . 20. *A. simplex*

Subg. 3. *Aristea*

1a Plants forming diffuse tufts, producing aerial stolons rooting at nodes; flower clusters and flowers pendent; capsules 3-lobed, containing 1(2) seeds per locule; seeds compressed-elliptic with deeply sunken chalaza (doughnut-like), with funicle forming a pale fleshy body (sect. *Singulares*). . . . . 39. *A. singularis*
1b Plants not as above, growing in tufts or singly but without aerial stolons; flower clusters ± upright and flowers upright to nodding; capsules with prominent, narrow radial wings; seeds radially compressed, lamellate:

2a Plants often large, 150 to > 1 000 mm tall; style obscurely 3-notched at apex (lobed in *A. zeyheri*); spathes entire or irregularly torn with age (never regularly fringed when young); pollen grains usually with single elliptic aperture (sometimes with 2 ring-like apertures in *A. zeyheri*) (sect. *Racemosae*):
3a Leaves terete to elliptic in transverse section and 1–3 mm wide, without differentiated translucent margins; capsules oblong in outline, at least twice as long as wide:
4a Plants robust, usually 600–1 300 mm high; capsules (20–)25–33 mm long; bracts subtending flower clusters and branches narrowly lanceolate, not attenuate-cuspidate . . . . . 37. *A. rigidifolia*
4b Plants relatively small, 120–150(–400) mm high; capsules 10–25 mm long:
5a Leaves usually elliptic in section, 2–3 mm wide; flower clusters each subtended by a prominent green bract keeled above and often folded in lower midline, and at least those subtending lower flower clusters exceeding spathes . . . . . 33. *A. juncifolia*
5b Leaves terete; lower flower clusters not subtended by a prominent green bract:
6a Flower clusters several; spathes and floral bracts dry, usually rust-brown, transparent toward margins, 15–24 mm long; capsules 10–15 mm long . . . . . 36. *A. racemosa*
6b Flower clusters usually 1 or 2(3), lateral clusters sessile; spathes and floral bracts green, drying blackish, with narrow transparent margins, 20–25 mm long; capsules (16–)22–28 mm long . . . . . 38. *A. zeyheri*
3b Leaves ± plane or slightly elliptic in section, with acute, translucent margins (drying hyaline), larger basal leaves (2–)3–12 mm wide; capsules broadly ovate to oblong, ± as long as to > twice as long as wide:
7a Spathes and floral bracts lanceolate and acuminate, dark green to brown in centre with wide transparent margins, glabrous; capsules 8–12 mm long, slightly longer than to almost twice as long as wide:
8a Flower clusters crowded in upper ⅓ of stem, largely or completely concealing main axis; stamens equal . . . . . 30. *A. capitata*
8b Flower clusters laxly arranged on long branches with lower branches diverging; stamens unequal, lower (anterior) filament ± 2 mm longer than upper two filaments . . . . . 31. *A. inaequalis*
7b Spathes and floral bracts broadly ovate/obovate, glabrous or lightly hairy to scabrid; capsules 7–30 mm long:
9a Plants small, 200–400 mm high; lower leaves 2–3 mm wide; flowering stems dichotomously branched and all flower clusters stalked . . . . . 35. *A. rupicola*
9b Plants taller, (500–)800–1 500 mm high; lower leaves (3–)4–12 mm wide; flowering stems unequally branched and some upper flower clusters sessile:
10a Lower leaves (7–)12–25 mm wide:
11a Flower clusters laxly arranged on branched stem; spathes usually finely hairy to scabrid; capsules 14–30 mm long; seeds 2 to 5 per locule . . . . . 28. *A. bakeri*
11b Flower clusters crowded in upper half of stem; spathes glabrous; capsules 11–14 mm long; seeds 2 per locule . . . . . 29. *A. rufobracteata*
10b Lower leaves 3–6 mm wide:
12a Plants 600–1 300 mm high, usually branched and with sessile and stalked flower clusters; spathes (10–)12–16(–18) mm long; capsules 8–10 mm long . . . . . 34. *A. bracteata*
12b Plants moderate-sized, 300–600 mm high, usually all lateral flower clusters sessile; spathes 7–14 mm long; capsules 14–18 mm long . . . . . 32. *A. cuspidata*
2b Plants often small, 120–1 000 mm high; style dividing into 3 discrete lobes, these entire to slightly undulate or shallowly fringed; inflorescence spathes entire, irregularly torn with age, or regularly fringed when young; pollen grains with 3-lobed aperture or 3 confluent apertures (sect. *Aristea*):
13a Spathes and bracts regularly fringed:
14a Capsules 12–15 mm long . . . . . 40. *A. fimbriata*
14b Capsules ± 8 mm long:
15a Spathes fringed up to half their length, usually silvery-translucent (rarely fading rust-coloured at tips); plants mostly 100–150 mm high; leaves mostly 2–3 mm wide . . . . . 45. *A. africana*
15b Spathes fringed for < ⅓ their length, always rust-brown at tips; plants mostly 200–400 mm high; leaves mostly 3–5 mm wide . . . . . 46. *A. recisa*
13b Spathes entire or becoming torn with age:
16a Spathes leathery, green to brown with narrow translucent margins:
17a Stem usually dichotomously 3- to 6-branched, stem usually ± terete to elliptic in section; tepals 14–18 mm long . . . . . 39. *A. dichotoma*
17b Stem often simple or unevenly 1- to 3-branched, stem flattened and winged; tepals 10–14 mm long . . . . . 42. *A. glauca*
16b Spathes and bracts silvery-translucent with narrow green to brown keels:
18a Plants up to 250 mm high; flower clusters 15–20 mm long . . . . . 43. *A. oligocephala*
18a Plants up to 1 000 mm high; flower clusters 10–12 mm long . . . . . 44. *A. palustris*

Subg. 1. **Eucapsulares**

Subg. **Eucapsulares** (*Goldblatt*) *Goldblatt* in Novon 22: 416 (2013). *Aristea* sect. *Eucapsulares* Goldblatt in Goldblatt & Le Thomas: 228 (1992), as a new name for *A.* sect. *Euaristea* Pax: 152 (1888), invalid name. Type: *A. angolensis* Baker [lecto., designated by Goldblatt in Goldblatt & Le Thomas: 228 (1992)].

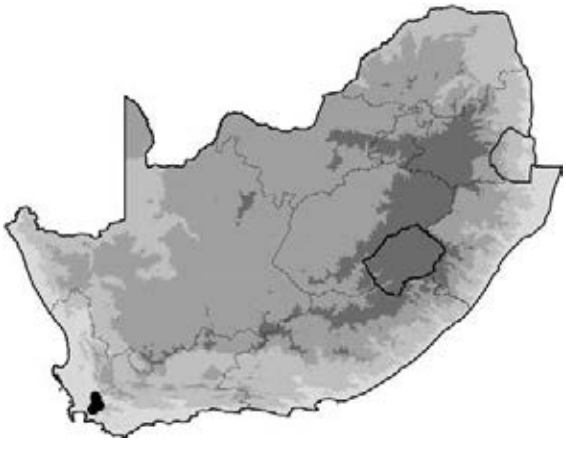
Plants often large and stems usually several- to many-branched. *Flower clusters* mostly several-flowered; spathes green or becoming dry from tips. *Flowers* always fugaceous, deep to pale blue, lasting one morning. *Stamens* always equal; anthers porose in 4 species of Madagascar. *Style* 3-lobed apically, margins usually undulate. *Capsules* short and ovoid to ovoid-trigonous or elongate-trigonous. *Seeds* ovoid to angular-prismatic or shortly cylindric. *Pollen grains* occasionally shed as tetrads, mostly zonasulculate with aperture concealed by exine masses, or sulcate with broad, smooth aperture, exine rugulate, rarely reticulate.

Species ±32: sub-Saharan Africa and Madagascar.

Sect. 1. **Latifoliae** *Goldblatt* in Goldblatt et al. in Botanical Journal of the Linnean Society 144: 64 (2004). Type: *Aristea latifolia* G.J.Lewis

Plants large, up to 1 m high, leaves broad, firm textured, stem multi-branched. *Flower clusters* many in compound pseudopanicle, terminal, multiflowered. *Flowers* blue; tepals connate at base, subequal. *Style* 3-lobed. *Capsules* ovoid. *Seeds* angular-prismatic. *Pollen grains* monosulcate, exine reticulate.

Species 1: higher mountains of southwestern Western Cape, South Africa.



1. **Aristea latifolia** *G.J.Lewis* in Annals of the South African Museum 40: 9 (1952). Type: South Africa, [Western Cape], Wemmershoek Peak, gully in west side, 4 000–5 000 ft [1 200–1 500 m], *Lewis s.n. SAM57345* (SAM, holo.).

Plants mostly 800–1 200 mm high. *Stem* weakly compressed, ovoid in section, usually several-branched in upper half. *Leaves* several, broad, ½ to ⅔ as long as stem, 15–25 mm wide, firm, fibrous, margins hyaline, acute. *Flower clusters* several per stem in lax pseudopanicle, each (2)6- to 8-flowered; spathes 7–9 mm long, lanceolate, bracts pale grey or brown, papery, becoming torn with age. *Flowers* on pedicels 5–7(–9) mm long, deep blue; tepals subequal, ± 12 mm long, spreading. *Filaments* ± 5 mm long; anthers ± 4 mm long. *Style* ± 8 mm long, terminating in three, short, entire stigmatic lobes. *Capsules* ovoid, shallowly 3-lobed, 8–9 mm long, on pedicels 5–9 mm long. *Seeds* angular-prismatic, ± 2 mm diam., surface sculpturing unknown. *Flowering time*: November to early January.

Distribution and ecology: a local endemic of Western Cape, South Africa, from Bain's Kloof to the Hottentots Holland Mtns; in shady kloofs and gullies, 500–1 800 m altitude, usually near streams.

Diagnosis: a tall plant, the flowering stem usually exceeding 1 m in height, *Aristea latifolia* has broad leaves 15–25 mm wide and a multibranched stem. This, together with ovoid, multi-seeded capsules and prismatic seeds, makes the species easy to recognise among the Western Cape members of the genus.

Although restricted to the higher mountains of the southwestern corner of the winter-rainfall region, *A. latifolia* is most closely related to the eastern, southern and tropical African species of subg. *Eucapsulares*, with which the capsules and seeds closely accord. The sulcate pollen grains of *A. latifolia* do not conform to the derived, sulculate type with exine-covered apertures typical of the subgenus but are monosulcate with a broad, elliptic aperture. Vegetatively, plants most closely resemble *A. bakeri* and *A. capitata* (subg. *Aristea*), but the capsules and seeds are quite different. The presence of pollen and capsules and seeds of the ancestral type suggest that *A. latifolia* is a relict of the ancestral stock of the genus, hence its placement as the first species in this account. Molecular studies confirm this interpretation in retrieving it as sister to the remaining species of the genus. The geographic disjunction at subgeneric level of *A. latifolia* has few parallel examples in the flowering plants of the southwestern Cape.

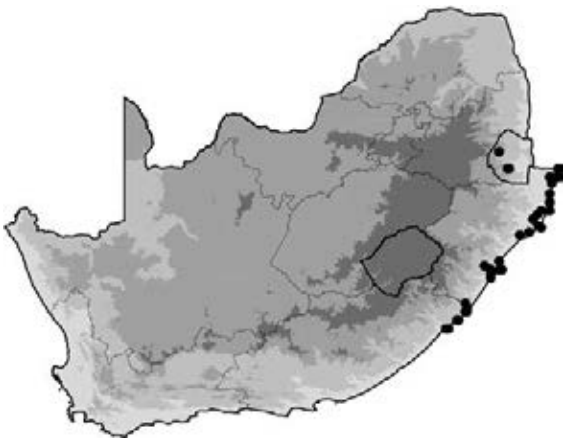
Distribution of ***Aristea latifolia***.

Sect. 2. **Cladocarpae** *Weim.* in Acta Universitatis Lundensis, ser. 2, 36(1): 48 (1940). Type: *Aristea cladocarpa* Baker

Sect. *Trilobatae* Weim.: 49 (1940). Type: *Aristea platycaulis* Baker

Sect. *Eucapsulares* Goldblatt in Goldblatt & Le Thomas: 228 (1992), as a new name for *Aristea* sect. *Euaristea* Pax: 152 (1888), invalid name. Type: *A. angolensis* Baker, lecto., designated by Goldblatt in Goldblatt & Le Thomas: 228 (1992).

Plants small to moderate in size, up to 1 m high, leaves broad, firm- or soft-textured, stem usually several- to many-branched. *Flower clusters* many in compound pseudopanicle, terminal, multiflowered. *Flowers* blue; tepals connate at base, subequal. *Style* 3-lobed. *Capsules* ovoid. *Seeds* angular-prismatic. *Pollen grains* rarely monosulcate, exine reticulate.



Species ± 23; 12 spp. in southern Africa: extending through eastern southern Africa as far south as Albertinia, also in tropical Africa and Madagascar.

2. **Aristea compressa** *Buching. ex Baker* in Journal of the Linnean Society, Botany 16: 111 (1877); Weim.: 14 (1940, including *A. parviflora*). Type: South Africa, [KwaZulu-Natal], forest margins near Umlaas River, 1840, *Krauss 358* (K, holo.; MO, iso. [2 sheets]).

Aristea gerrardii Weim.: 17 (1940); Vincent: 240 (1985). Type: South Africa, [KwaZulu-Natal], without precise locality or date, *Gerrard 393* (K, holo.; P, iso.).

[*Aristea compressa* Buching. in Krauss: 309 (1845), invalid name without description.]

Plants 300–750 mm long. *Stem* flattened almost to apex, narrowly winged, several- to many-branched (one order), but never dichotomously, bearing sessile and stalked flower clusters. *Leaves* narrowly sword-shaped to linear, leathery, sometimes weakly pleated, mostly 8–12 mm wide, ± ½ as long as stem. *Flower clusters* many, sessile and stalked, each 2- to 4-flowered; spathes and bracts lanceolate, mostly 5–8 mm long, green or brown in midline, transparent in upper half, becoming torn. *Flowers* blue, outer tepals 8.5–11 × 3.5–3.5 mm, inner 9.5–11 × 5–7 mm. *Filaments* 2.5–4.5 mm long; anthers 1.8–2.5 mm long. *Ovary* on short pedicel 1–2 mm long; style ± 5 mm long, broadly 3-lobed, reaching middle or apex of anthers and slightly deflexed. *Capsules* ovoid, ± 5 × 4 mm long, mostly ± sessile. *Seeds* angular-prismatic, sculpturing foveate. *Flowering time*: mainy September to mid-January.

Distribution of ***Aristea compressa***.

Distribution and ecology: mainly coastal eastern South Africa and Mozambique, extending from Port St Johns in Eastern Cape to Pebane in coastal northern Mozambique, also locally inland, as at Drummond (KwaZulu-Natal) and Mbabane (Eswatini); mainly on coastal flats, often in marshy habitats, and locally inland in areas with sandstone or quartzite substrates.

Diagnosis: the branched flowering stem and numerous flower clusters suggest that *Aristea compressa* is related to *A. flexicaulis* and the two species may sometimes be confused. The flattened stem with a pronounced main axis, straight, stiff lateral branches, soft-textured leaves 8–12 mm wide and the shorter spathes and bracts less than 9 mm long separate it from the taller, round-stemmed *A. flexicaulis*. The stems of *A. compressa* are flattened with the longer axis twice as long as the short axis and more-or-less winged. Although a second species, *A. gerrardii*, was recognised by Weimarck (1940) and Vincent (1985) it hardly differs from *A. compressa* and the two have been united.

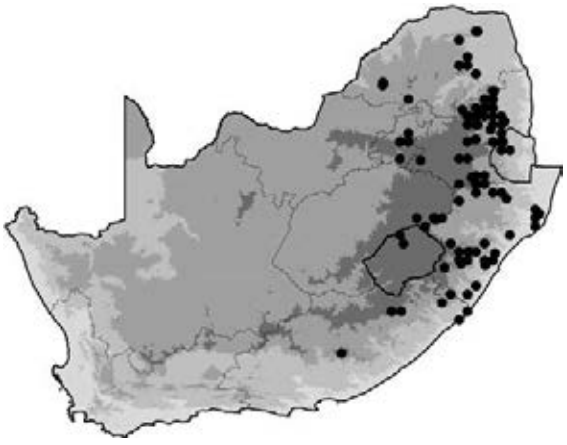
3. **Aristea torulosa** *Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 382 (1882); Weim.: 27 (1940). Type: South Africa, [Eastern Cape], between 'Gekau und Bashee', Dec. 1832, *J.F. Drège 4558* (B, holo. [photo at K]; P, iso.).

Aristea torulosa var. *monostachya* Baker: 49 (1896). Type: South Africa, [KwaZulu-Natal], without precise locality, *Buchanan s.n.* (K, holo.).

Aristea affinis N.E.Br.: 192 (1931). Type: South Africa, [Mpumalanga, as Transvaal], upper Moodies, near Barberton, grassy slopes, *Galpin 1209* (K, holo.; BOL, PRE, SAM, iso.).

Aristea congesta N.E.Br.: 192 (1931). Type: South Africa, [Eastern Cape], between Msikaba and Mtentu rivers, Dec. 1832, *J.F. Drège 4559* (B [not seen], P, syn.).

Aristea curvata N.E.Br.: 193 (1931). Type: South Africa, [Limpopo], Houtbosch, *Rehmann 5770* (K, holo.).



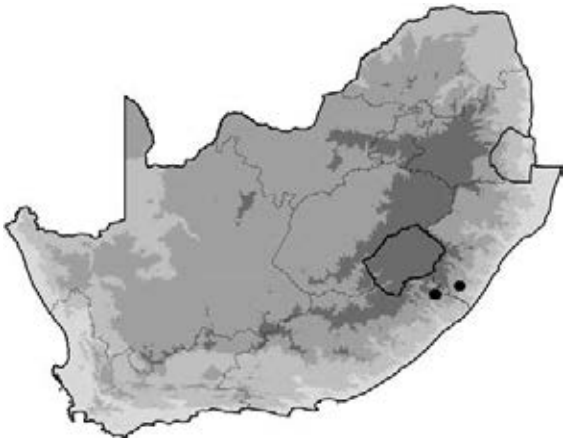
Aristea gracilis N.E.Br.: 193 (1931). Type: South Africa, [Mpumalanga, as Eastern Transvaal], Lydenburg, Spitzkop Gold Mine, *Wilms 1420* (K, holo.; P, iso.).

Aristea woodii N.E.Br.: 192 (1931); Weim.: 28 (1940); Vincent: 225 (1985). Type: South Africa, [KwaZulu-Natal], Inanda, *J.M. Wood 751* (K, holo.; BOL, NH, NU, SAM, iso.).

Plants 300–700 mm high. *Stem* lightly compressed, more so below, simple or with 1 or 2(4) slender branches at lower nodes of synflorescence, with few to several sessile lateral flower clusters in upper half. *Leaves* mostly basal, linear to narrowly lanceolate or falcate, 3–7 mm wide, ± $^1/_3$ to $^1/_2$ as long as stem, firm-textured, cauline leaves smaller, sometimes entirely sheathing. *Flower clusters* several per axis in lax or rarely crowded spicate arrangement, each mostly 4- to 6-flowered (rarely 8-flowered), lower flower clusters often subtended by a prominent bract-like spathe 9–12 mm long; spathes and bracts green becoming dry and brown below, pale membranous above feathered with brown, lacerate with age. *Flowers* pale to deep blue, ± sessile; tepals obovate, 10–14 mm long, outer slightly smaller than inner. *Filaments* suberect, ± 3 mm long; anthers 2.0–2.5 mm long. *Style* 5–6 mm long, with deltoid apical lobes. *Capsules* ellipsoid-ovoid and 3-lobed, 5–6(–7) mm long, ± sessile (or on pedicels up to 2 mm long). *Seeds* angular-prismatic, foveate-reticulate. *Flowering time*: December to February.

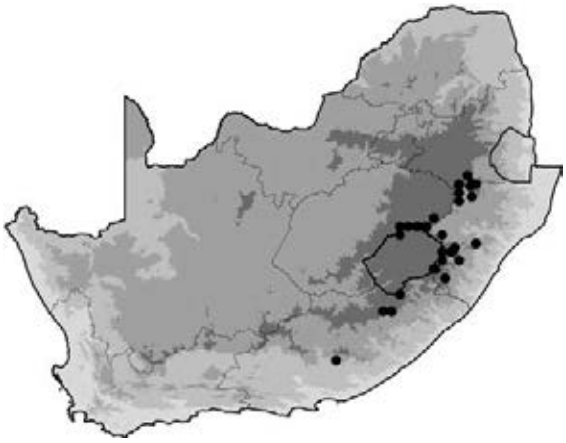
Distribution and ecology: widespread in eastern southern Africa, extending from northern Limpopo through eastern Gauteng, Mpumalanga, eastern Free State, KwaZulu-Natal and Eastern Cape as far south as the Amathole Mtns, and also in Lesotho, Eswatini and eastern Zimbabwe; in montane or coastal grassland or sometimes in marshy grassland, mostly 1 200–2 000 m altitude but at lower elevations near the coast.

Diagnosis: *Aristea torulosa* is recognised primarily by the distinctive spathes and bracts, these dark green below edged reddish brown and grading unevenly into broad translucent margins darker along the veins thus giving them a feathered appearance. The pale edges of the spathes and bracts become torn and irregularly fringed with age. The spathes are fairly large, especially those of the lower flower clusters. The flowering stem bears several sessile lateral flower clusters and is often unbranched or the lower fertile nodes may bear one or more, short erect branches. It broadly resembles the Eastern Cape *A. schizolaena* in its unbranched or few-branched stem with several sessile lateral flower clusters, but *A. schizolaena* has uniformly rusty brown spathes and bracts that are often somewhat longer than those of *A. torulosa*. Particularly robust plants from the Graskop and Sabie areas of Mpumalanga stand out in their height, up to 700 mm, with up to 6 or 8 large flowers in the upper flower clusters.



Distribution of ***Aristea torulosa***.

The type of *Aristea congesta* from the Transkei [Eastern Cape] corresponds closely to that of *A. torulosa* in its bracts and spathes but is unusual in its congested axis, and may represent plants collected in early flowering, before the floral axis has fully elongated. Weimarck regarded *A. curvata* as a synonym of *A. schizolaena*, but the type, from Woodbush in Limpopo, is better referred to *A. torulosa*, which extends from central Eastern Cape to Limpopo. *Aristea schizolaena* is not recorded north of Cala and Baziya in Eastern Cape. The synonyms *A. affinis* and *A. curvata* represent plants with unusually long bracts subtending the lower flower clusters, the latter also with falcate leaves. Specimens of the type of *A. gracilis* are unusually slender but hardly different from those of *A. torulosa* var. *monostachya* and *A. woodii*.



4. **Aristea parviflora** *Baker* in Bulletin of Miscellaneous Information Kew 1906: 25 (1906); Goldblatt & Manning: 209 (2013). Type: South Africa, [Eastern Cape], Insizwe [Ntsizwa] Mtns, 28 Jan. 1895, *Krook in Herb. Penther 556* (K, holo.)

Plants 400–600 mm high. *Stem* slightly compressed, oval in section, with low raised angles decurrent on cauline leaves, repeatedly branched (one or two orders), main axis remaining dominant, branches ascending. *Leaves* ± linear, leathery, basal ± ½ as long as stem, mostly 4–6 mm wide, cauline leaves progressively shorter above. *Flower clusters* many in false panicle, sessile or stalked, each (1)2- to 4-flowered; spathes and bracts ovate to lanceolate, mostly 3.5–4.5 mm long, evidently translucent membranous with brown keels and shading brown near bases, becoming torn with age. *Flowers* blue, ± sessile; tepals ± 6 mm long. *Filaments* ± 2.5 mm long; anthers ± 1.5 mm long. *Style* unknown. *Capsules* globose, ± 4 mm diam., sessile. *Seeds* unknown. *Flowering time*: January and February, probably also March.

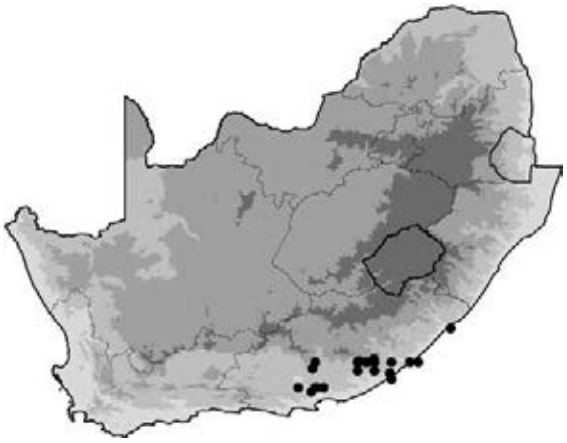
Distribution and ecology: a narrow endemic known only from the Ntsizwa and Mt Ayliff ranges of the southern Drakensberg near Kokstad and Clydesdale in Eastern Cape and adjacent KwaZulu-Natal, South Africa; evidently occurring on the margins of forest and bush.

Distribution of ***Aristea parviflora***.

Distribution of ***Aristea montana***.

Diagnosis: *Aristea parviflora* has well-branched stems (one or two orders of branching) and the smallest flowers in the genus, the tepals ± 6 mm long and the flower thus ± 12 mm diam., and correspondingly short filaments, ± 2.5 mm long. The globose capsules up to 4 mm long are also distinctive. It was included in *A. compressa* by both Weimarck (1940) and Vincent (1985), but the stems are only slightly compressed with narrow raised angles whereas the stems of *A. compressa* are flattened and ± winged with the wider axis twice as long as the narrow axis. The tepals of *A. compressa* are 10–11 mm long, filaments 3.5–4.0 mm long, and the capsules are ovoid and ± 5 mm long. Despite its past association with *A. compressa, A. parviflora* is probably more closely related to the larger flowered *A. torulosa*.

5. **Aristea montana** *Baker* in Flora capensis 6: 49 (1896); Weim.: 25 (1940); Vincent: 223 (1985). Type: South Africa, [KwaZulu-Natal], Mt Amajuba, 7 Dec. 1892, *Wood 4768* (K, holo.; NH, iso.).



Plants mostly 120–300 mm high. *Stem* strongly compressed, 2- or 3-angled below first flower cluster, simple or with 1 or 2 short branches, lateral flower clusters sessile. *Leaves* mostly basal, linear to narrowly lanceolate or falcate, 3–7 mm wide, ± half as long as stem, firm-textured, cauline leaves smaller, sometimes entirely sheathing. *Flower clusters* usually 2 to 6 per axis, sessile except the terminal or those at the lower nodes shortly stalked, each (2)4-flowered; spathes 8–12 mm long, initially green below, becoming dry and rust-brown with pale dry margins, becoming lacerate; inner spathes and bracts shorter, dry, becoming irregularly lacerate. *Flowers* deep blue, ± sessile or pedicels up to 2 mm long; tepals obovate, mostly 8–10 × 4–8 mm. *Filaments* 3.0–4.5 mm long; anthers ± 2.5 mm long. *Style* up to 7 mm long, deflexed, with deltoid apical lobes. *Capsules* ± ovoid, weakly 3-lobed, 6–10 mm long, ± sessile or on pedicels up to 2 mm long. *Seeds* angular-prismatic, sculpturing foveate. *Flowering time*: mainly December and January.

Distribution and ecology: Lesotho and South Africa in Eastern Cape, Free State and KwaZulu-Natal; in stony high altitude grassland, often on basalt substrates, 1 800–2 750 m elevations.

Diagnosis: evidently allied to *Aristea torulosa, A. montana* has similar dark green spathes and bracts with broad pale margins irregularly grading to darker colour and becoming irregularly fringed with age. The two are often difficult to distinguish, but *A. montana*, a high mountain species, is relatively low in stature, seldom exceeding 250 mm. They can best be distinguished by the stem, which is at most weakly compressed in *A. torulosa* and bears several, relatively laxly spaced flower clusters, those at the lower nodes sometimes on short branches. The stem of *A. montana* in contrast is strongly compressed and 2-angled and seldom bears more than 3 to 6 flower clusters, the lower ones often on short, relatively stout branches. The bracts of *A. montana*, while virtually identical to those of *A. torulosa*, seem less delicate and do not become fringed and torn as early.

6. **Aristea schizolaena** *Harv. ex Baker* in Journal of Botany, British and foreign 14: 267 (1876); Weim.: 31 (1940); Vincent: 235 (1985). Type: South Africa, [Eastern Cape], near Grahamstown, shady cliffs, without date, *MacOwan 195* (K ['sheet 1'], lecto., designated here).

Plants 350–800 mm high. *Stem* elliptic in section, simple or with one or more short, slender branches, lateral flower clusters sessile. *Leaves* linear to sword-shaped, ± ⅓ as long as stem, 4–8 mm wide, relatively firm-textured, pale green. *Flower clusters* several per axis in lax arrangement, each mostly 4-flowered; outer spathe green below, dry distally; inner spathes and bracts greenish-translucent below, dry and rust-brown above, becoming irregularly torn with age. *Flowers* ± sessile or on pedicels up to 2 mm long, deep blue; tepals subequal, 11–14 mm long. *Filaments* 3–5 mm long; anthers ± 2.5 mm long; *Style* 7–9 mm long; stigma lobes ± wedge-shaped. *Capsules* ovoid, sessile, ± 7 mm long, slightly

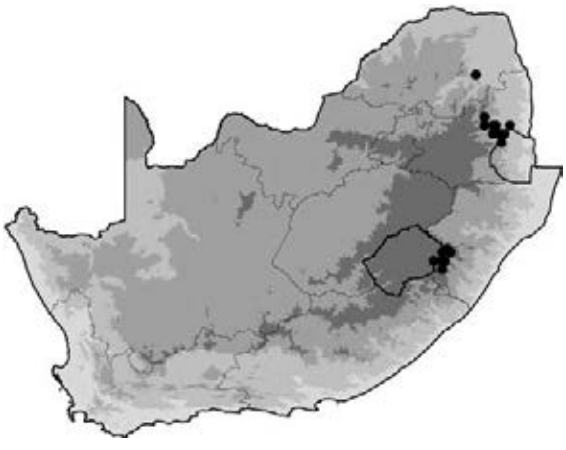
Distribution of ***Aristea schizolaena***.

3-lobed. *Seeds* angular-prismatic, sculpturing foveate. *Flowering time*: mainly December to February.

Distribution and ecology: restricted to Eastern Cape in southeastern South Africa, from the Zuurberg and Grahamstown to Cala and Baziya in the southern Drakensberg, and on the Boschberg near Somerset East; in coastal and inland rocky grassland.

Diagnosis: the relatively tall and slender *Aristea schizolaena* broadly resembles the more widespread *A. torulosa* in its few-branched or unbranched stem with several sessile lateral flower clusters but is distinguished by the spathes and bracts subtending the flower clusters, these membranous distally and red-brown even before the first flowers open. The different spathes and floral bracts prevent confusion with otherwise similar *A. torulosa*, which has the spathes subtending the flower clusters green below becoming membranous and pale-translucent distally feathered with green or brown.

Formal typification of *Aristea schizolaena* is necessary as Baker cited two collections in the protologue, *Baur 447* and *Macowan 195*, of which there are two sheets at K. Weimarck (1940: 31) cited the MacOwan collection as the 'spec. orig' and merely listed the Baur collection in the exsiccatae. This has been accepted as effective lecotypification but as there are two sheets of the MacOwan collection at K, the specimen annotated 'sheet 1' is designated here as the lectotype.



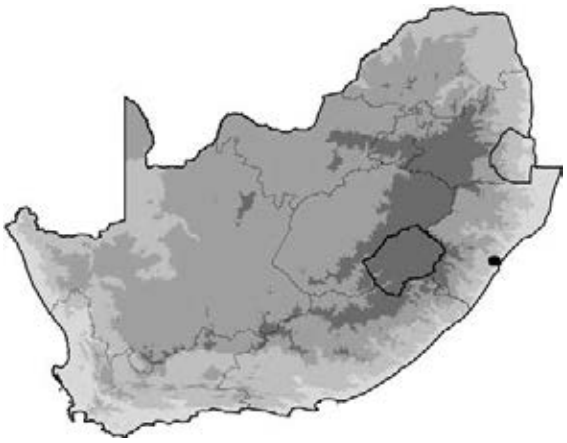
7. **Aristea galpinii** *N.E.Br. ex Weim.* in Acta Universitatis Lundensis, ser. 2, 36: 26 (1940); Vincent: 221 (1985). Type: South Africa, [Mpumalanga], Saddleback Range, Sept./Nov. 1890, *Galpin 1015* (K, holo.; BOL, PRE, SAM, iso.).

Plants 200–650 mm high. *Stem* simple or rarely shortly branched below, lightly compressed in the lower half, most flower clusters sessile. *Leaves* several, the basal ± linear, 4–9 mm wide, ± half as long as stem, markedly firm-textured in northern populations, the upper cauline, largely to entirely sheathing. *Flower clusters* 3 to several per axis, sessile except the terminal (occasionally lowermost flower cluster shortly stalked), crowded, with up to 12-flowers each; outer spathe prominent, green to brown, 15–20 mm long; inner spathes and bracts greenish to translucent below, becoming dry and red-brown in upper half, irregularly torn with age. *Flowers* ± sessile except the terminal, mid- to deep blue; tepals 12–14 × 5–7 mm, outer smaller than inner. *Filaments* ± 3 mm long; anthers 2–3 mm long. *Style* ± 8 mm long, deflexed, with small deltoid apical lobes. *Capsules* narrowly ovoid-oblong, 7–8 mm long, shallowly 3-lobed. *Seeds* angular with slightly flattened sides, ± 1.5 mm long, sculpturing foveate. *Flowering time*: November to January.

Distribution and ecology: eastern southern Africa, extending from the central KwaZulu-Natal Drakensberg to eastern Mpumalanga and southern Limpopo in South Africa, and in Eswatini; in grassland at 1500–2600 m elevation.

Diagnosis: *Aristea galpinii* closely resembles *A. grandis* from coastal KwaZulu-Natal in its large flower clusters, each containing 8 to 12 flowers and subtended by a prominent spathe, initially green below but aging rust-brown from the apex. *Aristea galpinii* is a shorter and less robust species, up to 650 mm high (although the type is less than 300 mm high), with narrower leaves up to 9 mm wide, whereas *A. grandis* has leaves 10–16 mm wide and may reach up to 950 mm high. The capsules are relatively short, up to 8 mm long, ± oblong to obovoid in outline and slightly 3-lobed. Like most other southern African species of sect. *Cladocarpae*, the seeds have a foveate surface whereas those of *A. grandis* are smooth.

As circumscribed here, *Aristea galpinii* is relatively widespread, extending from the KwaZulu-Natal Drakensberg at Sani Pass to eastern Mpumalanga and southern Limpopo. Plants from the Barberton area of southeastern Mpumalanga, the type locality, have deep blue flowers and firm-textured, slightly striate leaves, whereas populations from KwaZulu-Natal have



Distribution of ***Aristea galpinii***.

softer leaves and slightly smaller, paler blue flowers with somewhat broader style lobes. These populations are provisionally included here but require additional study. A seemingly outlying population from Lekgalameetse Nature Reserve near The Downs in southern Limpopo represents the northernmost population so far recorded. *Aristea galpinii* was not associated with any particular species by Vincent (1985), but we consider it to be closely allied to *A. grandis*, a coastal species from Inanda and the highlands near Kloof and Hillcrest in KwaZulu-Natal.

8. **Aristea grandis** *Weim.* in Acta Universitatis Lundensis, ser. 2, 36: 30 (1940); Vincent: 237 (1985). Type: South Africa, [KwaZulu-Natal], Inanda, Dec. 1880, *Wood 738* (K, lecto., effectively designated by Weim.: 30 (1940); BOL, NH, SAM, iso.).

Plants 700–950 mm high. *Stem* simple, lightly compressed in lower half, flower clusters sessile except the terminal. *Leaves* several, the basal ± ½ as long as stem, ± linear, relatively soft-textured, 10–16 mm wide, the upper cauline, shorter, partly to entirely sheathing. *Flower clusters* 5 to 6 per axis, sessile except the terminal (?or lowermost flower cluster shortly stalked), subtended by a prominent green spathe up to 24 mm long, crowded with up to 16 flowers each; remaining spathes and floral bracts pale green below, becoming dry and reddish brown with age, often ultimately irregularly torn, 15–20 mm long. *Flowers* ± sessile, deep blue; tepals 12–15 × 5–6 mm, outer whorl smaller than inner. *Filaments* ± 4 mm long; anthers ± 3 mm long. *Style* ± 5 mm long, slightly lobed apically. *Capsules* narrowly ovoid-oblong, 7–8 mm long, shallowly 3-lobed. *Seeds* angular with slightly flattened sides, ± 1.5 mm long, surface smooth. *Flowering time*: December and January.

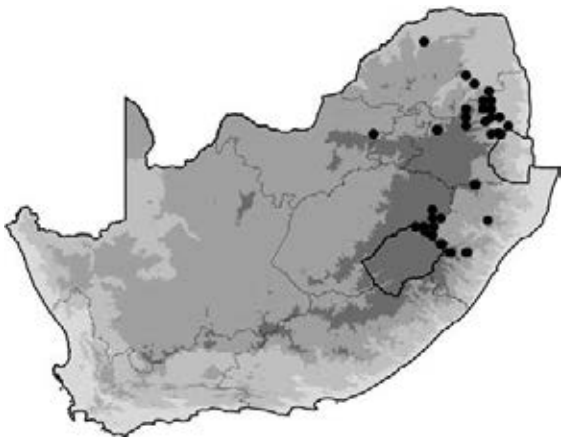
Distribution and ecology: restricted to coastal KwaZulu-Natal, South Africa, from Inanda near Durban and a short distance inland in the Kloof–Hillcrest area; in grassland.

Distribution of ***Aristea grandis***.

Diagnosis: *Aristea grandis* Weim. (1940) was described from a single collection from Inanda, near Durban, collected in 1880 by J. Medley Wood, and the few additional records since then are from the Kloof and Hillcrest areas inland of Durban. The species is robust, up to 950 mm tall, and has leaves 10–16 mm wide. The distinctive flowering stem may bear up to 6 large flower clusters, each with up to 16 flowers in a complex arrangement. The inner floral spathes and bracts are greenish to translucent below, light red-brown above, and closely resemble those of *A. galpinii* and *A. schizolaena.* Most significantly, the angular seeds have a smooth surface, in marked contrast to those of most other eastern southern African species, which have foveate sculpturing. *Aristea grandis* is evidently most closely related to the more widespread *A. galpinii*, a smaller species with stems up to 650 mm high, narrower leaves 2–9 mm wide, and seeds with foveate sculpturing.

9. **Aristea majubensis** *Baker* in Scott Elliot in Journal of Botany, British and foreign 29: 70 (1891). *A. angolensis* subsp. *majubensis* (Baker) Weim.: 21 (1940); Vincent: 234 (1985). Type: South Africa, [KwaZulu-Natal], Majuba, Nkwela Mt, Nov. 1890, *Scott Elliot 1638* (K, holo.).

Aristea cooperi Baker: 143 (1892). Type: South Africa, OFS [Free State], Tugela Valley, 1862, *Cooper 3212* (K, holo.).



[*Aristea angolensis* of multiple authors, not of Baker (1877)]

Plants mostly 200–500 mm high. *Stem* compressed below and ± broadly elliptic in section, rounded above, (2) 3- to 6-branched, branching subdichotomous, rarely branches also branched, branches terete, fairly short, slender, diverging, rarely with sessile lateral flower clusters, all clusters thus terminal. *Leaves* several, mostly basal, a few cauline and smaller, linear to narrowly lanceolate, 1.5–6.0 mm wide, ± ½ as long as stem. *Flower clusters* (2)4-flowered; spathes and bracts mostly 7–8 mm long, green below aging and drying black with broad, dull-translucent, membranous margins, becoming torn with age. *Flowers* ± sessile or on pedicels up to 2 mm long, usually deep blue; inner tepals obovate, 9–10 × 4–5 mm, outer slightly smaller. *Filaments* suberect, 2.5–3.5 mm long, anthers ± 2.5 mm long. *Style* 6–8 mm long, deflexed, broadly to narrowly 3-lobed apically. *Capsules* ovoid, 3-lobed, (4–)5 mm long, usually ± sessile or on pedicels up to 4 mm long. *Seeds* angular-prismatic, sculpturing foveate. *Flowering time*: mainly November to February.

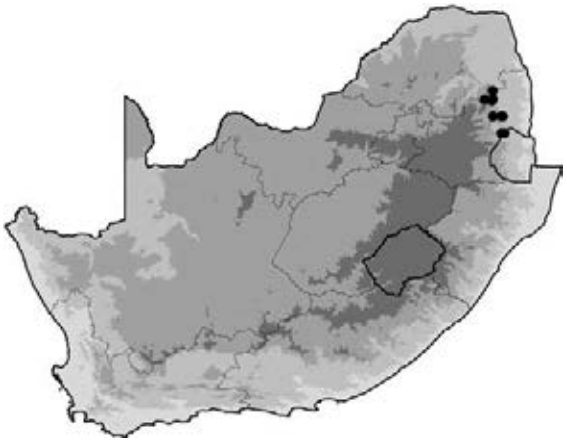
Distribution and ecology: restricted to northeastern southern Africa, extending from Blouberg and Soutpansberg in Limpopo through the highlands of Mpumalanga to northern KwaZulu-Natal as far south as Cathedral Peak and adjacent eastern Free State, also in Eswatini and probably Lesotho; mainly in rocky, montane sites, usually above 1 000 m elevation but only 550 m on the Blouberg.

Diagnosis: *Aristea majubensis* is recognised by the weakly compressed stem (sometimes lightly angled but not winged) becoming terete in the upper half, subdivaricate branching with lateral branches usually simple (rarely with 1 or more sessile lateral flower-clusters), and the comparatively short, partly transparent, entire or lightly torn spathes and bracts, 7–8 mm long. The flowers are typical of subg. *Eucapsulares* in their moderate size and medium to dark blue perianth. The style is relatively long and the stigmatic lobes are fan- to wedge-shaped. Plants in fruit (and herbarium specimens) are almost uniformly black, less so distally. In the Sentinel area of the northern Drakensberg *A. majubensis* co-occurs with *A. montana,* the latter usually past flowering when *A. majubensis* is in bloom. It also grows near populations of *A. torulosa*, which occurs on different soils there, and we have not seen them growing together. In the upper Mahai Valley there are a surprising number of white-flowered plants among those with the usual dark blue perianth. Plants from the Blouberg are unusually slender in stem and leaves and have slightly smaller spathes and bracts, but the divaricate branching is typical of the species.

Both Weimarck (1940) and Vincent (1985) included *Aristea majubensis* in *A. angolensis* as subsp. *majubensis,* but we conclude that *A. angolensis* is exclusively tropical African and recognised by the straight axis and mostly smaller flower clusters of 2 blooms. Some collections of *A. torulosa* were also included in *A. angolensis* as subsp. *angolensis* and subsp. *acutivalvis* but differ in their bracts and flower clusters usually bearing 4 or more blooms. The type material of *A. majubensis* and *A. cooperi* are nearly identical and clearly represent the same divaricately branched species. *Aristea majubensis* is likely most closely related to the wetland species, *A. flexicaulis*, a taller and more robust plant often exceeding 1 m, with broader leaves, sessile lateral flower clusters on the branches and often some axillary flower clusters as well, and larger, often pale blue flowers with widely divergent stamens.

Distribution of ***Aristea majubensis***.

10. **Aristea flexicaulis** *Baker*, Handbook of the Irideae: 143 (1892); Weim.: 24 (1940); *Vincent*: 221 (1985). Type: South Africa, 'Transvaal' also subsequently annotated 'Fall Creek,' and 'near Howick' in different hands, in 1877, *Mudd s.n.* (K, holo.).



Aristea angolensis subsp. *pulchella* N.E.Br. ex Weim.: 22 (1940). Type: South Africa, [Mpumalanga], Lomati Valley, Nov. 1924, *Thorncroft 2118* (K, holo.; PRE, iso.).

Plants mostly 700–1 200 mm high. *Stem* compressed below and ± elliptic in section, rounded to weakly 2-angled above, subdichotomously several-branched, branches terete, with 1 to 3 sessile lateral flower clusters and 1 or more axillary branches or sessile flower clusters. *Leaves* several, mostly basal, a few cauline and smaller, linear to narrowly lanceolate with prominent white margins, the largest (4–)5–12 mm wide, ± $^1/_4$ to $^1/_3$ as long as stem. *Flower clusters* each 2- to 6-flowered; spathes and bracts mostly 7–11 mm long, brown at anthesis, drying black, with broad, transparent, membranous margins or bracts entirely translucent, becoming torn with age. *Flowers* ± sessile or on pedicels up to 2 mm long, pale to medium blue; tepals spreading, inner obovate, 9–12 × 5–8 mm, outer 8–10 × 4–5 mm. *Filaments* divergent, 3–4 mm long; anthers ± 2 mm long. *Style* 6–7 mm long, strongly deflexed, minutely 3-lobed apically. *Capsules* ovoid, 3-lobed, (5–)6–7 mm long, on pedicels 1–4 mm long. *Seeds* angular-prismatic, ± 1.5 mm long, sculpturing foveate. *Flowering time*: mainly November to February.

Distribution and ecology: extending from Mariepskop and Graskop to Mt Schagen and the Lomati Valley and the mountains between Barberton in Mpumlanga, South Africa and adjacent Eswatini; along streams and in wet or marshy grassland at 1 000 to 1 400 m elevation. Collections reported from KwaZulu-Natal are *Aristea congesta* or *A. majubensis*.

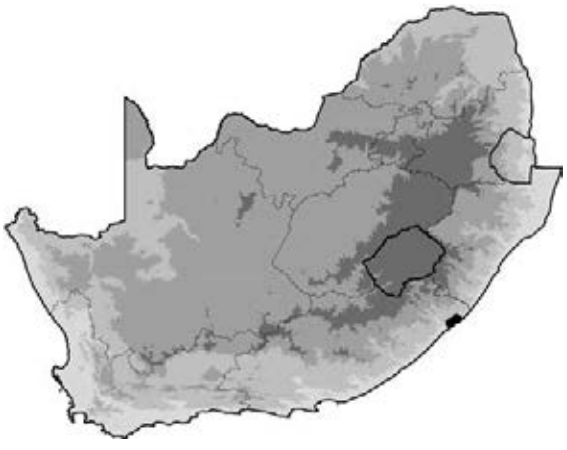
Diagnosis: first recorded in 1877 by Christopher Mudd, collecting for Messrs Veitch & Sons Ltd., and described by Baker (1892), *Aristea flexicaulis* has been recollected occasionally since then along the Mpumalanga Escarpment, including near Graskop. It is quite distinctive but poorly documented. Both Weimarck (1940) and Vincent (1985) recognised the species, but mistook the type locality as 'Fall Creek, near Howick' in KwaZulu-Natal. Baker (1892) recorded the locality simply as 'Transvaal'. There is no record that Mudd ever travelled in what is now KwaZulu-Natal. He entered southern Africa at Delagoa Bay (now Maputo) and travelled through eastern Mpumalanga to MacMac near Sabie and thence to the interior (Gunn & Codd, 1981), later visiting Durban (according to information on specimens).

Aristea flexicaulis is immediately recognised by the tall stature, some individuals exceeding 1 200 mm high, with stems divaricately branched in the upper quarter. Some of the branches bear sessile lateral flower clusters

Distribution of ***Aristea flexicaulis***.

plus one or two sessile axillary flower clusters. Flowers of plants from Graskop and Blyde are pale blue but elsewhere are deeper sky blue. The branching pattern and black colour on drying recalls the smaller *A. majubensis*, a species that rarely exceeds 350 mm in height, with mostly narrower leaves 1.5–6.0 mm wide, lacking white margins, and fewer branches typically without sessile lateral flower clusters. In habit and inflorescence *A. flexicaulis* resembles *A. compressa* from coastal areas along the eastern seaboard and has been much confused with it in the past, but that species has distinctive compressed, winged stems. The Eastern Cape and southern KwaZulu-Natal endemic *A. parviflora*, also with branches bearing several sessile lateral flower clusters, is distinguished from *A. flexicaulis* and other species in the alliance by its smaller spathes and bracts, up to 6 mm long, and smaller flowers with tepals ± 6 mm long and short, erect stamens.

11. **Aristea platycaulis** *Baker* in Gardeners' Chronicle, ser. 3, 1: 732 (1887); Weimarck: 50 (1940); Vincent: 250 (1985). Type: South Africa, [Eastern Cape], Pondoland coast, without precise locality but possibly Port Grosvenor, cultivated in Great Britain, *Tillet s.n.* (K, holo.).



Plants up to 250 mm high. *Stem* flattened and broadly winged, 5–6 mm wide below first fertile node, lower fertile nodes bearing short branches, lateral flower clusters sessile. *Leaves* sword-shaped, mostly 10–25 mm wide, soft-textured, basal ± as long as stem, cauline progressively smaller above. *Flower clusters* few to several in lax racemose arrangement, mostly 2- to 4-flowered; spathes and bracts narrow, 4–5 mm long, green becoming rust-brown, apices attenuate. *Flowers* blue, on pedicels ± 3 mm long; tepals 6–8 × 2–3 mm. *Filaments* 2–3 mm long; anthers ± 1.5 mm long. *Ovary* 3-lobed, papillate; style ± 5 mm long; stigma lobes narrowly deltoid. *Capsules* deeply 3-lobed, 3.5–4.0 × 4.0–4.5 mm, wider than high, conspicuously warty. *Seeds* evidently 2 per locule in a single row, ± globose, surface reticulate. *Flowering time*: mainly November and December.

Distribution and ecology: a narrow endemic of Eastern Cape, South Africa, known only from the Pondoland coast between Port St Johns and Port Edward; in clearings and forest margins in partly to fully shaded sites.

Diagnosis: the very distinctive *Aristea platycaulis* resembles the widespread *A. ecklonii* in general aspect, notably the modest stature, compressed, 2-winged stem and fairly soft-textured leaves, but the small flowers are crowded in shortly stalked or sessile flower clusters and have a short, papillate ovary that develops into a conspicuously warty, deeply 3-lobed capsule only 3.5–4.0 mm long and slightly wider than high. The distinctive capsules contrast starkly with the elongate, smooth-walled capsules of *A. ecklonii* and its allies. Weimarck (1940) placed *A. platycaulis* in his monospecific sect. *Trilobatae* because of its unusual fruits, but the deeply lobed capsules with rounded outlines and seeds placed in a single vertical row in each locule are comparable to the situation in *A. ecklonii* and *A. ensifolia* and it seems that it is mainly the proportions of the capsules, shorter than wide, and their warty surface that are unusual. Given the similar, broadly compressed stems in the three species, *A. platycaulis* remains included in a now more broadly circumscribed sect. *Cladocarpae* close to *A. ecklonii*. The pollen is not, however, shed in tetrads as is characteristic of *A. ecklonii* and *A. ensifolia*.

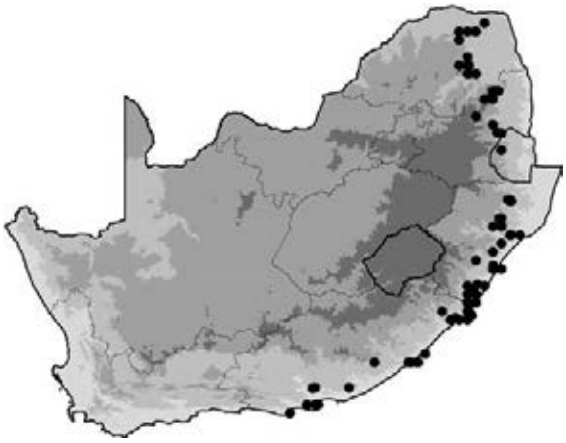
12. **Aristea ecklonii** *Baker* in Journal of the Linnean Society, Botany 16: 112 (1877); Weim.: 58 (1940); Vincent: 244 (1985); Goldblatt: 5 (1993); Goldblatt: 4 (1996). Type: South Africa, [Eastern Cape], banks of Kowie R., and to the east, June 1829, *Ecklon & Zeyher 59* [S, lecto., designated by Vincent: 244 (1985)].

Aristea stipitata R.C.Foster: 50 (1936), as a new name for *A. cyanea* De Wild.: 51 (1921), illegitimate homonym, not *A. stipitata* Aiton (1789). Type: Congo (DR), [Shaba], without precise locality, 7 Oct. 1914, *Bequaert 6025* (BR, syn., two sheets).

Distribution of ***Aristea platycaulis***.

Aristea dichotoma Eckl. ex Klatt: 551 (1866), illegitimate homonym, not *A. dichotoma* (Thunb.) Ker Gawl. (1827). Type: three syntypes cited, no lectotype designated.

Aristea paniculata Pax: 151 (April 1892). *A. lastii* Baker: 142 (Sept. 1892), illegitimate superfluous name for *A. paniculata* Pax [based on same type]. Type: Mozambique, Makua country, Namuli, *Last s.n.* (K, holo.).



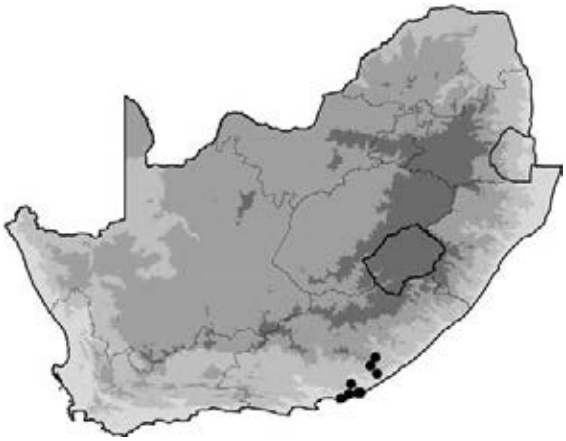
[*Aristea maitlandii* Hutch. in Hutchinson & Dalziel: 374 (1936), invalid name without description.]

Plants mostly 350–600 mm high. *Stem* compressed, 2-winged, usually several-branched and with sessile axillary flower clusters in upper axils subtended by short, sometimes bract-like leaves, when dry often turning rusty brown. *Leaves* sword-shaped, mostly 8–15 mm wide, soft-textured, mostly basal, cauline leaves shorter. *Flower clusters* several in lax arrangement, each mostly 4-flowered; spathes green with dry margins or completely dry and rust-brown, ± 10 mm long, bracts papery, rusty brown, shorter than spathes. *Flowers* deep blue; tepals elliptic, mostly 8–10 mm long. *Filaments* ± 4 mm long; anthers ± 2.5 mm long. *Style* short, erect, ± 5 mm long, broadly lobed apically. *Capsules* oblong-elongate, deeply 3-lobed, 12–20 mm long, on pedicels up to 4 mm long. *Seeds* shortly columnar, sculpturing reticulate, many per locule lying in a single vertical row. *Flowering time*: mostly September to December.

Distribution and ecology: widespread, extending from Humansdorp in Eastern Cape through KwaZulu-Natal and Mpumalanga to Limpopo in South Africa, and in Eswatini; also in tropical Africa in Cameroon, Democratic Republic of the Congo, Mozambique, Malawi, Kenya, Nigeria, Tanzania and Zimbabwe; in coastal and montane habitats, usually in shade in evergreen forest or forest margins. Widely cultivated today, both in Africa and in the Old and New World tropics and subtropics (notably in India, Sri Lanka and New Zealand).

Diagnosis: *Aristea ecklonii* is recognised by the compressed and relatively broad, sharply 2-winged flowering stem, rust-coloured floral bracts and sometimes spathes, and the relatively long, cylindric ovary (up to 8 mm long). The species is unmistakable in fruit as the elongated capsules are up to 20 mm long and deeply 3-lobed, showing the outline of the seeds. Unusually, the pollen is shed in tetrads, a condition rare in the Iridaceae and shared in the genus only with the closely allied *A. ensifolia* and with the unbranched *A. pusilla*. The tetrads are loosely held together and are best seen in microscopic preparations of fresh or recently dried collections. The related *A. cladocarpa* from Madagascar is often difficult to distinguish from *A. ecklonii* but is a smaller plant with shorter capsules, (6–)8–15 mm long compared to 12–20 mm in *A. ecklonii*, and the pollen is shed in monads.

Plants are self-compatible and autogamous, and the ample seed produced helps ensure its persistence in marginal situations, where it can even become weedy, remaining for years in abandoned gardens. In Africa it is sometimes uncertain whether plants encountered in the wild are native or introduced.



Distribution of ***Aristea ecklonii***.

13. **Aristea elliptica** *Goldblatt & A.P.Dold* in Goldblatt et al. in Bothalia 35: 3 (2005). Type: South Africa, Eastern Cape, Kariega Park, between Kenton-on-Sea and Salem, stony quartzitic outcrops, 21 Aug. 2003, *A.P. Dold 4604* (GRA, holo.; MO, NBG, iso.).

Plants 200–350(–500) mm high. *Stem* oval in section and prominently 2-winged, 2.5–3.0 mm wide, normally unbranched, with (2)3 or 4 sessile lateral flower clusters or lowermost shortly stalked. *Leaves* clustered basally, with 2 cauline leaves, linear to narrowly sword-shaped, (2.5–)4.0–6.0 mm wide, firm to leathery, with narrow hyaline margins. *Flower clusters* 3 to 5, terminal cluster 2-flowered, lateral clusters 1- or 2-flowered; spathes green with membranous, hyaline or brown margins, (25–)30–38 mm long; bracts green to dry, ⅓ as long as spathes. *Flowers* pale blue, outer tepals with broad green stripe on reverse; tepals unequal, outer 16–18 × ± 7 mm, inner ± 16 × ± 9 mm. *Filaments* ± 3 mm long; anthers ± 3 mm long. *Ovary* cylindric, 3-lobed, 12–16 mm long, on pedicels up to 3 mm long; style ± 6.5 mm long; stigma lobes fringed. *Capsules* cylindric, deeply 3-lobed, (20–)24–30 mm long. *Seeds* ellipsoid, many per locule in single row, often oriented obliquely to capsule axis, smooth, surface cells ± plane to weakly domed. *Flowering time*: August to October.

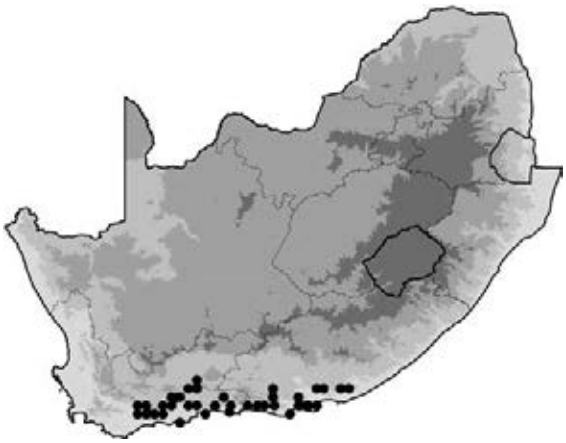
Distribution and ecology: restricted to central Eastern Cape, South Africa, extending from the Zuurberg Mtns to the Fish River Mouth; mainly on sandstone slopes and often on rock outcrops, in fynbos or grassy fynbos.

Diagnosis: *Aristea elliptica* most closely resembles the diminutive southern Cape species *A. pusilla*, in which it has been included as *A. pusilla* subsp. *robustior* (although the type illustration more likely represents a well-grown specimen of typical *A. pusilla*). It is

Distribution of ***Aristea elliptica***.

recognised by its low stature, combined with relatively broad stem and leaves, these rather firm and more leathery, and by the long, angular ovary and elongate capsules 20–30 mm long. The seeds are ellipsoid and unique in *Aristea*, with the surface cells plane or only weakly domed. The seeds lie in a single row in each locule, as in the related *A. ecklonii, A. ensifolia* and *A. pusilla*, but, unlike the horizontally packed seeds in these species, those of *A. elliptica* are loosely arranged and often oriented obliquely to the long axis of the capsule in a zig-zag arrangement with only their tips touching. The pollen grains are disulculate and shed singly with the two large apertures covered with exine, whereas pollen of the related species is shed in tetrads, with the apertures operculate.

14. **Aristea pusilla** *(Thunb.) Ker-Gawl.* in König & Sims, Annals of Botany 1: 236 (1804); Weimarck: 68 (1940); Vincent: 246 (1985). *Moraea pusilla* Thunb.: no. 7 (1787). Type: South Africa, without precise locality or date, *Thunberg s.n.* (UPS–THUNB 1262, holo.).



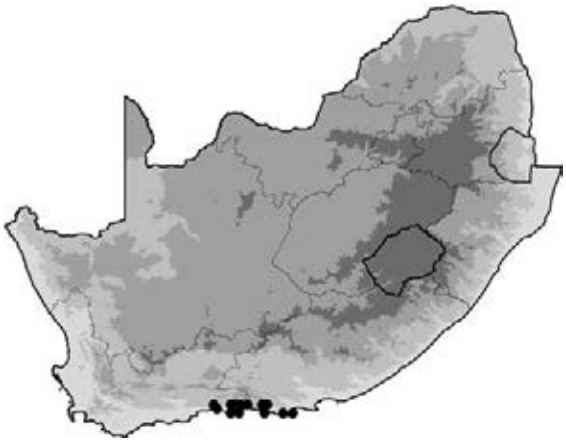
Aristea pusilla subsp. *robustior* Weim.: 69 (1940); Vincent: 248 (1985). Type: South Africa, without precise locality, illustration entitled *Aristea pusilla* in Ker Gawl.: t. 1231 (1809).

Plants (50–)80–150 mm high. *Stem* oval in section and narrowly 2-winged, 1.5–2.2 mm wide, unbranched, sometimes with 1 or 2 sessile lateral flower clusters. *Leaves* linear to sword-shaped, mostly 2–4 mm wide, fairly soft-textured, with narrow hyaline margins. *Flower clusters* 1 to 3, terminal cluster 2-flowered, lateral clusters usually 1-flowered; spathes subequal or unequal, green with membranous, hyaline or rust-coloured margins, 16–20 mm long, bracts ± dry, < ⅓ as long as spathes, sometimes minute, concealed in spathes. *Flowers* deep blue, outer tepals with a broad green strip outside; tepals unequal, outer 11–14 × 5–7 mm, inner 9–11 × 8–9 mm. *Filaments* ± 2 mm long; anthers ± 2.5 mm long. *Ovary* triangular-columnar, up to 12 mm long, on pedicels up to 2 mm long; style ± 6.5 mm long, stigma lobes slightly fringed. *Capsules* cylindric, 3-lobed, lobes with rounded to acute edges, (14–)20–25(–30) mm long. *Seeds* round in section, flattened or lightly concave at top and bottom, many per locule in a single row, sculpturing foveate, surface cells domed to papillate. *Flowering time*: September to November.

Distribution and ecology: occurring in South Africa in Western and Eastern Cape, along the southern coast from Swellendam to Alexandria and inland in the Swartberg and Langeberg; mainly on stony clay flats and lower slopes, typically in renosterveld or in grassland in the east of its range.

Diagnosis: a dwarf plant, typically 80–120 mm high but sometimes shorter, *Aristea pusilla* is readily recognised by its soft-textured, sword-shaped leaves and compressed and narrowly 2-winged flowering stem, 1.5–2.0 mm wide, bearing one or more leaves along its length. The stem is often unbranched with a single terminal flower cluster but particularly robust plants may have one or two sessile lateral flower clusters. The flower clusters have at most two flowers and the lateral clusters often just a single flower. The flowers are contained within relatively long, green spathes and are ± sessile and carried on elongate ovaries above the spathes. The ovary is triangular in cross section, but mature capsules, (14–)20–25(–30) mm long, are 3-lobed with each locule having a broad, rounded outline. The seeds lie closely packed in a single row in each locule, and are round in cross section with the top and bottom flattened due to pressure. As in other members of sect. *Cladocarpae*, the seeds have foveate sculpturing and fairly prominently domed to papillate surface cells. *Aristea pusilla* shares an elongate, 3-lobed capsule with *A. elliptica*, *A. ecklonii* and *A. ensifolia*, and this evidence of relationship is supported by a second derived feature, pollen shed in tetrads in the latter two species (but not in *A. elliptica*).

Weimarck (1940) recognised subsp. *robustior* for somewhat larger plants with thicker, fibrous leaves. The type of this name, an illustration in *Curtis's Botanical*



Distribution of ***Aristea pusilla***.

Magazine, seems in no significant way different from typical *A. pusilla*, but some specimens cited by Weimarck as subsp. *robustior* are now included in *A. elliptica*, usually a taller plant 200–350(–500) mm high. Typical *A. pusilla* rarely exceeds 120 mm and the tallest plants are 150 mm high, with specimens less than 80 mm tall not uncommon. Associated with its larger size, *A. elliptica* has flowering stems with up to 4(5) flower clusters, the lowermost sometimes shortly stalked, and flowers with tepals 16–18 mm long, thus larger than those of *A. pusilla*, which has tepals 12–14 mm long.

At some sites in the southern Cape *Aristea pusilla* grows close to or mixed with *A. nana* and the two are superficially very alike. Plants of *A. nana* always have an extended, leafless terminal internode and flowers borne on pedicels 10–20 mm long, a short ovary 5–8 mm long, and ovoid capsules 6–12 mm long. In contrast, *A. pusilla* has at least one cauline leaf inserted at about the middle of the stem, often one or more sessile lateral branches, flowers borne on short pedicels, an elongate ovary up to 12 mm long and triangular in outline, and cylindric, 3-lobed capsules (14–)20–25(–30) mm long. No hybrids between the two are known even though bees visit and pollinate flowers of both species.

15. **Aristea ensifolia** *Muir* in L.Bolus in Annals of the Bolus Herbarium 3: 139 (1922); Weim.: 63 (1940). Type: South Africa, [Western Cape], Albertinia, Nov. 1922, *Muir 2458* (BOL, holo.).

Plants up to 500 mm high. *Stem* compressed and 2-winged, few- to several-branched, bearing several sessile, lateral flower clusters. *Leaves* sword-shaped, ± ⅔ as long as stem, 6–12 mm wide, soft-textured. *Flower clusters* several per axis in lax arrangement, each mostly 2 or 3(rarely 4)-flowered; spathes green, bracts ± membranous. *Flowers* blue; tepals ellipsoid, ± 15 mm long. *Filaments* ± 5 mm long; anthers ± 3 mm long. *Ovary* on pedicels up to 5 mm long; style ± 7 mm long; stigma lobes deltoid, fringed. *Capsules* on pedicels 10–15 mm long, 35–50 mm long, cylindric, 3-lobed, erect or drooping, indehiscent, decaying with age to release seeds. *Seeds* shortly columnar, with foveate sculpturing, many per locule, in single row. *Flowering time*: mainly October and November.

Distribution of ***Aristea ensifolia***.

Distribution and ecology: restricted to southern South Africa, extending from near Albertinia in Western Cape to the Van Stadens Mtns in Eastern Cape; in coastal evergreen forest, in shade or clearings.

Diagnosis: *Aristea ensifolia* is distinguished by the strongly compressed and winged stem, often with a few branches but with sessile lateral flower clusters, relatively small flowers and elongate, often drooping capsules 35–50 mm long. The seeds are shortly columnar and arranged in a single row in each locule. The pollen of *A. ensifolia* is shed in tetrads, a feature found elsewhere in the genus only in *A. ecklonii* and *A. pusilla*. The three species evidently comprise a clade within sect. *Cladocarpae*. The Madagascan *A. cladocarpa*, which also has elongate capsules and locules with seeds in a single vertical row, has pollen grains shed singly. The capsules are indehiscent, the walls decaying irregularly to release the seeds.

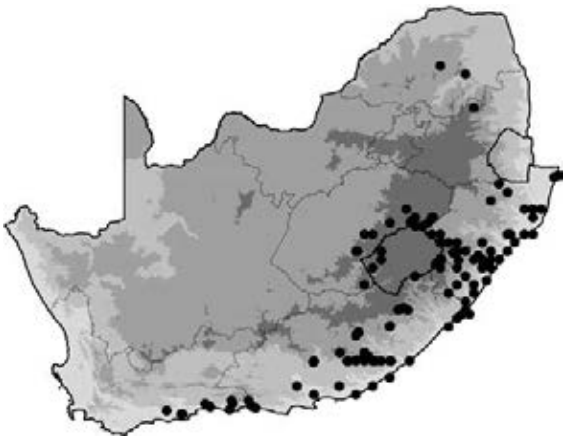
Sect. 3. **Ancipites** *Weim.* in Acta Universitatis Lundensis, ser. 2, 36(1): 36 (1940). Type: *Aristea anceps* Eckl., lecto., designated here.

Plants small to moderate in size, up to 50 mm high. *Stem* usually unbranched, compressed and broadly 2-winged, of a single internode, bearing a small leaf below first flower cluster (or leafless in *A. nana*). *Flower clusters* 1(2, rarely 3), 2 to 4-flowered. *Flowers* blue; tepals connate at base, subequal. *Style* 3-lobed. *Capsules* ovoid to ellipsoid or ± shortly cylindric. *Seeds* angular-prismatic. *Pollen grains* zonasulculate, exine reticulate.

Species ± 5: eastern southern Africa as far south as George, also in tropical Africa as far north as Ethiopia.

16. **Aristea abyssinica** *Pax ex Engler*, Über die Hochgebirgsflora des tropischen Afrika: 173 (1892); Goldblatt: 7 (1993); Goldblatt: 10 (1996); Goldblatt: 165 (1997). *A. alata* subsp. *abyssinica* (Pax) Weim.: 44 (1940). *A. cognata* subsp. *abyssinica* (Pax) Marais: 932 (1987). Type: Ethiopia, Tigre and Begemder, *Schimper 279* (B, holo.; BM, K, iso.).

Aristea johnstoniana Rendle: 48 (1894). Type: Malawi, Mt Mulanje, June 1891, *Whyte 14* (BM, lecto., designated by Goldblatt: 10 (1996); K, isolecto.).



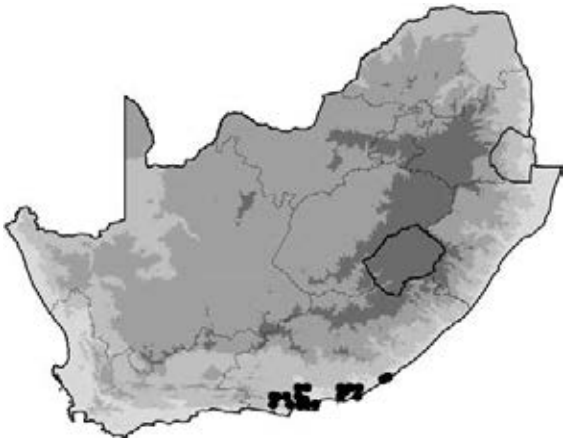
Aristea tayloriana Rendle: 48 (1894). Type: Tanzania, Kilimanjaro, *W.E. Taylor s.n.* [BM, lecto., designated by Goldblatt: 10 (1996)].

Aristea cognata N.E.Br. ex Weim.: 174 (1937); Weim.: 39 (1940). Type: South Africa, Transvaal, [Limpopo], Houtbosch, 1875–1880, *Rehmann 5769* (K, holo.).

Plants (80–)120–300(–500) mm high. *Stem* compressed and 2-winged, 1–2(–3) mm wide, consisting of 1 long internode with a short, subterminal leaf, simple or with short subterminal branch. *Leaves* linear to narrowly sword-shaped, in a basal fan, half to ± ⅔ as long as stem; cauline leaf solitary, 8–20 mm long, subtending apical flower cluster. *Flower clusters* mostly 1 or 2(3) on short branches or ± sessile, crowded near stem apex, each mostly 2-flowered, rarely with ± sessile flower cluster at stem base; spathes green with dry margins or entirely dry, 6–11 mm long, bracts slightly shorter than spathes, dry-membranous, often rust-brown, torn with age. *Flowers* blue, ± sessile; tepals elliptic, unequal, outer ± 6–11 × 3–6 mm, inner ± as long but 5–7 mm wide. *Filaments* 3–4 mm long; anthers ± 2.2 mm long. *Style* 5–6 mm long; stigma lobes broad, undulate. *Capsules* ovoid-oblong, (4–)5–8 mm long, subsessile or on pedicels up to 2 mm long. *Seeds* angular-prismatic, sculpturing reticulate. *Flowering time*: November to January.

Distribution and ecology: widespread in eastern South Africa, extending from near Knysna in Western Cape through Eastern Cape, Free State, KwaZulu-Natal and Mpumalanga to Limpopo, also Lesotho and Eswatini, and in tropical Africa as far north as Ethiopia; in coastal and montane grassland.

Diagnosis: Aristea abyssinica is readily recognised by the compressed, 2-winged stem, comprising a long terminal internode bearing a subterminal leaf subtending one or two flower clusters. This growth form is matched only in *A. alata* of eastern tropical Africa and *A. anceps* and *A. nana* of Eastern Cape, South Africa. *Aristea anceps* has dry, rust-coloured spathes and bracts 15–20 mm long, whereas the more robust *A. alata* has broader, softer-textured leaves (3–)4–6 mm wide, and capsules typically borne on well-developed stalks 5–16(–25) mm long. Diminutive *A. nana* does not have a subterminal leaflet and the flowers are enclosed in green spathes and are borne on pedicels ± 10 mm long.



Distribution of ***Aristea abyssinica***.

With so wide a range it is not surprising that *Aristea abyssinica* is somewhat variable. Dwarfed plants from eastern South Africa and Lesotho may be only 80–100 mm high and were described as *A. cognata*. Marais (1987) later reduced *A. abyssinica* to subspecies rank in *A. cognata* (despite the nomenclatural priority of the former name), recognising their strong similarity but emphasizing the smaller size of southern African plants. *Aristea cognata* is regarded here as a synonym of *A. abyssinica* because of the absence of a discrete separation between the two taxa. In southern Africa both short (*A. cognata*-type) plants and taller ones 150–300 mm high, virtually identical to *A. abyssinica* from Zambia, Tanzania and elsewhere, can often be found growing together, the shorter plants in exposed, rocky or trampled places and the taller ones in deeper soils in dense grass. Other features, including flower size, leaf and stem width, cited by Marais (1987) as separating the two taxa, overlap considerably and plants from South Africa often match those from tropical Africa closely.

A characteristic feature of *Aristea abyssinica* that appears not to have been recorded in the literature is the production of flower clusters at the base of some plants on very short flowering stems in both southern and tropical Africa. The flowers of these almost stemless flower clusters are not known, but apparently normal capsules are produced, possibly the result of cleistogamous reproduction. *Aristea abyssinica* is heteroploid, with chromosome numbers of $2n = 32$ and 64 reported for different populations.

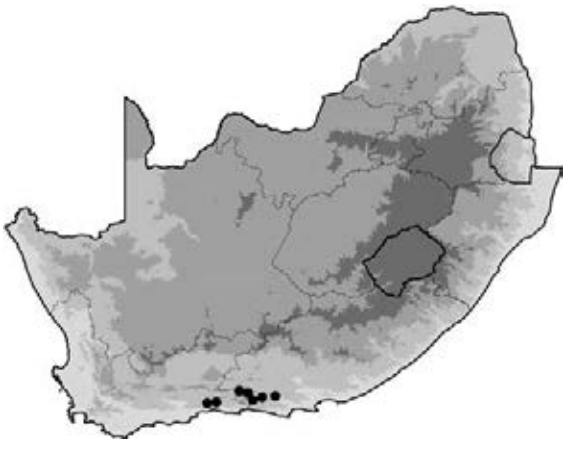
17. **Aristea anceps** *Eckl. ex Klatt* in Linnaea 34: 550 (1866); Weimarck: 37 (1940); Vincent: 215 (1985). Type: South Africa, [Eastern Cape], banks of the Kowie River and to the east, Nov. [without year], *Ecklon & Zeyher Irid 55* (S, lecto., designated by Vincent: 215 (1985); BSB, C, LD, MO, isolecto.).

Plants (80–)150–350 mm high, usually in small tufts. *Stem* flattened and 2-winged, mostly consisting of 1 long internode 2.0–3.5 mm wide, usually with a short, subterminal leaf up to 60 mm long, this sometimes evidently not developed or indistinguishable from spathes. *Leaves* narrowly sword-shaped, half to ± as long as stem, (1.5–)2.5–4.0 mm wide, with narrow, acute hyaline margins. *Flower clusters* (1)2(3) crowded at stem apex, nearly sessile or on short stalks up to 5 mm long, each (2)4-flowered; spathes dry rusty brown (or green toward base), 15–22 mm long, bracts slightly shorter or longer than spathes, dry rust-brown, becoming torn with age. *Flowers* subsessile, deep blue; tepals united basally for ± 3 mm, outer tepals 15–18 × 6–7 mm, inner ± 17 × 8–9 mm. *Filaments* ± 4 mm long; anthers ± 3 mm

Distribution of ***Aristea anceps***.

long. *Style* ± 5 mm long, stigma lobes rounded, undulate. *Capsules* ovoid-oblong, 8–12 mm long, subsessile. *Seeds* angular-prismatic, sculptering foveate. *Flowering time*: mainly September to November, occasionally as late as January.

Distribution and ecology: endemic to Eastern Cape, South Africa, extending from Joubertina in the Long Kloof through the Baviaanskloof and Zuurberg Mtns to Grahamstown and as far east as East London; mainly on rocky sandstone slopes and flats, but in montane grassland up to 700 m elevation. [Published records of the species from Sir Lowry's Pass and the Hottentots Holland in Western Cape are incorrect and should be ignored].



Diagnosis: *Aristea anceps* has the distinctive growth form of sect. *Ancipites*, the flowering stem comprising a long upper internode with a small subterminal leaf subtending the terminal flower cluster. Although broadly similar to *A. abyssinica*, it is distinguished by the sturdier stem and the longer, firm-textured, rusty brown spathes and bracts ± 15–20 mm long. *Aristea abyssinica*, which has sometimes been included in *A. anceps* (Baker, 1896), has shorter spathes and bracts 6–11 mm long, either green or dry and translucent but not rust-coloured. The two are sympatric around Grahamstown in Eastern Cape, but they normally have different habitats, *A. anceps* largely restricted to sandy soils in stony, montane or lowland grassland and grassy fynbos, and *A. abyssinica* a grassland species most often found in montane habitats in areas of higher rainfall.

18. **Aristea nana** *Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 35: 1 (2005). Type: South Africa, Eastern Cape, hill slopes immediately north of Joubertina (growing with *A. pusilla*), 19 Sept. 2004, *P. Goldblatt & L.J. Porter 12492* (NBG, holo.; K, MO, PRE, iso.).

Plants 80–150(–180) mm high. *Stem* flattened and 2-winged, 1.2–1.7 mm wide, 1 or 2 per plant, with an elongate, leafless upper internode up to 105 mm long, occasionally with a second short stem up to 30 mm long; stems each with a single terminal flower cluster. *Leaves* narrowly sword-shaped to linear, ± as long as stem or slightly longer, 1.5–3.0 mm wide, with narrow, acute hyaline margins sometimes flushed red. *Flower clusters* solitary, terminal, (1)2-flowered; spathes green, acute-attenuate, margins dry, translucent, (13–)15–22(–26) mm long, bracts similar, 6–15 mm long. *Flowers* on pedicels 10–15 mm long, blue, outer tepals green outside; tepals unequal, outer 10–16 × 3.5–5.0 mm, inner 11–17 × 5.5–11.0 mm. *Filaments* 3–4 mm long; anthers 2.5–3.0 mm long, yellow. *Style* 5.5–8.0 mm long; stigma lobes slightly fringed. *Capsules* ovoid, 6–12 mm long, on pedicels up to 20 mm long. *Seeds* globose, without sculpturing, surface cells tuberculate. *Flowering time*: September and October.

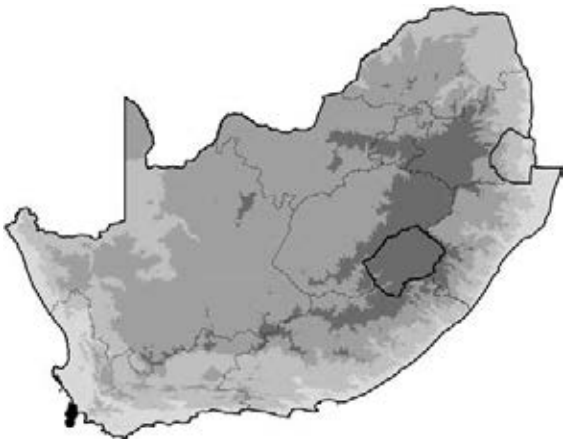
Distribution and ecology: occurring in Western and Eastern Cape, South Africa, from Robinson's Pass to Bathurst; on sandy and rocky slopes, in grassy fynbos.

Diagnosis: a dwarf species mostly less than 120 mm tall, *Aristea nana* has rarely been collected and has then usually been confused with similarly low-growing *A. pusilla*. The two sometimes co-occur but can be distinguished not only by height but also by the leaves, those of *A. nana* having a glaucous bloom and wider translucent margins, whereas the pale green leaves of *A. pusilla* are softer textured. The flowering stem of *A. nana* is almost always unbranched and bears leaves only near the base. The terminal internode is several times longer than the rest of the stem and terminates in a single inflorescence of 2(3) flowers. Particularly striking are the well-developed pedicels of the flowers, 10–12 mm long, and the ovoid ovary 4–6 mm long, quite different to the short pedicels, ± 2 mm long and triangular-columnar ovary 12 mm long of *A. pusilla*. The two species also differ in pollen, the grains in *A. pusilla* shed in tetrads and monosulcate with exine masses over the aperture, but shed singly in *A. nana* and dizonasulculate with 2 smooth, well-defined apertures at opposite ends of the grains.

Distribution of ***Aristea nana***.

Despite their superficial similarity, *Aristea nana* and *A. pusilla* are probably not closely related, with *A. nana* evidently most closely allied to the eastern southern African *A. abyssinica* Pax (including *A. cognata* N.E.Br.) and *A. anceps* Eckl. ex Klatt. These two species also have unbranched, flattened and broadly winged flowering stems with an extended upper internode, thus bearing leaves only near the base. In addition, *A. nana*, *A. abyssinica*, and *A. anceps* are unusual in the genus in sometimes producing a short flowering stem held close to the base of the plant in addition to the normal extended flowering stems.

Subg. 2. **Pseudaristea**



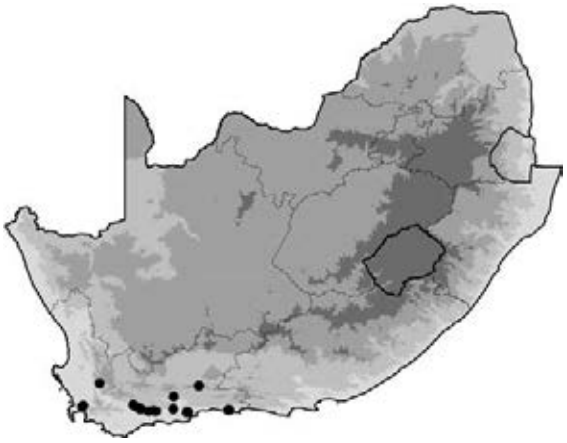
Pseudaristea *(Pax) Goldblatt* in Novon 22: 416 (2013). *Aristea* sect. *Pseudaristea* Pax: 153 (1888). Type: *A. spiralis* (L. f.) Ker Gawl., lecto., designated by Goldblatt: 416 (2013).

Flowers either deep to pale blue and fugaceous, or pale blue, cream-coloured or white with contrasting markings and lasting 1 full day or 2 days; tepals subequal or outer slightly to much smaller than inner. *Capsules* cylindric, 3-angled or 3-lobed, tardily or not dehiscent. *Seeds* columnar-triangular, many per locule in single row. *Pollen grains* dizonasulculate, exine reticulate.

Species 9: restricted to the southern African winter-rainfall region.

19. **Aristea pauciflora** *Wolley-Dod* in Journal of Botany, British and foreign 38: 171 (1900); Weim.: 65 (1940). Type: South Africa, [Western Cape], Cape Peninsula, Orange Kloof, below farm, Oct. 1897, *Wolley Dod 3507* (K, lecto., effectively designated by Weim.: 65 (1940); BOL, isolecto.).

Plants 200–400 mm high, forming tufts. *Stem* elliptic in section, 2-angled to narrowly winged, usually unbranched with sessile lateral flower clusters. *Leaves* linear, leathery, mostly 2–4 mm wide, oval in cross section with rounded edges and without defined margins. *Flower clusters* 2 to 4, each (2)3- or 4-flowered; spathes greenish becoming dry and blackish above, 15–20 mm long, bracts dry, shorter than spathes. *Flowers* deep blue, upright; tepals subequal, 15–22 × 8–10 mm, outer slightly shorter than inner. *Filaments* ± 3.5 mm long; anthers 3–4 mm long. *Ovary* cylindric-trigonous; style ± 9 mm long; stigma lobes broad, fringed. *Capsules* elongate, 3-lobed, lobes acutely angled, woody, indehiscent, (20–)25–35 mm long. *Seeds* triangular-columnar, many per locule in a single row, surface smooth. *Flowering time*: October to December.



Distribution of ***Aristea pauciflora***.

Distribution and ecology: a rare local endemic of the Cape Peninsula, Western Cape, South Africa; mainly on granitic slopes.

Diagnosis: the small, deep blue flowers of *Aristea pauciflora* are unremarkable for the genus, but the elongate, 3-angled ovary and long, indehiscent capsules place the species in subg. *Pseudaristea*, an association confirmed by the pollen grains with two circular apertures, thus dizonasulculate as in other members of the subgenus. The relatively small flowers with subequal tepals 15–22 mm long and short anthers 3–4 mm long resemble those of most species of *Aristea* whereas other species of sect. *Pseudaristea* often have longer anthers, mostly 4.5–6.0 mm long. The leaves of *A. pauciflora* are unique in the section in their rounded margins lacking the typical marginal anatomy of translucent, thickened marginal epidermal cells of other members of subg. *Pseudaristea*, in which the margins have acute edges that become hyaline when dry. *Aristea pauciflora* is most easily confused with *A. simplex*, which has either pale or sometimes deep blue flowers of similar proportions but half to fully nodding, and plane leaves with acute margins.

20. **Aristea simplex** *Weim.* in Acta Universitatis Lundensis, ser. 2, 36: 64 (1940). Type: South Africa, [Western Cape], Grootvadershoek, stony slopes near Rietkuil, Oct. [without year], *Zeyher 4058* (B [? Destroyed], C, K, S, syn.).

Plants up to 500 mm high, forming tufts. *Stem* elliptic in section, usually unbranched, bearing sessile lateral flower clusters. *Leaves* linear, narrow, 2–4 mm wide, firm to stiff and leathery, margins angular, translucent, hyaline when dry. *Flower clusters* (2)3 to 6, each (2)4-flowered; spathes dark green with translucent margins, bracts dry-membranous. *Flowers* half to fully nodding, pale to deep blue, greenish in throat; outer tepals 16–19 × 6–8 mm, inner tepals 15–22 × 10–12 mm. *Filaments* ± 4 mm long; anthers ± 3.5 mm long. *Ovary* elongate, >20 mm long, triangular in section; style broadly 3-lobed;

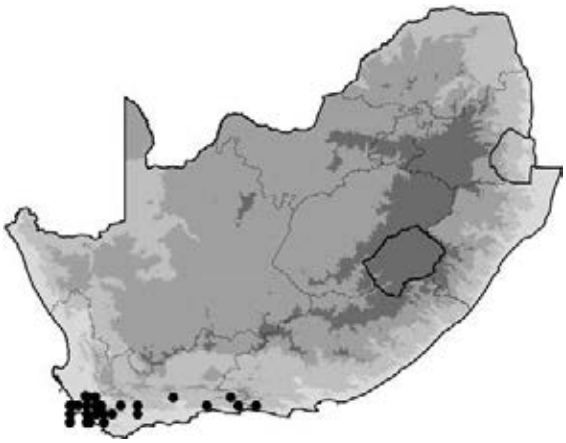
Distribution of ***Aristea simplex***.

stigma lobes fringed. *Capsules* elongate, deeply 3-lobed, up to 35 mm long, woody, indehiscent. *Seeds* triangular-columnar, many per locule in a single row, surface smooth. *Flowering time*: September and October.

Distribution and ecology: widespread in the southwestern and southern Western Cape, South Africa, extending from the Witzenberg to George, and local in the Swartberg Mtns; on clay and sandy loam flats and lower slopes in renosterveld or fynbos.

Diagnosis: superficially similar to *Aristea spiralis* and often confused with it, *A. simplex* has narrower leaves and significantly smaller, pale to deep blue flowers with tepals 15–20 mm long versus white or pale blue flowers with tepals 30–35 mm long in *A. spiralis*. The ovate to broadly elliptic stems of *A. simplex* and narrow, ± linear, leathery leaves, 2–4 mm wide, also contrast with the compressed, prominently winged stems of *A. spiralis* and its broader, sword-shaped, softer-textured leaves, 4–7 mm wide. Flowers of *A. spiralis* are unique in the genus in producing small quantities of nectar from nectaries at the tepal bases, while the flowers of two populations of *A. simplex* examined do not produce nectar. Although their ranges appear to overlap, *A. spiralis* is predominantly a species of sandstone or granitic mountain slopes, whereas *A. simplex* favours heavier soils of clay or sandy loam and is known mainly from relatively low elevations.

21. **Aristea spiralis** *(L.f.) Ker Gawl.* in König & Sims, Annals of Botany 1: 236 (1804); Weim.: 51 (1940). *Moraea spiralis* L.f.: 99 (1782). *Sisyrinchium spirale* (L.f.) Eckl.: 16 (1827). Type: South Africa, [Western Cape], without precise locality or date, *Thunberg s.n.* (UPS–THUNB, holo.).



Plants 200–500 mm high, often in small tufts. *Stem* flattened, elliptic in section, 2-winged, often broadly so in lower half, usually unbranched, bearing (2)4 to 7 sessile lateral flower clusters. *Leaves* narrowly sword-shaped, 4–7 mm wide, relatively soft-textured, margins angular, translucent, hyaline when dry. *Flower clusters* several, each (2)4-flowered; spathes greenish with translucent margins, 33–45 mm long, bracts dry-membranous, shorter than spathes. *Flowers* half to fully nodding, on pedicels 3–5 mm long, white or pale blue, with linear or V-shaped purple markings at tepal bases; tepals 28–35 mm long, inner slightly larger than outer. *Filaments* usually 22–26 mm long (rarely half as long); anthers 4.5–6.3 mm long. *Ovary* elongate, 3-lobed, 12–15 mm long; style 30–35 mm long, stigma lobes spreading, deeply fringed. *Capsules* elongate, ± woody, tardily dehiscent, deeply 3-lobed, 30–50 mm long. *Seeds* triangular-columnar, many per locule in a single row. *Flowering time*: mainly September to November.

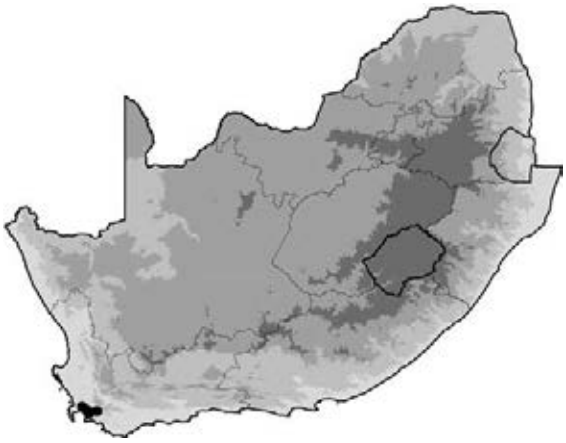
Distribution and ecology: fairly widespread in Western Cape, South Africa, extending from Bain's Kloof to the Cape Peninsula and east to Knysna; mainly on stony sandstone and granite slopes, up to 1 000 m elevation and flowering well only after fire.

Diagnosis: the most widespread and common species of sect. *Pseudaristea*, *Aristea spiralis* is recognised by the large, half to fully nodding flowers, mostly white with light purple markings near the bases of the tepals but an attractive pale blue in the southern part of its range in the Langeberg and the mountains around Hermanus and Bredasdorp. It is the only species of *Aristea* that produces nectar, secreted from perigonal nectaries at the base of the tepals. The stamens and style extend horizontally and most populations have particularly long filaments, 22–26 mm long, whereas allied species have filaments 5–6 mm long or only 3–4 mm in *A. pauciflora*.

The elongate filaments and nectar production are adaptations to its unique pollination system as the only species of the genus pollinated by long-proboscid flies, *Philoliche* species (Tabanidae) (Goldblatt & Manning, 1997a).

Some populations currently included in *Aristea spiralis* have unusually short filaments but otherwise match the species in their distinctive, strongly compressed,

Distribution of ***Aristea spiralis***.



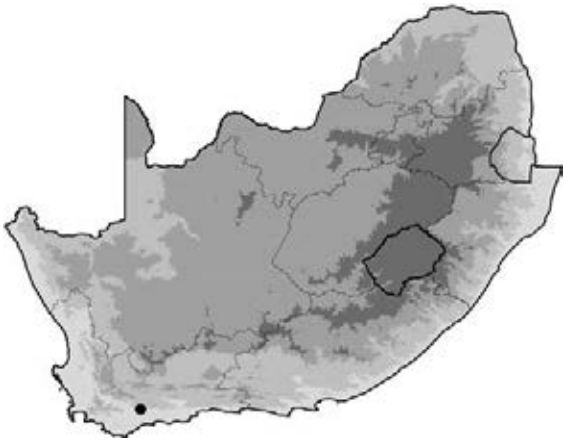
broadly 2-winged flowering stem and tepals with purple markings near the base. Whether flowers of this morph produce nectar or not is unknown. It is noteworthy that plants with either long or short stamens have the same unique pollen grains with rounded, supratectal exine deposits termed gemmules (Goldblatt & Le Thomas, 1997; Goldblatt et al. 2004).

22. **Aristea cantharophila** *Goldblatt & J.C.Manning* in Novon 7: 138 (1997a). Type: South Africa, Western Cape, foot of Sir Lowry's Pass, 1 Sept. 1995, *Goldblatt & Manning 10284* (NBG, holo.; K, MO, iso.).

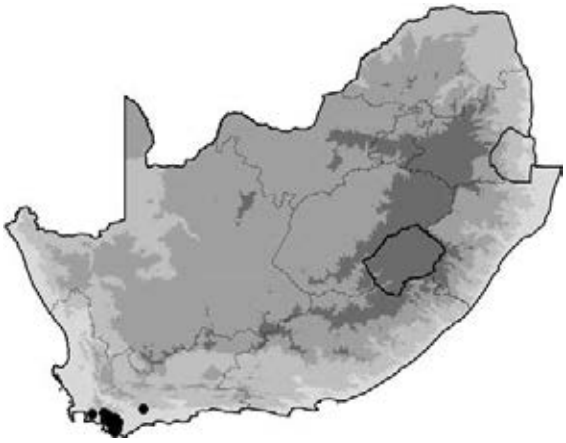
Plants 200–400 mm high, forming tufts. *Stems* oval to elliptic in section, usually unbranched, bearing 1 or 2 sessile lateral flower clusters. *Leaves* linear, reaching to ± middle of stem, 2–4 mm wide. *Flower clusters* 2 or 3, sessile except the terminal, each 2- to 4-flowered; spathes greenish with translucent margins, becoming dry from apex, 20–28 mm long, bracts dry-membranous, ± 10 mm long, membranous. *Flowers* on pedicels 8–10 mm long, pale lilac, mauve, or whitish with a dark greenish black central eye 6–7 mm diam. grading to turquoise at edges, reverse of outer tepals greenish along midlines and the right halves flushed beige; tepals obovate, 22–26 × 12–15 mm, outer three slightly smaller than inner. *Filaments* ± 5 mm long; anthers ± 5.5 mm long; pollen orange. *Ovary* cylindric-trigonous, curving outward, 15–18 mm long, rapidly elongating after fertilisation; style 12–15 mm long, stigma lobes broad, fringed. *Capsules* cylindric, deeply 3-lobed in cross section, woody, indehiscent, (25–)35–50(–60) mm long. *Seeds* many per locule in a single vertical row, obliquely truncate, surface smooth. *Flowering time*: August and September; opening ± 9:00, fading in late afternoon the same day.

Distribution and ecology: local in Western Cape, South Africa, from Du Toit's Kloof to Bot River; on clay and granite slopes in fynbos or renosterveld.

Diagnosis: typical of subg. *Pseudaristea*, *Aristea cantharophila* has sessile lateral inflorescences, a cylindric ovary and elongate capsules 50–60(–75) mm long, longer than any other species of the subgenus. The flower colour is distinctive, pale lilac, mauve, or whitish with a dark greenish black central eye 6–7 mm diam. grading to turquoise at edges. Both the filaments and style are also dark greenish black. The relatively large tepals are 22–26 × 12–15 mm with the outer three slightly smaller than the inner, and the large anthers, ± 5.5 mm long, bear orange pollen. The relationships of *A. cantharophila* appear to be with *A. pauciflora* and *A. simplex*, both of which have pale or dark blue flowers without a dark centre. All three species have flowers that last a single day each, the flowers of *A. pauciflora* opening shortly after sunrise and fading early in the afternoon whereas those of *A. cantharophila* open at ± 9:00 and fade late in the afternoon (phenology unknown for *A. simplex*). Apart from the distinctive colouring of the tepals, filaments and anthers, there are no major differences among the three species. *Aristea cantharophila* appears to have particularly long capsules and is the smallest of the three, plants mostly ± 200 mm high, occasionally up to 300 mm. More robust, *A. pauciflora* stands 350–600 mm high and has dark blue flowers with subequal tepals 15–18 mm long. *Aristea simplex* has pale or sometimes dark blue flowers with an unusual secund orientation, and stands 300–500 mm high. Flowers of *A. cantharophila* are pollinated by hopliine beetles, species of which assemble and mate on the horizontally oriented flowers (Goldblatt & Manning 1997a).



Distribution of ***Aristea cantharophila***.



23. **Aristea cistiflora** *J.C.Manning & Goldblatt* in Goldblatt et al. in Bothalia 35: 5 (2005). Type: South Africa, Western Cape, Swellendam, Marloth Reserve, Reservoir Hill, 22 Aug. 2003, *J.C. Manning 2875* (NBG, holo.; MO, PRE, iso.).

Plants (100–)300–500 mm high, forming tufts up to 150 mm diam. *Stem* erect, occasionally with 1 or 2 short branches, elliptic in cross section, with (1)4 to 6 sessile lateral flower clusters. *Leaves* linear, mostly 2.5–3.0 mm wide, reaching to ± middle of stem, loosely twisted. *Flower clusters* (1)4 to 6, mostly sessile, each 2- to 4-flowered; spathes greenish with translucent margins becoming dry above, 15–18 mm long, bracts shorter than the spathes. *Flowers* half nodding, held at 45° to horizontal, pale pink to pale lilac, streaked dull brownish outside, outer tepals copper-brown in the lower ⅓, usually with a yellow central streak; outer tepals 22–23 × 13–14 mm, inner 23–25 × 15–17 mm. *Filaments* ± 4 mm long; anthers ± 5 mm long; pollen yellow. *Ovary* ± 10 mm long, slightly curved; style ± 11 mm long, stigma lobes broad, deeply fringed. *Capsules* elongate, woody, indehiscent, 35–40 mm long. *Seeds* triangular-columnar, truncate at apex and base, fringed with papillae along angles, sculptering obscurely foveate, epidermal cells domed, reddish brown, 1.5–1.8 × ± 1.5 mm. *Flowering time*: August to mid-September.

Distribution and ecology: a narrow endemic of the Langeberg near Swellendam in Western Cape, South Africa; on lower southern slopes in peaty sandstone soil, flowering after fire.

Distribution of ***Aristea cistiflora***.

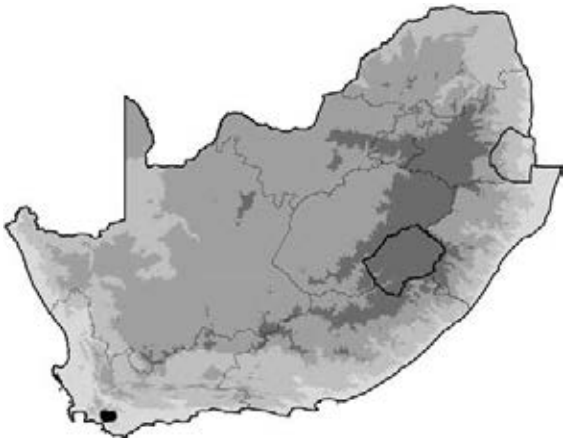
Distribution of ***Aristea teretifolia***.

Diagnosis: *Aristea cistiflora* is evidently most closely related to *A. teretifolia* (Goldblatt & Manning, 1997a), which also has the outer tepals with dark markings, the markings extending to the middle of the tepals in *A. teretifolia* versus close to the base in *A. cistiflora*. *Aristea teretifolia* is additionally distinguished by the leaves sometimes terete or linear and up to 2 mm wide, the flowering stem bearing at most two lateral flower clusters (versus up to six in *A. cistiflora*), and by the slightly smaller flowers with ascending tepals, the outer ± 20 mm long and the inner 24–28 mm long, thus substantially longer than the outer. In *A. cistiflora* the inner tepals are only 1–2 mm longer than the outer. *Aristea teretifolia* also has smaller capsules, 20–30 mm long versus 35–40 mm long in *A. cistiflora*. As in other members of subg. *Pseudaristea*, pollen grains of *A. cistiflora* are dizonasulculate, with two smooth, ring-shaped apertures.

24. **Aristea teretifolia** *Goldblatt & J.C.Manning* in Novon 7: 141 (1997a). Type: South Africa, Western Cape, Bredasdorp District, Fairfield Estate, 25 Aug. 1994, *Nänni 48* (NBG, holo.).

Plants 200–400 mm high, forming tufts up to 80 mm diam. *Stem* broadly elliptic in section, rarely with a single slender branch, bearing 1 or 2 sessile flower clusters. *Leaves* several, mostly basal, linear or terete, 1–2 mm wide. *Flower clusters* 1 to 3, sessile except the terminal, 2- to 4-flowered; spathes greenish with translucent margins becoming dry above, 15–18 mm long, bracts dry-membranous, shorter than spathes. *Flowers* on pedicels 8–10 mm long, large, lilac to cream-coloured, rarely pale yellow, with a large dark mark toward base of outer tepals; outer tepals obliquely obovate, 20–22 × ± 12 mm, inner fiddle-shaped, 24–28 × 15–18 mm. *Filaments* ± 6.5 mm long; anthers ± 4.5 mm long, yellow; pollen light orange. *Ovary* cylindric-trigonous, slightly curved, 12–15 mm long, rapidly elongating after fertilization; style 9–10 mm long, dividing into three short, broad, fringed lobes ± 1.3 mm long, white with purple fringes. *Capsules* elongate, woody, indehiscent, 20–30 mm long. *Seeds* triangular-columnar, many per locule, arranged in a single vertical row. *Flowering time*: August and September.

Distribution and ecology: restricted to southern Western Cape, South Africa, from Shaw's Pass near Caledon to Elim in the south and Tradouw Pass in the Langeberg; mostly on clay or clay loam slopes and flats.



Diagnosis: *Aristea teretifolia* is distinguished in subg. *Pseudaristea* by the narrow, fibrous leaves either terete or plane and up to 2 mm wide, and by its relatively large flowers, 50–58 mm diam., and largely pale lilac, mauve or creamy yellow, with the outer tepals marked with a dark bronze-brown blotch in the lower half edged in pale blue or turquoise. The outer tepals are obovoid and relatively small, ± 20 mm long, compared with the inner which are fiddle-shaped and 24–28 mm long.

The relationships of *Aristea teretifolia* are with pale pink to pale lilac-flowered *A. cistiflora* and possibly with *A. biflora*, which also has lilac or mauve flowers and shares with *A. teretifolia* the curious feature of having the outer tepals asymmetric about the midline, the one half larger than the other. The flowers of *A. biflora* lack dark markings on the outer tepals, which have instead a pair of transparent windows at their lower sides that appear dark when viewed from above against the dark brown or green background. *Aristea biflora* has ± linear, plane leaf blades, 2–3 mm wide, and grows in dense clumps reminiscent of the growth form of *A. teretifolia*.

Aristea teretifolia was based on plants with terete leaves from Fairfield, near Napier in the southern Cape, but other populations have plane leaves, sometimes up to 2 mm wide. Like most species of subg. *Pseudaristea* with dark markings on the tepals, flowers of *A. teretifolia* are pollinated by hopliine scarab beetles (Goldblatt & Manning, 1997a).

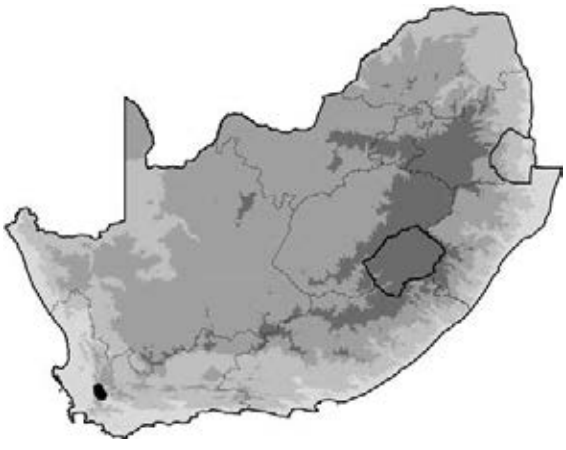
25. **Aristea biflora** *Weim.* in Acta Universitatis Lundensis, ser. 2, 36: 54 (1940). Type: South Africa, [Western Cape], Caledon commonage, Sept. 1931, *W.F. Barker 30* (K, holo.).

Plants 300–450 mm high, forming tufts. *Stem* usually unbranched, lightly compressed, bearing several sessile

Distribution of ***Aristea biflora***.

lateral flower clusters. *Leaves* several, mostly basal, linear, mostly 3–5 mm wide, firm and leathery. *Flower clusters* several, each (1)2- to 4-flowered; spathes greenish with translucent margins, 20–28 mm long, bracts dry-membranous, shorter than spathes. *Flowers* on pedicels 7–10 mm long, large, blue to pale mauve, outer tepals with transparent to translucent, light brown windows on lower margins; tepals 25–30 mm long, outer ± obliquely obovate, inner ± fiddle-shaped, slightly larger than outer. *Filaments* 5–6 mm long; anthers 7–8 mm long. *Ovary* cylindric-trigonous, 8–12 mm long; style 12–16 mm long, stigma lobes broad, spreading, deeply fringed. *Capsules* elongate, woody, indehiscent, deeply 3-lobed, 35–50 mm long. *Seeds* triangular-columnar, many per locule, arranged in a single vertical row. *Flowering time*: mainly late August and September.

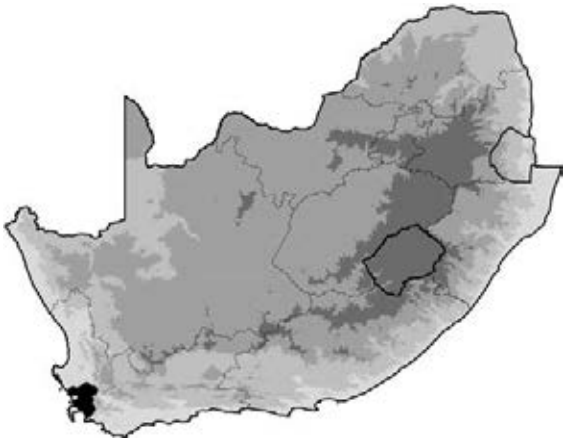
Distribution and ecology: a narrow endemic of the Caledon District of Western Cape, South Africa, known only from the lower southern slopes of Caledon Swartberg and adjacent low hills; in loamy clay in transitional fynbos–renosterveld, flowering best after fire. Its narrow range in prime agricultural land leaves it endangered and it survives today in a few isolated sites.



Diagnosis: one of the most striking species in the genus, *Aristea biflora* is readily recognised by the large, pale blue to mauve flowers 50–60 mm diam. with the outer tepals asymmetric about the midline and each with a pair of transparent to slightly bronzed windows near the base. Seen from above the windows appear dark green or brown depending on lighting. Like most other members of the subgenus the flowers open in midmorning and last till sunset, sometimes even opening again the following day, when they appear flaccid and partly wilted.

26. **Aristea nigrescens** *J.C.Manning & Goldblatt* in Bothalia 37: 189 (2007). Type: South Africa, Western Cape, Wolseley, Farm Romansrivier, southwestern slopes of hill above dam behind farmhouse, in rocky alluvium, 2 Sept. 2006, *J. Manning 3054* (NBG, holo.; K, MO, iso.).

Plants mostly 250–400 mm high, in small clumps. *Stem* angled to slightly winged, bearing 2 or 3 short, reduced leaves, unbranched, rarely with one sessile lateral flower cluster. *Leaves* in a basal fan, linear, ⅓ to ± ½ as long as stem, loosely twisted, 3–5 mm wide. *Flower clusters* 4- to 6-flowered; spathes broadly lanceolate, acute, green at base, dry and papery brown in distal ⅔ with paler margins, sometimes irregularly torn, (10–)12–15 mm long; bracts entirely dry and papery, 5–7 mm long. *Flowers* on pedicels ± 1.5 mm long, upright, white or pale to mid-blue but paler in centre, outer tepals partially glossy black on reverse; tepals spreading, obliquely obovate-spathulate, subequal or inner slightly broader, (20–)25–25 × 13–14 mm. *Filaments* suberect, 5–7 mm long, white to pale blue; anthers 6–7 mm long, yellow; pollen yellow. *Ovary* cylindric, ± 10 mm long, elongating rapidly after fertilization; style 12–15 mm long; stigma lobes broad, deeply fringed, 1.5–2.5 mm long. *Capsules* on pedicels up to 12 mm long, cylindric, 3-lobed in section, 40–50 mm long. *Seeds* numerous per locule, triangular-columnar, base and apex truncate, papillate along angles, apex and base, obscurely alveolate on faces, reddish brown. *Flowering time*: late August to mid-September; opening midmorning ± 10:00 and fading in afternoon ± 17:00.



Distribution and ecology: a highly local endemic known from two sites along the foot of the Waaihoek Mtns overlooking the Breede River south of Wolseley in Western Cape, South Africa; on ferricrete or sandstone alluvium overlying Malmesbury shale in transitional fynbos–renosterveld. Its range is largely lost to agriculture and the species is highly endangered.

Diagnosis: *Aristea nigrescens* is characterised by unbranched stems usually with a solitary, terminal flower cluster, rarely with a sessile lateral flower cluster in the axil of the upper stem leaf. The large, white or blue flowers lack dark markings, but the undersides of the outer tepals are flushed blackish and the buds thus appear dark. Most plants at the type locality, Romansrivier Farm near Wolseley, have pale blue flowers, but flower colour varies through the population from white to mid-blue; at its second known site all plants were white-flowered.

Distribution of ***Aristea nigrescens***.

In its unbranched stems and broad, rather blunt rhipidial spathes the species resembles *A. lugens*, and it is likely that the two are closely allied. *Aristea lugens* is distinguished by its strongly dimorphic tepals, the outer about half as long as the inner, dark brown or black over most of the surface, and strongly incurved, exposing both upper and lower surfaces. Thus *A. lugens*, like *A. nigrescens*, utilises the underside of the tepals for pollinator attraction but, unlike the latter, only in the mature flower and not in bud. Other species in subg. *Pseudaristea* typically have branched stems or at least several lateral flower clusters, and smaller, acute or acuminate rhipidial spathes that are ± entirely leathery and green. Pollen grains, as in other species of subg. *Pseudaristea,* are dizonasulculate with reticulate exine. Like *A. lugens*, the species is adapted to pollination by hopliine beetles (Manning & Goldblatt 2007).

Distribution of ***Aristea lugens***.

27. **Aristea lugens** *(L.f.) Steud.,* Nomenclator botanicus, edn. 2, 1: 130 (1840); Weim.: 56 (1940). *Moraea lugens* L.f.: 99 (1782). *Cleanthe lugens* (L.f.) Asch. & Graebn.: 534 (1906). Type: South Africa, without precise locality [reported as from Paarl, Paardeberg, and near Riebeek Kasteel], Sept.–Oct., *C.P. Thunberg s.n* [LINN 62.1, lecto., designated here (one of two sheets in LINN said by Weimarck to be spec. orig., the other LINN 62.2 '*Moraea lugens*')].

Moraea melaleuca Thunb.: 5 (1787), illegitimate superfluous name for *M. lugens* L.f. *Aristea melaleuca* Ker Gawl.: 236 (1804) & t. 1277 (1810), illegitimate superfluous name. *Sisyrinchium melaleucum* Eckl.: 16 (1827). *Cleanthe melaleuca* Salisb. ex Pax in Engler & Prantl: 152 (Mar. 1888), as a new name for *M. melaleuca*. Type: South Africa, [Western Cape], as 'Paarl, Paardeberg, and near Riebeek Kasteel,' Sept.–Oct., *C.P. Thunberg s.n* (UPS–THUNB 1224 '*Moraea melaleuca B*', lecto., designated here).

[*Cleanthe bicolor* Salisb.: 312 (1812), invalid name without description.]

[*Sisyrinchium inundatum* Eckl.: 16 (1827), invalid name without description.]

Plants 300–500 mm high, in loose colonies. *Stem* flattened and winged below, slightly angled above, unbranched, sometimes with 1(2) sessile lateral flower clusters. *Leaves* mostly ± half as long as stem, falcate, 3–6 mm wide, soft-textured. *Flower clusters* 2- or 3-flowered; spathes green with translucent margins, 23–26 mm long, bracts dry-membranous, shorter than the spathes. *Flowers* on pedicels 12–18 mm long, inner tepals pale blue to whitish, outer tepals ± erect in upper half, dark blue-black or brownish; outer tepals 16–20(–25) × 10–15 mm, inner spreading, 28–45 × 28–32 mm. *Filaments* 5–7 mm long; anthers 6–9 mm long. *Ovary* elongate-trigonous, 15–22 mm long; style 12–15 mm long, stigma lobes spreading, deeply fringed. *Capsules* on pedicels up to 20 mm long, woody, indehiscent, cylindric, deeply 3-lobed, 38–45(–65) mm long. *Seeds* triangular-columnar, many per locule in a single vertical row. *Flowering time*: September and October; lasting 2 or 3 days.

Distribution and ecology: local in Western Cape, South Africa, from Riebeek Kasteel and Malmesbury to Stellenbosch; on low granitic hills in renosterveld or transitional fynbos.

Diagnosis: unmistakable in the genus, *Aristea lugens* has upright, predominantly white to blue flowers with the small outer tepals dark brown or black on both surfaces. The inner tepals are obovate and outspread, and the outer tepals, ± half as long as the inner, are suberect and curved inward distally. Plants grow in sparse colonies, spreading by rhizomes, thus unlike the usual solitary or tufted habit of other species. *Aristea lugens* has the dizonasulculate pollen grains and elongate, tardily dehiscent capsules typical of subg. *Pseudaristea*, and like most other species of the subgenus, the flowers are adapted for pollination by hopliine beetles (Goldblatt & Manning, 1996, 1997).

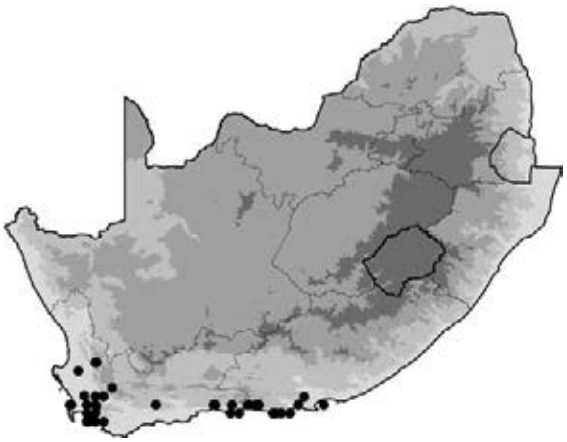
Subg. 3. **Aristea**

Flowers deep blue, always fugaceous, lasting one morning. *Capsules* usually about as short as wide (rarely longer than wide), with narrow, radial wings or deeply 3-lobed (sect. *Singulares*). *Seeds* tangentially compressed, less so in *A. singularis*. *Pollen grains* mostly monosulcate, zonasulculate in 1 sp. or trisulcate (sect. *Aristea*), with smooth aperture, exine reticulate.

Species 19: restricted to the Southern African winter-rainfall region.

Sect. 4. **Racemosae** *Weim.* in Acta Universitatis Lundensis, ser. 2, 36(1): 70 (1940). Type: *Aristea racemosa* Baker

Flowers with style minutely notched at apex. *Capsules* always with 3 narrow radial wings. *Seeds* radially compressed, lamellate, ± kidney-shaped with margins smooth or fringed with papillae. *Pollen grains* monosulcate, but zonasulculate in 1 sp.



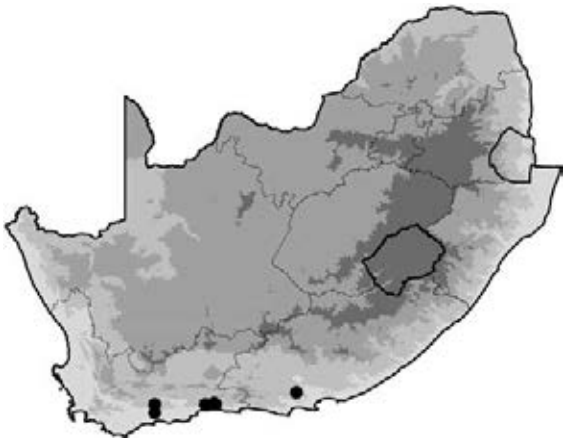
Species 11: Cape Flora region from the Bokkeveld Mtns to Uitenhage.

28. **Aristea bakeri** *Klatt* in Th.Durand & H.Schinz, Conspectus florae africae 5: 169 (1894), as a new name for *A. paniculata* Baker: 144 (Sept. 1892), illegitimate homonym, not *A. paniculata* Pax (Apr. 1892) [= *A. ecklonii* Baker]. Type: South Africa, [Western Cape], Galgebosch, near Van Staden's River, Dec. 1872, *P. MacOwan 2077* (K, holo.; GRA, SAM, iso.).

Aristea macrocarpa G.J.Lewis in Weim.: 74 (1940); Lewis: t. 1084 (1950b). Type: South Africa, [Western Cape], Cape Peninsula, Kirstenbosch, Nov. 1935, *G.J. Lewis s.n. BOL21665* (BOL, holo.).

Aristea confusa Goldblatt in Goldblatt & Barnard: 308 (1970). Type: South Africa, [Western Cape], Palmiet River Mtns, 30 Dec. 1923, *T.P. Stokoe s.n. BOL17518* (BOL, holo.).

Plants mostly 0.9–1.5 m high. *Stems* rounded in section, usually much branched, branches ascending, with few sessile lateral flower clusters. *Leaves* narrowly sword-shaped, broad, mostly 10–14(–25) mm wide, leathery and fibrous. *Flower clusters* many, mostly stalked, each mostly 4- or 5-flowered; spathes boat-shaped, mostly 9–15 mm long, dry, rust-brown with broad, pale transparent margins, minutely hairy or scabrid outside or glabrous. *Flowers* blue, upright to half nodding; tepals obovate, 16–20 × 6–8 mm. *Filaments* 7–8 mm long; anthers 4–5 mm long. *Ovary* obovoid, 3-lobed; style 8–10 mm long, apex minutely 3-notched. *Capsules* oblong in outline, 3-winged, 14–25(–30) mm long. *Seeds* lamellate, kidney-shaped, ± 3.0–3.5 mm long, mostly 2 or 3, rarely up to 5, per locule, margins papillate. *Flowering time*: mainly October to December.



Distribution of ***Aristea bakeri***.

Distribution and ecology: widespread in winter rainfall South Africa, extending from Piketberg and the Cape Peninsula in Western Cape to Port Elizabeth in Eastern Cape; on stony sandstone or clay loam slopes, from near sea level to 1 500 m, flowering well only after fire.

Diagnosis: the interpretation of *Aristea bakeri* (also called *A. capitata* in earlier accounts) has varied in the past, but the species is recognised by its robust habit with a relatively open, branched flowering stem bearing relatively large flowers with tepals up to 20 mm long, and most significantly, elongate capsules 15–25(–30) mm long, thus oblong in outline but with broad, narrow vertical wings. The capsules contain 2 or 3 (occasionally more) flat seeds per locule, each seed always with a fringe of papillae along the margins. The inflorescence spathes and bracts are dry, papery and rust-brown and usually minutely hairy to scabrid on the abaxial (outer) surfaces. *Aristea macrocarpa* G.J.Lewis (Weimarck, 1940) from the Cape Peninsula and nearby was distinguished by the particularly long capsules 20–35 mm long and rough, somewhat bristly spathes but is now included in *A. bakeri*, populations of which nearly always have bristly to scabrid spathes and capsules up to 25 mm long across its entire range.

29. **Aristea rufobracteata** *Goldblatt & J.C.Manning* in Bothalia 45: 132 (2015). Type: South Africa, Western Cape, George, below the power station, 5 Nov. 1928, *J.B. Gillett 2096* (NBG, holo.).

Plants 0.8–1.0 m high, solitary or growing in clumps. *Stem* rounded in section, with suberect branches borne at lower fertile nodes, lateral flower clusters sessile, branches short, crowded. *Leaves* several, linear, 7–14 mm wide, firm and fibrous. *Flower clusters* many, crowded, those below the terminal mostly sessile but lower nodes with short to long branches, each mostly 2- to 4-flowered; spathes and bracts rusty brown, 8–10 mm long, thinner and somewhat translucent near the edges, glabrous, becoming slightly crinkled and torn with age. *Flowers* subsessile, blue; tepals obovate, ± 15 mm long. *Filaments* ± 4 mm long; anthers ± 4.5 mm long. *Ovary* 3-lobed; style ± 7 mm long, minutely 3-notched. *Capsules* oblong in outline, narrowly 3-winged, 11–14 mm long. *Seeds* lamellate, kidney-shaped, mostly 2 per locule, margins papillate. *Flowering time*: mainly November and December, sometimes in October.

Distribution of ***Aristea rufobracteata***.

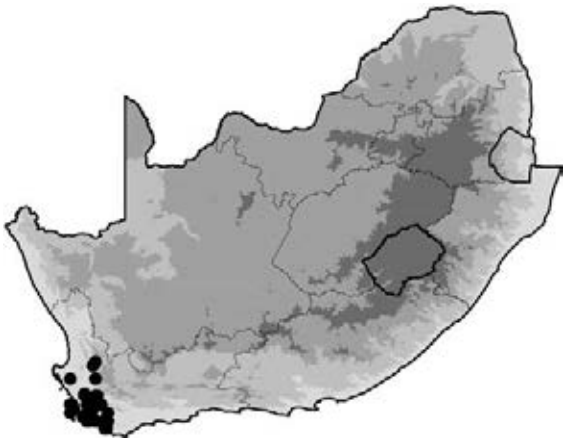
Distribution and ecology: South Africa, from the Langeberg near Grootvadersbosch and Riversdale to the Outeniqua Mtns in Western Cape, to Loerie in Eastern Cape; on stony sandstone slopes, especially common after fire.

Diagnosis: the southern coastal *Aristea rufobracteata* is broadly similar to *A. capitata* from the southwestern parts of Western Cape in the columnar and relatively dense flowering axis with fairly short branches and sessile flower clusters but is readily distinguished by the rusty brown spathes and floral bracts that are thinner and slightly paler toward the margins, unlike those of *A. capitata*, which are pale and silvery-translucent with a dark brown central keel extending upward as an attenuate, cusp-like tip.

Aristea bakeri, also with rust-coloured bracts, is sometimes confused with *A. rufobracteata*, but the bracts in the former always have pale, more-or-less semi-transparent margins and are in addition usually minutely hairy to scabrid beneath. Both species occur at Loerie and near George. Capsules, particularly important in distinguishing species of sect. *Racemosae*, are not well known for *A. rufobracteata*, but two collections in early fruit and one with mature fruit have capsules 11–14 mm long, shorter than most collections of *A. bakeri*, which are typically 18–30 mm long. The seeds are lamellate and kidney-shaped with the margins of brown papillae, thus like those of *A. bakeri* and its allies, *A. juncifolia* and *A. racemosa*, whereas the seed margins of *A. capitata* are smooth.

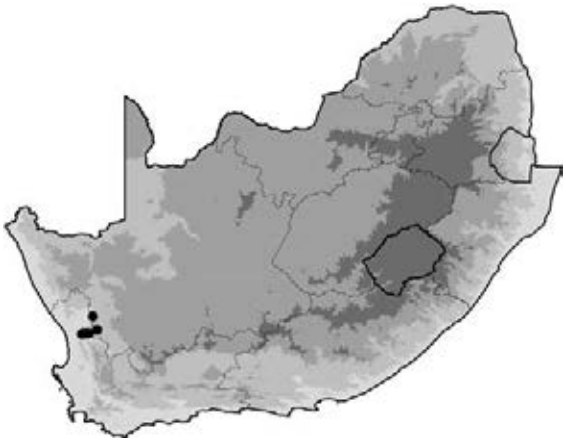
Weimarck's (1940) circumscription of *Aristea capitata* included several collections from the George and Knysna Districts of southern Western Cape now referred to *A. rufobracteata* plus a few poorly preserved specimens from the southwestern corner of the province that are *A. bakeri.* The name *A. capitata* is now reserved for plants from the Cape Peninsula and nearby, also called either *A. major* or *A. thyrsiflora* in the past. Plants illustrated in *Curtis's Botanical Magazine* (Ker Gawler, 1802) as *A. capitata* are almost certainly *A. rufobracteata.*

30. **Aristea capitata** *(L.) Ker-Gawl.* in Curtis's Botanical Magazine 17: t. 605 (1802) [excluding illustration]. *Gladiolus capitatus* L.: 37 (1753). Type: South Africa [Western Cape], foot of Du Toit's Kloof, 15 Oct. 1949, *W.F. Barker 6075* (NBG, neo., designated by Goldblatt et al.: 191 (2002); K, MO, PRE, iso.).



Aristea major Andrews: t. 160 (1801). *A. spicata* Pers.: 41 (1805), illegitimate superfluous name for *A. major*. Type: South Africa, without precise locality or collector, illustration in Andrews: t. 160 (1801).

[*Aristea thyrsiflora* sensu N.E.Br.: 36 (1929, misapplied to *A. capitata*); Weim.: 75 (1940): basionym *Ixia thyrsiflora* D.Delaroche: 20 (1766) probably not *A. capitata* but type unknown: the so-called type in Herb. Burman does not match the protologue, which is not adequate for identification of the species.]



Plants up to 1.5 m high, usually forming clumps. *Stems* ± terete, bearing crowded, short branches above. *Leaves* linear, strap-like, broad, ± half as long as stem, mostly 10–15 mm wide, fibrous. *Flower clusters* numerous, borne on short branches or sessile, crowded in upper part of stem, each 4- to 6-flowered; spathes and bracts 5–10 mm long, lanceolate, dry-membranous, translucent with dark keels. *Flowers* nodding, blue (pale pink in some cultivated forms), greenish yellow in throat; tepals 14–16 mm long. *Filaments* ± 6 mm long; anthers 4–5 mm long. *Style* 10–12 mm long, minutely 3-notched at apex. *Capsules* short, narrowly 3-winged, 8–12 mm long. *Seeds* lamellate, kidney-shaped, mostly 2 per locule, ± 4 × 2.5 mm, margins smooth. *Flowering time*: October to December.

Distribution and ecology: South Africa, Western Cape, extending from the Piketberg and the upper Olifants River Valley to the Klein River and Riviersonderend Mtns, especially common on the Cape Peninsula; mainly mountain slopes on sandstone- or granite-derived soils, at 100–1 200 m elevation, often on cooler or damper slopes.

Diagnosis: the tall, robust *Aristea capitata* with flowering stems up to 1.5 m high and bearing a crowded compound inflorescence of hundreds of flowers is one of the most easily recognised members of the genus. The spathes are also distinctive, being dry-membranous, lanceolate, and translucent with narrow, dark keels extending upward as a short cusp. The relatively short, narrowly winged capsules are 8–12 mm long and contain one or two lamellate seeds per locule that are unusual in sect. *Racemosae* in having smooth rather than papillate margins. The distinctive spathes, together with the compact, columnar and crowded compound inflorescence, make *A. capitata* unlikely to be confused with other species except for the eastern Langeberg and Outeniqua Mountain species, *A. rufobracteata*, which has a similar habit although often a somewhat less compact arrangement of flower clusters but uniformly rust-coloured rhipidial spathes.

Distribution of ***Aristea capitata***.

Distribution of ***Aristea inaequalis***.

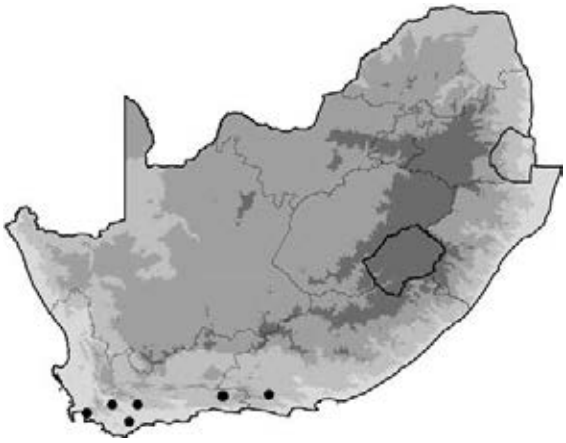
This species has been variously known under the names *A. capitata*, based on the mysterious *Gladiolus capitatus* L. (1753), *A. major*, and *A. thyrsiflora*, a combination based on D. Delaroche's *Ixia thyrsiflora*, which, like *G. capitatus*, is of uncertain identity and lacks a known type specimen or illustration. *Aristea major* (Andrews, 1801) is clearly this species and a neotype has been designated for *G. capitatus* fixing the application of the name. The plant illustrated in Curtis's Botanical Magazine where Ker-Gawler (1802) made the combination, *A. capitata*, has the large, rust-brown spathes and bracts of the allied *A. rufobracteata* and is evidently the earliest record of that species.

Aristea capitata is one of the few species of *Aristea* suitable for cultivation and is a common sight in Cape Town gardens and street plantings. It appears to be easy to grow and rewarding in its generous display of brilliant blue flowers in October and November. A form with pale pink flowers is also in cultivation.

31. **Aristea inaequalis** *Goldblatt & J.C.Manning* in Novon 7: 357 (1997b). Type: South Africa, Western Cape, rocky sandstone plateau at the top of Gifberg Pass, 3 Oct. 1996, *P. Goldblatt & J.C. Manning 10561* (NBG, holo.; K, MO, iso.).

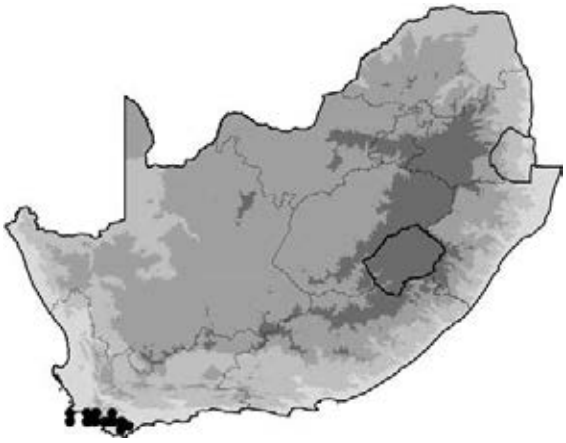
Plants 1.0–1.5 m high. *Stems* ± terete, with long spreading branches, bearing several to many sessile and stalked flower clusters. *Leaves* several, linear, glaucous, with acute, often reddish margins, 4–5 mm wide, fibrous. *Flower clusters* numerous, stalked or sessile, laxly spaced, each usually 4-flowered; spathes lanceolate, 8–10 mm long, dry-membranous and translucent, with dark keels extending as a long cusp, bracts similar but 6–8 mm long. *Flowers* blue, secund, subsessile, tepals 14–16 mm long. *Stamens* unequal; lower (abaxial) filament 8 mm long, upper (adaxial) two filaments ± 6 mm long; anthers ± 3 mm long. *Ovary* obovoid, 3-lobed, ± 4 mm long; style 9–10 mm long, minutely 3-notched at apex. *Capsules* short, broadly 3-winged, 7–8 mm long. *Seeds* radially compressed, lamellate, kidney-shaped, ± 4 × 2.5 mm, margins smooth. *Flowering time*: October to November.

Distribution and ecology: restricted to the western coastal mountains, from the Bokkeveld Mtns of Northern Cape as far south as Pakhuis Pass in the northern Cederberg in Western Cape, South Africa; on sandstone outcrops, often in seasonal seeps and locally wet sites.



Diagnosis: the half-nodding, dark blue flowers of *Aristea inaequalis* are unique in the genus in having unequal stamens, the lower filament being ± 2 mm longer than the other two. The species is also distinctive in the laxly branched flowering stem, the branches bearing shortly stalked and sessile flower clusters. Apart from the unequal stamens the flowers are typical of sect. *Racemosae* in size, shape and colour. The inflorescence spathes and bracts are lanceolate, tapering to a narrow cuspidate apex, and have broad transparent margins with a dark brown central keel very much like those of *A. capitata*. On this basis the two are considered to be related although they are otherwise very different in appearance, *A. capitata* having flowered clusters crowded together in short branches forming a dense, compact, compound inflorescence. Molecular phylogenetic studies place *A. inaequalis* close to *A. bracteata*, but that species has quite different, broadly ovate, rust-brown spathes and bracts that are thinly hairy to scabrid.

32. **Aristea cuspidata** *Schinz* in Bulletin of Miscellaneous Information Kew 1906: 25 (1906); Weim.: 83 (1940). Type: South Africa, [Western Cape], Caledon District, Leoskraal, Oct. 1894, *Penther 555* (K, lecto., effectively designated by Weim.: 83 (1940); S, isolecto.).



Aristea intermedia Eckl. ex Klatt: 549 (1865–66). Type: South Africa, [Western Cape], several syntypes listed, none designated as lectotype.

[*Aristea bracteata* Eckl.: 16 (1827), invalid name without description.]

[*Aristea intermedia* Eckl.: 16 (1827), invalid name without description.]

Distribution of ***Aristea cuspidata***.

Distribution of ***Aristea juncifolia***.

Plants (150–)300–600 mm high. *Stem* lightly compressed above, often partly sheathed by large cauline bracts 50–80 mm long; lower flower clusters subtended by narrow, almost linear to narrowly lanceolate bracts 12–20 mm long. *Leaves* linear, fairly narrow, mostly 3–5 mm wide, with translucent or reddish, acute margins. *Flower clusters* up to 7, sessile except terminal, or lower 1 or 2 shortly stalked, each 4-flowered; spathes boat-shaped, rust-brown with broad transparent margins, (7–)10–14 mm long, sometimes sparsely and obscurely scabrid, bracts similar but often narrower. *Flowers* dark blue, green in the throat; tepals obovate, 14–18 × 8–10 mm. *Filaments* 5–6 mm long; anthers initially ± 4 mm long. *Ovary* obovoid, 3-lobed, 4–6 mm long; style 6–7 mm long, minutely 3-notched apically. *Capsules* narrowly 3-winged, mostly 14–18 mm long. *Seeds* unknown. *Flowering time*: mainly October and November.

Distribution and ecology: relatively widespread in the Western Cape, South Africa, extending from the Cape Peninsula to Plettenberg Bay and in the Swartberg; on stony sandstone slopes, flowering well after fire.

Diagnosis: one of the smaller species of sect. *Racemosae*, *Aristea cuspidata* is recognised by the comparatively slender, usually unbranched stem bearing several sessile flower clusters or the lower clusters sometimes on short stalks, with relatively prominent spathes, initially green but soon turning rust-brown. The spathes and bracts are usually rough and minutely scabrid. The flowers are typical of the section in their deep blue colour and fairly large size.

33. **Aristea juncifolia** *Baker* in Journal of Botany, British and foreign 14: 267 (1876); Weim.: 88 (1940). Type: South Africa, [Western Cape], without precise locality or date, *J. Grey s.n.* [K, lecto., effectively designated by Weim.: 88 (1940)].

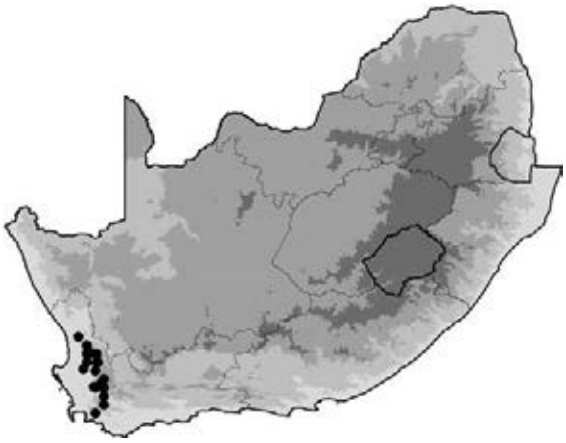
Plants 120–350 mm high, usually forming small tufts. *Stem* terete, usually unbranched or with 1 or 2 short branches, bearing sessile flower clusters. *Leaves* several, in a basal fan, centric, without defined margins, elliptic to subterete in section, mostly 1.5–3.0 mm wide, often somewhat twisted, relatively thick, tough and fibrous. *Flower clusters* few, sessile below the terminal, or lower on short stalks, subtended by prominent rust-coloured, keeled bracts, each 2- to 4-flowered; spathes and bracts rust-brown, becoming transparent toward the edges, the spathes 12–18 mm long, folded in the midline and keeled. *Flowers* deep blue, tepals 16–20 × ± 12–14 mm. *Filaments* 6–7 mm long; anthers ± 3 mm long. *Ovary* obovoid, 3-lobed; style 8–10 mm long, minutely 3-notched apically. *Capsules* oblong in outline, 3-winged, 15–25 mm long. *Seeds* radially compressed, lamellate, kidney-shaped, mostly 2 per locule, with fringe of marginal papillae. *Flowering time*: November to December.

Distribution and ecology: restricted to southern coastal Western Cape, South Africa, from the Cape Peninsula to the Klein River Mtns near Stanford; on slopes and coastal flats in sandy or stony ground, usually in wet or marshy places, flowering well only after fire.

Diagnosis: one of three similar dwarf species of sect. *Racemosae*, *Aristea juncifolia* rarely reaches 300 mm in height and has terete, mostly unbranched stems and relatively large, boat-shaped, rhipidial spathes 12–18 mm long, green with broad transparent margins. The rigid, somewhat twisted leaves are elliptic or nearly round in section and without true margins. Related *A. racemosa* typically has rigid, terete, usually straight leaves rarely exceeding 1.5 mm diam., and somewhat shorter spathes, ± 10 mm long. The third species in the group, *A. cuspidata*, has plane leaves 3–5 mm wide, with hyaline, lightly thickened, acute margins, and the bracts subtending the lower flower clusters are often conspicuously cuspidate, the apex tapering to a filiform point.

34. **Aristea bracteata** *Pers.*, Synopsis plantarum 1: 41 (1805), as a new name for *Moraea caerulea* Thunb.: no. 15 (1787), possibly illegitimate and superfluous name for *Gladiolus capitatus* L. (1753) cited but not unambiguously excluded; Lewis: t. 1083 (1950a) [as *A. coerulea*];

Goldblatt et al.: 192 (2002). *A. caerulea* Vahl: 124 (1805), superfluous name for *G. capitatus* L. (1753). *Aristea monticola* Goldblatt: 234 (1971), as a new name for *M. caerulea* Thunb. Type: South Africa, without precise locality or date, *Thunberg s.n.* [UPS–THUNB '*M. caerulea* α', lecto., effectively designated by Weimarck: 71 (1940)]. [Of the two localities mentioned for the species by Thunberg, 'hills around the Cape,' probably applies to the lectotype; the other 'between the Outeniqua Mtns and the Langkloof [Long Kloof]' is out of range for the species].



Aristea caerulea var. *elongata* Weim.: 73 (1940). Type: South Africa, [Western Cape], Saron, Sept. 1919, *L. Bolus s.n.* (BOL, K, syn.).

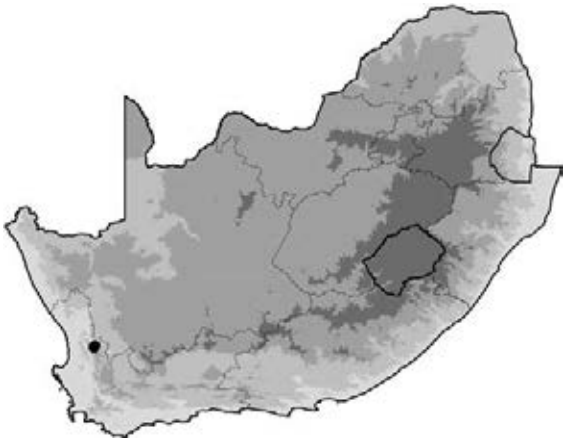
Aristea caerulea var. *robusta* Weim.: 74 (1940). Type: South Africa, [Western Cape], without precise locality, Oct. 1915, *Marloth 7173* (PRE, holo.)

Plants 600–1 300 mm high. *Stem* subterete, often much branched, branches short, also bearing sessile or subsessile lateral flower clusters. *Leaves* linear to sword-shaped, often fairly broad, 3–6 mm wide, leathery and fibrous. *Flower clusters* several to many, those below terminal usually sessile, mostly 5- or 6-flowered; spathes and bracts ovate, spoon-shaped, dry-membranous, rust-coloured, becoming translucent on margins, bracts often entirely transparent, (10–)12–16(–18) mm long, sparsely hairy or scabrid, bracts often slightly exceeding spathes. *Flowers* on pedicels ± 1.5 mm long, blue, greenish in throat; tepals obovate, 18–20(–25) mm long. *Filaments* ± 6 mm long; anthers 4–5 mm long. *Ovary* ± obconic, 3-lobed, ± 3.5 mm long; style ± 12 mm long, minutely 3-notched at apex. *Capsules* on pedicels up to 3 mm long, short, 3-winged, mostly 8–10 mm long, *Seeds* radially compressed, irregularly 4-sided, 2 to 4 per locule, surface cells domed, margins smooth or papillate. *Flowering time*: mainly September to November.

Distribution and ecology: restricted to the western half of Western Cape, South Africa, from the Olifants River Mtns and Cederberg south to the Piketberg, Michell's Pass and Du Toit's Kloof; on stony sandstone slopes, at 300–1 000 m elevation, especially conspicuous after fire but also flowering in mature vegetation.

Diagnosis: *Aristea bracteata* is readily recognised by the relatively large flower clusters enclosed by large, more-or-less dry, firm-textured, ovate, spoon-shaped spathes 10–18 mm long. Both the spathes and floral bracts are minutely hairy, papillate or scabrid, a feature shared with *A. rupicola* and many populations of *A. bakeri*. *Aristea bracteata* has relatively narrow, firm-textured leaves with conspicuous, acute, transparent to reddish margins (a distinctive feature shared with *A. inaequalis*). As in most of the tall species of sect. *Racemosae*, there is considerable variation in the branching pattern. Most commonly, the flowering stem has relatively long lateral branches, and one or more of the upper flower clusters on each branch is sessile. Var. *elongata* represents a plant

Distribution of ***Aristea bracteata***.



with short lateral branches and an elongate main axis while var. *robusta* resembles var. *elongata* but is larger in most features. Floral bracts of var. *elongata* are especially long, 15–18 mm, where the normal range is 12–16 mm. There seems to be no need to formally recognise these local variants as they intergrade, sometimes even within the same populations.

Seeds of *Aristea bracteata* as circumscribed here vary from those with smooth margins in the north of its range to those with papillate margins from the south. The significance of this variation remains to be investigated.

A confused taxonomic history surrounds this fairly common Western Cape species. C.P. Thunberg associated *Gladiolus capitatus* L. with his *Moraea caerulea* Thunb. (1787), with the caveat 'vid. differt. nostr. tab. 1' [different from the plant shown in our figure 1]. Nomenclaturally *M. caerulea* has been interpreted as superfluous and thus an illegitimate name, as is the name *A. caerulea* Vahl. The substitute name *A. monticola* was proposed for the species by Goldblatt (1971), who was then unaware that the name *A. bracteata* Pers. (1805) was available for it. Persoon (1805) actually renamed Thunberg's *Moraea caerulea* when he placed the species in *Aristea*, normally an unacceptable action. Happily, in hindsight, this provided a legitimate name for Thunberg's plant, although one that was overlooked for almost 200 years.

35. **Aristea rupicola** *Goldblatt & J.C.Manning* in Novon 7: 360 (1997b). Type: South Africa, Western Cape, track to Heuningvlei, on sandstone outcrops and low cliffs, 19 Dec. 1995, *P. Goldblatt 10446* (NBG, holo.; K, MO, PRE, iso.).

Plants mostly 180–400 mm high. *Stems* broadly elliptic in section, divaricately 2- to several-branched, terete above first branch. *Leaves* several in a tight fan, linear, narrow, ± ⅔ as long as stem, sometimes longer, 3–4 mm wide, leathery and fibrotic, margins acute, hyaline. *Flower clusters* several, usually all stalked, (2)5- or 6-flowered;

Distribution of ***Aristea rupicola***.

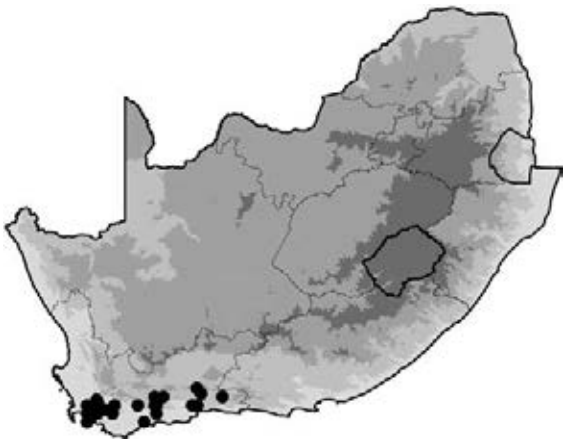
spathes and bracts ovate, spathes 6–7 mm long, bracts 7–8 mm long, rust-coloured, translucent toward edges, flecked with brown, sparsely hairy to scabrid. *Flowers* on pedicels ± 1 mm long, blue, yellow in throat edged darker blue; tepals obovate, 8–14 × 5–9 mm. *Filaments* ± 4 mm long; anthers ± 3 mm long. *Ovary* ± obconic in outline, 3-lobed, ± 3.5 mm long; style ± 8 mm long, apex minutely 3-notched. *Capsules* broadly 3-lobed (to ± winged), ± 7 mm long. *Seeds* radially compressed, irregularly 4-sided, (1)2 per locule, surface cells colliculate. *Flowering time*: late October to mid-December.

Distribution and ecology: a narrow endemic of the northern Cederberg in Western Cape, South Africa; on sandstone outcrops and cliffs, at ± 1 000 m elevation, flowering well after fire but also at other times.

Diagnosis: *Aristea rupicola* is distinguished by its low stature, dichotomous branching pattern, and prominently 3-lobed to -winged capsules, which place the species in sect. *Racemosae*. Consistent with the section, the style is minutely 3-notched and the pollen grains are monosulcate. The species is mostly closely allied to *A. bracteata* with which it shares shortly hairy to scabrid spathes and bracts, ± dichotomous branching (not always in *A. bracteata*), and laterally compressed, somewhat irregularly shaped, colliculate seeds. *Aristea rupicola* is a small plant, rarely exceeding 350 mm in height, with spathes 6–7 mm long, and floral bracts 7–8 mm long. All the flower clusters are normally carried on short branches and are therefore stalked, whereas taller *A. bracteata*, which may reach 1.3 m in height, has some of the flower clusters sessile, and the spathes (10–)14–18 mm long. Consistent with its smaller size, the capsules of *A. rupicola* are ± 7 mm long, whereas those of *A. bracteata* are typically 8–10 mm long.

36. **Aristea racemosa** *Baker* in Journal of Botany, British and foreign 14: 267 (1876); Weim.: 78 (1940). Type: South Africa, [Western Cape], Genadendal, Baviaanskloof, without date, *W.J. Burchell 7883* [K, lecto., effectively designated by Weim.: 78 (1940)].

Aristea racemosa var. *inflata* Weim.: 80 (1940), new synonym. Type: South Africa, [Western Cape], Steenbras Siding, Nov. 1913, *Kensit s.n. BOL21903* (BOL, holo.).



[*Witsenia spicata* E.Mey. ex Baker: 267 (1876), invalid name only in synonymy.]

[*Aristea juncifolia* Eckl.: 16 (1827), invalid name without description.]

Plants up to 400 mm high. *Stems* rounded, usually unbranched, or with 1 or 2 slender branches from lower cauline nodes, these often subtended by large inflated bracts, bearing several sessile lateral flower clusters. *Leaves* several, terete or broadly elliptic in section, 1.5–3.0 mm wide, fibrous, margins rounded, not differentiated. *Flower clusters* several, sessile except the terminal, each 2- to 4-flowered; spathes and bracts dry-membranous, rust-coloured, translucent on the edges, spathes ± 10 mm long. *Flowers* deep blue, ± sessile, tepals 12–16 mm long. *Filaments* ± 5–6 mm long; anthers ± 3.5 mm long. *Style* 6–7 mm long, minutely 3-notched. *Capsules* oblong in outline, narrowly 3-winged, 10–14 mm long. *Seeds* several, lamellate, densely papillate on margins. *Flowering time*: October to December.

Distribution and ecology: endemic to Western Cape, South Africa, extending from the Du Toit's Kloof and Hottentots Holland Mtns to George and the Swartberg; on rocky sandstone slopes, at 200–1 000 m elevation, flowering mainly after fire.

Diagnosis: Aristea racemosa, frequently seen in flower after fire in montane habitats, it is one of a group of three species of sect. *Racemosae* of similar low stature with boat-shaped, rust-brown spathes with broad membranous margins, and sessile rhipidia, the lower sometimes shortly stalked. It is readily recognised in the alliance by the relatively short spathes, inconspicuous bracts subtending the rhipidia, and the stiff, fibrous leaves, terete or elliptic in section without differentiated margins.

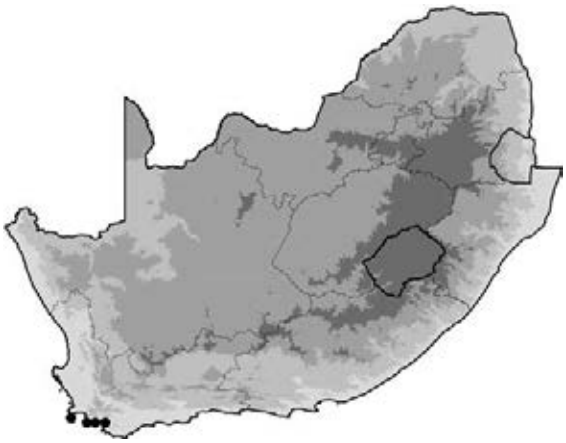
Distribution of ***Aristea racemosa***.

37. **Aristea rigidifolia** *G.J.Lewis* in Weim. in Acta Universitatis Lundensis, ser. 2, 36(1): 81 (1940). Type: South Africa, [Western Cape], Cape Peninsula, southwest of Smith's farm, Nov. 1932, *T.M. Salter 2881* (BOL, holo.).

Plants 0.6–1.3 m high, growing singly. *Stems* ± terete to broadly elliptic in section, usually with 1 or 2 short branches, each bearing several sessile lateral flowering clusters; in fruit a new leafy shoot emerging from base. *Leaves* usually ± 4, lower 2 basal, reaching to ± base of flower clusters, centric, elliptic in cross section with rounded margins, 3–5 mm wide, fibrous. *Flower clusters* several, each mostly 5- or 6-flowered; spathes and bracts ovate, rust-coloured, becoming irregularly torn, 3–4 mm long. *Flowers* blue; tepals obovate, 20–25 × ± 15 mm, inner slightly larger than outer. *Filaments* 6–7 mm long; anthers ± 3.5 mm long. *Ovary* obovoid, obscurely 3-lobed; style ± 12 mm long, apex minutely 3-notched. *Capsules* oblong, narrowly 3-winged, (20–)25–33 mm long. *Seeds* lamellate, ± rectangular, up to 12 per locule, ± 3 × 2 mm, surface ± plane, with short- to long-papillate margins. *Flowering time*: October to November.

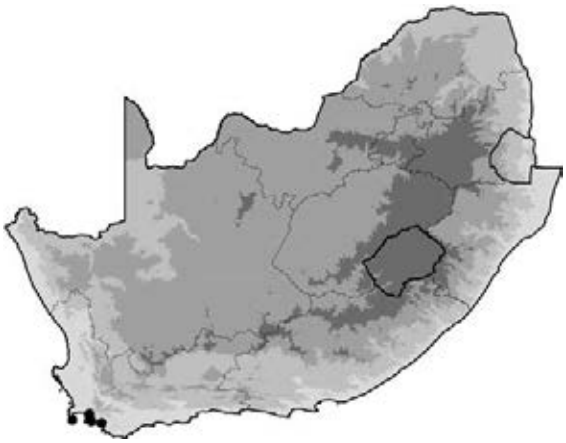
Distribution and ecology: rare and local, extending from the southern Cape Peninsula to the Klein River Mtns near Hermanus in Western Cape, South Africa; in seeps and marshes on sandy slopes and flats, flowering only after fire.

Diagnosis: allied to the widespread *Aristea bakeri* and often confused with it, *Aristea rigidifolia* is a tall species with a much-branched stem, readily distinguished in having only two basal leaves, the blades narrow, 1.5–3.0 mm wide, and more-or-less elliptic in section with rounded margins of solid green tissue. *Aristea bakeri* has a basal fan of several plane leaves usually 8–12 mm wide, always with acute, translucent margins of thinner texture than the rest of the leaf. The two species have virtually identical floral spathes and bracts that are dry-membranous at flowering time and brown below but with pale, transparent margins. The capsules of *A. rigidifolia* can be distinguished immediately by their larger size, (20–)25–33 mm long with an acute apex, whereas those of *A. bakeri* are (12–)15–25 mm long with a somewhat truncate apex. Capsules of *A. rigidifolia* have up to 12 seeds per locule, unique in sect. *Racemosae*, other species of which have fewer seeds, mostly 2 to 5 per locule. *Aristea bakeri* has no more than 5 seeds per locule even in populations with the largest capsules.



38. **Aristea zeyheri** *Baker*, Handbook of the Irideae 143 (1892); Weim.: 67 (1940); Goldblatt & Manning: 137 (1997a). Type: South Africa, [Western Cape], Hottentots Holland Mtns, western slopes above Grietjiesgat, without date, *Zeyher 4050* (K, holo.; P; iso.).

[*Aristea juncea* Eckl. ex Weim.: 67 (1940), invalid name only in synonymy.]



Plants 180–400 mm high. *Stem* terete, slender, unbranched. *Leaves* terete, filiform, lower basal, half as long as stem, upper shorter, ± 1 mm diam. *Flower clusters* 1 or 2(3), sessile except terminal, mostly 2-flowered; spathes dark green with narrow silvery-transparent margins, mostly 20–25 mm long, bracts transparent becoming lacerated. *Flowers* blue, evidently nodding; tepals obovate, 16–18 × 8–10 mm, obtuse to emarginate. *Filaments* 5 mm long; anthers ± 3 mm long. *Ovary* obovoid to subcylindric, 3-lobed, 5–10 mm long; style 3-lobed, lobes lightly fringed. *Capsules* elongate, broadly 3-winged, (16–)22–28 mm long. *Seeds* lamellate, kidney-shaped, ± 3 mm long, with prominently fringed margins. *Flowering time*: November to December.

Distribution and ecology: restricted to the southwestern corner of Western Cape, South Africa, from the Cape Peninsula to Hermanus; in seeps and marshes on sandy ground, flowering only after fire.

Diagnosis: *Aristea zeyheri* is distinguished by the slender habit, growing singly (not in tufts as originally

Distribution of ***Aristea rigidifolia***.

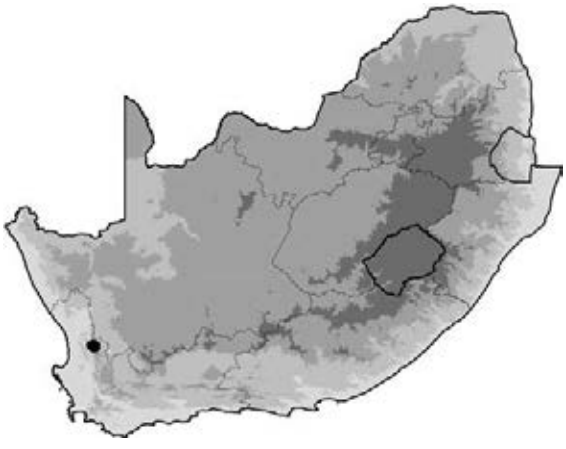
Distribution of ***Aristea zeyheri***.

suggested) with an unbranched stem and terete leaves, and broadly lobed, style with fringed stigmatic lobes. The relatively large flowers, up to 35 mm diam., are evidently nodding and unusual in the elongate ovary as well as the fringed stigmatic lobes. Although the two latter features accord with subg. *Pseudaristea*, the winged capsule and lamellate, half-ovate seeds with papillate, fringe-like margins match exactly those of sect. *Racemosae* of subg. *Aristea* and are quite unlike the terete seeds in roundly lobed capsules of sect. *Pseudaristea*. The pollen grains are either monosulcate or zonasulculate in plants from Hermanus and some from the Cape Peninsula, both conditions unlike the dizonasulculate condition in subg. *Pseudaristea*. The monosulcate grains are consistent for sect. *Racemosae*, in which capsules are always broadly winged and the seeds tangentially flattened and usually with fringed margins, and *A. zeyheri* seems best placed here on the basis of current knowledge. The unusual vegetative morphology, lobed stigmas, and the aberrant pollen grains in some plants must then be seen as derived within the section.

Sect. 5. **Singulares** *Weim.* in Acta Universitatis Lundensis, ser. 2, 36(1): 12 (1940). Type: *Aristea singularis* Weim.

Plants forming diffuse tufts with trailing aerial stems rooting at nodes. *Flowering stems* bearing 1 or 2 flower clusters, nodding. *Style* obscurely 3-lobed. *Capsules* obscurely 3-lobed. *Seeds* compressed-ellipsoid with sunken chalaza.

Species 1: northern Cederberg–Pakhuis Mtn complex.



39. **Aristea singularis** *Weim.* in Acta Universitatis Lundensis, ser. 2, 36: 12 (1940); Goldblatt: 142 (1995). Type: South Africa, [Western Cape], Clanwilliam District, Boontjies River, July 1927, *Leipoldt s.n. BOL18888* (BOL holo.; K, iso.).

Plants up to 400 mm high, forming diffuse tufts, somewhat trailing. *Stems* slightly flattened, rooting at aerial nodes, dichotomously branched. *Leaves* sword-shaped, 3–6 mm wide, fairly soft-textured. *Flower clusters* (1)2 per flowering stem, nodding, (1)2-flowered; spathes greenish-translucent becoming dry and torn above, ± 5 mm long, lightly lacerate, bracts similar but smaller. *Flowers* blue, pendent; tepals subequal, elliptic, 12–15 mm long. *Filaments* ± 2.5 mm long; anthers ± 4 mm long. *Style* obscurely 3-lobed. *Capsules* 3-lobed, ± 7 mm long. *Seeds* 1(2) per locule, compressed-ellipsoid, with a deeply sunken chalaza (doughnut-shaped), with funicle forming a pale fleshy body, surface smooth, epidermal cells domed. *Flowering time*: mainly July and August.

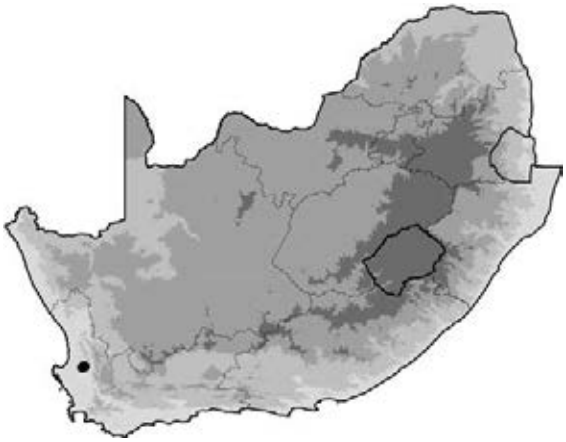
Distribution and ecology: restricted to the northern Cederberg and Pakhuis Mtns in Western Cape, South Africa; on sandstone slopes in light shade near streams or in shelter of rocks.

Diagnosis: *Aristea singularis* was mistakenly interpreted by Weimarck (1940), who had only the type collection available to him, as a creeping or even vine-like plant but we now know that it has tufts of leaves at ground level and produces persistent aerial stolon-like stems that root at nodes some distance from the parent plant, a feature unique in *Aristea*, and in a sense it is a trailing plant. The slender flowering stems, produced from leaf clusters, are usually dichotomously branched and bear pendent flower clusters. The immature capsules led Weimarck (1940) to believe they were ovoid-spherical and many-seeded and hence to assume that its closest relationships lay with his sections *Euaristea* (now sect. *Cladocarpae*) and *Ancipites* (both now subg. *Eucapsulares*). A remarkable species in many ways, its affinities seem to be with subg. *Aristea*, some taxa of which also have dichotomously branched flowering stems. The broadly 3-lobed capsules are not exactly like the narrowly 3-winged capsules of subg. *Aristea* and contain only two seeds per locule (or by reduction one). Furthermore, the rounded, ± doughnut-shaped seeds with a depression at the chalazal end are quite unlike the tangentially flattened, lamellate seeds of other members of subg. *Aristea*. The seed funicle is persistent and fleshy, forming an irregularly lobed body that possibly serves as an elaiosome for ants, which would disperse the seeds by carrying them to their nests, later consuming the fleshy tissue.

Pollen grains of *Aristea singularis* are moderate in size for the genus and monosulcate, with a broad, elliptic aperture, the assumed ancestral condition for *Aristea*. Such grains are typical of sect. *Racemosae* of subg. *Aristea* but in other features *A. singularis* exhibits little in common with the section, which includes tall, robust plants with several to many, upright branched

Distribution of ***Aristea singularis***.

stems. In its small size it better resembles sect. *Aristea*, but pollen grains of that section differ in being much larger with complex apertures, typically trisulcate with three confluent apertures (Goldblatt & Le Thomas, 1997; Goldblatt et al., 2004). Preliminary molecular studies show *A. singularis* to be allied to species of sect. *Racemosae*, but its several morphological differences merit placement in its own section. The short stigmatic lobes resemble those of sect. *Racemosae*, in which the style is apically notched, whereas the stigmatic lobes of sect. *Aristea* are broad, fan-like and deeply fringed.



Sect. 6. **Fimbriatae** *Goldblatt & J.C.Manning*, new section. Type: *Aristea fimbriata* Goldblatt & J.C.Manning

Plants moderate in size, up to 350 mm high. *Stems* usually few-branched, flattened and 2-winged below. *Flower clusters* with spathes and bracts with broad, translucent margins fringed on upper edges. *Flowers* with style minutely notched at apex. *Capsules* narrowly 3-winged. *Seeds* lamellate.

Species 1: Western Cape, South Africa.

40. **Aristea fimbriata** *Goldblatt & J.C. Manning* in Novon 7: 361 (1997b). Type: South Africa, Western Cape, Piketberg Mountains, high plateau south of Zebrakop, 6 Jan. 1995, *P. Goldblatt & J.C. Manning 10167* (NBG, holo.; E, K, MO, PRE, WAG, iso.).

Plants 200–350 mm high, forming rounded cushions. *Stems* compressed, winged below, angled above, mostly 2- or 3-branched, branches crowded near apex. *Leaves* linear to sword-shaped, 3–4 mm wide, slightly shorter than stems, firm-textured. *Flower clusters* 2 to 4, lateral clusters on short branches and mostly concealed by a subtending leafy bract, each 4- to 8-flowered; spathes dry and translucent with a narrow green or brown keel, margins closely fringed and rust-brown, 11–14 mm long, bracts entirely translucent, smaller than spathes. *Flowers* blue, on pedicels 2–3 mm long; tepals obovate, 15–20 × 8–9 mm. *Filaments* ± 5 mm long; anthers ± 3 mm long. *Ovary* 3-winged, 4–5 mm long; style ± 8 mm long, minutely 3-notched. *Capsules* oblong in outline, broadly 3-winged, 12–15 mm long. *Seeds* lamellate, up to 4 per locule, mature seeds not known. *Flowering time*: December and January.

Distribution of ***Aristea fimbriata***.

Distribution and ecology: one of several narrow endemics in the genus, known only from higher elevations on the Piketberg in Western Cape, South Africa; on sandy plateaus in fynbos, at 500–800 m elevation, flowering well after fire.

Diagnosis: *Aristea fimbriata* is distinguished by the regularly fringed spathes and floral bracts, minutely notched style, and relatively long, narrowly winged capsules up to 15 mm long. The fringed bracts are matched in the apparently distantly related *A. africana* and *A. recisa* of sect. *Aristea* but these species have broad, fringed stigmatic lobes. Plants grow in compact low tufts 200–350 mm high. The pollen grains stand out in the *Aristea* in having a 3-lobed aperture confined to one face of the grain. Species of sect. *Racemosae* have monosulcate pollen grains with a single broadly elliptic aperture and those of sect. *Aristea* have more complex trisulculate grains with three, sometimes confluent apertures. Its apparently isolated position in subg. *Aristea* is supported by molecular studies and *A. fimbriata* is accordingly referred to a separate section.

Sect. 7. **Aristea**

Plants mostly small, mostly up to 250 mm, rarely up to 1 m high. *Stems* usually ± dichotomously few-branched, often flattened and 2-winged. *Flower clusters* with dry spathes and bracts with translucent margins or mostly white to silvery-translucent with dark keels, sometimes fringed, occasionally brown-tipped. *Flowers* with broad, prominent stigmatic lobes fringed distally. *Capsules* narrowly 3-winged. *Seeds* lamellate.

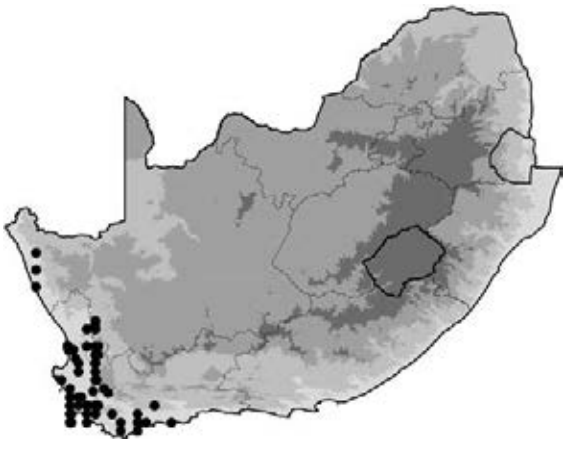
Species 6: western South Africa.

41. **Aristea dichotoma** *(Thunb.) Ker Gawl.*, Iridearum generum: 13 (1827); Weim.: 90 (1940). *Moraea dichotoma* Thunb.: 186 (1800); Thunb.: 266 (1811). Type: South Africa, [Western Cape], without precise locality or date, *Thunberg s.n.* (UPS–THUNB, holo.).

[*Aristea diffusa* Eckl.: 16 (1827), invalid name without description.]

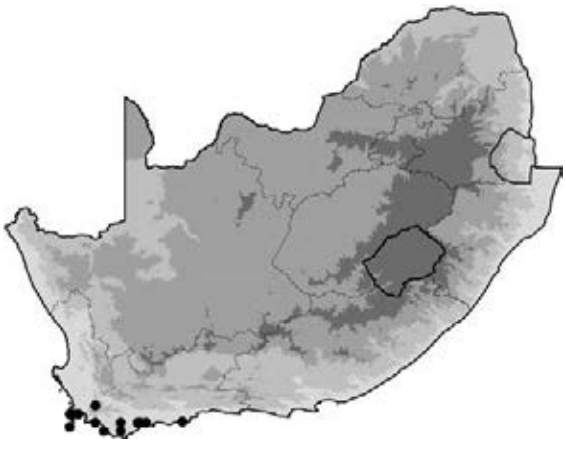
Plants 150–300 mm high, forming low, rounded cushions. *Stems* flattened below and 2-winged, dichotomously 3- to 6-branched. *Leaves* linear, 1.5–3.0 mm wide, grey-glaucous, firm-textured. *Flower clusters* mostly 4 to 6, stalked, each 2- to 4-flowered; spathes and bracts dry, brown with broad, translucent margins, spathes 8–10 mm long, bracts ± as long or slightly longer. *Flowers* subsessile, blue; tepals obovate, 14–18 mm long. *Filaments* ± 5 mm long; anthers ± 2.5 mm long. *Style* 7–8 mm long, stigmatic lobes broad, prominently fringed. *Capsules* on pedicels 3–4 mm long, narrowly 3-winged, 8–10 mm long, pale with dark margins. *Seeds* lamellate, kidney-shaped, 2 per locule, sculpturing foveate, margins papillate. *Flowering time*: December to March.

Distribution and ecology: western South Africa, extending from Port Nolloth in Northern Cape to the Cape Peninsula and Swellendam in Western Cape; on well-drained, sandy lower mountain slopes and plateaus and coastal flats.



Diagnosis: the cushion-like habit, tuft of narrow basal leaves, and dichotomously branched stem make *Aristea dichotoma* easy to recognise. When dry it can be confused with closely related *A. glauca*. The two species have similar spathes and bracts with broad translucent margins, but *A. glauca* does not normally form cushions, and the stems are simple or 1- to few-branched and obviously flattened and 2-winged below the flower clusters, whereas the stems of *A. dichotoma* are narrower and obscurely winged. Flowers of *A. glauca* are deep blue and often larger, with tepals 15–20 mm long whereas the tepals of *A. dichotoma* are paler blue and typically 14–16 mm long. The two species have partially overlapping ranges and are sometimes sympatric and co-blooming, as at sites in the Cape Peninsula and then their differences become quite clear.

42. **Aristea glauca** *Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 321 (1882); Weim.: 93 (1940). Type: South Africa, Western Cape, Piekenierskloof, Dec. 1831, *Drège 2612* (B [probably destroyed], lecto., effectively designated by Weim.: 93 (1940); S, isolecto.).



Plants 100–150 mm high, forming diffuse low cushions, spreading by slender underground stolons. *Stem* strongly compressed, 2-winged, dichotomously 1- to few-branched or simple. *Leaves* linear, slightly shorter than stems, 1–3 mm wide, glaucous, firm textured, cauline sometimes lacking as when unbranched. *Flower clusters* single or few, each 2- to 4-flowered; spathes and bracts green to brown with narrow translucent margins, 10–14 mm long. *Flowers* deep blue, tepals obovate, often emarginate, 15–20 mm long. *Style* 8–12 mm long, stigmatic lobes narrow, obscurely fringed *Capsules* on pedicels up to 5 mm long, 3-winged, 7–8 mm long. *Seeds* lamellate, kidney-shaped, 2 per locule, margins papillate, with sculpturing foveate. *Flowering time*: mainly October to December.

Distribution and ecology: Western Cape, South Africa, extending from Ceres and the Cape Peninsula to Riversdale; on sandy coastal and lower mountain slopes.

Diagnosis: one of the smallest species in the genus, *Aristea glauca* forms diffuse low tufts up to 150 mm high, and as the name suggests, has grey-glaucous leaves, mostly 2–3 mm wide. The flowering stems are relatively stout, conspicuously flattened, and often simple or 1- to 3-branched. The species appears to be closely related to *A. dichotoma* and the two are sometimes confused although the latter has narrower, often terete or slightly flattened stems bearing up to six branches and overtopping the leaves, and often smaller flowers with tepals 14–18 mm long and usually paler blue in colour. *Aristea glauca* spreads vegetatively by short underground stolons, sometimes forming diffuse mats.

Distribution of ***Aristea dichotoma***.

Distribution of ***Aristea glauca***.

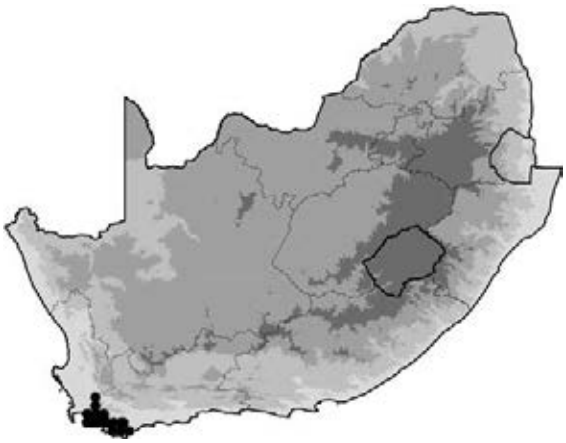
43. **Aristea oligocephala** *Baker*, Handbook of the Irideae: 144 (1892); Weim.: 95 (1940). Type: South Africa, [Western Cape], Babylon's Tower, Dec., *Zeyher 4049* (K, holo.; B, P, S, SAM, iso.).

Aristea dichotoma var. *macrocephala* Schltr. in Baker: 529 (1897), new synonym. Type: South Africa, [Western Cape], [Sir] Lowry's Pass, Jan. 1896, *Schlechter 7250* (B, BOL, GRA, P, PRE, syn.).

[*Aristea dichotoma* var. *monocephala* Schltr. ex Weim.: 95 (1940), invalid name only in synonymy.]

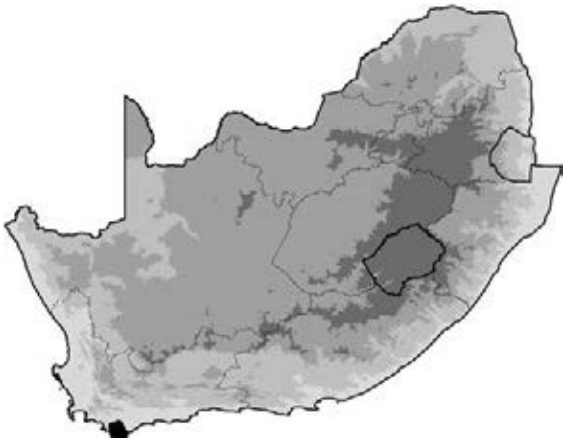
Plants 150–250 mm high, usually growing singly. *Stem* compressed, dichotomously branched, rarely simple. *Leaves* mostly basal, linear, about half as long as stem, 1.5–3.0 mm wide, rigid, elliptic in section, margins translucent. *Flower clusters* terminal, stalked, each 2- to 4-flowered; spathes and bracts silvery-translucent with narrow, dark keels, 15–20 mm long. *Flowers* blue; tepals 18–25 × 14–16 mm. *Filaments* 6–7 mm long; anthers ± 2.5 mm long. *Style* 8–9 mm long, stigma lobes broad, slightly fringed. *Capsules* 3-winged, 10–12 mm long. *Seeds* lamellate, kidney-shaped, 2 per locule, sculpturing foveate, margins fringed. *Flowering time*: November to January.

Distribution and ecology: restricted to southern Western Cape, South Africa, extending from the Hottentots Holland Mtns and Kleinmond to Bredasdorp; on stony sandstone slopes and flats.



Diagnosis: a relatively short plant, seldom exceeding 200 mm, *Aristea oligocephala* has a few-branched or rarely simple stem bearing large flower clusters up to 20 mm long. The spathes and bracts are papery and shiny-translucent with narrow dark keels. The firm, fibrous leaves are about half as long as the stem and up to 3 mm wide. The short, prominently winged capsules and lamellate seeds are typical of sect. *Aristea*.

44. **Aristea palustris** *Schltr.* in Botanische Jahrbücher für Systematik 27: 96 (1899); Weim.: 97 (1940). Type: South Africa, [Western Cape], Bredasdorp, mountains near Koude River, Dec. 1896, *Schlechter 9586* (B, lecto., effectively designated by Weimarck: 97 (1940); BR, K, MO, P, PRE, SAM, S, isolecto.).



Plants up to 1 m high. *Stem* rounded in section, ± dichotomously several-branched. *Leaves* linear to sword-shaped, 4–9 mm wide, soft-textured, margins translucent. *Flower clusters* several, all terminal on branches, each mostly 4- to 6-flowered; spathes and bracts 10–12 mm long, silvery-translucent with narrow dark keels. *Flowers* blue; tepals 12–14 mm long. *Filaments* ± 5 mm long; anthers ± 2.5 mm long. *Style* with 3 shortly fringed lobes. *Capsules* short, deeply 3-winged, 7–8 mm long. *Seeds* lamellate, kidney-shaped, sculpturing foveate, 2 per locule, mature seeds with margins evidently fringed. *Flowering time*: November to January.

Distribution and ecology: restricted to the Agulhas Plain and slopes of the Bredasdorp Mtns in Western Cape, South Africa; in seasonally wet sites, mostly (?exclusively) on limestone substrates.

Diagnosis: despite its height, up to 1 m but usually only 500 mm, and robust habit, *Aristea palustris* is typical of sect. *Aristea* in the nearly dichotomous branching pattern, largely translucent spathes, and broadly winged capsules. Pollen is likewise consistent with the section, the large grains with specialised trisulcate apertures. The dry, silvery spathes and bracts with a narrow dark keel most closely resemble those of *A. oligocephala*, which is common throughout the Caledon and Bredasdorp Districts of Western Cape, and we assume the two species are immediately related. A shorter plant, *A. oligocephala* has firm-textured, fibrous leaves 1.5–3.0 mm wide, whereas those of *A. palustris* are sword-shaped, relatively soft-textured and 4–9 mm wide.

Distribution of ***Aristea oligocephala***.

Distribution of ***Aristea palustris***.

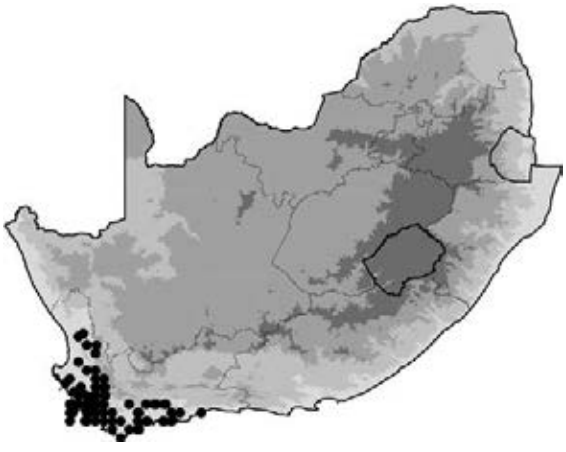
45. **Aristea africana** *(L.) Hoffmanns.*, Verzeichniss der Pflanzenkultur zu Dresden und Rammenau: 40 (1824); Weim.: 98 (1940). *Ixia africana* L.: 36 (1753). *Moraea africana* (L.) Thunb.: 7 (1787). *M. aristea* Lam.: 114 (1791), illegitimate superfluous name for *M. africana* (L.) Thunb. *A. eriophora* Pers.: 41 (1805), illegitimate superfluous name for *Ixia africana* L. Type: South Africa, Western Cape, without precise locality or collector (LINN, holo.).

Aristea cyanea Aiton: 67 (1789), illegitimate superfluous name for *Ixia africana* L. (1753). Type: unknown, possibly as for *I. africana* but collection made by F. Masson cited, possibly at BM.

Aristea lacera Stokes: 224 (1830), illegitimate superfluous name for *Ixia africana* L. (1753). Type: unknown, probably as for *I. africana*.

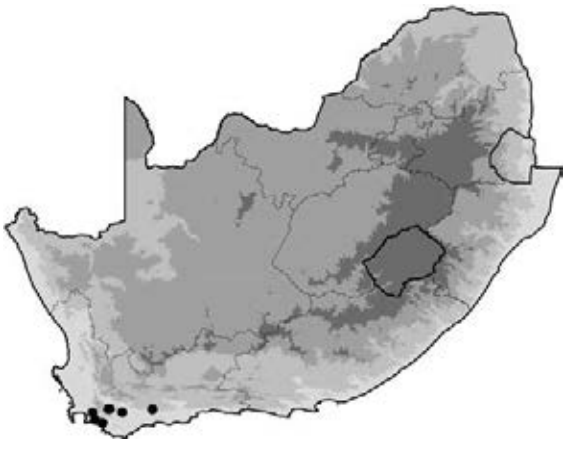
Plants mostly 100–150 mm high. *Stem* compressed, several-branched, sometimes ± dichotomously, sometimes simple. *Leaves* linear, 1.5–4.0 mm wide, relatively soft-textured, upper leaves with margins fringed near base. *Flower clusters* few in lax arrangement, each 3- to 6-flowered; spathes and bracts 8–12 mm long, green to brown in centre with wide silvery-translucent margins closely and deeply fringed, sometimes rust-coloured near tips. *Flowers* blue; tepals ± obovate, mostly 8–12 mm long. *Filaments* ± 4 mm long; anthers ± 2 mm long. *Style* 5–6 mm long, stigmatic lobes broad. *Capsules* deeply 3-winged, ± 8 mm long. *Seeds* lamellate, kidney-shaped, 2 per locule, sculpturing foveate, margins shortly papillate. *Flowering time*: mainly September to December.

Distribution and ecology: widespread in the Western Cape, South Africa, from the Gifberg to Bredasdorp and Riversdale; often on sandstone substrates but also on granitic or clay soils in areas of high rainfall, relatively common and rapidly colonising disturbed places.



Diagnosis: type of the genus, the diminutive *Aristea africana* stands 100–150 mm high and is readily distinguished by the prominently fringed, silvery-translucent spathes and bracts, sometimes brown at the tips and appearing almost woolly, the feature that prompted one of its later synonyms, *A. eriophora*. Typical of subg. *Aristea* in the short, broadly winged capsules and flattened, lamellate seeds, *A. africana* has relatively soft-textured linear to narrowly sword-shaped leaves. The only species with which it may be confused is *A. recisa*, often a somewhat taller species, which has similar spathes and bracts but almost always with the spathes rusty brown in the upper half or third. The two species have similar large, trisulcate pollen grains with three confluent narrow apertures.

46. **Aristea recisa** *Weim.* in Acta Universitatis Lundensis, ser. 2, 36: 101 (1940). Type: South Africa, [Western Cape], Wildepaardeberg, Waterkloof, Jan. 1925, *Stokoe 1128* (PRE, holo.; BOL, iso.).



Plants mostly 200–400 mm high, forming small tufts. *Stems* compressed, simple or with 1 to 3 slender, suberect branches. *Leaves* in a basal tuft, sword-shaped, as long as or longer than stem, 3–5 mm wide, soft-textured. *Flower clusters* few in lax arrangement, each 2- to 4-flowered; spathes and bracts 12–13 mm long, green to brown in the centre with broad translucent margins closely and shallowly fringed, rust-brown in distal ⅓. *Flowers* blue; tepals ± 12 mm long. *Filaments* ± 5 mm long; anthers ± 2.5 mm long. *Style* ± 7 mm long; stigma lobes shortly fringed. *Capsules* ± 8 mm long, deeply 3-winged. *Seeds* lamellate, mature seeds unknown but evidently kidney-shaped, with foveate sculpturing, 2 per locule, margins shortly papillate. *Flowering time*: mainly October to December.

Distribution and ecology: a relatively narrow endemic of Western Cape, South Africa, extending from the Du Toit's Kloof Mtns to Hermanus and the central Langeberg; on moist sandstone slopes, at 600–1 200 m elevation.

Diagnosis: broadly similar to the more common and widespread *Aristea africana*, *A. recisa* shares with that

Distribution of ***Aristea africana***.

Distribution of ***Aristea recisa***.

species distinctive dry-papery, prominently fringed spathes and floral bracts. The two might easily be confused but the bracts of *A. recisa* are rusty brown along the margins, the leaves are often broader, up to 5 mm wide, and soft-textured, and the flowering stems are usually held well above the leaves, whereas the stems in *A. africana* are usually (but not invariably) not much longer than the leaves. The critical distinction between the two species lies in the spathes and bracts, which in *A. recisa* are fringed for less than a third of their length, whereas in *A. africana* they are fringed for half their length or more, as well as usually being uniformly coloured. A montane species, *A. recisa* is seldom found below 600 m, whereas *A. africana* occurs from near sea level on coastal flats to mountain slopes but rarely above 500 m.

UNCERTAIN SPECIES

Aristea thyrsiflora (D.Delaroche) N.E.Br.: 36 (1929) [applied to *A. capitata*]; Weim.: 75 (1940). *Ixia thyrsiflora* D.Delaroche: 20 (1766). Type: unknown. The so-called type in Herb. Burman does not match the protologue, which alone is not adequate for identification of the species.

EXCLUDED SPECIES

Aristea angolensis subsp. *acutivalvis* Weim. in Acta Universitatis Lundensis, ser. 2, 36: 20 (1940). Type: Southern Rhodesia [Zimbabwe], Macheke, *Eyles 1996* (K, holo.; SAM, iso.). This taxon is based on plants from Zimbabwe, but both Weimarck (1940) and Vincent (1985) cited specimens of *A. torulosa* and possibly also *A. majubensis* from southern Africa under this name. A final resolution of its identity requires study of tropical African material.

2. Subfamily **NIVENIOIDEAE**

Nivenioideae *Schulze ex Goldblatt* in Annals of the Missouri Botanical Garden 77: 621 (1990). Type: *Nivenia* Vent.

Evergreen woody shrubs with a woody underground caudex. *Stems* woody, with anomalous, monocot-type secondary growth. *Leaves* unifacial, in 2 ranks, without main vein. *Inflorescence units* binate rhipidia (flower clusters) enclosed in paired, opposed leafy or dry spathes, units variously aggregated into false corymbs, racemes or heads. *Flowers* long lasting, radially symmetric, with septal nectaries; tepals united in a tube below, spreading or upright above. *Filaments* free; anthers loculicidal and extrorse; pollen grains monosulcate, exine reticulate. *Ovary* inferior; style slender, apically 3-notched or dividing into 3 slender branches. *Capsules* ± woody. *Seeds* tangentially compressed, shield-shaped. *Basic chromosome number x* = 16.

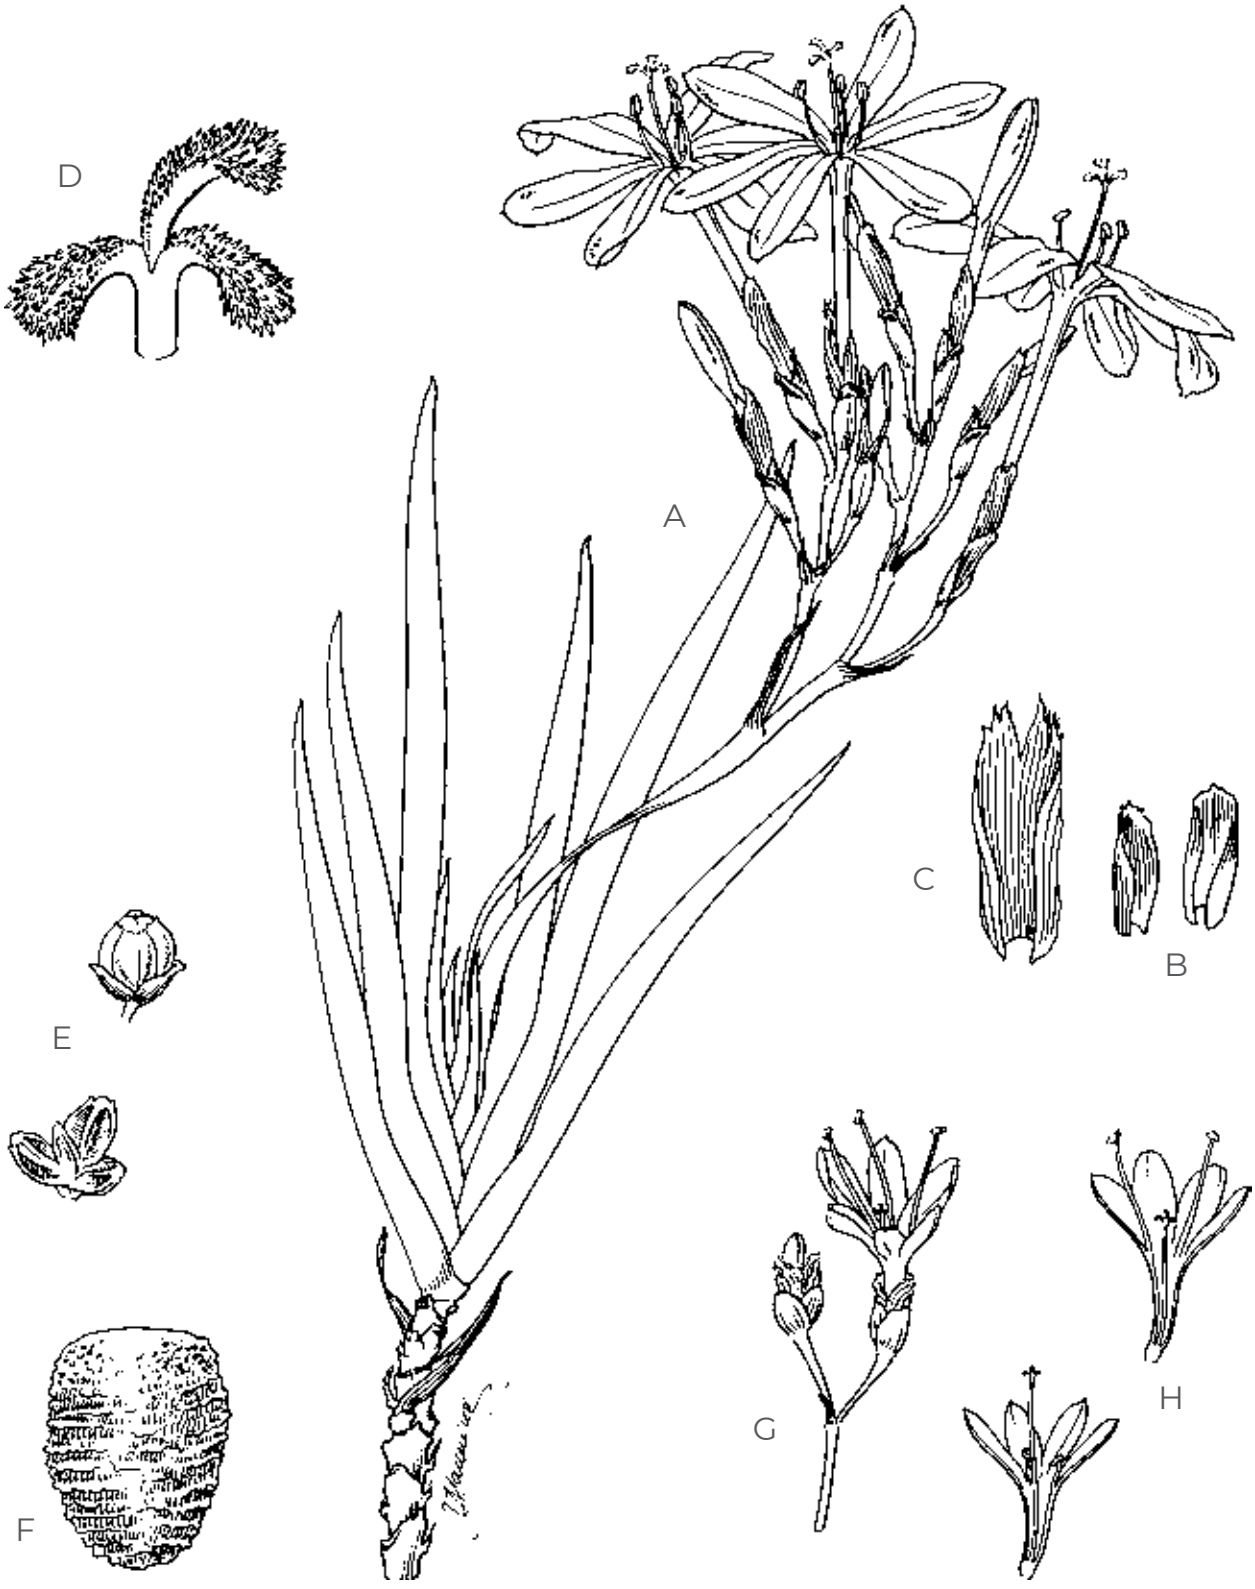
Genera 3, species 15, all of southern Western Cape.

Key to genera

1a Inflorescence compound, forming a compressed capitulum enclosed by enlarged green or coloured leaves; perianth tube shorter than the linear, spathulate tepals . . . . . 3. *Klattia*
1b Inflorescence either compound, forming branched panicles or corymbs, or flowers borne in isolated pairs, enclosed in green or brown spathes; perianth tube shorter or longer than the oblong to ovate tepals:
2a Flowers pale to deep blue; tepals patent, not villous on the outside; stamens and/or style well exserted, species often heterostylous . . . . . 2. *Nivenia*
2b Flowers green to blackish with the tepals yellow on the reverse; tepals remaining erect, densely villous on the outside; stamens included . . . . . 4. *Witsenia*

2. **Nivenia**

Nivenia *Vent.*, Decas generum novorum 3 (1808). *Aristea* subg. *Nivenia* (Vent.) Baker: 145 (1892). Type: *N. corymbosa* (Ker Gawl.) Baker, lecto., designated by Brown: 265 (1933).



Genlisia Reichenb.: 60 (1828), superfluous name for *Nivenia* Vent. (1808).

[*Witsenia* sensu Ker Gawl.: 236 (1804), including *Klattia*; Thunb.: 65, 66 (1824).]

Revisionary account: Goldblatt: 51–99 (1993) but see Goldblatt (1997) and Goldblatt & Manning (2007).

Named for James Niven, Scottish botanist employed in the late 18th and early 19th century to collect plants in southern Africa. Niven was one of the first to collect the genus and was responsible for the introduction of *Nivenia* to the British Isles and thence to Western Europe.

Evergreen shrubs or subshrubs, sometimes forming cushion-like tufts, with woody underground caudex. *Stems* few to many, upright or inclined, compressed, becoming rounded below, conspicuously marked by leaf scars; major axes simple or branched or with short-lived spur-shoots. *Leaves* isobilateral, lanceolate to ± linear, sheathing below, clustered apically, without main vein; lasting more than a year; margins narrowly hyaline. *Inflorescence* terminal, peduncle compressed, short (vestigial in *N. fruticosa*) and included in leaves or long and exserted; forming a pseudopanicle with short to long axillary branches, thus either somewhat corymb- or raceme-like, (one)few- to many-flowered; ultimate branches of peduncle terminating in a pair of opposed spathes, these enclosing paired or single bracteate flowers (thus binate rhipidia); spathes leathery to ± less dry, long with membranous margins or short and ± obtuse, bracts usually conspicuous, often exceeding spathes, scarious, silvery-transparent to brown, smooth or wrinkled. *Flowers* sessile, salver-shaped, heterostylous in several spp., pale to deep blue, usually white at tepal bases, odourless; perianth tube well developed, ± cylindric but slightly wider toward mouth; tepals lanceolate to elliptic or obovate, subequal or inner slightly smaller, extended horizontally or ascending. *Filaments* filiform, equal or one shorter (*N. inaequalis*), inserted at or just below base of tepals, in heterostylous species either very short, sometimes occluding mouth of tube (pin flowers) or well exserted and much exceeding style (thrum flowers); initially extrorse, versatile after anthesis, yellow to ± white or deep blue; pollen yellow or blue. *Ovary* usually 2-ovulate, rarely 6-ovulate (*N. levynsiae*); style filiform, well exserted or (in heterostylous spp.) thrum flowers with style included or barely exserted; 3-lobed (*N. inaequalis*) or 3-branched, then branches

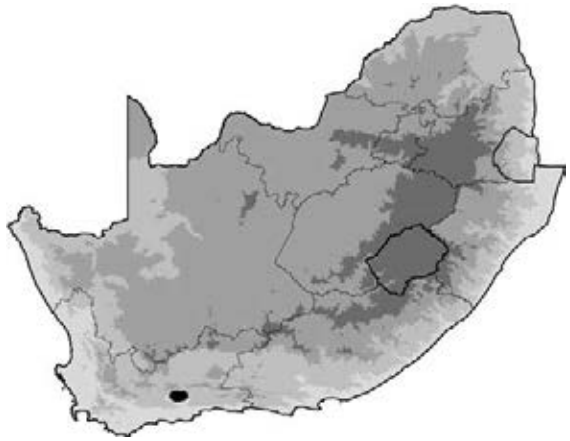
NIVENIA. N. stokoei: A, flowering stem; B, inner spathe (left) and outer spathe (right); C, bract; D, stigma; E, indehisced capsule (top) and dehisced capsule (bottom); F, seed showing outer surface. ***N. parviflora***: G, portion of inflorescence; H, half-flower of long-styled pin morph (bottom) and short-styled thrumb morph (top).

filiform. *Capsules* ± woody, with rudimentary beak. *Seeds* shield-shaped, tangentially compressed, usually 1 per locule, rarely 2 (2 to 4 in *N. levynsiae*), rugose, brown to blackish with translucent outer layer sometimes partially exfoliated. *Basic chromosome number x* = 16.

Species 11: southern and southwestern Cape, restricted to sandstones of the Table Mountain Series of the Cape System and mostly montane.

Largest of the three genera of shrubby Iridaceae, *Nivenia* species have pale to deep blue flowers that vary modestly, mainly in the length of the perianth tube. Variation in inflorescence morphology is, however, extensive. The basic inflorescence is a binate rhipidium (or flower cluster) bearing one or two flowers per unit enclosed in leathery bract-like spathes and arranged in flat-topped corymbose false panicles, the entire flowering stem thus a compound inflorescence, or in a spike-like arrangement. An unusual feature in the genus is the condition of heterostyly, with six species heterostylous, thus including plants with a long style and short stamens (pin flowers) or a short style and long stamens (thrum flowers).

The *Nivenia binata* species-group, restricted to the Swartberg Mtns of the Little Karoo, has distinctive dry, brown, wrinkled bracts and blue anthers and pollen. In other species the pollen is yellow to white. Pollination in short-tubed species is by bees foraging for nectar and in species with elongate perianth tubes by long-proboscid flies likewise seeking nectar.



Key to species

1a Inflorescence compound, a flat-topped false panicle of > 10 flowers; ultimate peduncles slender and much exceeding subtending bracts:
  2a Flowers paired in ultimate flower clusters; anthers and pollen blue; plants from Little Karroo mtns:
    3a Perianth tube 20–25 mm long; floral bracts 8–9 mm long . . . . . 6. *N. stenosiphon*
    3b Perianth tube 5–15 mm long; floral bracts 5.5–10.5 mm long:
      4a Perianth tube 9–15 mm long; floral bracts 9–10 mm long . . . . . 4. *N. binata*
      4b Perianth tube ± 5 mm long; floral bracts ± 5.5 mm long (tepals 6–7 mm long) . . . . . 5. *N. parviflora*
  2b Flowers mostly or exclusively solitary in terminal clusters; anthers and pollen yellow or ± white; plants from southwestern coastal mtns:
    5a Perianth tube 27–33(–37) mm long; floral bracts (10–)12–15 mm long . . . . . 9. *N. stokoei*
    5b Perianth tube 11–21 mm long; floral bracts 6–7 mm long:
      6a Perianth tube 11–13 mm long; tepals 9–11 mm long . . . . . 7. *N. corymbosa*
      6b Perianth tube 16–18(–21) mm long; tepals 11–14 mm long . . . . . 8. *N. dispar*
1b Inflorescence of 1 to few(6) flowers or a dense false raceme; if many-flowered then ultimate peduncles short and concealed by subtending bracts:
  7a Inflorescence a dense false raceme; floral bracts (not spathes) silvery-membranous in upper half or entirely; flowers heterostylous; style branches lobed or filiform:
    8a Flowers paired in individual flower clusters; stamens unequal with one filament much shorter; floral bracts silvery-translucent throughout; plants from Rooiberg . . . . . 1. *N. inaequalis*
    8b Flowers solitary in individual flower clusters; stamens equal; floral bracts silvery only in upper half; plants from Riviersonderend Mtns and Langeberg . . . . . 2. *N. argentea*
  7b Inflorescence of 1 to few (6) flowers; floral bracts ± concealed by leaves or brown-membranous; flowers homostylous; style branches filiform:
    9a Perianth tube 20–30 mm long; flowers paired in spathes; plants from Langeberg. . . . . 3. *N. fruticosa*
    9b Perianth tube 5–15 mm long; flowers solitary within spathes; plants from Hottentots Holland Mtns and Kogelberg:
      10a Perianth intense blue; tepals spreading horizontally, 18–22 × 8–9 mm; perianth tube ± 15 mm long 10. *N. concinna*
      10b Perianth pale blue; tepals cupped, 13–15 × 6–8 mm; perianth tube ± 7 mm long . . . . . 11. *N. levynsiae*

1. **Nivenia inaequalis** *Goldblatt & J.C.Manning* in Bothalia 37: 195 (2007). Type: South Africa, [Western Cape], Rooiberg Mtns, next to forestry track near Bailey's Peak, 3 300–4 600 ft [± 1 000–1 400 m], 29 Dec. 1986, *J.H.J. Vlok 1794* (NBG, holo.; K, MO, PRE, iso.).

[*Nivenia argentea* sensu Goldblatt: 54 (1993).]

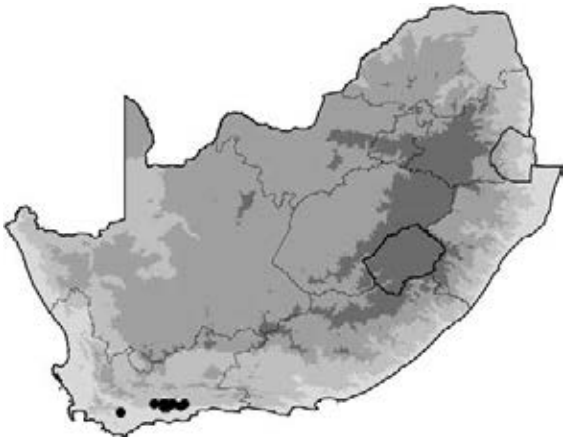
Rounded evergreen shrubs, 400–800 mm high, branching from base. *Stems* ascending, with short spur-shoots in upper part, leafy portions ± 3 mm diam. *Leaves* crowded apically, narrowly lanceolate, (40–)55–90 × 2–3 mm. *Inflorescence* a compound, congested, false raceme, primary peduncle axis compressed, exserted (10–)15–30 mm from leaves, up to 20-flowered; secondary peduncles 3–4 mm long, bearing a shortly stalked, 2-flowered binate rhipidium subtended by a lanceolate-attenuate, keeled bract ± 17 mm long, dry and white-translucent with brown midline; spathes tightly enclosing binate rhipidia, lanceolate-attenuate, 13–15 mm long, dry and membranous, brown below and in midline, margins white-transparent; floral bracts open to base, 22–25 mm long, dry and silvery-translucent throughout, becoming torn apically. *Flowers* salver-shaped, heterostylous, blue, darker at tepal bases, white in throat and tube; perianth tube 30–40 mm long, slightly wider toward mouth; tepals elliptic-lanceolate, ± 18 × 5–6 mm, spreading. *Filaments* unequal, either two exserted 7–8 mm and one exserted ± 5 mm (thrum flower) or two exserted 3 mm and one included 1.5–2.5 mm (pin flower); anthers 1.0–1.5 mm long before anthesis, yellow; pollen yellow. *Style* either

Distribution of ***Nivenia inaequalis***.

included 2–3 mm below mouth of tube (thrum flower) or exserted 6–8 mm, reaching 2–4 mm beyond anthers (pin flower); style branches rounded lobes 0.5 mm long. *Capsules* subglobose, ± 6 × 4.0–4.5 mm. *Seeds* 1 per locule, shield-shaped, rugose, ± 4.5 × 3.5 mm. *Flowering time*: mainly November and December, occasionally out of season in February and March.

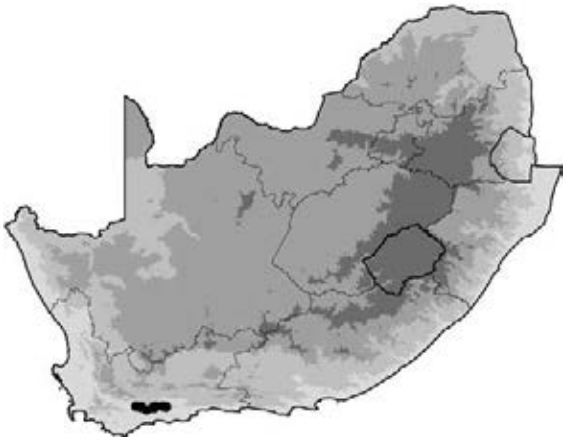
Distribution and ecology: restricted to upper elevations of the Rooiberg, an isolated massif southeast of Ladismith, in Western Cape, South Africa; on rocky, sandstone ridges and summits above 1 000 m elevation in arid fynbos, usually in exposed sites in rock outcrops.

Diagnosis: *Nivenia inaequalis* is recognised in the genus by its unequal stamens, with one filament shorter than the other two, and by the short, rounded rather than linear or ± filiform style branches. The species is heterostylous and in the pin morph the shorter stamen is included in the elongate perianth tube, 30–40 mm long. The floral bracts are particularly conspicuous, being silvery-translucent throughout their length. It is most likely to be confused with *N. argentea* from the Langeberg and Riviersonderend Mtns as both have a similar general aspect, forming rounded, leafy shrubs, with similar dry, lanceolate-attenuate spathes and a distinctive, congested, raceme-like compound inflorescence, possibly the ancestral type for the genus. The individual flower clusters of *N. inaequalis* are always paired within the spathes whereas those of *N. argentea* are solitary, with partly or entirely brown spathes and floral bracts, and shorter perianth tube, 14–25 mm long. Illustrations published as *N. argentea* in *The Woody Iridaceae* (Goldblatt, 1993) actually represent *N. inaequalis*.



2. **Nivenia argentea** *Goldblatt*, Woody Iridaceae: 54 (1993) [including *N. inaequalis*], as a new name for *N. capitata* (Klatt) Weim.: 366 (1940), illegitimate homonym, not *N. capitata* R.Br. (1810) (Proteaceae). *Witsenia capitata* Klatt: 546 (1866). Type: South Africa, [Western Cape], banks of the Riviersonderend, Appelskraal, Eksteen, and surrounding mountains, 500–4 000 ft [150–1 200 m], *Ecklon & Zeyher Irid. 62* (90.9) (B, holo.; MO, S, iso.).

Rounded shrubs up to 400 mm high, forming low cushions. *Stem* branching from base, branches ascending, compressed, leafy portions 2–4 mm diam. *Leaves* crowded apically, linear-lanceolate, (20–)40–80 × 1.5–3.5 mm. *Inflorescence* a congested, branched false raceme, up to 15-flowered, lateral branches short, 3-flowered, each node shortly stalked, with 1 flower within spathes; primary peduncle axis compressed, extending (10–)20–40 mm from leaf cluster, ultimate branches ± 2 mm long, subtended by lanceolate-attenuate, keeled, bracts 15–25 mm long, dry, brown with brown membranous margins; spathes tightly enclosing flower, lanceolate-attenuate, 13–18 mm long, dry and papery, brown below and in midline, margins and apices transparent-membranous; floral bracts tubular, 18–25 mm long, dry and membranous, usually silvery-transparent in upper ½–⅓, brown in lower ½ –⅔, sometimes ± entirely shining brown, becoming torn apically. *Flowers* salver-shaped, heterostylous, deep blue, darker in centre, white in throat and tube; perianth tube 14–20(–25) mm long, widening gradually toward mouth; tepals oblong-oblanceolate, 13–18 × 4–6 mm, spreading. *Filaments* either 4–5 mm long (thrum flower) or 1.0–1.5 mm long (pin flower); anthers 1.0–1.5 mm long before anthesis, yellow; pollen yellow. *Style* either included 0.5–4.0 mm below mouth of tube (thrum flower) or exserted ± 7 mm, reaching ± 5 mm beyond anthers (pin flower), dividing into filiform branches ± 1.5 mm long. *Capsules* obovoid, ± 7 × 3.5–4.0 mm. *Seeds* unknown. *Flowering time*: mainly October to December, occasionally out of season in March and April.



Distribution and ecology: South Africa, restricted to middle and upper elevations on the Riviersonderend Mtns and adjacent Langeberg, extending from Tradouwberg and Grootvadersbosch north of Heidelberg in the west to Garcia's Pass and Perdeberg near Riversdale in the east; on exposed, rocky ridges.

Diagnosis: *Nivenia argentea* is distinguished by its congested, compound, ± raceme-like inflorescence with lanceolate-attenuate subtending spathes that entirely brown and dry. The ultimate branches bear single-flowered rhipidia, each flower surrounded by a tubular, dry, membranous bract 18–25 mm long, usually silvery-transparent in the upper half and brown below but sometimes entirely shining brown. The species is heterostylous and the flowers have a perianth tube 14–25 mm long with the anthers exserted on filaments either 4–5 mm long (thrum flowers) or 1.0–1.5 mm long (pin flowers). The style branches are slender and typical of most other species in the genus, and differ from those of related *N. inaequalis*, which are short and rounded.

In the structure of the compound inflorescence *Nivenia argentea* closely resembles *N. inaequalis* from the Rooiberg, but that species has inflorescence bracts and spathes with broad, silvery margins and floral bracts that are entirely silver-transparent. The binate rhipidia

Distribution of ***Nivenia argentea***.

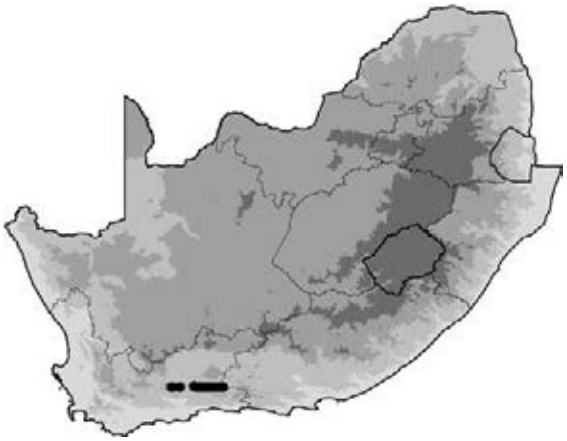
Distribution of ***Nivenia fruticosa***.

in *N. inaequalis* are 2-flowered and the flowers themselves are distinctive in the longer tube, 30–40 mm long versus 14–20(–25) mm long in *N. argentea*, and in their unique, short, rounded style branches. The tubular floral bracts of *N. argentea* are unusual in the genus in having the lower margins fused to form a closed cylinder, as the bract margins in most other *Nivenia* species are free to the base, although overlapping and enclosing the perianth tube. *Nivenia fruticosa*, also from the Langeberg, is the only other species with tubular floral bracts, suggesting a possible relationship between the two.

3. **Nivenia fruticosa** *(L.f.) Baker* in Journal of the Linnean Society, Botany 16: 109 (1877) [including *N. argentea* Weim.: 360 (1940)]; Goldblatt: 60 (1993). *Ixia fruticosa* L.f.: 93 (1782). *Witsenia fruticosa* (L.f.) Ker Gawl.: 237 (1804). *Aristea fruticosa* (L.f.) Pers.: 41 (1805). Type: South Africa, [Western Cape], Platte Kloof [Langeberg near Grootvadersbosch] and Riviersonderend Mtns, *Thunberg s.n.* (UPS–THUNB, holo.; C–Herb. Vahl, probable iso.).

Witsenia ramosa Vahl: 47 (1805), illegitimate superfluous name for *Ixia fruticosa* L.f. Type: uncertain, probably as for *I. fruticosa* L.f.

Subshrub forming compact, rounded cushions 100–250 mm high. *Stems* several to many from base, central nearly erect, laterals inclined, compressed, occasionally branched but showing apical dominance with a few spur-shoots produced each season, leafy part ± 2 mm wide. *Leaves* crowded apically, grey-green, 35–45 × 2.0–2.5 mm, narrowly lanceolate, acute. *Inflorescence* a single flower pair on a terminal peduncle 2–3 mm long, a single leafy bract subtending paired spathes; spathes green; floral bracts tubular, 9–15 mm long, membranous, light straw-coloured. *Flowers* ± salver-shaped, blue, darker at tepal bases, tube pale; perianth tube 20–25(–30) mm long, cylindric, ± 1 mm diam. At base, 1.5 mm at mouth; tepals lanceolate, ± 12 mm long, 3.5–4.0 mm wide, ascending below, ultimately recurved in upper half. *Filaments* ± 2.5 mm long; anthers ± 1 mm long; pollen yellow. *Style* dividing opposite or sometimes 2–3 mm above anthers, branches filiform, ± 2.5 mm long, white. *Capsules* obovoid, 4.5–5.5 mm long, often only one locule with a seed. *Seeds* ± 3 mm long, 1 per locule. *Flowering time*: December to January, rarely extending into mid-February.



Distribution and ecology: restricted to the central Langeberg in southern Western Cape, South Africa, extending from the mountains above Swellendam in the west to Grootvadersbosch and Gysmanshoek some 40 km to the east; in open low fynbos above 1 000 m elevation in shallow stony soil in exposed situations where the plants are not overshadowed by surrounding vegetation.

Diagnosis: the growth form of *Nivenia fruticosa* is unmistakable, but herbarium specimens can also easily be recognised by the slender stems, narrow leaves 2.0–2.5 mm wide, and inflorescence of a single flower pair. The flowers are unusual in their long perianth tube and relatively short tepals ascending below and ultimately recurved, unlike the horizontally extended tepals of most other species of *Nivenia*. Apparently specialised in its vegetative morphology and in the inflorescence reduced to a single flower pair, *N. fruticosa* is probably most closely related to *N. argentea*. The two species have similar long inflorescence bracts and floral spathes and long, tubular, pale, partly membranous and transparent bracts. In other species of *Nivenia* the inflorescence bracts are relatively short, the spathes are leathery and brown, and the floral bracts brown and opaque.

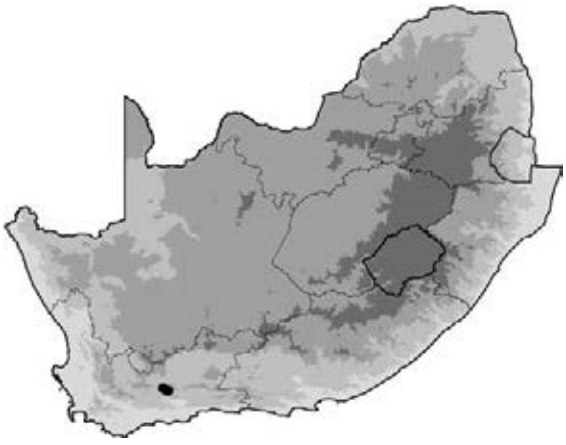
4. **Nivenia binata** *Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 382 (1882); Goldblatt: 65: (1993). *Witsenia binata* (Klatt) Klatt: 172 (1894). Type: South Africa, [Western Cape], Great Swartberg at Klaarstroom, 30 July 1829, *Drège 2184* (B, holo.; BM, E, G, K, P, iso.).

Aristea lignosa Adamson: 373 (1931). Type: South Africa, [Western Cape], Seven Weeks Poort, *Adamson 3015* [BOL, lecto., designated by Goldblatt: 65 (1993)].

[*Witsenia ramosa* sensu Klatt: 547 (1866), non Vahl: 47 (1805) (= *Nivenia fruticosa* (L.f.) Baker).]

Distribution of ***Nivenia binata***.

Shrubs 150–900 mm high, usually rounded and with several branches from the base. *Stem* few and irregularly branched, the leafy part ± 2.5 mm diam. *Leaves* narrowly lanceolate, (40–)60–100 mm long, 2–3 mm wide. *Inflorescence* a compound, corymb-like false panicle, (12)20- to 60-flowered (6 to 30 flower pairs), primary peduncles exserted, compressed, 2–4 mm wide, ultimate peduncles bearing paired flowers within spathes; spathes 4–5 mm long, dry, brown, brittle-chaffy, green near base, bracts dry and red-brown, 9–10 mm long, firm-membranous, dry, brown, much-wrinkled above spathes. *Flowers* salver-shaped, heterostylous, deep to light blue, tube nearly white; perianth tube 9–15 × 1.3–1.8 mm, cylindric; tepals spreading horizontally, elliptic, 7.5–10.0 × 4.3–5.0 mm. *Filaments* either short, 2–3 mm long (pin flower) or 7–9 mm long (thrum flower); anthers ± 1.8 mm long before anthesis, later ± 1 mm long, dark blue-violet; pollen blue. *Style* either short, 7–12 mm long (thrum flower), dividing just below to ± 1.5 mm above mouth of tube, or 15–18 mm long, exserted 7–8 mm from tube (pin flower); style branches filiform, ± 1 mm long (± 0.3 mm in some long-styled plants). *Capsules* subglobose, ± 4 mm × 3 mm. *Seeds* usually 1 per locule, rugose, blackish with a transparent outer layer, ± 3.3 × 1.8–2.0 mm. *Chromosome number* 2*n* = 32. *Flowering time*: September to November (rarely also in April or in August).



Distribution and ecology: restricted to the Swartberg Mtns of the Western Cape, South Africa, from Towerkop above Ladismith in the west to the mountains near Meiringspoort (the type collection was reported to have been made at Klaarstroom, at the north end of Meiringspoort, but no recent collections have been made in this area); in rocky sites on both southern and northern slopes under conditions variable in rainfall and sun exposure with more robust plants on southern slopes.

Diagnosis: the paired flowers in large corymbose inflorescences and long, brown, wrinkled bracts are the most distinctive features of *Nivenia binata*. The flowers have a relatively short perianth tube and are heterostylous. The unusual dark blue anthers and blue pollen are shared with *N. parviflora* and *N. stenosiphon*, restricted to the Klein Swartberg and adjacent Touwsberg, just east of the range of *N. binata*. *Nivenia stenosiphon* is also heterostylous and has a similar inflorescence and wrinkled floral bracts but is distinguished by its long-tubed flowers with relatively short tepals, the tube 32–38 mm long and tepals 10–12 mm long. The flowering time of *N. stenosiphon* is late autumn, from late March to early June, a significant difference from *N. binata*.

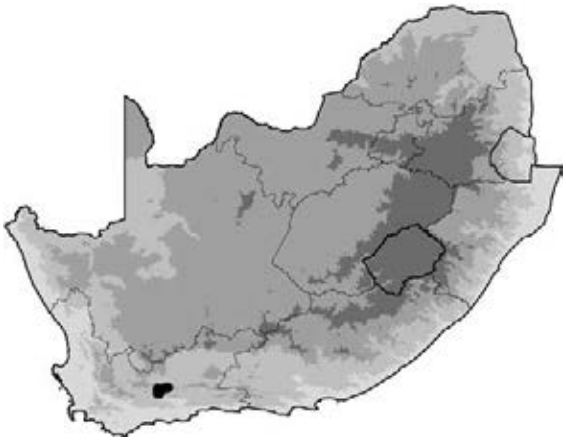
5. **Nivenia parviflora** *Goldblatt* in Bothalia 27: 101 (1997). Type: South Africa, Western Cape, Klein Swartberg Mtns, slopes of Toringberg, ± 800 m, 25 Mar. 1996, *Goldblatt 10498* (NBG, holo.; BOL, K, MO, PRE, WAG, iso.).

Shrubs 300–500(–800) mm high. *Stem* with several branches from base, branching irregularly, leafy terminal branches compressed, ± 3 mm wide. *Leaves* narrowly lanceolate to ± linear, mostly 50–70 × 3–4 mm, veins not evident when alive. *Inflorescence* compound, a flat-topped false panicle of 40 to 120 flowers (20 to 60 flower pairs), primary peduncles exserted from leaves, compressed, 2-winged, 3.0–4.5 mm wide, ultimate branches bearing paired flowers within opposed spathes; spathes 3–4 mm long, outer slightly larger than inner, leathery, red-brown, or green near bases, dry and dark brown above; floral bracts dry, reddish brown, much wrinkled, ± 5 mm long. *Flowers* salver-shaped, heterostylous, mostly pale blue, sometimes middle blue (rarely white), white at base of tepals and in tube; perianth tube cylindric, ± 5.5 mm long; tepals subpatent, held ± 30° above horizontal, lanceolate-elliptic, 6.3–7.0 × ± 2.4–3.0 mm. *Filaments* suberect, ± 6 mm long (thrum morph) or ± 2 mm long (pin morph); anthers ± 1.3 mm long, pale blue; pollen whitish. *Style* filiform, either emerging 2 mm from tube (thrum morph) or 7–8 mm from tube (pin morph), dividing into 3 linear stigma lobes, each ± 0.4 mm long. *Capsules* ovoid, ± 5 mm long, usually only 1 fertile locule fertile. *Seeds* usually single, 3.0–3.5 mm long. *Flowering time*: March to May.

Distribution and ecology: restricted to the lower southern slopes of the Klein Swartberg near Ladismith in

Distribution of ***Nivenia parviflora***.

Western Cape, South Africa; on rocky sandstone slopes, mostly in rock outcrops, in fynbos vegetation dominated by *Protea repens* L.



Diagnosis: *Nivenia parviflora* is an autumn-flowering species distinguished by the dark brown and much wrinkled floral bracts, and relatively small flowers with tepals 5–6 mm long and tube ± 5.5 mm long, and blue anthers. The brown, wrinkled floral bract and blue anthers are shared with *N. binata* and *N. stenosiphon*, but these two species have larger flowers with longer perianth tubes, usually 10–15 mm long in *N. binata* and 32–38 mm long in *N. stenosiphon*. The spathes in *N. parviflora* are 3–4 mm long and the floral bracts ± 5 mm long, whereas the spathes of *N. binata* are 4–5 mm long and the floral bracts 9–10 mm long, and it flowers in late spring, mainly October and November. Like its relatives, *N. parviflora* is heterostylous and has filaments are either ± 2 mm or ± 6 mm long (for long- or short-styled morphs) and the styles either 4 mm longer or shorter than the stamens.

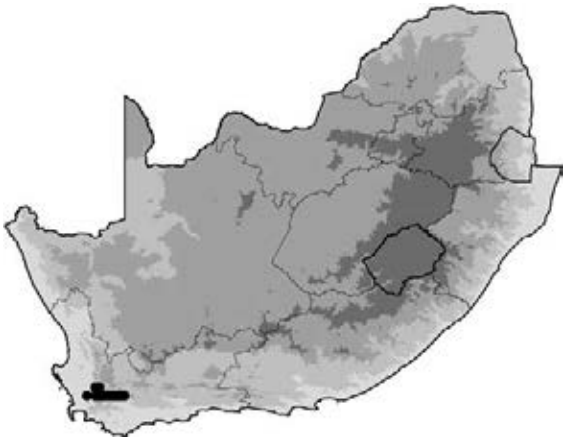
6. **Nivenia stenosiphon** *Goldblatt*, Woody Iridaceae: 70 (1993). Type: South Africa, Western Cape, Klein Swartberg above Buffels River Poort, rocky sandstone slopes, 900–1 200 m, *Goldblatt & Manning 8864* (NBG, holo.; B, C, E, K, MO, PRE, S, US, WAG, iso.).

Shrubs (200–)400–900 mm high. *Stem* several-branched from base and in upper part, leafy shoots 3–4 mm diam. *Leaves* narrowly lanceolate, 50–90 × 2.5–3.5 mm. *Inflorescence* panicle-like, (20)40- to 80-flowered (10 to 40 flower pairs), peduncles exserted, 3–4 mm wide, ultimate branchlets bearing a pair of flowers within spathes; spathes 3–4 mm long, leathery, green below, dry and brown above, floral bracts dry and reddish brown, 8–9 mm long, firm-membranous below, much-wrinkled above. *Flowers* salver-shaped, heterostylous, deep blue throughout; perianth tube 32–38 mm long, ± 1.5 mm wide, cylindric, lower 2–5 mm filled with nectar; tepals ± patent, elliptic, 10–12 × 3–4 mm. *Filaments* either long, nearly 10–12 mm long (thrum flowers) or short, 2–3 mm long (pin flowers); anthers ± 1.4 mm long before anthesis, dark blue; pollen pale blue. *Style* either short and dividing just below to ± 1 mm above mouth of tube, 33–36 mm long (thrum flower) or 40–50 mm long, exserted ± 10 mm from tube (pin flower), branches filiform, 0.5–1.0 mm long, often shorter in thrum flowers, diverging after anther dehiscence. *Capsules* subglobose, 4–5 mm long. *Seeds* 1 per locule, rugose, dark brown, 3.0–3.5 × 1.8–2.0 mm. *Flowering time*: April to early June.

Distribution and ecology: a narrow endemic of the western Little Karoo in Western Cape, South Africa, recorded only from the western Klein Swartberg west of Ladismith and on the adjacent Touwsberg; on rocky, south-facing slopes and open level sites from 1 000–1 500 m elevation.

Diagnosis: *Nivenia stenosiphon*, which flowers in the autumn and early winter, closely resembles the late spring-flowering *N. binata* in the form of the inflorescence

Distribution of ***Nivenia stenosiphon***.



and in the long, wrinkled flower bracts, and the blue anthers and pollen. The flowers in both species are heterostylous and paired within the binate inflorescence units, and there seems little doubt that they are immediately related. They are distinguished by the phenology and dimensions of the floral bracts and perianth tube, the bracts 8–9 mm long and the perianth tube 32–38 mm long in *N. stenosiphon* versus bracts 9–10 mm long and perianth tube 9–15 mm long in *N. binata*.

The long-tubed flowers of *Nivenia stenosiphon* are adapted to pollination by the long-proboscid fly *Prosoeca ganglbaueri* (Nemestrinidae).

7. **Nivenia corymbosa** *(Ker Gawl.) Baker* in Journal of the Linnean Society, Botany 16: 109 (1877); Goldblatt: 74 (1993). *Witsenia corymbosa* Ker Gawl.: t. 895 (1805). *N. stylosa* Salisb.: 311 (1812), illegitemate superfluous name for *W. corymbosa* Ker Gawl. *Genlisia corymbosa* (Ker Gawl.) Reichb.: t. 24 (1836). *Aristea corymbosa* (Ker Gawl.) Benth. & J.D.Hook.: 701 (1883). Type: South Africa, without precise locality, illustration in Ker Gawl.: t. 895 (1805).

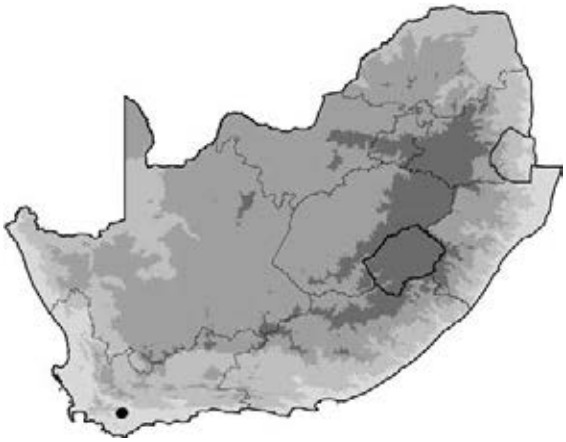
Nivenia filamentosa Salisb.: 311 (1812). Type: South Africa, Cape, locality unknown, type material not located.

Shrubs 0.8–2.0(–3.5) m high, occasionally only up to 0.3 m. *Stems* erect to inclined, usually several from base, compressed, leafy stems 5–6 mm diam., old stems reaching up to 30(–50) mm diam. At base, older plants with lateral branches smaller than main axes, these sometimes like spur-shoots. *Leaves* narrowly lanceolate, 10–20 × ± 8 mm, acuminate, usually 8 to 12 per growth flush. *Inflorescence* a compound, flat-topped false panicle of up to 120 flowers, primary peduncle strongly compressed, secondary branches subtended by leafy bracts below, or dry brown scales above, pedicels of variable length, 1–6(–8) mm long or ± lacking and some flowers sessile; spathes enclosing 1 or rarely 2 flowers, leathery, subequal, brown above, herbaceous

Distribution of ***Nivenia corymbosa***.

below, ± 4 mm long, inner floral bracts 6–7 mm long, dry and membranous, light to medium brown. *Flowers* salver-shaped, heterostylous, pale to deep blue, ± white at base of tepals and in tube; perianth tube 11–13 mm long, nearly cylindric, widening from 1.2 mm at base to ± 2 mm at mouth; tepals spreading, oblong, obtuse to subacute, 9–11 × 3.5–4.5 mm, inner slightly narrower than outer. *Filaments* either long, exserted ± 8.5 mm (thrum flower) or short, 0.5 mm long (pin flower), white; anthers ± 1.2 mm long after anthesis, yellow. *Style* 8–9 mm long (thrum flower) and included 1–2 mm below mouth of tube with branches 0.3 mm long, or ± 19 mm long (pin flower), exserted ± 9 mm, branches ± 0.8 mm long. *Capsules* obovoid, 3–4 mm long, 1 or 2 locules sometimes empty. *Seeds* 1(2) per locule, 2–3 × 1.8 mm. *Chromosome number* 2*n* = 32. *Flowering time*: late January to March.

Distribution and ecology: restricted to the southwestern corner of the Western Cape, South Africa, extending from Tulbagh Waterfall and the Elandskloof Mtns south to Bain's Kloof, a distance of some 30 km; mostly in sites where moisture is available during the dry summer, along streams and seeps, in crevices in cliffs and in rock outcrops.



Diagnosis: the heterostylous *Nivenia corymbosa* can easily be recognised by its relatively small, dark blue flowers in large corymb-like compound inflorescence often comprising more than 100 flowers. The binate rhipidia bear a single flower each, and the two style morphs are quite different, with the filaments either prominently exserted ± 8.5 mm from the tube (thrum flowers), or nearly sessile with the anthers placed immediately above the mouth of the perianth tube (pin flowers). *Nivenia corymbosa* is most closely related to *N. dispar,* which occurs in the Riviersonderend Mtns to the east. The latter has larger, usually paler blue flowers with the perianth tube (16–)18–20 mm long and tepals 10.5–14.5 mm long compared with a tube 11–13 mm long and tepals 10–11 mm long in *N. corymbosa*.

Like most species of *Nivenia*, *N. corymbosa* flowers in the late summer, at the driest season of the year. The flowers open early in the morning just after sunrise and closing in the evening, usually wilting the following day but sometimes opening weakly although the tepals remaining flaccid. The intense blue flowers are visited and pollinated by a number of bees, the most important of these evidently the large-bodied, long-tongued *Amegilla fallax* (Anthophoridae).

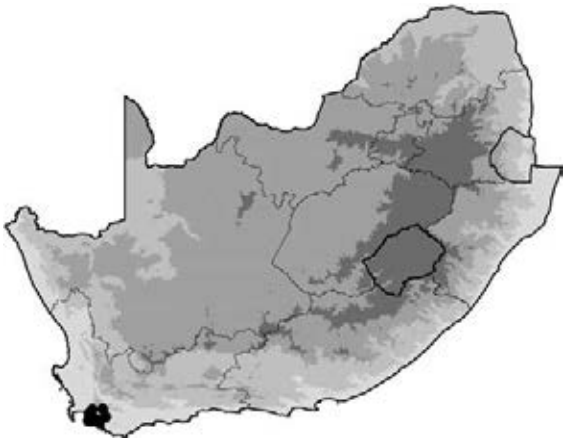
8. **Nivenia dispar** *N.E.Br.* in Transactions of the Royal Society of South Africa 21: 268 (1933); Goldblatt: 81 (1993). Type: South Africa, [Western Cape], near Riviersonderend 'felsige Stellen bei Appelkraal, Rivier Zonder Einde,' [without date], *Zeyher s.n.* (K, holo.; K, SAM [20760], iso.).

Shrubs 0.8–2.0 m high, occasionally stunted and to only 300 mm. *Stems* erect to inclined, usually several from base, leafy shoots 2–3 mm wide. *Leaves* narrowly lanceolate, 100–200 × 7–8 mm. *Inflorescence* a false panicle of (15)30 to 80 flowers, peduncle strongly compressed, 3–4 mm wide, branches subtended by leafy bracts below, or dry brown scales above, ultimate peduncles of variable length, 4–15 mm long; spathes subequal, leathery, green below, brown above, ± 4 mm long, floral bracts 6–7 mm long, dry and membranous, brown. *Flowers* salver-shaped, heterostylous, pale to deep blue, paler at tepal bases and in tube; perianth tube (16–)18–20 mm long, ± cylindric, widening from 1.2 mm at base up to 2 mm at mouth; tepals obovate, obtuse to emarginate, 11–14 mm × (4.5–)5.0–6.0 mm, inner slightly narrower than outer. *Filaments* either ± 6 mm (thrum flower) or 0.5 mm (pin flower) long, white; anthers ± 1.2 mm long after anthesis. *Style* either 18–20 mm long and included 1–2 mm below mouth of tube (thrum flower) with branches < 0.5 mm long, or ± 25–27 mm long and exserted ± 7–9 mm (pin flower) with branches ± 1.4 mm long; branches filiform, slightly expanded in upper half and recurved. *Capsules* obovoid-ellipsoid, ± 4 mm × 3.5 mm. *Seeds* 1 per locule, ± 3 × 2 mm. *Flowering time*: late January to March.

Distribution and ecology: a narrow endemic of the Riviersonderend Mtns in southern Western Cape, South

Distribution of ***Nivenia dispar***.

Africa, and currently known only from only one locality, Olifant's Kloof north of the town of Riviersonderend; the small population occurs at the relatively low elevation of ± 200 m in sheltered sites at the base of cliffs, in rock crevices, and along a stream where moisture is available throughout the dry summer.



Diagnosis: the large, congested and flat-topped compound inflorescence of single-flowered rhipidia in *Nivenia dispar* closely resembles that of *N. corymbosa* and the two species can be distinguished only by comparison of flower size. Both species are heterostylous, but flowers of *N. corymbosa* are consistently smaller, with the perianth tube 11–13 mm long and tepals 9–11 mm long versus the perianth tube 16–20 mm long and the tepals 11–14 mm long in *N. dispar*.

9. **Nivenia stokoei** *(L.Guthrie) N.E.Br.* in Transactions of the Royal Society of South Africa 21: 267 (1933); Obermeyer: t. 1504 (1967); Goldblatt: 85 (1993). *Aristea stokoei* L.Guthrie: 24 (1925). Type: South Africa, [Western Cape], mountains near Palmiet River Mouth, *Stokoe 946* (BOL, lecto., designated by Goldblatt: 85 (1993); B, BOL, K, P, PRE [2 sheets], Z, isolecto.).

Rounded, woody, evergreen shrubs (0.3–)0.8–1.5 m high. *Stems* simple or irregularly branched, leafy stems 3–4 mm wide. *Leaves* narrowly lanceolate, 80–130 × 3–5(–6) mm, margins narrowly hyaline. *Inflorescence* a ± flat-topped false panicle of (12)20 to 40 flowers, bracts subtending branches of peduncle dry, 2–4 mm long, ultimate peduncles bearing single flowers; spathes 6–8 mm long, leathery, dry and dark brown near apices, inner slightly longer than outer; floral bracts dry, light brown, upper margin often lacerate, (10–)12–15 mm long. *Flower* salver-shaped, not heterostylous, but styles somewhat variable in length, pale or deep blue, ± white at base of tepals and in tube; perianth tube 27–33(–37) mm long, ± cylindric, 1.2 mm wide at base, expanding up to 2 mm at mouth; tepals spreading, elliptic-oblanceolate, 16–22(–25) mm long, outer 8–10 mm wide, inner 6.5–8.0 mm wide. *Filaments* (6.5–)8–10 mm long; anthers 2.0–2.8(–3.0) mm long. *Style* exserted (8–)10–15 mm from tube, usually dividing 3–5 mm beyond anther tips, in some plants ± as long as filaments, branches filiform, 2–3 mm long, recurved. *Capsules* globose-obovoid, 5–6 mm long, ± 4.5 mm diam., rarely with seeds in all locules. *Seeds* mostly 1 or 2 per locule, rugose, blackish with a loose translucent outer layer, ± 5 × 2.8 mm, smaller if 2 per locule. *Chromosome number* 2*n* = 32. *Flowering time*: mid-January to March.

Distribution and ecology: restricted to the southwestern corner of the Caledon District of Western Cape, South Africa, from the foot of the mountains at Betty's Bay and Kleinmond, close to sea level, to elevations of ± 800 m at Highlands; in open rocky sites in sandstone derived soil.

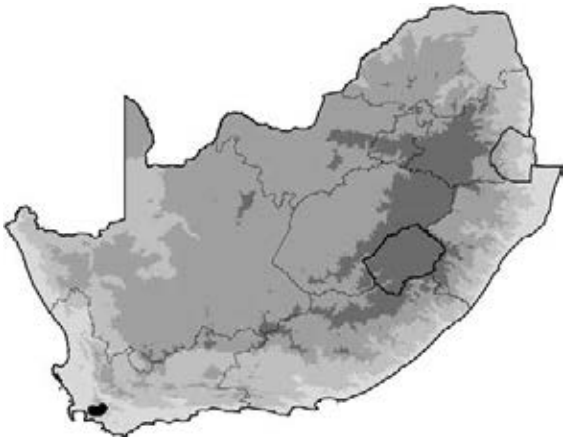
Diagnosis: *Nivenia stokoei* has the largest flowers in the genus, with relatively crowded inflorescences of pale to deep blue flowers with a perianth tube 27–37 mm long. The large flower size is reflected in the bracts and spathes so that the species can also be identified after flowering. Each inflorescence normally comprises 20 to 40 flowers although there may be as few as 12 flowers in depauperate plants. The flowers are not heterostylous but the style varies in length in different plants. The flowers are solitary in the binate rhipidia, as in *N. concinna*, and it is to this species that *N. stokoei* seems most closely allied. *Nivenia concinna* is a dwarf plant up to 200 cm high, with inflorescences of only 2 to 6, slightly smaller flowers with a perianth tube ± 15 mm long.

Distribution of ***Nivenia stokoei***.

In sheltered sites plants may reach heights of up to 1.5 m but in very rocky or exposed places individuals are usually dwarfed and less than a metre, sometimes no more than 300 mm high. *Nivenia stokoei* is a particularly handsome species and well grown, healthy plants in full bloom are a wonderful sight.

10. **Nivenia concinna** *N.E.Br.* in Transactions of the Royal Society of South Africa 21: 267 (1933); Lewis: t. 548 (1934); Goldblatt: 91 (1993) Type: South Africa, [Western Cape], Viljoen's Pass, *Salter 2033* (K, holo.; BM, BOL, iso.).

Low, often rounded, evergreen shrublets 120–200 mm high. *Stems* seldom branched except near base; leafy stems 2–3 mm wide. *Leaves* linear (rarely narrowly lanceolate), 60–100 × 1.3–2.5 mm. *Inflorescence* flat-topped, usually branched and with 2 to 6 flowers but rarely only one; primary peduncle compressed and included in leaf cluster, first node bearing a dry brown bract 5–9 mm long, bracts at other nodes smaller, individual flowers single in paired spathes, spathes green with brown apices, ± 6 mm long; bracts brown-membranous, semi-transparent, 10–12 mm long. *Flower* salver-shaped, homostylous, deep blue, ± white at tepal bases and in tube; perianth tube ± 15 mm long, ± cylindric, ± 1 mm wide at base, expanding gradually up to 2 mm at mouth; tepals spreading, elliptic-oblanceolate, up to 22 mm long, outer 9 mm wide, inner 8 mm wide. *Filaments* ± 6 mm long; anthers ± 3 mm long. *Style* exserted from tube for ± 6 mm, dividing near middle



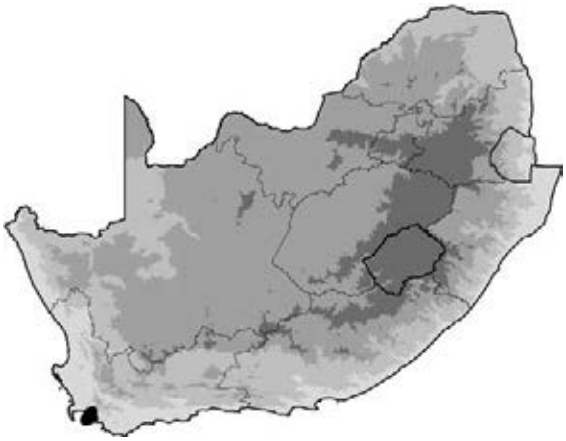


Plate 3: A, ***Nivenia corymbosa***, Wellington, WC, Long-style pin morph; B, ***N. corymbosa***, Wellington, WC, Short-style thrum morph; C & D, ***N. stokoei***, Kogelberg, WC.

Distribution of ***Nivenia concinna***.

Distribution of ***Nivenia levynsiae***.

of anthers, white, branches filiform, ± 4 mm long, ciliate in upper ⅓, arching upwards. *Capsules* obovoid, ± 6 × 4 mm. *Seeds* usually 1 per locule, dark brown, ± 5 × 2 mm. *Flowering time*: February and March.

Distribution and ecology: *Nivenia concinna* is restricted to a small area of mountainous terrain north of Grabouw in Western Cape, South Africa, near Viljoen's Pass in the Nuweberg Forest Reserve and in the western Groenland Mtns; growing in rocky ground with rootstocks wedged in weathered Cape sandstone. Like all species of *Nivenia* it is fire-tolerant and resprouts and flowers well after the surrounding vegetation has been burned.

Diagnosis: one of the smaller species in the genus, *Nivenia concinna* rarely exceeds 200 mm in height and has dark blue flowers with a relatively short perianth tube, ± 15 mm long, and unusually long, ascending style branches. The inflorescence is apparently a reduced pseudopanicle and homologous to the multi-flowered inflorescences of *N. corymbosa* and *N. dispar*. The species is not heterostylous but is evidently derived from heterostylous ancestors and the flowers are solitary in the paired spathes. These features, together with the general form of the inflorescence, suggest a close relationship with *N. stokoei*.

11. **Nivenia levynsiae** *Weim.* in Svensk Botanisk Tidskrift 34: 364 (1940). Type: South Africa, [Western Cape], mtns at Palmiet River Mouth, in rock crevices, 1 700–2 000 ft [± 550–600 m], *Levyns 5360* (BOL, holo.; BOL, K, MO, S, SAM, iso.).

Low tufted or somewhat straggling shrublets, 60–150(–250) mm high. *Stem* sparsely branched above, few to several(–20) per plant, leafy part ± 1 mm wide, older stems up to 2 mm diam. *Leaves* linear-lanceolate to linear, 20–40 × 1.3–2.0 mm. *Inflorescence* 1- to 4-flowered, congested, subtended by a dry bract 7–9 mm long, peduncle compressed, angular, 10–20(–30) mm long, flowers solitary within opposed spathes; spathes ± 6.5 mm long, green in lower ⅓, dry and dark brown above, acute, upper margins hyaline; floral bract ± 7 mm long, dark brown, upper margin ± transparent, ± lacerate. *Flowers* salver-shaped with tepals cupped, not heterostylous, pale blue with darker blue mark at base of each tepal; perianth tube ± 7 mm long, narrowly funnel-shaped; tepals obovate, obtuse, widest in upper ⅓, 13–15 × 6–8 mm. *Filaments* ± 2 mm long; anthers initially 1.5 mm long, 1.0–1.2 mm after pollen shed, yellow; pollen yellow. *Style* 10–12 mm long; branches filiform, 2.5–3.0 mm long, ascending, white. *Capsules* obovoid, ± 4.5 mm long. *Seeds* compressed to ± irregularly angled, (1)2–4 per locule, ± 2 mm wide. *Chromosome number* 2*n* = 32. *Flowering time*: late January and February.

Distribution and ecology: restricted to the southwestern corner of Western Cape, South Africa, in the mountains between False Bay, Houw Hoek and Kleinmond; in rocky situations above 500 m elevation, often growing in the driest most exposed outcrops, but sometimes in deeper soils, flowering well two to three years after fire.

Diagnosis: *Nivenia levynsiae* is recognised by its low, tufted, often cushion-like habit, and pale blue, particularly short-tubed flowers with widely cupped tepals. It is the only species of the genus in which the tepals are substantially longer than the perianth tube, and one of only two species with ± cupped tepals. The other, *N. fruticosa* from the Langeberg, is also a cushion plant and has a longer perianth tube, 20–30 mm long. The affinities of *N. levynsiae* probably lie with *N. concinna* and *N. stokoei*, which also have homostylous flowers in one-flowered rhipidia but have inflorescences with more flowers, up to 6 in *N. concinna* and 12 to 40 in *N. stokoei*. We interpret the inflorescence of *N. levynsiae* as being a reduced false panicle in which there are no more than 4 flowers.

REFERENCES [See under 3. *Witsenia*]

3. Klattia

Klattia *Baker* in Journal of the Linnean Society, Botany 16: 109, 110 (1877); Goldblatt: 99 (1993). Type: *Klattia partita* Ker Gawl. ex Baker.

Revisionary account: Goldblatt: 99–107 (1993).

The name honours the 19th century German botanist, F.W. Klatt, who made a life-long study of the Iridaceae.

Evergreen shrubs with a woody underground caudex. *Stems* upright, primary growth compressed, becoming rounded below, secondary growth woody, with conspicuous leaf scars, ultimately up to 20 mm diam.; major axes either simple, branched or with short-lived spur-shoots. *Leaves* lanceolate to sub-linear, sheathing below, clustered apically, without a main vein; lasting more than a year; margins narrowly hyaline. *Inflorescence* compound, capitate, peduncle not differentiated from stem; enclosed in 2 or 3 opposed sheathing leafy bracts, sheathing part pale greenish to creamy yellow or red, usually green near base; flowers paired in binate rhipidia, each of these subtended by a short transparent bract and opposed prophyll; spathes membranous, acute; floral bracts membranous, transparent, 2-keeled, slightly smaller than spathes, sheathing lower part of flower. *Flowers* sessile, transparent below, coloured above, odourless; perianth tube short, cylindric inserted on ovary ± ⅓ below apex; tepals subequal, linear-spathulate, ± clawed, claws mostly included in inflorescence bracts, limbs exserted, intensely pigmented. *Stamens* inserted at base of outer tepals, filaments flattened below, terete and filiform above; anthers linear, sub-basifixed with connective forming pouch around filament apex, exserted from inflorescence bracts, yellow; pollen yellow. *Ovary* globose, each locule with 2 ovules; style filiform, exceeding or slightly shorter than tepals, minutely trifid. *Fruit* a woody capsule, ovoid-elliptic, shortly beaked, locules 1-seeded, or seeds not developed. *Seeds* compressed tangentially, shield-shaped, light grey-brown, outer layer translucent, lightly striate. *Basic chromosome number x* = 16.

Species 3: all of the southern and southwestern part of Western Cape, extending from Bain's Kloof and the Cape Peninsula east through the Caledon District to the Langeberg near Riversdale; restricted to moist or semi-marshy montane sites in peaty, sandstone-derived soils.

Klattia species are moderate-sized shrubs producing multiple, woody stems from a large underground rootstock. The broadly similar inflorescences are actually compound structures consisting of numerous individual binate rhipidia, each bearing two flowers enclosed in shared bract-like spathes, all crowded together in a head. The entire inflorescence in enclosed enlarged leafy bracts, these green (*K. partita*), red (*K. stokoei*) or yellow (*K. flava*). Apart from the colour of the prominent sheathing bracts, the species are separated by small floral differences, including length and colour of the tepals and length of the style. Seeds of *Klattia* are tangentially compressed as in the two other genera of woody Iridaceae, but the seed coat is striate and comprised of fusiform cells that remain intact. The tepals of all *Klattia* species are united basally in a short perianth tube, and the much longer tepals are spathulate and extend upward, enclosing the stamens and style, the latter minutely 3-notched at the tip as in *Witsenia*. The flowers secrete ample amounts of sugary nectar, some of which spills over the surrounding bracts as a sticky residue. All species are pollinated by sunbirds.

Key to species

1a Leafy bracts enclosing inflorescence red; upper leaves 8–14 mm wide . . . . . 3. *K. stokoei*
1b Leafy bracts enclosing inflorescence pale greenish to translucent cream-coloured; upper leaves 3–8 mm wide:
2a Upper leaves (3–)4–5 mm wide, deep green; limbs of tepals intense blackish purple; styles shorter than to nearly as long as tepals; tepals (47–)55–64 mm long . . . . . 1. *K. partita*
2b Upper leaves (3–)5—8 mm wide, glaucous-green; limbs of tepals yellow; styles exceeding tepals by (1–)2–5 mm; tepals 44–48 mm long. . . . . 2. *K. flava*

1. **Klattia partita** *Ker Gawl. ex Baker* in Journal of the Linnean Society, Botany 16: 110 (1877); Goldblatt: 101 (1993). *Witsenia partita* Ker Gawl. ex Spreng.: 147 (1824), illegitimate superfluous name for *Sophronia caespitosa* Licht. ex Roem. & Schult.: 482 (1817). Type: South Africa, [Western Cape], Riversdale, Kampscheberg [Rooielsberg], *Burchell 7159* (K, lecto., designated by Goldblatt: 101 (1993); B, GH, P, isolecto.).

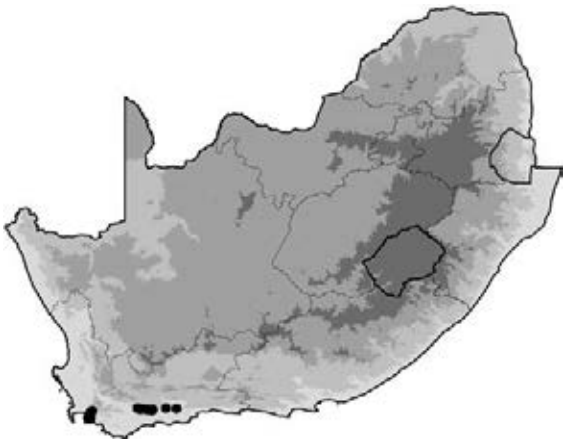
Witsenia partita Ker Gawl. ex Klatt: 546 (1866), illegitimate homonym, not *W. partita* Ker Gawl. ex Spreng. (1824). Type: South Africa, [Western Cape], Swellendam, 'am Berge bei Puspasvlei', *Ecklon & Zeyher Irid. 263* (B, MO, iso.).

Klattia stokoei: A, flowering and fruiting branches; B, outer bract; C, inner bract; D, flower; E, anther; F, stigma; G, dehisced capsule; H, seed showing inner (left) and outer (right) surface.

[*Witsenia partita* Ker Gawl.: 237 (1804), invalid name without description.]

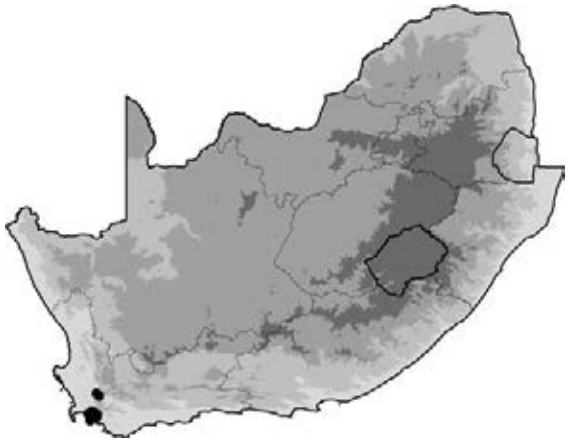
Shrubs up to 1 m high from woody base. *Stem* irregularly branched, leafy stems 3–4 mm wide, up to 6 mm diam. near base. *Leaves* deep green, narrowly lanceolate, 90–120 × (3–)4–5 mm. *Inflorescence* a compound head with (4)8 to 16 flowers (2 to 8 flower pairs); foliar bracts with sheathing part pale translucent green, dark green at tips; spathes membranous, 15–20 mm long, outer ± larger than inner; floral bracts membranous, translucent, 12–14 mm long. *Flowers* pale yellow-green below, dark blackish purple on exserted part of limbs; perianth tube 3.3–4.0 mm long; tepals (47–)55–64 mm long, limbs ± 12 mm long. *Filaments* ± 43 mm long, ± white, reaching to base of tepal limbs; anthers ± 7 mm long, reaching to within 5–8 mm of tepal tips, yellow; pollen yellow. *Ovary* ± 2.5 mm long; style 53–58 mm long, 2–3 mm shorter than tepals, stigmatic lobes minute. *Capsules* narrowly ovoid-oblong, 8–9 mm long, 4–5 mm at widest. *Seeds* ± 7 × 3 mm. *Flowering time*: October to December.

Distribution and ecology: a rare montane endemic of Western Cape, South Africa, extending from a few isolated sites in the Kogelberg–Hottentots Holland Mtn complex to the Langeberg near Riversdale [records from the Cape Peninsula and from Clanwilliam are evidently incorrect]; on cooler south trending slopes in seeps and marsh margins above 600 m elevation. Good drainage and year-round moisture appear to be a requirement for its survival. The species is believed to be adapted for pollination by sunbirds but this remains to be established.



Diagnosis: the dark blackish purple tepals distinguish *Klattia partita* from the other species of *Klattia*. This unusual colour is rare in flowering plants. Apart from flower colour, *K. partita* can be recognised by the long tepals up to 64 mm long versus 44–48 mm in the related *K. flava*, and the stamens and style are shorter than the tepals. In *K. flava* the anthers reach to within 1–5 mm of the tepal apices and the styles are exserted up to 5 mm, whereas the anthers of *K. partita* are usually 5–8 mm short of the tepal apices and the styles are not exserted.

Vegetatively *K. partita* most closely resembles *K. flava* in having relatively narrow leaves, and inflorescence bracts not markedly different in colour from the foliage leaves. *Klattia stokoei* has broader leaves, 8–14 mm wide, and bright red inflorescence bracts.



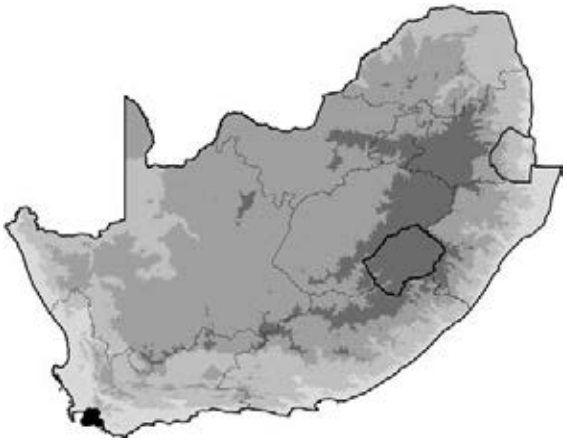
2. **Klattia flava** *(G.J.Lewis) Goldblatt*, The Woody Iridaceae: 108 (1993). *K. partita* var. *flava* G.J.Lewis: 51 (1941). Type: South Africa, [Western Cape], Landdrostkop, Dec., *Stokoe s.n.* (SAM [54461]; lecto., designated by Goldblatt: 108 (1993); NBG, PRE, SAM, isolecto.).

Shrubs 0.9–1.3 m high, with long straight stems. *Stem* simple or with a few branches produced in upper ⅓; leafy stems (2–)3–4 mm wide, 8–10 mm diam. near base. *Leaves* glaucous to pale green, sometimes densely papillose, 12–180(–210) × (3–)5–8 mm. *Inflorescence* with 10 to 20 flowers (5 to 10 flower pairs); foliage bracts with sheathing part translucent creamy yellow, apices green; spathes membranous, 16–20 mm long, outer somewhat larger than inner, bracts membranous and translucent, 12–14 mm long. *Flowers* transparent below, creamy yellow above and deep yellow on exserted part of limbs; perianth tube 4.5(–6.0) mm long; tepals 42–48 mm long, limbs ± 6–8 mm long, obtuse, outer ± 2 mm wide, spooned above, inner ± 1.4 mm wide, ± flat, slightly longer than outer, exserted from inflorescence bracts. *Filaments* 35–40 mm long, cream-coloured; anthers 7–8 mm long, reaching to within 1–5 mm of tepal tips, yellow; pollen yellow. *Ovary* ± 2.5 mm long; style 48–55 mm long, ultimately exceeding tepals by 3–4 mm, stigmatic lobes minute. *Capsules* narrowly ovoid, ± 7 × 3–4 mm at widest. *Seeds* pale grey, ± 7 × 2.5–3.0 mm. *Flowering time*: mid-November to December.

Distribution and ecology: centred in the Grabouw area of southwestern Western Cape, South Africa, in the Hottentots Holland and Groenland Mtns but also further north in the Bain's Kloof Mtns; on damp slopes, seeps and gullies, often near perennial streams above 800 m elevation, where summer cloud and precipitation are frequent.

Distribution of ***Klattia partita***.

Distribution of ***Klattia flava***.



The flowers are pollinated by sunbirds, of which the Orange-breasted Sunbird is probably the most important, if not the only pollinator.

Diagnosis: *Klattia flava* is distinguished from the other species of *Klattia* by its bright yellow perianth and straight, somewhat glaucous, relatively narrow leaves, (3–)5–8 mm wide. It is evidently most closely related to *K. partita*, which has similar but narrower, deep green leaves, rarely exceeding 5 mm wide, and differently proportioned flowers with the perianth tube 3.4–4.0 mm long and the tepals 47–58 mm long versus the perianth tube ± 4.5 mm long and the tepals 42–48 mm long in *K. flava*. Moreover, the outer tepals are spooned at the apex in *K. flava*, and the style is exserted (1–)3–4 mm from the tepals, whereas the style in *K. partita* is usually 2–3 mm short of the tepal apices.

Leaves of populations of *Klattia flava* from Bain's Kloof, Landdrost Kop and Somerset Sneeukop have a densely papillate leaf surface, easily visible under low magnification, but plants from the Groenland Mountains to the east have smooth leaves, as does *K. partita*.

3. **Klattia stokoei** *L.Guthrie* in Annals of the Bolus Herbarium 3: 75 (1921); Pole Evans: t. 80 (1922); Goldblatt: 113 (1993). Type: South Africa, [Western Cape], Steenbras River Valley, eastern mountain slopes, *Stokoe s.n.* (BOL [16906], holo.; BOL, K, S, iso.).

Shrubs 0.5–1.2 m high. *Stem* simple or irregularly branched, leafy stems (3–)4–5 mm wide, 8–10 mm diam. Toward base. *Leaves* dark green, 9–15(–20) × (4–)7–14 mm, linear-lanceolate, becoming ± falcate below inflorescence, sometimes curving upward near tip. *Inflorescence* with 6 to 8 flowers (3 or 4 flower pairs), foliage bracts with sheathing part crimson-red, apices of outer bracts green, apices of inner reduced and usually entirely red; spathes membranous, 25–37 mm long, subequal, bracts membranous, transparent, 18–33 mm long, slightly shorter than spathes. *Flowers* transparent below, flushed reddish above, orange-red on exserted parts; perianth tube 2–5 mm long; tepals ± linear, limbs spathulate, obtuse to emarginate, exserted from inflorescence bracts, orange-red, 5.5–7.5 mm long, limbs 12–14 mm long, ± 1 mm wide just below apex, ± flat, inner slightly longer than outer, claws pale red fading to transparent toward base. *Filaments* ± 5 mm long, cream-coloured; anthers ± 7.5 mm long, exserted, reaching to within (2–)5–8 mm of tepal apices, yellow; pollen yellow. *Ovary* ± 2.5 mm long; style 5.7–7.8 mm long, exceeding tepals by 1–5 mm, stigmatic lobes minute. *Capsules* ± 6 mm long. *Seeds* unknown. *Chromosome number* 2*n* = 32. *Flowering time*: mid-December to early February.

Distribution of ***Klattia stokoei***.

Distribution and ecology: restricted to the Kogelberg Mtn complex of southwestern Western Cape, South Africa, extending from the ridges above Steenbras Dam in the west to Betty's Bay and the mountains above Kleinmond in the east; on damp south trending slopes, seeps and streambanks in peaty sand.

There are recorded visits of Malachite Sunbirds to plants near Pringle Bay.

Diagnosis: the most distinctive species in the genus, *Klattia stokoei* is immediately recognised by the large red bracts enclosing the inflorescence, and the bright red tepals. The leaves are also distinctive, comparatively wide, mostly 7–14 mm wide in the midline and usually somewhat falcate, unlike the narrow, linear leaves of *K. flava* and *K. partita*.

REFERENCES [See under 3. *Witsenia*]

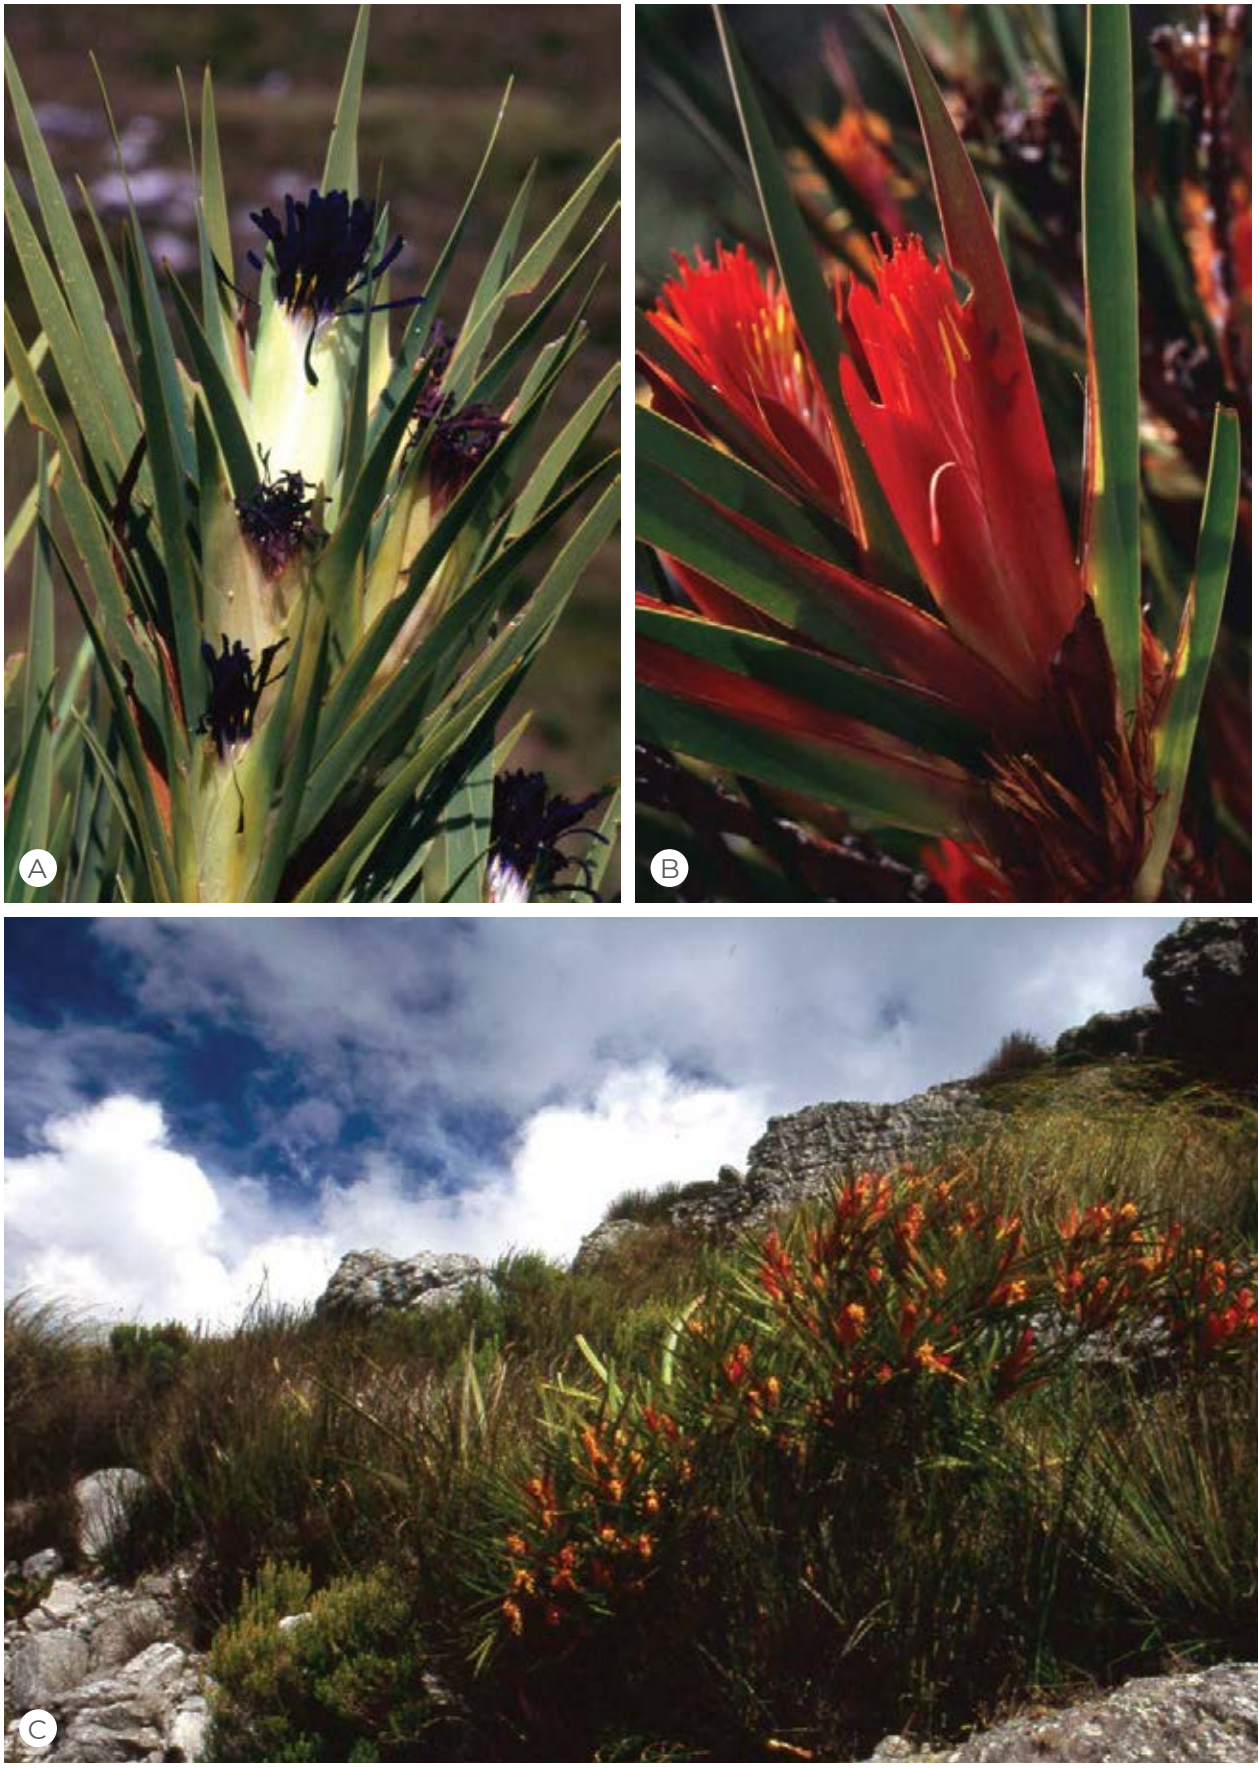


Plate 4: A, ***Klattia partita***, Kogelberg, WC; B & C, ***K. stokoei***, Gordon's Bay, WC.

4. Witsenia

Witsenia *Thunb.*, Nova genera plantarum: 33 (1782) [as *Witsena*]; Baker: 46 (1896). Type: *W. maura* (L.) Thunb.

Revisionary account: Goldblatt: 117–126 (1993).

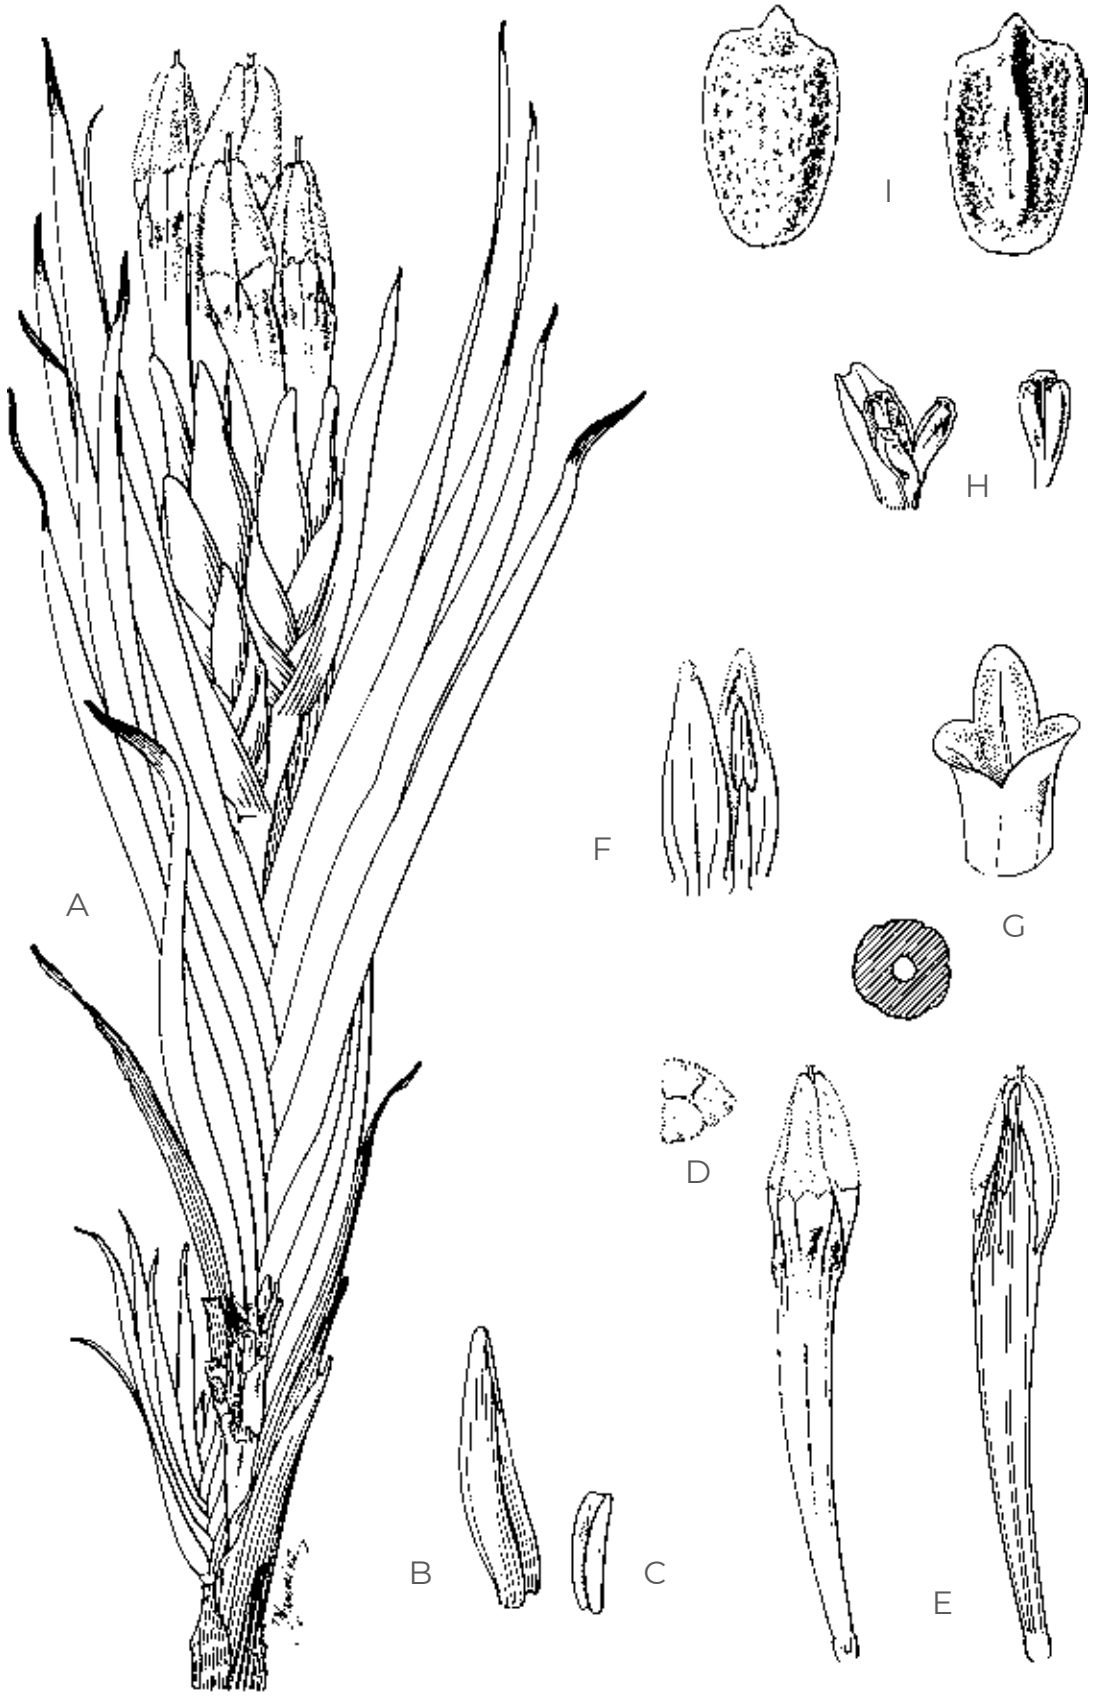
Named after the Dutch Nicholas Witsen, counsellor to the Chief Magistrate of Amsterdam, and a patron of botany. Witsen financed the Swedish botanist. C.P. Thunberg's travels to South Africa and Japan and was rewarded in this commemoration.

Evergreen shrub with a woody caudex. *Stems* upright or inclined, compressed, becoming rounded below, brittle and woody (with secondary growth), marked with leaf scars, main axes simple, sparsely branched. *Leaves* sword-shaped, crowded apically, in 2 ranks. *Inflorescence* compound, upper lateral branches short, terminating in shortly stalked binate rhipidia, subtended by large green bracts, collectively forming a false panicle; binate rhipidia each 2-flowered, spathes large, leathery, pale green, floral bracts membranous, shorter than spathes. *Flowers* radially symmetric, sessile, long-lived, tubular, greenish and black with upper half of tepals yellow outside, tepals remaining erect throughout flowering, unscented, with nectar produced from septal nectaries; perianth tube elongate, widely cylindric; tepals obscurely clawed, limbs velvety-hairy outside. *Stamens* free, enclosed in flower; filaments inserted at mouth of tube, flattened, reaching to ± middle of tepal limbs; anthers oblong, connective pouched below around filament apex, splitting longitudinally. *Ovary* globose, domed above insertion of tepals, enclosing enlarged septal nectaries, locules with 2 ovules; style filiform, shortly exserted from flower, shortly 3-notched apically. *Capsules* narrowly ovoid, ± woody, with central axis separating from septa. *Seeds* tangentially compressed, shield-shaped, 1 per locule, smooth, surface granulate, testa often partially exfoliated. *Basic chromosome number x* = 16.

Species 1: local in southern Western Cape.

Witsenia includes just a solitary species, remarkable for its large, long-tubed flowers with the tube green to almost black outside. The short tepals remain closed thus covering the entrance to the tube, and the abaxial surfaces, those visible from outside, are densely covered with velvety yellow hairs. The only possible pollinators are animals strong enough to push their mouthparts past the closed tepals to reach the nectar. The most likely pollinators are sunbirds, and the Malachite Sunbird has been reported to visit *Witsenia* flowers. The shield-shaped seeds of *Witsenia*, with exfoliating seed coat, resemble those of *Nivenia*.

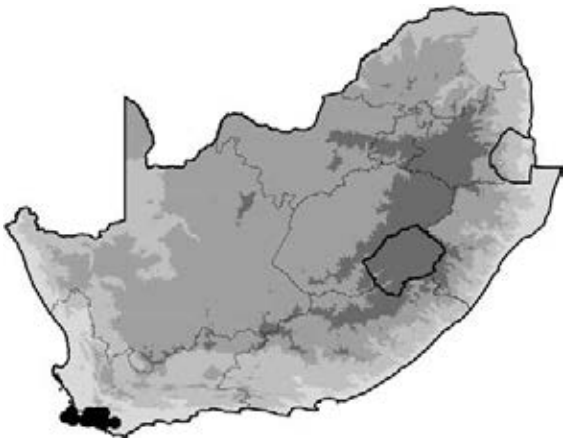
1. **Witsenia maura** *(L.) Thunb.*, Dissertatio generum novum: 234 (1782). *Antholyza maura* L.: 175 (1771). *Ixia disticha* Lam.: 333 (1789), illegitimate name for *A. maura* L. Type: South Africa, without precise locality, collector unknown, (LINN, holo.).



[*Witsenia tomentosa* Salisb.: 312 (1812), invalid name without description.]

Plants 1–3 m high, ± erect or sprawling in dense vegetation. *Stem* upright or inclined, simple or with a few branches, leafy part 3–5 mm wide, 10–15 mm diam. near base. *Leaves* narrowly lanceolate, 100–150 × 4–7 mm, dark green. *Inflorescence* with 8 to 16 flowers (4 to 8 flower pairs), each pair subtended by 3 to 5 acute bracts at base of each binate rhipidium, each with stalks 2–4 mm long; spathes 35–40 mm long, strongly emarginate, sheathing lower half of tube, floral bracts 2-keeled, 15–18 mm long, concealed by spathes. *Flowers* pale green below, dark green above shading to blackish at top of tube, tepals blackish in lower half, outer tepals densely villous and yellow in upper half, inner mostly concealed by outer, pale green, yellow and villous at tips where exposed; perianth tube 50–55 mm long, ± 3 mm wide at base, wider above bracts, 6 mm wide at apex, lower half usually filled with nectar; tepals lanceolate, ± erect, closed over stamens, 25–30 mm long, limbs 10–12 mm long, outer tepal limbs velvety-pubescent outside, inner tepals covered by outer except at apex, inner tepals pubescent at tips. *Filaments* ± 10 mm long; anthers oblong-linear, 5–6 mm long, appressed to inner surface of outer tepals, yellow; pollen yellow. *Style* extending 2–3 mm from tepals when receptive, later retracting, minutely 3-forked. *Capsules* narrowly obovoid, 9–12 mm long. *Seeds* 6–7 mm long, 1 per locule. *Flowering time*: mainly late spring and summer, October to December but also at other times.

Distribution and ecology: endemic to southern Western Cape, South Africa, extending from the southern Cape Peninsula through the Caledon District to at least the eastern end of the Riviersonderend Mtns and possibly the Langeberg at Swellendam; at low to middle elevations in marshy or peaty ground.



Flowers of *Witsenia maura* are adapted for pollination by sunbirds. The firmly closed tepals evidently prevent insects entering the flowers, thus limiting their access to both pollen and the nectar-filled lower perianth tube. Only Malachite Sunbirds seem strong enough to part the tepals with their beaks and this is the only pollinator so far noted visiting the flowers, which contain large quantities of sugary nectar of relatively low concentration.

Diagnosis: the shrubby evergreen habit and apical fans of leaves of *Witsenia maura* indicate a close relationship with *Klattia* and *Nivenia*, but the structure of the

Witsenia maura: A, flowering stem; B, outer bract; C, inner bract; D, flower from side and above; E, half-flower; F, inner and outer tepals showing attachment of stamen; G, stigma and diagrammatical section of style (shaded); H, fully and partially dehisced capsules; I, seed showing outer (left) and inner (right) surfaces.

inflorescence and the flower is so different from these two genera that it is difficult to accurately assess their interrelationships. The inflorescence in *Witsenia* is a false panicle with short lateral branches, each of which bears a pair of flowers arranged in a binate rhipidium, a pattern similar in basic organisation to that in some species of *Nivenia*. This is the putatively primitive inflorescence organisation for the woody Iridaceae and recalls the condition in some species of *Aristea*. Thus the inflorescence structure of *Witsenia* is probably fairly primitive, although the enlarged, leathery, apically notched spathes and bracts are unlike anything found in the other shrubby genera. Despite their obvious differences, similarities in the flowers of *Klattia* and *Witsenia* suggest the two genera are more closely related to one another than to *Nivenia*, namely the clawed tepals, flattened filaments inserted in a pouch at the bases of the anthers, and minutely trifid styles. *Klattia* is, however, very different from *Witsenia* in its crowded, head-like inflorescences, linear-spathulate tepals, short perianth tube, and enlarged leaves enclosing the inflorescences. The velvet pubescence on the tepals of *Witsenia* is unusual in Iridaceae. It is produced by densely arranged multicellular hairs containing yellow chromoplasts.

3. Subfamily **CROCOIDEAE**

Crocoideae *G.T.Burnett*, Outlines of botany: 451 (1835) [as Crocideae]. Type: *Crocus* L.

Ixioideae Klatt in Linnaea 34: 543 (1866) [as subordo Ixieae].

Plants deciduous or rarely evergreen geophytes. *Rootstock* a corm (rarely corm vestigial and rootstock a rhizome), producing rooting from lower half or base, axillary or terminal in origin. *Leaves* several, basal and cauline, the lowermost bladeless sheathing cataphylls; foliage leaves unifacial (isobilateral), plane, ribbed or H- or X-shaped in cross section or oval to terete, with or without longitudinal grooves, with multiple (*Tritoniopsis*) or a single main vein; margins often thickened, hyaline when dry, or raised as wings at right angles to surface; marginal anatomy various, sometimes with marginal vein and subepidermal sclerenchyma or with columnar epidermal cells and lacking marginal vein. *Stem* usually aerial, branched or not, or subterranean, usually terete, occasionally angled, or winged. *Inflorescence* a spike or rarely flowers solitary on branches, always subtended by a pair of opposed bracts at ovary base, thus without pedicels. *Flowers* long lasting, mostly zygomorphic, or radially symmetric, with septal nectaries; tepals united in a tube. *Stamens* unilateral or symmetrically arranged; filaments mostly free, or united; anthers loculicidal and extrorse to latrorse. *Ovary* inferior; style slender, dividing into 3 slender branches (rarely ± undivided); sometimes each deeply divided. *Fruit* a capsule. *Seeds* angular to globose, winged in some genera. *Pollen grains* usually monosulcate-operculate with (1)2-banded operculum, rarely trisulcate or zonasulculate, exine mostly perforate-scabrate, rarely reticulate. *Basic chromosome number x* = ?16, with many other base numbers in different genera.

Genera 32, 28 in southern Africa; species ± 1 170, 913 in southern Africa; in three tribes Ixieae, Tritoniopsideae and Watsonieae.

REFERENCES

BURNETT, G.T. 1835. *Outlines of botany*. Churchill, London
KLATT, F.W. 1866. Revisio Iridearum (Conclusio). *Linnaea* 34: 537–689.

Key to Tribes:

1a Corm development axial, the corm formed from basal internodes of current flowering stem and stem thus inserted apically, or rootstock a rhizome . . . . . .3. *Ixieae*
1b Corm development axillary, the corm formed from an axillary bud at the base of current flowering stem and stem thus inserted at base of new corm:
2a Inner floral bract longer than outer and not forked or notched apically; leaves plane, usually with 2 or more major veins (unless very narrow) and without a thickened midrib; style branches undivided. . . . . 1. *Tritoniopsideae*
2b Inner floral bract usually shorter than outer, usually with 2 prominent veins and forked or notched apically or sometimes deeply to fully divided; leaves plane, corrugately ridged or terete, when plane with an evident main vein [midrib]; style branches usually deeply divided, sometimes notched apically or undivided . . . . . .2. *Watsonieae*

Keys to genera are placed after their respective tribal descriptions

Tribe 1. **Tritoniopsideae**

Tritoniopsideae *Goldblatt & J.C.Manning* in Goldblatt et al. in Aliso 22: 408 (2006). Type: *Tritoniopsis* L.Bolus

Subtribe *Exohebeinae* G.J.Lewis ex Goldblatt in Goldblatt: 442 (1971). Type: *Tritoniopsis* L.Bolus

Plants with axillary corm development, tunics fibrous; flowering stem always well developed. *Leaves* with multiple major veins and with subepidermal sclerenchyma associated with a marginal vein. *Inflorescence* a spike; inner bract exceeding outer bract, not forked apically or 2-keeled. *Flowers* usually zygomorphic with stamens unilateral, rarely actinomorphic; tepals usually gaping gradually before anthesis; stamens often diverging after dehiscence; style branches undivided; ovules hypotropous; seed epidermal cell outlines prominent; ovular vascular trace intact. *Basic chromosome number x* = ?16.

Genera 1, only *Tritoniopsis* (23 spp.): mainly western South Africa but as far east as East London in Eastern Cape.

5. **Tritoniopsis**

Tritoniopsis *L.Bolus* in South African Gardening and Country Life 19: 123 (1929). Type: *T. lesliei* L.Bolus

Anapalina N.E.Br.: 274 (1932). Type: *A. triticea* (Burm. f.) N.E.Brown = *Tritoniopsis antholyza* (Lam.) Goldblatt

Tanaosolen N.E.Br.: 262 (1932). Type: *T. nudus* N.E.Br. = *Tritoniopsis nervosa* (Baker) G.J.Lewis

Exohebea R.C.Foster: 36 (1939). Type: *E. parviflora* (Jacq.) R.C.Foster = *Tritoniopsis parviflora* (Jacq.) G.J.Lewis

Revisionary accounts: G.J.Lewis: 319–355 (1959) & 51–72 (1960); Goldblatt: 577–582 (1990); Manning & Goldblatt: 175–181 (2001).

Alluding to the fancied resemblance of the type species to the African genus *Tritonia*, and *opsis* from the Greek suffix, looking like.

Deciduous or ± evergreen perennials. *Corm* depressed-globose, axillary in origin, often deep-seated; tunics of matted, coarse to medium-textured fibres often in a dense mass and usually forming a collar. *Cataphylls* 2 or 3. *Leaves* several, mostly basal, in 2 ranks, usually partly or entirely dry at flowering, blade linear to lanceolate or ovate, sometimes abruptly narrowed below into a slender false petiole, cauline leaves usually reduced and entirely sheathing, mostly scale-like, rarely attenuate-involute; marginal vein present. *Stem* simple or few-branched. *Inflorescence* a spike, spirally twisted at anthesis; bracts leathery, becoming dry and brown at flowering, fairly short, inner longer than the outer and acute not forked. *Flowers* zygomorphic or rarely actinomorphic, long-lived, pink to purple or red, or white, yellow, brown or cream-coloured, lower tepals usually with contrasting markings, sometimes scented; with nectar from septal nectaries; perianth tube short to long, cylindric, funnel-shaped or narrow below and broadly tubular above; tepals subequal, or unequal with dorsal largest, the lower tepals often forming a prominent lip and sometimes markedly clawed. *Stamens* unilateral and arcuate or horizontal, rarely symmetrically disposed and erect; filaments inserted near top or well within perianth tube, recurving after dehiscence; anthers often apiculate. *Style* filiform, 3-branched distally, branches short or cuneate, sometimes forked or shortly 2-lobed at the tips. *Capsules* ovoid to globose, leathery, often somewhat to much inflated. *Seeds* tetrahedral, narrowly or conspicuously winged on angles (rarely 2-winged at opposite ends), rugose or irregularly sculpted on faces, with chalazal crest; coat somewhat spongy, surface cells prominent. *Pollen grains* monosulcate-operculate, operculum 2-banded, exine perforate-scabrate. *Basic chromosome number x* = 16, also 15 and possibly 17.

Species 23: South Africa, centred in the winter-rainfall region, extending from Nieuwoudtville in the north to East London in the east, mainly in stony, sandstone-derived soils in fynbos.

Tritoniopsis is taxonomically isolated within Crocoideae and molecular phylogenetic analysis places it sister to the rest of the subfamily. The genus is distinguished by its short, leathery floral bracts with the inner bract longer than the outer and not apically forked, and in several species ± petiolate leaves with more than one vein, thus lacking a definite main vein, unless very narrow and then with only one vein developed. The unique bracts and leaves led Lewis (1954) to place the genus in the separate subtribe Exohebeinae (Goldblatt, 1971). The flowers in *Tritoniopsis* are extremely variable in form and colour, but are markedly and uniquely herkogamous, with the stamens recurving strongly after anther dehiscence. In many species the anthers are prominently apiculate. In most species (*T. nervosa* excepted), the tepals separate from one another in the

TRITONIOPSIS. T. toximontana: A, corm, leaves and flowering stems; B, front view of flower (top) and half-flower (bottom); C, dehisced capsule; D, seed. ***T. lesliei***: E, flower. ***T. parviflora***: F, flower front view (left) and side view (right). ***T. caffra***: G, flower side view (top) and front view (bottom). ***T. unguicularis***: H, flower side view (top) and front view (bottom). ***T. nervosa***: I, flower, side view.

bud stage well before the flowers expand, unlike all other Iridaceae, in which the tepals remain joined until the flower actually opens.

Species of *Tritoniopsis* are adapted to a wide range of pollination systems (Manning & Goldblatt, 2005), including bimodal systems that use pollinators of two classes. The short-tubed species are mostly pollinated by bees and those with long, slender tubes mainly by long-proboscid flies or in *T. nervosa* by moths. The red-flowered *T. leslei*, with salver-shaped, radially symmetric flowers, is probably pollinated by the butterfly *Aeropetes*. Other red-flowered species, with zygomorphic flowers, are adapted for pollination by sunbirds but some may also be pollinated by *Aeropetes* butterflies. The light, spongy seeds with winged angles are wind-dispersed.

The species were initially placed in three different genera, with *Tritoniopsis* restricted to *T. leslei*, unique in the alliance in having actinomorphic flowers; *Anapalina* including those species with large, bright red flowers with an elongate perianth tube, now understood to be adapted for pollination by sunbirds; and *Exohebea* comprising species with smaller, mostly short-tubed flowers. *Exohebea* was later united with *Tritoniopsis* (Phillips, 1951) and the genus subsequently expanded to include *Anapalina* (Goldblatt, 1990).

Key to species

1a Basal leaves with blade abruptly constricted into a wiry petiole; cauline leaves all alike, relatively long, attenuate and firmly involute; capsules woody (sect. *Aristatae*):
2a Plants up to 300 mm high; flowers pale pink with slender, subcylindric perianth tube; floral bracts lanceolate-attenuate, 25–35 mm long. . . . . 2. *T. flexuosa*
2b Plants 400–700 mm high; flowers red or scarlet with dimorphic perianth tube, slender lower portion abruptly expanded into broadly cylindric upper portion; floral bracts oblong-lanceolate, 10–15 mm long . . . . . .1. *T. triticea*
1b Basal leaves linear to lanceolate, rarely narrowed below into slender petiole; upper cauline leaves reduced to small bract-like structures; capsules leathery and often inflated:
3a Perianth tube dimorphic, with slender lower portion abruptly expanded into broadly cylindric upper portion; flowers red or dark reddish pink (sect. *Anapalina*):
4a Dorsal tepal spathulate, ± twice as long as the others; upper lateral tepals adnate to the dorsal for 3–8 mm; anthers obtuse:
5a Leaves not narrowed and subpetiolate below, reaching ± halfway to base of spike; flowers with conspicuous dark purple or black blotch in tepal sinuses; upper lateral tepals adnate to dorsal tepal for 3–5 mm; filaments 40–45 mm long. . . . . 22. *T. intermedia*
5b Leaves narrowed and subpetiolate below, reaching ± to base of spike; flowers with or without small dark markings; upper lateral tepals adnate to dorsal tepal for 6–8 mm; filaments 33–38 mm long . . . . . .23. *T. caffra*
4b Dorsal tepal oblong to spathulate, slightly longer than the others; upper lateral tepals adnate to dorsal for up to 2 mm; anthers acute or apiculate:
6a Leaves in a basal fan, not narrowed and subpetiolate below, 8–20 mm wide with 3 to 5(6) veins; tepals linear-oblanceolate, dorsal 22–30 × 4–5 mm; anthers yellow, obtuse or acute; capsules strongly inflated, 20–40 mm long . . . . . 21. *T. antholyza*
6b Leaves narrowed and subpetiolate or petiolate below, 5–8(–10) mm wide with 2 or 3 veins; tepals oblanceolate to oblong or obovate, dorsal 15–20 × 6–10 mm; anthers red to purple, apiculate; capsules not or slightly inflated, 9–16 mm long:
7a Flowers carmine to deep pinkish red or purple; tepals oblong to obovate, dorsal 8–10 mm wide; filaments relatively short, 20–23 mm long, shortly exserted from the tube; capsule smooth, ± 16 mm long . . . . . 20. *T. pulchra*
7b Flowers scarlet; tepals oblanceolate, dorsal ± 6 mm wide; filaments ± 28 mm long, well exserted from the tube; capsules rugose-verrucose, 9–16 mm long. . . . . 19. *T. williamsiana*
3b Perianth tube cylindric or funnel-shaped and widening gradually to apex; flowers pink, white or yellow:
8a Flowers yellow or cream-coloured to white, rarely flushed pink or purple, fragrant; filaments 3–14 mm long with yellow anthers 3–5 mm long, with reduced apiculus up to 0.5 mm long (sect. *Schweiggera*):
9a Perianth tube slender and subcylindric, 30–40 mm long. . . . . .13. *T. nervosa*
9b Perianth tube short, 3–5 mm long:
10a Flowers strongly bilabiate, lower three tepals fused basally for 3–4 mm to form a distinct palate; filaments 12–14 mm long:
11a Perianth creamy white with apices of all tepals and outer surface of midline flushed dark brownish pink; tepals linear, dorsal 2.0–2.5 mm wide, upper laterals ± 1.5 mm wide; filaments 15–16 mm long 18. *T. cinnamomea*
11b Perianth yellow with tube and three lower tepals flushed maroon or purple in basal half; dorsal tepal spathulate-oblanceolate, 3–6 mm wide, upper laterals 2–5 mm wide; filaments 12–14 mm long . . . 17. *T. parviflora*
10b Flowers weakly bilabiate, lower three tepals fused for up to 2.5 mm, not forming a distinct palate; filaments 3–10 mm long:
12a Stem relatively robust, 4–5 mm diam.; tepals 5–6 mm wide; filaments ± 10 mm long. . . . . 15. *T. flava*
12b Stem slender, 1.5–4.0 mm diam.; tepals 2–4 mm wide; filaments 3–7 mm long:
13a Flowers strongly bicoloured, yellow with basal half of lower tepals maroon; leaves contracted into semi-terete pseudopetiole 30–35 mm long; dorsal tepal 14–16 × 3–4 mm. . . . . .16. *T. bicolor*

13b Flowers not bicoloured, white to pale yellow, lower tepals at most flushed purplish at base; leaves not obviously pseudopetiolate; dorsal tepal 10–13 × 2–3 mm. . . . . 14. *T. unguicularis*
8b Flowers pink to red, rarely yellow in one species, unscented; filaments 12–20 mm long with yellow to lilac anthers (4–)5–10 mm long, with well-developed apiculus 0.5–2.0 mm long (sect. *Tritoniopsis*):
14a Flowers scarlet, actinomorphic, widely funnel-shaped or salver-shaped with tepals subequal or outer slightly wider than inner; stamens central . . . . . 5. *T. lesliei*
14b Flowers pink or rarely yellow, zygomorphic, ± bilabiate with dorsal tepal larger than others; stamens arcuate:
15a Perianth tube (20–)30–70 mm long, ± as long as to much longer than the dorsal tepal or rarely slightly shorter; outer bracts (12–)15–50 mm long . . . . . 4. *T. revoluta*
15b Perianth tube up to 20 mm long, shorter than the dorsal tepal; outer bracts 7–12 mm long:
16a Basal leaves in a fan with longitudinally folded, overlapping sheaths and lanceolate blades, 8–25 mm wide with 4 to 8 veins:
17a Stem less than 0.5 m tall; flowers cream-coloured to pink . . . . . 11. *T. latifolia*
17b Stem 1 m or more tall; flowers yellow. . . . . 12. *T. nemorosa*
16b Basal leaves not in a distinct fan, with slender sheaths and linear to narrowly lanceolate blades, 2–7 mm wide with 1 to 3(4) veins:
18a Basal foliage leaves 1 or 2, distinctly petiolate; perianth tube 20–21 mm long; plants from Gifberg . . . . . 3. *T. toximontana*
18b Basal foliage leaves not petiolate; perianth tube mostly less than 20 mm long; plants from south of Cederberg:
19a Spike very long and densely many-flowered, 150–400 mm long, longer than the non-flowering part of the stem; stem stiffly erect, (1.5)2.0–3.0 mm diam., flowering from near base; bracts conspicuously apiculate. . . . . 10. *T. elongata*
19b Spike lax or dense but always shorter than the non-flowering part of the stem; stem sometimes branched, not flowering from near base; bracts obtuse to acute or sometimes shortly apiculate:
20a Flowers larger, dorsal tepal (20–)23–33 × 5–8(–12) mm; tepals clawed in basal half and recurved in distal half:
21a Stem 300–600 mm tall, unbranched; perianth tube 6–11 mm long; bracts somewhat soft-textured, pale brown. . . . . 8. *T. lata*
21b Stem 150–300 mm tall, unbranched or closely branched with up to three short branches; perianth tube (10–)15–18 mm long; bracts firm and leathery, dark brown . . . . . 7. *T. pulchella*
20b Flowers smaller, dorsal tepal 16–28 × 2–6 mm; tepals clawed in lower ⅔ and recurved only in distal ⅓:
22a Stem unbranched; spike usually dense; bracts firm and leathery; flowers dusty pink; anther apiculus up to 1 mm long; style branches up to 2 mm long; capsules inflated, 20–25 × 10–15 mm; coastal lowland species . . . . . 9. *T. dodii*
22b Stem usually laxly branched; spike usually lax; bracts soft-textured; flowers clear pink; anther apiculus 1–2 mm long; style branches 3–4 mm long; capsules not much inflated, pale with dark bands along sutures, (6–)8–12(–15) × 8–10 mm; mainly montane species . . . . . 6. *T. ramosa*

Sect. 1. **Aristatae** *J.C.Manning & Goldblatt*, new section. Type: *Tritoniopsis triticea* (Burm.f.) N.E.Br.

Plants unbranched. *Leaves* elliptic to narrowly lanceolate, abruptly contracted into wiry, terete pseudopetiole often ± as long as blade; cauline leaves all alike, linear-attenuate, closely sheathing in lower part with upper part closely involute and appearing terete. *Flowers* pink or red, unscented; perianth tube 20–40 mm long, slender throughout or dimorphic and abruptly expanded into a broadly cylindric upper part. *Filaments* 12–15 mm long; anthers 5–6 mm long, shortly or conspicuously apiculate, yellow or lilac to purple. *Capsules* woody, not or slightly inflated.

Species 2: southwestern Western Cape, South Africa.

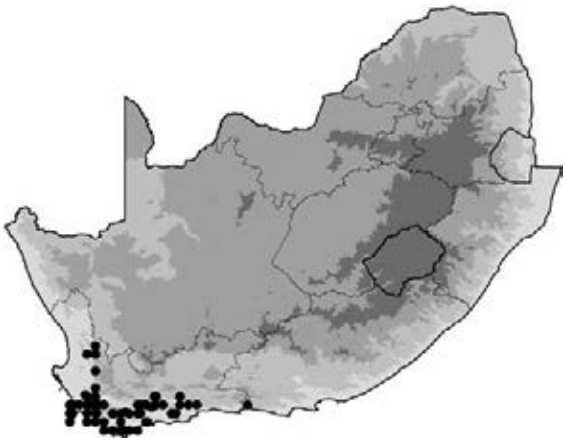
This small section includes two species with similar vegetative features, notably a solitary basal leaf with ovate to narrowly lanceolate blade and conspicuous, wiry petiole, and several cauline leaves, all linear-attenuate and either scarcely or closely sheathing at the base but slender and tightly involute above. The capsules are woody and relatively small. The flowers of the two species are very different, representing adaptation to pollination either by long-proboscid flies or a combination of sunbirds and butterflies. Although the vegetative similarity between the two species was known, the differences in their flowers resulted in their segregation in separate genera until *Anapalina* and *Tritoniopsis* were combined (Goldblatt, 1990).

N.E.Br.: 136 (1929). *Anapalina triticea* (Burm.f.) N.E.Br.: 275 (1932). Type: South Africa, without precise locality or collector (G: Herb. Burman, holo.).

Antholyza lucidior L.f.: 96 (1782). *Watsonia lucens* Pers., illegitimate superfluous name for *A. lucidior* L.f. (1782). *Watsonia lucidior* (L.f.) Eckl.: 36 (1827). *Homoglossum lucidior* (L.f.) Baker: 161 (1877). *Gladiolus lucidior* (L.f.) Baker: 227 (1892). Type: South Africa, without precise locality, *Thunberg s.n. LINN 60.9* (LINN, holo.).

Antholyza burchellii N.E.Br. in Bulletin of Miscellaneous Information Kew 1929: 136 (1929), new synonym. *Anapalina burchellii* (N.E.Br.) N.E.Br.: 275 (1932). *Tritoniopsis burchellii* (N.E.Br.) Goldblatt: 580 (1990). Type: South Africa, [Western Cape], between Donkerhoek and Houw Hoek Mtns, *Burchell 8013* (K, holo.).

[*Watsonia pottbergensis* Eckl.: 36 (1827), invalid name without description.]



[*Watsonia tigrina* Eckl.: 36 (1827), invalid name without description.]

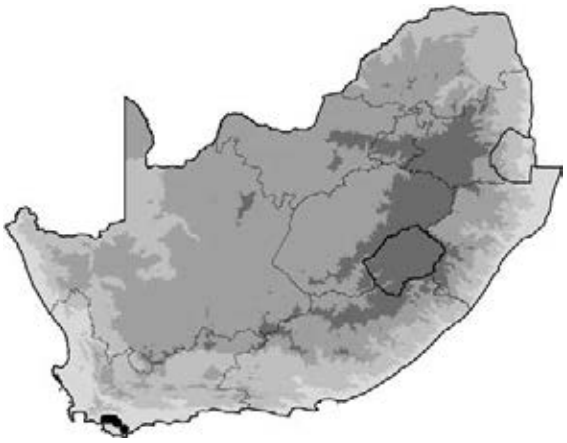
Plants 400–750 mm high. *Corm* 25–40 mm diam., tunics of densely matted fibres, with thick collar. *Stem* stout, often ± flexuose, unbranched, 2.5–4.0 mm diam. *Basal leaf* usually 1, dry at flowering, contracted abruptly into slender, terete pseudopetiole 200–300 mm long, blade lanceolate to linear-lanceolate, 200–350 × 7–11 mm, acute, obliquely cuneate at base, with 2 or 3 veins; cauline leaves 6 to 8, ± loosely overlapping, dry and brown, linear-attenuate, entirely free, closely involute and appearing terete, (50–)100–300 mm long, uppermost closely associated with spike. *Spike* compact, densely many-flowered, 80–140 mm long; bracts dry brown at flowering, leathery, oblong or oblong-lanceolate, outer bracts 10–15 mm long, acute or subobtuse, inner up to 10 mm longer than outer. *Flowers* zygomorphic, bright red or scarlet, 3 lower tepals sometimes with dark red or black median mark in lower part, unscented; perianth tube dimorphic, geniculate, slender and erect below abruptly widened at bend, cylindric and ascending or horizontal above, 25–40 mm long with lower part 8–15 mm long; tepals unequal, dorsal largest, suberect at first but later reflexed, others recurved and ± twisted or coiled, dorsal oblanceolate, 15–25 × 5–8 mm, upper lateral tepals elliptic to oblong, 12–20 × 5–7 mm, lower tepals ± as long as upper laterals or slightly shorter, 10–18 mm long. *Filaments* arcuate but later recurving, inserted at base of upper part of tube, 20–37 mm long; anthers yellow, 6–10 mm long with short apiculus 0.5–1.0 mm long, submedifixed. *Style* 30–60 mm long, dividing just below anther apices, branches 1.5–2.0 mm long. *Capsules* ellipsoid or obovoid, woody, 12–14 × 8–10 mm long. *Seeds* 5–6 mm long, winged at apex and base. *Chromosome number* 2*n* = 34 (Goldblatt 1971). *Flowering time*: January to April.

Distribution and ecology: widely distributed through the coastal mountains of Western Cape, South Africa, from the Cederberg and the Piketberg to the Hottentots Holland and Cape Peninsula and along the Langeberg as far as Mossel Bay; on rocky granite and sandstone slopes or sometimes dry shale.

The species is adapted to pollination by sunbirds, including the Orange-breasted and Lesser Double-collared Sunbirds, as well as the Mountain Pride butterfly, *Aeropetes tulbaghia* (Satyridae).

Diagnosis: one of two species with a solitary, petiolate basal leaf and long-attenuate cauline leaves, *Tritoniopsis triticea* is a robust species with stems 400–750 mm high and compact spikes of red flowers with dimorphic perianth tube 25–40 mm long. The mouth of the tube is not evidently oblique and the tepals are not markedly unequal, the dorsal and often the laterals only slightly larger than the lower three. All the tepals are ultimately strongly reflexed and often twisted during the female phase of flowering. The relatively small, woody capsules 12–14 mm long are also distinctive. Flower size is variable, with larger-flowered populations especially common between Paarl and Stellenbosch. Such large-flowered forms, with the perianth tube 30–40 mm long and tepals usually more than 20 mm long and only rarely with dark markings, were segregated by Lewis (1959) as *Anapalina burchellii*, but we are unable to maintain this distinction in the face of the considerable variation among populations in all these features and without any associated ecological or geographical differences.

Distribution of ***Tritoniopsis triticea***.



2. **Tritoniopsis flexuosa** *(L.f.) G.J.Lewis* in Journal of South African Botany 25: 352 (1959). *Gladiolus flexuosus* L.f.: 96 (1782). *Sphaerospora flexuosa* (L.f.) Klatt: 726 (1864). *Acidanthera flexuosa* (L.f.) Baker ex C.D.Bouché & Wittm.: 15 (1876). *Exohebea flexuosa* (L.f.) G.J.Lewis: 4 (1952). Type: South Africa, [Western Cape], without precise locality, *Thunberg s.n.* (UPS–THUNB, lecto., designated by Lewis: 5 (1952); LINN, isolecto.).

Plants 150–300 mm high. *Corm* 15–20 mm diam.; tunics of densely matted fibres, with thick collar. *Stem* slender, flexuose, unbranched. *Basal leaf* 1, dry at flowering, contracted abruptly into slender, terete pseudopetiole 25–70 mm long, blade elliptic to ovate-lanceolate, 30–55 × 10–20 mm, acute or obtuse, truncate or cuneate at base, sometimes obliquely so, with 2 veins, margins ± undulate or crisped; cauline leaves 4 or 5, ± overlapping, dry and brown, linear-attenuate, closely sheathing below, distally closely involute, appearing terete, free part 10–60 mm long, uppermost grading into floral bracts. *Spike* short, compact, densely 3- to 7-flowered, 20–40 mm long; bracts dry and reddish brown at flowering, leathery, lanceolate, outer 25–35 mm long,

attenuate, obscurely 2-keeled, inner firm-papery, up to 5 mm longer than outer, acuminate. *Flowers* zygomorphic, pale pink, lower 3 tepals and sometimes also upper tepals with dark red median streak, unscented; perianth tube subcylindric, straight or slightly curved, slightly widened to throat, 34–38 mm long; tepals unequal, dorsal largest, slightly ascending and recurved above, others directed forward below and recurved distally, dorsal oblanceolate, 25–30 × 5–8 mm, narrowed below, upper laterals 20–26 × 2.5–4.0 mm, lower tepals as long as upper laterals but usually slightly narrower, joined to one another for 4–8 mm. *Filaments* arcuate but later recurving, 12–15 mm long; anthers 5–6 mm long, lilac or purple, with recurved, usually bifid apiculus ± 2 mm long. *Style* 50–55 mm long, dividing just below anther apices, branches 3–4 mm long. *Capsules* ellipsoid, woody, 15–22 × 8 mm long. *Seeds* tetrahedral, ± 5 × 3 mm, shortly winged on angles. *Chromosome number* 2*n* = ± 32 (or 30). *Flowering time*: January to February.

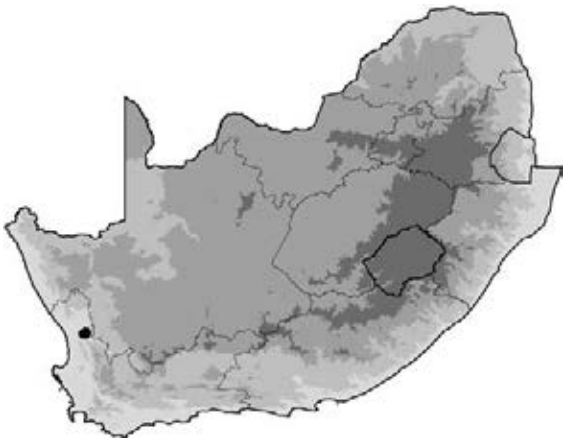
Distribution and ecology: a very local endemic of the Overberg, Western Cape, South Africa, known from a few locations between Caledon and Bredasdorp; in hard, stony clay in renosterveld shrubland.

The long-tubed pink flowers resemble those of *T. revoluta* and *T. toximontana* and are likewise assumed to be adapted for pollination by long-proboscid flies in the absence of recorded observations.

Distribution of ***Tritoniopsis flexuosa***.

Diagnosis: a distinctive species with a short, compact spike of long-tubed, pink flowers with long, attenuate bracts 25–35 mm long. The solitary basal leaf, dry at flowering, has a conspicuous long false petiole and relatively small, elliptic to ovate-lanceolate blade 30–55 mm long with crisped or undulate margins. The cauline leaves are linear-attenuate, ± overlapping and concealing the stem, closely sheathing below with the distal free portion involute and appearing terete. The uppermost cauline leaves are closely associated with the flowering spike and grade into the floral bracts.

Sect. 2. **Tritoniopsis**



Plants usually branched. *Leaves* linear to narrowly lanceolate, rarely contracted into a wiry, terete pseudopetiole; lower cauline leaves leaf-like, upper reduced and bract- or scale-like. *Flowers* usually pink, rarely red or yellow, unscented; perianth tube short or long, 5–70 mm long, slender throughout or slightly expanded apically. *Filaments* 12–20 mm long; anthers 5–10 mm long, shortly or prominently apiculate, yellow or lilac to purple. *Capsules* leathery, inflated.

Species 10: Western Cape, South Africa.

This section, which includes most of the pink-flowered species of *Tritoniopsis*, is characterised by the upper cauline leaves reduced to bracts or scales, stems often branched, and unscented flowers with a ± funnel-shaped perianth tube scarcely or slightly and evenly widened toward the mouth. The capsules are leathery and ± inflated.

3. **Tritoniopsis toximontana** *J.C.Manning & Goldblatt* in Bothalia 31: 178 (2001). Type: South Africa, Western Cape, Gifberg, near top of pass, sheltered sandstone slope in arid fynbos, 22 Mar. 2000, *Manning 2234* (NBG, holo,; K, PRE, iso.).

Plants 300–650 mm high. *Corm* 30–50 mm diam.; tunics of densely matted fibres, with thick collar. *Stem* slender, straight or slightly flexuose, usually unbranched, rarely with one or two short branches, 1.0–1.5 mm diam. *Basal leaves* 1 or 2, dry at flowering, contracted abruptly into terete pseudopetiole 100–150 mm long, blade linear-lanceolate, 200–300 × 5–10 mm, attenuate, oblique at base, 3-veined, abaxial vein diverging first; cauline leaves 3, reddish brown, lanceolate, clasping throughout, lowermost up to 60 mm long, upper reduced and bract-like. *Spike* laxly 5- to 9(–12)-flowered, 300–600 mm long, lateral spikes 1-flowered; bracts green at base, dry and flushed pink in upper half at flowering, ± membranous, oblong, outer 10–12 mm long, acute, inner 14–16 mm long, acuminate. *Flowers* zygomorphic, pale pink, three 3 tepals each with dark red median streak outlined in white and flanked at base by dark pink streak and upper laterals usually with darker median streak near apices, mouth of tube and bases of filaments flushed dark red, unscented; perianth tube subcylindric, straight or slightly curved, slightly widened to throat, 20–21 mm long; tepals unequal, dorsal largest, slightly ascending and recurved above, others directed forward below and recurved above, dorsal oblanceolate, 23–25 × 7–9 mm, narrowed below, upper laterals 22–25 × 3.5–5.0 mm, lower tepals as long as upper laterals but usually slightly narrower, joined

Distribution of ***Tritoniopsis toximontana***.

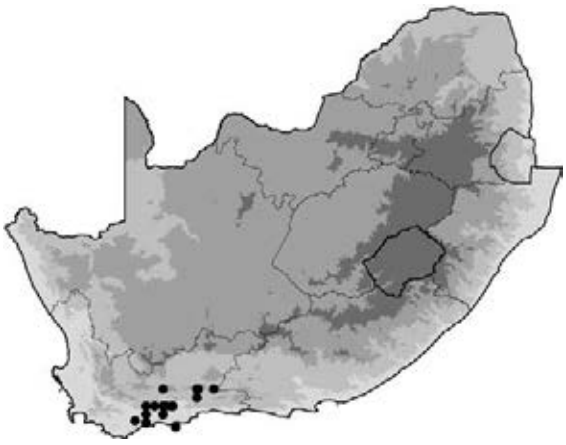
to one another for 5–6 mm. *Filaments* arcuate but later recurving, 13–15 mm long; anthers purple, 5–6 mm long with recurved, usually bifid apiculus ± 2 mm long. *Style* 35–37 mm long, dividing just below anther apices, branches 3–4 mm long. *Capsules* ovoid to ellipsoid, inflated, 15–23 × 10 mm long. *Seeds* ± 6 × 4 mm, winged on angles. *Flowering time*: March to early May.

Distribution and ecology: endemic to the Gifberg and Matsikamma Mtns of Western Cape, South Africa, and quite common on the summit plateau; in sandstone outcrops in sheltered situations, often on cooler slopes.

The leaves are dry at flowering time or sometimes those of the next season's growth are emergent.

The pink, long-tubed flowers are pollinated by a combination of *Amegilla* bees (Anthophorinae) and long-proboscid nemestrinid flies in the genus *Prosoeca*.

Diagnosis: recognised by its one or two distinctly petiolate leaves with terete pseudopetiole, simple or branched stems with relatively soft-textured, acute bracts 10–12 mm long and pink flowers with moderately long, slender perianth tube 20–21 mm long.



4. **Tritoniopsis revoluta** *(Burm.f.) Goldblatt* in Wijnands & Goldblatt in Candollea 47: 364 (1992). *Antholyza revoluta* Burm.f.: 1 (1768). *Homoglossum revolutum* (Burm.f.) Baker: 161 (1877). *Anapalina revoluta* (Burm.f.) N.E.Br.: 275 (1932). Type: South Africa, without precise locality or collector, drawing by J.C. Cuno in HS 1877, fol. 19, Utrecht University Library [lecto., designated by Goldblatt in Wijnands & Goldblatt: 364 (1992)].

   Gladiolus apiculatus F.Bolus: 106 (1917). *Hebea apiculata* (F.Bolus) L.Bolus: 123 (1929). *Exohebea apiculata* (F.Bolus) R.C.Foster: 36 (1939). *Tritoniopsis apiculata* (F.Bolus) G.J.Lewis: 353 (1959). Type: South Africa, [Western Cape], Langeberg, Vrijersberg, 1 500 ft [460 m], *Muir 2016* (BOL, holo.).

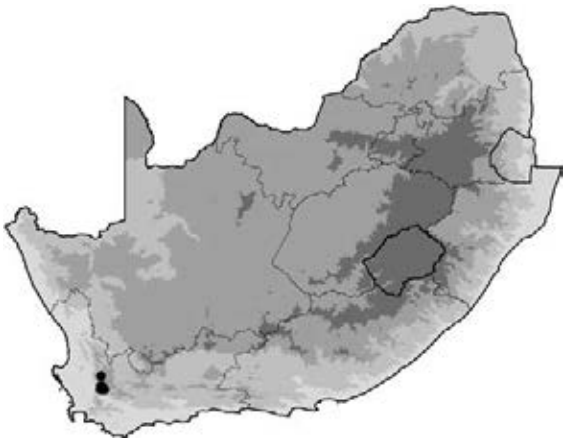
   Tritoniopsis apiculata var. *minor* G.J.Lewis: 355 (1959), new synonym. Type: South Africa, [Western Cape], south slopes of Swartberg Pass, *T.M. Salter 3126* (BOL, holo.).

Plants 200–400(–500) mm high. *Corm* 35–65 mm diam.; tunics of densely matted fibres, with long fibrous collar. *Stem* slender to moderately stout, suberect, simple or rarely with 1 or 2 short suberect branches, 2–3 mm diam. *Basal leaves* 1 to 3, dry at flowering, blades lanceolate to linear-lanceolate, 150–320 × 5–20 mm, acuminate, (2)3- to 5-veined, narrowed below (not pseudopetiolate); cauline leaves 4 or 5, lowermost small, leaf-like or subulate and clasping, upper 1 or 2 bract-like, dry and reddish brown. *Spike* moderately densely or laxly 3- to 10-flowered, 20–160 mm long, lateral spikes 1- to 3-flowered; bracts dry, brown, leathery, lanceolate, (12–)15–50 mm long, acute to acuminate, inner up to 9 mm longer than outer. *Flowers* zygomorphic, pale to deep salmon-pink or mauve-pink, lower tepals with red median streak or line, unscented; perianth tube subcylindric or widening slightly and evenly from near base, straight or slightly curved, (20–)40–70 mm long; tepals unequal, dorsal arched over stamens and recurved distally, oblanceolate, 25–40 × 6–10 mm, obtuse or subacute, others suberect but recurved in distal half, oblanceolate-spathulate, 18–35 × 4–8 mm, lower 3 joined for 4–8 mm. *Filaments* arched, later suberect, 15–20 mm long; anthers 8–10 mm long, purple, with recurved bipartite apiculus 1.5–2.0 mm long. *Style* (30–)60–90 mm long, dividing shortly below or beyond anther tips, branches 5–7 mm long. *Capsules* inflated, ellipsoid or ovoid, 20–30 × 10–12 mm. *Seeds* up to 8 mm long, usually broadly winged on angles at base and apex and narrowly so laterally. *Flowering time*: March to May.

Distribution and ecology: scattered along the lower slopes of the coastal and inland mountains of Western Cape, South Africa, from Bredasdorp and the Potberg, along the Langeberg from Tradouws Pass to Herbertsdale and on the southern slopes of the Swartberg between Ladismith and Oudtshoorn; on clay or loamy soils in renosterveld or fynbos, up to 1 000 m elevation.

Distribution of ***Tritoniopsis revoluta***.

Populations from the coastal lowlands between Bredasdorp and Potberg and from the Swartberg have smaller flowers with shorter tubes 20–35 mm long, while those from the western and eastern Langeberg consistently have the largest flowers, with tubes 50–70 mm long. Populations from Gysmanshoek in the central Langeberg are variable for tube length. The marked inter-population variation in tube length appears to represent adaptation to local pollinator faunas. Long-tubed forms are pollinated by the long-proboscid flies *Prosoeca ganglbaurii* and *P. longipennis* and shorter-tubed forms at least partially by bees but probably also by local long-proboscid flies.



Diagnosis: Tritoniopsis revoluta is recognised by the long-tubed pink flowers with slender perianth tube (25–)40–70 mm long and ± as long as or usually much longer than the dorsal tepal, 20–40 mm long, and the long bracts, the outer (12–)15–50 mm long.

5. **Tritoniopsis lesliei** *L.Bolus* in South African Gardening and Country Life 19: 123 (1929). Type: South Africa, [Western Cape], Ceres, *Leslie s.n. NBG417/27* (BOL, holo.).

Plants 350–650 mm high. *Corm* 15–20 mm diam.; tunics of densely matted fibres, with long fibrous collar. *Stem* slender, suberect, with 1 or 2 slender, suberect branches, 1–2 mm diam. *Basal leaves* 3 to 5, dry at flowering, blade linear to linear-lanceolate, 130–250 × 3–5 mm, acuminate, with 1 or 2 veins, narrowed into a slender pseudopetiole ± as long as the blade; cauline leaves 3 to 5, lowermost leaf-like with blade up to 80 mm long, upper reduced and bract-like, entirely clasping, acuminate, dry and reddish brown. *Spike* laxly 3- to 7(–10)-flowered, 70–150 mm long, lateral spikes 1- to 3-flowered; bracts dry and brown, leathery, lanceolate, 12–16 mm long, acute to acuminate, inner oblong, as long as or slightly longer than outer. *Flowers* actinomorphic, suberect, bright red, unscented; perianth tube slender, subcylindric, 20–25 mm long, expanded in upper 2–3 mm; tepals subequal or outer slightly broader, suberect below, spreading in distal half, forming a wide cup, shortly and broadly clawed near base, obtuse or subacute, 18–28 mm long, outer oblong or obovate, 7–12 mm wide, inner oblong or oblanceolate, 7–9 mm wide. *Filaments* central, erect, later slightly arcuate, 16–19 mm long; anthers 6–7 mm long, reddish, with apiculus 0.5 mm long. *Style* erect, 30–35 mm long, dividing below base of anthers, branches 3–4 mm long. *Capsules* inflated, ovoid, 12–18 × 7–10 mm. *Seeds* up to 6 mm long, narrowly winged on angles. *Chromosome number* 2*n* = 32. *Flowering time*: February to April.

Distribution and ecology: a narrow endemic so far known only from the southern foot of the Skurweberg near Ceres in Western Cape, South Africa; in marshy ground along streams and seeps at ± 900 m elevation.

The distinctive flowers are adapted for pollination by butterflies.

Distribution of ***Tritoniopsis lesliei***.

Diagnosis: unique in the genus in its bright red, actinomorphic, almost salver-shaped flowers with slender perianth tube 18–28 mm long, and spreading tepals forming a shallow bowl. The style is relatively short, dividing just below the anthers.

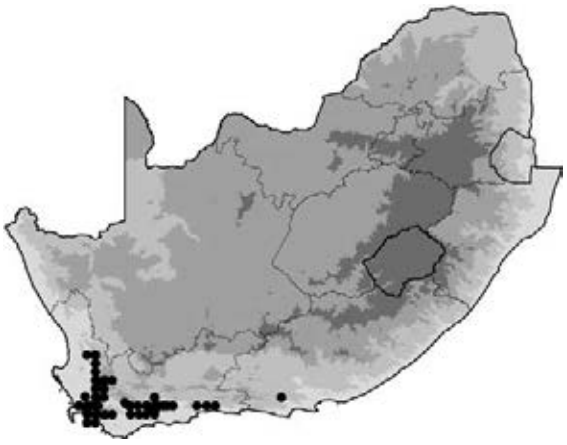
6. **Tritoniopsis ramosa** *(Eckl. ex Klatt) G.J.Lewis* in Journal of South African Botany 25: 326 (1959). *Antholyza ramosa* Eckl. ex Klatt: 733 (1864). *Gladiolus ramosus* (Eckl. ex Klatt) N.E.Br.: 27 (1928), illegitimate homonym, not *G. ramosa* L. (1762). *Exohebea ramosa* (Eckl. ex Klatt) R.C.Foster: 39 (1939). Type: South Africa, [Western Cape], mountains near Caledon and Genadendal, *Ecklon & Zeyher Irid 70* [G, lecto., designated by G.J.Lewis: 328 (1959); MO, isolectotype).

Tritonia nervosa Baker: 864 (1901), illegitimate homonym, not *T. nervosa* Klatt (1882), new synonym. Type: South Africa, [Western Cape], Outeniqua Mtns, Montagu Pass, *Rehmann 86* (Z, holo.).

Tritoniopsis ramosa var. *robusta* G.J.Lewis in Journal of South African Botany 25: 330 (1959), new synonym. Type: South Africa, [Western Cape], Grootvadersbos, lower mountain slopes, *G.J. Lewis 5447* (NBG, holo).

Tritonia unguiculata Baker: 196 (1892), new synonym. *Gladiolus unguiculatus* (Baker) N.E.Br.: 27 (1928), illegitimate homonym, not *G. unguiculatus* Baker (1877). *Hebea unguiculata* (Baker) L.Bolus: 123 (1929). *Exohebea unguiculata* (Baker) R.C.Foster: 39 (1939). *Tritoniopsis ramosa* var. *unguiculata* (Baker) G.J.Lewis: 329 (1959). Type: South Africa, without precise locality, *Kitching s.n.* (K, holo.).

[*Hebea ramosa* Eckl.: 43 (1827), invalid name without description.]



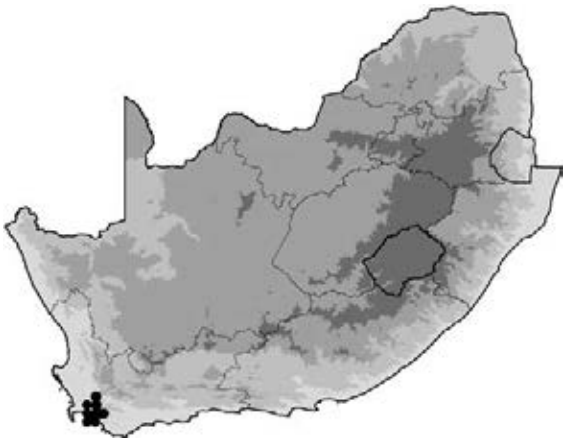
Plants 120–500 mm high. *Corm* 18–30 mm diam.; tunics of densely matted fibres, with short or long collar. *Stem* decurved at base then suberect or erect, simple or usually branched with up to 4 suberect or rarely divaricate

branches, short to half as long as stem, slender or relatively robust. *Basal leaves* 3 to 6, green or dry at flowering, blade linear-lanceolate or lanceolate, 100–250 × 2–8(–12) mm, acuminate, narrowed and pseudopetiolate below, with 1 or 2(4) veins; cauline leaves 3 to 6, lower 1 to 3 subulate, upper 1 or 2 bract-like, brown. *Spike* laxly or moderately densely 4- to 18-flowered, 50–180 mm long, lateral spikes shorter, 1- to 8-flowered; bracts greenish at base, dry and brown above, soft-textured or leathery, oblong or ovate, outer 5–10 mm long, acute or obtuse or shortly apiculate, inner slightly longer. *Flowers* zygomorphic, pale to deep pink, lower 3 tepals with red median streak flanked by white streaks, unscented; perianth tube narrowly funnel-shaped, 7–15(–20) mm long; tepals unequal, dorsal larger, arched over stamens, oblanceolate-spathulate, clawed in lower ⅔, 20–28 × (3–)4–6 mm, obtuse or emarginate, other tepals recurved in distal ⅓, 20–25 × 3–5 mm, upper laterals joined to lower laterals for ± 1 mm and lower 3 joined at base for 5–7 mm. *Filaments* arcuate, later recurved, 15–18 mm long; anthers 5–7 mm long, pink or lilac, with acuminate, recurved apiculus 1.0–1.5 mm long. *Style* 24–28 mm long, dividing opposite upper half or beyond anthers, branches 3–4 mm long. *Capsules* ellipsoid to obovoid, slightly inflated, (6–)8–12(–15) × 8–10 mm, pale or greenish with dark bands along the sutures. *Seeds* tetrahedral, 3–4 mm long, narrowly winged on angles. *Flowering time*: mainly January to April.

Distribution and ecology: relatively widespread through the coastal mountains of Western Cape, South Africa, extending from the Cederberg and Cold Bokkeveld to the Kogelberg and from the Riviersonderend Mtns and Langeberg to the Outeniqua Mtns, and the Kouga Mtns in Eastern Cape; on sandy, rocky or seasonally marshy sandstone slopes, from 600–1 500 m elevation.

The species is pollinated by long-tongued solitary bees (Apidae: Anthophorinae).

Diagnosis: a variable species with moderately sized pink flowers with perianth tube 7–15(–20) mm long and narrow tepals, the dorsal 20–28 × (3–)4–6 mm and the lower tepals 3–5 mm wide. The capsules are diagnostic for the species, being unusually small, (6–)8–12(–15) × 8–10 mm, and pale or greenish with dark bands along the sutures. Flowering plants are sometimes less easily identified. Typical forms with laxly branched stems are readily recognised but unbranched plants are more difficult to place. It is separated from *T. laxa* by the generally smaller flowers with narrower tepals; from *T. pulchella* by the mostly shorter perianth tube and more slender stems; and from *T. dodii* by the usually softer bracts and the conspicuously apiculate anthers.



Distribution of ***Tritoniopsis ramosa***.

Populations with a longer perianth tube, 13–20 mm long, were distinguished from the typical variety with perianth tube 7–10 mm long as var. *unguiculata* by G. J.Lewis (1959) but the species is very variable for this character even in one locality, probably as an adaptation to the local pollination fauna. There is a trend for longer-tubed populations in the southern Cape east of the Hottentots Holland Mtns, but this is not consistent. Collections of relatively robust plants from the Langeberg near Swellendam, with leaves up to 12 mm wide and perianth tube 12–15 mm long, were separated as var. *robusta* G.J.Lewis (1959) but represent only one extreme in the variation recorded in the species.

7. **Tritoniopsis pulchella** *G.J.Lewis* in Journal of South African Botany 25: 331 (1959). Type: South Africa, [Western Cape], Bain's Kloof, 2 000 ft [600 m], *Compton 16929* (NBG, holo.).

Plants 100–300 mm high. *Corm* 15–35 mm diam.; tunics of densely matted fibres, with short collar. *Stem* decurved at base then suberect or erect, simple or with 1 to 3 short, suberect branches, (1)2–3 mm diam. *Basal leaves* 5 to 7, usually green at flowering, blades linear or linear-lanceolate, 100–180 × 2–8 mm, acuminate, narrowed below, with 1 or 2(3) veins; cauline leaves 3 to 5, lower 1 or 2 like the basal but smaller, upper 1 or 2 brown and bract-like. *Spike* moderately densely ± 8- to 16-flowered, 50–120 mm long; bracts dry and dark reddish or blackish brown, leathery, oblong, outer 8–12 mm long, acute or often apiculate, inner slightly longer, obscurely 2-keeled. *Flowers* zygomorphic, salmon or pink, lower 3 tepals with red median lozenge or streak flanked by white streaks, unscented; perianth tube narrowly funnel-shaped, (10–)15–18 mm long; tepals unequal, dorsal larger, arched over stamens, oblanceolate-spathulate, clawed in lower half, 23–25 × 5–8 mm, obtuse or truncate, other tepals recurved in distal half, 16–20 × 4–5 mm, upper laterals joined to lower laterals for ± 1 mm and lower 3 tepals joined at base for 5–7 mm. *Filaments* arcuate, later recurved, 17–25 mm long; anthers 6–7 mm long, pink or lilac, with acuminate or bifid, often recurved apiculus 1–2 mm long. *Style* 27–33 mm long, dividing opposite upper half of anthers or beyond, branches 4–5 mm long. *Capsules* ovoid, inflated, 15–18 × 10–12 mm, rugulose-verrucose. *Seeds* tetrahedral, up to 6 mm long, winged on angles and rugose on faces. *Flowering time*: (December) January to February (April).

Distribution and ecology: a montane species endemic to Western Cape, South Africa, extending from Bain's Kloof

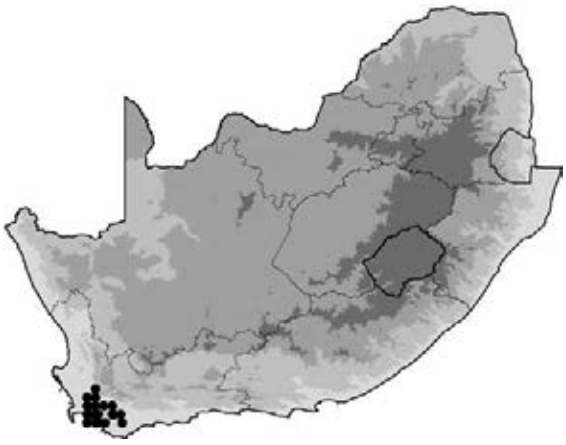
Distribution of ***Tritoniopsis pulchella***.

along the Hottentots Holland Mtns to Kogelberg and the Riviersonderend Mtns; on seasonally moist sandy flats, 600–1 000 m elevation, flowering only after fire.

Diagnosis: a short species up to 300 mm high, with the stem simple or often with up to three short suberect branches, and a spike of salmon- or rose-pink flowers with a moderately long perianth tube (10–)15–17 mm long and dark blackish brown, leathery bracts. The basal leaves are narrowly lanceolate, usually with 1 or 2 (rarely 3) veins, and the lowermost cauline leaf resembles the basal leaves in having a well-developed blade. We have seen only a single collection of capsules and these are highly distinctive, inflated and irregularly wrinkled-warty. This remains to be confirmed when additional material is collected and if so is diagnostic for the species. Similar warty capsules are otherwise known only in *Tritoniopsis williamsiana* but are less inflated in that species.

8. **Tritoniopsis lata** *(L.Bolus) G.J.Lewis* in Journal of South African Botany 25: 335 (1959). *Hebea lata* L.Bolus: 106 (1930). *Exohebea lata* (L.Bolus) R.C.Foster: 38 (1939). Type: South Africa, [Western Cape], Houw Hoek Mtns, 1800 ft [550 m], *H. Bolus 18914* (BOL, holo.).

Hebea lata var. *longibracteata* L.Bolus: 107 (1930), new synonym. *Exohebea lata* var. *longibracteata* (L.Bolus) R.C.Foster: 38 (1939). *Tritoniopsis lata* var. *longibracteata* (L.Bolus) G.J.Lewis: 337 (1959). Type: South Africa, [Western Cape], southern slopes of Drakensteinberg near Bain's Kloof, 1 600 ft [490 m], *H. Bolus 4069* (BOL, holo.).



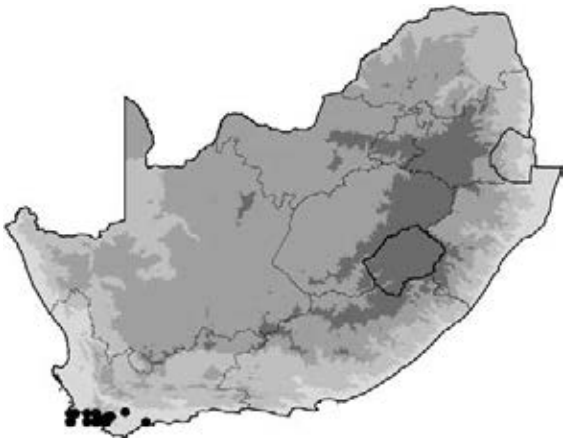
Tritoniopsis pulchella var. *alpina* G.J.Lewis: 333 (1959), new synonym. Type: South Africa, [Western Cape], Klein Winterhoek, south slopes, among rocks, 6 000 ft [1 800 m], *E. Esterhuysen 13758* (BOL, holo.).

Plants 300–700 mm high. *Corm* 30–60 mm diam.; tunics of densely matted fibres, with long collar. *Stem* erect, unbranched or rarely with single short erect branch, 2.0–3.5 mm diam. *Basal leaves* 1 to 3, usually green at flowering, blade linear or linear-lanceolate, 150–600 × 3–8 mm, acuminate, narrowed below, with 3 or 4 veins; cauline leaves 3 to 5, lower 2 or 3 subulate, upper 1 or 2 reduced to scales or vestigial. *Spike* moderately densely ± 5- to 18-flowered, 70–150 mm long; bracts dry and brown, leathery or papery and fairly soft, oblong or ovate-oblong, outer 6–16 mm long, acute or mucronulate, inner slightly longer. *Flowers* zygomorphic, pale to deep pink, lower 3 tepals with red median lozenge or streak flanked by white streaks, unscented; perianth tube narrowly funnel-shaped, 6–11 mm long; tepals unequal, dorsal larger, arched over stamens, recurved apically, oblanceolate-spathulate, clawed in lower half, 23–33 × 5–8(–12) mm, obtuse, other tepals recurved in distal half, 18–25 × 5–9 mm, upper laterals joined to lower laterals for ± 1 mm and lower 3 tepals joined at base for 5–7 mm. *Filaments* arcuate, later diverging, (15–)17–20 mm long; anthers 5–7 mm long, pink or yellow, with acuminate or bifid, often recurved apiculus 1–2 mm long. *Style* 26–28 mm long, dividing opposite middle of anthers, branches 3–4 mm long. *Capsules* ovoid, slightly inflated, 15–20 × 8–10 mm. *Seeds* up to 5 mm long, winged on angles. *Chromosome number* 2*n* = 32. *Flowering time*: (February) April to May.

Distribution and ecology: a montane species endemic to Western Cape, South Africa, extending from the Witzenberg and Bain's Kloof south along the coastal mountains to the Kleinrivier, Bredasdorp and Riviersonderend Mtns; on rocky, south-facing sandstone slopes. The species is absent from the Cape Peninsula.

The flowers are pollinated by long-tongued solitary bees (Apidae: Anthophorinae).

Diagnosis: distinguished from similar short-tubed, pink-flowered species by its mostly larger, candy-pink flowers, the dorsal tepal 23–33 × 5–8(–12) mm and the filaments 15–20 mm long with conspicuously apiculate anthers, and the relatively long style branches 3–4 mm long. The tepals are clawed in the basal half and recurved distally, giving the flowers a rather open



Distribution of ***Tritoniopsis lata***.

appearance, with the lower tepals almost as wide as the upper. The stems are mostly 300–600 mm high and unbranched (rarely with a solitary short erect branch). Smaller-flowered forms can be confused with *T. dodii*, a coastal lowland species with dusty pink flowers with narrower tepals, very shortly apiculate anthers, and short style branches up to 2 mm long.

Plants from the northern part of the range, between Du Toit's Kloof and Ceres, with slightly narrower tepals, the dorsal 5–8 mm vs. 7–12 mm wide, and bracts up to 16 mm long vs. up to 13 mm, were segregated as var. *longibracteata* by G.J.Lewis (1959), but these differences are insignificant. Plants from Klein Winterhoek near Tulbagh with unbranched stems up to 650 mm tall and flowers with the perianth tube ± 10 mm long were described as *Tritoniopsis pulchella* var. *alpina* G.J.Lewis (1959). Both the tall stems and the short perianth tubes are anomalous for that species, as are the relatively soft-textured bracts, but all these features are consistent with *T. lata*. After examining the type and a later collection from the same locality we conclude that these plants are better included in *T. lata*.

9. **Tritoniopsis dodii** *(G.J.Lewis) G.J.Lewis* in Journal of South African Botany 25: 345 (1959). *Hebea dodii* G.J.Lewis: t. 549 (1934). *Exohebea dodii* (G.J.Lewis) R.C.Foster: 37 (1939). Type: South Africa, [Western Cape], [Cape Peninsula], Cirkels Vlei, *Salter 2986* (BOL, holo.).

Plants 200–550 mm high. *Corm* 30–50 mm diam.; tunics of densely matted fibres, with long collar. *Stem* erect, unbranched or rarely with a solitary short erect branch, 2.0–2.5 mm diam. *Basal leaves* 1 to 3, usually green at flowering, blade linear or linear-lanceolate, 150–350 × 3–6(–)8 mm, acuminate, narrowed below, with 2 or 3(4) veins; cauline leaves 3 to 5, lowest linear and leaf-like, concealed by collar, upper 2 to 4 reduced to scales or vestigial. *Spike* moderately to densely ± 5- to 22-flowered, 5–120 mm long; bracts dry and brown, leathery or cartilaginous, ovate or oblong, outer 7–11 mm long, acute or obtuse, rarely mucronulate, inner slightly longer. *Flowers* zygomorphic, dingy or brownish pink sometimes tipped with crimson, the lower three tepals with red median lozenge or streak, unscented; perianth tube narrowly funnel-shaped, 5–8 mm long; tepals unequal, dorsal larger, arched over stamens, apically recurved, oblanceolate-spathulate, clawed in lower ⅔, 20–23 × 3–5 mm, obtuse or emarginate, other tepals suberect and recurved in distal ⅓, 16–20 × 2–4 mm, upper laterals joined to lower laterals for ± 1 mm and lower 3 tepals joined at base for 3–5 mm. *Filaments* arcuate, later diverging, 12–14 mm long; anthers yellow, 4–6 mm long with short apiculus 0.5–1.0 mm long. *Style* ± 20 mm long, dividing opposite base to middle of anthers, branches 1.5–2.0 mm long. *Capsules* ovoid or subglobose, inflated, 20–25 × 10–15 mm. *Seeds* up to 6 mm long, winged on angles. *Chromosome number 2n* = 30. *Flowering time*: usually February to April but also at other times.

Distribution of ***Tritoniopsis dodii***.

Distribution and ecology: a coastal lowland species form Western Cape, South Africa, described from the southern Cape Peninsula but now collected further east from Hermanus to Bredasdorp inland to Caledon; on sandy or gravelly flats in lowland fynbos.

Diagnosis: a somewhat variable species, *Tritoniopsis dodii* typically has a short, compact spike but includes forms with more lax, subsecund spikes. It is recognised essentially by its unbranched stems and short-tubed, pink flowers with narrow tepals clawed in the lower two thirds, the dorsal tepal 20–23 × 3–5 mm, the anthers only shortly apiculate, and the style branches up to 2 mm long. The flowers are typically rather dingy pink, with the tepals erect below and recurved only in the distal third, thus essentially like those of *T. elongata*, which is distinguished by its much longer spike, the flowering portion much longer than the non-flowering stem. Hybrids with *T. parviflora* have been recorded near Hermanus.

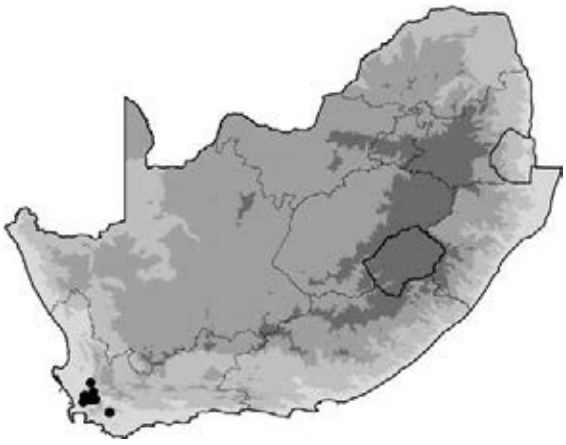
10. **Tritoniopsis elongata** *(L.Bolus) G.J.Lewis* in Journal of South African Botany 25: 344 (1959). *Hebea elongata* L.Bolus: 106 (1930). *Exohebea elongata* (L.Bolus) R.C.Foster: 37 (1939). Type: South Africa, [Western Cape], Daljosephat, hills 600 ft [200 m], *Tyson 853* (SAM, holo.).

Plants 150–500 mm high. *Corm* 25–60 mm diam.; tunics of densely matted fibres, with long collar. *Stem* flexed outward at ground level and then stiffly erect or inclined, unbranched, (1.5)2.0–3.0 mm diam. *Basal leaves* 4 or 5, dry and fragmented at flowering, in a basal fan, blades linear-lanceolate, 100–220 × 4–8 mm, acuminate, with 3 or 4 veins, not narrowed to a pseudopetiole below, firm-textured; cauline leaves 2 or 3, lowermost subulate and concealed in collar, uppermost vestigial and scale-like. *Spike* moderately densely ± 12- to 40-flowered, 150–400 mm long; bracts dry and brown, cartilaginous with membranous margins, oblong or ovate-oblong, 7–13 mm long, conspicuously apiculate, inner slightly longer. *Flowers* zygomorphic, dull dingy pink with dark reddish veins, unscented;

perianth tube narrowly funnel-shaped, 6–11 mm long; tepals unequal, dorsal slightly larger, arched over stamens, oblanceolate-spathulate, clawed in lower ⅔, 20–25 × 3–4 mm, obtuse, other tepals suberect and recurved distally, 15–18 × 2.5–4.0 mm, upper laterals connate to lower laterals for ± 1 mm and lower 3 tepals joined at base for 3–5 mm. *Filaments* arcuate, later suberect, 13–16 mm long; anthers 6–7 mm long, yellow with small apiculus up to 1 mm long. *Style* 18–23 mm long, dividing opposite middle of anthers, branches ± 2 mm long. *Capsules* ovoid to subglobose, inflated, 25–35 × 10–15 mm. *Seeds* up to 10 mm long, winged on angles. *Flowering time*: (January) March to April.

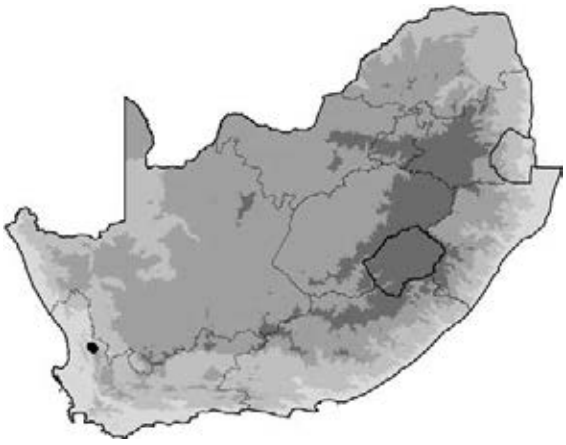
Distribution and ecology: a narrow endemic of Western Cape, South Africa, known from a few populations between Gouda and Paarl, with a single outlying collection from the southern foot of the Riviersonderend Mt near Greyton; on hard gravelly or stony slopes in open fynbos or transitional fynbos-renosterveld.

The flowers are pollinated by honeybees and long-tongued bees in the genus *Amegilla* (Apidae: Anthophorinae).



Diagnosis: distinguished from other species with similar, relatively small, pink flowers with narrow tepals, by the stiff stems, mostly 2–3 mm diam., bearing numerous dingy or brownish pink flowers from near the base of a long spike much longer than the non-flowering part of the stem, and by the conspicuously apiculate bracts that are hard and cartilaginous at flowering time. The leaves are dry and fragmented at flowering time, although the leaves from the next season may be emergent. The species can be confused with *T. dodii*, which has similar flowers but much fewer, in a short spike much shorter than the non-flowering part of the stem, and typically obtuse or acute, rarely shortly apiculate, bracts. Populations from the western lowlands have a perianth tube 6–8 mm long but the isolated population from near Greyton has a slightly longer tube 10–11 mm long and was collected in flower in January and February.

11. **Tritoniopsis latifolia** *G.J.Lewis* in Journal of South African Botany 25: 333 (1959). Type: South Africa, [Western Cape], Pakhuis Mtns, above 3 500 ft [1 067 m], *Leipoldt 3580* (BOL, holo.).

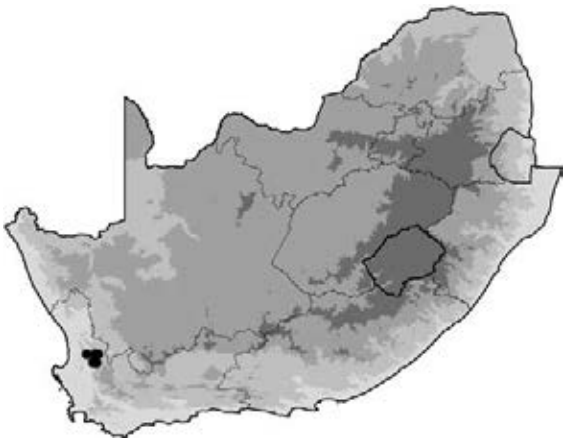


Plants 120–350 mm high. *Corm* ± 40 mm diam.; tunics of densely matted fibres, with long collar. *Stem* usually with 2 or 3 short, suberect branches, 1.5–4.0 mm diam. *Basal leaves* 4 or 5, green at flowering, in a fan with longitudinally folded, overlapping sheaths, blades lanceolate, 80–250(–40) × 8–25 mm, acuminate, with 4 to 6 veins (not narrowed to a pseudopetiole below), firm-textured; cauline leaves 2 to 4, lowermost leaf-like but much smaller, upper 2 or 3 reduced and subulate. *Spike* moderately densely or laxly ± 6- to 12-flowered, 70–120 mm long, lateral spikes up to 5-flowered; bracts dry and brown, leathery, oblong, outer 8–12 mm long, acute or apiculate, inner slightly longer. *Flowers* zygomorphic, pale or creamy pink, lower 3 tepals with red median streak or line, unscented; perianth tube narrowly funnel-shaped, 8–10 mm long; tepals unequal, dorsal slightly larger, arched over stamens, oblanceolate-spathulate, clawed in lower half, 20–25 × 3–5 mm, obtuse or truncate-emarginate, other tepals suberect, 17–20 × 3–4 mm, lower 3 tepals joined at base for 2–5 mm. *Filaments* arcuate, later suberect, 12–14 mm long; anthers 5.0–5.5 mm long, yellow, with small bifid apiculus 0.5 mm long. *Style* 20–22 mm long, dividing opposite middle of anthers, branches 2.0–2.5 mm long. *Capsules* ovoid, inflated, 20–25 × 10–15 mm. *Seeds* unknown. *Flowering time*: December to January.

Distribution and ecology: endemic to the Pakhuis Mtns and northern Cederberg north of Heuningvlei in Western Cape, South Africa; in rocky outcrops, around 800 m elevation.

Diagnosis: a short, relatively stout species with a basal fan of broad, lanceolate leaves, 8–25 mm wide with 4 to 6 veins, and shortly branched flowering stems up to

Distribution of ***Tritoniopsis elongata***.



Distribution of ***Tritoniopsis latifolia***.

350 mm tall, with pale to creamy pink flowers, the lower tepals marked with a red median streak or line, and tube 8–10 mm long. The yellow anthers are 5.0–5.5 mm long and shortly apiculate. The broad leaves with overlapping sheaths distinguish *Tritoniopsis latifolia* from others with similar pink flowers. The foliage is remarkably similar to another Cederberg endemic, *T. nemorosa*, which has taller stems a metre or more high and yellow flowers similar in shape but with a slightly shorter tube 7–8 mm long.

12. **Tritoniopsis nemorosa** *(E.Mey. ex Klatt) G.J.Lewis* in Journal of South African Botany 25: 337 (1959). *Antholyza nemorosa* E.Mey. ex Klatt: 346 (1882). *Gladiolus nemorosus* (E.Mey. ex Klatt) N.E.Br.: 27 (1928). *Hebea nemorosa* (E.Mey. ex Klatt) L.Bolus: 123 (1929). *Exohebea nemorosa* (E.Mey. ex Klatt) R.C.Foster: 38 (1939). Type: South Africa, [Western Cape], Olifants River Valley, *Drège 1578* (P, holo.).

[*Schweiggera nemorosa* E.Mey., manuscript name in herb. Drège.]

Plants 1 000–1 500 mm high. *Corm* 30–50 mm diam.; tunics of densely matted fibres, with long collar. *Stem* robust, usually with 2 or 3 short, spreading branches, 5–8 mm diam. *Basal leaves* 5 to 7, green at flowering, in a fan with longitudinally folded, overlapping sheaths, blades lanceolate, 150–350 × 9–25 mm, acuminate, with 5 to 7 veins, not narrowed to a pseudopetiole below, firm-textured; cauline leaves 3 to 5, lower 1 or 2 leaf-like but much smaller, upper 2 or 3 reduced, subulate or scale-like. *Spike* moderately densely or laxly ± 15- to 25-flowered, 250–350 mm long, lateral spikes up to 5-flowered; bracts dry and brown or greenish brown, leathery, oblong or oblong-ovate, outer 6–9 mm long, obtuse or acute, inner slightly longer. *Flowers* zygomorphic, yellow, lower 3 tepals with dark brown median lozenge-shaped streak or line, unscented; perianth tube funnel-shaped, 7–8 mm long; tepals unequal, dorsal slightly larger, arched over stamens, recurved apically, oblong-spathulate, clawed in lower half, 20–25 × 6–8 mm, obtuse or truncate, other tepals suberect and recurved distally, 18–20 × 5–6 mm, lower 3 tepals joined at base for ± 4 mm. *Filaments* arcuate, later suberect, 12–15 mm long; anthers 7–9 mm long, yellow, with bifid apiculus 1 mm long. *Style* 20–23 mm long, dividing opposite middle of anthers, branches 2.5–3.0 mm long. *Capsules* ovoid, inflated, 20–30 × 10–15 mm. *Seeds* 6–8 mm long, winged on angles. *Flowering time*: November to December.

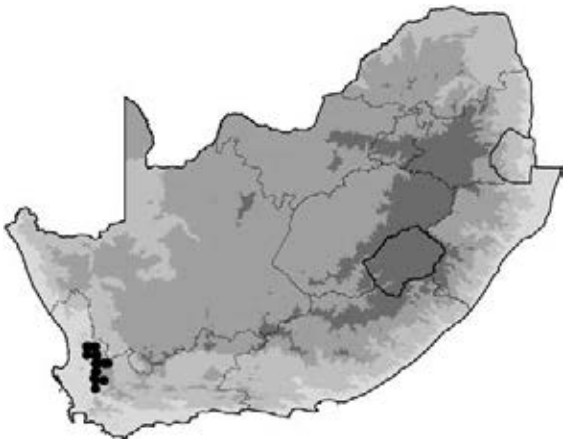
Distribution of ***Tritoniopsis nemorosa***.

Distribution and ecology: a narrow endemic of the Cederberg, between Clanwilliam and Citrusdal in Western Cape, South Africa; on rocky sandstone slopes and outcrops, from 300–700 m elevation, flowering mainly after fire.

Diagnosis: a robust species with stout, shortly branched flowering stems a metre or more tall, and a basal fan of overlapping, lanceolate leaves, 9–25 mm wide with 5 to 7 veins. The short-tubed, bright yellow flowers have the lower tepals marked with a brown median streak or line. The yellow anthers are 7–9 mm long, with a bifid apiculus ± 1 mm long. The yellow flowers with relatively short, obtuse to subacute bracts suggest a possible relationship with species in sect. *Schweiggera*, but the branched stem, lack of floral fragrance, and long anthers are anomalous there.

Sect. 3. **Schweiggera** *(E.Mey. ex Baker) G.J.Lewis* in Journal of South African Botany 23: 323 (1959). *Gladiolus* subg. *Schweiggera* E.Mey. ex Baker: 178 (1877). Type: *Tritoniopsis parviflora* (Jacq.) G.J.Lewis

Plants unbranched. *Leaves* linear to lanceolate, sometimes narrowed into linear pseudopetiole much shorter than blade; upper cauline leaves reduced to small scales; bracts usually short and obtuse. *Flowers* white or cream-coloured to yellow, sometimes flushed pink on reverse, lower tepals sometimes bicoloured with basal portion purple, fragrant. *Filaments* 3–14 mm long; anthers 3–5 mm long, shortly apiculate, yellow. *Capsules* leathery, inflated.



Species 6: Western Cape, South Africa.

A small group of species defined by the often relatively small, white or cream-coloured to yellow flowers with short, yellow anthers 3–5 mm long lacking a prominent apiculus, and always with a strong herbaceous or spicy/acrid fragrance. The upper cauline leaves are reduced to small, scale-like structures, and the floral bracts are short and acute or obtuse.

13. **Tritoniopsis nervosa** *(Baker) G.J.Lewis* in Journal of South African Botany 25: 351 (1959). *Morphixia nervosa* Baker: 237 (1876). *Tritonia nervosa* (Baker) Klatt: 358 (1882). *Ixia nervosa* (Baker) Baker: 166 (1892). *Tanaosolen nervosus* (Baker) G.J.Lewis: 55 (1941). Type: South Africa, [Western Cape], Cardouw Mtns, *Zeyher 1632* (K, holo.).

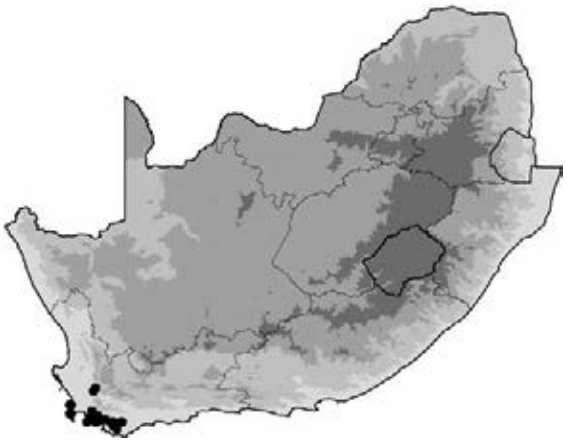
Tanaosolen nudus N.E.Br.: 262 (1932). Type: South Africa, [Western Cape], Cold Bokkeveld, Tandfontein, *R. Schlechter 10136* (K, probable holo.; BOL, G, PRE, iso.).

Plants 500–1 100 mm high. *Corm* 25–35 mm diam.; tunics of densely matted fibres, with long fibrous collar. *Stem* slender, curved outward at ground level then erect, unbranched, 2.0–3.5 mm diam. *Basal leaves* 5 or 6, dry at flowering, blade linear to narrowly lanceolate, 200–400 × 4–8 mm, acuminate, with 2 to 4 veins; cauline leaves 3 to 6, lowermost concealed among leaf bases, reddish brown, subulate, up to 70 mm long, clasping throughout, upper 1 to 3 reduced to a minute scales. *Spike* moderately densely 12- to 25-flowered, 100–300 mm long; bracts dry and brown, leathery, oblong, outer 5–9 mm long, acute to apiculate, inner slightly longer. *Flowers* weakly zygomorphic, pale yellow or creamy white, tepals sometimes flushed purplish distally and on reverse and usually purplish in sinuses at base, sweetly scented; perianth tube cylindric, 30–40 mm long; tepals subequal or dorsal slightly larger, suberect and recurved distally, upper laterals sometimes obliquely ascending, spathulate or oblong-spathulate, narrowed or clawed in basal ⅓ or ½, obtuse or truncate-emarginate, crispulate, dorsal 9–13 × 3–4 mm, others slightly shorter, lower 3 tepals united for 1–2 mm. *Filaments* subarcuate, later diverging, 5–6 mm long; anthers 4–5 mm long, yellow, with apiculus 0.5 mm long. *Style* 38–48 mm long, dividing opposite middle of anthers, branches 1–2 mm long. *Capsules* inflated, ovoid or subglobose, 15–20 × 10–15 mm. *Seeds* up to 6 mm long, winged on angles. *Flowering time*: (November) December to January (February).

Distribution of ***Tritoniopsis nervosa***.

Distribution and ecology: endemic to the mountains along the West Coast of Western Cape, South Africa, from Pakhuis through the Cederberg, Cold Bokkeveld and Olifants River Mtns to Groot Winterhoek; in rocky outcrops from 500–1 000 m elevation.

Diagnosis: a very distinctive species, 500–1 100 mm high, with relatively long spikes of creamy white to pale yellow flowers with a slender, subcylindric tube 30–40 mm long and relatively short tepals 9–13 mm long. The sweetly scented flowers are pollinated by sphinx moths. Unlike other species in the genus, in which the tepals start to gape several days before the flowers open fully, the tepals in *Tritoniopsis nervosa* remain joined at the tips until anthesis.



14. **Tritoniopsis unguicularis** *(Lam.) G.J.Lewis* in Journal of South African Botany 25: 347 (1959). *Moraea unguicularis* Lam.: 275 (1797). *Vieusseuxia unguicularis* (Lam.) Roem. & Schult.: 491 (1817). *Exohebea unguicularis* (Lam.) G.J.Lewis: 132 (1954). Type: South Africa, without precise locality, *Sonnerat s.n.* (P: Herb. Lamarck, holo.).

Gladiolus tabularis Pers.: 44 (1805), illegitimate superfluous name for *G. montanus* L.f. (1782). *Hebea tabularis* Eckl.: 43 (1827). Type: South Africa, [Western Cape], Table Mtn., without precise locality, *Thunberg s.n* (UPS: Herb. Thunberg '*Gladiolus montanus*', holo.).

Gladiolus fraternus N.E.Br.: 26 (1928). *Exohebea fraterna* (N.E.Br.) R.C.Foster: 37 (1939). Type: South Africa, [Western Cape], top of Table Mtn., *Burchell 640* (K, holo.).

Exohebea caledonensis R.C.Foster in Contributions from the Gray Herbarium of Harvard University 127: 37 (1939), new synonym. *Tritoniopsis caledonensis* (R.C.Foster) G.J.Lewis: 349 (1959). Type: South Africa, [Western Cape], near Caledon, *Hafström & Lindberg s.n.* (GH, holo.).

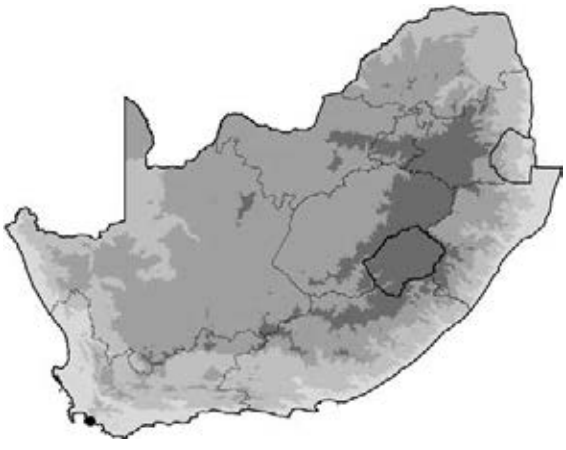
Plants (200)300–600 mm high. *Corm* 25–35 mm diam.; tunics of densely matted fibres, with fibrous collar. *Stem* slender, curved outward at ground level, unbranched, 1.5–2.0 mm diam. *Basal leaves* 3 to 9, dry at flowering, blade linear to narrowly lanceolate, 90–250 × 1–7 mm, acuminate, 1- to 3-veined; cauline leaves 2 or 3, lowermost concealed among leaf bases, reddish brown, subulate, up to 60 mm long, clasping throughout, uppermost reduced to a minute scale. *Spike* densely 7- to 20-flowered, 30–100 mm long; bracts green at base but dry and brown above, leathery, ovate, outer 4–9 mm long, obtuse, inner slightly longer. *Flowers* zygomorphic, pale yellow or creamy white flushed pink, lower 3 often flushed purple toward bases or with small maroon median streak in basal ⅓, with a herbaceous or acrid fragrance; perianth tube funnel-shaped, 3–4 mm long; tepals subequal or dorsal slightly larger, suberect and recurved distally, upper laterals sometimes obliquely ascending, spathulate

Distribution of ***Tritoniopsis unguicularis***.

or oblong-spathulate, strongly narrowed or clawed in basal ½ or ⅓, obtuse or truncate, crispulate, dorsal 10–13 × 2.5–3.0 mm, others slightly shorter, lower 3 tepals joined for 1.5–2.0 mm. *Filaments* arcuate, later erect, (3–)4–7 mm long; anthers 3–5 mm long, yellow, with short apiculus 0.5 mm long. *Style* 8–9 mm long, dividing opposite anther bases, branches 1 mm long. *Capsules* inflated, ovoid or subglobose, 15–20 × 10–20 mm. *Seeds* up to 8 mm long, winged on angles. *Chromosome number* 2*n* = 32. *Flowering time*: November to January (March).

Distribution and ecology: scattered along the coastal mountains of Western Cape, South Africa, and recorded from the Elandskloof Mtns near Tulbagh, the Cape Peninsula, the Hottentots Holland–Kogelberg–Groenlandberg complex, and Bredasdorp Mtn; on rocky sandstone outcrops from 500–1 000 m elevation.

The flowers are pollinated by long-tongued bees in the genus *Amegilla* (Apidae: Anthophorinae).



Diagnosis: distinguished by its small, short-tubed, pale yellow to creamy white flowers, sometimes flushed pinkish, with tepals 9–13 mm long and short filaments (3–)4–7 mm long. The capsules are moderately to well inflated, 15–20 mm long. The smaller flowers separate *Tritoniopsis unguicularis* from species such as *T. bicolor* and *T. flava*, also with yellow flowers and small anthers up to 5 mm long.

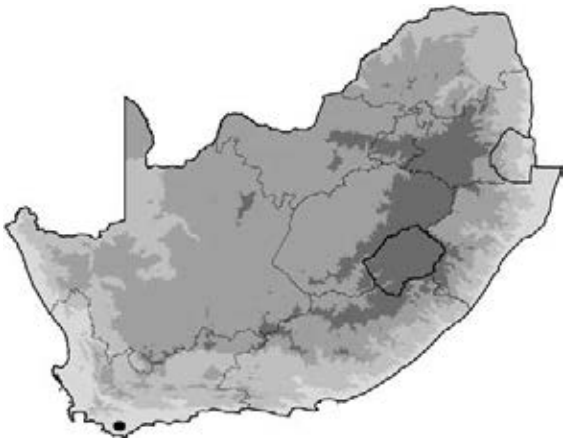
The typical form of *Tritoniopsis unguicularis*, as represented by populations on the Cape Peninsula, has leaves 2–7 mm wide with (1)2 or 3 veins, and cream-coloured or white flowers with filaments 6–7 mm long. Populations from the Groenland Mtns with linear, 1-veined leaves up to 2 mm wide and yellow flowers with short filaments 3–5 mm long have been treated as the separate species *T. caledonensis* until now (Lewis, 1959), but these distinctions do not hold elsewhere, and a range of intermediates has been recorded from the Kogelberg and Bredasdorp. This has been compounded by later collections of yellow-flowered plants with narrowly lanceolate leaves from the Elandskloof Mtns, and we adopt a broader view of the species here to include these populations.

Hybrids with *Tritoniopsis parviflora* have been recorded on the Elandskloof Mtns near Tulbagh and with *T. bicolor* on Bredasdorp Mtn.

15. **Tritoniopsis flava** *J.C.Manning & Goldblatt* in Bothalia 31: 178 (2001). Type: South Africa, Western Cape, Kogelberg State Forest, along footpath and next to stream, 10 Dec. 1991, *I. Kruger* (NBG, holo.).

Plants 300–600 mm high. *Corm* 20–35 mm diam.; tunics of densely matted fibres, with short collar. *Stem* robust, curved outward at ground level, unbranched, 4–5 mm diam. *Basal leaves* 6 or 7, green at flowering, blade narrowly lanceolate, 130–190 × (3–)5–8 mm, acuminate, 2- or 3-veined, narrowed into flattened pseudopetiole below; cauline leaves 2 or 3, lowermost concealed among leaf bases, reddish brown, lanceolate, up to 60 mm long, clasping throughout, upper 1 or 2 reduced to minute scales. *Spike* densely ± 18- to 25-flowered, 150–180 mm long; bracts green at base, dry and brown above, leathery, ovate, outer 6–9 mm long, obtuse, inner slightly longer. *Flowers* zygomorphic, yellow with lower 3 tepals paler or flushed purple toward base and with small maroon median streak in basal ⅓, with a herbaceous or acrid fragrance; perianth tube funnel-shaped, slightly curved, 4–5 mm long; tepals unequal, crispulate, dorsal slightly larger, arched over stamens, oblanceolate, strongly narrowed in lower ⅓, 15–16 × 6 mm, obtuse, other tepals suberect and recurved distally, upper laterals obovate-spathulate, abruptly clawed in basal half, 13–14 × 5–6 mm, obtuse, lower 3 tepals joined below for ± 2.5 mm, obovate-pandurate, ± 12 × 5–6 mm, truncate, claws 1–2 mm long. *Filaments* arcuate, later diverging, ± 10 mm long; anthers 4–5 mm long, yellow, with apiculus 0.5–0.8 mm long. *Style* ± 9 mm long, dividing opposite anther bases, branches 1 mm long. *Capsules* and *seeds* unknown. *Flowering time*: December.

Distribution of ***Tritoniopsis flava***.



Distribution and biology: a highly local endemic from the lower Palmiet River Valley near Kleinmond, Western Cape, South Africa; along streams in humic, seasonally damp soils, at ± 100 m elevation. The riparian vegetation regenerates rapidly and within a few years the plants are smothered; flowering only after fire.

Diagnosis: recognised by its relatively large, bright yellow flowers with the lower tepals not heavily bicoloured with purple, and shortly joined at the base without forming a well-defined lower lip. The perianth tube is short, 4–5 mm long, and the filaments are ± 10 mm long with anthers 4–5 mm long. The leaves are subpetiolate below with a narrowly lanceolate blade mostly 4–8 mm wide, with 2 or 3 veins. The fruits are unknown.

Tritoniopsis flava is most likely to be confused with *T. bicolor* from the Bredasdorp Mtns but that species has strongly bicoloured flowers, narrower tepals 3–4 mm wide, and shorter filaments 6–7 mm long, papillate at the base and in the mouth of the tube.

16. **Tritoniopsis bicolor** *J.C.Manning & Goldblatt* in Bothalia 31: 175 (2001). Type: South Africa, Western Cape, western end of Bredasdorp Mtn., plateau west of Grootkop and Normanskop, 6 Dec. 2000, *Manning 2286* (NBG, holo.; NBG, K, MO, PRE, iso.).

Plants 200–400(–600) mm high. *Corm* 20–30 mm diam.; tunics of densely matted brown fibres, with well-developed collar. *Stem* moderately slender to robust, curved outward at ground level, then suberect or weakly inclined, unbranched, 2.5–4.0 mm diam. *Basal leaves* (4)5 to 7, green at flowering or outermost drying, blades narrowly lanceolate, acuminate, with 1 or 2(3) veins, (85–)100–150 × (5–)6–10 mm, contracted abruptly into semiterete pseudopetiole 30–35 mm long; cauline leaves 1 or 2, lowermost concealed by corm fibres, scale-like. *Spike* densely 20- to 35-flowered, 80–100(–150) mm long; bracts green at base, dry and brown above, leathery, oblong, outer 7–10 mm long, obtuse or acute, inner slightly longer. *Flowers* zygomorphic, yellow with lower 3 tepals flushed maroon in basal half and with darker median streak, strongly acrid or musty scented; perianth tube 2–5 mm long; tepals unequal, dorsal slightly larger, suberect and recurved distally, crisped or undulate, base of lower tepals and mouth of tube minutely papillate, dorsal tepal narrowly oblanceolate, 14–16 × 3–4 mm, obtuse, upper laterals oblanceolate- to obovate-spathulate, 9–13 × 2–4 mm, obtuse, strongly clawed in basal 2–4 mm, lower 3 tepals joined for 1.0–1.5 mm, oblong-spathulate, 9–10 × 2.0–4.5 mm, truncate, with or without short claw up to 1.5 mm long. *Filaments* arcuate, later erect, 6–7 mm long, base of median filament minutely papillate; anthers 3 mm long, yellow, with short apiculus 0.5 mm long. *Style* ± 9 mm long, dividing opposite anther bases, branches 1.0–1.5 mm long. *Capsules* much inflated, ovoid to broadly ellipsoid, 23–28 × 15–20 mm. *Seeds* 10–12 × 10 mm, winged on angles. *Flowering time*: November to December.

Distribution of ***Tritoniopsis bicolor***.

Distribution and ecology: a highly local endemic from the summit plateau of the Bredasdorp Mtns, Western Cape, South Africa; on seasonally waterlogged flats at 400–500 m elevation, in deep, humus-enriched sands, flowering only after fire.

The flowers are pollinated by the solitary bee *Amegilla spilostoma* (Apidae: Anthophorinae).

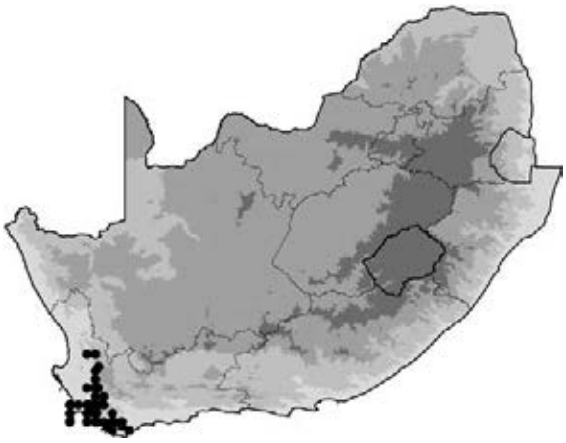
Diagnosis: *Tritoniopsis bicolor* is recognised by its moderately-sized, bright yellow flowers with the bicoloured lower tepals maroon in the lower third and joined at the base for up to 1.5 mm without forming a well-defined lower lip. The perianth tube is short, 2–5 mm long, and the filaments are 6–7 mm long, with the base of the tepals and mouth of the tube minutely papillate. The leaves are conspicuously petiolate with a narrowly lanceolate blade 6–10 mm wide, with 1 or 2(3) veins, and the capsules are conspicuously inflated. It is most likely to be confused with *T. parviflora*, with which it co-occurs and which has similar, balloon-like fruits, but linear or linear-lanceolate leaves, 2–5 mm wide, and more prominently bilabiate flowers with the lower tepals joined together in a distinct palate 3–4 mm long, and with much longer filaments, 12–14 mm long, arching well over the lower lip. Occasional hybrids with *T. unguicularis* have been recorded

17. **Tritoniopsis parviflora** *(Jacq.) G.J.Lewis* in Journal of South African Botany 25: 340 (1959). *Gladiolus parviflorus* Jacq.: 2, t. 78 (1771). *Hebea parviflora* (Jacq.) L.Bolus: 123 (1929). *Exohebea parviflora* (Jacq.) R.C.Foster: 38 (1939). Type: South Africa, without precise locality or collector, illustration in Jacq.: 2, t. 78 (1771).

Gladiolus montanus L.f.: 95 (1782). *Antholyza montana* (L.f.) Ker Gawl.: 233 (1804) [as *A. montana* Thunb.). Type: South Africa, without precise locality, *Sparrman 162* [LINN59.24, lecto., designated by Lewis: 342 (1959)].

Gladiolus arenarius Baker: 178 (1877), as replacement name for *Hebea orchidiflora* Eckl.: 43 (1827)

[not *G. orchidiflorus* Andrews]. *Hebea arenaria* (Baker) L.Bolus: 123 (1929). Type: none cited in protologue but at least *Ecklon & Zeyher 71* and *72* and *Drège s.n.* '*Schweiggera montana* E.Mey.' are potential syntypes.



Hebea angusta L.Bolus: 106 (1930), new synonym. *Exohebea angusta* (L.Bolus) R.C.Foster: 36 (1939). *Tritoniopsis parviflora* var. *angusta* (L.Bolus) G. J.Lewis: 343 (1959). Type: South Africa, [Western Cape], foot of the mountains near Ceres, *H. Bolus 7455* (BOL, holo.).

[*Schweiggera montana* E.Mey. ex Baker: 178 (1877), invalid name only in synonymy of *Gladiolus arenarius* Baker (1877).]

[*Gladiolus scorpius* L. ex B.D.Jacks., Index Linn. Herb. 80 (1912), invalid name only in synonymy of *Gladiolus montanus* ?L.f.]

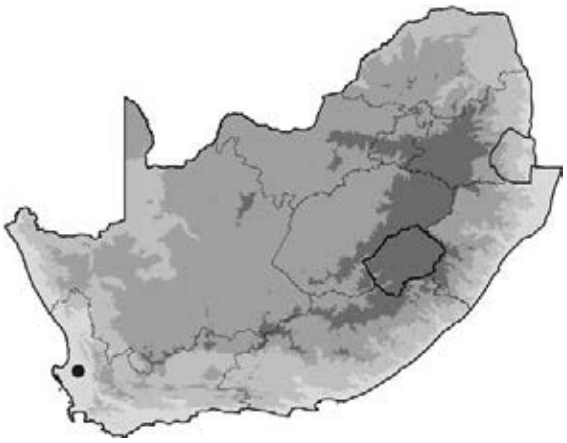
Plants 150–400 mm high. *Corm* 20–30 mm diam.; tunics of densely matted brown fibres, with well-developed collar. *Stem* moderately slender, curved outward at ground level and then erect, unbranched, 1.5–3.0 mm diam. *Basal leaves* 5 to 7, green at flowering or drying, blade linear, acuminate, with 1(2) veins, 80–220 × 2–5 mm, contracted into semiterete pseudopetiole usually, extending shortly above ground; cauline leaves 2 or 3, lowermost concealed by tunic fibres, subulate, upper 1 or 2 minute and scale-like. *Spike* densely 8- to 22-flowered, 30–120 mm long; bracts green at base but dry and brown above, leathery, ovate to oblong, outer 5–8 mm long, obtuse or acute, inner slightly longer. *Flowers* zygomorphic, yellow with tube and three lower tepals flushed maroon or purple in basal half and with the apex yellow but soon turning brown, strongly acrid or musty scented; perianth tube 3–4 mm long; tepals unequal, dorsal larger, arching over stamens and recurved apically, crisped or undulate, base of lower tepals and mouth of tube minutely papillate, dorsal tepal spathulate-oblanceolate, 14–17 × (3–)4–6 mm, obtuse, clawed in basal half, upper laterals oblanceolate- to obovate-spathulate, 10–14 × (2–)3–5 mm, obtuse, strongly clawed in basal half, connate with lower tepals for up to 1 mm and then curved back and up toward dorsal, three lower tepals fused to one another for 3–4 mm forming a lip, oblong-spathulate or panduriform, 10–13 × 3–4 mm, truncate, with short claws 2–3 mm long. *Filaments* arcuate, later diverging, 12–14 mm long, base of median filament minutely papillate; anthers yellow, 3–4 mm long with short or obsolete apiculus up to 0.5 mm long. *Style* ± 15 mm long, dividing opposite anther bases, branches ± 1 mm long. *Capsules* much inflated, ovoid to subglobose, 24–34 × 15–25 mm. *Seeds* 9–10 mm long, winged on angles. *Chromosome number* 2*n* = 32. *Flowering time*: November to January (early February).

Distribution and ecology: relatively widely distributed along the southwestern coastal mountains of Western Cape, South Africa, from the Cold Bokkeveld to the Peninsula and east to Bredasdorp; on rocky sandstone slopes and flats, from 200–1 000 m elevation, flowering only after fire

Distribution of ***Tritoniopsis parviflora***.

This is the only African Iridaceae known to secrete floral oils, and populations on the Kogelberg are pollinated mainly by the large oil-collecting bee *Rediviva gigas* (Melittidae), which collects the oils from the base of the tepals (Manning & Goldblatt, 2002). This bee has a limited distribution, however, and over most of its range *Tritoniopsis parviflora* is pollinated by nectar-feeding bees in the genus *Amegilla* (Apidae: Anthophorinae).

Hybrids have been recorded with *T. dodii* (G.J.Lewis) G.J.Lewis at Hermanus and with *T. unguicularis* (Lam.) G.J.Lewis on the Elandskloof Mtns above Tulbagh Waterfall.



Diagnosis: recognised by its moderately sized, yellow flowers with bicoloured lower tepals flushed maroon or purple in the lower third and joined at the base for 3–4 mm to form a well-defined lower lip. The perianth tube is short, 3–4 mm long but the filaments are relatively long, 12–14 mm long and strongly arched. The base of the tepals and mouth of the tube are minutely papillate. The leaves are characteristically narrow and linear, 2–5 mm wide, with 1 or rarely 2 veins, and the capsules are conspicuously inflated.

Tritoniopsis parviflora is most likely to be confused with *T. bicolor*, with which it co-occurs on Bredasdorp Mountain and which has similar, balloon-like fruits, but that species has narrowly lanceolate leaves, 6–10 mm wide, with 1 or 2(3) veins, and flowers with the lower tepals joined together only at the base without forming a distinct palate, and much shorter filaments, 6–7 mm long. The closely allied Piketberg endemic, *T. cinnamomea* J.C.Manning & Goldblatt, is distinguished by its creamy white flowers flushed dark brownish pink, with a linear dorsal tepal 2.0–2.5 mm wide and upper lateral tepals ± 1.5 mm wide, lower tepals shortly joined at the base for up to 2 mm without forming a distinct palate, slightly longer filaments 15–16 mm long, and much smaller capsules 8–12 mm long.

Plants with narrower lateral and lower tepals 2–3 mm wide, mainly from the Cold Bokkeveld, were treated as var. *angusta* (L.Bolus) G.J.Lewis (1959) but grade imperceptibly into typical forms and cannot be maintained as taxonomically distinct.

18. **Tritoniopsis cinnamomea** *J.C.Manning & Goldblatt* in Manning et al. in South African Journal of Botany 102 (online): 128 (2015 [hardcopy 2016]). Type: South Africa, Western Cape, Piketberg, plateau at SW foot of Zebrakop, 24 Dec. 2014, *J.C.Manning 3489* (NBG, holo.; MO, iso.).

Plants 200–300 mm high. *Corm* globose, ± 20 mm diam.; tunics of densely matted brown fibres, with well-developed collar. *Stem* moderately slender, curved outward at ground level and then erect, unbranched, 1.0–1.5 mm diam. *Basal leaves* 3 or 4, green at flowering or outermost drying, blade linear to linear-lanceolate, acute, with 1 vein, 90–150 × 1–4 mm, contracted gradually into semiterete pseudopetiole 60–80 mm long; cauline leaves 3, lowermost concealed by corm collar, linear-conduplicate, ± 20 mm long, uppermost minute and scale like. *Spike* moderately densely 5- to 15-flowered, 60–120 mm long; bracts green at base but dry and brown above, leathery, oblong, outer bracts 5–6 mm long, acute, inner slightly longer, obtuse. *Flowers* zygomorphic, creamy white with apices of all tepals and outer surface of midline flushed dark brownish pink, acrid scented; perianth tube 3–4 mm long; tepals unequal, dorsal slightly larger, arching over stamens, crisped or undulate, base of lower tepals and mouth of tube minutely papillate, dorsal tepal linear, acute, 17–18 × 2.0–2.5 mm, upper laterals spreading horizontally, strongly clawed and recurved above, 10–12 × ± 1.5 mm, claw involute, 3–5 mm long, blade narrowly oblanceolate, acute, lower 3 tepals fused to one another for ± 2 mm, with short, involute claws up to 3 mm long, 13–15 × 2–3 mm. *Filaments* arcuate but later erect, 15–16 mm long, base of median filament minutely papillate; anthers yellow flushed reddish, 3 mm long with short apiculus 0.5 mm long. *Style* ± 20 mm long, dividing opposite anther bases, branches 0.5–1.0 mm long. *Capsules* much inflated, ovoid to subglobose, 8–12 × 8–15 mm. *Seeds* 4–5 mm long, winged on angles. *Flowering time*: December.

Distribution of ***Tritoniopsis cinnamomea***.

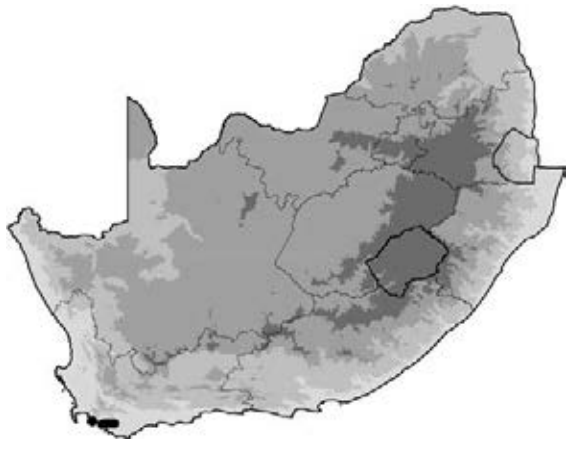
Distribution and ecology: a narrow endemic known only from the Piketberg in Western Cape, South Africa; on a seasonally wet plateau among low restios.

Diagnosis: a recently discovered species evidently closely allied to *Tritoniopsis parviflora* but distinguished from it by the creamy white flowers with the apices and outer surface of the tepals flushed dark brownish pink. The tepals are linear, the dorsal 2.0–2.5 mm wide and the upper laterals ± 1.5 mm wide, and the filaments are relatively long, 15–16 mm long. *Tritoniopsis parviflora*, which does not occur on the Piketberg, has yellow flowers with the tube and three lower tepals flushed maroon or purple in basal half and wider tepals, the dorsal tepal spathulate-oblanceolate, 3–6 mm wide, and the upper laterals 2–5 mm wide, and slightly shorter filaments 12–14 mm long; and larger capsules, 24–43 mm long.

Sect. 4. **Anapalina** *(N.E.Br.) Goldblatt* in South African Journal of Botany 56: 580 (1990). *Anapalina* N.E.Br.: 274 (1932). Type: *Tritoniopsis antholyza* (Lamarck) Goldblatt

Plants usually unbranched, rarely with one short branch. *Leaves* linear to lanceolate, sometimes narrowed and subpetiolate below; lower cauline leaves leaflike, upper reduced and bract-like or scale-like. *Flowers* usually scarlet, rarely carmine or pinkish red to purple, unscented; perianth tube long, sharply bent or geniculate, 20–40 mm long, dimorphic, with slender, suberect lower portion inflated at knee into a horizontal, cylindric portion. *Filaments* 20–45 mm long; anthers 6–9 mm long, obtuse or acute to conspicuously apiculate, yellow or red to purple. *Capsules* leathery, scarcely to strongly inflated.

Species 5: Western and Eastern Cape, South Africa.



The section comprises all except one (*Tritoniopsis triticea*) of the species with flowers adapted for pollination by sunbirds, thus shades of red or rarely carmine with a well-developed, dimorphic perianth tube that is sharply bent near the middle, with a slender, suberect lower portion widening ± abruptly into a horizontal, cylindric upper portion. The filaments are inserted at the knee bend and thus relatively long, 20–40 mm long. The species appear to fall into three groups: *T. pulchra* and *T. williamsiana* with narrow, subpetiolate leaves and purple anthers with a well-developed apiculus; *T. antholyza* with a basal fan of broad leaves, subacute anthers, and strongly inflated capsules; and *T. caffra* and *T. intermedia* with markedly bilabiate flowers with the dorsal tepal ± twice as long as the others, and obtuse,

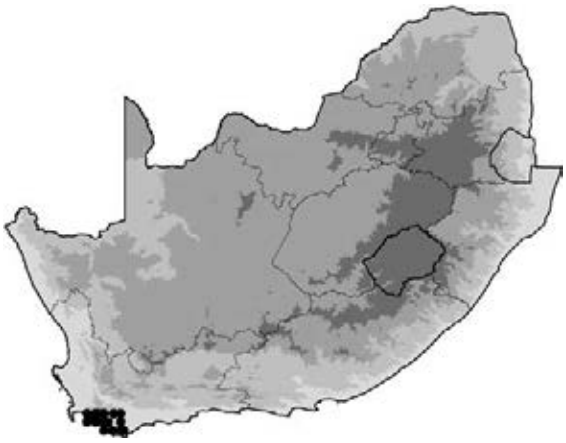
yellow anthers. It is possible that the three groups are not immediately related.

19. **Tritoniopsis williamsiana** *Goldblatt* in South African Journal of Botany 56: 580 (1990). Type: South Africa, [Western Cape], Hermanus, Vogelgat Nature Reserve, marsh after fire, 30 Jan. 1987, *P. Goldblatt 8471* (NBG, holo.; K, MO, PRE, iso.).

Plants 400–800 mm high. *Corm* 12–20 mm diam.; tunics of soft, fine fibres or papery, without a collar. *Stem* flexed outward at ground level then erect, unbranched or rarely with one short branch, 3–4 mm diam. *Basal leaves* 3 or 4, green at flowering, reaching less than halfway to base of spike, blade linear-lanceolate, 120–250 × 5–8 mm, acute or acuminate, narrowed and subpetiolate below, with 2 or 3 veins; cauline leaves 2 or 3, lower 1 or 2 like basal but smaller, upper 1 or 2 scale-like. *Spike* moderately densely ± 12- to 20(40)-flowered, 120–200(–300) mm long; bracts dark brown, dry and leathery, lanceolate, outer 12–15 mm long, acute or acuminate, inner slightly longer. *Flowers* red, lower 3 tepals darker in midline, unscented; perianth tube dimorphic, sharply bent, 24–28 mm long, slender in lower 12–15 mm, widening obliquely at bend into cylindric upper part ± 12 mm long; tepals unequal, dorsal tepal largest, horizontal at first later reflexed, oblanceolate, ± 20 × 6 mm, obtuse, other tepals spreading but later reflexed, oblanceolate-elliptic, obtuse or acute, upper lateral tepals 13–15 × 4 mm, adnate to dorsal tepal for ± 2 mm, lower 3 tepals joined for ± 2 mm, subequal or lower slightly shorter, 15–18 × 4 mm. *Filaments* inserted obliquely at base of upper part of tube, arcuate, later diverging, ± 28 mm long; anthers 6 mm long, purple or red, with bifid apiculus 1 mm long. *Style* 40–45 mm long, dividing opposite lower half of anthers, branches 2 mm long, sometimes bifid. *Capsules* obovoid, slightly inflated, 7–10 × 6–9 mm, rugose-verrucose. *Seeds* ± 5 mm long, winged at opposite ends. *Chromosome number* $2n = \pm 32$ (or 30). *Flowering time*: January to February.

Distribution and ecology: a poorly collected local endemic of the southwestern coastal mountains of Western Cape, South Africa, originally known only from Vogelgat Nature Reserve on the Kleinrivier Mtns near Hermanus but now also from the northern foot of the Dwarsrivierberg just west of Kogelberg; in marshes and seeps at 300–450 m elevation, flowering only after fire.

Distribution of ***Tritoniopsis williamsiana***.



The species is adapted to pollination by sunbirds, including the Orange-breasted Sunbird.

Diagnosis: recognised by its soft corm tunics without a collar and narrow, linear-lanceolate leaves, 5–7 mm wide with 2 or 3 veins, and long-tubed red flowers with oblanceolate tepals. The capsules are unique for the genus, relatively small and only slightly inflated, 7–10 × 6–9 mm, with conspicuously wrinkled-warty walls. Similarly wrinkled-warty but larger capsules are otherwise known only in *Tritoniopsis pulchella*. The seeds are winged only at the apex and base, unlike the tetrahedral seeds winged on the angles that are typical of the genus. Similar two-winged seeds are also found in the two species of sect. *Aristatae*, which likewise have small capsules but with smooth, woody walls.

Tritoniopsis williamsiana co-occurs with both *T. antholyza* and *T. pulchra* and has a general resemblance to both. It is distinguished from the former by its narrow leaves and soft corm tunics, and from the latter by its narrower, oblanceolate tepals, the dorsal ± 20 × 6 mm vs. 15–19 × 8–10 mm, and by its longer filaments ± 28 mm long vs. 20–23 mm long.

20. **Tritoniopsis pulchra** *(Schltr. ex Baker) Goldblatt* in South African Journal of Botany 56: 580 (1990). *Antholyza pulchra* Schltr. ex Baker: 531 (1897). *Homoglossum pulchrum* Schltr.: 453 (1897), superfluous name based on same type. *Anapalina pulchra* (Schltr. ex Baker) N.E.Br.: 275 (1932). Type: South Africa, [Western Cape], Bredasdorp, near Elim, 500 ft [150 m], *R. Schlechter 7611* (K, lecto., designated by Lewis: 59 (1960); PRE, S, WAG, isolecto.).

Plants 250–500 mm high. *Corm* 20–30 mm diam.; tunics of moderately coarse fibres or papery, with a short collar. *Stem* flexed outward at ground level then erect, unbranched or rarely with one short branch, 1.5–3.0 mm diam. *Basal leaves* 3 to 5, dry at flowering, blades linear to linear-lanceolate, 150–300 × 3–6(–10) mm, acute or acuminate, narrowed and petiolate below, 2- or 3-veined; cauline leaves 3–5, lower 1 to 3 subulate, upper 1 or 2 reduced or scale-like. *Spike* moderately densely ± 7- to 20-flowered, 50–150 mm long; bracts brown or reddish, dry and leathery or softer, oblong-lanceolate, outer 8–12 mm long, acute or acuminate, inner slightly longer. *Flowers* carmine to dark red or purplish, lower 3 tepals with darker midline between white bands, unscented; perianth tube dimorphic, sharply bent, 25–30 mm long, slender in lower 10–15 mm, widening at bend into cylindric upper part ± 15 mm long; tepals unequal, all suberect to spreading and later reflexed, arising at same level or upper lateral tepals adnate

Distribution of ***Tritoniopsis pulchra***.

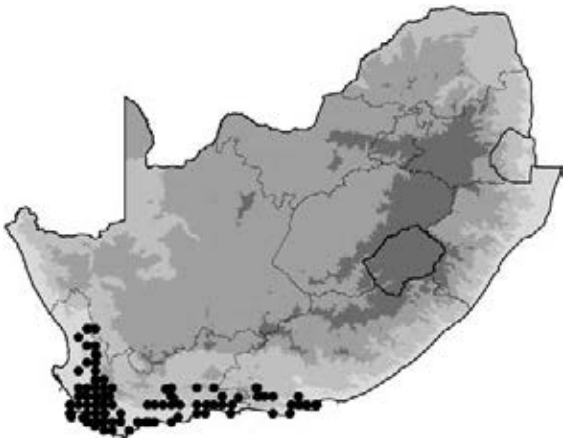
to dorsal for up to 1 mm, ovate or oblong to obovate-oblong, obtuse to truncate, very shortly clawed, dorsal tepal largest, 15–19 × 8–10 mm, others subequal, 12–15 × 7–9 mm. *Filaments* arcuate, later recurved, 20–23 mm long; anthers 6–7 mm long, purple or red, with bifid apiculus 1.0–1.5 mm long. *Style* 30–40 mm long, dividing opposite lower half of anthers, branches 2–3 mm long, sometimes bifid. *Capsules* ellipsoid, inflated, 16 mm long. *Seeds* 2–3 mm long, shortly winged on angles. *Flowering time*: February to June.

Distribution and ecology: restricted to the extreme south-western mountains of Western Cape, South Africa, from the Du Toit's Kloof, Hottentots Holland and Kogelberg onto the Riviersonderend and Kleinrivier Mountains east to Pearly Beach near Elim, with an outlying collection from the eastern end of the Langeberg; on cooler sandstone slopes up to 1 000 m elevation.

Diagnosis: recognised among species with similarly shaped, red flowers by its characteristic carmine to deep pinkish red or purple perianth with broad, oblong to obovate tepals arising ± at the same level, the dorsal 8–10 mm wide, and its relatively short filaments, 20–23 mm long and only shortly exserted from the tube, with apiculate, purple anthers. *Tritoniopsis williamsiana* from the Kleinrivier Mtns has similar flowers with purple anthers but the perianth is scarlet and the tepals are narrower and oblanceolate, the dorsal ± 6 mm wide, and filaments ± 28 mm long, and the capsules are unusually short and warty.

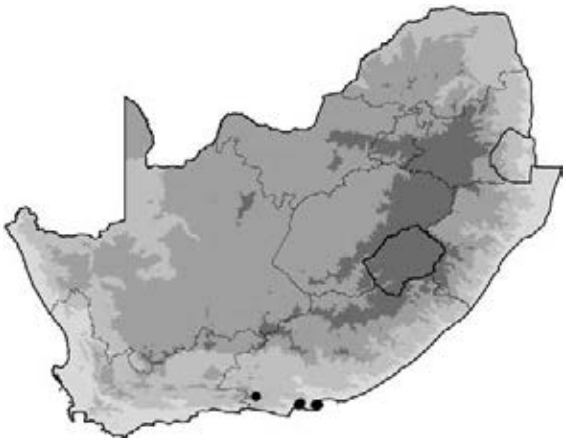
21. **Tritoniopsis antholyza** *(Poir.) Goldblatt* in South African Journal of Botany 57: 226 (1991). *Gladiolus antholyza* Poir. in Lam.: 795 (1812), as replacement name for *Antholyza nervosa* Thunb.: 7 (1794) [not *G. nervosus* Lam. (1788)]. *G. nervosus* (Thunb.) Baker: 228 (1892), illegitimate homonym, not *G. nervosus* Lam. (1788). *Anapalina nervosa* (Thunb.) G.J.Lewis: 63 (1960). *T. nervosa* (Thunb.) Goldblatt: 580 (1990), illegitimate homonym, not *T. nervosa* (Baker) G.J.Lewis (1959). Type: South Africa, without precise locality, *Thunberg s.n.* (UPS-THUNB, holo).

Antholyza spicata Brehm ex Klatt: 345 (1882), illegitimate homonym, not *A. spicata* Mill. (1768). Type: South Africa, [Western Cape], Du Toit's Kloof, *Drège 1576* (B: Herb. Lubeck, holo.; P, possible iso. [as 'Paarlberg']).



Anapalina longituba Fourc.: 76 (1932). *Tritoniopsis longituba* (Fourc.) Goldblatt: 580 (1990). Type: South Africa, [Western Cape], Prince Alfred's Pass, 2 900 ft [890 m], *Fourcade 2063* (BOL, holo.).

Plants 250–600 mm high. *Corm* 30–60 mm diam.; tunics of coarse fibres, with a long collar. *Stem* flexed outward at ground level then erect, unbranched or with 1, rarely 2 short branches, 3–6 mm diam. *Basal leaves* 3 to 6, in a fan with longitudinally folded, overlapping sheaths, green or drying at flowering, blades lanceolate, 150–400 × 8–20 mm, acute or acuminate, not subpetiolate below, with 3 to 5(6) veins; cauline leaves 3 to 5, lower 1 or 2 lanceolate or subulate, rarely up to 100 mm long, upper 1 to 3 reduced, bract- or scale-like. *Spike* moderately to densely ± 7- to 40-flowered, 50–200 mm long; bracts brown or reddish, dry and leathery, ovate or ovate-lanceolate, outer 8–15 mm long, acute or acuminate, inner slightly longer. *Flowers* usually dull pink or pinkish red, rarely bright red, the tube often yellowish, lower tepals often with dark median line between white bands, unscented; perianth tube dimorphic, sharply bent, 25–40 mm long, slender in lower 8–25 mm, widening at bend into cylindric upper part, lower part much shorter to ± as long as upper part; tepals unequal, all suberect to spreading, later reflexed, arising at same level or lower arising progressively up to 5 mm beyond upper, all narrowly spathulate to oblanceolate-spathulate, obtuse, narrowed or clawed in lower half, dorsal tepal largest, 22–30 × 4–7 mm, others subequal or upper lateral slightly smaller, (12–)15–24 × 3–5 mm. *Filaments* arcuate, later recurved, 30–40 mm long; anthers 5–8 mm long, yellow, subacute or shortly apiculate with apiculus up to 1.5 mm long. *Style* 45–60 mm long, dividing opposite lower half of anthers, branches 3–4 mm long, often bifid. *Capsules* ellipsoid to subglobose, usually strongly inflated, 20–40 × 15–20 mm. *Seeds* 4–6 mm long, shortly winged on angles. *Chromosome number* 2*n* = 34. *Flowering time*: October to March.



Distribution and ecology: common and widespread through the mountains of the Western and Eastern Cape, South Africa, from the Bokkeveld Escarpment to the Cape Peninsula and along the Swartberg and southern coastal ranges to Port Elizabeth; on stony and rocky slopes and flats from near sea level to over 1 000 m elevation.

The species is primarily adapted to pollination by sunbirds, but later-flowering forms with a pinkish perianth and longer tubes are probably also visited by long-proboscid flies.

Diagnosis: the most common species in the genus, recognised by the basal fan of lanceolate leaves, 8–20 mm

Distribution of ***Tritoniopsis antholyza***.

Distribution of ***Tritoniopsis intermedia***.

wide, and the yellowish or pinkish to red flowers with dimorphic perianth tube 25–40 mm long, and narrowly spathulate to oblanceolate-spathulate tepals, the dorsal 22–30 × 4–7 mm, and arising either at the same level as the other tepals or below them. The capsules are somewhat to markedly inflated.

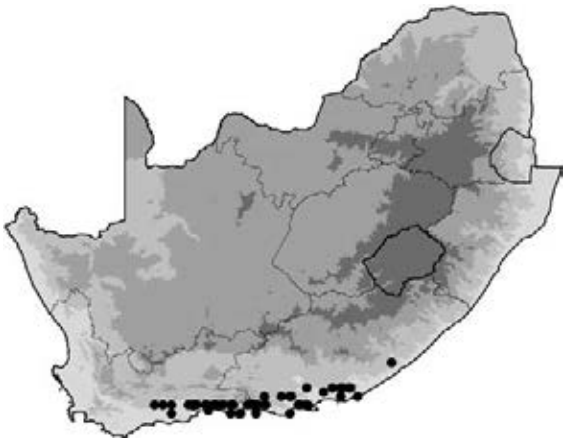
22. **Tritoniopsis intermedia** *(Baker) Goldblatt* in South African Journal of Botany 56: 580 (1990). *Antholyza intermedia* Baker: 230 (1892). *Chasmanthe intermedia* (Baker) N.E.Br.: 273 (1932). *Petamenes intermedia* (Baker) E.Phillips: 44 (1941). *Anapalina intermedia* (Baker) G.J.Lewis: 66 (1960). Type: South Africa, [Eastern Cape], Port Elizabeth, Van Stadenshoogte, *MacOwan 2070* (K, holo.).

[*Antholyza intermedia* Baker: 180 (1877), invalid name without description.]

[*Antholyza caffra* Ker Gawl. in Herb. Banks m.s.]

Plants 300–450 mm high. *Corm* 30–40 mm diam.; tunics of moderately coarse fibres, with short or long collar. *Stem* erect or flexed outward basally, unbranched, 3–4 mm diam. *Basal leaves* 3 to 7, green at flowering, in a fan, reaching ± halfway to base of spike, blades lanceolate, 100–150 × 7–15 mm, acute or acuminate, not narrowed and subpetiolate below, with 3 or 4 veins; cauline leaves 2 or 3, lower 1 or 2 like basal but smaller, upper 1 or 2 reduced and subulate, 15–50 mm long. *Spike* moderately densely ± 10- to 25-flowered, 150–240 mm long, secund; bracts flushed red or purplish, softly leathery or submembranous, lanceolate, outer 9–15 mm long, acute or acuminate, inner slightly longer. *Flowers* red with paler tube and conspicuous black or purple blotch in sinuses between all tepals, especially lower 3, unscented; perianth tube dimorphic, sharply bent, 25–30 mm long, slender in lower 5–8 mm, widening at bend into cylindric upper part ± 20 mm long, with ventral pouch at base; tepals unequal, arising obliquely, lower lateral tepals joined to upper laterals for ± 2 mm and upper laterals joined to the dorsal for an additional 3–5 mm, dorsal tepal largest, horizontal, oblanceolate-spathulate, clawed in lower half, 25–30 × 7–8 mm, obtuse, lower tepals spreading but later reflexed, elliptic to oblong, shortly clawed, subequal or lower slightly shorter, 12–18 × 4–6 mm. *Filaments* arcuate but later recurved, 40–45 mm long; anthers 7–9 mm long, yellow flushed red, obtuse, almost medifixed. *Style* 50–60 mm long, dividing opposite upper half of anthers, branches 3–4 mm long, oblanceolate-conduplicate. *Capsules* and *seeds* unknown. *Flowering time*: September to December.

Distribution and ecology: a local endemic of Eastern Cape, South Africa, from the Kouga, Baviaanskloof, Groot Winterhoek and Van Stadens River Mtns to Port Elizabeth; in sandy and loamy soil on rocky sandstone slopes.



The flowers are clearly adapted to pollination by sunbirds, but no observations have been recorded.

Diagnosis: resembling *Tritoniopsis caffra* in its strongly bilabiate flowers with large, spathulate upper tepal but distinguished from it by the basal fan of shorter leaves reaching ± halfway to the base of the spike, and the characteristic dark purple or black blotches in the tepal sinuses. The perianth tube is slightly but distinctly pouched ventrally at the base of the cylindric upper potion, the upper lateral tepals are connate to the dorsal for 3–5 mm, and the filaments are 40–45 mm long. *Tritoniopsis caffra*, which occurs nearer the coast, has longer, subpetiolate leaves reaching ± to the base of the spike and unmarked flowers without a pouch at the base of the upper part of the perianth tube, upper lateral tepals joined to the dorsal for 6–8 mm, and slightly shorter filaments 33–38 mm long.

23. **Tritoniopsis caffra** *(N.E.Br.) Goldblatt & J.C.Manning* in Strelitzia 29: 808 (2012). *Chasmanthe caffra* N.E.Br.: 273 (1932), as a replacement name for *Antholyza caffra* Ker Gawl. ex Baker: 179 (1877) [not *A. caffra* Ker Gawl. m.s. in Herb. Banks], illegitimate superfluous name for *Anisanthus splendens* Sweet [= *Gladiolus splendens* (Sweet) Herbert]. *Petamenes caffra*

(N.E.Br.) E.Phillips: 44 (1941). *Anapalina caffra* (N.E.Br.) G.J.Lewis: 68 (1960). *T. caffra* Goldblatt: 580 (1990), invalidly published name without Latin description [proposed as a replacement name for *Antholyza caffra* Baker, illegitimate superfluous name]. Type: South Africa, [Western Cape], George, lower slopes of Posberg, *W. Burchell 6010* [K, lecto., designated by Milne-Redhead: t. 9470 (1937) [as *Burchell 3487*], corrected by Lewis: 69 (1960)].

Plants 250–700 mm high. *Corm* 20–40 mm diam.; tunics of soft to moderately coarse fibres, sometimes papery, with short or long collar. *Stem* unbranched or with 1 or 2 short ascending branches, 2–4 mm diam. *Basal leaves* 3 to 6, green at flowering, reaching ± to base of spike, blades linear-lanceolate to lanceolate, 150–500 × 4–10 mm, acuminate or often attenuate, narrowed below and subpetiolate, with 2 or 3(4) veins; cauline leaves 2 to 4, lower 1 or 2 like basal but smaller, upper 1 or 2, subulate, 25–30 mm long. *Spike* moderately densely ± 7- to 25-flowered, 70–300 mm long, 2-ranked; bracts flushed red or purplish, softly leathery, lanceolate, outer 12–20 mm long, acute or acuminate, inner slightly longer. *Flowers* bright or dark red, with or without small black or purple marks in sinuses between lower 3 tepals, unscented; perianth tube dimorphic, sharply bent, 20–30 mm long, slender in lower 8–15 mm, widening at bend into cylindric upper part ± 12–15 mm long; tepals unequal, arising very obliquely, lower lateral tepals joined to upper laterals for 2–4 mm and the upper laterals joined to dorsal for an additional 6–8 mm, dorsal tepal largest, horizontal, oblanceolate-spathulate, clawed in lower half, 26–33 × 6–9 mm, obtuse, lower tepals spreading, later reflexed, elliptic to oblong, shortly clawed, upper lateral tepals and lower median tepal smallest, 10–13 × 4–6 mm, lower lateral tepals, 12–16 × 5–7 mm. *Filaments* arcuate, later recurved, 33–38 mm long; anthers 6–8 mm long, yellow flushed red, obtuse, almost medifixed. *Style* 45–60 mm long, dividing opposite upper half of anthers, branches 2.5–4.0 mm long, sometimes bifid. *Capsules* elliptic to oblong, slightly inflated, (12–)15–30(–40) × 10–15 mm, pale creamy flushed pink with darker impressed-reticulate sculpturing. *Seeds* up to 5 mm long, winged on angles. *Chromosome number* 2*n* = 32 ± 0–2b. *Flowering time*: usually September to December.

Distribution of ***Tritoniopsis caffra***.

Distribution and ecology: occurring along the southern coastal mountains of Western and Eastern Cape, South Africa, from the Langeberg near Heidelberg eastward to Grahamstown and East London; on cooler slopes among sandstone and quartzite rocks.

The bright red, strongly bilabiate flowers with reduced lower tepals bear a remarkable superficial similarity to those of *Gladiolus cunonius* and *G. splendens* and, like these species, are adapted for pollination by sunbirds, including Malachite and Orange-breasted Sunbirds.

Diagnosis: allied to *Tritoniopsis intermedia*, with which it shares the green leaves at flowering, similar, red, strongly bilabiate flowers with a dimorphic perianth tube with a strongly oblique mouth resulting from the progressive adnation of the lower tepals to the dorsal, and an oblanceolate-spathulate dorsal tepal twice as long as the lower tepals. *Tritoniopsis caffra* is distinguished from *T. intermedia* by its longer, attenuate, subpetiolate leaves reaching ± to the base of the spike and its unmarked flowers without a ventral pouch at the base of the upper part of the perianth tube, upper lateral tepals joined to the dorsal for 6–8 mm, and slightly shorter filaments 33–38 mm long.

Tribe 2. **Watsonieae**

Watsonieae *Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 351 (1882). Type: *Watsonia* P.Miller

Subtribe *Watsoniinae* G.J.Lewis ex Goldblatt in Goldblatt in Journal of South African Botany 37: 438 (1971). Type: *Watsonia* Miller

Subtribe *Lapeirousiinae* Goldblatt in Journal of South African Botany 37: 439 (1971). Type: *Lapeirousia* Pourr.

Plants with axillary corm development; corm with rounded or flat base, tunics fibrous or woody; flowering stem usually well developed (subterranean in some *Lapeirousia* spp.). *Leaves* with a main vein (except *Pillansia*), plane or ribbed, margins with subepidermal sclerenchyma associated with a marginal vein (lacking in *Pillansia*). *Inflorescence* a spike, sometimes contracted, or paniculate (*Pillansia*); inner bracts shorter than outer, forked apically. *Flowers* usually actinomorphic with stamens unilateral, rarely actinomorphic; style branches often deeply divided or sometimes undivided (*Cyanixia, Pillansia, Zygotritonia*); ovules campylotropous; seed epidermal cell outlines prominent; ovular vascular trace intact; *Basic chromosome number x* = 10 (9, 8, 7).

Genera 11, 8 in southern Africa, 118 species in southern Africa: *Watsonia* (53 spp.); *Pillansia* (1 sp.); *Thereianthus* (11 spp.); *Micranthus* (7 spp.); *Codonorhiza* (7 spp.); *Schizorhiza* (1 sp.); *Lapeirousia* (27 spp.); *Afrosolen* (11 spp).

Key to genera

1a Corm bell-shaped, ellipsoid or obconic (triangular in outline), with flat base and roots emerging from basal margin:
2a Corm ± ellipsoid, diameter of flat base narrower than midline; lower axils of stem bearing multiple cormlets; inflorescence a many-branched false panicle. . . . . 11. *Schizorhiza*
2b Corm bell-shaped or obconic, widest at base; lower axils of stem with a single cormlet or without cormlets; inflorescence a spike or a false panicle:
3a Corm tunic layers woody, base sometimes serrated to spiny; leaves corrugate (plicately ridged); inflorescence a spike or a crowded rosette when plants lacking aerial stem; floral bracts large, fleshy, the inner significantly smaller than outer; seeds globose . . . . . 12. *Lapeirousia*
3b Corm tunic layers not woody, composed of compressed fibres, the outer layers often becoming loosely fibrous with age, base never serrated to spiny; leaves plane or terete; inflorescence a spike or a many-branched false panicle, the individual flowers always sessile (subtended by a pair of opposed bracts at base of ovary); floral bracts subequal, the inner slightly shorter or slightly longer than outer; seeds ovoid or globose:
4a Floral bracts green, firm and ± leathery, apices ± rounded or emarginate; seeds ovoid with surface reticulate to rugose; pollen grains with 1-banded operculum . . . . . 10. *Codonorhiza*
4b Floral bracts green to dry, soft-textured, often becoming membranous, apices acute; seeds globose with smooth surface; pollen grains with 2-banded operculum . . . . . 13. *Afrosolen*
1b Corm globose to obconic with rounded base and roots emerging from lower half of corm:
5a Inflorescence a panicle with individual flowers stalked; flowers actinomorphic, bright orange; style branches divided less than halfway. . . . . 7. *Pillansia*
5b Inflorescence a spike with individual flowers sessile; flowers usually zygomorphic, rarely actinomorphic then white or pink; style branches usually deeply divided:
6a Leaves ± clustered in a basal fan, with thickened, hyaline margins; flowers medium to large, usually at least 20 mm long, never blue; bracts usually green, sometimes becoming dry . . . . . .6. *Watsonia*
6b Leaves superposed, only lowermost basal, with or without thickened, hyaline margins; flowers small to medium, mostly less than 30 mm long, blue or mauve to white; bracts ± dry:
7a Spikes 2-ranked; flowers small, < 12 mm long, crowded in dense spikes; perianth tube curved; bracts with broad membranous margins . . . . . .9. *Micranthus*
7b Spikes spiral; flowers > 15 mm long, not noticeably crowded; perianth tube ± straight; bracts with narrow membranous margins . . . . . .8. *Thereianthus*

6. Watsonia

Watsonia *Miller*, Figures of plants in the Gardener's dictionary 2: pl. 276 (1758 [1760]), conserved name. Type: *W. meriana* (L.) Miller

Meriana Trew: 11 & pl. 40 (1754), rejected name. Type: *M. flore rubello* Trew = *W. meriana* (L.) Miller

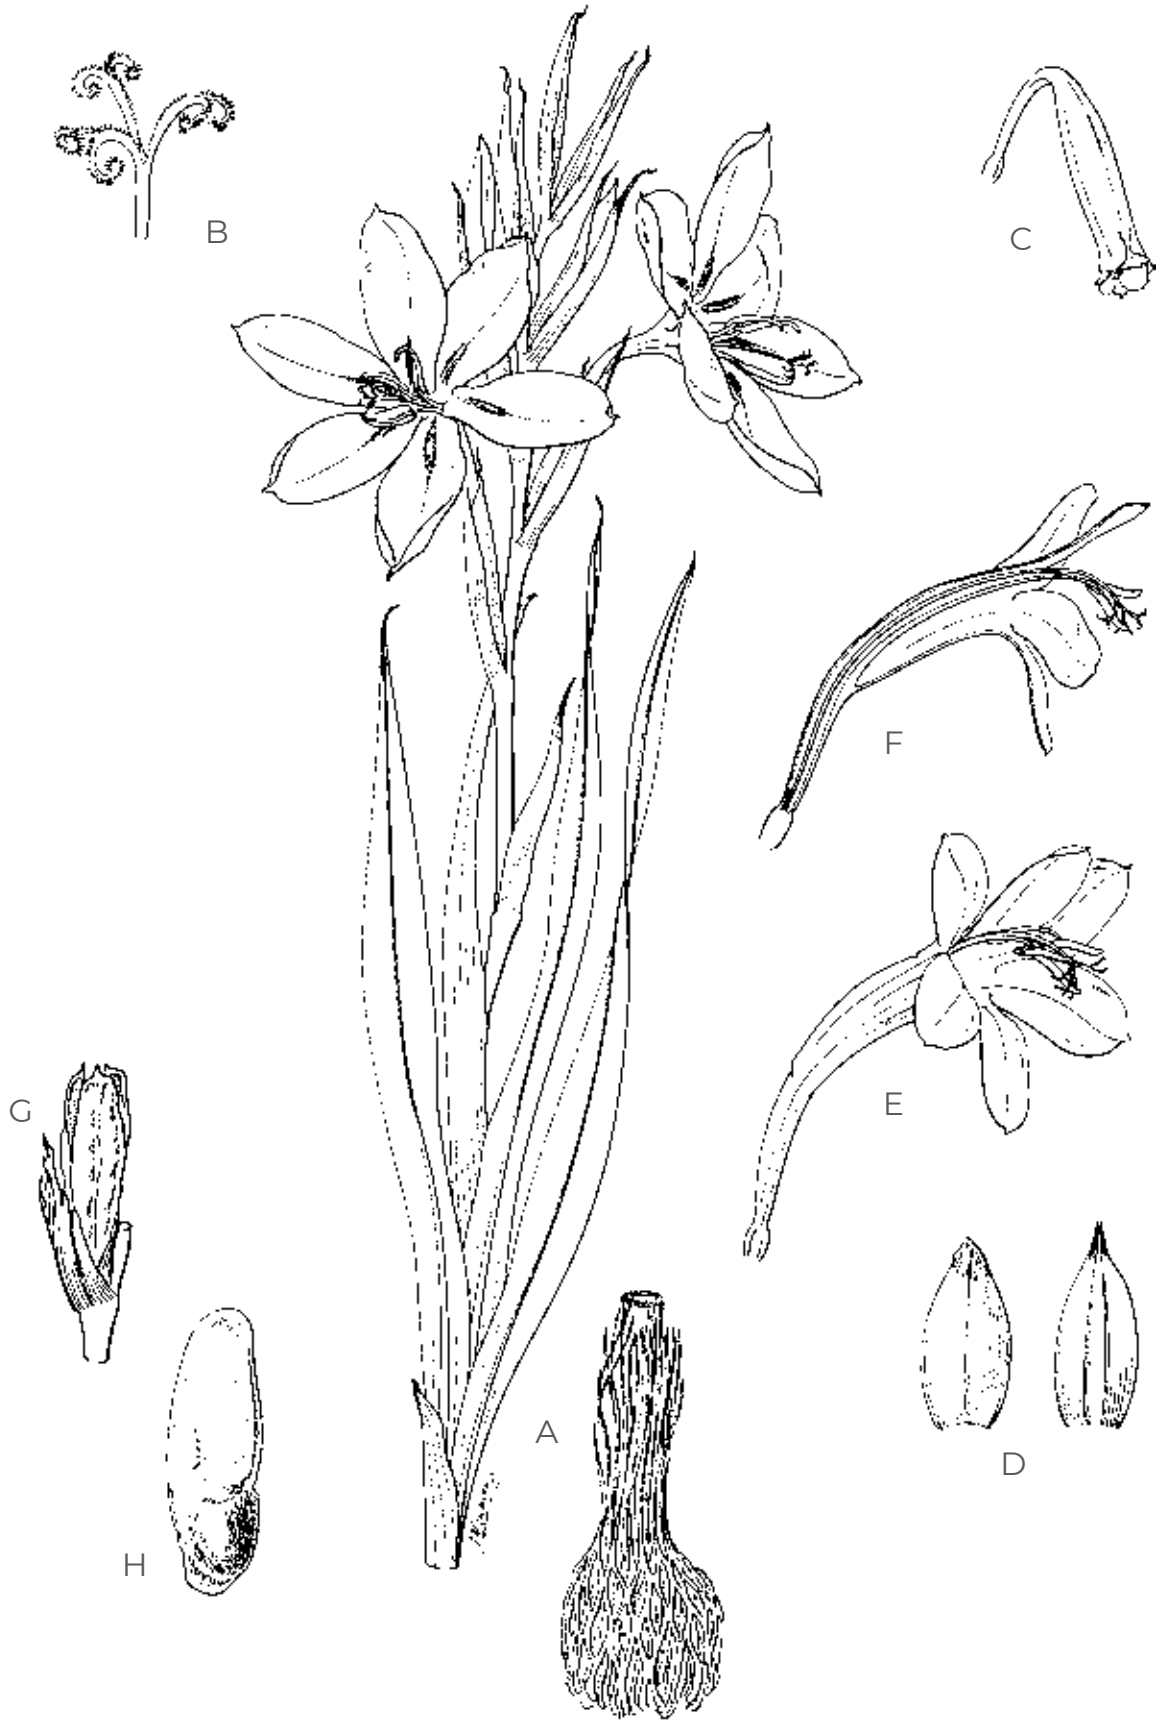
Lomenia Pourr.: 74 & pl. 5 (1788). Type: *Lomenia borbonica* Pourret = *Watsonia borbonica* (Pourret) Goldblatt

[*Neuberia* Eckl.: 37 (1827), invalid name without description.]

Revisionary account: Goldblatt (1989).

Named for the eighteenth century British botanist, William Watson.

Deciduous or sometimes evergreen perennials. *Corm* depressed-globose, axillary in origin, old corms often not resorbed, tunics leathery becoming fibrous and netted with age. *Cataphylls* 2 or 3, dry and papery or leathery. *Leaves* several, foliage leaves mostly in a basal fan, lanceolate to linear, leathery and sclerotic, plane with midrib and margins often thickened and prominent, cauline leaves smaller, inserted on upper ½ of stem, entirely sheathing and bract-like; marginal vascular bundle present, epidermis unspecialised. *Stem* aerial, simple or with one to several short, ascending branches, subterete. *Inflorescence* a distichous spike; bracts firm-textured, partly to completely dry at anthesis, inner shorter to longer than outer, 2-nerved, usually forked apically. *Flowers* zygomorphic (radially symmetric in *W. marginata*), long-lived, pink, orange or red, rarely cream-coloured to pale yellow, sometimes with darker markings on lower tepals, unscented or rarely lightly scented, with nectar from septal nectaries; perianth tube slightly to strongly curved, lower part narrowly cylindric, upper part flared or broadly cylindric; tepals subequal, ± spreading or dorsal horizontal. *Stamens* unilateral and arcuate or sometimes deflexed, rarely central and symmetrically disposed; filaments inserted well below top of perianth tube at junction between lower and upper parts. *Ovary* ovoid; style filiform, 3-branched distally, branches slender and forked for half their length. *Capsules* globose to oblong or elongate, sometimes spindle-shaped, leathery to woody, tardily dehiscent. *Seeds* large, angular or compressed and winged at chalazal end or at both ends, areolate, matte. *Pollen grains* monosulcate-operculate, operculum 2-banded, exine perforate-scabrate. *Basic chromosome number* $x = 9$.



Species 53: southern Africa, centred in the southwestern parts of Western Cape but extending north into Namaqualand, and east into the summer-rainfall zone of eastern South Africa, Eswatini, and Lesotho.

Watsonia can be recognised by its basal fan of leathery or fibrous leaves often with thickened midrib and margins, and the sturdy, erect, 2-ranked spike, often with numerous closely packed flowers subtended by firm, leathery bracts. The flowers are usually quite large, mostly pink to orange or red to purple, rarely pale yellow, with slender style branches divided for half their length. The large, somewhat flattened corms are axillary in origin, and the leaves have the ancestral marginal anatomy type, with a marginal vein with phloem cap. *Watsonia* has a unique basic chromosome number in the subfamily, $x = 9$, and a karyotype with one large pair of chromosomes. Seeds of many species are specialised in having the proximal and distal ends flattened and drawn into wing-like processes. In a few species the seeds may have only one large distal wing. Winged seeds are found only in species of the southern African winter-rainfall zone and it is here that the species diversity is greatest.

Flower colour is closely correlated with perianth shape and pollination system. Pink or pale yellow flowers, with either a relatively short, flared tube or a moderately long, slender tube are adapted for pollination by bees or long-proboscid flies, whereas red or orange flowers, nearly always with a perianth tube that is narrow below and wide and tubular above, are pollinated by sunbirds.

The relationships of *Watsonia* lie with the other genera of Crocoideae with similar, deeply divided style branches and axillary corm development, together comprising tribe Watsonieae. Within the tribe, *Watsonia* is sister to *Pillansia*, with a very different leaf and inflorescence structure and radially symmetric, orange flowers and large, areolate seeds. Basic chromosome number for the tribe is evidently $x = 10$, and *Watsonia* appears derived in its secondary base of $x = 9$.

The existing classification of the genus is largely intuitive and is based on proposed morphological specialisations (Goldblatt 1989). In that system *Watsonia marginata* was segregated as the monospecific subg. *Neuberia* for its unique, actinomorphic flowers, which were then interpreted as plesiomorphic, and the remaining, zygomorphic-flowered species were segregated in three sections in subg. *Watsonia*. Outgroup comparison now suggests that the actinomorphic flower is secondarily derived in the genus. In the absence of corroborative phylogenetic data we favour a non-hierarchical classification system in which we treat *Neuberia* as a fourth section.

WATSONIA. W. dubia: A, flowering plant; B, detail of style branches. ***W. aletroides***: C, flower. ***W. meriana***: D, outer bract (left) and inner bract (right); E, flower; F, half-flower. ***W. vanderspuyiae***: G, dehisced capsule; H, seed.

Keys to species

A. Species of summer rainfall eastern southern Africa (Port Elizabeth to Limpopo):

1a Upper part of perianth tube above stamen insertion ± cylindric, barely wider at mouth than near middle of upper part; tepals usually shorter than to ± as long as upper part of tube; filaments usually well exserted, 7–15 mm from tube, rarely less; flowers usually red to orange, or pink to purple:
2a Floral bracts short, 5–14(–16) mm long (disregard lower 1–3 flowers):
3a Filaments 10–20 mm long, included in perianth tube or exserted up to 5 mm . . . . . 39. *W. bachmannii*
3b Filaments 25–45 mm long, well exserted from perianth tube:
4a Filaments 16–28 mm long; flowers pink to purple or rarely red; tepals 8–15 mm wide; capsules narrowly obovoid . . . . . 37. *W. knysnana*
4b Filaments 30–38 mm long; flowers scarlet to dark red; tepals 4–10 mm wide; capsules elongate-fusiform . . . . . 43. *W. angusta*
2b Floral bracts longer, 15–45 mm long:
5a Inner (broader) tepals at least 10 mm wide and at least half as wide as long:
6a Flowers pink to purple; filaments 16–25(–30) mm long . . . . . 37. *W. knysnana*
6b Flowers orange to red; filaments (25–)30–45 mm long . . . . . 38. *W. pillansii*
5b Inner (broader) tepals 4.5–9.0 mm wide and more than twice as long as wide:
7a Leaves 30–60 mm wide; bracts green below; plants from northern KwaZulu-Natal to Mpumalanga . . . . 23. *W. latifolia*
7b Leaves 3–25 mm wide; bracts entirely dry and brown; plants from southern KwaZulu-Natal to Eastern Cape . . . . . 26. *W. gladioloides*
1b Upper part of perianth tube above stamen insertion flared evenly from base to apex, usually ± twice as wide at mouth as near centre; tepals usually 1.5–2.0 times as long as upper part of tube; filaments included or shortly exserted up to 5 mm from tube; flowers usually pink to purple, rarely red, white or yellow:
8a Lower part of perianth tube 30–55 mm long:
9a Bracts dry and brown above, 25–35 mm long; upper part of perianth tube ± 15 mm long; spike 15- or more-flowered . . . . . 17. *W. wilmsii*
9b Bracts herbaceous, 33–55 mm long; upper part of perianth tube ± 6 mm long; spike 3- to 7-flowered . . . . . 18. *W. occulta*
8b Lower part of perianth tube 7–25 mm long:
10a Flowers pale yellow to cream-coloured, rarely maroon, small, tepals 10–18 mm long; basal leaves 1 or 2, linear, 3–6 mm wide, with heavily thickened midrib and margins . . . . . 16. *W. watsonioides*
10b Flowers usually pink to purple or red, rarely white, tepals usually longer; basal leaves usually 3 or more, 2–80 mm wide, with or without heavily thickened midrib and margins:
11a Bracts entirely dry at flowering, uniformly brown or with pale veins, (10–)20–40 mm long, strongly overlapping and at least 2 internodes long; spike crowded with (10)20 to 60 flowers:
12a Plants solitary with erect stems:
13a Leaves channelled with margins curved inward; bract-like cauline leaves not or hardly inflated . . . . . 29. *W. canaliculata*
13b Leaves plane, the lower usually dead and dry at flowering; bract-like cauline leaves inflated . . . . . 25. *W. lepida*
12b Plants forming clumps, with stems ± erect or inclined below:
14a Spike internodes (7–)9–15 mm long; tepals 25–32 mm long; spike 15- to 30-flowered . . . . . 27. *W. confusa*
14b Spike internodes 4–8 mm long; tepals 16–25 mm long; spike 30- to 60-flowered:
15a Bracts 22–28 mm long, dark brown with venation not evident; leaves mostly 15–30 mm wide . . . 28. *W. pulchra*
15b Bracts 16–40 mm long, pale brown with dark margins and paler veins; leaves mostly 10–15 mm wide . . . . . 30. *W. densiflora*
11b Bracts usually partly green and herbaceous below, 5–30 mm long, sometimes overlapping but then *either* shorter than 2 internodes long *or* green below; spike relatively lax and with 3 to 30 flowers:
16a Flowers bright orange; upper part of perianth tube subcylindric, ± as long as lower part . . . . . 39. *W. bachmannii*
16b Flowers pink to purple; upper part of perianth tube funnel-shaped:
17a Anthers 5–6 mm long; leaves linear, 3–6 mm wide:
18a Bracts herbaceous with brown papery margins, becoming dry and brown apically, (15–)20–25 mm long, not clasping rachis below; filaments exserted 3 mm from perianth tube . . . . . 21. *W. vicschuettei*
18b Bracts dry and brown, (10–)12–16 mm long, clasping rachis below; filaments included in tube . . . . . 22. *W. bella*
17b Anthers 6–9 mm long; leaves linear to lanceolate, 2–40 mm wide:
19a Basal leaves linear, 2–3 mm wide, at least as long as spike (sometimes dry and broken); bracts dry and brown; tepals 14–16 mm long. . . . . 24. *W. mtamvunae*
19b Basal leaves linear to lanceolate, 4–40 mm wide; bracts herbaceous or dry and brown; tepals 16–28 mm long:
20a Spike 3- to 8-flowered; anthers ± 9 mm long:
21a Stem inclined at ground level; tepals 24–28 mm long; plants of open, stony, well-drained slopes . . . . . 19. *W. inclinata*
21b Stem erect; tepals 20–22 mm long; plants of permanently wet vleis and marshes. . . . . 20. *W. pondoensis*
20b Spike 10- to 25-flowered; anthers 6–9 mm long:
22a Tepals 20–25 mm long; stems always simple . . . . . 14. *W. transvaalensis*
22b Tepals 16–19 mm long; stems frequently branched, branches sometimes 1- or 2-flowered, thus resembling stalked flowers:
23a Leaves 14–40 mm wide; spike 25- to 35-flowered; plants from Mpumalanga . . . . . 15. *W. strubeniae*
23b Leaves 5–14 mm wide; spike 10- to 20-flowered; plants from Eastern Cape . . . . . 13. *W. amatolae*

B. Species of winter rainfall western southern Africa (Namaqualand to Port Elizabeth):

1a Flowers actinomorphic, rotate; upper part of perianth tube less than half as long as tepals; stamens central 1. *W. marginata*
1b Flowers zygomorphic; upper part of perianth tube half as long or more as tepals; stamens unilateral, rarely pseudosymmetrical, but then median stamen curved upward between laterals: shortly exserted up to 5 mm from tube; flowers usually pink to purple, rarely red, white or yellow:
2a Stamens declinate:
3a Floral bracts (15–)20–50(–70) mm long; perianth tube 25–50 mm long:
4a Bracts (15–)20–25(–33) mm long; upper part of perianth tube 8–14 mm long; filaments 13–15 mm long, well exserted from tube. . . . . 6. *W. strictiflora*
4b Bracts (25–)30–50(–70) mm long; upper part of perianth tube 5–8 mm long; filaments usually 6–12 mm long, shortly exserted from tube. . . . . 7. *W. dubia*
3b Floral bracts 6–20 mm long; perianth tube 15–30 mm long:
5a Anthers 4–8 mm long; plants small, rarely taller than 500 mm:
6a Bracts narrow throughout, not clasping stem; anthers 7–8 mm long, dark purple. . . . . 5. *W. amabilis*
6b Bracts broad-based and clasping stem; anthers 4–5 mm long, yellow (rarely purple):
7a Tepals up to half as long as upper part of perianth tube, ± 10 mm long; leaves up to 10 mm wide. . . . . 9. *W. aletroides*
7b Tepals more than half as long as upper part of perianth tube, 14–16 mm long; leaves often > 10 mm wide . . . . . 8. *W. laccata*
5b Anthers 9–13 mm long; plants taller, usually more than 500 mm tall:
8a Plants usually more than 1 000 mm tall; leaves glossy apple-green, rarely less than 20 mm wide; tepals (26–)30–36 mm long . . . . . 2. *W. borbonica*
8b Plants usually up to 500 mm tall; leaves dull green, 5–10 mm wide; tepals 22–30(–35) mm long . . . . . 4. *W. rogersii*
2b Stamens arcuate to horizontal:
9a Upper part of perianth tube above stamen insertion flared evenly from base to apex, usually ± twice as wide at mouth as near centre; tepals usually 1.5–2.0 times as long as upper part of tube; filaments included or
10a Spikes with at least 2 branches, each with at least 5 flowers; seeds 2-winged:
11a Upper part of perianth tube 8–12 mm long; bracts 10–18 mm long . . . . . 2. *W. borbonica*
11b Upper part of perianth tube 20–30 mm long; bracts 15–26 mm long . . . . . 3. *W. versfeldii*
10b Spikes unbranched or with short branches rarely with more than 2 flowers each:
12a Filaments ± twice as long as upper part of perianth tube, exserted 6–10 mm beyond tube; bracts 5–10 mm long . . . . . 32. *W. galpinii*
12b Filaments ± as long as upper part of perianth tube, included or shortly exserted up to 3 mm; bracts 9–30 mm long:
13a Plants 150–350 mm high, unbranched; upper part of perianth tube 9–12 mm long; anthers 5–6 mm long; plants from Hottentots Holland Mtns . . . . . 11. *W. distans*
13b Plants 400–600 mm high, often branched; upper part of perianth tube 6–8 mm long; anthers 8–9 mm long; plants from Langeberg and Swartberg. . . . . 10. *W. emiliae*
9b Upper part of perianth tube above stamen insertion ± cylindric, barely wider at mouth than near middle of upper part; tepals usually shorter than to ± as long as upper part of tube; filaments arcuate, usually well exserted, 7–15 mm from tube, rarely less; flowers usually red to orange, or pink to purple:
14a Floral bracts shorter, 5–14(–16) mm long (disregard lower 1 to 3 flowers):
15a Filaments 10–20 mm long, included in perianth tube or exserted up to 5 mm:
16a Flowers pink . . . . . 12. *W. paucifolia*
16b Flowers orange to scarlet:
17a Filaments exserted up to 5 mm from tube, 15–16 mm long; upper part of perianth tube 9–10 mm long, style dividing beyond anthers and well exserted . . . . . 35. *W. minima*
17b Filaments included in perianth tube, ± 10 mm long; upper part of perianth tube 10–15 mm long, style dividing below anthers with branches included in perianth tube. . . . . 36. *W. elsiae*
15b Filaments 25–45 mm long, well-exserted from perianth tube:
18a Tepals 12–16 mm long:
19a Floral bracts 5–8 mm long, usually shorter than spike internodes; leaf margins hardly thickened; plants from western mountains . . . . . 33. *W. stokoei*
19b Floral bracts 9–12 mm long, usually ± as long as spike internodes; leaf margins heavily thickened; plants from southern mountains . . . . . 34. *W. marlothii*
18b Tepals 18–33 mm long:
20a Cauline bract leaves much inflated; plants from Cape Peninsula . . . . . 44. *W. tabularis*
20b Cauline bract leaves not inflated; plants from Cape Peninsula and elsewhere:
21a Floral bracts 7–10 mm long; capsules globose to ovoid; plants from Swartberg and east of George . . . . . 31. *W. wilmaniae*
21b Floral bracts 9–14 mm long but, if only 9–10 mm long, then capsules elongate-fusiform; capsules ovoid to fusiform:
22a Inner bracts forked for 2–4 mm:
23a Tepals 20–22 mm long; anthers ± 7 mm long; plants of marshes and seeps . . . . . 42. *W. zeyheri*
23b Tepals 24–33 mm long; anthers 9–12 mm long; plants of open slopes . . . . . 41. *W. fourcadei*
22b Inner bracts entire or shortly forked up to 1.5 mm:
24a Filaments 16–28 mm long; flowers pink to purple or rarely red; tepals 8–15 mm wide; capsules narrowly obovoid. . . . . 37. *W. knysnana*
24b Filaments 30–38 mm long; flowers scarlet to dark red; tepals 4–10 mm wide; capsules elongate-fusiform . . . . . 43. *W. angusta*
14b Floral bracts longer, 15–45 mm long:
25a Inner bracts forked for 2–4 mm:

26a Foliage leaves dry at flowering; plants from Saldanha Bay; flowering April to July . . . . . 50. *W. hysterantha*
26b Foliage leaves green at flowering; plants not from Saldanha Bay; flowering September to January:
27a Tepals 20–22 mm long; anthers ± 7 mm long; plants of marshes and seeps . . . . . .42. *W. zeyheri*
27b Tepals 24–33 mm long; anthers 9–12 mm long; plants of open slopes . . . . . 41. *W. fourcadei*
25b Inner bracts entire or shortly forked up to 1.5 mm:
28a Outer floral bracts consistently longer than inner (disregard upper flowers):
29a Inner (broader) tepals 4.5–9.0 mm wide and more than twice as long as wide; flowers pink; plants from Namaqualand . . . . . .49. *W. rourkei*
29b Inner (broader) tepals at least 10 mm wide and at least half as wide as long; flowers pink to purple or orange; plants from Cape Floristic Region:
30a Flowers pink to purple; filaments 16–25(–30) mm long . . . . . 37. *W. knysnana*
30b Flowers orange to red; filaments (25–)30–45 mm long:
31a Leaves (7–)12–18 mm wide, margins lightly to moderately thickened; plants from Langeberg eastward . . . . . 38. *W. pillansii*
31b Leaves 6–15 mm wide, margins heavily thickened; plants from Langeberg westward . . . . . 40. *W. schlechteri*
28b Outer floral bracts ± as long as or shorter than inner:
32a Leaves 50–85 mm wide, with pale, heavily thickened margins . . . . . 51. *W. vanderspuyiae*
32b Leaves 2–40(–50) mm wide:
33a Tepals (28–)30–35 mm long; anthers 10–12 mm long:
34a Flowers red: bracts 28–40 mm long. . . . . .48. *W. spectabilis*
34b Flowers pink; bracts 15–24 mm long . . . . . 3. *W. versfeldii*
33b Tepals 15–26(–30) mm long; anthers 6–12 mm long:
35a Flowering stem branched and more than 400 mm high . . . . . 45. *W. meriana*
35b Flowering stem usually simple and up to 400 mm high:
36a Filaments (10–)15–20(–22) mm long:
37a Bracts keeled and curving outwards apically; flowers white or pale pink to salmon-pink; filaments usually included in perianth tube . . . . . 47. *W. humilis*
37b Bracts not keeled nor curving outwards apically; flowers orange or salmon-pink; filaments usually exserted from perianth tube . . . . . 53. *W. stenosiphon*
36b Filaments 25–35 mm long:
38a Bracts clasping stem only at base, usually flushed red; anthers violet; plants from loamy and sandstone soils. . . . . 46. *W. coccinea*
38b Bracts clasping stem in lower half, green; anthers yellow; plants from limestone soils. . . . .52. *W. fergusoniae*

Sect. 1. **Neuberia** *(Eckl. ex Baker) Goldblatt & J.C.Manning*, new rank. *Watsonia* subg. *Neuberia* Eckl. ex Baker in Flora capensis 6: 99 (1896). Type species: *W. marginata* (L.) Ker Gawl.

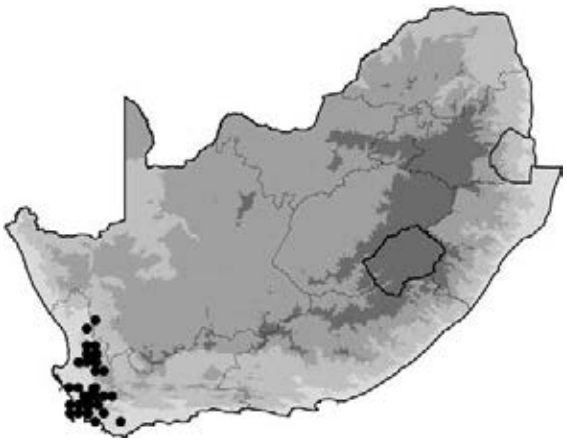
Stems usually branched; bracts dry and pale above or throughout, becoming lacerate. *Flowers* actinomorphic, rotate, pink; perianth tube funnel-shaped with upper part short and flared; tepals spreading, ± twice as long as upper part of tube. *Stamens* erect and symmetrically disposed. *Capsules* subglobose. *Seeds* elongate-angular.

Species 1: southwestern parts of Northern and Western Cape, South Africa.

1. **Watsonia marginata** *(L.f.) Ker Gawl.* in Curtis's Botanical Magazine 17: t. 608 (1802c). *Gladiolus marginatus* L.f.: 95 (1782). *Ixia marginata* (L.f.) Aiton: 59 (1789). *Neuberia marginata* (L.f.) Eckl.: 37 (1827) [genus not validly published]. *Antholyza marginata* (L.f.) Page ex Steud.: 106 (1840a). Type: South Africa, without precise locality, *Sparrman s.n.* (LINN ['*Gladiolus 32*'], holo.).

Gladiolus glumaceus Thunb.: 186 (1800). *Watsonia glumacea* (Thunb.) Aschers. & Graebn.: 583 (1907). Type: South Africa, without precise locality, *Thunberg s.n. 'Gladiolus marginatus* δ' (UPS-THUNB, holo.).

Watsonia marginata var. *minor* Ker Gawl.: t. 1530 (1813). Type: South Africa, without precise locality or collector, illustration in Curtis's Bot. Mag. 37: t. 1530 (1813).



[*Ixia sceptrum* Baker: 158 (1877), invalid name, as a synonym.]

Plants 700–2 000 mm high. *Corm* subglobose, 20–50 mm diam.; tunics coarsely netted. *Stem* erect or inclined, simple or with several short, ascending branches. *Leaves* 3 or 4, lower 2 basal, others sheathing stem below or entirely, lanceolate to linear, (20–)30–50 mm wide, glaucous, midrib moderately and margins heavily thickened and yellowish hyaline or becoming purple; bract-like cauline leaves 1 or more. *Spike* 10- to 20-flowered; bracts entirely dry and pale straw-coloured, or green or reddish below, attenuate, becoming lacerate, 10–18 mm long, inner usually 1–2 mm longer, barely forked apically. *Flowers* actinomorphic, rotate with upper part of tube flexed outward, usually pale pink or mauve (rarely magenta or white), each tepal with white streak at base edged in darker colour; perianth tube funnel-shaped, lower part 7–9(–12) long, included or shortly emerging from bracts, upper part flaring and ± horizontal, 6–7 mm long, 4–5 mm diam. at mouth; tepals spreading, obovate, (14–)20–22 × (7–)11–13 mm, with short peg-like callus at base. *Filaments* ± 10 mm long, contiguous below and surrounding style, diverging above; anthers 7–9 mm

long, incurved apically, yellow or bluish. *Style* erect, usually dividing shortly below to opposite middle of anthers, branches 4–5 mm long. *Capsules* subglobose, up to 8 mm long. *Seeds* angular and prominently ridged, more so distally, 4–6 × 2 mm. *Flowering time*: mid-September to early December.

Distribution and ecology: endemic to the southwestern part of Northern and Western Cape, South Africa, from the Bokkeveld Escarpment along the western mountain chain and isolated coastal massifs to Hermanus; mostly in seasonally marshy sites and seeps on sandstone or granitic soils.

Diagnosis: unique in the genus in its pale, dry bracts and actinomorphic flowers with short, narrowly cupped perianth tube 7–12 mm long. Forms with lateral branches are highly floriferous, the branches appressed to the main axis and giving the appearance of a single, densely-flowered inflorescence. The peg-like callus at the base of each tepal is distinctive. Most populations have pinkish flowers but the dwarf form, which occurs almost throughout the range, may have white, pink or magenta flowers. The latter colour form is restricted to the Cederberg.

Distribution of ***Watsonia marginata***.

Sect. 2. **Lomenia** *(Pourr.) Goldblatt*, Annals of Kirstenbosch Botanic Gardens 19: 32 (1989). *Lomenia* Pourr.: 74 (1788). Type species: *Watsonia borbonica* (Pourr.) Goldblatt

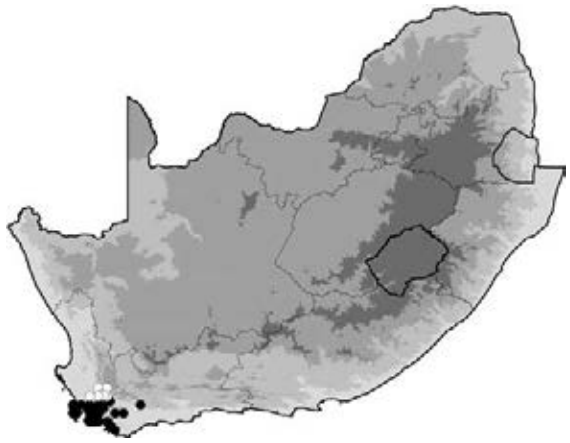
Stems usually branched; bracts firm-textured. *Flowers* zygomorphic, usually pale to deep pink or purple, rarely red or orange; perianth tube narrowly funnel-shaped with upper part flared, or subcylindric throughout; tepals spreading or suberect, usually ± as long as upper part of tube, rarely less than half as long. *Stamens* arcuate or declinate. *Capsules* oblong or flask-shaped. *Seeds* elongate, unequally 2-winged with distal wing larger.

Species 8: southwestern and southern parts of Western and Eastern Cape, South Africa.

2. **Watsonia borbonica** *(Pourr.) Goldblatt* in Annals of the Missouri Botanical Garden 74: 571 (1987). *Lomenia borbonica* Pourr.: 76 (1788). *Gladiolus lomenia* J.F.Gmel.: 112 (1791), illegitimate superfluous name for *Lomenia borbonica* Pour. (1788). Type: South Africa, [said to be from Réunion], *Commerson s.n.* (P, holo.).

Gladiolus pyramidalis Lam.: 726 (1788), illegitimate homonym, not *G. pyramidalis* Burm.f. (1768). Type: South Africa, without precise locality or collector (P, holo.).

Gladiolus pyramidatus Andrews: t. 335 (1803). *Watsonia rosea* Ker Gawl.: 230 (1804), illegitimate superfluous name for *G. pyramidatus* Andrews. *Neuberia rosea* (Ker Gawl.) Eckl.: 37 (1827), invalidly published name [*Neuberia* without description]. *Watsonia pyramidata* (Andrews) Klatt in Th.Durand & H.Schinz: 194 (1894). Type: South Africa, without precise locality or collector, illustration in Andrews, Botanist's Repository 5: t. 335 (1803).



Gladiolus striatus Herb. Banks ex Roem. & Schult.: 435 (1817), as a synonym.

Watsonia striata Klatt: 352 (1882). Type: South Africa, [Western Cape], Cape Town, *Spilhaus s.n.* (B: Herb. Lubeck, holo, believed destroyed).

Watsonia cooperi L.Bolus: 135 (1929b), as a replacement name for *Tritonia cooperi* Baker: 192 (1892), illegitimate homonym, not *T. cooperi* (Baker) Klatt (1882). *Tritonia quinquenervata* R.C.Foster: 46 (1936), as a replacement name for *T. cooperi* Baker. Type: South Africa, [Western Cape], Worcester Division, *Cooper 3182* (K, holo.).

[*Watsonia pyramidata* var. *zeyheri* Baker ex Klatt in Th.Durand & H.Schinz: 194 (1894), invalid name as a synonym of *W. punctata* var. *zeyheri* Baker].

Plants 1 200–2 000 mm high. *Corm* depressed-globose, 30–50 mm diam.; tunics coarsely netted. *Stem* erect or inclined below, usually with several short, ascending branches. *Leaves* 5 to 8, mostly basal, upper basal leaf sheathing stem below or entirely, ⅓–⅔ as long as spike, lanceolate to linear, 20–40 mm wide, bright apple-green, midrib lightly and margins lightly to moderately thickened; bract-like cauline leaves 2 or more, overlapping. *Spike* up to 20-flowered; bracts green below and dry and brownish above or entirely, often ± sticky, 10–18 mm long, inner ± as long or 2–3 mm shorter, acute or forked apically for 1–2 mm. *Flowers* zygomorphic, pale to deep pink or pale purple, darker in midline of lower 3 or all tepals and with white streak at base, rarely entirely white, faintly scented; perianth tube funnel-shaped, lower part 12–15(–20) long, emerging 3–8 mm from bracts, upper part flaring, ± horizontal to slightly pendulous, 8–20 mm

Distribution of ***Watsonia borbonica*** subsp. ***borbonica*** ●; subsp. ***ardernei*** ○.

long, 7–10 mm diam. at mouth; tepals spreading, oblanceolate to obovate, (26–)30–36 × 13–18 mm. *Filaments* unilateral, either arcuate-horizontal and somewhat spreading or decumbent, 13–18(–25) mm long; anthers 10–13 mm long, purple (yellowish when flowers white). *Style* arching above or below stamens, dividing at or below anther apices, branches up to 7 mm long. *Capsules* ovoid to obovoid-truncate, 20–25(–30) × 7–10 mm. *Seeds* unequally 2-winged, 8–12 mm long, distal wing 2–3 mm long, proximal smaller or vestigial. *Flowering time*: October to early December (January).

Distribution and ecology: endemic to the extreme southwestern part of Western Cape, South Africa, from Tulbagh to the Cape Peninsula eastward to Gansbaai; on rocky, usually well-drained sandstone or granite slopes.

Diagnosis: a robust species with bright apple-green leaves and well-branched stems more than 1 000 mm tall, with funnel-shaped, pink flowers, the perianth tube flared in the upper ± half and 20–40 mm long. The filaments vary in orientation from arcuate-horizontal to decumbent. *Watsonia rogersii* is a shorter species, up to 500 mm high, with narrower, dull green leaves 5–10 mm wide with heavily thickened margins, and often slightly smaller flowers with tepals 22–30(–35) mm long. The two species are sympatric along the lower slopes of the Hottentots Holland and Kogelberg ranges and may hybridise there.

The orientation of the stamens in *Watsonia borbonica* varies between the northern and southern populations and this variation, combined with small differences in the length of the perianth tube, forms the basis for the recognition of two subspecies.

Hybrids between subsp. *borbonica* and *W. zeyheri* have been reported from Betty's Bay.

Key to subspecies

1a Stamens arcuate-horizontal, anthers horizontal; upper part of perianth tube 14–20 mm long . . . . . 2a. subsp. *ardernei*

1b Stamens declinate, anthers decumbent; upper part of perianth tube 8–15 mm long . . . . . 2b. subsp. *borbonica*

2a. subsp. **ardernei** *(Sander) Goldblatt* in Annals of Kirstenbosch Botanic Gardens 19: 35 (1989). *Watsonia ardernei* Sander: 19, fig. 1897). Type: unknown, possibly illustration in Sander's New Plants for 1897: 18–20 (1897).

Watsonia alba Arderne: 229 (1893). Type: South Africa, without precise locality or collector, illustration in Arderne in The Garden 63: 229 (1893).

Watsonia ardernei Mathews & L.Bolus in Bolus: 25 (1925), illegitimate homonym, not *W. ardernei* Sander (1897). Type: South Africa, [Western Cape], Farm Romans River, ex hort Kirstenbosch, *Tredgold s.n.* (BM, lecto., designated by Goldblatt in Strelitzia 19: 35 (1989); BOL, isolecto.).

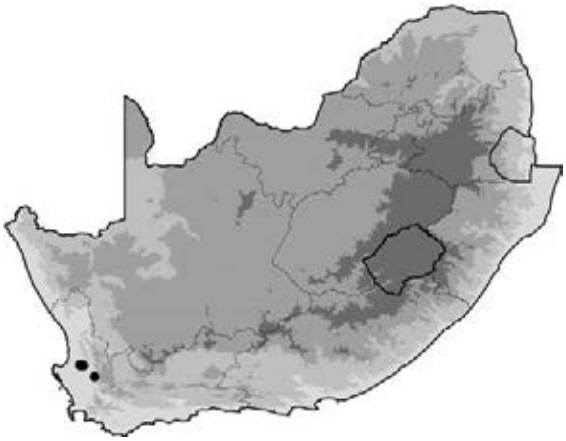
Watsonia iridifolia var. *obrienii* N.E.Br.: 350 (1889). Type: South Africa, [Western Cape], ?Romans River, ex hort. Kew [K, lecto. and isolecto., designated by Goldblatt: 35 (1989)].

[*Watsonia obrienii* Tubergen: 701 (1894), invalid name without description.]

Perianth tube with upper part 14–20 mm long. *Stamens* arcuate-horizontal, anthers horizontal, sometimes widely separated with central anther above two lower anthers. *Style* arched above stamens.

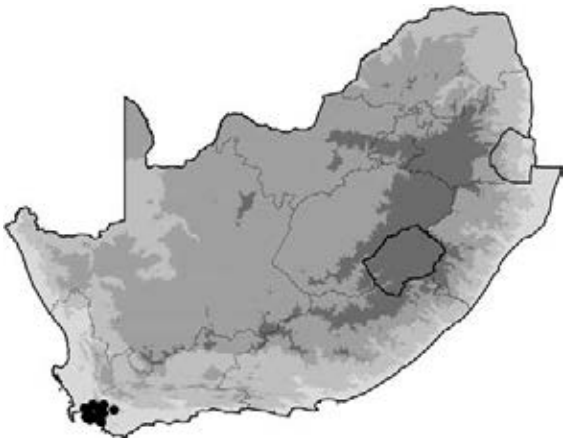
Distribution and ecology: restricted to the northern part of the range of the species, from Paarl through the Du Toit's Kloof Mtns into the upper Breede River Valley between Rawsonville and Tulbagh.

The typical white-flowered form is widely cultivated, but only pink-flowered plants are known in the wild.



2b. subsp. **borbonica**

Perianth tube with upper part 8–15 mm long. *Stamens* declinate, anthers decumbent above lower tepal. *Style* curving below stamens.



Distribution and ecology: restricted to the southern part of the range of the species, from the Cape Peninsula through the Stellenbosch and Hottentots Holland Mtns to the Riviersonderend Mtns and Kleinrivier Mtns east to Gansbaai.

3. **Watsonia versfeldii** *J.W.Mathews & L.Bolus* in Bolus in Annals of the Bolus Herbarium 3: 139 (1922). Type: South Africa, [Western Cape], mountains near Piketberg, *Versfeld s.n.* (BOL [Nat. Bot. Gard. 6125/14], lecto., designated by Goldblatt: 37 (1989); BOL, isolecto.).

Watsonia versfeldii var. *alba* J.W.Mathews & L.Bolus in Bolus: 140 (1922). Type: South Africa, mountains near Piketberg, *Versfeld s.n.* [BOL

Distribution of ***Watsonia versfeldii***.

Distribution of ***Watsonia rogersii***.

(Nat. Bot. Gard. 2670/16), lecto., designated by Goldblatt: 37 (1989)].

Watsonia ecklonii L.Bolus: 53 (1926). Type: South Africa, without precise locality, *Ecklon 938* (B, lecto., designated by Goldblatt: 37 (1989); BOL, isolecto.).

Plants 1 200–2 000 mm high. *Corm* depressed-globose, 50–60 mm diam.; tunics coarsely netted. *Stem* erect, with several short, ascending branches. *Leaves* 6 to 8, mostly basal, uppermost sheathing stem below, ⅓–⅔ as long as spike, lanceolate, 25–40 mm wide, apple-green, midrib weakly defined, margins lightly thickened and hyaline; cauline leaves 2 or more, sheathing and slightly inflated. *Spike* up to 24-flowered; bracts dry and brownish above or entirely, ± sticky, 15–26 mm long, inner ± as long as or slightly shorter, emarginate or forked for 1–2 mm. *Flowers* zygomorphic, purplish pink; perianth tube narrowly funnel-shaped, lower part 15–22 mm long, emerging 10–12 mm from bracts, upper part gradually flaring or almost cylindric and nearly horizontal to slightly pendulous, 20–25(–30) mm long, 6–10 mm diam. at mouth; tepals spreading, lanceolate, 33–46 × 10–15 mm. *Filaments* unilateral, extending horizontally beneath upper tepal, 25–33 mm long; anthers 12–16 mm long, purple. *Style* arching above stamens, dividing near anther apices, branches ± 5 mm long. *Capsules* ovoid to narrowly obconic, 18–35 × 8–10 mm. *Seeds* unequally 2-winged, with prominent distal wing. *Flowering time*: late October to November.

Distribution and ecology: restricted to the Piketberg and the Twenty-Four Rivers Mtns above Porterville and Saron in Western Cape, South Africa; on open, stony sandstone slopes and plateaus.

Diagnosis: recognised by the lanceolate leaves, 25–40 mm wide, and the long-tubed pinkish purple flowers with the upper part of the perianth tube 20–30 mm long, and declinate stamens with purple anthers. *Watsonia borbonica* from south of Tulbagh is similar in habit and foliage but has shorter flowers with the upper part of the perianth tube 8–15(–20) mm long.

4. **Watsonia rogersii** *L.Bolus* in Annals of the Bolus Herbarium 4: 54 (1926). Type: South Africa, [Western Cape], Steenbras, *Rogers 17841* (K, lecto., designated by Goldblatt: 39 (1989); BOL, isolecto.).

Watsonia middlemostii L.Bolus: 27 (1929a). Type: South Africa, [Western Cape], near Steenbras, ex hort. Kirstenbosch, *Middlemost s.n.* (BOL [Nat. Bot. Gard. 2082/26], lecto., designated by Goldblatt: 39 (1989); BOL, isolecto.).

Plants (200–)300–500 mm high. *Corm* depressed-globose, 15–25 mm diam.; tunics coarsely netted. *Stem* erect or inclined below, simple or with few short, ascending branches. *Leaves* 4 or 5, mostly basal, uppermost sheathing stem below or entirely, ⅓–⅔ as long as spike, narrowly lanceolate to linear, 5–10 mm wide, main vein and margins strongly thickened and hyaline; bract-like cauline leaves 1 or more, sheathing and bract-like. *Spike* 5- to 16-flowered; bracts green below and dry and brownish above or entirely, often ± sticky, 9–16 mm long, inner slightly shorter, acute or forked apically for 1–2 mm. *Flowers* zygomorphic, pink or pale purple, darker in midline of lower 3 or all tepals and with white streak at base; perianth tube funnel-shaped, lower part 12–15 mm long, emerging 3–4 mm from bracts, upper part flaring and nearly horizontal to slightly pendulous, 8–10 mm long, ± 5 mm diam. at mouth; tepals spreading, obovate to oblanceolate, 22–30(–35) × 9–12(–15) mm. *Filaments* unilateral, decumbent above lower tepal, 10–12(–15) mm long; anthers 9–11(–13) mm long, purple. *Style* arching below stamens, dividing at ± middle of anthers, branches ± 5 mm long. *Capsules* elongate-ovoid, up to 14 mm long. *Seeds* 2-winged. *Flowering time*: October to early December.

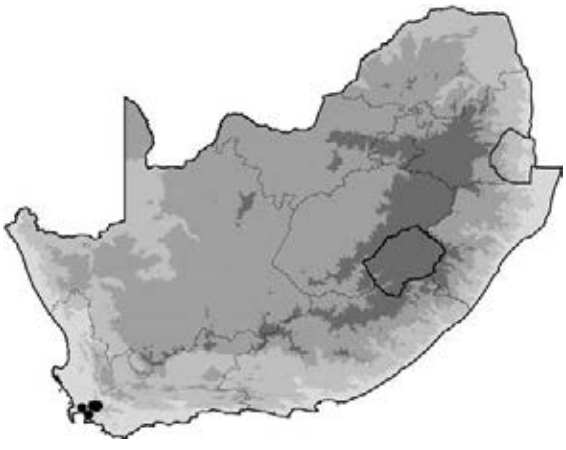
Distribution and ecology: restricted to the extreme southwestern part of Western Cape, from the foot of the Hottentots Holland and Kogelberg ranges to the Kleinrivier and Riviersonderend Mtns; in rocky sand or granite.

Diagnosis: a relatively small species, up to 500 mm high, with narrow leaves, 5–10 mm wide with strongly thickened midrib and margins, and pink flowers with a funnel-shaped perianth tube 20–25 mm long, and decumbent stamens with purple anthers 9–13 mm long. *Watsonia borbonica* is a larger species, 1 000 mm or more tall, with broader, apple-green leaves 20–40 mm wide. The two species co-occur along the foot of the Hottentots Holland and Kleinrivier Mtns, and may hybridise.

5. **Watsonia amabilis** *Goldblatt* in Annals of Kirstenbosch Botanic Gardens 19: 41 (1989). Type: South Africa, [Western Cape], Wemmershoek, *Barker 4904* (NBG, holo.; NBG, SAM, iso.).

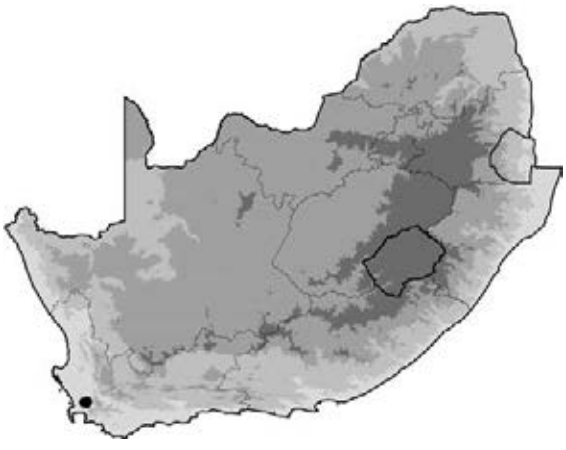
Plants (80–)150–300(–500) mm high. *Corm* subglobose, 15–20 mm diam.; tunics coarsely netted. *Stem* erect, simple or 1 or 2 short, ascending branches. *Leaves* 4 to 7, all basal or upper inserted on lower part of stem and partly sheathing, linear to lanceolate, 5–20 mm wide, midrib and margins lightly thickened and hyaline; bract-like cauline leaf 1. *Spike* 4- to 8(16)-flowered; bracts green, 12–20 mm long, inner ± as long, acute or minutely forked apically. *Flowers* zygomorphic, rose-pink with dark star-shaped marking in centre; perianth tube funnel-shaped, lower part 10–17 mm long, upper part flaring and nearly horizontal, 6–10 mm long, ± 6 mm diam. at mouth; tepals spreading, elliptic to obovate, 19–25 × 7–13 mm. *Filaments* unilateral and declinate, ± 12 mm long; anthers 7–8 mm long, dark purple. *Style* arching below stamens, usually dividing near base of anthers, branches ± 3 mm long. *Capsules* and *seeds* unknown. *Flowering time*: mid-October to mid-November.

Distribution and ecology: a rare and local species restricted to the foot of the Groot Drakenstein and Hottentots Holland Mtns between Paarl and Sir Lowry's Pass in Western Cape, South Africa; on granite soils in renosterveld.



Diagnosis: a small species with linear to lanceolate leaves and pink flowers with funnel-shaped perianth tube 16–27 mm long, and declinate stamens with relatively short, purple anthers 7–8 mm long. *Watsonia rogersii* is superficially similar, but has longer anthers 9–13 mm long.

6. **Watsonia strictiflora** *Ker Gawl.* in Curtis's Botanical Magazine 34: t. 1406 (1811). *Gladiolus strictiflorus* (Ker Gawl.) Delile in Redouté: t. 399 (1812). Type: South Africa, without precise locality or collector, illustration in Ker Gawl. in Curtis's Botanical Magazine 34: t. 1406 (1811).



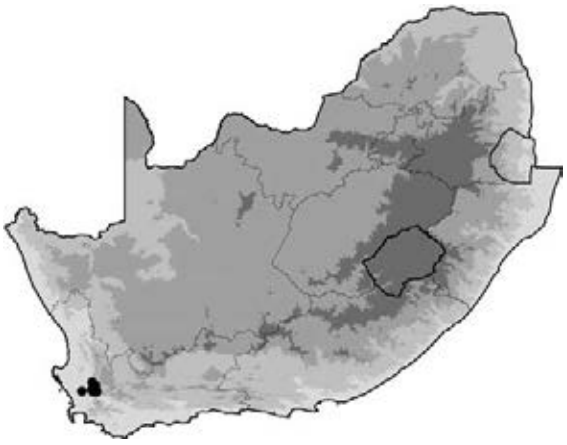
Plants 250–400 mm high. *Corm* subglobose, 20–30 mm diam.; tunics coarsely netted. *Stem* erect, simple or 1 or 2 short, ascending branches. *Leaves* 5 to 7, mostly ± basal with uppermost partly sheathing stems below, ± half as long as spike, narrowly lanceolate, up to 16 mm wide, midrib and margins lightly thickened and hyaline; bract-like cauline leaf 1. *Spike* 4- to 10-flowered; bracts overlapping, green, becoming dry at brown apically at flowering, (15–)20–25(–33) mm long, inner somewhat shorter, acute or minutely forked apically. *Flowers* zygomorphic, rose-pink with dark maroon star-shaped marking in centre; perianth tube slender and weakly funnel-shaped, lower part 20–35 mm long, upper part flaring slightly and nearly horizontal, 8–14 mm long, ± 6 mm diam. at mouth; tepals spreading, obovate, 22–25 × 11–15 mm. *Filaments* unilateral and declinate, 13–15 mm long, recurved apically; anthers 8–10 mm long, dark purple. *Style* arching below stamens, dividing between middle and upper half of anthers, branches 4–5 mm long. *Capsules* ovoid, 14–20 × 6–9 mm. *Seeds* 4–5 mm long, 2-winged. *Flowering time*: November to early December.

Distribution and ecology: a rare and local endemic of lower slopes and flats between Durbanville and Klapmuts in Western Cape, South Africa; mainly granite outcrops in renosterveld. Now known only from two severely fragmented populations.

Diagnosis: distinguished from other pink-flowered species with declinate stamens and purple anthers by the longer perianth tube, 30–50 mm long with the lower part 20–35 mm long and the upper part 8–14 mm long,

Distribution of ***Watsonia amabilis***.

Distribution of ***Watsonia strictiflora***.



and comparatively short bracts, mostly 15–30 mm long. *Watsonia dubia* from Wellington and Tulbagh has slightly longer bracts, mostly 30–50 mm long enclosing all or most of the lower part of the perianth tube, with the upper part of the tube relatively short, 5–8 mm long, and proportionally shorter filaments usually 6–12 mm long.

7. **Watsonia dubia** *Eckl. ex Klatt* in Linnaea 32: 741 (1864). *Watsonia meriana* var. *dubia* (Eckl. ex Klatt) Baker: 158 (1877). Type: South Africa, 'Worcester, beim Wasserfal,' etc., *Ecklon & Zeyher Irid. 186* (†B, holo.; G, MO, P, PRE, S, Z, iso. [some with different locality data]).

Plants (150–)250–400 mm high. *Corm* subglobose, 20–30 mm diam.; tunics coarsely netted. *Stem* erect, simple or with 1 to 3 short, ascending branches. *Leaves* 4 to 6, mostly ± basal with uppermost partly sheathing stems below, ⅔ to as long as spike, narrowly lanceolate to linear, (3–)6–12 mm wide, midrib and margins moderately thickened and hyaline; bract-like cauline leaves 2 or more. *Spike* 7- to 14-flowered; bracts slightly diverging, dry and brown distally or throughout at flowering, (25–)30–50(–70) mm long, inner slightly shorter to longer, minutely forked apically. *Flowers* zygomorphic, pale to deep pink with dark maroon streak near base of each tepal; perianth tube slender and weakly funnel-shaped, lower part 26–35(–40) mm long, usually enclosed in bracts, upper part flaring slightly and suberect or nearly horizontal, 5–8 mm long, ± 6 mm diam. at mouth; tepals spreading, obovate to oblanceolate, 24–30 × 9–15 mm. *Filaments* unilateral and declinate, 6–10 mm long; anthers 8–10 mm long, dark purple. *Style* arching below stamens, dividing between base and apex of anthers, branches 2–3 mm long. *Capsules* oblong, 16–25 × 4–9 mm long. *Seeds* unknown. *Flowering time*: early October to mid-November.

Distribution and ecology: a local endemic of the Swartland in Western Cape, South Africa, from Tulbagh to Wellington and Malmesbury; on granite and clay soils in renosterveld.

Diagnosis: distinguished from other pink-flowered species with declinate stamens and purple anthers by the long perianth tube, 30–50 mm long with the lower part 26–40 mm long and a short upper part 5–8 mm long, and the long bracts, mostly 30–50 mm long, usually diverging from the stem, and the relatively short filaments 6–12 mm long. *Watsonia strictiflora* from south of Wellington has slightly shorter bracts, (15–)20–25(–33) mm long, and a longer upper part of the perianth tube, 8–14 mm long, with proportionally longer filaments, 13–15 mm long.

Distribution of ***Watsonia dubia***.

8. **Watsonia laccata** *(Jacq.) Ker Gawl.* in Curtis's Botanical Magazine 17: t. 631 (1803). *Gladiolus laccatus* Jacq.: 171 (1791). Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 232 (1794 [1788–1795]).

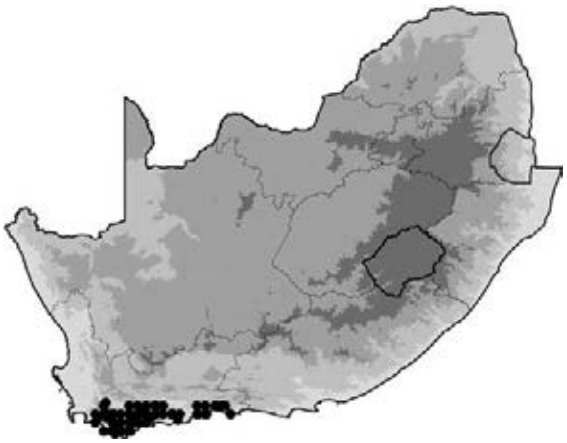
Watsonia hyacinthoides Pers.: 43 (1805), as replacement name for *Antholyza spicata* Andrews in Botanists Repository 1: t. 56 (1799), illegitimate homonym, not *A. spicata* Mill. (1768). *Gladiolus testaceus* Vahl: 105 (1805), as replacement name for *A. spicata* Andrews and an illegitimate homonym and superfluous name for *W. hyacinthoides* Pers. *Watsonia spicata* Klatt in Th.Durand & H.Schinz: 195 (1894), as replacement name for *A. spicata* Andrews and an illegitimate homonym, not *W. spicata* Ker Gawl. (1803) and a superfluous name for *W. hyacinthoides* Pers. Type: South Africa, without precise locality or collector, illustration in Andrews in Botanists Repository 1: t. 56 (1799).

Watsonia brevifolia Ker Gawl. in Curtis's Botanical Magazine 17: t. 601 (1802b). Type: South Africa, without precise locality or collector, illustration in Ker Gawl. in Curtis's Botanical Magazine 17: t. 601 (1802).

Watsonia caledonica Baker: 27 (1906). Type: South Africa, [Western Cape], Caledon, Leos Kraal, *Penther 725* [K, lecto., designated by Goldblatt: 47 (1989)].

Watsonia muirii E.Phillips: 351 (1917). Type: South Africa, [Western Cape], near Albertinia, *Muir s.n.* (SAM [*SAM5122*], lecto., designated by Goldblatt: 47 (1989); BOL, GRA, J, Z, isolecto.).

Watsonia albertiniensis R.Glover in Bolus: 162 (1918). Type: South Africa, [Western Cape], near Albertinia, *Muir s.n.* (BOL [*Nat. Bot. Gard. 911/13*], lecto., designated by Goldblatt: 47 (1989); SAM, isolecto.).



Plants 200–500(–650) mm high. *Corm* subglobose, 20–30 mm diam.; tunics coarsely netted. *Stem* erect, simple or with up to 3 short, ascending branches. *Leaves* 4 to 6, mostly ± basal with uppermost partly or entirely sheathing stem below, ⅓–⅔ as long as spike, lanceolate to linear, (3–)6–20(–28) wide, often glossy, midrib and margins lightly to strongly thickened and hyaline; bract-like cauline leaves 1 or more. *Spike* usually 8- to 20-flowered; bracts usually overlapping, broadly clasping below, green below but dry and pale brown distally with evident netted venation, becoming dry

throughout and lacerate, 10–20 mm long, inner ± as long, minutely forked apically. *Flowers* zygomorphic, pale pink to purple or orange, rarely white; perianth tube funnel-shaped, lower part 10–15 mm long, emerging ± 5 mm from bracts, upper part flaring slightly or rarely ± subcylindric and horizontal or slightly pendent, 7–15(–25) mm long, ± 6 mm diam. at mouth, usually with well-developed longitudinal ridges between filament bases; tepals spreading, obovate to oblanceolate, 14–16 × ± 8 mm. *Filaments* unilateral and declinate, 8–15(–25) mm long; anthers 4–5 mm long, yellow (rarely purple). *Style* arching below stamens, dividing near apex of anthers, branches ± 3 mm long. *Capsules* fusiform, 15–20 × ± 4 mm long, dehiscing only above. *Seeds* linear, 5–8 × 1.0–1.3 mm, 1- or 2-winged. *Flowering time*: late August to October (early November).

Distribution and ecology: distributed widely along the southern coastal plain, from Villiersdorp, Worcester and Kleinmond in Western Cape eastward to Jeffrey's Bay in Eastern Cape, South Africa; mostly on clay or loamy soils in renosterveld and transitional fynbos.

Diagnosis: a relatively short species with funnel-shaped, white or pale pink to mauve or rarely orange flowers with declinate stamens and short, pale yellow (rarely purple) anthers 4–5 mm long. The broad-based bracts, pale and dry above with netted venation, and the fusiform capsules are also distinctive.

The flowers are mostly pink to mauve (rarely orange near Heidelberg) and broadly funnel-shaped with the upper part of the perianth tube flared and 7–10 mm long but up to 15 mm long in some populations. Populations in the upper Breede River Valley between Montagu and Worcester represent a distinct variant with consistently bright orange, narrowly funnel-shaped flowers with the upper part of the perianth tube scarcely or only weakly flared and 15–25 mm long, thus ± 1.0–1.5 times as long as the tepals, and often purple anthers. These populations represent a shift toward bird-pollination. *Watsonia laccata* does hybridise with bird-pollinated *Watsonia aletroides*, especially around Caledon, and some of the longer-tubed forms may also indicate introgression with that species. *Watsonia aletroides* has ± tubular flowers with the tepals less than half as long as the upper part of the perianth tube. Both species have similar bracts and unusual, fusiform capsules.

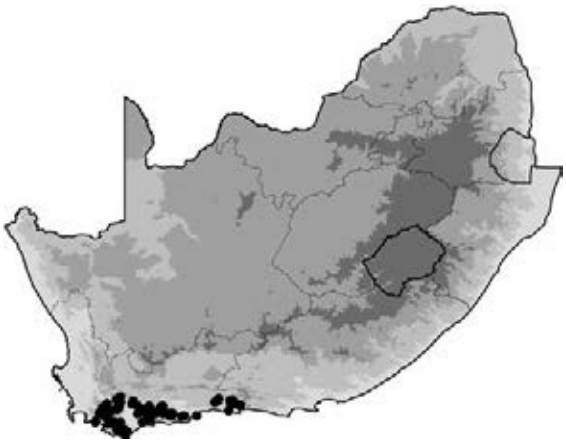
Distribution of ***Watsonia laccata***.

9. **Watsonia aletroides** *(Burm.f.) Ker Gawl.* in Curtis's Botanical Magazine 15: t. 533 (1801a). *Antholyza aletroides* Burm.f.: 1 (1768). *Gladiolus aletroides* (Burm.f.) Vahl: 96 (1805). Type: South Africa, without precise locality or collector (G: Herb. Burman, holo.).

Watsonia jacquinii Pers.: 42 (1805), as a replacement name for *Gladiolus tubulosus* Jacq.: 153 (1791), illegitimate homonym, not *G. tubulosus* Burm.f. (1768). Type: South Africa, [Western Cape], illustration in Jacquin: t. 229 (1792 [1788–1795]).

Antholyza tubulosa Andrews: t. 174 (1801a). *Watsonia tubulosa* (Andrews) Pers.: 42 (1805). Type: South Africa, [Western Cape], illustration in Andrews: t. 174 (1801a).

[*Watsonia tubulosa* Eckl.: 36 (1827), invalid name without description.]



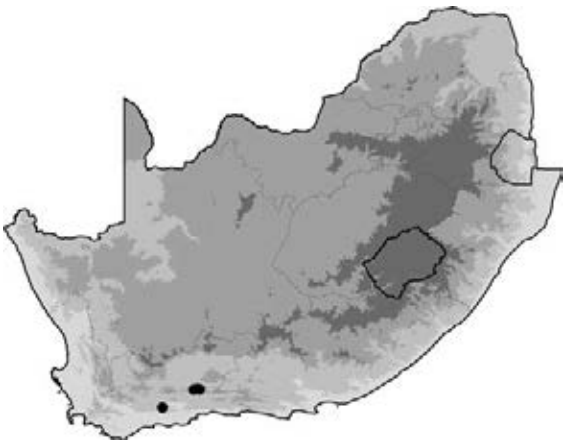
Plants 250–600 mm high. *Corm* subglobose, 20–30 mm diam.; tunics coarsely netted. *Stem* erect, simple or with 1 or 2 short, ascending branches. *Leaves* 4 to 6, mostly ± basal with uppermost partly or entirely sheathing stem below, ½–⅔ as long as spike, lanceolate to linear, (3–)5–10 mm wide, glossy, midrib and margins lightly to moderately thickened and hyaline; bract-like cauline leaves 1 or more. *Spike* usually 8- to 20-flowered; bracts usually overlapping, broadly clasping below, green below but dry and pale brown distally with evident netted venation, becoming dry throughout and lacerate, 11–24 mm long, inner ± as long, minutely forked apically. *Flowers* zygomorphic, reddish or orange, occasionally purple or pink, inner tepals usually paler or whitish; perianth tube with lower part 12–15 mm long, emerging 5–8 mm from bracts, upper part subcylindric and slightly to strongly pendent, 25–28 mm long, 5–8 mm diam. in middle; tepals weakly spreading distally, obovate to oblanceolate, ± 10 × 7–9 mm. *Filaments* unilateral and declinate, 30–35 mm long, shortly exserted from tube but included in flower; anthers 4–5 mm long, yellow. *Style* arching below stamens, dividing near base of anthers, branches ± 4 mm long. *Capsules* fusiform-attenuate, 15–25(–30) × 4–8 mm long, dehiscing only above, rarely aborted and replaced by cormlets. *Seeds* linear, 6–8 × 1.0–1.5 mm, shortly 2-winged. *Flowering time*: late August to October (early November).

Distribution and ecology: distributed widely along the southern coastal plain of Western Cape, from Bot River to Knysna, extending up the Breede River Valley to Worcester; on clay soils in renosterveld.

Diagnosis: a relatively short species distinguished by its ± pendent, tubular reddish or purple flowers with

short, barely spreading tepals ± 10 mm long and less than half as long as the upper part of the perianth tube, and declinate filaments with short, yellow anthers 4–5 mm long. The broad-based bracts, pale and dry above with netted venation, and the fusiform capsules are also distinctive and are shared with *Watsonia laccata*, which has funnel-shaped flowers with the tepals ± as long as or longer than the upper part of the perianth tube, and shorter filaments up to 20 mm long. The two species hybridise in the wild, producing a range of fertile intermediates (Goldblatt, 1989).

Unusual populations in the Bredasdorp district with pale pink flowers develop cormlets in the axils of the lower floral bracts in place of the buds or capsules, which abort after flowering. One of these populations has been established to be triploid (Goldblatt, 1989).



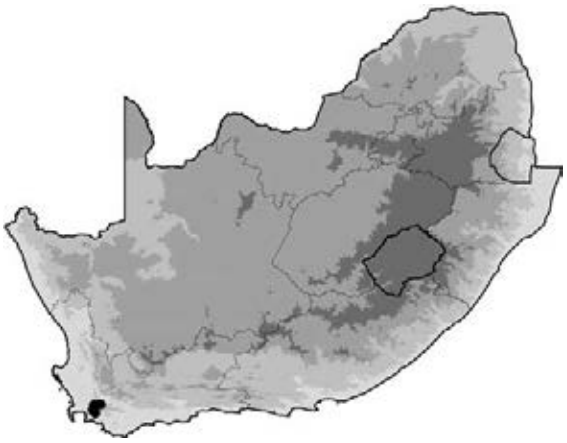
Distribution of ***Watsonia aletroides***.

Sect. 3. **Gladioloides** *Goldblatt*, Annals of Kirstenbosch Botanic Gardens 19: 52 (1989). Type species: *Watsonia densiflora* Baker

Stems usually unbranched; bracts firm-textured. *Flowers* zygomorphic, mostly pale to deep pink or purple, rarely red or pale yellow; perianth tube funnel-shaped with upper part flared or rarely subcylindric; tepals usually ± as long as or longer than upper part of tube. *Stamens* arcuate. *Capsules* ovoid or obovoid-globose. *Seeds* elongate-angular, not winged.

Species 21: southwestern and eastern southern Africa.

10. **Watsonia emiliae** *L.Bolus* in Bulletin of Miscellaneous Information Kew 1932: 327 (1932). Type: South Africa, [Western Cape], Riversdale, Garcia's Pass, *Ferguson s.n.* (BOL [*BOL19975*], lecto., designated by Goldblatt in Annals of Kirstenbosch Botanic Garden 19: 53 (1989); BOL, K, isolecto.).



Distribution of ***Watsonia emiliae***.

Plants 400–600 mm high. *Corm* depressed-globose, 25–30 mm diam.; tunics finely to coarsely netted. *Stem* erect, simple or with short, ascending branches. *Leaves* 2 to 4, lower 1 or 2 basal, linear, 4–5 mm wide, midrib and margins moderately thickened and hyaline, others smaller and partly sheathing; bract-like cauline leaves 2 or more, distant in upper part of stem. *Spike* 7- to 20-flowered; bracts probably dry and brown, 12–15 mm long, acute, inner somewhat shorter, forked apically for 2–4 mm. *Flowers* zygomorphic, pale pink with dark streak in lower midline of each tepal; perianth tube with lower part 10–12 mm long, usually included in bracts, upper part funnel-shaped, 6–8 mm long; suberect below and spreading distally, oblanceolate, 16–20 × 7–9 mm. *Filaments* unilateral and arcuate, 9–14 mm long, exserted 2–4 mm from tube; anthers 8–9 mm long, yellow. *Style* arching over stamens, dividing near apex of anthers, branches ± 3.5 mm long. *Capsules* narrowly obovoid, 9–12 mm long. *Seeds* unknown. *Flowering time*: November to December.

Distribution and ecology: a rare and localised endemic of Western Cape, South Africa, recorded only from Garcia's Pass in the Langeberg above Riversdale and high in the Swartberg east of Swartberg Pass; on rocky sandstone slopes, flowering only after fire.

Diagnosis: a small species with narrow, linear leaves 4–5 mm wide, laxly spaced cauline leaves, and pale pink flowers with funnel-shaped tube, the upper part ± as long as the tepals, and arcuate stamens with yellow anthers 8–9 mm long. *Watsonia distans* from marshy sites in the Hottentots Holland Mtns has unbranched stems with mostly fewer flowers with shorter anthers, 5–6 mm long.

11. **Watsonia distans** *L.Bolus* in Annals of the Bolus Herbarium 4: 51 (1926). Type: South Africa, [Western Cape], Franschhoek, *Schlechter 9305* (K [as '*9303*'], lecto., designated by Goldblatt: 54 (1989); B, BM, E, G, GRAMO, K, P, PRE, S, Z, isolecto.).

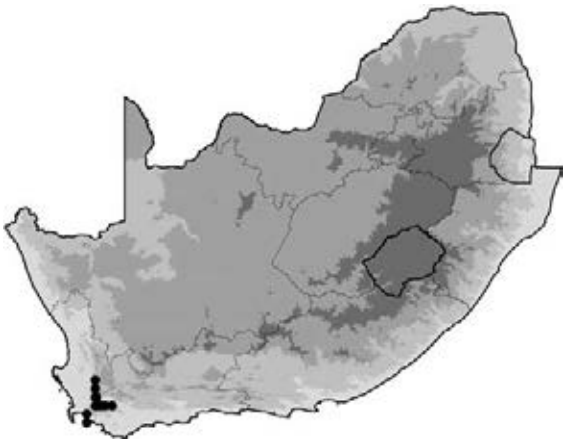
Distribution of ***Watsonia distans***.

Watsonia pauciflora L.Bolus: 328 (1932). Type: South Africa, [Western Cape], Caledon, near Elgin, *Ryder s.n.* (K [*BOL19973*], lecto., designated by Goldblatt: 54 (1989); BOL, isolecto.).

Plants 150–350 mm high. *Corm* depressed-globose, 15–25 mm diam.; tunics finely to coarsely netted. *Stem* erect, simple. *Leaves* 3 or 4, lower 2 or 3 basal, linear, 3–6 mm wide, midrib and margins moderately thickened and hyaline, others sheathing stem below, ± half as long to as long as spike; bract-like cauline leaves 1 or more, tightly sheathing, brown and dry. *Spike* 2- to 7(10)-flowered; bracts probably dry and brown, 10–13 mm long, inner somewhat shorter, forked apically. *Flowers* zygomorphic, pale pink to purple; perianth tube with lower part 8–12 mm long, shortly emerging from bracts, upper part horizontal and weakly funnel-shaped or subcylindric, 9–12 mm long, 3–5 mm diam. at mouth; tepals spreading, obovate, 15–20 × 7–9 mm. *Filaments* unilateral and arcuate, 10–14(–17) mm long; anthers 5–6 mm long, evidently yellow. *Style* arching over stamens, dividing ± at middle of anthers, branches 3–4 mm long. *Capsules* and *seeds* unknown. *Flowering time*: October to November.

Distribution and ecology: a poorly known species, restricted to the mountains in the extreme southwest part of Western Cape, from Franschhoek Pass to Houwhoek; in marshy sites, flowering only after fire.

Diagnosis: resembling *Watsonia amabilis* Goldblatt and *W. rogersii* L.Bolus in its short, simple stems and funnel-shaped pink flowers but distinguished from them by its arcuate stamens with shorter, yellow anthers 5–6 mm long. The funnel-shaped flowers with short upper portion of the tube, 9–12 mm long, distinguish it from the vegetatively similar *W. paucifolia*.



12. **Watsonia paucifolia** *Goldblatt* in Annals of Kirstenbosch Botanic Gardens 19: 56 (1989). Type: South Africa, [Western Cape], Slanghoek Mtns, Cossacks, *Esterhuysen 24000* (BOL, holo.; K, MO, PRE, iso.).

Plants 200–450 mm high. *Corm* depressed-globose, 15–25 mm diam.; tunics finely netted. *Stem* erect, simple. *Leaves* 1 to 3, lower 1 or 2 basal, third leaf, if present, small and inserted near middle of stem, lowermost longest and reaching or exceeding spike, linear to narrowly lanceolate, 2–8(–11) mm wide, midrib and margins moderately thickened and hyaline; bract-like cauline leaves 1 or 2. *Spike* 4- to 12-flowered; bracts green or flushed purple, becoming dry and rusty brown from apex, 10–18(–20) mm long, inner ½–⅔ (rarely almost as long), forked apically. *Flowers* zygomorphic, pale pink with dark purple median streak at base of tepals; perianth tube with lower part 10–12 mm long, shortly or not emerging from bracts, upper part ascending, subcylindric, 12–16 mm long, 6 mm diam. at mouth; tepals spreading, obovate, 14–16 × 6–9 mm. *Filaments* unilateral and arcuate, 14–18 mm long, exserted ± 3 mm from tube; anthers 6–7 mm long, purple. *Style* arching over stamens, dividing near apex of anthers, branches ± 3 mm long. *Capsules* obovoid, 7–9 mm long. *Seeds* angular with pronounced proximal and distal ridges, 4.5–5.5 × 2–3 mm. *Flowering time*: November to January.

Distribution and ecology: distributed through the mountains of the southwestern part of Western Cape, South Africa, from Groot Winterhoek above Tulbagh southward along the Witsenberg and Du Toit's Kloof Mtns to the Wemmershoek Mtns thence eastward onto the Riviersonderend Mtns, with outlying populations on the lower slopes of the Kogelberg near Kleinmond and the Kleinrivier Mtns near Stanford; on damp slopes or seeps, typically above 600 m elevation but at low altitudes along the coast.

The long-tubed, pale pink flowers with dark streaks around the mouth are adapted to pollination by long-proboscid flies (Manning et al. 1999).

Diagnosis: a delicate species with 1 or 2 narrow, basal leaves and a mostly unbranched stem with pink flowers with narrowly subcylindric perianth tube, the upper part 12–16 mm long, and purple anthers. *Watsonia*

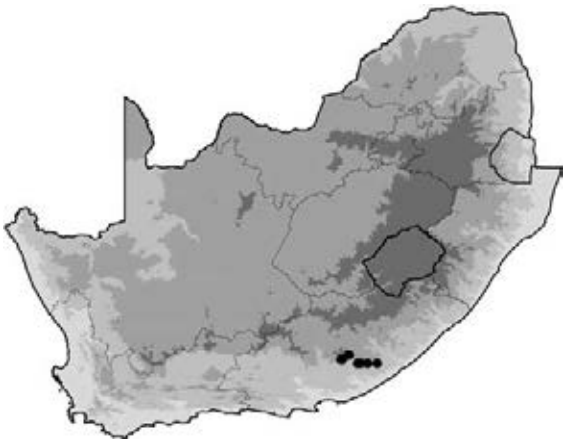
Distribution of ***Watsonia paucifolia***.

distans has funnel-shaped flowers with the upper part of the perianth tube flared and 9–12 mm long, and evidently yellow anthers.

13. **Watsonia amatolae** *Goldblatt* in Annals of Kirstenbosch Botanic Gardens 19: 58 (1989). Type: South Africa, [Eastern Cape], Katberg Pass, above Forrester's Cottage, *Hutchinson 1684* (PRE, holo.; BM, BOL, K, iso.).

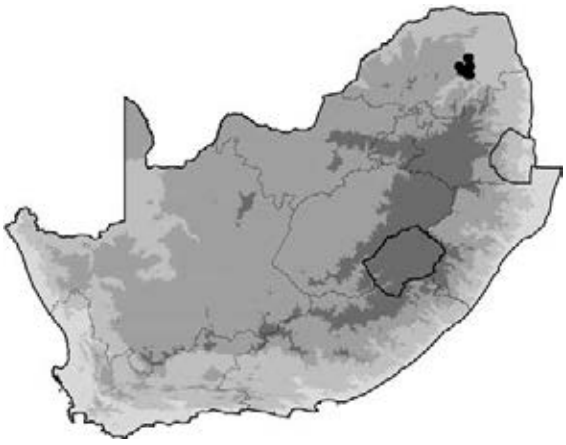
Plants 400–600 mm high. *Corm* subglobose, 25–35 mm diam.; tunics finely to coarsely netted. *Stem* erect, simple or with 1 or 2 short branches. *Leaves* 2 to 4, lower 1 to 3 basal, reaching to ± base of spike, linear to narrowly lanceolate, 5–10(–14) mm wide, midrib and margins moderately or sometimes heavily thickened and hyaline, uppermost sheathing lower half of stem; bract-like cauline leaves 2 or more, overlapping. *Spike* (6)10- to 20-flowered; bracts green below but dry and brown in upper half or throughout, 1.0–1.5(2.0) internodes long and usually shortly overlapping or somewhat lax, (10–)12–15 mm long, inner somewhat shorter, forked apically for 2–4 mm. *Flowers* zygomorphic, bright pink or purplish pink; perianth tube with lower part 10–12 mm long, usually included in bracts, upper part ascending, funnel-shaped, 6–8 mm long; tepals suberect, oblanceolate, 16–20 × 7–9 mm. *Filaments* unilateral and arcuate, 9–14 mm long, shortly exserted from tube; anthers 6–8 mm long, purple or pale pinkish. *Style* arching over stamens, dividing near apex of anthers, branches ± 3.5 mm long. *Capsules* obovoid, 9–11 mm long. *Seeds* angular with pronounced proximal and distal ridges, 5–6 × 1.5 mm. *Flowering time*: November to January (rarely later).

Distribution and ecology: restricted to the Amatole Mtns in Eastern Cape, South Africa, from the Katberg and Gaika's Kop in the west to Hogsback and Dohne Peak in the east; favouring marshes or rarely moist rocky slopes, in mountain grassland.



Diagnosis: distinguished from other summer-rainfall species with similar pink, funnel-shaped flowers by the relatively short bracts mostly 1.0–1.5 internodes long and thus not closely overlapping, and often green and leathery in the lower half at flowering. The stems are simple or branched and the anthers are moderately large, 6–8 mm long.

14. **Watsonia transvaalensis** *Baker* in Bulletin de l' Herbier Boissier, ser. 2, 1: 868 (1901). Type: South Africa, Transvaal, [Limpopo], Houtbosch, *Rehmann 5779* (Z, lecto., designated by Goldblatt: 59 (1989); K, Z, isolecto.).



Plants 350–500 mm high. *Corm* subglobose, 20–30 mm diam.; tunics coarsely netted. *Stem* erect, simple or rarely branched. *Leaves* 3 or 4, all basal or upper 1 or 2 sheathing lower part of stem or below or entirely, reaching to base or apex of spike, lanceolate, 8–20(–25) mm wide, midrib and especially margins moderately thickened and hyaline; bract-like cauline leaves 1 or more, often concealed by leaves. *Spike* 10- to 16-flowered; bracts greenish but dry and brownish in upper half with paler margins, later lacerate, ± 2 internodes long, barely clasping stem below, 13–20(–28) mm long, inner ½–⅔ as long, forked apically for 1–2 mm. *Flowers* zygomorphic, bright pink; perianth tube with lower part 10–12 mm long, usually included in bracts, upper part horizontal, funnel-shaped, 7–10 mm long; tepals suberect and flaring distally, oblanceolate-attenuate, 20–25 × 6–8 mm. *Filaments* unilateral and arcuate, 10–12 mm long; anthers 6–8 mm long, violet or pink. *Style* arching over stamens, dividing near apex of anthers, branches ± 4 mm long. *Capsules* and *seeds* unknown. *Flowering time*: late January to April.

Distribution and ecology: endemic to the eastern Drakensberg Escarpment in Limpopo, South Africa, from Duiwelskloof and Magoebaskloof to The Downs; in open rocky sites in montane grassland.

Diagnosis: distinguished from other summer-rainfall species with similar pink, funnel-shaped flowers by the unbranched stems with narrow bracts not or hardly

Distribution of ***Watsonia amatolae***.

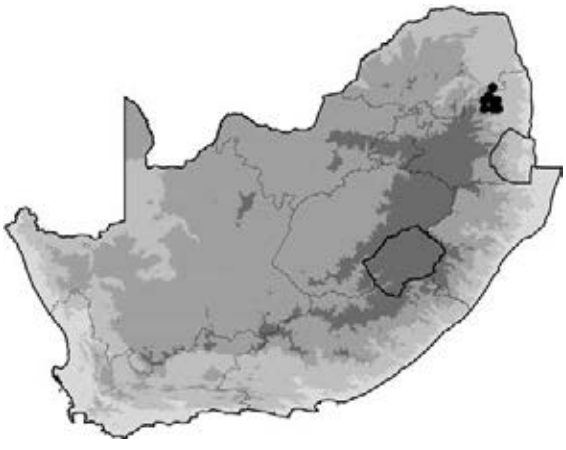
Distribution of ***Watsonia transvaalensis***.

clasping the stem below, relatively large flowers with attenuate tepals 20–25 mm long, and more northerly distribution.

15. **Watsonia strubeniae** *L.Bolus* in Journal of Botany, British and foreign 69: 261 (1931). Type: South Africa, Transvaal, [Mpumalanga], near Sabie, *Struben s.n.* (BOL [*Nat. Bot. Gard. 1209/30*], lecto., designated by Goldblatt: 60 (1989); BOL, GRA, K, isolecto.).

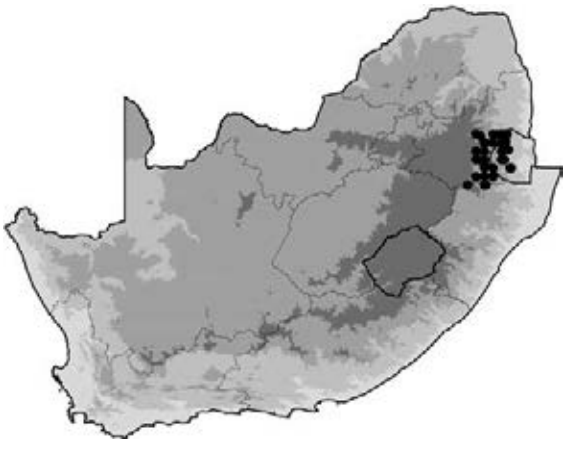
Watsonia transvaalensis var. *drakensbergensis* L.Bolus: 55 (1926). Type: South Africa, Transvaal, [Mpumalanga], valley near Pilgrims Rest, *Roe s.n.* (K [*BOL 2655*], lecto., designated by Goldblatt: 60 (1989); BOL [fragment], isolecto.).

Watsonia alpina G.J.Lewis: t. 689 (1938). Type: South Africa, Transvaal, [Mpumalanga], Mt Anderson near Lydenburg, *Galpin s.n.* (BOL, holo.).



Plants 600–1 000 mm high. *Corm* subglobose, 30–40 mm diam.; tunics coarsely netted, extending upward as a fibrous collar. *Stem* erect, with 3 to 5 rigid, diverging branches. *Leaves* 4 or 5, lower 2 or 3 ± basal, reaching to ± base of spike, lanceolate, 14–20 mm wide, midrib and especially margins heavily thickened and hyaline, remaining leaves inserted on lower part of stem, smaller and partly to entirely sheathing; bract-like cauline leaves 1 or 2 in upper part of stem. *Spike* 25- to 35-flowered; bracts greenish but dry and brownish in upper half, later lacerate, not or barely clasping stem only at base, 9–14 mm long, inner somewhat shorter, entire or forked apically for ± 1 mm. *Flowers* zygomorphic, pale pink; perianth tube with lower part 7–9 mm long, barely emerging from bracts, upper part horizontal, funnel-shaped, 6–7 mm long, ± 6 mm diam. at mouth; tepals suberect and flaring distally, lanceolate, 17–19 × 5–6 mm. *Filaments* unilateral and arcuate, 6–7 mm long; anthers 6–7 mm long, violet. *Style* arching over stamens, dividing near apex of anthers, branches 4–5 mm long. *Capsules* globose, up to 6 mm long. *Seeds* elongate-angular. *Flowering time*: late February to April.

Distribution and ecology: endemic to the eastern Drakensberg Escarpment in Mpumalanga, South Africa, between Sabie and Pilgrim's Rest; in well-watered montane grassland on shallow soils.



Diagnosis: distinguished by its long spikes of relatively small, pale pink flowers with the upper part of the perianth tube 6–7 mm long and tepals 17–19 mm long, and short, ± dry floral bracts 9–14 mm long, not clasping the stem. *Watsonia transvaalensis* from the escarpment north of Graskop has mostly narrower leaves, 8–20(–25) mm wide, with moderately thickened margins, and mostly unbranched stems with larger bracts, 13–28 mm long, and larger flowers with tepals 20–25 mm long.

16. **Watsonia watsonioides** *(Baker) Oberm.* in Bothalia 8: 116 (1962). *Tritonia watsonioides* Baker: 195 (1892). *Watsonia flavida* Bolus in Bolus & Kensit: 162 (1909), illegitimate superfluous name for *T. watsonioides* Baker (1892). Type: South Africa, [Mpumalanga], Saddleback, Barberton Mtns, *Galpin 814* (K, lecto., designated by Goldblatt: 62 (1989); BOL, GRA, NH [as *813*], isolecto.).

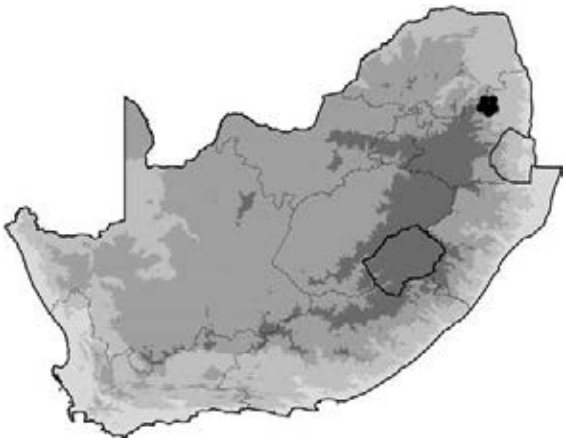
Plants 500–1 000 mm high. *Corm* depressed-globose, 20–30 mm diam.; tunics finely netted, extending upward as a fibrous collar. *Stem* erect, with simple or with 1 or more short, erect branches. *Leaves* (1)2 or 3, lower 2 ± basal, ± as long as stem, linear, 4–6 mm wide, midrib moderately and margins heavily thickened and hyaline, third leaf, if present, inserted on lower part of stem and partly to entirely sheathing; bract-like cauline leaves overlapping upper part of stem up to spike. *Spike* congested, 25- to 35-flowered; bracts green at base, dry and brownish in upper half, clasping stem only at base, 7–10(–15) mm long, inner shorter, forked for 2–3 mm. *Flowers* zygomorphic, pale yellow to cream-coloured or maroon; perianth tube with lower part 8–9 mm long, emerging 2–3 mm from bracts, upper part horizontal to drooping, funnel-shaped, 7–9 mm long, ± 5 mm diam. at mouth; tepals suberect and flaring distally, obovate, 10–18 × 5–7 mm. *Filaments* unilateral and arcuate,

Distribution of ***Watsonia strubeniae***.

Distribution of ***Watsonia watsonioides***.

10–12 mm long; anthers 5–8 mm long, yellow. *Style* arching over stamens, dividing near base of anthers, branches ± 2 mm long. *Capsules* globose, 5–8 mm long. *Seeds* narrowly ovoid-angular, 3–4 × 2 mm. *Flowering time*: (December) January to March.

Distribution and ecology: distributed along the eastern escarpment in southeastern Mpumalanga, South Africa and Eswatini; in rocky montane grassland, usually from 1 300 to 1 800 m elevation.



Diagnosis: a distinctive species readily recognised by the one or two linear basal leaves and dense spikes of small flowers, the upper part of the perianth tube 7–9 mm long and the tepals 10–18 mm long. The flowers are typically and uniquely pale yellow to cream-coloured, but maroon-flowered populations occur around Mankayane in southwestern Eswatini.

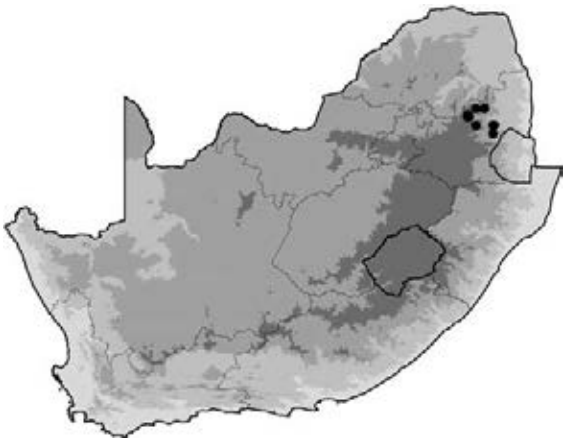
17. **Watsonia wilmsii** *L.Bolus* in Annals of the Bolus Herbarium 4: 54 (1926). Type: South Africa, [Mpumalanga], Parade Platz near Lydenburg, *Wilms 1440* (B, lecto., designated by Goldblatt: 64 (1989); BM, E, K, G, isolecto.).

Plants 450–750 mm high. *Corm* subglobose, 20–30 mm diam.; tunics coarsely netted. *Stem* erect, simple or with 1 or 2 diverging branches. *Leaves* 4 or 5, ± basal or upper inserted on lower part of stem, upper 1 or 2 partly or entirely sheathing, ± half as long as spike, lanceolate, 10–20(–25) mm wide, midrib moderately and margins heavily thickened and hyaline; bract-like cauline leaves 1 or 2, inserted on upper part of stem and often concealed by leaves. *Spike* 16- to 24-flowered; bracts greenish below but dry and brownish in upper half or entirely, later lacerate, usually clasping stem below, (20–)25–35 mm long, completely enclosing inner, inner 3–5 mm shorter, forked for ± 1 mm. *Flowers* zygomorphic, deep pink with dark median streak in basal half of lower tepals; perianth tube with lower part 25–30 mm long, emerging 7–10 mm from bracts, upper part poorly differentiated, horizontal, narrowly funnel-shaped, ± 15 mm long, ± 8 mm diam. at mouth; tepals suberect and flaring distally, lanceolate, 22–26 × 6–9 mm. *Filaments* unilateral and arcuate, 20–22 mm long; anthers 6–8 mm long, violet. *Style* arching over stamens, dividing near apex of anthers, branches ± 5 mm long. *Capsules* narrowly oblong, up to 16 mm long. *Seeds* angular, ± 4 × 2 mm. *Flowering time*: January to early April.

Distribution and ecology: a narrow endemic of the higher parts of the eastern escarpment in Mpumalanga, South Africa, between Mauchsberg above Lydenburg and Pilgrim's Rest and Ohrigstad; in rocky montane grassland, usually above 1 600 m elevation.

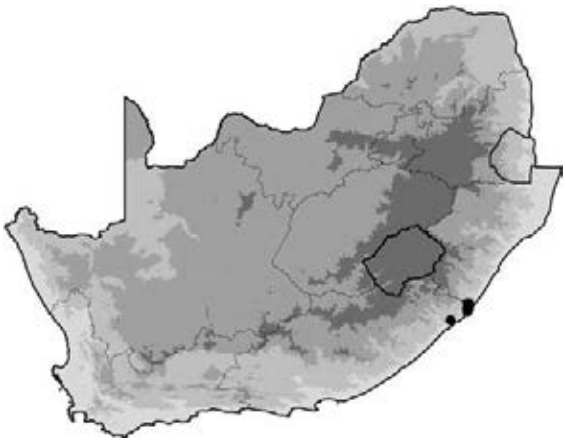
Diagnosis: recognised by the long bracts, (20–)25–35 mm long, and especially the very long lower part of the perianth tube, 25–30 mm long, with a narrowly funnel-shaped upper part ± 15 mm long. *Watsonia occulta* has

Distribution of ***Watsonia wilmsii***.



even longer bracts, 35–55 mm long, and similarly long-tubed flowers with a much shorter upper part of the tube, just ± 6 mm long.

18. **Watsonia occulta** *L.Bolus* in Annals of the Bolus Herbarium 4: 51 (1926). Type: South Africa, Transvaal, [Mpumalanga], Lydenburg, Crocodile River, *Wilms 1439* (B, lecto., designated by Goldblatt: 66 (1989); BM, isolecto.).



Plants 180–400 mm high. *Corm* subglobose, 20–30 mm diam.; tunics finely netted, extending upward as a collar. *Stem* erect, simple. *Leaves* 3 or 4, lower 2 or 3 basal, ± as long as stem, linear-lanceolate, 3–8 mm wide, midrib and margins thickened and hyaline, uppermost leaf smaller and basal or inserted on lower part of stem, sheathing for half its length; bract-like cauline leaves 1 to 3, inserted on upper part of stem, overlapping, 60–80 mm long. *Spike* 3- to 7-flowered; bracts green, dry and brownish apically, 35–55 mm long, clasping and concealing stem, reaching to middle of next bract, completely enclosing inner bract, inner ± half as long, pale green, entire or forked for 1–2 mm. *Flowers* zygomorphic, pale pink; perianth tube with lower part 30–35(–50) mm long, enclosed, upper part poorly differentiated, horizontal, narrowly funnel-shaped, ± 6 mm long, ± 6 mm diam. at mouth; tepals suberect and flaring distally, lanceolate, 20–22 × 7–8 mm. *Filaments* unilateral and arcuate, ± 10 mm long; anthers 5.5–6.5 mm long, pale bluish. *Style* arching over stamens, dividing opposite anthers, branches 5–6 mm long. *Capsules* and *seeds* unknown. *Flowering time*: December to January.

Distribution and ecology: a narrow endemic of the higher parts of the eastern escarpment in Mpumalanga, South Africa, from near Lydenburg to Kaapschehoop; in montane grassland, usually above 1 400 m elevation.

Diagnosis: a very distinctive but inconspicuous species, with a spike of 3 to 7 pale pink flowers largely concealed by unusually long bracts, 35–55 mm long. The flowers are long-tubed, with the lower part of the perianth tube 30–50 mm long and the upper part relatively short, ±

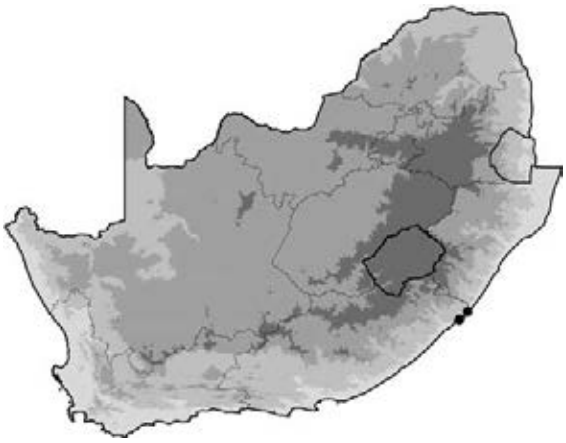
Distribution of ***Watsonia occulta***.

Distribution of ***Watsonia inclinata***.

6 mm long. *Watsonia wilmsii* is a larger, more conspicuous species with similarly long-tubed flowers but with a much longer upper part of the tube ± 15 mm long, and shorter bracts (20–)25–35 mm long.

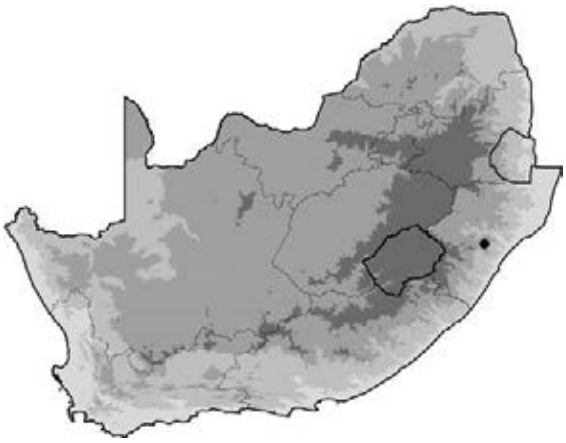
19. **Watsonia inclinata** *Goldblatt* in Annals of Kirstenbosch Botanic Gardens 19: 67 (1989). Type: South Africa, [KwaZulu-Natal], Umtamvuna Nature Reserve, Gogosa, north side of Umtamvuna [Mtamvuna] Gorge, sloping stony grassland, *Goldblatt 7895* (PRE, holo.; MO, NU, iso.).

Plants 300–600 mm high. *Corm* subglobose, 20–30 mm diam.; tunics coarsely netted, extending upward as a thick collar. *Stem* flexed at ground level and inclined, simple. *Leaves* 3 or 4, lower 2 basal, ± half as long as stem, narrowly lanceolate, 4–14 mm wide, pale green, midrib and margins thickened and hyaline, uppermost leaf or leaves smaller and inserted on lower part of stem, largely sheathing and becoming bract-like; bract-like cauline leaves 2 or more, inserted on upper part of stem, overlapping. *Spike* (3)6- to 11-flowered; bracts green and herbaceous, dry and brown apically, (18–)20–30 mm long, clasping stem in lower half, up to 2 internodes long, inner shorter and concealed. *Flowers* zygomorphic, pink with whitish throat and tube, sweetly scented; perianth tube with lower part 15–18 mm long, included or shortly exserted from bracts, upper part horizontal and funnel-shaped, 8–10 mm long, ± 6 mm diam. at mouth; tepals spreading distally, obovate, 24–28 × 10–12 mm. *Filaments* unilateral and arcuate, 6–10 mm long, included in tube; anthers ± 9 mm long, pale bluish mauve. *Style* arching over stamens, dividing near apex of anthers, 3–4 mm long. *Capsules* obovate-truncate, 8–10 mm long. *Seeds* elongate-angular, 3–4 × ± 1.5 mm. *Flowering time*: September to October.



Distribution and ecology: a local endemic of the East Coast of South Africa, from Umtamvuna Nature Reserve near Port Edward in southern KwaZulu-Natal to Kokstad in Eastern Cape; in open, stony grassland, flowering best after fire or grazing.

Diagnosis: recognised by its inclined, unbranched stem and relatively lax spike of pink, funnel-shaped flowers with largely herbaceous bracts 18–27 mm long. *Watsonia pondoensis* from marshy habitats in the same region forms small clumps, with stiffly erect stems, glaucous leaves, and slightly smaller, purple flowers with tepals 20–22 mm long.



20. **Watsonia pondoensis** *Goldblatt* in Annals of Kirstenbosch Botanic Gardens 19: 69 (1989). Type: South Africa, [KwaZulu-Natal], Umtamvuna Nature Reserve, vlei in swamp forest, *Abbott 2760* (PRU, holo.; MO, iso.).

Plants 300–600 mm high, forming small clumps. *Corm* subglobose, 20–30 mm diam.; tunics coarsely netted. *Stem* erect, simple. *Leaves* 3 or 4, lower 2 basal, ± half as long as stem, narrowly lanceolate, 4–12 mm wide, glaucous with bluish tinge, midrib and margins thickened and hyaline, uppermost leaf or leaves smaller and inserted on lower part of stem, largely sheathing and becoming bract-like; bract-like cauline leaves 2 or more, inserted on upper part of stem, overlapping. *Spike* 3- to 8-flowered; bracts green and herbaceous flushed purple, becoming dry and brown apically, 17–25 mm long, clasping stem in lower half, up to 1.5 internodes long, inner shorter and concealed, acute. *Flowers* zygomorphic, mauve or purplish pink with whitish throat and darker median streak near base of tepals; perianth tube with lower part 15–20 mm long, included or shortly exserted from bracts, upper part horizontal and funnel-shaped, 7–10 mm long, ± 6 mm diam. at mouth; tepals spreading distally, obovate, 20–22 × ± 7 mm. *Filaments* unilateral and arcuate, 6–10 mm long, included or just reaching mouth of tube; anthers ± 9 mm long, purple. *Style* arching over stamens, dividing near apex of anthers, branches slender and not recurving, 3–4 mm long. *Capsules* narrowly obovate-truncate, 10–13 mm long. *Seeds* elongate-angular, usually with wing-like ridge at distal end, 5–6 × ± 2 mm. *Flowering time*: September to October.

Distribution and ecology: a poorly known species endemic to the East Coast of South Africa, from Umtamvuna

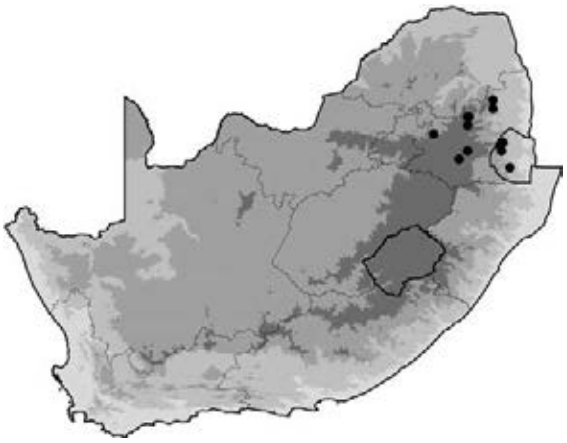
Distribution of ***Watsonia pondoensis***.

Distribution of ***Watsonia vicschuettei***.

Nature Reserve near Port Edward in southern KwaZulu-Natal and nearby Port Grosvenor in Eastern Cape; forming small clumps in marshy grassland and vleis.

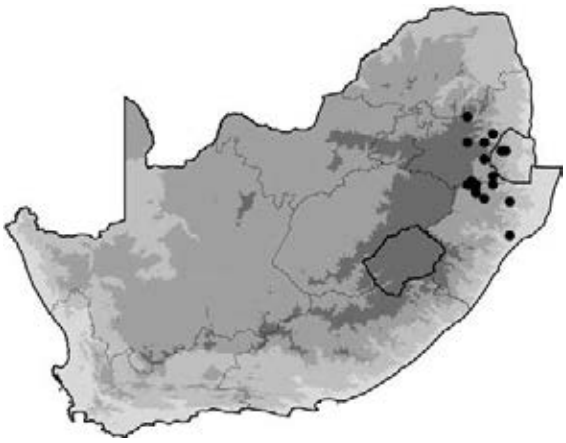
Diagnosis: recognised by its clump-forming habit, erect, unbranched stems, and relatively lax spike of dark pink or mauve, funnel-shaped flowers with largely herbaceous bracts 17–25 mm long, and the relatively long lower part of the perianth tube, 15–20 mm long. *Watsonia inclinata* from drier grasslands in the same region has pale green leaves and inclined stems of slightly larger flowers with tepals 24–28 mm long.

21. **Watsonia vicschuettei** *C.J.Potgieter & I.M. Johnson* in Phytotaxa 364: 209 (2018), as a replacement name for *W. palustris* Goldblatt & J.C.Manning in South African Journal of Botany 106: 151 (2016), illegitimate homonym, not *W. palustris* Pers. (1805). Type: South Africa, KwaZulu-Natal, Umvoti District, Lake Merthley, western shores, 1 350 m, 15 Feb. 2011, *Johnson 1487* (NBG, holo.; MO, iso.).



Plants 450–600 mm high, forming large clumps. *Corm* subglobose, 10–20 mm diam.; tunics finely netted, extending upward as a collar. *Stem* erect, simple. *Leaves* 3 to 5, lower 2 to 4 basal, ± as stem, linear, 3–5 mm wide, midrib lightly and margins moderately thickened and hyaline, sometimes dry and broken at flowering, uppermost leaf or leaves smaller and inserted on lower part of stem, partly or largely sheathing and becoming bract-like; bract-like cauline leaves 3 or more, inserted on upper part of stem, overlapping. *Spike* 6- to 15-flowered, internodes mostly 8–10 mm long; bracts green and herbaceous flushed purple, with brown papery margins, becoming dry and brown apically, (15–)20–25 mm long, not clasping stem, apiculate to attenuate, 2.0–2.5 internodes long, inner shorter and concealed, acute. *Flowers* zygomorphic, bright pink or purplish; perianth tube with lower part 13–15 mm long, included in bracts, upper part ascending to horizontal and funnel-shaped, 7–10 mm long, ± 6 mm diam. at mouth; tepals spreading distally, obovate, 13–15 × 5–6 mm. *Filaments* unilateral and arcuate, 10–12 mm long, exserted 3 mm from tube; anthers 6–7 mm long, purple. *Style* arching over stamens, dividing near apex of anthers, branches slender and not recurving, ± 5 mm long. *Capsules* and *seeds* unknown. *Flowering time*: February to March.

Distribution and ecology: a highly localised endemic of north-central KwaZulu-Natal, South Africa, known only from around Greytown and specifically Lake Merthley; forming large clumps in seasonal wetlands in grassland at 1 000 m elevation or above.



Diagnosis: a slender species with small, dark pink, funnel-shaped flowers, linear leaves 3–5 mm wide, and simple, erect stems forming large clumps, distinguished from other pink-flowered species by its narrow, largely herbaceous bracts, (15–)20–25 mm long, not clasping the stem at the base. The flowers are among the smallest in the group, with the lower part of the perianth tube 13–15 mm long and the upper part 7–10 mm long, and are distinctive in having the filaments exserted ± 3 mm from the perianth tube, with short anthers, 6–7 mm long. The late summer flowering, in February and March, is also characteristic. *Watsonia bella* has similarly small flowers with short anthers but has shorter, dry brown bracts, (10–)12–16 mm long, clasping the stem in the lower part, and filaments included in the tube. Spring-flowering *Watsonia inclinata* and *W. pondoensis* have similar, largely herbaceous bracts 17–30 mm long but larger flowers with the lower part of the perianth tube 15–20 mm long, tepals 20–28 mm long, and included filaments with larger anthers, ± 9 mm long.

22. **Watsonia bella** *N.E.Br. ex Goldblatt* in Annals of Kirstenbosch Botanic Gardens 19: 71 (1989). Type: Swaziland [Eswatini], Mbabane, Dalriach, *H. Bolus s.n.* (BOL 12344, holo.; K, iso.).

Plants 500–600 mm high. *Corm* subglobose, 20–30 mm diam.; tunics finely netted. *Stem* erect, simple. *Leaves* 3 or 4, lower 2 or 3 basal, usually ± half as long as stem or as long as, narrowly lanceolate, 4–6 mm wide, midrib hardly and margins moderately thickened and hyaline,

Distribution of ***Watsonia bella***.

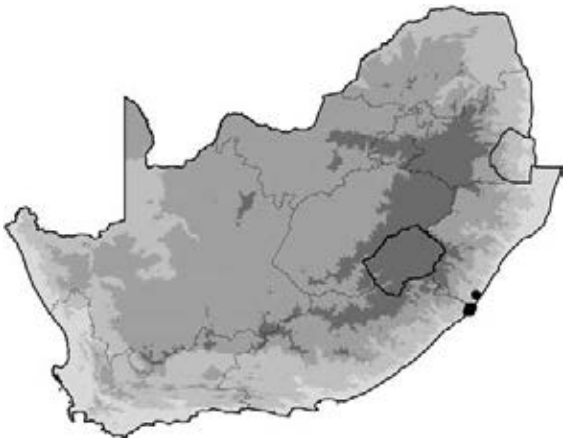
Distribution of ***Watsonia latifolia***.

uppermost leaf or leaves sheathing below; bract-like cauline leaves 2 or 3, overlapping. *Spike* 8- to 10-flowered, internodes 8–15 mm long; bracts dry and brown, (10–)12–16 mm long, clasping stem in lower ⅓–½, usually not reaching node above, often apiculate to attenuate, inner shorter and concealed, usually forked apically for 2 mm or more. *Flowers* zygomorphic, pink to purple; perianth tube with lower part 10–12 mm long, emerging 2–4 mm from bracts, upper part horizontal and funnel-shaped, 8–10 mm long, ± 6 mm diam. at mouth; tepals spreading distally, obovate, 15–18 × 6–8 mm. *Filaments* unilateral and arcuate, 10–12 mm long, included in tube; anthers 5–6 mm long, ?yellow. *Style* arching over stamens, dividing near apex of anthers, branches 2–3 mm long. *Capsules* and *seeds* unknown. *Flowering time*: late October to December.

Distribution and ecology: a relatively rare species of the eastern highveld and escarpment, from Pilgrim's Rest and Dullstroom in Mpumalanga, South Africa to western Eswatini; in wet and marshy grassland on lower slopes.

Diagnosis: distinguished from other species with similar dry, clasping bracts and pink, funnel-shaped flowers with included filaments, by the relatively few-flowered spike with non-overlapping bracts 10–16 mm long, and small flowers with tepals 15–18 mm long and anthers 5–6 mm long.

23. **Watsonia latifolia** *N.E.Br. ex Oberm.* in Bothalia 8: 115 (1962). Type: South Africa, [KwaZulu-Natal], Ngotshe District, near Ngome, foot of granite slopes, *Codd & Robertson 6403* (PRE, lecto., designated by Goldblatt: 72 (1989); K, NBG, PRE, SRGH, isolecto.).



Plants 700–1 500 mm high. *Corm* subglobose, 40–60 mm diam.; tunics coarsely netted. *Stem* erect, usually simple. *Leaves* 4 to 6, lower 3 or more basal, ½–⅔ as long as stem, lanceolate, (30–)50–90 mm wide, bright glossy green, midrib hardly and margins lightly thickened and hyaline, uppermost leaf partly or entirely sheathing; bract-like cauline leaves several, decreasing in size above. *Spike* 15- to 25-flowered; bracts becoming dry and brown above, 15–30 mm long, clasping stem in lower ½, inner ⅔ to ± as long, forked apically for up to 2 mm. *Flowers* zygomorphic, dull red to maroon; perianth tube with lower part 15–25 mm long, emerging from bracts, upper part horizontal and nearly cylindric, 18–20(–24) mm long, 5–6 mm diam. in middle; tepals spreading outward, lanceolate, 20–30 × 4.5–8.0 mm. *Filaments* unilateral and arcuate, 28–35 mm long, exserted up to 10 mm from tube; anthers 7–10 mm long, dark violet. *Style* arching over stamens, dividing near or just beyond anther apices, branches 6–8 mm long. *Capsules* oblong-fusiform, 14–20 mm long. *Seeds* angular, up to 4 × 2 mm. *Flowering time*: December to February.

Distribution and ecology: a summer-flowering species of the eastern escarpment of South Africa, from Nelshoogte in southern Mpumalanga to Vryheid and Ngome in northern KwaZulu-Natal; on rocky quartzite slopes and granite outcrops in grassland, usually above 1 800 m elevation.

Diagnosis: a distinctive species with broad, bright green leaves, 30–60 mm wide, and long-tubed, dull red to maroon flowers with the upper part of the perianth tube subcylindric, 18–24 mm long and slightly shorter than the tepals. *Watsonia gladioloides* from the Eastern Cape Drakensberg has similar, orange to scarlet flowers but narrower leaves, less than 18 mm wide, and bracts completely dry at flowering.

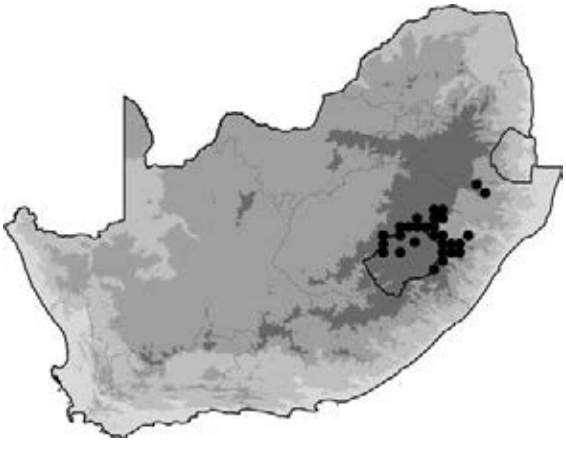
24. **Watsonia mtamvunae** *Goldblatt* in Annals of Kirstenbosch Botanic Gardens 19: 74 (1989). Type: South Africa, [KwaZulu-Natal], Port Shepstone, Umtamvuna [Mtamvuna] River Bridge, *Strey 5987* (PRE, holo.; E, MO, NH, NU, iso.).

Plants 300–450 mm high. *Corm* subglobose, 12–16 mm diam.; tunics finely netted, extended into a fibrous collar. *Stem* erect, simple. *Leaves* 3 to 5, sometimes dry and broken at flowering, ± basal, ± as long as spike, linear, 3–4 mm wide, midrib and margins thickened and hyaline,

Distribution of ***Watsonia mtamvunae***.

uppermost leaf sometimes short and partly sheathing stem; bract-like cauline leaves 2 to 4, distant. *Spike* 2- to 12(14)-flowered; bracts dry and brown above or throughout, often flushed purple below, 12–16(–25) mm long, clasping stem in lower half, overlapping, 2 internodes long, inner shorter and concealed, deeply forked apically. *Flowers* zygomorphic, pale pink; perianth tube with lower part 10–12 mm long, included or barely emerging from bracts, upper part horizontal and funnel-shaped, 7–9 mm long, ± 6 mm diam. at mouth; tepals spreading outward, obovate, 14–16 × 5–7 mm. *Filaments* unilateral and arcuate, 7–10 mm long, included in tube; anthers 7 mm long, pale yellow. *Style* arching over stamens, dividing near anther apices, branches 3–4 mm long. *Capsules* narrowly obovoid, 7–9 mm long. *Seeds* angular-elongate, 3.0–3.5 × 1.3 mm. *Flowering time*: August to early October.

Distribution and ecology: a narrow endemic of the East Coast of South Africa, restricted to the plateau and slopes surrounding the Mtamvuna River Gorge near Port Edward in southern KwaZulu-Natal and across the border in Eastern Cape; on well-drained, grassy slopes on quartzite.



Diagnosis: one of three early flowering, locally endemic species with pink, funnel-shaped flowers restricted to the southeast coast around the Mtamvuna River Gorge, distinguished by its linear leaves, 3–4 mm wide and usually dry and broken at flowering, the plants thus sometimes apparently leafless, the ± dry bracts, and the small flowers with tepals 14–16 mm long. *Watsonia pondoensis* from marshy sites has leaves 4–14 mm wide, ± herbaceous bracts, and larger flowers with the lower part of the tube 15–20 mmm long and tepals 20–22 mm long.

25. **Watsonia lepida** *N.E.Br.* in Bulletin of Miscellaneous Information Kew 1931: 194 (1931). Type: South Africa, [Free State], near Harrismith, *Cooper 886* (K, lecto., designated by Goldblatt: 76 (1989); BOL, Z, isolecto.).

Plants 250–650 mm high, usually solitary but sometimes forming small clumps. *Corm* subglobose, 20–40 mm diam.; tunics coarsely netted. *Stem* erect, simple. *Leaves* 3 or 4, dry and sometimes broken at flowering, lower 2 or 3 basal, ± as long as spike or longer, linear to lanceolate, (3–)5–15 mm wide, midrib and margins strongly thickened and hyaline, uppermost leaf or leaves partly sheathing stem; bract-like cauline leaves 2 or more, overlapping, large and somewhat inflated. *Spike* 12- to 22(30)-flowered; bracts dry and cinnamon- to dark brown, veins not evident, 16–25(–40) mm long, 10–12 mm wide, clasping stem in lower ⅓ or less, strongly overlapping, inner shorter and concealed, usually forked apically up to 2 mm. *Flowers* zygomorphic, weakly bilabiate, pink to pinkish purple, paler in throat and tube; tepals usually with dark median streak in lower half; perianth tube with lower part 12–18 mm long, included in bracts, upper part horizontal and funnel-shaped, ± 15 mm long, ± 8 mm diam. at mouth; tepals lanceolate, upper three spreading, lower three nearly horizontal, ± 20 × 8–9 mm. *Filaments* unilateral and arcuate, 12–16 mm long, reaching mouth of tube; anthers 9–10 mm long, mauve to whitish. *Style* arching over stamens, dividing near anther apices, branches ± 4 mm long. *Capsules* narrowly ovoid, 10–14 mm long. *Seeds* angular-elongate, 4–5 × 2 mm. *Flowering time*: mainly November to early January (July).

Distribution and ecology: centred in the KwaZulu-Natal Drakensberg, South Africa and the Maluti Mtns, from Richmond to Harrismith and inland through northern Lesotho to Clocolan and Ficksburg in eastern Free State; on open grassy slopes. Flowering is delayed for an entire season, the spike appearing in the spring or summer following the development of the basal leaves, by which time they are dry and broken.

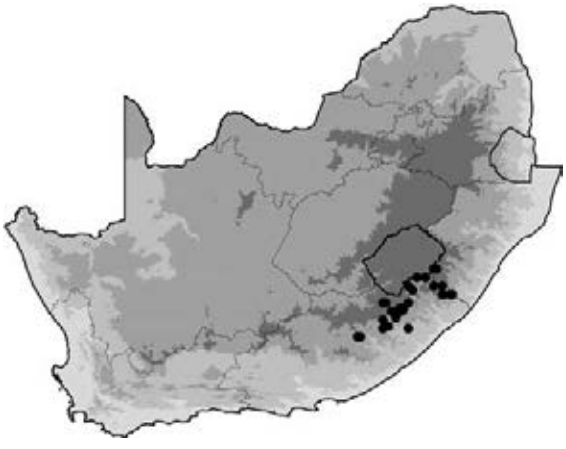
Diagnosis: one of several species with dense spikes of moderate-sized, pink, funnel-shaped flowers and coarse, dry, brown, overlapping bracts and distinguished by its solitary habit and comparatively short, stout, erect stem up to 650 mm tall with the basal leaves dry and withered at flowering time. It is most likely to be confused with *Watsonia confusa*, often a taller plant up to 1 500 mm tall with the leaves green at flowering and broader bracts, 14–18 mm wide.

Distribution of ***Watsonia lepida***.

26. **Watsonia gladioloides** *Schltr.* in Journal of Botany, British and foreign 35: 222 (1897). Type: South Africa, [Eastern Cape], Queenstown, Hangklip Mtn., *Galpin 1784* (B, holo.; BOL, GRA, K, PRE, SAM, iso.).

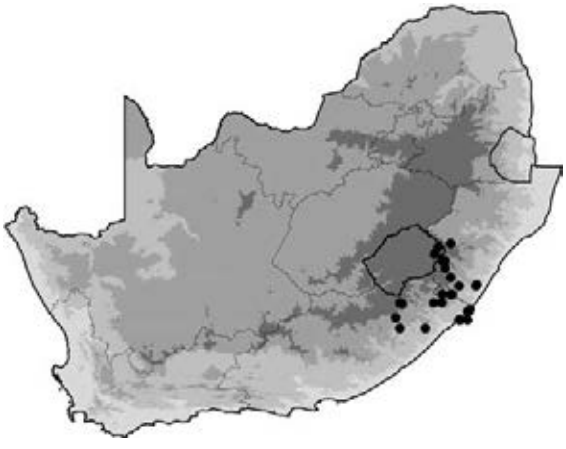
Watsonia baurii L.Bolus: 49 (1926). Type: South Africa, [Eastern Cape], Transkei, Baziya Mtn, *Baur 499* (K, holo.; GRA, SAM, iso.).

Plants (250–)350–500 mm high. *Corm* subglobose, 20–50 mm diam.; tunics coarsely netted. *Stem* erect, simple. *Leaves* 2 to 4, lower 2 basal, reaching to base or middle of spike, linear to lanceolate, 3–15 mm wide, midrib and margins strongly thickened and hyaline, remaining leaves partly or entirely sheathing and grading into bract leaves; bract-like cauline leaves 1 or more, overlapping. *Spike* up to 25-flowered; bracts dry and brown, (20–)24–32 mm long, wide and clasping below, inner ± ⅔ as long and concealed, deeply forked apically for 3 mm or more. *Flowers* zygomorphic, dark red with darker median streak in basal half of lower tepals; perianth tube with lower part ± 20 mm long, included in bracts, upper part ascending to horizontal and subcylindric, (20–)25–30 mm long, ± 5 mm diam. at mouth; tepals spreading, lanceolate, 20–22 × 7–8 mm. *Filaments* unilateral and arcuate, 25–35 mm long, exserted 5–7 mm from tube; anthers ± 9 mm long, violet. *Style* arching over stamens, dividing near anther apices, branches ± 5 mm long. *Capsules* and *seeds* unknown. *Flowering time*: November to January.



Distribution and ecology: widely distributed through the southern Drakensberg, from Queenstown in Eastern Cape to Kokstad in KwaZulu-Natal, South Africa and Sehlabathebe in southeastern Lesotho; on open grassy slopes and ridges among rocks, mostly above 1 000 m elevation.

Diagnosis: recognised by the narrow leaves, 3–15 mm wide and unbranched stem of tubular, dark red flowers, the upper part of the tube subcylindric, (20–)25–30 mm long and slightly longer than the tepals, and dry, brown bracts. The filaments are 25–35 mm long, exserted 5–7 mm from the perianth tube. *Watsonia latifolia* from northern KwaZulu-Natal and southern Mpumalanga with similar long-tubed, red flowers has broad, bright green leaves, 30–60 mm wide, and the upper part of the perianth tube 18–24 mm long and slightly shorter than the tepals.

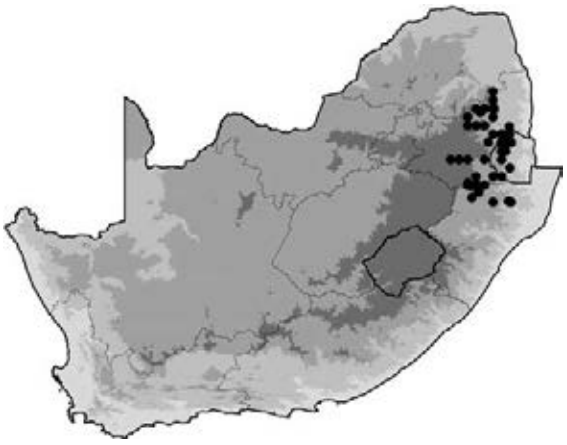


27. **Watsonia confusa** *Goldblatt* in South African Journal of Botany 57: 226 (1991). Type: South Africa, [KwaZulu-Natal], Ellesmere, Alexandria, *Rudatis 1276* (K, holo.; BM, E, G, P, NBG, Z, iso.).

Plants 500–1 500 mm high, growing singly or in small clumps. *Corm* subglobose, 30–50 mm diam.; tunics coarsely netted. *Stem* erect, simple. *Leaves* 3 or 4, lower 2 or 3 ± basal, usually reaching to base of spike or higher, lanceolate, (6–)15–25 mm wide, midrib and margins moderately to strongly thickened and hyaline, pale to glaucous green, upper leaf partly or entirely sheathing; bract-like cauline leaves 3 or more, overlapping and often slightly inflated. *Spike* 15- to 30-flowered, internodes (7–)9–12(–15) mm long; bracts initially herbaceous below but later dry and pale to medium brown, usually darker below, (18–)22–30(–35) mm long, clasping stem in lower ½–⅔, strongly overlapping, 2 or 3 internodes long, often apiculate to attenuate, inner shorter and concealed, deeply forked apically for 2 mm or more. *Flowers* zygomorphic, pink to purple, often with darker median streak in basal half of lower tepals; perianth tube with lower part 22–25 mm long, shortly exserted from bracts, upper part ascending to horizontal and funnel-shaped, 12–18 mm long, 6–8 mm diam. at mouth; tepals curving outward, lanceolate, (22–)25–32 × 8–11 mm. *Filaments* unilateral and arcuate, 10–12 mm long, reaching to mouth of tube; anthers 9–11 mm long, whitish to mauve. *Style* arching over stamens, dividing near anther apices, branches ± 6 mm long. *Capsules* narrowly ovoid, 8–10 mm long. *Seeds* elongate-angular, with rudimentary terminal wings, 4–5 × 2 mm. *Flowering time*: (October) December to March.

Distribution and ecology: restricted to the East Coast and near interior South Africa, from Engcobo and Umtata in Eastern Cape to Durban in KwaZulu-Natal; on damp or

Distribution of ***Watsonia gladioloides***.



Distribution of ***Watsonia confusa***.

south-facing grassy slopes, sometimes among boulders, seldom above 1 000 m elevation. Plants are solitary or form small clumps.

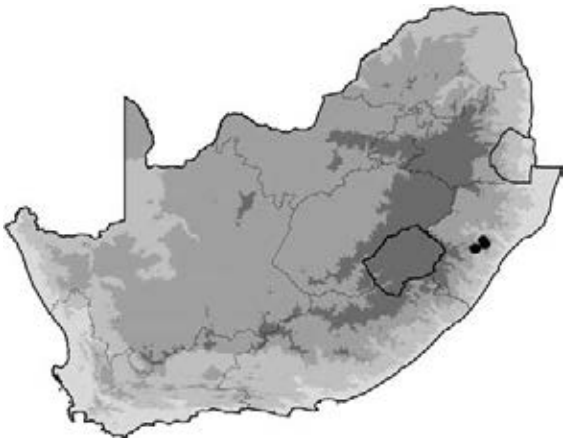
Diagnosis: one of several species with dense spikes of moderate-sized, pink, funnel-shaped flowers and coarse, dry, brown, overlapping bracts and distinguished by its comparatively tall, erect stem, 500 to 1 500 mm tall. The bracts are broad, 14–18 mm wide, and usually noticeably darker in the upper half, and the flowers are often large, with tepals (22–)25–32 × 8–11 mm. It is most likely to be confused with *Watsonia lepida*, a shorter species up to 650 mm tall, with the leaves dry and withered at flowering, and with narrower bracts, mostly occurring above 1 000 m.

28. **Watsonia pulchra** *N.E.Br. ex Goldblatt* in Annals of Kirstenbosch Botanic Gardens 19: 81 (1989). Type: Swaziland [Eswatini], Mbabane, Dalriach, *H. Bolus s.n.* (BOL [*BOL 12345*], holo.; K, iso.).

Plants 600–1 200 mm high, growing in clumps. *Corm* subglobose, 30–50 mm diam.; tunics coarsely netted. *Stem* sometimes inclined below, simple (abnormally with 1 or 2 branches). *Leaves* 4 to 7, mostly ± basal, usually half as long as spike or reaching to base of spike, lanceolate or narrowly lanceolate, (10–)15–30 mm wide, midrib hardly and margins moderately to strongly thickened and hyaline, upper leaf or leaves partly sheathing; bract-like cauline leaves 3 or more, overlapping. *Spike* densely 30- to 60-flowered, internodes 4–8 mm long; bracts dry and cinnamon-brown with darker margins, 18–30 mm long, clasping stem in lower ⅓–⅔, strongly overlapping, 2 to 3 internodes long, often apiculate to attenuate, inner shorter and concealed, deeply forked apically for 2 mm or more. *Flowers* zygomorphic, weakly bilabiate, pink to purple, or maroon (rarely white), often with darker median streak in basal half of tepals; perianth tube with lower part 14–20 mm long, shortly exserted from bracts, upper part ascending to horizontal and funnel-shaped, 10–15 mm long, 8 mm diam. at mouth; tepals lanceolate, 16–25 × 8–11 mm, upper three spreading and lower three nearly horizontal. *Filaments* unilateral and arcuate, 10–15 mm long, included in tube; anthers 7–9 mm long, whitish to mauve or violet. *Style* arching over stamens, dividing near anther apices, branches 4–6 mm long. *Capsules* narrowly ovoid, 10–14 mm long. *Seeds* unknown. *Flowering time*: mainly December to March.

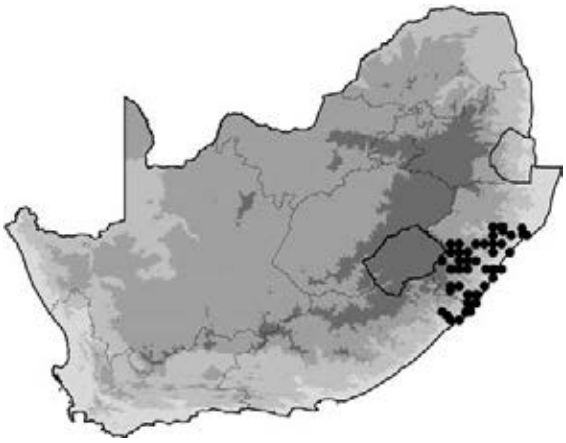
Distribution of ***Watsonia pulchra***.

Distribution and ecology: common along the northeastern escarpment, from Mariepskop and Pilgrim's Rest in Mpumalanga, South Africa through western Eswatini to Vryheid and Ngome in northern KwaZulu-Natal; in grassland and open savanna, typically growing in small clumps but also as solitary plants.



Diagnosis: distinguished from other species with dense spikes of moderate-sized, pink, funnel-shaped flowers and coarse, dry, brown, overlapping bracts by its comparatively tall, erect stem, 600–1 200 mm tall, lanceolate leaves (10–)15–30 mm wide, with strongly thickened margins but only weakly thickened midrib, and dark brown bracts without paler venation.

29. **Watsonia canaliculata** *Goldblatt* in Annals of Kirstenbosch Botanic Gardens 19: 83 (1989). Type: South Africa, [KwaZulu-Natal], Karkloof, 17 Jan. 1987, *Goldblatt & Manning 8357* (NU, holo.; E, MO, NBG, PRE, iso.).



Plants 300–450 mm high, solitary. *Corm* subglobose, 25–40 mm diam.; tunics coarsely netted, extending into a fibrous collar. *Stem* erect, simple. *Leaves* 3 or 4, ± basal or uppermost sub-basal, reaching to base of spike or more, linear to narrowly lanceolate, 4–7 mm wide, channelled or sigmoid in section with margins curved up, midrib and margins moderately thickened and hyaline; bract-like cauline leaves 2 or 3, large. *Spike* densely 10- to 20(30)-flowered, internodes 4–8 mm long; bracts dry and cinnamon-brown, often greenish brown, with evident pale netted veins, 16–20(–25) mm long, clasping stem in lower ⅓–½, strongly overlapping, acute to attenuate, inner shorter, concealed, forked apically for up to 2 mm. *Flowers* zygomorphic, weakly bilabiate, pink to purple with paler throat, often with darker median streak in basal ½ of tepals; perianth tube with lower part 12–18 mm long, upper part ascending and funnel-shaped, ± 15 mm long, 8 mm diam. at mouth; tepals lanceolate, 20–25 × 9–13 mm, upper 3 spreading and lower 3 nearly horizontal. *Filaments* unilateral and arcuate, 14–20 mm long, reaching mouth of tube; anthers 8–11 mm long, whitish to mauve or violet. *Style* arching over stamens, dividing near anther apices, branches 5–6 mm long. *Capsules* narrowly ovoid, ± 10 mm long. *Seeds* unknown. *Flowering time*: November to December (January).

Distribution and ecology: a narrow endemic of central KwaZulu-Natal, South Africa, on the Noodsberg and Karkloof; in open grassland.

Diagnosis: distinguished from other species with dense spikes of moderate-sized, pink, funnel-shaped flowers

Distribution of ***Watsonia canaliculata***.

Distribution of ***Watsonia densiflora***.

and coarse, dry, brown, overlapping bracts by its comparatively short, erect stem, 300–450 mm tall, and narrow leaves, 4–7 mm wide, with the margins curved inward so that the leaves are markedly channelled or sometimes sigmoid in section. *Watsonia lepida*, also a solitary-growing species, has flat leaves 5–15 mm wide, the lowermost dry and broken at flowering, and uniformly dark brown bracts.

30. **Watsonia densiflora** *Baker* in Journal of Botany, British and foreign 14: 336 (1876). Type: South Africa, [Eastern Cape], between the St Johns [Umzimvubu] and Umtata rivers, *Drège 4536* (K, lecto., designated by Brown: 194 (1931); BM, CGE, E, OXF, P, S, isolecto.).

Watsonia densiflora var. *alba* N.E.Br.: 393 (1891). Type: South Africa, [KwaZulu-Natal], without precise locality or collector (K, holo.).

Watsonia neglecta N.E.Br.: 195 (1931). Type: South Africa, [KwaZulu-Natal], without precise locality, *Cooper 3186* (K, lecto., designated by Goldblatt: 85 (1989); Z, isolecto.).

Watsonia plantii N.E.Br.: 194 (1931). Type: South Africa, [KwaZulu-Natal], near Durban, *Plant s.n.* (K, holo.; BM, CGE, G, OXF, P, S, iso.).

Plants 600–1 200(–1 500) mm high, growing in clumps. *Corm* subglobose, 30–50 mm diam.; tunics coarsely netted, extending into a fibrous collar. *Stem* inclined below then erect, simple. *Leaves* 4 or 5, lower 2 or 3 basal, usually ± half as long as spike or rarely reaching to base of spike, linear to narrowly lanceolate, 10–15(–18) mm wide, midrib and margins lightly to moderately thickened and hyaline, uppermost leaf or leaves partly sheathing; bract-like cauline leaves 3 or more, tightly sheathing. *Spike* densely 30- to 42-flowered, internodes 4–6(–8) mm long; bracts dry and brown, often greenish straw-coloured with darker brown margins, with evident pale netted veins, 22–25(–28) mm long, clasping stem in lower half, strongly overlapping, apiculate to attenuate, inner shorter and concealed, forked apically for at least 2 mm. *Flowers* zygomorphic, weakly bilabiate, bright pink (rarely white), often with darker median streak in basal half of tepals; perianth tube with lower part 12–18 mm long, upper part ascending and funnel-shaped, 9–12 mm long, 8 mm diam. at mouth; tepals lanceolate, 18–24 × 7–9 mm, upper three spreading and lower three nearly horizontal. *Filaments* unilateral and arcuate, 10–12 mm long, included in tube; anthers 9–11 mm long, whitish to mauve or violet. *Style* arching over stamens, dividing near anther apices, branches ± 6 mm long. *Capsules* narrowly ovoid, 10–12 mm long. *Seeds* elongate-angular, with rudimentary distal and proximal wings, 4–5 × 2 mm. *Flowering time*: mainly December to March.

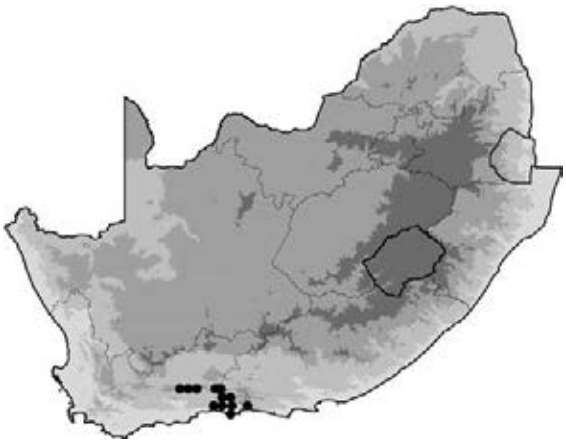
Distribution and ecology: widely distributed along the East Coast and near interior South Africa, from Port St Johns in Eastern Cape to St Lucia Bay in northern KwaZulu-Natal, extending inland to Dundee; on open grassy slopes, usually in well-watered sites, rarely above 1 000 m elevation.

Diagnosis: distinguished from other species with dense spikes of moderate-sized, pink, funnel-shaped flowers and coarse, dry, brown, overlapping bracts by its densely clumped habit, with the stems inclined at the base and then sharply erect below the spike. The bracts are greenish straw-coloured with noticeably darker brown margins and pale venation. *Watsonia canaliculata* has similar pale bracts but is a solitary-growing species with erect stems and channelled leaves; *W. pulchra* has dark brown bracts and broad leaves, (10–)15–30 mm wide with heavily thickened margins; and *W. lepida* is a shorter, solitary-growing species, with the lowermost leaves dry and broken at flowering, and uniformly dark brown bracts.

Sect. 4. **Watsonia**

Stems branched or simple; bracts firm-textured. *Flowers* zygomorphic, usually red to orange, sometimes pink to purple; perianth tube trumpet-shaped, with upper part cylindric (rarely funnel-shaped); tepals half as long to ± as long as upper part of tube (rarely longer). *Stamens* arcuate. *Capsules* obovoid to elongate or fusiform. *Seeds* elongate-angular, or prominently winged and then usually 2-winged with distal wing larger, or 1-winged with proximal wing reduced, or with circumferential wing.

Species 23: mainly winter-rainfall South Africa extending along into eastern southern Africa.



Ser. **Brevibractea** *(Goldblatt) Goldblatt & J.C.Manning*, new rank. *Watsonia* subsection *Brevibractea* Goldblatt in Annals of Kirstenbosch Botanic Gardens 19: 87 (1989). Type: *W. wilmaniae* J.W.Mathews & L.Bolus

Stems usually branched; bracts short, less than 12 mm long. *Capsules* obovoid, shorter than bracts. *Seeds* elongate-angular.

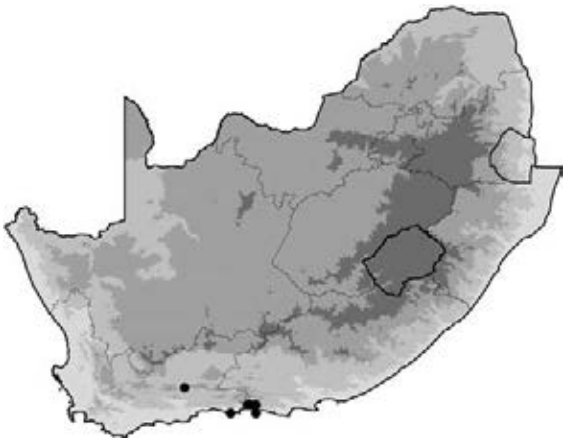
31. **Watsonia wilmaniae** *J.W.Mathews & L.Bolus* in Bolus in Annals of the Bolus Herbarium 4: 114 (1927). Type: South Africa [Western Cape], without precise locality, ex hort. Kirstenbosch, *Wilman s.n.* (BOL [BOL18578], lecto., designated by Goldblatt: 88 (1989); BOL, isolecto.).

Watsonia starkeae L.Bolus: 134 (1929b). Type: South Africa [Western Cape], Oudtshoorn, Swartberg, *Starke s.n.* (BOL [*Nat. Bot. Gard. 10/27*], lecto., designated by Goldblatt: 88 (1989); BOL, K, isolecto.).

Watsonia desmidtii L.Bolus: 124 (1933). Type: South Africa [Western Cape], Wilderness, Touws River, *Flugge de Smidt s.n.* (BOL 20071, lecto., designated by Goldblatt: 88 (1989); BOL, isolecto.).

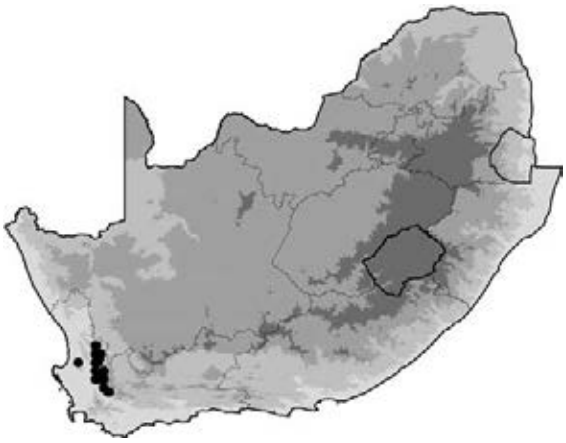
Distribution of ***Watsonia wilmaniae***.

Plants 800–1 500 mm high. *Corm* depressed-globose, 20–30 mm diam.; tunics coarsely netted. *Stem* erect, usually with 1 or more short, suberect branches. *Leaves* 5 to 7, ± basal but upper partly sheathing stem, ± half as long as spike, lanceolate, 16–30 mm wide, midrib and margins lightly thickened and narrowly hyaline; bract-like cauline leaves 1 or more, tightly sheathing. *Spike* moderately densely 20- to 35-flowered; bracts green below, dry and brownish above, 7–12 mm long, inner slightly shorter to slightly longer, acute. *Flowers* zygomorphic, usually red to purple, sometimes pink, orange or cream-coloured; perianth tube with lower part ± 15 mm long, emerging ± 10 mm from bracts, upper part horizontal, subcylindric, 15–20 mm long, 5 mm diam.; tepals ovate, 18–22 × 7–10 mm, uppermost somewhat hooded, others widely spreading. *Filaments* unilateral and arcuate, 20–30 mm long, exserted 10–15 mm from tube; anthers 7–10 mm long, mauve to grey. *Style* arching over stamens, dividing near anther apices, branches 3–4 mm long. *Capsules* narrowly obovoid, 10–12 mm long. *Seeds* elongate-angular, with rudimentary distal and proximal wings, 4–5 × 2 mm. *Flowering time*: mainly November to January (February).



Distribution and ecology: endemic to the mountains along the southern seaboard of South Africa, inland on the Swartberg and Kammanassie Mtns in Western Cape and along the coast in the lower valleys and foothills of the Outeniqua and Tsitsikamma mtns, from George to Uniondale in Eastern Cape; along streams and the edges of marshes, forming dense clumps and blocking streambeds.

Diagnosis: characterised by the short bracts, 7–12 mm long, long-tubed flowers with the upper part 15–20 mm long, and obovoid capsules 10–12 mm long. *Watsonia angusta* from similar habitats has slightly longer bracts, 9–16 mm long, and characteristic fusiform capsules, 25–30 mm long, with longer seeds 9–10 mm long.



32. **Watsonia galpinii** *L.Bolus* in Annals of the Bolus Herbarium 3: 11 (1920). Type: South Africa, [Eastern Cape], Lottering Bush, river's edge, *Galpin 4698* (BOL [*BOL19031*], lecto., designated by Goldblatt: 90 (1989); K, isolecto.).

Watsonia starkeae var. *rubra* L.Bolus: 134 (1929b). Type: South Africa, [Western Cape], Swartberg, *Starke s.n.* (BOL as *Nat. Bot. Gard. 10A/27*, lecto., designated by Goldblatt: 90 (1989); BOL, isolecto.).

Plants 1 200–2 000 mm high. *Corm* depressed-globose, 20–30 mm diam.; tunics coarsely netted. *Stem* slender, erect to inclined, usually with 1 or 2 short, suberect branches. *Leaves* 5 to 7, ± basal but upper partly sheathing stem, much shorter than spike, lanceolate, up to 300 mm long, 16–30 mm wide, midrib and margins narrowly hyaline but not noticeably thickened; bract-like cauline leaves 1 or more, tightly sheathing. *Spike* moderately densely 30- to 40-flowered; bracts green below,

Distribution of ***Watsonia galpinii***.

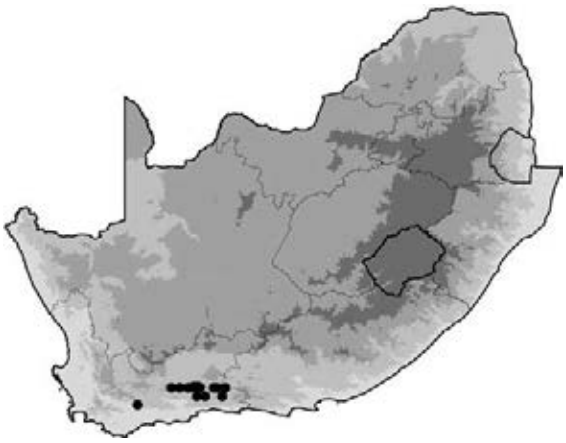
Distribution of ***Watsonia stokoei***.

dry and brownish apically, 6–12 mm long, inner slightly shorter to slightly longer, acute. *Flowers* zygomorphic, reddish orange or sometimes mauve-pink; perianth tube with lower part 10–13 mm long, emerging 6–7 mm from bracts, upper part nearly horizontal, subcylindric to flared, 4–8 mm long, 5 mm diam. at mouth; tepals obovate, 15–20 mm long, outer 7–8 mm wide, inner ± 13 mm wide, all widely spreading. *Filaments* unilateral and arcuate, 12–15 mm long, exserted 7–10 mm from tube; anthers 7–9 mm long, yellow. *Style* arching over stamens, dividing near anther apices, branches ± 4 mm long. *Capsules* obovoid, 10–12 mm long. *Seeds* elongate-angular to shortly winged with flattened distal ridge, 4–5 mm long. *Flowering time*: mainly January to April.

Distribution and ecology: a rare species of southern South Africa, from the Swartberg in Western Cape, and in the Outeniqua and Tsitsikamma mtns between Knysna and Humansdorp in Eastern Cape; confined to wet sites along streams.

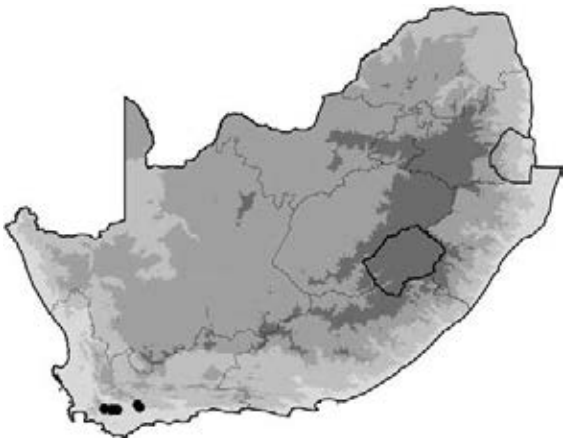
Diagnosis: easily distinguished by its slender stems up to 2 m tall, short bracts 6–12 mm long, and short perianth tube with the upper part 4–8 mm long but relatively long filaments 12–15 mm long, thus ± twice as long as the upper part of the tube. *Watsonia wilmaniae* from much the same habitats and location and with similar short bracts has the upper part of the perianth tube 15–20 mm long.

33. **Watsonia stokoei** *L.Bolus* in South African Gardening and Country Life 25: 56 (1935). Type: South Africa, [Western Cape], Ceres, summit plateau of the Schurfdeberge, *Stokoe s.n. Nat. Bot. Gard. 8/34* (BOL, holo.).



Plants 350–900 mm high. *Corm* depressed-globose, 20–30 mm diam.; tunics coarsely netted, outer becoming finely fibrous. *Stem* with (1) several short, suberect branches. *Leaves* 5 or 6, ± basal but upper partly sheathing stem, ½–⅔ as long as spike, linear-lanceolate, 8–15 mm wide, midrib and margins lightly thickened and hyaline; bract-like cauline leaves 2 or more, long and tightly sheathing. *Spike* 10- to 18-flowered; bracts ± dry and brown, 5–8 mm long, inner as long as or slightly longer, somewhat membranous, forked apically. *Flowers* zygomorphic, pale red; perianth tube with lower part 10–14 mm long, emerging 7–8 mm from bracts, upper part horizontal, subcylindric, 12–15(–20) mm long, 4–5 mm diam. at mouth; tepals oblanceolate, 12–15 × 5–8 mm, all widely spreading. *Filaments* unilateral and arcuate, 22–26(–30) mm long, exserted 8–12 mm from tube; anthers 6.5–8.0 mm long. *Style* arching over stamens, dividing near anther apices, branches 3–4 mm long. *Capsules* obovoid-globose, up to 10 mm long. *Seeds* angular with distal ridge, 5–6 × 2 mm. *Flowering time*: November to early January (February).

Distribution and ecology: widely distributed through the mountains along the Atlantic coast of Western Cape, South Africa, from the Gifberg through the Cederberg to the Cold Bokkeveld and Twenty Four Rivers mtns and the Piketberg; in damp sites, mostly in seeps but also along streambanks, flowering well only after fire.



Diagnosis: recognised by the small bracts, 5–8 mm long and dry at flowering, and the dull red, tubular flowers with the upper part of the perianth tube 12–15(–20) mm long, and relatively small tepals, 12–15 × 5–8 mm. The small flowers separate it from the southern Cape *Watsonia wilmaniae*, which has the upper part of the perianth tube 15–20 mm long and tepals 18–22 mm long. *Watsonia angusta* also has larger flowers with the upper part of the perianth tube 20–22 mm long, tepals 19–25 mm long, and filaments 30–38 mm long; and characteristic fusiform capsules 25–35 mm long.

34. **Watsonia marlothii** *L.Bolus* in Annals of the Bolus Herbarium 4: 50 (1926). Type: South Africa, [Western Cape], Swartberg Pass, Oudtshoorn side, *Mathews s.n.* (BOL [*Nat. Bot. Gard. 4312/14*], lecto., designated by Goldblatt: 94 (1989); BOL, isolecto.).

Plants 600–1 200 mm high. *Corm* depressed-globose, 30–45 mm diam.; tunics coarsely netted. *Stem* with up

Distribution of ***Watsonia marlothii***.

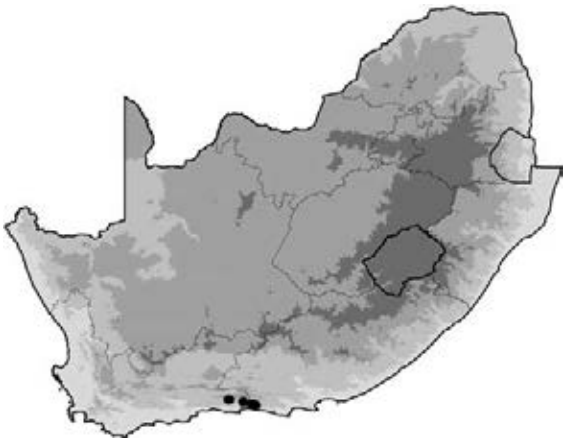
Distribution of ***Watsonia minima***.

to 6 short, stiffly erect branches. *Leaves* 4 to 6, lower 3 or 4 ± basal, uppermost partly sheathing stem, ± half as long as spike, narrowly lanceolate, 14–30 mm wide, midrib and margins heavily thickened and hyaline; bract-like cauline leaves 1 or more, tightly sheathing. *Spike* 16- to 40-flowered; bracts green below, dry and brown apically, 9–12 mm long, acuminate, inner ⅔ to ± as long, somewhat membranous, deeply forked up to halfway. *Flowers* zygomorphic, red to pale pink, rarely purple or whitish; perianth tube with lower part 10–12 mm long, emerging 3–4 mm from bracts, upper part ascending to horizontal, subcylindric, 14–18(–22) mm long, 4–5 mm diam. at mouth; tepals oblanceolate, 12–16 × 6–8 mm, all widely spreading. *Filaments* unilateral, arcuate, 25–30 mm long, exserted 7–12 mm from tube; anthers 5–9 mm long. *Style* arching over stamens, dividing near middle of anthers, branches ± 7 mm long. *Capsules* ovoid to subglobose, 9–11 mm long. *Seeds* unknown. *Flowering time*: late November to February.

Distribution and ecology: originally thought to be endemic to the Swartberg in Western Cape, South Africa, but now also known from the Kammanassie Mtns, and a single collection from the Langeberg above Swellendam; on open slopes above 1 000 m elevation, flowering well after fire.

Diagnosis: distinguished from other species with small bracts up to 12 mm long by the heavily thickened leaf margins and branched, multi-flowered spike of relatively small flowers with the upper part of the perianth tube 14–18(–22) mm long, and deeply forked inner bracts. *Watsonia fourcadei* is a superficially similar species with forked inner bracts but larger flowers, the upper part of the tube 22–26 mm long, and elongate, tapering capsules 18–20 mm long.

35. **Watsonia minima** *Goldblatt* in Annals of Kirstenbosch Botanic Gardens 19: 95 (1989). Type: South Africa, [Western Cape], Riviersonderend Mtns above Greyton, 3 000 ft [900 m], 5 Dec 1987, *Goldblatt 8708* (NBG, holo.; K, MO, PRE, US, WAG, iso.)



Plants 100–300(–450) mm high. *Corm* subglobose, ± 15 mm diam.; tunics finely netted. *Stem* usually simple or occasionally with 1 or 2 branches. *Leaves* 2 to 4, lower 2 or 3 basal, uppermost partly sheathing stem, reaching ± base of spike, linear to narrowly lanceolate, (2–)3–5 mm wide, margins lightly thickened and purplish; bract-like cauline leaves 1 or 2. *Spike* (3)6- to 12-flowered; bracts dry and brown in upper half, 8–14 mm long, inner slightly shorter, forked apically for ± 2 mm. *Flowers* zygomorphic, orange to orange-red, lower tepals with darker median streak; perianth tube with lower part 8–10 mm long, upper part ascending, subcylindric, 9–10 mm long, ± 3 mm diam. at mouth; tepals oblanceolate, 13–15 × 5–7 mm, all widely spreading. *Filaments* unilateral and arcuate, 15–16 mm long, exserted ± 5 mm from tube; anthers ± 5 mm long, violet. *Style* arching over stamens, dividing near apex of anthers, branches ± 3.5 mm long. *Capsules* obovoid-truncate, ± 7 mm long. *Seeds* unknown. *Flowering time*: mid-November to mid-December.

Distribution and ecology: a local endemic of Western Cape, South Africa, recorded from the Riviersonderend Mtns and the central Langeberg above Swellendam; on sandstone slopes above 700 m elevation, often in seasonal seepages.

Diagnosis: a small species with short bracts 8–14 mm long and relatively small, orange-red flowers, the upper part of the perianth tube 9–10 mm long and slightly shorter than the tepals.

36. **Watsonia elsiae** *Goldblatt* in Annals of the Kirstenbosch Botanic Gardens 19: 97 (1989). Type: South Africa, [Western Cape], Potjieshoogte Pass, south of Uniondale, 6 Dec 1985, *Goldblatt 7464* (NBG, holo.; BOL, E, K, MO, NBG, PRE, S, US, WAG, iso.)

Plants 450–650 mm high. *Corm* subglobose, 25–35 mm diam.; tunics coarsely netted. *Stem* simple. *Leaves* 3 or 4, ± basal but uppermost partly sheathing stem, seldom reaching base of spike, linear to narrowly lanceolate,

Distribution of ***Watsonia elsiae***.

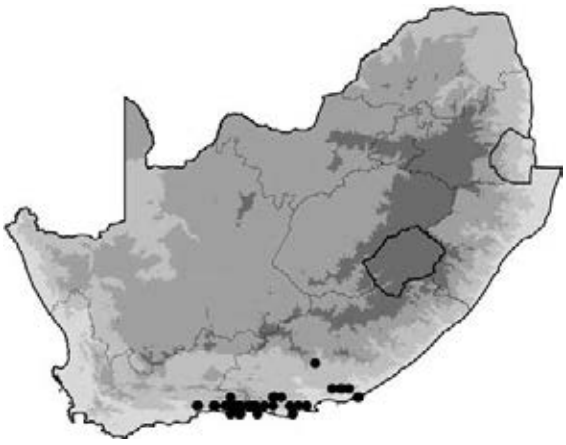
7–10(–12) mm wide, midrib and margins moderately to heavily thickened and hyaline; bract-like cauline leaves 2 or 3, tightly sheathing. *Spike* moderately densely 20- to 30-flowered; bracts green below, dry and brown above, 8–12(–15) mm long, inner ⅔ to ± as long, acute to bifid apically. *Flowers* zygomorphic, bright scarlet-red; perianth tube with lower part 10–12 mm long, upper part nearly horizontal becoming somewhat pendent, bent at right angles to lower part, subcylindric, 12–15 mm long, ± 4 mm diam. at mouth; tepals oblanceolate, 13–16 × 6–8 mm, widely spreading. *Filaments* unilateral, arcuate, 8–10 mm long, included in tube; anthers included in tube, 4.5–6.0 mm long, yellow. *Style* included in tube, dividing near middle of filaments, branches 3–4 mm long. *Capsules* obovoid, 7–9 mm long. *Seeds* ± compressed, up to 5 mm long, with flattened wing-like ridge distally. *Flowering time*: November to mid-December and March.

Distribution and ecology: endemic to the central Long Kloof, extending from near Uniondale in Western Cape to Joubertina and Misgund in Eastern Cape, South Africa; on relatively dry stony slopes, flowering well only after fire.

Diagnosis: the scarlet-red flowers are unique in the genus in having the stamens and style included in the perianth tube, the filaments reaching to ± the middle of the upper part of the tube with the anthers reaching almost to the mouth, and the style branching below the anthers.

Ser. **Grandibractea** *(Goldblatt) Goldblatt & J.C.Manning*, new rank. *Watsonia* subsection *Grandibractea* Goldblatt in Annals of Kirstenbosch Botanic Gardens 19: 99 (1989). Type: *W. pillansii* L.Bolus

Stems simple; bracts large and relatively broad, more than 15 mm long. *Capsules* obovoid, shorter than bracts. *Seeds* 2-winged.



37. **Watsonia knysnana** *L.Bolus* in South African Gardening and Country Life 20: 63 (1930b). Type: South Africa, [Western Cape], Knysna [?District], *Willis s.n.* (BOL [*Nat. Bot. Gard. 382/24*], lecto., designated by Goldblatt: 99 (1989); BOL, isolecto.).

[?*Neuberia longifolia* Eckl.: 37 (1827), invalid name without description.]

Plants (500–)1 200–1 600 mm high. *Corm* depressed-globose, 35–70 mm diam.; tunics coarsely netted. *Stem* usually simple, or with 1 to 3 branches. *Leaves* 3 to several, lower ± basal but uppermost partly sheathing stem, ± half as long as spike, lanceolate, 8–24 mm wide, midrib and margins lightly to moderately thickened and hyaline; bract-like cauline leaves 2 or more, long and tightly sheathing. *Spike* 10- to 30-flowered; bracts green below, drying above and reddish to brown, (12–)14–20(–24) mm long, inner ⅔ to ± as long, acute to bifid for 1 mm. *Flowers* zygomorphic, pale pink to purple or rarely scarlet, sometimes faintly scented; perianth tube with lower part 12–20 mm long, usually exserted 2.5 mm from bracts, upper part ascending to nearly horizontal, subcylindric, 17–20(–24) mm long, ± 6 mm diam. at mouth; tepals obovate, 19–22(–25) × 8–12(–15) mm, widely spreading. *Filaments* unilateral, arcuate, 16–28 mm long, usually well exserted from tube; anthers 7–11 mm long, violet. *Style* dividing near middle of anthers, branches 5–6 mm long. *Capsules* narrowly obovoid, 12–15 mm long. *Seeds* elongate, 8–10 mm long, unequally winged. *Flowering time*: (October) November to January, rarely later.

Distribution and ecology: widespread along the southern coast of South Africa, from Robinson Pass in Western Cape to East London in Eastern Cape, extending inland through the Baviaanskloof Mtns to Grahamstown and between Somerset East and Hogsback; on well-drained rocky slopes and mesic grassland.

Diagnosis: distinguished from other species with similar long-tubed flowers by the mostly pink to purple (only rarely red) perianth, the lower part of the tube 12–20 mm long and the upper part 17–20(–24) mm long, the mostly unbranched stem, and the herbaceous bracts (12–)14–20(–24) mm long. Populations from the

Distribution of ***Watsonia knysnana***.

mountains around George, especially Ruitersberg at Robinson's Pass, are unusual in their dry bracts, suberect tepals and shorter filaments only shortly exserted from the tube.

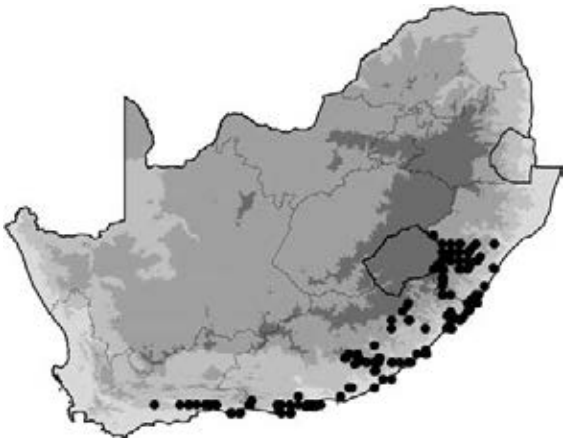
Closely related *Watsonia pillansii* has consistently orange flowers with bracts (19–)23–33(–40) mm long, and a perianth tube with both the lower and upper parts 17–25 mm long, the filaments thus slightly longer, 30–40 mm long. The two species hybridise extensively along the southern Cape coast, notably near Prince Alfred's Pass and Kareedouw Pass but also elsewhere.

38. **Watsonia pillansii** *L.Bolus* in Annals of the Bolus Herbarium 3: 75 (1921). Type: South Africa, [Western Cape], Montagu Pass, *Pillans s.n.* (BOL [*Nat. Bot. Gard. 1549/14*], holo.).

Watsonia priorii L.Bolus: 49 (1926). Type: South Africa, [Western Cape], Georgetown [George], Aug. 1847, *Proir s.n.* (K, holo.).

Watsonia masoniae L.Bolus: 50 (1926). Type: South Africa, without precise locality, ex hort. Cantabr., *Mason s.n.* (K, holo.).

Watsonia beatricis J.W.Mathews & L.Bolus in Bolus: 52 (1926). Type: South Africa, [Western Cape], George District, ex hort. Kirstenbosch, flor. 1925, *Hops s.n.* (BOL, lecto., designated by Goldblatt: 102 (1989); BOL, isolecto.).



?*Watsonia westiae* L.Bolus: 50 (1926). Type: South Africa, [Eastern Cape], Port Elizabeth, *West s.n.* (K, holo.).

Watsonia socium J.W.Mathews & L.Bolus in Bolus: 134 (1929b). Type: South Africa, [KwaZulu-Natal], Pietermaritzburg, Swartkop, *Der Mole & Kitsh s.n* (BOL [*Nat. Bot. Gard. 937/25*], lecto., designated by Goldblatt: 102 (1989); BOL, isolecto.).

Watsonia hutchinsonii L.Bolus: 328 (1932). Type: South Africa, without precise locality, *Hutchinson s.n.* (BOL [*Nat. Bot. gard. 2563/30*], lecto., designated by Goldblatt: 66 (1989); BOL, isolecto.).

Watsonia archbelliae L.Bolus: 329 (1932). Type: South Africa, [KwaZulu-Natal], Underberg, 5 120 ft [1 560 m], *Archbell 1439* (BOL [*Nat. Bot. Gard. 772/30*], lecto., designated by Goldblatt: 102 (1989); BOL, K, isolecto.).

Plants 500–1 200 mm high, often forming clumps. *Corm* depressed-globose, 30–50 mm diam.; tunics coarsely netted. *Stem* usually simple, or with 1 to 3 branches. *Leaves* 4 to 6, lower 3 or 4 basal, uppermost partly or entirely sheathing stem, ± half as long as spike, linear-lanceolate to lanceolate, (7–)12–18 mm wide, midrib and margins moderately thickened and hyaline; bract-like cauline leaves several, sheathing. *Spike* (20)25- to 35-flowered; bracts green or often partly reddish, dry and brown apically, (19–)23–33(–40) mm long, inner ⅔ to ± as long, greenish and completely enclosed, obtuse to barely bilobed. *Flowers* zygomorphic, bright orange to orange-red; perianth tube with lower part 17–25 mm long, included or shortly emerging from bracts, upper part ascending to horizontal, subcylindric, 18–25 mm long, ± 6 mm diam. at mouth, usually with longitudinal ridges between filament bases; tepals lanceolate, 20–26 × 9–15 mm, all widely spreading or dorsal somewhat hooded. *Filaments* unilateral, arcuate, 30–40 mm long, well exserted from tube; anthers 7–11 mm long, violet to cream-coloured. *Style* dividing near middle of anthers, branches ± 7 mm long. *Capsules* globose to narrowly obovoid, 10–12 mm long. *Seeds* elongate, 7–10 mm long, shortly 2-winged. *Flowering time*: (November) December to January (February).

Distribution of ***Watsonia pillansii***.

Distribution and ecology: widespread along the southern and eastern seaboard of South Africa, from the Langeberg at Swellendam in Western Cape along the Outeniqua and Tsitsikamma Mtns through Eastern Cape to Dundee in KwaZulu-Natal, extending inland along the foothills of the Drakensberg; on stony slopes in rock outcrops in grassland.

Diagnosis: distinguished by the long-tubed, orange flowers with the lower and upper parts of the perianth tube 17–25 mm long, the filaments 30–40 mm long, and the mostly herbaceous bracts (19–)22–35(–40) mm long. The perianth tube usually bears internal longitudinal ridges between the lower part of the filaments. Populations from the Hogsback–Katberg mountains represent a distinct race of tall plants with up to 35 flowers per spike, and unusually short inner bracts up to ± half as long as the outer.

Watsonia knysnana has mostly pink to purple (rarely red) flowers with the lower part of the perianth tube 12–20 mm long, the filaments thus 16–28 mm long, and bracts (12–)14–20(–24) mm long. The two species hybridise extensively along the southern Cape coast, notably near Prince Alfred's Pass and Kareedouw Pass but also elsewhere.

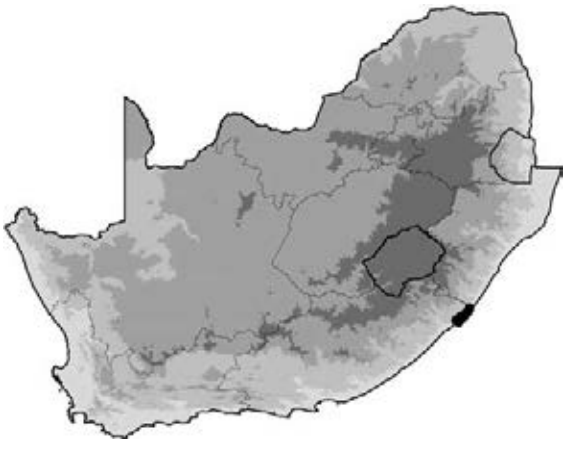
Watsonia schlechteri from further west and inland has similar bracts and flowers but lacking the ridges inside

the perianth tube and mostly narrower leaves 6–15 mm wide with heavily thickened midrib and margins. The two species converge in the Langeberg between Cloete's Pass and Riversdale, and plants from this area are difficult to identify with confidence.

39. **Watsonia bachmannii** *L.Bolus* in Annals of the Bolus Herbarium 4: 47 (1926). Type: South Africa, [KwaZulu-Natal], Pondoland, *Bachmann 355* (B, lecto., designated by Goldblatt: 105 (1989); BOL, isolecto.).

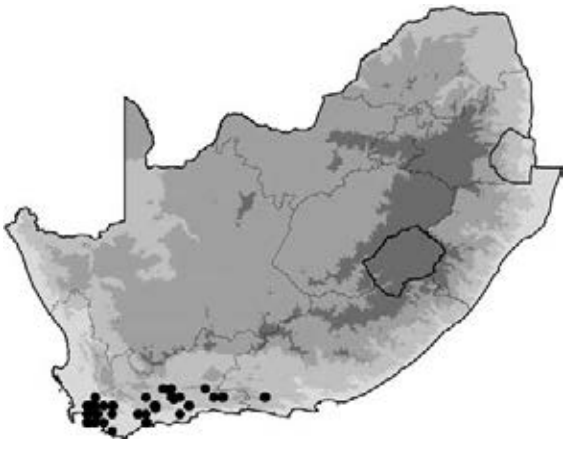
Plants 250–500 mm high. *Corm* subglobose, 14–20 mm diam.; tunics finely netted. *Stem* simple. *Leaves* usually 2, lower 1 basal, sometimes burned and apparently lacking, upper leaf partly sheathing stem, ± half as long as spike, linear to narrowly lanceolate, 2.5–6.0(–9.0) mm wide, midrib and margins lightly thickened and hyaline; bract-like cauline leaves 2 to 4, short, green, sheathing, sometimes overlapping. *Spike* 2- to 7-flowered; bracts green below, dry and brownish apically, 10–16 mm long, inner ± ⅔ as long, bifid apically. *Flowers* zygomorphic, orange; perianth tube with lower part 8–12 mm long, included or shortly emerging from bracts, upper part horizontal, tubular or narrowly flared, 10–12 mm long, ± 5 mm diam. at mouth; tepals obovate, 18–20 × 7–10 mm, all somewhat spreading. *Filaments* unilateral, arcuate, ± 10 mm long, not or barely exserted from tube; anthers 7–9 mm long, white. *Style* dividing shortly beyond anther apices, branches 2–4 mm long. *Capsules* obovoid, 8–10 mm long. *Seeds* elongate-angular, up to 4.5 mm long, distal end shortly winged. *Flowering time*: early July to mid-October.

Distribution and ecology: restricted to the southeastern coast of South Africa, from Lusikisiki in Eastern Cape to Port Edward in southern KwaZulu-Natal; in open or marshy grassland.



Diagnosis: a small, orange-flowered species up to 500 mm high, with the upper part of the perianth tube narrowly trumpet-shaped, 10–12 mm long and slightly shorter than the tepals, and short filaments ± 10 mm long just included in the tube.

40. **Watsonia schlechteri** *L.Bolus* in Annals of the Bolus Herbarium 4: 47 (1926). Type: South Africa, [Western Cape], Houw Hoek Mtns, *R. Schlechter 7349* (K, lecto., designated by Goldblatt: 106 (1989); B, BM, BOL, G, K, PRE, Z, isolecto.).



Watsonia schinzii L.Bolus: 53 (1926). Type: South Africa, [Western Cape], Table Mtn., *Schinz s.n.* (Z, lecto., designated by Goldblatt: 106 (1989); Z, isolecto.).

Plants 400–1 000 mm high. *Corm* depressed-globose, 30–50 mm diam.; tunics coarsely netted. *Stem* usually simple, rarely with short erect branches. *Leaves* 3 or 4, lower 2 or 3 ± basal, uppermost leaf partly sheathing stem, ½–⅔ as long as spike, narrowly lanceolate, 6–15 mm wide, midrib and margins heavily thickened and hyaline; bract-like cauline leaves 2 or 3, sheathing. *Spike* (6)12- to 30-flowered; bracts herbaceous and reddish below, becoming dry and brownish apically, 18–30 mm long, inner enclosed, greenish, up to 17 mm long, entire or forked apically for 1–2(–5) mm. *Flowers* zygomorphic, bright reddish orange or occasionally deep pink, paler in tube; perianth tube with lower part 17–20 mm long, included or shortly emerging from bracts, upper part ascending to horizontal, subcylindric, 22–30 mm long, ± 9 mm diam. at mouth; tepals obovate-oblong, 20–24 × 12–15 mm, all spreading widely. *Filaments* unilateral, arcuate, 35–45 mm long, well exserted from tube; anthers 7–10 mm long, violet. *Style* dividing between middle and apex of anthers, branches ± 6 mm long. *Capsules* subglobose to obovoid, up to 10 mm long. *Seeds* elongate-angular, 4–5 × 2 mm, distal end ridged or shortly winged. *Flowering time*: late November to early February.

Distribution and ecology: relatively widespread through the mountains of Western Cape, South Africa, from near Citrusdal south to Cape Hangklip, Bredasdorp, Potberg and the Langeberg and inland on the Klein Swartberg, Rooiberg and Kammanassie mtns as far east as the Kouga Mtns in Eastern Cape; growing singly or in small

Distribution of ***Watsonia bachmannii***.

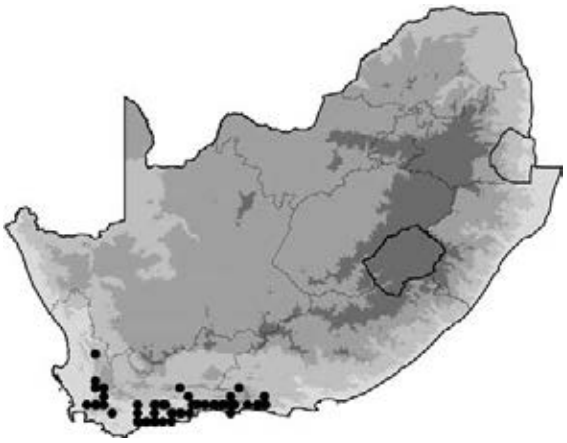
Distribution of ***Watsonia schlechteri***.

clumps on exposed, sandstone slopes and plateaus. Flowering is stimulated by fire.

Diagnosis: recognised by the long-tubed, orange flowers with the lower part of the perianth tube 17–20 mm long and the upper part 22–30 mm long, filaments 35–45 mm long, and reddish, mostly herbaceous bracts 18–30 mm long. *Watsonia pillansii* from further east and along the coast has similar bracts and flowers, often with longitudinal ridges inside the perianth tube between the bases of the filaments, and mostly broader leaves, (7–)12–18 mm wide, with moderately thickened midrib and margins. The two species converge in the Langeberg between Cloete's Pass and Riversdale, and plants from this area are difficult to identify with confidence.

Watsonia fourcadei may have similar red to orange-red flowers but typically has shorter bracts, 13–18(–25) mm long, attenuate and somewhat scarious with the inner strongly forked, and diagnostic, obconic capsules tapering above.

Ser. **Angustae** *(Goldblatt) Goldblatt & J.C.Manning*, new rank. *Watsonia* subsection *Angustae* Goldblatt in Annals of Kirstenbosch Botanic Gardens 19: 109 (1989). Type: *W. angusta* Ker Gawl.



Stems branched; bracts of intermediate size, 9–18(–25) mm long. *Capsules* obconic-tapering or elongate-fusiform, longer than bracts. *Seeds* 2-winged.

41. **Watsonia fourcadei** *J.W.Mathews & L.Bolus* in Bolus in Annals of the Bolus Herbarium 4: 26 (1925). Type: South Africa, [Eastern Cape], Witte Els Bosch, *Fourcade s.n.* (BOL [Nat. Bot. Gard.], holo.; BOL, iso.).

Watsonia stanfordiae L.Bolus: 133 (1929b). Type: South Africa, [Western Cape], kloof at Banhoek, Stellenbosch, ex hort. K, *Stanford s.n.* (BOL [*BOL18893*], holo.).

Watsonia ryderae L.Bolus: 326 (1932). Type: South Africa, [Western Cape], Riversdale, Garcia's Pass, *Ryder s.n.* (BOL [19974], holo.; BOL, iso.).

Plants 900–1 800 mm high. *Corm* depressed-globose, 30–50 mm diam.; tunics coarsely netted. *Stem* with up to 4 short, suberect branches. *Leaves* 5 to 8, lower ± basal, uppermost leaf partly sheathing stem, ± ⅓ as long as spike, lanceolate, (15–)20–40 mm wide, midrib and margins lightly to moderately thickened and hyaline; bract-like cauline leaves 1 or 2, sheathing. *Spike* 25- to 40-flowered; bracts herbaceous and usually reddish, becoming dry and brownish above, 10–18(–25) mm long, acute to attenuate, inner ⅔ to as long, deeply forked apically for 3–6 mm. *Flowers* zygomorphic, pink or purple to orange-red or orange, sometimes with a paler tube and tepals, then darker on the reverse; perianth tube with lower part (20–)25–30 mm long, usually well exserted from bracts for up to 20 mm, upper part horizontal to drooping, subcylindric, ± 22–26 mm long, 6–8 mm diam. at mouth; tepals oblanceolate, 24–33 × 9–13 mm, all suberect and weakly cupped. *Filaments* unilateral, arcuate, 38–45 mm long, well exserted from tube; anthers 9–12 mm long, violet. *Style* dividing between upper ⅓ and apex of anthers, branches ± 4.5 mm long. *Capsules* obconic, tapering above, 18–20 × 5–6 mm. *Seeds* elongate-angular, 9–12 mm long, with well-developed distal wing and rudimentary proximal wing. *Flowering time*: October to early January (February).

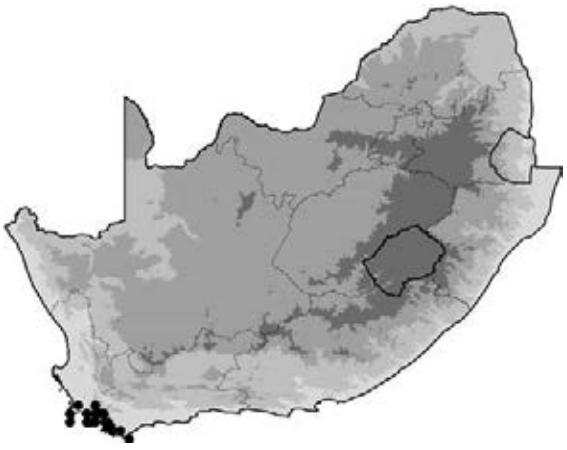
Distribution of ***Watsonia fourcadei***.

Distribution and ecology: relatively widespread through the mountains in southwestern South Africa, from the Cederberg to Villiersdorp thence eastward along the Langeberg and coastal plain of Western Cape to the Van Stadens River Mtns in Eastern Cape; on moist sandstone slopes, flowering mainly after fire. The species is absent from the Cape Peninsula, the Kogelberg–Klein River–Bredasdorp Mtns and the Riviersonderend Mtns.

Diagnosis: distinguished by the combination of acute to attenuate, moderate-sized bracts, 10–18(–25) mm long, the inner deeply forked apically for 3–6 mm, and the very long flowers, typically rather drooping, with the lower part of the tube (20–)25–30 mm long and usually well-exserted from the bracts. The obconic, tapering capsules are diagnostic. *Watsonia angusta* has acute or shortly bilobed inner bracts and smaller flowers, with the lower part of the tube (15–)18–22 mm long and narrower tepals 4–10 mm wide, and elongate, fusiform capsules. *Watsonia schlechteri*, also with entire or shortly forked inner bracts and shorter lower and upper parts of the perianth tube, 15–20 mm long, has subglobose to obovoid capsules up to 10 mm long.

42. **Watsonia zeyheri** *L.Bolus* in Annals of the Bolus Herbarium 4: 48 (1926). Type: South Africa, [Western Cape], Caledon, *Ecklon & Zeyher s.n.* or *Irid. 181* (K, holo.).

Watsonia elimensis L.Bolus: 48 (1926). Type: South Africa, [Western Cape], hills near Elim, *Schlechter 9692* (K, lecto., designated by Goldblatt: 115 (1989); B, BOL, G, GRA, K, PRE, Z, isolecto.).



Watsonia comptonii L.Bolus: 330 (1932). Type: South Africa, [Western Cape], Cape Peninsula, marsh near Smitswinkel, *Salter 1840* (BOL, lecto., designated by Goldblatt: 115 (1989); BM, BOL, K, isolecto.).

Watsonia comptonii var. *angustifolia* L.Bolus: 330 (1932). Type: South Africa, [Western Cape], marsh near Redhill, *Salter 1900* (BOL, lecto., designated by Goldblatt: 115 (1989); BOL, K, SAM, isolecto.).

[*Watsonia strictiflora* Eckl.: 36 (1827), invalid name without description.]

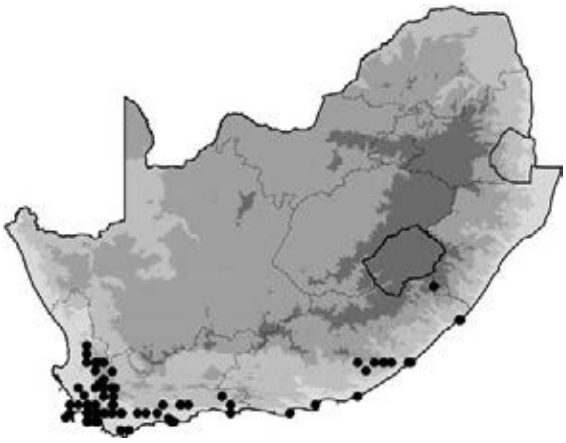
Plants (150–)350–800 mm high. *Corm* depressed-globose, 18–25 mm diam.; tunics finely netted. *Stem* simple or with 2 to 4 short, erect branches. *Leaves* ± 4, lower 3 ± basal, upper leaves partly sheathing stem, ± half as long as spike, narrowly lanceolate to lanceolate, 12–18 mm wide, midrib and margins thickened and hyaline; bract-like cauline leaves 2, sheathing, 60–90 mm long. *Spike* (3)9- to 14-flowered; bracts green, often reddish above, dry and brown on upper margins for ± 1 mm, (10–)14–18 mm long, inner ⅔ to as long, forked apically for 2–4 mm. *Flowers* zygomorphic, orange or salmon-pink; tepals with darker median streak in lower midline; perianth tube with lower part 15–18 mm long, emerging up to 10 mm from bracts, upper part ascending, subcylindric, 16–20 mm long, ± 5 mm diam. at mouth; tepals oblanceolate, 20–22 × 9–11 mm, all spreading wide. *Filaments* unilateral and arcuate, 25–33 mm long, well exserted from tube; anthers ± 7 mm long, violet. *Style* dividing near middle of anthers, branches ± 5 mm long. *Capsules* oblong-fusiform, 20–24 × 5–6 mm. *Seeds* nearly linear, 10–12 × 1.5–2.0 mm, 2-winged. *Flowering time*: (September) October to early December.

Distribution and ecology: restricted to the extreme south-western part of Western Cape, South Africa, from the southern Cape Peninsula and Hottentots Holland Mtns to Bredasdorp and Cape Infanta, usually at lower elevations but occurring at higher altitudes in the marshes at the eastern end of Franschhoek Pass and at Grabouw; usually in marshes and seeps or along streambanks.

Distribution of ***Watsonia zeyheri***.

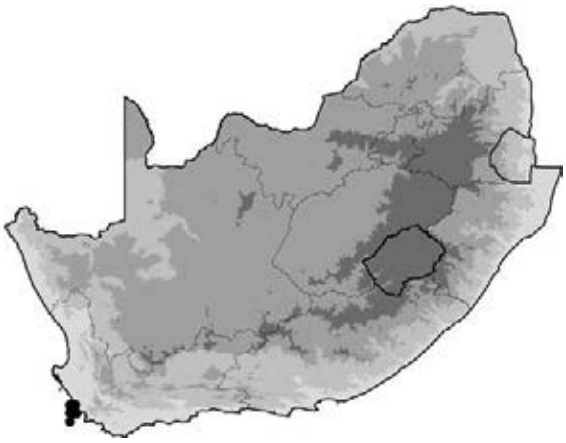
Diagnosis: distinguished from other species with similar long-tubed, red to orange flowers by the relatively short bracts, (10–)14–18 mm long and the oblong-fusiform capsules tapering at the tips. *Watsonia angusta* is a generally taller species, with dull red flowers with narrower tepals mostly 4–8 mm wide and a longer upper perianth tube, 20–22 mm long. *Watsonia fourcadei* is likewise a more robust species with much longer, typically rather drooping flowers with the upper part of the tube 22–26 mm long, and deeply forked inner bracts.

43. **Watsonia angusta** *Ker Gawl.* in König & Sims, Annals of Botany 1: 230 (1804). *Gladiolus jacquinii* Schrank: 195 (1822), illegitimate superfluous name based on same type. Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 231 (1795 [1788–1795]) '*Gladiolus merianus* var.'.



Antholyza ludwigii Eckl.: 34 (1827). Type: South Africa, [Western Cape], ex hort. Ludwig, Cape Town, *Ecklon s.n.* (S, holo.).

Watsonia atrosanguinea Klatt: 738 (1864). Type: South Africa [but said to be from Java], *Zollinger 440* (†B, holo.; P, iso.).



Plants 1 000–1 200 mm high. *Corm* depressed-globose, 40–60 mm diam.; tunics coarsely netted. *Stem* branched, with 1 to several short, suberect branches. *Leaves* 5 to several, lower ± basal, upper leaves partly sheathing stem, ± half as long as spike, narrowly lanceolate to lanceolate, 12–20 mm wide, midrib and margins lightly thickened and narrowly to obscurely hyaline; bract-like cauline leaves 1 or more, long and tightly sheathing. *Spike* lax, up to 18-flowered; bracts herbaceous and often dull reddish purple, dry and brownish apically, 9–14(–16) mm long, inner as long as or slightly longer, acute or bilobed apically for up to 1 mm. *Flowers* zygomorphic, scarlet (rare yellow mutants recorded), often with pale longitudinal streaks running down tube from tepal sinuses; perianth tube with lower part (15–)18–22 mm long, emerging 10–14 mm from bracts, upper part horizontal, subcylindric, 20–22 mm long, 5–7 mm diam. at mouth; tepals narrowly oblanceolate, 19–25 × 4–8(–10) mm, upper ascending to horizontal, lower recurved. *Filaments* unilateral and arcuate, 30–38 mm long, well exserted from tube; anthers 7–10 mm long, purple-black. *Style* dividing near apex of anthers, branches ± 4 mm long. *Capsules* fusiform, 25–35 × 8 mm. *Seeds* nearly linear, 9–15 × 1.5–2.0 mm, 2-winged with distal wing largest. *Flowering time*: November to December or February at high elevations.

Distribution and ecology: widely distributed through southern and southeastern South Africa, from the Cederberg in Western Cape to the Cape Peninsula thence eastward along the coastal ranges through Eastern Cape to near Underberg in southern KwaZulu-Natal; in marshes and seeps and along streams.

Diagnosis: diagnosed by the lanceolate leaves without strongly thickened midrib and margins, the branched

Distribution of ***Watsonia angusta***.

Distribution of ***Watsonia tabularis***.

spike with relatively short bracts 9–14(–16) mm long, and long-tubed red flowers with narrow tepals 4–8(–10) mm wide, and fusiform capsule 25–35 mm long. *Watsonia stokoei*, with remarkably similar flowers, has small, obovoid capsules up to 10 mm long containing angular seeds only 5 mm long. *Watsonia zeyheri*, also with fusiform capsules, has the upper part of the perianth tube 16–20 mm long, and broader, slightly cupped tepals 8–11 mm wide.

Ser. **Watsonia**

Stems often branched; bracts moderately large to large and relatively broad, often more than 15 mm long, inner often as long as or longer. *Capsules* obovoid, large and often somewhat inflated. *Seeds* 2-winged, or distally 1-winged, or circumferentially winged.

44. **Watsonia tabularis** *J.W.Mathews & L.Bolus* in Bolus, Annals of the Bolus Herbarium 3: 141 (1922). Type: South Africa, [Western Cape], Table Mtn. and Klaasenbosch, *Mathews s.n.* (BOL [5193], lecto., designated by Goldblatt: 112 (1989); BM, BOL, PRE, isolecto.).

Watsonia tabularis var. *concolor* G.J.Lewis in Barker et al.: 34 (1948). Type: South Africa, [Western Cape], Redhill, *Salter 1896* (SAM, lecto., designated by Goldblatt: 112 (1989); BOL, K, SAM, isolecto.).

[*Watsonia tabularis* Eckl.: 35 (1827), invalid name without description.]

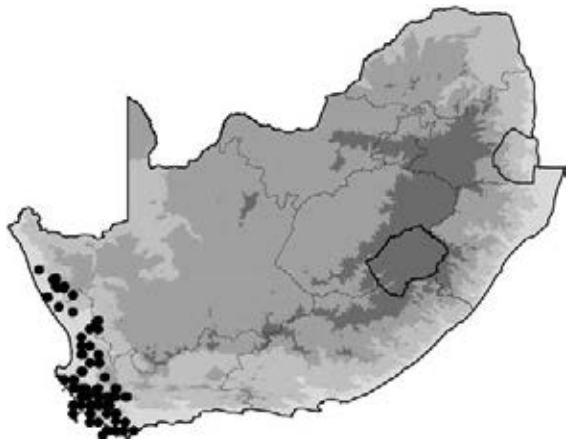
Plants 900–1 500 mm high. *Corm* depressed-globose, 40–60 mm diam.; tunics coarsely netted. *Stem* branched. *Leaves* several, lower ± basal, uppermost leaf partly sheathing stem, ± half as long as spike, lanceolate, 20–35 mm wide, midrib and margins lightly thickened and hyaline; bract-like cauline leaves 80–200 mm long, conspicuously inflated, sheathing. *Spike* 20- to 30-flowered; bracts herbaceous and usually reddish, dry and brownish apically, 10–15 mm long, inner as long as or slightly longer, forked apically for up to 3 mm. *Flowers* zygomorphic, reddish to pinkish orange with paler, nearly white inner tepals, often white at base of tepals and in tube; perianth tube with lower part 20–25 mm long, emerging 10–18 mm from bracts, upper part horizontal, subcylindric, 20–25 mm long, 7–9 mm diam. at mouth; tepals oblanceolate, 20–26 × 9–17 mm, all suberect with dorsal somewhat hooded and lower median slightly recurved. *Filaments* unilateral and arcuate, 35–40 mm long, well exserted from tube; anthers 10–12 mm long, violet. *Style* dividing between middle and apex of anthers, branches ± 6 mm long. *Capsules* large, oblong-truncate, 20–30 × 8–11 mm. *Seeds* 9–11 × 2.5–3.5 mm, with lateral wing enlarged distally and ± twice as long as seed body. *Flowering time*: late November to January (March).

Distribution and ecology: a narrow endemic of Western Cape, South Africa, restricted to the mountains and adjacent flats on the Cape Peninsula; on rocky sandstone slopes and plateaus, from near sea level to 900 m elevation, flowering best after fire.

Diagnosis: readily distinguished from other species with similar, long-tubed orange flowers by the strongly inflated cauline bract leaves and the large, oblong-truncate capsules 20–30 mm long. The floral bracts are relatively short, 10–15 mm long, with the inner as long as or slightly longer and forked apically for up to 3 mm.

Plants from Table Mountain to Vlakkenberg have the inner tepals markedly paler than the outer, almost white but populations from Vlakkenberg to Kalk Bay have more uniformly coloured flowers.

45. **Watsonia meriana** *(L.) Mill.*, Gardener's Dictionary, edn. 8: no. 1 (1768). *Antholyza meriana* L.: 863 (1759). *Gladiolus merianus* (L.) Thunb.: 14 (1784). *Ixia meriana* (L.) Link: 52 (1821). *Gladiolus amoenus* Salisb.: 39 (1796), illegitimate superfluous name for *A. meriana* L. Type: South Africa, without precise locality or collector, illustration in Trew, Plantae selectae: t. 40 (1754).



Gladiolus infundibuliformis Schrank: 198 (1822). Type: Unknown, possibly at BR.

Watsonia vivipara J.W.Mathews & L.Bolus in Bolus: 117 (1927). Type: South Africa, [Western Cape], near Montagu, *Compton & Cook fl. 1925* (BOL [*Nat. Bot. Gard. 1894/23I*], lecto., designated by Goldblatt: 94 (1989); BOL, K [fragment], isolecto.).

Watsonia leipoldtii L.Bolus: 328 (1932). Type: South Africa, [Western Cape], Worcester, wet sites between Brandvlei and Villiersdorp, *Leipoldt s.n.* (BOL [*Nat. Bot. Gard. 4312/14*], lecto., designated by Goldblatt: 94 (1989); BOL, isolecto.).

Plants 500–2 000 mm high. *Corm* depressed-globose, 30–50 mm diam.; tunics coarsely netted. *Stem* simple or usually with a few suberect or diverging branches, sometimes with 1 to several cormlets in axils of lower leaves and branches, or at the spike nodes (var. *bulbillifera*). *Leaves* 4 to 6, lower 3 or 4 ± basal, uppermost leaf partly or entirely sheathing stem, ± half as long as spike, lanceolate, 12–25(–35) mm wide, midrib and margins lightly to moderately thickened and hyaline; bract-like cauline leaves 2 or more, progressively smaller above, sheathing. *Spike* up to 25-flowered; bracts herbaceous and usually reddish, dry and brownish above, (18–)24–30 mm long, inner as long as or slightly longer, acute or barely forked apically. *Flowers* zygomorphic, usually orange or red, sometimes pink or purple (rarely yellow mutants recorded); perianth tube with lower part 22–25 mm long, emerging shortly from bracts, upper part horizontal, subcylindric, 20–25 mm long, (4–)5–6 mm diam. at mouth, usually with longitudinal ridges between filament bases; tepals oblanceolate to obovate, 21–26 × 8–15 mm, all widely spreading or dorsal somewhat hooded. *Filaments* unilateral and arcuate, 35–45 mm long, well exserted from tube; anthers 8–10(–12) mm long, violet. *Style* dividing near between middle of anthers, branches 6–7 mm long. *Capsules* large, elongate-oblong, 22–30 × 7–9 mm. *Seeds* (10–)15–18 × 2–4 mm, with distal wing well developed and pale. *Flowering time*: mainly September to November.

Distribution and ecology: widespread along the southwest coast and adjacent interior of South Africa, on the Kamiesberg in Northern Cape and from the Bokkeveld Escarpment in Western Cape to Bredasdorp in the south; usually in seasonally wet situations, vleis and along streams, in sandy soils.

Distribution of ***Watsonia meriana***.

Diagnosis: distinguished from other species with similar flowers by its large stature and relatively long, herbaceous bracts, (18–)24–30 mm long, the inner as long or slightly longer and acute or barely forked apically. The bracts remain relatively soft in texture and do not turn dark brown on drying. The capsules are large and leathery, 22–30 mm long. *Watsonia coccinea* is a shorter species up to 400 mm tall, often unbranched, with narrower leaves mostly 2–8 mm wide and slightly smaller flowers, the filaments 25–30 mm long.

Key to varieties

1a Plants sometimes developing clusters of cormlets in leaf or branch axils but never at spike nodes, developing capsules after pollination .... 45a. var. *meriana*
1b Plants developing clusters of cormlets in leaf and branch axils and at floral nodes, never developing capsules..... 45b. var. *bulbillifera*

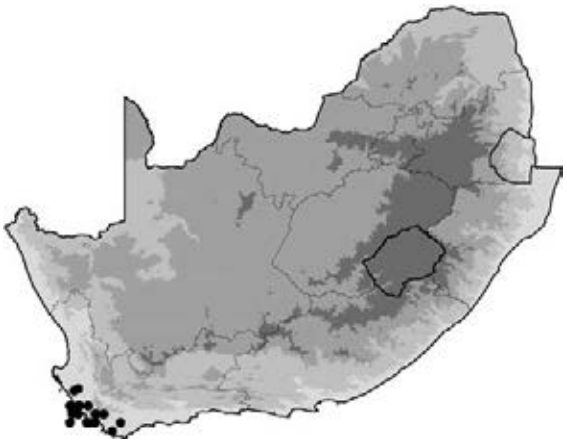
45a var. **meriana**

Plants sometimes developing clusters of cormlets in leaf or branch axils but never at floral nodes, developing capsules after pollination. Fertile diploids *2n* = 18.

45b. var. **bulbillifera** *(J.W.Mathews & L.Bolus) D.A.Cooke* in Journal of the Adelaide Botanical Garden 18: 6 (1998). *Watsonia bulbillifera* J.W.Mathews & L.Bolus in Bolus: 140 (1922). Type: South Africa, [Western Cape], Joostenberg, without collector (BOL [*Nat. Bot. Gard. 707/13*], lecto., designated by Goldblatt: 94 (1989); B, M, BOL, K, PRE, SAM, isolecto.).

Plants developing clusters of cormlets in leaf and branch axils and at floral nodes, never developing capsules. Sterile triploids *2n* = 27.

Distribution and ecology: recorded from a few localities in the Breede River Valley and on the flats around Cape Town, notably Joostenberg and Kenilworth Race Course, in seasonal vleis, forming dense and sometimes extensive stands due to its exceptional capacity for vegetative reproduction. It is a weed in Australia, Mauritius and Réunion (Goldblatt 1989).



46. **Watsonia coccinea** *(Herb. ex Baker) Baker*, Handbook of the Irideae: 175 (1892). *Watsonia meriana* var. *coccinea* Herb. ex Baker: 158 (1877). Type: South Africa, without precise locality or collector, illustration in Ker Gawl. in Curtis's Botanical Magazine 30: t. 1194 (1809b) '*Watsonia meriana* var. γ.

[*Watsonia merianella* Eckl.: 36 (1827), invalid name without description.]

Plants 150–300(–450) mm high. *Corm* depressed-globose, 18–40 mm diam.; tunics coarsely netted. *Stem* simple or rarely with 1 or 2 suberect branches. *Leaves* 4 to 6, lower 3 or 4 ± basal, uppermost leaf partly or entirely sheathing stem, ± half as long or as long as spike, linear to linear-lanceolate, 2–8 mm wide, midrib and margins lightly thickened and hyaline; bract-like cauline leaves 2 or more, sheathing. *Spike* 3- to 6-flowered; bracts herbaceous and green, dry and brownish apically, 20–25 mm long, inner ± as long as or slightly longer or shorter, barely forked apically. *Flowers* zygomorphic, dull to bright scarlet, purple or translucent pink; tepals usually with dark median line; perianth tube with lower part 20–24 mm long, emerging shortly from bracts, upper part ascending to horizontal, subcylindric, 18–24 mm long, 5–6 mm diam. at mouth; tepals obovate, 16–23 × 8–12 mm, all widely spreading or dorsal somewhat hooded. *Filaments* unilateral, arcuate, 25–30 mm long, well exserted from tube; anthers 5–8 mm long, violet. *Style* dividing between middle and apex of anthers, branches ± 5 mm long. *Capsules* large, often somewhat inflated, narrowly obovoid-ellipsoid, 20–25 × 10–14 mm. *Seeds* 8–12 mm long, either 2-winged or with large asymmetrical circumferential wing. *Flowering time*: August to November.

Distribution and ecology: restricted to the extreme southwestern part of Western Cape, from Malmesbury to the Cape Peninsula to Bredasdorp, on moist sandy flats or plateaus, often in seeps, flowering best after fire. The species is threatened by urban development.

Diagnosis: distinguished from other species with similar flowers by its short stature, mostly less than 400 mm high, and relatively long, herbaceous bracts, 20–25 mm long, the inner as long or slightly longer than the outer and barely forked apically. The bracts remain relatively soft in texture and do not turn dark brown on drying. The capsules are large and leathery, 20–25 mm long. *Watsonia meriana* is a larger species, 500–2 000 mm tall, usually branched, with broader leaves 12–35 mm wide and slightly longer flowers, the filaments 35–45 mm long. *Watsonia humilis* has white to pink flowers with relatively short filaments 10–20 mm long included or scarcely exserted from the tube.

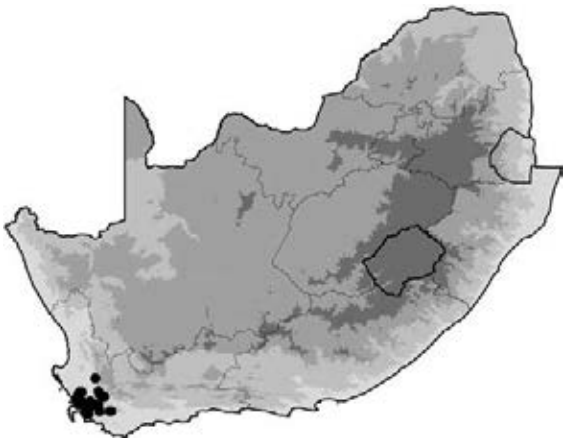
Distribution of ***Watsonia coccinea***.

47. **Watsonia humilis** *Mill.*, Gardener's Dictionary, edn. 8: 2 (1768). Type: South Africa, without precise locality or collector, illustration in Miller, Figures of plants described in the Gardener's Dictionary 2: t. 297, f. 2 (1760).

Gladiolus marmoratus Lam.: 727 (1788). *Peyrousia marmorata* (Lam.) Poir.: 364 (1826). *Lapeirousia marmorata* (Lam.) Steud.: 9 (1840b). Type: South Africa, without precise locality, *Sonnerat s.n.* (P-Herb. Lamarck, holo.).

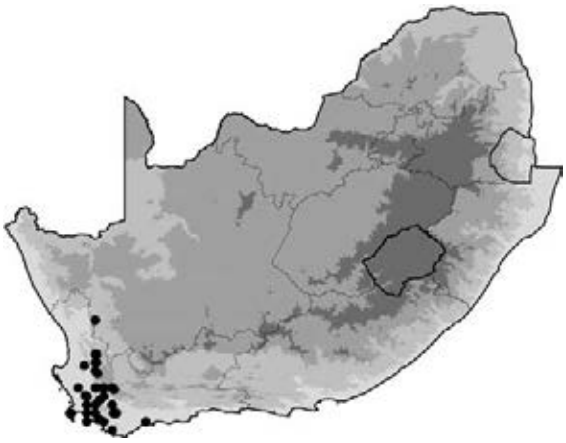
Gladiolus roseoalbus Jacq.: 7 (1797). *Watsonia roseoalba* (Jacq.) Ker Gawl.: t. 537 (1801b). *W. meriana* var. *roseoalba* (Jacq.) Baker: 158 (1877). Type: South Africa, without precise locality or collector, illustration in Jacq.: 7 (1797).

Watsonia litura Klatt: 353 (1882). Type: South Africa, without precise locality or collector, illustration in Curtis's Botanical Magazine 30: t. 1193 (1809a) '*Watsonia roseo-alba* β'.



Watsonia maculata Klatt: 352 (1882). Type: South Africa, without precise locality or collector, illustration in Ker Gawl. in Curtis's Botanical Magazine 30: 1195 (1809c) '*Watsonia humilis* β'.

[*Watsonia erubescens* Banks ex Ker Gawl.: t. 631 (1803), invalid name cited as a synonym of *W. laccata* (Jacq.) Ker Gawl.]



[*Neuberia humilis* Eckl.: 37 (1827), name without description.]

Plants (100–)150–300 mm high. *Corm* subglobose, 10–20 mm diam.; tunics finely netted. *Stem* simple or rarely with 1 suberect branch. *Leaves* 5 or 6, lower 4 or 5 basal, uppermost partly or entirely sheathing stem, ± ½ as long as spike, lanceolate, 8–14 mm wide, midrib and margins not thickened; bract-like cauline leaves 1 or 2, sheathing. *Spike* 6- to 12-flowered; bracts herbaceous and green, sometimes reddish above, recurved apically, (15–)20–30 mm long, inner ± ⅔ as long, forked apically. *Flowers* zygomorphic, white flushed pink with pink tube or pale to deep pink; perianth tube with lower part (13–)17–30 mm long, included to well exserted from bracts, upper part ascending or horizontal to slightly drooping, subcylindric, (13–)17–30 mm long, ± 5 mm diam. at mouth; tepals oblanceolate to obovate, 15–22 × 7–12 mm, all widely spreading. *Filaments* unilateral, arcuate, (10–)15–20(–22) mm long, not or barely exserted up to 5 mm from tube; anthers 5–7 mm long, dark blue or violet. *Style* dividing between middle and apex of anthers, branches 3–4 mm long. *Capsules* oblong, 15–20 mm long. *Seeds* 8–12 mm long, 2-winged with distal wing largest or proximal wing vestigial. *Flowering time*: late September to November.

Distribution and ecology: restricted to the lowlands in the extreme southwestern part of Western Cape, South

Distribution of ***Watsonia humilis***.

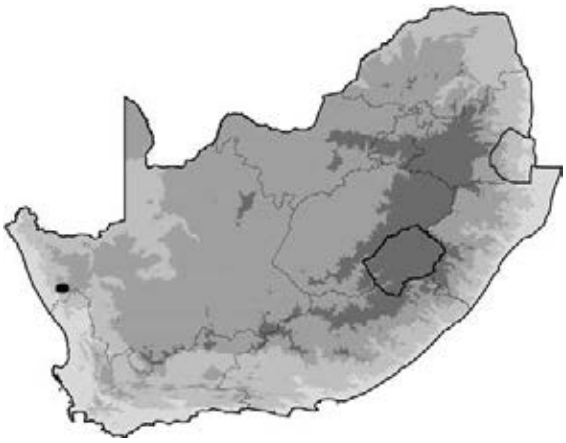
Distribution of ***Watsonia spectabilis***.

Africa, from Malmesbury to Gordon's Bay inland to Worcester but absent from the Cape Peninsula; on seasonally wet sandy flats and lower slopes. The species is threatened by urbanisation.

Diagnosis: distinguished by its short stature, up to 300 mm high, relatively long, herbaceous bracts, (15–)20–30 mm long and recurved apically, and moderately to long-tubed, white to pink flowers with relatively short filaments, 10–20 mm long, not or shortly exserted up to 5 mm from the perianth tube. The bracts remain relatively soft in texture and do not turn dark brown on drying. *Watsonia coccinea* has red to pink flowers with longer filaments, 25–30 mm long, well exserted from the perianth tube, and narrower leaves 2–8 mm wide. *Watsonia stenosiphon* from east of Gordon's Bay also has flowers with short filaments 15–20 mm long but an orange to salmon-pink perianth, and the bracts are not recurved apically.

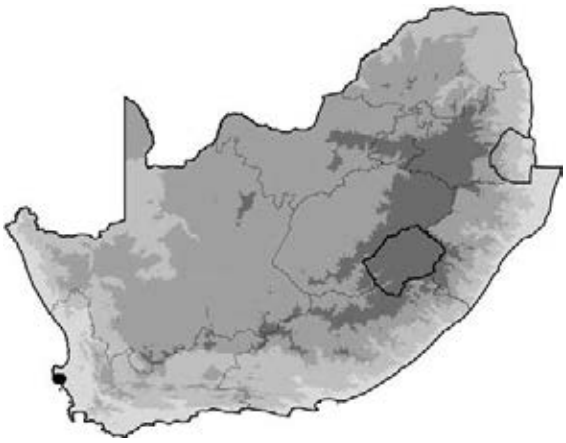
48. **Watsonia spectabilis** *Schinz* in Memoires de l'Herbier Boissier 20: 14 (1900). Type: South Africa, [Western Cape], Sir Lowry's Pass, *Schlechter 1127c* (Z, holo.).

[*Watsonia pellucida* Eckl.: 36 (1827), invalid name without description.]



Plants 200–500 mm high. *Corm* subglobose, 20–30 mm diam.; tunics coarsely netted. *Stem* usually simple. *Leaves* 3 to 5, lower 2 to 4 basal, upper leaf partly or entirely sheathing stem, reaching to base of spike or longer, linear to narrowly lanceolate, 2–8 mm wide, midrib lightly thickened but margins not thickened; bract-like cauline leaves 1 to 3, progressively shorter, sheathing. *Spike* 2- to 5(10)-flowered; bracts herbaceous, green or flushed red, 20–40 mm long, inner ± as long or slightly longer, minutely forked apically. *Flowers* zygomorphic, bright red to pale orange, often translucent; perianth tube with lower part 18–22 mm long, not exserted from bracts, upper part horizontal, widening abruptly, subcylindric, 20–25 mm long, slightly compressed, oblique, up to 11 mm diam. at mouth; tepals lanceolate, acute, 30–35 × 7–12 mm, upper tepals connate ± 3 mm beyond lower, dorsal tepal hooded, upper laterals weakly spreading and lower tepals strongly recurved. *Filaments* unilateral and arcuate, 30–40 mm long, well exserted from tube; anthers 9–11 mm long, yellow or violet. *Style* dividing near anther apices, branches 5–6 mm long. *Capsules* large, obovoid to subglobose, 25–30 × 20–30 mm. *Seeds* 9–12 × 4 mm, with large pale wing, sometimes vestigial proximally. *Flowering time*: (July) August to October.

Distribution and ecology: widely distributed along the western near interior of Western Cape, South Africa, from the Bokkeveld Escarpment to Bredasdorp and Potberg; on seasonally moist, stony sandstone flats and slopes. The species is extinct on the Cape Peninsula.



Diagnosis: a short species up to 500 mm high with bracts 20–40 mm long and large, strongly bilabiate, red to orange flowers with acute tepals 30–35 mm long. The perianth tube is markedly oblique at the mouth, the lower three tepals separating ± 3 mm before the upper three tepals and strongly recurved. *Watsonia coccinea* has slightly shorter bracts 20–25 mm long, and smaller flowers with ± obtuse tepals 16–23 mm long, the lower not strongly recurved, and filaments 25–30 mm long.

49. **Watsonia rourkei** *Goldblatt* in Annals of Kirstenbosch Botanic Gardens 19: 132 (1989). Type: South Africa, [Northern Cape], Kamiesberg, Rooiberg, upper slopes, *Rourke 1681* (NBG, holo.; NBG, iso.).

Plants 1 500–2 000 mm high. *Corm* subglobose, 35–50 mm diam.; tunics coarsely netted. *Stem* with 3 or more short branches. *Leaves* 5 or 6, lower 4 or 5 basal, upper partly sheathing stem, ± half as spike, lanceolate, 15–25 mm wide, midrib and margins moderately thickened and hyaline; bract-like cauline leaves sheathing. *Spike* 20- to 30-flowered; bracts herbaceous, dry and brownish apically, acuminate, 15–20 mm long, inner ± ⅔ as long, forked apically up to 2 mm. *Flowers* zygomorphic, pale pink with darker tube, evidently scented;

Distribution of ***Watsonia rourkei***.

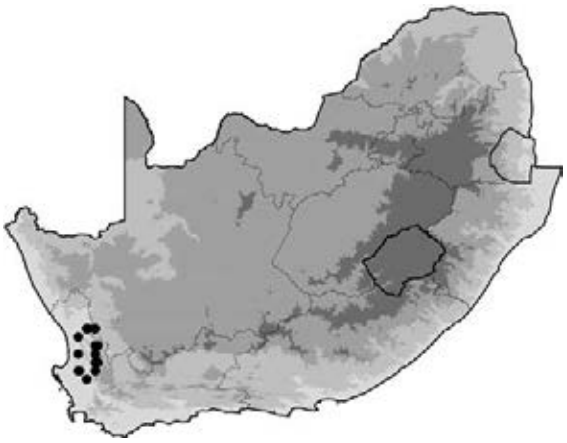
Distribution of ***Watsonia hysterantha***.

perianth tube with lower part ± 15 mm long, upper part ascending or horizontal, subcylindric, ± 25 mm long, ± 5 mm diam. at mouth; tepals oblanceolate, 20–22 × 6–8 mm, all widely spreading. *Filaments* unilateral and arcuate, ± 30 mm long, well exserted from tube; anthers 10–12 mm long, yellow. *Style* dividing near apex of anthers, branches 5–6 mm long. *Capsules* and *seeds* unknown. *Flowering time*: probably November.

Distribution and ecology: a narrow endemic known only from the type collection from Rooiberg in the Kamiesberg Mtns in Northern Cape, South Africa, from the northern slopes below the summit at 1 600 m elevation; in gullies and seasonal watercourses.

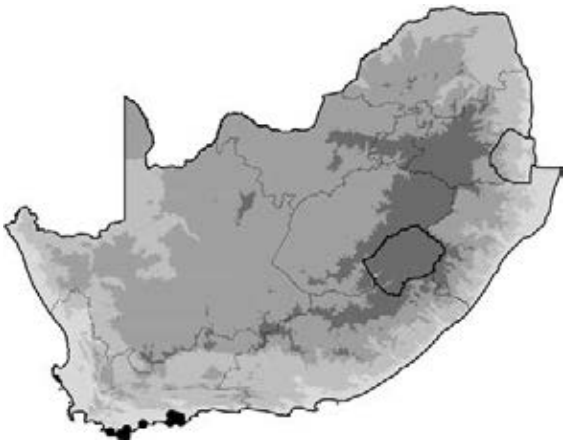
Diagnosis: a tall species, 1 500–2 000 mm high, with herbaceous bracts 15–20 mm long, and pale pink flowers, the upper part of the perianth tube ± 22 mm long and tepals 20–22 mm long. The yellow anthers are diagnostic. The capsules are unknown. *Watsonia meriana*, the only other species of *Watsonia* recorded on the Kamiesberg, has slightly longer bracts, bracts (18–)24–30 mm long, and reddish orange flowers with tepals 21–26 mm long, and violet anthers.

50. **Watsonia hysterantha** *J.W.Mathews & L.Bolus* in L. Bolus in Annals of the Bolus Herbarium 4: 116 (1927). Type: South Africa, [Western Cape], Olifantskop, Langebaan, *Mathews s.n.* (BOL [*Nat. Bot. Gard. 1723/24*], lecto., designated by Goldblatt: 134 (1989); BOL, isolecto.).



Plants 500–800 mm high. *Corm* subglobose, 40–55 mm diam.; tunics coarsely netted. *Stem* simple. *Leaves* 3 or 4, basal, dry and withered at flowering, ± as long as spike, linear, 4–10 mm wide, midrib and margins lightly thickened; bract-like cauline leaves several, sheathing, dry at flowering. *Spike* laxly up to 10-flowered; bracts herbaceous and green, becoming dry and brownish apically, attenuate, 15–24 mm long, inner ± ⅔ to as long, deeply forked ± halfway. *Flowers* zygomorphic, red; perianth tube with lower part 14–20 mm long, exserted 5–7 mm from bracts, upper part horizontal, subcylindric, ± 25 mm long, ± 6 mm diam. at mouth; tepals oblanceolate, 25–30 × 8–12 mm, all widely spreading or dorsal hooded. *Filaments* unilateral, arcuate, 30–35 mm long, well exserted from tube; anthers 9–12 mm long, violet. *Style* dividing near middle of anthers, branches 6–7 mm long. *Capsules* narrowly obovoid, (18–)25–30 × 10–15 mm. *Seeds* 8–10 × 4–5 mm, with broad distal wing. *Flowering time*: March to July.

Distribution and ecology: a local endemic of the West Coast of Western Cape, South Africa, restricted to coastal granite outcrops between Saldanha and Langebaan; wedged in rock crevices.



Diagnosis: distinguished from similar species with long-tubed, red flowers by the flowering time, autumn and winter, at which time the foliage is dry and withered, and by the deeply forked inner bracts, divided up to half their length. The leaves are unusually narrow, up to 10 mm wide but usually less.

51. **Watsonia vanderspuyiae** *L.Bolus* in Annals of the Bolus Herbarium 4: 45 (1926). Type: South Africa, [Western Cape], Piketberg Mtn., *Van der Spuy s.n.* (BOL [17838], lecto., designated by Goldblatt: 134 (1989); BOL, isolecto.).

Plants robust, 1 200–2 000 mm high. *Corm* depressed-globose, 60–100 mm diam.; tunics coarsely netted. *Stem* with 2 to 4 stiffly erect branches. *Leaves* 3 or 4, lower 2 or 3 basal, upper leaf partly sheathing stem, one ⅓–½ as long as spike, lanceolate, (33–)55–85 mm wide, midrib poorly defined, margins heavily thickened and hyaline; bract-like cauline leaves 2 or more, inflated, progressively smaller. *Spike* up to 30-flowered; bracts dry, brown and submembranous, becoming lacerate, 25–45 mm long, inner ± ⅔ as long, apically forked for 1–2 mm. *Flowers* zygomorphic, bright red; perianth tube with lower part ± 25 mm long, emerging from bracts, upper part horizontal, subcylindric, ± 25 mm long, ± 6 mm diam. at mouth; tepals narrowly lanceolate to lanceolate, 25–35 × 7–13 mm, uppermost hooded, others spreading or variously recurved. *Filaments* unilateral, arcuate, 30–35 mm

Distribution of ***Watsonia vanderspuyiae***.

Distribution of ***Watsonia fergusoniae***.

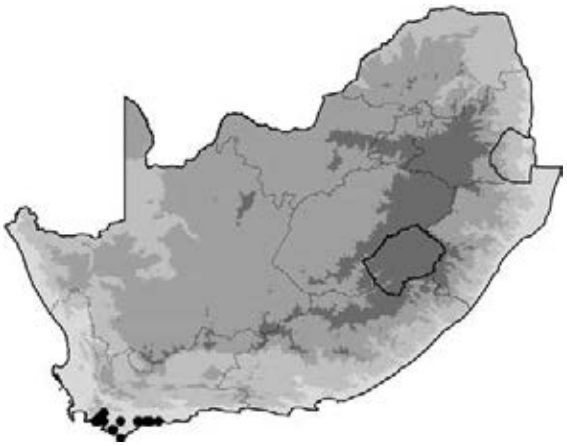
long, well exserted from tube; anthers 13–15 mm long, violet. *Style* dividing near apices of anthers, branches ± 6 mm long. *Capsules* oblong to ellipsoid, (24–)30–50 × ± 10 mm. *Seeds* 12–15 × ± 4 mm, with broad distal wing. *Flowering time*: September to November.

Distribution and ecology: endemic to the West Coast of South Africa, extending from the Bokkeveld Escarpment in Northern Cape south through the Matsikamma Mtns and Cederberg to Piketberg, the Cold Bokkeveld and Groot Winterhoek in Western Cape; in crevices in sandstone outcrops, flowering well after fire.

Diagnosis: a particularly robust species readily recognised by its broad leaves, (33–)55–85 mm wide with the midrib poorly defined but the margins heavily thickened, somewhat inflated bract-like cauline leaves, dry, lacerate floral bracts 25–45 mm long and large, long-tubed red flowers, the tube alone up to 50 mm long.

52. **Watsonia fergusoniae** *L.Bolus* in South African Gardening and Country Life 20: 14 (1930a). Type: South Africa, [Western Cape], limestone hills 8 miles from Still Bay, *Ferguson s.n.* (BOL [*BOL19031*], lecto., designated by Goldblatt: 137 (1989); BOL, isolecto.).

Plants (220–)400–1 100 mm high. *Corm* depressed-globose, 25–35 mm diam.; tunics finely netted. *Stem* simple. *Leaves* 2 to 4, ± basal, upper leaf partly sheathing stem, usually reaching to base of spike, linear, 3–7(–14) mm wide, midrib poorly defined and margins not thickened; bract-like cauline leaves 2 or more, sheathing. *Spike* 7- to 18-flowered; bracts green, dry and brown apically, (14–)20–26(–30) mm long, overlapping, ± as long or slightly longer, entire or barely notched apically. *Flowers* zygomorphic, scarlet-red; perianth tube with lower part 17–25 mm long, emerging 3–6 mm from bracts, upper part ascending to horizontal, subcylindric, 20–25(–30) mm long, (4–)6 mm diam. at mouth; tepals obovate, 20–25 × 9–12 mm, spreading widely or slightly cupped. *Filaments* unilateral and arcuate, 25–35 mm long, well exserted from tube; anthers 7–8(–10) mm long, yellow. *Style* dividing between base and middle of anthers, branches 5–7 mm long. *Capsules* narrowly cylindric, 20–25 × 4–6 mm. *Seeds* narrow, 6–9 × ± 2 mm, with broad distal wing and smaller or obsolete proximal wing. *Flowering time*: October to November.



Distribution and ecology: endemic to the Agulhas Plain in Western Cape, South Africa, from the Agulhas Peninsula to Gouritz River Mouth; wedged in limestone outcrops, flowering well only after fire.

Diagnosis: a relatively small species seldom more than 500 mm tall, the leaves with unthickened midrib and margins, green bracts, and scarlet-red flowers with the upper part of the tube 20–25(–30) mm long and (4–) 6 mm diam. at mouth, with filaments 25–35 mm long, and unusual yellow anthers. *Watsonia stenosiphon* from sandstone habitats has the upper part of the tube 13–16 mm long and ± 4 mm diam., and shorter filaments 15–20 mm long, only shortly exserted from the tube.

53. **Watsonia stenosiphon** *L.Bolus* in Annals of the Bolus Herbarium 4: 46 (1926). Type: South Africa, [Western Cape], Caledon Division, without precise locality, ex Cape Town Wild Flower Show (BOL [15458], lecto., designated by Goldblatt: 138 (1989); BOL, K, isolecto.).

[*Watsonia pottbergensis* Eckl.: 36 (1827), invalid name without description; specimen at S.]

Plants 200–450 mm high. *Corm* depressed-globose, 15–20 mm diam.; tunics finely netted. *Stem* simple. *Leaves* 3 or 4, ± basal, uppermost leaf partly or entirely sheathing stem, ± half as long as spike, linear, 5–12 mm wide, midrib poorly defined and margins not or lightly thickened; bract-like cauline leaves 1 or 2, sheathing. *Spike* 8- to 14-flowered; bracts green, dry and brown above, 15–22 mm long, overlapping, ± as long as, shortly notched apically. *Flowers* zygomorphic, bright salmon-orange or rarely mauve, lower 3 tepals often with darker median line toward base; perianth tube with lower part 14–18 mm long, enclosed or emerging 2–5 mm from

Distribution of ***Watsonia stenosiphon***.

bracts, upper part ascending, subcylindric, 13–16 mm long, 4 mm diam. at mouth; tepals obovate, 17–20 × 9–19 mm, spreading widely or slightly cupped. *Filaments* unilateral and arcuate, 15–20 mm long, not or barely exserted from tube; anthers 6–7 mm long, violet or yellow. *Style* dividing between base and middle of anthers, branches 5–7 mm long. *Capsules* narrowly cylindric to prismatic, 15–18 × 2 mm. *Seeds* slender, 7–10 × ± 2 mm, 2-winged. *Flowering time*: mid-September to late October.

Distribution and ecology: endemic to the southwestern coast of Western Cape, South Africa, from Kleinmond to the Agulhas Peninsula and Cape Infanta in the east; on stony sandstone flats and lower slopes, flowering best after fire. The species is especially common between Hermanus and Onrus, but urbanisation here is rapidly encroaching on its habitat.

Diagnosis: a short species, up to 450 mm high, with distinctive, narrow perianth tube 25–34 mm long and ± 4 mm diam. at the mouth, with spreading tepals and filaments 15–20 mm long and barely exserted from the perianth tube. *Watsonia fergusoniae* from limestone habitats is taller, usually more than 400 m high, with larger flowers, the tube 35–50 mm long and mostly ± 6 mm diam. at the mouth, and longer filaments 25–35 mm long well exserted from the perianth tube.

UNCERTAIN SPECIES

Watsonia cylindrica Baker in Journal of Botany, British and foreign 14: 336 (1876). Type: unknown, said to be from Madagascar.

Watsonia fulgens (Andrews) Pers., Synopsis plantarum 1: 42 (1805). *Antholyza fulgens* Andrews, The Botanists' Repository 3: t. 192 (1801b). *Watsonia iridifolia* var. *fulgens* (Andrews) Ker Gawl.: 600 (1802a). *W. fulgida* Salisb.: 323 (1812), illegitimate superfluous name. Type: South Africa, without precise locality or collector, illustration in Andrews, The Botanists' Repository 3: t. 192. Identity uncertain, possibly *W. fourcadei* or *W. wilmaniae*.

Watsonia iridifolia (Jacq.) Ker Gawl. in Curtis's botanical magazine 17: sub t. 600 (1802). *Gladiolus iridifolius* Jacq.: 151 (1791). *Ixia iridifolia* (Jacq.) Link: 52 (1821), illegitimate homonym, not *I. iridifolia* D.Delaroche (1766). *W. meriana* var. *iridifolia* (Jacq.) Baker: 158 (1877). Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 234 (1792 [1788–1795]). Identity uncertain, possibly a variant of *W. borbonica* or hybrid with that species.

Watsonia meriana var. *platypetala* Baker, Handbook of the Irideae: 175 (1892). Type: not designated and identity unknown. Said to differ from typical *Watsonia meriana* by its bright rose-red flowers with shorter, broader, somewhat overlapping tepals. Baker's circumscription of the species was very broad and included several taxa now accepted as distinct.

Watsonia stricta Spreng., Novi proventus hortorum academicorum halensis et berolinensis: 43 (1818). *Gladiolus sprengelianus* Schult. in Roemer & Schultes: 296 (1822), as a new name for *W. stricta* Spreng. [not *G. strictus* Jacq.]. Type: unknown. Said by Lewis & Obermeyer (1972) to be *W. strictiflora* Ker Gawl. (1811).

Watsonia vittata J.W.Mathews & L.Bolus in Bolus in Annals of the Bolus Herbarium 4: 25 (1925). Type: South Africa, without precise locality or collector, ex hort. Kirstenbosch [BOL (*BOL32351*), lecto., designated by Goldblatt: 141 (1989); BOL, isolecto.]. Identity uncertain.

Watsonia wordsworthiana J.W.Mathews & L.Bolus in Bolus in Annals of the Bolus Herbarium 4: 26 (1925). Type: South Africa, [Western Cape], Tulbagh, Romans River, ex hort. Kirstenbosch, *Tredgold s.n.* (BOL [*Nat. Bot. Gard. 652/13*], lecto., designated by Goldblatt: 141 (1989); BOL, PRE, isolecto.). Identity uncertain, possibly *W. meriana* or a hybrid.

EXCLUDED SPECIES

Watsonia lamarckii A.Dietr., Species plantarum 2: 570 (1832), illegitimate superfluous name for *Gladiolus spicatus* Lam., Tableau encylopédique et méthodique Botanique 1: 120 (1791). Type: P-Herb. Lamarck. This is a species of Lamiaceae, perhaps *Lavandula*.

7. Pillansia

Pillansia *L.Bolus* in Annals of the Bolus Herbarium 1: 20 (1914). Type: *P. templemannii* (Baker) L.Bolus

[*Wredowia* Eckl.: 16 (1827), invalid name without description]

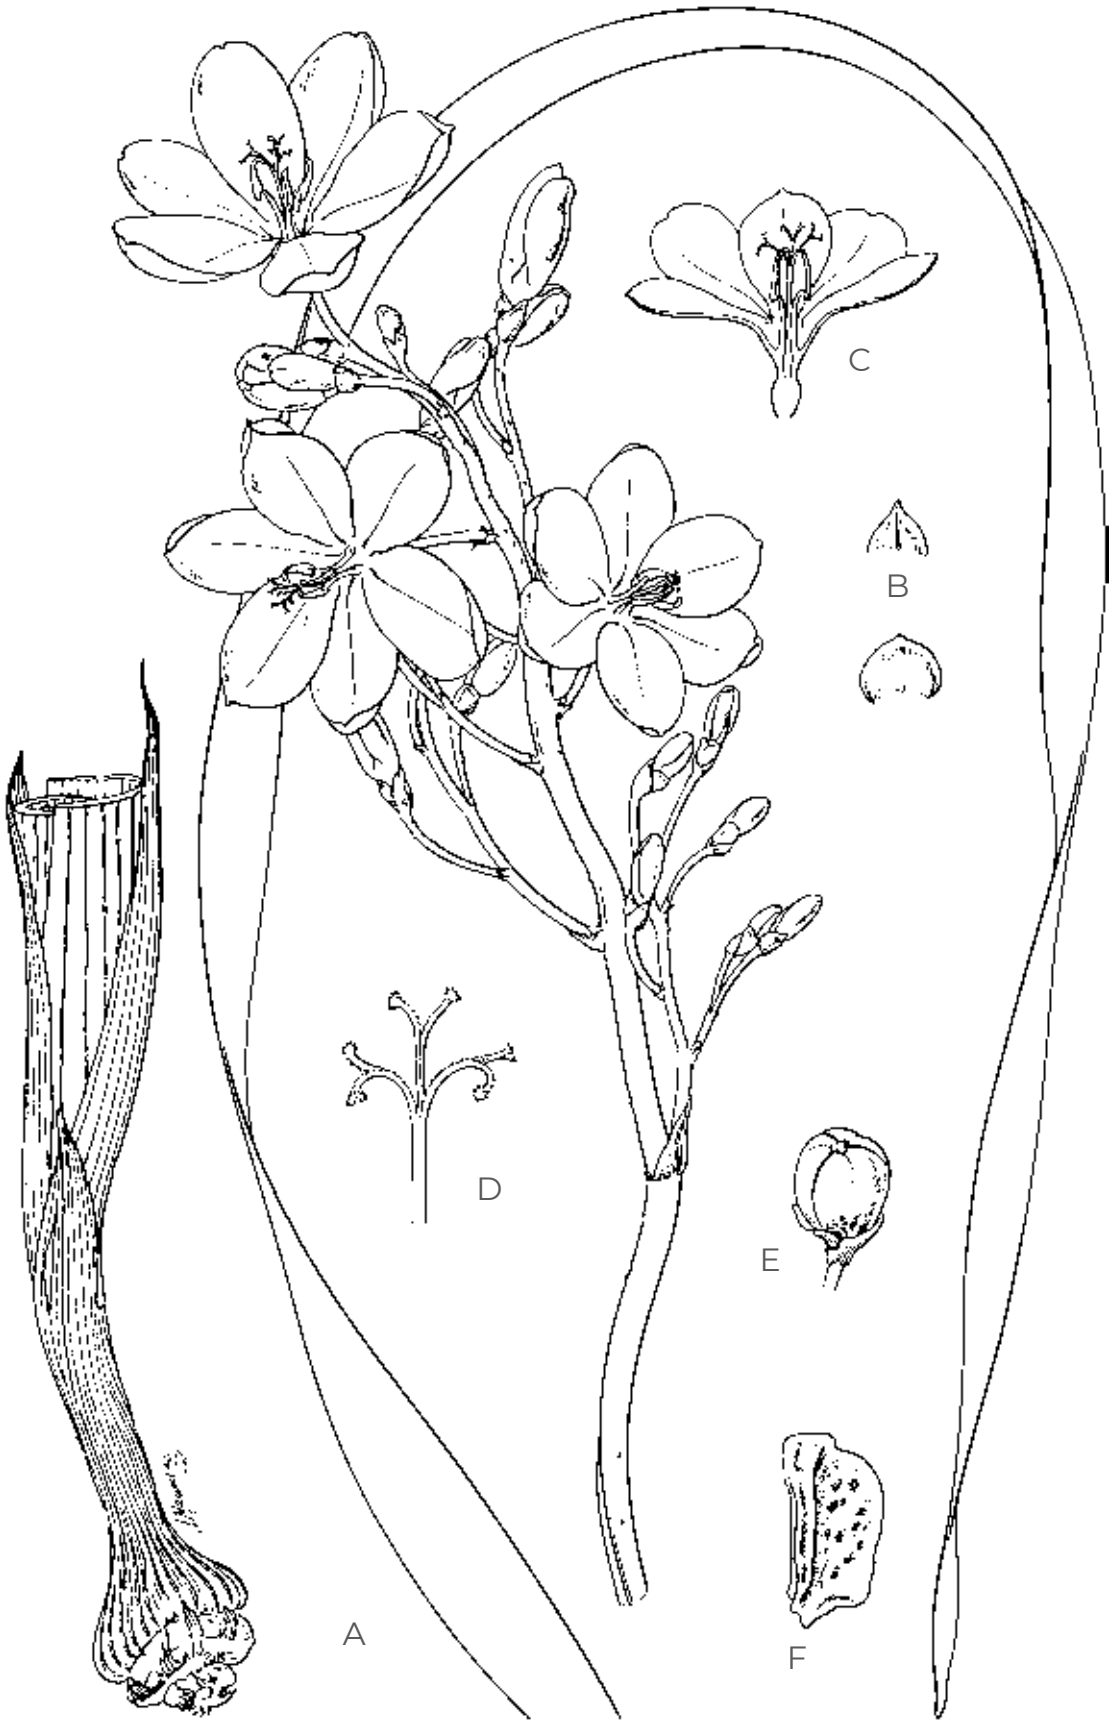
Revisionary account: Obermeyer: t. 1381 (1962).

Honouring the South African botanist, N.S. Pillans (1884–1964), who collected the species and drew the plant to the attention of L. Bolus.

Evergreen geophyte. *Corm* depressed-globose, axillary in origin, past season's corms not resorbed; tunics coarsely fibrous. *Cataphylls* 2 or 3, leathery and brownish. *Stem* aerial, erect, repeatedly branched above, 2-angled or narrowly winged below, inflorescence axis often sparsely warty. *Leaves* several, unifacial, leathery and closely sclerotic, without evident main vein, lowermost leaf longest, linear, twisted, sometimes trailing, with 3 or 4 progressively smaller ± sheathing cauline leaves, dry and brown; margins simple, without vascular bundle, epidermis unspecialised. *Inflorescence* panicle-like, much-branched, with a solitary, sessile flower terminal on each axis; bracts leathery, green with reddish brown margins, glutinous inside, inner ± as long as outer and similar in texture, clasping ovary, multinerved and acute. *Flowers* actinomorphic, long-lived, cup-shaped, orange, unscented, not closing at night, with traces of nectar from septal nectaries; perianth tube short, funnel-shaped; tepals subequal, spreading, obovate. *Stamens* symmetrically arranged; filaments inserted just below mouth of perianth tube; anthers suberect or apically incurved, yellow. *Ovary* covered in mucilage from bracts; style filiform, 3-branched distally, branches slender, bifid or divided apically for ¼–⅓ their length, longitudinally folded. *Capsules* subglobose, woody. *Seeds* 1–3 per locule, large, angular with chalazal crest, smooth and shiny, testal cells finely reticulate-foveate. *Pollen grains* monosulcate-operculate, operculum 2-banded, exine perforate-scabrate. *Basic chromosome number x* = 20.

Species 1: coastal mountains of the Caledon District in Western Cape, South Africa, mostly on wetter slopes, flowering after fire.

Readily recognised by the multi-branched, panicle-like inflorescence of bright orange, radially symmetric flowers and the fibrous, strap-like leaves without a main vein. The mucilaginous secretion from the inner epidermis of the paired floral bracts is unique. Although collected in 1827 by C.F. Ecklon who called it *Wredowia* but without formal description, the species was only described by J.G. Baker, who placed it in the genus *Tritonia* due to its radially symmetric, orange flowers. The multibranched inflorescence, leathery floral bracts and divided style branches are anomalous in that genus and it was accordingly removed to the monotypic genus *Pillansia* by L. Bolus (1914), who considered it to be closely allied to *Watsonia*.



The main vein of the leaves is poorly developed and the species is also highly unusual in Crocoideae in having both a marginal bundle and columnar marginal epidermal cells in the leaf blade, only one or other of which typically occur in other genera of the subfamily. The basic chromosome number, *x* = 20, is polyploid. *Pillansia templemannii* has been regarded as an ancient relict polyploid surviving in local equable sites in the southwestern Cape coastal mountains, and was considered to be close to the ancestral type of Crocoideae and was assigned to its own tribe Pillansieae by Goldblatt (1990). Recent molecular analyses place it within tribe Watsonieae, as sister to *Watsonia*, confirming Bolus's (1914) early hypothesis. The axillary corm development accords with other genera in the tribe and the unusual leaves, inflorescence and flowers are best viewed as specialisations, not primitive in the subfamily, as has sometimes been suggested.

1. **Pillansia templemannii** *(Baker) L.Bolus* in Annals of the Bolus Herbarium 1: 20 (1914). *Tritonia templemannii* Baker: 193 (1892). Type: South Africa, [Western Cape], [Caledon] Zwartberg [Swartberg], *Templemann s.n.* (K, holo.).

   [*Wredowia pulchra* Eckl.: 16 (1827), invalid name without description.]

   [*Aristea wredowia* Steud.: 130 (1840), invalid name without description.]

Plants 600–800(–1 200) mm high. *Corm* relatively small, 15–25 mm diam., persistent; tunics of coarse, wiry fibres. *Stem* stout, angled or narrowly winged below, many-branched, branches ascending, smooth or warty; stem bracts small, ovate to lanceolate, dry, brown and papery. *Leaves* 4 or 5, lowermost longest, linear or strap-like, 45–120 × 6–10 mm, suberect or trailing, twisted, leathery and sclerotic, closely veined with main vein obscure, remaining leaves cauline, progressively smaller, upper 2 or 3 entirely sheathing, dry and dark reddish brown. *Inflorescence* multibranched, terminal branches ascending, 1-flowered, smooth or warty; bracts broadly to transversely ovate, 5–8 mm long, acute or apiculate, leathery and green below or entirely dark brown with narrow, membranous margins, inner ± as long as outer and similar in texture, multinerved and clasping ovary, both mucilaginous on inner surfaces. *Flowers* suberect or slightly nodding, cup-shaped, bright orange, unscented, firm-textured; perianth tube funnel-shaped, 5–7 mm long; tepals suberect below then spreading, obovate, subequal or inner slightly broader, 20–30 ×

Pillansia templemannii: A, corm, leaf and inflorescence; B, outer bract (bottom) and inner bract (top); C, half-flower; D, detail of style branches; E, capsule; F, seed.

Distribution of ***Pillansia templemannii***.

7–15(–20), obtuse, weakly cupped. *Filaments* erect or curved outward above, 8–10 mm long; anthers 7–8 mm long, yellow. *Style* dividing opposite anthers, branches 5–8 mm long, forked at tips or divided up to ⅓. *Capsules* subglobose to obovoid, woody, 12–20 × 10–12 mm. *Seeds* ± 8 mm long, reddish brown. *Flowering time*: October to November.

Distribution and ecology: a local endemic of the south-western coastal mountains of Western Cape, South Africa, from Kogelberg to the Klein River Mtns; on cooler south-facing sandstone slopes and sandy flats, mostly 300–700 m elevation but also at lower altitudes near the coast, flowering only after fire.

Diagnosis: the evergreen habit with solitary, fibrous, strap-like basal leaf and panicle-like inflorescence of thick-textured, radially symmetric, orange flowers are highly distinctive. The floral bracts are small and leathery, glutinous on their inner surface, and the style branches are divided up to one third their length. Preliminary observations suggest that the bright orange flowers are pollinated mainly by pollen-collecting bees but also by hopliine beetles.

8. Thereianthus

Thereianthus *G.J.Lewis* in Journal of South Africa Botany 7: 33 (1941). Lectotype: *T. spicatus* (L.) G.J.Lewis, designated by Goldblatt & Manning: 130 (2008).

Beilia Eckl. ex Kuntze: 305 (1898) [*Beilia* Eckl.: 43 (1827), invalid name without description], illegitimate superfluous name for *Paulomagnusia* Kuntze (1891) [= *Micranthus* (Pers.) Eckl., conserved name]. Type: *B. spicata* (L.) Eckl. ex Kuntze = *Thereianthus spicatus* (L.) G.J.Lewis

Watsonia [unranked] *Beilia* Eckl. ex Baker 16: 158 (1877). Type: *W. punctata* (Andrews) Ker Gawl. = *Thereianthus bracteolatus* (Lam.) G.J.Lewis

Watsonia subg. *Beilia* Eckl. ex Baker: 177 (1892). Lectotype: *W. punctata* (Andrews) Ker Gawl. = *Thereianthus bracteolatus* (Lam.) G.J.Lewis, designated by J.C.Manning & Goldblatt: 246 (2011).

Revisionary accounts: Lewis: 33–43 (1941); Manning & Goldblatt: 241–269 (2011).

From the Greek, *thereios*, summer, *anthos*, flower.

Deciduous geophytes. *Corm* globose, axillary in origin, tunics of coarsely netted fibres. *Cataphylls* 2, dry and papery, reddish brown. *Leaves* 3 or 4(to 6), all cauline and superposed, usually ± dry at flowering, lowermost longest, blade falcate or linear, plane and either with definite main vein or with several equally prominent veins, or ± terete, glabrous or rarely scabridulous, upper leaves progressively shorter, uppermost sometimes entirely sheathing; margin simple, without submarginal vein, epidermis unspecialised. *Stem* usually unbranched, rarely with short branch from upper leaf axil. *Inflorescence* a spike, loosely spirally twisted at anthesis; bracts firm-textured, short, often overlapping, green below with apices dry and brown or entirely dry and papery, smooth or prominently veined, inner strongly 2-veined and apically forked (entire in *T. juncifolius*), mostly membranous (leathery in *T. juncifolius*). *Flowers* zygomorphic or rarely actinomorphic, long-lived, closing at night, usually blue to purple, rarely white or pink to magenta, unmarked or lower 3 tepals with darker markings or all tepals with white markings, usually unscented, with nectar from septal nectaries; perianth tube short to long, funnel-shaped or cylindric; tepals subequal, ± spreading. *Stamens* unilateral and arcuate or declinate, or central and symmetrically arranged; filaments inserted shortly below top of perianth tube; anthers usually purple. *Ovary* subglobose; style filiform, 3-branched distally, branches slender, deeply divided, recurved. *Capsules* woody, ovoid to spindle- or flask-shaped, tardily dehiscent. *Seeds* angular-elongate with chalazal crest or narrowly ovoid-fusiform with thread-like or filiform chalazal extension, smooth or wrinkled, matte. *Pollen grains* monosulcate-operculate, operculum 1- or 2-banded, exine perforate- or reticulate-scabrate (Table 1). *Basic chromosome number x* = 10.

Species 11: South Africa, Western Cape, winter-rainfall region, mostly in nutrient-poor, stony sandstone soils; most species are pyrophytes to some degree.

A small Western Cape genus closely allied to *Micranthus*, *Thereianthus* shares with that genus superposed leaves, ± dry bracts with membranous margins, and small to moderate-sized, often blue flowers (also white, pink or magenta). The foliage in both *Micranthus* and *Thereianthus* is strictly cauline, with the lowermost leaf subbasal. The corm tunics are thus formed solely from the cataphylls, without any contribution from the bases of the lower leaves. Chromosome number, $2n$ = 20, and a karyotype of one long and nine short chromosome pairs in *Micranthus* and *Thereianthus* is likely ancestral for the tribe.

The moderately short spikes of spirally inserted flowers, bracts with narrow membranous margins, and monosulcate pollen grains distinguish *Thereianthus* from *Micranthus*, which has elongate, two-ranked spikes, bracts with broad membranous margins, and zonasulculate pollen grains (Goldblatt & Manning, 2008). The simple leaf margin, without marginal bundle or specialised epidermis, is an additional anatomical specialisation for *Thereianthus* (Manning & Goldblatt, 2011).

TABLE 1.—Pollen operculum type and exine sculpturing in *Thereianthus*. Square brackets [] indicate closely associated operculum bands; curved brackets () indicate a less common operculum character state (from Goldblatt et al. 1991 and Manning & Goldblatt 2011).

Species	Operculum	Exine sculpturing

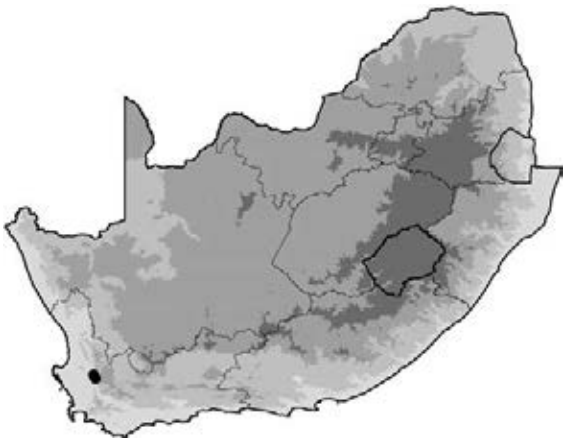
Thereianthus racemosus: A, flowering plant; B, flower front view (top) and side view (bottom); C, stamens and detail of style branches side view (top) and front view (bottom); D, capsule; E, seed.

Key to species

1a Bracts short, 3–8 mm long, uniformly leathery or soft-textured without prominent veins (sect. *Brevibracteae*):
2a Leaf blades filiform-terete; spike lax, bracts distant (lower internodes 3–5 × longer than bracts); inner bracts as long as or slightly longer than outer and similar in texture, both leathery and green with dry, papery apices; tepals ovate-obovate; stamens central ..... 5. *T. juncifolius*
2b Leaf blades linear to falcate, plane; spike dense, bracts ± overlapping (lower internodes < twice as long as bracts); inner bracts shorter than outer and membranous-papery except along veins; tepals lanceolate; stamens unilateral-arcuate:
3a Perianth tube very short, 1.0–1.5 mm long, included in bracts ..... 1. *T. racemosus*
3b Perianth tube longer, 10–30 mm long, exserted from bracts:
4a Bracts 3–5 mm long; perianth tube 10–13 mm long; capsules ovoid, 4–5 mm long; plants from Cold Bokkeveld and Hex River mtns ..... 2. *T. intermedius*
4b Bracts (5–)6–8 mm long; perianth tube 20–30 mm long; plants from Grootwinterhoek to Riviersonderend mtns and Kogelberg:
5a Leaves ± falcate, lowermost mostly 3–7 mm wide and usually much shorter than stem, with pseudomidrib but without evident secondary veins, the pseudomidrib raised when dry but secondary veins never raised; perianth magenta or deep pink; anthers pale yellow; filaments 3–4 mm long; capsules flask-shaped, 6–8 mm long ..... 4. *T. minutus*
5b Leaves linear, lowermost 2.5–2.8 mm wide and mostly longer than stem, with main and secondary veins raised when dry; perianth and anthers purple; filaments 6–8 mm long; capsules unknown ..... 3. *T. montanus*
1b Bracts longer, (7–)8–15 mm long, with prominently raised, closely set veins (sect. *Thereianthus*):
6a Leaves leathery without strongly raised veins; perianth tube curved and flowers thus ± nodding; filaments declinate, 6–10 mm long (ser. *Bracteolatus*):
7a Stem developing cluster of large cormels in axil of lowest leaf; leaves linear with evident veins; perianth tube 7–9 mm long; tepals pale to midblue with white markings at base, veins not mottled, lateral longitudinal veins with numerous branches in distal half; filaments 6–8 mm long ..... 6. *T. bulbifer*
7b Stem without cormels; leaves terete or elliptic in section, without evident veins; perianth tube (7–)8–10(–15) mm long; tepals purple to violet with prominent, darkly mottled veins, lateral longitudinal veins mostly without branches in distal half; filaments 8–10 mm long ..... 7. *T. bracteolatus*
6b Leaves striate or corrugate with strongly raised veins; perianth tube straight or slightly curved distally and flowers thus suberect; filaments central or arcuate, 3–5 mm long (ser. *Thereianthus*):
8a Perianth tube 7–12(–15) mm long, filiform, tightly clasping style for most of length and then abruptly dilated at mouth; filaments central, symmetrical and completely exposed, blocking mouth of perianth tube ..... 9. *T. ixioides*
8b Perianth tube (12–)15–40 mm long, narrowly funnel-shaped or ± cylindric, not tightly clasping style; filaments arcuate, included within upper part of tube and not blocking mouth:
9a Perianth tube 25–40 mm long, > twice as long as tepals ..... 11. *T. longicollis*
9b Perianth tube 12–25 mm long, < twice as long as tepals:
10a Flowers usually blue, rarely white or pink, lower three tepals with white markings near base outlined distally with dark blue chevron; tepals lanceolate, 3–5 mm wide ..... 8. *T. spicatus*
10b Flowers pale flesh-pink with purple tube, lower three tepals marked with purple in basal half; tepals linear, 1.5–3.0 mm wide ..... 10. *T. elandsmontanus*



Sect. 1. **Brevibracteae** *Goldblatt & J.C.Manning* in Bothalia 41: 246 (2011). Type species: *Thereianthus racemosus* (Klatt) G.J.Lewis

Leaves filiform and terete, or linear to falcate and plane, with or without prominent main vein but never strongly ribbed; bracts short, 3–8 mm long, uniformly leathery or moderately soft-textured, without prominent veins. *Pollen* operculum ± 2-banded, exine perforate or reticulate. *Seeds* (where known) ellipsoid-fusiform with filiform or thread-like chalazal extension, reddish brown; testa sculpturing longitudinally rugose or obscurely scalariform.

Species 5: southwestern Western Cape, South Africa.

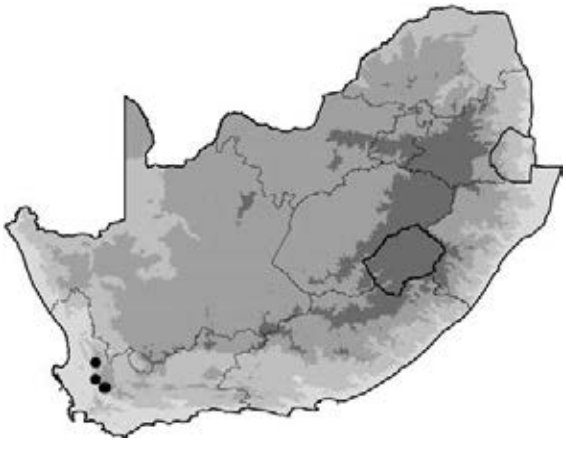
1. **Thereianthus racemosus** *(Klatt) G.J.Lewis* in Journal of South African Botany 7: 36 (1941). *Watsonia racemosa* Klatt 15: 354 (1882). Type: South Africa, [Western Cape], 'in montibus ad Vier en Twintig Rivieren', Dec. without year, *Zeyher 1609* (B, holo.; BOL, GRA, K (2 sheets), PRE, SAM (3 sheets), iso.).

Plants 130–250 mm high. *Corm* ± 10 mm diam.; tunics of moderately fine-textured to coarsely netted fibres. *Stem* erect or flexed slightly outward above sheath of second leaf, rarely with short branch from upper leaf axil. *Leaves* (3)4(5), lowermost reaching base of spike or not, linear or falcate, 60–130(–190) × 1–3(–4) mm, thick-textured and plane with main vein not thickened or raised when fresh and usually without evident secondary veins, rarely with 1 secondary vein visible on each side, uppermost leaf entirely sheathing, well separated from spike. *Spike* erect, moderately densely 5- to 25-flowered; bracts shortly overlapping, outer

Distribution of ***Thereianthus racemosus***.

3–5 mm long, up to 1 internode long, acute, green below or entirely brown and leathery with narrow membranous margins and papery tip, without evident veining, inner ± as long as or slightly longer, ± membranous with narrow brown zone along veins. *Flowers* suberect, pale blue, lower 3 tepals white at base with purple median chevron in lower ¼, strongly honey-scented, perianth subactinomorphic; tube narrowly funnel-shaped, 1.0–1.5 mm long, included in bract; tepals elliptical-oblanceolate, subequal, spreading and slightly cupped, 7–9 × 3–4 mm. *Stamens* unilateral but laterals slightly spreading; filaments arcuate, 3–4 mm long, exserted 1.5–2.5 mm from tube; anthers 4–5 mm long, dark blue; pollen pale blue. *Style* arching over stamens, dividing between base and middle of anthers, branches 2.0–2.5 mm long, divided for ± ½ their length. *Capsules* ovoid, 4–5 × 2.5–3.0 mm. *Seeds* ovoid, ± 1 mm long, with ± straight, thread-like chalazal extension ± 0.5 mm long, reddish brown. *Flowering time*: December.

Distribution and ecology: restricted to the Voorberg (Twenty Four Rivers Mtns) above Porterville in Western Cape, South Africa, especially the Grootwinterhoek Wilderness Area; on seasonally moist or marshy, sandy flats in restioid communities, flowering only after fire.



Diagnosis: unique in the genus in its very short perianth tube, 1.0–1.5 mm long and entirely included in the floral bracts, the outer bracts only 3–5 mm long. The small, pale blue flowers are strongly honey-scented.

2. **Thereianthus intermedius** *J.C.Manning & Goldblatt* in Bothalia 41: 247 (2011). *T. lapeyrousioides* var. *elatior* G.J.Lewis in Journal of South African Botany 7: 38 (1941). Type: South Africa, [Western Cape], 'Ceres Hills', Jan. 1892, *L. Guthrie 2208* (BOL, holo.).

Plants 200–350 mm high. *Corm* ± 10 mm diam.; tunics of fine-textured, netted fibres accumulating with age. *Stem* erect, flexed slightly outward above sheath of second leaf. *Leaves* (3)4, lowermost reaching base of spike or not, linear, 70–150 × 2–3 mm, thick-textured with main vein ± evident but not thickened or raised when fresh, plus a pair of secondary veins, uppermost leaf entirely sheathing or with short blade up to 20 mm long, well separated from spike. *Spike* moderately densely 12- to 40-flowered; bracts not or scarcely overlapping, outer 3–5 mm long, up to 1 internode long, obtuse, brown and leathery with narrow membranous margins, without evident veining, inner ± as long or slightly longer, ± membranous with narrow brown zone along veins. *Flowers* suberect, violet (rarely pale blue), lower 3 tepals whitish at base with purple or dark blue median chevron in lower ¼; perianth subactinomorphic; tube straight or slightly arching in upper ± 3 mm, 10–13 mm long, cylindric, widening slightly in upper ± 3 mm; tepals narrowly oblanceolate, subequal, spreading and slightly cupped, 10–11 × 3.0–3.5 mm. *Stamens* unilateral; filaments erect, ± 7 mm long, exserted ± 4 mm from tube; anthers purple, 4–5 mm long; pollen violet. *Style* arching over stamens, dividing below base of anthers, branches ± 2.5 mm long, divided for ± ½ their length. *Capsules* ovoid, 4–5 × 3–4 mm. *Seeds* ovoid, ± 1.5 × 1.0 mm, with thread-like chalazal extension up to 3 mm long abruptly reflexed from near middle, reddish brown, testa striate-rugulose. *Flowering time*: December.

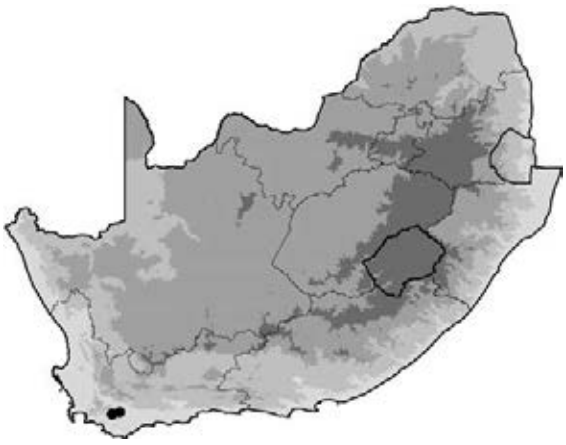
Distribution and ecology: Cold Bokkeveld Mtns to western Hex River Mtns above Ceres in Western Cape, South Africa [the record from Piketberg cited in Manning & Goldblatt (2011) is *T. spicatus*]; on seasonally waterlogged or marshy, sandy flats dominated by restioids, between ± 500 and 1 000 m elevation, flowering only after fire.

Diagnosis: recognised among the species in sect. *Brevibracteae* by the very short bracts 3–5 mm long and moderately elongate perianth tube 10–13 mm long. The small, ovoid capsules are 4–5 mm long and the seeds have thread-like chalazal extensions up to 3 mm long, abruptly reflexed near the middle.

Distribution of ***Thereianthus intermedius***.

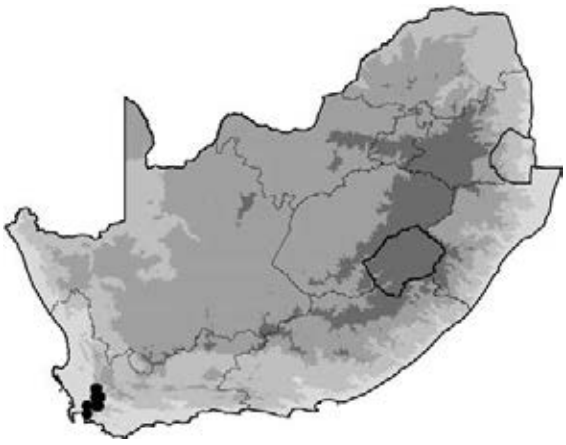
3. **Thereianthus montanus** *J.C.Manning & Goldblatt* in Bothalia 34: 103 (2004). Type: South Africa, Western Cape, Riviersonderend, Pilaarkop, ridge WNW of peak, 31 Jan. 2004, *E.G.H. Oliver 12197* (NBG, holo.; MO, iso.).

Plants 200–350 mm high. *Corm* 7–10 mm diam.; tunics of fine-textured, netted fibres accumulating with age. *Stem* erect, flexed outward above sheath of second leaf. *Leaves* 3 or 4, lowermost reaching or exceeding spike, linear, 150–300 × 2.5–2.8 mm, thick-textured with main vein evident but not thickened or raised when fresh, plus 1 or 2 evident secondary veins on each side, uppermost leaf well separated from spike, short and entirely sheathing. *Spike* erect, compact, densely 7- to 10-flowered; bracts overlapping, outer 6–8 mm long, obtuse to truncate, green and leathery below, dry and brown in upper ½, ± 2 internodes long, inner ± 1.5 mm shorter than outer, brown and papery with narrow darker zone along veins. *Flowers* suberect, purple, lower three or all tepals each with spear-shaped, purple median streak near base, throat and lower part of tube white; perianth subactinomorphic, salver-shaped; tube straight or slightly arching in upper ± 5 mm, 22–27 × 1.2–1.5 mm, cylindric and widening slightly in upper ± 5 mm; tepals spreading and slightly cupped, narrowly elliptical to lanceolate, subequal, 9–15 × 3.5–5.0 mm. *Stamens* unilateral; filaments erect, 6–8 mm long, exserted 3–4 mm from tube; anthers 4–5 mm long, purple; pollen violet. *Style* arching over stamens, dividing between base and middle of anthers, branches ± 2.5 mm long, divided for ± ½ their length. *Capsules and seeds* unknown. *Flowering time*: late January to February.



Distribution and ecology: endemic to the Riviersonderend Mtns in Western Cape, South Africa; on steep, south-facing slopes in moist, loamy soil in short, grassy fynbos at ± 1 500 m elevation.

Diagnosis: resembling *Thereianthus minutus* in the moderately long bracts 6–8 mm long and perianth tube 22–27 mm long but differing in the narrower, linear leaves less than 3 mm wide, the lower mostly longer than the stem, and in the purple perianth with concolorous anthers on relatively longer filaments 6–8 mm long.



4. **Thereianthus minutus** *(Klatt) G.J.Lewis* in Journal of South African Botany 7: 43 (1941). *Watsonia minuta* Klatt: 353 (1882). Type: South Africa, [Western Cape], Tulbagh Waterfall, *Ecklon & Zeyher Irid. 189* (B, lecto., designated by Goldblatt 19: 143 (1989); MO, S, SAM, isolecto.).

Watsonia lapeyrousioides Baker: 178 (1892). *Thereianthus lapeyrousioides* (Baker) G.J.Lewis 7: 38 (1941). Type: South Africa, [Western Cape], 'clivis montium inter Villiersdorp & French Hoek [Franschhoek]', Nov. 1879, *Bolus 5251* (BOL, lecto., designated by Manning & Goldblatt: 250 (2011); K, isolecto.).

Plants 100–200(–300) mm high. *Corm* 7–10 mm diam.; tunics of fine-textured, netted fibres, sometimes accumulating with age. *Stem* usually inclined but flexed outward above sheath of second leaf and then erect. *Leaves* 3 or 4(–6), lowermost mostly much shorter than spike, usually falcate but rarely linear-arcuate, (30–)40–100(–350) × (1.5–)3.0–7.0 mm, thick-textured with main vein evident but not raised when fresh (becoming raised when dry), plus 1 or 2 evident secondary veins on each side, uppermost leaf well separated from spike, short and entirely sheathing. *Spike* erect, compact, moderately densely (3–)5- to 10(–20)-flowered; bracts shortly overlapping, outer (5–)6–8 mm long, obtuse to truncate, green and leathery below, dry and brown in upper ½, ± 1.5 internodes long, inner ± 1.0–1.5 mm shorter than outer, brown and papery with narrow darker zone along veins. *Flowers* suberect, dark pink to magenta, lower 3 tepals usually with darker median mark near base, throat white; perianth subactinomorphic, salver-shaped; tube straight, 20–30 × 1.2–1.5 mm, widening gradually and evenly from base; tepals spreading and slightly cupped, elliptical to oblanceolate, subequal, 7–10 × 2–4 mm. *Stamens* unilateral; filaments erect, 3–4 mm long, exserted ± 2 mm from top of tube;

Distribution of ***Thereianthus montanus***.

Distribution of ***Thereianthus minutus***.

anthers 3–4 mm long, pale yellow; pollen cream-coloured. *Style* arching over stamens, dividing just below or just above base of anthers, branches ± 4 mm long, divided for ± ½ their length. *Capsules* flask-shaped, 6–8 mm long. *Seeds* fusiform, 1.5–2.0 mm long, with chalazal extension to 4 mm long, thus ± twice as long as seed body, sharply bent back ± midway and hooked or crook-like, sometimes twisting around adjacent seeds, reddish brown, longitudinally rugulose. *Flowering time*: (late October)December to January.

Distribution and ecology: mountains in the extreme southwestern part of Western Cape, South Africa, from above Porterville southward to the Kogelberg and western Riviersonderend Mtns; in moist habitats such as rock ledges, damp cliffs and streamsides, growing in flushes, peaty seepages and mossy turf.

Diagnosis: readily recognised in the wild by the ± falcate leaves, the lowermost mostly 3–7 mm wide and usually much shorter than stem, with a more-or-less distinctive pseudomidrib, and magenta or deep pink flowers with pale yellow anthers on filaments 3–4 mm long. The flask-shaped capsules, 6–8 mm long, are highly diagnostic, and the fusiform seeds have a hooked, thread-like chalazal extension ± twice as long as the seed body.

5. **Thereianthus juncifolius** *(Baker) G.J.Lewis* in Journal of South African Botany 7: 37 (1941). *Morphixia juncifolia* Baker: 238 (1876a). *Watsonia juncifolia* (Baker) Baker: 178 (1892). *Freesia juncifolia* (Baker) Klatt in Th.Durand & H.Schinz: 188 (1894). *Lapeirousia juncifolia* (Baker) N.E.Br.: 194 (1931). Type: South Africa, [Western Cape], without precise locality or date, [Piquetberg Div. fide Baker (1896)], *Zeyher 1619* (K [*K320516 ex herb. Wallich*], lecto., designated by Manning & Goldblatt: 252 (2011); BOL, K (3 sheets), S, SAM (2 sheets), isolecto.).

   Anomatheca calamifolia Klatt: 355 (1882), illegitimate superfluous name for *Morphixia juncifolia* Baker (1876b). Type: South Africa, [Western Cape], Twenty Four Rivers, *Zeyher* [as *Drège*] *1619* (S, 'Herb. Klatt', holo.; BOL, K (3 sheets), S, SAM (2 sheets), iso.).

   Ixia zeyheri Baker: 166 (1892), illegitimate superfluous name for *Morphixia juncifolia* Baker (1876a) [based on the same type]. Type: South Africa, [Western Cape], without precise locality or date, *Zeyher 1619* (K [*K320516 ex herb. Wallich*], lecto., designated by Manning & Goldblatt: 252 (2011); BOL, K (3 sheets), S, SAM (2 sheets), isolecto.).

Slender plants 120–200(–300) mm high. *Corm* 5–10 mm diam.; tunics of fine-textured, netted fibres, accumulating with age. *Stem* flexed outward above sheath of second leaf and then erect, rarely with short branch from axil of uppermost scale-leaf. *Leaves* (3)4, lowermost mostly reaching to spike or exceeding it, filiform-terete, 150–500 × 0.5–1.5 mm, thick-textured, striate with slightly raised veins when dry, uppermost 1 or 2 leaves scale-like and entirely sheathing, inserted ± midway between foliage leaves and spike. *Spike* erect, elongate, laxly (2)3- to 10-flowered, lower internodes 3–5(–7) × longer than bracts but progressively shorter and uppermost internodes ± as long as bracts; bracts not overlapping, outer 3–5 mm long, acute to truncate, soft-textured and green with papery brown tips, inner slightly longer than outer and similar in texture, acute or truncate. *Flowers* suberect, purple to lilac with white throat; perianth actinomorphic, salver-shaped; tube straight, 11–18 mm long, widening gradually and evenly from base, 1.0–1.5 mm diam. at mouth; tepals spreading and slightly cupped, ovate or obovate, subequal, 10–15 × 3.5–6.0 mm. *Stamens* central; filaments erect, 4–6 mm long, exserted 3–4 mm from tube; anthers 3–4 mm long, lilac or pale yellow; pollen lilac or cream-coloured. *Style* central, dividing between base and middle of anthers, branches ± 3 mm long, divided for > ½ their length, spreading or recurved. *Capsules* flask-shaped, 9–15 mm long. *Seeds* fusiform, 6–7 mm long, with chalazal thread ± 13 mm long, thus ± twice as long as seed body, sharply bent back ± midway and hooked or crook-like, sometimes twisting around adjacent seeds, reddish brown, longitudinally rugulose. *Flowering time*: December to February(March).

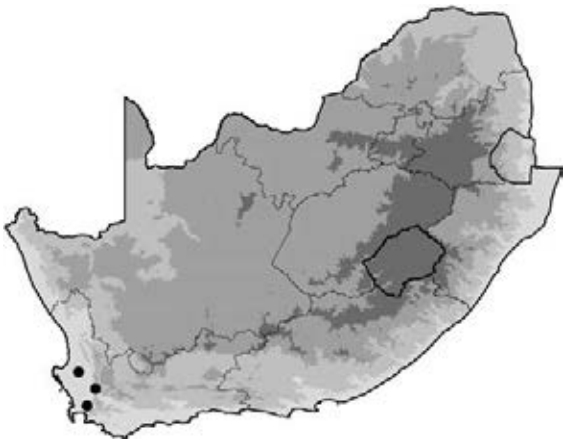
Distribution and ecology: mainly montane in southwestern Western Cape, South Africa, from the southern Cederberg through the Olifants River Mtns to the Skurweberg north of Ceres, with a disjunction to the Hottentots Holland, Kogelberg and Klein River mtns in the south, and also recorded on the lower southern slopes of the Riviersonderend Mtns, thus apparently absent from the mountains between Ceres and Stellenbosch; restricted to seeps, streamsides, drainage lines and marshy ground, mostly between 500 and 1 000 m elevation but to near sea level along the coastal ranges.

Diagnosis: readily recognised by the filiform-terete leaves and lax spike with distant bracts, the lower

Distribution of ***Thereianthus juncifolius***.

internodes 3–5 times longer than the bracts. Uniquely in the genus, the inner bracts are as long as or slightly longer than the outer and similar in texture, both leathery and green with dry, papery apices – in other species the inner bracts are smaller than the outer and ± membranous.

Sect. 2. **Thereianthus**



Leaves linear or falcate, plane and either leathery without raised veins or strongly ribbed or corrugate with prominently raised veins, or ellipsoid in section; bracts (7–)8–15 mm long, closely and prominently veined with raised veins (sclerenchymatous phloem caps prominent). *Pollen* operculum 1-banded, exine perforate. *Seeds* (where known) ellipsoid-ovoid and angled, without chalazal extension, brown to blackish.

Species 6: southwestern Western Cape, South Africa.

Ser. **Bracteolatus** *J.C.Manning & Goldblatt* in Bothalia 41: 254 (2011). Type species: *Thereianthus bracteolatus* (Lam.) G.J.Lewis

6. **Thereianthus bulbifer** *Goldblatt & J.C.Manning* in Bothalia 41: 254 (2011) [as *T. bulbiferus*]. Type: South Africa, Western Cape, Bo-Hermon, Elandsberg Nature Reserve, alluvial flats near river, after fire, 97 Nov. 2010, *J.C.Manning 3312* (NBG, holo.; MO, iso.).

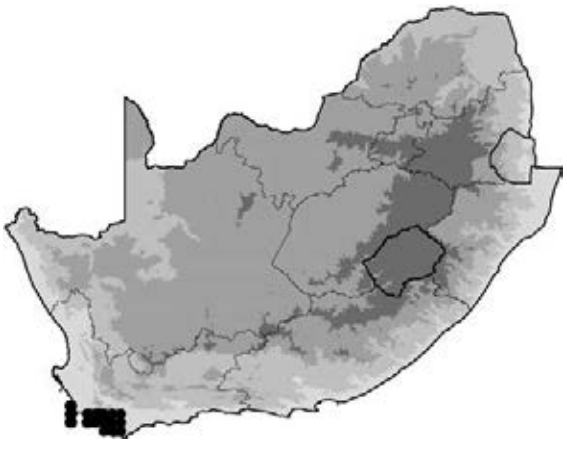
Plants 140–200 mm high. *Corm* 10–15 mm diam.; tunics of coarsely netted fibres, sometimes forming claws below, accumulating with age. *Stem* erect, flexuous or flexed outward only above sheath of second leaf, rarely with short branch from upper leaf axil, developing a conspicuous cluster of 5–7 cormels in axil of lowest leaf. *Leaves* 4, lowermost reaching base of spike or not, ± dry at flowering, linear-falcate, often sinuous-twisted, 70–120 × (1.5–)2.0–3.0 mm, leathery, with 3 ± equally distinct veins or with main vein slightly more distinct, not thickened or raised when fresh but prominent when dry, uppermost leaf well separated from spike, usually with short blade 20–50 mm long, rarely almost entirely sheathing. *Spike* erect, densely 7- to 15-flowered; bracts overlapping for ± ½ their length, outer 7–9(–10) mm long and up to two internodes long, obtuse or truncate, either green below or entirely brown and leathery, conspicuously and closely veined, with narrow membranous margins, inner bract ½–¾ as long as outer, ± membranous with narrow brown zones along veins. *Flowers* patent, pale to midblue, lower 3 tepals with white median mark near base; perianth actinomorphic; tube slightly curved, 7–9 mm long, funnel-shaped, exserted 2–5 mm from bracts; tepals oblanceolate, subequal or inner slightly broader, spreading and slightly cupped, (10–)13–20 × 3–6 mm. *Stamens* ± declinate; filaments 6–8 mm long, exserted ± 5–6 mm from tube; anthers all facing upward or median (lower) facing downward or outward, 4 mm long, purple; pollen lilac. *Style* ± deflexed to lie beneath stamens, dividing at middle of anthers, branches 3–5 mm long, divided to near base. *Capsules* ovoid, 6 × 3 mm long, slightly shorter to slightly longer than bract. *Seeds* subglobose-angled, 1.5–2.0 mm long, chalaza ± excavated, yellowish brown, obscurely scalariform-rugulose. *Flowering time*: November, rarely to early December.

Distribution of ***Thereianthus bulbifer***.

Distribution and ecology: a local endemic of the Piketberg and the flats between Porterville and Joostenburg in Western Cape, South Africa, notably along the western foot of the Elandskloof Mtns near Hermon; on seasonally moist or wet alluvial flats in fynbos and renosterveld.

Diagnosis: unique in the genus in developing a cluster of large cormels in the axil of the lowest leaf, *Thereianthus bulbifer* is further characterised by linear leaves and pale to midblue flowers, marked with white at the base of the lower tepals, with a relatively short, curved perianth tube 7–9 mm long and declinate stamens.

7. **Thereianthus bracteolatus** *(Lam.) G.J.Lewis* in Journal of South African Botany 7: 42 (1941). *Gladiolus bracteolatus* Lam.: 725 (1788). Type: South Africa, without precise locality, said to have been collected by *Sonnerat s.n.* (P-Herb. Lamarck, holo.).



Ixia punctata Andrews: t. 177 (1801). *Watsonia punctata* (Andrews) Ker Gawl.: 229 (1804). *Gladiolus punctatus* (Andrews) Roem. & Schult.: 425 (1817). Type: South Africa, 'Cape of Good Hope', said to have been collected and sent by G. Hibbert, illustration in Andrews' *The Botanist's Repository* 3: t. 177 (1801).

Gladiolus subulatus Vahl: 97 (1805), illegitimate superfluous name for *G. bracteolatus* Lam. (1788).

Watsonia subulata Klatt, as a replacement name for *G. subulatus* Vahl. Type: South Africa, without precise locality or date, *Bulow s.n. C1000844* (C, holo.).

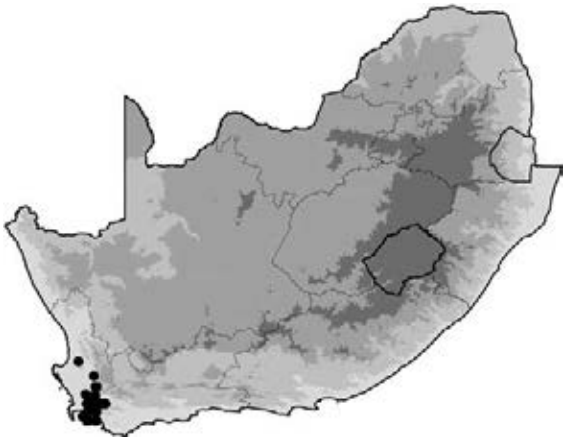
Gladiolus triticeus Thunb.: 194 (1807). *Watsonia triticea* (Thunb.) Spreng.: 150 (1824). *Beilia triticea* (Thunb.) Eckl.: 43 (1827). *Micranthus triticeus* (Thunb.) Heynh.: 405 (1847). *W. punctata* var. *triticea* (Thunb.) Baker: 177 (1892). *B. spicata* var. *triticea* (Thunb.) Kuntze: 305 (1898). Type: South Africa, without precise locality, *Thunberg s.n. UPS-THUNB1084* (UPS-THUNB, holo.).

Plants (80–)150–200(–300) mm high. *Corm* 10–15 mm diam., developing several large cormels at base; tunics of coarsely netted fibres, thickened and forming woody claws below, accumulating with age. *Stem* flexuose or flexed outward only above sheath of second leaf. *Leaves* 4(5), lowermost reaching base of spike or not, ± dry at flowering, linear, elliptic in section or terete, 70–170 × 0.5–1.5(–2.0) mm, leathery, with 3 ± equally veins or with main vein slightly more prominent, not thickened or raised when fresh but prominent when dry, uppermost leaf well separated from spike, entirely sheathing or with short blade 20–50 mm long. *Spike* erect, densely 7–15(–30)-flowered; bracts overlapping for ± ½ length, 8–10(–12) mm long and ± two internodes long, outer entirely brown and leathery, obtuse or truncate (rarely apiculate), conspicuously and closely veined, with narrow membranous margins, inner ½–¾ as long as outer, ± membranous with narrow brown zones along veins. *Flowers* ± patent, purple to violet with dark blotches and streaks on longitudinal veins and especially midline; perianth actinomorphic; tube slightly curved, (7–)8–10(–15) mm long, funnel-shaped, usually exserted 2–6(–10) mm beyond bracts, rarely just included; tepals oblanceolate, subequal or inner slightly broader, spreading and slightly cupped, (10–)11–17 × 3–6 mm. *Stamens* ± declinate, sometimes weakly so and then ± central; filaments 8–10 mm long, exserted ± 6–8 mm from tube, usually flexed sharply upward apically; anthers all facing upward, usually white (rarely purple), 4–6 mm long; pollen white (brown when anthers purple). *Style* ± deflexed to lie beneath stamens, dividing opposite middle of anthers, branches 3–5 mm long, divided to near base. *Capsules* ovoid, ± 6 mm long. *Seeds* subglobose- or ellipsoid-angled, ± 2 mm long, chalaza truncate, brown, testa colliculate. *Flowering time*: late November to early January.

Distribution of ***Thereianthus bracteolatus***.

Distribution and ecology: endemic to Western Cape, South Africa, from Stellenbosch and the Cape Peninsula along the coastal ranges of the Hottentots Holland, Kogelberg and Klein River/Babilonstoring mtns to Bredasdorp in the east, with isolated records from near Caledon (Drayton Siding) and the lower slopes of the Riviersonderend Mtns above Greyton; locally common on sandy flats and lower slopes below 1 000 m elevation.

Diagnosis: a distinctive species with the leaves terete or elliptic in section and without evident veins, and deep purple to violet, sideways-facing flowers with a curved perianth tube 7–15 mm long and tepals with prominent, darkly mottled veins. The filaments are declinate and relatively long, 8–10 mm long. The anthers are usually white, but some populations have purple anthers with brown pollen. It is the only species of *Thereianthus* on the Cape Peninsula.



Ser. **Thereianthus**

Leaves ribbed or corrugate, with thickened and raised veins. *Flowers* suberect with ± straight tube; perianth actinomorphic or more usually zygomorphic. *Stamens* arcuate, rarely central.

8. **Thereianthus spicatus** *(L.) G.J.Lewis* in Journal of South African Botany 7: 39 (1941). *Gladiolus spicatus* L.: 37 (1753). *Ixia spicata* (L.) Willd.: 200 (1797), illegitimate homonym, not *I. spicata* Burm.f. (1768). *G. alopecuroides* Pers.: 46 (1805), illegitimate superfluous name for *G. spicatus* L. and an illegitimate homonym, not *G. spicatus* L. (1756). *Micranthus spicatus* (L.) Heynh.: 405 (1847). *Paulomagnusia spicata* (L.) Kuntze: 702 (1891). *Beilia spicata* (L.) Eckl. ex Kuntze: 305 (1898) [*B. spicata* (L.) Eckl., not validly published]. Type: from South Africa without any details ex Herb. van Royen (?L, not found). Neotype, designated by Manning & Goldblatt: 259 (2011): South Africa, [Western Cape], Jonkershoek Valley, contour path below Berg River Collar, 29 Dec. 1989, *Goldblatt & Manning 9028* (NBG, neo.; K, MO, PRE, iso.).

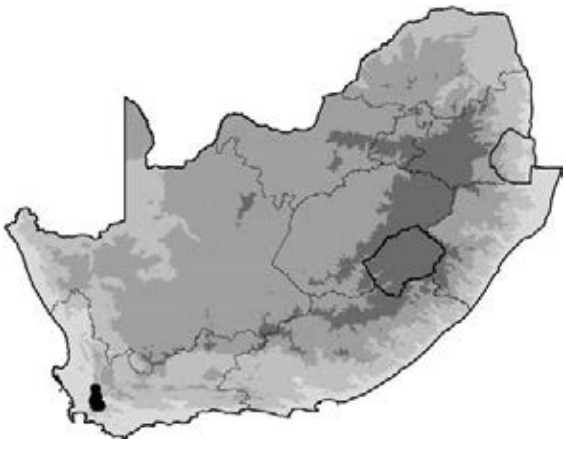
Thereianthus spicatus var. *linearifolius* G.J.Lewis: 40 (1941). Type: South Africa, [Western Cape], mountains near Franschhoek, *Salter 2973* (BOL, holo.).

Gladiolus rubens Vahl: 98 (1805). *Watsonia rubens* (Vahl) Ker Gawl.: sub t. 1072 (1807). Type: South Africa, not cited, probably at C.

Distribution of ***Thereianthus spicatus***.

Plants (150–)200–500(–600) mm high. *Corm* 10–20 mm diam.; tunics of coarsely netted fibres, thickened and claw-like at base, accumulating with age. *Stem* erect or flexed outward above sheath of second leaf, rarely with short branch from axil of uppermost leaf. *Leaves* 4(5), lowermost mostly reaching or exceeding spike, ± dry at flowering, linear, (100–)200–250 × 1–2(–4) mm, closely 3–5(–7)-ribbed, smooth or minutely scabrid on ribs and margins, uppermost leaf only rarely reaching base of spike, entirely sheathing or with short blade 20–60 mm long. *Spike* closely (3–)6- to 20(–30)-flowered; bracts overlapping for ½–⅔ length, (7–)8–13(–15) mm long and two or three internodes long, outer acute, either green below or entirely brown and leathery, conspicuously and closely veined, with narrow membranous margins, inner slightly shorter, ± membranous with narrow brown zones along veins. *Flowers* suberect, mostly pale to midblue, rarely white or pink, lower three tepals each with white marking near base outlined distally with purple chevron; perianth subactinomorphic or weakly zygomorphic; tube ± straight or slightly curved outward in distal 3 mm, (12–)15–18(–25) mm long, 1.0–1.5 mm diam. at mouth, ± dilated gradually and evenly from base to tip, exserted 6–15 mm beyond bracts, 0.8–1.8 × as long as tepals; tepals elliptical-oblanceolate, inner 3 slightly smaller, spreading and slightly cupped, 10–18 × 3–5 mm. *Stamens* arcuate; filaments 3–4 mm long, exserted 2 mm from tube; anthers 4–5 mm long, purple; pollen purple. *Style* arching above anthers, dividing at ± middle of anthers, branches 4–5 mm long, divided to near base. *Capsules* narrowly ovoid, 6–7 × 3 mm. *Seeds* ellipsoid-angled, ± 2 mm long, black or brown, testa striate-colliculate. *Flowering time*: (November)December to January(early February).

Distribution and ecology: common along the coastal mountains and foothills in the southwestern Western Cape, South Africa, from Piketberg and Porterville south to the Palmiet River Mouth and onto the lower slopes of the Riviersonderend Mtns, but absent from the Cape Peninsula; mostly on sandstone slopes but also shale bands and on granite, from near sea level to over 1 000 m elevation.



Diagnosis: distinguished from the other species with strongly ribbed leaves by the moderately long perianth tube, (12–)15–18(–25) mm long, usually curved outward slightly near the tip and dilating gradually and evenly from base to apex, elliptic-oblanceolate tepals, 10–18 × 3–5 mm, and filaments 3–4 mm long. Although usually glabrous, the leaves in some plants are scabridulous along the ribs and margins.

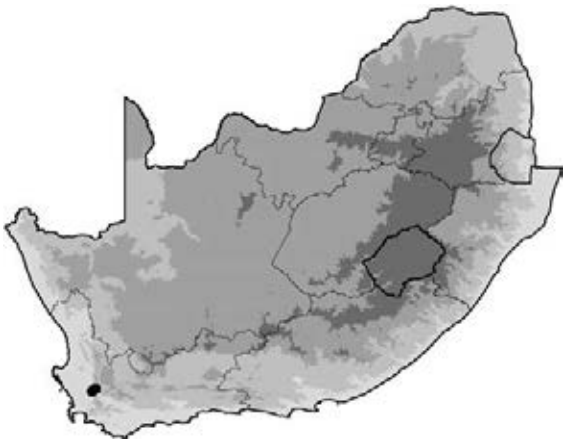
9. **Thereianthus ixioides** *G.J.Lewis* in Journal of South African Botany 7: 41 (1941). Type: South Africa, [Western Cape], Bain's Kloof at summit, 8 Dec. 1934, *T.M. Salter 5117* (BOL, holo.).

[*Watsonia filifolia* E.Mey. in Drège: 82 (1843), invalid name without description.]

[*Watsonia punctata* var. *filifolia* E.Mey. ex Baker: 16: 159 (1877), invalid name without description.]

Plants 250–500 mm high. *Corm* 12–20 mm diam.; tunics of coarsely netted fibres, thickened and claw-like at base, accumulating with age. *Stem* erect or flexed outward above second sheath. *Leaves* 4(5), lowermost reaching or exceeding spike, green or dry at flowering, linear, 200–400 × 1.0–2.0 mm, closely 3-ribbed, uppermost leaf entirely sheathing. *Spike* erect, compact, densely 6- to 12-flowered; bracts overlapping for ½–⅔ length, 8–13 mm long and two or three internodes long, outer acute or obtuse, either green below or entirely brown and leathery, conspicuously and closely veined, with narrow membranous margins, inner slightly shorter, ± membranous with narrow brown zones along veins. *Flowers* suberect, white to pale mauve (rarely midblue), unmarked or lower three tepals each with purple marking near base (rarely ± all tepals marked); perianth actinomorphic; tube straight, 7–12(–15) mm long, 0.5–1.0 mm diam. at mouth, filiform and tightly clasping style throughout, abruptly expanded in distal 1 mm, exserted 1–9 mm beyond bracts, 0.5–1.0 × as long as tepals; tepals elliptical-oblanceolate, spreading and slightly cupped or flat, 12–15 × 4–6 mm. *Stamens* central, erect or diverging apically with anthers spreading; filaments 3–4 mm long, swollen slightly at base

Distribution of ***Thereianthus ixioides***.



and occluding mouth of perianth tube; anthers 5–7 mm long, lilac or pale yellow; pollen cream-coloured. *Style* central, dividing between base and middle of anther, branches ± 3–4 mm long, divided to near base. *Capsules* ovoid, 7–10 × 3–5 mm. *Seeds* ellipsoid-angled, 2–3 mm long, yellowish brown testa striate-colliculate. *Flowering time*: late November to December(early January).

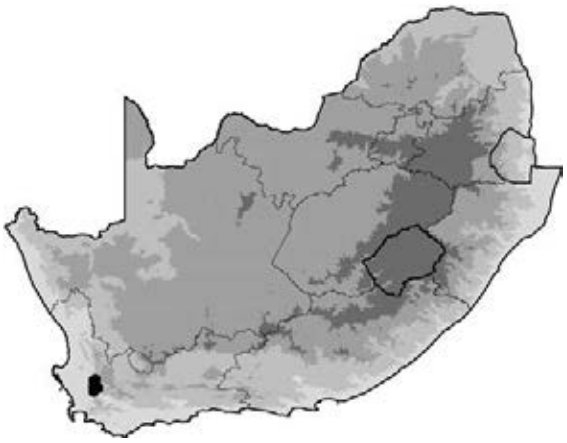
Distribution and ecology: a narrow endemic of the mountains between Wellington and Franschhoek in Western Cape, South Africa, where it is best known from Bain's Kloof and Du Toit's Kloof passes and the Wemmershoek Mtns; on cooler, south-facing sandstone slopes at mid-altitudes, mainly around 1 000 m elevation, often in seasonally damp places, along drainage lines or water courses.

Diagnosis: recognised by its compact, subcapitate spike of actinomorphic, white or pale lilac (rarely midblue) flowers with filiform, straight perianth tube, 7–12(–15) mm long and up to 0.5 mm diam., tightly clasping the style for most of its length and abruptly dilated only in the distal 1 mm, with the filaments thus completely exserted. The stamens are symmetrically arranged, with ± horizontally spreading anthers, and the filaments occlude the mouth of the perianth tube.

10. **Thereianthus elandsmontanus** *Goldblatt & J.C.Manning* in Bothalia 41: 263 (2011). Type: South Africa, Western Cape, Bo-Hermon, Elandsberg Nature Reserve, Slangkop, low sandstone ridge, two years after fire, (–AC), 7 Nov. 2010, *J.C.Manning 3313* (NBG, holo.; MO, iso.).

Plants 140–240 mm high. *Corm* 10–15 mm diam.; tunics of coarse, matted fibres, accumulating with age. *Stem* erect. *Leaves* 4, lowermost exceeding spike, ± dry at flowering, linear, 200–250 × 2–3 mm, closely 3- or 4-ribbed, uppermost leaf with short blade 20–30 mm long. *Spike* erect, densely 7- to 15-flowered; bracts overlapping for ½–⅔ length, 8–10(–13) mm long and two or three internodes long, outer acute, either green below or entirely brown and leathery, conspicuously and closely veined, with narrow membranous margins, inner slightly shorter, ± membranous with narrow brown zones along veins. *Flowers* suberect, cream-coloured to pale flesh-pink, flushed purple on tube, lower three tepals with median linear maroon streak extending halfway along blade; perianth weakly zygomorphic; tube slightly curved outward in distal 3 mm, (17–)20–23 mm long, ± 1.5 mm diam. at mouth, ± cylindric but widening slightly distally, exserted 13–15 mm beyond bracts; tepals linear-oblanceolate, inner three slightly smaller, spreading and slightly cupped, 12–15 × 1.5–3.0 mm. *Stamens* arcuate; filaments 4–5 mm long, exserted 2–3 mm from tube; anthers 4 mm long, blackish purple; pollen purple. *Style* arching above anthers, dividing between base and middle of anthers, branches, ± 3 mm long, divided to near base. *Capsules* narrowly ovoid, 5–7 × 3 mm. *Seeds* ellipsoid-angled, ± 2 mm long, yellowish brown, testa striate-colliculate. *Flowering time*: November.

Distribution of ***Thereianthus elandsmontanus***.



Distribution and ecology: restricted to Slangkop Ridge on Elandsberg Nature Reserve near Hermon in Western Cape, South Africa; on sandstone in grassy fynbos.

Diagnosis: distinguished by its cream-coloured to pale flesh-pink flowers with moderately long tube, 17–23 mm long and 1.5–1.8 × as long as the tepals, which are unusually narrow, almost linear, and just 2–3 mm wide. Unfortunately the flowers do not retain their colour in the herbarium, drying bluish lilac. It is most likely to be confused with *Thereianthus spicatus*, which has a tube of similar length, but this species has blue (rarely white or pink flowers) with broader, lanceolate tepals, 3–5 mm wide.

11. **Thereianthus longicollis** *(Schltr.) G.J.Lewis* in Journal of South Africa Botany 7: 39 (1941). *Watsonia longicollis* Schltr.: 106 (1899). Type: South Africa, [Western Cape], Tulbagh Waterfall, ± 1 200 ft [365 m], 10 Nov. 1896, *R. Schlechter 9055* (B, holo.; BOL, GRA, MO, PRE (4 sheets), iso.).

Watsonia punctata var. *longicollis* Baker: 177 (1892). Type: South Africa, [Western Cape], Worcester [District], *Zeyher s.n. K400455* (K, holo.).

Plants 150–350 mm high. *Corm* 10–15 mm diam.; tunics of coarsely netted fibres, thickened and claw-like at base, accumulating with age. *Stem* erect. *Leaves* 4, lowermost reaching or exceeding spike, ± dry at flowering, linear, 200–250 × 1–2 mm, closely 3-ribbed, uppermost leaf with short blade 20–60 mm long. *Spike* densely 7- to 15(–20)-flowered; bracts overlapping for ½–⅔ length, 8–12(–17) mm long and 2 or 3 internodes long, outer acute, either green below or entirely brown and leathery, conspicuously and closely veined, with narrow membranous margins, inner slightly shorter, ± membranous with narrow brown zones along veins. *Flowers* suberect, white or pale pink to purple-pink with purple tube, lower three tepals each with purple chevron or diamond-shaped markings near base;

Distribution of ***Thereianthus longicollis***.

perianth weakly zygomorphic; tube slightly curved outward in distal 3 mm, 25–40 mm long, ± 2 mm diam. at mouth, ± cylindric but dilated slightly distally, exserted 20–30 mm beyond bracts, 2.0–2.5 × longer than tepals; tepals oblong-oblanceolate, inner 3 slightly smaller, spreading and slightly cupped, 12–17 × 2.5–5.5 mm. *Stamens* arcuate; filaments 6 mm long, exserted 3 mm from tube; anthers 4–6 mm long, purple; pollen purple. *Style* arching above anthers, dividing at ± middle of anthers, branches ± 4–5 mm long, divided to near base. *Capsules* narrowly ovoid, 6–7 × 2.5–3.0 mm. *Seeds* ellipsoid-angled, ± 2.5 mm long, yellowish brown, testa striate-colliculate. *Flowering time*: mostly mid-November to late December.

Distribution and ecology: a narrow endemic of the mountains between Porterville and Wolseley in Western Cape, South Africa, including the southern end of the Grootwinterhoek Mtns, Saronsberg and the Elandskloof Mtns; in sandy gravel or loamy ground on rocky sandstone slopes open proteoid or restioid fynbos.

Diagnosis: separated from all other species in the genus by its unusually long perianth tube, 25–40 mm long and 2.0–2.5 times longer than the tepals. The flowers vary in colour from pale pink or almost white to purple-pink, with darker tube and purple, chevron-shaped markings on the lower tepals. The species may be confused with longer-tubed forms of *T. spicatus*, but the perianth tube in that species is shorter, mostly less than 20 mm long (rarely up to 25 mm) and always less than twice as long as the tepals, and also narrower, at most 1.5 mm diam. at the mouth.

UNCERTAIN SPECIES

Beilia spicata var. *brevifolia* Kuntze: 305 (1898). Type: South Africa, [Western Cape], 'Mowbray bei Capstadt', collector and date unknown (specimen not located). The brief description of this taxon '*foliis brevibus 1–2 cm latis acuminatus*' and its collection at Mowbray, Cape Town, make it certain that it is not *Thereianthus spicatus*, which has narrower leaves and is absent from the Cape Peninsula. The only possibility in *Thereianthus* is thus *T. bracteolatus*, but the broad leaves are inconsistent with this species as well and suggest that it might be a species of *Watsonia*.

9. Micranthus

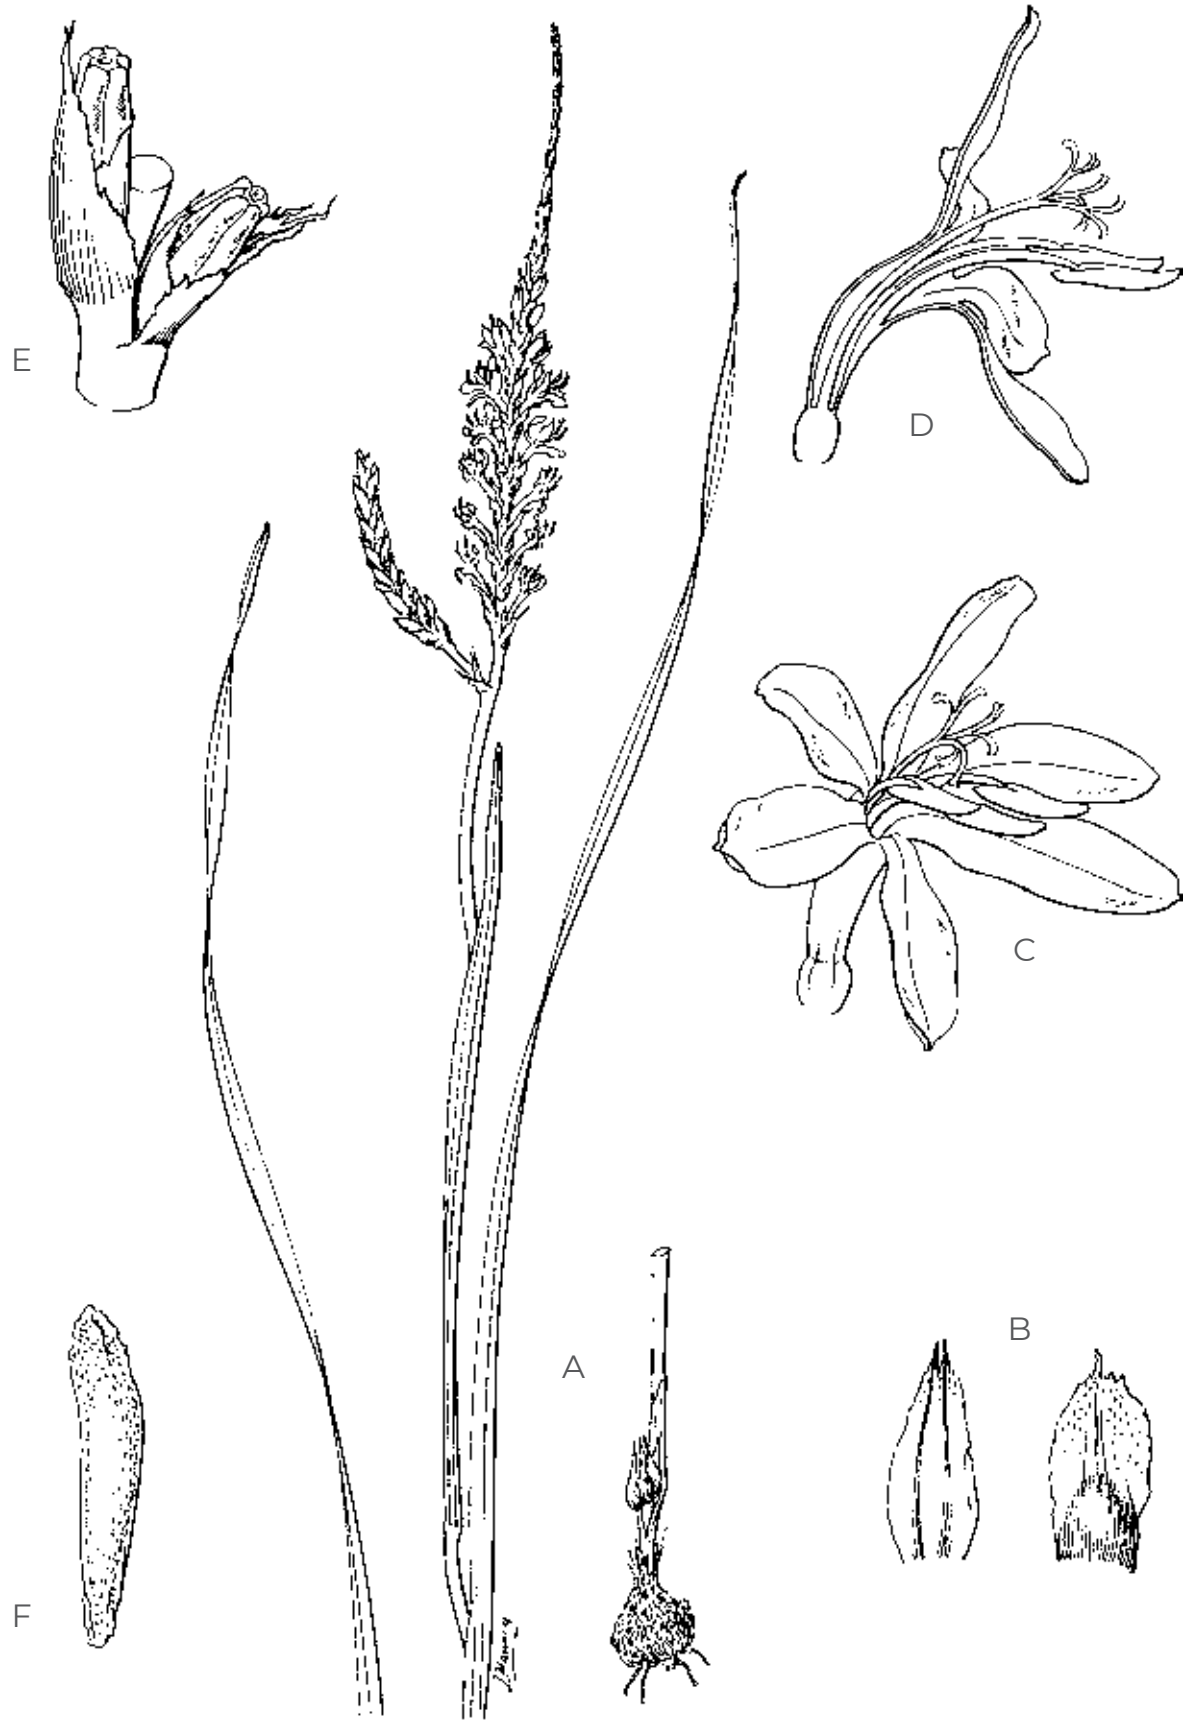
Micranthus *(Pers.) Eckl.*, Topographisches Verzeichniss der Pflanzensammlung von C.F. Ecklon: 43 (1827), name conserved, not *Micranthus* J.C.Wendl. (1798) [Acanthaceae]. *Gladiolus* subg. *Micranthus* Pers.: 46 (1805). *Hebea* subg./unranked *Micranthus* (Pers.) R.Hedw.: 24 (1806). Type (conserved): *G. alopecuroides* L. = *M. alopecuroides* (L.) Eckl.

Paulomagnusia Kuntze: 702 (1891). Type: *P. alopecuroides* (L.) Kuntze, lecto., designated by Goldblatt & Manning: 133 (2008) = *Micranthus alopecuroides* (L.) Eckl.

Revisionary account: Goldblatt et al.: 127–144 (2013).

Named for the unusually small flowers, from the Greek *micro* (small) and *anthos* (flower).

Deciduous geophytes. *Corm* axillary in origin, subglobose, rooting from below; tunics coarsely fibrous. *Leaves* few, the lower 2 or 3 cataphylls, lowermost foliage leaf longest, inserted on stem above corm, blades either plane with a definite main vein and falcate or lanceolate with margins moderately to heavily thickened, or ± tubular and hollow, or terete and ± solid with heavily thickened central vein and margins separated by narrow longitudinal grooves, margins with subepidermal sclerenchyma associated with a marginal vein, *Stem* straight or ± flexuose, simple or few- to several-branched. *Inflorescence* a congested, 2-ranked spike, usually weakly rotated; bracts short, overlapping, with leathery or dry central portion and broad membranous margins, inner forked apically and shorter than to ± as long as outer. *Flowers* zygomorphic, lasting several days, blue to violet, mauve, white or flushed lilac, scentless or pleasantly scented, with nectar from septal nectaries; perianth tube short, curving outward, ± cylindric below, flaring in upper half; tepals ± equal, dorsal slightly larger and arching over stamens, lower tepals extended ± horizontally. *Filaments* unilateral, arcuate, slender, free; anthers oblong, held under the dorsal tepal, splitting longitudinally. *Ovary* ovoid, sessile; style branches slender, usually deeply divided and recurved, or barely notched at apex. *Capsules* woody, small, narrowly ovoid-ellipsoid or urn-shaped with ovules in lower fourth. *Seeds* 2 to 4(5) per locule, 3(4)-sided below, elongate, widest at micropylar end with micropylar crest and micropyle above base, tapering and pointed at chalazal end, surface slightly wrinkled. *Pollen grains* zonasulculate, exine reticulate. *Basic chromosome number x* = 10.



Species 7: Core Cape Floristic Region, South Africa.

This small genus restricted to the southern African winter-rainfall region stands out in its tiny flowers that have tepals seldom longer than 8 mm, a perianth tube typically about as long and spikes of numerous flowers crowded on 2-ranked spikes. *Micranthus thereianthoides* stands out in having an elongate perianth tube up to 25 mm long. The flowers are usually pale to deep blue, rarely white or lilac and always zygomorphic, with a hood-like dorsal tepal and unilateral, arcuate stamens. Corms of *Micranthus* are axillary in development and this together with the deeply divided style branches (not in *M. simplex*) place the genus in tribe Watsonieae. Molecular phylogenetic studies retrieve the genus closest to *Thereianthus* with which it was historically associated. *Micranthus* shares with *Thereianthus* an unusual feature, foliage leaves inserted at the base of the stem and only the cataphylls contribute to the formation of the corm tunics. Pollen grains of *Micranthus* are zonasulculate, thus strikingly different to the typical monosulcate-operculate condition of Crocoideae, where the operculum is usually 2-banded (sometimes 1-banded as in some species of *Thereianthus*). Variation in *Micranthus* species is mainly in the leaves, which range from plane and sword-shaped, to linear with prominent veins, cross-shaped in section or terete and hollow or inflated.

Key to species

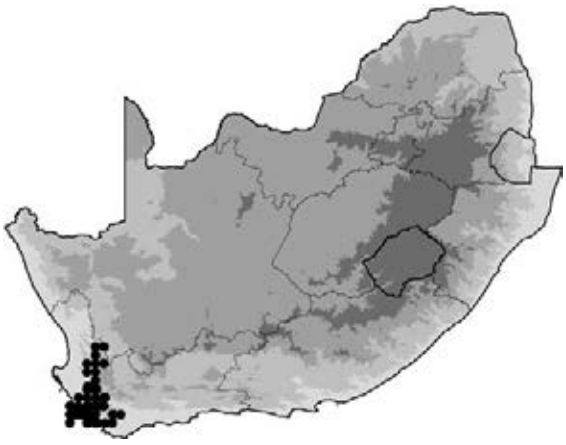
Note: plants with the lower part of the spike bearing smaller, paler floral bracts subtending one or more small cormlets may be *Micranthus plantagineus* or *M. tubulosus* or may be hybrids involving these two species or with *M. alopecuroides* and are not accommodated in the key.

1a Leaf blades either plane with evident central vein or one or two prominently thickened veins, or terete and 4-grooved with thickened margins, not hollow; style variously dividing between mouth of perianth tube to opposite middle of anthers:
2a Lowermost leaves plane and linear to lanceolate or falcate, (2–)4–12 mm wide; style branches divided ± halfway ..... 1. *M. alopecuroides*
2b Lowermost leaves either plane and linear or terete and cross-shaped in section, up to 2 mm wide; style branches divided up to halfway or undivided:

Micranthus alopecuroides: A, flowering plant; B, outer bract (right) and inner bract (left); C, flower; D, half-flower; E, capsules; F, seed.

3b Flowers white, outer tepals tipped palest lilac, fading slightly darker lilac; style branches undivided or barely notched at apex . . . . . 2. *M. simplex*
3b Flowers pale blue, blue-mauve or deep blue or white; style branches divided up to halfway:
4a Style dividing at mouth of perianth tube opposite middle of filaments; style branches ± 2.5 mm long, divided less than ⅓; leaves at least 1.5 mm wide. . . . . 6. *M. cruciatus*
4b Style dividing between base and middle of anthers; style branches usually ± 1.0 mm (up to 1.5 mm) long, divided up to halfway; leaves < 1 mm wide . . . . . 5. *M. filifolius*
1b Leaf blades tubular and hollow, round or ± compressed in section; style dividing opposite base to middle of anthers (rarely just below anther bases):
5a Perianth tube elongate and ± twice as long as bracts, 22–25 mm long; bracts 8–15 mm long. . . . . 3. *M. thereianthoides*
5b Perianth tube shorter than bracts, < 10 mm long; bracts 5–7 mm long:
6a Flowering stem ± flexed at each aerial node; stem with prominent, coarsely fibrous collar around base . . . . . *M. plantagineus* × *M. tubulosus*
6b Flowering stem straight, stiffly erect; stem with or without collar of fibres around base:
7a Blade of lowermost leaf terete or oval in section, ± straight, green at flowering and smooth when fresh (with evident thickened veins when dry); stem without collar of fibres around base; capsules narrowly ovoid to ± urn-shaped. . . . . 7. *M. plantagineus*
7b Blade of lowermost leaf tubular and inflated, falcate with prominent apical mucro, often dry at flowering, without prominent veins when alive or dry; stem with collar of fibres around base; capsules narrowly ovoid . . . . . 4. *M. tubulosus*

1. **Micranthus alopecuroides** *(L.) Eckl.*, Topographisches Verzeichniss der Pflanzensammlung von C.F. Ecklon: 43 (1827); Goldblatt et al.: 132 (2013). *Gladiolus alopecuroides* L.: 5 (1756). *Ixia alopecuroides* (L.) L.f.: 92 (1782). *I. plantaginea* Aiton: 59 (1789), illegitimate superfluous name for *G. alopecuroides* L. *Paulomagnusia alopecuroides* (L.) Kuntze: 702 (1891). Type: South Africa, [Western Cape], Somerset West, 19 Nov. 1944, *Barker 3384* (NBG, neo., designated by Goldblatt & Manning: 132 (2013); PRE iso.).



[*Watsonia compacta* G.Lodd.: t. 1577 (1830), invalid name without description.]

[*Micranthus plantagineus* sensu auct., non Eckl. (1827).]

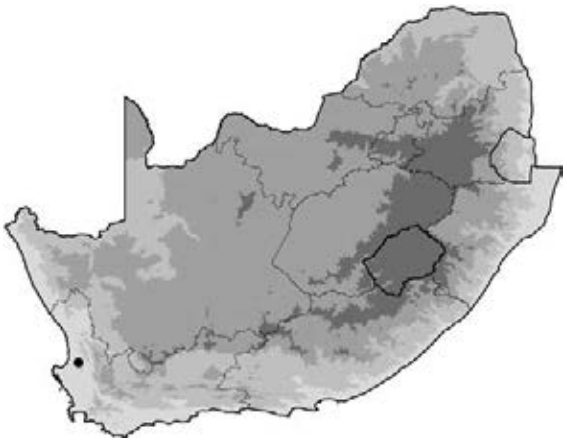
Plants mostly 200–450 mm high, base usually sheathed with collar of short fibres. *Corm* mostly 10–12 mm diam., tunics of dark brown, relatively coarse, reticulate fibres, drawn into short bristles above. *Stem* usually simple or 1- or 2(3)-branched, when unbranched often with one or more scales below base of spike; usually bearing 1 or more cormlets in axil of lowermost foliage leaf. *Leaves* 2 to 4(5), lowermost 1 or 2 plane, broadly to narrowly falcate (occasionally ± lanceolate) or linear, (2–)5–10(–15) mm wide, with moderately prominent main vein; margins slightly or occasionally heavily thickened, hyaline when dry; upper 1 or 2(3) leaves largely sheathing. *Spike* mostly 40- to 80-flowered, often much congested, with internodes 1.5–3.0 mm long; bracts 5–7 mm long, outer with broad to narrow brown centre and translucent membranous margins, inner ± as long as outer, notched apically, translucent with 2 dark veins slightly broader toward base; lower or all nodes sometimes vegetative and then bracts paler in colour and subtending one (or more) cormlets in each axil. *Flowers* usually dark blue, sometimes pale blue, often lower ⅓–¼ of tepals paler blue or white, distally edged with a thin darker blue line, unscented; perianth tube ± 5 mm long; tepals subequal, elliptic, 7–8 × ± 3 mm, with short narrow, claw-like base. *Filaments* ± 5 mm long, diverging in upper half; anthers oblong, 3–4 mm long, pale mauve; pollen white to pale blue. *Style* ± 7 mm long, usually dividing between upper ⅓ of filaments and lower ⅓ of anthers; branches ± 1.2–1.6 mm long, divided for ± half their length. *Capsules* oblong to narrowly ovoid, ± 5 mm long but ± 4 mm long when dry. *Seeds* 3.5–4.0 mm long, 3 or 4 per locule. *Flowering time*: October in the north, November to December in the south.

Distribution and ecology: centred in southwestern Western Cape, South Africa, extending from the Cape Peninsula north into the Olifants River Valley and east locally to Hermanus and Swellendam; typically on well-drained clay or loamy, seasonally wet slopes and flats but also recorded on sandy ground and thin clay or sandy gravel, on rocky pavement.

Diagnosis: *Micranthus alopecuroides* is distinctive in its plane, sometimes very broad lanceolate to linear or falcate, basal leaves sometimes up to 12 mm wide or exceptionally up to 15 mm. Exceptions are numerous and there are populations with ± linear leaves 3–5 mm

Distribution of ***Micranthus alopecuroides***.

wide and only up to 25 mm long. The flowers are typically dark blue but also pale blue, with a perianth tube ± 5 mm long. The spikes of 40 or more flowers are often unusually congested with the internodes ± 1.5 mm long. Populations from the Olifants River Valley and flowering in October, at least three weeks earlier than elsewhere, stand out in their relatively lax spikes with internodes 2.5–3.0 mm long (vs. ± 1.5–2.0 mm elsewhere) and relatively short, straight leaves, 5–8 mm wide with particularly prominent mucronate tips.



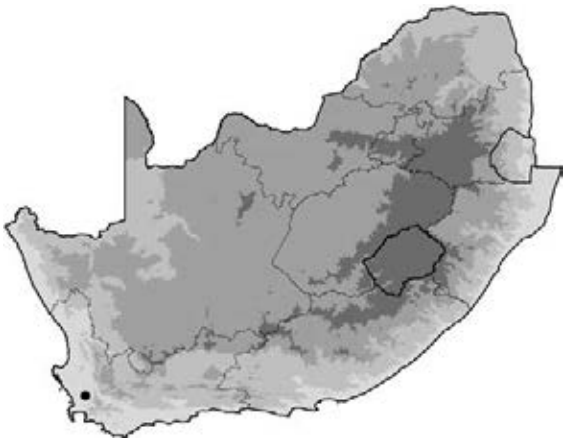
Hybrids from sandy flats south of Malmesbury have abnormally elongated spikes up to 120 mm long, more than ¾ of their length bearing small, pale bracts each enclosing not a flower but a small cormlet. The leaves, either tubular or plane with a central vein, correspond to *Micranthus tubulosus* or *M. alopecuroides* respectively. These plants likely constitute hybrids or a hybrid swarm with *M. alopecuroides* as one parent and *M. tubulosus* or possibly *M. plantagineus* as the other. Similar plants from other sites, notably Rondebosch Common and Vogelgat, Hermanus, show the same striking features. Populations at Elandsberg near Bo-Hermon, with plane, narrowly lanceolate leaves have the inflorescence sterile throughout and bearing a cormlet in all bract axils as do many individuals of the species from Rondebosch Common, Cape Town. The status of these plants is uncertain but they most likely have a hybrid origin.

Micranthus alopecuroides was long known as *M. plantagineus*, but examination of the type shows that the latter is in fact the species previously known as *M. junceus*.

2. **Micranthus simplex** *Goldblatt & J.C.Manning* in Bothalia 43: 133 (2013). Type: South Africa, Western Cape, Piketberg, southwestern slopes of Zebrakop, shallow soil on sandstone pavement, 4 Jan. 1995, *Goldblatt & Manning 10172* (NBG, holo.; K, MO, PRE, iso.)

Plants (100–)140–200 mm high, base sheathed by short collar of brittle fibres. *Corm* tunics of dark brown, reticulate fibres. *Stem* usually simple, rarely 1-branched. *Leaves* (2)3, plane, linear or falcate, ± 1 mm wide, usually with 1 or 2 prominent veins, margins thickened, hyaline when dry. *Spike* 16- to 40-flowered; bracts purple-brown with broad translucent, brown-flecked membranous margins, ± 5 mm long, inner bracts ± as long as outer, membranous with 2 dark keels, notched at apex. *Flowers* white fading to lilac, outer tepals tipped pale lilac, with subapical brown ridge on reverse; perianth tube ± 3 mm long; tepals oblong, ± 4 × 1.2 mm. *Filaments* ± 2.5 mm long; anthers oblong, ± 2.5 mm long. *Style* ± 7 mm long, dividing opposite middle of anthers; branches ± 1 mm long, barely notched at apex. *Capsules* oblong, slightly warty in distal half, ± 4 mm long. *Seeds* ± 3 mm long. *Flowering time*: December to at least mid-January.

Distribution and ecology: known only from the slopes of Zebrakop, the highest peak in the Piketberg, Western Cape, South Africa; in shallow soils in moss or in rock crevices on wet sandstone rocks, a habitat that remains moist as late as January when the plants flower.



Distribution of ***Micranthus simplex***.

Diagnosis: unusually short for the genus, stems of *Micranthus simplex* rarely exceed 180 mm and the white flowers with lilac-tipped outer tepals are distinctive, other species having flowers in shades of deep to pale blue or blue-mauve, or occasionally white. The inflorescence is relatively lax, the bracts of the lower flowers of the spike not overlapping those above them, but the upper bracts are as closely set as in other species. It is one of two species of *Micranthus* with consistently plane leaves; the other, *M. alopecuroides*, is a taller plant with congested spikes of 40 to 80 flowers and broader leaves mostly 5–12 mm wide. The flowers of *M. simplex* are the smallest in the genus, the perianth tube just 3 mm long and the short anthers ± 2.5 mm long. The short, undivided style branches, ± 1 mm long, are likewise unusual for *Micranthus*, other species of which have style branches divided for at least one third their length.

3. **Micranthus thereianthoides** *Goldblatt & J.C.Manning* in Bothalia 43: 134 (2013). Type: South Africa, Western Cape, Paardeberg, Vondeling, rock cracks and sands along stream, 9 Jan. 2013, *Nicolson 995* (NBG, holo.; K, MO, iso.).

Plants 300–800(–1 200) mm high, base weakly sheathed by fine fibres. *Corm* 10–15 mm diam., tunics of fine to moderately coarse, dark brown, reticulate fibres. *Stem* simple or rarely branched, with solitary cormlet in axil of second leaf and sometimes also third leaf. *Leaves* (4)5 or 6, green or drying at flowering, lowermost 2 or 3 longest, blades 100–300(–800) mm long, 2.5–5.0(–15.0) mm diam., tubular and hollow, sometimes inflated, acute-mucronate, upper leaves progressively shorter and narrower, uppermost bract-like and entirely sheathing. *Spike* 10- to 40(–70)-flowered, bracts brown with broad translucent membranous margins, 8–11(–15) mm long, as long as 1.5–2.0 spike internodes, inner bracts slightly shorter than outer, forked apically, membranous with 2 dark keels broadened toward base. *Flowers* suberect,

Distribution of ***Micranthus thereianthoides***.

dark violet or purple, unscented; perianth tube ± cylindric, 22–25 mm long; tepals oblong, 5–6 × 1.5–2.5 mm, reverse of outer tepals with prominent subapical ridge. *Filaments* 6–8 mm long, exserted ± 3 mm; anthers oblong, 3.5–4.0 mm long. *Style* 24–27 mm long, dividing between middle and slightly beyond anthers, branches ± 1.5(–2.0) mm long, divided for ± half their length. *Capsules* ovoid, smooth, 5–6 mm long, with ± 4 seeds per locule. *Seeds* ± 3.5 mm long. *Flowering time*: January.

Distribution and ecology: a narrow endemic of the Paardeberg near Malmesbury in Western Cape, South Africa; at mid- to upper elevations along the banks of seasonal streams, the corms usually wedged among granite rocks, sometimes in humic loam.

Diagnosis: *Micranthus thereianthoides* closely resembles *M. plantagineus* and *M. tubulosus* in its cylindric leaves but is unique in the genus in the relatively large floral bracts, 8–11 mm long, and most strikingly in its dark violet flowers with elongate, cylindric perianth tube 22–25 mm long, thus ± twice as long as the bracts. The species appears never to develop cormlets in the floral bract axils. The species was discovered in January 2012 by local plant enthusiasts Greg Nicholson and Dewan Roets during a botanical survey of the Paardeberg. The long-tubed, violet flowers are evidently adapted to pollination by long-proboscid flies. The incomplete fruit set in wild plants suggests that *M. thereianthoides* is an obligate outcrosser.

4. **Micranthus tubulosus** *(Burm.f.) N.E.Br.* in Bulletin of Miscellaneous Information Kew 1929: 133 (1929); Goldblatt et al.: 134 (2013). *Gladiolus tubulosus* Burm.f.: 2 (1768). *Ixia cepacea* Basseporte ex DC. in Redouté: t. 96 (1804), as new name in *Ixia,* not *I. tubulosa* Burm. f. (1768) (= *Babiana tubulosa* (Burm.f.) Ker Gawl.). Type: South Africa, without precise locality or collector (G: Herb. Burman, holo.).

   Gladiolus fistulosus Jacq.: 8 (1797). *Ixia fistulosa* (Jacq.) Sims: t. 523 (1801), illegitimate homonym, not *I. fistulosa* Andrews (1799) [= *Hesperantha radiata* (L.f.) Ker Gawl.]. *Micranthus fistulosus* (Jacq.) Eckl. ex Baker: 179 (1892), illegitimate superfluous name for *G. tubulosus* Burm.f. Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 16 (1797), left hand plant, lecto., designated by Goldblatt & Manning: 134 (2013).

   Watsonia spicata Sol. ex Ker Gawl.: sub t. 553 (1803), illegitimate superfluous name for *Gladiolus spicatus* L. (1753), *G. tubulosus* Burm.f. (1768) & *G. fistulosus* Jacq. (1797). [The citation *Watsonia spicata* (L.) Ker Gawl.: 229 (1804) is an error]. Type: South Africa, without precise locality, illustration in Ker Gawler: t. 523 '*Ixia fistulosa*' (1801).

   [*Ixia teretifolia* Herb. Banks ex Sims: t. 523 (1801), invalid name only in synonymy.]

   [*Micranthus fistulosus* Eckl.: 44 (1827), invalid name without description. Probably intended as a combination but basionym not cited.]

Plants (70–)150–350(–600) mm high, base sheathed by collar of short, stiff, bristly fibres. *Corm* 14–18 mm diam., tunics of coarse, dark brown, reticulate fibres. *Stem* simple or branched, occasionally with cormlets in axil of lowermost leaf and of uppermost cataphyll. *Leaves* (2)3 to 5, usually dry at flowering, lowermost 1 or 2 longest, blades 50–200 mm long (up to 300 mm in sterile plants), 4–7 mm diam., inflated, tubular and hollow, apex obtuse-mucronate, upper leaves progressively shorter and narrower. *Spike* 16- to 40-flowered; bracts mid- to dark brown, 5–6 mm long, outer with broad translucent membranous margins, inner bracts ± as long as outer, forked apically, membranous with 2 dark keels broadened toward base; lower nodes sometimes vegetative with one or more cormlets and bracts then pale. *Flowers* pale or dark blue or white, sweetly scented; perianth tube 5–6 mm long; tepals oblong, 5–6(–10) × 1.2–2.5 mm, reverse of outer tepals with prominent subapical ridge. *Filaments* 6–8 mm long; anthers oblong, 3.5–4.0 mm long. *Style* 7–8 mm long, dividing opposite or slightly below base of anthers, branches ± 1.5(–2.0) mm long, divided for ± half their length. *Capsules* ovoid, smooth, 4–5 mm long, with 3 or 4 seeds per locule. *Seeds* ± 3 mm long. *Flowering time*: November to December.

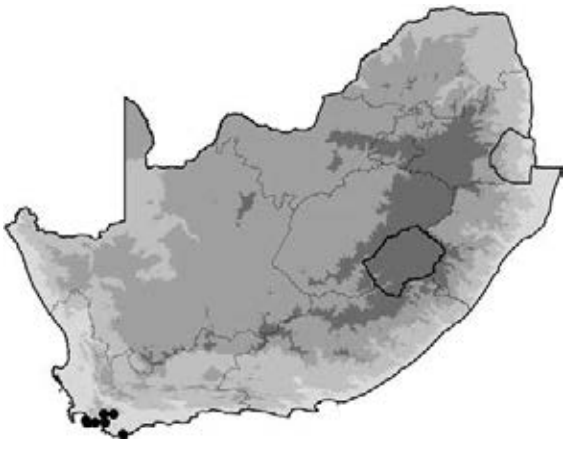
Distribution and ecology: restricted to the western half of Western Cape, South Africa, extending from the Cape Peninsula as far as the northern Cederberg at Heuningvlei and east to Suurbraak and the Agulhas Peninsula; on flats and lower slopes, usually on clay and granite-derived soils but also on sandstone.

Diagnosis: the inflated, tubular, falcate leaves are diagnostic for *Micranthus tubulosus*, the spikes and flowers of which differ hardly at all from those of *M. alopecuroides*. A particularly distinctive feature of the leaves is the prominent brown mucro at the obtuse to ± truncate apices. The leaves are often ± dry at flowering time. Marloth (1915: plate 41) has a particularly apt illustration of

Distribution of ***Micranthus tubulosus***.

the species. As in *M. plantagineus*, one or more cormlets may be produced in the lower axils of the spike. The condition is more frequent, although not consistent, in *M. plantagineus*. Despite its apparently preferred habitat on relatively dry slopes, *M. tubulosus* can occasionally be found on moist sandy flats, sometimes co-occurring with *M. alopecuroides* and *M. plantagineus*. Hybrids between these two species at shared sites blur their usually clear foliar differences. A curious feature of *Micranthus tubulosus* is that populations may consist of a mixture of some plants with entirely fertile spikes and others with the lower part of the spike sterile.

Hybrids: the following interspecific hybrids are known involving *Micranthus tubulosus*: *M. tubulosus* × *M. alopecuroides* and *M. tubulosus* × *M. plantagineus*. Those with *M. plantagineus* can form large populations locally, probably backcrossing with one other parental species.



5. **Micranthus filifolius** *Goldblatt & J.C.Manning* in Bothalia 43: 137 (2013). Type: South Africa, Western Cape, Akkedisberg Pass, sandy hillside, 18 Nov. 2011, *Goldblatt & Porter 13370* (NBG, holo.; MO, PRE, iso.).

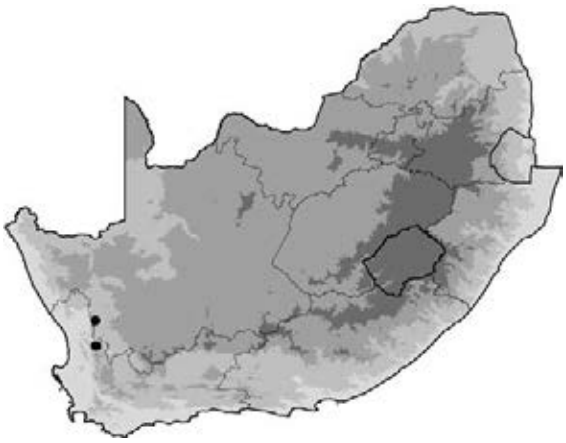
Plants 180–300 mm high, base sheathed with sparse to well-developed collar of fibres. *Corm* 12–16 mm diam., tunics of relatively soft, fine or thicker fibres. *Stem* unbranched or rarely with single short branch, without cormlets in leaf axils. *Leaves* 4–6, green or beginning to dry from tips at flowering time, lowermost longest, reaching to middle of spike to shortly exceeding it, blade either ± terete and ± 1 mm diam. or ± plane and ± 2 mm wide, with heavily thickened central vein and margins, separated when dry by narrow longitudinal grooves, upper leaves shorter, with sheaths overlapping, uppermost 1 or 2 leaves sheathing for most of their length, with short free tips. *Spike* mostly 18- to 50-flowered, closely congested, lower bracts always subtending flowers; bracts mid- to dark brown, ± 5 mm long, outer with broad translucent membranous margins, inner slightly shorter than outer, with 2 dark keels broadened toward base, notched apically. *Flowers* pale mauve or midblue, unscented; perianth tube ± 5 mm long; tepals oblong, ± 5 × 2.2–2.8 mm. *Filaments* ± 5 mm long, exserted ± 2.5 mm; anthers oblong, ± 3 mm long. *Style* ± 7 mm long, dividing between base and middle of anthers; branches 1.0–1.6 mm long, divided for up to half their length, rarely only notched at apex. *Capsules* narrowly ovoid, smooth, 4–6 × ± 2 mm, with up to 4 seeds per locule. *Seeds* 3–5 mm long. *Flowering time*: mid-November to late February.

Distribution and ecology: centred in the Caledon District of Western Cape, South Africa, extending from Steenbras and Cape Hangklip east to Elim, including the lower slopes of Caledon Swartberg; mostly on clay or loamy soils, particularly abundant after fire.

Diagnosis: with its narrow leaves, the lowermost of which is linear or terete, *Micranthus filifolius* is most like *M. plantagineus* in general appearance. It differs, however, from that species in several respects, particularly in the solid, rather than hollow, leaf blades of the lowermost and sometimes the upper leaves. The leaves closely overlap one another and sheath the stem up to the base of the spike. Plants typically have four or five leaves but sometimes even six leaves, the upper one or two largely to entirely sheathing. Unlike *M. plantagineus*, plants do not produce cormlets in the leaf axils and the corm tunics are usually soft-textured with the base enclosed by a collar of fibres, whereas *M. plantagineus* has coarser corm tunics, lacks a basal collar of fibres, and cormlet production is conspicuous in the lowermost and sometimes other leaf axils. The flowers, although typical of *Micranthus*, are somewhat smaller than in *M. plantagineus,* having a perianth tube mostly 4–5 mm long and tepals ± 4 mm long, and are more often pale mauve (drying white), although the western populations are dark blue (drying blue), the flower colour in most populations of *M. plantagineus.* Typical *M. plantagineus* has been recorded close to most localities of *M. filifolius*, flowering in November and December.

Plants bloom unusually late in the season, with mostly after mid-January, and sometimes in mid- to late

Distribution of ***Micranthus filifolius***.



February. Inland populations, as from Drayton Siding, east of Caledon, and Akkedisberg Pass, flower from mid-November to early January and are in fruit before any coastal populations come into flower, the early flowering possibly due to warmer and drier conditions well inland of the coast. The coarser corm tunic fibres and collar of fibres around the base of the stems in these populations are perhaps adaptations to the drier habitat. Plants sometimes co-occur with or grow close to *M. plantagineus*, which is in fruit when *M. filifolius* begins to bloom, two or three weeks after the last flowers of *M. plantagineus* have faded, both at the coast and at inland sites. *Micranthus filifolius* also occasionally co-occurs with *M. tubulosus*.

6. **Micranthus cruciatus** *Goldblatt & J.C.Manning* in Bothalia 43: 139 (2013). Type: South Africa, Western Cape, Pakhuis Mtns, trail to Heuningvlei, local in wet seep on rocky sandstone slope, 19 Dec. 1995, *Goldblatt 10438* (NBG, holo.; MO, iso.).

Plants 300–450 mm high. *Corm* globose, 8–10 mm diam., tunics of brown, soft membranous layers not accumulating. *Stem* simple or 1-branched, usually with 1 or 2 small cormlets in lowermost leaf axil. *Leaves* (3)4 or 5, lower 3 linear to subterete, ± 1.5 mm wide, margins and midrib heavily thickened with narrow longitudinal grooves between (often cross-shaped in section with 4 narrow longitudinal grooves), reaching to base or middle of spike, uppermost leaf sheathing stem almost to base of spike, with short free portion. *Spike* up to 70-flowered; bracts brown or straw-coloured with broad translucent membranous margins, ± 4 mm long, inner ± as long as outer, membranous with 2 dark keels, apically notched. *Flowers* pale blue-mauve (drying ± white) or deep blue; perianth tube ± 3 mm long; tepals oblong, ± 4 × 1.5 mm. *Filaments* ± 5 mm long; anthers oblong-linear, ± 3 mm long. *Style* ± 4 mm long, dividing ± at mouth of tube opposite middle of filaments, branches ± 2.5 mm long, divided for ± ⅓ their length. *Capsules* oblong, smooth, ± 2.5 mm long, evidently immature. *Seeds* unknown. *Flowering time*: mid-November to late December, possibly January.

Distribution and ecology: restricted to the northern Cape flora region of South Africa, extending from the Bokkeveld Mtns southwest of Nieuwoudtville in Northern Cape to the northern Cederberg near Pakhuis Pass in Western Cape; on rocky slopes, in seeps on thin sandy soil over sandstone pavement. The species is poorly documented.

Diagnosis: linear- to terete-leaved *Micranthus cruciatus* is immediately distinguished by its solid, narrow leaf blades, ± 1.5 mm wide, with heavily thickened veins and margins separated by narrow longitudinal grooves. Leaves are either linear or terete becoming cross-shaped in section distally with only the margins and central vein thickened. Plants broadly resemble *M. plantagineus* but are more slender than is usual in that species, which has hollow leaves 2–3 mm diam. and is

Distribution of ***Micranthus cruciatus***.

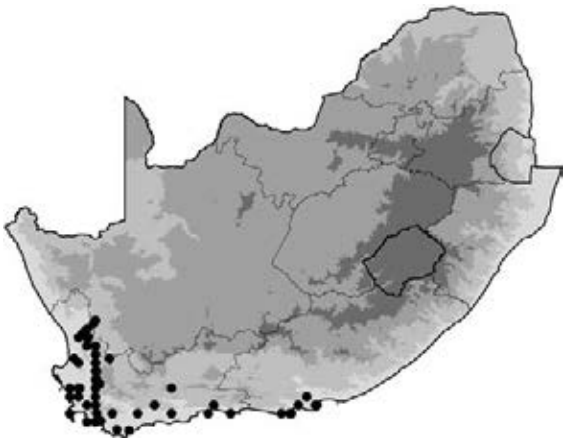
conspicuous in the production of cormlets in the lowermost and sometimes upper leaf axils. *Micranthus cruciatus* bears no more than one or two small cormlets, these in the axil of the lowermost leaf. The pale mauve-blue or sometimes dark blue flowers are notable in the short perianth tube, ± 3 mm long, in the style dividing at the mouth of the perianth tube and in the unusually long style branches up to 2.5 mm long, divided for up to one third their length. The narrow, heavily thickened leaf in *M. cruciatus* is similar to that in *M. filifolius*, but in other critical details the two are very different, the latter with coarsely fibrous corm tunics and a collar of fibres around the base of the stem.

Typical, hollow-leaved *M. plantagineus* with dark blue flowers also occurs in the Pakhuis and Bokkeveld mtns, as well as in the Cederberg but has not been recorded growing near *M. cruciatus*.

7. **Micranthus plantagineus** *Eckl.*, Topographisches Verzeichniss der Pflanzensammlung von C.F. Ecklon: 43 (1827), as a new name for *Ixia plantaginea* Aiton: 59 (1789), illegitimate superfluous name for *Gladiolus alopecuroides* L.; Goldblatt et al.: 140 (2013). *Watsonia plantaginea* Ker Gawl.: t. 553 (1803), as a new name for *Ixia plantaginea* Aiton and illegitimate superfluous name for *G. alopecuroides* L. Type: South Africa, without precise locality, *Masson s.n. BM922008* (BM, holo.: narrow-leaved specimens mounted with the type (*Nelson 1777*) with broad, flat leaves are *M. alopecuroides*]).

Phalangium spicatum Houtt.: 115 (1780). Type: South Africa, without precise locality or collector, illustration in Houttuyn: t. 80 f. 2 (1780).

Micranthus plantagineus var. *junceus* Baker: 179 (1892). *M. junceus* (Baker) N.E.Br.: 138 (1929). Type: South Africa, [Western Cape], Groenekloof and vicinity, *Zeyher 1611* (K, lecto., designated by Goldblatt & Manning: 140 (2013), K000320508; PRE, isolecto.; other collections numbered



Zeyher 1611 in PRE and SAM are from Klipfontein or Tulbagh, thus not type material).

[*Phalangium spicatum* Burm.f.: 3 (1768), invalid name without description. The cited illustration, Plukenet: t. 310, f. 1 (1694), lacks text or figure analysis and probably represents *Ixia scillaris* L.; specimen in G: Herb. Burman is *Micranthus* and designated the 'type'. *Micranthus spicatus* (Burm.f.) N.E.Br.: 138 (1929), invalid name.]

Plants 200–400(–650) mm high, base without collar of fibres. *Corm* globose, 12–15 mm diam., tunics of dark brown, medium-textured, reticulate fibres drawn into fine points above. *Stem* simple or with up to 9 short branches, with cormlets in axil of lowermost leaf, sometimes of upper cataphyll, rarely other leaf axils. *Leaves* (2)3(4), green at flowering, lowermost leaf longest, blades terete or oval in section, hollow, 2.0–3.5 mm diam., smooth when fresh with translucent veins, when dry, veins appearing thickened with homologue of marginal vein pair more prominent, usually reaching to middle of spike to shortly exceeding spike, uppermost 1 or 2 leaves sheathing for most of length, with free part often slightly longer than sheath. *Spike* (16–)40- to 100-flowered, lower bracts sometimes subtending cormlets; bracts mid- to dark brown, ± 6 mm long but slightly smaller if subtending cormlets, outer with broad translucent margins, apices sharply acute and ultimately curved outward, inner bracts ± as long as outer, with 2 dark keels broadened toward base. *Flowers* usually dark blue, occasionally pale blue or white, evidently sometimes slightly sweetly scented, perianth tube 6–7 mm long; tepals oblong, with thickened subapical ridge on reverse, (4–)6–7 × ± 1.2 mm. *Stamen* filaments ± 5 mm long; anthers oblong, 3–4 mm long. *Style* ± 7 mm long, dividing between lower ⅓ and middle of anthers (rarely ± 1 mm below anthers), branches 1.0–1.8 mm long, divided for ⅓–½ their length. *Capsules* smooth, ± urn-shaped or narrowly ovoid, (3)4–5 × 2–3 mm, with (2)3 or 4 seeds per locule. *Seeds* ± 4 mm long. *Flowering time*: October to December (rarely in May).

Distribution and ecology: widespread in the Cape flora region of South Africa, extending from the Bokkeveld Mtns near Nieuwoudtville in Northern Cape south through Western Cape to the Cape Peninsula and east to Port Elizabeth in Eastern Cape but poorly represented in the Little Karoo and Swartberg; typically in seasonally wet habitats, often in marshy sites, along streams, or at least in places that are waterlogged in the winter months.

Diagnosis: identification of *Micranthus plantagineus* depends largely on leaf morphology: the two to four leaves are straight, firm-textured, erect, hollow and round to oval in section, ± 2–3 mm diam., and reach or shortly exceed the spike. When alive the leaves are smooth with the veins evident as paler, translucent lines. On drying, the veins appear hyaline and the veins at the adaxial and abaxial poles are somewhat more prominent. The stem is often branched, and as many as four (exceptionally

Distribution of ***Micranthus plantagineus***.

nine) short branches may be produced shortly below the base of the main spike, these seldom exceeding half the length of the main spike. The lower flowers of the spike are often replaced by cormlets [as many as five may be present in an axil]. The feature is not universal and plants may have normal flowers and capsules from base to apex of the spike. A second characteristic feature of *M. plantagineus* is the presence of one or more cormlets in the lowermost leaf axil (not invariably present in other species) and occasionally in the axils of the upper cataphyll and one or more of the upper leaves. Plants lack a collar of fibres around the base (in contrast to superficially similar *M. filifolius* and *M. tubulosus*).

There are two, somewhat poorly defined morphs of the species. One has narrow leaves, ± 2 mm diam. when alive, and slender capsules, ± 4.3 × 1.5 mm. Plants with mature capsules have (1)2 fusiform-angular seeds per capsule, ± 3.7–4.0 mm long. The second morph has broader leaves, 2–3 mm diam. when alive, and urn-shaped capsules ± 5 × 2–3 mm. Capsules have 4 seeds per locule, these flattened-angular, 3.0–3.5 mm long. A collection from a marshy site on Viljoen's Pass made in May 1935 conforms exactly to *Micranthus plantagineus*, the only apparent difference being the flowering time.

Interspecific hybrids are not uncommon in *Micranthus* and are likely to occur when two or more species co-occur. Most striking are those between *M. plantagineus* and *M. tubulosus*. The two species flower together at the foot of the Elandskloof Mtns in Elandsberg Nature Reserve and present a remarkable sight. The hybrids are locally very common growing with typical *M. tubulosus* and are always slightly shorter that the parent, 100–150 mm high, and like it have a well-developed collar of fairly coarse fibres around base. The other parent is less common but present in small clumps, recognised by its erect habit, straight leaves and pale blue flowers. The hybrid is evidently fertile and stands out in having a slightly flexuose stem and narrower leaves than either parent. Unlike *M. tubulosus*, which they otherwise most closely resemble, hybrid individuals bear small cormlets at aerial nodes and sometimes at the base of

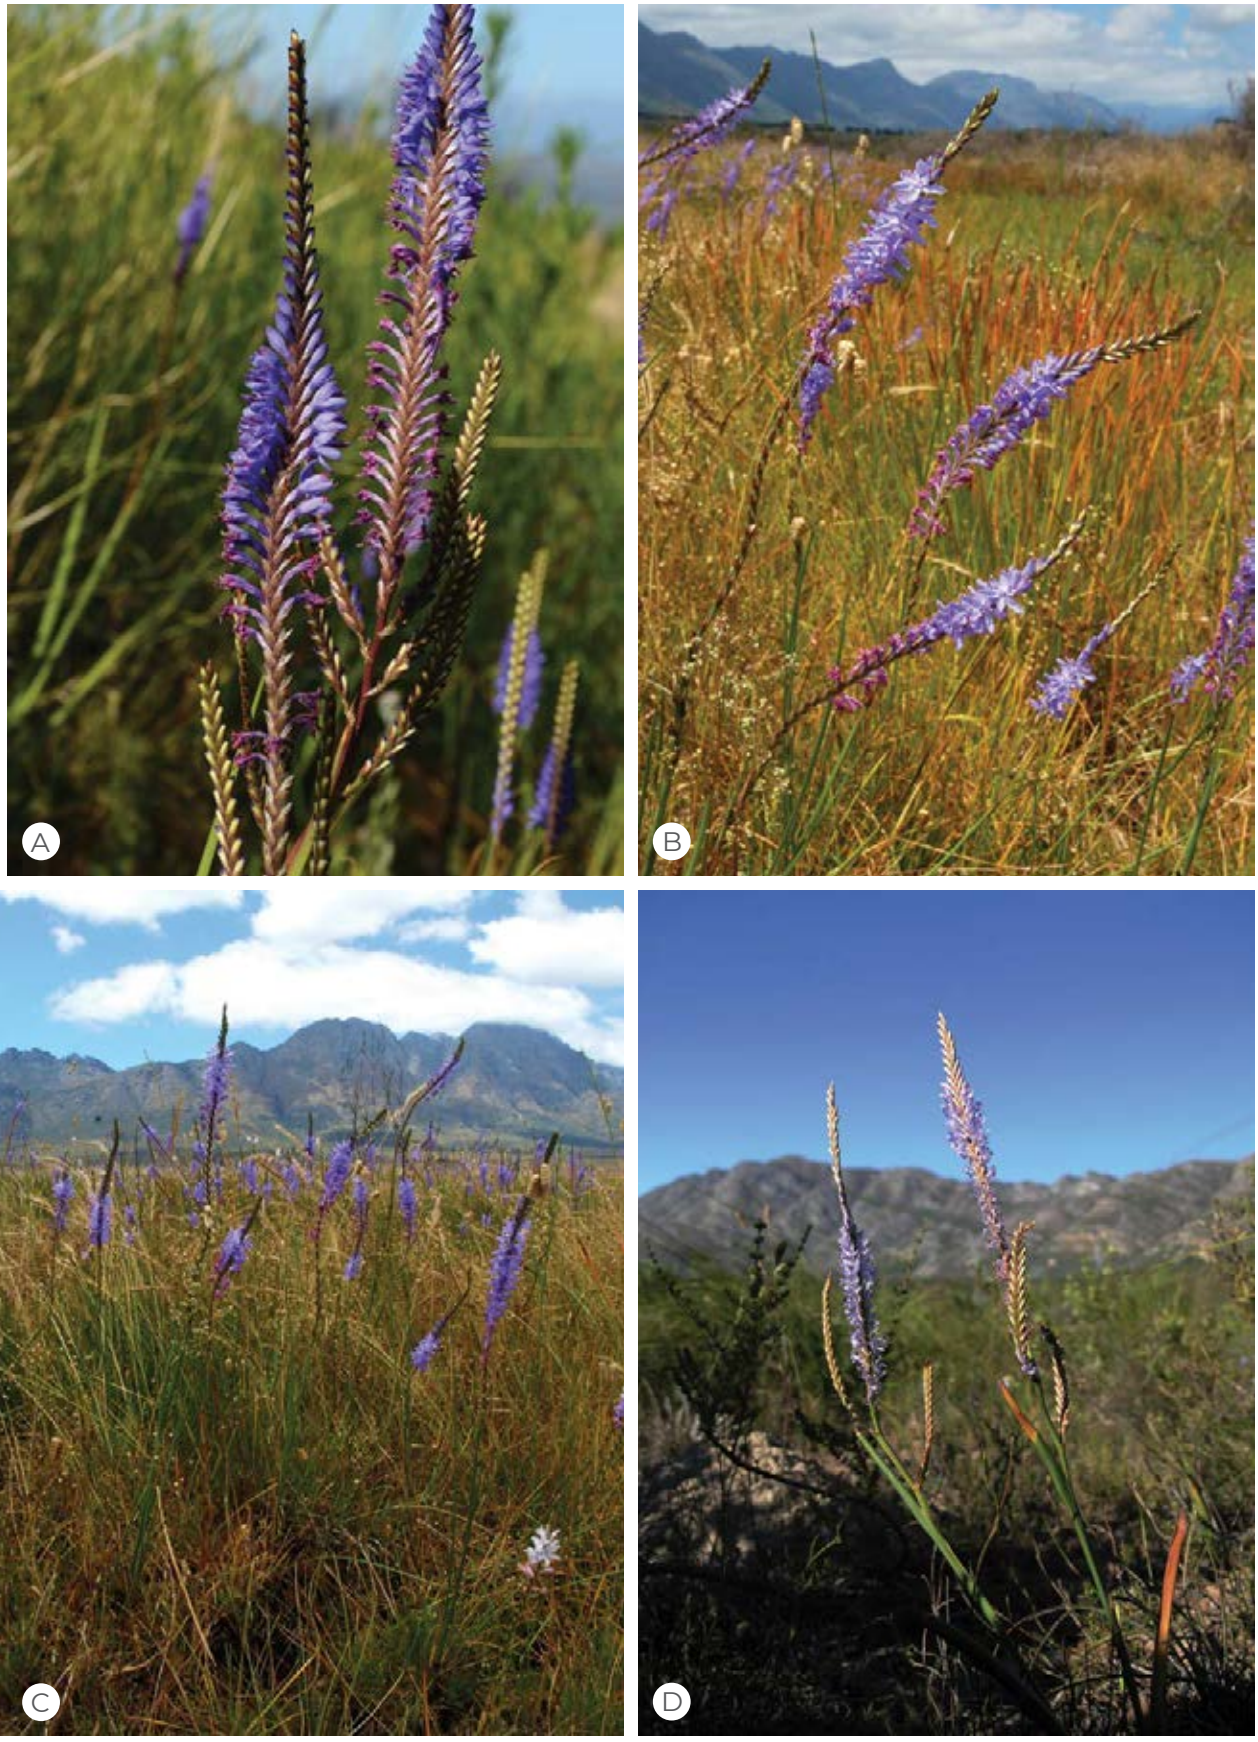


Plate 14: A, ***Micranthus plantagineus***, Cape Peninsula, WC; B & C, ***M. plantagineus***, Hermon, WC; D, ***M. tubulosus***, Hermon, WC.

the spike. Similar hybrid plants have also been recorded near Elim where *M. tubulosus* and *M. plantagineus* also grew side by side.

Less common are hybrids between *Micranthus tubulosus* and *M. alopecuroides*, but at Elandsberg Nature Reserve we noted both species growing close to one another with apparent hybrids between them. The putative hybrids have short, plane leaves, in outline like those of *M. tubulosus* but not round in section, although the leaves have an airspace between the two surfaces and lack the visible main veins of *M. alopecuroides*.

10. **Codonorhiza**

Codonorhiza *Goldblatt & J.C.Manning* in Strelitzia 35: 88 (2015).
Type: *C. corymbosa* (L.) Goldblatt & J.C.Manning

Lapeirousia sect. *Fastigiatae* [as *Fastigiata*] Goldblatt: 15 (1972). *L.* subg. *Paniculatae* sect. *Fastigiatae* (Goldblatt) Goldblatt & J.C.Manning 77: 373 (1990). Type: *L. corymbosa* (L.) Ker Gawl. = *Codonorhiza corymbosa* (L.) Goldblatt & J.C.Manning

Revisionary account: Goldblatt & Manning: 88–103 (2015).

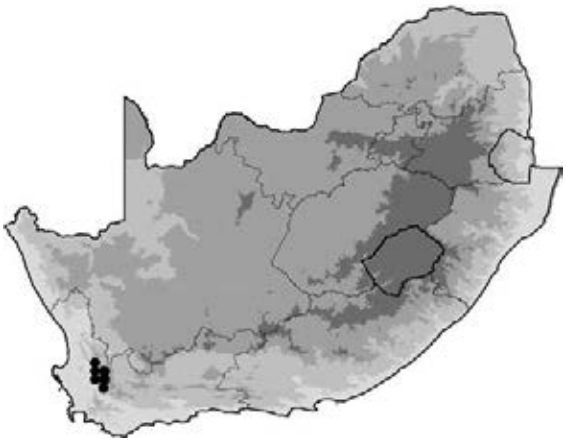
Named for the bell-shaped corm, *codon* (Greek for bell), *rhizon* (Greek for root).

Deciduous geophytes. *Corm* flat-based, broadly obconic (± triangular in profile), rooting from base and axillary in origin; tunics of dark brown to blackish, densely compacted fibres. *Foliage leaves* 2 or 3, lowermost inserted at ground level, longest, plane with ± prominent main vein, upper leaves progressively smaller. *Stem* aerial, compressed and angled to winged, simple or repeatedly branched. *Inflorescence* either a spike or a ± flat topped false panicle with sessile flowers; bracts two, opposed, green, firm-textured, usually obtuse to ± truncate, inner ± as long as outer, sometimes notched apically. *Flowers* radially symmetric or zygomorphic, long-lived, salver- or bowl-shaped, blue, purple, red, pink or white, usually with contrasting darker or lighter markings, sometimes sweetly scented; perianth tube ± cylindric or funnel-shaped, short or elongate; tepals subequal or unequal with outer whorl larger. *Stamens* symmetrically disposed or unilateral and arcuate; filaments slender, free; anthers oblong-linear, dehiscence longitudinal. *Ovary* globose; style filiform, branches usually forked for ± ½ their length, occasionally barely forked at tips. *Capsules* cartilaginous, globose to ± top-shaped and 3-lobed. *Seeds* ovoid(–orbicular), flattened at chalazal end, with reticulate to rugulose sculpturing; funicular collar prominent, surface cells ± flat (obscurely domed). *Pollen grains* monosulcate-perforate with 1-banded operculum. *Basic chromosome number x* = 10.

Species 7: restricted to Western Cape, South Africa.

Historically included in *Lapeirousia* because of the shared divided style branches and flat-based corms, *Codonorhiza* has been separated from that genus as a result of a molecular study, which shows the species comprising a clade sister to *Lapeirousia*, *Cyanixia, Savannosiphon* plus the tropical members of *Lapeirousia. Codonorhiza* holds together morphologically, sharing blackish corm tunics, often a flat-topped panicle-like inflorescence, and green, leathery floral bracts. The pollen grains are unusual in this alliance in having a 1-banded operculum rather than the ancestral 2-banded one. Despite its small size, *Codonorhiza* shows some floral diversity, flowers being adapted for bee, moth, hopliine beetle and possibly bee fly pollination. Flowers are blue in most species, but pale yellow (to white) in *C. fastigiata*, dull yellow or dark maroon in *L. micrantha* and mauve-pink in *L. falcata*, the only species with a spicate inflorescence.

Key to species



1a Inflorescence a spike; flowers white to pink, lower tepals with purple or red marks in basal half; perianth tube cylindric. . . . . 1. *C. falcata*
1b Inflorescence a flat-topped false panicle with ultimate branches bearing 1 to 5 sessile flowers; flowers predominantly blue, yellow or maroon to light brown; perianth tube cylindric or funnel-shaped:
2a Perianth tube (14–)18–20 mm long; tepals 7–8 mm long . . . . . 3. *C. pillansii*
2b Perianth tube 3–12 mm long:
3a Flowers dull yellow, creamy brown or maroon; perianth tube cylindric 8–10 mm long, ± twice as long as tepals . . . . . 2. *C. micrantha*
3b Flowers blue to violet or pale yellow; perianth tube funnel-shaped, shorter than tepals:
4a Flowers zygomorphic with unilateral stamens; perianth blue to violet, with white or dark blue-black contrasting markings:
5a Flowers medium to dark blue(–violet) with white, bracket-shaped band in basal ⅓ of lower tepals; anthers 3–4 mm long; pollen blue or grey; tepals 12–15 mm long. . . . . 5. *C. elandsmontana*
5b Flowers deep blue(–violet) with dark blue, red-purple or blackish mark (sometimes outlined in white) at base of lower tepals; anthers 3–5 mm long; pollen usually dark red-brown, blue or pale grey; tepals 14–20 mm long . . . . . 4. *C. azurea*
4b Flowers actinomorphic with stamens ascending; perianth blue (rarely white) or pale yellow:
6a Perianth light to dark blue with white, star-shaped mark in centre outlined in darker colour; tepals 6–10 mm long; filaments 5–6 mm long . . . . . 6. *C. corymbosa*
6b Perianth pale yellow, each tepal with small dark mark in lower midline; tepals 14–15 mm long; filaments ± 10 mm long . . . . . 7. *C. fastigiata*

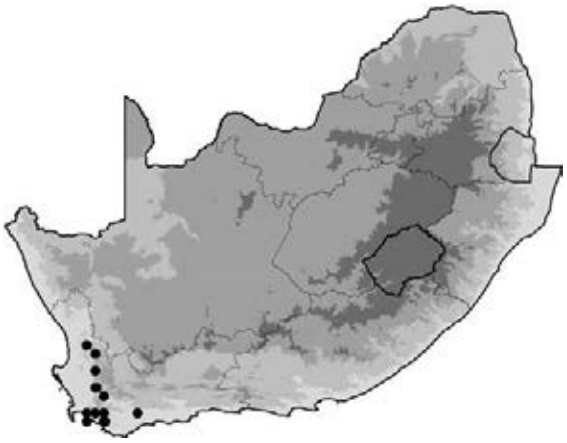
1. **Codonorhiza falcata** *(L.f.) Goldblatt & J.C.Manning* in Strelitzia 35: 89 (2015). *Gladiolus falcatus* L.f.: 96 (1782). *Lapeirousia falcata* (L.f.) Ker Gawl.: 238 (1804); Goldblatt: 28 (1972). *Ovieda falcata* (L.f.) Spreng.: 147 (1824). *Peyrousia falcata* (L.f.) Sweet: 499 (1830a). *Meristostigma falcatum* (L.f.) A.Dietr.: 594 (1833). Type: South Africa, without precise locality, *Thunberg s.n.* (UPS-THUNB 1025, holo.).

Lapeirousia pappei Baker: 170 (1892). Type: South Africa, [Western Cape], Winterhoeksberg, Tulbagh, *Pappe s.n.* (K, holo.; BOL, iso.).

Plants short and compact to fairly slender, seldom exceeding 100 mm, simple or with up to 3 branches from near base, stem terete. *Corm* ± 8 mm diam., broadly obconic, tunics dark brown to black, rugose, split longitudinally at base and apex. *Leaves* usually 2, lowermost basal, longest, falcate, ± plane with main vein slightly raised, ± leathery, mostly 5–8 mm wide; upper leaf much shorter. *Inflorescence* a spike, with up to 12 flowers in 2 ranks; bracts green with red margins, outer ± 6 mm long, inner 4–5 mm long. *Flowers* zygomorphic, pale pink to nearly white, lower 3 tepals each with dark pink to mauve or red spot in lower midline, unscented; perianth tube ± cylindric, 12–17 mm long, slightly wider in upper 3–4 mm; tepals ovate-oblong 7–8 × ± 3 mm. *Filaments* unilateral, ± erect, ± 6 mm long, exserted ± 3 mm; anthers ± 1.2 mm long, white; pollen white. *Style* erect, dividing shortly below apex of filaments, branches ± 2.3 mm long, deeply divided, spreading between anthers. *Capsules* top-shaped and 3-angled, 4–5 mm long. *Seeds* ovoid-orbicular, flattened at chalazal end, brown, ± 0.6–0.9 × 0.5 mm, reticulate, funicular collar up to 0.3 mm long. *Chromosome number* 2*n* = 20. *Flowering time*: mainly September and October at lower elevations but as late as mid-December at high elevations.

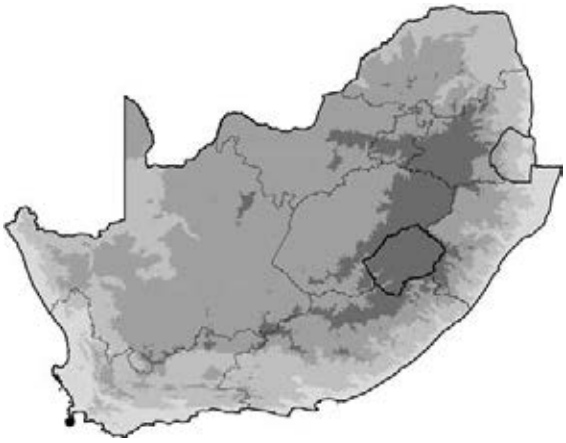
Distribution and ecology: restricted to the mountains of interior Western Cape, South Africa, extending from Matroosberg and Lakenvlei, east of Ceres, through the Agterwitsenberg Vlakte and Cold Bokkeveld to Elandskloof, south of Citrusdal; on sandstone substrates and often in crevices in rock outcrops or in seeps on sandstone pavement, mostly at middle elevations between 800 and 1 200 m elevation but at 2 200 m on Matroosberg.

Distribution of ***Codonorhiza falcata***.



Diagnosis: taxonomically isolated in the genus, *Codonorhiza falcata* is distinguished by the spike-like inflorescence unlike the flat-topped false panicle in other species. The flowers are pale pink to ± white with dark pink to mauve or red markings on the lower tepals, colours unique in the genus. *Codonorhiza falcata* is one of only three species with a cylindric perianth tube, but the other two, *L. micrantha* and *L. pillansii* are immediately distinguished by their flat-topped inflorescences and flowers of different colours.

2. **Codonorhiza micrantha** *(E.Mey. ex Klatt) Goldblatt & J.C.Manning* in Strelitzia 35: 90 (2015). *Ovieda micrantha* E.Mey. ex Klatt: 781 (1864). *Lapeirousia micrantha* (E.Mey. ex Klatt) Baker: 156 (1877); Goldblatt: 27 (1972). Type: South Africa, [Western Cape], Worcester, waterfall, *Ecklon & Zeyher Irid 253* (K, lecto., designated by Goldblatt & Manning: 90 (2015); MO, isolecto.).



[*Lapeirousia manuleiflora* Eckl.: 31 (1827), invalid name without description.]

[*Meristostigma manuleiflorum* Eckl. ex Steud.: 130 (1841), invalid name without description.]

Plants mostly 120–250 mm high. *Corm* 10–12 mm diam., broadly obconic; tunics dark brown to blackish, basal rim ± crenate, splitting vertically from base. *Stem* flexuose, repeatedly branched, branches subtended by bracts (1–)2–5 mm long, these sometimes leaf-like below, compressed and 2- to 4-winged *Leaves* 2 or 3, lowermost basal, ± falcate, 80–300 × 8–16 mm, margins usually undulate or slightly crisped, main vein prominent, upper leaves inserted near middle of stem, smaller than basal, not or hardly sheathing at base. *Inflorescence* a congested, ± flat-topped false panicle, flowers crowded at branch tips, ultimate branchlets 1- to 3-flowered; bracts green, ± leathery, 2–3 mm long, margins red, inner ± as long as outer, obtuse or inner slightly emarginate. *Flowers* weakly zygomorphic with perianth radially symmetric and stamens and style unilateral, dull yellow to buff-coloured or brown to dull maroon, acrid-sweet or clove-scented; perianth tube ± cylindric, 8–10 mm long; tepals subequal, ± elliptic, obtuse, 3–5 × ± 1.5–2.0 mm. *Stamens* unilateral, ± erect; filaments ± 3.5 mm long, exserted ± 1.5 mm; anthers 1.5–2.0 mm long; pollen dull yellow to buff-coloured. *Style* dividing between base and upper ⅓ of anthers; style branches ± 1 mm long, usually divided for up to ½ their length or undivided. *Capsules* top-shaped, triangular, 5–6 mm long, with up to 6 seeds per locule. *Seeds* ± ovoid, dark brown, 1.3–1.6 mm long, funicular appendage up to 0.5 mm long, surface reticulate. *Chromosome number* 2*n* = 20. *Flowering time*: late September to December.

Distribution of ***Codonorhiza micrantha***.

Distribution of ***Codonorhiza pillansii***.

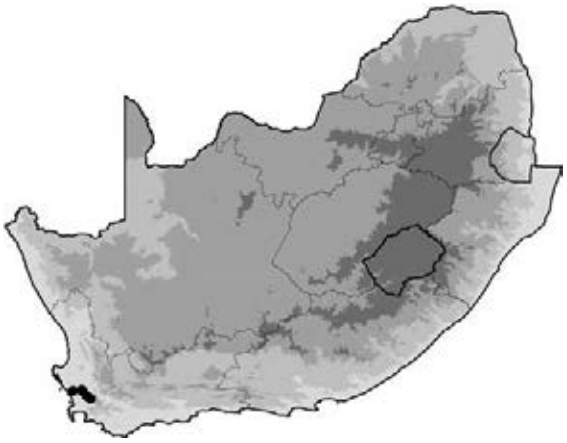
Distribution and ecology: extending from the Gifberg-Matsikamma Mtn. complex in the northwest to the Langeberg at Garcia's Pass in the southeast of Western Cape, South Africa; on sandy or stony ground, flowering only after fire.

Diagnosis: *Codonorhiza micrantha* stands out among the species with crowded, flat-topped inflorescences in its narrow, cylindric perianth tube, 8–10 mm long, and small, yellow to brown or maroon, strongly scented flowers. Pollination by settling moths is likely because of the dull flower colour and heavy, often clove-like floral odour that are matched in many other moth-pollinated species.

3. **Codonorhiza pillansii** *Goldblatt & J.C.Manning* in Strelitzia 35: 93 (2015). Type: South Africa, [Western Cape], Cape Peninsula, western edge of plateau west of Buffels Bay, 22 Nov. 1921, *Pillans 8928* (BOL, holo.; MO, iso.).

Plants 100–150 mm high, repeatedly branched, upper branches subtended by bracts up to 10 mm long, stem ± flexuose, compressed and 2-winged. *Corm* ± 10 mm diam., broadly obconic; tunics blackish, splitting vertically at base and apex. *Leaves* 2 or 3, lowermost basal and longest, usually falcate, 40–100 × 3–4 mm, acute, with prominent main vein, margins plane, slightly thickened, not or hardly sheathing at base; upper leaves similar, inserted in middle of stem, 25–30 mm long. *Inflorescence* a congested, flat-topped false panicle, flowers crowded at branch tips, ultimate branchlets mostly 2- or 3-flowered; bracts 5–7 mm long, green, leathery, inner ± as long as outer or slightly longer, obtuse or inner ± emarginate. *Flowers* zygomorphic, dark blue, evidently uniformly coloured, scent unknown; perianth tube ± cylindric, (14–)18–20 mm long, ± 1 mm diam. at base, ± 2 mm diam. at mouth; tepals 7–8 × ± 3 mm. *Filaments* unilateral, inserted ± 4 mm below mouth of tube, 7–8 mm long, exserted 3–4 mm; anthers ± 3 mm long; pollen colour unknown. *Style* dividing opposite middle and apex of anthers, ± 2.5 mm long, divided for ± ½ their length. *Capsules* top-shaped, 3-lobed, ± 5 mm long (mature capsules and seeds unknown). *Flowering time*: October and November.

Distribution and ecology: poorly understood and known from a single collection made in 1921 in the Cape Point Nature Reserve in Western Cape, South Africa; most likely in low fynbos on sandy, stony ground, probably flowering only after fire.



Diagnosis: *Codonorhiza pillansii* broadly resembles *C. corymbosa* in the falcate leaf and many-flowered, flat-topped inflorescence, but is immediately recognised by the flowers with a slender tube (14–)18–20 mm long. The filaments are unilateral and the tepals are subequal in size and evidently symmetrical in disposition. The tepals appear uniformly coloured, which accords with the comment 'flowers blue' on the type collection.

4. **Codonorhiza azurea** *(Eckl. ex Baker) Goldblatt & J.C.Manning* in Strelitzia 35: 93 (2015). *Lapeirousia corymbosa* var. *azurea* Eckl. ex Baker: 90 (1896). *L. azurea* (Eckl. ex Baker) Goldblatt in Goldblatt & Manning: 333 (1992). Type: South Africa, [Western Cape], between Paarl and Pont, *Drège 8509a* (K, lecto., designated by Goldblatt & Manning: 334 (1992); BM, G, MO, P, isolecto.).

[*Lapeirousia azurea* Eckl.: 31 (1827), invalid name without description.]

[*Meristostigma azureum* Eckl. ex Steud.: 131 (1841), invalid name without description.]

Plants 70–180(–260) mm high. *Corms* 12–16 mm in diam., tunics blackish, basal rim split vertically. *Stem* 5- to 7-branched, branches subtended by bracts (1–)2–5 mm long, those below appearing leaf-like, stem compressed and winged. *Leaves* 2, lowermost inserted at ground level, largest, falcate, 50–120(–240) × (6–)10–15 mm, margins undulate and crisped, obtuse to subapiculate, with prominent main vein and a pair of secondary veins (rarely one) on either side almost as prominent, second leaf inserted near middle of

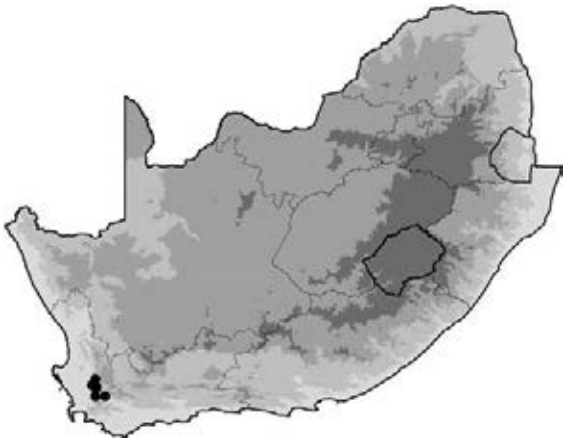
Distribution of ***Codonorhiza azurea***.

stem, 20–70 mm long, oblong-lanceolate, margins ± straight, not or hardly sheathing at base. *Inflorescence* a congested, flat-topped false panicle, flowers crowded at branch tips, ultimate branchlets with 1 or 2 sessile flowers; bracts green, firm-textured, 9–11 mm long, outer folded in midline, margins often red, inner obtuse or slightly emarginate. *Flowers* zygomorphic, tilted backward, dark blue to violet, with triangular, dark blue-black or red-purple blotch at base of lower 3 and sometimes adjacent upper lateral tepals; perianth tube funnel-shaped, 10–12 mm long; tepals elliptic-ovate, obtuse, mostly 17–20 × 7–8 mm. *Filaments* unilateral, ascending or extended horizontally due to adaxial tilting of flower, 11–15 mm long, exserted for 8–10 mm; anthers 3–5 mm long; pollen dark blue or red-brown. *Style* dividing opposite upper ⅓ of anthers; branches 2.5–3.0 mm long, divided for ± ½ their length. *Capsules* ± top-shaped and 3-lobed, ± 6 mm long, with up to 8 seeds per locule. *Seeds* red-brown, ovoid, truncate at chalazal end, rugulo-reticulate, ± 1.0 × 1.0–1.3 mm, with funicular appendage 0.2–0.4 mm long. *Chromosome number* 2*n* = 20 ± 0–2b *Flowering time*: late September to late October.

Distribution and ecology: restricted to lowland sites in southwestern Western Cape, South Africa, between Paarl, Mamre and Riebeeck Kasteel north of Malmesbury; in granite-derived gravel soils rather than the shale-derived clay soils also common in the area, becoming increasingly rare.

The flowers with dark blue-black or red-purple markings are evidently adapted for pollination by hopliine beetles, but visits by large anthophorine bees have also been recorded.

Diagnosis: *Codonorhiza azurea* is distinguished by its large, zygomorphic, intensely dark blue flower bearing large black or dark red blotches on the adaxial tepals. The perianth tube is 8–12 mm long and the tepals (12–)16–20 mm long. The flower is tilted back toward the axis, especially in crowded inflorescences, when the posterior (adaxial) tepals, usually erect, are tilted out of position and come to lie horizontally, thus below the abaxial (lower) tepals, a type of floral presentation also occurring in *C. elandsmontana*.



5. **Codonorhiza elandsmontana** *Goldblatt & J.C.Manning* in Strelitzia 35: 96 (2015). Type: South Africa, Western Cape, Bo-Hermon, foot of Elandskloof Mtns, Elandsberg Nature Reserve, stony ground, 11 Sept. 2010, *Goldblatt & Manning 13518* (NBG, holo.; MO, PRE, iso.).

Plants 150–210 mm high, several-branched, branches subtended by bracts (1–)2–5 mm long, or sometimes leaf-like below and longer; stem ± flexuose, compressed and 2-winged. *Corm* obconic, 10–15 mm diam., tunics blackish, splitting vertically from base and apex. *Leaves* 2(3), lower 1(2) basal, usually falcate (lanceolate), 100–250(–400) × 10–14 mm, subacute to acute, with prominent main vein and 1 or a pair of secondary veins on either side also raised; margins usually ± straight to slightly undulate, rarely slightly crisped; uppermost leaf inserted near middle of stem, 25–80 mm long, narrowly oblong, not or hardly sheathing at base. *Inflorescence* a congested, flat-topped false panicle, ultimate branchlets 1- or 2-flowered; bracts green, leathery, 4–7 mm long, usually red distally and slightly warty, outer obtuse to truncate, keeled, inner ± obtuse to slightly emarginate. *Flowers* zygomorphic, tilted backward with adaxial (dorsal and upper lateral) tepals often nearly horizontal, light to dark blue with white throat and basal ½ of abaxial tepals with white, bracket-shaped band, not scented; perianth tube funnel-shaped, 8–10 mm long; tepals elliptic, obtuse, 10–15 × 4–5 mm. *Stamens* ± unilateral, ± horizontal and facing upward; filaments 9–10 mm long, exserted 7–8 mm; anthers 3.0–3.5 mm long; pollen blue to blue-grey, or purple. *Style* unilateral, dividing opposite or shortly beyond anther apices, held below stamens; style branches 1.5–2.0 mm long, divided for ± ½ their length. *Capsules* top-shaped, 3-lobed, ± 5 mm long, with up to 6 seeds per locule. *Seeds* ovoid, reticulately sculptured, ± flattened to concave at chalazal end, dark brown, ± 0.8–1.0 × 1.0–1.2 mm; funicular collar up to 0.3 mm long. *Flowering time*: late September and October.

Distribution and ecology: locally common in the Tulbagh Valley, in Western Cape, South Africa, but extending eastward through the upper Breede River Valley to Botha and westward to Gouda and the lower slopes of the Elandskloof Mtns as far south as Bain's Kloof; in rocky ground, often in clay or clay loam.

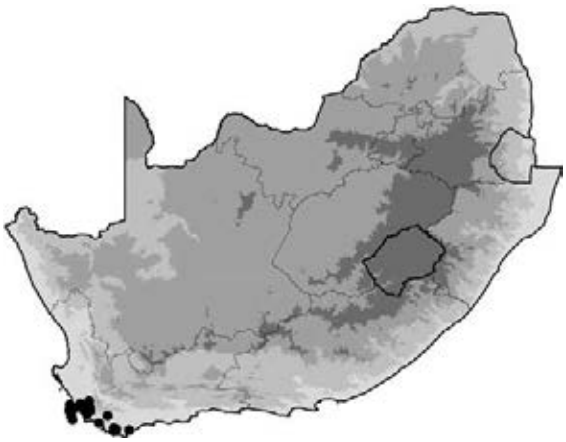
The tabanid fly, *Philoliche angulata*, which has a proboscis ± 8 mm long, is an important and possibly only pollinator of the species.

Diagnosis: long confused with *Codonorhiza corymbosa* or sometimes with *C. azurea*, both of which it broadly resembles, especially in herbarium specimens, *C. elandsmontana* is recognised by the zygomorphic flowers with unilateral stamens and white, bracket-shaped markings only on the three abaxial tepals. Other floral details

Distribution of ***Codonorhiza elandsmontana***.

include a perianth tube, 8–10 mm long vs. 4–7(8) mm long and the larger tepals, 10–15 mm long (vs. 6–10 mm long in *C. corymbosa*). Flowers of *C. corymbosa* are radially symmetric with all six tepals bearing white, bracket-shaped markings. *Codonorhiza elandsmontana* may also be confused with *C. azurea* and *C. fastigiata*, which are similar in stature and have a broad basal leaf with undulate to crisped margins. The larger flowers of *C. azurea* are zygomorphic like those of *C. elandsmontana* but have a perianth tube 10–12 mm long and tepals mostly 17–20 × 7–8 mm and the three abaxial tepals have a dark blue-black or red markings in the lower half. Possible hybrids between *C. azurea* and *C. fastigiata* have been recorded at Piketberg Road (Gouda).

6. **Codonorhiza corymbosa** *(L.) Goldblatt & J.C.Manning* in Strelitzia 35: 98 (2015). *Ixia corymbosa* L.: 4 (1756). *Ovieda corymbosa* (L.) Spreng.: 140 (1824). *Lapeirousia corymbosa* (L.) Ker Gawl.: t. 595 (1802); Baker: 90 (1896) [incl. *C. azurea*]; Marloth: pl. 43 (1915); Goldblatt: 20 (1972, excl. subsp. *fastigiata* and subsp. *alta*). *Peyrousia corymbosa* (L.) Poir.: 365 (1826). *Meristostigma corymbosum* (L.) A.Dietr.: 594 (1833). Type: South Africa, [Western Cape], near Camps Bay, sandy rocky ground, *MacOwan s.n.* in *Herb. Norm. Austr. Afr. 268* (SAM, neo., designated by Goldblatt & Manning: 332 (1992); BM, BOL, G, iso.).



Ixia crispifolia Andrews: t. 35 (1798). Type: South Africa, without precise locality or collector, figure in Andrews: t. 35 (1798).

Lapeirousia corymbosa var. *grandiflora* Klatt: 204 (1885). Type: South Africa, [Western Cape], mountains near 'Houw Hoek' (Noord Hoek probably intended), Sept. 1883, *MacOwan 2284a* (K, SAM 20988, syn.).

Lapeirousia corymbosa var. *purpurea* Klatt: 204 (1885). Type: South Africa, [Western Cape], sandy depressions, Fish Hoek, Sept. 1883, *MacOwan 2284b* (SAM [as Noord Hoek], syn.).

Plants 60–150 mm high, 4- to 10-branched, branches subtended by bracts (1–)2–5 mm long, these sometimes leaf-like below and longer, stem ± flexuose, compressed and 2-winged. *Corm* obconic, 10–15 mm diam., tunics blackish, splitting vertically from base and apex. *Leaves* 2 or 3, lower 1(2) basal, usually falcate (or ± lanceolate), 100–130 × 4–8(–10) mm, subacute to acute, with prominent main vein and 1 or a pair of secondary veins on either side slightly less prominent, margins ± straight, slightly undulate, rarely slightly crisped, uppermost leaf inserted in middle ⅓ of stem, 25–80 mm long, narrowly oblong, not or hardly sheathing at base. *Inflorescence* a congested, flat-topped false panicle, ultimate branchlets bearing 1 or 2 sessile flowers; bracts green, leathery, 3.5–7.0 mm long, margins usually red, obtuse or inner slightly emarginate. *Flowers* actinomorphic, light to dark blue with white throat and lower half of tepals with white, bracket-shaped band (rarely ± white with pale blue markings), not scented; perianth tube funnel-shaped, 4–7(–8) mm long; tepals elliptic, obtuse, 6–10 × 2.3–3.5 mm. *Stamens* symmetrically arranged around style; filaments 5–6 mm long, exserted 3–4 mm; anthers 1.8–3.0 mm long, usually blue; pollen blue to grey, or ± white. *Style* dividing between base and upper ⅓ of anthers, often deflexed in older flowers; style branches 1.5–2.0 mm long, divided for ± ½ their length. *Capsules* top-shaped, 3-lobed, 4.5–6.5 mm long, with up to 6 seeds per locule. *Seeds* ovoid, reticulately sculptured, flattened to concave at chalazal end, dark brown, 0.7–1.0 mm long; funicular collar up to 0.5 mm long. *Flowering time*: late September and October, occasionally until mid-November.

Distribution and ecology: extending along the coastal plain of Western Cape, South Africa, from near Darling through the Cape Peninsula and Cape Flats to Bredasdorp and Elim; flowering relatively late in spring, on sandy, well-drained soils derived from Cape sandstone or weathered granite but occasionally also on clay loam. Once fairly common, it is becoming rare, especially on lowland sites, now mostly given over to farmland or urban development. It can still be found on lower mountain slopes and, especially after fires, may be common.

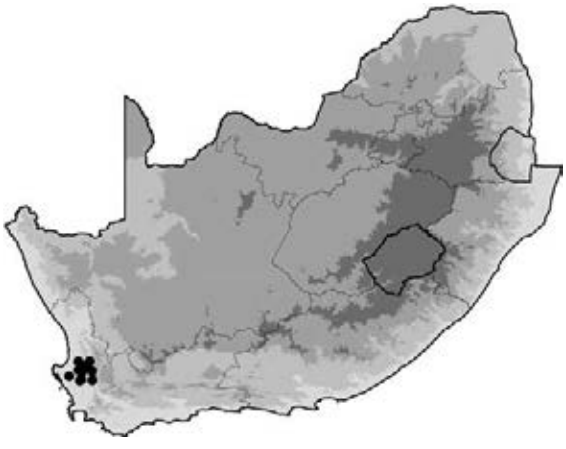
Distribution of ***Codonorhiza corymbosa***.

Diagnosis: the crowded, ± flat-topped inflorescence of radially symmetric flowers with a pale to fairly dark blue perianth and white bracket-shaped marks in the lower middle of the tepals distinguish *Codonorhiza corymbosa* from other *Codonorhiza* species. Although small, the upright flowers are particularly attractive with their white star-shaped central marking. *Codonorhiza corymbosa* is most easily confused with *C. elandsmontana* from the Worcester and Tulbagh Districts, but that species has unilateral stamens, and although the perianth shape and colouration is similar, the flowers are larger and only the lower (abaxial) tepals have white markings. The perianth tube of *C. elandsmontana* is 8–10 mm long and the tepals 10–15 mm long (vs. a tube 4–7(8) mm long and tepals 6–10 mm in *C. corymbosa*). Confusion is also possible with the deep blue-flowered *C. azurea*, especially when specimens are poorly preserved, but the flowers and bracts of *C. corymbosa* are always smaller than those of *C. azurea*, the tepals of which are 17–20 mm long. When alive the larger, dark blue, zygomorphic, abaxially tilted flowers of *C. azurea* with unilateral, horizontally extended stamens are unmistakable.

White-flowered plants occur occasionally in populations across the range of *Codonorhiza corymbosa*, but at Riverlands near Malmesbury the entire population has white flowers. In other respects the plants from Riverlands appear to conform closely with typical *C. corymbosa*. Plants tentatively included in *C. corymbosa* in the past from Cape Point Nature Reserve with slender perianth tube 18–20 mm long and tepals 7–8 × ± 3 mm are now regarded as a separate species, *C. pillansii*. The perianth tube length and shape are inconsistent with *C. corymbosa*, the funnel-shaped perianth tube of which is 4–7 mm long.

7. **Codonorhiza fastigiata** *(Lam.) Goldblatt & J.C.Manning* in Strelitzia 35: 101 (2015). *Lapeirousia fastigiata* (Lam.) Ker Gawl.: 238 (1804). *Ixia fastigiata* Lam.: 337 (1789). *L. corymbosa* subsp. *fastigiata* (Lam.) Goldblatt: 25 (1972). Type: South Africa, without precise locality or collector (P: Herb. Lamarck, holo.).

Ovieda purpureolutea Klatt: 781 (1864). *Lapeirousia purpureolutea* (Klatt) Baker: 515 (1877); 91 (1896). Type: South Africa, [Western Cape], Tulbagh, collector unknown, *Herb. Bergius s.n.* [SBT, lecto. designated by Goldblatt: 25 (1972)].



Lapeirousea corymbosa var. *rosea* Suess.: 88 (1951). Type: South Africa, [Western Cape], Saron, 29 Sept. 1946, *Rehm s.n.* (M, holo.).

Plants 100–200 mm high, several-branched, branches subtended by bracts (1–)2–3 mm long, lower sometimes ± leaf-like and longer, stem ± flexuose, compressed and narrowly winged, sheathed below by 2 membranous, pale or light brown cataphylls. *Corm* obconic, 10–16 mm diam., tunics blackish, splitting vertically from base and apex. *Leaves* 2, lowermost inserted at ground level, largest, falcate, 80–150(–250) × 11–18 mm, obtuse to subacute, with prominent main vein and pair of secondary veins on either side almost as prominent, margins usually undulate and crisped, rarely ± straight; upper leaf inserted near middle of stem, (12–)25–45 mm long, oblong-lanceolate, margins straight, not or hardly sheathing at base. *Inflorescence* a congested, ± flat-topped false panicle, ultimate branchlets bearring (1)2–5 sessile flowers; bracts green, often red on margins, 6–10 mm long, obtuse or inner emarginate. *Flowers* actinomorphic, pale yellow to nearly white with purple or brown median triangular mark in basal ⅓ of each tepal, sometimes flushed dull purple or brown outside, not scented; perianth tube funnel-shaped, 6.5–8.0 mm long; tepals elliptic, obtuse, 14–15 × 5–6 mm. *Stamens* symmetrically disposed, diverging; filaments ± 10 mm long; anthers 3–4 mm long, yellow; pollen white to pale yellow. *Style* dividing between base and middle of anthers; style branches 2.5–3.5 mm long, divided for ± ½ their length. *Capsules* top-shaped and 3-lobed, 5–6 mm long, with up to 6 seeds per locule. *Seeds* ovoid, reticulately sculptured, red-brown, darker on ridges, 0.8–0.9 mm long with funicular appendage up to 0.4 mm long. *Chromosome number* 2*n* = 20. *Flowering time*: late September to mid-October.

Distribution and ecology: once fairly common locally in Western Cape, South Africa, extending from Piekenierskloof Pass to Piketberg and Saron; most often on shale soils on hills and lower mountain slopes in renosterveld but sometimes on rocky, sandstone slopes; flowering is enhanced by clearing or burning.

Pollination of *C. fastigiata* has been little studied, but visits to the species by the large-bodied anthophorine and megachilid bees have been reported.

Diagnosis: pale yellow flowers and relatively large perianth with a tube 6–8 mm long and tepals 14–15 mm long are sufficient to distinguish *Codonorhiza fastigiata* from other species of the genus with flat-topped inflorescences, all of which have light to dark blue or violet flowers except *C. micrantha*, which has a buff-coloured to brown or maroon perianth but smaller flowers with a cylindric perianth tube. Both perianth and stamens

Distribution of ***Codonorhiza fastigiata***.

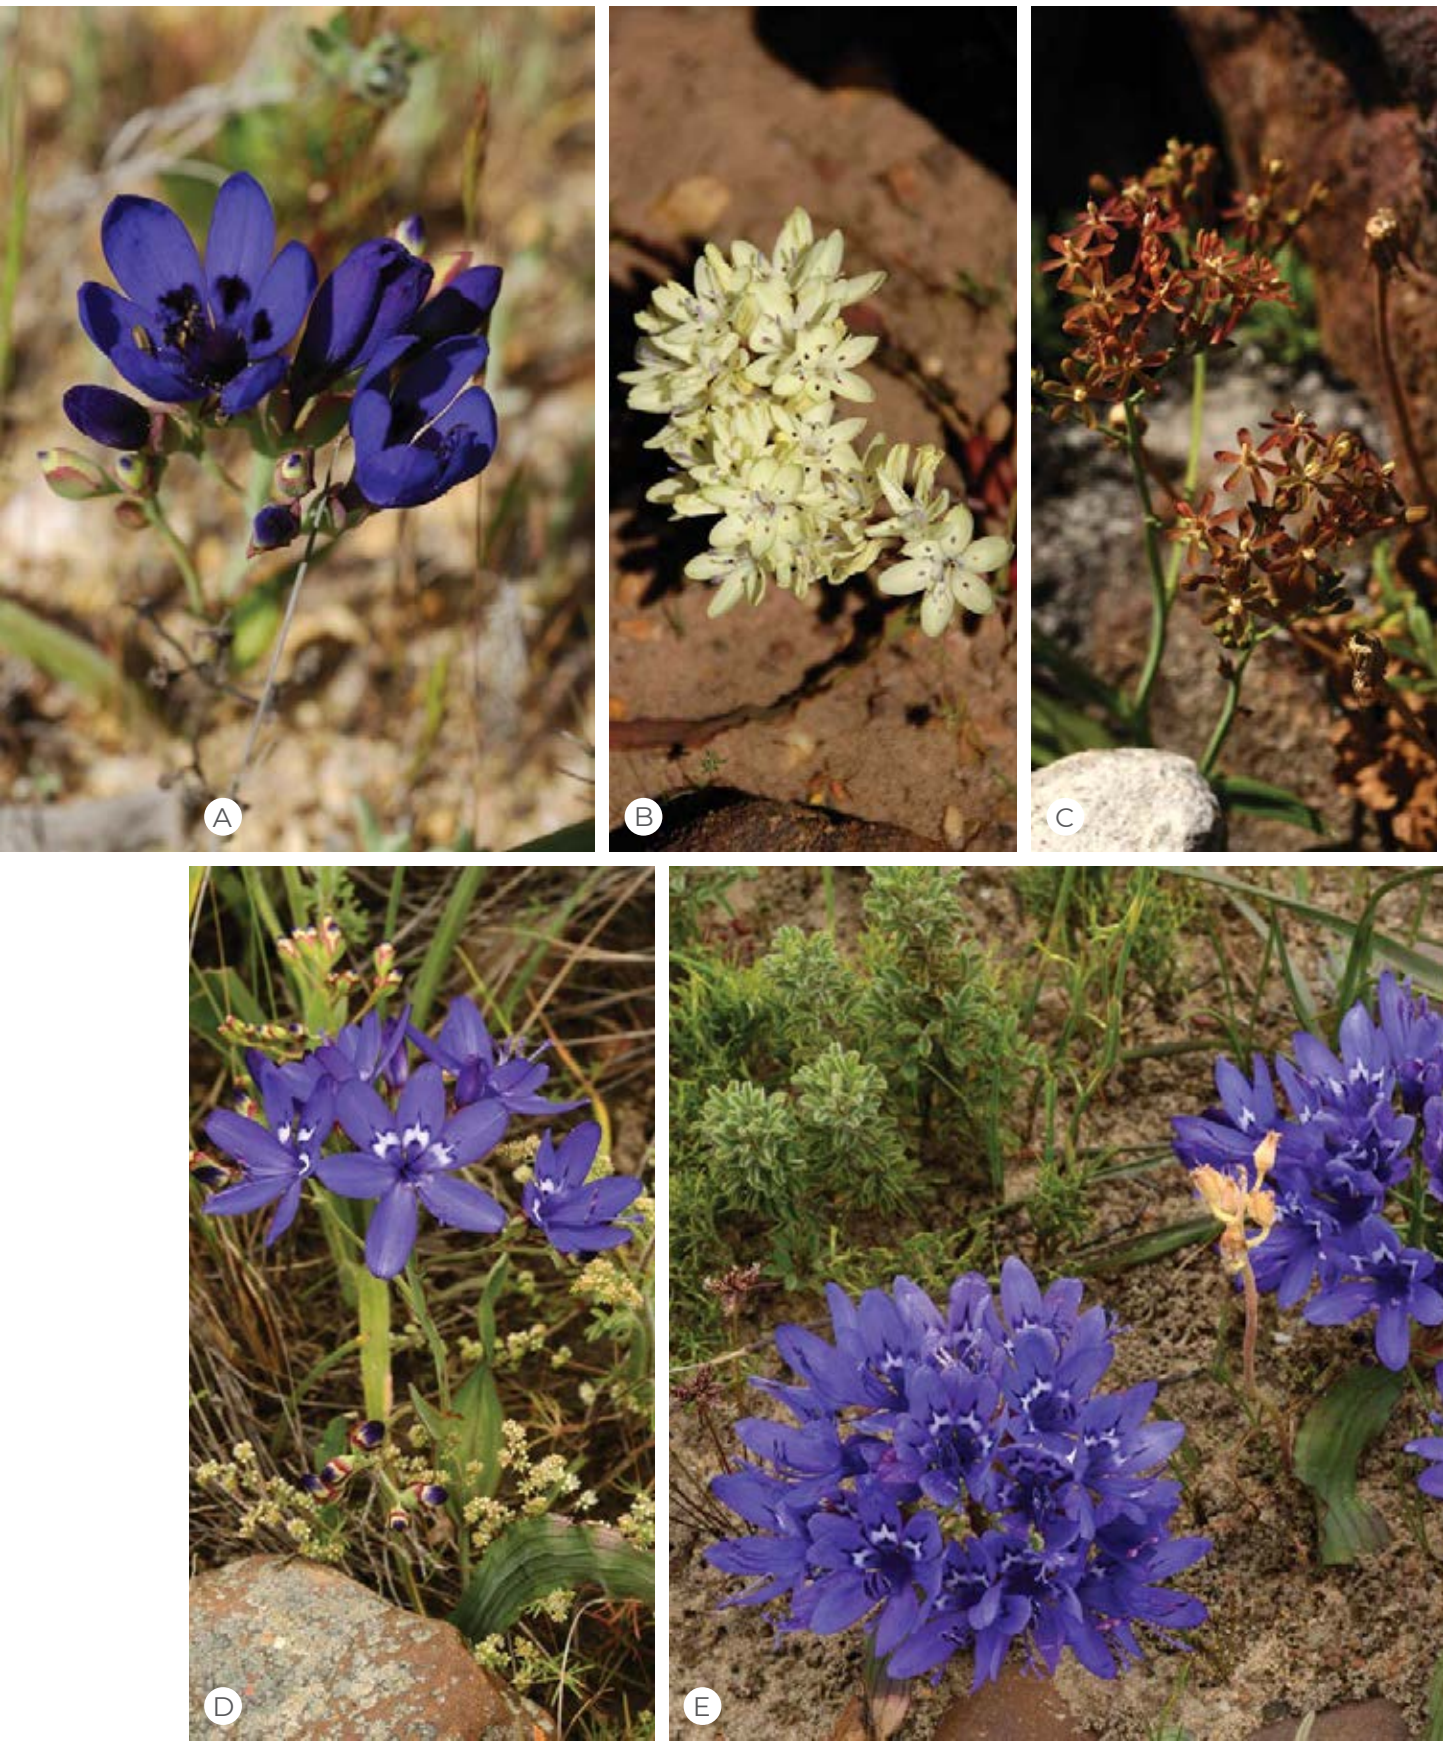


Plate 15: A, ***Codonorhiza azurea***, Malmesbury, WC; B, ***C. fastigiata***, Piketberg, WC; C, ***C. micrantha*** Bain's Kloof, WC; D & E, ***C. elandsmontana***, Hermon, WC.

of *C. fastigiata* are symmetrically arranged so that *C. azurea*, which has flowers of similar size and shape, can immediately be distinguished by its asymmetrically disposed stamens and perianth with markings only on the lower three tepals, as well as by its dark blue perianth.

Collections from Piketberg and Gouda that comprise plants with both yellow and blue flowers were thought to represent populations of plants intermediate between *Codonorhiza fastigiata* and *C. azurea* but likely represent hybrid individuals.

REFERENCES [See under 13. *Afrosolen*]

11. Schizorhiza

Schizorhiza *Goldblatt & J.C.Manning* in Strelitzia 35: 104 (2015).
Type: *S. neglecta* (Goldblatt) Goldblatt & J.C.Manning

Revisionary account: Goldblatt & Manning: 104–107 (2015).

For the coms that divide into several daughter corms at the end of the growing season, from the Greek *schizo* (split) and *rhizon* (root)

Deciduous geophytes. *Corm* ellipsoid with small flat base, rooting from base, axillary in origin, producing several new corms in place of parent corm at end of growing season; tunics of ± corky layers. *Foliage leaves* several, linear to sword-shaped, evidently plane but slightly pleated, with visible main vein; lowermost often longest and inserted on stem near ground level, upper leaves progressively smaller. *Stem* aerial, compressed and angled, branching repeatedly, producing cormlets in leaf axils above and below ground. *Inflorescence* much branched, forming a ± round-topped false panicle, with sessile flowers; bracts green, firm, inner ± as long as outer, acute or emarginate. *Flowers* zygomorphic, long-lived, often salver-shaped, lower (abaxial) tepals with contrasting darker markings; perianth tube ± cylindric; tepals subequal but dorsal slightly larger. *Stamens* unilateral; filaments slender, free; anthers oblong-linear, dehiscence longitudinal. *Ovary* globose, sessile; style filiform, branches forked for ± ½ their length. *Capsules* cartilaginous, ± top-shaped, 3-lobed above. *Seeds* ± globose, flattened at chalazal end, slightly wrinkled; surface cells ± flat. *Pollen grains* monosulcate-operculate, operculum 1-banded. *Basic chromosome number* $x = 6$; $2n = 12$ and 24.

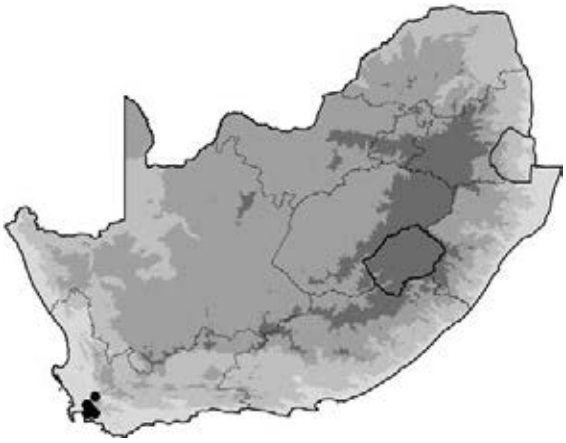
Species 1, only *S. neglecta*: mountains of southwestern Western Cape, South Africa.

Schizorhiza was recognised as a result of a molecular study, which retrieved the single species as sister to *Lapeirousia*¸ *Cyanixia, Savannosiphon* plus *Afrosolen* (Goldblatt & Manning 2015). It thus falls between the basal clade, *Codonorhiza*, and the remainder of the *Lapeirousia* group. Morphologically it shares somewhat leathery floral bracts, a many-branched, more-or-less corymbose compound inflorescence, and pollen grains with 1-banded operculum. It stands apart in the nearly ellipsoid corm with a small flat base, splitting into several daughter corms and cork-like tunics at the end of the growing season. The basic chromosome number, $x = 6$ also departs from that in *Codonorhiza*, $x = 10$. The flowers, however, most closely resemble those of short-tubed members of the eastern and tropical African genus *Afrosolen*, notably *A. sandersonii*.

1. **Schizorhiza neglecta** *(Goldblatt) Goldblatt & J.C.Manning* in Strelitzia 35: 104 (2015). *Lapeirousia neglecta* Goldblatt in Goldblatt & Manning in South African Journal of Botany 58: 335 (1992). Type: South Africa, [Western Cape], Jonkershoek, slopes near Berg River Nek, Nov. 1989, *Esterhuysen 36923* (BOL, holo.; B, BR, E, G, K, M, MO, NBG, P, PRE, S, SRGH, US, WAG, iso.).

   Lapeirousia corymbosa subsp. *alta* Goldblatt: 24 (1972). Type: South Africa, [Western Cape], near Steenbras Dam, Dec. 1945, *Lewis 1595* (SAM, holo.; BOL, SAM, iso.).

Plants 280–450(–550) mm high, laxly 5- to 7-branched, branches subtended by bracts 3–5(–12) mm long, those subtending lower branches becoming ± leaf-like, stem ± straight, compressed, 2-winged below, often ± square above and 4-angled to narrowly 4-winged; bearing 2 or more cormlets in axils of lower leaves. *Corm* 12–14 mm diam., with several cormlets at base; tunics corky to somewhat papery, brown, not accumulating. *Leaves* 3 to 6, lower 2 to 4 inserted below ground level and largest, narrowly lanceolate, lowermost reaching to middle to shortly exceeding inflorescence, 7–15 mm wide, with prominent main and a pair of secondary veins (rarely two pairs) on either side ± as prominent; upper 1 to 3 leaves inserted in lower half of stem, progressively shorter above, not or hardly sheathing at base. *Inflorescence* a lax, rounded to ± flat-topped false panicle, flowers crowded distally, ultimate branchlets bearing 1 or 2(–4) sessile flowers; bracts green, margins often red, 4–7 mm long, inner usually slightly longer than outer, ± membranous above at anthesis, acute or inner slightly emarginate. *Flowers* zygomorphic, either white, then lower tepals usually with one or a pair of purple median spots (Jonkershoek), or blue with darker blue to violet spear-shaped markings in lower midline and often white-dotted in centre of dark colour (Bain's Kloof), with slight sweet scent; perianth tube ± cylindric, 7–10 (Jonkershoek), 12–14 (Bain's Kloof and Steenbras) mm long, flared from 1 mm diam. at base to 2 mm at mouth; tepals elliptic, obtuse, unequal, dorsal 10–13 × ± 4.5 mm, lower held closely together, 10–12 × ± 4 mm wide. *Stamens* unilateral and arcuate; filaments 5 or 6 (Jonkershoek), ± 9 (Bain's Kloof) mm long, exserted 3–5 mm; anthers 3.3–4.5 mm long; pollen ± white. *Style* arching adaxial to filaments, dividing opposite lower to middle ⅓ of anthers; style branches ± 2 mm long, divided for ± ⅓ their length. *Capsules* top-shaped and 3-lobed, 4–5 mm long, sometimes flushed red before drying; with 1 or 2(3) per locule. *Seeds* globose to ovoid, sometimes flattened by pressure, slightly wrinkled, ± 2.0–2.5 × 1.7–2.5 mm, with small funicular collar. *Chromosome numbers* $2n = 12, 24$. *Flowering time*: mid-November to late January.



Distribution and ecology: restricted to a 65 km portion of the north–south trending mountains in the extreme

southwest of Western Cape, South Africa, from Bain's Kloof south to Jonkershoek and Steenbras; in rocky sandstone-derived soil at elevations of 400–1 000 m, generally in sheltered, wetter sites such as slopes below cliffs and near streams; flowering well only after fire the previous summer.

Pollination has not been critically studied, but visits by large-bodied but short-tongued xylocopid bees have been reported.

Diagnosis: when first described, *Schizorhiza neglecta* was associated with the Cape species of *Codonorhiza* (then *Lapeirousia*), but its basic chromosome number of x = 6 is discordant with those species, which have x = 10. Corm morphology is likewise unlike that of *Codonorhiza* and is unique for Crocoideae in the ellipsoid shape with the flat base of narrower diameter than the middle of the corm. The corky to papery tunics, rather than woody (*Lapeirousia*) or of compacted fibres (*Codonorhiza, Afrosolen*) are likewise distinctive. The large, smooth to slightly wrinkled, ± globose seeds nearly match those of *Lapeirousia* and *Afrosolen* but are quite unlike the smaller, ovoid, reticulate seeds of *Codonorhiza*. Leaf anatomy, including the absence of marginal veins or subepidermal sclerenchyma strands and closed vascular bundle sheaths conform to the condition in *Codonorhiza*, as do the pollen grains with a single banded operculum. All *Lapeirousia* and *Afrosolen* species examined for the character, have a 2-banded operculum. Morphologically, the flowers of *S. neglecta* appear most like those of the short-tubed *A. erythranthus* alliance, particularly the southern African *A. sandersonii*, especially in having the upper tepal reflexed to lie in the same plane as the lower tepals. The production of multiple cormlets in the lower nodes of the stem and in place of the parent corm at the end of the growing season are also unique for the *Lapeirousia* group of genera.

Although *Schizorhiza neglecta* accords with the subtropical and tropical *Afrosolen* in its floral and seed morphology and cytology, it is anatomically discordant in lacking a marginal vein in the leaves and in its temperate distribution.

Distribution of ***Schizorhiza neglecta***.

The type population of *Schizorhiza neglecta* from Jonkershoek, with white flowers and a shorter perianth tube, 8–10 mm long is diploid, $2n$ = 12, but counts from blue-flowered plants from Bain's Kloof with a longer perianth tube, 12–14 mm, are tetraploid, $2n$ = 24. These differences suggest that they might be better regarded as separate taxa and in the description above the significant differences between these populations are noted. The longer-tubed Bain's Kloof and Steenbras populations also have longer floral bracts 6–7 mm long (vs. 4–6 mm) and anthers 4.0–4.5 mm long (vs. 3.3–3.8 mm) than the Jonkershoek plants. The size differences may be explained by the ploidy difference (chromosome number for the Steenbras population is unknown and flower colour is uncertain, but residual pigmentation on herbarium specimens suggests that they were blue). Recognition of infraspecific taxa for this rare Cape plant awaits additional study.

12. **Lapeirousia**

Lapeirousia *Pourr.* in Histoire et Mémoires de l'Académie Royale des Sciences, Toulouse 3: 79 (1788). *Ovieda* Spreng.: 258 (1817), illegitimate homonym and superfluous name, not *Ovieda* L. (1753). *Meristostigma* A.Dietr.: 593 (1833), superfluous name. *Peyrousia* Poir.: 363 (1826), possible orthographic variant of *Lapeirousia* (also spelled *Lapeyrousia*), or superfluous name. Type: *L. compressa* Pourr. = *L. fabricii* (D.Delaroche) Ker Gawl.

Sophronia Licht. ex Roem. & Schult.: 482 (1817). Type: *S. caespitosa* Licht. ex Roem. & Schult. = *Lapeirousia plicata* (Jacq.) Diels

Chasmatocallis R.C.Foster: 40 (1939). Type: *C. macowanii* R.C.Foster = *Lapeirousia divaricata* Baker

Revisionary account: Goldblatt &Manning: 24–87 (2015).

Named in honour of the Compte de la Peyrouse, 18th century patron of French science and contemporary of the Abbe Pourret, author of the genus.

Deciduous geophytes. *Corms* bell-shaped with flat base, rooting from lower edges; axillary in origin; tunics of hard, woody layers, sometimes spiny at base. *Foliage leaves* few, lowermost linear to sword-shaped, inserted on stem near ground level, closely corrugate, upper leaves progressively smaller. *Stem* aerial or sometimes subterranean, compressed, often and angled, angles sometimes winged, simple or branched. *Inflorescence* a spike or when acaulescent, a dense rosette; bracts paired and opposed, outer green and firm to ± succulent, sometimes ridged, keeled, crisped or toothed; inner much shorter, usually hidden by outer, 2-keeled and often partly membranous, forked at apex. *Flowers* zygomorphic or actinomorphic in acaulescent species, often salver-shaped, blue, purple, red, pink or white, lower or all tepals usually with contrasting darker or lighter markings, sometimes sweetly scented; perianth tube cylindric or obliquely funnel-shaped, short to extremely long; tepals subequal or unequal, with dorsal largest. *Stamens* unilateral and arcuate or symmetrically disposed; filaments slender, free; anthers linear, splitting longitudinally. *Ovary* ± ovoid; style filiform, 3-branched; style branches usually forked for ± ½ their length, occasionally not divided. *Capsules* ovoid to oblong, cartilaginous, often showing outline of seeds. *Seeds* globose, flattened at chalazal end, either smooth with surface cells domed (rarely tuberculate) or rugulo-reticulate or reticulate with surface cell walls flat. *Pollen grains* monosulcate-operculate, operculum 2-banded. *Basic chromosome number* $x = 9$; diploid numbers $2n = 18, 16$.

Species 27: mainly in winter-rainfall western South Africa and southwestern Namibia, also central South Africa, Botswana and south tropical Africa, mainly in sandy soils or rock outcrops.

Molecular phylogenetic study has resulted in a narrower circumscription of *Lapeirousia* than was accepted until now through the removal of the tropical and eastern southern African species to *Afrosolen* (= *Psilosiphon*) and of several Cape species to *Codonorhiza*. *Lapeirousia* is now restricted to species with spicate inflorescences (unless acaulescent), unequal floral bracts with the outer large and foliose and the inner much smaller, and bell-shaped or obconic corms with hard, woody tunics. The pollen grains, unlike *Codonorhiza* and *Schizorhiza*, have a 2-banded operculum and the basic chromosome numbers, $x = 9$ or 8, depart from those in these two genera.

Lapeirousia species are strikingly diverse in floral morphology, with actinomorphic or zygomorphic flowers with short to extremely long floral tubes and perianth colours of white to pink, deep violet or red, usually with contrasting markings on the lower tepals. *Lapeirousia odoratissima* has the longest perianth tube in the genus, up to 140 mm long, and the fragrant white flowers of this species are adapted for pollination by long-proboscid hawk moths. Species with deeply pigmented but unscented flowers with tubes of moderate length are pollinated by long-proboscid nemestrinid flies. Speciation in the genus has been associated with repeated shifts in pollination systems (Goldblatt & Manning 1996). Several species have underground stems with the flowers crowded in a basal cluster or rosette. The genus has its greatest diversity in western southern Africa, where it is centred in Namaqualand and adjacent Western Cape and the western Karoo of Northern Cape.

Key to sections

Note: Measure corm diameter at corm base, and bract length from the middle of spike if there is considerable variation along the spike. Seeds may shrink with age through desiccation.

1a Corm bell-shaped, basal margin bluntly ridged to crenate or minutely spiny with fine teeth directed downward (not with laterally directed spines or teeth); flowers radially symmetric or zygomorphic:

LAPEIROUSIA. L. simulans: A, flowering plant (including front view of detached flower); B, capsules; C, seed. ***L. fabricii*** subsp. ***fabricii***: D, flower side view (top) and front view (bottom). ***L. oreogena***: E, flower side view (left) and front view (right). ***L. pyramidalis*** subsp. ***pyramidalis***: F, flower side view (left) and front view (right).

2a Plants with aerial stems (unless depauperate); flowers zygomorphic . . . . . 1. sect. *Chasmatocallis*
2b Plants acaulescent; flowers radially symmetric . . . . . 2. sect. *Sophronia*
1b Corm bell-shaped to obconic, thus ± triangular in profile, basal margin serrated to spiny and bearing short to long teeth; flowers zygomorphic . . . . . 3. sect. *Lapeirousia*

Key to species

1a Plants tufted, ± acaulescent with axis contracted above ground level and inflorescence congested; flowers radially symmetric:
2a Floral bracts 60–150 mm long; perianth tube 100–140 mm long . . . . . 13. *L. odoratissima*
2b Floral bracts 40–50 mm long; perianth tube 12–60 mm long:
3a Flowers violet, lower ⅓ of tepals dark violet to black with wedge-shaped white mark in centre of dark zone; perianth tube 50–60 mm long . . . . . 10. *L. oreogena*
3b Flowers whitish or pale blue, sometimes with dark blue to purple mark near base of tepals; perianth tube 12–45(-55) mm long:
4a Perianth tube 12–30 mm long; tepals 7–9 mm long; anthers 1.8–3.0 mm long, blue or whitish. . . . . 9. *L. plicata*
4b Perianth tube (33–)35–55 mm long; tepals 10–12 mm long; anthers 3–4 mm long, white or pale yellow:
5a Flowers ± white; leafy upper parts of floral bracts ± straight, channelled to apex, not ribbed. . . . . 12. *L. kalahariensis*
5b Flowers white or pale blue; leafy upper parts of floral bracts falcate, unifacial above and strongly ribbed . . . . . 11. *L. montana*
1b Plants with aerial stems unless depauperate (e.g. *L. exilis*, *L. arenicola*); flowers zygomorphic with stamens unilateral:
6a Flowers predominantly white to creamy white, often flushed pink outside; perianth tube 7–15 mm long:
7a Corm bell-shaped, basal rim minutely serrated or entire and lobed:
8a Perianth tube 7–10 mm long, obliquely funnel-shaped; corm margin with short fine teeth directed downward; plants of the Cederberg, Gifberg and Bokkeveld Mtns. . . . . 1. *L. divaricata*
8b Perianth tube 13–15 mm long, ± slender throughout; corm margins entire; plants of the Knersvlakte . . . . . 7. *L. angustifolia*
7b Corm obconic (triangular in profile), basal rim bearing prominent, spreading spines:
9a Dorsal tepal 18–23 × 5–8 mm . . . . . 20. *L. spinosa*
9b Dorsal tepal 9–11 × 2–3 mm . . . . . 21. *L. tenuis*
6b Flowers variously coloured; perianth tube 20–70 mm long:
10a Corm bell-shaped, basal rim bluntly ridged to crenate or minutely serrate with teeth directed downward:
11a Outer floral bracts obtuse to retuse when opened flat . . . . . 8. *L. pyramidalis*
11b Outer floral bracts tapering to an acute apex:
12a Flowers deep violet or cherry-red to magenta, lower tepals with white to yellow markings near base:
13a Floral bracts with median keel, without white patches; flowers cherry-red to magenta; perianth tube 40–55 mm long . . . . . 3. *L. silenoides*
13b Most or all floral bracts 2-keeled, fenestrate with white patches; flowers violet to purple, lower tepals streaked with white; perianth tube 30–40 mm long . . . . . 2. *L. jacquinii*
12b Flowers not as above:
14a Outer floral bracts mostly 6–10 mm long; lower tepals ± linear to narrowly lanceolate with a short, filiform tooth near base . . . . . 5. *L. anceps*
14b Outer floral bracts (10–)12–25 mm long; lower tepals broadly lanceolate to ovate, with or without teeth:
15a Perianth white to pink, pale blue or maroon-brown, not marked with red on lower tepals:
16a Perianth tube slender below, ± abruptly expanded to wider upper part; tepals ascending below to form part of floral cup, spreading distally; tepals predominantly pink to lilac with yellow nectar guides on lower tepals; style dividing opposite or beyond anther tips . . . . . 14. *L. barklyi*
16b Perianth tube slender ± throughout, slightly wider distally; tepals spreading from base; tepals predominantly white to ivory-coloured or pale blue; style dividing between base and middle of anthers:
17a Plants slender, less than 60 mm high, often unbranched; flowers pale blue (rarely ± white) with violet streaks on lower tepals . . . . . 6. *L. exilis*
17b Plants usually > 100 mm high, usually repeatedly branched from base; flowers white, pale yellow, yellow-brown or dull maroon, usually without contrasting markings on lower tepals:
18a Perianth tube 28–35 mm long; tepals 13–15 × 2–3 mm; bracts (12–)15–20(–25) mm long. . . . . 15. *L. littoralis*
18b Perianth tube (25–)30–45(–70) mm long; tepals 18–30 × 1.3–2.0 mm; bracts 10–18(–23) mm long. . . . . 16. *L. caudata*
15b Perianth white to pink or creamy beige, lower tepals always marked with red to brown near base:
19a Perianth tube 40–55 mm long; corm with basal margins entire to crenately lobed. . . . . 4. *L. verecunda*
19b Perianth tube (10–)12– 35 mm long; corm with basal margins minutely serrated:
20a Lower tepals ± 13 × 5 mm. . . . . 17. *L. macrospatha*
20b Lower tepals 8–11 × 3–4 mm:
21a Corm relatively shallowly buried, and underground part of stem not bearing cormlets at nodes; perianth tube mostly 15–25 mm long . . . . . 18. *L. arenicola*
21b Corm relatively deeply seated, with underground part of stem bearing cormlets at nodes; perianth tube mostly 27–35 mm long. . . . . 19. *L. simulans*
10b Corm obconic (triangular in profile) with margins bearing prominent, spreading spines:
22a Flowers white to beige or blue-mauve (rarely pink), usually with red markings on lower tepals:

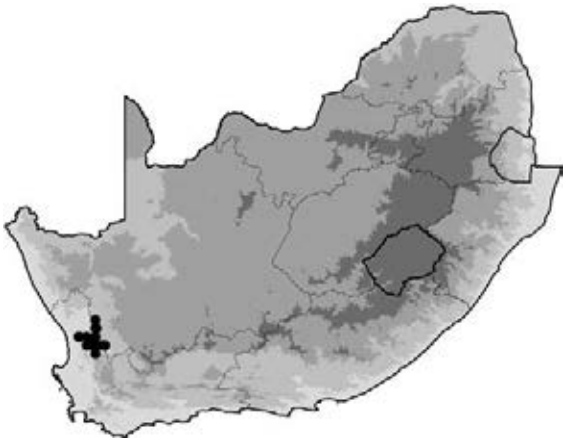
23a Perianth tube slender below, expanded in upper 5–10 mm into a wider gullet; tepals spreading from above base; lower tepals without tooth at base; style dividing opposite base to upper ⅓ of anthers; basal leaf smooth . . . . . 27. *L. fabricii*
23b Perianth tube slender, ± uniformly wide throughout; tepals spreading from base; lower tepals not bearing a tooth at base; style dividing opposite or above base of anthers; basal leaf sparsely hairy. . . . 26. *L. kamiesmontana*
22b Flowers predominantly blue, violet, purple or magenta, variously marked on lower tepals:
24a All or only median lower tepal with tooth-like projection near base:
25a Only lower median tepal with tooth near base; upper lateral tepals strongly recurved; lower tepals with white V-shaped mark near base on darker violet background . . . . . .23. *L. purpurea*
25b All three lower tepals with tooth near base; upper lateral tepals not obviously recurved; lower tepals white near base with large red to purple blotch in centre . . . . . 22. *L. violacea*
24b All lower tepals without tooth-like projections:
26a Basal leaf smooth or minutely papillate along edges of ribs; perianth tube (25–)35–45 mm long; perianth pale to deep blue to violet, lower tepals white(–pale yellow) at base . . . . . 24. *L. dolomitica*
26b Basal leaf sparsely hairy; perianth tube 40–50 mm long; perianth deep magenta to purple marked with white lines on lower margins and darker magenta in lower midline. . . . . 25. *L. lewisiana*

Sect. 1. **Chasmatocallis** *(R.C.Foster) Goldblatt & J.C.Manning* in Strelitzia 35: 27 (2015). *Chasmatocallis* R.C.Foster: 40 (1939). Type: *C. macowanii* R.C.Foster = *Lapeirousia divaricata* Baker

Corm bell-shaped; tunics with basal rim bluntly lobed or minutely denticulate with minute teeth directed downward. *Stem* mostly aerial (sometimes ± subterranean in *L. exilis* and *L. silenoides*) and often branched, stems compressed with angles often crisped. *Inflorescence* a spike. *Flowers* bilaterally symmetric, lower tepals usually with nectar guides of contrasting colour; variously coloured and perianth tube short to elongate, cylindric or funnel-shaped. *Capsules* often with auriculate lobes and locular ridges. *Seeds* smooth (scarcely wrinkled) with surface cells domed or tuberculate (*L. pyramidalis*). *Basic chromosome number x* = 9 (or 10).

Species 9: winter-rainfall parts of Northern and Western Cape, South Africa.

1. **Lapeirousia divaricata** *Baker* in Journal of Botany, British and foreign 14: 337 (1876). Goldblatt & Manning: 27 (2015). Type: South Africa, [Northern Cape], without precise locality or date, *Thom s.n.* (K, holo.).



Gladiolus setifolius L.f.: 96 (1782). *Lapeirousia setifolia* (L.f.) N.E.Br.: 30 (1928), illegitimate homonym, not *L. setifolia* Harms (1901). Type: South Africa, without precise locality, probably in 1774, *Thunberg s.n.* (UPS-THUNB 1067, holo.).

Chasmatocallis macowanii R.C.Foster: 40 (1939). Type: South Africa, [Western Cape], Pakhuis Pass, Oct. 1897, *MacOwan 1975* (GH, holo.; G, SAM, iso.).

Plants 120–250 mm high, with axillary cormlets below ground. *Corm* bell-shaped, ± 10 mm diam.; tunics dark brown, often glossy, basal margin finely serrated, teeth directed downward. *Stem* simple or more often branched and then mostly well above ground, ± terete. *Leaves* 3 to 6 (or more), lowermost usually exceeding others, linear, suberect or falcate, 2.0–3.5 mm wide, strongly ribbed, generally exceeding stem, up to 350 mm long, upper cauline leaves shorter, sometimes resembling bracts and not ribbed, usually subtending branches. *Inflorescences* 5- to 12-flowered spikes, usually crowded; outer bracts green or flushed reddish, often white to semitransparent below, firm, 8.5–12.0 mm long, obtuse or acute, usually folded in midline or channelled, margins hyaline, inner bracts ½–⅔ as long. *Flowers* zygomorphic, white or sometimes flushed with pink to lilac (aging pink), lower tepals often with pink to purple streak in midline and bearing tooth-like ridge in lower midline; perianth tube short, 7–10 mm long, narrow below, curved and widening toward apex; tepals unequal, lanceolate, acute, dorsal 14–16 mm long, erect, separating from tube below lower tepals, margins undulate, remaining tepals joined for ± 4 mm, upper lateral tepals sharply reflexed shortly above base, lower 3 tepals united for additional 2–3 mm, ± 12 mm long, bent at right angles shortly above base, directed downward distally. *Stamens* unilateral and arcuate; filaments ± 6 mm long, exserted 4 mm from tube; anthers ± 4 mm long, white; pollen white. *Style* dividing opposite anther tips; branches forked for ± ⅔ their length, recurved. *Capsules* obovoid, 4.5–7.0 mm long, apices of locules forming auriculate lobes decurrent on low locular ridges. *Seeds* ± globose, flattened at chalazal end, 1.0–1.2 mm diam., light brown. *Chromosome number* 2*n* = 20 (? or 18 ± 2B). *Flowering time*: mainly late August to late September, but October at higher elevations.

Distribution and ecology: restricted to northern Western Cape and southwestern Northern Cape, South Africa, extending from Citrusdal in the Olifants River Valley north through the valleys of the Cederberg to the Gifberg and Bokkeveld Mtns; exclusively in sandy ground in soils derived from Cape sandstones, in valley bottoms, seeps or poorly drained flats.

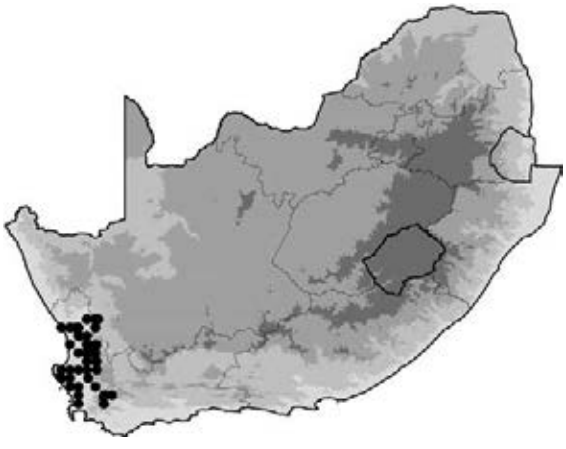
Diagnosis: named for its uneven and widely angled (divaricate) branching pattern, *Lapeirousia divaricata* is readily recognised by its short-tubed, white to pale pink flowers, a stem normally branched well above the ground, and short floral bracts that are white to

Distribution of ***Lapeirousia divaricata***.

translucent on the sides. The lower tepals bear a conspicuous tooth-like ridge in the lower midline, a feature shared with only a few other species of the genus. The bell-shaped corm has finely toothed margins with the teeth directed downward. The relatively small capsules of *L. divaricata* are ridged with apically auriculate locules, a feature consistent with several other species of sect. *Chasmatocallis*.

Lapeirousia spinosa, originally subsp. *spinosa* of *L. divaricata*, has similar, short-tubed white flowers but a corm that is triangular in profile with the basal rim bearing prominent spreading spines. The sister relationship of *L. divaricata* with *L. jacquinii* retrieved in the molecular phylogeny is unexpected as the flowers of the two are very different, but they do share virtually identical corms and distinctive fenestrate floral bracts with white or semitransparent patches.

The flowers of *Lapeirousia divaricata* remain open at night, unlike most species of the genus, and are visited by a range of large, long-tongued bees from midmorning until sunset, and in the later afternoon and early evening by settling moths. The flowers are self-compatible and readily self-pollinate as the style branches remain in contact with the anthers during anthesis.



2. **Lapeirousia jacquinii** *N.E.Br.* in Journal of the Linnean Society, Botany 48: 20 (1928); Goldblatt & Manning: 29 (2015). Type: South Africa, without precise locality, illustration in Jacq.: t. 269 (1794 [1788–1795]) '*Gladiolus anceps*'.

Plants 80–120(–200) mm high. *Corm* bell-shaped, 7–9 mm diam.; tunics light to dark brown, basal rim minutely serrate, teeth directed downward. *Stem* often ± prostrate below for a short distance, erect above, often branched close to ground, compressed and triangular in cross section, one side narrower than other two, angles strongly winged, wings undulate and usually slightly denticulate. *Leaves* 3 to 5, ± crowded at ground level, lowermost longest, ascending or arcuate, often quite short, lanceolate to falcate, 50–200 × 4–12 mm, strongly ribbed, remaining leaves smaller, weakly ribbed, progressively bract-like above. *Inflorescences* 2- to 5(–10)-flowered spikes; outer bracts green-glaucous, often ± translucent on sides, (10–)15–20 mm long, margins narrowly hyaline, prominently 2-keeled or lowermost sometimes 1-keeled, keels undulate to crisped, minutely denticulate, inner bracts ± ⅔ as long, membranous and translucent with two prominent green keels, forked apically for 2–3 mm. *Flowers* zygomorphic, violet (rarely white), lower 3 tepals darker violet or reddish in lower midline with margins white to pale yellow in proximal half, scentless; perianth tube cylindric, 30–40 mm long, widening and weakly curved near apex; tepals unequal, dorsal largest, 8–10 × 4–5 mm, oblanceolate, initially erect but usually reflexed when fully open, then held in same plane as lower; upper lateral tepals spreading at right angles to tube, weakly spooned, apices curved upward, lower 3 tepals directed forward with upcurved tips, 7–8 × ± 2 mm. *Stamens* unilateral, ± erect; filaments ± 7 mm long, exserted 4–5 mm; anthers parallel, ± 3 mm long, violet; pollen usually blue-violet. *Style* dividing near base of anthers, style branches deeply forked and recurved. *Capsules* oblong, 7–9 mm long, apices of locules forming auriculate lobes decurrent on weakly developed locular ridges. *Seeds* globose, 1.1–1.5 mm diam., dark brown. *Chromosome number* 2*n* = 18. *Flowering time*: (late July) August to mid-September.

Distribution and ecology: one of the most common species in the genus, extending from Cape Town along the Atlantic Coast of Western Cape, South Africa as far north as southern Namaqualand near Garies in Northern Cape, also inland through the Breede River Valley east of Worcester as far as Overhex, Aan de Doorns and into the western valleys of the Cederberg and Bokkeveld Mtns; in sandy ground, often disturbed.

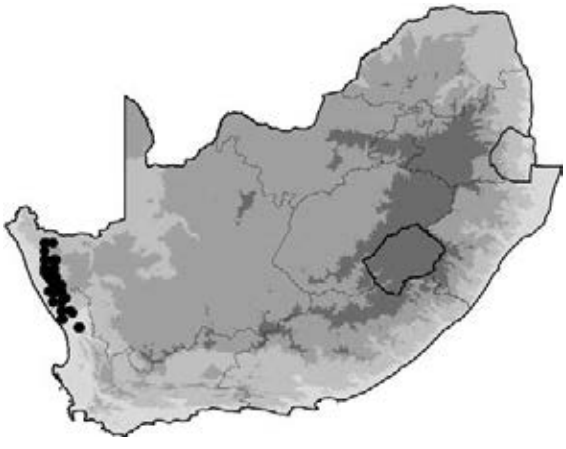
Hybrids with *Lapeirousia pyramidalis* subsp. *pyramidalis* have been recorded near Rawsonville.

Diagnosis: *Lapeirousia jacquinii* is easily distinguished in flower and in fruit by the prominently 2-keeled outer floral bracts (occasionally 1-keeled, especially the

Distribution of ***Lapeirousia jacquinii***.

lowermost). The stems are conspicuously 3-angled with the angles winged and undulate and sometimes minutely toothed. The long-tubed flowers are deep violet (rarely white) with darker violet or red markings outlined in white on the lower tepals, a colour combination very similar to that in *L. violacea*, with which it is sometimes sympatric. This last species has quite different corms, triangular in profile and bearing long spines radiating from the base, unlike the bell-shaped corm of *L. jacquinii*, the basal rim of which bears minute, downward-directed teeth. The outer bracts of the two species also differ, those in *L. violacea* being folded or keeled and the keels minutely crisped. The floral similarity in the two species is evidently due to convergence for the same long-proboscid fly pollinators. *Lapeirousia jacquinii* is self-compatible and facultatively autogamous, and reproduces readily from seed, thus rapidly colonising new habitats. It is also often cross-pollinated in the parts of its range where long-proboscid flies are active.

The immediate relationships of *Lapeirousia jacquinii* have been shown by molecular study to be with *L. divaricata*, which has similar corms but short-tubed, white to palest pink flowers, and short, 1-keeled floral bracts. The two species share unique, fenestrate outer bracts with pale, almost translucent sides.



3. **Lapeirousia silenoides** *(Jacq.) Ker Gawl.* in König & Sims, Annals of Botany 1: 238 (1804); Goldblatt & Manning: 31 (2015). *Gladiolus silenoides* Jacq.: 168 (1791). *Ovieda silenoides* (Jacq.) Spreng.: 147 (1824); *Peyrousia silenoides* (Jacq.) Poir.: 365 (1826). *Meristostigma silenoides* (Jacq.) A.Dietr.: 596 (1833). Type: South Africa without precise locality or collector, illustration in Jacq.: t. 270 (1794 [1788–1795]).

   Lapeirousia speciosa Schltr.: 105 (1900). Type: South Africa, [Western Cape], Kareebergen, 17 July 1896, *Schlechter 8187* (B, holo.; BM, BOL, COI, E, G, GRA, K, PH, PRE, iso.).

Plants 50–150(–200) mm, taller in sheltered or shaded sites, ± acaulescent in exposed sites or in seasons of low rainfall. *Corm* bell-shaped, 8–10 mm diam.; tunics light brown, basal rim ridged (minutely serrate in plants from Spektakel Mtns). *Stem* aerial or sometimes ± entirely underground, often branched close to base, compressed, 2-angled, often 2-winged below first flower, wings often minutely serrate. *Leaves* few, lowermost longer than others, lanceolate to linear, ribbed or corrugate, ± as long or longer than stem, 1.5–5.5 mm wide; remaining leaves shorter and broader, progressively bract-like above. *Inflorescence* usually a crowded to lax spike, or a head-like cluster at ground level, up to 12-flowered, initially 2-ranked, spiral with age; outer bracts linear to lanceolate, sometimes very broad at base, occasionally ± succulent, outer 15–20 mm long, unifacial for distal 2–4 mm, acute and curving upward, folded or lightly keeled below, keels usually minutely serrate, margins membranous; inner bracts ± ½ as long, with broad transparent margins. *Flowers* zygomorphic, bright cerise to dark magenta (rarely white), lower 3 tepals each with creamy white markings near base, limbs with large central blotch of dark red or purple, scentless; perianth tube cylindric, slender, ± erect, 40–55 mm long, curved outward near apex; tepals subequal, ± broadly obovate, obtuse, limbs concave, 10–12 × ± 5 mm, dorsal erect or sometimes slightly inclined toward stamens, upper lateral tepals reflexed, lower 3 united basally for ± 1 mm, inclined at ± 45° to horizontal. *Stamens* unilateral, ± erect; filaments 7–8 mm long, exserted ± 4 mm from tube; anthers 3–4 mm long, blue-violet; pollen white or pale blue to mauve. *Style* erect, dividing close to or just beyond anther tips, ultimately exceeding them; branches 1.0–1.5 mm long, forked for ± ½ their length, recurved. *Capsules* obovoid to oblong, trigonous, 10–15 × 5–7, usually with well-developed wing-like locular ridges in distal half. *Seeds* globose, light brown, variable in size even on same plant, 1.2–2.2 mm diam. *Chromosome number* 2*n* = 18. *Flowering time*: (July) August to mid-September.

Distribution and ecology: widespread in Namaqualand, South Africa, extending from near Nuwerus in Western Cape northward to the Anenous Mtns west of Steinkopf in Northern Cape; restricted to granite-derived soils, either in deep, coarse granitic sand, where plants tend to be robust in years of adequate rainfall, or in granite outcrops where the corms are usually wedged in rock cracks in little or no soil.

Diagnosis: the bright magenta to cerise flower with darker colour in the centres of the lower tepals and cream-coloured streaks or blotches on the lower tepal bases instantly identify *Lapeirousia silenoides* over most of its range. To the south, in the Vanrhynsdorp and Clanwilliam districts, *L. pyramidalis* may be similarly coloured, though more often purple to violet, but the two species can be separated by their different bracts, narrow to fairly broad and acute with an upturned apex in *L. silenoides* but broad and often retuse with the apex curving downward in *L. pyramidalis*. The

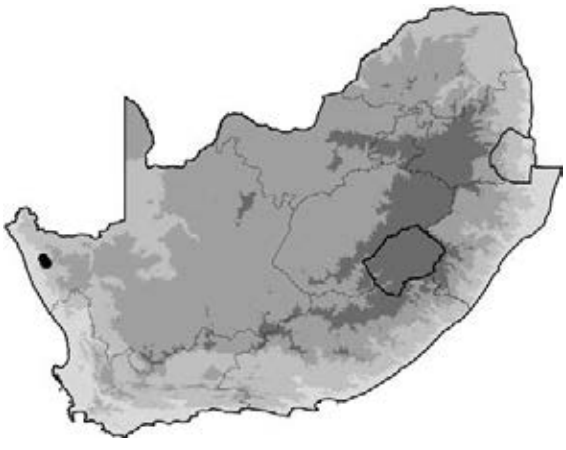
Distribution of ***Lapeirousia silenoides***.

two are undoubtedly related as is evidenced not only by their similarly marked and sometimes almost identically coloured flowers but by the similar, red-brown corms and capsules with wing-like locular ridges, a character shared by relatively few other species of *Lapeirousia*.

Bract shape is fairly variable in *L. silenoides*. In the centre of its range, in the Kamieskroon area, the bracts are narrow and often quite long, and plants there are often tallest and are occasionally slender. Both south and north of this area the plants are smaller, and generally less robust, with the bracts shorter and broader. Plants with particularly broad-based bracts occur in the south of its range, notably in the vicinity of Bitterfontein. This variant, named *L. speciosa* by Rudolf Schlechter (1900), has flowers identical with those of plants from further north and although the difference in the shape of the bracts in the type material is striking, the presence of populations intermediate for bract shape and the consequent difficulty in placing these makes an infrageneric classification seem unnecessary.

On rocks plants tend to be fairly dwarfed, but in years of ample rainfall the main stem branches repeatedly at the base, producing a cushion-like form. In years of poor rainfall, plants can be virtually acaulescent with the flowers produced close to ground level. Similarly, at higher elevations in the Kamiesberg the aerial stem is often hardly or not at all produced above the ground, and plants assume a low tufted growth habit.

Self-incompatible, *Lapeirousia silenoides* often has relatively low seed set in the wild, and in cultivation does not produce capsules unless actively cross pollinated even though the recurved style branches do come into contact with pollen. Pollination studies show that the species is regularly visited by long-proboscid nemestrinid flies. Plants reproduce very successfully by seed and *L. silenoides* can be seen flowering along roadsides in masses, the seed having fallen from parent plants growing on banks and slopes above the road.



4. **Lapeirousia verecunda** *Goldblatt* in Contributions from the Bolus Herbarium 4: 38 (1972); Goldblatt & Manning: 33 (2015). Type: South Africa, [Northern Cape], Namaqualand, upper east slopes of Spektakel Pass, 24 Aug. 1970, *Goldblatt 573* (BOL, holo.; K, MO, NBG, PRE, iso.).

Plants 80–150 mm high. *Corm* bell-shaped, 10–13 mm diam.; tunics red-brown, slightly rugose, basal rim slightly lobed. *Stem* simple or with 1 to 3 branches from base, slightly compressed and 2-angled, one or both angles winged, wings decurrent on leaves or bracts. *Leaves* 5 to 7 (more depending on number of branches), lowermost longest, linear, ascending to falcate, closely ribbed, 70–100 × 3.5–5.0 mm, seldom exceeding stem; upper leaves < ½ as long as lowermost, progressively shorter and bract-like distally. *Inflorescences* 9- to 12-flowered, 2-ranked, spikes; outer bracts green, firm, narrowly lanceolate, acute, often recurved at tips, 10–20 mm long, margins membranous, channelled or folded in midline; inner bracts ± ½ as long, notched at tips. *Flowers* zygomorphic, white, tube and reverse of tepals copper-pink, lowermost or all 3 lower tepals with red, heart-shaped mark in lower midline; perianth tube cylindric, slender, 40–50(–55) mm long, slightly curved forward distally; tepals subequal, ovate-elliptic, slightly narrowed at base, subacute or obtuse, 10–12 × 5.5–6.0 mm, dorsal erect, lower 3 tepals ± horizontal. *Stamens* unilateral, erect; filaments ± 6 mm long, exserted ± 3 mm; anthers parallel, contiguous, ± 3 mm long, purple; pollen purple. *Style* dividing opposite anther tips, branches ± 2 mm long, divided for ½ their length, recurved. *Capsules* obovoid-trigonous, ± 10–13 × 7 mm, with prominent wing-like locular ridges in distal half. *Seeds* ± globose, smooth, dark brown, 1.6–1.9 mm diam. *Chromosome number* 2*n* = 18. *Flowering time*: late August to the end of September, rarely early October.

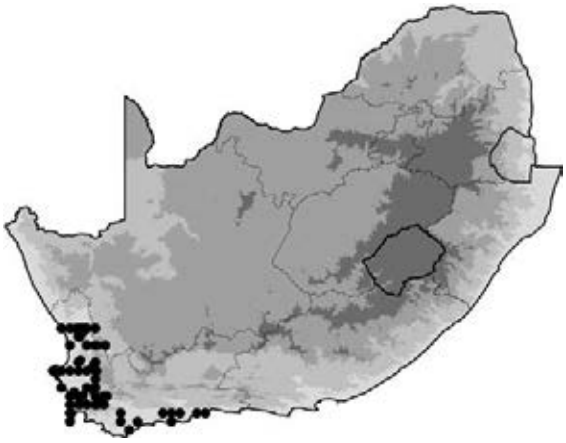
Distribution and ecology: a narrow endemic of the Spektakel Mtns west of Springbok in Northern Cape, South Africa, recorded from the eastern slopes of Spektakel Pass, at elevations of 700–800 m and to the north near Nigramoep; mainly on stony shale slopes (Nama Shale Formation).

The flower colour and the long perianth tube of *L. verecunda* are stereotypical adaptations for the *Moegistorhynchus longirostris* long-proboscid fly pollination system, but to date no pollinators have been recorded visiting the flowers.

Diagnosis: this attractive species has odourless, long-tubed, usually 50–55 mm long, white flowers with red, round to heart-shaped marks on one or more of the three lower tepals, and flushed red on the reverse of the tepals and tube. The plane tepals, and fairly long and comparatively narrow bracts with deflexed apices are distinctive. *Lapeirousia verecunda* belongs to the group of species in sect. *Chasmatocallis* with bell-shaped corms that are ridged or regularly lobed on the basal

Distribution of ***Lapeirousia verecunda***.

rim. *Lapeirousia silenoides* has similar bracts but cerise flowers with spoon-shaped lower tepals.



5. **Lapeirousia anceps** *(L.f.) Ker Gawl.* in König & Sims, Annals of Botany 1: 238 (1804); Goldblatt & Manning: 34 (2015). *Gladiolus anceps* L.f.: 94 (1782). *Ovieda anceps* (L.f.) Spreng.: 147 (1824). *Peyrousia anceps* (L.f.) Poir.: 363 (1826). *Meristostigma anceps* (L.f.) A.Dietr.: 596 (1833). Type: South Africa, without precise locality, *Sparrman 192* (LINN 59/19, holo.).

Lapeirousia pentheri Baker: 27 (1906). Type: South Africa, [Western Cape], Breede River, *Penther 728* (BOL, BM, K, syn.).

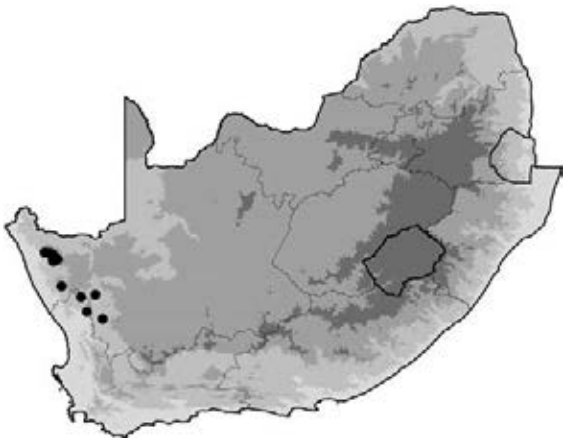
Plants 100–300 mm high. *Corm* bell-shaped, red-brown, 8–10 mm diam.; tunics lightly ridged, rim bluntly lobed. *Stem* usually repeatedly divaricately branched, compressed and elliptic in cross section, 2- or 3-angled, angles slightly winged, wings weakly serrated. *Leaves* 5 to 7, lowermost usually longer and wider than others, (40–)80–200 × 3–15 mm, ascending to falcate, lanceolate, ribbed, remaining leaves shorter, mostly crowded near base, becoming increasingly bract-like above. *Inflorescences* (2)4- to 8-flowered spikes, at first 2-ranked, ultimately spiral; outer bracts grey-green, (5–)6–10 mm long, apices and margins often tinged red, channelled, folded along upper midline, acute in profile; inner 3–5 mm long, transparent with two green keels. *Flowers* zygomorphic, white to beige or faintly flushed pink, reverse of tepals and tube pink, lower 3 tepals each with red mark in lower midline, and usually with small, claw-like cusp near base; perianth tube narrow and cylindric, weakly arched distally, (20–)40–80 mm long (3–6 times as long as tepals); tepals narrowly lanceolate to ± linear, acute, dorsal largest, 12–14 × 4–5 mm, erect or recurved when fully open, upper lateral 12–14 × ± 3 mm, widely separated from dorsal, lower tepals united basally for 2–3 mm, free parts 12–14 mm long, extended horizontally. *Stamens* unilateral, ± erect; filaments ± 6 mm long, exserted ± 4 mm from tube; anthers parallel, ± 2.5 mm long; pollen grey-blue or white. *Style* arching adaxial to anthers, dividing between base and middle of anthers; branches 2–3 mm long, divided for ½ their length and recurved. *Capsules* ± barrel-shaped, 9–10 × ± 7 mm. *Seeds* red-brown, globose, smooth, somewhat flattened at chalazal end, ± 1.5 mm diam. *Chromosome number* 2*n* = 18. *Flowering time*: (late September–)October, to late November at higher elevations and in the south.

Distribution and ecology: a widely distributed species, extending from the sandy coastal plain of central Namaqualand near Hondeklip Bay in Northern Cape, South Africa southward through the mountains and coastal plain of Western Cape to near Mossel Bay in the east; almost always in deep sandy soils, sometimes growing among tufts of Restionaceae, flowering profusely following fires.

Diagnosis: *Lapeirousia anceps* is readily recognised by the combination of short floral bracts 5–10 mm long and white to ivory-coloured flowers flushed pink on the outside of the tepals and tube, usually with a relatively long perianth tube, mostly 50–80 mm but occasionally only 20–40 mm, and narrow tepals 3–4 mm wide (sometimes the dorsal up to 5 mm). The lower tepals usually have a claw-like projection just above the base. The bell-shaped corms have either bluntly lobed or minutely serrated basal rims. The species has no close allies, and the short floral bracts are particularly surprising in view of its long perianth tube. *Lapeirousia anceps* is pollinated by species of long-tongued nemestrinid and tabanid flies. The variation in the length of the perianth tube in the species correlates with variation in the proboscis length in the pollinators, thus shorter tubed populations are pollinated by flies with correspondingly shorter probosces.

Distribution of ***Lapeirousia anceps***.

6. **Lapeirousia exilis** *Goldblatt* in Contributions from the Bolus Herbarium 4: 44 (1972); Goldblatt & Manning: 37 (2015). Type: South Africa, [Northern Cape], Namaqualand, Ratelpoort, ± 25 km north of Springbok, 6 July 1970, *Tölken 3238* (BOL, holo.; K, MO, NBG, iso.).



Plants small, usually 30–50 mm high. *Corm* ± 8 mm diam., light brown, bell-shaped, ridged at base, margin slightly lobed (not serrated). *Stem* subterranean or produced shortly above ground, rarely taller, usually unbranched. *Leaves* usually 2, basal longest, falcate or ± trailing, 80–160 × 1–2 mm, ribbed, second leaf much shorter, often only slightly longer than floral bracts, 2–3 mm wide, channelled in lower half. *Inflorescence* a congested spike, sometimes ± a basal rosette, 6- to 13-flowered, 2-ranked in bud, becoming spiral as flowers open; outer bract 15–25 mm long, lowermost longest, with unifacial apices, upper leaves channelled, apices rounded without unifacial tips, not keeled, translucent over veins, margins pale, membranous; inner bract ± ⅓ as long as outer, transparent with two green keels. *Flowers* zygomorphic, white to pale blue with proximal 1–2 mm fading to ± white, lower 3 tepals with a dark blue median streak in lower midline (fading in dried material), strongly and sweetly scented; perianth tube slender, erect, curved and widening at apex,

20–25 mm long; tepals subequal, ± 8 mm long, spreading, dorsal suberect at anthesis, later spreading, lower 3 tepals slightly smaller broadly to narrowly ovate, obtuse, narrowed at base and ± clawed. *Stamens* unilateral, ± erect; filaments ± 4 mm long, inserted close to top of tube, ± fully exserted; anthers ± 3 mm long, pale blue; pollen ± white. *Style* arching adaxial to stamens, dividing opposite anther bases; style branches forked for ½ their length and recurved. *Capsules* broadly ovoid, trigonous, 8–11 × ± 6.5 mm. *Seeds* globose, smooth, flattened at chalazal end, ± 1.3 mm diam., light brown. *Chromosome number* 2*n* = 18. *Flowering time*: mid-June to mid-August.

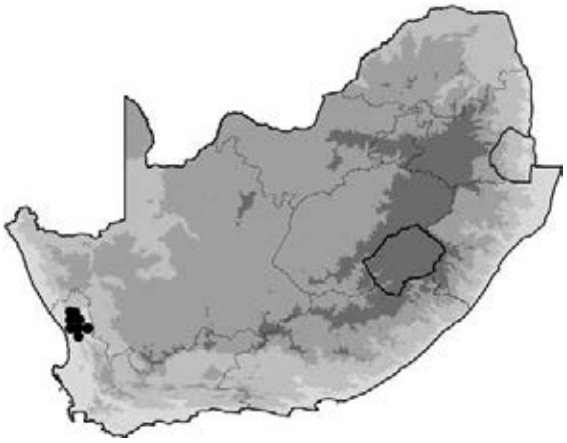
Distribution and ecology: scattered range across Northern Cape, South Africa, from Steinkopf north of Springbok southward to the rugged northern edge of the Bokkeveld Escarpment northeast of Nieuwoudtville; in stony ground in granitic gravel, sand, or occasionally clay.

The species is pollinated by large-bodied bees and bombyliid flies. The moderately long perianth tube appears to indicate a pollinator with long mouthparts, but nectar is held fairly high in the tube and within reach of bees and bombyliid flies.

Diagnosis: *Lapeirousia exilis* is distinguished by the short, usually underground stem and tufted habit, and pale blue flowers with a perianth tube up to 25 mm long. The flowers are zygomorphic, with white and darker blue markings only on the lower tepals, and unilateral stamens. *Lapeirousia plicata* is superficially similar but has radially symmetric flowers with markings on all tepals and the stamens diverge widely as the flowers age. In addition, *L. exilis* has channelled, dorsiventral floral bracts typical of sect. *Chasmatocallis* whereas the bracts in *L. plicata* have elongated leaf-like tips above the sheathing bases. The seeds of *L. exilis* also accord with sect. *Chasmatocallis* in their smooth surface and domed surface cells, thus quite different from the sculptured, ± reticulate to rugose surface and flat surface cells of *L. plicata* and its acaulescent allies of sect. *Sophronia*.

Distribution of ***Lapeirousia exilis***.

Molecular data support the differences in flower, bract and seed morphology in allying *L. exilis* with sect. *Chasmatocallis* rather than with sect. *Sophronia*.



7. **Lapeirousia angustifolia** *Schltr.* in Botanische Jahrbucher für Systematik 27: 105 (1900); Goldblatt & Manning: 39 (2015). Type: South Africa, [Western Cape], Zoutrivier, 15 July 1896, *Schlechter 8144* (B, holo.; BOL, BM, COI, F, G, GRA, K, PH, PRE, iso.). [Schlechter's handwritten collection number has also been misread as *8149* or *8188*]

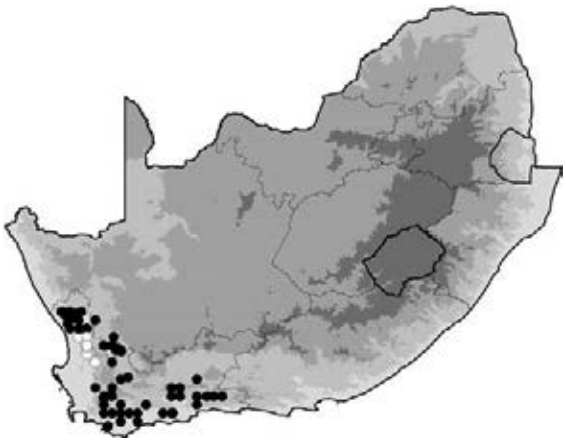
Plants 30–140(–180) mm high. *Corm* bell-shaped, 7–10 mm diam.; tunics brown, surface lightly ridged, basal rim smooth or bluntly lobed. *Stem* simple or sometimes 1- or 2-branched from base, slightly compressed. *Leaves* few, lowermost longest, linear, ascending, usually exceeding stem, up to 100(–180) mm long, ribbed, cauline leaves broader and shorter than basal, ± bract-like. *Inflorescence* a 6- to 15-flowered spike, spiral in flower; outer bracts green, firm, 8–13 mm long, oblong to broadly ovate, channelled, obtuse (retuse when opened), apex deflexed in profile, margins hyaline; inner bracts ± ½ as long, transparent with two green keels. *Flowers* zygomorphic, white to pale lilac or mauve, lower 3 tepals pale yellow at base and with violet median streak, tube pink outside, lower tepals each with small claw-like tooth in lower midline, with light sweet scent; perianth tube 13–15 mm long, slender below, ± abruptly curved and expanded in upper 5–6 mm; tepals unequal, dorsal erect or slightly arched over anthers, 7–9 × 4 mm, oblanceolate, upper lateral tepals outspread, lower 3 united basally for ± 2 mm, 7–9 mm long, directed downward 35°–40°. *Stamens* unilateral, suberect; filaments 7–8 mm long, exserted 3.0–3.5 mm; anthers parallel, 2.5–3.0 mm long, lilac; pollen ± white. *Style* dividing opposite middle ⅓ of anthers; style branches ± 2.5 mm long, forked for slightly > ½ their length. *Capsules* obovoid-trigonous, 5–8 mm long, without locular ridges. *Seeds* globose, somewhat flattened to irregularly lobed at chalazal end, 1.0–1.2 mm diam., brown, smooth with outer epidermal walls weakly colliculate. *Flowering time*: early July to late August.

Distribution and ecology: restricted to the Knersvlakte of southern Namaqualand in Western Cape, South Africa; in sandy or light clay soils, sometimes in areas covered with quartz pebbles.

The appearance, size and exact flowering of *L. angustifolia* are very unpredictable from season to season. Pollination of the pale, faintly scented flowers is unknown but is likely to be by long-tongued bees.

Diagnosis: the flowers of *Lapeirousia angustifolia*, like those of *L. pyramidalis* subsp. *pyramidalis*, are white to pale lilac or mauve in colour and also pleasantly, if not as strongly sweet-scented, but are readily distinguished by the shorter perianth tube, 13–15 mm long vs. 25–40 mm, and the claw-like cusps on the lower tepals.

Distribution of ***Lapeirousia angustifolia***.



The small capsules lack the wing-like locular ridges characteristic of *L. pyramidalis* and the small seeds, 0.9–1.3 mm diam., slightly wrinkled with colliculate epidermal cells, also differ from the slightly larger seeds of *L. pyramidalis* subsp. *pyramidalis*, 1.5–1.9 mm diam., which have derived, tuberculate epidermal cells (hedgehog-like under the microscope). Molecular phylogenetic studies confirm the immediate close relationship of the two taxa.

8. **Lapeirousia pyramidalis** *(Lam.) Goldblatt* in Contributions from the Bolus Herbarium 4: 41 (1972); Goldblatt & Manning: 40 (2015). *Ixia pyramidalis* Lam.: 334 (1789). *Witsenia pyramidalis* (Lam.) Pers.: 42 (1805). Type: said to be from Isle de France [Mauritius], but certainly from western South Africa, said to be collected by *Commerson* but probably by *P. Sonnerat s.n.* (P-Herb. Jussieu, holo.).

Plants (50–)80–140 mm high. *Corm* bell-shaped, ± 10 mm diam.; tunics light red-brown, lightly ridged, basal margin entire or bluntly lobed. *Stem* simple or 1- to few-branched from near base, slightly compressed. *Leaves* 4 or 5, lowermost longest, up to 160 mm long, linear to lanceolate, 2–6 mm wide, strongly ribbed, upper leaves shorter and broader, becoming progressively bract-like above. *Inflorescences* 6- to 20-flowered spikes, initially 2-ranked, later becoming spiral; outer bracts green, firm, ± succulent, 10–20 mm long, channelled, ovate when flattened, obtuse in side view (deltoid and retuse when unfolded), apex deflexed in profile, margins hyaline; inner bracts ⅓–½ as long, transparent with 2 green keels. *Flowers* zygomorphic, either white to pale mauve, pale blue or pale pink, lower tepals each with a small triangular to diamond-shaped median mark in lower half (subsp. *pyramidalis*) or violet, purple or dark carmine, lower tepals each with white or cream-coloured markings near base and a central zone of darker pigment (subsp. *regalis*), either intensely sweet-scented day and night (subsp. *pyramidalis*) or evidently scentless (subsp. *regalis*); perianth tube 25–55 mm long, slender, straight or widening slightly in upper 5 mm; tepals subequal, narrowly to broadly ovate, narrowed into claw-like base ± 1.5 mm long, lower tepals each occasionally with a small claw-like cusp near base, dorsal tepal 9–15 × 6–7 mm, erect, held apart from others, upper lateral tepals slightly reflexed, lower 3 tepals usually held closely together and at right angles to tube, 8 × 5 mm. *Stamens* unilateral, ± erect to ascending; filaments 5–6 mm long, exserted ± 3.5 mm; anthers ± 3 mm long, usually pale yellow to white; pollen ± white. *Style* dividing between base and apex of anthers or slightly beyond; branches ± 2.5 mm long, forked for ½ their length, often becoming tangled in anthers. *Capsules* obovoid, 8–10 mm long, with wing-like locular ridges in distal half. *Seeds* ± globose to ovoid, usually somewhat flattened at chalazal end, 1.3–1.5 × 1.4–1.9 mm, epidermal cells tuberculate. *Chromosome number* 2*n* = 18. *Flowering time*: July to September.

Distribution and ecology: one of the more widespread species of the genus, extending from the southern edge of Namaqualand, South Africa through dry areas of the northwestern parts of Northern Cape to interior and southern Western Cape and the Little Karoo; mostly on clay slopes and flats.

Diagnosis: *Lapeirousia pyramidalis* is immediately recognised by the broadly ovate to deltoid bracts with obtuse to retuse apices, combined with a relatively long perianth tube 25–55 mm long. In profile the bracts do not taper to a point but curve outward and have blunt tips. The flowers have shortly clawed, subequal tepals with broadly oval to rounded limbs resembling the Namaqualand species, *L. silenoides*, and we consider the two to be closely allied. Both have unusual capsules with prominent ridges on the locules and similar red-brown corms with a ridged or lobed basal margin, features also shared with the local Namaqualand endemic, *L. verecunda*. The tuberculate seeds of *L. pyramidalis* are unusual in *Lapeirousia*, in which most species of sect. *Chasmatocallis*, including those of *L. silenoides* and *L. verecunda*, have epidermal cells with evenly domed

Distribution of ***Lapeirousia pyramidalis*** subsp. ***pyramidalis***, ●; subsp. ***regalis***, ○.

(colliculate) outer walls. The difference is often striking, making it possible to distinguish the seeds of *L. pyramidalis* from other species of the genus.

Lapeirousia pyramidalis has a fairly consistent appearance over much of its range. Plants are compact with broadly obtuse floral bracts, and the flowers are white to pale blue or pale pink to lilac with a perianth tube 25–35 mm long, slightly curved and wider in the upper 5–7 mm, and always strongly scented during the day and in the evening. In the west of its range, in the Olifants and Biedouw River Valleys, and at Karoo Poort to the south, plants segregated as subsp. *regalis* are distinguished by bright red, purple, or dark violet flowers with a long, nearly straight perianth tube, 35–55 mm long, and lacking any discernible odour. As far as we know the two variants never grow sympatrically, but their ranges are more-or-less complementary, and they also favour different habitats, subsp. *pyramidalis* normally on shale and clay soils and subsp. *regalis* on stony sandstone ground. There is a marked size difference between the seeds of the two subspecies, with subsp. *pyramidalis* with seeds 1.7–2.0 mm diam. and subsp. *regalis* with seeds ± ½ this size, 1.0–1.2 mm diam.

The floral differences between the two subspecies reflect a shift in pollination strategy. Strongly scented subsp. *pyramidalis* is thought to be pollinated primarily by sphinx moths, which are most active at sunset and at night, whereas subsp. *regalis* is pollinated by long-proboscid flies.

Key to subspecies

1a Flowers whitish to pale blue (occasionally pale pink to mauve), strongly scented; perianth tube 25–40 mm long, cylindric below but expanded and curved outward in distal 5 mm . . . . . 8a. subsp. *pyramidalis*

1b Flowers dark purple, violet-blue or red, not scented; perianth tube (35–)40–55 mm long, ± cylindric throughout . . . . . 8b. subsp. *regalis*

8a. subsp. **pyramidalis**

Gladiolus fissifolius Jacq., Collectanea 4: 164 (1791) illegitimate superfluous name for *G. anceps* L.f. (= *Lapeirousia anceps* (L.f.) Ker Gawl.). *Lapeirousia fissifolia* Ker Gawl.: 238 (1804), as a new name for *G. fissifolius* Jacq.; Baker: 92 (1896). *Ovieda fissifolia* (Ker Gawl.) Spreng.: 147 (1824). *Peyrousia fissifolia* (Ker Gawl.) Poir.: 364 (1826). *Meristostigma fissifolium* (Ker Gawl.) A.Dietr.: 595 (1833). *L. homoidea* Klatt in Th.Durand & H.Schinz: 191 (1894), as a new name for *G. fissifolius* Jacq. Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 268 (1794 [1788–1795]).

Gladiolus bracteatus Thunb.: 186 (1800). *Lapeirousia bracteata* (Thunb.) Ker Gawl.: sub. t. 1246 (1810). *Ovieda bracteata* (Thunb.) Spreng.: 147 (1824). *Peyrousia bracteata* (Thunb.) Sweet: 499 (1830a). *Meristostigma bracteatum* (Thunb.) A.Dietr.: 597 (1833). Type: South Africa, without precise locality, *Thunberg s.n.* (UPS-THUNB 1008, holo.).

Flowers whitish to pale bluish, or flushed with pale pink, lower tepals cream-coloured at base with small basal median streak of purple and larger median purple mark, intensely sweetly scented night and day; perianth tube 25–40 mm long, narrow and cylindric below, broadened and curving outward in upper 4–5 mm; tepals subequal, dorsal ± erect, 9–12 × 6–7 mm, upper laterals spreading to reflexed, lower 3 directed downward, with short claw ± 1.5 mm × 2 mm, limbs abruptly expanded, broadly oval, 7.5–8.0 × 6 mm. *Stamens* unilateral, ± erect; filaments 5–6 mm long, exserted ± 3.5 mm; anthers ± 3 mm long, cream-coloured or light purple; pollen yellowish to white. *Style* usually dividing shortly above anther bases; style branches becoming tangled in anthers. *Seeds* 1.5–1.9 mm diam. *Flowering time*: late July to September.

Distribution and ecology: fairly widespread in Western Cape, extending from Worcester and Grabouw in the southwest through the Little Karoo and the Overberg to Riversdale in the east and into the arid Tanqua Karoo, and in dry sites along the interior Cederberg and Bokkeveld Mtns as far north as Nuwerus and Loeriesfontein in Northern Cape; mainly on clays and shale soils, occasionally on alluvial sands.

Populations in the Tanqua Karoo vary considerably in colour, from white to deep pink but even the darker forms are fragrant, with the perianth tube curved outward at the end and thus represent the typical subspecies and not subsp. *regalis*. The closely related *Lapeirousia angustifolia*, which has smaller flowers with a shorter perianth tube, 13–15 mm long, and faintly scented flowers, is restricted to dry flats of the Knersvlakte west and north of Vanrhynsdorp. Both species have been recorded near Hol River, north of Vredendal.

Hybrids with *Lapeirousia jacquinii* have been recorded near Rawsonville.

8b. subsp. **regalis** *Goldblatt & J.C.Manning* in Novon 4: 342 (1994); Goldblatt & Manning: 43 (2015). Type: South Africa, [Western Cape], Middelplaas, ± 5 km from Farm Biedouw on road to Wuppertal, 8 July 1941, *Leipoldt 3866* (BOL, holo.; BOL, NBG, iso.).

Flowers red, purple, violet or navy blue, lower tepals with cream-coloured markings on claws and darker blue or red markings in centre of limbs, unscented; perianth tube 40–50(–55) mm long, cylindric and ± straight; tepals subequal, 10–12 mm long, dorsal held apart from others when fully open. *Stamens* and *style* as in subsp. *pyramidalis*. *Capsules* oblong-trigonous, locules with prominent ridges, 7–9 mm long. *Seeds* 1.3–1.4 mm diam. *Flowering time*: late July to early September.

Distribution and ecology: restricted to the northwestern corner of Western Cape in the middle Olifants River

Valley between Citrusdal and Klawer, extending inland into the interior valleys of the Cederberg and Pakhuis Mtns; on light sandy soils, in stony habitats.

The unscented, dark red to violet flowers with pale markings on the tepals are adapted for pollination by long-proboscid nemestrinid flies.

Sect. 2. **Sophronia** *(Licht. ex Roem. & Schult.) Goldblatt & J.C.Manning* in Annals of the Missouri Botanical Garden 77: 373 (1990); 41 (2015). *Sophronia* Licht. ex Roem. & Schult.: 482 (1817). *Lapeirousia* subg. *Sophronia* (Licht. ex Roem. & Schult.) Baker: 482 (1892). Type: *S. caespitosa Licht. ex Roem. & Schult.* = *Lapeirousia plicata* (Jacq.) Diels

Corm bell-shaped; tunics with basal rim not produced into teeth or spines. *Stem* subterranean, internodes at ground level crowded. *Inflorescence* a head-like congested spike. *Flowers* radially symmetric, with perianth tube ± cylindric, short to elongate; stamens symmetrically arranged. *Seeds* with reticulate sculpturing. *Basic chromosome number x* = 8.

Species 5: western and central southern Africa extending to tropical Africa.

9. **Lapeirousia plicata** *(Jacq.) Diels* in Engler & Prantl, Die naturlichen Pflantzenfamilien, edn. 2, 15a: 488 (1930); Goldblatt & Manning: 44 (2015). *Galaxia plicata* Jacq.: 8, t. 292 (1795 [1788–1795]). *Ixia heterophylla* Willd.: 199 (1798), as a new name for *G. plicata* in *Ixia* [not *I. plicata* L. (1756)]. *Meristostigma heterophyllum* (Willd.) A.Dietr.: 199 (1833). *L. heterophylla* (Willd.) R.C.Foster: 4 (1939). *L. fasciculata* Ker Gawl.: 238 (1804), illegitimate superfluous name for *G. plicata* Jacq. *Ovieda fasciculata* (Ker Gawl.) Spreng.: 147 (1824). *Peyrousia fasciculata* (Ker Gawl.) Sweet: 499 (1830a). Type: South Africa, without precise locality, illustration in Jacq.: t. 292 (1795 [1788–1795]). Epitype: South Africa, Western Cape, Matjiesfontein, gravel flats near village, flowers white, 18 July 1974, *Goldblatt 2115* (MO, NBG), designated by Goldblatt & Manning: 44 (2015).

Plants small, acaulescent, forming diffuse or compact cushions, seldom > 50 mm high. *Corm* bell-shaped; tunics red-brown, rough-surfaced, basal rim slightly crenate. *Stem* entirely under ground. *Foliage leaves* up to 3, lowermost longest, usually exceeding inflorescence, up to 300 mm long, blades linear, suberect to strongly inclined, closely ribbed, margins of sheaths undulate or often crisped, remaining leaves broader than basal. *Inflorescence* congested, head-like, few- to several-flowered; bracts ovate at base, outer larger than inner, with apex often produced as ribbed leaf-like tip, margins usually crisped especially in basal half. *Flowers* actinomorphic, pale blue, ± white or pale yellow, with blue to violet spot at base of each tepal, scented of cloves or with light, sweet odour; perianth tube 12–30 mm long, ± cylindric, straight; tepals subequal, ± lanceolate, 7–9 mm long, acute, spreading or often slightly deflexed when fully open. *Stamens* symmetrically arranged around style; filaments exserted 1.5–2.0 mm, arching outward later in anthesis; anthers mostly 1.8–3.0 mm long, usually blue (or ± white), initially erect, later ± horizontal. *Style* dividing opposite base to middle of anthers, rarely below anther bases; style branches forked for ⅓–½ their length or undivided (subsp. *effurcata*). *Capsules* ovoid-oblong, 8–10 mm long. *Seeds* 6–9 per locule, ± globose, with reticulate to rugulose surface, dark brown, 1.0–1.5 mm diam. *Chromosome number* 2*n* = 16 (subsp. *plicata*). *Flowering time*: autumn, winter or spring, mostly June to mid-August, occasionally in May.

Distribution and ecology: widespread in South Africa, extending from Vanrhynsdorp and Robertson in the southwest of Western Cape, through the Little and Great Karoo to Northern Cape, North West and Free State Provinces and into southern Namibia; in fairly heavy clay soils, less often in light clay or sand, in fairly flat places, as well as on limestone or calcrete, usually where drainage is poor. Flowering is earliest in the north and east of its range, mainly in June but sometimes in May or July; in the west and south flowering usually begins in July lasting into August.

Diagnosis: smallest of the several acaulescent species of sect. *Sophronia*, the tufts of *Lapeirousia plicata* seldom reach 50 mm including the flowers. The perianth tube ranges from 12–20 mm long in southern and western populations, to as much as 30 mm in the northeastern populations. A distinctive feature of *L. plicata* is the orientation of the stamens, the filaments of which are initially erect but arch outward during anthesis, so that the dehisced anthers come to lie in a ± horizontal position. The style typically divides opposite the base to middle of the anthers but sometimes below the anther bases and rarely slightly beyond the anther tips.

Three subspecies of *Lapeirousia plicata* were recognised by Goldblatt (1972), based on morphological differences and by a moderate degree of geographical discontinuity. One of these, subsp. *longifolia*, is now a separate species, *L. kalahariensis*. Two other subspecies are recognised, subsp. *effurcata*, with unusually broad, widely channelled outer floral bracts with undulate margins and consistently white flowers and undivided style branches, and subsp. *plicata* with blue or white flowers with apically notched to deeply divided style branches and somewhat narrower floral bracts, sometimes with short, leafy, ribbed apices. A third series of populations from Bushmanland, the Great and Upper Karoo, subsp. *foliosa*, extending into Free State, mostly have white or cream-coloured flowers (sometimes described as pale yellow) but rarely blue and the outer floral bracts have

leaf-like, ribbed tips up to 30 mm long, sometimes unifacial toward the apices. These populations are also usually early blooming, often in flower in May and June.

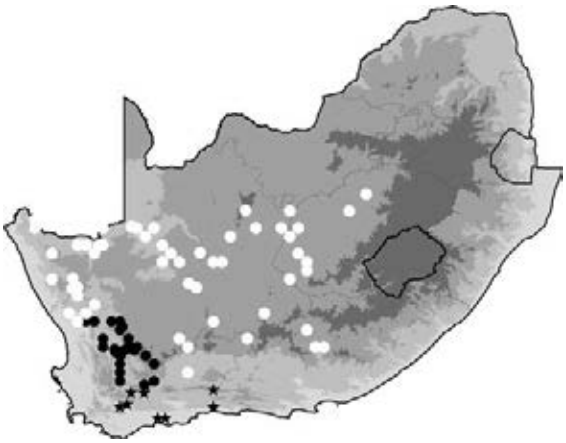
Key to subspecies

1a Outer floral bracts with ribbed, leafy tips up to 30 mm long; perianth tube mostly 19–30 mm long; flowers white to cream-coloured (pale yellow), occasionally with a blue to purple spot near tepal bases . . . . . 9c. subsp. *foliosa*

1b Outer floral bracts channelled to apices or with short, ribbed, leafy tips < 10 mm long; perianth tube mostly 12–22 mm long; flowers blue or white with blue to violet mark in lower midline of tepals:

2a Style branches usually forked for ⅓–½ their length, rarely undivided; flowers blue or white . . . . . 9a. subsp. *plicata*

2b Style branches always undivided; flowers white, flushed blue outside . . . . . .9b. subsp. *effurcata*



9a. subsp. **plicata**

Leaves usually 2 or 3, only lowermost with unifacial blade, ± linear, up to 150 × 2–3 mm, suberect, ribbed, usually ciliate or papillate on rib edges, margins plane or undulate, ciliolate. *Bracts* green, outer usually falcate, channelled throughout or with short, ribbed leafy apex up to 10 mm long, margins undulate to slightly crisped, usually ciliate. *Flowers* either blue with white zone at tepal bases and violet or purple triangular mark at distal edge of white zone or white with violet mark near tepal bases; perianth tube mostly 12–22 mm long; tepals 7–8 mm long, spreading or slightly reflexed. *Stamens*: filaments exserted ± 2 mm, diverging; anthers 1.8–3.0 mm long, blue to purple. *Style* dividing below to opposite base (rarely opposite middle) of anthers; style branches usually forked for ⅓–½ their length or shortly notched at apex, 1.0–1.5 mm long, recurving. *Flowering time*: mainly July and early August.

Distribution and ecology: restricted to the southern African winter-rainfall zone, subsp. *plicata* occurs in the Western Karoo from Calvinia and the Bokkeveld Plateau in Northern Cape south through the Tanqua Basin to Touws River, Matjiesfontein and Laingsburg in Western Cape, where it meets the range of subsp. *effurcata* in the western Little Karoo.

9b. subsp. **effurcata** *(G.J.Lewis) Goldblatt* in Annals of the Bolus Herbarium 4: 51 (1972). Goldblatt & Manning: 47 (2015). *Lapeirousia effurcata* G.J.Lewis: 7 (1952). Type: South Africa, [Western Cape], near Riversdale, Elands Drift, limestone koppies, Aug. 1946, *Ferguson s.n.* (BOL 24923, SAM, syn.).

Plants with foliage leaves usually 2 or 3, only lowermost unifacial, ± linear, up to 150 × 2–3 mm, suberect to spreading, margins plane. *Bracts* green, outer much exceeding flowers, channelled throughout, margins undulate to slightly crisped. *Flowers* usually white

Distribution of ***Lapeirousia plicata*** subsp. ***plicata***, ●; subsp. ***effurcata***, ★; subsp. ***foliosa***, ○.

(rarely pale blue) with blue mark in lower midline of tepals; perianth tube mostly 12–20 mm long; tepals ± 7 × 2–3 mm, ± spreading. *Stamens*: filaments exserted ± 3 mm, arching outward; anthers ± 2 mm long, blue. *Style* dividing slightly below to opposite base of anthers; style branches entire, recurved, ± 1 mm long. *Flowering time*: mainly July and August.

Distribution and ecology: restricted to stony flats in the Worcester–Robertson Karoo, the western Little Karoo and locally in the limestone belt of the southern Cape near Riversdale; on limestone outcrops and also on stony, sandy or clay ground.

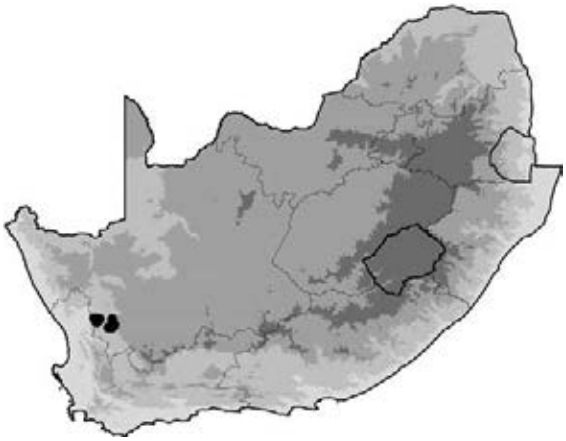
A curious feature of subsp. *effurcata* is that the flowers are reported to be heavily scented toward evening. Flowers of subsp. *plicata* have a light, sweet scent during the day, but we have not noted an increase in scent toward evening.

9c. subsp. **foliosa** *Goldblatt & J.C.Manning* in Strelitzia 35: 48 (2015). Type: South Africa, Northern Cape, Loeriesfontein, between Graafwater and Donkiedam, 4 July 1990, *Oliver 9484* (NBG, holo.).

Sophronia caespitosa Licht. ex Roem. & Schult.: 482 (1817). *Lapeirousia caespitosa* (Licht. ex Roem. & Schult.) Baker: 174 (1892). Type: South Africa, [Northern Cape], Sakrivierspoort, *Lichtenstein s.n.* (probably originally at B, no longer extant). Neotype: South Africa, Northern Cape, 10 km NE of Fraserburg on Loxton Road, 5 July 1000, *Manning* et al. *2260* (NBG, neo.).

Lapeirousia galaxioides Baker: 174 (1892). Type: South Africa, [Northern Cape], diamond fields at Klipdrift, without date, *Bowker s.n.* (K, holo.).

Plants often larger in vegetative features than subsp. *plicata*, with foliage leaves 2 or 3, lowermost longest, 150–350 × 2–3 mm, suberect, ribbed, smooth or ciliate to papillate on rib edges, margins usually plane,



often ciliate. *Outer bracts* upright below, tapering distally to leaf-like, channelled or unifacial tip mostly 15–30 mm long, linear, straight or falcate. *Flowers* white to cream-coloured (pale yellow), occasionally pale blue, tepals often with purple spot in lower midline, often (?always) scented of cloves; perianth tube mostly 19–30 mm long, well exserted from sheathing part of bracts; tepals 7–9 mm long. *Stamens*: filaments exserted ± 2 mm; anthers 2–3 mm long, blue (often fading white in herbarium specimens). *Style* dividing opposite base to apex of anthers (rarely exceeding anthers); style branches 1.2–2.0 mm long, usually deeply forked. *Flowering time*: mainly May and June.

Distribution and ecology: widespread across the arid parts of southern Africa, extending from the Knersvlakte of southern Namaqualand in Western Cape, along the eastern margins of Namaqualand north to southern Namibia and east across Bushmanland to Gordonia and the Kimberley District in Northern Cape, and in the western Free State and Upper Karoo as far east as Colesberg and Murraysburg and with records in Eastern Cape near Cradock.

Diagnosis: subsp. *foliosa* is recognised by the floral bracts with leaf-like, ribbed, unifacial tips at least 12 and up to 40 mm long, versus floral bracts usually channelled to the tips or with short, unifacial tips up to 10 mm long but the distinction is not absolute. Flowers are usually white to cream-coloured, occasionally pale yellow, and are strongly clove-scented according to notes with several collections. The flowers are sometimes larger than those of subsp. *effurcata* and subsp. *plicata*, with a perianth tube 19–30 mm long. Plants from the Roggeveld Escarpment with blue flowers are included in subsp. *foliosa*, evidently the only blue-flowered populations of the subspecies, on the basis of their floral bracts with leafy tips up to 20 mm long.

10. **Lapeirousia oreogena** *Schltr. ex Goldblatt* in Contributions from the Bolus Herbarium 4: 53 (1972) & t. 1670 (1973); Goldblatt & Manning: 49 (2015). Type: South Africa, [Northern Cape], 6 km east of Nieuwoudtville, 14 Sept. 1970, *Goldblatt 541* (BOL, holo.; K, MO, PRE, iso.).

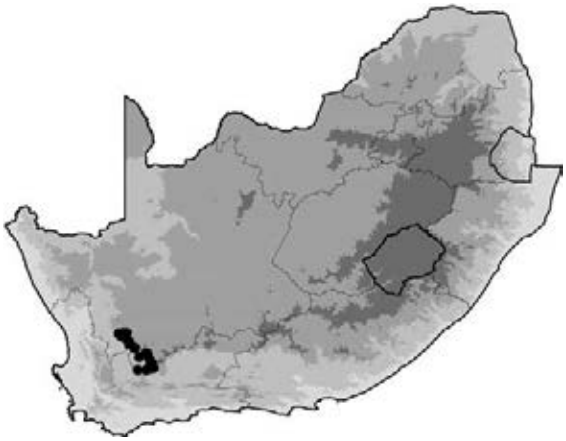
Plants forming dense tufts at ground level, 50–100 mm high, including flowers. *Corm* bell-shaped, ± 10 mm diam.; tunics light brown, surface lightly wrinkled. *Stem* subterranean, upper internodes contracted. *Foliage leaves* usually solitary, linear, straight, ribbed, 120–200 mm long. *Inflorescence* several- to many-flowered, congested in head-like tuft; outer bracts 30–60 mm long, bifacial and channelled throughout, usually ± falcate, often twisted, margins undulate and crisped, inner up to ½ as long, margins often plane. *Flowers* actinomorphic, salverform, dark blue-violet, almost black in centre with white triangular to arrowhead markings close to tepal bases; perianth tube erect, cylindric, 50–60 mm long; tepals subequal, 12–14 mm long, lanceolate, acute, spreading but becoming slightly deflexed with age. *Stamens* symmetrically disposed around style, erect; filaments exserted ± 3 mm; anthers erect, contiguous around style, ± 3.5 mm long. *Style* erect, usually dividing opposite middle ⅓ of anthers; style branches ± 2.5 mm long, deeply forked and recurved. *Capsules* ovoid to oblong, 7–10 mm long, without locular ridges. *Seeds* globose, ± 2 mm diam., red-brown, reticulately sculptured. *Chromosome number* 2*n* = 16. *Flowering time*: August to mid-September, rarely late July.

Distribution of ***Lapeirousia oreogena***.

Distribution and ecology: restricted to the Calvinia District of Northern Cape, South Africa, from the hills just to the north of Nieuwoudtville extending south at least as far as the Farm Matjiesfontein, ± 12 km from Nieuwoudtville, and also recorded in the hills southeast of Calvinia and northeast of the town in the Agterhantam; in heavy red, dolerite-derived clay soil, either in open ground or among rocks in shallow soil, occasionally on stony tillite ground.

Lapeirousia oreogena flowers fairly early in the season before the plants are overshadowed by annuals and taller geophytes that reach maturity some weeks later. Although plants are invariably autogamous when grown in the greenhouse, they produce ample nectar and are regularly pollinated by long-proboscid nemestrinid flies. Evidently *L. oreogena* is outcrossed when pollinators are available, but in seasons when pollinators are scarce (or emerge late), self-pollination ensures seed production.

Diagnosis: the acaulescent *Lapeirousia oreogena* is distinguished from its allies of similar habit by its large dark blue to violet flowers with slightly reflexed tepals and a perianth tube 50–60 mm long. The tepals are almost black at the base with white, triangular to arrowhead-shaped marks. The centrally placed purple anthers form a ring around the style and have dark purple pollen. Like some other acaulescent members of sect. *Sophronia*, the leafy outer bracts extend well above the flower buds and have wavy to crisped margins.

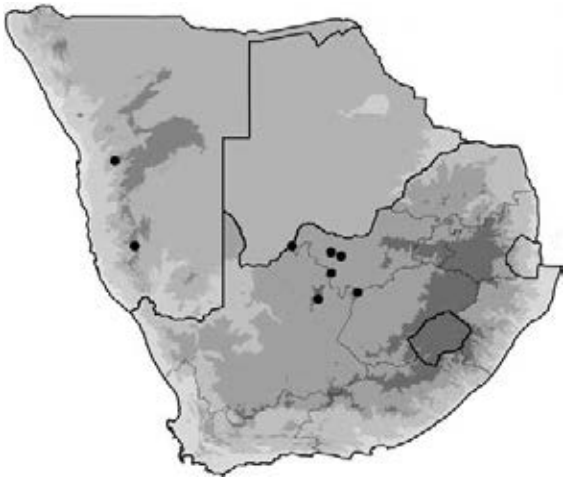


11. **Lapeirousia montana** *Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 359 (Ergänzungen: 25) (1882). Baker: 93 (1896). Goldblatt & Manning: 50 (2015). Type: South Africa, [Northern Cape], without precise locality, as 'Hantams Gebirge', 1869, *Meyer 10* (B, holo.).

Plants acaulescent, branched at base, forming compact tufts 30–50 mm high, including flowers. *Corm* bell-shaped, 8–10 mm diam.; tunics light brown, basal rim crenate. *Stem* underground. *Leaves* 1 or 2, lowermost always longest, linear, 80–180 mm × 2–3 mm, straight or falcate, remaining foliage floral bracts but often resembling leaves and identifiable as bracts by position. *Inflorescence* of several to many flowers in congested head-like structure borne at ground level, internodes very short but evident on dissection or in fruit; bracts leaf-like, wide and pale below for 15–25 mm, tapering to a green unifacial upper half resembling leaf blade and 15–40 mm long. *Flowers* actinomorphic, white to pale blue, then with lower third of tepals white, usually with dark blue triangular or diamond-shaped median mark near base, slightly scented of narcissus, lily or carnation; perianth tube cylindric, (25–)32–45(–55) mm long, with filaments decurrent as intrusive ridges dividing tube into 3 compartments and ± blocking tube in lower half; tepals subequal, lanceolate, (10–)12–15 × 4–5 mm, spreading horizontally or deflexed up to 30° below horizontal. *Stamens* symmetrically disposed around style; filaments exserted 2–3 mm from tube; anthers erect, 3–4 mm long, ± white; pollen white to ivory-coloured. *Ovary* oblong, 4–5 mm long; style straight and erect, usually dividing opposite middle to just below anther tips; style branches divided for ½ their length, 1.8–2.5 mm long. *Capsules* ± ovoid, 8–10 mm long, showing outline of seeds. *Seeds* globose, dark brown, ± 2 mm diam., with reticulate sculpturing, *Chromosome number* unknown. *Flowering time*: late August to late September.

Distribution and ecology: a relatively narrow endemic of the western Karoo in Northern Cape, South Africa, centred in the southern Roggeveld, but extending from the escarpment edge near Middelpos to sites in the Klein Roggeveld (the type, said to be from the Hantam Mtns 'Hantams Gebirge', has not been recollected there); in seasonally wet ground in relatively light clay or sandy soil in valley bottoms, around seasonal pools or in shallow soil over rocky pavement.

Lapeirousia montana is a generalist species despite its long perianth tube, and nectar ascends well up into the tube where it is accessible to settling moths, butterflies, bee flies (Bombyliidae) and bees. Floral scent is usually strong but variable, sometimes reminiscent of narcissus, lily, carnation or even an unpleasant acrid odour.



Diagnosis: the acaulescent *Lapeirousia montana* is allied to the widespread *L. plicata*, which it replaces in the southern Roggeveld, and is distinguished from that species by the larger flower with longer perianth tube, mostly 32–45 mm long, and tepals 10–15 mm long, always with ± straight margins. The anthers are ± white and 3–4 mm long. *Lapeirousia plicata* has smaller flowers with a perianth tube 12–30 mm long, tepals 7–9 mm with undulate margins, and anthers usually blue and mostly 1.8–3.0 mm long. The upper leaves and floral bracts are typically crisped in *L. plicata* vs. with straight margins in *L. montana*.

Distribution of ***Lapeirousia montana***.

12. **Lapeirousia kalahariensis** *Goldblatt & J.C.Manning* in Strelitzia 35: 51 (2015), as a new rank and name for *L. plicata* subsp. *longifolia* Goldblatt: 50 (1972). Type: South Africa, [Northern Cape], Danielskuil, in sand, 22 Mar. 1939, *Esterhuysen 1157* (BOL, holo.).

Plants ± acaulescent or shortly caulescent, 50–100 mm high excluding basal leaves. *Corm* bell-shaped, 10–12 mm diam.; tunics brown, rough-surfaced, basal rim lightly crenate. *Stem* usually reaching 10–40 mm above ground, several-branched, branches crowded to form a compact, stalked rosette. *Foliage leaves* ± 5, usually lowermost longest, up to 200 mm long, linear, lightly ribbed, margins of sheathing portion ± straight, remaining leaves shorter than basal, becoming ± bract-like. *Inflorescence* congested, head-like, many-flowered; outer bracts ovate at base, tapering to apex, channelled throughout, often hooked at tips, 50–100 mm long, leaf-like distally, reaching or slightly exceeding flowers, margins undulate to slightly crisped; inner ± ½ as long, transparent with 2 green keels. *Flowers* actinomorphic, evidently uniformly white to cream-coloured, ?probably sweetly scented; perianth tube (30–)33–40 mm long, slender, straight; tepals subequal, ± lanceolate, 10–14 × ± 3 mm, acute, held ± at right angles to tube. *Stamens* symmetrically disposed in a ring around style; filaments exserted ± 2 mm, arching outward after anthers split; anthers (3–)4 mm long, white. *Style* dividing opposite middle ⅓ of anthers; style branches ± 2.3 mm long, recurved, forked for ± ½ their length, rarely undivided. *Capsules* obovoid, ± 5 mm long, concealed in leaf bases, papillate in upper ⅓. *Seeds* probably globose (only immature known), surface reticulate. *Flowering time*: March, probably also April.

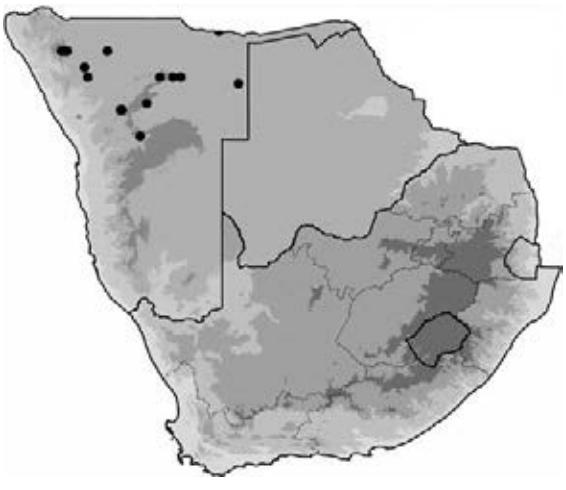
Distribution of ***Lapeirousia kalahariensis***.

Distribution and ecology: relatively widely distributed across the southern edge of the Kalahari, extending from Danielskuil and Kuruman west of Kimberley in Northern Cape, South Africa to south-central Namibia; habitat uncertain but including compacted calcareous sand flats.

Nothing is known about the pollination biology of *L. kalahariensis*, but the relatively long perianth tube and white flowers are consistent with pollination by moths.

Diagnosis: important diagnostic features for the species that distinguish it from *Lapeirousia plicata* include outer floral bracts that are channelled throughout and not unifacial distally, and a stem produced up to 40 mm above ground. The flowers are recorded as being uniformly white, or in one collection yellowish, always lacking the blue or purple markings characteristic of *L. plicata*. The tepals, 10–14 mm long, and tube, 30–40 mm long, are somewhat longer than in *L. plicata*, which has tepals 7–10 mm long and a tube typically 12–20 mm long, rarely up to 35 mm. Significantly, *L. plicata* occurs within the range of *L. kalahariensis* but typically blooms there later in the year, in May and June, sometimes in July. *Lapeirousia kalahariensis* also shows a resemblance to *L. odoratissima* from southern tropical Africa, but that species has much larger flowers, the perianth tube 100–140 mm long, and a well-developed, strongly ribbed basal leaf.

13. **Lapeirousia odoratissima** *Welw. ex Baker* in Transactions of the Linnean Society of London, Botany ser. 2, 1: 273 (1878); Sölch: 10 (1969); Geerinck *et al.*: 344 (1972); Goldblatt: 480 (1990b); Goldblatt & Manning: 53 (2015). Type: Angola, [Huila], sandy woods near Lopollo, in 1859, *Welwitsch 1551* (BM, lecto., so annotated in unrecognised hand; B, BM, C, G, K, iso.).



Lapeirousia stenoloba Vaupel: 548 (1912). Type: Namibia, Omaheke, 1 300 m, in brown sand, 17 Mar. 1911, *Seiner 329* (B, lecto., designated by Sölch on sheet).

Lapeirousia congesta Rendle: 435 (1895); Baker: 354 (1898). Type: Tanzania, ‚between Zanzibar and Uyui' [near Tabora], in 1866, *Taylor s.n.* (BM, holo.).

Lapeirousia juttae Dinter: 13 (1912). Type: not cited, unknown.

Plants 100–180(–250) mm high, with condensed aerial axis and often rosette-like. *Corm* bell-shaped, 15–20 mm diam.; tunics woody, brown, outer layers fragmenting irregularly, rarely becoming fibrous by decay. *Stem* ± underground or partly aerial and up to 100 mm long, with expanded internodes, simple or with several branches, each subtended by leaves or by leafy bracts *Leaves* few, often only 2 (hardly distinguishable from the bracts except by position), linear, strongly ridged, lowermost inserted below ground, exceeding bracts and up to twice as long, up to 300 × 3–5 mm. *Inflorescence* comprising 1 or more congested spikes, ± umbellate in appearance, flowers 3 to 6 per branch; *bracts* leafy, outer 60–150 mm long, lanceolate, lightly ridged, inner ± ⅓ shorter than outer, ± membranous. *Flowers* actinomorphic, salver-shaped, white to ivory-coloured, usually strongly scented especially in evenings; perianth tube cylindric, 100–140 mm long; tepals narrowly lanceolate to ± ovate, often attenuate, (25–)35–40(–50) × 3–11 mm, extended horizontally or sometimes slightly drooping. *Stamens* symmetrically arranged in a ring around style; filaments ± 4 mm long, exserted for 1.5–2.0 mm; anthers 6–8 mm long, linear, white; pollen yellow. *Style* usually ultimately reaching to ± apex of anthers, sometimes shorter; style branches 3–4 mm long, forked for ± ½ their length, diverging and recurved. *Capsules* obovoid-oblong, 15–18 mm long, concealed in leaf and bract bases. *Seeds* ± globose, 2.1–2.3 mm diam., with reticulo-rugose sculpturing. *Chromosome number* 2*n* = 16, 16 ± 0–2b *Flowering time*: December to March, occasionally in April.

Distribution and ecology: distributed widely across south tropical Africa but apparently common only in Namibia, extending from southwestern Angola across Zambia and adjacent Shaba in Congo to central and northern Malawi,

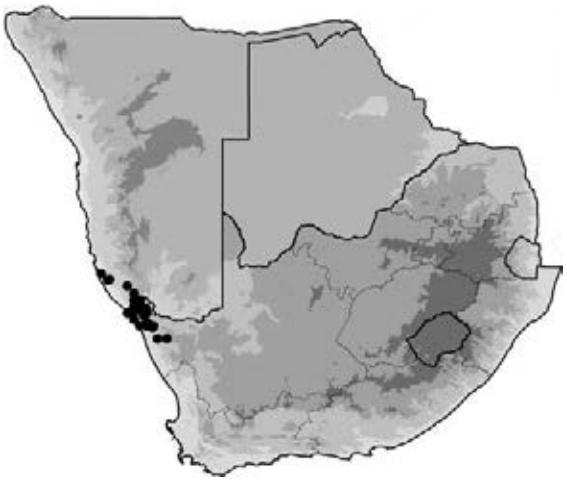
Distribution of ***Lapeirousia odoratissima***.

Zimbabwe, and in locally dry sites in western and central Tanzania; mostly on sandy flats in semi-arid habitats, sometimes in savanna woodland and even in exposed places in montane sites.

Diagnosis: the tufted or rosette-like growth habit combined with the large white flowers with an exceedingly long perianth tube, 100–140 mm long, set *Lapeirousia odoratissima* well apart in the genus. The other tufted to rosette-forming species of sect. *Sophronia* are all southern African with smaller, shorter-tubed flowers, coloured pale blue to violet, or white to pale yellow. One of only two species of the genus extending into tropical Africa, *L. odoratissima* has a chromosome number, $2n$ = 16 (x = 8) and reticulo-rugose seed sculpturing, thus corresponding with the southern African species of the section. The interior southern African *L. kalahariensis*, with white flowers and a perianth tube 30–40 mm long, appears to provide a link between *L. odoratissima* and the smaller southern African members of sect. *Sophronia*.

Sect. 3. **Lapeirousia**

Corm obconic, ± triangular in outline; tunics with basal rim produced into teeth, short or long, usually spreading. *Stem* mostly aerial (sometimes ± subterranean in *L. arenicola*) and often branched, stems compressed with angles often crisped. *Inflorescence* a spike. *Flowers* bilaterally symmetric, lower tepals with nectar guides of contrasting colour; perianth tube ± cylindric or funnel-shaped, short to elongate; stamens unilateral. *Capsules* without auriculate lobes or locular ridges. *Seeds* smooth (scarcely wrinkled) with surface cells domed. *Basic chromosome number* x = 8.



Species 14: mainly winter-rainfall western South Africa and southwestern Namibia extending into south tropical Africa.

14. **Lapeirousia barklyi** *Baker*, Handbook of the Irideae: 171 (1892); Goldblatt: 68 (1972) [including *L. macrospatha* Baker]; Goldblatt & Manning: 56 (2015). Type: South Africa, Namaqualand, without precise locality, Sept. 1876, *Barkly s.n.* (K, lecto. [not holo. as indicated by Goldblatt (1972)], designated here).

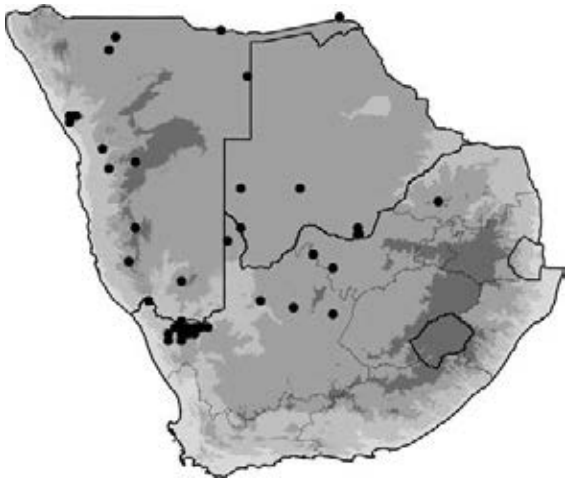
Plants 70–150 mm high, usually branched, sometimes repeatedly, mainly from base; stem compressed and 2-angled to 2-winged, wings often lightly serrated, with cormlet at each of 2 underground nodes. *Corm* bell-shaped, usually 60–90 mm below ground, ± 8 mm diam., tunics brown, fairly smooth, basal rim lightly serrated, teeth directed downward. *Leaves* 4 to 6 (or more), lowermost 1 or 2 longest and slightly to about twice as long as stem, linear, ascending to ± falcate, 1.5–2.0 mm wide, corrugately ribbed, upper leaves shorter than stem. *Inflorescences* 2- to 5-flowered spikes; outer bracts green, veins translucent, lanceolate and acute or acuminate, (10–)20–25 mm long, folded and angular along upper midline, often keeled near apex, margins broadly hyaline; inner bracts ± ½ as long as outer, transparent with 2 green keels, forked and turning brown at apex. *Flowers* zygomorphic, light purple-pink to lilac, lower tepals with basal ridge or claw-like tooth near base, marked with median yellow streak edged distally in dark red to purple, odourless; perianth tube obliquely funnel-shaped, (15–)20–25 mm long (often shorter in dry years, or apparently shorter in herbarium material), narrowly cylindric below, abruptly expanded in upper 4–5 mm into wide cylindric throat; tepals subequal, lanceolate, acute, upper 3 slightly larger, 24–27 × ± 6–7 mm, lower 3 united for 2–3 mm and thus slightly shorter, 18–22 × 5–6 mm, all weakly differentiated below into claws ± 8 mm long, claws forming wide cup, limbs spreading at right angles to claws, when fully open held ± in one plane. *Stamens* unilateral, arcuate; filaments ± 10 mm long, exserted ± 5 mm from tube but included in cup formed by tepal claws; anthers 5–6 mm long, included in floral cup, shortly apiculate, usually ± white; pollen white. *Style* arching over stamens, dividing close to or 1–2 mm beyond anther tips; branches ± 5 mm long, divided for ⅔ their length, spreading beyond anthers. *Capsules* oblong to ovoid, 8–10 mm long. *Seeds* 1.2–1.3 mm diam., round, smooth. *Chromosome number* $2n$ = 16. *Flowering time*: usually mid-September to early October, occasionally in late August.

Distribution and ecology: a species of the coastal Namib Desert, extending along the Atlantic coastal plain and adjacent coastal mountains from near Lüderitz Bay in Namibia in the north to Lekkersing and Port Nolloth in Northern Cape, South Africa in the south; in deep sands.

Diagnosis: the purple to violet perianth and relatively short-tubed flower combined with a broadly conical corm with well-developed basal teeth distinguish

Distribution of ***Lapeirousia barklyi***.

Lapeirousia barklyi. The floral tube, 15–25 mm long, is normally shorter than to about as long as the rest of the flower. This contrasts with *L. macrospatha*, which has a cream-coloured to beige perianth flushed pink on the reverse, and a tube 30–35 mm long and one and a half times as long as the rest of the flower. The closest relationships of *L. barklyi* may be with *L. fabricii*, a species of southern to central Namaqualand and Western Cape with a similar corm with marginal teeth but differing notably in its longer-tubed flower. The two can easily be distinguished by their bracts, which have an almost plane, smooth margin and keel in *L. barklyi* but are strongly crisped and serrate in *L. fabricii*.



15. **Lapeirousia littoralis** *Baker* in Transactions of the Linnean Society, London, Botany ser. 2, 1: 272 (1878). Goldblatt & Manning: 57 (2015). Type: Angola, [Namibe], sandy coastal hills at Praia da Amelia near Villa de Mossamedes, July 1859, *Welwitsch 1546* (BM, holo.).

Lapeirousia burchellii Baker: 171 (1892). *L. caudata* subsp. *burchellii* (Baker) Marais & Goldblatt in Goldblatt: 30 (1972). Type: South Africa, [?North West], Morokweng, Chooi Desert, (–AC), Oct. 1812, *Burchell 2350* (K, lecto., designated by Goldblatt: 30 (1972); G, P, isolecto.).

Lapeirousia ramosissima Dinter: 255 (1931). Type: Namibia, Lüderitz: dunes near Gründorn, *Dinter 5043* (B, holo.; BOL, BR, G, K, PRE, SAM, Z, iso.).

Lapeirousia streyii Suess. in Suess. & Merxm.: 88 (1951). Type: Namibia, Lüderitz: dunes south of the Kuiseb, *Strey 2587* (M, holo.; PRE, iso. [not holo. as cited by Goldblatt (1972)]).

Plants 100–150(–200) mm high. *Corm* bell-shaped, 10–14 mm diam.; tunics woody, brown, outer layers breaking irregularly, rarely becoming ± fibrous, basal rim shortly denticulate. *Stem* several- to many-branched, branches short, clustered near base, stem ± rounded to weakly angled below nodes. *Leaves* few to several, linear, 2–4 mm wide, slightly corrugately ribbed, lowermost longest, inserted at or just below ground, often as long as inflorescence, rarely slightly longer, ascending to falcate, upper leaves progressively shorter. *Inflorescence* 1 or more short, 4- to 8-flowered spikes; outer bracts green, succulent, weakly keeled, (12–)15–20(–25) mm long; inner ½–⅔ as long, ± membranous with 2 green keels, forked at apex. *Flowers* zygomorphic, white to cream-coloured, scented or not; perianth tube slender below, curving outward and expanded above, 28–35 mm long, slightly wider in upper ± 4 mm; tepals subequal, narrowly lanceolate, 13–15 × 2–3 mm, acute, spreading. *Stamens* unilateral, arcuate; filaments 7–8 mm long, exserted 2–3 mm; anthers parallel, 4–5 mm long, ± white; pollen white or yellow. *Style* arching adaxially to stamens, branching between base and middle of anthers; style branches divided in distal ⅓–⅔, recurved above and usually tangled in anthers. *Capsules* globose, 8–12 mm long. *Seeds* globose, 1.7–2.1 mm diam., dark brown, with reticulate sculpturing. *Chromosome number* $2n = 16$. *Flowering time*: mainly July to October in southern Africa but also at other times, March and April in northern Namibia.

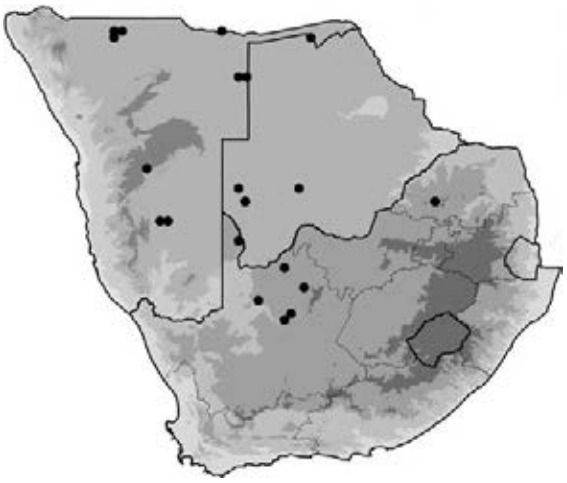
Distribution of ***Lapeirousia littoralis***.

Distribution and ecology: relatively widespread, extending from southwestern Angola and western, mainly coastal Namibia from near the Brandberg in the central west to the Lüderitz District in the south inland through Bushmanland and Gordonia as far east as Kimberley in Northern Cape, South Africa, and also in western Botswana; in sandy, well-drained soils, often on red sand flats.

Diagnosis: characterised by pale, uniformly coloured flowers with a long perianth tube expanded and curving outward distally, *Lapeirousia littoralis* can usually be recognised by its white flowers and relatively low stature with short branches from near the base. Plants mostly bloom in late winter or spring soon after the first rains of the season and are usually 100–150 mm high, and sometimes congested. The flowers have acute tepals ± 20 mm long and 2.0–2.5 mm wide and the floral bracts are usually 15–20(–25) mm long. *Lapeirousia littoralis* is closely related to *L. caudata* and the two have at times been united, but the latter is readily distinguished by the long slender branches, the main stem and branches up to 300 mm tall, and the creamy yellow to buff-brown or maroon flowers with particularly long, narrow, attenuate tepals 25–30 mm long and ± 1.3 mm wide. As the flowers fade and dry the tepals appear virtually filiform.

Molecular phylogenetic studies link *L. littoralis* and *L. caudata* with the western southern African *L. barklyi*, which has markedly different flowers. The seeds of *L. littoralis* and *L. caudata* are somewhat unusual, having a sculptured, ± reticulate surface, otherwise known only in sect. *Sophronia*. This suggests a possible link with sect. *Sophronia*, but neither molecular data nor any other morphological features point to a connection with that section.

16. **Lapeirousia caudata** *Schinz* in Verhandlungen des botanische Vereins der Provinz Brandenburg 31: 213 (1890); Goldblatt & Manning: 60 (2015). *L. littoralis* subsp. *caudata* (Schinz) Goldblatt: 478 (1990a). Type: Namibia, Amboland, Olukonda, *Rautanen 2* (Z, lecto., designated by Sölch on sheet; Z, isolecto.).



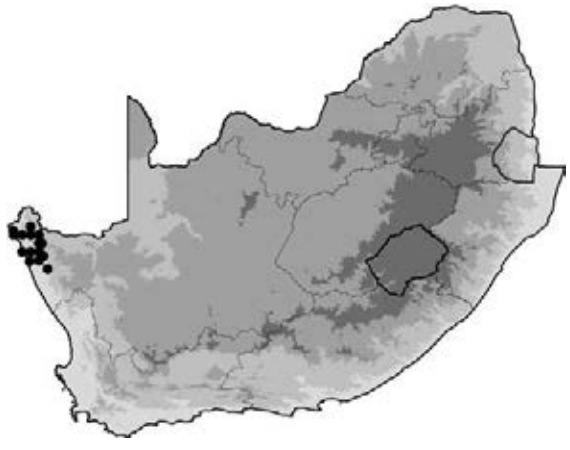
Lapeirousia delagoensis Baker: 171 (1892); Baker: 94 (1896). Type: Mozambique, Delagoa Bay, Lourenço Marques [Maputo], sandy places, *H. Bolus 7618* (K, lecto., designated by Goldblatt: 478 (1990a); BOL, G, SAM, isolecto.).

Lapeirousia lacinulata Vaupel: 546 (1912). Type: Zambia, Kantanina Hills, *Kässner 2170* (B, holo.; BM, BR, E, HBG, K, P, Z, iso.).

Plants 200–300 mm high. *Corm* bell-shaped, 10–14 mm diam.; tunics woody, brown, outer layers breaking irregularly, rarely becoming ± fibrous, basal rim shortly denticulate. *Stem* usually with several (up to 12) long branches, produced from near base, stem ± rounded to weakly angled below nodes. *Leaves* few to several, linear, 1.5–4.0 mm wide, lightly corrugately ribbed, lowermost longest, inserted ± at ground level, usually slightly longer than stems, ascending to falcate or trailing, upper leaves progressively shorter. *Inflorescence* comprising (1–)several, relatively lax, 8- to 12-flowered spikes; outer bract green, succulent, weakly keeled, 10–18(–23) mm long; inner ½–⅔ as long, ± membranous with 2 green keels, forked at apex. *Flowers* zygomorphic, greenish yellow, light yellow-brown or dull maroon, with strong sweet scent; perianth tube slender below, curving outward and expanded above, (8–)30–45(–70) mm long, wider upper part ± 6 mm long; tepals subequal, narrowly linear-filiform, (18–)25–30 × 1.3–2.0 mm, attenuate, spreading at right angles to tube, dorsal ± erect, upper laterals arching backward, lower 3 arching toward ground. *Stamens* unilateral, arcuate; filaments 7–8 mm long, exserted 2–3 mm; anthers parallel, 4–5 mm long, ± white; pollen white or yellow. *Style* arching adaxial to stamens, branching between base and middle of anthers; style branches divided in distal ⅓–⅔, recurved above and usually tangled in anthers. *Capsules* globose, 6–8(–11) mm long. *Seeds* globose, 1.7–2.1 mm diam., dark brown, with reticulate sculpturing. *Chromosome number* 2*n* = 16. *Flowering time*: mainly January to April (almost any month in Mozambique).

Distribution and ecology: occurring in a wide swath across south tropical Africa and northern southern Africa, from northern Namibia and Zambia, across Botswana to Zimbabwe and in South Africa to western Limpopo and Northern Cape, with isolated populations in southern Mozambique; in southern Africa in arid western and southern Namibia and Northern Cape, South Africa; in sandy, well-drained ground, sometimes growing on sand dunes.

The likely pollinators are moths, in light of the pale coloured, long-tubed flowers and often clove-like fragrance. The style branches are tangled with the anthers, suggesting that self-pollination may occur in the absence of insect-mediated pollen transfer.



Distribution of ***Lapeirousia caudata***.

Diagnosis: *Lapeirousia caudata* is characterised by uniformly coloured, pale dull yellow, yellow-brown or maroon flowers with a long perianth tube, mostly 30–45 mm long, expanded and curving outward distally. The relatively long tepals, 25–30 mm long, are up to 2 mm wide and as the flowers fade and dry the tepals appear filiform and less than 1 mm wide. The habit is also distinctive, and well-grown plants have several (up to 12) long branches 200–300 mm high, produced from near the base, and relatively lax spikes with short bracts, 10–18(–23) mm long. The tepals spread outward from the base in somewhat lax fashion with the dorsal tepal ± erect and the lower three arching toward the ground. Plants from southern Mozambique, mostly from immediately around Maputo, stand out in having particularly long-tubed flowers, the tube up to 70 mm long, and in often being very robust. Floral variation is notable in plants from western Zambia, and flowers with a perianth tube 8–13 mm long and tepals ± 18 mm long have been recorded.

Lapeirousia caudata was treated by Goldblatt (1990b) as subsp. *caudata* of *L. littoralis* as collections then available suggested the existence of plants intermediate between the two species, especially for bract and perianth tube length. Observation of living material of both taxa suggests that differences between them in overall habit and tepal dimensions and orientation are best interpreted as evidence that they are separate but closely allied species. The overlap in perianth tube and bract length in the two species most likely varies independently in each and does not indicate the existence of truly intermediate plants. Both species are included in sect. *Lapeirousia*, with which corm morphology and chromosome number accord, but they have seeds with reticulate to rugose surface sculpturing, a feature otherwise found in *Lapeirousia* only in sect. *Sophronia*.

17. **Lapeirousia macrospatha** *Baker* in Flora capensis 6: 94 (1896); Goldblatt & Manning: 345 (1994); Goldblatt & Manning: 61 (2015). Type: South Africa, [Northern Cape], between Port Nolloth and Eleven Mile Station, 22 Aug. 1883, *H. Bolus 697* (K, holo.; B, BOL, G, SAM, iso.).

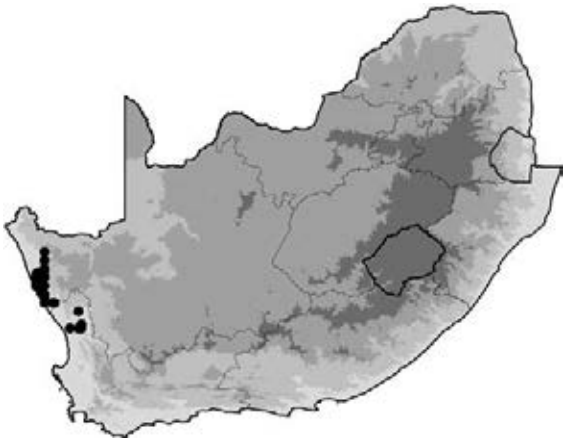
Plants 60–100 mm high, including flowers. *Corm* ± 7–8 mm diam., ± bell-shaped, usually 40–60 mm below ground; tunics dark brown, fairly smooth, basal margin lightly serrated with teeth directed downward. *Stem* usually branched, then from base, compressed and lightly 2-angled, angles smooth or lightly serrated. *Leaves* 3 to 6 (or more), lowermost usually conspicuously longer than others, ± twice as long as stem, linear, ascending to falcate, 2.0–3.5 mm wide, strongly ribbed, upper cauline leaves shorter, sometimes resembling bracts and not ribbed, usually subtending branches. *Inflorescences* 2- to 4-flowered spikes; outer bracts green, firm, 20–35 mm long, lanceolate, acute, slightly keeled, margins hyaline, those of lower flowers unifacial and ribbed distally; inner bracts forked at tips, transparent in centre, ± ½–⅔ as long as outer. *Flowers* zygomorphic, cream- to ivory-coloured, fading to dull pink, pink on outside of tepals and tube, lower tepals each marked with a small yellowish basal mark surrounded by a dark purple zone, usually with a small claw-like cusp at base of lowermost or all 3 lower tepals; perianth tube 30–35 mm long, widening and lightly curving outward near apex; tepals unequal, lanceolate and acute, dorsal largest, ± 20 × 7 mm, initially erect or arching forward over stamens later reflexed, upper lateral tepals slightly reflexed, lower three tepals united for ± 2 mm, ± 13 × 5 mm, held at right angles to tube, tilted at ± 30° below horizontal. *Stamens* unilateral, arcuate; filaments ± 9 mm long, reaching mouth of tube or exserted up to 2 mm; anthers contiguous, 3–5 mm long, mauve; pollen pale violet. *Style* dividing opposite middle of anthers; style branches ± 3 mm long, divided for ± ⅔ their length. *Capsules* oblong, 12–15 × ± 7 mm, apices of locules forming auriculate lobes decurrent on weakly developed locular ridges. *Seeds* globose, ± flattened or lobed at chalazal end, ± 1.6 mm diam., red-brown. *Flowering time*: August to late September.

Distribution of ***Lapeirousia macrospatha***.

Distribution and ecology: restricted to the southern Richtersveld and coastal northern Namaqualand in Northern Cape, South Africa, from near Eksteenfontein south at least as far as Grootmis; mainly in deep, fine-grained red sand, sometimes common locally and even dominant.

Diagnosis: *Lapeirousia macrospatha* is recognised by its large flowers with a long, slender perianth tube 30–35 mm long, widening noticeably toward the apex and white to ivory-coloured flushed red on the outside and with red markings on the lower tepals. The red-brown, bell-shaped corms bear fine marginal, downward directed teeth and are virtually identical with those of *L. arenicola*, which has similarly coloured flowers but much smaller in size with a ± cylindric perianth tube 20–33 mm long. The larger flower of *L. macrospatha* is reflected in a dorsal tepal ± 20 × 7 mm, whereas the smaller flowers of *L. arenicola* have a dorsal tepal 8–11 × 3–4 mm. The longer anthers of *L. macrospatha*, 3–5 mm long, also reflect the larger flowers than those of *L. arenicola*, in which the anthers are 1.5–2.5 mm long. The two species appear to grow in an identical habitat, deep red sand, *L. arenicola* extending along the Cape West Coast from near Klawer through the sand plains and coastal dunes of western Namaqualand to the southern Richtersveld on the Anenous flats, slightly overlapping but largely complementing the more northern distribution of *L. macrospatha*. DNA sequence-based phylogeny supports the hypothesis that *L. arenicola* and *L. macrospatha* are sister species.

Lapeirousia macrospatha was until recently regarded as merely a longer-tubed variant of then poorly understood *L. barklyi*, but that species has mauve-pink flowers with a relatively wide floral cup formed by the upper part of the perianth tube and the tepal bases. The corms also differ, those of *L. barklyi* triangular in profile with laterally extended spines, like those of L. *fabricii* and its allies.



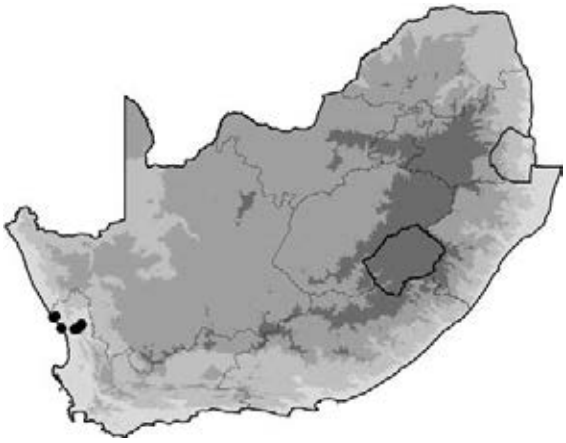
18. **Lapeirousia arenicola** *Schltr.* in Botanische Jahrbücher für Systematik 27: 105 (1900); Goldblatt & Manning: 64 (2015). Type: South Africa, [Western Cape], Atties [near Vredendal], 30 July 1896, *Schlechter 8329* (B, holo.; BM, BOL, COI, E, G, GRA, K, MO, P, PH, PRE, S, UPS, iso.).

Plants 100–120(–150) mm high, often ± tufted. *Corm* bell-shaped, 35–55 mm below ground, ± 6 mm diam.; tunics red-brown, smooth, basal rim lightly serrated, teeth directed downward. *Stem* usually branched, mainly at base, compressed and 2-angled, angles often weakly winged and slightly serrated, normally without cormlets at below ground nodes. *Leaves* 3 to 6(–many), lowermost usually conspicuously longer than others, linear, ascending to falcate, 2–3 mm wide, strongly

ribbed, upper cauline leaves shorter, usually resembling bracts and not or barely ribbed, usually subtending branches. *Inflorescences* 2- to 6-flowered spikes, lax or crowded; outer bracts green, leaf-like, 15–25 mm long, lanceolate, acute, keeled throughout or at least distally, unifacial apically for 3–5 mm, keels often red, minutely serrated, margins hyaline, inner bract transparent with two green keels, ½–⅔ as long as outer, forked at tip. *Flower* zygomorphic, cream-coloured to beige-pink, lower tepals each with red mark near base; perianth tube 15–25(–33) mm long, cylindric, curving slightly outward at apex; tepals subequal or dorsal slightly larger, lanceolate and acute or obtuse, 8–11 × 3–4 mm, usually spreading ± horizontally when fully open, all in same plane. *Stamens* unilateral, erect; filaments ± 7 mm long, exserted ± 3.5 mm from tube; anthers contiguous, 1.5–2.5 mm long, violet; pollen mauve. *Style* dividing opposite upper half of anthers; style branches ± 1.5 mm long, divided for ± half their length. *Capsules* oblong, (8–)10–12 × ± 6 mm, apices of locules forming auriculate lobes decurrent on wing-like locular ridges in upper half. *Seeds* globose, flattened at chalazal end, ± 1.4 mm diam., dark shiny brown. *Chromosome number* $2n = 16$. *Flowering time*: August to September, occasionally in early October.

Distribution and ecology: restricted to the South African Atlantic Coast and near interior, extending from near Vanrhynsdorp and Vredendal in Western Cape northward through the sandveld and low coastal hills of Namaqualand as far north as the Anenous Flats at the southern edge of the Richtersveld in Northern Cape; in deep sandy soils, especially the rather fine-grained red-tinged sands of lowland and coastal Namaqualand.

Diagnosis: low-growing and typically a small plant, *Lapeirousia arenicola* is distinguished by its small size, pale beige-pink, slender-tubed flowers with narrow tepals. Perhaps most easily confused with *L. macrospatha* which has similarly coloured flowers, *L. arenicola* has a uniformly narrow, cylindric perianth tube 17–33 mm long and tepals 10–11 × 3–4 mm whereas *L. macrospatha* has a wider tube, 25–35 mm long, expanded toward the apex and considerably larger tepals, the uppermost ± 20 × 7 mm. Although the two species appear similar on casual examination, they are quite distinct and do not intergrade although their ranges overlap slightly. Both have been found growing together just north of the road to Port Nolloth below Anenous Pass. Perianth tube length may coincide but the tepals of *L. arenicola* are always smaller and the tube more often than not is substantially shorter than in *L. macrospatha*. The two species are closely related and have been shown to be immediately related in molecular phylogenetic studies.



Distribution of ***Lapeirousia arenicola***.

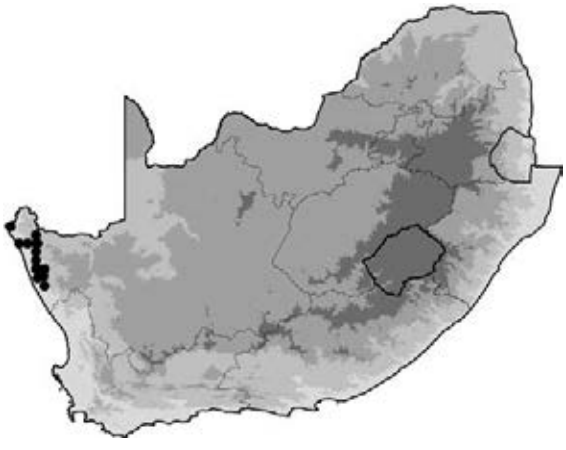
Lapeirousia arenicola has a striking supefficial similarity to *L. simulans*, which co-occurs with it at several sites along the West Coast and where their nearly identical flowers make a strong impression. *Lapeirousia arenicola* is always more compact in habit and often has a somewhat shorter perianth tube, so that they can be distinguished when seen growing side-by-side, but more significant differences are underground: the corms of *L. arenicola* lie 35–55 mm below the surface and the underground part of the stem rarely produces cormlets whereas corms of *L. simulans* are usually 55–85 mm below ground and always have a fairly large cormlet at each of two underground nodes. *Lapeirousia arenicola* is self-compatible but probably facultatively outcrossing early in the flowering season, when plants produce fairly large, long-tubed flowers with stronger colouring than later in the season, at which time the flowers of some populations have weakly contrasting markings, are smaller, and have a perianth tube 15–18 mm long (compared with ± 25 mm on the same plants earlier in the season). We assume these late-blooming flowers are primarily autogamous.

19. **Lapeirousia simulans** *Goldblatt & J.C.Manning* in Novon 4: 341 (1994); Goldblatt & Manning: 66 (2015). Type: South Africa, [Western Cape], sandveld ± 11 km north of Vanrhynsdorp, 14 Sept. 1992, *Goldblatt & Manning 9454* (NBG, holo.; K, MO, PRE, WAG, iso.).

Plants 100–180 mm high. *Corm* bell-shaped, 7–8 mm diam., 55–85 mm below ground; tunics dark brown, glossy, margins lightly serrate, teeth directed downward. *Stem* 2- or 3(5)-branched (rarely simple), branching ± divaricate, bearing a cormlet at each of 2 underground nodes, compressed and 2-angled, angles minutely serrated. *Leaves* 3 or more, lowermost longest, usually ± twice as long as stem, linear, 2.0–4.5 mm wide, corrugately ribbed, remaining leaves progressively shorter, becoming ± bract-like and usually subtending branch. *Inflorescence* lax spikes of (2)3 to 5 flowers; outer bracts green, transparent on veins, with slightly serrate keels decurrent on stem angles, 10–18 mm long; inner bracts ± ½ as long as outer. *Flowers* zygomorphic, ± white, reddish brown on reverse, lower 3 tepals each with small claw-like tooth near base and with small basal and larger median dark red spot, unscented; perianth tube cylindric, 27–35 mm long, slightly wider and curved near apex; tepals unequal, upper 3 slightly larger than lower 3, when fully open all held ± horizontally at right angles to tube, ± 11 × 4 mm, lower 3 held closely together,

Distribution of ***Lapeirousia simulans***.

10 × 3.0–3.3 mm. *Stamens* unilateral, erect; filaments 5–6 mm long, exserted ± 3 mm from tube; anthers 2.0–2.5 mm long, purple; pollen light purple. *Style* erect, adaxial to stamens, dividing between mouth of tube and anther bases; style branches ± 2 mm long, divided for slightly > ½ their length. *Capsules* oblong, 8–12 mm long, slightly warty in upper ½, without auriculate apices or locular ridges. *Seeds* globose, light brown, 1.2–1.4 mm diam. *Flowering time*: early to late September.



Distribution and ecology: restricted to southern Namaqualand, South Africa, from the Groen River west of Garies in Northern Cape south to Vanrhynsdorp in Western Cape; mainly in sandy ground.

Pollination of *Lapeirousia simulans* is unknown, but flower colouring and perianth tube length indicate a strategy using long-proboscid flies. Self-compatibility and autogamy assure reproduction by seed in the absence of cross pollination by insects. Vegetative reproduction is ensured by production of cormlets at the underground nodes of the deeply buried corm.

Diagnosis: the small corms with glossy dark brown tunics and a basal rim of minute, downward directed teeth closely resemble those of *Lapeirousia arenicola* and several other members of sect. *Lapeirousia*. The flowers in *L. simulans* and *L. arenicola* are so similar in tube length and general size and markings that they can be distinguished only with difficulty, and their flowering times overlap although that of *L. simulans* is generally somewhat later in the season, usually mid- to late September, by which time the last flowers of *L. arenicola* are often depauperate, and have shorter tubes and duller colouring than earlier in the season. The two species are most readily distinguished by the underground part of the stem. The corms of *L. arenicola* lie 35–55 mm below the surface on a straight stem that lacks axillary cormlets but the underground stem of *L. simulans* is 55–85 mm long so that the corm lies at a greater depth than in *L. arenicola*, and each of the two underground nodes consistently bears a large cormlet, a feature fairly rare in the genus, although also known in a few other species.

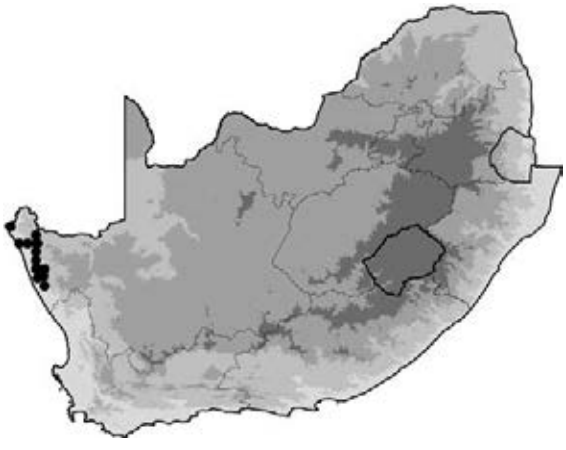
20. **Lapeirousia spinosa** *(Goldblatt) Goldblatt & J.C.Manning* in Novon 4: 343 (1994); Goldblatt & Manning: 68 (2015). *L. divaricata* var. *spinosa* Goldblatt: 66 (1972). Type: South Africa, [Northern Cape], ± 68 km west of Steinkopf to Port Nolloth, 24 Sept. 1970, *Goldblatt 567* (BOL, holo.).

Plants 50–90(–140) mm high. *Corm* ± bell-shaped (to ± obconic), 9–15 mm diam., 20–40 mm below ground; tunics blackish, often glossy, basal rim with prominent horizontal spines. *Stem* ± erect, sometimes branched at base, somewhat compressed but not often angled; without cormlets at nodes below ground. *Leaves* 3 or 4 (or more if plants branched), lowermost usually longest, usually shortly exceeding stem, linear to narrowly lanceolate, ascending or falcate, 2–4 mm wide, strongly corrugately ribbed; remaining leaves shorter and progressively more bract-like above, ribs weakly or not developed. *Inflorescences* spikes of (3–)5 to 9 flowers, usually moderately crowded; outer bract green or flushed reddish below, firm, 12–20(–35) mm long, enclosing slender part of tube, veins transparent, margins narrowly hyaline; channelled below, lightly keeled in upper ½, keels minutely serrated or crisped; inner bract up to ½ as long as outer, 2-keeled, with broad transparent margins. *Flowers* zygomorphic, white or flushed pink to lilac (more so with age and when dry), lower tepals yellow below and each with one or two purple median marks near limb base, bearing basal tooth-like ridge ± 2 mm long, lightly sweet-scented; perianth tube 9–12 mm long (shorter in dried material), narrow below, curved and widening above; tepals unequal, lanceolate, acute, dorsal largest, 18–23 × 7–8 mm, erect, held apart from others, lower margins undulate or lightly crisped, upper lateral tepals united with lower 3 for ± 5 mm, directed forward below, reflexed distally, lower 3 tepals horizontal below, limbs 12–14 × 7–8 mm, flexed sharply downward at ± 45°, margins undulate. *Stamens* unilateral and arcuate; filaments 9–12 mm long, exserted 7–9 mm from tube; anthers parallel, 4–6 mm long, white; pollen white. *Style* arching over stamens, dividing between

Distribution of ***Lapeirousia spinosa***.

base and middle of anthers; branches 4–5 mm long, forked for slightly more than ½ their length, recurved. *Capsules* ovoid, 6–7 mm long, with auricular lobes above locules. *Seeds* globose, ± 1.2 mm diam., flattened at chalazal end, smooth, brown. *Chromosome number* 2*n* = 16. *Flowering time*: mid-August to mid-September.

Distribution and ecology: restricted to west-central and northern Namaqualand, from the Orange River at Arris Drift in Northern Cape, South Africa, southward to Wallekraal east of Hondeklipbaai (not recorded in Namibia but almost certainly occurring there); usually in compacted sandy soil in places where the ground is covered by small quartz pebbles but on the plains west of Anenous Pass occurring in thousands in light clay devoid of stones.



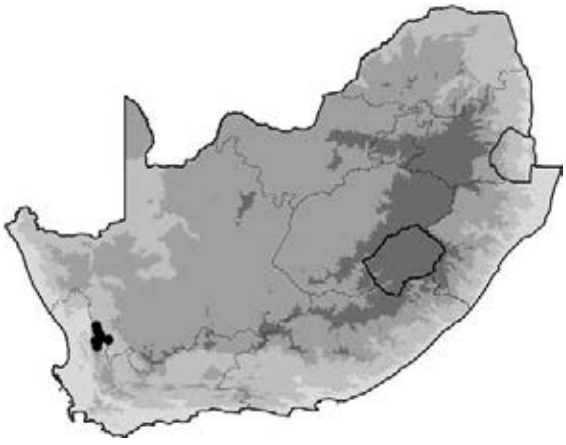
Diagnosis: early collections of *Lapeirousia spinosa* were first included in the broadly similar *L. divaricata* and flowers of the two species are alike in their white (or palest pink) colour, short perianth tube, and general shape, with the lower three tepals united with the upper laterals for several millimetres and ornamented with a tooth-like median ridge. The flowers of *L. spinosa* are larger, with a perianth tube 9–12 mm long and a dorsal tepal 18–23 mm long vs. a tube 7–10 mm long and dorsal tepal 14–16 mm long in *L. divaricata*. The latter species is restricted to moist or seasonally waterlogged, sandy habitats in the Bokkeveld, Cederberg and Olifants River Mtns, and is also taller with relatively lax spikes, and bell-shaped corms with minutely serrated lower margins. *Lapeirousia spinosa* occurs on dry, well-drained sandy flats, is a fairly compact plant, and has obconic corms and tunics with prominent, laterally directed spines. Molecular studies place the two species in separate clades, with *L. spinosa* now assigned to sect. *Lapeirousia* and *L. divaricata* in sect. *Chasmatocallis*.

21. **Lapeirousia tenuis** *(Goldblatt) Goldblatt & J.C.Manning* in Novon 4: 344 (1994); Goldblatt & Manning: 70 (2015). *L. divaricata* var. *tenuis* Goldblatt: 66 (1972). Type: South Africa, [Northern Cape], between Eleven Mile Station and Oograbies Poort (Port Nolloth and the mountains of the interior), 23 Aug. 1883, *H. Bolus 6575* '*Lapeirousia divaricata* Baker' (BOL, holo.; G, K, SAM, iso.).

Plants 60–160(–220) mm high. *Corm* broadly obconic (triangular in outline), 10–15 mm diam., up to 40 mm below ground, tunics dark brown to blackish, basal margins with fine laterally extended teeth 1–3(–4) mm long, tunics often accumulating. *Stem* mostly 2- or 3-branched or unbranched; branches produced well above ground level, slightly compressed, oval in section, occasionally lightly or obscurely angled, angles smooth. *Leaves* 3 or 4, only lowermost well developed, straight and linear or falcate, usually ± as long as to twice as long as stem, rarely slightly shorter, 2–3(–4) mm wide, corrugately ribbed; remaining leaves < ½ as long as lowermost and progressively more bract-like above. *Inflorescences* spikes of 9 to 16 flowers, lateral spikes with fewer flowers, 2-ranked in bud, becoming spiral after anthesis; outer bract grey-green, transparent on veins, acute, 7–11 mm long, folded on midline but not keeled, apices acute and curving upward, inner bract ⅓–½ as long as outer, transparent with two green keels, forked at tip. *Flowers* zygomorphic, pale lilac-pink, lower tepals each with darker blotch or streak in midline and claw-like cusp near base, cusp ± white surrounded basally by red-purple zone, occasionally upper lateral tepals also lightly marked in lower ½, lightly sweet-scented; perianth tube 10–15 mm long, slender below, curving outward and wider in upper ⅓; tepals narrowly lanceolate to ± linear, dorsal 9–11 × 2–3 mm, ± erect, upper laterals recurving from base, lower 3 united for ± 2 mm, extending horizontally below, flexed downward distally. *Stamens* unilateral, ± erect; filaments ± 6 mm long, exserted ± 3 mm from tube; anthers ± 3 mm long, parallel, light purple; pollen ± white. *Style* straight, adaxial to stamens, dividing between middle and apex of anthers; branches ± 2.5 mm long, deeply divided and recurved. *Capsules* globose-trigonous, ± 4–5 mm long. *Seeds* globose, 1.6–2.0 mm diam., smooth, brown, glossy. *Flowering time*: mainly in July, occasionally mid- to late August, and once recorded in bloom in early September.

Distribution and ecology: restricted to coastal central and northern Namaqualand from Kleinzee to near Port Nolloth in Northern Cape, South Africa; rare and poorly documented; on stony slopes in clay mixed with granite and quartzite pebbles.

Diagnosis: *Lapeirousia tenuis* and *L. divaricata* share corms with spiny basal rims and comparatively small bracts but have markedly different flowers. In *L. divaricata* (and allied *L. spinosa*) the lower tepals are united with the upper laterals for some distance and the lower tepals have large, tooth-like median ridges whereas the flowers of *L. tenuis* have narrow tepals that spread ± uniformly from the apex of the perianth tube. The lower tepals appear to be united for a short distance but are not fused to the upper tepals at all, and they have claw-like basal cusps rather than tooth-like median ridges.



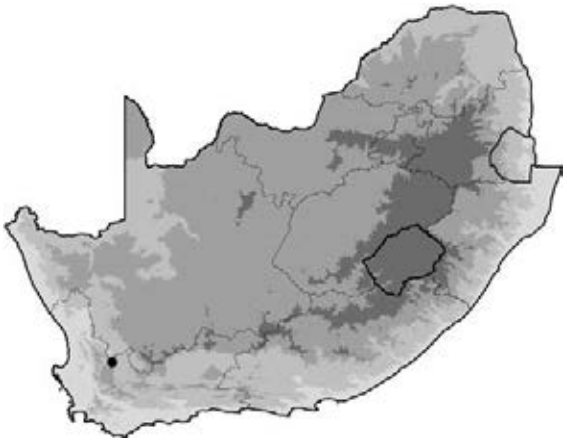
Distribution of ***Lapeirousia tenuis***.

22. **Lapeirousia violacea** *Goldblatt* in Contributions from the Bolus Herbarium 4: 59 (1972); Goldblatt & Manning: 71 (2015). Type: South Africa, [Western Cape], Biedouw Valley, 26 Aug. 1970, *Goldblatt 569* (BOL, holo.; K, MO, iso.).

Plants 60–100 mm high. *Corm* broadly obconic, 8–10 mm diam.; tunics dark brown, with light vertical ridging, basal rim with spreading spines 2–5 mm long. *Stem* simple or 1- to 4-branched from near base, stem lightly compressed, generally 1-angled, angles decurrent on leaves or bract keels. *Leaves* 4 to 6 (or more when stem branched), lowermost longest, generally shorter than stem and ascending, narrowly lanceolate or falcate, 5–7 mm wide, corrugately ribbed, other leaves ½ as long or less, only lightly ribbed, upper of these often bract-like. *Inflorescences* (2)3- or 4-flowered spikes; outer bracts pale green, firm, 15–22(–30) mm long, folded and keeled in midline, keels minutely crisped, often 2–3 mm wide near apex; inner bracts mostly green with broad transparent margins, ⅔ to ± as long. *Flowers* zygomorphic, dark violet, lower tepals each with dark purple to red spear-shaped basal mark and white lines along lower margins; when fully open tepals held ± in one plane, lowermost or all three lower tepals bearing a small basal claw-like cusp; perianth tube 35–40 mm long, slender, widening and curving toward apex; tepals unequal, narrowly lanceolate, dorsal largest, ± 10 × 5 mm wide, separated from others, upper lateral tepals reflexed, lower 3 tepals joined basally for 3–4 mm, free parts held closely together, 7–8 × ± 4 mm. *Stamens* unilateral, ± erect; filaments ± 9 mm long, exserted ± 5 mm from tube; anthers ± 2.5 mm long, purple; pollen purple. *Style* dividing opposite base or middle of anthers; style branches ± 2 mm long, deeply forked and recurved. *Capsules* oblong-trigonous, remaining enclosed in bracts, 9–11 mm long, without locular ridges. *Seeds* globose, slightly domed outward at chalazal end, 1.1–1.3 mm diam., light brown. *Chromosome number* 2*n* = 16. *Flowering time*: August to mid-September.

Distribution and ecology: restricted to the mountains and intermontane valleys of northwestern Western Cape and adjacent Northern Cape, South Africa, extending from the valleys of the Biedouw and Doorn Rivers in the south through Botterkloof as far north as Papkuilsfontein south of Nieuwoudtville; in sandy soil, mostly in stony ground, rarely common, in valley bottoms and exposed hilly sites.

Distribution of ***Lapeirousia violacea***.



Diagnosis: *Lapeirousia violacea* shares dark violet flowers with reddish to purple and white markings on the lower tepals with *L. jacquinii*, but they differ markedly in their floral bracts and corms. The corms of *L. jacquinii* are bell-shaped without the long spiny, laterally projecting teeth typical of the obconic corms of *L. violacea*, which has inflated outer bracts folded or slightly keeled, thus very different from the shorter, typically two-keeled bracts of *L. jacquinii*. The two species share pollinators but hybrids between them are unknown in the wild. Both species are self-compatible and facultatively autogamous.

The large bracts and obconic, basally toothed corms of *L. violacea* suggest a relationship with *L. dolomitica* and its allies of Namaqualand and southern Namibia, as well as *L. purpurea* from the Swartruggens of Western Cape. *Lapeirousia violacea* and *L. jacquinii* share the same pollinators, long-proboscid *Prosoeca* flies.

23. **Lapeirousia purpurea** *Goldblatt & J.C.Manning* in Strelitzia 35: 74 (2015). Type: South Africa, Western Cape, Swartruggens, Gansfontein, rocky sandstone slopes, Sept. 2008, *Manning & Roux 3179* (NBG, holo.; K, MO, PRE, S, iso.).

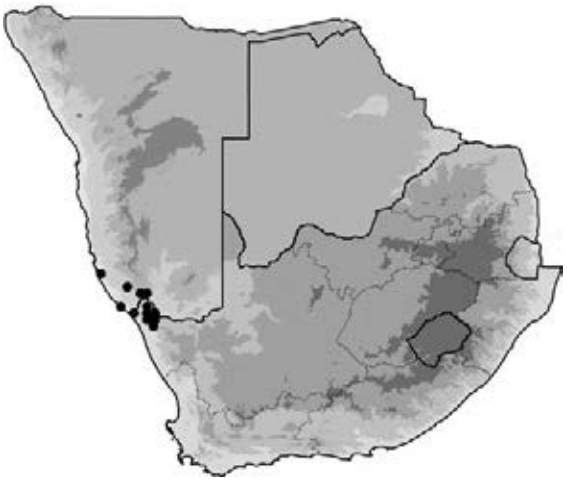
Plants 100–150 mm high, simple or few- to many-branched, mostly from base, stem compressed and 1- or 2-angled. *Corm* triangular in outline, basal rim prominently serrated, 24–28 mm diam. at base. *Leaves* several, the basal ribbed, ⅓ to ± as long as stem, to 5 mm wide, upper leaves progressively smaller above, smooth, the uppermost resembling floral bracts. *Spike* 6- to 10-flowered; bracts green, outer 10–18 mm long, with shallow, slightly serrated keel, inner ± ⅓–½ as long as outer, membranous with two darker keels, notched at apex. *Flowers* blue-purple, lower tepals with V-shaped white mark above base surrounded by darker violet to ± black zone, lower median tepal with a small claw-like tooth above base, unscented; perianth tube slender below, widening and curving outward in upper ⅓, 35–38 mm long; tepals unequal, dorsal erect, ovate, ± 15 × 6 mm, upper laterals slightly smaller, recurved, lower tepals united basally for ± 3 mm, curving downward, ± 8 × 4 mm. *Stamens* unilateral, arcuate; filaments ± 7 mm long, exserted ± 3 mm from mouth of tube; anthers suberect, prominently tailed, ± 4 mm long; pollen yellow. *Style* arching above stamens, dividing opposite lower ⅓ to middle of anthers; style branches ± 3.5 mm long, divided for slightly > ½ their length. *Capsules* ovoid, ± 12 mm long, showing outline of seeds, with moderately well developed locular ridges. *Seeds* unknown. *Chromosome number* unknown. *Flowering time*: September.

Distribution and ecology: known from just two collections from interior valleys of the Swartruggens that

Distribution of ***Lapeirousia purpurea***.

drain into the Tanqua Basin in Western Cape, South Africa; in sandy ground among sandstone rocks.

The long-tubed, purple flowers with white markings on the lower tepals are evidently adapted for the *Prosoeca peringueyi* long-proboscid fly pollination system, but the floral biology of the species remains to be investigated.



Diagnosis: The obconic corms of *Lapeirousia purpurea* have fine teeth projecting from the base and resemble the corms of *L. dolomitica*, *L. lewisiana* and *L. violacea*, also long-tubed species, but can be distinguished by the rich violet colour of the perianth, with the upper lateral tepals strongly reflexed and the lower three tepals with a V-shaped white mark above the base surrounded by a dark violet to black zone. The lower median tepal bears a small claw-like cusp near the base. In *L. violacea* all three lower tepals usually bear a small tooth near the base, and such teeth are lacking in *L. dolomitica* and *L. lewisiana*.

24. **Lapeirousia dolomitica** *Dinter* in Repertorium specierum novarum regni vegetabilium 29: 255 (1931); Goldblatt & Manning: 74 (2015). Type: Namibia, Alicetal, pump station near Pomona, June 1929, *K. Dinter 6432* (B, holo.; BM, BOL, G, GH, K, iso.).

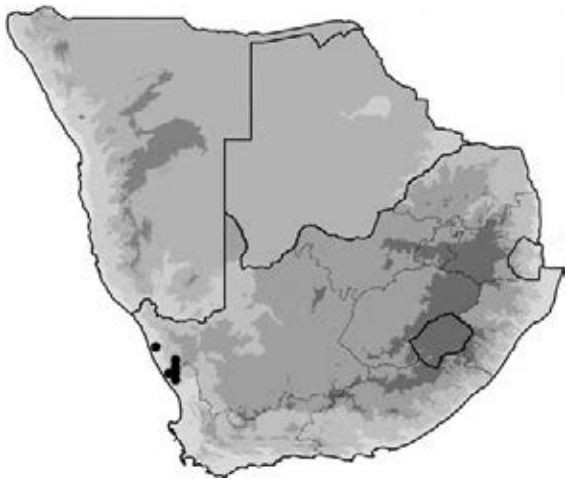
Plants (50–)100–150 mm high. *Corm* 10–15 mm diam., broadly obconic (triangular in outline); tunics dark brown, rugose, basal rim with prominent laterally projecting spines. *Stem* simple or 1- or 2-branched from base, stem terete or compressed and 2-ridged to 2-winged below first flower. *Leaves* 1 to 3, lowermost basal and longest, straight to falcate, 100–150 mm long, usually ± as long as stem, 3.5–5.0 mm wide, strongly ribbed, smooth or minutely papillate along rib margins, remaining leaves much smaller, resembling floral bracts. *Inflorescences* spikes of (5–)8 to 15 flowers, initially 2-ranked, becoming spiral; outer bract 12–20 mm long, pale to dark green, margins hyaline or red, semi-transparent over veins, inflated, ± round in section, abaxial surface weakly keeled, keels usually restricted to distal half, inner bract ⅓–½ as long as outer, with two broad green keels. *Flowers* zygomorphic, pale blue to violet or lilac, lower 3 tepals partly or entirely yellow near base and darker blue or purple in median upper half, sometimes with short median ridges near base usually curving downward, sometimes sweetly scented; perianth tube slender, ascending, arching outward near apex, 25–35(–40) mm long (in severely stressed plants occasionally less than 25 mm); tepals unequal, lanceolate and acute, dorsal longest and erect, (12–)15–17 × 5–7 mm, narrowed below, upper laterals slightly shorter, spreading or reflexed, lower 3 tepals united for 2–3 mm, slightly narrowed toward base, held closely together, (10–)12–14 mm long. *Stamens* unilateral, ± erect; filaments ± 10 mm long, exserted 2–4 mm, arching outward; anthers 4.0–4.8 mm long, parallel, purple or cream-coloured; pollen lilac or cream-coloured. *Style* arching adaxial to stamens, usually dividing opposite middle ⅓ of anthers (rarely below anther bases in northern populations), dark violet; style branches 3–4 mm long, recurved, divided for ½ their length. *Capsules* ovoid-oblong, weakly trigonous, 12–14 mm long, without locular ridges, usually warty or papillose. *Seeds* globose, chalazal end somewhat flattened, ± 1.8 mm diam., glossy dark brown. *Chromosome number* 2*n* = 16. *Flowering time*: June to late July, sometimes in August.

Distribution and ecology: restricted to the most arid parts of the southern African winter-rainfall zone, extending from Pomona in southwestern Namibia south into the Richtersveld of Northern Cape, South Africa; in rocky places, often on quartzite shale but not normally in dolomite or any other type of limestone.

Diagnosis: *Lapeirousia dolomitica* is recognised by its distinctive, obconic corms with blackish, rough-surfaced tunics bearing prominent spines extending outward from the base, and by the somewhat inflated bracts with only weakly developed keels. When seen alive the bracts are unusual in having alternating longitudinal bands of pale translucent and dark opaque colouring. The flowers are pale blue or lilac (recorded in some collections as violet),

Distribution of ***Lapeirousia dolomitica***.

with pale yellow markings at the bases of the lower tepals and sometimes also short tooth-like, basal ridges. Among the long-tubed species of *Lapeirousia*, it has a perianth tube shorter than usual, mostly 25–35 mm long.



Lapeirousia dolomitica resembles *L. lewisiana* in its corms with spiny basal margins and particularly long style branches, up to 4 mm long but has glabrous leaves, only lightly inflated floral bracts, generally with weakly developed keels, paler coloured flowers with a somewhat shorter tube, mostly 25–35 mm long, and often papillose to warty whereas. In contrast, *L. lewisiana* has hairy leaves, strongly inflated bracts lacking keels, larger, deep magenta red flowers with a tube mostly 40–48 mm long, and consistently smooth capsules.

25. **Lapeirousia lewisiana** *B.Nord.* in Botaniska Notiser 123: 434 (1970); Goldblatt & Manning: 77 (2015). *L. dolomitica* subsp. *lewisiana* (B.Nord.) Goldblatt: 64 (1972). Type: South Africa, [Western Cape], Komkans, 11 Aug. 1962, *Nordenstam 965* (NBG, holo.; S, iso.).

Plants (50–)100–200 mm high. *Corms* 10–15 mm diam., broadly obconic; tunics dark brown, rugose, basal rim with well-developed, slender, laterally projecting spines. *Stem* simple or 1- or 2-branched from base, stem terete or compressed and 2-ridged to 2-winged below first flower. *Leaves* 1 to 3, lowermost basal and longest, straight to somewhat falcate, 100–150 mm long and usually ± as long as stem, 3.5–5.0 mm wide, strongly ribbed, sparsely and irregularly white-hairy on rib edges at least in lower half, remaining leaves small, resembling floral bracts. *Inflorescences* spikes of up to 14 flowers; outer bract ± 20 mm long, inflated, usually rounded and without keels except occasionally near tips. *Flowers* reddish purple to magenta, lower tepals with broad ± white median streak in lower, narrow half and darker red-purple blotch in upper centre; perianth tube (35–)40–48 mm long; tepals unequal, lanceolate to ± spathulate or obovate, apex acute or rounded, dorsal ± 12 × 6–7 mm, lower 3 united for ± 3 mm, narrow at base for 2–3 mm, held at ± 45° to horizontal, ± 10 × 5.5 mm. *Stamens* unilateral, ± erect; filaments exserted ± 3.5 mm; anthers 3–4 mm long, dark violet. *Style* arching over stamens, between middle and apex of anthers; style branches 3–4 mm long, recurved, divided for ½ their length. *Capsules* ovoid-oblong, weakly trigonous, 12–14 mm long, without locular ridges, smooth. *Seeds* globose, ± flattened at chalazal end, 1.9–2.2 mm diam., glossy dark brown. *Flowering time*: mid-July to mid-August.

Distribution and ecology: never common, but recorded from several collections from central and southern Namaqualand, where it is best known from the area between Garies and Bitterfontein in Northern Cape, South Africa, but also occurring locally to the west toward the coast as far south as Komkans in Western Cape; in stony, fine-grained soils.

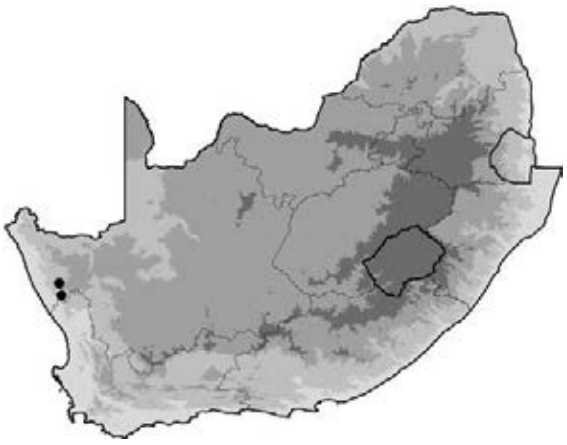
Diagnosis: *Lapeirousia lewisiana* is closely allied to *L. dolomitica*, and the two species share virtually

Distribution of ***Lapeirousia lewisiana***.

identical obconic corms with prominent, spreading marginal spines, and long-tubed flowers, but the differences between them include flower colour and markings, perianth tube length, and leaf vestiture. *Lapeirousia lewisiana* has magenta-red (also sometimes described as purple) flowers, the lower three tepals with prominent white, median streaks in the proximal third, and the perianth tube is typically 40–45 mm long, and the basal foliage leaf is finely but sparsely hairy. In contrast *L. dolomitica* always has hairless leaves and a pale blue to violet perianth with paired white streaks on the lower tepals, the perianth tube 25–35 mm long or rarely slightly longer. Capsules are poorly known in *L. dolomitica* but are slightly warty or papillose where recorded, whereas *L. lewisiana* has smooth capsules. There are also slight differences in the bracts of the two species: although somewhat inflated in both species, the bracts of *L. dolomitica* have a weakly developed keel in the distal half whereas those of *L. lewisiana* are rounded or become slightly folded only along the midline near the tips.

Despite its close relationship to *Lapeirousia dolomitica*, *L. lewisiana* is most easily confused with the common Namaqualand species, *L. silenoides*, which it resembles in its long-tubed, darkly pigmented magenta-red flowers, but the latter has bell-shaped corms without spiny projections, and smaller bracts.

Also closely related to *Lapeirousia lewisiana*, *L. kamiesmontana* has similar vegetative features, including the corm tunics with spiny margins and slightly hairy foliage leaf, but flowers later in the season, usually two to three weeks after *L. lewisiana*, even at the same elevation and has white flowers, the lower tepals marked with red, the tube and the reverse of the tepals flushed dark red, and a perianth tube mostly 45–56 mm long.



26. **Lapeirousia kamiesmontana** *Goldblatt & J.C.Manning* in Strelitzia 35: 79 (2015). Type: South Africa, Northern Cape, Kamiesberg, between De Kom and Garies, 27 Aug. 1976, *Goldblatt 3980* (NBG, holo.; K, MO, PRE, S, iso.).

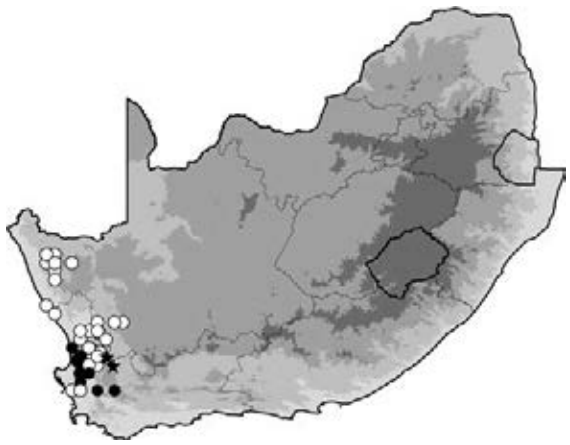
Plants 100–180 mm high. *Corm* 10–14 mm diam., broadly obconic; tunics dark brown, rugose, basal rim with long, slender, spreading spines. *Stem* simple or 1- or 2-branched from base; stem round to slightly compressed. *Leaves* 1 to 3, lowermost basal and longest, straight to somewhat falcate, 80–160 mm long, sometimes exceeding flowers, 3.5–5.0 mm wide, strongly ribbed, sparsely woolly (rarely ± smooth), remaining leaves much smaller, resembling floral bracts. *Inflorescences* spikes of (5–)8 to 10 flowers, initially 2-ranked, becoming spiral; outer bract 10–15 mm long, acute, ± inflated, rounded, without keels, inner bract ± half as long, transparent with 2 green keels. *Flowers* white (pale yellow when dry), flushed red on reverse of tepals and tube, lower tepals with red blotch in lower ⅓ and paired, red lines near base running into throat (purple when dry); perianth tube mostly 45–56 mm long, ± uniformly wide throughout; tepals unequal, obovate and markedly narrowed in basal 2 mm, dorsal 16–18 × (7–)9–10 mm, lower tepals held ± horizontally, united basally for ± 1.5 mm, ± 15 × 5.5–6.5 mm. *Stamens* unilateral ± erect; filaments ± 10 mm long, exserted 2–3 mm; anthers 4.5–5.0 mm, violet; pollen purple. *Style* dividing opposite anther tips; style branches ± 3.5 mm long, divided for half their length, recurved, white. *Capsules* and *seeds* unknown. *Flowering time*: late August to early October.

Distribution and ecology: restricted to the southern Kamiesberg in Northern Cape, South Africa, from the flats around the Farm Doornkraal at ± 600 m elevation and in the Langkloof at elevations up to 950 m at least; in decomposed granitic soil and occasionally in granite outcrops.

The form and colour of the long-tubed flowers suggests pollination by long-proboscid flies, but no insect visitors have been recorded for the species.

Diagnosis: the broadly obconic corm with dark brown, rugose tunics spiny along the rim of *Lapeirousia kamiesmontana* are shared with *L. dolomitica* and *L. lewisiana*, from which it is distinguished by white flowers with distinctive red markings on the lower tepals, and a perianth tube mostly 45–60 mm long. The earlier-blooming *L. lewisiana* has dark red-purple to magenta flowers with white markings and a perianth tube (35–)40–48 mm long. The distinctive, somewhat woolly indumentum on the basal leaf is also shared in the genus only with *L. lewisiana*, but the ranges of the two species do not overlap, and the flowering times, even at the same elevation, are separated by at least two to three weeks in any particular year.

Distribution of ***Lapeirousia kamiesmontana***.



27. **Lapeirousia fabricii** *(D.Delaroche) Ker Gawl.* in Curtis's Botanical Magazine 31: sub t. 1246 (1810); Goldblatt & Manning: 81 (2015). *Ixia fabricii* D.Delaroche: 18, no. 5 (1766). *Gladiolus fabricii* (D.Delaroche) Thunb.: 186 (1800). *Oviedа fabricii* (D.Delaroche) Spreng.: 147 (1824). *Peyrousia fabricii* (D.Delaroche) Sweet: 499 (1830a). *Meristostigma fabricii* (D.Delaroche) A.Dietr.: 597 (1833). Type: South Africa, Olifants River Valley, *Leipoldt s.n.* [BOL [17111], neo., designated by Goldblatt & Barnard: 305 (1970)].

Plants mostly 100–250 mm high, usually 4- to 6-branched; stem compressed, angled and 2-winged, wings irregularly serrated. *Corm* 10–15 mm diam., broadly obconic; tunics brown, lightly ridged vertically, basal rim with short, spreading spines 1–2 mm long. *Leaves* several, lowermost longest, linear to falcate, ribbed, shorter or longer than stem; remaining leaves cauline, progressively shorter, not or barely ribbed, often subtending branches, upper becoming bract-like. *Inflorescences* (2–)4- to 8-flowered spikes; outer bract green or flushed red, (10–)14–20(–25) mm long, keeled, acute, margins often reddish, keel crisped or minutely serrate; inner bract transparent with 2 green keels, ½–⅔ as long as outer, forked at apex. *Flowers* zygomorphic, white to pale yellow or beige, purple or rarely pink, usually red or pink on reverse of tepals and tube, lower tepals each with red spot in midline, throat marked with fine red lines inside and out, decurrent on lower part of tube; perianth tube obliquely funnel-shaped, 30–65 mm long, narrow and cylindric below, abruptly expanded into wide upper part up to 10 mm long; tepals usually unequal (rarely subequal), all straight below and continuing upper part of tube as a tepal cup, then spreading horizontally, upper 3 largest, 20–24 × 7–12 (subsp. *fabricii*), 15–18 × 7–10 mm (subspp. *compressa* and *purpurascens*), lower 3 with claws ± 4 mm long, limbs 10–20 × 3.0–7.5 mm, each often with short claw, bearing claw-like cusp arching over limb base. *Stamens* unilateral, arched; filaments 6–10 mm long (subspp. *compressa* and *purpurascens*) or 10–17 mm long (subsp. *fabricii*), exserted 3–7 mm from upper part of tube and 1–3 mm from tepal cup; anthers 3–5 mm long, dark purple; pollen purple. *Style* arching over stamens; branches 3–5 mm long, usually dividing near middle of anthers, forked for ½ their length, recurved. *Capsules* oblong, 10–12 mm long, apices of locules forming ear-like lobes decurrent on low locular ridges. *Seeds* globose, flattened at chalazal end, 1.2–1.3 mm diam. *Chromosome number* 2*n* = 16. *Flowering time*: August to October depending on subspecies, usually fairly late in spring.

Distribution and ecology: widespread in the drier, western half of Western Cape, South Africa and common in Namaqualand in Northern Cape, extending from near Steinkopf in the north to Malmesbury in the south and inland to the western edges of the Tanqua Basin along the eastern foothills of the Swartruggens and Cederberg Mtns; most often in rocky sandstone or granite derived soils but occasionally in deep, hard sand, or in crevices in rocks.

Diagnosis and relationships: the flowers of *Lapeirousia fabricii* are among the largest in the genus, with a long perianth tube and often wide throat. The perianth tube ranges from 30–65 mm long and is usually expanded in the upper 5–10 mm in a short to long cup or gullet. The tepals are shortly clawed, particularly the lower three, which are united basally for ± 2 mm and the erect claws form the upper part of the floral cup. When fully open the lower and sometimes the upper tepal limbs spread at right angles to the tube, or the dorsal is suberect. The lower tepal claws often bear claw-like cusps that arch forward over the limb bases, but these cusps are sometimes absent and represented by thickened median ridges. Vegetatively, *L. fabricii* has distinctive flattened, narrowly winged stems, the wings usually minutely crisped or serrated. The well developed outer floral bracts are ribbed and have crisped to serrated keels.

Variation across the range of *Lapeirousia fabricii* is reflected in the recognition of three subspecies. The most common and widespread, subsp. *fabricii*, is centred in the northern half of the range and has predominantly pale yellow to beige flowers with red markings, lower tepals about half as wide as the dorsal, and a perianth tube mostly 50–65 mm long with a wide, deep throat up to 10 mm long. Populations south and west of the Olifants River Mtns with white or pale pink flowers with pink markings, lower tepals not or only slightly narrower than the dorsal, a perianth tube 30–45 mm long, and a short, relatively narrow throat usually only ± 5 mm long are treated as subsp. *compressa*. The third subspecies, subsp. *purpurascens*, is restricted to the dry interior valleys of the Cederberg and northern Swartruggens and has blue-purple flowers, lower tepals ± ½ as wide as the upper and a perianth tube 30–45 mm long. Its flowers also differ from the typical form in having a relatively shallow gullet ± 5 mm deep, and correspondingly shorter filaments 7–9 mm long.

Distribution of ***Lapeirousia fabricii*** subsp. ***fabricii***, ○; subsp. ***compressa***, ●; subsp. ***purpurascens***, ★.

The long-tubed flowers of the typical subspecies are known to be pollinated by long-proboscid flies and the same pollination strategy is inferred for subsp. *compressa* and subsp. *purpurea*, probably using a different fly species in the latter.

Key to subspecies

1a Flowers with deep gullet 9–13 mm long including limbs of lower tepals; perianth usually beige to pale yellow, or ± white, flushed red on reverse, with prominent red stripes in lower throat; filaments 13–20 mm long. . . . . .27a. subsp. *fabricii*

1b Flowers with shallow gullet ± 5 mm long; filaments 7–9 mm long:

2a Perianth white to pale or deep pink; anthers 3–4 mm long; lower tepals only slightly narrower than upper tepals and with or without tooth-like cusps. . . . . 27b. subsp. *compressa*

2b Perianth blue-purple (rarely pink-purple) with red markings; anthers 4–5 mm long; lower tepals ± half as wide as upper tepals and always with short tooth-like cusp near limb base. . . . . .27c. subsp. *purpurascens*

27a. subsp. **fabricii**

Gladiolus denticulatus Lam.: 728 (1786), illegitimate superfluous name for *G. anceps* L.f. (1782). *Lapeirousia denticulata* G.H.M.Lawr.: 134 (1955), as a new name for *G. denticulatus* Lam. Type: South Africa, without precise locality or collector, Herb. Lamarck (P, holo.).

Peyrousia aculeata Sweet: t. 39 (1830b). *Meristostigma aculeatum* (Sweet) Steud.: 130 (1841). *Ovieda aculeata* (Sweet) Klatt: 777 (1864). *Lapeirousia anceps* var. *aculeata* (Sweet) Baker: 156 (1877). Type: South Africa, without precise locality or collector, illustration in Sweet, British Flower Garden ser. 2: t. 39 (1830b).

Lapeirousia serrulata Schltr.: 432 (1897). Type: South Africa, [Western Cape], Clanwilliam, *Leipoldt 383* (B, holo.; BOL, SAM, iso.).

[*Lapeirousia aculeata* Sweet: 396 (1827), invalid name without description.]

Flowers pale yellow or beige to ± white, often red or pink on reverse of tepals and tube, lower tepals each with red spot in midline and claw-like projection at top of claw, throat marked with fine red lines inside and out decurrent on lower part of tube; perianth tube mostly 50–65 mm long, slender and cylindric below, expanded upper part 9–13 mm long; tepals unequal, straight below and continuing upper part of tube as a cup for ± 4 mm, then spreading, upper 3 tepals largest, 20–24 × 7–12 mm, lower 3 tepals much narrower, 10–12 × 3–4 mm. *Filaments* 14–17 mm long, exserted ± 7 mm

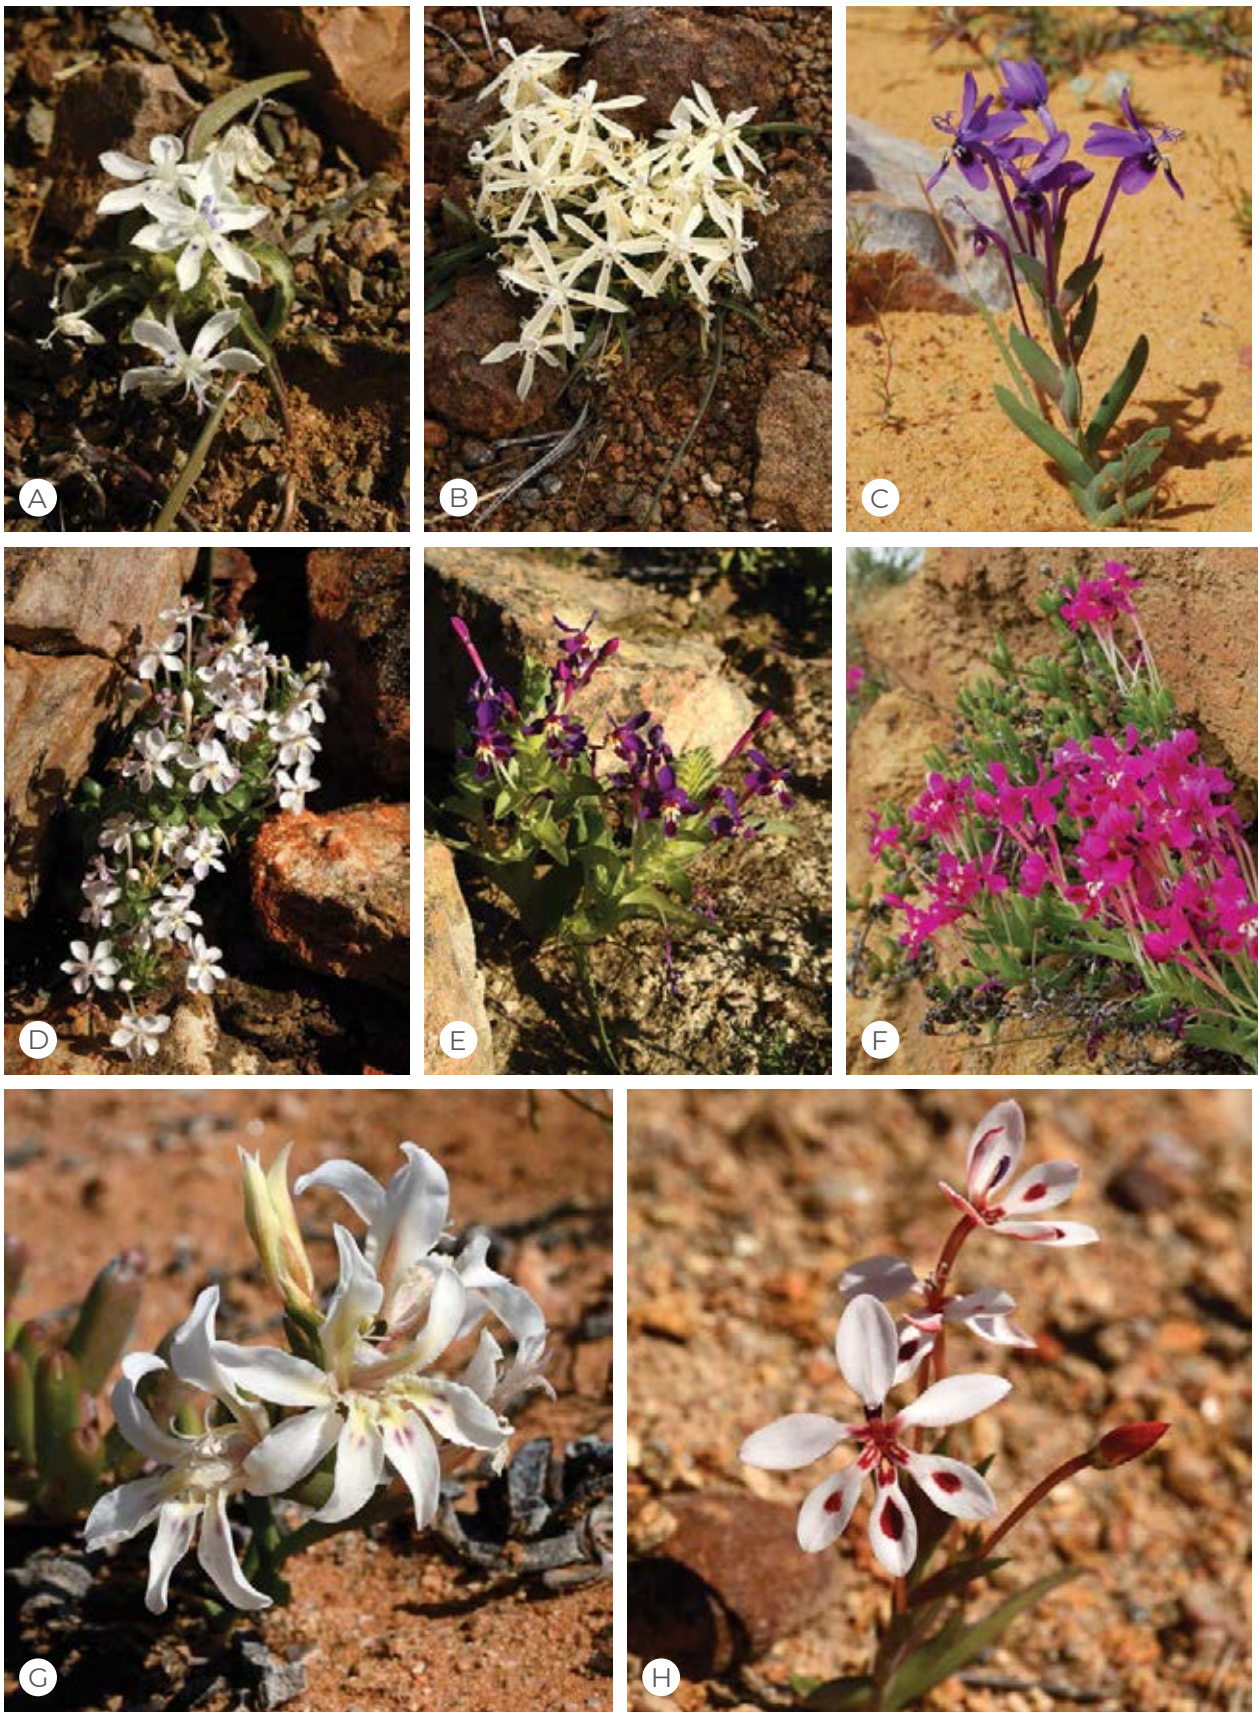

Plate 18: A, ***Lapeirousia plicata*** subsp. ***effurcata***, Matjiesfontein, WC; B, ***L. plicata*** subsp. ***foliosa***, Carnarvon, NC; C, ***L. purpurea***, Ceres, WC; D. ***L. pyramidalis*** subsp. ***pyramidalis***, Worcester, WC; E, ***L. pyramidalis*** subsp. ***regalis***, Clanwilliam, WC; F, ***L. silenoides***, Kamieskroon, NC; G, ***L. spinosa***, Steinkopf, NC; H, ***L. verrucunda***, Springbok, NC.

from tube and ± 3 mm from tepal cup; anthers 5–6 mm long. *Style* dividing between base and apex of anthers; style branches ± 5 mm long.

Distribution and ecology: subsp. *fabricii* ranges from near Steinkopf in northern Namaqualand along the Bokkeveld Mtns to Clanwilliam and the Biedouw Valley, and along the Atlantic Coast as far south as Darling.

The flowers are adapted for pollination by long-proboscid flies. Recorded pollinators include the horse fly, *Philoliche gulosa* and the nemestrinid, *Moegistorhynchus longirostris* (Goldblatt *et al.* 1995; Manning & Goldblatt 1997).

27b. subsp. **compressa** *(Pourr.) Goldblatt & J.C.Manning* in Strelitzia 35: 86 (2015). *Lapeirousia compressa* Pourr.: 79 (1788). *Ixia lapeirousia* J.F.Gmel.: 108 (1791), illegitimate superfluous name for *L. compressa* Pourr. Type: South Africa, without locality, said to have been collected by Philibert Commerson in Isle de France [Mauritius], but probably by Pierre Sonnerat, his colleague, who spent a short time at the Cape en route to Mauritius (P: Herb. Lamarck, holo.).

Like subsp. *fabricii* in vegetative features. *Flowers* white to ivory-coloured or pale (rarely dark) pink, flushed pink to red on reverse, lower tepals with red markings at limb bases; perianth tube 35–55 mm long, expanded in upper ± 5 mm into wide throat; tepals extending upward for ± 3 mm as a cup, spreading distally, dorsal 16–18 × 6–8 mm, lower tepals 15–20 × 5.5–7.5 mm. *Filaments* 6–10 mm long; anthers 3–4 mm long. *Style* dividing opposite lower to middle ⅓ of anthers, branches ± 3 mm long. *Flowering time*: September to mid-October, occasionally in early November.

Distribution and ecology: local in the upper Olifants River Valley, more common south and west of the Olifants River Mtns, extending as far south as Moorreesburg with isolated populations to the east along the margins of the Tanqua Basin from the interior Cederberg south to Karoo Poort.

Diagnosis: subsp. *compressa* is usually recognised by the nearly subequal tepals and almost radially symmetric flowers with a white to ivory-coloured or pink (rarely almost red) perianth, the lower tepals marked with pink to red near the base of the limbs. It intergrades with subsp. *fabricii* in the mid- to upper Olifants River Valley at Piekenierskloof and south of Citrusdal, where it can be difficult to assign plants to subspecies. Further north and to the west and south, populations with a beige to almost yellow perianth and lower tepals ± half as wide as the upper can readily be recognised as subsp. *fabricii*.

Hybrids between *Lapeirousia fabricii* subsp. *compressa* and *L. jacquinii* have been recorded south of Piketberg near the old bridge over the Berg River, where flowering times of the two taxa overlap, and between subsp. *compressa* and *L. anceps* at sites where both were in flower and growing together. These are among the few interspecific hybrids known in the genus.

27c. subsp. **purpurascens** *Goldblatt & J.C.Manning* in Strelitzia 35: 86 (2015). Type: South Africa, Western Cape, rocky sandstone slope 2 km south of Wuppertal, 25 Aug. 2009, *Goldblatt & Manning 13252* (NBG, holo.; K, MO, PRE, iso.).

Plants mostly 100–200 mm high. *Flowers* pale to deep purple, darker on reverse of tepals and tube, lower tepals each with dark red ± triangular mark in lower midline and with short yellow, claw-like cusp near base, throat dark turquoise to violet, often with pale narrow lines; perianth tube ± straight, slender, 30–45 mm long, expanded in upper ± 5 mm; tepals unequal (rarely subequal), upper three 15–18 × 7–10 mm, spreading distally; lower 3 erect below continuing upper part of tube as tepal cup for ± 4 mm, spreading distally, 10–12 × 4–5 mm. *Filaments* ± 7–8 mm long, dark turquoise, exserted 2–3 mm from tube; anthers 4–5 mm long. *Style* suberect, usually dividing between middle and apex of anthers; branches ± 3.5 mm long. *Flowering time*: mid-August to mid-September, thus early to midspring.

Distribution and ecology: a narrow endemic of the interior valleys of the northern Western Cape, extending from Wuppertal in the north through the drier valleys of the interior northern Cederberg and adjacent Swartruggens; in stony sandstone-derived ground.

The long-tubed, dark blue- or rarely red-purple flowers suggest pollination by long-proboscid *Prosoeca* flies, but there are no published observations on pollination of the subspecies.

Diagnosis: subsp. *purpurascens* is distinguished by its predominantly purple flowers with darker purple markings on the lower tepals, each of which bears a short, yellow, claw-like cusp near the base, and the short, dark violet to turquoise throat ± 5 mm long. Flowers of subsp. *fabricii*, which occurs within the range of subsp. *purpurascens* but blooms two to three weeks later, are creamy yellow to beige with bright red markings on the lower tepals. The throat in subsp. *fabricii* is up to 10 mm deep and the perianth tube is usually longer, 40–60 mm vs. 35–45 mm in subsp. *purpurascens*. Flowering in subsp. *fabricii* usually begins in mid-September, continuing into October, sometimes even as late as November so that the two subspecies are isolated by flowering time as well as pollinator preference. The stony sandstone habitat is essentially the same for both species although in Namaqualand subsp. *fabricii* grows on granite-derived soils and granite outcrops.

13. Afrosolen

Afrosolen *Goldblatt & J.C.Manning* in Bothalia 46: 3 (2016), as a new name for *Psilosiphon* Welw. ex Goldblatt & J.C.Manning: 108 (2015), illegitimate homonym, not *Psilosiphon* Entwhistle (1989). Type: *P. sandersonii* (Baker) Goldblatt & J.C.Manning = *A. sandersonii* (Baker) Goldblatt & J.C.Manning

Lapeirousia subg. *Paniculatae* [as *Paniculata*] Goldblatt & J.C.Manning: 373 (1990a). Type: *L. erythrantha* (Klotzsch ex Klatt) Baker = *Afrosolen erythranthus* (Klotzsch ex Klatt) Goldblatt & J.C.Manning

Revisionary account: Goldblatt & Manning: 108–138 (2015) [as *Psilosiphon*].

From the Greek *solen* (a pipe) compounded with Africa, for the tubular flowers of this African genus, the tube of which is elongate, hence pipe-like, in many species.

Deciduous geophytes. *Corm* flat-based, bell-shaped, rooting from base, axillary in origin; tunics of compacted fibres, outer layers decaying into loose fibrous network or vertical strips. *Foliage leaves* few to several, linear to sword-shaped, falcate or ± terete, plane with visible main vein; lowermost often longest and inserted on stem near ground level, upper leaves progressively smaller. *Stem* aerial, compressed and angled to winged, usually branched, often repeatedly. *Inflorescence* either much branched, forming a ± a round or flat-topped false panicle, with sessile flowers, or a simple or branched spike; bracts green and ± soft-textured, often becoming dry distally, inner ± as long as outer, often forked near apex. *Flowers* usually zygomorphic, or radially symmetric, long-lived, often salver-shaped or rotate, when zygomorphic, lower tepals usually with contrasting darker or lighter markings, sometimes sweetly scented; perianth tube cylindric or funnel-shaped, short to extremely long; tepals subequal or unequal with dorsal largest. *Stamens* symmetrically disposed or unilateral and arcuate; filaments slender, free; anthers oblong-linear, dehiscence longitudinal. *Ovary* globose, sessile; style filiform, branches forked for ⅓–½ their length, undivided or notched apically. *Capsules* cartilaginous, ± globose. *Seeds* ± globose, flattened at chalazal end, smooth or slightly wrinkled; surface cells usually domed or ± flat. *Pollen grains* monosulcate-operculate, operculum 2-banded. *Basic chromosome number* uncertain, diploid numbers, 2*n* = 16, 12, 10, 8 (diploids); 2*n* = 14, 12, 10, 8, 6 (tetraploids).

Species 15: sub-Saharan Africa, from Ethiopia to Zimbabwe, Mozambique and Angola, one species also in Nigeria; 11 species in southern Africa, mainly Botswana and Namibia.

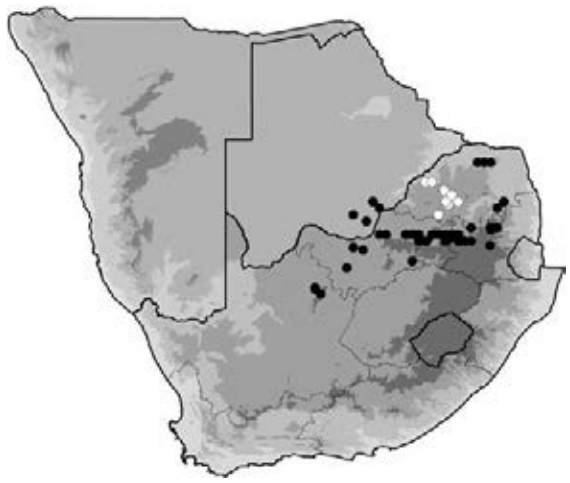
The majority of species of *Lapeirousia* from tropical and eastern southern Africa have been transferred to the genus *Afrosolen* (= *Psilosiphon*) after molecular phylogenetic study showed them to fall outside the main clade of *Lapeirousia* and sister to the two tropical genera *Cyanixia* and *Savannosiphon*. *Afrosolen* is recognised by the flat-based corms with tunics of compacted fibres, soft-textured to submembranous floral bracts, and often undivided style branches, although they are deeply divided in some species. The inflorescence is typically a flat- to round-topped false panicle but tends in some species to a spike. Chromosome numbers are unusually varied, ranging from *2n* = 16 to 6 and including polyploidy and dysploidy. As in *Lapeirousia*, the monosulcate pollen grains have a 2-banded operculum.

Flowers of most species are zygomorphic with short to very long perianth tubes, up to 100–140 mm long in white-flowered *Afrosolen schimperi*. Two species, *A. coeruleus* and *A. avasmontanus*, have short-tubed, radially symmetric flowers, but on the basis of chromosome number and other characters appear not to be immediately related, suggesting that the radially symmetric flower has evolved independently in the two species. Pollination includes hawk moths in species with white or pale pink flowers with an elongate tube, bees for short-tubed species, and possibly long-proboscid flies or butterflies in species with deeply pigmented flowers with a long tube, although to date no long-proboscid flies have been recorded in northern Namibia where some of these species occur.

Key to species

1a Perianth tube 1–2 mm long; flowers actinomorphic; all tepals with contrasting markings:
2a Tepals 11.0–15.5 × (4–)5–7 mm (appearing shorter in poorly preserved specimens); flowers 1(2) on ultimate branches of inflorescence; corm tunics dark brown to blackish and decaying irregularly into vertical strips. . . . . 2. *A. avasmontanus*
2b Tepals 7.0–9.5 × 3–5 mm; flowers (2)3 to 5 on ultimate branches of the inflorescence; corm tunics light brown, outer layers of fine reticulate fibres . . . . . 6. *A. coeruleus*
1a Perianth tube 3–150 mm long; flowers zygomorphic with arcuate to ± erect unilateral stamens; contrasting markings, when present, confined to 3 lower (abaxial) tepals:

3a Perianth tube 100–150 mm long; flowers white, sometimes flushed pale blue to purple outside . . . . . .11. *A. schimperi*
3b Perianth tube 3–50 mm long; flower variously coloured:
4a Inflorescence a divaricately branched false panicle with main branches 1- or 2(3)-flowered:
5a Perianth white to pale pink; corms tunics straw-coloured and outer layers ± fibrous and reticulate; floral bracts dry before anthesis, becoming membranous, dry and light brown with tips often darker brown 10. *A. bainesii*
5b Perianth blue to violet, lower tepals with white markings edged dark blue to violet; corms tunics dark brown and outer layers breaking into vertical strips, not fibrous; floral bracts acute-attenuate and dark brown in distal half . . . . . 1. *A. sandersonii*
4b Inflorescence a ± false panicle or spike with at least some main branches 3- to 8-flowered:
6a Perianth tube 25–50 mm long:
7a Flowers creamy white; lower tepals with purple median spear-shaped markings; perianth tube 40–45 mm long; tepals 15–19 × 4–5 mm . . . . . .9. *A. otaviensis*
7b Flowers blue to violet, rarely pale blue to almost white; lower tepals with blue to violet markings; perianth tube 25–38 mm long; tepals 10–14 × 3–6 mm:
8a Flowers violet, lower tepals with white median mark edged in darker violet; tepals ± 14 mm long; floral bracts 8–10 mm long; perianth tube 35–37 mm long . . . . . 4. *A. erongoensis*
8b Flowers pale blue to white with bluish markings on lower tepals; tepals 10–12 mm long; floral bracts 3–6(–7) mm long; perianth tube 25–38 mm long. . . . . 3. *A. gracilis*
6b Perianth tube 3–25 mm long:
9a Perianth tube (15–)18–25 mm long:
10a Perianth greenish or blue-violet with red to purple and white markings on lower tepals; floral bracts 5–7 mm long; plants of Malawi, Mozambique, South Africa (Limpopo) and Zimbabwe . . . . . .8. *A. masukuensis*
10b Perianth pale blue or white; floral bracts 3–6(–7) mm long; plants of Namibia . . . . . 3. *A. gracilis*
9b Perianth tube (5–)7–15 mm long:
11a Dorsal tepal suberect or arched over stamens; lower tepals often (?always) with tooth-like median ridge up to 1 mm long; style branches undivided or notched at tips . . . . . 5. *A. rivularis*
11b Dorsal tepal reflexed, lying in same plane as lower tepals; lower tepals without tooth-like median ridges; style branches divided for ⅓–½ their length . . . . . .7. *A. erythranthus*



1. **Afrosolen sandersonii** *(Baker) Goldblatt & J.C.Manning* in Bothalia 46: 4 (2016). *Lapeirousia sandersonii* Baker: 169 (1892). *Psilosiphon sandersonii* (Baker) Goldblatt & J.C.Manning: 109 (2015). Type: South Africa, 'Transvaal,' *Sanderson s.n.* [K, lecto., designated by Goldblatt: 463 (1990b)].

Plants 200–350(–450) mm high. *Corm* 25–30 mm in diam., tunics dark brown, hard-leathery internally, decaying irregularly into vertical sections, seldom becoming fibrous and never netted. *Stem* divaricately and often intricately branched, compressed, 2-angled below, 3-angled above branches, slightly winged, sheathed below by dark brown cataphylls. *Leaves* 2 to 4, ± linear to falcate, 2–3 mm wide, firm to rigid, main and secondary vein pairs ± prominent, closely set; lowermost leaf longest, sometimes exceeding inflorescence, upper leaves progressively shorter. *Inflorescence* a rounded to ± flat-topped false panicle, but with main axis sometimes evident, ultimate branches 1- or 2(3)-flowered; bracts 5–12 mm long, green with brown tips in bud, often flushed purple, becoming dry and dark brown with age, acute-attenuate, inner sometimes longer than outer, usually notched at apex. *Flowers* zygomorphic, blue to violet, lower 3 tepals each with deep red to purple and white spear-shaped mark guide in lower midline; perianth tube 8–12 mm (subsp. *limpopoensis*), or mostly 15–30 mm (subsp. *sandersonii*), slender, widening slightly in upper 2–3 mm; tepals subequal, lanceolate, 10–11 × 2–4 mm, dorsal held apart from others, reflexed, lower 3 joined for ± 1 mm and held close together, when fully open all ± spreading. *Filaments* unilateral, ± erect, ± 5 mm long, exserted 2.5–3.5 mm from tube; anthers 3–5 mm long, purple; pollen pale yellow or white. *Style* dividing near apex of anthers or shortly (rarely much) exceeding anther tips; branches 1–2 mm long, divided for up to ⅓ their length, notched apically or undivided. *Capsules* depressed globose, 4–5 × 4–5 mm. *Seeds* nearly globose, ± 1.5–2.0 mm diam. *Chromosome number* 2*n* = 10. *Flowering time*: mainly February and March, occasionally from late December or in April.

Distribution and ecology: occuring in eastern Botswana and in South Africa in Limpopo, North West Province and Northern Cape and locally in Mpumalanga; in rocky, and usually well-drained sites, including hill slopes, ridges and summits.

Diagnosis: allied to the *Afrosolen erythranthus* complex of short-tubed species, *A. sandersonii* has the repeatedly branched, panicle-like inflorescence with 1 or 2 (rarely 3) flowers on the major terminal branches. The blue-violet flowers have a moderately long perianth tube, mostly 15–30 mm long, and the floral bracts are often relatively long, 8–12 mm, acute-attenuate and flushed purple or brown and aging dark brown. The corm tunics are distinctive, being dark brown and fragmenting into vertical strips rather than becoming a fibrous network. *Afrosolen erythranthus* typically has fewer-branched inflorescences with 3 to 6 flowers per main terminal branch, floral bracts 4–6 mm long, and a perianth tube usually 6–11 mm long.

The variation in perianth tube length correlates with geographical distribution, with plants from Limpopo, mainly in the Waterberg and nearby, having particularly short tubes, 8–12 mm long, whereas populations in the southwest of the range, in the Kuruman Hills and adjacent country in Northern Cape, stand out in having a much longer perianth tube, 25–30 mm long. The regional

Distribution of ***Afrosolen sandersonii*** subsp. ***sandersonii***, ●; subsp. ***limpopoensis***, ○.

variation is not always consistent and plants from Mpumalanga sometimes have perianth tubes almost as long as those from further west. The long- and short-tubed plants are alike in other respects, especially the branching pattern and the rust-brown, acute-attenuate floral bracts. The populations from the Waterberg are referred to subsp. *limpopoensis* and the remaining, longer-tubed populations to subsp. *sandersonii*. The short-tubed subsp. *limpopoensis* broadly resembles *A. erythranthus* in its short perianth tube, 8–12 mm long, and relatively short floral bracts, 5–6 mm long, but the plants have the divaricately branched stem and brown floral bracts typical of *A. sandersonii*. They may represent recent or ancient hybridisation between *A. sandersonii* and *A. erythranthus*, although the ranges of the two taxa do not overlap today.

Afrosolen masukuensis is sometimes confused with *A. sandersonii*, but the inflorescence of that species is comparatively sparsely branched with the main branches 5- to 9-flowered and the flowers are smaller, although perianth tube length, 20–25 mm long, overlaps. *Afrosolen masukuensis* also differs in its smaller corms with paler, fibrous tunics, and appears to favour wetter, lowland sites in contrast to the montane, rocky well-drained habitats favoured by *A. sandersonii*.

Key to subspecies

1a Perianth tube mostly 15–30 mm long; floral bracts 8–12 mm long; style branches 1.5–2.0 mm long . . . . . 1a. subsp. *sandersonii*

1b Perianth tube mostly 8–12 mm long; floral bracts 5–6 mm long; style branches 1.0–1.3 mm long. . . . . 1b. subsp. *limpopoensis*

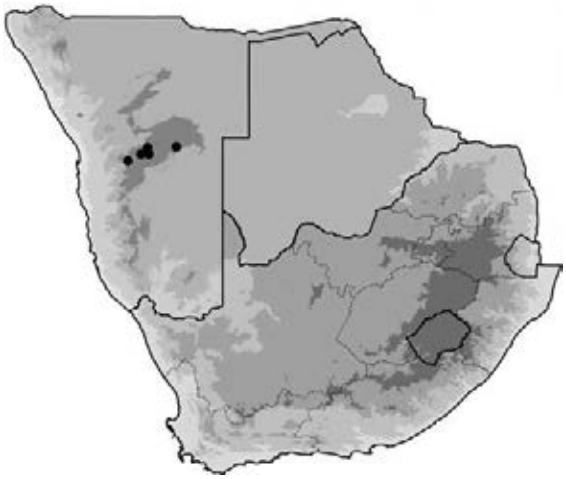
1a subsp. **sandersonii**

[*Lapeirousia bainesii* var. *breviflora* Baker: 156 (1877), invalid name without description. No specimens cited, but *Nelson 402* (K) from Rhenosterpoort is so annotated by Baker]

Plants 200–350(–450) mm high. *Corms* 25–30 mm diam. *Inflorescence* with bracts 8–12 mm long. *Flowers* with perianth tube 15–30 mm long; tepals 10–12 × 3–4 mm. *Filaments* 5–7 mm long, exserted 3.0–4.5 mm. *Style* dividing near apex of anthers, branches 1.5–2.0 mm long, divided for up to ¼ their length or barely notched at tips (or apparently undivided).

Distribution: encompassing almost the entire range of the species, thus extending from eastern Botswana into South Africa in northern Limpopo, North West Province and Northern Cape and local in Mpumalanga.

1b subsp. **limpopoensis** *(Goldblatt & J.C.Manning) Goldblatt & J.C.Manning* in Bothalia 46: 4 (2016). *Psilosiphon sandersonii* subsp. *limpopoensis* Goldblatt & J.C.Manning: 114 (2015). Type: South Africa, Limpopo, Waterberg, between Groothoek and Vaalwater, 1 000 m, 6 Jan. 1959, *Werdermann & Oberdieck 1640* (PRE, holo.; B, BR, GH, K, MO, WAG, iso.).



Like subsp. *sandersonii*, but *corms* 15–25 mm diam., tunics sometimes becoming fibrous and netted with age. *Spike* with floral bracts 5–6 mm long. *Flowers* with perianth tube 8–12 mm long; tepals 10–11 × 3.0–3.5 mm. *Filaments* ± 5 mm long, exserted 2.5–3.0 mm. *Style* dividing near or beyond apex of anthers, branches ± 1.0–1.3 mm long, divided for up to ⅓ their length.

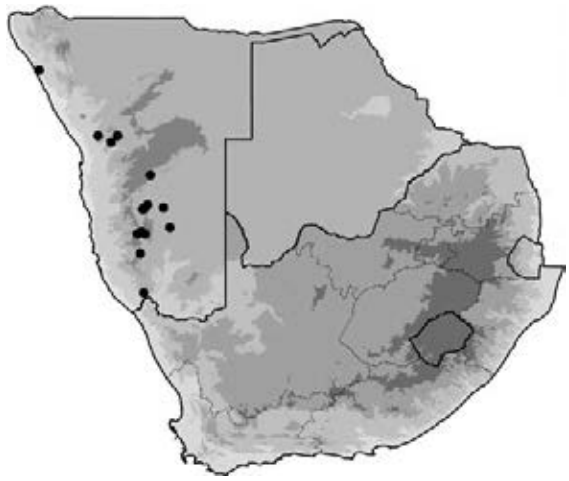
Distribution and ecology: restricted to western Limpopo, South Africa, in the Waterberg Mtns and surrounding country.

Diagnosis: As outlined above subsp. *limpopoensis* bears a superficial similarity to the largely tropical African *Afrosolen erythranthus* in its relatively short perianth tube, but the dark, tough, non-reticulate corm tunics, intricate branching pattern, and rather dark floral bracts all accord better with *A. sandersonii*.

2. **Afrosolen avasmontanus** *(Dinter) Goldblatt & J.C.Manning* in Bothalia 46: 4 (2016). *Lapeirousia avasmontana* Dinter: 256 (1931). *Psilosiphon avasmontanus* (Dinter) Goldblatt & J.C.Manning: 114 (2015). Type: Namibia, Lichtenstein, Auas Mtns, 20 Feb. 1923, *Dinter 4454* (B, holo. [K, photo.]; GH, S, Z [3 sheets], iso.).

Plants 200–300 mm high. *Corm* bell-shaped, 15–20 mm diam., tunics dark brown to blackish, inner layers ± woody, outer decaying irregularly, often into vertical strands. *Stem* ± divaricately branched in upper half, rounded to slightly triangular in section, sometimes obscurely winged or ridged at one or more angles. *Leaves* 3 or 4, linear, 2–3 mm wide, main vein prominent, lowermost inserted near ground level and longest, usually slightly exceeding inflorescence, others inserted above ground, progressively smaller above, those subtending branches ± bract-like. *Inflorescence* a rounded, ± flat-topped false panicle, ultimate branches with 1(2)

Distribution of ***Afrosolen avasmontanus***.



flowers; bracts 5–6 mm long, green below, membranous in upper half and bent outward by tepals, becoming completely dry in fruit, inner ± as long as or slightly longer than outer. *Flower* actinomorphic, blue to light purple with median white heart-shaped mark feathered purple on edges in basal half of each tepal; perianth tube ± 1 mm long, cylindric below, widening in upper ½; tepals spreading but curving upward near tips, subequal, lanceolate to elliptic, 11.0–15.5 × (4–)5–7 mm. *Stamens* symmetrically arranged; filaments 4–5 mm long, diverging distally; anthers diverging, 4–5 mm long, apices curving inward after dehiscence; pollen light blue-purple to ± white. *Style* straight, 6–7 mm long, dividing near anther apices, branches ± 1.2 mm long, barely notched apically. *Capsules* ± globose, weakly 3-lobed, showing outline of seeds, 6–8 × ± 7 mm. *Seeds* globose, dark brown, 1.5–2.0 mm diam., rounded to weakly angled by pressure, tapering toward attached funicle, surface smooth. *Chromosome number* 2*n* = 16. *Flowering time*: February to April.

Distribution and ecology: endemic to central interior Namibia in the hills and mountains around Windhoek, extending north toward Okahandja and east to Wit Vlei; in well-drained sites on open stony ground or sometimes in light bush.

Diagnosis: the relatively large, pale blue flowers with a white centre, radially symmetric perianth and stamens, and large, ± flat-topped inflorescence distinguish *Afrosolen avasmontanus* from other tropical and subtropical African species of the genus. It may be confused with the more widespread *A. coeruleus*, which also has radially symmetric flowers, but those of *A. avasmontanus* have relatively larger, pale blue tepals, 11.0–15.5 mm long, with heart-shaped white markings, whereas *A. coeruleus* has smaller tepals, 8–9 mm long, with spear-shaped white markings. The corm tunics in *A. avasmontanus* are dark brown and ± woody, breaking into vertical strips as they decay, and the inflorescence is divaricately branched, the terminal branches with a solitary (rarely 2) flowers. The corm tunics in *A. coeruleus* are light brown, becoming finely fibrous and netted as they decay, and the inflorescence has fewer, ascending branches, some of which terminate in spikes of 3 to 5 flowers. Although they are the only two species of *Afrosolen* in Namibia with radially symmetric flowers, chromosome cytology confirms that *A. avasmontanus* and *A. coeruleus* are not immediately related. *Afrosolen avasmontanus* is diploid with 2*n* = 16 whereas *A. coeruleus* has 2*n* = 8. The two karyotypes have about the same total chromosome length (a proxy for total DNA per cell), making it clear that a polyploid relationship is not involved here. The similar corm tunics and dichotomously branched inflorescences of *A. avasmontanus* and the eastern southern African *A. sandersonii* suggest that the two are closely related.

3. **Afrosolen gracilis** *(Vaupel) Goldblatt & J.C.Manning* in Bothalia 46: 4 (2016). *Lapeirousia gracilis* Vaupel: 548 (1912). *Psilosiphon gracilis* (Vaupel) Goldblatt & J.C.Manning: 117 (2015). Type: Namibia, 'Great Namaqualand, Doorns', dolomite, 1 450 m, Mar. 1907, *Range 292* (B, holo. (K, photo); m [fragment], iso.)

Plants 120–300 mm high. *Corm* bell-shaped, 12–18 mm diam.; tunics light brown, of layers of compacted fibres, becoming loosely fibrous with age, fibres extending upward as short, soft spines. *Stem* often slender, 2–several-branched, main axis dominant, branches ascending, flexed at base of main spike, 2-angled and winged below first branch, 3-angled or ± winged above. *Leaves* 2 or 3(4), lowermost inserted just below ground, linear to narrowly lanceolate, 3–5(–8) mm wide, ± as long as or somewhat longer than inflorescence, thickened around main vein, second leaf usually largest, upper leaves decreasing in size, becoming bract-like. *Inflorescence* a spike or false panicle, main terminal branches 2- to 6-flowered; bracts 3–6(–7) mm long, soft, green below, becoming ± membranous above, sometimes flushed purple, or membranous and dry before anthesis, then usually transparent with fine brown veins, subequal or outer slightly larger. *Flowers* zygomorphic, pale blue to mauve or white, then often with blue tube, lower three tepals white or pale yellow in lower ⅓ edged distally with darker blue to violet, occasionally one or more lower tepals with a small median tooth-like ridge, lightly fragrant [also said to be unpleasantly scented]; perianth tube cylindric, slightly curved outward at apex, (18–)25–38 mm long; tepals lanceolate, dorsal largest and held apart, suberect to reflexed, 10–12 × 4–6 mm, margins slightly undulate, lower three slightly smaller, held close together. *Stamens* unilateral; filaments exserted ± 2 mm; anthers 4–5 mm long, pale lilac, blue or ± white; pollen cream-coloured. *Style* arching over to filaments, dividing between middle and tips of anthers, branches 1.5–2.0 mm long, divided for ± ¼ their length. *Capsules* ± globose, obtusely trigonous, 4–5 × 5–6 mm. *Seeds* globose to weakly angular, ± 2 mm diam., dark brown, smooth. *Chromosome number* 2*n* = 12. *Flowering time*: mainly late January to April (May), also recorded in October.

Distribution of ***Afrosolen gracilis***.

Distribution and ecology: restricted to western and south-central Namibia, occurring in a relatively broad band along the western part of the country from the Fish River Canyon in the south to the Hoanib River in the Kaokoveld in the northwest; in rocky sites, often on limestone, dolomite or other calcareous rock types, but is also said to grow on sandy flats and, especially in more arid places, is often associated with springs and places where additional water is available.

Flowering normally occurs at the end of summer, mostly in February and March but sometimes as late as May. One collection from the Brandberg blooming in October is difficult to explain, and perhaps indicates an unusual pattern of rainfall that particular year. The relatively long perianth tube of *A. gracilis* plus the pale perianth and floral scent suggests that the flowers are adapted for pollination by moths or butterflies with relatively long probosces.

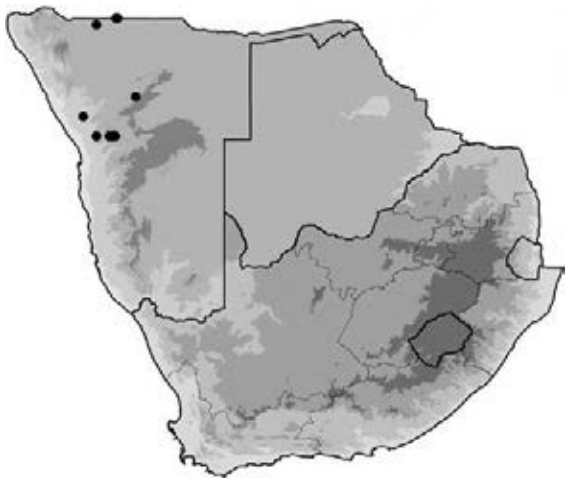
Diagnosis: *Afrosolen gracilis* is recognised by the slender perianth tube, typically 22–35 mm long (occasionally slightly longer or shorter), pale blue or white perianth, usually short floral bracts, 3–6(–7) mm long, and comparatively slender habit with up to 6 flowers per terminal branch. It most closely resembles *A. bainesii* and *A. otaviensis*, both of which also have long-tubed flowers but *A. bainesii* has white to pale pink flowers with dark red to brown markings, a tube 40–47 mm long, a more robust habit, longer floral bracts, 7–12 mm long, and the highly ramified inflorescence has only 1(2) flowers per ultimate branch. Confusion is more likely with *A. otaviensis*, which has 2 to 5 flowers per terminal branch, but larger, unscented flowers with a perianth tube 40–45 mm long, and longer floral bracts, (7–)8–11 mm long.

4. **Afrosolen erongoensis** *(Goldblatt & J.C.Manning) Goldblatt & J.C.Manning* in Bothalia 46: 4 (2016). *Psilosiphon erongoensis* Goldblatt & J.C.Manning: 119 (2015). Type: Namibia, Erongo Mtns, western edge of the Erongo Mtns above Farm Ameib, 27 Mar. 1976, *Craven & Craven 115* (WIND, holo.; PRE, iso.).

Plants 300–550 mm high. *Corm* bell-shaped, 15–20 mm diam., tunics light brown, coarsely fibrous. *Stem* repeatedly branched, main axis ± straight, dominant, lateral branches diverging at ± 30°, weakly compressed below, triangular in middle and rectangular above, angles slightly winged. *Leaves* 4 to 7, ± linear, grey-green, main vein prominent, lowermost 2 basal and longest, mostly 4–5 mm wide, reaching to ± apex of inflorescence, upper leaves cauline and decreasing in size above, those subtending branches becoming ± bract-like. *Inflorescence* ± a rounded to flat-topped false panicle, main terminal branches with (2–)4 or 5 flowers in short spikes; bracts 8–10 mm long, soft-textured, ± green with translucent, membranous margins, lanceolate, acute, becoming dry apically, inner slightly shorter than outer. *Flowers* zygomorphic, violet-blue, lower three tepals with white mark near base edged dark violet distally, ?unscented; perianth tube 36–38 mm long, cylindric, expanded and curved in upper 3 mm; tepals subequal or dorsal slightly larger, lanceolate, ± acute, margins evidently straight, ± 14 × 3–4 mm, lower 3 united for 1.5 mm. *Stamens* unilateral, ± erect; filaments ± 8 mm long, exserted ± 5 mm; anthers 5–6 mm long, evidently yellow; pollen yellow. *Style* nearly straight, dividing opposite anther tips; branches ± 3 mm long, forked for ± ⅓ their length, violet. *Capsules* and *seeds* unknown. *Chromosome number* unknown. *Flowering time*: March and April.

Distribution and ecology: restricted to the Erongo Mtns of west central Namibia; among granite outcrops.

Diagnosis: the violet flowers with shorter perianth tube, ± 37 mm long, and short, narrower tepals, ± 14 × 3–4 mm, distinguish *Afrosolen erongoensis* from *A. otaviensis*, which has creamy white flowers with violet longitudinal markings on the lower tepals, a perianth tube 40–45 mm long, tapering gradually from



Distribution of ***Afrosolen erongoensis***.

base to apex, and tepals 15–19 × 4–5 mm. The branching of the inflorescence and general aspect of the two species differ hardly at all. Despite these similarities, *A. erongoensis* may be more closely related to *A. gracilis*, which has pale blue or less often white flowers, a perianth tube (18–)25–38 mm long and, significantly, short, pale floral bracts 4–6(–7) mm long (vs. 8–10 mm in *A. erongoensis*). Chromosome number, useful in determining relationships in *Afrosolen*, is unknown.

5. **Afrosolen rivularis** *(Wanntorp) Goldblatt & J.C.Manning* in Bothalia 46: 4 (2016). *Lapeirousia rivularis* Wanntorp: 53 (1971). *Psilosiphon rivularis* (Wanntorp) Goldblatt & J.C.Manning: 119 (2015). Type: Namibia, Karibib, Ameib Ranch, ± 25 km NE of Usakos, granite kopje [koppie] south of track, ± 5 km east of farmhouse, 15 Apr. 1968, *Wanntorp & Wanntorp 907* (S, holo.; M, iso.).

Plants 100–300 mm high, laxly few-branched. *Corm* bell-shaped, 8–12 mm diam.; tunics dark brown, fibres medium-textured, reticulate. *Stem* weakly compressed and 3- or 4-angled, usually few branched. *Leaves* mostly 2(3), lower 1 or 2 ± basal, linear, 2–3 mm wide, reaching to ± middle of inflorescence, firm, main vein lightly raised, lowermost longest, upper leaves subtending branches, progressively shorter. *Inflorescence* a spike, main axis mostly 2- to 5(6)-flowered; bracts 4–5 mm long, membranous in upper half, apices becoming dry and brown, inner bract ± as long as outer, entire or shallowly forked at tip. *Flowers* zygomorphic, pale blue with white nectar guides on lower three tepals outlined in blue-violet, with tooth-like median ridge up to 1 mm long, distal half of throat lined dark blue on abaxial side; perianth tube ascending, widening gradually from base, ± 1.3 mm wide at base, 3 mm at mouth, (5–)7–9 mm long, ± straight; tepals narrowly lanceolate, margins usually straight, subequal, (7–)10–13 × 2.0–2.5 mm wide, dorsal tepal suberect to arching forward, held apart from others, lower tepals directed forward, nearly horizontal, united basally for ± 1.5 mm. *Stamens* unilateral and arcuate; filaments ± 7.5 mm long, exserted ± 4 mm; anthers parallel, contiguous, ± 4 mm long, pale blue-mauve; pollen pale blue-mauve. *Style* suberect, adaxial to stamens, ± 15 mm long, dividing opposite upper ⅓ of anthers; branches ± 1 mm long, undivided or notched at apex, spreading. *Capsules* 3.5–4.5 mm long, top-shaped in profile, 3-lobed in distal half, with 2 or 3 seeds per locule. *Seeds* ± globose, dark brown, ± 2 mm diam. *Chromosome number* unknown in Namibian populations, $2n = 12$ (in one Zambian population). *Flowering time*: mostly late February to early April. (Description based only on plants from Namibia.)

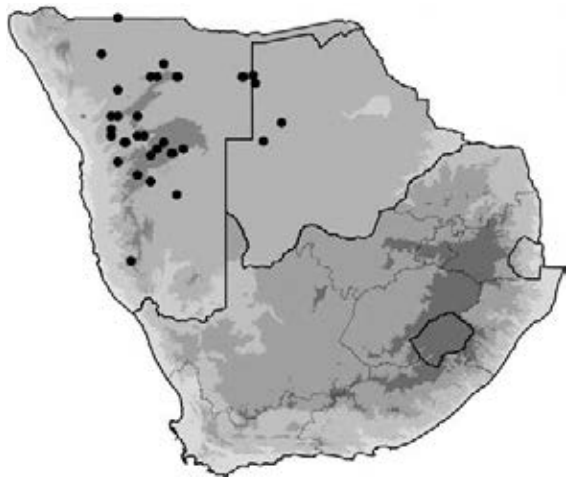
Distribution and ecology: extending across the northern half of Namibia into adjacent Angola and Zambia, particularly common in the Erongo Mtns in Namibia, and also occuring on the Brandberg, the Paresis Mtns near Otjiwarongo and north of Etosha Pan; usually in seasonally wet depressions on rock outcrops and seasonally waterlogged grassland on shallow soils.

Distribution of ***Afrosolen rivularis***.

Diagnosis: typically a diminutive plant, *Afrosolen rivularis* is recognised by the pale blue, zygomorphic flowers with a relatively narrow perianth tube mostly 7–9 mm long and tepals usually 10–13 mm long (occasionally smaller), the lower three bearing white markings edged in darker blue and often a prominent tooth-like ridge in the lower midline. The style, ± 15 mm long, divides into short, undivided branches ± 1 mm long. Plants at the type area in the Erongo Mtns rarely exceed 200 mm in height but elsewhere in Namibia may reach up to 270 mm. Plants from Zambia and central Angola, currently included in *L. rivularis*, are taller, sometimes up to 450 mm, have larger flowers that lack ridges on the lower tepals, and among other differences have a longer style, 16–20 mm long and style branches 2–3 mm long, divided for ± one third to half their length. More field work is needed to establish the status of these populations. Zambian plants have a diploid chromosome number of $2n = 12$, suggesting a relationship with the widespread *A. erythranthus*, which has the same number in south-tropical African populations. Chromosome number is not known for *L. rivularis* in Namibia.

6. **Afrosolen coeruleus** *(Schinz) Goldblatt & J.C.Manning* in Bothalia 46: 4 (2016). *Lapeirousia coerulea* Schinz: 212–213 (1890). *Psilosiphon coeruleus* (Schinz) Goldblatt & J.C.Manning: 121 (2015). Type: Namibia, Ombale, südost Ondonga, Mar. 1886, *Schinz 13* (K, lecto., designated by Goldblatt: 445 (1990b); COI, isolecto.).

Ixia dinteri Schinz: 14 (1900). Type: Namibia, Karibib, Spitzkop, marshy ground, in 1898, *Dinter 22* (*32* on the type) (Z, holo.).



Plants (120–)150–300 mm high. *Corm* bell-shaped, 12–16 mm diam., light brown, tunics of pale compacted fibres decaying to become coarsely to finely fibrous and netted. *Stem* repeatedly branched, compressed, 2- or 3-angled. *Leaves* 2 to 4, lowermost inserted at base, longest, reaching to at least middle, and sometimes shortly exceeding inflorescence, ± linear, 2–4(–5) mm wide,

remaining leaves decreasing in size above. *Inflorescence* a laxly branched, round-topped false panicle, larger ultimate branches (2)3- to 5-flowered; bracts 3–4 mm long, subequal, green below, membranous distally, becoming completely dry in fruit, inner ± as long as outer. *Flower* actinomorphic, ± rotate, blue to light purple with white, spear-shaped mark outlined in dark blue to purple on basal ½ of each tepal; perianth tube 1.5–2.0 mm long, narrowly funnel-shaped; tepals spreading below, curving upward distally, subequal, lanceolate, 7.0–9.5 × 3–5 mm. *Stamens* symmetrically arranged; filaments united basally for < 0.5 mm by an obscure corona-like ring, erect, ± 4 mm long, nearly contiguous around style; anthers diverging, 3.0–3.5 mm long, curving inward after anthesis; pollen pale blue-purple (white to yellow when dry). *Style* erect, 6–7 mm long, dividing near anther tips; style branches ± 1.2 mm long, shallowly notched apically. *Capsules* obovoid–globose, weakly 3-lobed, ± 4 mm long. *Seeds* dark brown, globose to weakly angled by pressure, 1.3–2.0 mm diam., tapering near attached funicle. *Chromosome number* 2*n* = 8. *Flowering time*: (January) February to April, occasionally in December.

Distribution and ecology: widespread throughout the summer-rainfall part of Namibia, extending locally into northwestern Botswana; in seeps, seasonal marshes, poorly drained grassland and shallow soil in rock outcrops where water accumulates in the wet season.

Pollination biology is unknown, but the flowers produce no detectable nectar and the only potential pollinators recorded are small bees (family unknown) nestling in the open flowers. Several collections are accompanied by notes indicating that the corms were in the past eaten by the indigenous population, particularly the Kung, for whom the corms may have been a staple, eaten after roasting in hot ash or sometimes raw.

Diagnosis: with its radially symmetric flower, short perianth tube 1.5–2.0 mm long, and undivided style branches, *Afrosolen coeruleus* is taxonomically isolated in the genus. It favours moist habitats. The chromosome number, 2*n* = 8, recorded in seven populations, and small corm with dark brown, fibrous tunics match other blue-flowered species including *A. erythranthus* (some populations 2*n* = 12) and *A. rivularis* (2*n* = 12), suggesting a relationship with this group of species, which have zygomorphic, bilaterally symmetric flowers, often of the same colour, although sometimes red in *A. erythranthus*. *Afrosolen avasmontanus*, also with radially symmetric flowers, is a more robust species from well-drained stony banks and hills with a different inflorescence in which the ultimate branches bear 1 or 2 larger flowers, and dark brown corm tunics that fragment into vertical strips, like those of *A. sandersonii*. Its chromosome number, 2*n* = 16, with a karyotype consisting of one long and seven short chromosome pairs, makes *A. avasmontanus* an unlikely close relative of *A. coeruleus*.

Distribution of ***Afrosolen coeruleus***.

7. **Afrosolen erythranthus** *(Klotzsch ex Klatt) Goldblatt & J.C.Manning* in Bothalia 46: 4 (2016). *Ovieda erythrantha* Klotzsch ex Klatt in Peters: 516, t. 58 (1864). *Lapeirousia erythrantha* (Klotzsch ex Klatt) Baker: 155 (1877). *Psilosiphon erythranthus* (Klotzsch ex Klatt) Goldblatt & J.C.Manning: 123 (2015). Type: Mozambique, Boror, Caboceira, *Peters s.n.* (B, holo.).

Full synonymy in Goldblatt, 1990b.

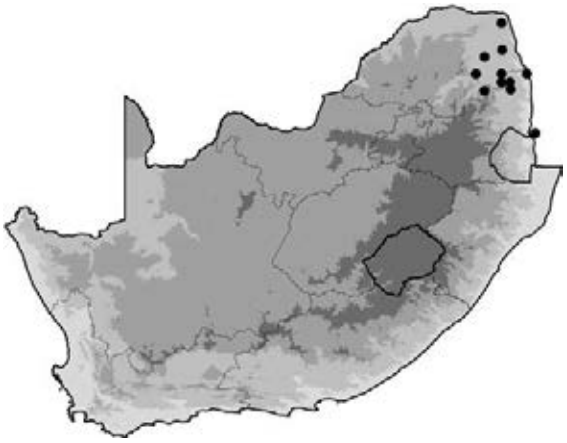
Plants (150–)200–450 mm high. *Corm* ± bell-shaped, 8–16 mm diam.; tunics light to dark brown, of densely compacted fibres, outer layers becoming coarsely fibrous, ultimately forming a matted mass. *Stem* branched repeatedly, compressed, 2-angled below, 3-angled above. *Leaves* 3 or 4, lower 2 or 3 longest and ⅓–⅔ as long as stem, ± linear to lanceolate or ± falcate, (2–)4–8(–11) mm wide, main vein prominent when alive; upper leaves becoming progressively bract-like. *Inflorescence* a several- to many-branched false panicle, often ± flat-topped, ultimate branches mostly (2)3- to 6-flowered, flowers crowded terminally; bracts 3–6 mm long, green below, dry and membranous above, becoming entirely dry and transparent, brownish in upper ⅓, outer obtuse, inner acute or apically forked, usually slightly shorter than outer. *Flowers* zygomorphic, either blue-violet with spear-shaped white mark outlined in dark blue to purple on lower tepals or crimson red, then without markings or lower tepals each with white or dark red median streak; perianth tube (6–)7–11(–15) mm long, slender below, expanded and slightly curved near throat; tepals subequal, lanceolate-spathulate, acute to obtuse, (6–)7–11 × 2–3(–4) mm, dorsal held apart, reflexed to lie ± on same plane as lower tepals; lower 3 tepals narrowed at base thus ± clawed, set closely together and joined for ± 1 mm. *Stamens* unilateral, ± erect; filaments 4–6 mm long, exserted 3.5–5.5 from tube; anthers 2.5–4.0 mm long, pale bluish to white, purple or red; pollen ± white. *Style* arched to erect, adaxial to stamens, dividing opposite middle to apex of anthers, ± 15 mm long; branches 1.0–1.5 mm long, forked for ⅓–½ their length, recurved. *Capsules* ± globose in profile, 3-lobed, 3–4 mm

Distribution of ***Afrosolen erythranthus***.

long, showing outline of seeds. *Seeds* 2 to 5 per locule, ± globose, 1.6–1.9 mm diam., dark brown, ± smooth to rugulose. *Chromosome number* 2*n* = 14, 12 ± 0–3B (polyploids), 8 (diploids). *Flowering time*: late January to March, occasionally from mid-December.

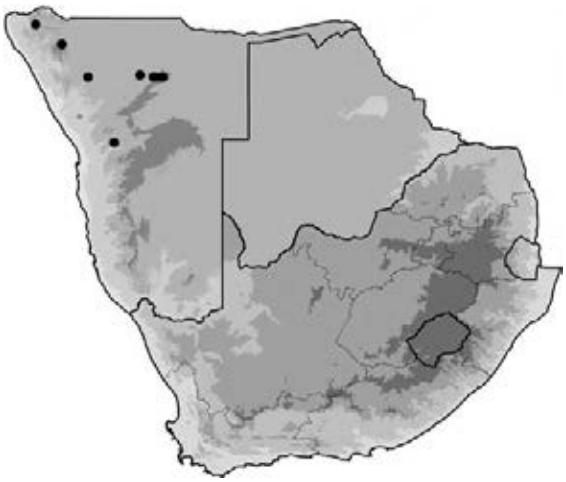
Distribution and ecology: restricted in southern Africa to eastern Botswana, but widespread across tropical Africa, extending from eastern Angola and southern Democratic Republic of the Congo, through Zambia to Zimbabwe, Malawi, western and southern Tanzania, central Mozambique and in northeastern Nigeria; often in rocky outcrops or in open grassland or woodland.

The small flowers, conspicuous in the many-flowered inflorescences, are visited and presumably pollinated by a variety of bees, wasps and even butterflies, which forage in large numbers in warm weather for nectar and/or pollen. Annotations on two collections state that corms are edible and 'eaten in time of great famine', but there appears to be no record of the species being significant in the regular diet of human populations.



Diagnosis: one of the several species of *Afrosolen* with a strongly branched, ± round- or flat-topped inflorescence, *A. erythranthus* can be distinguished by its typically (but not always) soft-textured leaves with a conspicuous main vein, and relatively small flowers with a short perianth tube seldom exceeding 12 mm. The flowers are somewhat crowded at the branch tips, which are in effect spikes of up to 6 sessile flowers. The orientation of the tepals is also distinctive, lying ± in the same plane with the three lower tepals joined together for ± 1 mm and held closely together whereas the upper tepal is reflexed and held apart from the others. Similar flowers also characterise *A. sandersonii* and *A. masukuensis*, both of which have a longer perianth tube, mostly at least 15 mm long up to 30 mm long in some populations of *A. sandersonii*, which also has different corms tunics and an inflorescence with 1- or 2-flowered ultimate branches. Notably *A. sandersonii* subsp. *limpopoensis* has a perianth tube 8–12 mm long, thus comparable with that of *A. erythranthus*, but the subspecies can immediately be distinguished by the branching pattern and different corm tunics.

8. **Afrosolen masukuensis** *(Vaupel & Schltr.) Goldblatt & J.C.Manning* in Bothalia 46: 4 (2016). *Lapeirousia masukuensis* Vaupel & Schltr. in Vaupel: 545 (1912). *Psilosiphon masukuensis* (Vaupel & Schltr.) Goldblatt & J.C.Manning: 126 (2015). Type: Mozambique, Inhambane: Masuku Forest [Insilva Maseku], 10 Feb. 1898, *Schlechter 12109* (B, holo.; BR, COI, G, K, P, PRE, SAM, iso.).



Plants 400–600 mm high. *Corm* bell-shaped, ± 15 mm diam.; tunics light brown, of ± leathery layers with reticulate surface, becoming loosely fibrous and netted with age. *Stem* usually several-branched, compressed and 2-angled to winged below, 3-angled and slightly winged above branches. *Leaves* 4 to 6, lowermost inserted close to ground and longest, usually shortly exceeding inflorescence, linear-lanceolate, central vein prominent, 3–5 mm wide, remaining leaves progressively shorter above. *Inflorescence* a branched spike or round-topped false panicle, main axis ± straight, dominant, major ultimate branches with 5 to 9 sessile flowers, often crowded distally with bracts overlapping and (1.0–)1.5–2.0 internodes long; bracts 5–7 mm long, green at anthesis, later dry and membranous, then either pale below or throughout or brownish above, streaked brown on veins, inner ± as long as outer or slightly shorter. *Flowers* zygomorphic, either dark blue to violet or greenish cream-coloured, lower tepals each with purple to red and white spear-shaped median streak in basal half; perianth tube cylindric, (15–)20–25 mm long, slightly expanded in upper 4 mm; tepals subequal with dorsal slightly larger, lanceolate, 8–10 × ± 3 mm, spreading at right angles to tube and lying in ± same plane with dorsal reflexed and held apart. *Stamens* unilateral, ± erect; filaments ± 5 mm long, exserted 2.5–3.0 mm; anthers 3.5 mm long, probably pale yellow when alive. *Style* unilateral, arching over stamens, dividing opposite middle to upper ⅓ of anthers; branches ± 2.2 mm long, divided for ± ½ their length. *Capsules* ± globose, slightly 3-lobed, 3.5–5.0 mm diam., showing outline of seeds. *Seeds* globose, ± 2 mm diam. *Flowering time*: February to April.

Distribution and ecology: restricted to southeastern Africa, extending from central and southern Mozambique and adjacent Malawi south and west into southeastern Zimbabwe and lowland Limpopo and Mpumalanga in South Africa; mainly in seasonally wet habitats, including vleis, the edge of marshes, and seasonally waterlogged flats. The Mozambique populations are all coastal and probably from sandy habitats.

Diagnosis: the comparatively tall stature, usually over 450 mm high, alternate branching pattern with the main axis dominant, ultimate inflorescence branches bearing 5 to 9 apically crowded flowers, and the long straight perianth tube, usually 20–25 mm long,

Distribution of ***Afrosolen masukuensis***.

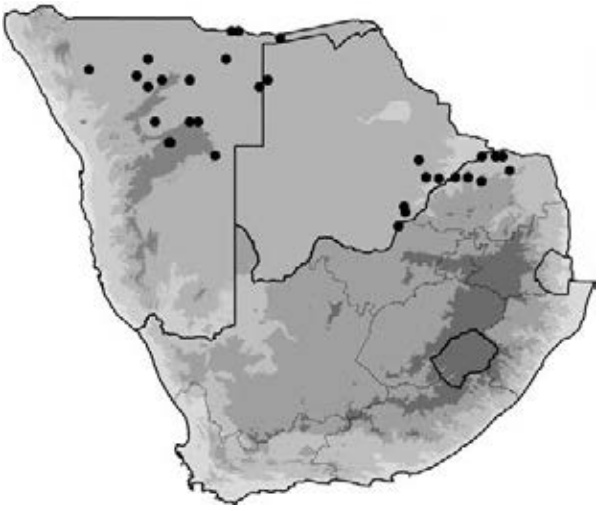
Distribution of ***Afrosolen otaviensis***.

are diagnostic for *Afrosolen masukuensis*. Plants from the Mozambique Coast have greenish flowers with red markings, unusual in the genus, but elsewhere the flowers are blue-mauve or violet with white and dark blue markings. The long perianth tube and general appearance of the flowers, including their colour, suggest a relationship with *A. sandersonii* of eastern South Africa and Botswana, but that species is typically a shorter plant, rarely exceeding 350 mm, with a divaricate, often intricately branched habit, and the ultimate branches of the inflorescence bear 1 or 2, rarely 3 flowers. The corms of the two species also differ, those of *A. masukuensis* being relatively small with the outer tunic layers fibrous and reticulate whereas the larger corms of *A. sandersonii* have dark brown tunics that decay irregularly into vertical strips. The corm tunics of *A. masukuensis* resemble closely the brown, fibrous and reticulate tunics of *A. erythranthus*.

9. **Afrosolen otaviensis** *(R.C.Foster) Goldblatt & J.C.Manning* in Bothalia 46: 4 (2016). *Lapeirousia otaviensis* R.C.Foster: 45–46 (1939). *Psilosiphon otaviensis* (R.C.Foster) Goldblatt & J.C.Manning: 128 (2015). Type: Namibia, Farm Auros near Otavi, 11 Feb. 1925, *Dinter 5577* (GH, holo.; B, G, PRE, SAM, Z [3 sheets], iso.).

Plants 300–550 mm high. *Corm* bell-shaped, 20–25 mm diam.; tunics light brown, firm-leathery at first, becoming coarsely fibrous with age, sometimes ultimately finely fibrous. *Stem* branched repeatedly above with main axis ± straight and dominant, lateral braches diverging at 45–80°, weakly compressed below, triangular in middle, ± rectangular above, angles lightly winged. *Leaves* 4 to 7, ± linear (–narrowly lanceolate), glaucous, main vein prominent, lower 2 to 4 basal and longest, 5–9 mm wide, exceeding inflorescence by 50–100 mm, upper leaves decreasing in size above, becoming ± bract-like. *Inflorescence* a rounded to ± flat-topped false panicle, main terminal branches with 3 to 5 sessile flower; bracts soft-textured, green, lanceolate, acute, often flushed red above, becoming dry from tips toward end of flowering, (7–)8–11 mm long, inner often slightly longer than outer. *Flowers* zygomorphic, white to cream-coloured, sometimes flushed pale lilac, lower three tepals with broad violet or purple median streak, with darker, paired purple to red lines near base, rarely upper 3 tepals with pale purple median line, unscented; perianth tube 40–45 mm long, straight, gradually flared from base, ± 1.2 mm diam. below, ± 2.2 mm diam. at mouth; tepals unequal, dorsal slightly larger than others, lanceolate, ± acute, margins straight, 15–19 × 4–5 mm, reflexed ± at right angles to tube. *Stamens* unilateral, ± erect; filaments 5–6 mm long, exserted for 2–4 mm, white; anthers 5–6 mm long, grey-purple; pollen light yellow-brown. *Style* nearly straight, adaxial to filaments, usually dividing between apex of anthers to 3 mm beyond apex; branches ± 2 mm long, forked for ⅓–½ their length, diverging but barely or not at all recurved. *Capsules* ± globose, 3-lobed, ± 7 mm long. *Seeds* not known. *Chromosome number* 2*n* = 10. *Flowering time*: February to April.

Distribution and ecology: restricted to northern Namibia, extending in a wide arc from the hills west and south of Etosha Pan to the Otavi Hills in the northeast and locally also in adjacent southern Angola; apparently confined to rocky sites, often in granite but on shale in the Otavi Hills.



Diagnosis: the relatively large, white to lilac flowers with lanceolate tepals and a perianth tube 40–45 mm long, and ultimate branches of the inflorescence with up to 5 flowers (rarely less than 2) distinguish *Afrosolen otaviensis*. It has been confused with similarly long-tubed *A. bainesii*, which can be separated by a series of characters including a shorter perianth tube, 30–40 mm long, often flushed pink to red-purple outside, white to pale pink tepals with undulate margins and narrowed below into claws, and a divaricately branched inflorescence with ultimate branches bearing 1, rarely 2 flowers. *Afrosolen otaviensis* is evidently restricted to rocky sites, mostly granite or shale, whereas *A. bainesii* occurs in deep, hard sand in savanna or bushveld. Plants with

blue-violet flowers from the Erongo Mtns included in the past in *A. otaviensis* are a separate species, *A. erongoensis,* distinguished in addition to perianth colour by a shorter perianth tube ± 37 mm long and shorter, narrower tepals, ± 12 × 3 mm vs. 15–19 × 4–5 mm.

10. **Afrosolen bainesii** *(Baker) Goldblatt & J.C.Manning* in Bothalia 46: 4 (2016). *Lapeirousia bainesii* Baker: 338 (1876). *Psilosiphon bainesii* (Baker) Goldblatt & J.C.Manning: 130 (2015). Type: Botswana, Kobe Pan [as 'inter Koobie et N Shaw valley'], *Baines s.n.* (K, lecto., effectively designated by N.E.Brown on specimen).

    Lapeirousia vaupeliana Dinter: 436 (1922). Sölch: 8 (1969). Type: Namibia, Gameros (cultivated at Okahandja), *Dinter 3087* [B, lecto., designated by Sölch: 8 (1969)].

Plants 300–600 mm high. *Corm* bell-shaped, 13–20 mm diam.; tunics mid- to dark brown, ± leathery internally with veins sharply outlined, becoming ± fibrous, fibres coarse and wiry. *Stem* usually repeatedly branched, compressed and 2-winged below, 3- or 4-angled and winged above, wings sometimes slightly crisped or finely serrated. *Foliage leaves* narrowly lanceolate to linear, main vein prominent and a pair of lateral veins on either side evident, 5–7 mm wide, usually slightly exceeding inflorescence. *Inflorescence* a rounded, divaricately branched false panicle, ultimate branches 1(2)-flowered, axes sharply 3-angled; bracts green below, becoming dry and membranous at anthesis, later dry and light brown, apices often darker brown, 7–10(–12) mm long, inner slightly larger than outer. *Flowers* zygomorphic, ± white, often flushed or fading pale pink, tube pale pink to purple outside, lower 3 tepals each usually marked with red to brown streak in basal ½ and with dark mark at base, top of throat red on abaxial side, sweetly scented; perianth tube cylindric, slightly expanded in upper 5 mm, (25–)32–40 mm long, usually inclined; tepals subequal or dorsal slightly larger, ± spathulate, ± clawed (rarely with a tooth-like ridge in lower midline of lower tepals, margins undulate, dorsal ± upright to reflexed at right angles to tube, 9–12(–15) × 3–4 mm, lower 3 tepals held close together, forming lip. *Stamens* unilateral, straight; filaments exserted 3.5–5.0 mm, white; anthers 4.5–6.2 mm long, pale purple; pollen ± white. *Style* arching over stamens, dividing between middle and apex of anthers or exceeding them, branches spreading, ± 2 mm long, ± undivided or notched apically. *Capsules* obovoid to globose, 5–6 mm long. *Seeds* globose, ± 2 mm diam. *Chromosome number* $2n = 10, 6$. *Flowering time*: January to April, rarely late November or December.

Distribution of ***Afrosolen bainesii***.

Distribution and ecology: occurring on the dry plains of central interior southern Africa, in Namibia from near Windhoek north into southern Angola and across the Kalahari to eastern Botswana and northwestern Limpopo in South Africa; in hard flat sandy ground where the corms may be lodged up to 300 mm below the surface.

The flowers open in the late afternoon and last through the night and into the following day but rapidly become wilted in the dry and hot daylight conditions. The freshly opened flowers have a strong sweet and pleasant odour and produce a fair quantity of nectar and this combined with the pale perianth colour suggest adaptation to pollination by hawk moths.

Diagnosis: the divaricately branched inflorescence with branches bearing 1 or rarely 2 flowers, long perianth tube 25–35(–45) mm long, and ± white perianth with pink to red markings near the base of the lower tepals are diagnostic for *Afrosolen bainesii*. The corm tunics are composed of light brown, densely compacted fibres, the outer layers becoming increasingly netted with age. These corm tunics, combined with the pale, long-tubed flower, and the basic chromosome number of $x = 5$ and similar karyotype, suggest a close relationship with *A. otaviensis* and *A. schimperi*. The resemblance in the size and general shape of the flowers of *A. bainesii* and *A. otaviensis* led to their confusion in the past, but field studies have shown that they are separate species with different ranges, habitat preferences and different floral and inflorescence morphology. Populations of *A. bainesii* from west-central Namibia have a derived chromosome number, $2n = 6$, and evidently represent a chromosomal race of the species but show no morphological differences.

Specimens from eastern Botswana near Macheng represent an unusual form of *Afrosolen bainesii* with a short tube, 14–20 mm vs. 25–40 mm in most other collections of the species. One of the few collections from Chibia in Angola consists of plants with a wine-red perianth tube and reverse of the outer tepals. These plants cannot be adequately assessed until more material from Angola becomes available.

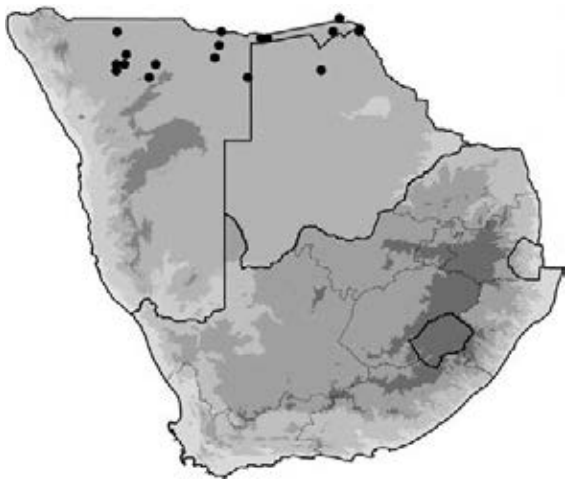
Type: Angola, without precise locality, cult. Hort. Kew, *Monteiro s.n.* (K, holo.).

Lapeirousia fragrans Welw. ex Baker: 272 (1878). Type: Angola, Huila: ad Morro de Lopollo, 5 200 ft [1 585 m], stony and rocky places, Dec. 1859, *Welwitsch 1552* (K, holo.; BM, C, COI, G, P, iso.).

Lapeirousia cyanescens Welw. ex Baker: 272 (1878). Type: Angola, Huila: hills near Humpata, Apr. 1860, *Welwitsch 1553* (K, lecto. designated by Goldblatt: 472 (1990b); B, BM, COI, G, iso.).

Lapeirousia edulis Schinz: 49 (1896). Type: Namibia, Amboland, west of Olukonda, 5 Apr. 1893, *Rautanen 106* (Z, lecto., designated by Goldblatt: 472 (1990b); K, P [2 sheets], Z [3 sheets], isolecto.).

Lapeirousia porphyrosiphon Baker: 353 (1898). Type: Botswana, Ngamiland, Kalahari Desert near Mamunwe, 26 Feb. 1897, *Lugard 338* (K, holo.).



Lapeirousia erythreae Chiovenda: 139 (1911). Type: Eritrea, Accheli Guzai (Ocule Cusai) near Loggo Sarda, Deggahen, 2 600 m, 15 Sept. 1902, *Pappi 1414* (G, lecto., designated by Goldblatt: 472 (1990b); GH, MO, isolecto.).

Lapeirousia montaboniana Chiovenda: 140 (1911). Type: Eritrea, Bogos near Cheren, 24 Aug. 1906, *Pappi 7087* (? FI).

Lapeirousia dinteri Vaupel: 544–545 (1912). Type: Namibia, Damaraland, Aukos-Kreyfontein, 28 Dec. 1908, *Dinter 810* (B, holo.; B, SAM [2 sheets], iso.).

Lapeirousia uliginosa Dinter: 13, 14 (1912). Type: unknown, none cited.

Plants (200–)300–800 mm high. *Corm* bell-shaped, 18–22 mm diam.; tunics of compacted fibres, light to dark brown, outer layers becoming loosely fibrous and netted. *Stem* usually laxly few(several)-branched, rounded below becoming ± square and 4-angled to 4-winged above. *Leaves* 3 or more, lower 2 largest, usually slightly exceeding inflorescence, decreasing in size above, narrowly lanceolate to ± linear, 5–10(–15) mm wide, main vein slightly raised. *Inflorescence* a lax false panicle or branched spike, ultimate branches 1- to 3-flowered; bracts (10–)20–35(–45) mm long, green, becoming membranous to ± dry and papery above, then light to dark brown, tips dark brown. *Flowers* zygomorphic, white to cream-coloured, rarely pale violet, when whitish sometimes fading lilac on drying especially on tube; opening at sunset and then sometimes scented; perianth tube cylindric, slender, 100–140(–150) mm long; tepals lanceolate, extended ± at right angles to tube, 18–22(–25) × 6–8(–11) mm. *Stamens* unilateral, ± erect; filaments exserted 5–7 mm from tube; anthers 6–7 mm long, cream-coloured; pollen cream-coloured. *Style* filiform, arching over filaments, dividing opposite anther apices or to up to 3 mm beyond anthers; branches ± 2 mm long, forked for ± ⅓ their length. *Capsules* obovoid-oblong, 8–12 mm long, partly enclosed in bracts. *Seeds* globose to slightly angular, 2.0–2.5 mm in diam. *Chromosome number* 2*n* = 10. *Flowering time*: mid- to late summer, December to March, in central and south tropical Africa [north of the equator mostly in September and October but in Kenya and Ethiopia also April to June].

Distribution of ***Afrosolen schimperi***.

Distribution and ecology: widespread across Africa, extending from southwestern Angola and north-central Namibia across northern Botswana, southern Zambia and Zimbabwe in an almost continuous belt, then with a scattered distribution in northern Tanzania, eastern Kenya, southern Ethiopia and then again in northern Ethiopia, Eritrea, Somalia and the Jebel Marra and Jebel Gurgeil Highlands of NW Sudan, possibly also in Yemen; usually in local moist sites in otherwise largely arid country, typically in washes, the omurambas of Namibia, dambo margins, streambanks and seasonal marshes, as well as in damp grassland.

The flowers open in late afternoon and last through the night, but gradually wilt the next day. Some collections note a sweet odour when the flowers are open, but others are scentless during the day and early evening

hours, indicating variation for scent. The corms are edible, and eaten either raw or roasted by the Ovambo of northern Namibia (Rodin, 1985).

Diagnosis: *Afrosolen schimperi* is readily distinguished from related species by its large white flower with a perianth tube 100–150 mm long and laxly branched inflorescence. Its immediate relationships probably lie with the Namibian and Angolan long-tubed species, *A. bainesii* and *A. otaviensis*, with which it shares a diploid chromosome number of $2n = 10$. These two species also have pale flowers with relatively long perianth tubes, up to 45 mm long, but more compact inflorescences and are not likely to be confused with *A. schimperi*.

Tribe 3. **Ixieae**

Ixieae *Dumort.*, Commentationes botanicae: 58 (1822). Type: *Ixia* L.

Plants with corm development axial, rootstock rarely a slender rhizome; corm with rounded or flat base, tunics fibrous, papery or woody; flowering stem sometimes subterranean. *Leaves* with main vein, margins with columnar epidermal cells or with subepidermal sclerenchyma. *Inflorescence* a spike, sometimes contracted, or flowers solitary. *Flowers* actinomorphic or zygomorphic with stamens unilateral, arcuate or decumbent; style branches simple or deeply divided, sometimes extremely long; ovule campylotropous; seed epidermal cell outlines smooth or prominent; ovular vasculature intact or excluded; $x = 15$ (many other numbers).

Genera 20: tropical Africa, Madagascar and Eurasia, with 19 genera in southern Africa; ± 940 species with ± 760 in southern Africa.

Key to genera

1a Leaf blades pleated, lanceolate to ovate, sometimes ± linear to subterete and then with several longitudinal grooves; stems and/or leaves or bracts pubescent to pilose; style branches undivided, often expanded at tips. . . . . 22. *Babiana*
1b Leaf blades plane or elliptic to terete in section, rarely terete but then stem, leaves and bracts glabrous; style branches either undivided or forked to deeply divided:
2a Outer floral bracts green with narrow or broader, colourless or brown-flecked, membranous margins, inner bracts with broad membranous margins or ± entirely membranous; style branches shallowly to deeply divided; flowers solitary at branch tips, actinomorphic . . . . . .30. *Romulea*
2b Outer floral bracts either green without conspicuous membranous margins or ± membranous to dry, inner bracts similar to outer; style branches simple or divided; flowers solitary or in spikes, actinomorphic or zygomorphic:
3a Plants acaulescent; leaves usually entirely bifacial, mostly channelled to adaxially grooved, or terete distally; corm tunics woody or fibrous but then leaves always entirely bifacial; flowers actinomorphic, blue or mauve to white:
4a Corm strongly compressed laterally; leaf solitary, round in section distally; capsules splitting open when dry . . . . . 31. *Afrocrocus*
4b Corm globose; leaves usually more than one, channelled or round in section distally; capsules splitting open when wet. . . . . 32. *Syringodea*
3b Plants either with aerial stems or acaulescent but then leaves unifacial, oriented edgewise to stem, blades plane and linear to lanceolate or oval to terete in transverse section; corm tunics woody or papery to fibrous; flowers actinomorphic to zygomorphic, variously coloured:
5a Corm bell-shaped with a flat base, tunics splitting radially from middle of base, not forming a circular baseplate; flowering stem wiry and well-branched; ovary deeply 3-lobed; perianth tube vestigial . . . . . .15. *Melasphaerula*
5b Corm with round or flat base then ± bell-shaped and tunics fragmenting circumferentially to form circular baseplate; flowering stem not wiry; ovary not or only slightly 3-lobed; perianth tube variously short to long:
6a Style branches deeply divided:
7a Flowers solitary on branches; leaves prostrate . . . . . 16. *Xenoscapa*
7b Flowers in suberect or inclined, subsecund and scalloped spikes; leaves usually erect or prostrate . . . . . 17. *Freesia*
6b Style branches undivided or notched at tips, sometimes expanded at apex:
8a Leaves oval in section with 4 longitudinal grooves; flowers dusty pink, actinomorphic with stamens rotated anticlockwise . . . . . .19. *Devia*
8b Leaves plane or rarely oval to terete, then solid or with 4 longitudinal grooves; flowers variously coloured, zygomorphic with stamens unilateral, or actinomorphic but stamens never rotated anticlockwise:
9a Outer and inner floral bracts dry and papery or membranous, outer bracts often toothed or sometimes lacerate:
10a Bracts pale, dry, papery and crinkled or solid below, irregularly streaked with dark flecks or veins:
11a Flowers borne on wiry stems and usually nodding; leaves linear, narrow, tough and fibrotic, without an evident main vein when mature; perianth always radially symmetric . . . . . 26. *Dierama*
11b Flowers borne on firm somewhat succulent stems and held upright or facing to the side; leaves lanceolate to linear, relatively succulent and not tough and fibrotic, usually with an evident main vein; perianth radially symmetric or zygomorphic . . . . . 24. *Sparaxis*
10b Bracts pale or rust-brown, membranous or dry but not papery and crinkled, sometimes streaked with dark flecks or veins:
12a Flowers usually zygomorphic with stamens unilateral and arcuate or tepals actinomorphic but stamens irregularly spreading and style eccentric, rarely perfectly actinomorphic with stamens symmetrically arranged; lower tepals sometimes with median ridge, tooth or callus; stems firm and relatively thick, never wiry . . . . . .27. *Tritonia*
12b Flowers either actinomorphic with stamens symmetrically disposed around a central style, or perianth symmetrical but stamens unilateral and decumbent with anthers drooping and with a right-angled bend near base; lower tepals never with median ridge or tooth; stems often more-or-less wiry, or plants acaulescent:
13a Stem usually aerial and ± wiry, rarely plants acaulescent but then flowers not stalked below ovary; outer bract usually 3-lobed to 3-toothed; pollen grain apertures with a 1-banded operculum . . . . . 28. *Ixia*

13b Stem subterranean; flowers distinctly stalked below ovary; outer bract acute; pollen grain apertures with a 2-banded operculum . . . . . 25. *Duthieastrum*
9b Outer and inner floral bracts green or brown and firm-textured to leathery, sometimes dry distally, outer bracts never toothed or lacerate:
14a Style branches usually dividing near mouth or within perianth tube, with branches relatively long and laxly spreading to decumbent (rarely branches erect then included in tube, or when style dividing beyond mouth of tube then corms tunics woody); perianth usually actinomorphic . . . . . 21. *Hesperantha*
14b Style branches usually dividing well above mouth of perianth tube, branches relatively short and spreading to recurved, rarely style dividing within perianth tube but then corm tunics woody; corm tunics woody to papery or fibrous; perianth actinomorphic or zygomorphic:
15a Flowers perfectly actinomorphic (with eccentric style) or only perianth actinomorphic, but stamens and style unilateral and decumbent or declinate; corm tunics hard, brittle and woody, rarely fibrous in a few species; seeds globose to somewhat angular. . . . . .20. *Geissorhiza*
15b Flowers usually zygomorphic with tepals unequal and stamens and style arcuate, rarely perfectly actinomorphic in a few species but then flower either pendent or seeds broadly winged; corm tunics fibrous; seeds globose to angular or winged:
16a Floral bracts relatively short, firm and leathery, dry distally to entirely; flowers predominantly red to orange; seed testa smooth and waxy:
17a Flowers zygomorphic; perianth tube narrow and cylindric below, abruptly expanded into a broad upper cylindric part with pouch at base of upper part; seeds bright orange; leaves always plane 23. *Chasmanthe*
17b Flowers actinomorphic and pendent, or zygomorphic, but then perianth tube usually not abruptly expanded at top of lower cylindric portion and upper part not forming a pouch at base; seeds brown to blackish; leaves pleated or plane . . . . . 18. *Crocosmia*
16b Floral bracts relatively long, soft- to firm-textured but not leathery, sometimes becoming dry distally; flowers variously coloured; seed testa colliculate, not waxy
18a Style branches slender throughout; seeds globose; leaves soft-textured; stem lightly angled; flowers pink . . . . . 29. *Radinosiphon*
18b Style branches expanded and bilobed at tips; seeds usually with broad circumferential wing, occasionally wing obsolete and seed irregularly angled to subglobose; stem usually round in section, rarely angled to winged; flowers variously coloured. . . . . 14. *Gladiolus*

Subtribe 1. **Gladiolinae**

Gladiolinae *Goldblatt* in Journal of South African Botany 37: 440 (1971). Type: *Gladiolus* L.

Corm tunics fibrous or papery; flowering stem always well developed. *Leaf* margins with subepidermal sclerenchyma associated with a marginal vein. *Inflorescence* a spike; inner bracts shorter than outer, forked apically. *Flowers* usually zygomorphic; style branches well developed, undivided, expanded at tips; seeds mostly with prominent circumferential wing, epidermal cell outlines prominent; ovular vasculature intact; $x = 15$.

Genera 1, only *Gladiolus*; ± 270 species, 169 in southern Africa.

14. **Gladiolus**

Gladiolus *Tourn. ex L.*, Species plantarum: 36 (1753). Type: *G. communis* L.

Antholyza L.: 37 (1753). Type: *A. cunonia* L. = *Gladiolus cunonius* (L.) Gaertn., lecto. designated by Hitchcock & Green (1929).

Cunonia Buettner ex Mill.: 75 (1756), name rejected in favour of *Cunonia* L. (1759) (Cunoniaceae). Type: *C. antholyza* Miller = *Gladiolus cunonius* (L.) Gaertn.

Hebea (Pers.) Eckl.: 42 (1827), illegitimate homonym, not *Hebea* R.Hedw. Type: not designated.

Anisanthus Sweet: 396 (1826). Type: *A. splendens* Sweet = *Gladiolus splendens* (Sweet) Herb.

Sphaerospora Sweet ex J.W.Loudon: 66, t. 14 (1841). Type: *S. imbricata* (Jacq.) Sweet ex J.W.Loudon = *Gladiolus italicus* Mill.

Petamenes Salisb. ex J.W.Loudon: 42, t. 8 (1841). *Petamenes* Salisb. ex N.E.Br.: 276 (1932a), illegitimate superfluous name. Type: *P. quadrangularis* (Burm.f.) Salisb. ex J.W.Loudon = *Gladiolus quadrangularis* (Burm.f.). Ker Gawl.

Acidanthera Hochst.: 25 (1844). Type: *A. bicolor* Hochst. = *Gladiolus murielae* Kelway

Homoglossum Salisb.: 143 (1866). Type: *H. watsonium* (Thunb.) N.E.Br. = *Gladiolus watsonius* Thunb., lecto., effectively designated by De Vos: 301 (1976).

Hyptissa Salisb.: 142 (1866). Type: *H. rosea* Salisb., name without description, identity uncertain.

Ophiolyza Salisb.: 142 (1866). Type: *Gladiolus alatus* L., lecto., designated by Goldblatt: 78 (1996).

Ranisia Salisb.: 143 (1866). Type: *Gladiolus tristis* L.

Symphydolon Salisb.: 142 (1866). Type: *Gladiolus floribundus* Jacq.

Oenostachys Bullock: 465 (1930). Type: *O. dichroa* Bullock = *Gladiolus dichrous* (Bullock) Goldblatt

Anomalesia N.E.Br.: 270 (1932a). Type: *A. cunonia* (L.) N.E.Br. = *Gladiolus cunonius* (L.) Gaertn.

Kentrosiphon N.E.Br.: 271 (1932a). Type: *K. saccatus* (Klatt) N.E.Br. = *Gladiolus saccatus* (Klatt) Goldblatt & M.P.de Vos

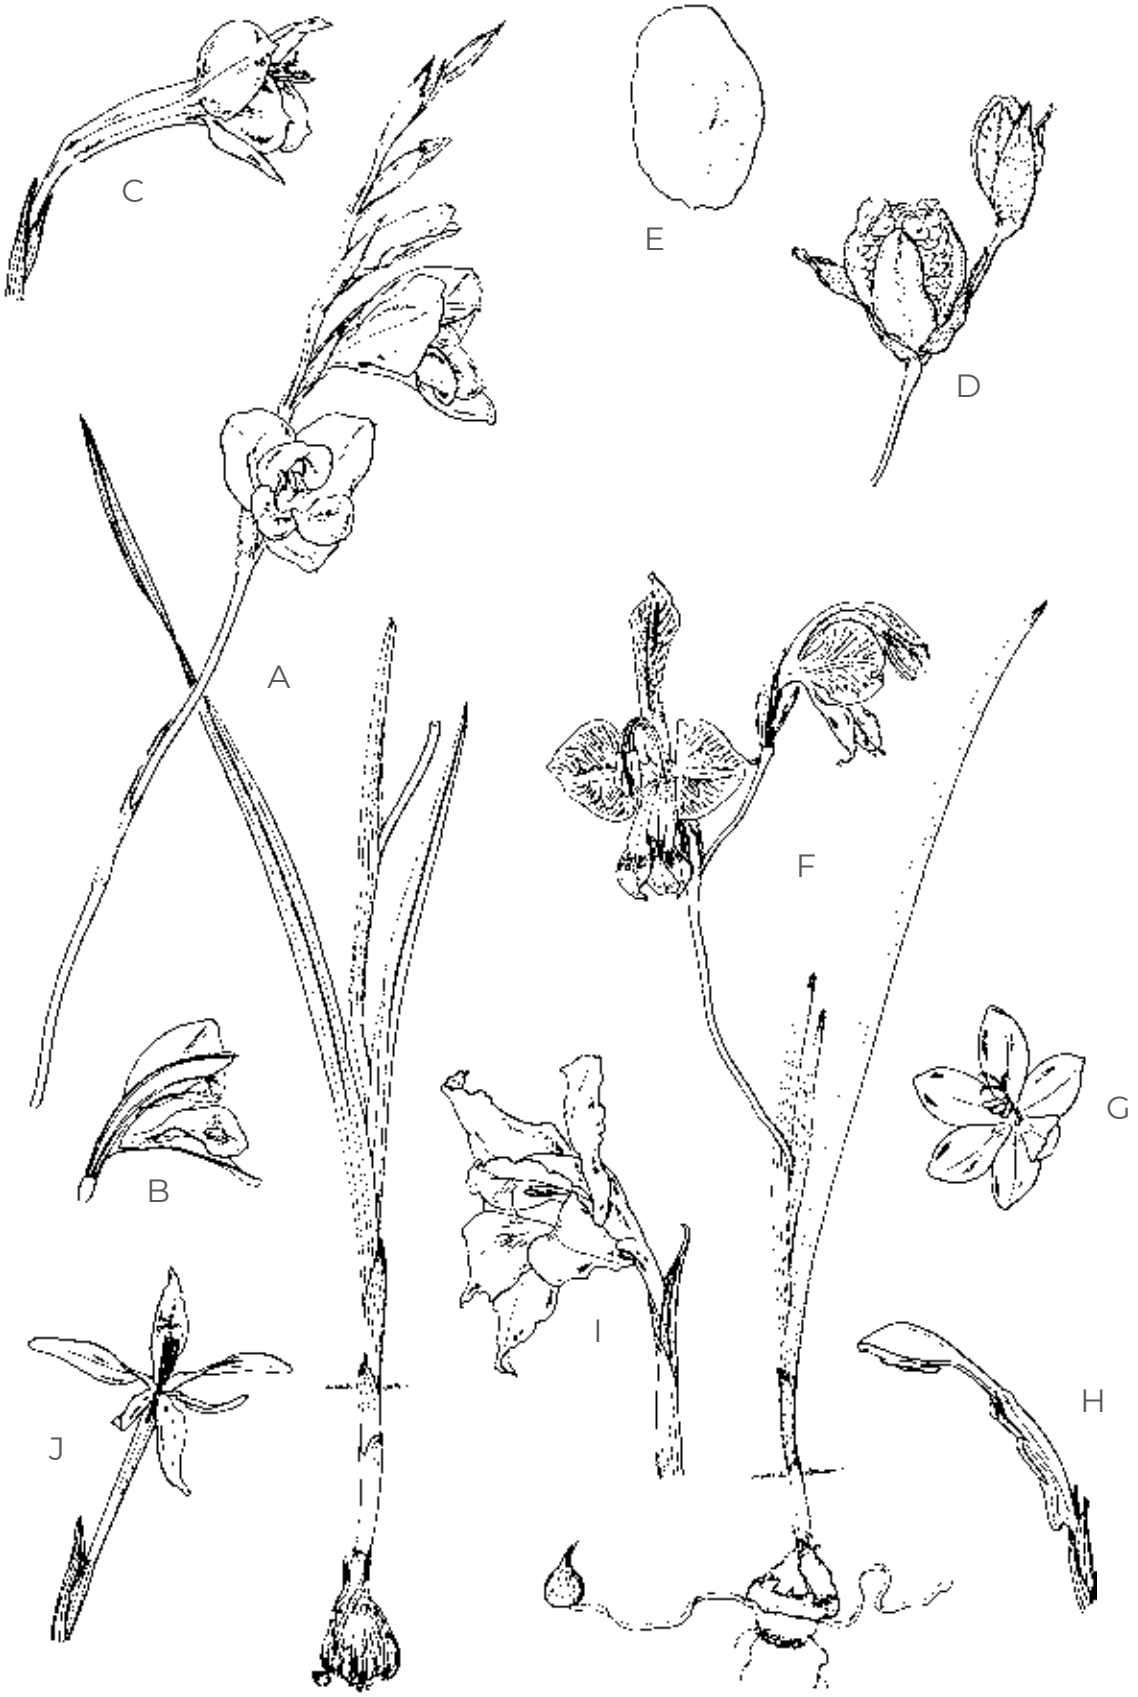
Dortania A.Chev.: 402 (1938). Type: *D. amoena* A. Chev. = *Gladiolus chevalieranus* Marais

[*Sphaerospora* Sweet: 398 (1826), invalid name without description].

Revisionary accounts: Lewis et al. (1972); Goldblatt (1996 for tropical Africa); Goldblatt & Manning (1998).

From the Latin, *gladiolus,* diminutive of *gladius*, sword, for the sword-shaped leaves.

Deciduous (rarely evergreen) geophytes. *Corm* globose to depressed-globose, axial in origin, tunics of fine or coarse fibres, leathery or woody, rarely papery. *Cataphylls* 3, pale and membranous. *Stem* well developed, usually terete or rarely angled or slightly winged, simple or branched, often flexuose, rarely scabrid to velvety. *Leaves* solitary to several, mostly basal and forming a 2-ranked fan or some cauline, rarely borne on a separate shoot, sometimes dry at flowering, blade sometimes reduced or lacking and leaves thus entirely sheathing, unifacial, usually with a definite midrib, plane and linear to lanceolate, rarely round to oval in section, occasionally the margins or midrib raised or winged and leaves thus X- or H-shaped in section, sometimes terete and longitudinally 4-grooved, cauline leaves usually few and reduced, rarely scabrid to velvety or pubescent; margin with vascular bundle and epidermal cells unspecialised. *Inflorescence* a spike, usually secund or in two ranks; bracts green and soft or firm, sometimes dry above, usually large, inner smaller than outer and 2-toothed or notched apically. *Flowers* usually zygomorphic, rarely radially symmetric, long-lived, bilabiate and funnel–salver-shaped or rarely rotate, variously coloured but often pink to mauve, lower tepals usually with contrasting nectar guides, unscented or variously scented, often closing at night, with nectar from septal nectaries; perianth tube funnel-shaped or cylindric, short or long; tepals subequal or unequal with dorsal largest and arched to hooded over the stamens, the lower three narrower and forming a lip, sometimes clawed and shortly united. *Stamens* usually unilateral and arcuate, rarely symmetrically disposed; filaments inserted well below top of perianth tube, included or exserted. *Ovary* globose; *style* filiform, usually unilateral and arcuate, 3-branched distally, branches oblanceolate-conduplicate, and expanded above, often bilobed. *Capsules* leathery, usually slightly inflated and relatively large, ovoid to ellipsoid, segments recurving strongly after dehiscence. *Seeds* discoid with a broadly circumferential papery wing, rarely wing obsolete, then subglobose or angled, domed on seed body and concave on wing. *Pollen grains* monosulcate-operculate, operculum 2-banded, exine perforate-scabrate. *Basic chromosome number x* = 15, other numbers 14, 12, 11.



Species ± 270, mainly sub-Saharan Africa and Madagascar, also Europe and the Middle East, 169 in southern Africa, centred in the winter-rainfall zone of southwestern Western Cape, with secondary centres of diversity in the eastern African highlands and in Shaba Province of Congo. As in most genera of Iridaceae with a significant representation of species in both summer- and winter-rainfall southern Africa there is minimal overlap among the species from the two rainfall regimes. *Gladiolus* species are most common in temperate habitats, mainly grasslands and open savanna in areas of summer rainfall and fynbos and other shrublands in the winter-rainfall region.

Gladiolus is highly variable in both floral and vegetative morphology, but most species have characteristic ovoid, leathery, somewhat inflated capsules and distinctive seeds with a broad circumferential wing. The style is also diagnostic, with oblanceolate-conduplicate branches that are expanded distally into broad, bilobed tips. The basic chromosome number, $x = 15$, indicates that the genus is palaeopolyploid. Most species are diploid, $2n = 30$, but the almost pan-African *G. dalenii* is heteroploid, with tetraploid, hexaploid, and occasionally diploid populations.

The affinities of *Gladiolus* have long been uncertain, but molecular phylogenetic analyses suggest that the genus is most closely allied to the monospecific *Melasphaerula* of the southern African winter-rainfall zone. The two genera have little morphological similarity.

A molecular phylogenetic analysis of *Gladiolus*, with an emphasis on the southern African and Mediterranean species, proposes an origin for the genus in southern Africa during the Miocene, followed by range extensions into tropical Africa, Madagascar and the Mediterranean (Valente et al. 2011). The high diversity in the southern African winter-rainfall region is interpreted as a result of the long history of the genus in the region, combined with comparatively low rates of extinction and higher rates of ecological speciation.

The large number of generic synonyms reflects the floral diversity in the genus, much of which is now

GLADIOLUS. G. paludosus: A, flowering plant; B, half-flower. ***G. merianellus***: C, flower. ***G. carneus***: D, dehiscing and undehisced capsules; E. seed. ***G. uysiae***: F, flowering plant. ***G. brevitubus***: G, flower. ***G. saccatus***: H, flower. ***G. oppositiflorus***: I, flower. ***G. lapeirousioides***: J, flower.

understood to represent adaptation to various specialised pollination systems. Pollination by large anthophorine bees foraging for nectar is the most common system in the genus but many southern African species have long-tubed white to pink flowers adapted for pollination by long-proboscid flies. Bird pollination is frequent in southern and tropical African species, as is moth pollination by large settling moths or hovering sphinx moths. Other species are pollinated by large butterflies, notably in southern Africa, where red-flowered species are pollinated largely or exclusively by the satyrid butterfly *Aeropetes tulbaghia*. Radial symmetry has evolved in a handful of species in both southern and tropical Africa, and these species appear mostly to be pollinated by female bees foraging for pollen.

The floral diversity is matched by numerous vegetative adaptations, notably reduction in leaf number and the development of winged midribs and/or margins, or reduction of the entire leaf blade. In some species flowering occurs before the leaves are produced or after they have dried, thereby separating the growth and reproductive phases of the life cycle.

The current classification of *Gladiolus* in southern Africa recognises seven sections, distinguished by the insertion of the foliage leaves on the stem, the shape and thickening of the blades, the shape and number of the flowers, and the shape and size of the capsules (Goldblatt & Manning, 1998). The molecular phylogenetic analysis of the genus by Valente et al. (2011) is only partially congruent with this classification and some marked anomalies make it difficult to interpret. However, many of the series or species groups recognised by Goldblatt & Manning (1998) are retrieved by Valente et al. (2011) in their phylogeny, providing independent support for species relationships at these lower taxonomic levels. Provisionally, therefore, we follow the slightly modified version of Goldblatt & Manning's (1998) classification proposed by Goldblatt & Manning (2009).

Synoptic key to sections

1a Leaves broadly to narrowly lanceolate, usually at least 4 mm wide, often with well-developed secondary veins, these sometimes finely and closely set; flowers mostly slightly bilabiate with the lower tepals not clawed but sometimes strongly clawed:
  2a Leaves usually superposed, blades often reduced, sheaths and sometimes blades pubescent or villous, rarely scabrid; corm tunics of flattened fibres . . . . . 4. sect. *Linearifolii*
  2b Leaves in a 2-ranked fan, glabrous or puberulous; corm tunics often papery:
    3a Flowers usually small; capsules less than 15 mm long; seeds smaller, usually less than 6 mm long, with wings often reduced or unevenly developed . . . . . .1. sect. *Densiflori*
    3b Flowers usually larger; capsules usually more than 20 mm long; seeds larger, usually more than 8 mm long, with well-developed wings:
      4a Flowers rarely white to pink, sometimes red but then lower tepals with white transverse bands or base . . . . . 2. sect. *Ophiolyza*
      4b Flowers usually cream-coloured to pale or deep pink or salmon-orange, lower tepals usually with red spade-, diamond- or spear-shaped markings, often with white centre, or median red streak, flowers sometimes red but then with longitudinal markings . . . . . .3. sect. *Blandi*
1b Leaves linear, usually less than 5 mm wide, usually without well-developed secondary veins, if broader then without well-developed midrib; flowers usually strongly bilabiate with lower tepals narrow and clawed:
  5a Leaves (2)3(4), one or two basal and others superposed and inserted serially up stem; stems unbranched; spike usually often strongly flexuose or sometimes stiffly erect; nectar guides on lower tepals usually of fine, longitudinal dark streaks and spots over a pale area or transverse bands of pale colour; capsules usually ellipsoid to ovoid and acute; flowers often fragrant, except when long-tubed and pink or orange to red, sometimes nocturnal . . . . . 7. sect. *Homoglossum*
  5b Leaves usually several, at least three basal:
    6a Leaf midrib and margins usually heavily thickened, the blades sometimes centric and cross-shaped in section or terete and with four longitudinal furrows or grooves; corm tunics fibrous, often accumulating in a neck around base of stem; flowers rarely lightly scented; capsules usually oblong and slightly 3-lobed above; seeds often with wings reduced, vestigial or sometimes lacking . . . . . 5. sect. *Heterocolon*
    6b Leaf midrib lightly thickened and raised but margins usually unthickened, rarely ridged or corrugated; corm tunics membranous, papery, woody or fibrous but rarely accumulating in a neck around base of stem; flowers often highly fragrant except red-flowered species; capsules usually ellipsoid and acute, rarely obovoid and 3-lobed above; seeds broadly and evenly winged . . . . . .6. sect. *Hebea*

1. Sect. *Densiflori* and 2. sect. *Ophiolyza*

1a Anthers with locules drawn into sterile basal tails at least 1.5 mm long:
  2a Perianth tube 40–45 mm long, at least one and a half times as long as dorsal tepal; tepals attenuate; flowers whitish to pale salmon-pink, lower tepals with median red streak . . . . . 13. *G. macneilii*
  2b Perianth tube 15–32(–40) mm long, shorter than to ± as long as dorsal tepal; tepals ± obtuse; flowers white to pink without median streak on lower tepals:
    3a Floral bracts 18–27 mm long; flowers white to pink; perianth tube 16–22 mm long . . . . . .11. *G. appendiculatus*

3a Floral bracts 35–55 mm long; flowers white with yellow throat; perianth tube 16–40 mm long . . . . . 12. *G. calcaratus*
1b Anthers without sterile basal tails:
4a Inner bracts with margins united below into a tube around ovary, or spikes 2-ranked and erect; bracts usually somewhat inflated below and pleated, the apices dry and light brown, attenuate and deflexed; plants usually with a fan of rigid, erect leaves often puberulous or scabridulous:
5a Perianth tube (28–)40–55 mm long; flowers bright mauve or pink to salmon pink; plants from Eastern Cape to southern KwaZulu-Natal . . . . . 24. *G. oppositiflorus*
5b Perianth tube 10–35 mm long; flowers pale pink to blue, cream-coloured or greenish, often minutely speckled; KwaZulu-Natal to Limpopo and Botswana:
6a Perianth tube 33–35 mm long; lower tepals streaked with red and base of filaments dull red . . . . . 20. *G. reginae*
6b Perianth tube 10–27 mm long; lower tepals not streaked and filaments pale:
7a Leaves in a tight basal fan usually shorter than spike, with numerous fine parallel veins and without a prominent midrib; plants never hairy . . . . . 26. *G. elliotii*
7b Leaves in a lax fan usually arising some distance above ground with a pseudostem formed by the sheaths, narrow and usually exceeding the spike, always with a prominent midrib and sometimes also secondary veins; plants usually hairy:
8a Perianth tube 18–27 mm long; tepals elliptic-attenuate; bracts 26–30 mm long, attenuate. . . . . 22. *G. dolomiticus*
8b Perianth tube 10–16 mm long; tepals lanceolate-acute; bracts 15–30 mm long, ± acute:
9a Filaments 10–12 mm long; bracts ± two internodes long . . . . . 25. *G. sericeovillosus*
9b Filaments 18–20 mm long, reaching almost to tepal apices; bracts one to one and a half internodes long . . . . . 23. *G. pole-evansii*
4b Inner bracts with margins free to the base and spikes never 2-ranked, usually inclined; bracts not normally inflated below, green or dry but then apices not attenuate and deflexed; plant habit varied:
10a Flowers carmine to red, lower tepals either with white markings or much reduced:
11a Dorsal tepal ± twice as long as upper laterals; lower tepals ± ⅔ as long as upper laterals, ± 10 mm long, marked with yellow . . . . . 33. *G. magnificus*
11b Dorsal tepal ± as long as upper laterals; lower tepals slightly shorter than upper laterals, 30–48 mm long, marked with white:
12a Perianth sigmoid, flowers obliquely tulip-shaped with lower tepals forming a shallow bowl; tepals 30–42 mm long, thick and succulent in texture, lower tepals with median white streak . . . . . 34. *G. flanaganii*
12b Perianth ± straight or curved apically, flowers flaring with lower tepals straight or recurved; tepals 45–67 mm long, moderately thin and delicate, lower tepals white in lower half speckled with red:
13a Stems erect; leaves firm-textured, in an erect basal fan shorter than stem, drooping; tepals ± recurved distally; plants from Drakensberg and Lesotho . . . . . 35. *G. saundersii*
13b Stems inclined or drooping; leaves soft-textured, as long as or longer than stem, drooping; tepals suberect or spreading; plants from coastal KwaZulu-Natal . . . . . 36. *G. cruentus*
10b Flowers never carmine to red, lower tepals variously coloured and marked:
14a Flowers pink to mauve, lower tepals with longitudinal reddish streaks; perianth tube 20–50 mm long:
15a Leaves and/or stems scabridulous to puberulous:
16a Stem, rachis and bracts glabrous; dorsal tepal 35–40 mm long; plants drooping from cliffs . . . 16. *G. microcarpus*
16b Stem, rachis and bracts scabridulous; dorsal tepal 40–45 mm long; plants erect on stony slopes and outcrops . . . . . 17. *G. scabridus*
15b Leaves and stems glabrous:
17a Leaves 3–9 mm wide, with prominently thickened midrib and margins, with fine, closely set veins between; dorsal tepal 26–32 mm long; bracts rusty brown above or entirely . . . . . 10. *G. varius*
17b Leaves broader, with prominent secondary veins between margins and midrib; dorsal tepal 35–48 mm long; bracts green throughout or dry above:
18a Leaves leathery with prominently thickened margins and veins; plants from Eastern Cape. . . . 15. *G. mortonius*
18b Leaves softer textured, with lightly thickened margins and other veins; plants from eastern Mpumalanga:
19a Bracts 50–70 mm long, green; perianth tube 40–50 mm long; dorsal tepal 40–48 mm long; lower tepals with prominent median red streak . . . . . 18. *G. cataractarum*
19b Bracts 38–48 mm long, rusty brown above; perianth tube 30–40 mm long; dorsal tepal 35–37 mm long; lower tepals with obscure median mark . . . . . 9. *G. saxatilis*
14b Flowers variously coloured but if pink then perianth tube less than 20 mm long:
20a Perianth tube 25–70 mm long; filaments 20–40 mm long:
21a Leaves superposed along stem, with blades shorter than to ± as long as sheaths . . . . . 31. *G. aurantiacus*
21b Leaves clustered at base of stem forming a 2-ranked fan, blades well-developed:
22a Dorsal tepal 25–30 × 14–16 mm, ascending and not hooded over stamens; anthers 9–11 mm long . . . . . 30. *G. antholyzoides*
22b Dorsal tepal 35–50 × 22–30 mm, horizontal and hooded over stamens; anthers 12–16 mm long . . . . . 32. *G. dalenii*
20b Perianth tube 10–35 mm long; filaments usually 7–18 mm long, rarely up to 22 mm long but then flowers nodding and bell-shaped with perianth tube 18–20 mm long:
23a Floral bracts imbricate, two to five internodes long, somewhat inflated and folded on the midline, mostly 40–100 mm long; flowers often speckled or spotted over a pale ground, rarely pure white or pale mauve:
24a Leaves lanceolate, in a tight basal fan, rarely reaching base of spike; filaments 12–15 mm long. . . . 27. *G. ecklonii*
24b Leaves linear-lanceolate, reaching at least to base of spike; filaments 7–12 mm long:

25a Flowers speckled or spotted with lilac to dark purple; anthers 10–13 mm long; style branches 3–4 mm long . . . . . 28. *G. vinosomaculatus*
25b Flowers uniformly white or pale mauve; anthers ±10 mm long; style branches 6–8 mm long . . . . . 29. *G. rehmannii*
23b Floral bracts not or shortly imbricate, up to two internodes long, hardly or not inflated or folded on the midline, mostly 20–40 mm long; flowers mostly uniformly coloured, rarely minutely speckled:
26a Flowers 40–55 mm long:
27a Leaves of flowering stem reduced with short or vestigial blades . . . . . 21. *G. brachyphyllus*
27b Leaves of flowering stem with well-developed blades:
28a Perianth tube 18–30 mm long and ± as long as or slightly longer than dorsal tepal . . . . . 4. *G. hollandii*
28b Perianth tube 10–20 mm long and ½ to ± ⅔ as long as dorsal tepal:
29a Bracts dry and rusty brown above; leaves mostly less than 10 mm wide, with thickened midrib and margins, and remaining veins fine and closely set . . . . . 8. *G. ferrugineus*
29b Bracts green; leaves with secondary veins conspicuous or inconspicuous but not closely set:
30a Leaves in a tight basal fan; flowers spreading on a slightly inclined spike; filaments 10–12 mm long . . . . . 14. *G. ochroleucus*
30b Leaves superposed, not forming a tight basal fan; flowers nodding on a strongly inclined spike; filaments 20–22 mm long . . . . . 2. *G. papilio*
26b Flowers 23–40 mm long:
31a Leaves with only midrib and margins thickened, sometimes strongly so, remaining veins fine and closely set:
32a Leaves several in a tight basal fan shorter than spike; upper stem and spike strongly inclined; filaments ± 15 mm long . . . . . 6. *G. exiguus*
32b Plants not as above:
33a Bracts green or flushed dull purple; spike usually with 20–45 flowers; filaments 10–12 mm long . . . . . 7. *G. densiflorus*
33b Bracts dry and rusty brown above or entirely; spike usually with 12–15 flowers; filaments 12–15 mm long . . . . . 8. *G. ferrugineus*
31b Leaves with midrib and main veins thickened and at least one pair of secondary veins thickened, or secondary veins obscure and not closely set:
34a Leaves soft-textured, secondary veins obscure; lower median tepal strongly streaked with red, mouth of tube also red; plants producing long stolons . . . . . 19. *G. pavonia*
34b Leaves firm-textured, secondary veins evident; tepal markings obscure or best developed on lower laterals; plants not stoloniferous:
35a Floral bracts 12–16 mm long, narrow and attenuate, dry and twisted above at flowering; flowers pale pink, lower tepals usually with median yellow streak surrounded by broad pink blotch. . . . . 5. *G. serpenticola*
35b Floral bracts 17–40 mm long, acute to attenuate, green; flowers variously coloured, lower lateral tepals often with broad transverse blotch:
36a Flowers larger, dorsal tepal 20–25 mm long; filaments ± 14 mm long; plants mostly 40–50 mm high; leaves without conspicuous secondary veins; flowering October to November . . . . . 1. *G. paludosus*
36a Flowers smaller, dorsal tepal 18–22 mm long; filaments 12–14 mm long; plants mostly 50–120 mm high; leaves fibrous with conspicuous secondary veins; flowering mainly February to March. . . . . 3. *G. crassifolius*

3. Sect. *Blandi*

1a Flowers carmine to red, sometimes with white markings on lower tepals:
2a Flowers pure red, tulip-shaped; tepals broadly obovate, 27–30 mm long; filaments ± 20 mm long . . . . . 50. *G. insolens*
2b Flowers with white markings on lower tepals, funnel-shaped; tepals lanceolate to elliptic, 35–67 mm long; filaments 21–50 mm long:
3a Leaves on flowering stem with blades reduced or vestigial:
4a Flowers large, dorsal tepal 53–58 mm long and perianth tube 35–45 mm long; filaments 30–42 mm long, exserted 20–32 mm from tube; lower 3 tepals smaller than dorsal; anthers purplish or yellow with purple lines . . . . . 53. *G. stefaniae*
4b Flowers medium-sized, dorsal tepal 35–45 mm long and perianth tube 30–35 mm long; filaments 21–26 mm long, exserted 10–15 mm from tube; lower 3 tepals scarcely smaller than dorsal; anthers yellow. . . . 54. *G. carmineus*
3b Leaves on flowering stem with well-developed blades:
5a Stems erect or inclined; corm vestigial, producing scaly stolons; plants from Outeniqua and Tsitsikamma Mtns, flowering mainly February to April . . . . . 52. *G. sempervirens*
5a Stems inclined to drooping; corm small but well-formed, without stolons; plants from Hex River to Franschhoek Mtns, flowering December to January . . . . . 51. *G. cardinalis*
1b Flowers white or pale to deep pink or mauve, with various markings on lower tepals:
6a Leaves somewhat succulent, without evident veins and margins unthickened; flowers blue-mauve, tepals subequal, lower marked with white streaks edged in red; strand plants growing down to the high-tide mark . . . . . 40. *G. gueinzii*
6b Leaves not succulent, secondary veins usually evident and margins usually prominent; flowers white to pink or salmon-pink, lower tepals often smaller, variously marked:

7a Leaves in a tight basal fan; blades firm-textured with strongly thickened margins and midrib; corm tunics coarsely fibrous, accumulating in a dense mass and forming a neck around base of stem:
8a Perianth tube 18–21 mm long; filaments 12–14 mm long; lower lateral tepals with pale yellow, spear-shaped marks outlined with purple; base of leaves heavily marked with raised white speckles . . . . . 55. *G. rudis*
8b Perianth tube 22–55 mm long; filaments 14–37 mm long; lower lateral tepals with dark median streak; base of leaves lightly marked but not textured with white or green speckles:
9a Perianth tube 22–35(–55) mm long; lower tepals ¾ to ± as long as dorsal . . . . . 56. *G. grandiflorus*
9b Perianth tube 40–70 mm long, if less than 50 mm long then lower tepals ½–¾ as long as dorsal:
10a Flowers white to creamy yellow or greenish; perianth tube slender in lower 20–55 mm and flaring above; filaments 20–23 mm long. . . . . 57. *G. floribundus*
10b Flowers salmon to orange-red; perianth tube slender in lower 20–35 mm and cylindric above; filaments 35–37 mm long . . . . . 58. *G. miniatus*
7b Leaves in a loose fan or superposed; blades soft-textured with often lightly thickened margins and midrib; corm tunics papery to medium-textured fibres, not accumulating in a dense mass and forming a neck around base of stem:
11a Corms scarcely developed, tunics not accumulating; plants with inclined to drooping stems, growing on wet rocks:
12a Spike usually 15- to 20-flowered; flowers ivory-coloured to greenish cream-coloured, lower tepals less than half as long as dorsal; perianth tube 45–50 mm long, completely enclosed within the bracts; plants from Cederberg . . . . . 47. *G. buckerveldii*
12b Spike usually less than 15-flowered; flowers pale mauve-pink, lower tepals ⅔ to nearly as long as dorsal; perianth tube 25–40 mm long, exceeding the bracts; plants from Swartberg . . . . . 44. *G. aquamontanus*
11b Corms well developed, tunics accumulating or not; plants with erect to inclined stems, not growing on wet rocks:
13a Perianth tube longer than dorsal tepal, (30–)40–100 mm long:
14a Tepals attenuate and strongly undulate; lower tepals slightly shorter than upper . . . . . 45. *G. undulatus*
14b Tepals obtuse to acute, not attenuate, weakly undulate; lower tepals usually about ⅔ as long as upper:
15a Leaves 4 or 5; flowers cream-coloured to yellowish with prominent red, spear-shaped marks on lower tepals; flowering October to November; plants from West Coast and near interior . . . . . 46. *G. angustus*
15b Leaves 3 to 7; flowers salmon-pink with red linear marks on lower tepals; flowering February to April; plants from southern coast and interior:
16a Leaves 6 or 7, with blades 1.5–6.5 mm wide; perianth tube 30–55 mm long; flowering February; plants from Little Karoo mountains . . . . . 48. *G. dolichosiphon*
16b Leaves 3, with blades 6–8 mm wide; perianth tube 50–70 mm long; flowering March to April; plants from southern foothills of Langeberg . . . . . 49. *G. bilineatus*
13b Perianth tube shorter than to as long as dorsal tepal, (15–)20–50 mm long:
17a Flowers large, dorsal tepal 40–55 mm long; plants from Plettenberg Bay to Uniondale . . . . . 43. *G. geardii*
17b Flowers smaller, dorsal tepal 18–40(–50) mm long; plants from west of Knysna:
18a Leaf blades with two prominently thickened veins on some or all leaves, 1–6 mm wide; tunics finely fibrous:
19a Flowers 33–46 mm long; leaves 2– 6 mm wide; bracts mostly 13–20 mm long; lower tepals with white to yellow, spear-shaped marking outlined with red . . . . . 37. *G. oreocharis*
19b Flowers 48–60 mm long; leaves 1–3 mm wide; bracts mostly 25–33 mm long; lower tepals with red chevron-shaped marking in middle and red-spotted toward base and in throat . . . . . 38. *G. crispulatus*
18b Leaf blades with only midrib prominently thickened, sometimes additional pairs of veins also evident, 1.6–20.0 mm wide; tunics usually accumulating, fibrous or firm-papery:
20a Floral bracts 13–16 mm long; perianth tube 18–20 mm long; lower tepals narrowed below into claws . . . . . 39. *G. phoenix*
20a Floral bracts 25–65 mm long; perianth tube (15–)25–45 mm long; lower tepals not narrowed below into claws:
21a Leaves (2–)6–19 mm wide; flowers usually at least 5 per spike; corm tunics fibrous to firm-papery, usually accumulating. . . . . 41. *G. carneus*
21b Leaves 1.5–3.0 mm wide; flowers 1 or 2(3) per spike; corm tunics membranous, not accumulating . . . . . 42. *G. pappei*

4. Sect. *Linearifolii*

1a Plants from summer-rainfall region; perianth tube 4–12 mm long; capsules oblong to globose, 3-lobed above and retuse; leaf blades reduced, shorter than sheaths or vestigial; lower tepals sometimes clawed:
2a Leaves 2 or 3, uppermost bract- or scale-like; perianth subactinomorphic with subequal tepals; tepals elliptic to lanceolate, not clawed:
3a Flowers greenish or pale mauve with attenuate tepals 17–23 mm long; uppermost leaf bract-like and inserted some distance below first flower; stem rigid. . . . . 62. *G. pubiger*
3b Flowers pale pink with acute to obtuse tepals 12–17 mm long; uppermost leaf a small scale inserted just below first flower; stem wiry . . . . . 63. *G. parvulus*
2b Leaves (2)3 or 4; perianth obviously zygomorphic with lower tepals smaller; lower lateral tepals obviously clawed:
4a Flowers pale yellow; outer whorl of tepals constricted below into claws; lower tepals strongly auriculate at base of limb; vegetative plants with 3 leaves . . . . . 61. *G. pardalinus*
4b Not as above:

5a Flowers pale lilac to cream-coloured, yellow or maroon, the lower lateral tepals with dark purple median streak; flowers smaller, dorsal tepal 17–24(–27) mm long; foliage usually densely villous . . . . . 59. *G. woodii*
5b Flowers pale mauve, the lower lateral tepals shading to purple basally; flowers larger, dorsal tepal 28–30 mm long; foliage sparsely hairy to subglabrous . . . . . 60. *G. malvinus*
1a Plants from winter-rainfall region; perianth tube 11–55 mm long; capsules ovoid to ellipsoid, acute; leaf blades well-developed, reduced or vestigial; lower tepals never clawed:
6a Leaves entirely sheathing and lacking blades, glabrous:
7a Flowers uniformly red to orange red:
8a Flowers congested, funnel-shaped with spreading tepals; tepals oblong-elliptic, 7–9 mm wide; filaments 8–10 mm long, included in tube . . . . . 74. *G. nerineoides*
8b Flowers laxly spaced, tulip-shaped with cupped tepals; tepals obovate to suborbicular, 22–28 mm wide; filaments ± 20 mm long, exserted ± 10 mm from tube . . . . . 75. *G. stokoei*
7b Flowers pink, mauve, white or cream-coloured to yellow, or mottled brown:
9a Perianth tube 11–13 mm long, obliquely funnel-shaped . . . . . 72. *G. brevifolius*
9a Perianth tube 22–45 mm long, cylindric and expanded only near apex:
10a Flowers cream-coloured to pale pink or pale apricot, lower tepals with red to yellow median streak, unscented; perianth tube 22–30 mm long; plants from Cape Peninsula . . . . . 73. *G. monticola*
10b Flowers mottled brownish or plain yellow, strongly scented; perianth tube 32–45 mm long; plants from Riviersonderend to Mossel Bay . . . . . 68. *G. emiliae*
6b Leaves with well-developed blades, the lowermost at least as long as the sheath, scabridulous or pubescent:
11a Flowers yellow to orange or scarlet; perianth tube longer than bracts, slender below and abruptly expanded above into flared or broadly cylindric upper part:
12a Flowers bright yellow; upper part of perianth tube flared; filaments 9–12 mm long . . . . . 71. *G. aureus*
12b Flowers orange to scarlet, rarely yellow; upper part of perianth tube subcylindric; filaments 28–32 mm long:
13a Leaves pubescent; tepals subequal, broadly obovate to suborbicular; plants from Cape Peninsula . . . . . 70. *G. merianellus*
13b Leaves scabridulous; tepals unequal, lower three smaller and elliptic; plants from Overberg . . . 69. *G. overbergensis*
11b Flowers pink, cream-coloured, purple or dull red to brownish; upper part of perianth tube gradually expanded and flared toward mouth:
14a Perianth tube cylindric for most of its length and expanded only in upper ⅕; tepals lanceolate, acute, not crisped or undulate . . . . . 66. *G. rhodanthus*
14b Perianth tube obliquely funnel-shaped and expanded only in upper ⅓–½; tepals ovate, obtuse, margins crisped or undulate:
15a Flowers brownish purple or dull pink to dull reddish brown, the lower tepals yellowish or ochre and mottled with brown; flowering April to July . . . . . 67. *G. guthriei*
15b Flowers cream-coloured to pink or purple, the lower tepals streaked with dark red or purple; flowering mainly July to October:
16a Perianth 34–58(–75) mm long; dorsal tepal 19–27(–35) mm long; flowers unscented or lightly sweet-scented; leaf margins and midrib lightly or rarely moderately thickened . . . . . 64. *G. hirsutus*
16b Perianth (67–)75–85 mm long; dorsal tepal 37–45 mm long; flowers usually strongly clove-scented; leaf margins and midrib strongly thickened . . . . . 65. *G. caryophyllaceus*

5. Sect. *Heterocolon*

1a Leaves hairy:
2a Leaf blades cross-shaped in section; flowers pale bluish, 33–40 mm long . . . . . 83. *G. marlothii*
2b Leaf blades plane; flowers pink with lower tepals marked pale green, ± 30 mm long . . . . . 84. *G. mostertiae*
1b Leaves smooth:
3a Leaf blades lanceolate, relatively short, plane with margins and midrib moderately thickened but blades never with two narrow grooves on each surface . . . . . 76. *G. oatesii*
3b Leaf blades linear, relatively long, margins and midrib heavily thickened, thus with two narrow grooves on each surface:
4a Floral bracts rusty brown on margins; flowers cream-coloured densely speckled with red; flowering mainly March and April . . . . . 80. *G. rufomarginatus*
4b Floral bracts and flowers not as above:
5a Lower tepals spathulate:
6a Leaves dry and withered at flowering; flowers pink; flowering July and August; plants from KwaZulu-Natal to Limpopo . . . . . 81. *G. vernus*
6b Leaves green at flowering; flowers pale greyish blue; flowering October; plants from Kamiesberg in Namaqualand . . . . . 82. *G. kamiesbergensis*
5b Lower tepals oblanceolate:
7a Flowers orange-red with conspicuous yellow transverse band on lower tepals; leaves linear with two grooves on each surface . . . . . 77. *G. rubellus*
7b Flowers pink to mauve; leaves terete to subterete with four narrow grooves:
8a Perianth tube 11–14 mm long . . . . . 78. *G. pretoriensis*
8b Perianth tube 25–40 mm long . . . . . 79. *G. filiformis*

6. Sect. *Hebea*

1a Flowers strongly zygomorphic with upper lateral and lower median tepals cordate at base and shortly stalked; filaments long and strongly arched, rarely shorter but then pilose; sutures between tepals raised into iridescent, papillate ridges ('*kalkoentjies*'):
2a Flowers orange to scarlet or salmon-pink; stems angled or winged; floral bracts sharply folded or keeled along midline:
3a Basal leaf plane, broadly lanceolate, 20–40 mm wide, margins thickened and often reddish, lower leaves often obtuse and apiculate. . . . . 113. *G. equitans*
3b Basal leaf plane or ridged, ± 2–12 mm wide, margins not or lightly thickened and never reddish, lower leaves acute or attenuate:
4a Leaf blades plane, midrib and other veins barely evident and not raised; stamens and style sparsely pilose or glabrous distally:
5a Dorsal tepal strongly hooded and concave; upper lateral tepals weakly spreading distally, limbs virtually sessile, often with large yellow blotch on reverse; stamens and style glabrous distally . . . . . 114. *G. speciosus*
5b Dorsal tepal inclined or suberect, ± plane; upper lateral tepals spreading with claws 3–4 mm long, uniformly salmon-orange on reverse; stamens and style sparsely pilose . . . . . 115. *G. pulcherrimus*
4b Leaf blades ribbed, midrib and sometimes other veins thickened and raised; stamens and style sparsely pilose:
6a Flowers orange to scarlet, lower tepals predominantly yellowish green with orange tips; filaments 20–26 mm long . . . . . 116. *G. alatus*
6b Flowers salmon-pink to brick-red, lower lateral tepals with small yellow mark edged reddish black distally; filaments ± 15 mm long . . . . . 117. *G. meliusculus*
2b Flowers green or grey to purple or brownish or pale yellow, rarely pale pink but then strongly veined with dark colour; stems terete; floral bracts not folded or keeled:
7a Leaf blades plane, midrib and other veins barely evident and not raised:
8a Dorsal tepal arched in a semi-circle over stamens, margins not recurved; leaves (4)5 to 8(10); corm producing small cormlets at base . . . . . 108. *G. orchidiflorus*
8b Dorsal tepal erect, margins recurved; leaves 3; corm producing long stolons terminating in a large cormlet . . . . . 112. *G. uysiae*
7b Leaf blades ribbed or terete, midrib and sometimes other veins thickened and raised:
9a Dorsal tepal boat-shaped and horizontal thus concealing stamens, partly translucent; leaf blades with several equal ribs, thus corrugate . . . . . 109. *G. watermeyeri*
9b Dorsal tepal erect to slightly inclined exposing stamens, not partly translucent; leaf blades with midrib more prominent than veins, thus not corrugate:
10a Leaves not completely imbricate, exposing the stem below the uppermost leaf, sometimes only very slightly; corm tunics pale and soft, almost membranous; plants from Breede River Valley to Long Kloof 110. *G. virescens*
10b Leaves imbricate and completely sheathing lower part of stem; corm tunics dark and firm-textured, almost woody; plants from Knersvlakte, Cold Bokkeveld and Roggeveld . . . . . 111. *G. ceresianus*
1b Flowers actinomorphic or weakly to strongly zygomorphic but upper lateral and lower median tepals not or obscurely cordate and stalked; filaments short to long, horizontal, ascending or strongly arched but always glabrous; sutures between tepals never raised into papillate ridges:
11a Flowers red to carmine, the lower tepals sometimes much reduced and marked with yellow or green:
12a Dorsal and upper lateral tepals subequal in size and lanceolate; upper part of perianth tube above stamen insertion 20–23 mm long . . . . . 88. *G. vandermerwei*
12b Dorsal tepal ± twice or more as long as upper laterals, spathulate; upper part of perianth tube above stamen insertion 2–10 mm long:
13a Upper part of perianth tube forming a short spur; upper lateral tepals reduced, scale-like, 2–5 mm long. . . . . 91. *G. saccatus*
13b Upper part of perianth tube not spurred; upper lateral tepals ovate and flexed upward, ear-like, 10–17 mm long:
14a Lower tepals subequal, scale-like, 1–4 mm long; spike inclined to nearly horizontal; plants from southwestern coast. . . . . 89. *G. cunonius*
14b Lower median tepal much larger than lower laterals and flexed sharply downward, boat-shaped, 8–11 mm long; spike stiffly erect; plants from Bokkeveld and Roggeveld . . . . . 90. *G. splendens*
11b Flowers variously coloured but never red to carmine:
15a Corm tunics hard, woody and somewhat gnarled, rarely membranous but then leaf sheaths hairy:
16a Upper cataphyll purple mottled with white:
17a Perianth strongly zygomorphic, greenish to brownish purple with yellow markings on lower tepals; flowering May to July . . . . . 102. *G. viridiflorus*
17b Perianth ± actinomorphic, blue with dark blue and white markings; flowering (July) August to September . . . . . 103. *G. deserticola*
16a Upper cataphyll not mottled:
18a Corm tunics softly membranous, not accumulating; sheaths and blades of lower leaves shortly hairy; capsules ellipsoid, acute . . . . . 101. *G. arcuatus*
18b Corm tunics hard, woody and gnarled, accumulating; leaves glabrous; capsules ovoid to subglobose, 3-lobed above and retuse:
19a Flowers yellowish to greenish or purple with basal half of lower tepals greenish yellow; lower tepals conspicuously narrowed below and flexed sharply downwards; perianth tube 12–17 mm long:

20a Lower tepals curved ± sharply downward at base of limb with upper margins of claws not or only weakly auriculate; perianth windowed in profile, with gap between upper lateral and dorsal tepals; plants north of Vanrhynsdorp–Calvinia axis ..... 104. *G. scullyi*
20b Lower tepals geniculately flexed downward at base of limb with upper margins of claws conspicuously auriculately lobed; perianth not windowed in profile, with upper lateral tepals suberect on either side of dorsal tepals; plants south of Vanrhynsdorp–Calvinia axis ..... 105. *G. venustus*
19b Flowers cream-coloured to pale pink with red and yellow chevron-shaped markings on lower tepals; lower tepals not conspicuously narrowed below; perianth tube 18–40 mm long:
21a Perianth tube narrowly funnel-shaped, 18–22 mm long; filaments ± 25 mm long ..... 106. *G. salteri*
21b Perianth tube cylindric, 35–40 mm long; filaments ± 8 mm long ..... 107. *G. lapeirousioides*
15b Corm tunics leathery, fibrous or papery to membranous:
22a Lower lateral tepals much shorter than median; upper lateral tepals flexed upward to overlap dorsal tepal on either side:
23a Leaves narrowly lanceolate, 4–8 mm wide, soft-textured; flowers lilac with purple feathering on lower tepals; perianth tube ± 5 mm long; plants from KwaZulu-Natal Drakensberg ..... 86. *G. loteniensis*
23b Leaves linear, 2–3 mm wide, firm-textured; flower white to pale yellow, lower tepals not feathered; perianth tube 16–50 mm long; plants from Western and Eastern Cape:
24a Perianth tube 45–50 mm long; upper three tepals subequal, 25–35 mm long; lower lateral tepals with red median streak ..... 85. *G. leptosiphon*
24b Perianth tube 16–18 mm long; dorsal tepal much shorter than upper laterals, 25–35 mm long; lower lateral tepals greenish yellow in lower half ..... 87. *G. involutus*
22b Lower lateral tepals ± as long as median or only slightly shorter; perianth often windowed in profile with gap between upper lateral and dorsal tepals; leaves always linear, 1–2 mm wide or terete to oval in section:
25a Flowers actinomorphic and unmarked, the perianth stellate with symmetrically disposed stamens ..... 97. *G. stellatus*
25b Flowers zygomorphic with lower tepals usually marked, the perianth bilabiate with arcuate stamens:
26a Perianth tube at least 1.5 times as long as dorsal tepal, 28–44 mm long; flowers white with ovate, acute tepals ..... 100. *G. robertsoniae*
26b Perianth tube less than 1.5 times as long as dorsal tepal; flowers variously coloured, often with lanceolate, attenuate tepals:
27a Tepals subequal, all recurved; perianth tube 16–30 mm long; filaments 6–10 mm long, included in tube or shortly exserted up to 2 mm; flowers greenish yellow, often flushed brown to purple on reverse, lower tepals unmarked ..... 96. *G. acuminatus*
27b Not as above:
28a Perianth not windowed in profile, not gaping between base of upper lateral and dorsal tepals; flowers usually unscented:
29a Leaves linear, green and evident at flowering ..... 98. *G. wilsonii*
29b Leaves terete or oval in section, dry and dead at flowering or those of new season emergent ..... 99. *G. inandensis*
28b Perianth windowed in profile, tepals ± clawed thus with a gap between base of upper lateral and dorsal tepals; flowers often scented:
30a Perianth tube shorter than dorsal tepal, 9–15 mm long:
31a Flowers whitish to dull grey, purple or brownish yellow; lower lateral tepals channelled and clawed below but not lobed ..... 92. *G. permeabilis*
31b Flowers bright yellow; lower lateral tepals with basal half of blade involute-tubular and auriculately lobed ..... 95. *G. karooicus*
30b Perianth tube longer than dorsal tepal, 22–35 mm long:
32a Perianth tube obliquely funnel-shaped; filaments ± 15 mm long; tepals acute; plants from Eastern Cape ..... 93. *G. uitenhagensis*
32b Perianth tube cylindric; filaments 11–12 mm long; tepals with ribbon-like apices; plants from Limpopo ..... 94. *G. sekukuniensis*

7. Sect. *Homoglossum*

1a Plants with only 3 leaves (including partly to entirely sheathing cauline leaves), lowermost longest with well-developed blade terete or cross-shaped in section or at least with midrib and margins heavily thickened; corm tunics often cartilaginous or woody, splitting from the base into claw-like sections:
2a Floral bracts 14–30 mm long, or if longer then perianth tube less than 25 mm long; perianth tube usually shorter than bracts but if longer then flowers pink with reddish markings on lower tepals:
3a Perianth almost actinomorphic with subequal tepals or only weakly zygomorphic and then white or yellow; markings confined to base of tepals:
4a Flowers white to yellow flushed dull purplish on reverse, sometimes with dark markings in throat, often scented; perianth tube 16–20 mm long; plants from seasonally wet habitats in Western Cape ..... 154. *G. trichonemifolius*
4b Flowers pink to mauve; perianth tube 8–12 mm long; plants from KwaZulu-Natal Drakensberg ..... 163. *G. symonsii*
3b Perianth zygomorphic and white to pink or purple; lower tepals marked near middle:

5a Lower lateral tepals with transverse yellow band or chevron outlined with purple; perianth tube strongly geniculate, up to half as long as dorsal tepal; corm tunics forming fibrous neck around base of stem . . . . . 150. *G. patersoniae*

5b Lower lateral tepals with median streak or diamond-shaped marking in red or yellow outlined with red; perianth tube usually curved, half as long as dorsal tepal or longer; corm tunics not forming fibrous neck around base of stem:

6a Flowers pale pink to whitish with red median streak on lower tepals; anthers purple; plants from Swartberg . . . . . 148. *G. nigromontanus*

6b Flowers purple or mauve to pink or whitish with diamond- or chevron-shaped markings on lower tepals; anthers grey to purple; plants from Cederberg to Langeberg:

7a Perianth tube 12–18(–30) mm long; flowers bell–trumpet-shaped with dorsal tepal ascending to hooded; filaments 12–18 mm long; flowering September to November, rarely into December . . . . . 146. *G. inflatus*

7b Perianth tube (25–)35–52 mm long; flowers salver-shaped with tepals spreading ± at right angles to tube; filaments 7–8 mm long; flowering December to January . . . . . 147. *G. cylindraceus*

2a Floral bracts (25–)30–80(–115) mm long; perianth tube at least 25 mm long, often as long as the bracts or longer:

8a Flowers white, cream-coloured, mauve, brown to dull purple or dull reddish orange, often scented in evening; perianth tube widening gradually from base to apex; filaments included in perianth tube or shortly exserted up to 5 mm:

9a Flowers mainly brown, dull purplish green or reddish orange; leaf blade oval in section with midrib and margins thickened, with 2 grooves on each surface:

10a Bracts short and not normally attenuate, 36–50 mm long; tepals obtuse to acute, upper 22–30 mm long; perianth tube 25–36 mm long; flowers not changing colour at night . . . . . 158. *G. hyalinus*

10b Bracts long and attenuate, 55–115 mm long; tepals attenuate, (31–)40–45 mm long; perianth tube 40–53 mm long; flowers changing colour at night . . . . . 159. *G. liliaceus*

9b Flowers white to cream-coloured or pale mauve, sometimes streaked or spotted with brown; leaves centric, terete or cross-shaped in section with 4 grooves or furrows:

11a Flowers pale mauve or opalescent, each lasting 1 day; bracts 22–25 mm long; plants from southern Namibia . . . . . 161. *G. diluvialis*

11b Flowers white to pale yellow, sometimes mottled brown, each lasting several days; bracts (25–)40–110 mm long; plants from South Africa:

12a Perianth tube up to 1.5 times as long as bracts; filaments (15–)18–25 mm long; plants from Bokkeveld Mtns to Port Elizabeth . . . . . 160. *G. tristis*

12b Perianth tube 1.3–3.0 times as long as bracts; filaments 5–13 mm long; plants from Swartberg to Limpopo . . . . . 162. *G. longicollis*

8b Flowers red to deep orange, the tepals sometimes marked with yellow or green, unscented; perianth tube narrow below stamen insertion, widening abruptly into a long, cylindric, horizontal upper portion; filaments exserted 4–15 mm from perianth tube:

13a Upper lateral tepals ±as long as to slightly longer than dorsal; leaf blades oblong to oval in section with midrib and margins thickened, with 2 grooves on each surface; corm tunics hard and ± woody, splitting below into claw-like segments:

14a Upper and lower lateral tepals lanceolate, more than twice as long as wide; lower leaf blade linear, oblong in section, (1.5–)3.0–5.0 mm wide; plants west of Hottentots Holland–Worcester axis . . . . 164. *G. watsonius*

14b Upper and lower lateral tepals ovate, up to twice as long as wide; lower leaf blade subterete, oval in section, 1–2 mm wide; plants east of Hottentots Holland–Worcester axis . . . . . 165. *G. teretifolius*

13b Upper lateral tepals half as long to slightly shorter than dorsal; leaves centric, terete or cross-shaped in section with 4 grooves or furrows; corm tunics cartilaginous to papery, splitting below into fibres:

15a Tepals lanceolate, upper laterals more than twice as long as wide; lower tepals uniformly red or orange; plants from Cold and Warm Bokkeveld . . . . . 166. *G. quadrangularis*

15b Tepals ovate to elliptic, upper laterals less than twice as long as wide; lower tepals with yellow to greenish markings; plants from Bot River to Grahamstown:

16a Dorsal tepal horizontal, boat-shaped, two to three times as long as upper laterals; lower tepals mostly dark green to reddish black, median shorter than laterals, 3–6 mm long . . . . . 169. *G. abbreviatus*

16b Dorsal tepal erect to inclined, less than 1.5 times as long as upper laterals; lower tepals mostly yellow, median as long as or slightly longer than laterals, 9–22 mm long:

17a Flowers larger, dorsal tepal 25–40 mm long; filaments 32–45 mm long; flowers mostly orange, upper part of tube with dark red longitudinal lines below sinuses on each sides of upper lateral tepals . . . . . 167. *G. huttonii*

17b Flowers smaller, dorsal tepal 15–20 mm long; filaments 26–32 mm long; flowers dull reddish or greenish, upper tepals veined with red to grey, and tube without longitudinal lines . . . . . 168. *G. fourcadei*

1b Plants with 2 to many leaves, if only 3 leaves then blade of the lowermost vestigial (much shorter than the sheathing part or lacking) or the blade with midrib and margins not or only lightly thickened; corm tunics various, woody or fibrous to papery or membranous:

18a Leaf sheaths and sometimes blades hairy:

19a Leaf blades centric and cross-shaped in section; flowers greenish to pale yellow without conspicuous dark markings on lower tepals . . . . . 155. *G. sufflavus*

19b Leaf blades linear with 1 or 2 raised veins, margins not thickened; flowers yellow with transverse brown to reddish markings on lower tepals . . . . . 156. *G. pritzelii*

18b Leaf sheaths and blades glabrous or scabridulous:

20a Leaf blades vestigial, lacking or less than 10 mm long:
21a Perianth tube cylindric, (22–)30–60 mm long. . . . . 149. *G. engysiphon*
21b Perianth tube funnel-shaped, 6–20 mm long:
22a Leaves 2, lowermost sheathing lower ⅔ of stem . . . . . 127. *G. vaginatus*
22b Leaves 2 to 4, all rather short:
23a Corm tunics fibrous; flowers blue, without a strong scent; leaves of non-flowering plants hairy . . . . . 151. *G. subcaeruleus*
23b Corm tunics softly membranous, not accumulating; flowers cream-coloured or pink to lilac, usually strongly scented; leaves on non-flowering plants glabrous:
24a Flowers mauve or pink; lower lateral tepals joined to upper laterals for 2–5 mm; flowering February to May; leaves of non-flowering plants 1(2) . . . . . 152. *G. martleyi*
24b Flowers cream-coloured, pale yellow or pale lilac; lower lateral tepals not joined to upper laterals; flowering November to January; leaves of non-flowering plants 2 or 3 . . . . . 153. *G. jonquilliodorus*
20b Leaf blades usually well-developed or short but always present:
25a Leaves linear, smooth and fleshy, midrib and margins not thickened:
26a Perianth tube shorter than bracts, 11–17 mm long; flowers pale blue or mauve to brown; filaments 10–15 mm long:
27a Leaves 4; tepals acute to obtuse; plants from Albertinia to Grahamstown . . . . . 125. *G. mutabilis*
27b Leaves 3; tepals acute to acuminate; plants from Ceres to Wellington . . . . . 126. *G. exilis*
26b Perianth tube slightly shorter than bracts to twice as long, 23–48 mm long; flowers red, pink, brownish or cream-coloured to yellow:
28a Perianth tube slender below, abruptly expanded at filament insertion into a cylindric upper part; flowers cream-coloured, pink or red, unscented; filaments 25–40 mm long:
29a Leaves 3; tepals ovate, laterals 15–17 mm wide; flowers yellow or pale to deep pink, not yellow in throat but lower tepals often darkly speckled basally. . . . . 130. *G. meridionalis*
29b Leaves (3)4; tepals lanceolate, laterals 10–12 mm wide; flowers red with yellow throat . . . . . 131. *G. priorii*
28b Perianth tube gradually expanding from base to apex; flowers cream-coloured to yellowish or brown to dull lilac or purple, scented; filaments 12–16 mm long:
30a Flowers dull yellow to lilac conspicuously mottled with brown to purple; perianth tube 23–37(–48) mm long, not or barely exserted from bracts. . . . . 128. *G. maculatus*
30b Flowers cream-coloured or white; perianth tube 37–65 mm long, well exserted from bracts . . . . . 129. *G. albens*
25b Leaves with midrib or margins thickened and raised:
31a Lower leaf blade H-shaped in section, with margins raised into wings of flanges extended at right angles to blade:
32a Perianth tube slightly shorter than to longer than bracts, 27–36 mm long; tepals attenuate and recurved, mostly pearl-grey to yellowish. . . . . 145. *G. recurvus*
32b Perianth tube shorter than bracts, 12–18 mm long; tepals ± acute, mostly blue (sometimes pink or grey to yellowish brown):
33a Leaves firm and narrow with marginal flanges arching over and almost concealing blade; lower tepals acute and streaked; flowers 2 to 7 per spike; mainly clay and granite soils in southwestern Western Cape . . . . . 143. *G. gracilis*
33b Leaves soft and broad with marginal flanges at right angles to blade; lower tepals obtuse and spotted; flowers (4)8 to 14 per spike; plants form West Coast limestone . . . . . 144. *G. caeruleus*
31b Lower leaf blade with margins weakly to strongly thickened but not raised into wings or flanges, or leaves reduced and clasping:
34a Upper cataphyll purple mottled with white:
35a Perianth actinomorphic and stellate, with subequal and spreading tepals. . . . . 124. *G. quadrangulus*
35b Perianth zygomorphic and bilabiate, with arched dorsal tepal and smaller lower tepals:
36a Flowers inflated and bell-like with sharply bent tube, lower tepals with transverse or median white or yellow mark; leaves (3)4; corm tunics firm-textured to almost woody, splitting into narrow strips below . . . . . 133. *G. rogersii*
36b Flowers funnel-shaped with curved tube, lower tepals pale yellow lightly streaked with lines or dots; leaves 3(4); corm tunics soft-textured and irregularly fragmented or somewhat fibrous:
37a Flowers larger, 37–54 mm long; perianth tube 13–16 mm long; flowering mainly late July to September. . . . . 122. *G. carinatus*
37b Flowers smaller, 22–36 mm long; perianth tube 6–10 mm long; flowering May to July . . . . . 123. *G. griseus*
34b Upper cataphyll uniformly coloured:
38a Flowers white to pink or pale blue-mauve with red to purple spots, streaks or diamond-shaped markings on lower tepals; leaves linear and usually with thickened margins:
39a Corm tunics membranous or papery to leathery, becoming fibrous with age:
40a Flowers whitish to pale pink, lower tepals feathered with deep red basally; perianth tube 36–44 mm long; corm tunics firm-papery to leathery, becoming fibrous; plants from Outeniqua Mtns . . . . . 121. *G. roseovenosus*
40b Flowers deep pink, lower tepals with pale median streak edged in darker pink; perianth tube 18–2 mm long; corm tunics soft-textured, membranous; plants from Cape Peninsula and nearby . . . . . 140. *G. ornatus*
39b Corm tunics woody, splitting below into claw-like segments:
41a Perianth tube 35–40 mm long, usually ± 1.5 times as long as bracts . . . . . 139. *G. vigilans*
41b Perianth tube 10–24 mm long, slightly shorter than to ± 1.5 times as long as bracts:

42a Leaves 3(4); floral bracts smooth, not ridged along veins; dorsal tepal 25–30 mm long; lower tepals with large red spots unevenly spread across basal half . . . . . 138. *G. variegatus*
42b Leaves 4; floral ridged along veins:
43a Filaments 4–10 mm long; dorsal tepal 17–27 mm long; flowers white (rarely pale pink) with red markings on lower tepals . . . . . .137. *G. debilis*
43b Filaments 12–16 mm long; dorsal tepal 28–44 mm long; flowers pale to deep pink or blue-mauve:
44a Perianth tube obliquely funnel-shaped, 13–24 mm long; lower tepals cream-coloured to pale yellow with dark longitudinal lines or spots . . . . . 135. *G. blommesteinii*
44b Perianth tube narrowly funnel-shaped to cylindric, 22–27 mm long; lower tepals with darker V-shaped markings . . . . . 136. *G. virgatus*
38b Flowers blue, yellow or orange to salmon or scarlet; leaves various:
45a Flowers yellow or orange to salmon or scarlet:
46a Perianth almost actinomorphic, orange; perianth tube 2.4–4.0 mm long . . . . . .132. *G. brevitubus*
46b Perianth zygomorphic and bilabiate, pale to bright yellow; perianth tube 8–14 mm long:
47a Flowers bright yellow; upper tepals lanceolate-attenuate; perianth tube 11–14 mm long; plants from Heerenlogement Mtn, flowering June and July . . . . . 120. *G. comptonii*
47b Flowers pale creamy yellow; upper tepals ovate; perianth tube ± 8 mm long; plants from Cederberg, flowering December and January . . . . . .157. *G. delpierrei*
45b Flowers blue to mauve:
48a Leaves 3:
49a Flowers irregularly mottled with purple, without transverse yellow or white markings on lower tepals; tepals lanceolate . . . . . 141. *G. inflexus*
49b Flowers veined with purple, with transverse yellow or white markings on lower tepals; tepals ovate . . . . . .142. *G. taubertianus*
48b Leaves 4 or 5:
50a Flowers obliquely funnel-shaped; tepals lanceolate-attenuate; perianth tube curved:
51a Leaf blade plane and identical on both surfaces; tepals violet and not darkly veined; plants from Riviersonderend Mtns . . . . . 118. *G. atropictus*
51b Leaf blade with midrib raised as a wing on one side, blade thus triangular in section; tepals pale blue with violet veins; plants from Gifberg to Cederberg . . . . . .119. *G. violaceolineatus*
50b Flowers inflated and bell-shaped; tepals lanceolate to ovate, obtuse to acute; perianth tube sharply bent:
52a Flowers usually 3 or more per spike; floral bracts smooth, not attenuate, 15–22 mm long . . . . . .133. *G. rogersii*
52b Flowers 1 or 2 per spike; floral bracts ridged and attenuate, mostly 30–50 mm long . . . . 134. *G. bullatus*

Regional Keys

A. Species from northern Namibia, Botswana, Eswatini and the northern provinces of South Africa (Northwest, Gauteng, Mpumalanga and Limpopo)

1a Upper lateral tepals much reduced, less than half as long as dorsal; flowers red:
2a Perianth tube 11–20 mm long, upper part shortly spurred; dorsal tepal spoon-shaped . . . . . 91. *G. saccatus*
2b Perianth tube 25–30 mm long, upper part cylindric; dorsal tepal oblanceolate and boat-shaped . . . . . .33. *G. magnificus*
1b Upper lateral tepals not reduced, slightly shorter to slightly longer than dorsal; flowers never red:
3a Leaf blades terete or oval in section and narrowly 4-grooved with midrib and margins strongly thickened:
4a Perianth tube cylindric, expanded only near apex, 25–150 mm long:
5a Flowers mauve to pink; perianth tube 25– 40 mm long; plants from near Zeerust . . . . . 79. *G. filiformis*
5b Flowers white to cream-coloured; perianth tube 100– 150 mm long; plants from Gauteng eastward . . . . 162. *G. longicollis*
4b Perianth tube obliquely funnel-shaped, 11–14 mm long:
6a Floral bracts rusty brown on margins; flowers cream-coloured densely speckled with red; flowering mainly March and April . . . . . .80. *G. rufomarginatus*
6b Floral bracts and flowers not as above:
7a Leaves dry and withered at flowering; lower tepals spathulate . . . . . 81. *G. vernus*
7b Leaves green at flowering; lower tepals oblanceolate:
8a Flowers orange-red with conspicuous yellow transverse band on lower tepals; leaves linear with two grooves on each surface . . . . . 77. *G. rubellus*
8b Flowers pink to mauve; leaves terete to subterete with four narrow grooves . . . . . 78. *G. pretoriensis*
3b Leaf blades plane with midrib and margins variously thickened:
9a Margins of inner bracts united below into a short tube enclosing ovary:
10a Perianth tube 33–35 mm long; lower tepals streaked with red and base of filaments dull red . . . . . 20. *G. reginae*
10b Perianth tube 10–27 mm long; lower tepals not streaked and filaments pale:
11a Leaves in a tight basal fan usually shorter than spike, with numerous fine parallel veins and without a prominent midrib; plants never hairy . . . . . .26. *G. elliotii*
11b Leaves in a lax fan usually arising some distance above ground with a pseudostem formed by the sheaths, narrow and usually exceeding the spike, always with a prominent midrib and sometimes also secondary veins; plants usually hairy:
12a Perianth tube 18–27 mm long; tepals elliptic-attenuate; bracts 26–30 mm long, attenuate . . . . *22. G. dolomiticus*

12b Perianth tube 10–16 mm long; tepals lanceolate-acute; bracts 15–30 mm long, ± acute:
13a Filaments 10–12 mm long; bracts ± two internodes long . . . . . 25. *G. sericeovillosus*
13b Filaments 18–20 mm long, reaching almost to tepal apices; bracts one to one and a half internodes long . . . . . 23. *G. pole-evansii*
9b Margins of inner bracts free to base:
14a Leaves superposed along stem with blades reduced or shorter than sheaths:
15a Plants robust, stem 3–4 mm diam. below base of spike; flowers 70–100 mm long, orange usually with reddish flecks; foliage leaves superposed along stem, blades variously developed . . . . . 31. *G. aurantiacus*
15b Plants not as above:
16a Cataphylls and leaves smooth:
17a Flowers small, 28–30 mm long, cream-coloured to mauve or purple; perianth tube 10–11 mm long . . . . . 76. *G. oatesii*
17a Flowers larger, 48–50 mm long, pink with white markings; perianth tube ± 20 mm long . . . 21. *G. brachyphyllus*
16a Upper cataphyll and sometimes leaf sheaths and blades distinctly hairy:
18a Leaves 2 or 3, uppermost bract- or scale-like; perianth subactinomorphic with subequal tepals; tepals lanceolate-attenuate, not clawed . . . . . 62. *G. pubiger*
18b Leaves (2)3 or 4; perianth obviously zygomorphic with lower tepals smaller; lower lateral tepals obviously clawed:
19a Flowers pale yellow; outer whorl of tepals constricted below into claws; lower tepals strongly auriculate at base of limb; vegetative plants with 3 leaves . . . . . 61. *G. pardalinus*
19b Not as above:
20a Flowers pale lilac to cream-coloured, yellow or maroon, the lower lateral tepals with dark purple median streak; flowers smaller, dorsal tepal 17–24(–27) mm long; foliage usually densely villous . . . . 59. *G. woodii*
20b Flowers pale mauve, the lower lateral tepals shading to purple basally; flowers larger, dorsal tepal 28–30 mm long; foliage sparsely hairy to nearly smooth . . . . . 60. *G. malvinus*
14b Leaves clustered at base of stem, with well-developed blades much longer than sheaths:
21a Anthers with locules drawn into sterile basal tails at least 1.5 mm long:
22a Perianth tube 40–45 mm long, at least one and a half times as long as dorsal tepal; tepals attenuate; flowers whitish to pale salmon-pink, lower tepals with median red streak . . . . . 13. *G. macneilii*
22b Perianth tube 15–32(–40) mm long, shorter than to ± as long as dorsal tepal; tepals ± obtuse; flowers white to pink without median streak on lower tepals:
23a Floral bracts 18–27 mm long; flowers white to pink; perianth tube 16–22 mm long. . . . . 11. *G. appendiculatus*
23a Floral bracts 35–55 mm long; flowers white with yellow throat; perianth tube 16–40 mm long . . . 12. *G. calcaratus*
21b Anthers without sterile basal tails:
24a Leaves linear, blades 2–4 mm wide, margins only lightly thickened:
25a Perianth not windowed in profile, not gaping between base of upper lateral and dorsal tepals; flowers with ovate, acute tepals and cylindric perianth tube 28–44 mm long . . . . . 100. *G. robertsoniae*
25b Perianth windowed in profile, tepals ± clawed thus with a gap between base of upper lateral and dorsal tepals; tepals lanceolate with attenuate, ribbon-like apices:
26a Perianth tube shorter than dorsal tepal, 9–15 mm long . . . . . 92. *G. permeabilis*
26b Perianth tube longer than dorsal tepal, 22–35 mm long . . . . . 94. *G. sekukuniensis*
24b Leaves narrowly lanceolate to lanceolate or rarely linear but margins always thickened, usually more than 5 mm wide:
27a Flowers pink to mauve, lower tepals with longitudinal reddish streaks; perianth tube 20–50 mm long:
28a Stem, rachis and bracts scabrid . . . . . 17. *G. scabridus*
28b Stem rachis and bracts smooth:
29a Leaves 3–9 mm wide, with prominently thickened midrib and margins, with fine, closely set veins between; dorsal tepal 26–32 mm long; bracts rusty brown above or entirely . . . . . 10. *G. varius*
29b Leaves broader, with prominent secondary veins between margins and midrib; dorsal tepal 35–48 mm long; bracts green throughout or dry above:
30a Bracts 50–70 mm long, green; perianth tube 40–50 mm long; dorsal tepal 40–48 mm long; lower tepals with prominent median red streak . . . . . 18. *G. cataractarum*
30b Bracts 38–48 mm long, rusty brown above; perianth tube 30–40 mm long; dorsal tepal 35–37 mm long; lower tepals with obscure median mark . . . . . 9. *G. saxatilis*
27b Flowers variously coloured but if pink then perianth tube less than 20 mm long:
31a Perianth tube 25–70 mm long; filaments 20–40 mm long:
32a Dorsal tepal 25–30 × 14–16 mm, ascending and not hooded over stamens; anthers 9–11 mm long . . . . . 30. *G. antholyzoides*
32b Dorsal tepal 35–50 × 22–30 mm, horizontal and hooded over stamens; anthers 12–16 mm long . . . . . 32. *G. dalenii*
31b Perianth tube 10–35 mm long; filaments usually 7–18 mm long, rarely up to 22 mm long but then flowers nodding and bell-shaped with perianth tube 18–20 mm long:
33a Floral bracts overlapping, 2 to 5 internodes long, somewhat inflated and folded on the midline, mostly 40–100 mm long; flowers often speckled or spotted over a pale ground, rarely pure white or pale mauve:
34a Leaves lanceolate, in a tight basal fan, rarely reaching base of spike; filaments 12–15 mm long . . . . . 27. *G. ecklonii*
34b Leaves linear-lanceolate, reaching at least to base of spike; filaments 7–12 mm long:

35a Flowers speckled or spotted with lilac to dark purple; anthers 10–13 mm long; style branches 3–4 mm long . . . . . 28. *G. vinosomaculatus*
35b Flowers uniformly white to pale mauve; anthers ±10 mm long; style branches 6–8 mm long . . . . . 29. *G. rehmannii*
33b Floral bracts not or shortly imbricate, up to two internodes long, hardly or not inflated or folded on the midline, mostly 20–40 mm long; flowers mostly uniformly coloured, rarely minutely speckled:
36a Flowers 40–55 mm long:
37a Perianth tube 18–30 mm long and ± as long as or slightly longer than dorsal tepal . . . . 4. *G. hollandii*
37b Perianth tube 10–20 mm long and ½ to ± ⅔ as long as dorsal tepal:
38a Bracts dry and rusty brown above; leaves mostly less than 10 mm wide, with thickened midrib and margins, and remaining veins fine and closely set . . . . . 8. *G. ferrugineus*
38b Bracts green; leaves with secondary veins conspicuous or inconspicuous but not closely set:
39a Flowers not nodding on a strongly inclined spike, flaring, pink with red streaks on lower tepals and red throat; filaments ± 16 mm long; plants usually of marshy sites . . . . . 19. *G. pavonia*
39b Flowers nodding on a strongly inclined spike, bell-shaped, cream-coloured to dull purple or greenish, usually with large dark blotch on lower tepals; filaments 20–22 mm long; plants usually of marshy sites . . . . . 2. *G. papilio*
36b Flowers 23–40 mm long:
40a Leaves with only midrib and margins thickened, sometimes strongly so, remaining veins fine and closely set:
41a Leaves several in a tight basal fan shorter than spike; upper stem and spike strongly inclined; filaments ± 15 mm long . . . . . 6. *G. exiguus*
41b Plants not as above:
42a Bracts green or flushed dull purple; spike usually with 20–45 flowers; filaments 10–12 mm long . . . . . 7. *G. densiflorus*
42b Bracts dry and rusty brown above or entirely; spike usually with 12–15 flowers; filaments 12–15 mm long . . . . . 8. *G. ferrugineus*
40b Leaves with midrib and margins thickened and at least one pair of secondary veins thickened, or secondary veins obscure and not closely set:
43a Floral bracts 12–16 mm long, narrow and attenuate, dry and twisted above at flowering; flowers pale pink, lower tepals usually with median yellow streak surrounded by broad pink blotch . . . . . 5. *G. serpenticola*
43b Floral bracts 17–40 mm long, acute to attenuate, green; flowers variously coloured, lower lateral tepals often with broad transverse blotch:
44a Flowers larger, dorsal tepal 20–25 mm long; filaments ± 14 mm long; plants mostly 40–50 mm high; leaves without conspicuous secondary veins; flowering October to November . . . . . 1. *G. paludosus*
44a Flowers smaller, dorsal tepal 18–22 mm long; filaments 12–14 mm long; plants mostly 50–120 mm high; leaves fibrous with conspicuous secondary veins; flowering mainly February to March . . . . . 3. *G. crassifolius*

B. Species from Lesotho, Eswatini and the southeastern South Africa (east of Port Elizabeth)

1a Leaf blades terete or oval in section and narrowly 4-grooved with midrib and margins strongly thickened:
2a Leaves several, dry and withered at flowering; lower tepals spathulate . . . . . 81. *G. vernus*
2b Leaves 3, upper 2 sheathing the stem, green at flowering:
3a Perianth almost actinomorphic with subequal tepals, pink to lilac; perianth tube less than 15 mm long . . . . . 163. *G. symonsii*
3b Perianth ± zygomorphic with lower tepals usually smaller than upper; perianth tube more than 40 mm long:
4a Flowers white to cream-coloured or yellow with brown markings, scented at night; perianth tube widening gradually from base; filaments less than 10 mm long . . . . . 162. *G. longicollis*
4b Flowers orange, unscented; perianth tube slender below widening abruptly into cylindrical upper part; filaments more than 20 mm long . . . . . 167. *G. huttonii*
1b Leaf blades plane with midrib and margins variously thickened or reduced and shorter than sheaths:
5a Leaves 2 to 4, superposed, with distinctly hairy sheaths and reduced blades shorter than sheaths or vestigial; perianth tube up to 1.5 times as long as bracts:
6a Leaves (2)3 or 4; perianth obviously zygomorphic with lower tepals smaller and lower lateral tepals obviously clawed . . . . . 59. *G. woodii*
6b Leaves 2 or 3, uppermost bract- or scale-like; perianth subactinomorphic with subequal tepals, elliptic to lanceolate, not clawed:
7a Flowers greenish or pale mauve with attenuate tepals 17–23 mm long; uppermost leaf bract-like and inserted some distance below first flower; stem rigid . . . . . 62. *G. pubiger*
7b Flowers pale pink with acute to obtuse tepals 12–17 mm long; uppermost leaf a small scale inserted just below first flower; stem wiry . . . . . 63. *G. parvulus*
5b Leaves and flowers not as above:
8a Flowers red to carmine with white markings on lower tepals:
9a Perianth sigmoid, flowers obliquely tulip-shaped with lower tepals forming a shallow bowl; tepals 30–42 mm long, thick and succulent in texture, lower tepals with median white streak . . . . . 34. *G. flanaganii*

9b Perianth ± straight or curved apically, flowers flaring with lower tepals straight or recurved; tepals 45–67 mm long, moderately thin and delicate, lower tepals white in lower half speckled with red:
10a Stems erect; leaves firm-textured, in an erect basal fan shorter than stem, drooping; tepals ± recurved distally; plants of the Drakensberg and Lesotho ..... 35. *G. saundersii*
10b Stems inclined or drooping; leaves soft-textured, as long as or longer than stem, drooping; tepals suberect or spreading; plants from coastal KwaZulu-Natal ..... 36. *G. cruentus*
8b Flowers never carmine to red, lower tepals variously coloured and marked:
11a Leaves 3 or 4, superposed or inserted serially up stem; blades without thickened midrib or margins, firm-textured, linear and rather short, up to 3 mm wide:
12a Perianth tube shorter than bracts, widely 11–17 mm long; flowers pale blue or mauve to brown; filaments 10–15 mm long ..... 125. *G. mutabilis*
12b Perianth tube slightly shorter than bracts to twice as long, 23–48 mm long; flowers brownish or cream-coloured to yellow:
13a Perianth tube slender below, abruptly expanded at filament insertion into a cylindric upper part; flowers cream-coloured, pink or red, unscented; filaments 25–40 mm long ..... 130. *G. meridionalis*
13b Perianth tube gradually expanding from base to apex; flowers cream-coloured to yellowish or brown to dull lilac or purple, scented; filaments 12–16 mm long:
14a Flowers dull yellow to lilac conspicuously mottled with brown to purple; perianth tube 23–37(–48) mm long, not or barely exserted from bracts ..... 128. *G. maculatus*
14b Flowers cream-coloured or white; perianth tube 37–65 mm long, well exserted from bracts ..... 129. *G. albens*
11b Leaves various but midrib and sometimes margins thickened:
15a Flowers uniformly pink to mauve, lower tepals with longitudinal reddish streaks; perianth tube 25–50 mm long:
16a Margins of inner bracts united below in a short tube around ovary ..... 24. *G. oppositiflorus*
16b Margins of inner bracts free to base:
17a Leaves and stems glabrous ..... 15. *G. mortonius*
17b Leaves and/or stems scabrid to puberulous:
18a Stem, rachis and bracts glabrous; dorsal tepal 35–40 mm long; plants drooping from cliffs ..... 16. *G. microcarpus*
18b Stem, rachis and bracts scabrid: dorsal tepal 40–45 mm long; plants erect on stony slopes and outcrops ..... 17. *G. scabridus*
15b Not as above, long-tubed species white or speckled but never pink:
19a Leaves linear or narrowly lanceolate, up to 10 mm wide, margins not thickened or raised (rarely lightly thickened but then tepals markedly attenuate):
20a Perianth tube 28–44 mm long, at least 1.5 times as long as dorsal tepal; dorsal tepal shorter than upper laterals ..... 100. *G. robertsoniae*
20b Perianth tube 9–28 mm long, less than 1.5 times as long as dorsal tepal; dorsal tepal shorter or longer than upper laterals:
21a Tepals equal or subequal, mauve; leaves subsucculent, without evident veins; strand plants growing above high-tide zone ..... 40. *G. gueinzii*
21b Tepals unequal, flowers ± zygomorphic; plants otherwise not as above:
22a Filaments strongly arched, 20–25 mm long; dorsal tepal narrowly oblanceolate ..... 108. *G. orchidiflorus*
22b Filaments ascending to slightly curved, 7–16 mm long; dorsal tepal oblanceolate to obovate:
23a Perianth windowed in profile, gaping between dorsal and upper lateral tepals; tepals ± clawed ..... 92. *G. permeabilis*
23b Perianth not windowed in profile, not gaping between dorsal and upper lateral tepals; tepals not clawed:
24a Lower lateral tepals much shorter than median; upper lateral tepals flexed upward to overlap dorsal on either side:
25a Leaves narrowly lanceolate, 4–8 mm wide, soft-textured; flowers lilac with purple feathering on lower tepals; dorsal tepal slightly longer than upper laterals; perianth tube ± 5 mm long; plants from KwaZulu-Natal Drakensberg ..... 86. *G. loteniensis*
25b Leaves linear, 2–3 mm wide, firm-textured; flowers white or flushed pink, lower lateral tepals greenish yellow in lower half; dorsal tepal much shorter than upper laterals; perianth tube 16–18 mm long; plants from Western and Eastern Cape ..... 87. *G. involutus*
24b Lower lateral tepals ± as long as median or only slightly shorter; upper lateral tepals not flexed upward to overlap dorsal on either side:
26a Leaves linear, green and evident at flowering ..... 98. *G. wilsonii*
26b Leaves terete or oval in section, dry and dead at flowering or those of new season emergent ..... 99. *G. inandensis*
19b Leaves narrowly lanceolate to lanceolate, more than 10 mm wide, margins thickened or raised:
27a Perianth tube 25–70 mm long; filaments 20–40 mm long:
28a Spike strongly inclined; flowers funnel-shaped, cream-coloured to greenish with dark median streak on tepals ..... 57. *G. floribundus*
28b Spike erect; flowers pale yellow, orange to red, or brownish green, lower tepals often yellowish below, without dark median streak:
29a Leaves superposed along stem, with blades shorter than to ± as long as sheaths ..... 31. *G. aurantiacus*
29b Leaves clustered at base of stem forming a 2-ranked fan, blades well-developed:
30a Dorsal tepal 25–30 × 14–16 mm, ascending and not hooded over stamens; anthers 9–11 mm long ..... 30. *G. antholyzoides*

30b Dorsal tepal 35–50 × 22–30 mm, horizontal and hooded over stamens; anthers 12–16 mm long . . . . . 32. *G. dalenii*
27b Perianth tube 10–35 mm long; filaments 10–18(–22) mm long:
31a Spike 2-ranked and erect; margins of inner bracts united below and tubular around ovary:
32a Leaves in a lax fan usually arising some distance above ground with a pseudostem formed by the sheaths, narrow and usually exceeding the spike, always with a prominent midrib and sometimes also secondary veins; plants usually hairy . . . . . 25. *G. sericeovillosus*
32b Leaves in a tight basal fan usually shorter than spike, with numerous fine parallel veins and without a prominent midrib; plants never hairy . . . . . 26. *G. elliotii*
31b Spike ± secund and inclined; margins of inner bracts free to base:
33a Floral bracts imbricate, 2 to 3 internodes long, somewhat inflated and folded along midline, 40–80 mm long; flowers entirely dotted or blotched . . . . . 27. *G. ecklonii*
33b Floral bracts weakly imbricate, 1 to 2 internodes long, not or hardly inflated or folded along midline, 12–40 mm long; flowers unspotted or rarely minutely speckled:
34a Anther locules drawn into sterile basal tails or spurs 3–4 mm long . . . . . 11. *G. appendiculatus*
34b Anther locules acute or obtuse:
35a Flowers 40–55 mm long:
36a Leaves ± superposed and not forming a tight basal fan; flowers nodding on a sharply inflexed spike; filaments 20–22 mm long . . . . . 2. *G. papilio*
36b Leaves in a tight basal fan; flowers secund on a lightly inclined spike; filaments 10–12 mm long . . . . . 14. *G. ochroleucus*
35b Flowers 23–38(–40) mm long:
37a Leaves with midrib and margins plus one or more pairs of secondary veins thickened . 3. *G. crassifolius*
37b Leaves with only midrib and margins thickened, secondary veins fine and closely spaced . . . . . 7. *G. densiflorus*

C. Species from the winter and adjacent aseasonal rainfall regions of southwestern Namibia and South Africa (western parts of Northern Cape and Western Cape, and southwestern part of Eastern Cape west of Port Elizabeth)

1a Flowers strongly zygomorphic with upper lateral and lower median tepals cordate at base and shortly stalked; filaments long and strongly arched, rarely shorter but then pilose; sutures between tepals raised into iridescent, papillate ridges ('*kalkoentjies*'):
2a Flowers orange to scarlet or salmon-pink; stems angled or winged; floral bracts sharply folded or keeled along midline:
3a Basal leaf plane, broadly lanceolate, 20–40 mm wide, margins thickened and often reddish, lower leaves often obtuse and apiculate. . . . . 113. *G. equitans*
3b Basal leaf plane or ridged, ± 2–12 mm wide, margins not or lightly thickened and never reddish, lower leaves acute or attenuate:
4a Leaf blades plane, midrib and other veins barely evident and not raised; stamens and style sparsely pilose or glabrous distally:
5a Dorsal tepal strongly hooded and concave; upper lateral tepals weakly spreading distally, limbs virtually sessile, often with large yellow blotch on reverse; stamens and style glabrous distally . . . . . 114. *G. speciosus*
5b Dorsal tepal inclined or suberect, ± plane; upper lateral tepals spreading with claws 3–4 mm long;, uniformly salmon-orange on reverse; stamens and style sparsely pilose . . . . . 115. *G. pulcherrimus*
4b Leaf blades ribbed, midrib and sometimes other veins thickened and raised; stamens and style sparsely pilose:
6a Flowers orange to scarlet, lower tepals predominantly yellowish green with orange tips; filaments 20–26 mm long . . . . . 116. *G. alatus*
6b Flowers salmon-pink to brick-red, lower lateral tepals with small yellow mark edged reddish black distally; filaments ± 15 mm long . . . . . 117. *G. meliusculus*
2b Flowers green or grey to purple or brownish or pale yellow, rarely pale pink but then strongly veined with dark colour; stems terete; floral bracts not folded or keeled:
7a Leaf blades plane, midrib and other veins barely evident and not raised:
8a Dorsal tepal arched in a semi-circle over stamens, margins not recurved; leaves (4)5 to 8(10); corm producing small cormlets at base . . . . . 108. *G. orchidiflorus*
8b Dorsal tepal erect, margins recurved; leaves 3; corm producing long stolons terminating in a large cormlet . . . . . 112. *G. uysiae*
7b Leaf blades ribbed or terete, midrib and sometimes other veins thickened and raised:
9a Dorsal tepal boat-shaped and horizontal thus concealing stamens, partly translucent; leaf blades with several equal ribs, thus corrugate . . . . . 109. *G. watermeyeri*
9b Dorsal tepal erect to slightly inclined exposing stamens, not partly translucent; leaf blades with midrib more prominent than veins, thus not corrugate:
10a Leaves not completely imbricate, exposing the stem below the uppermost leaf, sometimes only very slightly; corm tunics pale and soft, almost membranous; plants from Breede River Valley to Long Kloof . . . . . 110. *G. virescens*
10b Leaves imbricate and completely sheathing lower part of stem; corm tunics dark and firm-textured, almost woody; plants from Knersvlakte, Cold Bokkeveld and Roggeveld . . . . . 111. *G. ceresianus*
1b Flowers actinomorphic or weakly to strongly zygomorphic but upper lateral and lower median tepals not or obscurely cordate and stalked; filaments short to long, horizontal, ascending or strongly arched but always glabrous; sutures between tepals never raised into papillate ridges:

11a Plants with only 3 leaves (including partly to entirely sheathing cauline leaves), lowermost longest and with well-developed blade, linear with main vein and margins strongly thickened or terete to cross-shaped in section; corm tunics coarsely fibrous or hard and woody, splitting below into segments:
12a Floral bracts 14–30 mm long, or if longer then perianth tube less than 25 mm long; perianth tube usually shorter than bracts but if longer then flowers pink with red markings on lower tepals:
13a Perianth actinomorphic or only weakly zygomorphic, white to yellow with purple on reverse and purple markings at base of tepals; flowers often scented; plants of seasonally marshy flats ..... 154. *G. trichonemifolius*
13b Perianth zygomorphic and white to pink or purple, with markings near middle of lower tepals:
14a Lower lateral tepals with transverse yellow band or chevron outlined with purple; perianth tube strongly geniculate, up to half as long as dorsal tepal; corm tunics forming fibrous neck around base of stem ..... 150. *G. patersoniae*
14b Lower lateral tepals with median streak or diamond-shaped marking in red or yellow outlined with red; perianth tube usually curved, half as long as dorsal tepal or longer; corm tunics not forming fibrous neck around base of stem:
15a Flowers pale pink to whitish with red median streak on lower tepals; anthers purple; plants of the Swartberg. ..... 148. *G. nigromontanus*
15b Flowers purple or mauve to pink or whitish with diamond- or chevron-shaped markings on lower tepals; anthers grey to purple; plants from Cederberg to Langeberg:
16a Perianth tube 12–18(–30) mm long; flowers bell–trumpet-shaped with dorsal tepal ascending to hooded; filaments 12–18 mm long; flowering September to November, rarely into December ..... 146. *G. inflatus*
16b Perianth tube (25–)35–52 mm long; flowers salver-shaped with tepals spreading ± at right angles to tube; filaments 7–8 mm long; flowering December to January ..... 147. *G. cylindraceus*
12b Floral bracts (25–)30–115 mm long; perianth tube at least 25 mm long and often ± as long as bracts or longer:
17a Flowers white, cream-coloured, mauve, brown to dull purple or dull reddish orange, often scented in evening; perianth tube widening gradually from base to apex; filaments included in perianth tube or shortly exserted up to 5 mm:
18a Flowers mainly brown, dull purplish green or reddish orange; leaf blade oval in section with midrib and margins thickened, with 2 grooves on each surface:
19a Bracts short and not normally attenuate, 36–50 mm long; tepals obtuse to acute, upper 22–30 mm long; perianth tube 25–36 mm long; flowers not changing colour at night ..... 158. *G. hyalinus*
19b Bracts long and attenuate, 55–115 mm long; tepals attenuate, (31–)40–45 mm long; perianth tube 40–53 mm long; flowers changing colour at night ..... 159. *G. liliaceus*
18b Flowers white to cream-coloured or pale mauve, sometimes streaked or spotted with brown; leaves centric, terete or cross-shaped in section with 4 grooves or furrows:
20a Flowers pale mauve or opalescent, each lasting 1 day; bracts 22–25 mm long; plants from southern Namibia ..... 161. *G. diluvialis*
20b Flowers white to pale yellow, sometimes mottled brown, each lasting several days; bracts (25–)40–110 mm long; plants from South Africa:
21a Perianth tube up to 1.5 times as long as bracts; filaments (15–)18–25 mm long; plants from Bokkeveld Mtns to Port Elizabeth. ..... 160. *G. tristis*
21b Perianth tube 1.3–3.0 times as long as bracts; filaments 5–13 mm long; plants from Swartberg to Limpopo. ..... 162. *G. longicollis*
17b Flowers red to deep orange, the tepals sometimes marked with yellow or green, unscented; perianth tube narrow below stamen insertion, widening abruptly into a long, cylindric, horizontal upper portion; filaments exserted 4–15 mm from perianth tube:
22a Upper lateral tepals ±as long as to slightly longer than dorsal; leaf blades oblong to oval in section with midrib and margins thickened, with 2 grooves on each surface; corm tunics hard and ± woody, splitting below into claw-like segments:
23a Upper and lower lateral tepals lanceolate, more than twice as long as wide; lower leaf blade linear, oblong in section, (1.5–)3.0–5.0 mm wide; plants west of Hottentots Holland–Worcester axis ..... 164. *G. watsonius*
23b Upper and lower lateral tepals ovate, up to twice as long as wide; lower leaf blade subterete, oval in section, 1–2 mm wide; plants east of Hottentots Holland–Worcester axis ..... 165. *G. teretifolius*
22b Upper lateral tepals half as long to slightly shorter than dorsal; leaves centric, terete or cross-shaped in section with 4 grooves or furrows; corm tunics cartilaginous to papery, splitting below into fibres:
24a Tepals lanceolate, upper laterals more than twice as long as wide; lower tepals uniformly red or orange; plants from Cold and Warm Bokkeveld ..... 166. *G. quadrangularis*
24b Tepals ovate to elliptic, upper laterals less than twice as long as wide; lower tepals with yellow to greenish markings; plants from Bot River to Grahamstown:
25a Dorsal tepal horizontal, boat-shaped, two to three times as long as upper laterals; lower tepals mostly dark green to reddish black, median shorter than laterals, 3–6 mm long ..... 169. *G. abbreviatus*
25b Dorsal tepal erect to inclined, less than 1.5 times as long as upper laterals; lower tepals mostly yellow, median as long as or slightly longer than laterals, 9–22 mm long:
26a Flowers larger, dorsal tepal 25–40 mm long; filaments 32–45 mm long; flowers mostly orange, upper part of tube with dark red longitudinal lines below sinuses on each side of upper lateral tepals ..... 167. *G. huttonii*
26b Flowers smaller, dorsal tepal 15–20 mm long; filaments 26–32 mm long; flowers dull reddish or greenish, upper tepals veined with red to grey, and tube without longitudinal lines ..... 168. *G. fourcadei*

11b Plants with 2 to several leaves, if only 3 then lowermost either bladeless or with vestigial blade shorter than sheath, or if blade well developed then with midrib and margins not or only lightly thickened; corm tunics various:
27a Upper cataphyll, usually leaf sheaths and sometimes blades distinctly pubescent; perianth tube up to 1.5 times as long as bracts; leaves 2 to 4, not in a basal fan:
28a Leaf blades glabrous; flowers yellow or greenish:
29a Leaf blades centric and cross-shaped in section; flowers greenish to pale yellow without conspicuous dark markings on lower tepals. . . . . 155. *G. sufflavus*
29b Leaf blades linear with 1 or 2 raised veins, margins not thickened; flowers yellow with transverse brown to reddish markings on lower tepals . . . . . .156. *G. pritzelii*
28b Leaf blades hairy; flowers variously coloured:
30a Lower tepals spathulate, clawed below and abruptly expanded into limbs:
31a Leaf blades cross-shaped in section; flowers pale bluish, 33–40 mm long . . . . . 83. *G. marlothii*
31b Leaf blades plane; flowers pink with lower tepals marked pale green, ± 30 mm long. . . . . 84. *G. mostertiae*
30b Lower tepals not obviously clawed below:
32a Flowers yellow to orange or scarlet; perianth tube longer than bracts, slender below and abruptly expanded above into flared or broadly cylindric upper part:
33a Flowers bright yellow; upper part of perianth tube flared; filaments 9–12 mm long . . . . . .71. *G. aureus*
33b Flowers orange to scarlet, rarely yellow; upper part of perianth tube subcylindric; filaments 28–32 mm long:
34a Leaves pubescent; tepals subequal, broadly obovate to suborbicular; plants of the Cape Peninsula. . . . . .70. *G. merianellus*
34b Leaves scabrid; tepals unequal, lower 3 smaller and elliptic; plants from Overberg . . . . . 69. *G. overbergensis*
32b Flowers pink, cream-coloured, purple or dull red to brownish; upper part of perianth tube gradually expanded and flared toward mouth:
35a Perianth tube cylindric for most of its length and expanded only in upper ⅕; tepals lanceolate, acute, not crisped or undulate . . . . . 66. *G. rhodanthus*
35b Perianth tube obliquely funnel-shaped and expanded only in upper ⅓–½; tepals ovate, obtuse, margins crisped or undulate:
36a Flowers brownish purple or dull pink to dull reddish brown, the lower tepals yellowish or ochre and mottled with brown; flowering April to July. . . . . 67. *G. guthriei*
36b Flowers cream-coloured to pink or purple, the lower tepals streaked with dark red or purple; flowering mainly July to October:
37a Perianth 34–58(–75) mm long; dorsal tepal 19–27(–35) mm long; flowers unscented or lightly sweet-scented; leaf margins and midrib lightly or rarely moderately thickened . . . . . 64. *G. hirsutus*
37b Perianth (67–)75–85 mm long; dorsal tepal 37–45 mm long; flowers usually strongly clove-scented; leaf margins and midrib strongly thickened . . . . . 65. *G. caryophyllaceus*
27b Cataphylls, leaf sheaths and blades hairless or at most puberulous or scabridulous; perianth tube long or short; leaves various:
38a Flowers carmine to red, lower tepals sometimes with white marks or sometimes much reduced and with yellow or green markings:
39a Lower tepals much reduced, less than half as long as dorsal and sometimes scale-like, marked with yellow or green:
40a Dorsal and upper lateral tepals subequal in size and lanceolate; upper part of perianth tube above stamen insertion 20–23 mm long . . . . . .88. *G. vandermerwei*
40b Dorsal tepal ± twice or more as long as upper laterals, spathulate; upper part of perianth tube above stamen insertion 2–10 mm long:
41a Upper part of perianth tube forming a short spur; upper lateral tepals reduced, scale-like, 2–5 mm long 91. *G. saccatus*
41b Upper part of perianth tube not spurred; upper lateral tepals ovate and flexed upward, ear-like, 10–17 mm long:
42a Lower tepals subequal, scale-like, 1–4 mm long; spike inclined to nearly horizontal; plants from south-western coast . . . . . 89. *G. cunonius*
42b Lower median tepal much larger than lower laterals and flexed sharply downward, boat-shaped, 8–11 mm long; spike stiffly erect; plants from Bokkeveld and Roggeveld . . . . . 90. *G. splendens*
39b Lower tepals ± half as long as or as long as dorsal tepal and similar in shape:
43a Perianth tube slender below abruptly expanded into a long, horizontal, cylindric upper part, sometimes yellow in mouth:
44a Leaves narrowly lanceolate to linear, scabridulous on veins with midrib raised; tepals unequal, ovate, lower 3 ± half as long as dorsal . . . . . 69. *G. overbergensis*
44b Leaves linear, smooth, midrib and margins not thickened; tepals subequal, lanceolate to ovate:
45a Leaves 3; tepals ovate, laterals 15–17 mm wide; flowers yellow or pale to deep pink, not yellow in throat but lower tepals often darkly speckled basally . . . . . 130. *G. meridionalis*
45b Leaves (3)4; tepals lanceolate, laterals 10–12 mm wide; flowers red with yellow throat . . . . . 131. *G. priorii*
43b Perianth tube gradually expanded from base to apex, never yellow in mouth:
46a Flowers unicoloured; tepals obtuse, 26–30 mm long; filaments 8–20 mm long:
47a Leaves with well-developed blades at flowering; plants from Piketberg. . . . . 50. *G. insolens*
47b Leaves entirely sheathing, without blades; plants from Hottentots Holland to Riviersonderend Mtns:
48a Flowers congested, funnel-shaped with spreading tepals; tepals oblong-elliptic, 7–9 mm wide; filaments 8–10 mm long, included in tube . . . . . 74. *G. nerineoides*

48b Flowers laxly spaced, tulip-shaped with cupped tepals; tepals obovate to suborbicular, 22–28 mm wide; filaments ± 20 mm long, exserted ± 10 mm from tube . . . . . 75. *G. stokoei*
46b Flowers with large white markings on lower tepals; tepals acute, 35–67 mm long; filaments 21–50 mm long:
49a Leaves on flowering stem with blades reduced or vestigial:
50a Flowers large, dorsal tepal 53–58 mm long and perianth tube 35–45 mm long; filaments 30–42 mm long, exserted 20–32 mm from tube; lower 3 tepals smaller than dorsal; anthers purplish or yellow with purple lines . . . . . 53. *G. stefaniae*
50b Flowers medium-sized, dorsal tepal 35–45 mm long and perianth tube 30–35 mm long; filaments 21–26 mm long, exserted 10–15 mm from tube; lower 3 tepals scarcely smaller than dorsal; anthers yellow . . . . . 54. *G. carmineus*
49b Leaves on flowering stem with well-developed blades:
51a Stems erect or inclined; corm vestigial, producing scaly stolons; plants from Outeniqua and Tsitsikamma Mtns, flowering mainly February to April . . . . . 52. *G. sempervirens*
51a Stems inclined to drooping; corm small but well-formed, without stolons; plants from Hex River to Franschhoek Mtns, flowering December to January. . . . . 51. *G. cardinalis*
38b Flowers never carmine to red, lower tepals variously marked:
52a Leaves 2 to 4(5), superposed and inserted serially up stem, not forming a fan at base of stem:
53a Lower leaf blade H-shaped in section, with margins raised into wings of flanges extended at right angles to blade:
54a Perianth tube slightly shorter than to longer than bracts, 27–36 mm long; tepals attenuate and recurved, mostly pearl-grey to yellowish . . . . . 145. *G. recurvus*
54b Perianth tube shorter than bracts, 12–18 mm long; tepals ± acute, mostly blue (sometimes pink or grey to yellowish brown):
55a Leaves firm and narrow with marginal flanges arching over and almost concealing blade; lower tepals acute and streaked; flowers 2 to 7 per spike; mainly clay and granite soils in southwestern Western Cape . . . . . 143. *G. gracilis*
55b Leaves soft and broad with marginal flanges at right angles to blade; lower tepals obtuse and spotted; flowers (4)8 to 14 per spike; plants from West Coast limestone. . . . . 144. *G. caeruleus*
53b Lower leaf blade with margins weakly to strongly thickened but not raised into wings or flanges, or leaves reduced and clasping:
56a Leaves linear, smooth and fleshy, midrib and margins not thickened:
57a Perianth tube shorter than bracts, 11–17 mm long; flowers pale blue or mauve to brown; filaments 10–15 mm long:
58a Leaves 4; tepals acute to obtuse; plants from Albertinia to Grahamstown . . . . . 125. *G. mutabilis*
58b Leaves 3; tepals acute to acuminate; plants from Ceres to Wellington. . . . . 126. *G. exilis*
57b Perianth tube slightly shorter than bracts to twice as long, 23–48 mm long; flowers pink, brownish or cream-coloured to yellow:
59a Perianth tube slender below, abruptly expanded at filament insertion into a cylindric upper part; flowers cream-coloured or pink, unscented; filaments 25–40 mm long . . . . . 130. *G. meridionalis*
59b Perianth tube gradually expanding from base to apex; flowers cream-coloured to yellowish or brown to dull lilac or purple, scented; filaments 12–16 mm long:
60a Flowers dull yellow to lilac conspicuously mottled with brown to purple; perianth tube 23–37 (–48) mm long, not or barely exserted from bracts. . . . . 128. *G. maculatus*
60b Flowers cream-coloured or white; perianth tube 37–65 mm long, well exserted from bracts 129. *G. albens*
56b Leaves centric with midrib or margins thickened and raised:
61a Leaves on flowering stem with vestigial blades, either barely developed or up to 25 mm long; plants flowering December to May:
62a Perianth tube cylindric, expanded only near apex, 22–45 mm long:
63a Flowers yellow mottled brownish or plain yellow, strongly scented; perianth tube sharply bent near apex. . . . . 68. *G. emiliae*
63b Flowers cream-coloured to pale pink, lilac or apricot, lower tepals with median red streak, unscented; perianth tube straight or slightly curved:
64a Lowermost leaf not basal; perianth tube 22–30 mm long; plants from Cape Peninsula . . . . 73. *G. monticola*
64b Lowermost leaf basal and sheathing for some distance; perianth tube (22–)30–60 mm long; plants from Langeberg foothills. . . . . 149. *G. engysiphon*
62b Perianth tube obliquely funnel-shaped, 6.5–17.0 mm long, or rarely up to 20 mm long but then leaves only 2:
65a Leaves 2, lowermost sheathing lower ⅔ of stem . . . . . 127. *G. vaginatus*
65b Leaves 2 to 4, all rather short:
66a Corm tunics fibrous; flowers usually not strongly scented; leaves of non-flowering plants hairy:
67a Flowers pink or greyish brown; leaf of non-flowering plants narrowly lanceolate; plants from West Coast to Overberg. . . . . 72. *G. brevifolius*
67b Flowers pale blue; leaf of non-flowering plants terete with 4 longitudinal grooves (lowest leaf on flowering stem sometimes with a very short blade of this type); plants from Overberg . . . . . 151. *G. subcaeruleus*
66b Corm tunics soft-textured, membranous and not accumulating; flowers usually strongly sweetly scented; leaves of non-flowering plants glabrous, terete and 4-grooved:

68a Flowers mauve or pink; lower lateral tepals joined to upper laterals for 2–5 mm; flowering February to May; leaves of non-flowering plants 1(2) . . . . . 152. *G. martleyi*
68b Flowers cream-coloured, pale yellow or pale lilac; lower lateral tepals not joined to upper laterals; flowering November to January; leaves of non-flowering plants 2 or 3 . . . . . 153. *G. jonquilliodorus*
61b Leaves on flowering stem with blade usually well-developed, sometimes short but always present:
69a Flowers white or cream-coloured to pale or deep pink, lower tepals with red median streak or spade-, diamond- or spear-shaped mark (rarely without markings); leaves with well-developed secondary veins. . . . . couplet 107
69b Flowers not as above; leaves without well-developed secondary veins:
70a Uppermost cataphyll purple mottled with white:
71a Flowers greenish or brownish with yellow markings on lower tepals; spike strongly inclined and flexuose with upper leaf diverging from stem; corm tunics tough and woody, clawed below; plants flowering May to July. . . . . 102. *G. viridiflorus*
71b Flowers blue, mauve, pink, yellow, cream-coloured or greenish grey; spike weakly inclined with upper leaf clasping stem; corm tunics fibrous, rarely woody and clawed but then flowers blue; flowering June to September:
72a Perianth actinomorphic or almost so, ± rotate; flowers unscented:
73a Flowers deep blue with darker blue and white markings on lower tepals; spike inclined and flexuose; plants from Richtersveld . . . . . 103. *G. deserticola*
73b Flowers mauve, without conspicuous markings; stem erect; corm tunics softly fibrous; plants from seasonally marshy flats on West Coast and Cape Flats near Cape Town. . . . . 124. *G. quadrangulus*
72b Perianth zygomorphic and bilabiate; flowers often scented:
74a Flowers inflated and bell-like with sharply bent tube, lower tepals with transverse or median white or yellow mark; leaves (3)4; corm tunics firm-textured to almost woody, splitting into narrow strips below. . . . . 133. *G. rogersii*
74b Flowers funnel-shaped with curved tube, lower tepals pale yellow lightly streaked with lines or dots; leaves 3(4); corm tunics soft-textured and irregularly fragmented or somewhat fibrous:
75a Flowers larger, 37–54 mm long; perianth tube 13–16 mm long; flowering mainly late July to September. . . . . 122. *G. carinatus*
75b Flowers smaller, 22–36 mm long; perianth tube 6–10 mm long; flowering May to July 123. *G. griseus*
70b Uppermost cataphyll unicoloured:
76a Flowers predominantly blue, lower tepals usually yellow toward base and with purple streaks:
77a Leaves terete or oval in section with midrib and margins strongly thickened; flowers pale blue with spathulate lower tepals; plants from Kamiesberg. . . . . 82. *G. kamiesbergensis*
77b Leaves ± plane with midrib and margins not or lightly thickened; flowers usually mid to deep blue; plants from Western Cape:
78a Leaves 3:
79a Flowers ± irregularly blotched with purple, lower tepals without transverse yellow to cream-coloured band; plants from Worcester to Bredasdorp. . . . . 141. *G. inflexus*
79b Flowers blue with darker veins, lower tepals with transverse yellow to cream-coloured band; plants from Cederberg. . . . . 142. *G. taubertianus*
78b Leaves 4:
80a Upper tepals narrowly elliptic-attenuate; lower tepals finely streaked and spotted with purple:
81a Leaf blade plane and identical on both surfaces; tepals violet and not darkly veined; plants from Riviersonderend Mtns . . . . . 118. *G. atropictus*
81b Leaf blade with midrib raised as a wing on one side, blade thus triangular in section; tepals pale blue with violet veins; plants from Gifberg to Cederberg . . . . . 119. *G. violaceolineatus*
80b Upper tepals ovate to lanceolate, obtuse to acute:
82a Flowers usually 3 or more per spike; floral bracts smooth, not attenuate, 15–22 mm long . . . . . 133. *G. rogersii*
82b Flowers 1 or 2 per spike; floral bracts ridged and attenuate, mostly 30–50 mm long 134. *G. bullatus*
76b Flowers white to pink, yellow or orange:
83a Corm tunics woody, splitting below into claw-like segments:
84a Perianth tube 35–40 mm long, usually ± 1.5 times as long as bracts. . . . . 139. *G. vigilans*
84b Perianth tube 10–24 mm long, slightly shorter than to ± 1.5 times as long as bracts:
85a Leaves 3(4); floral bracts smooth, not ridged along veins; dorsal tepal 25–30 mm long; lower tepals with large red spots unevenly spread across basal half. . . . . 138. *G. variegatus*
85b Leaves (3)4; floral bracts ridged along veins:
86a Filaments 4–10 mm long; dorsal tepal 17–27 mm long; flowers white (rarely pale pink) with red markings on lower tepals . . . . . 137. *G. debilis*
86b Filaments 12–16 mm long; dorsal tepal 28–44 mm long; flowers pale to deep pink or blue-mauve:
87a Perianth tube obliquely funnel-shaped, 13–24 mm long; lower tepals cream-coloured to pale yellow with dark longitudinal lines or spots . . . . . 135. *G. blommesteinii*
87b Perianth tube narrowly funnel-shaped to cylindric, 22–27 mm long; lower tepals with darker V-shaped markings . . . . . 136. *G. virgatus*
83b Corm tunics leathery to fibrous or membranous:
88a Perianth ± actinomorphic, rotate, orange or salmon- to brick-red; perianth tube up to 4 mm long . . . . . 132. *G. brevitubus*

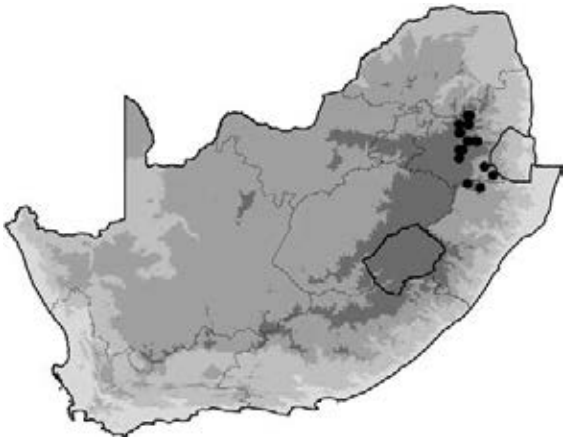
88b Perianth zygomorphic, bilabiate, never orange to red; perianth tube at least 8 mm long:
89a Flowers pale creamy yellow to bright yellow:
90a Flowers bright yellow; upper tepals lanceolate-attenuate; perianth tube 11–14 mm long; plants from Heerenlogement Mtn, flowering June and July . . . . . 120. *G. comptonii*
90b Flowers pale creamy yellow; upper tepals ovate; perianth tube ± 8 mm long; plants from Cederberg, flowering December and January . . . . . 157. *G. delpierrei*
89b Flowers pale to deep pink:
91a Lower tepals with lozenge-shaped pale median mark outlined with red; corm tunics softly membranous, not accumulating:
92a Leaf blades with margins not or lightly thickened; perianth tube ± 35 mm long. . . . . 42. *G. pappei*
92b Leaf blades with margins moderately to strongly thickened; perianth tube 18–20 mm long. . . . . 140. *G. ornatus*
91b Lower tepals blotched or streaked; corm tunics leathery to firm-papery, becoming fibrous and accumulating:
93a Flowers mottled with brown and yellow, strongly clove-scented; perianth tube 20–27 mm long; plants from Bokkeveld to Potberg. . . . . 67. *G. guthriei*
93b Flowers pale pink, lower tepals feathered with red below, unscented; perianth tube 36–44 mm long; plants from Outeniqua Mtns near Mossel Bay . . . . . 121. *G. roseovenosus*

52b Leaves 4 or more, at least lower 3 basal, either lanceolate and forming a fan, or linear and overlapping only near base:
94a Leaves linear, rarely more than 2 mm wide, margins not thickened (see also *G. venustus*):
95a Lower lateral tepals much shorter than median; upper lateral tepals flexed upward to overlap dorsal tepal on either side:
96a Perianth tube 45–50 mm long; upper three tepals sub equal, 25–35 mm long; lower lateral tepals with red median streak . . . . . 85. *G. leptosiphon*
96b Perianth tube 16–18 mm long; dorsal tepal much shorter than upper laterals, 25–35 mm long; lower lateral tepals greenish yellow in lower half. . . . . 87. *G. involutus*
95b Lower lateral tepals ± as long as median or only slightly shorter; perianth often windowed in profile with gap between upper lateral and dorsal tepals:
97a Flowers actinomorphic and unmarked, the perianth stellate with symmetrically disposed stamens . . . . . 97. *G. stellatus*
97b Flowers zygomorphic with lower tepals marked, the perianth bilabiate with arcuate stamens:
98a Tepals subequal, all recurved; perianth tube 16–30 mm long; filaments 6–10 mm long, included in tube or shortly exserted up to 2 mm; flowers greenish yellow, often flushed brown to purple on reverse, lower tepals unmarked . . . . . 96. *G. acuminatus*
98b Not as above:
99a Perianth not windowed in profile, not gaping between base of upper lateral and dorsal tepals; flowers usually unscented . . . . . 98. *G. wilsonii*
99b Perianth windowed in profile, tepals ± clawed thus with a gap between base of upper lateral and dorsal tepals; flowers often scented:
100a Perianth tube longer than dorsal tepal, 22–35 mm long; plants from Eastern Cape . . . 93. *G. uitenhagensis*
100b Perianth tube shorter than dorsal tepal, 9–15 mm long; plants from Western and Eastern Cape:
101a Flowers whitish to dull grey, purple or brownish yellow; lower lateral tepals channelled and clawed below but not lobed. . . . . 92. *G. permeabilis*
101b Flowers bright yellow; lower lateral tepals with basal half of blade involute-tubular and auriculately lobed . . . . . 95. *G. karooicus*
94b Leaves narrowly lanceolate to lanceolate, usually at least 3 mm wide, margins unthickened or thickened:
102a Corm tunics usually hard, woody and gnarled, accumulating, rarely membranous or papery but then lower leaf sheaths puberulous; perianth often windowed between dorsal and upper lateral tepals:
103a Flowers cream-coloured to pale pink with red and yellow chevron-shaped markings on lower tepals; lower tepals not conspicuously narrowed below; perianth tube 18–40 mm long:
104a Perianth tube narrowly funnel-shaped, 18–22 mm long; filaments ± 25 mm long . . . . . 106. *G. salteri*
104b Perianth tube cylindric, 35–40 mm long; filaments ± 8 mm long. . . . . 107. *G. lapeirousioides*
103b Flowers yellowish to greenish or purple with basal half of lower tepals greenish yellow; lower tepals conspicuously narrowed below and flexed downwards; perianth tube 12–17 mm long:
105a Corm tunics softly membranous; sheaths and blades of lower leaves puberulous; capsules ellipsoid, acute . . . . . 101. *G. arcuatus*
105b Corm tunics hard and woody; leaves glabrous; capsules ovoid to subglobose, 3-lobed above and retuse:
106a Lower tepals curved ± sharply downward at base of limb with upper margins of claws not or only weakly auriculate; perianth windowed in profile, with gap between upper lateral and dorsal tepals; plants north of Vanrhynsdorp–Calvinia axis . . . . . 104. *G. scullyi*
106b Lower tepals geniculately flexed downward at base of limb with upper margins of claws conspicuously auriculately lobed; perianth not windowed in profile, with upper lateral tepals suberect on either side of dorsal tepals; plants south of Vanrhynsdorp–Calvinia axis . . . . . 105. *G. venustus*
102b Corm tunics leathery, fibrous or papery to membranous; perianth never windowed:
107a Lower lateral tepals much shorter than median; upper lateral tepals flexed upward to overlap dorsal tepal on either side; dorsal tepal much shorter than upper laterals, 25–35 mm long; lower lateral tepals greenish yellow in lower half . . . . . 87. *G. involutus*

107b Not as above:
108a Leaves somewhat succulent, without evident veins and margins unthickened; flowers blue-mauve, tepals subequal, lower marked with white streaks edged in red; strand plants growing down to the high-tide mark. . . . . .40. *G. gueinzii*
108b Leaves not succulent, secondary veins usually evident and margins usually prominent; flowers white to pink or salmon-pink, lower tepals often smaller, variously marked:
109a Leaves in a tight basal fan; blades firm-textured with strongly thickened margins and midrib; corm tunics coarsely fibrous, accumulating in a densely mass and forming a neck around base of stem:
110a Perianth tube 18–21 mm long; filaments 12–14 mm long; lower lateral tepals with pale yellow, spear-shaped marks outlined with purple; base of leaves heavily marked with raised white speckles . . . . 55. *G. rudis*
110b Perianth tube 22–55 mm long; filaments 14–37 mm long; lower lateral tepals with dark median streak; base of leaves lightly marked but not textured with white or green speckles:
111a Perianth tube 22–35(–55) mm long; lower tepals ¾ to ± as long as dorsal . . . . .56. *G. grandiflorus*
111b Perianth tube 40–70 mm long, if less than 50 mm long, then lower tepals ½–¾ as long as dorsal:
112a Flowers white to creamy yellow or greenish; perianth tube slender in lower 20–55 mm and flaring above; filaments 20–23 mm long. . . . . 57. *G. floribundus*
112b Flowers salmon- to orange-red; perianth tube slender in lower 20–35 mm and cylindric above; filaments 35–37 mm long . . . . .58. *G. miniatus*
109b Leaves in a loose fan or superposed; blades soft-textured with often lightly thickened margins and midrib; corm tunics papery to medium-textured fibres, not accumulating in a densely mass and forming a neck around base of stem:
113a Corms scarcely developed, tunics not accumulating; plants with inclined to drooping stems, growing on wet rocks:
114a Spike usually 15- to 20-flowered; flowers ivory-coloured to greenish cream-coloured, lower tepals less than half as long as dorsal; perianth tube 45–50 mm long, completely enclosed within the bracts; plants from Cederberg . . . . 47. *G. buckerveldii*
114b Spike usually less than 15-flowered; flowers pale mauve-pink, lower tepals ⅔ to nearly as long as dorsal; perianth tube 25–40 mm long, exceeding the bracts; plants from Swartberg . . . . 44. *G. aquamontanus*
113b Corms well developed, tunics accumulating or not; plants with erect to inclined stems, not growing on wet rocks:
115a Perianth tube longer than dorsal tepal, (30–)40–100 mm long:
116a Tepals attenuate and strongly undulate; lower tepals slightly shorter than upper . . . . .45. *G. undulatus*
116b Tepals obtuse to acute, not attenuate, weakly undulate; lower tepals usually about ⅔ as long as upper:
117a Leaves 4 or 5; flowers cream-coloured to yellowish with prominent red, spear-shaped marks on lower tepals; flowering October to November; plants from West Coast and near interior . . . . 46. *G. angustus*
117b Leaves 3 to 7; flowers salmon-pink with red linear marks on lower tepals; flowering February to April; plants from southern coast and interior:
118a Leaves 6 or 7, with blades 1.5–6.5 mm wide; perianth tube 30–55 mm long; flowering February; plants from Little Karoo mountains . . . . .48. *G. dolichosiphon*
118b Leaves 3, with blades 6–8 mm wide; perianth tube 50–70 mm long; flowering March to April; plants from southern foothills of Langeberg. . . . . .49. *G. bilineatus*
115b Perianth tube shorter than to as long as dorsal tepal, (15–)20–50 mm long:
119a Flowers large, dorsal tepal 40–55 mm long; plants from Plettenberg Bay to Uniondale . . .43. *G. geardii*
119b Flowers smaller, dorsal tepal 18–40(–50) mm long; plants from west of Knysna:
120a Leaf blades with two prominently thickened veins on some or all leaves, 1–6 mm wide; tunics finely fibrous:
121a Flowers 33–46 mm long; leaves 2– 6 mm wide; bracts mostly 13–20 mm long; lower tepals with white to yellow, spear-shaped marking outlined with red . . . . 37. *G. oreocharis*
121b Flowers 48–60 mm long; leaves 1–3 mm wide; bracts mostly 25–33 mm long; lower tepals with red chevron-shaped marking in middle and red-spotted toward base and in throat . . . . .38. *G. crispulatus*
120b Leaf blades with only midrib prominently thickened, sometimes additional pairs of veins also evident, 1.6–20.0 mm wide; tunics usually accumulating, fibrous or firm-papery:
122a Floral bracts 13–16 mm long; perianth tube 18–20 mm long; lower tepals narrowed below into claws . . . . 39. *G. phoenix*
122a Floral bracts 25–65 mm long; perianth tube (15–)25–45 mm long; lower tepals not narrowed below into claws:
123a Leaves (2–)6–19 mm wide; flowers usually at least 5 per spike; corm tunics fibrous to firm-papery, usually accumulating. . . . . 41. *G. carneus*
123b Leaves 1.5–3.0 mm wide; flowers 1 or 2(3) per spike; corm tunics membranous, not accumulating . . . . .42. *G. pappei*

Sect. 1. **Densiflori** *Goldblatt & J.C.Manning*, *Gladiolus* in southern Africa: 70 (1998) [as Sect. *Densiflorus*]. Type species: *Gladiolus densiflorus* Baker

Plants medium-sized to large. *Stem* branched or unbranched. *Corm* tunics papery or leathery to fibrous. *Leaves* several, mostly basal in a fan, sometimes with a pseudostem formed by clasping sheaths, narrowly lanceolate, firm-textured, plane with thickened midrib and margins, usually at least 4 mm wide. *Spike* often many-flowered, usually crowded. *Flowers* usually small, mostly only weakly bilabiate, nectar guides sometimes present, unscented; perianth tube usually obliquely funnel-shaped and shorter than dorsal tepal, sometimes longer; lower tepals narrower but usually ± as long as upper. *Anthers* sometimes tailed basally. *Capsules* obovoid to subglobose, usually less than 15 mm long. *Seeds* usually less than 6 mm long, wings often reduced or unevenly developed.



Defined by the basal fan of lanceolate leaves and the dense spike of mostly relatively small, weakly bilabiate flowers without floral fragrance, sect. *Densifloris* is restricted to grasslands and savannas in the summer-rainfall region. The section includes 13 southern African species, as well as some from tropical Africa.

Ser. **Paludosi** *Goldblatt & J.C.Manning*, new series. Type species: *G. paludosus* Baker

Corm small or poorly developed and rhizome-like, producing short or long stolons from the base; tunics membranous or papery, sometimes fibrous. *Leaves* with moderately thickened margins and midribs; bracts green, 17–35 mm long. *Flowers* moderately large. Anthers not tailed.

1. **Gladiolus paludosus** *Baker* in Journal of Botany, British and foreign 29: 70 (1891). Type: South Africa, [Mpumalanga], Ermelo District, Lake Chrissie, marshy places, Nov. 1888, *Elliot 1588* (K, holo. [drawing at BOL]).

Plants 360–540 mm high. *Corm* globose, 10–12 mm diam.; tunics papery becoming fibrous, with one or two cormlets on short stolons. *Stem* erect, flexed outward above sheathing part of uppermost leaf then erect again, occasionally with one branch. *Leaves* 4 to 6, lower 2 to 4 basal and longest, reaching between middle of stem and base of spike, relatively short, lanceolate, 7–10 mm wide, margins moderately thickened and hyaline, main vein lightly raised, cauline leaves smaller, uppermost without blade. *Spike* erect, 5- to 9(–20)-flowered; bracts pale to grey-green, often flushed grey-purple, outer 17–20 mm long, inner slightly shorter than outer and bifid. *Flowers* zygomorphic, mauve to pink or reddish, lower lateral tepals with broad diamond-shaped to semi-circular band of dark mauve or purple across midline, unscented; perianth tube obliquely funnel-shaped, 10–14 mm long, lower cylindric part ± 6 mm long; tepals ovate, dorsal largest, extending ± horizontally over stamens, 20–25 × 14–19 mm, upper laterals directed forward in lower ½, gradually curving outward in upper half, 20–25 × 14–17 mm, lower 3 tepals sometimes joined to upper laterals for ± 1 mm, joined together for 1–2 mm, lower laterals 18–20 × 7–10 mm, lower median ± 20 × 14 mm. *Filaments* ± 14 mm long, exserted ± 10 mm from tube; anthers 7–8 mm long, yellow or light mauve with dark lines on ventral side; pollen cream-coloured to yellow. *Style* dividing near anther apices, branches 4–5 mm long. *Capsules* obovoid, 8–10 mm long, 3-lobed above and retuse. *Seeds* elliptic, broadly winged, ± 6 × 4 mm, rust-brown. *Flowering time*: mid-October to mid-November.

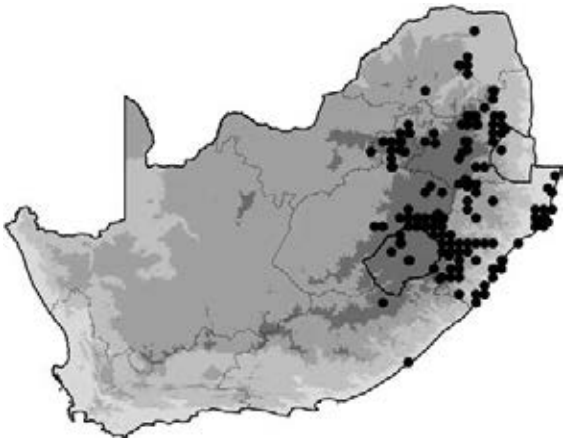
Distribution of ***Gladiolus paludosus***.

Distribution and ecology: endemic to Mpumalanga, South Africa, from Dullstroom to Wakkerstroom and Piet Retief; in marshy or vlei habitats, flowering in spring before the surrounding grass flora has grown up.

Diagnosis: recognised by its relatively short, soft-textured leaves with lightly thickened margins and midrib, and the moderately sized flowers, in combination with its wetland habitat and early flowering. *Gladiolus paludosus* is most likely to be confused with *G. crassifolius*, a summer-flowering species of drier, often stony habitats, that has longer leaves with thickened margins and prominent secondary veins, and longer spikes of smaller flowers.

2. **Gladiolus papilio** *Hook.f.* in Curtis's Botanical Magazine 92: t. 5565 (1866). Type: South Africa, without precise locality, cultivated at Kew Gardens, 1863, *Cooper s.n.* (K, lecto., designated by Goldblatt & Manning: 72 (1998) [photo at PRE]).

Gladiolus purpureo-auratus Hook.f.: t. 5944 (1872). Type: South Africa, [KwaZulu-Natal], without precise locality or collector, cultivated at Bull's



Nursery, London, illustration in Hook.f.: t. 5944 (1872).

Gladiolus brachyscyphus Baker: 210 (1892). Type: South Africa, [KwaZulu-Natal], Mt Currie, Kokstad, Feb. 1883, *Tyson 1427* (K, holo.; BOL, GRA, iso.).

Gladiolus spathulatus Baker: 223 (1892). Type: South Africa, [Limpopo], Waterberg Mtns, Zacharias de Beer's farm, near Nylstroom River, Aug. 1880, *Nelson 295* (K, holo.).

Gladiolus schlechteri Baker: 1006 (1904a). Type: South Africa, [Gauteng], Donkerhoek east of Pretoria, 4 Jan. 1894, *Schlechter 4132* (Z, presumed holo.; BOL, Z, iso.).

Plants (400–)500–750(–1 000) mm high. *Corm* hardly developed at flowering time, rhizome-like, producing slender stolons terminating in a single cormlet; tunics papery-membranous, fragmenting with age. *Stem* erect or slightly inclined, flexed outward above sheath of uppermost leaf, then inclined, unbranched. *Leaves* 6 or 7(9), lower 4 to 6 ± basal, reaching to ± middle of stem or above, narrowly lanceolate, 9–14(–19) mm wide, margins and main vein lightly thickened, cauline leaves smaller, largely to entirely sheathing. *Spike* inclined, usually strongly flexed at base, 4- to 8(–13)-flowered; bracts often flushed grey-purple, outer 20–35 mm long, inner slightly shorter, acute. *Flowers* nodding, cream-coloured to greenish or yellowish, flushed translucent pink or light purple on inside of upper tepals and greenish to grey or purple on reverse, lower lateral tepals with elongate, dark green or light to dark purple blotches extending into upper part of tube, and with obscure to well-defined crescent-shaped yellow to cream-coloured bands below apices, unscented; perianth tube obliquely funnel-shaped, curving outward at base of upper part, 18–20 mm long, emerging from just above middle of bracts; tepals obovoid, unequal, dorsal largest, 25–35 × 23–30 mm, hooded over stamens, horizontal or tilted toward ground, upper laterals directed forward and contiguous with dorsal and lower tepals to form a wide-mouthed bell, 24–35 × 17–24 mm, lower tepals joined together for ± 2 mm, narrowed below, 22–32 × 14–21 mm, lower median, 20–26 × 13–20 mm. *Filaments* 20–22 mm long, exserted 7–10 mm from tube; anthers 8–10 mm long, purplish on dorsal surface, cream-coloured below; pollen cream-coloured. *Style* arching over stamens, dividing opposite upper ⅓ of anthers, branches 4.0–6.5 mm long. *Capsules* ovate-oblong, 3-lobed above and retuse, 18–24 mm long. *Seeds* oblong, broadly winged, 8–9 × 4–5 mm, rust-brown. *Flowering time*: November to February, occasionally later.

Distribution of ***Gladiolus papilio***.

Distribution and ecology: occurring across eastern South Africa, from Limpopo and Mpumalanga through Eswatini, Gauteng, eastern Free State, Lesotho and KwaZulu-Natal to Butterworth in Eastern Cape; mostly in marshes, seeps or streambanks, also damp grassland.

Green-flowered plants occur through the central Drakensberg, and the yellow-flowered form in the eastern Free State and northern KwaZulu-Natal.

Diagnosis: readily recognised by the markedly inclined spike of relatively large, nodding, bell-like flowers with prominent nectar guides on the lower tepals and sharply curved perianth tube 18–20 mm long. The relatively small corm has papery tunics. Plants spread vegetatively by means of long stolons.

Ser. **Densiflori** *Goldblatt & J.C.Manning*, new series. Type species: *G. densiflorus* Baker

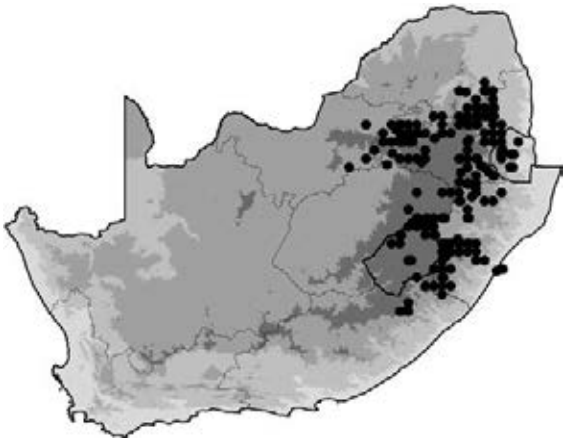
Corm globose to depressed-globose; tunics leathery or coarsely fibrous. *Leaves* with moderately thickened margins and midribs and sometimes secondary veins; bracts often dry and papery or membranous and brown above, 15–50(–70) mm long. *Flowers* small to moderately large. Anthers not tailed.

3. **Gladiolus crassifolius** *Baker* in Journal of Botany, British and foreign 14: 334 (1876b). Type: South Africa, [Eastern Cape], without precise locality, 1861, *Cooper 3185* (K, lecto., designated by Lewis et al.: 60 (1972), G, PRE, isolecto.).

Gladiolus rachidiflorus Klatt: 339 (1882). Type: South Africa, [KwaZulu-Natal], Port Natal [Durban], around the bay, Mar. 1832, *Drège 4537* (B†, holo.; P, [fide Lewis et al. (1972) but not located there], S [floral fragment without leaves], iso.).

Gladiolus tritoniiformis Kuntze: 308 (1898). Type: South Africa, [KwaZulu-Natal], Estcourt District, Highlands Station, 1 600 m, 15 Mar. 1894, *Kuntze s.n.* (NY, holo. [photo at PRE]; K, Z, iso.).

Gladiolus junodii Baker: 866 (1901). Type: South Africa, [KwaZulu-Natal], Lions River District, Howick, 1893, *Junod 320* (Z, holo. [photo at PRE]; G, Z, iso.).



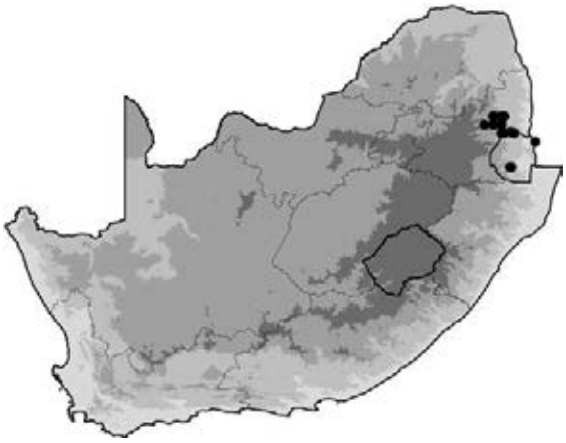
Gladiolus conrathii Baker: 1005 (1904a). Type: South Africa, [Gauteng], Modderfontein, Feb. 1898, *Conrath 582* (Z, holo. [photo at PRE]; GZU, iso.).

Gladiolus dieterlenii E.Phillips: 282 (1917). Type: Lesotho, Leribe, 5 000–6 000 ft [1 500–1 800], Mar. 1913, *Dieterlen 445* (SAM, holo.; GRA, K, P, PRE, iso.).

Plants (250–)350–900(–1 200) mm high. *Corm* subglobose to depressed-globose, 18–30 mm diam.; tunics leathery to ± coarsely fibrous. *Stem* erect below, usually flexed outward above sheath of uppermost leaf, simple or 1- to 3-branched. *Leaves* 4 to 8, mostly basal, sometimes forming a pseudostem, blades narrowly lanceolate to linear, reaching to base of spike or above, 5–12 mm wide, midrib and margins plus two or more pairs of secondary veins hyaline and moderately thickened, cauline leaves progressively shorter blades and uppermost sometimes entirely sheathing. *Spike* ± erect or weakly inclined, (12)16- to 22(40)-flowered; bracts usually pale green or flushed purple, soft-textured becoming dry and membranous above in fruit, 15–20(–28) mm long and ± 2 internodes long, acute to attenuate, inner shorter than outer and forked apically. *Flowers* pale to deep pink or light purple, orange-red or cream-coloured, lower lateral, and sometimes lowermost tepals with a band of darker colour across limbs often edged with cream-coloured, unscented; perianth tube obliquely funnel-shaped, 9–17 mm long; tepals broadly ovate, unequal, dorsal largest and arched to hooded over stamens, 18–22 × 10–12 mm, upper laterals directed forward and curving outward above, 18–20 × 16–18 mm, lower 3 tepals ± straight and directed downward, united below for 2–3 mm, narrowed into channelled claws below, lower laterals 12–16 × 5–7 mm, lower median 15–20 × 12 mm. *Filaments* 12–14 mm long, exserted 6–7 mm from tube; anthers 7–8 mm long, pale lilac to purple; pollen whitish to pale yellow. *Style* arching over the filaments, usually dividing opposite lower half of anthers, branches ± 3 mm long, seldom reaching past middle of anthers. *Capsules* obovoid, 9–12(–14) mm long, 3-lobed above and retuse. *Seeds* elliptic, broadly winged, 4–6 × 2.5–4.0 mm. *Flowering time*: mainly February and March, occasionally later or earlier [in tropical Africa usually April to June].

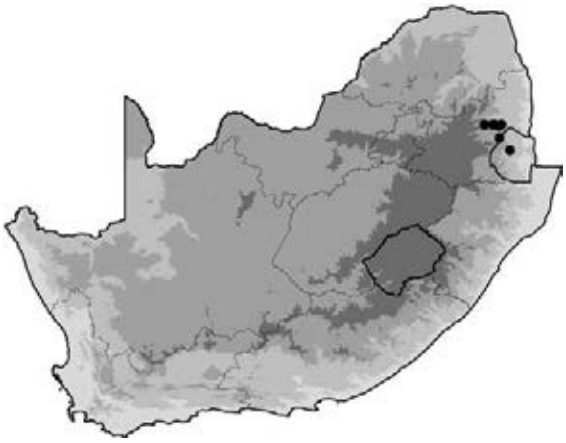
Distribution and ecology: widespread through the eastern southern Africa at mid to high elevations, from near Elliot in Eastern Cape, South Africa, to Limpopo, Eswatini and into tropical Africa; in rocky grassland.

Diagnosis: recognised by the dense spike of small flowers with overlapping bracts ± two internodes long and the basal fan of tough, fibrous leaves with the margins and midrib plus one or more pairs of secondary veins thickened and hyaline. The flowers vary greatly in colour but are most frequently pink to salmon or dull purplish with darker nectar guides highlighted with yellow. Plants with orange to coral-pink flowers occur locally in Mpumalanga. The species is often confused with *Gladiolus densiflorus*, which occurs mainly to the east



Distribution of ***Gladiolus crassifolius***.

and at lower elevations, but their distribution overlaps along the Mpumalanga Escarpment, where *G. crassifolius* typically flowers slightly later. The flowers in the two species are very similar, although the perianth in *G. densiflorus* is sometimes finely speckled, but the two are most reliably separated by their foliage: the leaves in *G. densiflorus* are characterised by numerous, fine, closely spaced tertiary veins uninterrupted by evident secondary veins between the margins and main vein. Some plants may, however, be difficult to place. *Gladiolus serpenticola* from near Barberton can also be confused with *G. crassifolius* but is typically a taller plant with erect stems 750–1 500 mm high, less fibrous leaves, and mostly shorter bracts 12–16 mm long.



4. **Gladiolus hollandii** *L.Bolus* in Journal of Botany, British and foreign 69: 261 (1931b). Type: South Africa, [Mpumalanga], Tomango near Nelspruit, cult. at Kirstenbosch Gardens, Apr. 1928, *Holland s.n. NBG 493/27* (BOL, holo.).

Gladiolus varius var. *elatus* F.Bolus in L.Bolus: 104 (1917). Type: South Africa, [Mpumalanga], Barberton, base of the mountains, 2 800–3 000 ft [850–900 m], 17 Mar. 1890, *Galpin 860* (BOL, holo.; K, PRE, SAM, iso.).

Plants 650–1 200(–1 500) mm high. *Corm* depressed-globose, 18–40 mm diam.; tunics leathery, fragmenting irregularly with age, bearing small cormlets at base. *Stem* erect, simple or 1- or 2-branched. *Leaves* 7 to 10, lower 4 to 6 ± basal, reaching between base and apex of spike, blades narrowly to broadly lanceolate, 8–18(–28) mm wide, main vein and margins lightly thickened, sometimes a second pair of veins also thickened, remaining veins fine and closely set, cauline leaves shorter and uppermost often entirely sheathing, imbricate, enclosing stem almost to base of spike. *Spike* erect, 18- to 30(–55)-flowered; bracts green, lanceolate- attenuate, becoming dry soon after flowering, outer 23–30(–35) mm long, inner shorter than outer, acute or subobtuse. *Flowers* pale pink, usually minutely dotted with dark pink, all tepals with a dark pink to

Distribution of ***Gladiolus hollandii***.

Distribution of ***Gladiolus serpenticola***.

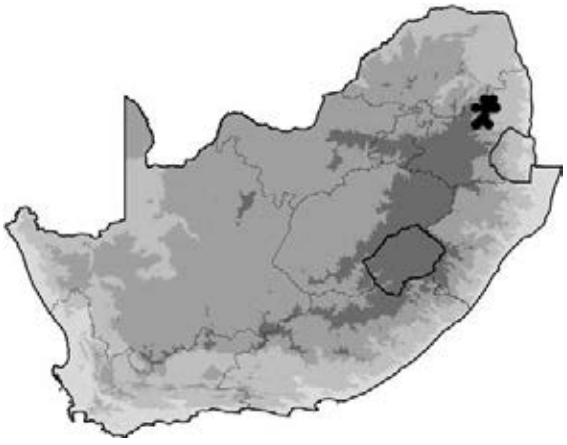
reddish median streak, most pronounced on lower lateral tepals, unscented; perianth tube obliquely and narrowly funnel-shaped, 18–25(–30) mm long, wider upper part ± 9 mm long; tepals subequal, lanceolate, dorsal inclined over stamens, 20–27 × 12–14 mm, upper laterals 18–25 × 11–12 mm, lower 3 tepals united for 1–2 mm, free parts (12–)18–20 × 10 mm, lower median slightly longer than lower laterals. *Filaments* 12–17 mm long, exserted 6.0–8.5 mm from tube; anthers 6.5–8.0 mm long, dark purple; pollen cream-coloured. *Style* arching over stamens, dividing at or just beyond anther apices, branches ± 3 mm long. *Capsules* narrowly obovoid, 10–12 mm long, 3-lobed above and truncate. *Seeds* oblong, poorly and unevenly winged, ± 5 × 3 mm. *Flowering time*: mid-February to April.

Distribution and ecology: restricted to the eastern lowveld of southern Africa, extending from Limpopo to Barberton in Mpumalanga, South Africa, and in Eswatini and southern Mozambique; on lower slopes and granite outcrops in open savanna and bush.

Diagnosis: distinguished from related species with similar small flowers by the relatively longer perianth tube, 18–30 mm long and ± as long as or longer than the dorsal tepal. This character serves to separate it from species such as *Gladiolus crassifolius, G. densiflorus* and *G. serpenticola*.

5. **Gladiolus serpenticola** *Goldblatt & J.C.Manning* in Novon 6: 173 (1996). Type: South Africa, Mpumalanga, Kaap Valley on Nelspruit–Barberton Road near Noordkaap River Bridge, serpentine outcrops, 9 Feb. 1994, *Goldblatt & Manning 9844* (NBG, holo.; E, K, MO, PRE, WAG, iso.).

Plants 750–1 500 mm high. *Corm* depressed-globose, 25–50 mm diam.; tunics initially leathery, fragmenting irregularly and becoming coarsely fibrous. *Stem* erect, usually with 1 or 2 branches, occasionally more, 2.0–2.5 mm diam. below base of spike. *Leaves* 8 to 10, lower 4 or 5 ± basal and reaching to ± base of spike, grey-green and somewhat glaucous, blades narrowly sword-shaped to linear, 7–10 mm wide, margins and midribs moderately thickened, cauline leaves progressively smaller above, imbricate and sheathing stem to ± base of spike. *Spike* slightly inclined, ± straight, 18- to 30-flowered; bracts pale green in bud, dry and light brown above by anthesis, lanceolate-attenuate, apices dry and twisted, 12–16 mm long, inner bracts slightly shorter than outer. *Flowers* pale pink to nearly white, lower lateral tepals each with a central yellow streak surrounded by a light purple blotch, unscented; perianth tube obliquely funnel-shaped, 10–12 mm long; tepals broadly ovate, dorsal inclined to hooded over stamens, 23 × 14 mm, upper laterals directed forward, weakly curving upward in distal third, 23 × 12 mm, lower 3 tepals united for ± 2 mm, lower laterals narrowed below, 13–14 × 5.5–6.0 mm, lower median 16–18 × ± 8 mm, arching downward. *Filaments* 14 mm long, exserted ± 8 mm from tube; anthers ± 6 mm long, purple; pollen cream-coloured. *Style* arching over stamens, dividing opposite lower to upper ⅓ of anthers, branches ± 2 mm long, not reaching anther tips. *Capsules* ovoid, 3-lobed apically, 5–8 mm long. *Seeds* ovate, ± 5–6 × 2.5–3.0 mm, wing unevenly developed, sometimes lacking on one side or across middle. *Flowering time*: early February to late March, rarely in late January.



Distribution and ecology: an edaphic endemic around Barberton in Mpumalanga, especially the Kaap Valley; in open woodland and savanna, on verdite and other serpentine outcrops.

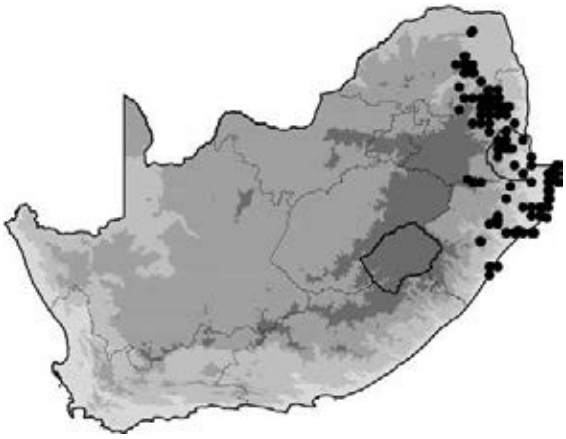
Diagnosis: distinguished from allied species by its tall stature, 750–1 500 mm high, narrow glaucous leaves 7–10 mm wide, and small, dry, brittle floral bracts 12–15 mm long. The short-tubed flowers resemble those of *Gladiolus densiflorus* and *G. crassifolius* and the three species are best distinguished vegetatively: *G. crassifolius* has strongly fibrous leaves with more heavily thickened midrib and margins plus at least one pair of secondary veins, and *G. densiflorus* has leaves with fine, closely set tertiary veins. Some plants in Mpumalanga, where the distribution of the species overlaps, may be difficult to place.

6. **Gladiolus exiguus** *G.J.Lewis* in Lewis et al. in Journal of South African Botany, Suppl. 10: 58 (1972). Type: South Africa, [Mpumalanga], Lydenburg District, Long Tom Pass, 19 km east of Lydenburg, 22 Feb. 1949, *Codd 5173* (PRE, holo.; BM, K, iso.).

Plants 300–400 mm high. *Corm* depressed-globose, 25–35 mm diam.; tunics of coarse, netted fibres, accumulating to form a thick collar of fibres around base of stem. *Stem* erect below, flexed outward above sheath of penultimate leaf, inclined in upper third, unbranched. *Leaves* 7 or 8, lower 5 or 6 ± basal, forming a crowded fan, reaching to between upper ⅓ of stem and base of spike, narrowly lanceolate, 9–15 mm wide, margins moderately thickened and main vein less so, with fine, closely set tertiary veins between, upper 1 or 2 leaves cauline, overlapping and largely sheathing. *Spike* inclined, 12- to 20-flowered; bracts dull green or flushed with grey-purple, outer 23–33 mm long, 1.5–2.0 internodes long, lightly folded along midline, acute to somewhat attenuate, inner bracts a little more than ½ as long, notched apically. *Flowers* pale creamy pink to deep pink, without noticeable nectar guides, unscented; perianth tube obliquely funnel-shaped, 14–16 mm long; tepals lanceolate-elliptic, dorsal arching over stamens and nearly horizontal, 20–22 × 14 mm, upper lateral and lower median ± 22 × 12 mm, lower laterals smallest, ± 18 × 10 mm. *Filaments* ± 15 mm long, exserted ± 7 mm from tube; anthers ± 6 mm long, brownish purple; pollen cream-coloured. *Style* arching over stamens, dividing opposite middle of anthers, branches ± 3 mm long. *Capsules* broadly ovoid, rounded apically, (9–)12–14 mm long. *Seeds* ovate to triangular, 4–6 mm long, unevenly winged or winged only at one end. *Flowering time*: late January to March.

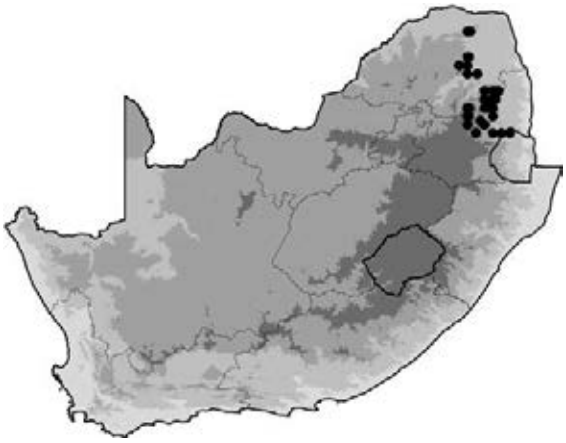
Distribution and ecology: a relatively narrow endemic of the Mpumalanga Escarpment between Mt Sheba and Waterval Boven; in open, well-drained grassland on stony quartzite slopes.

Distribution of ***Gladiolus exiguus***.



Diagnosis: distinguished by its low stature, seldom more than 400 mm high, with a fan of relatively short, often slightly twisted leaves not exceeding the spike. The leaf blades have thickened margins and midrib with fine, closely set tertiary veins between. The flowers are slightly larger than those of *Gladiolus densiflorus*, which has similar leaf venation, especially the perianth tube, 14–16 mm long vs. 12–14 mm long.

7. **Gladiolus densiflorus** *Baker* in Vierteljahrsschrift der Naturforschenden Gesellschaft Zürich 49: 178 (1904b). Type: South Africa, [Limpopo], Letaba District, Shilouvane, Apr. ± 1900, *Junod 1204* (Z, possible holo.; G, K, PRE, iso.).



Gladiolus invenustus G.J.Lewis in Lewis et al.: 65 (1972). Type: Swaziland [Eswatini], Little Usutu River at Evelyn Baring Bridge, 13 Dec. 1960, *Compton 30382* (NBG, holo.; PRE, iso.).

Plants (400–)650–1 200 mm high. *Corm* depressed-globose, 25–40 mm diam.; tunics leathery, fragmenting irregularly with age and becoming somewhat fibrous. *Stem* erect below, flexed outward and inclined above sheaths of upper 1 or 2 leaves, usually unbranched, occasionally 1-branched. *Leaves* 8 or 9, lower 4 or 5 ± basal, forming a 2-ranked fan, reaching to ± middle of stem or base of spike, linear-lanceolate to lanceolate, (5–)10–24 mm wide, margins and main vein thickened and raised, remaining veins fine and closely set, cauline leaves progressively smaller, upper 2 usually entirely sheathing. *Spike* inclined, lightly flexuose, 12- to 25(45)-flowered; bracts greenish or purple, outer 15–20(–28) mm long, acute to attenuate, 1–2 internodes long, inner shorter than outer, acute or minutely forked apically. *Flowers* cream-coloured, greenish, pink, mauve, slate-grey, or occasionally orange, usually minutely speckled with pink to purple, either without noticeable nectar guides or lower 3 tepals each with poorly defined pale yellow median patch, unscented; perianth tube obliquely funnel-shaped, 12–14 mm long; tepals narrowly to broadly ovate, dorsal 15–18(–20) × 11–13 mm, ascending and arching over stamens, upper laterals 15–20 × 10–12 mm, directed forward and curving weakly outward in upper ⅓, lower 3 tepals joined together for 1.0–1.5 mm, 13–17 × 6–9 mm, weakly clawed and channelled in lower 3 mm, flexed downward distally. *Filaments* 10–12 mm long, exserted 5–6 mm from tube; anthers 4.5–6.0 mm long, dark purple to blackish; pollen white to cream-coloured. *Style* arching over stamens, dividing opposite distal ½, branches 2–3 mm long. *Capsules* obovoid, 3-lobed above and sometimes retuse, ± 10 mm long. *Seeds* ovate to triangular, 4–6 × 3–4 mm, poorly and unevenly winged, only one end. *Flowering time*: December to March but at almost any time of the year on the northern KwaZulu-Natal coastal plain.

Distribution and ecology: relatively widespread through the lowveld and eastern littoral, from Tate Vondo in Limpopo, South Africa, through Mpumalanga into Eswatini, southern Mozambique and KwaZulu-Natal; in

Distribution of ***Gladiolus densiflorus***.

Distribution of ***Gladiolus ferrugineus***.

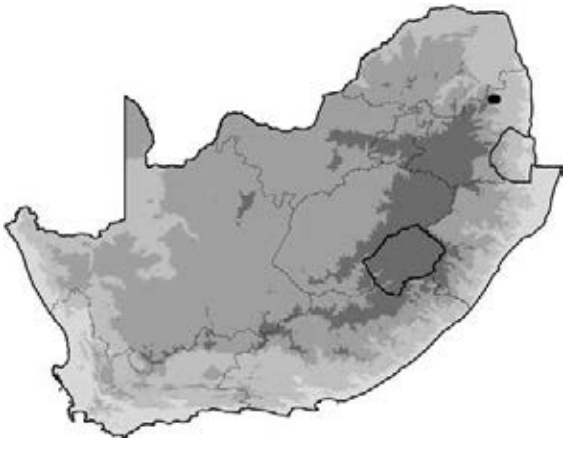
moist grassland, mainly below 300 m but up to 2 000 m elevation in the mountains south of Barberton.

Diagnosis: highly variable in size and flower colour and recognised by the fan of leaves with thickened margins and main vein and fine, closely set tertiary veins between, and the generally tall, dense spike of small, short-tubed flowers. The flowers are plain or speckled and variable in colour. The species is superficially similar to *Gladiolus crassifolius* and the two may be confused where they co-occur along the Mpumalanga Escarpment. They are distinguished by details of the leaf venation: the leaves in *G. crassifolius* are more fibrous, with one or more pairs of secondary veins thicker and more conspicuous than the tertiary veins developed on each side of the main vein.

8. **Gladiolus ferrugineus** *Goldblatt & J.C.Manning*, *Gladiolus* in southern Africa: 81 (1998), replacement name for *G. micranthus* Baker: 1005 (1904a), illegitimate homonym, not *G. micranthus* Stapf (1885). *G. varius* var. *micranthus* Oberm. in Lewis et al.: 34 (1972). Type: South Africa, [Limpopo], Sanatorium, Apr.–May 1901, *Junod 1716* (G, lecto., designated by Goldblatt & Manning: 81 (1998); G, Z, isolecto.).

Plants 350–600(–800) mm high. *Corm* globose, 15–20 mm diam.; tunics leathery, decaying into medium-textured fibres. *Stem* erect below, flexed outward above sheaths of cauline leaves and inclined, unbranched. *Leaves* 6 to 8, lower 3 or 4 ± basal, reaching to between base and apex of spike, narrowly lanceolate to linear, (3–)5–8(–15) mm wide, twisted several times, fibrotic and tough, margins and main vein thickened and raised, sometimes heavily so, remaining veins poorly developed, cauline leaves progressively smaller, upper 2 largely sheathing. *Spike* inclined, 8- to 15(–27)-flowered; bracts greenish in bud becoming dry and rusty brown in upper ⅓ at anthesis and soon entirely dry, outer 20–30 mm long, attenuate-apiculate, inner shorter, yellowish green, forked apically. *Flowers* white, cream-coloured to pearl-grey or pale pink, flushed with pink or blue on fading, lower lateral tepals with faint cream-coloured to pale yellow blotches in midline, markings sometimes darkening to purple with age, unscented; perianth tube obliquely funnel-shaped, 12–16(–25) mm long; tepals ovate, dorsal arching over stamens, nearly horizontal, 18–25(–28) × 12–15 mm, broadest in lower ⅓, upper laterals directed forward, barely curving outward toward apices, 18–30 × 15 mm, lower 3 tepals united basally for 1.5–6.0 mm, laterals 12–20 × ± 9 mm, narrowed below for ± 1.5 mm into claws, limbs abruptly widened and channelled below, lower median 15–25 × ± 11 mm. *Filaments* 12–15 mm long, exserted 7–8 mm from tube; anthers 6–8 mm long, lilac to purple; pollen yellow. *Style* arching over stamens, dividing between middle and apex of anthers, branches 3–4 mm long. *Capsules* obovoid, 3-lobed above and retuse, (6–)10–15 mm long. *Seeds* oval, ± 3–4 × 2.5 mm, narrowly and evenly or unevenly winged. *Flowering time*: mostly January to March, occasionally in late November and December or in April.

Distribution and ecology: extending along the eastern escarpment from the Soutpansberg in Limpopo, South Africa, through eastern Mpumalanga to the Saddleback Mtns near Barberton and Pigg's Peak in northern Eswatini; in marshy or well-watered grassland, often in peaty soil, on quartzite.



Diagnosis: recognised by the fibrous leaves with poorly developed secondary veins, and unbranched spike of white to pink flowers with relatively short perianth tube 13–16(–20) mm long and dry, rusty brown bracts 20–30 mm long. *Gladiolus ferrugineus* is closely related to *G. varius*, distinguished by its mostly larger flowers with longer perianth tube 30–50 mm long. Hybrids between the two species occur on the upper slopes of Long Tom Pass.

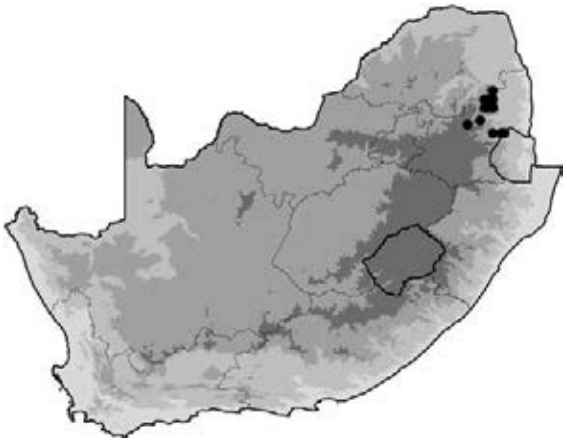
Gladiolus ferrugineus comprises two, more-or-less distinct forms that we interpret as ecological races: an early-flowering form from the lower escarpment with slightly broader leaves 6–15 mm wide and flowers with a short perianth tube, mostly 12–16 mm long, flowering

from late November to early February; and a later-flowering form from the upper escarpment with narrow, heavily thickened and often twisted leaves 3–6 mm wide and flowers with a slightly longer tube 18–25 mm long, flowering in March and April.

9. **Gladiolus saxatilis** *Goldblatt & J.C.Manning* in Bothalia 29: 63 (1999), as a replacement name for *G. lithicola* Goldblatt & J.C.Manning: 82 (1998), illegitimate homonym, not *G. lithicola* Goldblatt (1996). Type: South Africa, Mpumalanga, God's Window, Fanie Botha Hiking Trail, 3 Apr. 1996, *Lötter & Krynauw 86* (NBG, holo.)

Plants 450–800 mm high. *Corm* depressed-globose, 20–35 mm diam.; tunics firm-papery, becoming partly fibrous. *Stem* erect or inclined to horizontal below, lightly flexed in upper third, unbranched. *Leaves* 6 to 10, lower 4 to 8 in basal fan reaching to between base and middle of spike, drooping if stem inclined, lanceolate to narrowly sword-shaped, (12–)18–35 mm wide, margins and main vein barely thickened, main vein placed asymmetrically, uppermost leaf inserted on ± middle of stem and sheathing upper part of stem usually to ± base of spike, without blade. *Spike* inclined, straight, 9- to 16-flowered; bracts initially grey-green, soft-textured, becoming dry and rusty brown at tips or ± entirely rust-brown, lightly folded in midline, outer 38–48 mm long, ± 2 internodes long, inner shorter, minutely forked. *Flowers* whitish flushed pale mauve or mauve to pink, darkening with age, lower 3 tepals each with pale mauve, linear to narrowly diamond-shaped median streak, unscented; perianth tube narrowly and obliquely funnel-shaped, 30–40 mm long, flared outward in upper 10 mm; tepals ovate, margins slightly undulate, 3 upper largest, 30–37 × 18–20 mm, dorsal inclined, upper laterals spreading outward in distal ½, lower tepals joined to upper laterals for ± 4 mm and together for ± 2 mm, lower lateral tepals ± 28 × 15 mm, spreading in distal ½, lower median ± 33 × 16 mm long. *Filaments* 16–24 mm long, exserted 10–15 mm from tube; anthers ± 9 mm long, yellow; pollen cream-coloured. *Style* arching over stamens, dividing 1–2 mm below anther apices, branches 5–6 mm long. *Capsules* globose, 3-lobed above, 8–10 mm long. *Seeds* oblong, 4–6 × ± 3 mm, unevenly and weakly winged. *Flowering time*: mid-March to late April or early May.

Distribution of ***Gladiolus saxatilis***.



Distribution and ecology: a narrow endemic of the eastern escarpment between Graskop and Mariepskop in Mpumalanga, South Africa; on sheltered or partly shaded quartzite cliffs or outcrops in peaty soil in crevices.

Diagnosis: recognised by its broad, moderately soft-textured leaves, (12–)18–35 mm wide and relatively large, pale pink flowers with perianth tube 30–40 mm long, and rusty red-brown bracts 38–48 mm long. The leaves lack the fine, closely set tertiary veins of species such as *Gladiolus ferrugineus* and *G. varius*.

10. **Gladiolus varius** *F.Bolus* in Annals of the Bolus Herbarium 2: 104 (1917). Type: South Africa, [Mpumalanga], Pilgrim's Rest, Mar. 1915, *Rogers 14601* (BOL, holo.; J, K, iso.).

Gladiolus varius var. *brevifolius* F.Bolus: 104 (1917). Type: South Africa, [Mpumalanga], Barberton, Saddleback Mt, 5 000 ft [1 500 m], 22 Feb. 1890, *Galpin 828* (BOL, holo.; K, SAM, Z, iso.).

Plants 450–700 mm high. *Corm* depressed-globose, 18–25 mm diam.; tunics cartilaginous, becoming coarsely fibrous, often accumulating around base of stem in a collar of coarse fibres. *Stem* erect, flexed outward above sheath of penultimate leaf, inclined above, unbranched, ± 3 mm diam. at base of spike. *Leaves* usually 7, lower 4 or 5 ± basal, forming a lax 2-ranked fan, reaching to ± base of spike, blades narrowly lanceolate to nearly linear, (2.5–)4.0–9.0 mm wide, margins and main vein moderately or strongly thickened, cauline leaves shorter, uppermost usually entirely sheathing. *Spike* inclined, (6–)8- to 12-flowered; bracts pale greenish brown below and ± dry and rusty brown in distal half by anthesis, outer (25–)30–40(–70) mm long, 1.5–2.0 internodes long, inner bracts slightly shorter. *Flowers* usually deep pink, occasionally pale pink to nearly white, lower 3 tepals each usually with dark pink to purple median streak, unscented; perianth tube narrowly and obliquely funnel-shaped, (27–)37–50 mm long, cylindric lower part (20–)27–38 mm long, wider upper part ± 10 mm long; tepals lanceolate, unequal, dorsal largest, horizontal and hooded over stamens, 26–32 × 17–20 mm (often smaller in preserved specimens), upper laterals directed forward and curving outward in distal ½, 24–32 × ± 12 mm, lower 3 tepals united basally for 4–6 mm, lower lateral tepals 20–24 × 12 mm, narrowed below into claws ± 2 mm long, lower median tepal 23–26 × 12 mm. *Filaments* 12–16 mm long, exserted 5–8 mm from tube; anthers 8–9 mm long, lilac; pollen cream-coloured. *Style* arching over stamens, dividing below or up to 5 mm beyond anther apices, branches ± 6 mm long. *Capsules* oblong, 3-lobed and retuse apically, 12–15 mm long. *Seeds* discoid to angular, 2.5–3.5 × ± 2.5 mm, wing poorly and irregularly developed or vestigial. *Flowering time*: February to March, rarely late January.

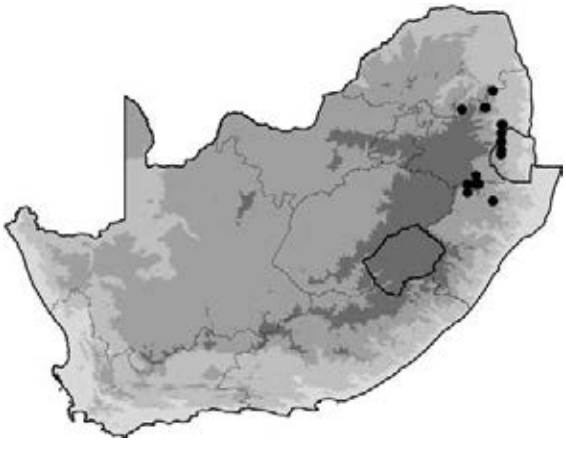
Distribution of ***Gladiolus varius***.

Distribution and ecology: endemic to the eastern escarpment in Mpumalanga, South Africa, from Mt Sheba to near Barberton; at high elevations in rock crevices on exposed rocky quartzite ridges and outcrops.

Diagnosis: recognised by the narrow, fibrous leaves up to 9 mm wide with strongly thickened margins and midrib, and the moderately large, long-tubed pink flowers with perianth tube (27–)37–50 mm long, and large, rusty brown bracts (25–)30–70 mm long. The narrow, thickened leaves distinguish the species from *Gladiolus saxatilis*. Shorter tubed plants may be confused with *G. ferrugineus*, with mostly paler pink flowers with perianth tube 12–16(–25) mm long. Hybrids between the two species are recorded from the upper slopes of Long Tom Pass.

Ser. **Calcarati** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus calcaratus* G.J.Lewis

Corm globose to depressed-globose; tunics leathery or firmly papery to fibrous. *Leaves* with moderately thickened margins and midribs and sometimes secondary veins; bracts often dry and papery or membranous and brown above, 18–55 mm long. *Flowers* small to moderately large. *Anthers* basally tailed or spurred.



11. **Gladiolus appendiculatus** *G.J.Lewis* in Lewis et al. in Journal of South African Botany, Suppl. 10: 68 (1972). Type: South Africa, [Mpumalanga], Wakkerstroom District, Farm Oshoek, 15 Feb. 1961, *Devenish 582* (PRE, holo.; K, NBG, iso.).

Gladiolus appendiculatus var. *longifolius* G.J.Lewis in Lewis et al.: 69 (1972). Type: Swaziland [Eswatini], Hlatikulu, May 1906, *Stewart s.n.* (BOL, holo.).

Plants 350–600(–850) mm high. *Corm* globose, 15–20 mm diam.; tunics leathery to firm-papery, becoming ± fibrous or irregularly broken. *Stem* evidently erect and ± straight, unbranched. *Leaves* 6 to 9, lower 4 or 5 basal, either narrow and reaching to at least base of spike and often shortly exceeding it or broad and reaching only to middle of stem, lanceolate or narrowly sword-shaped to linear, (2.5–)4.0–12.0(–20.0) mm wide, sometimes longitudinally concave or channelled, main vein usually lightly thickened, margins lightly to fairly heavily thickened, intercostal surface occasionally shortly hairy, cauline leaves progressively smaller, uppermost 1 or 2 usually entirely sheathing. *Spike* ± erect and straight, 6- to 14(–27)-flowered; bracts firm-textured, green to grey-purple but usually dry and brownish above by anthesis, outer 18–30 mm long, overlapping and usually ½–2 internodes long, inner shorter or almost as long. *Flowers* white or pale to deep pink, lower laterals or all 3 lower tepals with small purplish spot or sometimes crescent in upper ⅓, yellowish in throat, unscented; perianth tube obliquely funnel-shaped, ± 15 mm long; tepals ovate, ± acute, upper 3 largest, 15–18 × 10–12 mm, dorsal arching over stamens, strongly channelled, upper laterals directed forward, curving outward in distal ⅓, lower 3 tepals united for ± 3 mm, 9–12 mm long, channelled below, curving downward above. *Filaments* 9–11 mm long, exserted ± 3 mm from tube; anthers appressed to dorsal tepal, 8–9 mm long including sterile spurs 3–4 mm long, pale yellow fading to mauve, spurs white, held at right angles to anther thecae; pollen whitish. *Style* arching over stamens, dividing opposite upper ⅓ of anthers, branches ± 3 mm long. *Capsules* and *seeds* unknown. *Flowering time*: mainly April and May, occasionally March.

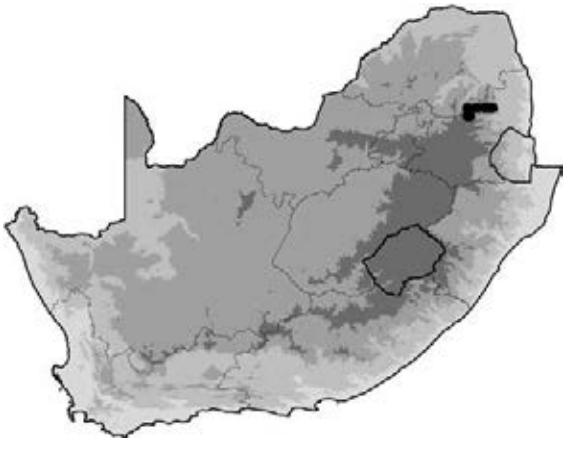
Distribution and ecology: extending along the eastern escarpment from Mariepskop and Pilgrim's Rest in Mpumalanga into Eswatini and as far as south as Vryheid in northern KwaZulu-Natal; in rocky grassland, at least sometimes in dolerite clay, usually above 1 800 m.

Diagnosis: among the three species with basally spurred anthers, *Gladiolus appendiculatus* is recognised by its short-tubed, white or pale pink flowers with perianth tube ± 15 mm long. The species includes two distinct forms. Taller plants, more than 450 mm tall, with narrow leaves 2.5–8.0 mm wide reaching to the middle of the spike and with up to 25 flowers per spike, are known from Eswatini and near Lydenburg in Mpumalanga. Shorter plants with broader leaves 8–12 mm wide not

Distribution of ***Gladiolus appendiculatus***.

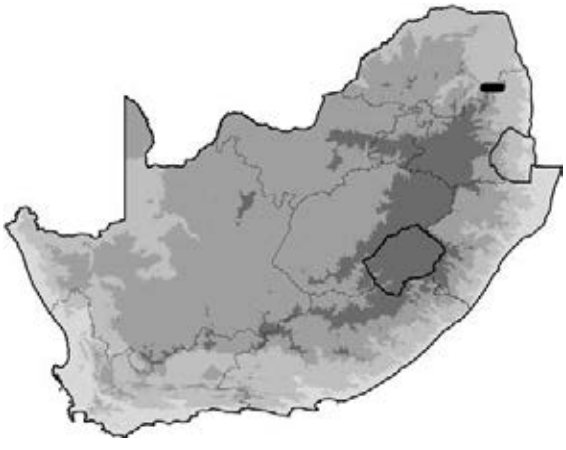
reaching the base of the spike and with 5 to 12 flowers per spike have been recorded from Pilgrim's Rest and Barberton to Wakkerstroom and Vryheid. Intermediates occur near Lydenburg and Barberton.

12. **Gladiolus calcaratus** *G.J.Lewis* in Lewis et al. in Journal of South African Botany, Suppl. 10: 67 (1972). Type: South Africa, [Mpumalanga], Lydenburg District, Long Tom Pass, near highest point, 4 Mar. 1968, *Mauve & Leistner 3218* (PRE, lecto., designated by Goldblatt & Manning: 87 (1998); K, PRE, isolecto.).



Plants 300–450 mm high. *Corm* globose, 12–15 mm diam., bearing small cormlets at base; tunics leathery to ± woody, decaying into fairly coarse vertical fibres. *Stem* erect, simple, usually slightly flexed above sheaths of upper 2 leaves. *Leaves* 6 to 8, lower 3 to 5 basal, reaching to between middle of stem and middle of spike, narrowly sword-shaped to nearly linear, 4–8 mm wide, main vein and margins moderately thickened, cauline leaves decreasing in size and progressively reduced, upper 1 or 2 ± entirely sheathing. *Spike* ± straight, 6- to 10-flowered; bracts firm-textured, dark green, dry and brownish above, outer 35–45(–55) mm long, overlapping, 1.5–2.0 internodes long, lightly folded in midline, inner shorter. *Flowers* white, fading to pale pink or lilac, especially in midlines of tepals, yellow in throat, lower tepals each with pale yellowish median longitudinal streak outlined in pale dull pink, unscented; perianth tube obliquely funnel-shaped, (16–)25–40 mm long, lower cylindric part (12–)20–32 mm long; tepals broadly lanceolate, upper 3 largest, 28–33 × 12–14 mm, dorsal extended horizontally and curving upward near tip, upper laterals sometimes up to 5 mm longer than dorsal, directed forward, curving outward in distal fourth, lower 3 tepals basally united for ± 2 mm, lower laterals 20–22 × ± 12 mm, lower median 23–30 × ± 12 mm. *Filaments* 12–14 mm long, exserted ± 7 mm from tube; anthers 9–12 mm long, including sterile tails or spurs 3–4 mm long, whitish; pollen cream-coloured. *Style* arching over stamens, dividing at or shortly beyond anther apices, branches 3.0–4.5 mm long. *Capsules* obovoid, 3-lobed above, 10–12 mm long. *Seeds* narrowly ovate to pear-shaped, 4–5 × ± 2 mm, unevenly and weakly winged, sometimes one half without a wing. *Flowering time*: mid-February to early April.

Distribution and ecology: endemic to the higher parts of the eastern escarpment in Mpumalanga, South Africa, from Dullstroom and Kemp's Heights to Mt Sheba, with an outlying record from Loskop Dam to the west; in seasonally damp grassland.



Diagnosis: recognised by the relatively large, white or pinkish flushed flowers with a moderately long perianth tube (16–)25–40 mm long and the basally spurred or tailed anthers.

13. **Gladiolus macneilii** *Oberm.* in Lewis et al. in Journal of South African Botany, Suppl. 10: 84 (1972). Type: South Africa, [Mpumalanga], Pilgrims Rest District, Abel Erasmus Pass, dolomite in red loam, 17 Apr. 1969, *Mauve & MacNeil 4788* (PRE, holo.; BOL, K, NBG, iso.).

Plants 700–900 mm high. *Corm* ovoid, 16–22 mm diam.; tunics cartilaginous, soon decaying into pale, medium-textured fibres. *Stem* erect, flexed outward above sheaths of upper 2 or 3 leaves, simple or with 1 or 2 short branches. *Leaves* 8 or 9, lower 4 basal and reaching to between base and middle of spike, blades linear, mostly 2.5–4.0 mm wide, main vein moderately thickened and raised, margins lightly thickened, cauline leaves progressively smaller and largely sheathing. *Spike* usually inclined, weakly flexuose, 7- to 17-flowered; bracts narrowly lanceolate-attenuate, pale green in bud, becoming membranous to dry and light pinkish brown above, dry at end of flowering, apices dark brown, outer (25–)30–40(–50) mm long, ± 2 internodes long, inner shorter. *Flowers* cream-coloured to pale salmon-pink, lower 3 tepals each with dark red longitudinal median streak, unscented; perianth tube 40–45 mm long, cylindric below, curved and flared outward in upper ± 8 mm; tepals lanceolate-attenuate, upper 3 largest, dorsal ± 30 × 15 mm, arching over stamens, upper laterals directed forward and curving outward lightly in distal ⅓, ± 27 × 13 mm, lower 3 tepals united basally for

Distribution of ***Gladiolus calcaratus***.

Distribution of ***Gladiolus macneilii***.

4–5 mm, apices narrow and recurving, lower laterals ± 18 × 4 mm, lower median ± 25 × 7 mm. *Filaments* 12–14 mm long, exserted ± 5 mm from tube; anthers 10–12 mm long, including sterile tails 1.5–2.5 mm long, apiculate, purple; pollen pale yellow. *Style* extending horizontally over stamens, dividing opposite anther apices, branches ± 2 mm long. *Capsules* obovoid, 3-lobed above and retuse, 15–20 mm long. *Seeds* oblong, broadly winged, ± 6 mm long. *Flowering time*: March and April.

Distribution and ecology: a local endemic known only from the Abel Erasmus Pass in Mpumalanga, South Africa; in dolomite outcrops in grassland and open woodland.

Diagnosis: readily recognised by the narrow leaves and long-tubed, white to pale salmon-pink flowers with attenuate tepals, slender perianth tube 40–45 mm long, and basally spurred anthers.

Sect. 2. **Ophiolyza** *(Klatt) Goldblatt & J.C.Manning*, *Gladiolus* in southern Africa: 99 (1998). *Gladiolus* subg. *Ophiolyza* Klatt: 343 (1882). Type species: *Gladiolus natalensis* Reinw. ex Hook.f. = *G. dalenii* Van Geel.

Plants medium-sized to large. *Stem* branched or unbranched, glabrous or pubescent. *Corm* tunics papery or leathery to fibrous. *Leaves* several, mostly basal in a fan, sometimes with a pseudostem formed by clasping sheaths, narrowly lanceolate to lanceolate, firm-textured, plane with thickened main vein and margins, usually at least 4 mm wide, smooth or pubescent. *Spike* often many-flowered, usually crowded, sometimes 2-ranked; bracts glabrous or pubescent, margins of inner bracts sometimes connate and tubular around ovary. *Flowers* medium to large, weakly or more strongly bilabiate, nectar guides usually present, often of streaks or speckles on a paler ground, unscented; perianth tube usually obliquely funnel-shaped, shorter or longer than dorsal tepal; lower tepals narrower but usually ± as long as upper. *Anthers* without tails. *Capsules* usually large, oblong and rounded or obscurely lobed above. *Seeds* broadly and evenly winged.

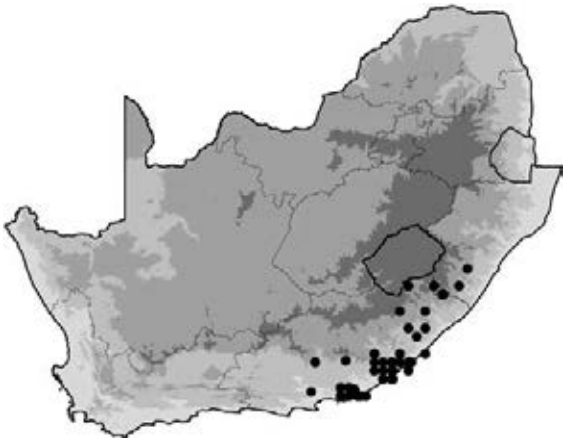
Defined by the basal fan of lanceolate leaves and the dense spike of mostly relatively large, unscented flowers often with nectar guides streaked or speckled on a paler ground, sect. *Ophiolyza* is restricted to grasslands and savannas in the summer-rainfall region. The section includes 21 southern African species, as well as several from tropical Africa.

Ser. **Scabridi** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus scabridus* Goldblatt & J.C.Manning

Corm globose to depressed-globose; tunics leathery or firmly papery to fibrous. *Stems* glabrous or scabrid-pubescent. *Leaves* leathery or relatively soft-textured, margins and midrib often only weakly thickened, glabrous or scabrid-pubescent; bracts glabrous or scabrid-pubescent. *Spike* subsecund. *Flowers* mostly moderate-sized, often deep pink with red streaks on lower tepals; perianth tube usually longer than dorsal tepal.

14. **Gladiolus ochroleucus** *Baker* in Journal of Botany, British and foreign 14: 182 (1876a). Type: South Africa, [Eastern Cape], Umtata District, Baziya Mountain, Dec.–Mar., *Baur 94* (K, holo.; B, BOL, SAM, iso.).

Gladiolus kirkii Baker: 524 (1890). Type: South Africa, [Eastern Cape], King William's Town, cultivated in Britain, 30 July 1890, *Kirk s.n.* (K, holo.).



Gladiolus reductus Baker: 4: 1006 (1904a). Type: South Africa, [Eastern Cape], East London, Feb. 1898, *Seifert sub Conrath 581* (GZU, holo. [photo at PRE]).

Gladiolus masoniorum C.H.Wright: 305 (1913). Type: South Africa, [Eastern Cape], Tembuland, cultivated in Britain, 30 May 1913, *Mason & Mason s.n.* (K, holo.).

Gladiolus stanfordiae L.Bolus: 293 (1927b). Type: South Africa, [Eastern Cape], without precise locality, cult. hort. Stanford, Stellenbosch, Feb. 1927, *Stanford s.n.* (BOL, holo.).

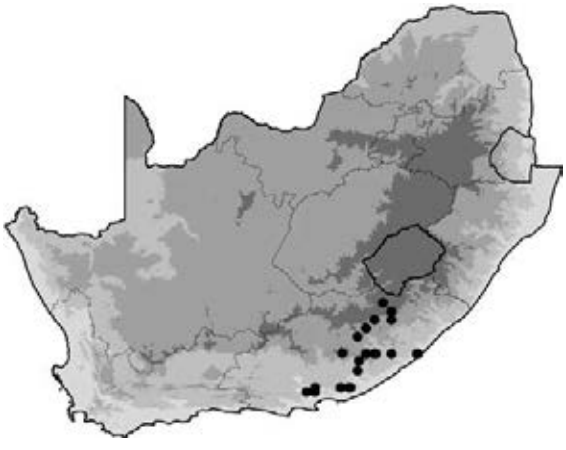
Gladiolus triangulus G.J.Lewis: 140, fig. a (1933). Type: South Africa, [Eastern Cape], Albany District, Bushman's River, cult. Kirstenbosch Gardens, 27 Apr. 1933, *Holland 4006* (BOL, lecto., designated by Goldblatt & Manning: 89 (1998); BOL, isolecto.).

Plants (300–)400–800 mm high, occasionally ± evergreen. *Corm* globose to depressed-globose, 25–35 mm diam.; tunics leathery to firm-papery, decaying into irregularly shaped fragments. *Stem* erect, simple or with 1 or 2 short branches. *Leaves* 7 to 12, mostly basal in a close fan, ± ½ as long as stem with longest reaching base of spike, blades narrowly lanceolate, (8–)15–25 mm wide, margins and main vein moderately thickened, margins sometimes minutely ciliate to scabrid, secondary and tertiary veins also lightly thickened, cauline leaves shorter than basal. *Spike* flexed at base and inclined (4–)12- to 18-flowered; bracts green, outer 25–40(–50) mm long, acute or sometimes attenuate, inner slightly shorter, bifid or deeply divided. *Flowers* pink to light purple or reddish, whitish or yellow flushed brownish on reverse, lower tepals white in basal ½, sometimes with dark red-purple median streaks, reddish at top of tube, unscented; perianth tube obliquely funnel-shaped, 15–20 mm long; tepals ovate, margins ± undulate, upper 3 largest, 24–28 × 18–20 mm, dorsal hooded and horizontal, upper laterals usually slightly longer than dorsal, usually flaring outward distally or

Distribution of ***Gladiolus ochroleucus***.

directed forward, lower lateral tepals smallest, 16–19 × ± 9 mm, narrowly channelled, directed forward, lower median curving downward distally. *Filaments* 10–12 mm long, exserted ± 5 mm from tube; anthers ± 9 mm long, pale mauve; pollen cream-coloured. *Style* arching over stamens, dividing opposite upper ⅓ of anthers, branches ± 4 mm long. *Capsules* narrowly obovoid-oblong, 3-lobed above and retuse, (20–)25–30 mm long, shorter than bracts. *Seeds* oval, 8–9 × ± 5 mm, broadly and evenly winged. *Flowering time*: December to April, or as late as May.

Distribution and ecology: extending along the southeastern seaboard of South Africa, from the Zuurberg west of Grahamstown in Eastern Cape to Byrne in southern KwaZulu-Natal; in grassland and open woodland, from near sea level to 1 200 m.



Diagnosis: recognised by the basal fan of lanceolate leaves and smallish, short-tubed flowers with relatively long, green bracts 25–50 mm long and perianth tube 15–20 mm long. The leaf margins are often ciliolate or scabrid. Plants from the northern and central parts of the range, in southern KwaZulu-Natal and Transkei [Eastern Cape], have creamy yellow flowers, while those from south of the Kei River are mostly bright pink. A dark purple form occurs near East London. *Gladiolus mortonius* from slightly higher elevations inland has a considerably longer perianth tube, 30–45 mm long, and firmer, more fibrous leaves.

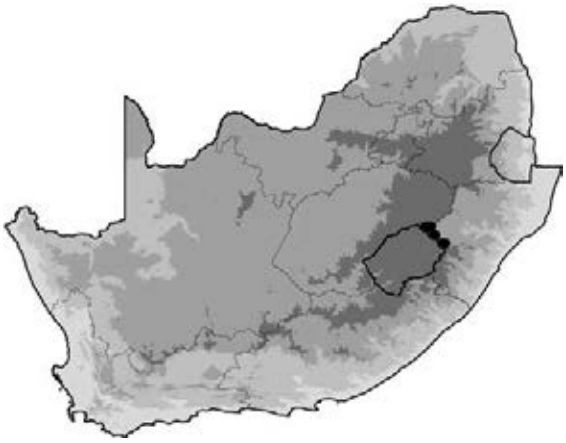
15. **Gladiolus mortonius** *Herb.* in Curtis's Botanical Magazine 65: t. 3680 (1838) & sub t. 3693 (1838). *G. blandus* var. *mortonius* (Herb.) Baker: 217 (1892). Type: South Africa, without precise locality, illustration in Herb.: t. 3680 (1838).

Gladiolus macowanii Baker: 219 (1892). *G. ochroleucus* var. *macowanii* (Baker) Oberm. in Lewis et al.: 37 (1972). *G. massonii* Klatt in Th.Durand & H.Schinz: 220 (1894), illegitimate superfluous name. Type: South Africa, [Eastern Cape], Somerset East, slopes of Boschberg, Apr. 1869, *MacOwan 236* (K, lecto., designated by Goldblatt & Manning: 91 (1998), K; BOL, G, GRA, S, Z, isolecto.).

Gladiolus davisoniae F.Bolus: 98 (1917). Type: South Africa, [Eastern Cape], Berlin, Somerset East mountains, cultivated in Cape Town, 17 Mar. 1915, *De Courcy s.n.* (BOL 14762, holo. [on 2 sheets]).

Plants 400–720 mm high. *Corm* globose to depressed-globose, (20–)30–50 mm diam.; tunics leathery to firm-papery, decaying into irregular fragments. *Stem* erect, simple, rarely with one branch. *Leaves* 7 to 12, mostly basal in a tight fan, ± ½ as long as stem with longest reaching to between middle of stem and base of spike, blades narrowly lanceolate, (8–)15–25 mm wide, margins and main vein moderately thickened, sometimes ciliolate on margins, secondary and tertiary veins also lightly thickened, cauline leaves shorter. *Spike* flexed at base and inclined, 5- to 16-flowered; bracts pale green, sometimes glaucous, the outer 40–60 mm long, acute to attenuate, inner shorter to ± as long as outer, usually minutely forked. *Flowers* pink, lower tepals each with red median streak flanked by a few fine reddish longitudinal lines, base of throat dark red, unscented; perianth tube cylindric and curving outward above, (20–)30–45 mm long, expanded gradually in upper 6–8 mm; tepals lanceolate-ovate, margins undulate, 3 upper largest, 32–40 × 20 mm, dorsal arching over stamens, upper laterals usually slightly longer and wider than dorsal, usually directed forward and flaring outward distally, lower 3 tepals joined basally for ± 4 mm, lower laterals 30–35 × 12–16 mm, lower median ± as long as upper tepals, 32–40 × 12–18 mm, directed forward, lowermost tepal curving downward distally. *Filaments* ± 14 mm long, exserted 4–7 mm from tube; anthers 12–15 mm long, shortly apiculate, usually purple; pollen whitish. *Style* arching over stamens, dividing opposite anther tips, branches 4–6 mm long. *Capsules* narrowly obovoid-oblong, 3-lobed above and retuse, 28–32 mm long, shorter than bracts. *Seeds* ovate, ± 8 × 5 mm, broadly and evenly winged. *Flowering time*: February to April.

Distribution of ***Gladiolus mortonius***.



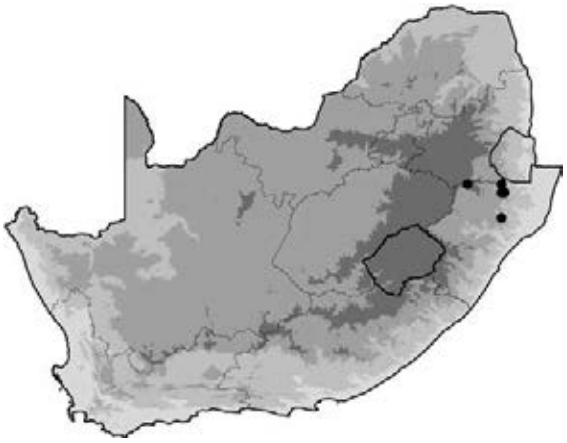
Distribution and ecology: endemic to the Eastern Cape, South Africa, from Elliot through the Winterberg and Amatole Mtns to the Boschberg near Somerset East and the Zuurberg; in stony grassland, mostly at moderate to higher elevations.

Diagnosis: distinguished from *Gladiolus ochroleucus* by the larger, consistently pink flowers with longer perianth tube, 30–45 mm long. *Gladiolus mortonius* can be confused with forms of *G. oppositiflorus*, but that species has a markedly 2-ranked spike and distinctive floral bracts, somewhat inflated below with the margins of the inner bracts connate and tubular around the ovary and the apices drawn into long, brown-tipped cusps.

16. **Gladiolus microcarpus** *G.J.Lewis* in Lewis et al. Journal of South African Botany, Suppl. 10: 85 (1972). Type: South Africa, [KwaZulu-Natal], Cathedral Peak Forest Station, cliffs in Ndumeni River Valley, 7 Feb. 1958, *Killick 1655* (PRE, holo.).

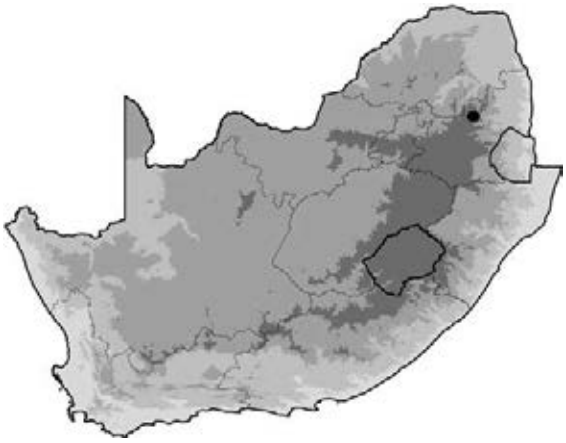
Plants up to 1 m high, usually inclined or pendent, with densely puberulous cataphylls. *Corm* ± globose, ± 20 mm diam.; tunics membranous to finely fibrous. *Stem* inclined or drooping, unbranched or with 1 to 3 branches. *Leaves* 5 to 7, lower 3 ± basal, ± as long or longer than stem but trailing, narrowly lanceolate, 6–12 mm wide, main vein strongly thickened and raised, a pair of secondary veins, 1 or 2 pairs of tertiary veins and margins lightly raised, with minute hairs on blades and sheaths, cauline leaves decreasing in size above. *Spike* inclined to ascending, lightly flexuose, (5)8- to 12-flowered, sub-2-ranked; bracts dull green to dull greenish purple, lightly ridged, outer 25–35 mm long, ± 2.5 internodes long, inner shorter and completely enclosed, forked apically. *Flowers* bright pink, lower 3 tepals each with broad white longitudinal zone in lower ⅔ with narrow reddish purple streak in midline, reddish at base of throat, unscented; perianth tube obliquely funnel-shaped, 35–40 mm long, cylindric in lower 30–35 mm; tepals lanceolate, outer whorl smaller than inner, dorsal largest, 35–40 × ± 17 mm, ascending and inclined over stamens, upper laterals curving outward near tips, 25–30 × ± 10 mm, lower laterals lightly inclined, tips curving downward, 32–35 × ± 13 mm, lower median 24–26 × ± 8 mm. *Filaments* ± 15 mm long, exserted ± 10 mm from tube; anthers ± 8 mm long, whitish to lilac, apiculate; pollen white. *Style* arching over stamens, dividing shortly beyond anther apices, branches ± 4 mm long. *Capsules* oblong, 3-lobed above and retuse, 12–15 mm long, enclosed in bracts. *Seeds* oblong, broadly and evenly winged, ± 5 × 4 mm. *Flowering time*: December to late January at lower elevations, to early March at higher elevations.

Distribution and ecology: a local endemic of the high Drakensberg of Lesotho and central KwaZulu-Natal and adjacent Free State, South Africa, from Witzieshoek and the Mahai Valley to Cathkin Park; on seasonally wet basalt or sometimes sandstone outcrops and cliffs, from 1 800 to 2 700 m elevation.



Distribution of ***Gladiolus microcarpus***.

Diagnosis: recognised by its drooping spikes of long-tubed pink flowers with slender perianth tube 35–40 mm long, attenuate tepals with the outer whorl subequal and notably wider than the inner whorl. The cataphylls and leaves are minutely pubescent. The habitat on wet cliffs and rocks is characteristic.



17. **Gladiolus scabridus** *Goldblatt & J.C.Manning*, *Gladiolus* in southern Africa: 94 (1998). Type: South Africa, [KwaZulu-Natal], Itala Nature Reserve, Craigadam Farm, Mabomvu Ridge, 2 950 ft [890 m], 5 Jan. 1978, *McDonald 399* (NU, holo.; K, PRE, iso.).

Gladiolus microcarpus subsp. *italaensis* Oberm.: 451 (1981). Type: South Africa, [KwaZulu-Natal], Itala Nature Reserve, hills above Pongola River, 10 Jan. 1980, *Mauve & Reid 5266* (PRE, holo.).

Plants up to 1 m high, sometimes puberulous on cataphylls. *Corm* ± globose, 30–35 mm diam.; tunics firm-papery becoming fibrous. *Stem* erect, scabrid, simple or 1- or 2-branched. *Leaves* 7 to 9, lower 5 or 6 ± basal in a loose fan reaching to between base and apex of spike, scabrid-papillose, sword-shaped, usually 10–20(–24) mm wide, main and a pair of secondary veins moderately thickened and raised, margins less so, cauline leaves decreasing in size above, uppermost often entirely sheathing. *Spike* erect and straight, 10- to 16-flowered; bracts dull green to dull greenish purple, scabrid, often ± dry above, apices twisted outward, outer 25–35 mm long, ± 2.5 internodes long, inner forked, shorter to slightly longer than outer. *Flowers* pink, lower 3 tepals with narrow white longitudinal zone in lower ⅔ and reddish median streak, unscented; perianth tube obliquely funnel-shaped, 35–40 mm long, cylindric in lower 30–35 mm; tepals lanceolate, upper 3 largest and subequal, 40–45 mm long, dorsal 18–20 mm wide, upper laterals 16–18 mm wide, lower 3 tepals joined to upper laterals for 3–4 mm and together for ± 4 mm, ± straight, tilted toward ground, 35–40 × 10–12 mm. *Filaments* 15–16 mm long, exserted ± 8 mm from tube; anthers 10–13 mm long, pale yellow; pollen white. *Style*

Distribution of ***Gladiolus scabridus***.

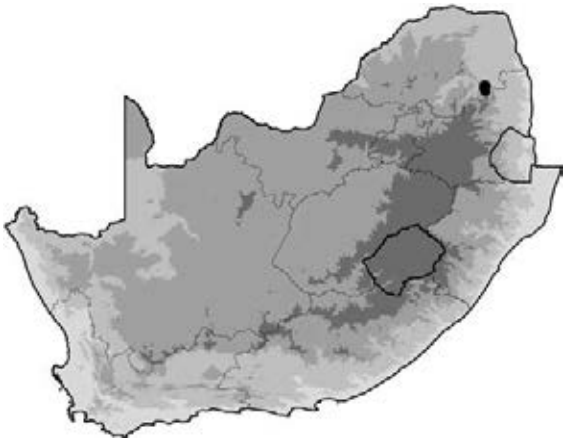
Distribution of ***Gladiolus cataractarum***.

arching over stamens, dividing opposite or shortly beyond anther apices, branches 5–6 mm long. *Capsules* oblong, 3-lobed above and retuse, 16–22 mm long. *Seeds* broadly ovate, 6–8 × 4–5 mm, ± evenly winged or wing only on one side. *Flowering time*: December to late January at lower elevations, sometimes into late February in cooler, wetter sites.

Distribution and ecology: restricted to southern Eswatini and northern KwaZulu-Natal and southern Mpumalanga, South Africa, along the Pongola River; in well-drained rocky sites in open woodland on quartzite outcrops, from 1 000 to 2 000 m elevation.

Diagnosis: distinguished by the scabridulous stems, leaves and floral bracts, and the long-tubed, pink flowers with slender perianth tube 35–40 mm long. *Gladiolus microcarpus* has similar long-tubed, pink flowers but hairless, drooping stems and attenuate tepals.

18. **Gladiolus cataractarum** *Oberm.* in Bothalia 14: 78 (1982). Type: South Africa, [Mpumalanga], near Dullstroom, Farm Waterval above Lunsklip Waterfall, Feb. 1981, *Krijt s.n.* (PRE 58472, holo. [on two sheets]).



Plants to 0.7 m high. *Corm* globose, ± 30 mm diam.; tunics leathery becoming partly fibrous. *Stem* erect, unbranched. *Leaves* 8 or 9, lower 6 basal and reaching to shortly below base of spike, narrowly to broadly lanceolate, (20–)35–45 mm wide, margins and main vein lightly thickened and hyaline, cauline leaves progressively shorter, largely sheathing. *Spike* straight and erect, 8- to 16-flowered; bracts green, firm-textured, outer 50–60(–70) mm long, attenuate, ± 2 internodes long, inner shorter, minutely forked. *Flowers* pink, lower 3 tepals marked with longitudinal reddish lines along midline, unscented; perianth tube cylindric below, 40–50 mm long, flared outward in upper 10 mm; tepals lanceolate, upper 3 largest, 44–48 × ± 16 mm, dorsal arched to nearly horizontal, upper laterals spreading outward in distal ½, lower lateral tepals ± 40 × 14 mm, spreading distally. *Filaments* ± 12 mm long, exserted ± 4 mm from tube; anthers ± 12 mm long, yellow; pollen yellow. *Style* arching over stamens, dividing shortly beyond anther apices, branches ± 5 mm long. *Capsules* oblong, 3-lobed above and retuse, ± 30 mm long. *Seeds* oblong, 7–8 × 4–5 mm, broadly and evenly winged. *Flowering time*: February to mid-March.

Distribution and ecology: a narrow endemic of the eastern escarpment in Mpumalanga, between Dullstroom and Lydenburg; on cliffs and steep south-facing rocky slopes on quartzite.

Diagnosis: a robust species with leaves 20–45 mm wide, large, long-tubed pink flowers with a perianth tube 40–50 mm long and firm-textured, green bracts 50–70 mm long. *Gladiolus cataractarum* has a general resemblance to *G. saxatilis*, but that species has unmarked flowers with shorter bracts, 40–50 mm long, that turn rusty brown at flowering.

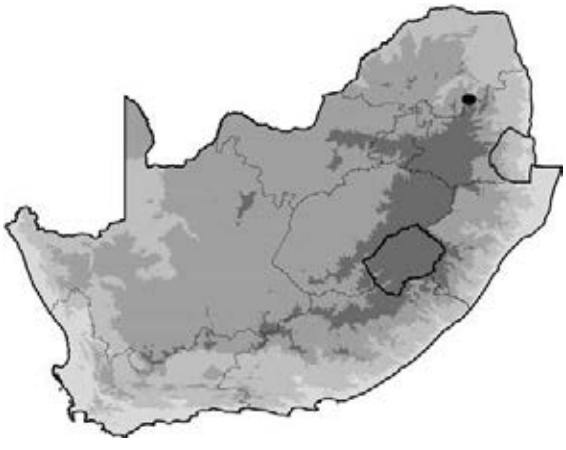
19. **Gladiolus pavonia** *Goldblatt & J.C.Manning* in Novon 6: 174 (1996). Type: South Africa, Mpumalanga, dolomite hill slopes between the top of Abel Erasmus Pass and Strydom Tunnel, 6 Dec. 1994, *Goldblatt & Manning 10131* (NBG, holo.; K, MO, PRE, iso.).

Plants 450–800 mm high. *Corm* ovoid, 8–13 mm diam., with long stolons from base; tunics ± papery, becoming irregularly broken and ± fibrous. *Stem* erect, sometimes flexed outward above sheaths of upper 2 leaves, but remaining erect, unbranched. *Leaves* 6 or 7, lower 3 or 4 ± basal and reaching to base or sometimes slightly exceeding spike, sword-shaped, 8–14 mm wide, usually slightly twisted in upper ½, cauline leaves much smaller, uppermost largely to entirely sheathing. *Spike* erect, (2)4- to 7-flowered, 2-ranked; bracts relatively soft-textured, apices becoming dry and light brown soon after anthesis, outer (15–)23–30 mm long, inner bracts slightly shorter to ± as long, apiculate or minutely forked. *Flowers* pale pink, upper tepals dark red toward base, dorsal ½ of tube dark red distally, lower margins of dorsal tepal with wide transparent band, lower lateral

Distribution of ***Gladiolus pavonia***.

tepals lightly streaked with pink longitudinal lines in basal half, lower median tepal whitish in lower ½ with purple streaks, lower tepals also with white zone and central red spot just below tepal sutures, unscented; perianth tube obliquely funnel-shaped, ± 16 mm long, lower cylindric part ± 8 mm long; tepals widely spreading, dorsal slightly larger than others, ± 25 × 16 mm, curving outward with margins curved back, upper laterals patent distally, 24–26 × 15 mm, lower 3 tepals recurved above, 21–24 × 12 mm. *Filaments* ± 16 mm long, reddish in lower ½, exserted ± 8 mm from tube; anthers ± 8 mm long, curved below the horizontal, dark purple; pollen cream-coloured. *Style* arching over stamens, dividing between base and middle of anthers, branches 5–6 mm long. *Capsules* obovoid, 3-lobed above and retuse, 21–24 mm long. *Seeds* evidently ovate, ± 7 mm long, broadly and evenly winged. *Flowering time*: late November and December, occasionally in late January.

Distribution and ecology: a local endemic restricted to the slopes of the Abel Erasmus Pass in Mpumalanga, South Africa; on steep dolomite slopes in dry woodland.



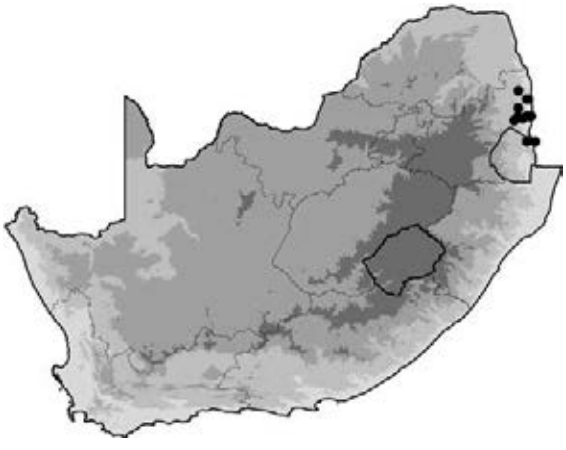
Diagnosis: evidently restricted to dolomite outcrops and distinctive in its long, relatively soft-textured leaves and short-tubed, pale shell-pink flowers with a conspicuous dark red mouth and purple anthers. The slender stolons are characteristic of the species.

20. **Gladiolus reginae** *Goldblatt & J.C.Manning* in Bothalia 39: 41 (2009). Type: South Africa, Mpumalanga, Kennedy's Vale, Two Rivers Mine, hills west of bridge over Klein Dwarsrivier, 26 Mar. 2008, *Manning & Valente 3156* (NBG, holo.; K, MO, NBG, PRE, iso.).

Plants 400–1 500 mm. *Corm* subglobose, ± 20 mm diam.; outer tunics papery, becoming ± fibrous. *Stem* erect or inclined outward above basal leaves, unbranched or occasionally 1-branched. *Leaves* 8 or 9, lower 6 or 7 basal and reaching to base of spike or above, narrowly sword-shaped, (3–)5–10 mm wide, relatively soft-textured with main vein raised, but other veins and margins not thickened, slightly twisted in distal ½, cauline leaves smaller, uppermost largely to entirely sheathing. *Spike* erect, 7- to 16-flowered, 2-ranked; bracts soft-textured, pale green becoming pale straw-coloured and dry shortly after anthesis, outer (20–)22–32 mm long, inner slightly shorter or ± as long, minutely forked apically, margins fused in basal ½ and thus tubular below; outer and inner bracts exuding photosynthate from tips. *Flowers* pale flesh-pink, tepal sutures and tube flushed deeper salmon-coloured, lower 3 tepals flushed deep red laterally in basal third, streaked with 3 main and 2 minor longitudinal lines in basal ½, upper 3 tepals flushed deep red at base, unscented; perianth tube obliquely funnel-shaped, slightly arched distally, 33–35 mm long, basal cylindric portion 25–27 mm long; tepals with upper 3 larger, erect below, recurved in distally, lanceolate-attenuate, margins slightly undulate, dorsal tepal horizontal in basal ½, deeply concave, 33 × 11–12 mm, upper laterals 32–34 × 10–12 mm, lower 3 tepals joined for 1 mm, lower laterals shortest, 28–29 × 9–10 mm, lower median 30 × 9–10 mm. *Filaments* 17 mm long, exserted 7 mm from tube, filaments deep red in basal ⅓; anthers 8–9 mm long, purple; pollen cream-coloured. *Style* arching under dorsal tepal, dividing at or beyond anther apices, branches 4 mm long. *Capsule* obovoid, 3-lobed above and retuse, 30 × 12 mm. *Seeds* oval to oblong, 8–10 × 4–6 mm, ± evenly winged or wing lacking on one side. *Flowering time*: mid-March to mid-April.

Distribution and ecology: a narrow endemic from the lower slopes of the Dwarsrivier Mtns near Kennedy's Vale in Mpumalanga, South Africa; in heavy metal-enriched rock outcrops in open woodland.

Diagnosis: recognised by its long, slender, relatively soft-textured leaves and two-ranked spikes of moderately long-tubed, pale pink flowers with dark red centre, purple anthers and lanceolate-attenuate tepals, the lower three streaked with red. The perianth tube is 33–35 mm long. The margins of the inner bracts are connate below forming a tube enclosing the ovary, and both outer and inner bracts exude drops of photosynthate from the tips that attract ants. The tubular inner



Distribution of ***Gladiolus reginae***.

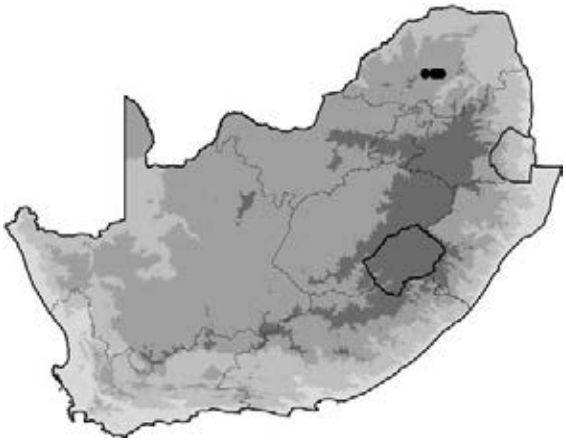
bracts are otherwise characteristic of ser. *Oppositiflori*, where similar exudates are produced by *G. dolomiticus* and *G. pole-evansii*.

21. **Gladiolus brachyphyllus** *F.Bolus* in Annals of the Bolus Herbarium 2: 103 (1917). Type: South Africa, [Mpumalanga], between Komatipoort and Letaba River on the Selati Railway, Nov. 1913, *Rogers 11807* (BOL, holo.; GRA, K, PRE, iso.).

Plants 550–800 mm high. *Corm* globose, ± 20–25 mm diam.; tunics leathery, becoming ± fibrous. *Stem* erect, scarcely flexed outward above sheaths of upper 2 leaves but becoming straight again, simple or occasionally with one branch. *Leaves* 3, all largely sheathing, with short or vestigial blades, lowermost basal, 80–100 mm long, usually overlapping next leaf, second leaf inserted on lower ⅓ of stem, blades of first and second leaves short to vestigial, 5–50 mm long, third leaf inserted in ± middle of stem, with vestigial blade; leaves of non-flowering plants present at flowering time but not fully developed, up to 4 produced, ultimately reaching to ± 600 mm long, linear to narrowly lanceolate, 6–12 mm wide, soft-textured, main vein moderately thickened and raised, margins lightly thickened. *Spike* erect, barely flexuose, 7- to 9-flowered; bracts pale green, relatively soft-textured, outer 25–30 mm long, inner slightly shorter to ± as long, minutely forked. *Flowers* deep pink, lower 3 tepals with broad median band of white in lower ⅔, usually with dark purple streak along midline, base of lower tepals and throat of perianth tube dark red-purple, unscented; perianth tube obliquely funnel-shaped, ± 20 mm long, lower cylindric part ± 10 mm long; tepals obovate to lanceolate, subacute or apiculate, subequal, lower 3 slightly shorter than upper, dorsal extending forward, ± horizontal, ± 28 × 17 mm, upper laterals arching outward from base, ± 30 × 14–15 mm, lower 3 tepals joined to upper laterals for ± 2 mm, curving outward from base, ± 26 × 9–13 mm, lower median slightly larger than lower laterals. *Filaments* ± 17 mm long, exserted ± 8 mm from tube; anthers ± 10 mm long, violet; pollen lilac. *Style* arching over stamens, dividing opposite middle and upper ⅓ of anthers, branches ± 3.5 mm long. *Capsules* ovoid, 3-lobed above and retuse, 20–25 mm long. *Seeds* ovate, ± 10 × 6 mm, broadly and evenly winged. *Flowering time*: October to mid-November.

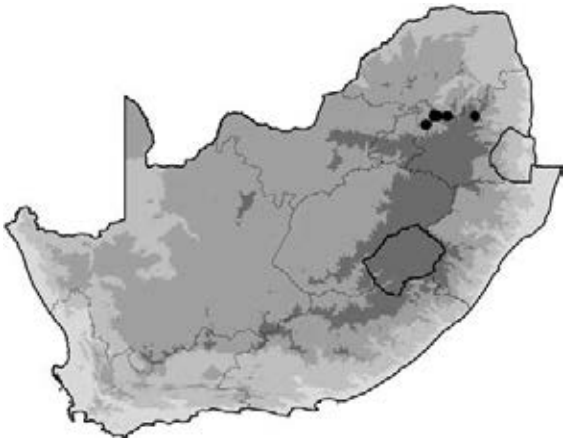
Distribution of ***Gladiolus brachyphyllus***.

Distribution and ecology: restricted to the lowveld and coastal plain of eastern southern Africa, from Klaserie in Limpopo, South Africa through the southern half of the Kruger National Park in Mpumalanga into northern Eswatini and southern Mozambique; on sandy flats and outcrops in dry woodland, flowering in spring at the start of the rainy season.



Diagnosis: flowering in late spring, *Gladiolus brachyphyllus* is distinctive in the foliage with short, largely sheathing leaves, and relatively large, deep pink flowers with dark red throat and violet anthers.

Ser. **Oppositiflori** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus oppositiflorus* Herb.



Corm globose to depressed-globose; tunics leathery or firmly papery to fibrous. *Stems* erect, glabrous or scabrid-pubescent to villous. *Leaves* leathery, margins and midrib thickened, smooth or scabrid-pubescent; bracts smooth or scabrid-pubescent to villous, inner bract margins united around ovary thus tubular below. *Spike* 2-ranked. *Flowers* mostly moderate-sized, with pale median markings on lower tepals; perianth tube usually shorter than dorsal tepal.

22. **Gladiolus dolomiticus** *Oberm.* in Bothalia 12: 636 (1979). Type: South Africa, [Limpopo], Makapansgat Valley, between Research Station and mountain top, 3 Mar. 1976, *Enslin s.n.* (PRE, lecto., designated by Goldblatt & Manning: 100 (1998); PRE, isolecto.).

Plants 700–1 000 mm high. *Corm* depressed-globose, ± 25 mm diam.; tunics leathery becoming coarsely fibrous. *Cataphylls* pubescent. *Stem* erect, softly pubescent, often with 1 to 3 short branches, lightly compressed, oval in section. *Leaves* 7 or 8, lower 4 or 5 basal in a lax fan, pale green, reaching or slightly exceeding spike, narrowly lanceolate, 10–15 mm wide, minutely scabrid on veins, intercostal surfaces minutely pubescent, margins, main and at least one secondary vein pair heavily thickened and raised, cauline leaves inserted well above ground, with short blades. *Spike* straight and erect, ± 2-ranked but flowers secund, 10- to 17-flowered; bracts pale green becoming dry and light brown above, minutely pubescent, often exuding photosynthate drops near apices, outer 26–30 mm long, attenuate, apex often twisted outward, inner slightly shorter to ± as long, forked, margins united below in a tube ± 10 mm long. *Flowers* pale pink, lower tepals each with yellow blotch in midline, throat pale yellow, unscented; perianth tube narrowly and obliquely funnel-shaped, 18–27 mm long; tepals lanceolate-elliptic, upper 3 largest, dorsal arching over stamens, 29–38 × 10–12 mm, upper laterals 30–40 × 12–15 mm, lower 3 tepals joined

Distribution of ***Gladiolus dolomiticus***.

Distribution of ***Gladiolus pole-evansii***.

below for 1–2 mm, laterals 25–30 × 7 mm, lower median 27–35 × 7–12 mm. *Filaments* 9–14 mm long, exserted 4–6 mm from tube; anthers (5–)8–10 mm long, shortly apiculate, pale yellow; pollen pale yellow. *Style* arching over stamens, dividing at or shortly beyond anther apices, branches 4–6 mm long, barely expanded above. *Capsules* narrowly obovoid-oblong, 3-lobed above and retuse, 25–35 mm long. *Seeds* ovate, ± 7 × 4.5 mm, broadly and evenly winged. *Flowering time*: March and April.

Distribution and ecology: a local endemic of Limpopo, South Africa, known only from Makapan Valley (Makapansgat); on rocky dolomite slopes in dry woodland.

Diagnosis: recognised by the pubescent cataphylls, stem, leaves and bracts, and the moderately-sized pale pink flowers with lanceolate-elliptic tepals, perianth tube 18–27 mm long, and relatively short anthers, 4–6 mm long. The leaves are fibrous and the inner bracts are tubular below.

23. **Gladiolus pole-evansii** *Verd.* in Flowering Plants of Africa 35: t. 1373 (1962). Type: South Africa, [Mpumalanga], bushveld near Bronkhorstspruit, Mar. 1936, *Pole Evans 3907* (PRE, lecto., designated by Goldblatt & Manning: 101 (1998); BOL, K, PRE, isolecto.).

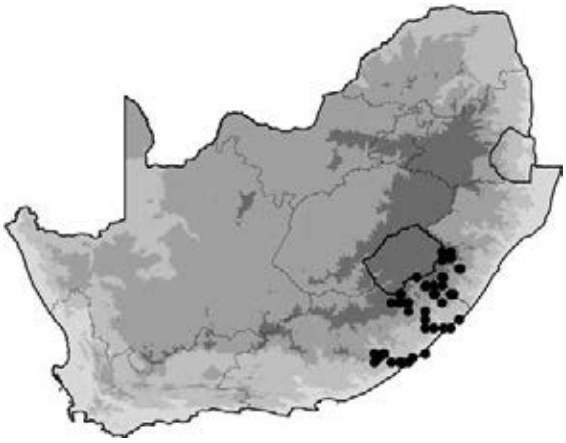
Plants 600–1 100 mm high, with pubescent cataphylls. *Corm* globose, 15–22 mm diam.; tunics firm-papery to coarsely fibrous. *Stem* erect, scabrid, often with 1, rarely up to 3 branches, lightly compressed. *Leaves* 8 or 9, lower 5 or 6 basal in a lax, 2-ranked fan, glaucous-green, reaching to ± base or middle of spike, narrowly lanceolate, 10–15 mm wide, minutely scabrid on veins, intercostal surfaces pubescent, main and at least one other vein pair heavily thickened and raised, margins lightly thickened, cauline leaves inserted well above ground, with fairly short blades or entirely sheathing. *Spike* weakly inclined, often weakly 2-ranked, ± straight, 15- to 20-flowered; bracts pale green, minutely papillose-pubescent, apices usually ± dry at anthesis, often exuding photosynthate drops near apices, 16–25 mm long, up to 1.0(–1.5) internodes long, inner bracts ± as long as to slightly shorter, sometimes obscurely notched, margins united around flower in lower ½. *Flowers* translucent flesh-pink, becoming almost colourless at tepal apices, upper lateral tepals with narrow red lines along midline, lower tepals, or sometimes only lower median, yellow in lower midline with red median streak distal to yellow mark, base of upper part of tube often dark red; perianth tube obliquely funnel-shaped, ± 15 mm long, wider upper part exserted from bracts; tepals lanceolate, dorsal largest, extended horizontally over stamens, ± 28 × 16 mm, upper laterals extended forward below, curving outward and patent above, 24–26 × ± 12 mm, lower 3 tepals straight, inclined toward ground, 21 × ± 9.5 mm. *Filaments* 18–20 mm long, exserted ± 10 mm from tube; anthers 7.5–9.0 mm long, pale purple; pollen yellow. *Style* arching over stamens, dividing close to anther apices, branches ± 4 mm long. *Capsules* oblong, 3-lobed above, retuse, 20–25 mm long. *Seeds* oval to oblong, 8–10 × 4.5–5.5 mm, wing usually developed only on one side. *Flowering time*: mid-January to March.

Distribution and ecology: a fairly narrow endemic of Gauteng and Mpumalanga, South Africa, between Bronkhorstspruit and Groblersdal; in granite outcrops in open woodland.

Diagnosis: recognised by puberulous cataphylls, stems, leaves and bracts, and the relatively small, pale flowers with short perianth tube ± 15 mm long. The bracts are short, 16–25 mm long, usually no more than one internode long, and the inner bracts are tubular in the lower half. The bracts and bracteoles exude photosynthate from the tips that attract ants onto the inflorescence, a remarkable feature otherwise known only in *Gladiolus dolomiticus* Oberm. and *G. reginae* Goldblatt & J.C.Manning.

24. **Gladiolus oppositiflorus** *Herb.* in Edwards' Botanical Register 28: Miscell. 86 (1842). Type: South Africa [said to be from Madagascar], without precise locality or collector, cult. at Spofforth, Yorkshire, England, *Herbert s.n.* (K, holo. [photo at PRE]).

Gladiolus salmoneus Baker: 217 (1892). *G. oppositiflorus* subsp. *salmoneus* (Baker) Oberm. in Lewis et al.: 26 (1972). Type: South Africa, [KwaZulu-Natal], mountains around Kokstad, 1 600 m, Mar. 1883, *Tyson 1180* (K, holo.; BOL, SAM, iso.).



Gladiolus blackwellii L.Bolus: 77 (1921). Type: South Africa, [Eastern Cape], Tembuland, cult. Cape Town, Dec. 1917, *Blackwell s.n.* (BOL, lecto., designated by Goldblatt & Manning: 102 (1998); K, PRE, isolecto.).

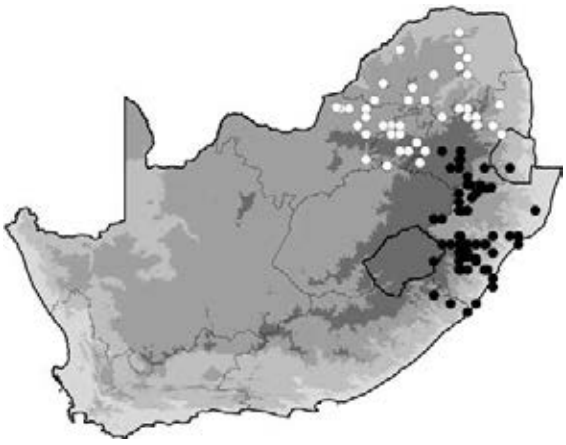
Plants (400–)600–1 600 mm high, with velvety cataphylls. *Corm* depressed-globose, 30–40 mm diam.; tunics firm-papery to leathery, fragmenting irregularly but usually extending upward a short distance as coarse fibrous collar around base of stem. *Stem* erect and straight, often sparsely pubescent, unbranched. *Leaves* usually 7 or 8, mostly basal, sometimes forming pseudostem, reaching at least to base of spike or sometimes shortly exceeding it, imbricate and concealing lower ⅔ of stem, narrowly sword-shaped to nearly linear, 12–18(–24) mm wide, firm to rigid, main vein and margins strongly thickened, usually notably velvety between veins, uppermost leaf inserted in middle of stem, shorter. *Spike* straight and erect, weakly or fully 2-ranked, 7- to 15(26)-flowered; bracts green, firm-textured, attenuate, sometimes sparsely pubescent to velvety below, (27–)32–50(–62) mm long, inner slightly shorter, with margins united below and sheathing base of tube, forked into attenuate cusps 2–4 mm long. *Flowers* salmon- to pale pink or mauve, lower 3 tepals paler in midline and with reddish to purple median streak in lower ½, tube red or purple in throat and sometimes on reverse, unscented; perianth tube narrow and curving outward, expanded slightly near apex, (28–)40–50(–55) mm long; tepals lanceolate-elliptic, margins undulate, upper 3 largest, (37–)45–60 mm long, dorsal 20–25(–30) mm wide, arching over stamens, upper laterals curving outward in distal ½ when fully open, lower 3 tepals united for 3–4 mm, laterals shorter than lower median, ± 13 mm wide, arching downward distally. *Filaments* 15–17(–20) mm long, exserted 6–10 mm from tube; anthers ± 11 mm long, reaching to ± middle of dorsal tepal, pale mauve; pollen cream-coloured. *Style* arching over stamens, dividing 2–4 mm beyond anther apices, branches 6–7 mm long. *Capsules* narrowly obovoid-oblong, 3-lobed above, truncate to retuse, 20–25 mm long. *Seeds* ovate, ± 6 × 4 mm, broadly and evenly winged. *Flowering time*: mostly February and March, occasionally in December or April to early May.

Distribution and ecology: scattered through the south-eastern parts of South Africa, from Polela in KwaZulu-Natal through the mountains of Eastern Cape (Transkei) to the coast near East London; in open grassland, often on rocky slopes.

Occasional hybrids with *Gladiolus saundersii* have been reported from Naude's Nek in Eastern Cape.

Diagnosis: recognised by the two-ranked spikes of large, long-tubed flowers, the perianth tube (28–)40–55 mm long, the bracts ± inflated and the inner tubular below. The stem, leaves and bracts are either smooth or more often puberulous. The typical form of the species from the coastal Eastern Cape is tall with markedly two-ranked spikes of bright pink to mauve flowers. Plants from higher elevations inland are shorter with salmon-pink flowers in less markedly two-ranked spikes. *Gladiolus oppositiflorus* is most likely to be confused with *G. mortonius*, but that species has the leaves in a short fan not reaching above the base of the 1-sided spike, and the inner bracts are open to the base and not drawn into cusps above.

Distribution of ***Gladiolus oppositiflorus***.



25. **Gladiolus sericeovillosus** *Hook.f.* in Curtis's Botanical Magazine 90: t. 5427 (1864). *Antholyza hirsuta* Klatt: 379 (1867b), illegitimate superfluous name for *G. sericeovillosus* Hook.f. and an illegitimate homonym, not *A. hirsuta* Lam. (1783). Type: South Africa, without precise locality, 'interior of the Cape Colony,' ± 1862, cult. in England, *Cooper s.n.*, illustration in Hook.f.: t. 5427 (1864).

Plants 350–1 000 mm high, with puberulous cataphylls. *Corm* depressed-globose, 25–35 mm diam., tunics firm-papery to leathery, decaying into vertical fibrous strips, usually drawn into stiff points above. *Stem* straight and erect, occasionally branched, sparsely pubescent where not sheathed by leaves, or smooth. *Leaves* 5 to 7, lower 4 or 5 basal, reaching to base of spike or much exceeding it, villous to microscopically pubescent on sheaths and blades, sometimes sparsely so on lower parts of leaves, or entirely smooth, narrowly sword-shaped to linear, 3–16 mm wide, margins, main and often 1 or more secondary vein pairs moderately to strongly thickened and hyaline, cauline leaves much shorter, uppermost entirely sheathing. *Spike* 2-ranked, erect and straight, rachis sometimes pubescent, 12- to 20(40)-flowered; bracts pale green and soft-textured, becoming membranous toward apices, usually dry and pale in upper 5 mm, ± inflated and pleated below, villous to minutely pubescent or smooth, 15–30 mm long, acute-attenuate, apices often twisted, inner bracts with

margins usually united around base of flower, slightly shorter to slightly longer, forked with attenuate cusps 2–4 mm long. *Flowers* greenish to cream-coloured, pink, pale lilac, or dull brownish red, tepals unicoloured or minutely dotted with dark red to maroon, often more densely along midlines, lower laterals or all lower tepals yellow-green in basal half or with darker spade-shaped markings distally, unscented; perianth tube obliquely funnel-shaped, widening and curving outward near apex, 10–16 mm long, extended between bracts; tepals with dorsal longest, hooded, (18–)25–32 × 12–15 mm, upper lateral tepals directed forward, usually curving outward in upper ⅓, 22–30 × 13–15 mm, lower 3 tepals united for ± 1.5 mm, laterals 16–22 × ± 7 mm, curving outward above, narrowed somewhat below, lower median curving toward ground, 20–25 × 10 mm. *Filaments* 10–12 mm long, exserted 6–8 mm from tube; anthers 8–10 mm long, reaching distal ⅓ of dorsal tepal, yellow; pollen whitish. *Style* arching over stamens, dividing between base and upper ⅓ of anthers, branches 4–5 mm long. *Capsules* obovoid to oblong, 3-lobed and auriculate above, 12–23 mm long. *Seeds* ovate, 5–7 × ± 4 mm, broadly and evenly winged. *Flowering time*: late summer and autumn, mainly February to April.

Distribution and ecology: widespread through eastern southern Africa, extending from Umtata in Eastern Cape, South Africa in the south to Eswatini and eastern Zimbabwe in the north; in a variety of subtropical habitats but mainly grassland, open woodland or savanna, usually in clay soils.

Diagnosis: recognised by the markedly two-ranked spikes of rather dull coloured, often greenish flowers with inflated, pleated bracts. The narrow, fibrous leaves often form a distinct pseudostem, the blades arising well above the ground, with strongly thickened midrib, margins and one or more pairs of other veins. Plants flower in the late summer and autumn. The typical form, ranging from Lydenburg southward, is more-or-less densely puberulous to villous on stems, leaves and bracts, and is treated as subsp. *sericeovillosus*. Plants from northern and northwestern South Africa into subtropical Africa are at best sparely pubescent or entirely glabrous, cataphylls excepted, and are treated as subsp. *calvatus*.

Type: South Africa, [Mpumalanga], Umvoti Creek, Apr. 1890, *Galpin 925* (K, lecto., designated by Lewis et al.: 31 (1972), K; BOL, SAM, isolecto.).

Gladiolus rigidifolius Baker: 1006 (1904a). Type: South Africa, [Gauteng], Modderfontein, Dec. 1897, *Conrath 577* (Z, holo.; GZU, K [photo at PRE], iso.).

Gladiolus sericeovillosus var. *glabrescens* L.Bolus: 213 (1928). Type: South Africa, [Mpumalanga], Waterval Boven (grown at Kirstenbosch Botanic Gardens, 1928), *Hutchinson s.n. Nat. Bot. Gard. 873/27* (BOL, holo.).

Gladiolus dehnianus Merxm. in Süssenguth & Merxmüller: 151 (1951). Type: Zimbabwe, Marondera (Marandellas), dry veld, 30 Mar. 1941, *Dehn 14* (M, holo.; K, SRGH, iso.).

Plants usually entirely glabrous excepting cataphylls. *Leaves* usually reaching top of spikes or up to twice as long as stems, blades linear, stiffly erect, 3–6(–8) mm wide, margins, midribs and other veins strongly thickened. *Flowers* usually greenish, irregularly flecked or streaked with red, sometimes greenish yellow or dull red, lower tepals each with cream-coloured nectar guides in lower half.

Distribution and ecology: restricted to the northern and northwestern parts of the range, from Lydenburg in Mpumalanga to Thabazimbi in Northwest Province and northward to the Soutpansberg in Limpopo and into Zimbabwe.

25b. subsp. **sericeovillosus**

Gladiolus sericeovillosus var. *ludwigii* Pappe ex Baker: 175 (1877). *G. ludwigii* (Pappe ex Baker) Baker: 215 (1892). Type: South Africa, [KwaZulu-Natal], without precise locality, Mar. 1845, *Pappe s.n.* (K, holo.).

Gladiolus sericeovillosus var. *rubicundus* Kuntze: 308 (1898). Type: South Africa, [KwaZulu-Natal], Estcourt District, Highlands Station, 15 Mar. 1894, *Kuntze s.n.* (NY, holo.; K, iso.).

Plants villous to pubescent on cataphylls, leaf sheaths, often blades, and stems and bracts. *Leaves* usually reaching to ± base of spike, lanceolate to sword-shaped, 8–16 mm wide, margins, main and other veins lightly to moderately thickened. *Flowers* usually yellowish green, irregularly flecked or streaked with purple, sometimes creamy yellow or green, rarely reddish, lower tepals with cream-coloured nectar guides in lower half.

Distribution and ecology: extending from near Lydenburg in Mpumalanga southward through Eswatini, KwaZulu-Natal and Lesotho to Umtata in Eastern Cape.

26. **Gladiolus elliotii** *Baker* in Journal of Botany, British and foreign 29: 70 (1891). Type: South Africa, [Mpumalanga], Bethal District, Steenkoolspruit, marshy places, '1891' on specimen but probably Nov. 1889, *Scott Elliot 1557* (K, holo.).

Plants 400–600 mm high, with glabrous cataphylls. *Corm* depressed-globose, 20–30 mm diam.; tunics firm-papery to leathery, fragmenting irregularly. *Stem* straight and erect, occasionally branched, slightly compressed. *Leaves* 5 or 6, lower 4 basal in a 2-ranked fan reaching to ± base of spike or occasionally somewhat longer, leathery, often puberulous, lanceolate or rarely almost linear, 14–20 mm wide, margins strongly thickened and hyaline, main vein not or barely distinguished from secondary veins, these also prominent but not hyaline, cauline leaves overlapping and uppermost inserted on middle of stem, largely sheathing and enclosing stem and sometimes base of spike. *Spike* straight and erect, 14- to 20(25)-flowered; bracts pale green and soft-textured, slightly inflated, outer (18–)25–37 mm long, slightly more than 2 internodes long, pleated in lower ½, dry toward apices and folded back, inner ± as long, lower margins fused around ovary. *Flowers* bluish grey to cream-coloured, minutely speckled with blue to red, more densely so along midline of upper tepals, lower lateral tepals yellow in lower half, unscented; perianth tube obliquely funnel-shaped, ± 16 mm long, lower cylindric part ± 8 mm long; tepals ovate-lanceolate, unequal, dorsal and upper laterals nearly equal, ± 28 × 17 mm, dorsal arching horizontally over stamens, lower laterals directed forward or curving outward toward apices, lower 3 tepals united for ± 2 mm, curving outward and downward from base, lower laterals ± 23 × 8.5 mm, lower median ± 25 × 11.5 mm. *Filaments* 11–12 mm long, exserted ± 4–5 mm from tube; anthers ± 12 mm long, mauve; pollen cream-coloured. *Style* dividing between base and middle of anthers, branches ± 6 mm long. *Capsules* oblong, 3-lobed and auriculate above, retuse, ± 25 mm long. *Seeds* oval to round, 6 × 5 mm long, broadly and evenly winged. *Flowering time*: late November to early February, occasionally later.

Distribution and ecology: fairly widespread across the southern African highveld, from the eastern Free State, South Africa through Gauteng to the Waterberg in Limpopo and into eastern Botswana; in rocky or stony grassland.

Distribution of ***Gladiolus elliotii***.

Diagnosis: distinguished from glabrous or subglabrous forms of *Gladiolus sericeovillosus* by its shorter stature, 400–600 mm high, with the basal fan of leaves typically reaching no higher than the base of the spike and with distinctive venation, the margins strongly thickened but the midrib and other veins fine and closely set. *Gladiolus elliotii* also flowers earlier in the season, mainly November to January or early February.

Ser. **Ecklonii** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus ecklonii* Lehm.

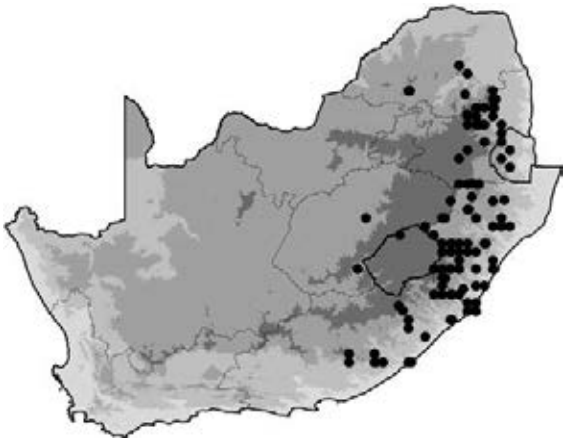
Corm globose to depressed-globose; tunics leathery or firmly papery to fibrous. *Stems* inclined, glabrous. *Leaves* leathery, margins and midrib thickened, glabrous; bracts glabrous, often large, inner bracts with margins free. *Spike* subsecund. *Flowers* mostly large, with pale median markings on lower tepals; perianth tube usually shorter than dorsal tepal.

27. **Gladiolus ecklonii** *Lehm.* in Delectum semina in horto botanico hamburgensi: 7 (1835). Type: South Africa, [Eastern Cape], Fort Beaufort District, Katberg, cult. Hort. Hamburg, Mar. 1830, *Ecklon & Zeyher Irid. 162* (12.3) (S, neo.; B, C, G, PRE, iso.).

Gladiolus marmoratus Tausch: 421 (1836), illegitimate homonym, not *G. marmoratus* Lam. (1788). Type: South Africa, without precise locality, cult. Vienna, *Ecklon s.n.* (no preserved specimen known).

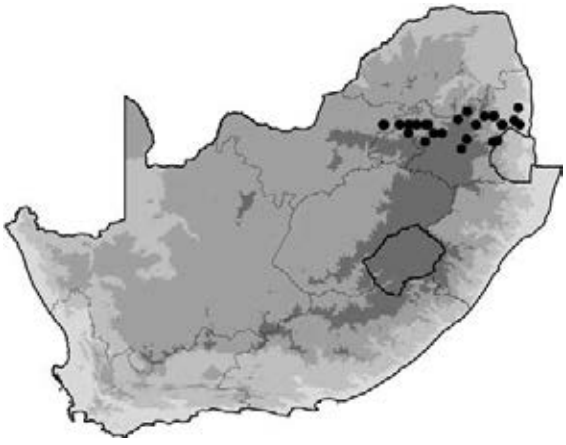
Gladiolus inclusus F.Bolus: 102 (1917). Type: South Africa, [Mpumalanga], Pilgrim's Rest, Dec. 1914, *Rogers 14311* (BOL, holo.).

Plants 150–350(–700) mm high, occasionally taller. *Corm* depressed-globose, 25–40 mm diam.; tunics brittle-papery to cartilaginous, decaying irregularly. *Stem* inclined in upper ⅔, unbranched. *Leaves* (6)7 to 9(13), lower 4 ± basal and usually forming a crowded fan



reaching to ± middle of stem, rarely to base of spike, lanceolate, 15–30(–53) mm wide, margins moderately to strongly thickened, main vein barely thickened, upper 2 leaves entirely sheathing or with vestigial blades, bract-like and slightly inflated. *Spike* inclined, 8- to 12(–26)-flowered; bracts sometimes flushed with purple below, strongly keeled, keels usually reddish, outer 43–53 mm long, (2–)3 internodes long, inner bracts shorter or rarely ± as long, acute and entire, those of lower flowers folded or keeled, those of upper flowers 2-keeled. *Flowers* variously spotted or speckled pink, red or purple on a white background, sometimes so densely spotted as to appear uniformly pink at least on distal ½ of tepals, lower 3 tepals with yellow to cream-coloured spear-shaped nectar guides on lower ½, closing tightly at night, unscented; perianth tube obliquely funnel-shaped, (14–)17–20 mm long; tepals broadly ovate-elliptic, sometimes emarginate-apiculate, dorsal horizontal, hooded over stamens, (25–)28–35 × (13–)15–20 mm, upper laterals usually longer than dorsal, (24–)28–37 × (11–)16–21 mm, lower lateral tepals smallest, 18–20 × 9–15 mm, lower median (22–)28–35 × (9–)13–20 mm, arching outward and downward. *Filaments* 12–15 mm long, exserted 4–5 mm from tube but included in lower part of flower; anthers 7–10 mm long, cream-coloured; pollen white. *Style* arching over stamens, dividing opposite middle of anthers, branches ± 4 mm long. *Capsules* obovoid, weakly 3-lobed above and retuse, 18–25 mm long. *Seeds* discoid, broadly and usually evenly winged, 7–8 × 4.5–6.0 mm. *Flowering time*: late December to early March, occasionally later.

Distribution and ecology: extending through temperate eastern South Africa from near Haenertsburg in Limpopo through Mpumalanga, interior KwaZulu-Natal and eastern Free State to the Amatole Mtns and Katberg in Eastern Cape, also Lesotho and Eswatini; in moist grasslands, often in stony places.



Diagnosis: a relatively low-growing species with a fan of short, often rather blunt leaves 15–53 mm wide borne at ground level, the main vein hardly thickened, other veins fine and close-set, and an inclined spike of finely speckled flowers with large, imbricate and keeled floral bracts. The flowers are short-tubed, the perianth tube 14–20 mm long. The species is variably in flower size and in the colour, degree and intensity of the speckling on the perianth. Populations around Dullstroom are especially attractive, with relatively large almost entirely pink or reddish flowers. The species can be confused with *Gladiolus vinosomaculatus*, but the latter has longer, narrower, ± glaucous leaves 4–12 mm wide with longer sheaths forming a pseudostem, and shorter filaments, 7–12 mm long, with longer anthers, 10–13 mm long.

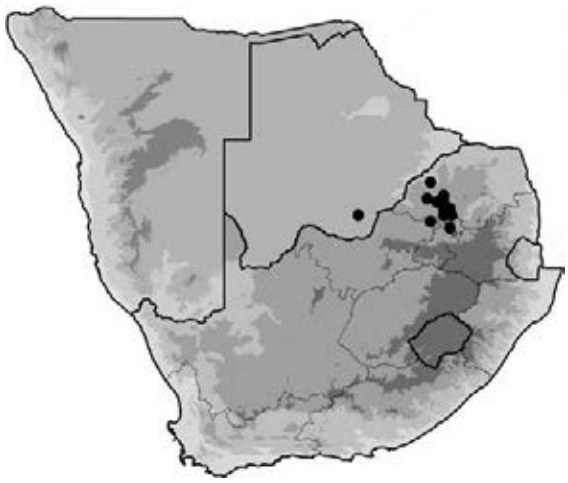
28. **Gladiolus vinosomaculatus** *Kies* in Flowering Plants of Africa 29: t. 1123 (1952). *G. ecklonii* subsp. *vinosomaculatus* (Kies) Oberm. in Lewis et al.: 43 (1972). Type: South Africa, [Gauteng], Pretoria, Waverley, 22 Jan. 1948, *Wasserfal s.n.* (PRE, holo.; K, iso.).

Plants up to 650 mm high. *Corm* depressed-globose, 15–30 mm diam.; tunics brittle-papery to cartilaginous, decaying irregularly. *Stem* inclined above, occasionally with one or two short branches. *Leaves* 5 to 8, lower 4 or 5 basal with a short pseudostem, ± fan-like above, reaching to between base and apex of spike, narrowly sword-shaped to nearly linear, (4–)6–12 mm wide, margins and main vein moderately thickened, cauline leaves shorter. *Spike* strongly flexed at base, inclined, ± straight, 9- to 14-flowered; bracts grey-green, usually conspicuously glaucous, (25–)40–80(–120) mm long, 4–5 internodes long, inner ± ½ as long, acute. *Flowers* variously speckled or blotched with red to purple on a white background, unscented; perianth tube obliquely funnel-shaped, 15–18 mm long; tepals narrowly lanceolate, usually acute, sometimes obtuse, dorsal largest, arched to nearly horizontal, 32–35 × 13–15 mm, upper laterals directed forward, curving outward in upper ⅓, 30–34 × 8–12 mm, lower tepals arching downward, laterals 28–30 × 5–8 mm, lower median 30–33 × 8–11 mm. *Filaments* 7–11 mm long, exserted 2–4 mm from tube but included in lower part of flower; anthers 10–13 mm long; pollen yellow. *Style* arching over stamens, dividing opposite upper third of anthers, branches 3–4 mm long.

Distribution of ***Gladiolus ecklonii***.

Distribution of ***Gladiolus vinosomaculatus***.

Capsules oblong, apices rounded and shallowly 3-lobed, 24–30 mm long, concealed in bracts. *Seeds* ovate, ± 9.5 × 6 mm, broadly and evenly winged. *Flowering time*: mainly mid-January to March.



Distribution and ecology: extending north of the Vaal River from the Magaliesberg west of Pretoria in Gauteng, South Africa to the mountains above Barberton in Mpumalanga; in open or dry, rocky grassland.

Diagnosis: recognised by the narrow, glaucous leaves 4–12 mm wide, forming a pseudostem at the base, large glaucous bracts up to 120 mm long partly concealing the flowers, pale tepals spotted of blotched red or purple and short filaments, 7–11 mm long and anthers 10–13 mm long. *Gladiolus ecklonii*, with similarly but often more finely spotted flowers, has a basal fan of bright green leaves and often smaller flowers with longer filaments, 12–15 mm long, and shorter anthers, 7–10 mm long.

29. **Gladiolus rehmannii** *Baker*, Handbook of the Irideae: 216 (1892). *G. ecklonii* subsp. *rehmannii* (Baker) Oberm. in Lewis et al.: 44 (1972). Type: South Africa, [Mpumalanga], Bronkhorstspruit District, between Elandsrivier and Klippan, 1879–1880, *Rehmann 5096* (K, holo.).

Gladiolus cymbarius Baker: 866 (1901). Type: South Africa, [Mpumalanga], Bronkhorstspruit District, between Elandsrivier and Klippan, ?1880, *Rehmann 5100* (Z, holo. [photo at PRE]; Z, iso.).

Plants 300–500(–900) mm high. *Corm* globose, 18–22 mm diam.; tunics brittle-papery to cartilaginous, decaying irregularly. *Stem* erect or flexed outward just below base of spike, occasionally branched, completely sheathed by bases of cauline leaves. *Leaves* (6–)8 or 9, lower (3)4 or 5 basal with a pseudostem, forming a lax fan above, reaching at least to base or shortly exceeding spike, narrowly lanceolate, (4–)8–16 mm wide, main vein moderately thickened, margins barely thickened, cauline leaves overlapping, progressively smaller above, upper 1 or 2 usually entirely sheathing and bract-like, sometimes slightly inflated. *Spike* inclined, flexuose, 6- to 10(16)-flowered, internodes fairly short, 12–14(–20) mm long; bracts pale green or flushed with purple, often glaucous on upper surfaces (facing sun), occasionally folded but not keeled, outer (40–)45–60(–115) mm long, overlapping, 3–4 internodes long, inner shorter, acute or shortly forked. *Flowers* white to pale lilac, lower lateral or all 3 lower tepals with yellow nectar guides sometimes outlined in light purple, unscented; perianth tube obliquely funnel-shaped, 15–20 mm long, enclosed in bracts; tepals lanceolate, dorsal inclined over stamens, (30–)38–50 × 12–18 mm, upper laterals usually 32–52 × 10–16 mm, usually longer than dorsal, directed forward, curving outward distally, lower lateral tepals 28–43 × 8–14 mm, lower median usually substantially larger, 30–45 × 8–14 mm, arching downward. *Filaments* 10–12 mm long, exserted 2–5 mm from tube but enclosed in lower part of flower; anthers 9–10 mm long; pollen pale lilac to blue or yellow. *Style* arching over stamens, dividing between middle and apex of anthers, branches 6–8 mm long. *Capsules* oblong, 3-lobed above, 25–35 mm long. *Seeds* ovate-oblong, 12–14 × 7–8 mm, broadly and evenly winged; *Flowering time*: mid-January to March.

Distribution of ***Gladiolus rehmannii***.

Distribution and ecology: fairly widespread in northern southern Africa, in eastern Botswana and South Africa, from the Waterberg in Limpopo to Sybrandskraal near Groblersdal in Mpumalanga; in sandy or stony soils in open bushveld and woodland.

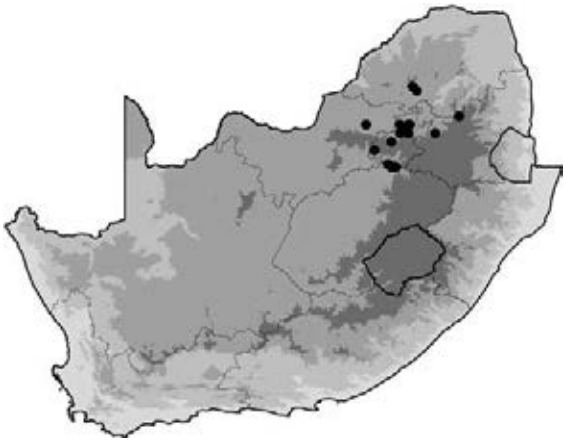
Diagnosis: vegetatively similar to *Gladiolus vinosomaculatus* and distinguished from it by the pure white to pale lilac flowers with slightly shorter anthers, 9–10 mm long but longer style branches, 6–8 mm long. The two species are allopatric, with *G. rehmannii* occupying subtropical habitats in drier bushveld and savanna to the north of *G. vinosomaculatus*.

Ser. **Ophiolyza** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus dalenii* Van Geel.

Corm globose to depressed-globose; tunics leathery or firmly papery to fibrous. *Stems* erect, glabrous. *Leaves* leathery, margins and main vein thickened, glabrous; leaves on flowering stem sometimes reduced, with foliage leaves produced from a separate shoot; bracts leathery, glabrous, inner bracts with margins free. *Spike*s secund. *Flowers* mostly large, with pale median markings on lower tepals; perianth tube usually longer than dorsal tepal, lower tepals often reduced.

30. **Gladiolus antholyzoides** *Baker* in Journal of Botany, British and foreign 29: 70 (1891). *Antholyza laxiflora* Baker: 170 (1896), illegitimate superfluous name for *G. antholyzoides* Baker. Type: South Africa, [Gauteng], Apies River near Pretoria, damp ground, Nov. 1890, *Scott Elliot 1447* (K, holo.).

Antholyza schlechteri Baker: 1007 (1904a). *Gladiolus brachylimbus* Baker: 178 (1904b), new name



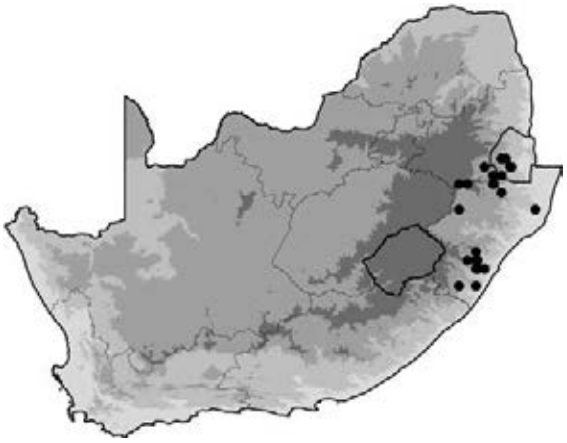
for *A. schlechteri* Baker [not *G. schlechteri* Baker (1904a)]. *G. magaliesmontanus* F.Bolus: 108 (1917), illegitimate superfluous name for *G. brachylimbus* Baker. Type: South Africa, [Gauteng], Magaliesberg near Apies River, 4 Nov. 1893, *Schlechter 3627* (as *3629*) (Z, holo. [drawing at BOL and K]; BOL, Z, iso.).

Gladiolus vogtsii L.Bolus: 133 (1929a). Type: South Africa, 'Transvaal', cult. Kirstenbosch Gardens, 4 Feb. 1919, *Vogts s.n. Natl. Bot. Gard. 617/28* (BOL, holo.).

Gladiolus strictiflorus L.Bolus: 15 (1931), illegitimate homonym, not *G. strictiflorus* (Ker Gawl.) Delile in Redouté (1812). Type: South Africa, [Free State], Reitz, cult. Kirstenbosch Gardens, 1930, (BOL, holo.).

?*Gladiolus anorthanthus* Ingram: 273 (1933). Type: South Africa, [Limpopo], Potgietersrust, cult. England, *Ingram s.n.* (BM, holo. [identity uncertain, flowers immature]).

Plants 0.6–0.9 m high, usually with 1 to 3 lateral leafing shoots as well as flowering stem. *Corm* depressed-globose, 23–35 mm diam.; tunics brittle-papery to membranous, decaying irregularly, with several cormlets around base. *Stem* erect, unbranched. *Leaves* 5 to 8, lower 3 to 5 basal and usually forming a fairly tight fan rarely reaching beyond lower ⅓ of stem, up to 300 mm long, lanceolate, (3–)10–20 mm wide, margins and main vein lightly raised, cauline leaves smaller, progressively shorter, uppermost sheathing for most of its length. *Spike* straight and erect, strongly secund, 8- to 12-flowered; bracts pale green, outer 30–35(–50) mm long, inner shorter, shortly notched. *Flowers* pale to deep yellow, sometimes streaked irregularly with red or orange and with an orange ring around throat, reverse of tube and lower part of tepals greenish yellow, lower tepals slightly darker yellow or yellow-green in basal ½, unscented; perianth tube narrowly and obliquely funnel-shaped, 28–40 mm long, flared upper part 15–25 mm long; tepals lanceolate, dorsal largest, 25–30 × 14–16 mm, extended ± horizontally over stamens, upper laterals directed forward below, curving outward distally, 25–28 × 16 mm, lower 3 tepals arching downward ± from base, lower laterals 17–20 × 9 mm, lower median 20–23 × 12 mm. *Filaments* 20–30 mm long, exserted 2–8 mm from tube; anthers 9–11 mm long, pale yellow; pollen cream-coloured. *Style* arching over stamens, dividing between middle and apex of anthers, branches ± 5 mm long. *Capsules* ovoid-oblong, 3-lobed above and retuse, 20–25 mm long. *Seeds* ovate, 7–9 mm long, broadly and evenly winged. *Flowering time*: mainly mid-November to early December, occasionally in late October.



Distribution of ***Gladiolus antholyzoides***.

Distribution and ecology: scattered through the central and eastern highveld of South Africa, from the Waterberg in Limpopo through Gauteng to Reitz in the Free State; in seasonally wet or waterlogged grasslands, flowering in spring.

Diagnosis: a spring-flowering species recognised by the short leaves seldom exceeding the lower third of the stem and the ± funnel-shaped flowers with perianth tube 28–40 mm long and relatively small tepals, the upper three 25–30 mm long and the lower three 17–23 mm long. The plants produce separate leafy shoots from the corms toward the end of the flowering season. In this respect it resembles *Gladiolus aurantiacus* Klatt from east of the escarpment, which has larger, orange flowers, the perianth tube 44–70 mm long and the dorsal tepal usually 35–45 mm long.

31. **Gladiolus aurantiacus** *Klatt* in Linnaea 35: 378 (1867b). Type: South Africa, [KwaZulu-Natal], near Pietermaritzburg, Sept.–Oct. 1858, *Sutherland s.n.* (K, S, syn.)

Plants 450–750 mm high. *Corm* depressed-globose, 25–35 mm diam.; tunics brittle-papery to membranous, decaying irregularly shaped fragments, with several cormlets around base. *Stem* erect, unbranched. *Leaves* of flowering stem 4 or 5, superposed, imbricate, blades usually shorter than sheaths or ± as long, lanceolate to sword-shaped, 6–15 mm wide, uppermost leaves sometimes entirely sheathing; foliage leaves 5 or 6, produced from separate shoots on same corm near end of flowering, ultimately reaching up to 600 mm, narrowly lanceolate, 10–15 mm wide, main vein thickened and raised, margins barely thickened. *Spike* straight and erect, 10- to 16-flowered; bracts pale green, outer (28–)32–45 mm long, inner shorter, notched apically. *Flowers* deep yellow, finely dotted or streaked irregularly with red or orange, sometimes so densely mottled as to appear orange, lower tepals clear yellow in basal ½, unscented; perianth tube narrowly and obliquely funnel-shaped, 44–70 mm long, slender and erect below for 25–33 mm, abruptly expanded into a wide cylindric and horizontal upper part 30–35 mm long; tepals lanceolate, unequal, dorsal largest, (26–)35–45 × ± 15–24 mm, extended ± horizontally over stamens, upper laterals directed forward below, curving outward distally, 25–42 × 14–25 mm, lower 3 tepals arching downward, 15–25 × (7–)12–16 mm, lower median slightly larger than laterals. *Filaments* 28–40 mm

Distribution of ***Gladiolus aurantiacus***.

long, exserted 12–15 mm from tube; anthers 9–12 mm long, yellow to orange; pollen yellow. *Style* arching over stamens, dividing between base and middle of anthers, branches 4–6 mm long. *Capsules* ovoid-oblong, 3-lobed above and retuse, 18–25 mm long. *Seeds* ovate, ± 10 × 7–8 mm, broadly and evenly winged. *Flowering time*: mainly October, occasionally September or November.

Distribution and ecology: scattered through eastern southern Africa below the escarpment, from Eswatini and Piet Retief and Vryheid in southern Mpumalanga, South Africa through the KwaZulu-Natal midlands to Richmond and Dumisa; in open grassland, flowering in spring, mostly after fire.

Diagnosis: a spring-flowering species recognised by the short leaves not forming a basal fan, and the narrowly funnel-shaped flowers more-or-less strongly flecked or blotched orange, with an elongate perianth tube 44–70 mm long, slender in the lower half and abruptly expanded and cylindric above. The dorsal tepal is ascending to nearly horizontal and usually 35–45 mm long. The plants produce separate leafy shoots from the corms toward the end of the flowering season. In this respect the species resembles *Gladiolus antholyzoides* from the highveld, but this has smaller, mostly yellowish flowers with a narrowly funnel-shaped perianth tube 28–40 mm long and upper tepals 25–30 mm long. The narrow flowers of *G. aurantiacus* distinguish it from *G. dalenii*, which has a funnel-shaped perianth tube up to 50 mm long and concave dorsal tepal arching over the stamens.

32. **Gladiolus dalenii** *Van Geel* in Sertum Botanicum 2(1): 18 (1829). Type: South Africa, Natal [KwaZulu-Natal], without precise locality or collector, cultivated in Holland, illustration in Van Geel: 18 (1829).

subsp. **dalenii**

Watsonia natalensis Eckl.: 34 (1827) [not *Gladiolus natalensis* Reinw. ex Hook.f. (1831)]. Type: South Africa, Natal Coast (cultivated in Cape Town), *Ecklon s.n.* (S, holo.).

Gladiolus psittacinus Hook.f.: t. 3032 (1830). *G. natalensis* Reinw. ex Hook.f.: sub t. 3084 (1831), illegitimate superfluous name for *G. psittacinus* Hook.f. Type: South Africa, 'Natal', without precise locality, illustration in Hook.f.: t. 3032 (1830).

Gladiolus dracocephalus Hook.f.: t. 5884 (1871). Type: South Africa, [KwaZulu-Natal], foot of the Drakensberg, cultivated at Royal Botanic Gardens, Kew, *Cooper 3593* (K, holo.).

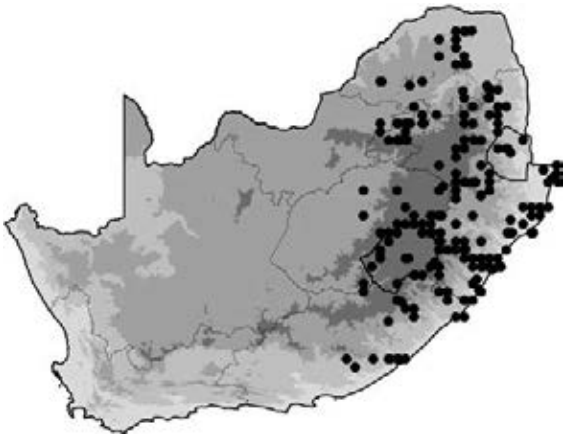
Gladiolus cooperi Baker: t. 6202 (1875). Type: South Africa, [KwaZulu-Natal], cultivated at Royal Botanic Gardens, Kew, *Cooper s.n.* (K, holo.).

Gladiolus adlami Baker: 233 (1889a). Type: South Africa, 'Transvaal', cultivated in Great Britain, *Adlam s.n.* (K, holo. [photos at NBG, PRE]).

Gladiolus leichtlinii Baker: 154 (1889b). Type: South Africa, without precise locality, as 'Transvaal,' cult. Hort. Leichtlin, July 1889, *Adlam s.n.* (K, holo.).

Gladiolus tysonii Baker: 220 (1892). Type: South Africa, [Eastern Cape], East Griqualand, near Fort Donald, *Tyson 1653* (K, holo.; SAM, iso.).

Gladiolus platyphyllus Baker: 456 (1893). Type: South Africa, [Eastern Cape], Transkei, cultivated in hort. Leichtlin, *Flanagan s.n* (K, holo.).



Gladiolus fuscoviridis Baker: 530 (1897a). Type: South Africa, location unknown.

Gladiolus pageae L.Bolus: 214 (1928). Type: Lesotho, Thaba Tseueu, *Page s.n. BOL 17030* (BOL, holo.).

Gladiolus leptophyllus L.Bolus in Bolus and Lewis: 204 (1932). Type: South Africa, [Limpopo], Blouberg, cult. Hort. Stellenbosch University, without date, *Neethling sub Grosskopf s.n.* (BOL, holo.; K, iso.).

Gladiolus retrocurvus G.J.Lewis Bolus and Lewis: 204 (1932). Type: South Africa, [Limpopo], Selati Estate, near Rubbervale, cultivated at Kirstenbosch Gardens, collector unknown, *Natl. Bot. Gard. 1361/30* (BOL, holo.).

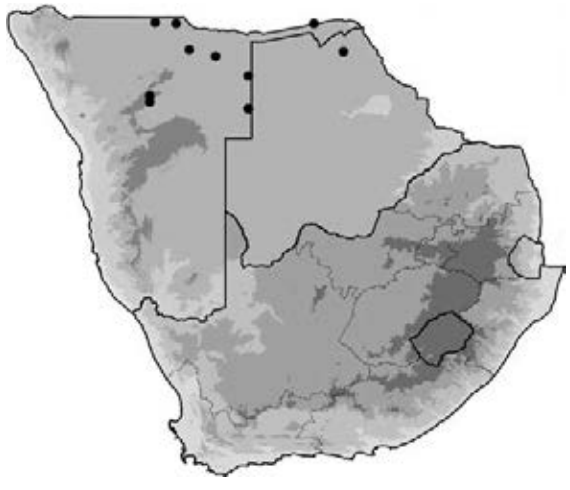
Plants (500–)700–1 500 mm high, with cataphylls sometimes densely puberulous. *Corm* (15–)20–30 mm diam., tunics brittle or leathery becoming irregularly broken or sometimes fibrous, usually with many tiny cormlets around base, sometimes with stolons. *Stem* erect and straight, unbranched. *Leaves* contemporary with flowering stem, 4 to 6(7), at least lower 2 basal or nearly so and usually ± ½ as long as spike, lanceolate to ± linear, (5–)10–30(–70) mm wide, firm textured with moderately raised and thickened main vein and margins, cauline leaves often imbricate and largely or entirely sheathing. *Spike* straight, (2)3- to 8(14)-flowered; bracts pale green to grey-purple on upper surfaces, sometimes dry and pale apically, outer (35–)40–70 mm long, inner shorter. *Flowers* either red to orange with yellow mark on basal half of lower tepals, or yellow to greenish and often with red to brown streaks on upper tepals, unscented;

Distribution of ***Gladiolus dalenii*** subsp. ***dalenii***.

perianth tube 35–50 mm long, nearly cylindric below, gradually widening above, curving outward in upper ½; tepals with upper 3 broadly ovate, dorsal largest, 35–50 × 22–30 mm, horizontal to downcurved, concave, concealing stamens, upper laterals ± as long as or slightly shorter than dorsal, 20–30 mm wide, directed forward, often curving outward distally, lower 3 tepals curving downward, 20–25(–30) × 8–12 mm, lowermost somewhat longer and narrower than laterals. *Filaments* 25–30 mm long, exserted 15–20 mm from tube; anthers 12–16 mm long, yellow to brownish; pollen pale yellow. *Style* arched over stamens, dividing near apex of anthers, branches (4–)5–6 mm long. *Capsules* ovoid-oblong, 3-lobed apically, (18–)25–35 mm long. *Seeds* 8–12 × 5–9 mm, wing well developed. *Flowering time*: December to May (to June) in southern and east tropical Africa.

Distribution and ecology: widespread through eastern southern Africa, in South Africa from Limpopo to the Zuurberg in Eastern Cape an inland to the eastern Free State and Gauteng, also in Lesotho and Eswatini, extending north into tropical and West Africa and Madagascar; in grassland and open woodland.

Diagnosis: recognised by the large flowers with the upper tepals 35–50 mm long and much exceeding the recurved lower tepals, the dorsal tepal concave and arching over and concealing the stamens. The species is variable in flower colour and flowering time. Madagascan populations of the species are diploid but most of those from continental Africa are polyploid.



33. **Gladiolus magnificus** *(Harms) Goldblatt* in Goldblatt & M.P. de Vos in Adansonia 11: 426 (1990). *Antholyza magnifica* Harms in Warburg: 201 (1903). *Petamenes magnifica* (Harms) R.C.Foster: 50 (1936). Type: Angola, on the Longa near Minnesera, 1 200 m, 11 Jan. 1901, *Baum 651* (B, holo.; BM, COI, K, W, iso.).

Antholyza zambesiaca Baker: 232 (1892) [not *Gladiolus zambesiacus* Baker (1892)]. *Petamenes zambesiaca* (Baker) N.E.Br.: 277 (1932a). *Oenostachys zambesiacus* (Baker) Goldblatt: 443 (1971). Type: Botswana (or northwestern Zimbabwe), south of the Zambezi River, Leshumo [Leshomo] Valley, in or before 1883, *Holub s.n.* (K, holo.).

Antholyza spectabilis Schinz: 13 (1900) [not *Gladiolus spectabilis* Baker (1904a)]. *Chasmanthe spectabilis* (Schinz) N.E.Br.: 274 (1932a). *Petamenes spectabilis* (Schinz) E.Phillips: 44 (1941). Type: Namibia, Waterberg Plateau, 19 Apr. 1899, *Dinter s.n.* (†B, holo.).

Plants 0.8–1.4 m high. *Corm* depressed-globose, 20–30 mm diam.; tunics of fine, wiry fibres. *Stem* straight, unbranched. *Leaves* 5 to 7, lower 4 or 5 basal and ± ½ as long as stem, reaching almost to base of spike, narrowly lanceolate, 6–9 mm wide, main vein and margins lightly thickened, upper leaves progressively smaller and sometimes entirely sheathing. *Spike* erect and straight, 6- to 15-flowered; bracts green, outer 25–30(–35) mm long, inner shorter. *Flowers* bright red with yellow markings on lower tepals and in throat, lower 3 tepals sometimes with dark red-purple blotch in midline; perianth tube 25–30 mm long, narrow below, expanded near top of bracts and curving outward and nearly horizontal, ± 4 mm wide at mouth; tepals very unequal, dorsal largest, hooded and horizontal, 35–42 × 18–22 mm, upper laterals broadly lanceolate, 13–15 mm long, curving outward apically, lower 3 tepals narrowly lanceolate, up to 10 mm long, ± horizontal or lowermost recurving. *Filaments* arched under dorsal tepal, ± 35 mm long, exserted ± 20 mm from tube; anthers 12–17 mm long, dull yellow; pollen yellow. *Style* dividing shortly below anther apices, branches ± 3 mm long. *Capsules* oblong, 20–30 mm long. *Seeds* ovate, ± 13 × 8 mm, broadly and evenly winged. *Flowering time*: January and February, occasionally in March.

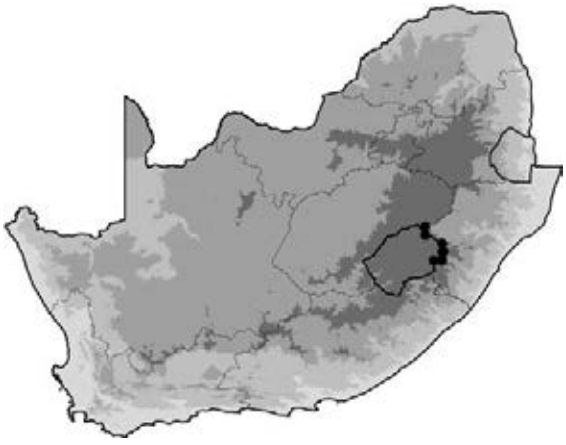
Distribution and ecology: extending across south tropical Africa from central Angola and Namibia through southern Zambia and northern Botswana to western Zimbabwe; in open Kalahari woodland on sandy soils.

Distribution of ***Gladiolus magnificus***.

Diagnosis: recognised by the scarlet flowers with enlarged, concave dorsal tepal 35–42 mm long and ± twice as long as the upper lateral tepals, and the reduced lower tepals ± one third as long as the dorsal.

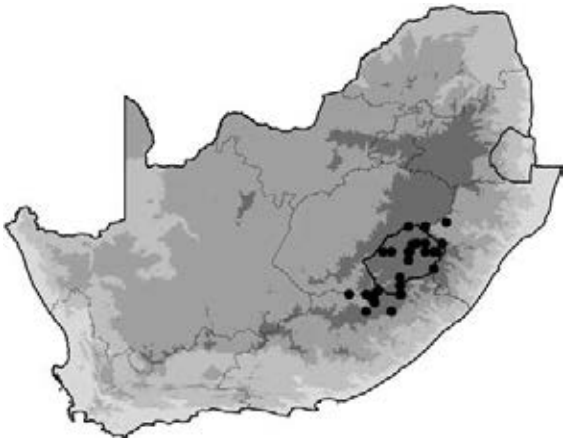
34. **Gladiolus flanaganii** *Baker* in Flora capensis 6: 530 (1897a). Type: Lesotho, Mont aux Sources, near the summit, 8 500 ft [2 600 m], Jan. 1894, *Flanagan 1832* (BOL, holo.; PRE, iso.).

Plants 350–600 mm high, erect or trailing. *Corm* globose, 20–28 mm diam.; tunics softly cartilaginous becoming coarsely fibrous. *Stem* usually inclined, occasionally ± erect, flexed outward above, unbranched. *Leaves* usually 5, lower 4 basal and reaching to between middle and apex of spike, lanceolate, 7–14 mm wide, main vein moderately thickened and hyaline, a pair of secondary veins also somewhat thickened, margins hardly thickened, uppermost leaf much shorter, narrowly channelled for almost entire length. *Spike* lightly flexuose, 4- to 7-flowered; bracts firm-textured, green or flushed dull purple, outer with a light median fold, 60–70 mm long, inner shorter and lightly 2-keeled, notched apically. *Flowers* dark carmine-red, somewhat urn-shaped, lower tepals each with narrow longitudinal, median white streak outlined with dark red, ventral part of upper part of tube whitish streaked with red, unscented; perianth tube gradually flared from base, slightly sigmoid in profile, 35–45 mm long; tepals obovate, ± cupped above, outer whorl subequal and slightly larger than inner, dorsal and lower laterals 30–38 × 18–20 mm, upper laterals and lower median 30–42 × 25 mm. *Filaments* 27–30 mm long, exserted 14–15 mm from tube; anthers ± 10 mm long, dark purple; pollen pale lilac. *Style* arching over stamens, dividing shortly beyond anther apices, branches ± 4.5 mm long. *Capsules* oblong, 16–20 mm long. *Seeds* oblong, 6–7 × 2.0–2.5 mm, wing developed only at ends. *Flowering time*: late November to early January.



Distribution and ecology: restricted to the high Drakensberg Escarpment along the frontier between Lesotho and South Africa, from the Sentinel in Free State to Sani Pass in KwaZulu-Natal; on basalt cliffs in moist places.

Diagnosis: readily recognised by the fan of stiff leaves, and thick-textured carmine-red flowers with a rather closed, urn-like shape and somewhat sigmoid perianth tube 35–45 mm long. The lower tepals are each marked with a median white streak outlined with dark red.



35. **Gladiolus saundersii** *Hook.f.* in Curtis's Botanical Magazine 96: t. 5873 (1870a). Type: South Africa, [Eastern Cape], Herschel District, summit of the Witteberg, 1861, *Cooper 605* (K, holo.; BM, Z, iso.).

Gladiolus spectabilis Baker: 1006 (1904a). Type: Lesotho, Maluti Mountains, Mt Machache (± 32 km east of Maseru), Mar. 1903, *Junod 1927* (Z, ?holo. [photo at PRE]; G, SAM, Z, iso.).

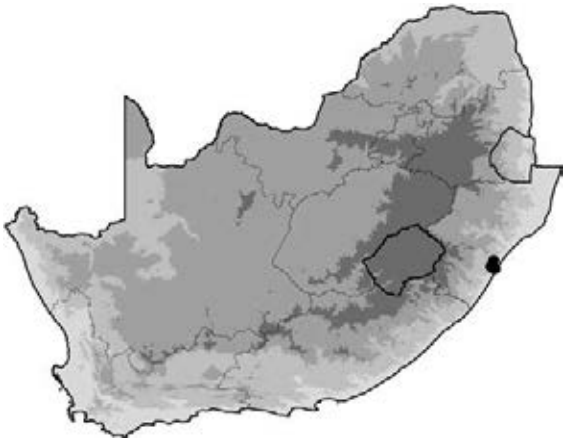
Plants (300–)400–600 mm high. *Corm* depressed-globose, (20–)30–50 mm diam.; tunics papery, with numerous small cormlets. *Stem* erect, unbranched. *Leaves* 7 to 9, mostly basal in a fan reaching to base of spike or exceeding it, lanceolate, 15–25 mm wide, main vein strongly thickened, margins usually less so, 1 or more secondary vein pairs also usually prominent, cauline leaves usually sheathing stem to base of spike. *Spike* erect to slightly inclined, ± straight, (2)4- to 9-flowered; bracts green, apices twisted, outer 40–60(–70) mm long, lightly folded in midline, inner bracts slightly shorter, forked into linear cusps. *Flowers* facing sideways or drooping, bright red, lower 3 tepals lightly to densely speckled in lower half with red on a white field, unscented; perianth tube obliquely funnel-shaped, 33–37 mm long; tepals lanceolate, unequal, upper 3 largest, 46–67 × 21–30 mm, dorsal extending horizontally or tilted downward over stamens, recurving distally, upper laterals curving outward from base, lower 3 tepals joined to upper laterals for ± 6 mm, and together for ± 2 mm, arching downward, recurved distally, somewhat smaller than upper, lower laterals 34–46 mm long, lower median 46–53 × 20–28 mm. *Filaments* 30–50 mm long, exserted 20–30 mm from tube; anthers 15–16 mm long, apiculate, tilted downward, purple; pollen cream-coloured. *Style* arching over stamens, dividing between middle

Distribution of ***Gladiolus flanaganii***.

Distribution of ***Gladiolus saundersii***.

and upper ⅓ of anthers, branches 7–8 mm long. *Capsules* oblong-obovate, 3-lobed above and retuse, 25–28 mm long. *Seeds* ovate, ± 6.5 × 8.5 mm, broadly and evenly winged. *Flowering time*: mid-January to March.

Distribution and ecology: scattered through the central and southern Drakensberg, from near Clarens in Free State, South Africa through Lesotho to Lady Grey and Joubert's Pass in Eastern Cape; on rocky outcrops and scree slopes.



Occasional hybrids with *Gladiolus oppositiflorus* have been reported from Naude's Nek in Eastern Cape.

Diagnosis: distinctive in its large, nodding, scarlet flowers with horizontal to drooping dorsal tepal and strongly recurving lower tepals splashed with white on the lower half. The perianth tube is strongly curved, 33–37 mm long, and the anthers are well-exserted on filaments 30–50 mm long. The unusually long style branches, 7–8 mm long, are distinctive.

36. **Gladiolus cruentus** *T.Moore* in The Gardeners' Chronicle 1868: 1138 (1868). Type: South Africa, [KwaZulu-Natal], without precise locality, ?*McKen*, illustration in Hook.f.: t. 5810 (1869).

Plants 500–700 mm long, usually arching horizontally from cliffs. *Corm* globose, 15–20 mm diam.; tunics of medium textured fibres. *Stem* inclined to drooping below horizontal, usually arching upward in upper part, unbranched. *Leaves* 7 or 8, lower 4 or 5 ± basal and usually slightly longer than spike but trailing, sword-shaped, 10–15 mm wide, main vein moderately thickened, margins not raised, all except uppermost cauline leaf with long blades. *Spike* arching upward and inclined or nearly erect, straight, 4- to 9-flowered; bracts with outer 40–60(–80) mm long, usually ± 2 internodes long, inner shorter, forked, often lightly 2-keeled. *Flowers* bright scarlet, lower tepals each with transverse white chevron at limb base, lower part of lower tepals and upper part of tube speckled red on white, unscented; perianth tube ± cylindric, ± 28 mm long, flaring in upper ± 6 mm long; tepals lanceolate, dorsal lightly inclined over stamens, ± 60 × 30 mm, remaining tepals patent, upper laterals ± 55 × 27 mm, lower 3 tepals united basally for 2–3 mm, narrowed and ascending below for ± 15 mm long, limbs patent, ± 33 × 19 mm. *Filaments* arcuate, ± 40 mm long, exserted ± 35 mm from tube; anthers ± 12 mm long, diverging, dark purple; pollen whitish. *Style* arching over stamens, dividing at or shortly beyond anther apices, branches ± 5 mm long. *Capsules* oblong, rounded to retuse apically, 18–25 mm long. *Seeds* narrowly oblong, 7–9 × ± 4 mm, wing unevenly developed, longest at micropylar end. *Flowering time*: mid-January to early March.

Distribution and ecology: a narrow endemic of central coastal KwaZulu-Natal, South Africa, from the Noodsberg and Kranskop to Gillits and Kloof; on damp sandstone cliffs.

Distribution of ***Gladiolus cruentus***.

Diagnosis: recognised by its relatively soft-textured leaves, trailing stems and large, scarlet flowers with white transverse chevrons near the base of the lower tepals, the dorsal tepal horizontal but the others ± spreading from a narrow perianth tube ± 28 mm long. The filaments are ± 40 mm long and well exserted.

Sect. 3. **Blandi** *(Baker) Goldblatt, Gladiolus* in tropical Africa: 176 (1996) [as *Blandus*]. *Gladiolus* group *Blandi* Baker: 176 (1877). Type species: *Gladiolus blandus* Ait. = *G. carneus* D.Delaroche, lecto., designated by Goldblatt: 176 (1996).

Gladiolus subg. *Hyptissa* Klatt: 342 (1882). Type species: *G. blandus* Ait. = *G. carneus* D.Delaroche, lecto., designated by Goldblatt: 176 (1996).

Plants medium-sized to large. *Stem* branched or unbranched. *Corm* tunics papery or leathery to fibrous. *Leaves* several, mostly basal in a fan, narrowly lanceolate to lanceolate, firm-textured, plane with thickened main vein and margins, usually at least 4 mm wide. *Spike* mostly few flowered; bracts smooth, margins of inner bracts free. *Flowers* medium to large, weakly or more strongly bilabiate, often pink, nectar guides pale and lozenge-shaped outlined with red or purple, unscented; perianth tube usually obliquely funnel-shaped, shorter or longer than dorsal tepal; lower tepals narrower but usually ± as long as upper. *Anthers* never tailed. *Capsules* usually large, oblong and rounded, rarely obscurely lobed above. *Seeds* broadly and evenly winged.

Species 22: mainly Cape flora region of Western and Eastern Cape.

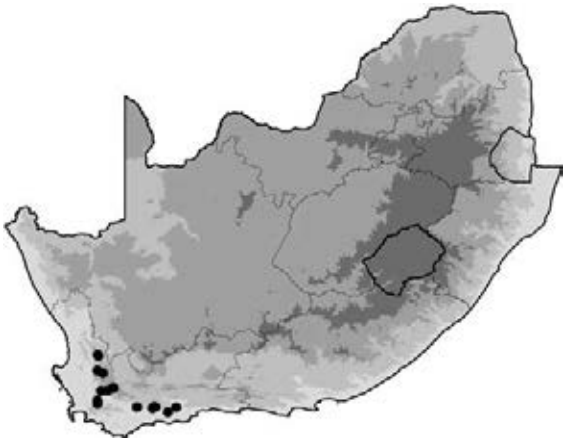
Ser. **Phoenices** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus phoenix* Goldblatt & J.C.Manning

Plants usually fire-adapted, small to moderate-sized. *Corm* tunics papery to fibrous. *Leaves* leathery, margins and main vein lightly thickened; bracts leathery, glabrous. *Spike*s secund. *Flowers* small or moderate-sized,

pink with pale median markings on lower tepals outlined with red; perianth tube shorter than dorsal tepal.

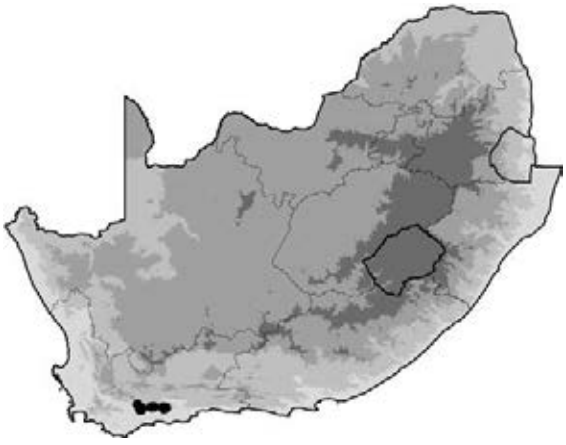
37. **Gladiolus oreocharis** *Schltr.* in Journal of Botany, British and foreign 34: 504 (1896). Type: South Africa, [Western Cape], Matroosberg, Dec. 1895, *Marloth 2265* (B, holo.; BOL, GRA, PRE, iso.).

Plants (120–)180–350(–500) mm high, with uppermost cataphylls sometimes hispid. *Corm* globose, 7–10 mm diam.; tunics of fine, reticulate fibres, often accumulating to form a collar around base. *Stem* erect or inclined, flexed outward above sheathing parts of uppermost 2 leaves. *Leaves* 3 to 5, lowermost 1 to 3 basal and reaching to between base and apex of spike, linear, (1–)2–6 mm wide, with (1)2 main veins and margins lightly to moderately thickened, cauline leaves largely to entirely sheathing. *Spike* inclined to almost horizontal, 2- to 7-flowered; bracts firm-textured, outer 13–20(–25) mm long, purple near apices, obtuse to truncate, inner shorter to slightly longer, minutely forked. *Flowers* pink to red-purple or violet (rarely white), lower 3 tepals with spear-shaped median dark red to purple mark with white to yellow centre, unscented; perianth tube obliquely funnel-shaped, 15–24 mm long, shortly exserted from bracts; tepals ovate, unequal, dorsal largest, inclined, 18–22 × 12–14 mm, upper laterals slightly smaller, 15–20 mm long; lower 3 tepals joined to upper laterals for ± 3–4 mm and together for 1–2 mm, free parts 14–20 mm long. *Filaments* 15–16 mm long, exserted 7–9 mm from tube; anthers 6–8 mm long, mauve. *Style* arching over stamens, dividing at or shortly beyond anther apices, branches ± 4 mm long. *Capsules* obovoid, 3-lobed above and retuse. *Seeds* unknown. *Flowering time*: mostly December, occasionally in early January.



Distribution and ecology: a high montane species of Western Cape, South Africa, extending from the Cederberg to the Hex River Mtns, the Langeberg and Swartberg; on moist, south-facing slopes mainly above 1 600 m elevation, flowering mainly the first year after fire.

Diagnosis: a summer-flowering species with narrow leaves, 2–6 mm wide and typically with two main veins, short, obtuse floral bracts, mostly 13–20 mm long, and small, pink flowers with lozenge-shaped nectar guides and perianth tube 15–24 mm long. The upper cataphyll is sometimes hispidulous. *Gladiolus crispulatus* from the Langeberg has linear leaves 1–3 mm wide, mostly larger bracts, 24–33 mm long, and undulate or crisped tepals, the lower marked with median red chevrons and speckles toward the base.



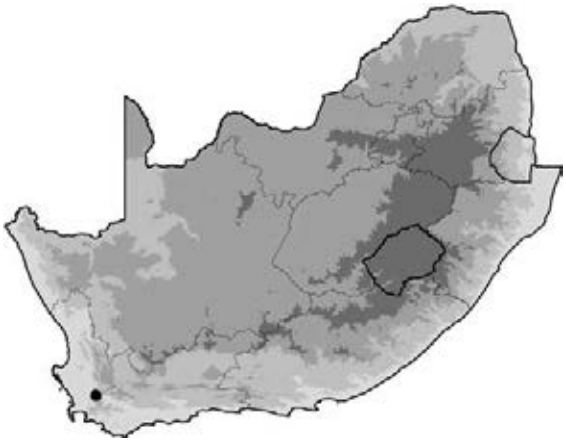
38. **Gladiolus crispulatus** *L.Bolus* in Annals of the Bolus Herbarium 3: 182 (1924). Type: South Africa, [Western Cape], Riversdale District, Corente River Farm, Dec. 1908, *Muir sub Galpin 5369* [BOL, lecto., Goldblatt & Manning: 125 (1998)].

Gladiolus tenuis Baker: 335 (1876b), illegitimate homonym, not *G. tenuis* M.Bieb. (1808). Type: South Africa, [Western Cape], Langeberg Mtns, Craggy Peak, Swellendam, 14 Jan. 1815, *Burchell 7303* (K, holo. [tracing at BOL]).

Plants slender, 300–400 mm high. *Corm* globose, 8–12 mm diam.; tunics of fine, netted fibres. *Stem* erect or inclined, unbranched. *Leaves* 4 or 5, superposed, lower 2 basal and reaching upper part of stem or shortly exceeding spike, linear, 1–3 mm wide, margins barely raised, main vein lightly thickened and usually paired on one side but single on other, cauline leaves progressively shorter and mainly sheathing. *Spike* flexed at base and lightly inclined, 2- to 4-flowered; bracts pale green, fairly soft-textured, outer 24–33 mm long, inner shorter, minutely bifid. *Flowers* deep pink, lower tepals with median dark red arrow-shaped streak and speckled with dark red toward base and in lower throat, base of throat red, unscented; perianth tube obliquely funnel-shaped, 20–26 mm long, widening in upper 8–10 mm; tepals lanceolate, margins undulate to lightly crisped, dorsal largest, 28–34 × 15–20 mm, arching over stamens, curving upward distally, upper laterals ± 30 × 16 mm, curving outward and spreading distally, lower 3

Distribution of ***Gladiolus oreocharis***.

Distribution of ***Gladiolus crispulatus***.



tepals joined to upper laterals for 6–8 mm and together for 1.5–3.0 mm, 20–25 × 8 mm, curving toward ground in distal ½. *Filaments* 14–19 mm long, exserted 5–9 mm from upper part of tube; anthers 8–11 mm long, lilac-pink; pollen whitish. *Style* arching over stamens, pink, dividing between upper ⅓ and slightly beyond apices of anthers, branches 3–5 mm long. *Capsules* and *seeds* unknown. *Flowering time*: mainly November to December.

Distribution and ecology: endemic to the Langeberg between Swellendam and Riversdale in Western Cape, South Africa; on south-facing sandstone slopes from 300 to 900 m elevation, flowering only after fire.

Diagnosis: a summer-flowering species with linear leaves, 1–3 mm wide with two main veins on one side, floral bracts 24–33 mm long, and deep pink flowers with undulate or crisped tepals, the lower three marked with median red chevrons and speckles toward the base. The species may be confused with local populations of *Gladiolus oreocharis*, but that species has mostly wider leaves (1–)2–6 mm wide and shorter, obtuse bracts mostly 13–20 mm long, and flowers with lozenge-shaped nectar guides on the lower tepals.

39. **Gladiolus phoenix** *Goldblatt & J.C.Manning*, *Gladiolus* in southern Africa: 126 (1998). Type: South Africa, [Western Cape], Bain's Kloof Mtns, Baviaanskloof, Nov. 1944, *Linley s.n.* (SAM, holo.; SAM, iso.).

Plants 500–750 mm high. *Corm* globose, 8–12 mm diam., with clusters of small cormlets around base on short fasciated stolons; tunics membranous, becoming finely fibrous but not accumulating significantly. *Stem* erect, usually with 1–3 branches. *Leaves* 6 to 9 (with an additional leaf per branch), lower 3 to 5 basal, reaching to base of spike, narrowly lanceolate to nearly linear, 6–12(–20) mm wide, main vein lightly raised, margins scarcely so, upper 1 or 2 leaves not normally sheathing stem, sometimes with short blades. *Spike* lightly flexed at base and inclined, secund, 9- to 12-flowered; bracts grey-green, outer lightly folded in upper midline, apices often slightly hooked, becoming brown near end of flowering, 13–16 mm long, inner shorter to nearly as long, minutely forked. *Flowers* deep pink, lower 3 tepals each with white, spear-shaped mark in midline outlined in deep pink, decurrent on the lower ½ of throat and with a broad white transverse band on reverse, unscented; perianth tube obliquely funnel-shaped, 18–20 mm long, lower cylindric part ± 10 mm long; tepals lanceolate, dorsal largest, 26–28 × 15 mm, ascending, upper laterals ± 23 × 13 mm, directed forward below, curved outward, becoming patent distally, lower 3 tepals united basally for ± 4 m, shortly clawed and channelled below, free parts of lower laterals ± 17 × 7.5–13.0 mm, lower median ± 20 × 9–13 mm. *Filaments* ± 20 mm long, exserted ± 13 mm from tube; anthers ± 8 mm long, dark purple; pollen pale yellow. *Style* arching over stamens, dividing just below anther tips, branches ± 6 mm long. *Capsules* narrowly ovoid, lightly 3-lobed above and retuse, 12–15 mm long. *Seeds* ovate, ± 8 × 5 mm, broadly and evenly winged. *Flowering time*: November to early December.

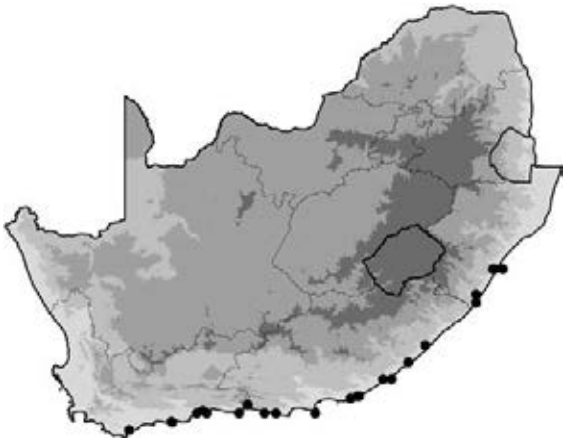
Distribution of ***Gladiolus phoenix***.

Distribution and ecology: restricted to moist banks and ravines in the Bain's Kloof Mtns above Wellington in Western Cape, South Africa; flowering only after fire,

Diagnosis: diagnosed by the branched stems up to 750 mm high, relatively soft-textured leaves 6–20 mm wide, and the small, dark pink flowers with short perianth tube 18–20 mm long, and lower tepals each with a white lozenge-shaped nectar guide outlined with red. The corms develop characteristic short, fasciated stolons bearing clusters of small cormlets.

Ser. **Sabulosi** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus gueinzii* Kunze

Plants littoral on dunes, moderate-sized. *Corm* producing dimorphic cormlets at base (cormlets from deeply buried corms small with soft tunics but cormlets from exposed or shallow corms larger with thick, leathery tunics), tunics leathery to fibrous. *Stem* suberect, producing clusters of cormlets at nodes. *Leaves* leathery, subsucculent; bracts leathery, smooth. *Spike* secund. *Flowers* small, subactinomorphic, mauve to purple with lozenge-shaped median markings on lower tepals; perianth tube shorter than dorsal tepal.



40. **Gladiolus gueinzii** *Kunze* in Hortus universitatis literarum Lipsiensis, seminum anno 1844 perceptorum offert delectum: [2] (1845). Type: South Africa, [KwaZulu-Natal], Durban (as Port Natal), without date, *Gueinzius 490* (*460* in protologue) (S, neo. [photo in NBG]).

Gladiolus sabulosus G.J.Lewis: 31 (1941), a replacement name for *Acidanthera brevicollis* Baker: 339 (1876b) [not *G. brevicollis* Klatt (1882). Type: South Africa, [Eastern Cape], Bathurst District, mouth of Fish River, Feb., *MacOwan 1890* (K, holo.).

Plants (200–)300–500 mm high. *Corm* globose, 25–35 mm diam., with numerous cormlets around base; tunics leathery, breaking up into fibrous fragments; corms near soil surface producing larger cormlets with dark brown, thickly leathery to corky, fissured tunics. *Stem* suberect, often branching after flowers of main axis have faded and capsules are ripening, with clusters of cormlets at nodes, cormlets sometimes sprouting on parent plant. *Leaves* usually 4 to 6, mostly basal, up to 600 mm long shorter or longer than stem, linear, 4–6 mm wide, slightly succulent, only midvein evident when live but hardly thickened (when dry midrib and margins evidently thickened), upper 1 or 2 leaves sometimes entirely sheathing. *Spike* weakly inclined at base, not or only weakly flexuose, (2)4- to 8-flowered; bracts pale grey-green or greyish pink, outer 18–27 mm long, acute, inner slightly shorter, usually forked. *Flowers* zygomorphic or occasionally actinomorphic, mauve to light purple, upper 3 tepals with red-purple median streak, lower 3 with white median streaks outlined in red-purple; perianth tube ± cylindric, 13–15 mm long; tepals subequal, obovate, 17–20 × 8–10 mm, or outer 3 slightly larger and to 13 mm wide, weakly to strongly spreading distally, lower 3 tepals slightly narrowed at bases and weakly clawed. *Filaments* unilateral or symmetrically disposed, 7–10 mm long, exserted 1.5–3.0 mm from tube; anthers 5.5–8.0 mm long, purple; pollen grey-blue to cream-coloured. *Style* dividing between base and middle of anthers, branches ± 5 mm long. *Capsules* obovoid to ellipsoid, 26–32 mm long. *Seeds* oval, 10–14 × 6–10 mm, broadly and evenly winged. *Flowering time*: mainly September to December (winter-rainfall zone), November to January (summer-rainfall zone).

Distribution and ecology: extending along the Indian Ocean Coast of South Africa from Arniston in Western Cape along the Eastern Cape Coast to Durban in KwaZulu-Natal; on sandy beaches and foredunes above the tidal high level.

Cormlets produced by deeply buried corms are small with soft-textured tunics but those produced by corms that have been exposed at the sand surface are larger, up to 15 mm long, with a dark, corky or leathery outer tunic. Buoyant and probably impermeable to sea water, these cormlets must be assumed to be floating propagules.

Distribution of ***Gladiolus gueinzii***.

Diagnosis: the littoral habitat is unique among southern African *Gladiolus* species and this, combined with the narrow, glaucous and subsucculent leaves and subactinomorphic, purplish flowers with white nectar guides, are diagnostic for the species.

Ser. **Blandi** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus carneus* D.Delaroche

Plants moderate-sized to large. *Corm* tunics papery to fibrous. *Stems* erect, glabrous. *Leaves* ± firm-textured, with thickened margins and main vein; bracts leathery, glabrous. *Spike*s secund. *Flowers* small to large, zygomorphic, usually pink to cream-coloured, rarely purple, with lozenge- or spear-shaped median markings on lower tepals outlined with red; perianth tube mostly longer than dorsal tepal.

41. **Gladiolus carneus** *D.Delaroche*, Descriptiones plantarum aliquot novarum 3: t. 4 (1766). *G. blandus* var. *carneus* (D.Delaroche) Ker Gawl.: 140 (1827) [misapplied by Andrews: t. 240 (1802) to *G. brevifolius* Jacq.]. Type: South Africa, without precise locality or collector (L, holo.).

Gladiolus trimaculatus Lam.: 727 (1788). Type: South Africa, without precise locality or date, *Sonnerat s.n.* (P, holo.).

Gladiolus ventricosus Lam.: 727 (1788). *G. cuspidatus* var. *ventricosus* (Lam.) Baker: 205 (1892). Type: South Africa, without precise locality or date, *Sonnerat s.n.* (P, holo.).

Gladiolus blandus Ait.: 64 (1789). Type: South Africa, without precise locality, cult. at Royal Botanic Gardens, Kew, *Masson s.n.* (BM, holo.).

Gladiolus albidus Jacq.: t. 256 (1795 [1788–1795]). *G. blandus* var. *albidus* (Jacq.) Ker Gawl.: 140 (1827). Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 256 (1795 [1788–1795]).

Gladiolus tristis var. *cordatus* Thunb.: 13 (1784). *G. cordatus* (Thunb.) Thunb.: 185 (1800). Type: South Africa, without precise locality, *Thunberg s.n.* (UPS-THUNB 1017, holo.).

Gladiolus campanulatus Andrews: t. 188 (1801). *G. blandus* var. *campanulatus* (Andrews) Ker Gawl.: 140 (1827). Type: South Africa, without precise locality or collector, illustration in Andrews: t. 188 (1801).

Gladiolus blandus var. *purpureo-albescens* Ker Gawl.: t. 645 (1803a). *G. lunulatus* Klatt: 342 (1882), as a replacement name for *G. blandus* var.

purpureo-albescens. Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 645 (1803a).

Gladiolus blandus var. *excelsus* Ker Gawl.: 2 (1821). *G. pictus* Sweet: 297 (1826), replacement name for *G. blandus* var. *excelsus* Ker Gawl. (1821). *G. excelsus* (Ker Gawl) Sweet: 501 (1830a), illegitimate superfluous name for *G. pictus* Sweet [based on same type]. Type: South Africa, without precise locality or collector, cultivated in England, illustration in Ker Gawler in Curtis's Botanical Magazine 40: t. 1665 (1814).

Gladiolus expallescens Schrank: 210 (1822). Type: South Africa, without precise locality or collector, cultivated in Belgium (BR, holo.).

Gladiolus vinulus Klatt: 199 (1885). Type: South Africa, [Western Cape], near Wynberg, Sept. 1884, *MacOwan 2651* in *Herb. Norm. Austr. Afr. 287* (SAM, holo.; B, BM, G, K, P, S, UPS, iso.).

Gladiolus macowanianus Klatt: 199 (1885). Type: South Africa, [Western Cape], Cape Peninsula, grassy slopes behind Hout Bay, Oct. 1884, *MacOwan 2065* (as *2605*) in *Herb. Norm. Austr. Afr. 284* (SAM, holo.; S, iso.).

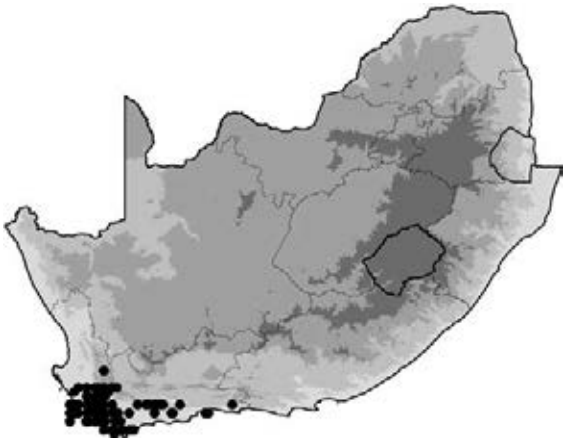
Gladiolus cuspidatus var. *ensifolius* Baker: 205 (1892). Type: South Africa, [Western Cape], Houw Hoek, Oct., *Pappe s.n.* (K, holo.).

Gladiolus prismatosiphon Schltr.: 102 (1899). Type: South Africa, [Western Cape], Bredasdorp Mtns near Napier, 9 Dec. 1896, *Schlechter 9656* (B, holo.; BM, BOL, K, Z, iso.).

Gladiolus callistus F.Bolus in L.Bolus: 105 (1917). Type: South Africa, [Western Cape], Worcester District, Orchard Siding, 5 Oct. 1915, *Dicey s.n.* (BOL [Natl. Bot. Gard. 1217/13], lecto., designated by Goldblatt & Manning: 130 (1998); BOL, PRE, isolecto.)

Gladiolus callistus var. *gracilior* F.Bolus: 105 (1917). Type: South Africa, Western Cape, Bredasdorp District, Ratel River, 12 Dec. 1896, *Bolus 8693* (BOL, holo.; BOL, K, PRE, iso.).

Gladiolus eximius Ingram: 40 (1931a). Type: South Africa, [Western Cape], Caledon District, Palmiet River Mouth, without date, *Ingram s.n.* [K, lecto., designated by Goldblatt & Manning: 130 (1998)].



Gladiolus carneus var. *hibbertii* Baker: 217 (1892). Type: unknown.

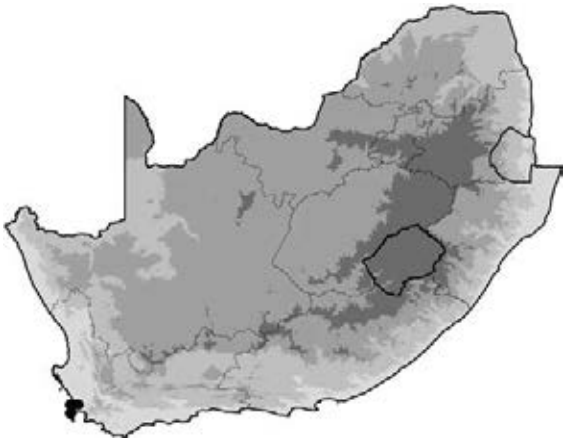
[*Gladiolus dubius* Eckl.: 41 (1827), invalid name without description.]

Plants 200–600(–800) mm high, with cataphylls purple with cream-coloured or greenish spots. *Corm* ± globose, 15–20 mm diam.; tunics papery, fragmenting irregularly or becoming ± fibrous. *Stem* erect, inclined or drooping, simple, occasionally with 1(2) branches. *Leaves* 4 or 5, lower 2 or 3 basal, usually forming a fan or sometimes superposed, reaching at least to base of spike or longer, sometimes trailing, narrowly lanceolate to nearly linear, (2–)6–14(–19) mm wide, main vein and 1 or more secondary veins lightly thickened, margins narrowly hyaline, cauline leaves sometimes with short blade. *Spike* usually lightly flexed at base, inclined or erect, flowers nearly 2-ranked, (3)5- to 8(11)-flowered; bracts pale green or flushed grey, outer 35–45(–65) mm long, shorter than outer, acute or forked apically. *Flowers* white to pale or deep pink, lower tepals usually with pink to red spade- or diamond marks decurrent on tube, sometimes with linear median streaks, or unmarked, or with pale yellow blotches, tube often spotted or lined with red at base of throat, unscented; perianth tube narrowly funnel-shaped, (15–)25–38(–45) mm long, lower cylindric part 22–29 mm long, usually just emerging from bracts; tepals lanceolate, margins usually undulate or sometimes almost crisped, unequal, upper 3 largest, dorsal 28–40(–50) × 12–20(–30) mm, ascending, upper laterals slightly smaller, gently curving outward from base, lower 3 tepals sometimes joined to upper laterals for up to 6 mm, 25–30(–40) × 7–15 mm, nearly straight and horizontal or spreading distally, rarely somewhat spooned. *Filaments* 12–17(–25) mm long, exserted 5–10(–15) mm from tube; anthers 6–11 mm long, mauve; pollen cream-coloured or purple. *Style* arching over stamens, dividing between bases and apices of anthers, branches 4–8(–10) mm long. *Capsules* oblong-ellipsoid, 3-sided, obscurely 3-lobed above, 20–30 cm long. *Seeds* oblong, 7–9 × 5–6 mm, broadly and evenly winged. *Flowering time*: October to mid-November, occasionally later.

Distribution and ecology: endemic to the coastal and near-inland mountains of Western Cape, South Africa, from Ceres to the Cape Peninsula and as far south as Bredasdorp, also on the Langeberg and occasional on the Outeniqua Mtns north of Knysna; on cooler, rocky slopes, often along streams.

Diagnosis: a polymorphic species, varying in most features, especially flower shape, colour and markings but recognised by the moderately soft-textured leaves and the large, white to pink flowers with the perianth tube

Distribution of ***Gladiolus carneus***.



± as long as the dorsal tepal and usually slightly exserted from the bracts. Plants from the Langeberg and Outeniqua Mtns have paler flowers with more strongly crisped tepals, whereas those from the west are usually pink with less undulate tepals. Populations from coastal marshes between Rooi Els and Kleinmond have unmarked flowers with the lower tepals spooned, although similar floral morphs occur elsewhere as well.

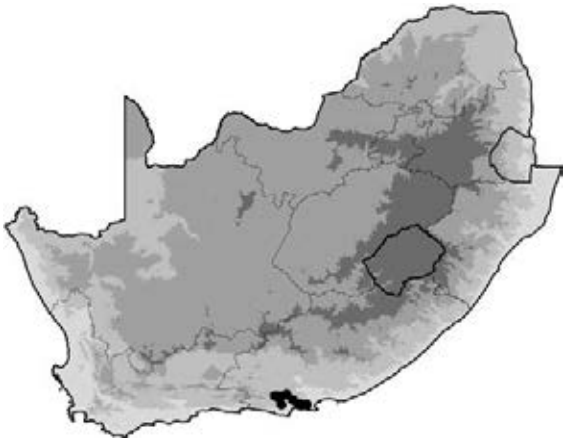
Gladiolus carneus is especially difficult to distinguish from forms of *G. pappei,* a slender species with narrow, superposed leaves and 2 to 4 dark pink flowers, and from *G. undulatus*, a hygrophilous species with cream-coloured, attenuate and crisped tepals, and a perianth tube longer than the dorsal tepal.

42. **Gladiolus pappei** *Baker*, Handbook of the Irideae: 208 (1892). Type: South Africa, [Western Cape], Table Mtn., Dec., *Pappe s.n.* (K, holo.; SAM, iso.).

Plants 250–350 mm high, with cataphylls often decayed. *Corm* globose, 5 mm diam.; tunics membranous. *Stem* usually erect below, flexed outward above sheaths of upper 2 leaves but usually becoming erect again, unbranched. *Leaves* 3 or 4(5), lower 2 basal, lowermost usually fairly small, second lowest reaching to between middle of stem and base of spike, linear, 1.6–3.0 mm wide, main vein and margins noticeably thickened, cauline leaves smaller and mostly sheathing. *Spike* nearly erect or lightly flexed at base and weakly inclined, lightly flexuose, (1)2- or 3(4)-flowered; bracts greyish green, often flushed purple-grey, outer 25–45 mm long, inner shorter to ± as long, notched apically. *Flowers* deep or sometimes pale pink, lateral tepals usually with white median diamond- to heart-shaped markings reddish on edges, lower median tepals less prominently marked, base of upper part of throat red, unscented; perianth tube obliquely funnel-shaped, 30–35 mm long, lower cylindric part ± 12 mm long; tepals ± lanceolate, dorsal inclined over stamens, straight or curving upward distally, 26–30 × 15–19 mm, upper laterals gently curving outward from base, barely fully patent near apex, 25–28 × 12–15 mm, lower 3 tepals joined to upper laterals for ± 2 mm and together for ± 2 mm, horizontal below and curving downward distally, 20–28 × 10–11 mm, lower median slightly longer than lower laterals. *Filaments* 12–17 mm long, exserted 5–8 mm from tube; anthers 6–8 mm long, pale grey-blue; pollen pale mauve. *Style* arching over stamens, dividing between middle and shortly beyond anther apices, branches 5–7 mm long. *Seeds* ovate, 6.0–7.5 × 4–6 mm, broadly and evenly winged. *Flowering time*: mid-October to mid-December.

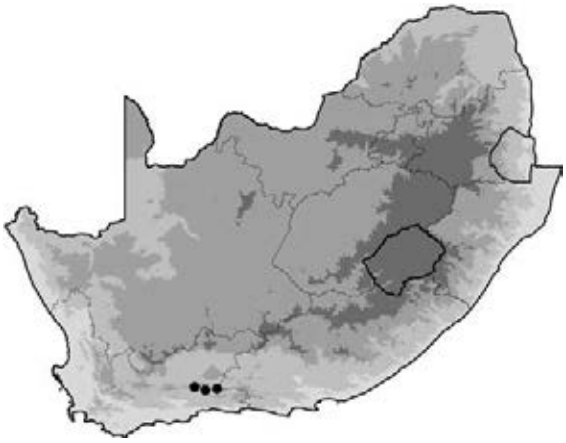
Distribution and ecology: a narrow endemic of Western Cape, South Africa, known with certainty only from the Cape Peninsula, from the Back Table to near Cape Point; in seasonally or perennially marshy habitats, flowering only after fire. Similar plants from the high plateau above Jonkershoek may be this species but are currently included in *G. carneus* on the basis of their wider leaves and more attenuate tepals.

Distribution of ***Gladiolus pappei***.



Diagnosis: difficult to separate from slender forms of *Gladiolus carneus* but diagnosed by its very narrow leaves, 1.6–3.0 mm wide, and few-flowered spike of one to four, mostly dark pink flowers with relatively short, lanceolate tepals, a preference for marshy habitats, and the very small corm, ± 5 mm diam. *Gladiolus pappei* is sympatric with *G. carneus* on the Cape Peninsula.

43. **Gladiolus geardii** *L.Bolus* in Annals of the Bolus Herbarium 4: 28 (1925). Type: South Africa, [Eastern Cape], Farm Hadley near Steytlerville, mountain slopes, cultivated at Kirstenbosch Gardens, Dec. 1923, *Paterson s.n. Natl. Bot. Gard. 135/23* (BOL, holo. [on 3 sheets]; K, iso.).



Gladiolus geardii var. *uitenhagensis* L.Bolus: 101 (1934). Type: South Africa, [Eastern Cape], Uitenhage District, Kamaehs, Apr. 1932, *Harcourt-Wood s.n.* (BOL [*BOL1319*], holo. [on 2 sheets]; K, SAM, iso.).

Gladiolus robustus Goldblatt: 453 (1984). Type: South African, [Eastern Cape], Baviaanskloof Mountains, Farm Enkeldoorn, 820 m, 16 Nov. 1982, *Vlok 475* (NBG, holo. [on 2 sheets]; MO, PRE, iso.).

Plants 0.8–1.5 m high. *Corm* depressed-globose, 15–20 mm diam.; tunics membranous, decaying to softly fibrous. *Stem* flexed outward below base of spike, inclined above, usually with 1 or 2 branches. *Leaves* 7 to 9, mostly basal, ± ½ as long as stem, narrowly lanceolate, 14–28 mm wide, main vein moderately thickened, margins lightly thickened. *Spike* inclined, lightly flexuose, 6- to 10-flowered; bracts green, outer 30–50(–60) mm long, inner shorter. *Flowers* pink to light purple, lower 3 tepals each with dark purple spear-shaped mark in lower midline, often pale in centre, unscented; perianth tube obliquely funnel-shaped, 30–40 mm long, cylindrical lower part 24–32 mm long; tepals lanceolate, dorsal largest, extending ± horizontally over stamens, 40–55 × 28–30 mm, upper laterals spreading, 45–50 × ± 20 mm, lower 3 tepals 35–40 × 15–18 mm,

Distribution of ***Gladiolus geardii*** .

Distribution of ***Gladiolus aquamontanus***.

lower median slightly longer than laterals. *Filaments* 20–30 mm long, exserted 14–18 mm from tube; anthers 9–14 mm long, purple; pollen cream-coloured. *Style* arching over stamens, dividing opposite upper ⅓ of anthers, branches ± 8 mm long. *Capsules* ovoid-ellipsoid, ± 28 mm long. *Seeds* ovate, 6.5–7.0 × 4–5 mm, broadly and evenly winged. *Flowering time*: November to mid-December.

Distribution and ecology: restricted to a few localities in Eastern Cape, South Africa, including Baviaanskloof and the Great Winterhoek, Kouga and Van Staden's River Mtns; in moist montane situations in seeps, streambanks and shady kloofs; flowering in late spring and early summer.

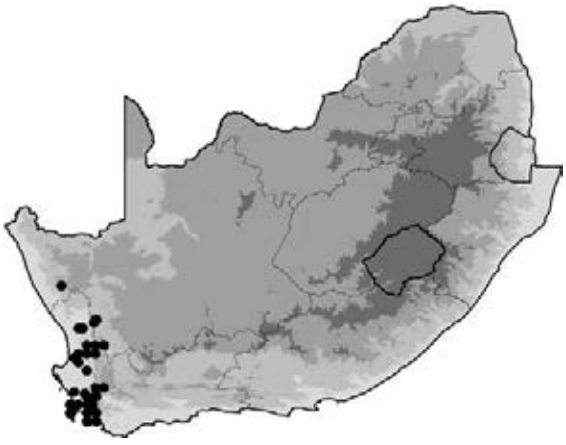
Diagnosis: a robust species, mostly more than 0.8 m tall, with seven to nine leaves and multi-flowered inflorescences of pink to purple flowers, the perianth tube 30–40 mm long and the dorsal tepal 40–55 mm long. *Gladiolus carneus*, which is not recorded east of Knysna, is a smaller plant, seldom more than 600 mm tall, with 4 or 5 leaves and mostly smaller flowers with the dorsal tepal 28–40(–50) mm long.

44. **Gladiolus aquamontanus** *Goldblatt* in South African Journal of Botany 55: 261 (1989). Type: South Africa, [Western Cape], Swartberg Mtns, northern slopes of Blesberg, in perennial stream, 1 585 m, 15 Dec. 1986, *Vlok 1774* (PRE, holo.; K, MO, NBG, SAAS, iso.).

Plants 400–1 000 mm high, inclined or drooping, with cataphylls often decaying. *Corm* vestigial, resembling an erect rhizome, 9–12 mm diam.; tunics softly papery, not persisting. *Stem* inclined to drooping, unbranched. *Leaves* (4)5 or 6, lower 3 basal, soft-textured, narrowly lanceolate, 8–15 mm wide, main vein lightly raised, cauline leaves shorter, uppermost bract-like, partly to entirely sheathing. *Spike* inclined or drooping, usually 4- to 8-flowered, occasionally less; bracts green, soft-textured, outer 25–40 mm long, inner shorter. *Flowers* pale mauve-pink, lower 3 tepals with fairly broad, dark purple longitudinal median streak in basal ⅔ and purple toward base of upper part of tube; perianth tube (25–)34–40 mm long, slender and cylindric below for 20–30 mm, curving outward and flared in upper 5–10 mm; tepals lanceolate, dorsal largest, inclined to arching over stamens, 30–35 × 10–12 mm, upper laterals curving outward distally, ± 28 × 7 mm, lower 3 tepals extending forward ± horizontally, 25–30 × ± 10 mm. *Filaments* 15–20 mm long, exserted 10–15 mm from tube; anthers ± 7 mm long, dark purple; pollen cream-coloured. *Style* arching over stamens, dividing between base and apex of anthers, branches 5–6 mm long. *Capsules* narrowly obovoid, 18–22 mm long. *Seeds* narrowly oblong to slightly sigmoid, 7–9 × ± 2.5 mm, unevenly winged with wing narrow at sides. *Flowering time*: mid-November to late December.

Distribution and ecology: a local endemic of the Swartberg in Western Cape, South Africa, where it has been recorded between Swartberg Pass and Blesberg near Meiringspoort; in perennial streams and on wet cliffs, flowering in late spring and early summer.

Diagnosis: recognised by the reduced, rhizome-like rootstock with a basal fan of four to six, relatively soft-textured leaves, and pale mauve-pink flowers with perianth tube 34–40 mm long and slightly longer than the dorsal tepal. The oblong or slightly sigmoid seeds are unusual in the series.



45. **Gladiolus undulatus** *L.*, Mantissa plantarum 1: 27 (1767). Type: South Africa, without precise locality or collector, ?cult. in Holland *LINN59/11* (LINN, holo.).

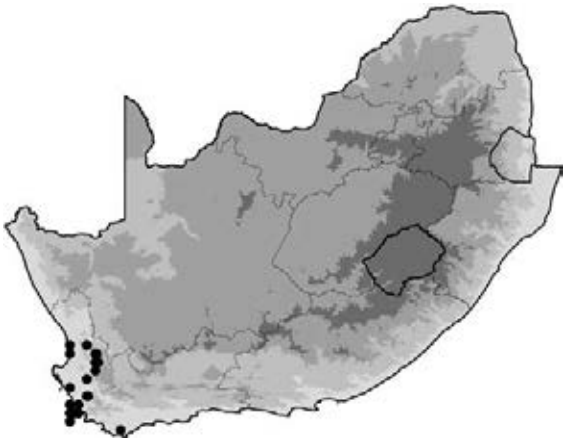
Gladiolus cuspidatus Jacq.: 5, t. 257 (1795) [1788–1795]. Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 257 (1795).

Gladiolus affinis Pers.: 45 (1805). Type: South Africa, Cape, without precise locality or collector, illustration in Andrews: t. 219 (1802) '*G. cuspidatus* Jacq.'.

Plants (250–)450–1 500 mm high, with cataphylls reddish purple speckled with white. *Corm* depressed-globose, 16–24 mm diam.; tunics soft-textured, not normally persisting. *Stem* erect below, lightly flexed above sheaths of upper 3 leaves, inclined above, unbranched or robust plants with 1 or 2 branches. *Leaves* 4 or 5, at least lower 2 basal and usually reaching to ± middle of spike, narrowly lanceolate, 5–12 mm wide, main vein lightly raised and thickened, margins hyaline but barely thickened, cauline leaves shorter. *Spike* inclined, ± 2-ranked, (3)6- to 9(12)-flowered; bracts firm-textured, dull green or flushed dull purple, outer 33–40(–70) mm long, inner shorter and completely enclosed by outer. *Flowers* pinkish cream-coloured to greenish or pale lilac, lower tepals each with reddish to purple diamond-, spear-shaped or linear marking in lower midline, base of upper part of tube with reddish to purple blotches opposite bases of tepals, unscented; perianth tube 52–75 mm long, cylindric below for 45–60 mm, flared in upper 7–9 mm; tepals narrowly lanceolate-attenuate, margins strongly undulate, dorsal largest, extended almost horizontally over stamens and arching distally, 40–50 × 12–15 mm, upper laterals gradually curving outward, 40–45 × 10–12 mm, lower 3 tepals united for ± 2 mm, directed forward below, somewhat twisted and curving downward distally, 33–36 × 6–9 mm, lower median slightly longer than laterals. *Filaments* (12–)15–28 mm long, exserted 6–13 mm from tube; anthers 8–9 mm long, cream-coloured above, purple below; pollen purple. *Style* arching over stamens, usually dividing shortly beyond anther apices or sometimes below, branches ± 6 mm long. *Capsules* oblong-ellipsoid, 20–27 mm long. *Seeds* ovate, ± 8 × 5 mm, broadly and evenly winged. *Flowering time*: mid-November to late December.

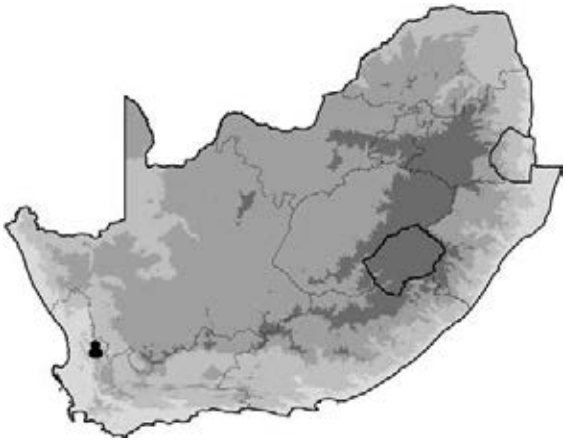
Distribution and ecology: essentially restricted to the Atlantic Coast and adjacent interior of Western and Northern Cape, South Africa, from Nieuwoudtville to Bredasdorp, with an outlying population to the north on the Kamiesberg; in seasonally wet or moist sites along streams and marshes, mainly on sandstone but also granite, flowering in late spring and early summer.

Distribution of ***Gladiolus undulatus***.



Diagnosis: vegetatively similar to *Gladiolus carneus* but distributed mostly north and west of that species and distinguished by the consistently paler flowers with longer perianth tube, 52–75 mm long, about twice as long as the bracts and longer than the dorsal tepal, and the attenuate, ± strongly undulate or crisped tepals. The distinction between the species is especially difficult between Wellington and Paarl, where their distributions overlap.

46. **Gladiolus angustus** *L.*, Species plantarum: 37 (1753). [*G. angustifolius* Salisb.: 40 (1796), ?orthographic variant or illegitimate homonym]. *G. telifer* Stokes: 217 (1830), illegitimate superfluous name for *G. angustus* L. Type: South Africa, without precise locality, cultivated in Holland, illustration in Linneaus, Hortus Cliffortianus: 20, t. 6 (1738), lecto., designated by Stearn in Introduction to Linnaeus' Species Plantarum (Ray Society Edition): 47 (1957). In error: Herb. Linnaeus *LINN59.16* (LINN, [as holotype]).



Plants 0.6–1.2 m high, with cataphylls obscurely mottled with green or white. *Corm* ± globose, 14–20 mm diam.; tunics papery, fragmenting irregularly. *Stem* erect or inclined, flexed outward above sheaths of 2 cauline leaves, simple or branched. *Leaves* 4 or 5, lower 2 or 3 basal and reaching or shortly exceeding spike, narrowly lanceolate, (3–)5–10 mm wide, main vein lightly thickened, margins narrowly hyaline, cauline leaves shorter. *Spike* flexed at base, inclined, weakly flexuose, (3)5- to 9-flowered; bracts with outer (30–)50–65(–80) mm long, pale green sometimes flushed reddish, inner shorter to ± as long, minutely forked. *Flowers* cream-coloured to pale yellow, lower 3 tepals with spade-shaped yellow marking in midline outlined in dark red, unscented; perianth tube cylindric, expanded in upper 10 mm, (45–)60–110 mm long; tepals lanceolate, dorsal largest, 32–40 × 16–18 mm, extended ± horizontally over stamens, upper laterals 28–38 × 10–13 mm, extending forward, curving outward distally, 3 lower tepals 25–30 × 9–10 mm, extending forward and nearly horizontal, in profile shorter than upper tepals. *Filaments* 17–24 mm long, exserted 8–12 mm from tube; anthers 9–11 mm long, whitish; pollen cream-coloured. *Style* extending over stamens, dividing just below anther apices, branches 6–8 mm long. *Capsules* ellipsoid, acute, (25–)35–40 mm long. *Seeds* ovate, 8–9 × 5–6 mm, broadly and evenly winged. *Flowering time*: October and November.

Distribution and ecology: occurring along the Atlantic Coast and near interior mountains of Western Cape, South Africa, extending from the Cederberg and Piketberg to the Cape Peninsula, with an isolated population near Elim; in seasonally moist places and along streams and in marshes.

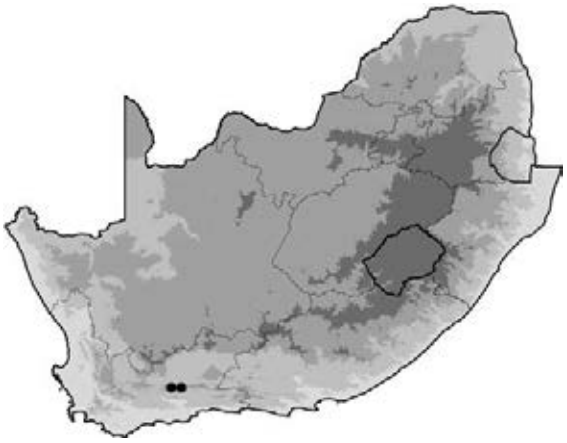
Diagnosis: distinguished from closely allied *Gladiolus carneus* and *G. undulatus* by the combination of a very long perianth tube, (45–)65–110 mm long, and relatively

Distribution of ***Gladiolus angustus***.

Distribution of ***Gladiolus buckerveldii***.

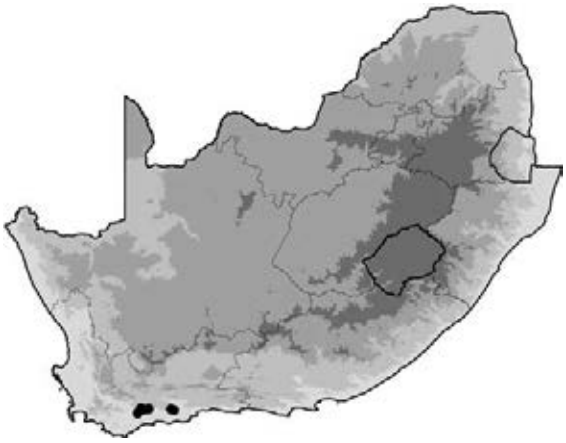
short tepals, the dorsal 32–40 mm long with the lower tepals markedly shorter. Lowland populations along the Atlantic Coast have especially long perianth tubes. The geographical variation in perianth tube length is associated with similar variation in the length of the proboscis of the local long-proboscid flies that are the pollinators (Manning & Goldblatt 1997).

47. **Gladiolus buckerveldii** *(L.Bolus) Goldblatt* in Journal of South African Botany 37: 443 (1971). *Antholyza buckerveldii* L.Bolus: 118 (1927). *Petamenes buckerveldii* (L.Bolus) N.E.Br.: 276 (1932a). Type: South Africa, [Western Cape], Clanwilliam District, mountains above Algeria Forest Station, 1 000 m, 1926, cultivated at Kirstenbosch Gardens 75/26, *Buckerveld s.n.* [as *Natl. Bot. Gard. 75/26*] (BOL, holo. [on 3 sheets]; K, iso.).



Plants 0.80–1.25 m high, trailing from cliffs, cataphylls usually light purple mottled pale green. *Corm* globose, 15–24 mm diam.; tunics soft-papery, soon decaying. *Stem* inclined to drooping, unbranched. *Leaves* 5 or 6, lower 3 or 4 basal, narrowly lanceolate, 25–35 mm wide, ± trailing distally, main vein and 1 or 2 pairs of secondary veins prominent, margins not thickened. *Spike* inclined or ± horizontal, strongly secund, 12- to 20-flowered; bracts fairly soft-textured, outer 50–80 mm long, reaching to between top of perianth tube and top of flower, inner bracts shorter, acute. *Flowers* ivory-coloured to creamy yellow, lower tepals with a spade- or heart-shaped dark red mark in centre, unscented; perianth tube 45–50 mm long, slender below, widening to 6–7 mm diam. in upper ½; tepals lanceolate, dorsal largest, 28–32 × 13 mm, extended horizontally, upper laterals ± 21 × 10 mm, curving outward ± from base, lower 3 much smaller, ± 12 × 6 mm, curving gradually outward. *Filaments* 25–28 mm long, exserted ± 10 mm from tube; anthers ± 10 mm long, cream-coloured turning to lilac; pollen cream-coloured. *Style* arching over stamens, dividing at or near anther tips, branches ± 5 mm long. *Capsules* oblong, obtuse, 22–26 mm long. *Seeds* oblong to slightly sigmoid, 8–9 × 3–4 mm, broadly winged at one end and sometimes weakly at opposite end but hardy at all on the sides. *Flowering time*: January, rarely in late December.

Distribution and ecology: a local endemic of the northern Cederberg in Western Cape, South Africa; on mossy cliffs along permanent streams and waterfalls, often in the spray zone, flowering in midsummer.



Diagnosis: a summer-flowering species characterised by its long spikes of narrowly tubular flowers, the upper part of the tube cylindric with comparatively short tepals, especially the lower, and disproportionately long bracts reaching at least to the top of the perianth tube and sometimes to the top of the flower.

48. **Gladiolus dolichosiphon** *Goldblatt & J.C.Manning* in Bothalia 39: 37 (2009). Type: South Africa, Western Cape, Rooiberg, south of track between Rooiberg Pass and Bailey's Peak, 7–23 Feb. 2008, *A.L. Schutte & J. Vlok 941* (NBG, holo.; K, MO, iso.).

Plants 200–400 mm high, with cataphylls purple obscurely mottled with green or white. *Corm* subglobose, 10–15 mm diam.; tunics softly fibrous. *Stem* inclined outward above basal leaves, unbranched or with small lateral branch from axil of 1 or both uppermost leaves. *Leaves* 6 or 7, lower 3 basal and reaching or shortly exceeding spike, linear to narrowly lanceolate, 1.5–4.0(–6.5) mm wide, main vein slightly thickened, margins hyaline, cauline leaves smaller and sheathing. *Spike* flexed at base, inclined, weakly flexuose, 4- or 5(7)-flowered, subsecund; bracts flushed purple, 20–30(–35) mm long, subacute or lower attenuate, inner shorter, subacute. *Flowers* pale creamy pink to salmon-coloured, lower 3 tepals with pale lozenge-shaped median mark outlined in dark red, unscented; perianth tube cylindric, expanded in upper 10 mm, straight or arched distally, (30–)40–55 mm long; tepals lanceolate, dorsal largest, 30–40 × 15–17 mm, arching forward over stamens, curving upward distally, upper laterals 25–28 × 12–14 mm, curving outward above, lower 3 tepals united basally

Distribution of ***Gladiolus dolichosiphon***.

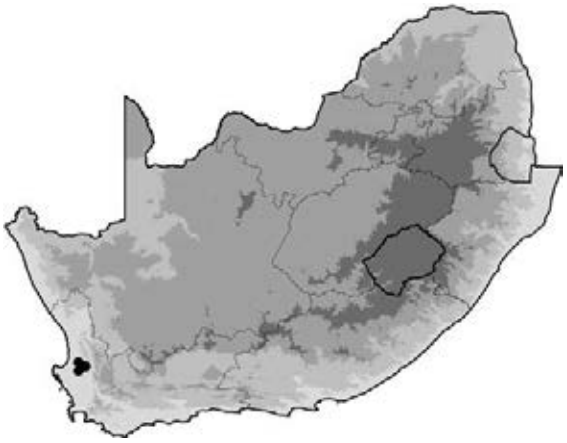
Distribution of ***Gladiolus bilineatus***.

for ± 2 mm, narrowly lanceolate, 20–25 × 4–5 mm. *Filaments* 16–20 mm long, exserted 10–14 mm from tube; anthers 8–9 mm long, purple; pollen cream-coloured. *Style* arching beneath dorsal tepal, dividing just below to just beyond anther apices, branches 5–6 mm long. *Capsules* obovoid, 3-lobed, 18–25 mm long. *Seeds* unknown. *Flowering time*: late January to mid-February.

Distribution and ecology: endemic to the mountains of the Little Karoo in Western Cape, South Africa, on the Klein Swartberg and the Rooiberg; on cooler south-facing slopes in seasonally moist situations, at 1 300 and 1 900 m elevation, flowering in midsummer.

Diagnosis: recognised by the narrow leaves and spikes of creamy pink or pale salmon-pink flowers with slender perianth tube 30–55 mm long and longer than the relatively shorter tepals. It broadly resembles autumn-flowering *Gladiolus bilineatus* from the southern foothills of the Langeberg, but that species has just three, mostly slightly wider leaves on the flowering stem and a slightly longer perianth tube 50–70 mm long, with the filaments shortly exserted only ± 2 mm.

49. **Gladiolus bilineatus** *G.J.Lewis* in Lewis et al. in Journal of South African Botany, Suppl. 10: 268 (1972). Type: South Africa, [Western Cape], Riversdale District, foothills of Langeberg Mtns, 27 Mar. 1934, *Ferguson s.n.* (BOL, holo.; K, SAM, iso.).



Plants 200–350 mm high, with cataphylls green or sometimes obscurely speckled with purple. *Corm* ± globose, 18–24 mm diam.; tunics finely fibrous. *Stem* erect or inclined, lightly flexed outward above sheaths of upper 2 leaves, unbranched. *Leaves* 3, lowermost basal and reaching to ± base of spike, linear-lanceolate, 6–8 mm wide, midvein evident but only lightly thickened, margins narrowly hyaline, cauline leaves progressively smaller, usually overlapping. *Spike* lightly inclined, ± straight, 2- to 5-flowered; bracts green or flushed dull purple, outer 40–50(–60) mm long, inner shorter, usually minutely forked. *Flowers* creamy pink to pale salmon-coloured, lower 3 tepals with long pale median streak edged in dark pink to red, unscented; perianth tube 50–70 mm long and cylindric in lower 40–50 mm, flared in upper 10–20 mm; tepals lanceolate, dorsal largest, 23 × 15–16 mm, inclined nearly horizontally over stamens, upper laterals 22–23 × 9 mm, curving outward distally, lower 3 tepals joined to upper laterals for ± 3 mm, 15–17 × 7–8 mm. *Filaments* ± 20 mm long, exserted ± 2 mm from tube; anthers ± 9 mm long, purple; pollen lilac. *Style* arching over stamens, dividing just beyond anther apices, branches ± 4 mm long. *Capsules* ovoid [mature capsules not seen]. *Seeds* ovate, 5.5–6.5 mm long, broadly and evenly winged. *Flowering time*: March and April.

Distribution and ecology: a poorly collected species of the southern foothills of the Langeberg in Western Cape, South Africa, from Tradouw Pass to Albertinia; in fynbos–renosterveld transitional vegetation on loamy soils, flowering in autumn.

Diagnosis: an autumn-flowering species with only three leaves on the flowering stem and few-flowered spikes of pale pink to salmon-pink flowers with long, slender perianth tube 50–70 mm long, the filaments mostly included and exserted just ± 2 mm. Non-flowering plants produce a single long leaf.

50. **Gladiolus insolens** *Goldblatt & J.C.Manning*, *Gladiolus* in southern Africa: 139 (1998). Type: South Africa, Western Cape, Piketberg Mtns, SW slopes of Zebrakop, 4 Jan. 1995, *Goldblatt & Manning 10166* (NBG, holo.; K, MO, PRE, iso.).

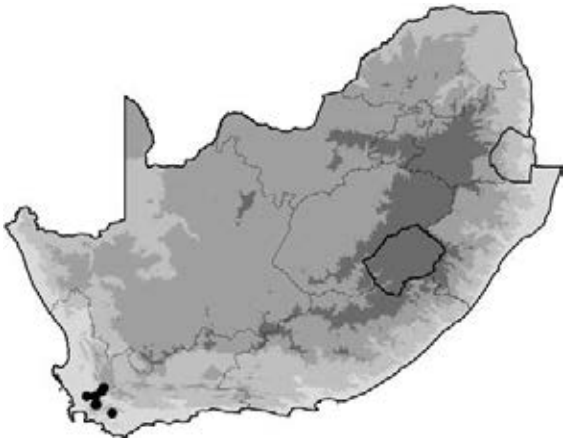
Plants 300–500 mm high. *Corm* globose, 18–20 mm diam.; tunics papery becoming softly and finely fibrous. *Stem* inclined to trailing, occasionally hanging from rocks, usually unbranched or with one short branch. *Leaves* 5 or 6, lower 3 basal, up to 300 mm long, inclined to trailing, linear, 3.5–5.5 mm wide, main vein thickened and lightly raised, margins narrowly hyaline, not thickened, cauline leaves progressively smaller, usually overlapping. *Spike* curving upward and inclined, 1- to

Distribution of ***Gladiolus insolens***.

4-flowered, lightly flexuose; bracts firm-textured, light green, outer 30–45 mm long, inner shorter, minutely notched. *Flowers* bright scarlet, tepals forming a wide bowl with apices curving inward, lower tepals each with obscure darker red median blotch in upper ½; perianth tube cylindric below, ± 38 mm long, slightly curved and flared in upper 10 mm; tepals subequal, upper 3 slightly larger than lower 3, broadly obovate, arching forward with apices curving inward, 27–30 × 18–20 mm, slightly spooned, in profile lower exceeding upper by ± 8 mm. *Filaments* ± 20 mm long, exserted ± 7 mm from tube; anthers ± 8 mm long, scarlet; pollen pale yellow. *Style* arching over stamens, dividing opposite lower ⅓ of anthers, branches ± 12 mm long. *Capsules* and *seeds* unknown. *Flowering time*: late December to mid-January.

Distribution and ecology: endemic to the Piketberg in Western Cape, South Africa, and known only from Zebrakop; on cooler slopes along streams and seeps, flowering in midsummer.

Diagnosis: unmistakable in its scarlet, tulip-shaped flowers with obovate, cupped tepals. The fan of several hairless leaves distinguishes it from the unrelated, autumn-flowering *Gladiolus stokoei* from the Riviersonderend Mtns, which has remarkably similar flowers but highly reduced, softly hairy foliage.



51. **Gladiolus cardinalis** *Curtis* in The Botanical Magazine 4: t. 135 (1790). Type: South Africa, without precise locality or collector, cultivated in England, illustration in Curtis: t. 135 (1790).

Gladiolus speciosus Eckl.: 41 (1827), illegitimate homonym, not *G. speciosus* Thunb. (1811). Type: unknown.

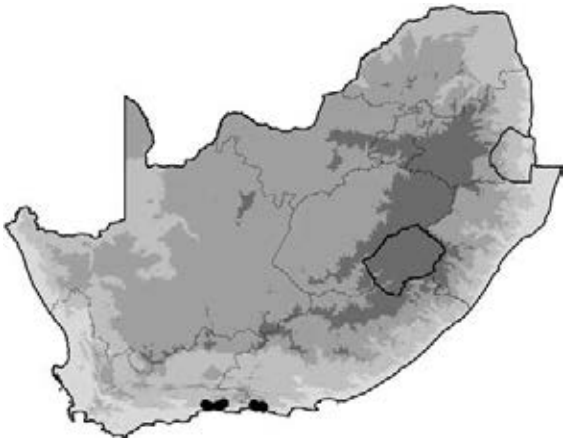
Plants 550–900 mm high. *Corm* poorly developed, globose, 12–18 mm diam., attached to rocks, not underground, tunics firm membranous to papery, decaying into fine fibres but not accumulating. *Stem* inclined to drooping, unbranched. *Leaves* 5 to 7, lower 3 or 4 basal, always drooping but reaching to base or sometimes slightly exceeding spike, narrowly lanceolate, 11–21 mm wide, main vein thickened and slightly raised and 1 other vein pair prominent, margins not thickened, cauline leaves smaller and largely sheathing. *Spike* inclined or drooping, flowers borne on upper side, (4) 8- to 11-flowered; outer bract 45–60(–70) mm long, inner shorter, acute, not normally notched apically. *Flowers* bright red, lower 3 tepals with broad median white longitudinal spear-shaped mark, unscented; perianth tube 32–40 mm long, straight or obliquely funnel-shaped, lower cylindric part ± 28 mm long; tepals lanceolate, acute or obtuse, unequal, dorsal largest, held apart, spreading or slightly recurved, 45–55 × 24–30 mm, upper laterals spreading distally, 48–56 × 20–22 mm, lower 3 tepals joined to upper laterals for 3–7 mm and together for 1–3 mm, 36–53 × 17–19 mm. *Filaments* (25–)35–42 mm long, exserted 23–29 mm from tube; anthers 11–14 mm long, upper surface reddish, lower surface white with violet sutures on thecae; pollen cream-coloured. *Style* arching over stamens, dividing opposite upper ⅓ of anthers, branches 8–14 mm long. *Capsules* obovoid, 18–27 mm long. *Seeds* ovate to oblong, 6–8 × 3.5–4.0 mm, wing evenly developed or reduced at sides. *Flowering time*: mid-December to mid-January.

Distribution and ecology: restricted to the mountains in the extreme southwest of Western Cape, South Africa, from the Hex River Mtns to Du Toit's Kloof and Worcester; usually on sheer cliffs close to waterfalls, flowering in midsummer.

Diagnosis: one of three allopatric species with similar, large red flowers with white marks on the lower tepals, *Gladiolus cardinalis* is distinguished by the well-developed foliage, small corm, and habitat, trailing from wet cliffs. Autumn-flowering *Gladiolus sempervirens* from the Outeniqua and Tsitsikamma Mtns is a more leafy, evergreen species with a rhizome-like rootstock and scaly stolons. Both have flowers adapted for pollination by the large butterfly, *Aeropetes tulbaghia*.

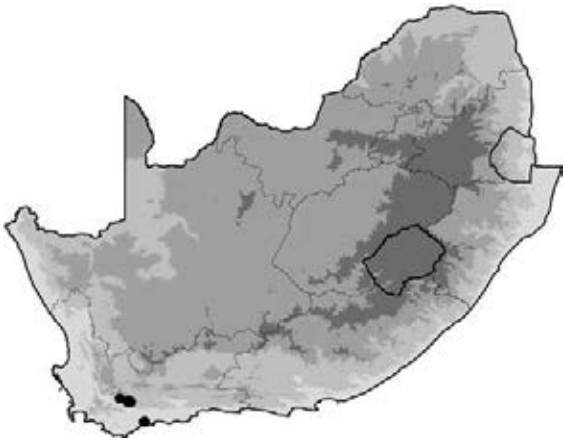
Distribution of ***Gladiolus cardinalis***.

52. **Gladiolus sempervirens** *G.J.Lewis* in Lewis et al. in Journal of South African Botany, Suppl. 10: 18 (1972), replacement name for *G. splendens* Baker: 333 (1876b), illegitimate homonym, not *G. splendens* (Sweet) Herb. (1843). Type: South Africa, Western Cape, George District, mountains near Oakhurst, Apr. 1870, *Dumbleton s.n.* (K, holo.).



Plants 350–1 000 mm high, evergreen. *Corm* 8–12 mm diam., shallowly seated, producing scaly, rhizome-like stolons from base; tunics leathery and not much distinguished from bases of leaves. *Stem* erect or inclined, flexed above sheathing parts of upper 1 or 2 leaves, sometimes with a branch, 2.5–4.0 mm diam. below base of spike. *Leaves* 7 to 12, lower 5 to 10 basal, reaching to ± the middle of stem, lanceolate, 6–18 mm wide, main vein and 1 other vein pair lightly thickened, margins not thickened. *Spike* inclined, bearing flowers on upper surface, 4- to 8-flowered; bracts soft-textured, outer 35–55(–70) mm long, inner shorter to about as long. *Flowers* deep carmine red, lower 3 tepals with narrow longitudinal white streak in lower midline, unscented; perianth tube funnel-shaped, 25–42 mm long, lower cylindric part ± 15 mm long; tepals elliptic, dorsal broadly elliptic, largest, 55–58 × 32–36 mm, upper laterals ± 54 × 31 mm, lower 3 joined basally for ± 4 mm, ± 50 × 20 mm. *Filaments* 28–42 mm long, exserted 20–24 mm from tube; anthers ± 14 mm long, purple; pollen yellow. *Style* arching over stamens, dividing opposite anther apices, branches 7–8 mm long. *Capsules* oblong, 3-lobed above and retuse, (15–)20–25 mm long. *Seeds* oval, ± 8 × 6 mm, wing well developed. *Flowering time*: February to March, rarely April.

Distribution and ecology: restricted to the southern slopes of the Outeniqua Mtns between George and Knysna in Western Cape, South Africa, and on both sides of the Tsitsikamma Mtns as far east as Kareedouw in Eastern Cape; in seeps and perennially damp, sheltered situations.



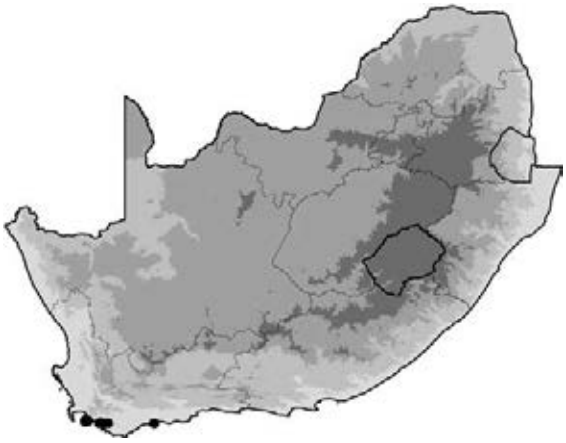
Diagnosis: one of three allopatric species with similar, large red flowers with white marks on the lower tepals, distinguished by the evergreen habit, numerous, relatively soft-textured leaves and the rhizome-like rootstock with well-developed, scaly stolons.

53. **Gladiolus stefaniae** *Oberm.* in Lewis et al. in Journal of South African Botany, Suppl. 10: 252 (1972). Type: South Africa, [Western Cape], Montagu District, mountains west of Cogmanskloof, Farm Kalkoensnes, 1 Apr. 1970, *Pienaar s.n.* (NBG, holo.).

Plants 400–650 mm high, with cataphylls dark purple and usually lightly mottled with cream-coloured or green. *Corm* globose, ± 20 mm diam.; tunics papery becoming soft and finely fibrous. *Stem* ± erect, slightly flexed outward above sheaths of upper 2 leaves, unbranched. *Leaves* 3 to 5(6), all cauline, lowermost lanceolate, blade shorter than sheath, others usually entirely sheathing; non-flowering plants producing 3 or 4 linear leaves ± 5 mm wide, main vein fairly strongly thickened, margins lightly raised. *Spike* erect, 2- to 4-flowered; bracts pale green or flushed grey, outer 55–65 mm long, inner shorter. *Flowers* bright scarlet or carmine, lower 3 tepals with median whitish streak in lower midline, sometimes paler on edges and shading to mauve, unscented; perianth tube 35–45 mm long, narrowly and obliquely funnel-shaped, lower cylindric part 25–30 mm long; tepals with outer whorl larger, broadly lanceolate to ovate, dorsal inclined over stamens, 53–58 × 25–32 mm, upper laterals 50–60 × 25–27 mm, spreading distally, lower 3 tepals joined to upper laterals for ± 3 mm, 45–48 × 23–25 mm. *Filaments* 30–42 mm long, exserted 20–32 mm from tube; anthers ± 13 mm long, yellow with purple lines on sutures of thecae or uniformly dark purple; pollen cream-coloured. *Style* arching over filaments, dividing opposite lower ⅓ of anthers, branches 10–12 mm long. *Capsules* oblong-ellipsoid, 18–25 mm long. *Seeds* oval, broadly and evenly winged, 6.5–8.0 × ± 5.5 mm. *Flowering time*: early March to mid-April.

Distribution of ***Gladiolus sempervirens***.

Distribution of ***Gladiolus stefaniae***.



Distribution and ecology: a local endemic of Western Cape, South Africa, with a disjunct distribution in the Langeberg near Montagu between 700 and 1 400 m elevation, and on the Potberg west of Cape Infanta; on rocky, south-facing slopes in fynbos, flowering in autumn.

Diagnosis: distinguished from *Gladiolus cardinalis* and *G. sempervirens* with similar, large red flowers by the upright habit, mottled cataphylls and reduced leaves with the blades shorter than the sheaths or lacking. Typical populations from the Langeberg are bright scarlet but those from the Potberg are carmine. The latter form especially resembles *G. carmineus* from coastal scrub between Pringle Bay and Cape Infanta and has been identified as that species in the past, but *G. carmineus* has smaller, more cupped flowers with perianth tube ± 30 mm long, dorsal tepal ± 35 mm long, and filaments 21–26 mm long.

54. **Gladiolus carmineus** *C.H.Wright* in Curtis's Botanical Magazine 132: t. 8068 (1906). Type: South Africa, [Western Cape], cliffs at Hermanus, cultivated at Royal Botanic Gardens, Kew, *Abercrombie Smith s.n.*, illustration in Wright: t. 8068 (1906), lecto., designated by Goldblatt & Manning: 145 (1998); K [flower fragment], isolecto.

Plants (160–)300–500 mm high, with cataphylls dark purple mottled with cream-coloured or green. *Corm* globose, 20–25 mm diam.; tunics membranous layers becoming fibrous, extending upward in collar around base. *Stem* erect, flexed outward above sheaths of 2 upper leaves, unbranched. *Leaves* 3 to 5, all cauline, lowermost with vestigial lanceolate blade shorter than sheath, up to 50 mm long, upper leaves smaller, usually bladeless; non-flowering plants usually with 2 long, trailing, falcate leaves, these dry and decaying at flowering, 8–10 mm wide, glaucous, main vein lightly thickened. *Spike* erect, flexuose, 2- to 6-flowered; bracts pale green or flushed grey, outer 30–40 mm long, inner shorter. *Flowers* pale to deep pink, lower 3 tepals each with a median whitish streak surrounded by a pale mauve halo, occasionally upper lateral tepals similarly marked, unscented; perianth tube 30–35 mm long, narrowly funnel-shaped; tepals broadly lanceolate, outer 3 larger and ± as long, dorsal 35–45 × 18–27 mm, upper laterals and lower median 33–48 × 16–28 mm, lower 3 tepals joined to upper laterals for up to 4 mm, spreading ± horizontally. *Filaments* 21–26 mm long, exserted 10–15 mm from tube; anthers 10–14 mm long, usually yellow; pollen cream-coloured. *Style* arching over stamens, dividing opposite lower half of anthers, branches ± 10 mm long. *Capsules* narrowly obovoid, 20–22 mm long. *Seeds* ovate, 8 × 6–7 mm, broadly and evenly winged. *Flowering time*: mid-February to late March.

Distribution and ecology: a local endemic of coastal cliffs and rock outcrops in southern Western Cape, South Africa, from Pringle Bay to Hermanus, Gansbaai and Cape Infanta; in low coastal scrub, flowering in late summer to autumn.

Distribution of ***Gladiolus carmineus***.

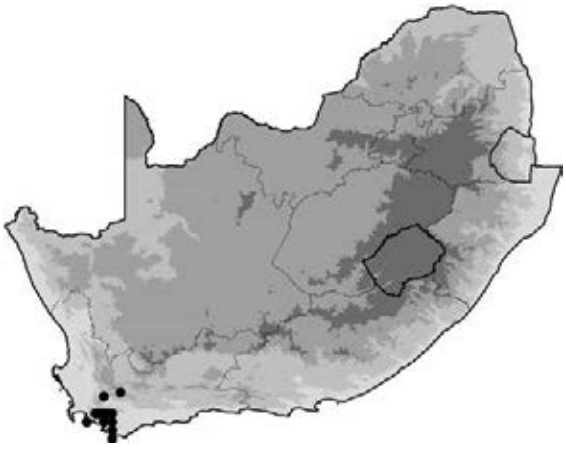
Diagnosis: an autumn-flowering species recognised by the reduced foliage and moderately large, funnel-shaped, carmine flowers with perianth tube 30–35 mm long. It has been confused with vegetatively similar *Gladiolus stefaniae* on the Potberg, but that species has larger, usually red flowers with perianth tube 35–45 mm long, dorsal tepal 53–58 mm long and filaments 30–42 mm long.

Ser. **Floribundi** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus floribundus* Jacq.

Plants moderate-sized to large. *Corm* tunics firm-papery to coarsely fibrous, accumulating in a thick mass. *Stems* short and mostly concealed by leaves. *Leaves* ± firm-textured, in a distinct fan, firm-textured with thickened margins and main vein; bracts leathery, glabrous. *Spike*s secund. *Flowers* moderate-sized to large, zygomorphic, pink to cream-coloured or yellow-green, with lozenge-, spade- or spear-shaped median markings on lower tepals outlined with red; perianth tube shorter or longer than dorsal tepal.

55. **Gladiolus rudis** *Licht. ex Roem. & Schult.*, Systema vegetabilium secundum 1: 408 (1817). *G. floribundus* subsp. *rudis* (Licht. ex Roem. & Schult.) Oberm. in Lewis et al.: 108 (1972). Type: South Africa, Cape, without precise locality or collector, but possibly *M. Lichtenstein* [B: Herb. *Willdenow 917* [photo at NBG], lecto., designated by Lewis et al.: 108 (1972)].

Gladiolus vomerculus Ker Gawl.: 142 (1827). Type: South Africa, Western Cape, without precise locality or collector, cultivated in Great Britain by William Herbert, illustration in Ker Gawler: t. 1564 (1813) as '*G. hastatus* Thunb.'.



[*Gladiolus tigrinus* Eckl. ex Baker: 173 (1877), invalid name only in synonymy under *G. hastatus* Thunb.]

Plants 150–550 mm high, with purple cataphylls mottled with green or white, roughly textured on mottling. *Corm* ± globose, 20–40 mm diam.; tunics firm-papery

becoming medium to coarsely fibrous, accumulating in a thick mass. *Stem* flexed outward above sheaths of two upper leaves, usually unbranched. *Leaves* 4 to 7, lower 3 to 5 basal and reaching base of spike or often shortly exceeding it, sheaths often mottled purple and green below, sword-shaped, 7–15(–20) mm wide, margins and main vein and 1 or 2 vein pairs lightly or sometimes moderately thickened, margins occasionally minutely crisped, cauline leaves shorter. *Spike* strongly inclined, sometimes horizontal, lightly flexuose, 2- to 5-flowered; bracts green or flushed brownish or purple, 35–50(–65) mm long, sometimes lightly folded in upper midline, inner shorter. *Flowers* cream-coloured, whitish or pale pink, lower half of tepals darker coloured on reverse, lower lateral tepals with yellowish spade-shaped longitudinal mark outlined in red or purple, throat yellow, unscented; perianth tube obliquely funnel-shaped, 18–21 mm long, lower cylindric part 8–10 mm long, emerging from middle of bracts, occasionally reaching bract apices; tepals lanceolate to elliptic, acute, subequal, dorsal slightly larger, ascending, arching upward distally, 32–36 × 18–20 mm, upper laterals 29–32 × 18–22 mm, spreading distally, lower tepals united for 2–3 mm, 26–32 × 13–15 mm. *Filaments* 12–14 mm long, exserted 5–7 mm from tube; anthers 9–12 mm long, white; pollen white. *Style* usually arching over stamens, rarely suberect, dividing opposite lower ½ of anthers, branches 6–8 mm long. *Capsules* and *seeds* unknown. *Flowering time*: early September to mid-October.

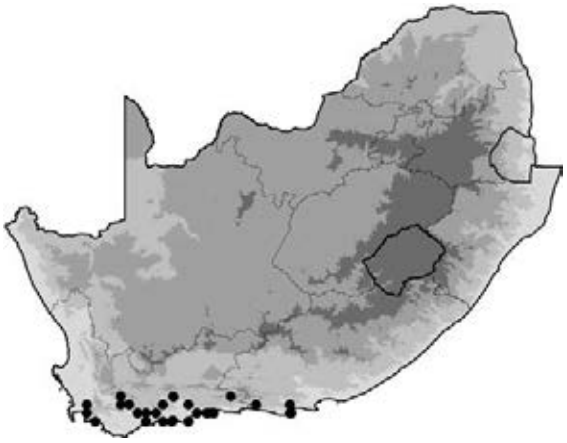
Distribution and ecology: a local endemic of Western Cape, South Africa, from the lower slopes of the Riviersonderend and Bredasdorp Mtns and south of Elim; on stony sandstone slopes in fynbos.

Diagnosis: distinguished from other species in the series with similar short stems and thickly fibrous tunics accumulating in a mass by the short-tubed flowers with perianth tube 18–21 mm long and lower tepals with a yellowish, spade-shaped marking outlined with red or purple, and the short filaments 12–14 mm long. The raised white mottling on the cataphylls is also distinctive.

Distribution of ***Gladiolus rudis***.

56. **Gladiolus grandiflorus** *Andrews*, The Botanist's Repository 2: t. 118 (1800). Type: South Africa, Cape, without precise locality or collector, cultivated in Great Britain, illustration in Andrews: t. 118 (1800).

Gladiolus milleri Ker Gawl.: t. 632 (1803b). *G. floribundus* subsp. *milleri* (Ker Gawl.) Oberm. in Lewis et al.: 104 (1972). Type: South Africa, without precise locality or collector, cultivated in Great Britain at Kensington, illustration in Ker Gawl.: t. 632 (1803b).



Gladiolus fasciatus Roem. & Schult.: 429 (1817), new name for *G. vittatus* Hornem.: 950 (1815), illegitimate homonym, not *G. vittatus* Zuccagni (1806). *G. floribundus* subsp. *fasciatus* (Roem. & Schult.) Oberm. in Lewis et al.: 107 (1972). Type: South Africa, without precise locality or collector (C, holo.).

Geissorhiza grandis Hook.f.: t. 5877 (1870b). Type: South Africa, [Eastern Cape], probably Port Elizabeth District, cultivated in Great Britain, *Wilson s.n.*, illustration in Hook.f.: t. 5877 (1870b).

Gladiolus scaphochlamys Baker: 217 (1892). Type: South Africa, [Western Cape], Swellendam District, Sparrbos near Buffeljags River, 30 July 1831, *Drège 8427* (K, lecto., designated by Goldblatt & Manning: 147 (1998); BM, G, K, L, MO, P, S, isolecto.).

Gladiolus socium L.Bolus: 14 (1931a). Type: South Africa, [Western Cape], George District, cultivated in Cape Town, Oct. 1929, *De Mole & Kisch s.n.* (BOL [*BOL 19083*], lecto., designated by Goldblatt & Manning: 147 (1998); BOL, K, isolecto.).

Plants (250–)350–500 mm high, with cataphylls purple, lightly mottled with green or white. *Corm* ± globose, 20–40 mm diam.; tunics papery, decaying into medium to coarsely textured fibres, accumulating in a thick mass. *Stem* erect below, flexed outward above sheaths of upper 2 leaves, usually unbranched. *Leaves* 4 to 7, lower 3 to 5 basal, reaching to base or often shortly exceeding spike, lanceolate, 6–15(–20) mm wide, margins and main vein and 1 or 2 other veins lightly or sometimes moderately thickened, margins occasionally minutely crisped, cauline leaves shorter. *Spike* strongly inclined to almost horizontal, lightly flexuose, (2)3- to 6(9)-flowered; bracts green or flushed brownish or purple, (30–)35–50(–65) mm long, sometimes lightly folded in upper midline, inner shorter. *Flowers* cream-coloured, whitish or pale pink, lower ½ of tepals darker coloured on reverse, upper lateral and lower tepals with pink to reddish median streak, throat yellow, sometimes with red at base, occasionally lightly scented; perianth tube obliquely funnel-shaped, (22–)27–35(–55) mm long, lower cylindric part 13–22(–40) mm long, reaching to between the middle and apices of bracts, rarely slightly longer; tepals obovate to oblanceolate, margins sometimes undulate or lightly crisped, obtuse to retuse, subequal or unequal, then upper 3 slightly larger or dorsal

Distribution of ***Gladiolus grandiflorus***.

largest, ascending, arching upward distally, 35–40(–44) × 13–20 mm, upper laterals 30–36 × 13–18 mm, curving outward distally, lower tepals united for 2–3 mm, 23–31(–37) × 8–13 mm. *Filaments* 14–22 mm long, exserted 4–12 mm from tube, cream-coloured or pink; anthers 7–11 mm long, white, cream-coloured, or purple; pollen white or mauve. *Style* usually arching over stamens, rarely suberect, dividing between middle and apex of anthers or slightly exceeding them, branches 5–9 mm long. *Capsules* narrowly obovoid to elliptic, 30–40 mm long. *Seeds* oval, 12–14 × 8–10 mm, broadly and evenly winged. *Flowering time*: August to mid-October.

Distribution and ecology: relatively widespread through the southern coastal and near-interior parts of South Africa, from Bot River in Western Cape to Port Elizabeth in Eastern Cape; often on clay soils, but also calcareous sands.

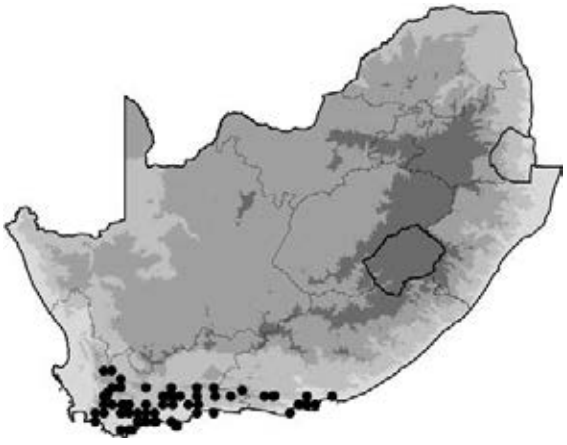
Diagnosis: separated from short-tubed *Gladiolus rudis* by the slightly longer perianth tube, usually 27–35(–50) mm long, the longer filaments, 14–22 mm long, and the different markings on the lower tepals, reddish median streaks rather than yellowish spade-shaped blotches outlined with red or purple. The white mottling on the cataphylls is not raised. *Gladiolus grandiflorus* may be difficult to separate from shorter-tubed forms of *G. floribundus* but that species usually has a longer perianth tube, 40–70 mm long, with the lower tepals markedly shorter than the upper.

Populations from calcareous sands along the coast near Stilbaai with pink flowers with crispulate tepals were treated as *G. fasciatus* but we regard them as a local form of *G. grandiflorus*. Populations from near Port Elizabeth, described as *Geissorhiza grandis*, have almost actinomorphic flowers.

57. **Gladiolus floribundus** *Jacq.*, Collectanea 4: 162 (1791). Type: South Africa, Cape, without precise locality or collector, illustration in Jacq.: t. 251 (1791 [1788–1795]) '*Gladiolus undulatus* L.'.

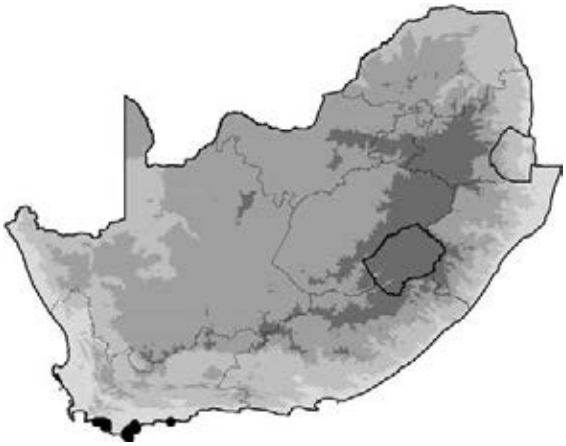
Antholyza spicata Mill.: 2 (1768) [not *Gladiolus spicatus* Linnaeus (1753)]. Type: South Africa, Western Cape, without precise locality or collector, cultivated in Great Britain, illustration in Miller, Figures of Plants 1: t. 40 (1755).

Gladiolus striatus Andrews: t. 111 (1800), illegitimate homonym, not *G. striatus* Jacq. (1791). *G. floribundus* var. *striatus* Pers.: 45 (1805). Type: South Africa, without precise locality or collector, cultivated at Hammersmith, London, illustration in Andrews: t. 111 (1800).



Gladiolus bowkeri G.J.Lewis: 26 (1941), as a replacement name for *Montbretia pauciflora* Baker: 336 (1876b) [not *G. pauciflorus* Baker in Oliver (1887)]. *Tritonia pauciflora* (Baker) Klatt: 358 (1882). *Acidanthera pauciflora* (Baker) Benth.: 706 (1883). Type: South Africa, Eastern Cape, Somerset East, without date, *Bowker s.n.* (K, holo., photo at BOL and PRE).

Acidanthera graminifolia Baker: 338 (1876b). *Gladiolus graminifolius* (Baker) G.J.Lewis in Lewis: 26 (1941). Type: South Africa, [Western Cape], plains between Swellendam and Gouritz River, in 1818 or 1819, *Bowie s.n.* (BM, holo.).



Acidanthera forsythiana Baker: 186 (1892). Type: South Africa, without precise locality, or collector (K: 'Herb. Forsyth', holo.).

?*Gladiolus vittatus* Zuccagni: 9, n. 16 (1806) [reprinted from J.J. Roemer, Collecteana: 121 (1806). Type: unknown.

Plants 250–450 mm high, with dull purple cataphylls usually mottled with green or white. *Corm* ± globose, 20–40 mm diam.; tunics of medium to coarsely textured fibres, accumulating in a mass. *Stem* flexed outward above sheath of uppermost leaf, inclined above, usually 1- or 2-branched. *Leaves* 6 to 8, lower 4 to 6 basal, reaching to ± base of spike but often flaccid and arching downward, lanceolate 12–20 mm wide, cauline leaves decreasing in size. *Spike* strongly inclined to nearly horizontal, flexuose, 3- to 8(13)-flowered; bracts dull green to grey-purple, outer (34–)40–50(–65) mm long, inner shorter or ± as long, minutely notched apically. *Flowers* cream-coloured or pale greenish yellow to ivory-coloured, rarely pale pink, all tepals or excepting dorsal with a broad streak of darker colour along midline, unscented; perianth tube obliquely funnel-shaped, 40–60(–70) mm long, cylindric lower part 25–35(–55) mm long; tepals lanceolate to elliptic, obtuse to retuse, margins usually undulate, dorsal largest, inclined over stamens, 30–45 × 16–20 mm, upper laterals 25–46 × 13–18 mm, lower tepals 18–29 × 7.5–10.0 mm, lower median slightly longer than laterals, up to 38 mm long. *Filaments* 20–22 mm long, exserted 4–10 mm from tube; anthers 6–9 mm long, purple; pollen cream-coloured to purple-brown. *Style* arching over stamens, dividing between middle and apex of anthers, branches ± 6 mm long. *Capsules* oblong-ellipsoid, 3-sided, 30–40 mm long. *Seeds* oval, 9–14 ×

Distribution of ***Gladiolus floribundus***.

Distribution of ***Gladiolus miniatus***.

7–10 mm, broadly and evenly winged. *Flowering time*: late September to November.

Distribution and ecology: widespread through the Cape Floristic Region of South Africa, mainly from Worcester in Western Cape to Port Elizabeth in Eastern Cape but as far east as Port Alfred and north into the Cederberg; mainly on sandstone but also limestone outcrops in drier situations. Pollinated by long-proboscid flies.

Diagnosis: distinguished from allied species by the pale flowers with longer, narrowly funnel-shaped perianth tube, 40–60(–70) mm long, and lower tepals markedly shorter than the upper. *Gladiolus miniatus* with salmon-pink to orange flowers has a differently shaped perianth, 50–65 mm long, divided into a narrow lower part and a broader cylindric upper part ± 30 mm long, and much longer filaments, 35–37 mm long.

58. **Gladiolus miniatus** *Eckl.*, Topographisches Verzeichniss der Pflanzensammlung von C.F. Ecklon: 40 (1827). *G. floribundus* subsp. *miniatus* (Eckl.) Oberm. in Lewis et al.: 103 (1972). Type: South Africa, without precise locality, probably from near Cape Agulhas, 25 Nov., *Ecklon 323* [S, lecto., designated by Lewis et al.: 103 (1972)].

Plants 150–400 mm high, with cataphylls dull purple usually lightly mottled with green or white. *Corm* ± globose, 20–30 mm diam.; tunics of medium to coarsely textured fibres, accumulating in a mass. *Stem* flexed outward above sheathing part of uppermost or upper 2 leaves, then strongly inclined to horizontal, simple or with a short branch. *Leaves* usually 6, lower 4 basal and longest, reaching or slightly exceeding spike, lanceolate, 7–18 mm wide, margins and main vein lightly thickened, cauline leaves shorter. *Spike* flexed outward at base and nearly horizontal, 3- to 7-flowered; bracts dull to greyish green often flushed purple, 40–55(–65) mm long, inner shorter, minutely notched. *Flowers* cream-coloured to light salmon on opening but soon becoming deep salmon-orange, reverse of tube reddish, tepals darker along midlines decurrent on tube, unscented; perianth tube 50–65 mm long, narrow and cylindric in lower 20–35 mm, curving outward in middle and broadly cylindric in upper 30 mm, 6–8 mm diam.; tepals lanceolate, margins lightly undulate, unequal, dorsal arching slightly above horizontal, 32–39 × ± 15 mm, upper laterals spreading distally, 30–37 × 10–13 mm, lower 3 tepals smaller, 28–34 × 8–9 mm, lower median sometimes slightly longer than laterals. *Filaments* 35–37 mm long, exserted 8–11 mm from tube; anthers 5–7 mm long, purple; pollen purple. *Style* arching over stamens, dividing opposite anther apices, branches ± 5 mm long. *Capsules* ovoid-ellipsoid, 25–30 mm long. *Seeds* ovate, ± 9 × 7 mm, broadly winged. *Flowering time*: October to mid-November, occasionally in December.

Distribution and ecology: a local endemic of coastal southern Western Cape, South Africa, from Hawston to Agulhas and The Downs near Riversdale; in calcareous sands and limestone outcrops.

Diagnosis: recognised by the distinctive flowers, pale to deep salmon-orange with darker tepal midlines and a distinctively shaped perianth tube, 50–65 mm long and divided into a narrow lower part and a broader cylindric upper part ± 30 mm long, and the relatively long filaments, 35–37 mm long. Related *Gladiolus floribundus* has a narrowly funnel-shaped perianth tube, cream-coloured to yellow-green flowers and shorter filaments, 20–22 mm long.

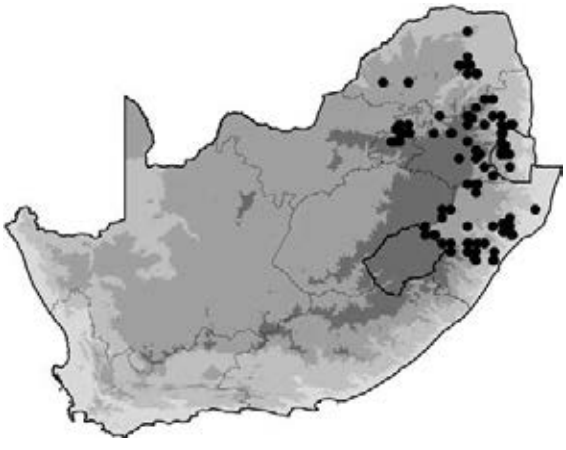
Sect. 4. **Linearifolii** *(M.P.de Vos) Goldblatt & J.C.Manning, Gladiolus* in southern Africa: 153 (1998) [as *Linearifolius*]. *Homoglossum* sect. *Linearifolii* M.P.de Vos: 336 (1976) [as *Linearifolius*]. Type species: *Gladiolus merianellus* (L.) Thunb.

Plants small to medium-sized. *Stem* unbranched. *Corm* tunics leathery to fibrous. *Leaves* several, either mostly basal in a fan or all cauline, sometimes much reduced on flowering stem, narrowly lanceolate to lanceolate, firm-textured, plane with thickened midrib and margins, usually at least 4 mm wide, usually villous or puberulous. *Spike* mostly few-flowered; bracts smooth, margins of inner bracts free. *Flowers* small to medium, weakly or more strongly bilabiate, nectar guides usually of streaks or spots, sometimes scented; perianth tube usually obliquely funnel-shaped, shorter or longer than dorsal tepal; lower tepals narrower but usually ± as long as upper. *Anthers* never tailed. *Capsules* oblong to subglobose and retuse above. *Seeds* broadly and evenly winged.

The section includes 17 southern African species plus several from tropical Africa.

Ser. **Pubigeri** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus pubiger* G.J.Lewis

Plants from the summer-rainfall region, flowering in spring. *Corm* tunics papery to fibrous. *Stems* erect but inclined above the upper leaf, smooth. *Leaves* reduced and mostly without blades on flowering stem. *Flowers* small, lower tepals often strongly clawed. *Capsules* subglobose, 3-lobed above and retuse.



59. **Gladiolus woodii** *Baker*, Handbook of the Irideae: 207 (1892). Type: South Africa, [KwaZulu-Natal], Inanda, Oct. 1880, *Wood 618* (K, holo.; BM, SAM, iso.).

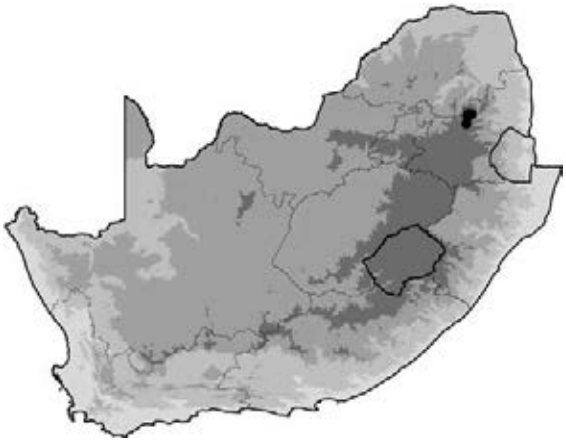
Gladiolus trichostachys Baker: 1007 (1904a). Type: South Africa, [Gauteng], Irene, date unknown, *Conrath 579* (GZU, holo.).

Gladiolus nudus N.E.Br.: 298 (1921). Type: South Africa, [Mpumalanga], Barberton (flowers yellow), Oct. 1919, *Thorncroft 1067* (K, holo.).

Plants 200–450(–900) mm high, with cataphylls sparsely to densely villous. *Corm* globose, 12–15 mm diam.; tunics of fine to moderately coarse-textured fibres, rarely accumulating. *Stem* lightly flexed outward above sheath of upper leaf, then inclined, unbranched. *Leaves* 2 or 3(4), lowermost basal and sheathing lower ½ of stem, blade lacking or linear to sword-shaped, 50(100) mm long, sparsely pilose, occasionally overlapping next leaf, cauline leaves sheathing, upper often bract-like, 20–28 mm long, glabrous; non-flowering plants with solitary, narrowly lanceolate leaf, 70–100 mm long at flowering but much longer later in season, densely pilose, margins and main and sometimes a second vein pair thickened and raised. *Spike* drooping in bud but straight and lightly flexed below base at anthesis, secund, (4)6- to 11-flowered; bracts pale grey-green to dark green or dorsal surface flushed brown to dull purplish, sometimes ± dry above at flowering, outer 12–16 mm long, inner slightly longer to shorter. *Flowers* either pale yellow, pale lilac or oyster-coloured, lower lateral tepals usually with longitudinal dark purple to brown streak along midline, rarely without markings, or maroon to reddish brown and lower laterals partly to entirely yellow with maroon median line, sometimes marked with purple spots at tepal sinuses, lower median tepal without markings, with a faint metallic odour (maroon flowers), a faint daffodil-like odour (oyster-coloured or lilac flowers), or evidently odourless (yellow flowers); perianth tube obliquely funnel-shaped, (4–)7–9(–12) mm long; tepals narrowly to broadly ovate, usually conspicuously apiculate, dorsal largest, inclined over stamens, 17–27 × 12–19 mm, margins sometimes lightly crisped, upper laterals nearly straight or spreading distally, margins undulate to strongly crisped, lower 3 tepals united with upper laterals for ± 2 mm and together for 2–3 mm, narrowed below into claws 2.5–4.0 mm long, becoming channelled toward base, lower laterals abruptly expanded into limbs 10–12 × 4–7 mm, auriculate at base, lower median limb 12–15 × 6–9 mm, often less strongly clawed, margins of lower tepal limbs lightly undulate to lightly crisped. *Filaments* 9–10(–13) mm long, exserted 5.5–8.0 mm from tube; anthers 6–9 mm long, blackish; pollen cream-coloured to pale yellow. *Style* arching over stamens, dividing between middle and apex of anthers, branches 3.5–5.0 mm long. *Capsules* ± globose, broadly 3-lobed above and retuse, 9–12 mm long. *Seeds* ovate to oblong, 6–7 × 4 mm, evenly winged. *Flowering time*: mainly September to early November, occasionally until mid-December.

Distribution and ecology: widespread through the higher-lying parts of Eswatini and eastern South Africa, from the Midlands and Drakensberg of southern KwaZulu-Natal

Distribution of ***Gladiolus woodii***.



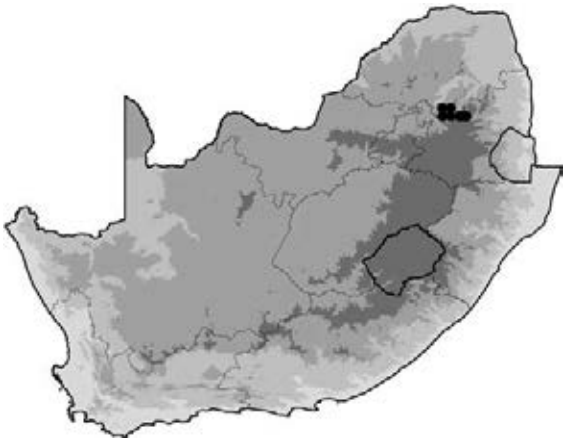
through Gauteng and Mpumalanga to the Soutpansberg in Limpopo; in low, stony grassland, often on clay soils, flowering best after fire, mostly early in the season soon after the first spring rains. The leaves on the flowering stem remain green and photosynthetic long after the seeds have been shed.

Diagnosis: recognised by the villous cataphylls and basal leaf sheaths, and the strongly bilabiate flowers with the upper tepals 17–27 mm long, the dorsal more-or-less hooded, and the lower tepals shortly clawed with auriculate limbs. Taller *Gladiolus malvinus* has sparsely hairy or glabrous leaves and larger, blue-mauve flowers with the upper tepals 28–30 mm long.

The species is highly polymorphic for flower colour, with an associated variation in floral scent. The distribution of the colour forms has no clear geographic pattern.

60. **Gladiolus malvinus** *Goldblatt & J.C.Manning*, *Gladiolus* in southern Africa: 155 (1998). Type: South Africa, Mpumalanga, dolerite mountain slopes north of Dullstroom, 29 Oct. 1994, *Goldblatt & Manning 10075* (NBG, holo.; K, MO, iso.).

Plants 550–700 mm high, with thinly villous cataphylls. *Corm* globose, 30–40 mm diam.; tunics of moderately coarse fibres, accumulating in a thick mass. *Stem* flexed lightly above sheaths of upper 2 leaves and inclined above, unbranched. *Leaves* (2)3, lowermost basal and sheathing lower ⅓ of stem, sheath usually sparsely villous or not, 10–50 mm long, narrowly lanceolate, overlapping second leaf, this entirely sheathing and glabrous, uppermost leaf shortest and bract-like; non-flowering plants with solitary, narrowly lanceolate leaf up to 300 mm long (probably longer later in season), pubescent, margins, main vein and one or more other vein pairs lightly thickened, margins not raised. *Spike* inclined, ± straight, 9- to 15-flowered; bracts grey-green, usually flushed purplish, becoming dry as flowers open, outer 20–25 mm long, inner slightly shorter. *Flowers* pale blue-mauve, lower lateral tepals with dark purple streak in midline and lightly to darkly shaded with purple in lower half, unscented; perianth tube obliquely funnel-shaped, ± 10 mm long; tepals broadly lanceolate, apiculate, dorsal largest, inclined over stamens, 28–30 × 14–16 mm, upper laterals directed forward, curving outward little or not at all distally, lower 3 tepals joined to upper laterals for ± 2 mm and together for ± 3 mm, lower laterals strongly clawed, claws ± 2.5 mm long, limbs oblong, ± 14 × 6 mm, channelled toward base, lower median obscurely clawed, ± 20 × 12 mm. *Filaments* ± 10 mm long, exserted ± 8 mm from tube; anthers ± 7 mm long, blackish; pollen cream-coloured. *Style* arching over stamens, dividing between middle and upper ⅓ of anthers, branches 2.5–3.0 mm long. *Capsules* obovoid, broadly 3-lobed above and retuse, (10–)12–14 mm long. *Seeds* ovate, ± 6 × 5–6 mm, evenly winged. *Flowering time*: October to early November.



Distribution of ***Gladiolus malvinus***.

Distribution and ecology: a local endemic of the eastern escarpment of Mpumalanga, South Africa, between Dullstroom and Belfast; on dolerite slopes in grassland and flowering after fire in spring soon after the first rains.

Diagnosis: very similar to *Gladiolus woodii* and co-occurring with it at the type locality but taller, 550–700 mm high, with sparsely villous or glabrous lower leaf sheaths and slightly larger, blue-mauve flowers with the upper tepals 28–30 mm long. The tunics accumulate in a mass around the stem base. *Gladiolus woodii* is usually less than 500 mm tall, often with more densely villous leaves, and smaller, lilac, yellow or brownish flowers with the upper tepals 17–27 mm long. The corm tunics do not accumulate.

61. **Gladiolus pardalinus** *Goldblatt & J.C.Manning*, *Gladiolus* in southern Africa: 157 (1998). Type: South Africa, Mpumalanga, 6 km (4 miles) northeast of Stoffberg, dolerite koppie, 2 Nov. 1994, *Goldblatt & Manning 10094* (NBG, holo.; K, MO, iso.).

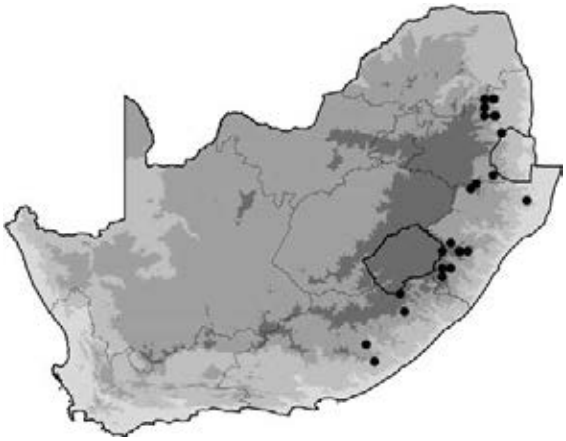
Plants 350–550 mm high, with lightly villous cataphylls. *Corm* ovoid to broadly conic, 18–22 mm diam.; tunics cartilaginous, decaying into fairly coarse vertical fibres, often accumulating in a dense mass. *Stem* erect, ± straight, unbranched. *Leaves* usually 3(4), entirely sheathing, lowermost basal, sheathing lower ¼ of stem, glabrous, normally not overlapping next leaf, second leaf inserted on lower ⅓ of stem, 100–150 mm long, uppermost leaf inserted on upper ⅓ of stem, 200–400 mm long; non-flowering plants ultimately with three leaves, 200–300 mm at flowering but later up to 500 mm long, sheaths sparsely villous, blades linear, 5–6 mm wide, lightly to fairly densely villous, margins and main vein moderately raised and thickened, secondary veins not or barely thickened. *Spike* drooping in bud, becoming straight as flowers open, 10- to 15-flowered; bracts pale grey-green often flushed grey-purple, outer 16–20 mm long, inner slightly shorter, notched apically. *Flowers* pale yellow, tepals of outer whorl densely speckled on lower ½ of limbs and on claws, lower lateral tepals irregularly

Distribution of ***Gladiolus pardalinus***.

streaked with dark purple lines, with a faint acrid odour; perianth tube obliquely funnel-shaped, ± 8 mm long; tepals narrowed below into claws, strongly apiculate, dorsal largest, inclined over stamens, 22–24 × ± 10 mm, upper laterals spreading distally, margins lightly crisped, 19–21 × ± 9 mm, limbs 11–12 mm long, lower 3 tepals united with upper laterals for ± 2 mm and together ± 3.5 mm, claws ± 4 mm long, abruptly expanded, lower laterals with limbs ± oblong, 10–11 × 4 mm, becoming channelled below and auriculate at base, lower margins raised and almost vertical, lower median ± 16 mm long, limb also abruptly expanded and auriculate at base, limb 11 × ± 7 mm. *Filaments* ± 15 mm long, exserted ± 11 mm from tube; anthers ± 6.5 mm long, dark red-purple; pollen cream-coloured. *Style* arching over stamens, dividing between base and lower third of anthers, branches ± 3 mm long. *Capsules* obovoid, 3-lobed above and retuse, 14–20 mm long. *Seeds* ovate–oblong, 7–8 × 4–5 mm, evenly winged. *Flowering time*: mid-October and November.

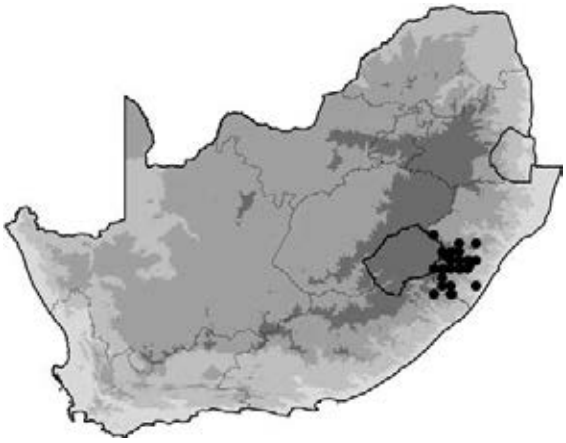
Distribution and ecology: endemic in the bushveld of Mpumalanga and Limpopo, South Africa, from Groblersdal to Nylstroom; in dolerite outcrops among boulders, flowering best after fire in spring after the first rains.

Diagnosis: distinguished from yellow-flowered forms of *Gladiolus woodii* by the glabrous lower leaf sheaths and the strongly clawed upper tepals. Non-flowering plants ultimately develop three leaves, unlike the solitary leaf developed in *G. woodii.* The two species are allopatric, with *G. woodii* occurring east and south of the range of *G. pardalinus*.



62. **Gladiolus pubiger** *G.J.Lewis* in Annals of the South African Museum 40: 132 (1954) [as *pubigerus*], replacement name for *G. pubescens* Baker: 333 (1876b), illegitimate homonym, not *G. pubescens* Lam. (1791). Type: South Africa, [Eastern Cape], as 'British Kaffraria', Oct. 1860, *Cooper 458* (K, holo.).

Gladiolus pugioniformis Hilliard & B.L.Burtt: 299 (1979). Type: South Africa, KwaZulu-Natal, Impendle District, Farm Umgeni Vlei, 27 Oct. 1976, *Hilliard & Burtt 9077* (NU, holo.; E, K, MO, PRE, iso.).



Plants (200–)300–500 mm high, with densely villous cataphylls often tipped purple. *Corm* globose, 12–20 mm diam.; tunics softly leathery, decaying into fine to coarse flat vertical fibres, usually accumulating in a dense mass. *Stem* flexed outward above apex of upper leaf, then inclined, unbranched. *Leaves* 2 or 3, lowermost basal and sheathing lower ½ of stem, ± bladeless or with blade up to 50(–100) mm long, sheath pubescent below or throughout but more densely so below, lightly ribbed, slightly inflated and compressed, thus elliptic in section, blade narrowly lanceolate, 3–4 mm wide, villous, margins thickened and hyaline, main vein raised, second leaf inserted on upper ⅓ stem, 15–45 mm long, entirely sheathing, glabrous, third leaf, if present, like second but shorter; leaves of non-flowering plants evidently solitary, linear and villous. *Spike* deflexed at base, lightly to strongly inclined, weakly flexuose to nearly straight, 4- to 9-flowered; bracts pale grey-green or flushed grey-purple or pink, outer (12–)15–18 mm long, inner shorter, minutely notched. *Flowers* blue-mauve or pale lemon-yellow tinged with green, sometimes tepals lightly flushed reddish brown, horizontal to drooping, tepals unmarked or lower median with a dark streak in lower midline, often with strong fruity and waxy scent in mornings; perianth tube narrowly trumpet-shaped, flared evenly, 7–8 mm long, emerging between bracts; tepals nearly equal, narrowly lanceolate-attenuate, upper 3 slightly larger than lower and held slightly apart from them, all slightly spreading distally, 3 upper 17–23 × 6–10 mm, lower 3 joined to upper laterals for 1–2 mm, 17–22 × 5–9 mm. *Filaments* 5–10 mm long, exserted 1–5 mm from tube but enclosed by tepals; anthers 6–7 mm long, dull yellow or purple; pollen cream-coloured. *Style* arching over stamens, dividing opposite upper ⅓ of anthers, branches 3.0–4.5 mm long. *Capsules* globose, lightly 3-lobed above, 8–10 mm long. *Seeds* oblong, 5–6 × 3.0–3.5 mm, evenly winged. *Flowering time*: September to November, occasionally as late as December at high elevations or in late seasons.

Distribution and ecology: scattered through the higher elevations of eastern South Africa, from Pilgrim's Rest in Mpumalanga through Eswatini and along the KwaZulu-Natal Drakensberg, with additional records from the Amatole Mtns and Katberg in Eastern Cape; in stony montane grassland. The recorded distribution is somewhat disjunct, with no records from the northern KwaZulu-Natal Drakensberg or Transkei [northern Eastern Cape].

Diagnosis: diagnosed by the two (rarely three), largely or entirely sheathing leaves, the lowermost villous and sheathing the lower half of the stem and the remaining one or two hairless and much smaller, and the almost actinomorphic perianth with lanceolate-attenuate tepals and the short stamens well concealed in the flower. Mauve-pink-flowered *Gladiolus parvulus* from southern KwaZulu-Natal is a smaller species with the upper leaf reduced to a bract-like scale inserted at the base of the spike, and smaller, acute but not attenuate tepals.

Distribution of ***Gladiolus pubiger***.

Distribution of ***Gladiolus parvulus***.

Gladiolus pubiger typically has lemon-yellow flowers, but the Eswatini and some Mpumalanga populations have blue-mauve, slightly larger flowers.

63. **Gladiolus parvulus** *Schltr.* in Botanische Jahrbücher für Systematik 40: 91 (1907). Type: South Africa, [KwaZulu-Natal], Umzinto District, short-grass slopes along the Umtwalumi near Fairfield, ± 750 m, Oct. 1905, *Rudatis 122* [as *132* in protologue] (B, holo.).

Geissorhiza gracilis Baker: 155 (1892), illegitimate homonym, not *G. gracilis* Jacq. (1791). Type: South Africa, [KwaZulu-Natal], Umzimkulu District, Zuurberg, between Kokstad and Clydesdale, Oct. 1883, *Tyson 1872* (K, holo.; BOL, MO, SAM, iso.).

Ixia brevifolia Baker: 165 (1892). Type: South Africa, [KwaZulu-Natal], East Griqualand, Oct. 1883, *Tyson 1892* (K, holo.).

Gladiolus subaphyllus N.E.Br.: 53 (1909). Type: South Africa, [KwaZulu-Natal], Pietermaritzburg, Swartkop, 4 000–5 000 ft [1 200–1 500 m], 17 Nov. 1906, *Wylie sub Wood 10153* (K, holo.; BOL, NH, PRE, Z, iso.).

Plants 150–350(–470) mm high, cataphylls not or barely reaching above ground. *Corm* globose, 7–14 mm diam.; tunics leathery to almost woody, decaying into wiry vertical fibres usually somewhat claw-like below. *Stem* slender and wiry, thickened for a short distance from below base of upper leaf to base of spike, flexed outward above sheath of upper sheathing leaf, unbranched. *Leaves* 2, lower 1 basal and sheathing lower ½ of stem, sheath ribbed and lightly villous, often slightly inflated, blade vestigial, 5–25 mm long, villous, margins and main vein thickened, upper leaf minute, scale-like, inserted just below spike, sometimes reaching base of lower floral bract, (4.0–)5.5–7.0 mm long; non-flowering plants with a single linear leaf 80–100 × ± 2 mm, sparsely villous, main vein and margins moderately thickened and hyaline. *Spike* flexed outward at base and inclined, lightly flexuose, 2- to 5-flowered; bracts greyish purple, sometimes dry and brownish toward apices, outer 9–11 mm long, inner narrower but slightly longer, minutely notched. *Flowers* with tepals equal in size and disposition but stamens unilateral and arcuate, pale pink, throat with narrow paired red lines below tepal bases, unscented; perianth tube funnel-shaped, 5–7 mm long, flared upper part ± 3.5 mm long; tepals lanceolate, subequal or upper slightly wider, 12–17 × 5.0–6.7 mm, flaring outward distally. *Filaments* 5–6 mm long, exserted ± 2 mm from tube but enclosed by tepals; anthers 4–6 mm long, pale pink; pollen creamy yellow. *Style* arching over stamens, dividing between upper ⅓ and just beyond anther apices, branches 2–3 mm long. *Capsules* globose to oblong, 3-lobed above and retuse, ± 7 mm long. *Seeds* oval, broadly winged. *Flowering time*: October to early December, rarely in September or as late as January.

Distribution and ecology: an inconspicuous species from southern KwaZulu-Natal, South Africa, and eastern Lesotho, from the Zuurberg and Ngeli Mtns in the south to Pietermaritzburg and Howick in the Midlands and along the eastern Drakensberg from Sehlabathebe to Cathedral Peak; in montane grassland in thin soil on sandstone pavement or crevices in sandstone outcrops.

Diagnosis: a dwarf species with wiry stems and reduced foliage, the lowermost leaf sheathing the lower half of the stem with a villous, often slightly inflated sheath and vestigial blade, and the upper leaf reduced to a minute scale inserted just below the spike. The flowers are pale pink with a sub-actinomorphic perianth and short tube 5–7 mm long. Similar *Gladiolus pubiger* is a taller plant with two or three leaves, the upper not inserted immediately below the spike, and larger flowers with attenuate tepals and slightly longer tube, 7–8 mm long.

Ser. **Linearifolii** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus merianellus* (L.) Thunb.

Plants from the winter-rainfall region, flowering in spring or in autumn. *Corm* tunics papery to fibrous. *Stems* erect or inclined above the upper leaf, smooth.

Leaves well-developed or reduced and without blades on flowering stem and then the foliage leaf solitary and produced separately. *Flowers* mostly small to medium, lower tepals never strongly clawed. *Capsules* ellipsoid, obtuse.

64. **Gladiolus hirsutus** *Jacq.*, Collectanea 4: 161 (1791). Type: South Africa, without precise locality or collector, ex hort. Vienna, illustration in Jacq.: t. 250 (1794 [1788–1795]).

Gladiolus tristis var. *purpureus* Thunb.: 12 (1784). *G. laccatus* Thunb.: 186 (1800), replacement name at species rank for *G. tristis* var. *purpureus* Thunb. and illegitimate homonym, not *G. laccatus* Jacq. (1791). Type: South Africa, [Western Cape], without precise locality, *Thunberg s.n.* (UPS-THUNB 1037, holo.).

Gladiolus hirsutus var. *villosiusculus* Ker Gawl.: sub t. 727 (1804). Type: South Africa, without precise locality, grown in Great Britain, *Auge s.n.* (BM, holo.).

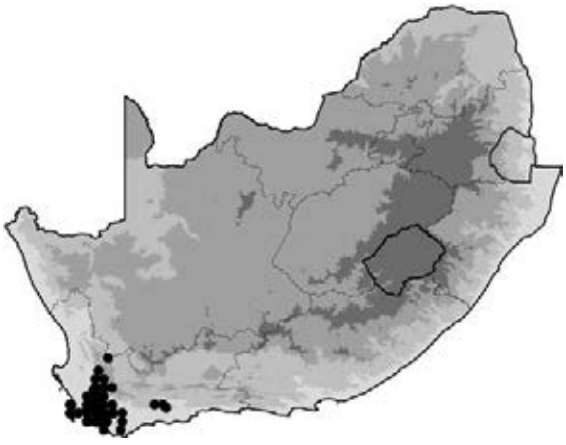
Gladiolus biflorus Roem. & Schult.: 416 (1817), illegitimate homonym, not *G. biflorus* Thunb. (1784). Type: South Africa, without precise locality or collector, ex hort. Hibbert, illustration in Ker Gawl.: t. 823 (1805).

Gladiolus punctulatus Schrank: 216 (1822). Type: South Africa, [Western Cape], without precise locality, *Brehm s.n.* (BRU: Herb Schrank, holo.).

Gladiolus villosus Ker Gawl.: 133 (1827), illegitimate homonym, not *G. villosus* Burm.f. (1768). Type: South Africa, Cape without precise locality, grown in Great Britain, *Masson s.n.* (BM, holo.).

Gladiolus pilosus Eckl.: 38 (1827). Type: South Africa, Western Cape, Cape Flats near Wynberg, Aug., *Ecklon s.n.* (S, holo.; SAM, iso.).

Gladiolus punctulatus var. *autumnalis* G.J.Lewis in Lewis et al.: 211 (1972). Type: South Africa, [Western Cape], Riversdale District, south side of Garcia's Pass, 3 Apr. 1959, *Lewis 5380* (NBG, holo.; K, MO, iso.).



[*Gladiolus rubromarginatus* Schrad. ex Roem. & Schult.: 415 (1817), invalid name only in synonymy.]

[*Gladiolus villosiusculus* Sol. in Herb. Banks ex Ker Gawl. et ex Baker: 174 (1877), invalid name only in synonymy.]

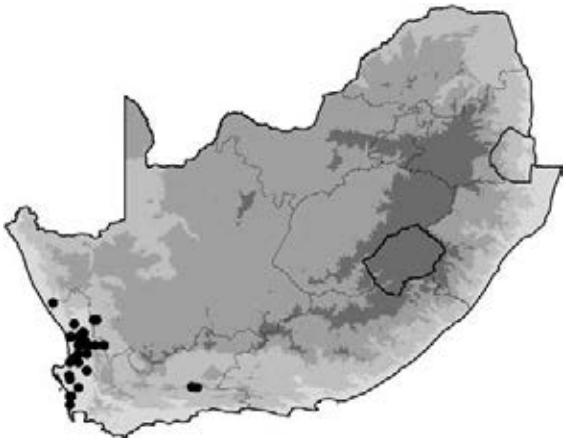
Plants 350–500 mm high, with cataphylls usually pubescent, often dry at flowering time. *Corm* ± globose, 18–30 mm diam.; tunics coarsely fibrous, often accumulating in a mass. *Stem* flexed outward above sheath of second leaf and inclined, unbranched, 1.0–1.5 mm diam. below base of spike. *Leaves* 3(4), lower 2 basal, second leaf sheathing lower ½ of stem, pubescent throughout or only on sheaths, blades relatively short, lowermost reaching upper ½ of stem or sometimes top of spike, lanceolate, 3–8(–13) mm wide, main vein and margins lightly thickened, secondary veins also evident, uppermost leaf inserted on upper ⅓ of stem, pubescent or not, margins united around stem. *Spike* inclined, lightly flexuose, 3- to 6(8)-flowered; bracts green or flushed greyish or purple, outer 18–26 mm long, inner shorter, acute. *Flowers* pale to deep pink or mauve, occasionally almost white, lower 3 tepals cream-coloured to pale yellow below with nectar guides irregularly spotted or streaked lines in lower ⅔, lines decurrent on tube, occasionally lightly scented; perianth tube obliquely funnel-shaped, 15–26(–40) mm long, cylindric lower part enclosed in tube; tepals obovate to broadly lanceolate, dorsal largest, arching over stamens, 19–27(–35) × 13–20 mm, spreading distally, upper laterals 17–23(–34) × 10–15 mm, lower 3 tepals joined to upper laterals for 2–5 mm and together for up to 3 mm, narrowly lanceolate, not clearly clawed below, subequal, 15–20(–23) × 7–12 mm. *Filaments* 11–13 mm long, exserted 4–6 mm from tube; anthers 6–9 mm long, pink; pollen white. *Style* arching over stamens, dividing opposite anther tips, branches 2–4 mm long. *Capsules* ovoid to ± ellipsoid, 20–24 mm long, ± as long as bracts. *Seeds* broadly oval, 6.0–7.5 × ± 5 mm, evenly winged or wing lacking on one side. *Flowering time*: Mostly mid-July to September, sometimes as early as June and rarely in March or April.

Distribution and ecology: relatively common in the southwestern Western Cape, South Africa, from the Cold Bokkeveld to the Cape Peninsula and eastward to the Potberg and along the Langeberg to Riversdale; on stony granite or sandstone slopes, flowering best in the first years after fire. Plants in the eastern part of the range where rainfall is less seasonal may flower as early as March or April but this is unusual.

Diagnosis: recognised by the hairy, superposed leaves, usually with relatively short, lanceolate blades 3–8(–13) mm wide, and the moderate-sized, weakly scented, pink to mauve flowers with red-streaked and spotted nectar guides on the lower tepals and perianth tube 15–26(–40) mm long. The filaments are 11–13 mm

Distribution of ***Gladiolus hirsutus***.

long. A collection from the Kogelberg is anomalous in its large flowers, 75 mm long with perianth tube 40 mm long. *Gladiolus caryophyllaceus* has broader leaves, 10–27 mm wide, with the margins thickened and often flushed pink or red, and large, strongly scented flowers with perianth tube 35–40 mm long and longer filaments 22–27 mm long.



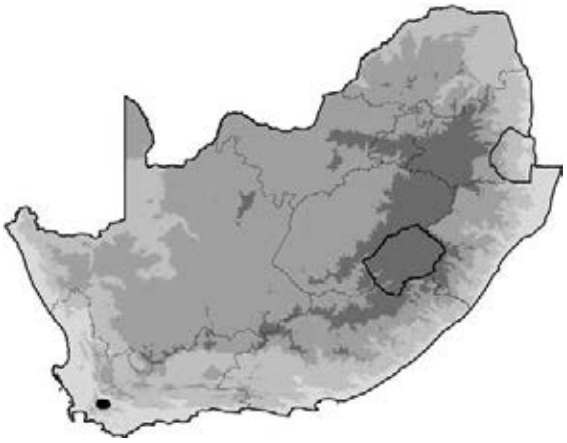
65. **Gladiolus caryophyllaceus** *(Burm.f.) Poir.* in Lamarck, Encyclopedie Méthodique Botanique, Suppl. 2: 795 (1812). *Antholyza caryophyllacea* Burm.f.: 1 (1768). *Anisanthus caryophyllaceus* (Burm.f.) Klatt: 344 (1882). *Homoglossum caryophyllaceum* (Burm.f.) N.E.Br.: 279 (1932a). Type: South Africa, without precise locality or collector, grown in Holland, *Houttuyn s.n.* [G: Herb. Burman [photo at K], lecto., designated in Lewis et al.: 114 (1972)].

Gladiolus roseus Andrews: t. 11 (1796), illegitimate homonym, not *G. roseus* Jacq. (1795) [1788–1795]. *Watsonia amoena* var. *rosea* Pers.: 43 (1805). Type: South Africa, without precise locality of collector, illustration in Andrews: t. 11 (1796).

Gladiolus hirsutus var. *roseus* Ker Gawl.: t. 574 (1802d). Type: South Africa, without precise locality of collector, illustration in Ker Gawl.: t. 574 (1802d).

Gladiolus similis Eckl.: 40 (1827). Type: South Africa, [Western Cape], without precise locality, cultivated in Cape Town, *Ecklon s.n.* [S, lecto., designated by Nordenstam: 292 (1972)].

Plants (0.45–)0.6–1.1 m high, with cataphylls usually pilose and often dry at flowering. *Corm* globose, 20–40 mm diam.; tunics of coarse vertical fibres. *Stem* unbranched, inclined above. *Leaves* 4 or 5, lower 1 to 3 basal, usually quite short and sometimes forming a loose fan, pilose, particularly on sheaths, lanceolate, 10–27 mm wide, margins, main and secondary veins raised and thickened, often flushed pink or purple, margins sometimes somewhat crisped, upper 2 leaves cauline, similar to basal but shorter. *Spike* (2)4- to 8-flowered; bracts pale green or greyish, 30–45(–70) mm long, inner slightly shorter, twisted, acute. *Flowers* pale to deep pink or mauve or cream-coloured, then more intensely pigmented along tepal midline, lower tepals and throat streaked with broken longitudinal lines and spots of white to cream-coloured and dark pink, usually sweetly carnation-scented; perianth tube obliquely funnel-shaped, 30–40 mm long, lower cylindric part 16–25 mm long; tepals lanceolate to elliptic or ovate, dorsal largest, ascending or weakly hooded over stamens, broadly oblanceolate, 37–45 × (13–)21–30 mm, upper laterals 30–35 × 18–25 mm, spreading gradually from base and flared outward distally, margins undulate, lower 3 tepals joined to upper laterals for 7–8 mm and together for 2–3 mm, 25–30 × 15–18 mm, not distinctly clawed, wider in distal ½, margins undulate. *Filaments* 22–27 mm long, exserted 8–9 mm from tube; anthers 10–14 mm long, cream-coloured; pollen yellow. *Style* arching over filaments, dividing slightly below to slightly beyond anther apices, branches 4–5 mm long. *Seeds* ovate, ± 10 × 7–8 mm, broadly and evenly winged. *Flowering time*: mid-August to end of September.



Distribution of ***Gladiolus caryophyllaceus***.

Distribution and ecology: centred on the West Coast of South Africa, from Hondeklipbaai in southern Namaqualand and the Bokkeveld Escarpment in Northern Cape to near Atlantis in Western Cape, with isolated populations in the Swartberg to the east; on open flats and stony plateaus in deep sands, typically among restios. The species is naturalised in Western Australia.

Diagnosis: resembling *Gladiolus hirsutus* in its superposed, villous leaves but with broader blades 10–27 mm wide, the margins thickened and often flushed pink or red, and the large, strongly scented flowers with perianth tube 35–40 mm long and longer filaments 22–27 mm long.

66. **Gladiolus rhodanthus** *J.C.Manning & Goldblatt* in Manning et al. in Bothalia 29: 217 (1999). Type: South Africa, Western Cape, Villiersdorp District, summit of Stettynsberg, 12 Jan. 1999, *Manning & Paterson-Jones 2207* (NBG, holo.; K, MO, PRE, iso.).

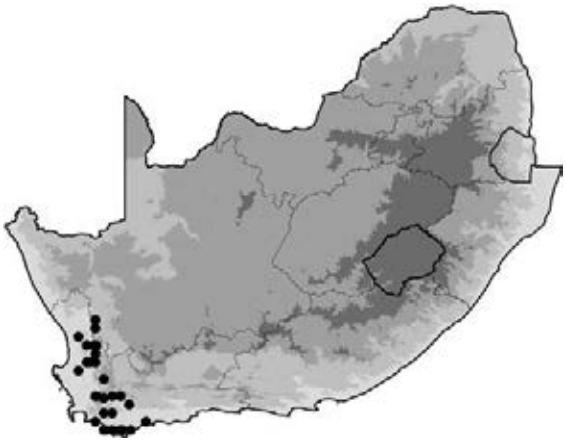
Plants 300–500 mm high. *Corm* globose, 18–25 mm diam., tunics of medium-textured to fine fibres, accumulating around. *Stem* flexed outward above sheath of second leaf and inclined, unbranched. *Leaves* 3, lower 1 or 2 basal, the second sheathing lower ½ of stem, pubescent throughout, lowermost with blade reaching to between base and apex of spike, sometimes becoming dry at flowering time, the second with blade rather short and reaching upper ⅓ of stem, ± linear, 3–6 mm wide, main vein thickened and raised and a second pair of veins lightly thickened, margins scarcely thickened, uppermost leaf with vestigial blade. *Spike* inclined, lightly flexuose, 2- to 5-flowered; bracts green or flushed brownish above, outer 26–45 mm long, acute, shorter 3 or rarely ± as long, lightly notched. *Flowers* deep pink, lower 3 tepals with

Distribution of ***Gladiolus rhodanthus***.

spear-shaped whitish median streak in lower half edged in dark pink, especially in upper half, sometimes darker edging expanded transversely across entire width of upper laterals, throat white with dark pink streaks, unscented; perianth tube 25–36 mm long, cylindric below for 20–28 mm, obliquely expanded in upper 5–7 mm, shortly exceeding bracts; tepals lanceolate, dorsal largest, inclined over stamens, 35–40 × 19–24 mm, upper laterals slightly shorter, 30–38 × 13–19 mm, recurved distally, lower 3 tepals joined to upper laterals for 5 mm and to one another for 1–2 mm, 27–30 × 12–13 mm. *Filaments* 15–17 mm long, exserted 8–10 mm from tube; anthers 8–9 mm long, light mauve; pollen cream-coloured. *Style* arching over stamens, opposite or slightly beyond anther apices, branches 5–7 mm long. *Capsules* ellipsoid, 20–22 × 8–9 mm. *Seeds* ovate, 5.5–7.0 × 4 mm, broadly and evenly winged, golden-brown. *Flowering time*: late December to mid-January.

Distribution and ecology: a high altitude endemic of the mountains near Villiersdorp in Western Cape, South Africa, recorded from the summit of Stettynsberg and from Jonaskop at the western end of the Riviersonderend Mtns; on north-facing, broken sandstone cliffs at 1 800 m elevation.

Diagnosis: allied to *Gladiolus caryophyllaceus* and *G. hirsutus* and distinguished by its summer-flowering habit and long-tubed flowers with perianth tube 25–36 mm long and cylindric for most of its length, flaring only in the upper 5–7 mm, and the more definitely lozenge-shaped nectar guides on the lower tepals.



67. **Gladiolus guthriei** *F.Bolus* in Annals of the Bolus Herbarium 2: 101 (1917). Type: South Africa, Western Cape, Bredasdorp District, Elim, July 1895, *Guthrie 3821* (BOL, holo.).

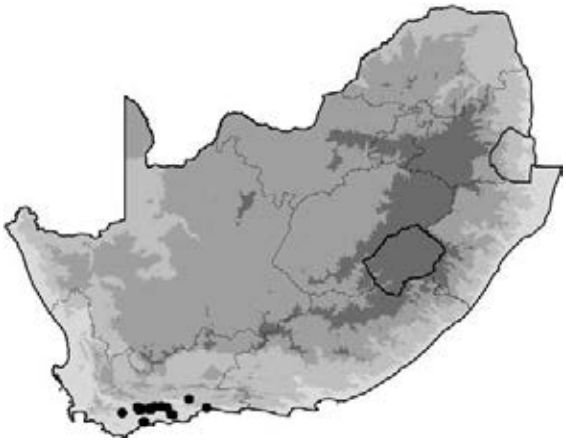
Gladiolus eulophioides F.Bolus: 99 (1917). Type: South Africa, [Western Cape], Caledon [District], Oct., *Pappe 461* (GRA, holo.).

Gladiolus odoratus L.Bolus: 294 (1927b). Type: South Africa, [Northern Cape], Calvinia District, Grasberg near Nieuwoudtville, grown at Kirstenbosch, 27 Apr. 1927, *Buhr s.n. Natl. Bot. Gard. 460/26* (NBG, holo.).

Plants 400–700 mm high, with cataphylls usually brownish purple, sometimes finely pubescent. *Corm* globose, 20–35 mm diam.; tunics of coarse vertical fibres, accumulating in a dense mass. *Stem* erect or inclined, unbranched. *Leaves* 3(4), sometimes hairy on sheaths, lower 2 ± basal, lowermost with short, rigid, lanceolate blade 20–80 × 3–6 mm, margins moderately and main and often a second vein pair lightly thickened, blades of remaining leaves vestigial or lacking; non-flowering plants with solitary leaf, sword-shaped to lanceolate, 12–20 mm wide, often trailing, sometimes pubescent, margins strongly thickened, main and 2 or more other vein pairs also prominent, juvenile leaves always pubescent. *Spike* usually lightly inclined, 3- to 9(13)-flowered; bracts dull green to greyish, soft-textured, outer 20–40 mm long, inner shorter. *Flowers* dull pink to brownish purple, upper laterals and lower 3 tepals dull yellow with broad irregular brownish median streak and lightly speckled with brown, margins lightly crisped, with strong sweet clove-like scent day and night; perianth tube obliquely funnel-shaped, 20–27 mm long, lower cylindric part 12–15 mm long, enclosed or exserted from bracts, abruptly curved above into flared part; tepals oblanceolate or dorsal obovate, largest, 22–30 × 14–19 mm, inclined over stamens, upper laterals 20–30 × 10–13 mm, spreading distally, lower 3 tepals joined to upper laterals for 3–5 mm and together for 1–2 mm, free parts 18–25 × 8–11 mm, lower median as long or slightly longer. *Filaments* 12–16 mm long, exserted 5–7 mm from tube; anthers 8–11 mm long, brownish; pollen yellow. *Style* arching over stamens, dividing opposite upper ½ of anthers, branches 3–4 mm long. *Capsules* ellipsoid, ± 20 mm long. *Seeds* broadly ovate, (5–)7–8 × 4–6 mm, broadly and evenly winged. *Flowering time*: April to June.

Distribution and ecology: relatively widespread through the mountains in the western part of the Cape Floristic Region in South Africa, from the Bokkeveld Escarpment

Distribution of ***Gladiolus guthriei***.



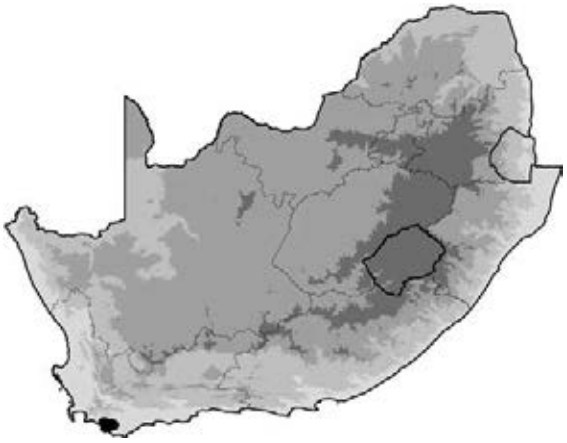
in Northern Cape to Bredasdorp and Potberg in Western Cape; on rocky sandstone outcrops and pavement, flowering in autumn and winter.

Diagnosis: flowering in autumn and winter, *Gladiolus guthriei* is recognised by the superposed, glabrous or villous leaves and relatively long-tubed, strongly clove-scented, dull pink to brownish flowers, with the perianth tube ± as long as the dorsal tepal and 20–27 mm long. The northern populations have glabrous or sparsely hairy leaves whereas those from the south are relatively densely hairy.

68. **Gladiolus emiliae** *L.Bolus* in Journal of Botany, British and foreign 71: 124 (1933b). Type: South Africa, [Western Cape], flats near Riversdale, rocky outcrop, 5 Apr. 1931, *Ferguson s.n. BOL19608* (BOL, holo.).

Plants (300–)450–600 mm high, with cataphylls sparsely hairy below or glabrous, apex often becoming dry and brown. *Corm* globose to depressed-globose, 20–25 mm diam.; tunics papery breaking irregularly and becoming fibrous. *Stem* lightly flexed outward above sheath of uppermost leaf, gently inclined above, unbranched. *Leaves* 2, both entirely sheathing, lower inserted shortly above ground, 60–80 mm long, upper inserted on upper ⅓ of stem, margins partially or completely united around stem; leaves of non-flowering plants and seedlings solitary, linear or narrowly lanceolate, ultimately 600–750 × 7 mm, pubescent, margins and main vein lightly thickened, emerging soon after flowering and growing during winter and spring. *Spike* inclined, 3- to 8(10)-flowered; bracts green, sometimes red to purple on upper margins, outer 20–25 mm long, obtuse to ± truncate, inner slightly longer or shorter, usually notched. *Flowers* brownish or pale to dull yellow and lightly to heavily dotted or streaked with reddish brown to maroon, or tepals almost uniformly dark red-brown, usually more intensely coloured along tepal midlines, lower tepals each with dark red streak in lower midline, spicy-sweet-scented day and night; perianth tube 32–45 mm long, slender lower part 25–35 mm long, sharply curved at apex of cylindric part into a flared upper part 7–10 mm long; tepals ovate-lanceolate, spreading distally, dorsal slightly larger than others, upper 3 tepals 14–18 × 8–10 mm, lower 3 tepals joined to upper laterals for 2–4 mm and together for up to 1–2 mm, 14–20 × 5–8 mm. *Filaments* 9–12 mm long, exserted 3–5 mm from tube; anthers 5–7 mm long, brownish dorsally, dark yellow ventrally; pollen cream-coloured. *Style* dividing between middle and apices of anthers, branches ± 3 mm long. *Capsules* obovoid to ellipsoid, 20–27 mm long, *Seeds* oval to oblong, 8–9 × 5–6 mm, broadly and evenly winged. *Flowering time*: March and April, rarely as early as mid-February.

Distribution and ecology: restricted to the foothills of the Riviersonderend Mtns and Langeberg along the southern coast of Western Cape, South Africa, with one collection from George; on rocky lower slopes in clay or loamy soils, usually at the junction between the basement shales and overlying sandstone, flowering in autumn.



Distribution of ***Gladiolus emiliae***.

Diagnosis: an autumn-flowering species with the foliage reduced to two sheathing cauline leaves and distinctive, long-tubed, fragrant flowers with a slender perianth tube 32–45 mm long abruptly curved or bent near the top. The flowers are pollinated by night-flying moths.

69. **Gladiolus overbergensis** *Goldblatt & M.P.de Vos* in Adansonia 11: 421 (1990), replacement name for *Antholyza guthriei* L.Bolus: 12 (1920) [not *G. guthriei* F.Bolus (1917)]. *Petamenes guthriei* (L.Bolus) N.E.Br.: 276 (1932a). *Homoglossum guthriei* (L.Bolus) L.Bolus: 47 (1933a). Type: South Africa, [Western Cape], Elim, 250 ft [76 m], July 1895, *Guthrie 3827* (BOL, lecto., designated by M.P.de Vos: 336 (1976); K, isolecto.).

Plants 350–500 mm high, with cataphylls green, firm-textured and pilose. *Corm* globose, 15–20 mm diam.; tunics leathery to woody, fragmenting into coarse woody fibres. *Stem* straight or slightly flexed above sheathing parts of 2 upper leaves but becoming erect again, occasionally branched. *Leaves* 4, lower 3 basal, lower 2 longest reaching to ± middle of stem, sheaths and blades with minute, recurved, prickly-scabrid hairs on veins, narrowly lanceolate to nearly linear, 2.5–4.0 mm wide, main and one other vein pair lightly raised, margins not thickened, uppermost leaf inserted on ± middle of stem, usually entirely sheathing, usually channelled throughout, also with recurved prickles. *Spike* ± erect, 2- to 5-flowered; bracts pale green or flushed grey-purple, outer 28–42 mm long, inner slightly shorter to ± as long, minutely notched apically. *Flowers* scarlet or lower 3 tepals orange or yellow, upper three and sometimes lower lightly streaked and spotted with darker red toward base, unscented; perianth tube 46–55 mm long, lower part narrow for 18–20 mm, abruptly expanded into a wider cylindric horizontal upper part 24–35 mm long and ± 7 × 6 mm diam.; tepals broadly obovate to round, upper 3 larger than lower, dorsal largest, arched slightly above horizontal, 22–26 × 18–22 mm, upper laterals slightly smaller, 18–24 × 12–16 mm, much overlapping dorsal, lower

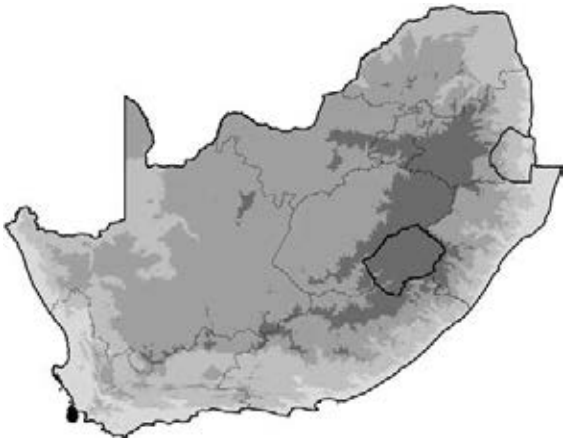
Distribution of ***Gladiolus overbergensis***.

lateral tepals 10–14 × 8–12 mm, lower median 13–16 × 8–10 mm, straight and tilted toward ground. *Filaments* 38–42 mm long, exserted ± 12 mm from tube; anthers 7–8 mm long, yellow; pollen pale yellow. *Style* extending horizontally over stamens, dividing shortly below anther tips, branches 3–4 mm long. *Capsules* and *seeds* unknown. *Flowering time*: late July to mid-September.

Distribution and ecology: a rarely seen local endemic of Western Cape, South Africa, from the Klein River Mtns near Hermanus to Elim and Bredasdorp; in loamy soil on cooler sandstone slopes, flowering only after fire.

Diagnosis: an obligate pyrophile recognised by the unusual, abrasive leaves with minute recurved-scabrid hairs on the veins and the trumpet-shaped flowers with dimorphic perianth tube 46–55 mm long, the lower 18–20 mm narrow and abruptly expanded into a wider cylindric upper part 24–35 mm long. The lower tepals are significantly smaller than the upper, about half as long, and rarely more than 15 mm long.

70. **Gladiolus merianellus** *(L.) Thunb.*, Dissertatio de Gladiolo no. 14 (1784). *Antholyza merianella* L.: 77 (1774) [name misapplied by Curtis, Botanical Magazine 13: t. 441 (1799) to *W. aletroides*, and to *Watsonia humilis* Mill. by others]. *Homoglossum merianellum* (L.) Baker: 161 (1877) [misapplied to *W. humilis* Mill.]. Type: South Africa, without precise locality or collector, *LINN 60.7* [LINN, lecto., designated by J.C.Manning & Goldblatt: 806 (2012)].



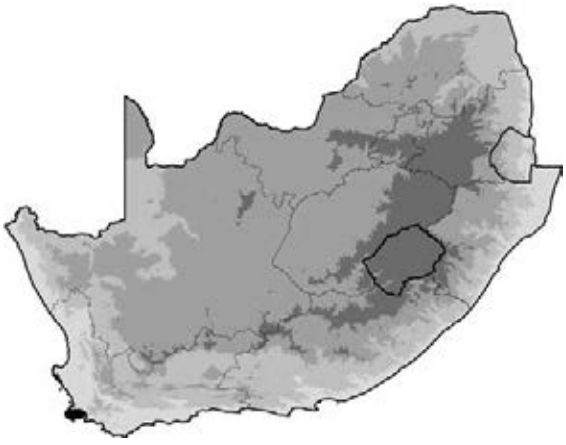
Gladiolus bonaspei Goldblatt & M.P.de Vos: 421 (1990) [as *bonaespei*], replacement name for *Watsonia pilosa* Klatt: 200 (1885) [not *Gladiolus pilosus* Eckl.]. *Petamenes pilosus* (Klatt) Goldblatt: 144 (1989). Type: South Africa, Western Cape, near Simonstown, May 1882, *MacOwan 2510* (B, holo.; G, iso.).

Homoglossum merianellum var. *aureum* G.J.Lewis in Barker et al.: 34 (1948). Type: South Africa, Western Cape, Cape Peninsula, between Scarborough and Klaasjagersberg, burnt marshy ground, Oct. 1945, *Linley s.n.* (SAM [*SAM58293*], holo.; SAM, iso.).

Gladiolus hirsutus var. *tenuiflorus* Ker Gawl.: sub t. 574 (1802d). Type: South Africa, [Western Cape], Cape Peninsula, without precise locality, *Thunberg s.n.* (UPS-THUNB 1047, holo.).

Plants (250–)350–500 mm high, with villous cataphylls. *Corm* globose, 15–20 mm diam.; tunics leathery to woody, fragmenting into coarse vertical fibres. *Stem* erect, flexed above sheathing parts of 2 upper leaves but becoming erect again, unbranched. *Leaves* 3, lower 2 basal, lowermost rarely reaching middle of stem, sheaths villous, blades linear, (2.0–)4.0–5.5 mm wide, pubescent, margins and main vein lightly thickened, uppermost leaf inserted on ± middle of stem, short and bract-like, often sparsely pubescent, margins of sheath united. *Spike* ± erect, lightly flexuose, 2- to 7-flowered; bracts pale green or flushed grey-purple, outer 15–20(–23) mm long, inner slightly shorter or slightly longer, minutely notched. *Flowers* bright orange, lower 3 tepals sometimes deep yellow and then usually minutely speckled with scarlet toward bases, rarely entirely yellow, unscented; perianth tube 35–43 mm long, with lower part narrow for 11–18 mm, abruptly expanded into a wide horizontal cylindric upper part 22–25 mm long, ± 7 × 6 mm diam.; tepals broadly obovate to ± orbicular, subequal or upper 3 larger, dorsal typically largest, horizontal, 18–23 × 14–18 mm, upper laterals slightly smaller, 15–18 × 14–15 mm, much overlapping dorsal, lower 3 tepals 12–20 × 10–18 mm, straight and tilted toward ground. *Filaments* 28–32 mm long, exserted 6–9 mm from mouth of tube; anthers 6–8 mm long, dark purple; pollen pale yellow. *Style* extending horizontally over stamens, dividing between middle or slightly beyond anther apices, branches 3–4 mm long. *Capsules* ovoid, subacute, 15–20 mm long. *Seeds* ovate, 8–10 × 6–7 mm, broadly winged with seed body asymmetrically placed. *Flowering time*: mainly July to September, occasionally as early as April.

Distribution and ecology: endemic to the southern Cape Peninsula in Western Cape, South Africa, from



Distribution of ***Gladiolus merianellus***.

Silvermine to Cape Point; on seasonally wet flats and plateaus in peaty soils, flowering well after fire.

Diagnosis: distinctive in its pubescent leaves and orange or yellow, trumpet-shaped flowers with dimorphic perianth tube 35–43 mm long, the lower part narrow for 11–18 mm and abruptly expanded into a wide horizontal cylindric upper part 22–25 mm long, with subequal, broadly obovate to suborbicular tepals.

71. **Gladiolus aureus** *Baker* in Flora capensis 6: 530 (1897a). *Homoglossum aureum* (Baker) Oberm. in Lewis et al.: 299 (1972). Type: South Africa, [Western Cape], Cape Peninsula, near Kommetjie in wet places at foot of mountains, 300 ft [90 m], Aug. 1894, *Fair sub BOL 7951* (K, presumed holo.; B, BOL, GRA, PRE, Z, iso.).

Plants 350–500 mm high, with villous cataphylls. *Corm* globose, 12–18 mm diam.; tunics leathery to woody, fragmenting into coarse woody fibres. *Stem* erect, flexed above sheathing parts of two upper leaves but becoming erect again, unbranched. *Leaves* 3, lower 2 basal, lowermost usually slightly exceeding spike, lower leaves villous, linear, 3.0–5.5 mm wide, several ribbed, margins lightly thickened, uppermost leaf inserted on upper ⅓ of stem, short and bract-like, usually channelled throughout, sparsely pubescent or glabrous. *Spike* ± erect, 3- to 8-flowered; bracts pale green or flushed dull red or brown, outer 15–22 mm long, inner slightly shorter or slightly longer, minutely notched apically. *Flowers* bright yellow, upper part of tube and base of tepals flushed red on fading, without contrasting markings, unscented; perianth tube 19–24 mm long, filiform below for 10–15 mm, ascending, barely exserted from bracts, abruptly expanded into a slightly flared, ± horizontal upper part; tepals obovate to elliptic, slightly unequal, dorsal 20–24 × 12–15 mm, lower 3 tepals joined to upper laterals for 3–4 mm, 20–22 × 9–12 mm. *Filaments* 9–12 mm long, reaching to mouth of tube or exserted up to 5 mm and enclosed by tepals; anthers 7.5–8.8 mm long, cream-coloured; pollen white.

Distribution of ***Gladiolus aureus***.

Style arching over stamens, dividing opposite or just beyond anther apices, branches ± 4 mm long. *Capsules* oblong, ± 18 mm long. *Seeds* oval, ± 9 × 7 mm, broadly and evenly winged. *Flowering time*: September, sometimes in late August.

Distribution and ecology: a highly localised endemic of the southern Cape Peninsula in Western Cape, South Africa, recorded historically near Kommetjie and Simonstown but now known only from from a single locality at Ocean View; in seasonal seepages in peaty soils, flowering best after fire.

Diagnosis: distinctive in its superposed, hairy leaves and small, bright yellow flowers with funnel-shaped perianth tube 19–24 mm long with the lower part filiform, and nearly equal tepals about as long as the tube, with the filaments just reaching the top of the tube or shortly exserted.

72. **Gladiolus brevifolius** *Jacq.*, Collectanea 4: 156 (1791). *Antholyza brevifolia* (Jacq.) Steud.: 105 (1840). *G. hirsutus* var. *brevifolius* (Jacq.) Ker Gawl.: sub t. 574 (1802d). Type: South Africa, Cape, without precise locality, illustration in Jacq.: t. 249 (1794 [1788–1795]).

Watsonia amoena Ehrh. ex Pers.: 412 (1805), illegitimate superfluous name for *Gladiolus brevifolius* Jacq. Type: unknown.

Gladiolus tristis var. *aphyllus* Thunb.: 12 (1784). *G. hirsutus* var. *aphyllus* (Thunb.) Ker Gawl.: sub. t. 727 (1804). *G. aphyllus* (Thunb.) Ker Gawl.: 134 (1827). Type: South Africa, [Western Cape], without precise locality, *Thunberg s.n.* (UPS-THUNB 1010, holo.).

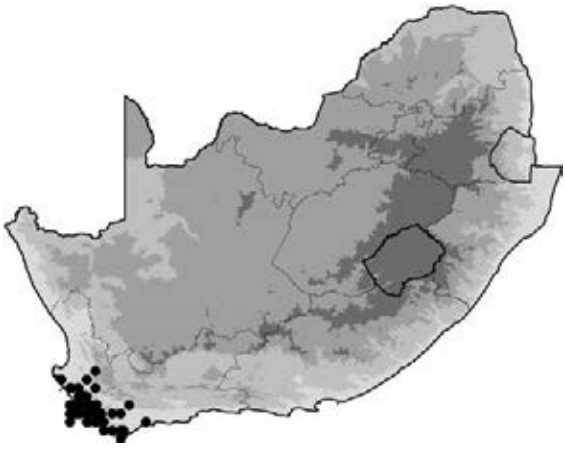
Gladiolus tristis var. *ruber* Thunb.: 12 (1784). Type: South Africa, [Western Cape], without precise locality, *Thunberg s.n.* (UPS-THUNB 1011, holo.).

Gladiolus orobanche DC. in Redouté: t. 125 (1805). *G. brevifolius* var. *orobanche* (DC.) Baker: 174 (1877). Type: South Africa, without precise locality or collector, grown in France, illustration in Redouté: t. 125 (1805).

Gladiolus festivus Herb.: 89 (1844). Type: South Africa, without precise locality or collector, ex hort. Kew (BM, holo.).

Gladiolus spilanthus Spreng. ex Klatt: 711 (1864). *G. andrewsii* Klatt: 340 (1882), illegitimate superfluous name for *G. spilanthus* Spreng. ex Klatt [based on same type]. Type: South Africa, Western Cape, without precise locality, or collector, grown in London, illustration in Andrews: t. 240 (1802) [as *G. carneus*].

Gladiolus brevicollis Klatt: 339 (1882). Type: South Africa, [Western Cape], without precise locality or collector, illustration in Ker Gawl.: t. 727 (1804) [as *G. hirsutus* var. *brevifolius*].



Gladiolus brevifolius var. *robustus* G.J.Lewis: 126 (1954). Type: South Africa, [Western Cape], near Saldanha Bay, 7 Jan. 1935, *Pole Evans s.n. BOL 21057* (BOL, holo).

Gladiolus brevifolius var. *minor* G.J.Lewis in Lewis et al.: 279 (1972). Type: South Africa, [Western Cape], Bredasdorp, 15 Apr. 1962, *Lewis 5948* (NBG, holo.).

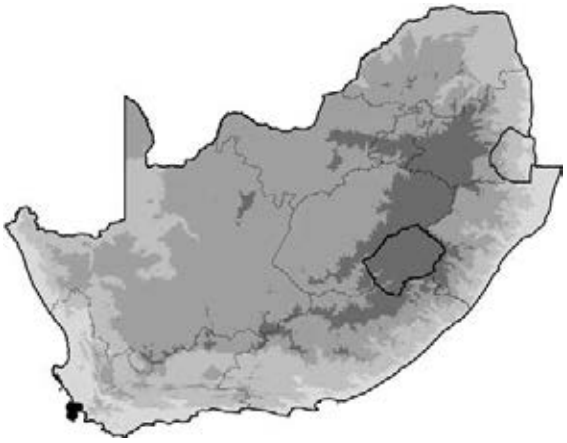
Gladiolus brevifolius var. *obscurus* G.J.Lewis in Lewis et al.: 280 (1972). Type: South Africa, [Western Cape], Malmesbury Commonage, grown at Kirstenbosch, Apr. 1963, *Lewis 6131* (NBG, holo.).

[*Gladiolus amoenus* Herb. Banks ex Roem. & Schult.: 409 (1817), invalid name only in synonymy.]

Plants (120–)250–550(–850) mm high, with cataphylls usually dry and dull purple and minutely pubescent on veins. *Corm* globose, 18–35 mm diam.; tunics leathery, decaying into fairly coarse fibres, often thicker below. *Stem* lightly flexed outward above sheath of uppermost leaf, unbranched. *Leaves* (1)3, not overlapping, 40–70 mm long, all largely to entirely sheathing, occasionally with short blades up to 40 mm long, linear, smooth or sparsely and shortly pubescent; foliage leaf produced later in season, solitary, linear to narrowly lanceolate, pubescent (rarely glabrous), dry and decayed at flowering time or lacking. *Spike* slightly inclined, lightly flexuose, 8- to 12(16)-flowered; bracts grey-green, flushed purple, (15–)18–22 mm long, inner slightly shorter than outer, notched apically. *Flowers* pale to deep pink, sometimes cream-coloured, light mauve or greenish grey, usually tepals more darkly coloured distally, lower tepals with yellow transverse to obscure median band, sometimes edged in darker pink or with a median dark streak when tepals pale, unscented or with a strong sweet rose scent; perianth tube obliquely funnel-shaped, 11–13 mm long, narrow lower part 6–7 mm long; tepals lanceolate, dorsal largest, 19–29 × 10–20 mm, upper laterals 14–25 × 8–15 mm, lower tepals joined to upper laterals for 2–5 mm and together for 2.0–3.5 mm, free parts 12–22 × 5–6 mm. *Filaments* 10–15 mm long, exserted 7–9 mm from tube but enclosed by tepals; anthers (4–)6–8 mm long, cream-coloured; pollen pale yellow. *Style* dividing at or just beyond anther apices, branches ± 3 mm long. *Capsules* ellipsoid, 16–22 mm long. *Seeds* oval, 7–8 × 4 mm, broadly and evenly winged. *Flowering time*: March to April, occasionally in February.

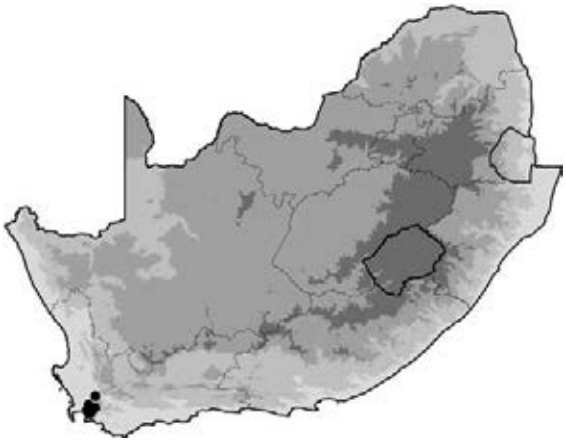
Distribution of ***Gladiolus brevifolius***.

Distribution and ecology: relatively widespread through southwestern Western Cape, South Africa, from near Aurora to the Cape Peninsula, east to Bredasdorp and inland to Montagu; mainly on stony flats and slopes in a variety of soils, flowering in autumn.



Diagnosis: recognised by the short, bladeless leaves on the flowering stem and relatively small, usually unscented pink to mauve flowers with short perianth tube 11–13 mm long. The solitary, linear-lanceolate and pubescent vegetative leaf produced in the winter is distinctive and dried remains from the previous season should always be sought for positive identification. In the absence of these remains the species is best separated from other superficially similar small-flowered species with bladeless leaves by the coarsely fibrous corm tunics. The species is most usually confused in flower with *Gladiolus martleyi*, typically from deep sands, which has almost identical but usually fragrant flowers and a soft, fleshy corm with softly membranous or finely fibrous tunics. The terete, 4-grooved leaf developed in *G. martleyi* later in the season is quite different from that of *G. brevifolius*.

73. **Gladiolus monticola** *Goldblatt & J.C.Manning*, *Gladiolus* in southern Africa: 173 (1998). Type: South Africa, Western Cape, Table Mountain, rocky upper slopes, Mar. 1949, *Esterhuysen 15147* (BOL, holo.; BM, K, PRE, S, iso.).



Gladiolus tabularis Eckl. ex Baker: 207 (1892), illegitimate homonym, not *G. tabularis* Pers. (1805) [= *Tritoniopsis unguicularis* (Lam.) G.J.Lewis]. Types: South Africa, Table Mtn., *Pappe s.n.* (K, SAM, syn.), *H. Bolus 7057* (BOL, K, syn.).

[*Gladiolus monticola* G.J.Lewis: 85 (1948) [as *monticolus*], invalid name without description; *G. monticola* G.J.Lewis in Lewis et al.: 257 (1972), invalid name without Latin diagnosis].

Plants 300–450 mm high. *Corm* globose, 20–25 mm diam.; tunics of fairly coarse to fine fibres. *Stem* erect, lightly flexed outward above sheath of uppermost leaf, unbranched. *Leaves* 2, not overlapping, largely to entirely sheathing, lowermost inserted shortly above ground, occasionally with short blade up to 30 mm long, linear, smooth or sparsely and shortly pubescent; foliage leaf produced later in season, solitary, linear to narrowly sword-shaped, pubescent, dry and decayed at flowering time or lacking. *Spike* slightly inclined, lightly flexuose, 3- to 9-flowered; bracts grey-green, flushed purple on upper surface, 15–24 mm long, inner shorter. *Flowers* pale apricot- to cream-coloured, upper tepals

Distribution of ***Gladiolus monticola***.

Distribution of ***Gladiolus nerineoides***.

flushed pale pink, lower tepals with yellow median stripe often outlined in dark pink, unscented; perianth tube 22–30 mm long, cylindric below, curved abruptly near apex, upper 6–8 mm horizontal and flaring outward; tepals lanceolate, unequal, dorsal largest, 20–25 × 10–12 mm, upper laterals 18–20 × 8–10 mm, lower 3 tepals united below for ± 5 mm, 15–18 × 6–8 mm. *Filaments* ± 12 mm long, exserted ± 4–5 mm from tube but enclosed by tepals; anthers 6–7 mm long. *Style* dividing at or just beyond anther apices, branches ± 4 mm long. *Capsules* ovoid-ellipsoid, 11–13 mm long. *Seeds* oblong, 6–7 × ± 4 mm, evenly winged. *Flowering time*: mid-December to February, occasionally in March.

Distribution and ecology: endemic to the Cape Peninsula in Western Cape, South Africa, from Table Mountain to Simonstown; in rocky sandstone outcrops, flowering mainly in mid- to late summer, rarely into autumn.

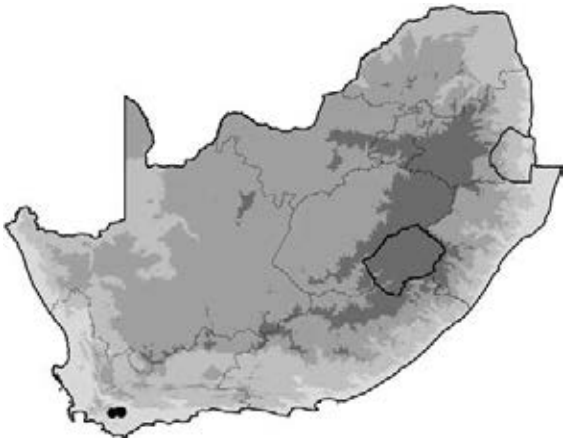
Diagnosis: related to but readily separated from *Gladiolus brevifolius* and other small-flowered, autumn-blooming species with reduced leaves and pale pink flowers by the longer perianth tube, 22–30 mm long and longer than the dorsal tepal.

74. **Gladiolus nerineoides** *G.J.Lewis* in Flowering Plants of Africa 25: t. 994 (1946). Type: South Africa, [Western Cape], Hottentot's Holland Mtns, Somerset Sneeukop, Mar. 1938, *Valpy s.n. SAM 54330* (SAM, holo.).

Plants 350–600 mm high, with cataphylls pubescent. *Corm* globose, 15–20 mm diam.; tunics of pale, finely netted fibres, often forming a collar around base. *Stems* generally inclined, unbranched. *Leaves* (1)2, inserted on middle and upper part of stem, widely spaced and entirely sheathing, lowermost 40–70 mm long, pubescent, upper 20–35 mm long; foliage leaf solitary, produced later in season, linear to narrowly lanceolate, 250–300 × 3–6 mm, lightly pubescent, dry at flowering but often remaining attached to corm, main and a pair of secondary veins lightly thickened, margins not thickened. *Spike* usually flexed outward at base and inclined to nearly horizontal, 3- to 5(10)-flowered, flowers crowded on upper side and subcapitate; bracts green, outer 14–18 mm long, obtuse, inner ± as long, minutely forked. *Flowers* scarlet red (rarely orange), lower 3 tepals sometimes with darker median streak toward base, unscented; perianth tube ± straight, cylindric below, widened somewhat in upper ½, 25–31 mm long; tepals subequal, narrowly ovate, held somewhat apart, lower three directed downward distally, somewhat undulate, upper sometimes recurving, 19–22 × 7–9 mm. *Filaments* 8–10 mm long, entirely included in tube; anthers 6–7 mm long, with upper third exserted from tube. *Style* dividing at or shortly beyond anther apices, branches 3–4 mm long, filiform and notched apically. *Capsules* obovoid, obtuse to subacute, ± 12 mm long. *Seeds* unknown. *Flowering time*: mostly December to February, occasionally in March.

Distribution and ecology: a local endemic of the mountains between Stellenbosch and Somerset West in Western Cape, South Africa; on cooler, rocky slopes mostly above 1 000 m elevation, flowering in mid-summer.

Diagnosis: recognised by the crowded, subcapitate spike of scarlet or reddish orange, funnel-shaped flowers with subequal tepals 19–22 mm long and ± straight perianth tube 25–31 mm long, almost entirely including the stamens.



75. **Gladiolus stokoei** *G.J.Lewis* in Flowering Plants of Africa 26: t. 1004 (1947). Type: South Africa, [Western Cape], Caledon District, Riviersonderend Mtns, Mar. 1945, *Stokoe s.n.* (SAM [*SAM 56457*], holo.; BOL, iso.).

Plants 300–450 mm high. *Corm* globose, 12–15 mm diam.; tunics of fine fibres, forming collar around base. *Stem* erect, unbranched, straight. *Leaves* (1)2, not overlapping, largely sheathing, up to 12 mm long, uppermost with margins sometimes united around stem; foliage leaf solitary, produced after flowering, linear, ultimately to 250 mm long or more, 2.0–3.5 mm wide, with 1 or 2 lightly raised veins, lightly pilose, margins and main vein

lightly raised. *Spike* erect, nearly straight, 1- to 3-flowered; bracts green and firm-textured, often reddish on margins, outer 25–30 mm long, inner slightly shorter or slightly longer, minutely forked. *Flowers* bright scarlet, nodding, tepals symmetrically disposed and forming a slightly compressed bowl with apices curving inward, lower 3 tepals with darker red median streak, unscented; perianth tube obliquely funnel-shaped, 30–35 mm long, lower cylindric part ± 20 mm long; tepals subequal, outer 3 suborbicular, ± 28–30 × 22–28 mm, inner 3 obovate, ± 25–27 × 15 mm. *Filaments* ± 20 mm long, exserted ± 11 mm from tube; anthers 10–12 mm long, yellow; pollen yellow. *Style* arching over stamens, dividing slightly below or beyond anther tips, branches 5–7 mm long. *Capsules* and *seeds* unknown. *Flowering time*: February to April.

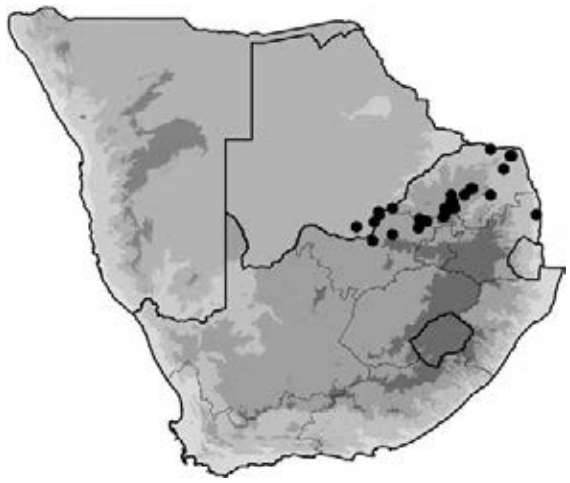
Distribution and ecology: a local endemic of the Riviersonderend Mtns in Western Cape, South Africa; on cooler, southern slopes from 700 to 1 400 m elevation, flowering in autumn.

Diagnosis: unmistakable in its nodding, scarlet flowers with obovate, cupped tepals. The reduced, bract-like and softly hairy leaves on the flowering stem distinguishes it from the unrelated, summer-flowering *Gladiolus insolens* from the Piketberg, which has remarkably similar flowers but a basal fan of smooth, well-developed leaves.

Distribution of ***Gladiolus stokoei***.

Sect. 5. **Heterocolon** *Kuntze*, Revisio generum plantarum 3: 66 (1898). Type species: *Gladiolus pretoriensis* Kuntze

Plants small to medium-sized. *Stem* occasionally unbranched. *Corm* tunics coarsely fibrous. *Leaves* several, either mostly basal in a fan or all cauline, sometimes much reduced on flowering stem, narrowly lanceolate linear, firm-textured, plane with thickened main vein and margins or terete and grooved, usually < 4 mm wide, rarely villous or puberulous. *Spike* mostly few-flowered; bracts glabrous, margins of inner bracts free. *Flowers* small to medium, strongly bilabiate, nectar guides usually of transverse bands edged in darker colour, usually unscented; perianth tube usually obliquely funnel-shaped, shorter or longer than dorsal tepal; lower tepals narrower and usually clawed. Anthers never tailed. *Capsules* oblong to subglobose and retuse above. *Seeds* evenly or unevenly winged, or wings vestigial.



The section includes 8 southern African species plus several from tropical Africa.

Ser. **Unguiculati** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus unguiculatus* Baker

Plants from the summer-rainfall region, flowering in spring. *Leaves* reduced on flowering stem, with short blades, margins and midrib thickened. *Flowers* small, lower tepals often strongly clawed. *Capsules* ellipsoid. *Seeds* broadly and evenly winged.

76. **Gladiolus oatesii** *Rolfe* in Oates, Matabeleland and the Victoria Falls, edn. 2: 410 (1889). Type: Zimbabwe, Matabeleland, in 1874, *Oates s.n.* (K, holo.).

Plants 400–500 mm high, with purple or purple-veined cataphylls, drying dark brown. *Corm* globose to obconic, 10–16 mm diam.; tunics of matted, fine fibres usually extending upward for a short distance. *Stem* erect, ± straight, unbranched. *Leaves* (2)3, lowermost sheathing lower ¼ of stem with blade vestigial to short, lanceolate, (10–)20–40 × 2.3–4.0 mm, margins and main vein moderately thickened and hyaline, second leaf inserted shortly above basal leaf, blade vestigial, uppermost leaf entirely sheathing, 20–50 mm long, margins overlapping around stem; non-flowering plants with solitary, narrowly lanceolate leaf emergent, at flowering 70–100 mm long but ultimately at least 200 mm long, grey-green, 3–4 mm wide, margins and main vein lightly thickened and raised. *Spike* erect, barely flexuose, 5- to 12-flowered; bracts pale green, apices and upper margins often flushed reddish purple, outer 11–18(–21) mm long, inner ± as long or slightly shorter. *Flowers* whitish to pale mauve with upper tepals flushed with purple and darker toward apices, lower lateral tepal limbs with transverse chevron of white (or yellow) edged with purple, unscented; perianth tube obliquely funnel-shaped, 10–11 mm long, cylindric lower part ± 4 mm long; tepals with upper lanceolate-elliptic, dorsal largest, extended horizontally over stamens, curving upward distally, 18–20 × 10–12 mm, upper laterals directed forward throughout or weakly spreading distally, ± 15 × 7 mm, sometimes narrowly windowed between bases of dorsal and upper lateral tepals, lower 3 tepals united with upper laterals for ± 4 mm and together for ± 3 mm, strongly clawed, limbs flexed downward and those of lower laterals

Distribution of ***Gladiolus oatesii***.

diverging, lower laterals 12–14 mm long, claws ± 6 mm long, limbs 6–8 × 3.5–4.5 mm, lower median ± 14 mm long, claw ± 4 mm long, limb ± 10 × 5 mm. *Filaments* 12–15 mm long, exserted 5–8 mm from tube; anthers ± 6.5 mm long, greenish or mauve with dark lines on ventral sides; pollen yellow. *Style* arching over stamens, dividing opposite lower third of anthers, branches 2.0–2.5 mm long. *Capsules* ellipsoid, 12–15 mm long. *Seeds* oval, ± 5 × 3.5 mm, broadly and evenly winged. *Flowering time*: mid-October to early December.

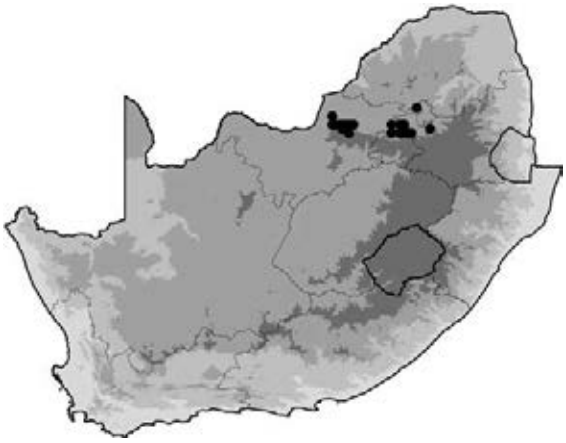
Distribution and ecology: scattered across northern southern Africa, from Botswana through North West Province and Limpopo to the southern Kruger National Park in South Africa, also in southern Zimbabwe and southern Mozambique; in open bushveld or grassland in rocky places, flowering in spring.

Diagnosis: recognised by the reduced foliage, the flowering stem bearing two or three glabrous leaves with reduced or vestigial blades, and the erect spike of pale mauve, strongly bilabiate flowers, the lower tepals clawed with oblong blades and usually slightly shorter than the median, the nectar guides transverse median chevrons of pale colour edged with purple. The species is closely allied to *Gladiolus atropurpureus* from tropical Africa but pale-flowered forms of that species can be distinguished from *G. oatesii* by their broader, spade-shaped lower tepals, the laterals ± as long as or slightly longer than the median and with nectar guides a solid, median blotch, and the shorter filaments 6–8 mm long.

Ser. **Heterocolon** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus pretoriensis* Kuntze

Plants from the summer-rainfall region, flowering in summer and autumn. *Leaves* slender, often terete and 4-grooved with heavily thickened main vein and margins. *Flowers* small, lower tepals often strongly clawed. *Capsules* ovoid. *Seeds* weakly and unevenly winged or wings vestigial.

77. **Gladiolus rubellus** *Goldblatt* in Flora Zambesiaca 12(4): 74 (1993). Type: Botswana, Molepolole, 20 May 1984, *Plowes 7085* (UCBG, holo.; MO, PRE, iso.).



Plants 250–450 mm high. *Corm* obconic, 15–20 mm diam.; tunics of medium-textured to fairly fine fibres, often forming neck around base of stem. *Stem* often with one or occasionally two branches, ± 1.2 mm diam. below base of spike. *Leaves* 3 or 4, at least lower 1 or 2 basal, usually slightly longer than stem, linear, (1.8–)3.0–4.5 mm wide, midrib and margins strongly thickened with margins raised at right angles to surface, cauline leaves shorter, uppermost sometimes entirely sheathing. *Spike* inclined, 10- to 16-flowered; bracts green, 12–14(–16) mm long, inner usually shorter. *Flowers* bright orange-red, lower lateral tepals with transverse yellow band outlined in dark red across distal half; perianth tube obliquely funnel-shaped, ± 14 mm long; tepals lanceolate, dorsal largest, 16–20 mm long, upper laterals slightly smaller, lower 3 tepals joined to upper laterals for 2–4 mm and together for ± 3 mm, 12–14 mm long, narrowed below into claws, limbs abruptly expanded, flexed downward distally. *Filaments* 12–14 mm long, exserted 8–10 mm from tube; anthers ± 6.5 mm long, yellow. *Style* arching over stamens, dividing between middle and apex of anthers, branches 2.5–3.0 mm long. *Capsules* obovoid, 3-lobed apically and retuse, 12–14 × 6 mm. *Seeds* oval, 3.5–5.0 × ± 3 mm, unevenly winged, sometimes ± ridged on angles rather than winged. *Flowering time*: January to March.

Distribution and ecology: originally known only from southeastern Botswana between Lobatse and Molepolole but now also recorded from the Baynes Mtns in northwestern Namibia; in stony ground in dry savanna, flowering in late summer.

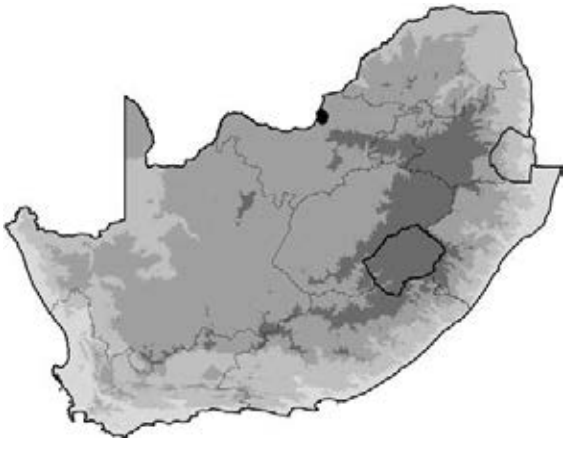
Diagnosis: recognised by the linear leaves with stringy thickened midrib and margins, and the small, bright orange-red flowers with yellow markings on the lower tepals.

78. **Gladiolus pretoriensis** *Kuntze*, Revisio generum plantarum 3(2): 308 (1898). Type: South Africa, [Gauteng], Transvaal, Pretoria, Feb. 1894, *Kuntze s.n.* (NY, holo.; K, iso.).

Plants 400–700 mm high. *Corm* 14–18 mm diam.; tunics of medium-textured fibres, not extending upward in a collar. *Stem* simple or up to 2-branched, usually flexed above sheath of uppermost leaf, ± 1 mm diam. at base of spike. *Leaves* 3 to 5(7), lower 1 or 2 basal, reaching at least to base of spike or longer, terete or oval in section and narrowly 4-grooved, ± 1.5–2.0 mm diam., midrib and margins thickened and raised, cauline leaves progressively shorter and thinner, becoming almost filiform, upper 1 or 2 cauline leaves often with vestigial blades, sheaths of cauline leaves sometimes overlapping and concealing stem up to base of spike.

Distribution of ***Gladiolus pretoriensis***.

Spike inclined, lightly flexuose, (5)9- to 13-flowered; bracts green below or purplish, becoming dry and brownish in upper half at flowering and completely dry and rusty brown in fruit, 9–12(–15) mm long, inner shorter to slightly longer, forked at apex. *Flowers* pale lilac to pink, upper three tepals darker in midline, lower lateral tepals each with yellow spade-shaped mark outlined in purple, unscented; perianth tube obliquely funnel-shaped, 11–14 mm long, curved outward above; tepals oblanceolate, dorsal largest, hooded over stamens, 14–18(–24) × 10–14 mm, upper laterals curving outward distally, 12–16(–23) mm long, lower 3 held close together and ± horizontal or tilted downward, united with upper laterals for 5–8 mm, free parts 11–15(–20) mm long, narrowed below into claws, limbs of lower laterals 2.5–4.0 wide, lowermost 4.5–6.5 mm wide. *Filaments* 10–13 mm long, exserted 5–7 mm from tube; anthers 4–6 mm long, yellow; pollen yellow. *Style* arching over filaments, dividing between lower third and apex of anthers, branches 1.5–2.0 mm long. *Capsules* globose-ovoid, 8–10 mm long. *Seeds* angular-prismatic, 1.7–2.0 mm long. *Flowering time*: mid-January and February.



Distribution and ecology: restricted to interior South Africa north of the Vaal River, from Zeerust and Rustenburg in North West to Pretoria and Krugersdorp in Gauteng; on stony, often clay hillsides in grassland and open woodland.

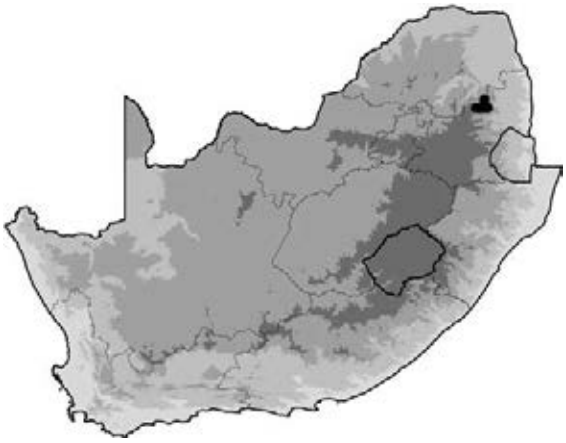
Diagnosis: recognised by its slender, terete and 4-grooved leaves and small, short-tubed, lilac to pink flowers, the lower tepals with a pale, transversely spade-shaped mark outlined with purple, and the subglobose capsules with completely wingless seeds. The relatively shorter perianth tube, 11–14 mm long separates it from *Gladiolus filiformis* from around Zeerust, characterised by its longer perianth tube, 25–40 mm long and longer than the dorsal tepal. *Gladiolus rubellus* from eastern Botswana and northern Namibia has linear leaves with thickened midrib and margins, bright orange-red flowers, and partially winged seeds.

79. **Gladiolus filiformis** *Goldblatt & J.C.Manning, Gladiolus* in southern Africa: 182 (1998). Type: South Africa, [North West], Gopane Mtns, 29 Dec. 1977, *Peeters, Gericke & Burelli 509* (PRE, holo.).

Plants 350–500(–720) mm high. *Corm* obconic, 20–30 mm diam.; tunics of medium-textured fibres, accumulating in a dense mass. *Stem* lightly flexed outward above sheaths of upper 2 leaves, simple or 1-branched, 1.5–2.0 mm diam. at base of spike. *Leaves* 3 or 4, lower 2 basal, reaching to ± base of spike, terete and narrowly 4-grooved, 1.0–2.5 mm diam., main vein and margins thickened and raised, second leaf sheathing lower third of stem, cauline leaves entirely sheathing. *Spike* ± straight and erect, 5- to 10(12)-flowered; bracts tinged reddish, ± dry and brown after flowering, outer (8–)10–25 mm long, inner slightly shorter. *Flowers* pale mauve or pinkish, lower tepals with white markings outlined with purple, unscented; perianth tube narrowly and obliquely funnel-shaped, 25–35(–40) mm long, narrow and cylindric below, widening in upper 6–10 mm, curved outward above; tepals oblanceolate, dorsal largest, hooded over stamens, 20–25 × 15–22 mm, upper laterals curving outward distally, 15–22(–25) × 9–13 mm, lower 3 held close together, shortly united with upper laterals, free parts 15–20 mm long, narrowed below into claws, limbs of lower laterals 6–10 mm wide, lowermost 7–12 mm wide. *Filaments* (9–)10–14 mm long, exserted 5–7 mm from tube; anthers 5–9 mm long, pale yellow. *Style* arching over stamens, dividing opposite anther tips, branches 3–6 mm long. *Capsules* ellipsoid, 8–12 mm long. *Seeds* angular-prismatic and unevenly winged, lateral and lower wings reduced or vestigial. *Flowering time*: mainly December, but as early as October and as late as February depending on rains.

Distribution and ecology: a highly localised endemic of North West Province west of Zeerust, South Africa, and adjacent eastern Botswana; on rocky slopes in grassland and open woodland.

Distribution of ***Gladiolus filiformis*** .



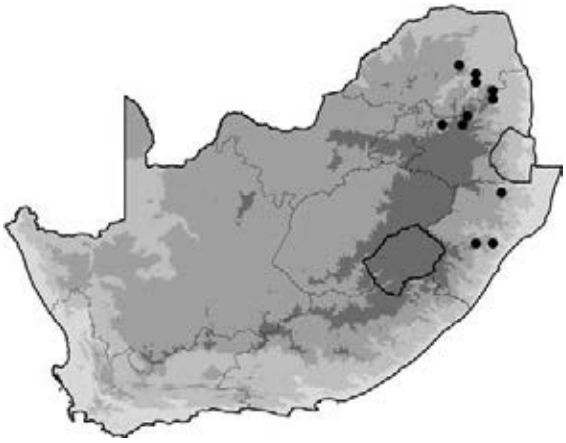
Diagnosis: recognised by its slender, terete and 4-grooved leaves and long-tubed mauve to pinkish flowers, the lower tepals with pale, spade-shaped markings outlined with purple, and the perianth tube 25–40 mm long and longer than the dorsal tepal. The seeds are unevenly winged with the lateral and lower wings reduced or vestigial. *Gladiolus pretoriensis* is separated by the shorter perianth tube, 11–14 mm long, and subglobose capsules with wingless, angular-prismatic seeds.

Ser. **Verni** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus vernus* Oberm.

Plants from the summer- and winter-rainfall regions, flowering from autumn to spring. *Leaves* slender, linear and 2-grooved on each surface or narrowly to widely 4-grooved and thus X-shaped in section, with thickened and sometimes raised midrib and margins. *Flowers* small to medium-sized, lower tepals joined to upper laterals and strongly clawed, lower laterals ± spathulate and often twisted outward, perianth often speckled. *Capsules* ellipsoid. *Seeds* usually broadly and evenly winged, rarely unevenly.

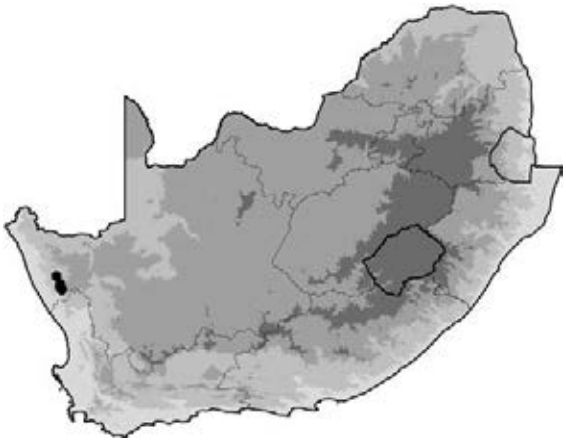
80. **Gladiolus rufomarginatus** *G.J.Lewis* in Lewis et al. in Journal of South African Botany, Suppl. 10: 145 (1972), replacement name for *G. marginatus* F.Bolus: 108 (1917), illegitimate homonym, not *G. marginatus* L.f. (1782) nor *G. marginatus* F.Bolus (1917). Type: South Africa, [Mpumalanga], Lydenburg, Jan. 1895, *Wilms s.n.* (PRE, holo.; BOL [tracing and flower], iso.).

Plants 300–500 mm high. *Corm* obconic, 15–18 mm diam.; tunics papery becoming ± fibrous. *Stems* flexed above sheaths of upper leaves, minutely scabrid, simple or occasionally 1-branched. *Leaves* usually 5, lower 2 or 3 basal, shortly exceeding stem, linear, 2–3 mm wide, ± oval in section and 2-grooved on each side with margins and main vein heavily thickened, a pair of secondary veins often evident, cauline leaves decreasing in size above, uppermost bract-like, mostly sheathing. *Spike* straight and erect, 8- to 20(30)-flowered; bracts pale-membranous, brown above at anthesis, margins rusty brown, outer lightly folded along midline, 14–18 mm long, inner shorter, forked. *Flowers* cream-coloured irregularly mottled with dark red, lower 3 tepals flushed yellow-green in lower ⅔ with veins showing dark red, tips of limbs flushed bright pink to red, unscented; perianth tube obliquely funnel-shaped, ± 9 mm long, lower cylindric part ± 4 mm long; tepals lanceolate, all distinctly clawed, dorsal largest, inclined over stamens, 18–20 × 12 mm, upper laterals ± 15 × 5 mm, limbs spreading, usually windowed between claws of dorsal and upper laterals tepals, lower tepals joined to upper laterals for ± 1.5 mm and together for ± 2 mm, free parts ± 8 mm long, claws ± 4 mm long, abruptly expanded at base of limbs. *Filaments* ± 13 mm long, exserted ± 9 mm from tube, spotted with dark red; anthers ± 5 mm long, tilting downward distally, olive-green; pollen white. *Style* arching over stamens, dividing opposite lower half of anthers, branches ± 2 mm long. *Capsules* oblong, 3-lobed above and retuse, 9–12 mm long. *Seeds* oblong, ± 5 × 2.5 mm, unevenly winged. *Flowering time*: mainly March and April, sometimes in May.



Distribution of ***Gladiolus rufomarginatus***.

Distribution and ecology: a narrow endemic of Mpumalanga, South Africa, between Lydenburg and Ohrigstad; on stony shale banks and outcrops in dry grassland and open woodland.



Diagnosis: a very distinctive species, with narrow, 4-grooved leaves, pale bracts with brown tips and margins, and pale, short-tubed flowers densely speckled with red. The spikes bear up to 30 flowers.

81. **Gladiolus vernus** *Oberm.* in Lewis et al. in Journal of South African Botany, Suppl. 10: 138 (1972). Type: South Africa, [Mpumalanga], Blyde River Canyon, lookout point ± 6.3 miles [10 km] north of Bourke's Luck, 23 Aug. 1963, *Leistner, Thom, & Gillham 3314* (PRE, lecto., designated by Goldblatt & Manning: 184 (1998); BOL, K, PRE, isolecto.).

Plants (350–)450–750 mm high. *Corm* ± globose, 20–40 mm diam.; tunics of moderately coarse fibres, accumulating in a thick mass. *Stem* inclined above, simple or with up to 2 branches. *Leaves* usually 6, lower 4 basal, partly or completely dry at flowering, up to 450 mm long, stiff and gently curving, linear, 2–3 mm wide, ± oval in section, 2-grooved on each side with margins and main vein raised and thickened, uppermost 2 leaves largely to entirely sheathing, ± dry and often flushed pink. *Spike* inclined, lightly flexuose, usually 12- to 18-flowered; bracts partly dry at flowering, often flushed pink above, 10–15(–22) mm long, inner shorter to as long, broad and enclosing flower. *Flowers* slightly laterally compressed, pale to deep pink or cream-coloured, upper tepals more darkly pigmented above, lower lateral or all lower tepals pale yellow in middle third sometimes edged dark pink or purple, basal ½ of lower tepals speckled with pink, unscented; perianth tube obliquely funnel-shaped, 8–13 mm long; tepals with dorsal largest, inclined over stamens, (17–)20–30 × 10–18 mm, upper laterals obliquely spathulate, narrow

Distribution of ***Gladiolus vernus***.

Distribution of ***Gladiolus kamiesbergensis***.

at base, 15–26 × 8–11 mm, usually windowed between dorsal and upper lateral tepals, lower 3 united with upper laterals for 5–8 mm and together for 1.5–3.0 mm, clawed, lower laterals 10–13 mm long, claws linear-channelled, 2–3 mm long, abruptly expanded into broadly oval-auriculate limbs ± 7 × 6 mm, lower median 11–15 × 6–8 mm long, claw 1–3 mm long. *Filaments* 10–16 mm long, exserted ± 8–10 mm from tube; anthers 6–8 mm long, purplish; pollen whitish. *Style* arching over stamens, dividing opposite base to upper ⅓ of anthers, branches 2–3 mm long. *Capsules* obovoid, 3-lobed above and retuse, 10–12 mm long. *Seeds* oval, ± 6 × 4 mm, evenly winged. *Flowering time*: July and August.

Distribution and ecology: scattered along the eastern escarpment of South Africa, from the Wolkberg in Limpopo through Mpumalanga to Hermannsburg in KwaZulu-Natal but poorly documented, especially in KwaZulu-Natal; in rocky grassland in quartzite, flowering in winter when the leaves are dry.

Diagnosis: a winter-flowering species with linear, grooved leaves dry at flowering, and pale pink to cream-coloured flowers with yellow markings on the lower tepals, and obliquely spathulate upper lateral tepals.

82. **Gladiolus kamiesbergensis** *G.J.Lewis* in Lewis et al. in Journal of South African Botany, Suppl. 10: 128 (1972). Type: South Africa, [Northern Cape], Kamiesberg, Farm Welkom, 16 Oct. 1954, *Esterhuysen 23716* (BOL, holo.; BOL, K, iso.).

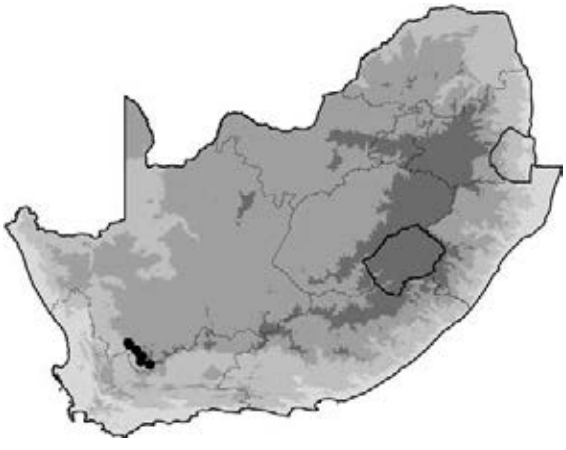
Plants 450–900 mm high. *Corm* globose, 18–22 mm diam.; tunics leathery, breaking into moderately thick vertical fibres. *Stem* ± erect, unbranched. *Leaves* usually 4, lowermost often exceeding spike, ± 1.3 mm diam., terete and finely 4-grooved with main vein and margins raised and strongly thickened, second leaf much shorter and more slender, sheathing stem below, upper 2 leaves entirely sheathing or with vestigial blades, lower margins overlapping or rarely sheaths closed near base. *Spike* ± erect or lightly flexed at base and barely inclined, 4- to 9(12)-flowered; bracts pale with hyaline margins, outer 13–18 mm long, inner shorter to ± as long. *Flowers* pale blue-lilac with minute purple dots on tepals, especially toward apices, lower lateral tepals yellow on lower half of limbs, sweetly apple-scented; perianth tube obliquely funnel-shaped, 12–13 mm long; tepals with dorsal largest, arching to hooded over stamens, 16–21 × 10–12 mm, upper laterals obliquely ovate, curving outward apically, 16–18 × 8–10 mm, windowed between bases of dorsal and upper laterals, lower tepals united with upper laterals for 5 mm and together for 1–2 mm, lower laterals twisted obliquely, narrowed below into linear, channelled claws 3–4 mm long, abruptly expanded into oval limbs ± 7 × 7 mm, limbs spooned, lower median lanceolate, ± 9 × 7 mm. *Filaments* arched below dorsal tepal, ± 12 mm long, exserted ± 9 mm from tube; anthers ± 6 mm long, lilac; pollen whitish. *Style* arching over stamens, dividing opposite middle of anthers, branches ± 2 mm long. *Capsules* obovoid, obtuse, 15–18 mm long. *Seeds* ovate, ± 5.5 × 6 mm, broadly and evenly winged. *Flowering time*: mainly October, sometimes in late September.

Distribution and ecology: endemic to the Kamiesberg in Northern Cape, South Africa, above 1 200 m elevation on Rooiberg, Sneeuberg and other peaks; in rocky sites, usually in fynbos.

Diagnosis: recognised by the long basal leaf with terete, finely 4-grooved blade, and pale blue-lilac flowers with darker speckling, the narrowly clawed lower tepals with abruptly expanded limbs coloured pale yellow at the base, and the obliquely ovate upper laterals forming a window with the dorsal tepal.

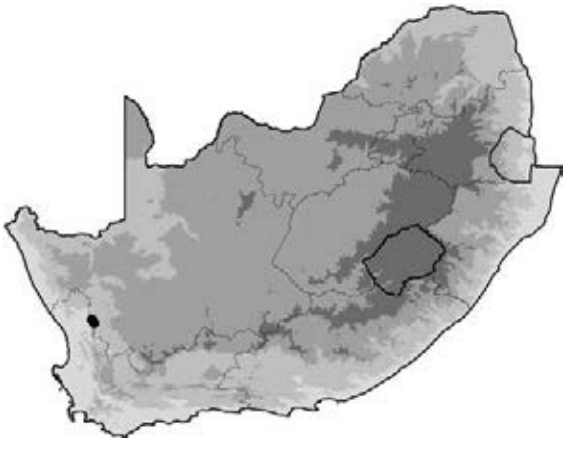
83. **Gladiolus marlothii** *G.J.Lewis* in Lewis et al. in Journal of South African Botany, Suppl. 10: 141 (1972). Type: South Africa, [Northern Cape], Farm Driefontein, north of Sutherland, 1 400 m, Oct. 1920, *Marloth 9757* (PRE, holo.; BOL, iso.).

Plants 450–600 mm high, with cataphylls often purple, velvety when young. *Corm* globose, 16–22 mm



diam.; tunics of coarsely textured fibres, accumulating in a dense mass. *Stem* normally erect or slightly inclined, unbranched. *Leaves* 4, sheaths villous and deflexed-scabrid on edges of ribs, blades ciliate and scabrid on margins of wings, lowermost sheathing lower ⅓ of stem, blade reaching or exceeding spike, centric and X-shaped in section, 3–4 mm wide, main vein raised and forming flanges either side of blade, margins and edges of main vein flanges thickened and shortly villous on edges, second leaf with a well-developed blade often reaching at least base of spike, upper leaves progressively shorter, blades sometimes reduced, uppermost leaf usually entirely or largely sheathing. *Spike* flexed at base and inclined, almost straight, 3- to 5-flowered; bracts pale green or becoming pale and dry toward apices, eventually ± entirely membranous, 16–24 mm long, inner bracts slightly shorter than outer. *Flowers* pale blue, often slightly darker toward tips of upper tepals, lower lateral tepals with transverse yellow band just above base of limb, fairly densely speckled with dark purple at edges, lower median tepal with yellow blotch in lower midline, lower part of throat also speckled, tepals forming a slightly inflated bell, unscented; perianth tube 9–10 mm long, obliquely funnel-shaped, lower ½ erect and cylindric, ± 4 mm long, upper ½ bent at right angles and flaring outward; tepals ± ovate, dorsal largest, arched over stamens and ± horizontal, 24–30 × 18–20 mm, upper laterals curving outward near apices, ± 20 × 17 mm, slightly concave just above base, lower tepals united with upper laterals for 5–8 mm and to one another for ± 2 mm, lower laterals spathulate, clawed below, claws ± 6 × 1.3 mm, expanded abruptly into a broadly ovate or oblong limb 12 × 10 mm, lower median tepal ± 14 mm long, narrowly clawed in lower 1–2 mm. *Filaments* ± 13 mm long, exserted ± 9 mm from tube but included in flower; anthers ± 9 mm long, lilac; pollen cream-coloured. *Style* arched over stamens, dividing opposite upper ⅓ of anthers, branches ± 4.5 mm long. *Capsules* obovoid, 3-lobed above and retuse, 16–19 mm long. *Seeds* ± ovate, 6–7 × 4–5 mm, broadly and evenly winged. *Flowering time*: mid-September to early October.

Distribution and ecology: a local endemic of the Roggeveld Escarpment and Klein Roggeveld in Northern Cape, South Africa, between Rooiwal and Sneeukrans at about 1 800 m elevation and below Komsberg Pass; in dolerite outcrops in open renosterveld scrub.



Diagnosis: an unmistakable species with villous leaves, the blades X-shaped, and pale blue, bell-shaped flowers with darker speckles and strongly clawed lower tepals with pale yellow nectar guides outlined with darker speckles on the limbs.

84. **Gladiolus mostertiae** *L.Bolus* in Annals of the Bolus Herbarium 3: 142 (1922). Type: South Africa, [Northern Cape], Calvinia District, Cloudskraal near Nieuwoudtville, cultivated at Kirstenbosch Gardens, Nov. 1921, *Mostert s.n. Natl. Bot. Gard. 1609/20* (BOL, holo.).

Plants (200–)300–500 mm high. *Corm* globose, ± 12–14 mm diam.; tunics papery to softly leathery, soon becoming finely fibrous. *Stem* erect, moderately to strongly flexed above sheathing parts of upper leaves and flexuose, usually 1(3)-branched. *Leaves* (3)4, lower 2 basal and reaching to between base and middle of spike, linear or narrowly lanceolate, 2.5–4.0 mm wide, lightly to densely villous, veins strongly thickened and ridged, margins lightly thickened, cauline leaves progressively smaller, usually channelled throughout and shortly sheathing. *Spike* ± straight or lightly flexuose, 4- to 10-flowered; bracts bright green or flushed dull purple, firm-textured, broadly truncate, upper margins usually dull purple, outer 10–14 mm long, inner shorter, minutely notched. *Flowers* pale to deep pink, darker toward tips of upper tepals, lower lateral tepal limbs cream-coloured with heart-shaped yellow mark with a greenish centre toward base, lower tepal claws and wide part of tube with minute reddish dots, with a faint acrid metallic odour; perianth tube obliquely funnel-shaped, ± 11 mm long; tepals ± ovate, dorsal largest, arching to hooded over stamens, ± 20 × 12 mm, upper laterals directed forward, curving outward only toward apices,

Distribution of ***Gladiolus marlothii***.

Distribution of ***Gladiolus mostertiae***.

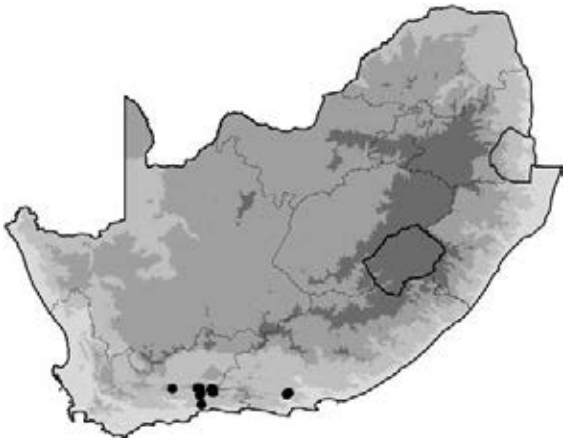
± 15 × 9 mm, sometimes windowed between bases of dorsal and upper lateral tepals or these overlapping, lower tepals united with upper laterals for ± 10 mm and together for ± 1 mm, lower laterals twisted obliquely, ± 11 mm long, narrowed below into linear channelled claws ± 4 mm long, abruptly expanded into broadly oval limbs ± 7 × 6 mm, lower median tepal broadly lanceolate, not clawed, ± 9 × 8 mm. *Filaments* ± 15 mm long, strongly arched, exserted ± 8 mm from tube; anthers ± 4 mm long, lilac; pollen whitish. *Style* arching over stamens, dividing opposite middle of anthers, branches ± 3.5 mm long. *Capsules* ellipsoid-trigonous, (14–)18–20 mm long. *Seeds* ovate, 4–5 × ± 3 mm, broadly and evenly winged. *Flowering time*: mid-November to mid-December.

Distribution and ecology: a rare and local endemic of the edge of the Bokkeveld Plateau near Nieuwoudtville in Northern Cape, South Africa; in seasonally wet marshy flats on sandstone, flowering in early summer.

Diagnosis: readily recognised by the linear, villous leaves with thickened veins, and usually branched stem with pale pink flowers with clawed tepals, the lower laterals with a yellowish green, heart-shaped blotch at the base of the limb.

Sect. 6. **Hebea** *(Pers.) Bentham & Hook.f.*, Genera plantarum 3(2): 710 (1883). *Gladiolus* group *Hebea* Pers.: 44 (1805). *G.* subg. *Hebea* (Pers.) Baker: 177 (1877). Type species: *Gladiolus alatus* L., lecto., designated by Goldblatt: 169 (1996).

Plants small to medium-sized. *Stem* often branched, sometimes compressed and angled to winged. *Corm* tunics membranous or papery to fibrous, leathery or woody. *Leaves* several or few, usually mostly basal in a fan, linear to narrowly lanceolate, soft or firm-textured, plane with thickened main vein or ridged or corrugate, rarely terete, margins usually unthickened. *Spike* few- to many-flowered; bracts glabrous, margins of inner bracts free. *Flowers* small to medium, weakly to strongly bilabiate, nectar guides usually of solid yellowish colour darker along distal edge, usually scented, often strongly; perianth tube usually obliquely funnel-shaped, usually shorter than dorsal tepal (or longer); lower tepals usually narrowed or clawed. *Anthers* not tailed. *Capsules* oblong-ellipsoid to subglobose, retuse. *Seeds* broadly and evenly winged, seed body dark.



Species 32: southern Africa, mainly winter-rainfall parts.

Ser. **Involuti** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus involutus* D.Delaroche.

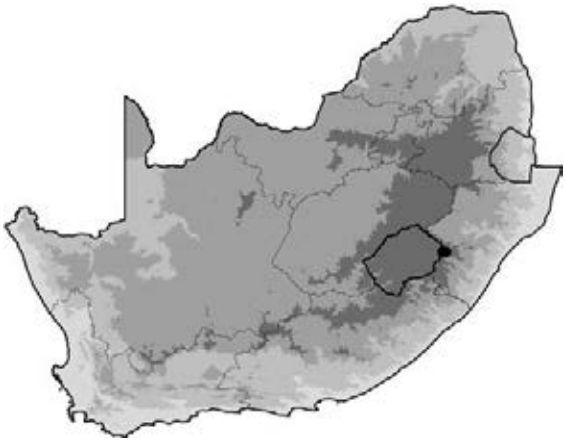
Plants mainly from winter-rainfall region. *Corms* often with slender stolons; tunics papery to fibrous. *Leaves* green at flowering, linear to lanceolate, plane, firm or soft-textured. *Flowers* small to medium, lower lateral tepals often involute or otherwise modified, sometimes highly reduced, usually much shorter than lower median, unscented.

85. **Gladiolus leptosiphon** *F.Bolus* in Annals of the Bolus Herbarium 1: 195 (1915). *Radinosiphon leptosiphon* (F.Bolus) N.E.Br.: 263 (1932a). Type: South Africa, [Western Cape], without precise locality, Cape Town Wild Flower Show, among plants probably from the Oudtshoorn or Riversdale Districts, Oct. 1914 (BOL [*BOL 13754*], holo.; K, PRE, iso.).

Plants 250–450 mm high. *Corm* 14–18 mm diam.; tunics of fairly coarse fibres, often claw-like below. *Stem* erect, flexed outward above sheath of uppermost leaf, simple or branched. *Leaves* ± 6, lower 4 basal and reaching to ± top of spike, linear, 2.0–2.5 mm wide, thickened in central area, margins not thickened, upper cauline leaves much shorter. *Spike* inclined, ± straight, 4- to 9-flowered; bracts fairly soft-textured, becoming pale and dry above, (15–)18–22 mm long, inner bract slightly shorter or longer than outer, forked apically. *Flowers* cream-coloured to pale yellow, lower 3 tepals with dark red to purple median streak in lower ½ extending to base of throat, unscented; perianth tube 45–50 mm long, lower part 40–45 mm long, cylindric, curving gently outward, expanding into a wider throat ± 5 mm long; tepals lanceolate-attenuate, upper 3 largest, 25–35 × 9–12 mm, arching outward distally, dorsal arched over stamens, lower 3 tepals united with upper laterals for ± 3 mm, lower laterals ± linear, 18–22 × ± 3.5 mm, lower median curving below lower laterals and exceeding them, 25–32 × 4–5 mm. *Filaments* ± 10 mm long, exserted 4–5 mm from tube, usually light purple; anthers 7–8 mm long, dark blue-purple; pollen purplish. *Style* arching over stamens, dividing close to anther apices, branches ± 2 mm long. *Capsules* obovoid-ellipsoid,

Distribution of ***Gladiolus leptosiphon***.

obtuse, ± 15 mm long. *Seeds* ovate, ± 4.5 × 3 mm, broadly and evenly winged, seed body blackish. *Flowering time*: mid-September to late October.



Distribution and ecology: restricted to the Little Karoo and Long Kloof in South Africa, from the Klein Swartberg near Ladismith in Western Cape to the Kouga and Baviaanskloof Mtns in Eastern Cape; on stony, often shale slopes in drier renosterveld and arid fynbos shrubland.

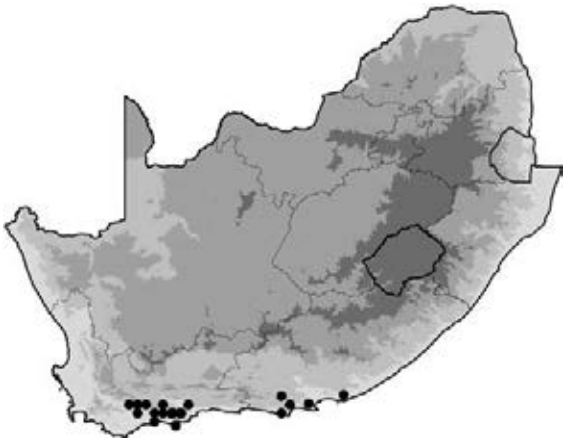
Diagnosis: distinctive in its slender, whip-like leaves and long-tubed, cream-coloured to pale yellow flowers with attenuate tepals, the lower lateral tepals much smaller and marked with a median purple streak, and a slender perianth tube, 45–50 mm long, more than twice as long as the bracts and longer than the dorsal tepal.

86. **Gladiolus loteniensis** *Hilliard & B.L.Burtt* in Notes from the Royal Botanic Garden, Edinburgh 43: 206 (1986). Type: South Africa, [KwaZulu-Natal], Loteni Nature Reserve, Loteni River Valley near Ash Cave, ± 6 000 ft [1 800 m], 13 Jan. 1982, *Hilliard & Burtt 15134* (NU, holo.; E, iso.).

Plants 300–600 mm high. *Corm* poorly developed, ± 5–8 mm diam., producing several long white stolons; tunics papery becoming finely fibrous. *Stem* erect, flexed outward above sheath of uppermost leaf, simple or 1-branched. *Leaves* 4 to 7, lower 3 basal, reaching to between middle of stem and base of spike, narrowly lanceolate, 4–8 mm wide, soft-textured, main vein lightly thickened and raised, margins hyaline, not thickened, cauline leaves progressively shorter. *Spike* flexed outward near base of spike, (3)6- to 12-flowered; bracts soft-textured, pale green flushed purple, 14–16 mm long, inner shorter, usually twisted to lie almost under outer, notched apically. *Flowers* pale lilac-pink flushed darker along tepal midline on reverse, lower 3 tepals cream-coloured to pale yellow below with dark purple veins, sinuses with dark purple spot, unscented; perianth tube obliquely funnel-shaped, ± 5 mm long; tepals oblanceolate-attenuate, dorsal largest, horizontal over stamens, 19–27 × 16–18 mm, upper laterals twisted upward, appressed to dorsal tepal below, obliquely spreading above, 17–19 × ± 13 mm, lower 3 tepals united for ± 1.5 mm, lower laterals 12.0–13.5 × ± 5 mm, narrowed below into claws ± 2 mm long, limbs abruptly expanded, channelled in lower ⅓, lower median 15–18 × 5.5–7.0 mm. *Filaments* ± 7 mm long, exserted ± 5 mm from tube; anthers ± 6 mm long, violet; pollen lilac. *Style* arching over the stamens, dividing between middle and upper ⅓ of anthers, branches ± 2 mm long. *Capsules* obovoid-ellipsoid, obtuse, 8–10 mm long. *Seeds* ovate, ± 6 × 3 mm, broadly and evenly winged, seed body not dark. *Flowering time*: early December to mid-January.

Distribution and ecology: a narrow endemic of the Drakensberg in KwaZulu-Natal, South Africa, known only from the upper Loteni River Valley at 1 800 m elevation; in peaty soil in damp grassland near the river, often in the lee of boulders or cliffs.

Distribution of ***Gladiolus loteniensis***.



Diagnosis: a summer-flowering species from the KwaZulu-Natal Drakensberg with poorly developed corm, recognised by the soft-textured leaves without thickened margins, and the small, pale lilac-pink flowers with prominent, dark veining on the lower lateral tepals, these much shorter than the lower median tepal, and a very short perianth tube ± 5 mm long. The slender stolons are characteristic of several species in the series.

87. **Gladiolus involutus** *D.Delaroche*, Descriptiones plantarum aliquot novarum: 28 (1766). Type: South Africa, without precise locality or collector (L: Herb. van Royen 904, 137-90, holo.).

Gladiolus bimaculatus Lam.: 727 (1788). Type: South Africa, without precise locality or collector, illustration without binomial in Miller: 158 & t. 236 f. 1 (1758).

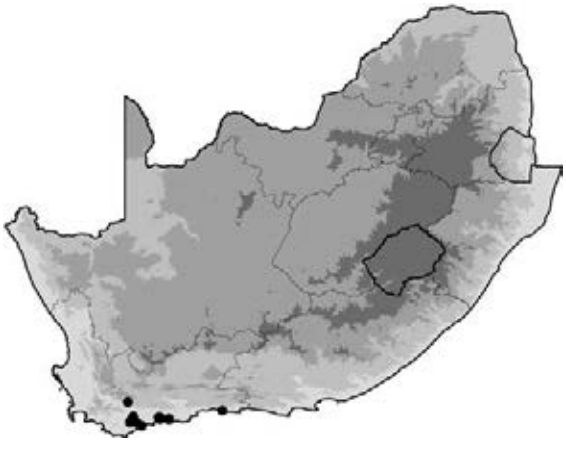
Gladiolus muirii L.Bolus: 132 (1915). Type: South Africa, Western Cape, Riversdale District, Tweekuilen, Oct. 1913, *Muir 588* (BOL, holo.; K, SAM, iso.).

Plants 200–500 mm high, with cataphylls purple, usually mottled white. *Corm* depressed-globose, 12–17 mm diam., with large cormlets on slender white stolons; tunics softly papery or rarely somewhat fibrous. *Stem* usually erect below, sometimes inclined, flexed outward above sheathing part of each cauline leaf, simple or 2- or 3-branched. *Leaves* 7 to 9, lower 4 or 5 basal, reaching to base of spike or sometimes much longer, linear, 1.7–3.0 mm wide, thickened toward the midline, margins hyaline but not thickened, cauline leaves progressively smaller, uppermost not or barely clasping stem. *Spike* lightly inclined, barely flexuose, 4- to 7-flowered; bracts pale green flushed greyish purple, outer 25–35(–40) mm long, inner shorter, obtuse or minutely notched apically. *Flowers* white flushed pink or pale pink, lower 3 tepals pale greenish yellow below, edged with a narrow pink or purple line, entire flower and especially nectar

Distribution of ***Gladiolus involutus***.

guides turning pink with age, unscented; perianth tube obliquely funnel-shaped, curving outward near apex of slender part, 16–18 mm long, emerging between bracts; tepals lanceolate-attenuate, upper laterals longest, 25–28 × 12.0–13.5 mm, directed forward below and twisted to lie over dorsal, curving outward distally, dorsal hooded over stamens, 20–24 × ± 13 mm, lower 3 tepals united below for 3–5 mm, lower laterals linear, 15–19 × 3–5 mm, narrowly clawed below for ± 2 mm, limb channelled-involute in lower ⅔, lower median 22–28 × 6–7 mm, obscurely clawed in lower 1 mm. *Filaments* 12–15 mm long, exserted 6–7 mm from tube; anthers 8–10 mm long, dull purplish; pollen pale orange. *Style* arching over stamens, dividing opposite middle of anthers, branches ± 3 mm long. *Capsules* obovoid-ellipsoid, 20–25 mm long, acute or obtuse. *Seeds* ovate, 6–7 × ± 4 mm long, broadly and evenly winged, seed body often dark brown. *Flowering time*: mid-August to late September, occasionally in October.

Distribution and ecology: extending along the coastal forelands south of the Langeberg–Outeniqua Mtns in South Africa, from Suurbraak to Mossel Bay and in the Little Karoo in Western Cape, and then further east from the Baviaanskloof and Van Stadens River Mtns to East London in Eastern Cape; on stony clay flats in grassy renosterveld shrubland.



Diagnosis: recognised by the rather triangular, white to pale pink flowers, the outer whorl of tepals lanceolate-attenuate and much larger than the inner whorl (including the dorsal tepal), and the lower lateral tepals narrowly involute with a broad greenish yellow band. The slender stolons are characteristic of several species in the series.

88. **Gladiolus vandermerwei** *(L.Bolus) Goldblatt & M.P.de Vos* in Adansonia 11: 421 (1990). *Antholyza vandermerwei* L.Bolus: 14 (1931a). *Homoglossum vandermerwei* (L.Bolus) L.Bolus: 47 (1933a). Type: South Africa, [Western Cape], Swellendam District, cultivated in Cape Town by P. Ross Frames, 19 Sept. 1929, *Van der Merwe s.n.* (BOL [BOL 19084], holo.; BOL, K, iso.).

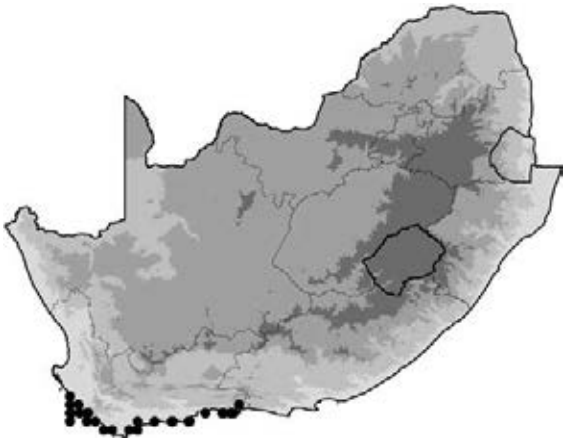
Plants 300–600 mm high, with cataphylls purple mottled white or cream-coloured. *Corm* globose, 8–12 mm diam., with 2 to several slender stolons; tunics papery to membranous, decaying irregularly. *Stem* flexed outward and inclined above, simple or 1- to 3-branched. *Leaves* 5 to 7 or more if stem branched, lower sheaths mottled purple and cream-coloured, lower 4 to 6 basal, reaching to ± base or shortly exceeding spike, linear to narrowly lanceolate, 2–5 mm wide, main vein lightly raised, margins not thickened, cauline leaves smaller, uppermost leaf often sheathing only near base. *Spike* usually erect, lightly flexuose, (2)3- to 8-flowered; bracts dull green to somewhat purplish, outer 35–50(–60) mm long, inner shorter, acute or apically notched. *Flowers* bright scarlet, lower 3 tepals yellow in lower ½, unscented; perianth tube 35–45 mm long, narrow and cylindric in lower 15–22 mm, gradually expanded into wider cylindric, horizontal upper part, 20–23 mm long, ± 7 × 6 mm diam.; tepals with upper 3 lanceolate, dorsal largest, 23–28 × 8–10 mm, inclined slightly above horizontal, upper laterals joined to dorsal for 2–3 mm, 20–30 × 9–11 mm, lower tepals linear, laterals spreading at right angles to tube, straight or twisted, 12–19 × 2–3 mm, lower median slightly longer. *Filaments* 35–40 mm long, extended horizontally, exserted 8–12 mm from tube; anthers 7–9 mm long, dark purple; pollen pale yellow. *Style* extended horizontally, dividing opposite upper ⅓ of anthers, branches 3–5 mm long. *Capsules* ovoid-ellipsoid, rounded, ± 20 mm long. *Seeds* irregularly ovate, ± 6 × 5 mm, evenly or unevenly winged, seed body blackish. *Flowering time*: September and October, occasionally in August.

Distribution and ecology: restricted to the lower Breede River Valley in Western Cape, South Africa, from near Bonnievale to Vermaaklikheid and Still Bay; in stony shale in renosterveld shrubland.

Diagnosis: recognised by the almost tubular, bright red flowers with elongate perianth tube 35–45 mm long, cylindric in the upper part, with ± connivent upper tepals and small, linear lower tepals. The mottled cataphylls and slender stolons are characteristic of several species in the series.

Distribution of ***Gladiolus vandermerwei***.

89. **Gladiolus cunonius** *(L.) Gaertn.*, De fructibus et seminibus plantarum 1: 31 (1788). *Antholyza cunonia* L.: 37 (1753). *Anisanthus cunonius* (L.) Sweet: 397 (1826). *Anomalesia cunonia* (L.) N.E.Br.: 271 (1932a). *Petamenes cunonia* (L.) E.Phillips: 44 (1941). *Gladiolus papilionaceus* Salisb.: 41 (1796), illegitimate superfluous name for *G. cunonius* L. Type: South Africa, without precise locality or collector, illustration in Cuno (1750).



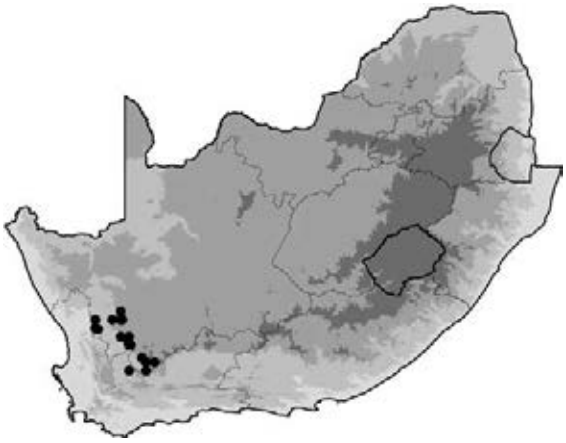
Cunonia antholyza Mill. (1768). Type: South Africa, Western Cape, without precise locality, figure in Miller, Figures of Plants 75: t. 113 (1756).

?*Antholyza coccinea* Spreng.: 253 (1820). Type: unknown.

Plants (120–)300–700 mm high. *Corm* depressed-globose, 6–9 mm diam.; tunics papery to membranous, rapidly decaying and fragmenting irregularly, with numerous slender stolons. *Stem* erect, flexed outward above the sheaths of the cauline leaves and inclined above, simple or 1- or 2-branched. *Leaves* (5)6 to 8, mostly basal, reaching to ± base of spike or shortly exceeding it, narrowly lanceolate, 5–12 mm wide, main veins evident but not or only lightly thickened, cauline leaves smaller, uppermost leaf usually sheathing only near base. *Spike* inclined, lightly flexuose, (3)5- to 8-flowered; bracts soft-textured, green to greyish purple, 20–35(–45) mm long, inner shorter, acute or notched. *Flowers* bright red, lower tepals and tube initially green fading to yellow and later turning reddish, unscented; perianth tube 12–15 mm long, slender below for 10–12 mm, abruptly expanded into short, ± cylindric upper part; tepals with dorsal spathulate, 26–29 mm long, extended horizontally, with a linear claw 10–13 mm long, limb obovate-concave, 13–18 × 11 mm, upper laterals joined to dorsal for 8–12 mm, free part directed forward and upward, ovate-concave, 10–13 × 8 mm, lower tepals united for ± 2 mm, much reduced, free parts 1–4 mm long, lower laterals curving upward distally to partially block mouth of tube. *Filaments* ± 30 mm long, exserted ± 27 mm from tube, median filament with enlarged flattened horny tooth at base in front thus dividing tube in half; anthers 5–7 mm long, attached to filaments near middle with thecae free below filament insertion, red; pollen yellow. *Style* extended horizontally over stamens, dividing shortly below anthers, branches 7–8 mm long, conduplicate, expanded and stigmatic only at apices. *Capsules* oblong-ellipsoid and 3-sided, 27–32 mm long. *Seeds* ovate to oblong, 7–8 × ± 5 mm, broadly and evenly winged. *Flowering time*: September to mid-November.

Distribution and ecology: extending from Blaauwberg just north of Cape Town to Knysna in Western Cape, South Africa; on dunes in sand or calcareous soils, sometimes just above the beach, in clearings and along the margins of coastal bush.

Diagnosis: distinctive in its scarlet flowers with spathulate-concave dorsal tepal flanked by suberect, ear-like lateral tepals, and highly reduced, scale-like lower tepals



Distribution of ***Gladiolus cunonius***.

flexed upward to form a small cup-like structure enclosing a tooth-like projection at the base of the median filament. Allied to and allopatric with *Gladiolus splendens* and *G. saccatus*, all sharing similar, bright red, highly bilabiate flowers with an enlarged, spathulate upper tepal partially adnate to the upper lateral tepals and reduced lower tepals with a thickened tooth or crest at the base of the median filament, ± versatile anthers, and involute style branches. All three are pollinated by sunbirds.

90. **Gladiolus splendens** *(Sweet) Herb.* in Edwards's Botanical Register 29 (Misc.): 46 (1843). *Anisanthus splendens* Sweet: t. 84 (1830b). *Antholyza splendens* (Sweet) Steud.: 106 (1840). *Anomalesia splendens* (Sweet) N.E.Br.: 271 (1932a). *Petamenes splendens* (Sweet) E.Phillips: 44 (1941). Type: South Africa, without precise locality or collector, illustration in Sweet: t. 84 (1830b).

Plants 0.5–1.1 m high, with cataphylls purple mottled with white. *Corm* globose, 15–22 mm diam., with 2 to several slender stolons from base; tunics papery to membranous, fragmenting irregularly. *Stem* erect, usually 1- or 2-branched, sometimes purplish. *Leaves* 5 to 7, lower 4 to 6 basal, reaching to base of spike, narrowly lanceolate to nearly linear, 4–9 mm wide, main and sometimes one other vein lightly raised, margins not thickened, cauline leaves smaller, often sheathing only near base. *Spike* usually erect, lightly flexuose, flowers in 2 ranks, (6)8- to 14-flowered; bracts usually purplish, outer 18–35 mm long, inner slightly shorter, acute or notched. *Flowers* bright scarlet, lower tepals and tube initially green or lower median tepal sometimes red distally, becoming red throughout on fading, unscented; perianth tube 16–18 mm long, narrow and cylindric in lower 8–9 mm, abruptly expanded into wider urn-shaped upper part ± 9 mm long; tepals with dorsal largest, spathulate, extended horizontally, 28–34 mm long, narrow lower part claw-like, 10–14 mm long, limb ovate-concave, 18–20 mm long, upper laterals joined to dorsal for 5–8 mm, free part ovate-concave, 16–17 × 10–12 mm, lower lateral tepals reduced, 4–6 × 1.5 mm,

Distribution of ***Gladiolus splendens***.

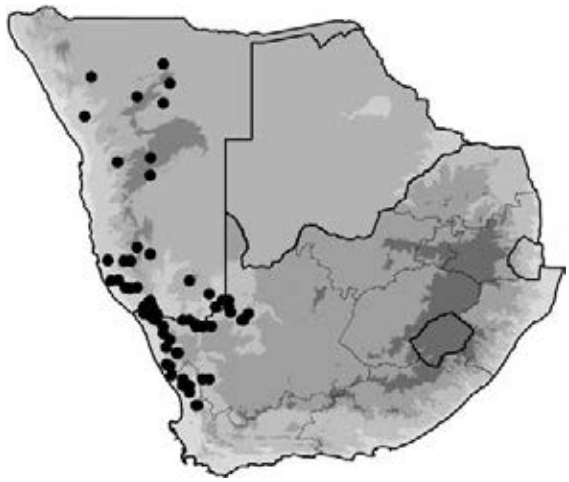
joined to upper lateral for ± 3 mm, free parts directed forward, lower flexed downward at right angles to tube, boat-shaped, 8–11 × ± 6 mm. *Filaments* 33–36 mm long, extended horizontally, exserted 25–29 mm from tube, median filament with enlarged flattened horny tooth at base in front thus dividing tube in half; anthers 5.5–8.0 mm long, attached to filaments near middle with thecae free below, red; pollen yellow. *Style* extended horizontally over stamens, dividing ± 5 mm below anthers, 9–10 mm long, conduplicate, expanded and stigmatic only at tips. *Capsules* ellipsoid to obovoid, 18–20 mm long, acute or ± truncate to retuse. *Seeds* ovate, 6–7 × 4–5, broadly and evenly winged. *Flowering time*: mainly October to mid-November, occasionally in September.

Distribution and ecology: restricted to the southwestern interior escarpment of Northern Cape, South Africa, from near Nieuwoudtville, the Hantamsberg at Calvinia along the Roggeveld Escarpment to the Moordenaars Karoo near Laingsburg; along seasonal streams and rivers or on damp rocky slopes in renosterveld and karroid shrubland.

Diagnosis: distinctive in its scarlet flowers with spathulate-concave dorsal tepal flanked by suberect, ear-like lateral tepals, the lower lateral tepals reduced and scale-like and the lower median boat-shaped and deflexed above the short, cup-like upper portion of the perianth tube enclosing a tooth-like projection at the base of the median filament.

Allied to and allopatric with *Gladiolus cunonius* and *G. saccatus*, the group sharing similar, bright red, highly bilabiate flowers with an enlarged, spathulate upper tepal partially adnate to the upper lateral tepals and reduced lower tepals with a thickened tooth or crest at the base of the median filament, ± versatile anthers, and involute style branches.

91. **Gladiolus saccatus** *(Klatt) Goldblatt & M.P.de Vos* in Adansonia 11: 424 (1990). *Anisanthus saccatus* Klatt: 300 (1867a). *Antholyza saccata* (Klatt) Baker: 180 (1877). *Kentrosiphon saccatus* (Klatt) N.E.Br.: 271 (1932a). *Petamenes saccata* (Klatt) E.Phillips: 44 (1941). *Anomalesia saccata* (Klatt) Goldblatt: 443 (1971). Type: South Africa, [Western Cape], near Hol River, Mierenkasteel, 5 Aug. 1830, *Drège 2646a* (K, P, syn.).



Antholyza steingroeveri Pax: 156 (1892). *Kentrosiphon steingroeveri* (Pax) N.E.Br.: 272 (1932a). *Petamenes steingroeveri* (Pax) E.Phillips: 44 (1941). *K. saccatus* subsp. *steingroeveri* (Pax) Oberm.: t. 1354 (1961). *Gladiolus saccatus* subsp. *steingroeveri* (Pax) Goldblatt & M.P.de Vos: 424 (1990). Type: Namibia, Halenberg, 29 Aug. 1929, *Dinter 6618* (K, syn.).

Antholyza duftii Schinz: 13 (1900). *Kentrosiphon duftii* (Schinz) N.E.Br.: 272 (1932a). *Petamenes duftii* (Schinz) E.Phillips: 44 (1941). Type: Namibia, near Rietfontein, Apr. 1899, *Duft 67* (Z, ?holo.).

Kentrosiphon propinquus N.E.Br.: 272 (1932a). *Petamenes propinqua* (N.E.Br.) E.Phillips: 44 (1941). Type: South Africa, [Western Cape], Knersvlakte, 600 ft [180 m], 16 July 1896, *Schlechter 8163* (K, holo.).

Kentrosiphon gracilis N.E.Br.: 272 (1932a). *Petamenes gracilis* (N.E.Br.) E.Phillips: 44 (1941). Type: Namibia, Otjiwarongo, stony koppie, 5 May 1929, *Bradfield 560* (K, holo.; PRE, iso.).

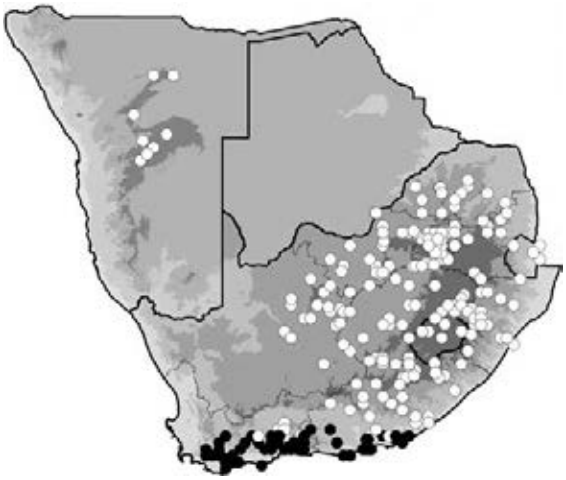
Plants (0.3–)0.4–0.6(–1.2) m high, with cataphylls purple mottled with white. *Corm* globose to conic, 12–15 mm diam., with large cormlets on short stolons; tunics papery, fragmenting irregularly or becoming ± fibrous. *Stem* flexed at each of upper nodes, inclined above, dark purplish green or purple, 2- or 3(6)-branched. *Leaves* 5 or 6(7), lower 3 basal, reaching to ± upper part of stem or rarely to base of spike, narrowly lanceolate, ± plane or lightly pleated, 3–15 mm wide, main and usually one other vein well developed, margins not thickened, cauline leaves shorter, diverging from stem, not or hardly sheathing. *Spike* inclined, 8- to 12(15)-flowered in 2 ranks; bracts ± succulent, purple-brown, outer 20–35(–42) mm long, inner shorter to ± as long. *Flowers* bright red, lower 3 tepals and spur green at anthesis becoming yellow to orange later, unscented; perianth tube 11–20 mm long, slender and cylindric in lower 6–12 mm, abruptly expanded into wider upper part, 5–8 mm long, with a sac-like spur 2–6 mm long at lower base; tepals markedly unequal, dorsal spathulate, extending horizontally, 30–45 mm long, claw 12–16 mm long, limb obovate-concave, 18–26 × 10–15 mm, upper laterals joined to dorsal for ± 5 mm, linear, free part 2–5 × 2–3 mm, lower tepals reduced, lower lateral tepals joined to upper laterals on one side, and together for ± 4 mm, free parts 1.5–3.0 mm long, lower median ± 1.5 mm long. *Filaments* 31–42 mm long, median filament with enlarged flattened horny crest at base in front projecting into spur thus dividing it in half; anthers 8–10 mm long, attached to filaments near middle with thecae free below, bright red; pollen yellow. *Style* arching over stamens,

Distribution of ***Gladiolus saccatus***.

dividing 2–3 mm below anthers, branches ± 10 mm long, conduplicate, expanded and stigmatic only at tips. *Capsules* ovoid, acute, (20–)25–30 mm long. *Seeds* ovate to oblong, 7–11 × 4.5–5.5 mm, broadly and sometimes unevenly winged, seed body blackish. *Flowering time*: in the winter-rainfall region July to mid-August, rarely later, occasionally in May when the first rains are early; in the summer-rainfall region mostly March to May.

Distribution and ecology: widespread through western southern Africa, from northern Namibia through the Richtersveld and Namaqualand in Northern Cape, South Africa to Vanrhynsdorp in Western Cape, and inland along the Orange River to Pofadder and Kakamas; on stony slopes and rock outcrops, often along drainage lines.

Diagnosis: distinctive in its scarlet flowers with only the dorsal tepal well developed and spathulate-concave, the remaining tepals reduced and scale-like. The upper portion of the perianth tube forms a sac-like spur enclosing a tooth-like crest at the base of the median filament. Allied to *Gladiolus cunonius* and *G. splendens,* all sharing similar, bright red, highly bilabiate flowers with an enlarged, spathulate upper tepal partially adnate to the upper lateral tepals and reduced lower tepals with a thickened tooth or crest at the base of the median filament, ± versatile anthers, and involute style branches.



Ser. **Permeabili** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus permeabilis* D.Delaroche

Plants mainly from winter-rainfall region, usually slender. *Corm* tunics papery to fibrous. *Leaves* usually green at flowering, linear to lanceolate, plane, firm or soft-textured. *Spike* usually suberect, sometimes nodding in bud. *Flowers* small to medium, zygomorphic or actinomorphic, perianth tube long or short, usually scented. *Capsules* ellipsoid.

92. **Gladiolus permeabilis** *D.Delaroche,* Descriptiones plantarum aliquot novarum: 27, fig. 2 (1766). Type: South Africa, without precise locality or collector, cultivated in Holland (L 904,137: Herb. D. van Royen 45, lecto., designated by Goldblatt & Manning: 200 (1998) [photos at NBG, PRE]).

Plants 150–600 mm high. *Corm* globose to conic, 8–12 mm diam.; tunics medium to coarsely fibrous. *Stem* usually erect, flexed outward above sheath of third leaf, simple or 1- or 2(4)-branched. *Leaves* usually 4 to 7, more in highly branched plants, lower 4 to 6 basal in loose fan, usually reaching at least to middle or shortly exceeding spike, linear or subsucculent and oval in section, 1.0–2.0(–3.5) mm wide, rigid, central area moderately thickened, margins sometimes lightly thickened, cauline leaves shorter, often without blade, upper either sheathing below or diverging from base. *Spike* inclined, lightly flexuose, 4- to 8-flowered; bracts pale greyish green sometimes flushed purplish, often dry and pale near apices, outer (7–)12–18(–24) mm long, inner shorter to almost as long, acute or minutely forked. *Flowers* whitish to greenish cream-coloured, dull blue-grey, dull purple, or yellow-brown, upper tepals or at least upper laterals each with brown to purplish longitudinal median stripe, lower tepals and throat streaked reddish to purplish, limbs usually yellow in lower ½ often edged distally with darker colour, often strongly sweet-scented or scentless; perianth tube obliquely funnel-shaped, 9–13(–15) mm long, slender lower part 7–10 mm long; tepals narrowed below into claws and ± spade-shaped, attenuate, sometimes extremely so, dorsal largest, (16–)20–33 × 10–15 mm, inclined over stamens, spreading distally, upper laterals arching outward distally, 16–23 × 7–8 mm, windowed between bases of dorsal and upper lateral tepals, lower 3 tepals joined to upper laterals for 2–5 mm and together for 3–6 mm with small thickened knobs at sinuses, free parts 14–16 × 6–8 mm, narrowed below into claws 2–4 mm long, abruptly flexed downward into a broader limb. *Filaments* 12–16 mm long, exserted 8–13 mm from tube; anthers 5–9 mm long, dull cream-coloured to grey-purple; pollen whitish. *Style* arching over stamens, dividing between base and apex of anthers, branches 1.5–4.0 mm long. *Capsules* ovoid-ellipsoid, (6–)9–16 × 5–6 mm. *Seeds* oval, 4–6 × 3–4 mm, broadly and sometimes unevenly winged. *Flowering time*: mainly mid-August to early October in Western Cape and Eastern Cape, October to February in the rest of southern and southern tropical Africa, including Botswana, Namibia and Zimbabwe.

Distribution and ecology: widespread across southern and south tropical Africa, extending from the Caledon District in Western Cape, South Africa into Eastern Cape and through eastern interior South Africa, Lesotho, Eswatini and eastern Botswana and Namibia to Zimbabwe but absent from the Atlantic Coast and arid western interior of South Africa; in stony grassland and open, grassy shrubland.

Distribution of ***Gladiolus permeabilis*** subsp. ***permeabilis***, ●; subsp. ***edulis***, ○.

Diagnosis: recognised by the narrow leaves and small, short-tubed, usually dull-coloured flowers with a wide gap or window between the bases of the dorsal and upper lateral tepals when viewed in profile. The corm tunics are finely fibrous and the capsules are ovoid-ellipsoid. Similar flowers with longer tubes 22–35 mm long, distinguish *Gladiolus uitenhagensis* and *G. sekukuniensis*. In the extreme west of the range it can be confused with *G. scullyi* which has woody, clawed corm tunics and obovoid, retuse capsules.

Key to subspecies

1a Tepals long-attenuate; flowers white or cream-coloured to grey, scented or not; plants mainly east and north of Port Elizabeth . . . . . .92a. subsp. *edulis*

1b Tepals acute or barely attenuate; flowers often purple, mauve or greenish brown, sweetly scented; plants west of Port Elizabeth . . . . 92b. subsp. *permeabilis*

92a. subsp. **edulis** *(Burch. ex Ker Gawl.) Oberm.* in Lewis et al. in Journal of South African Botany, Suppl. 10: 135 (1972). *Gladiolus edulis* Burch. ex Ker Gawl.: t. 169 (1817). Type: South Africa, [Northern Cape], Pellat Plains, *Burchell 2240* (K, holo.; B, G, iso.).

Gladiolus remotifolius Baker: 867 (1901). Type: South Africa, 'Transvaal', between 'Poster' and Trigaardsfontein, *Rehmann 6618* (Z, holo.).

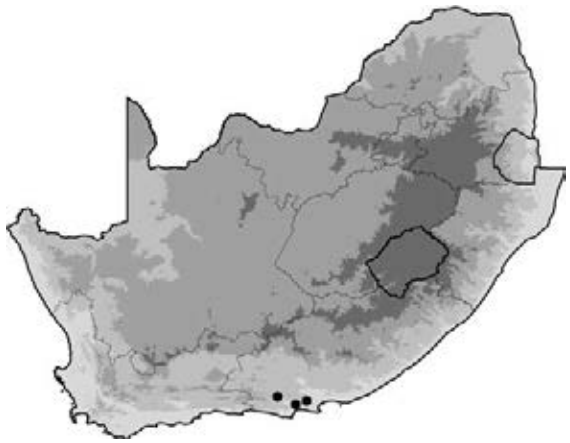
Plants up to 600 mm high, often slender. *Leaves* (3)4 to 6, at least lower 2 or 3 basal, shorter or longer than stem, margins sometimes lightly thickened. *Spike* usually 4- to 8-flowered; bracts 7–12 mm long. *Flowers* whitish to cream-coloured, sometimes grey or mauve, lower lateral tepals yellow in upper half, unscented or intensely sweet-scented; perianth tube 9–13(–15) mm long; tepals long-attenuate or with tailed appendages up to 11 mm long, twisted and undulate, dorsal (16–)20–25 mm long including appendages (often less when dry), lower 3 tepals joined for 1–2 mm with the upper laterals, and together for 3–5 mm, free parts 14–16 mm long, claws ± 4 × 1 mm. *Filaments* 13–15 mm long, exserted for 9–10 mm from tube; anthers 5–7 mm long. *Style* dividing between base and upper ⅓ of anthers, branches 1.5–2.0 mm long. *Capsules* nearly globose to obovoid, 6–10 mm long. *Flowering time*: mostly February to April, occasionally at other times.

Distribution and ecology: widespread through the summer-rainfall southern Africa extending as far south as Oudtshoorn, also in Zimbabwe.

Diagnosis: sometimes taller than subsp. *permeabilis* and distinguished by the mostly paler flowers with long-attenuate or tailed tepals. *Gladiolus sekukuniensis* has similar flowers but with a longer perianth tube, 22–35 mm long.

92b. subsp. **permeabilis**

[*Hebea zeyheri* Eckl.: 42 (1827), invalid name without description.]



Plants 150–450 mm high. *Leaves* 5 to 7 (rarely more), usually shorter than stem, margins usually not thickened. *Spike* 5- to 8-flowered; outer bracts 15–24 mm long, inner shorter. *Flowers* dull blue-grey, dull purple, or yellow-brown, lower tepals and throat streaked reddish to purplish, limbs usually yellow in lower ½ often edged distally with darker colour, often strongly sweet-scented, occasionally unscented; perianth tube 10–13(–15) mm long; tepals spade-shaped, dorsal 28–35 × 10–15 mm, lower 3 tepals united with upper laterals for 3–5 mm and together for 2–6 mm, free parts 15–23 × 6–8 mm, claws 2–3 mm long. *Filaments* 12–16 mm long, exserted 8–13 mm from tube; anthers 6.5–9.0 mm long. *Style* dividing shortly below anther apices, branches ± 3–4 mm long. *Capsules* ovoid and obtuse or ellipsoid and acute, (12–)14–16 mm long. *Flowering time*: late August and September.

Distribution and ecology: restricted to the southern coastal plain from Caledon in Western Cape to Alexandria and Grahamstown in Eastern Cape.

Diagnosis: often shorter than subsp. *edulis* and distinguished by the mostly darker flowers with acute or very shortly attenuate tepals. *Gladiolus uitenhagensis* has very similar flowers, pale in colour with a longer perianth tube, 22–35 mm long.

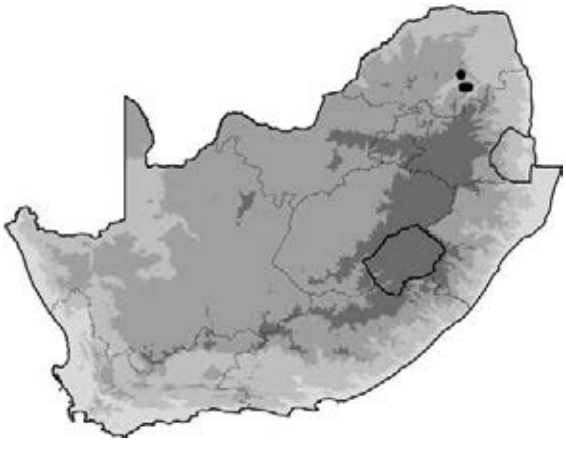
93. **Gladiolus uitenhagensis** *Goldblatt & Vlok* in South African Journal of Botany 55: 263 (1989). Type: South Africa, [Eastern Cape], Uitenhage District, Groendal State Forest, track along Ten Stop Hill, 12 Sept. 1983, *Vlok 702* (NBG, holo.; MO, iso.).

Plants 350–600 mm high, with dry brown cataphylls. *Corm* 15–20 mm diam.; tunics of coarse, blackish fibres. *Stem* erect or inclined above, usually unbranched. *Leaves* 7 or 8, lower 4 or 5 basal, reaching to ± base of spike or

Distribution of ***Gladiolus uitenhagensis***.

sometimes slightly beyond, terete or oval in section, 1.5–2.0 mm wide, when dry main vein appearing strongly thickened, margins barely if at all raised, cauline leaves smaller, uppermost small and largely sheathing. *Spike* inclined, slightly flexuose, 5- to 11-flowered; bracts grey-green, soft-textured, becoming dry and brown above, outer 15–20 mm long, inner slightly shorter, shallowly notched. *Flowers* pale mauve to drab white, lower tepals with yellow spear-shaped mark outlined in purple in midline, not scented; perianth tube obliquely funnel-shaped, (22–)28–35 mm long, well exserted from bracts, lower cylindric part ± 20 mm long; tepals lanceolate, dorsal largest, inclined over stamens, 28–32 × ± 15 mm, upper laterals ± 19 × 8–12 mm, windowed between bases of dorsal and upper lateral tepals, lower 3 tepals joined to upper laterals for 2–3 and together for 3–6 mm, 18–20 × 4–8 mm. *Filaments* ± 15 mm long, exserted 8–10 mm from tube; anthers ± 8 mm long, yellow or purple; pollen creamy yellow. *Style* arching over stamens, dividing near apex of anthers, branches ± 2.5 mm long, *Capsules* and *seeds* unknown. *Flowering time*: September.

Distribution and ecology: from the Baviaanskloof Mtns near Hankey to the eastern Great Winterhoek Mtns in Groendal State Forest in Eastern Cape, South Africa; on stony sandstone slopes, flowering mainly after fire.



Diagnosis: a poorly collected taxon resembling *Gladiolus permeabilis* subsp. *permeabilis* in the form of the flower but with a larger dorsal tepal 28–32 × 15 mm and longer perianth tube (22–)28–35 mm long. The habitat on sandstone in fynbos, flowering after fire, also differs.

94. **Gladiolus sekukuniensis** *P.J.D.Winter* in Manning et al. in Bothalia 29: 220 (1999). Type: South Africa, Limpopo, Haenertsburg District, Sekhukhuneland, Leolo Mtns, foothills, Farm Dsjate 249 KT, 800 m E of Motse River, 3 Apr. 1999, *Winter 3283* (NBG, holo.; K, MO, PRE, UNIN, iso.).

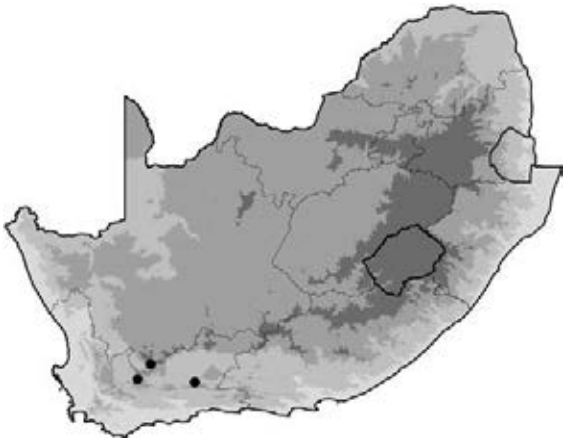
Plants 600–1 100 mm high. *Corm* globose to conic, 8–12 mm diam., with slender stolons with scattered scales; tunics of fine to medium fibres. *Stem* erect, flexed outward above sheath of fourth leaf, simple or branched. *Leaves* usually 5 to 7, sometimes more, lower 3 or 4 basal, usually reaching to base of spike or exceeding it, linear, (1–)2–4 mm wide, rigid, main vein thickened and raised, margins sometimes lightly thickened, cauline leaves shorter, uppermost mostly sheathing. *Spike* inclined, lightly flexuose, 8- to 17-flowered; bracts pale grey-green flushed pinkish, dry and pale above, outer 18–19 mm long, inner shorter to ± as long, acute or shortly notched. *Flowers* white or cream-coloured to pale salmon-pink, tepals with narrow, dark red, longitudinal median streak, lower tepals sometimes yellow in centre of streak, unscented; perianth tube 25–35 mm long, cylindric below for 20–30 mm, curved and weakly flared in upper 5–6 mm, much exceeding bracts; tepals all narrowed below into claws and ± spade-shaped, attenuate with twisted and undulate tail-like tips, dorsal largest, inclined over stamens, spreading distally, 25–35 × 8–11 mm, upper laterals arching outward distally, 19–25 × 4.0–4.5 mm, lower 3 tepals joined to upper laterals for 2–3 mm and together for 3–4 mm, with small thickened knobs at sinuses, free parts 15–18 × 1.5 mm, narrowed below into channelled claws 3–4 mm long, abruptly flexed downward into a narrowly lanceolate limb. *Filaments* 11–12 mm long, exserted 6–8 mm from tube; anthers 5.0–6.5 mm long, dull grey-purple; pollen cream-coloured. *Style* arching over stamens, dividing opposite upper ½ of anthers, branches 1.5–2.0 mm long. *Capsules* ovoid to ellipsoid. *Seeds* unknown. *Flowering time*: March to April.

Distribution and ecology: a narrow endemic of the Strydpoortberge and nearby Leolo Mtns in Limpopo, South Africa; on rocky, dolomitic or alkaline slopes in open woodland.

Diagnosis: resembling *Gladiolus permeabilis* subsp. *edulis* in the habit and in the form of the flowers, but distinguished by the much longer perianth tube, 25–35 mm long and red streaks on the tepals. The scaly suckers produced by the corms are also distinctive and not present in *G. permeabilis*.

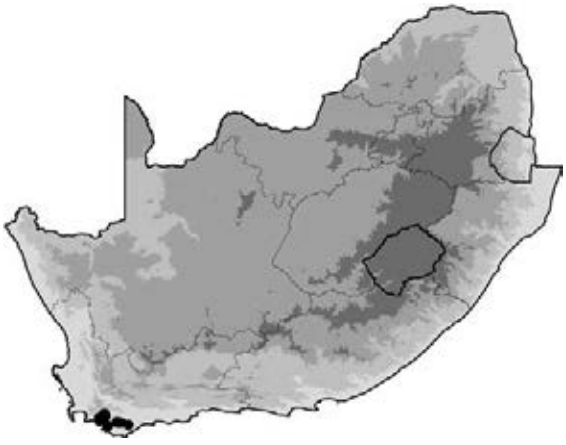
Distribution of ***Gladiolus sekukuniensis***.

95. **Gladiolus karooicus** *Goldblatt & J.C.Manning* in Bothalia 39: 39 (2009). Type: South Africa, Northern Cape, Klein Roggeveld, Komsberg Pass, along seasonal stream in damp gully, in shaly gravel, 8 September 2006, *Goldblatt & Porter 12804* (NBG, holo.; K, MO, PRE, iso.).



Plants 150–500 mm high. *Corm* conic-globose, 15 mm diam.; tunics papery, decaying into fine to medium-textured fibres. *Stem* suberect or inclined, flexed outward above sheath of third leaf, simple or with 1 or 2 branches. *Leaves* usually 4, more when branched, lower 2 basal, reaching to base shortly exceeding spike, linear, ± 2 mm wide, firm-textured, slightly twisted, main vein moderately thickened, margins not thickened, cauline leaves short and largely sheathing. *Spike* inclined, ± flexuose, 2- to 5-flowered; bracts grey-green sometimes flushed grey-purple, often dry and pale near tips, outer 20–25 mm long, inner shorter to ± as long, acute. *Flowers* yellow, dorsal and upper laterals flushed and veined grey-purple on reverse, lower laterals deep yellow in lower half turning dull purple on fading, violet-scented; perianth tube subcylindric, slightly wider near apex, ± 12 mm long; tepals lanceolate, all narrowed below into claws, dorsal largest, ± 25 × 10 mm, arched and hooded over stamens, spreading apically, upper laterals erect, arching over dorsal tepal with upper margins often contiguous, ± 25 × 7 mm, windowed between lower halves of dorsal and upper lateral tepals, lower 3 tepals joined to upper laterals for ± 2 mm and together for ± 3 mm, lower laterals with erect claws ± 1.5 mm long, limbs horizontal, ± 12 × 4 mm, expanded distally, lower margins half involute and forming a tube, extending backward as auricles, lower median ± 15 × 8 mm long. *Filaments* arched under dorsal tepal, ± 15 mm long, exserted 10 mm from tube; anthers ± 8 mm long, light purple; pollen creamy white. *Style* arching over stamens, dividing opposite upper ⅓ of anthers, branches ± 2.5 mm long. *Capsules* obovoid to ellipsoid, obtuse, 15–20 mm long. *Seeds* ovate, 5–7 × 4–5 mm, broadly winged. *Flowering time*: mid-August to mid-September.

Distribution and ecology: known from a few localities in the semi-arid Klein Roggeveld in Northern Cape, South Africa and the northern foothills of the Witteberg in Western Cape; in damp gullies and along seasonal streams in shale soils in karroid shrubland.



Diagnosis: recognised by its bright yellow, strongly windowed flowers with suberect upper lateral tepals and sharply deflexed lower tepals, the lower laterals strongly involute and auriculate at the base of the limb. The corm tunics are relatively soft-textured or papery. *Gladiolus venustus* has similar, mostly purple or pink flowers with yellow markings but woody corm tunics and obovoid-retuse capsules.

96. **Gladiolus acuminatus** *F.Bolus* in Annals of the Bolus Herbarium 2: 100 (1917). Type: South Africa, [Western Cape], without precise locality or collector, Caledon Wild Flower Show, Sept. 1916 (BOL [BOL 14793], lecto., designated by Goldblatt & Manning: 203 (1998); BM, BOL, G, K, PRE, SAM, Z, isolecto.).

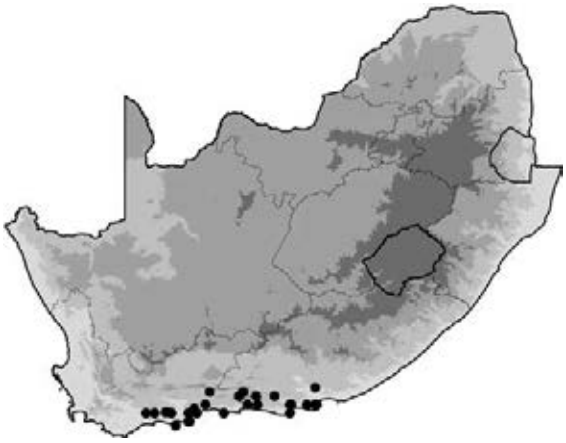
Plants 250–500 mm high. *Corm* globose, 12–15 mm diam., often with short stolons 10–20 mm long; tunics papery, becoming finely fibrous. *Stem* erect below, flexed outward above sheaths of cauline leaves and inclined above, simple or occasionally branched. *Leaves* 5 or 6, or more when branched, lower 3 or 4 basal, reaching middle of stem or higher, linear, 0.8–1.5 mm wide, main vein somewhat thickened, tapering toward margins, cauline leaves usually channelled throughout, sheaths of all leaves open. *Spike* inclined or erect, ± straight, 3- to 10-flowered; bracts pale green, outer (13–)14–25(–35) mm long, acute to attenuate, inner shorter, entire or notched apically. *Flowers* cream-coloured to pale yellow or pale greenish, tepals often flushed brown to dull purple on reverse, especially outer, lightly sweet-scented; perianth tube 16–22(–30) mm long, cylindric, upper half curving outward and slightly wider; tepals lanceolate-acuminate, margins undulate, recurved distally, apices lightly twisted, dorsal slightly larger, 15–21 × 8–10 mm, remaining tepals 12–18 × 6–8 mm. *Filaments* 6–10 mm long,

Distribution of ***Gladiolus karooicus***.

Distribution of ***Gladiolus acuminatus***.

reaching to top of tube or exserted up to 2 mm; anthers 4–6 mm long, included in flower, white; pollen white. *Style* arched over stamens, dividing near anther apices, branches ± 3.5 mm long. *Capsules* ellipsoid, acute, 10–15 mm long. *Seeds* round to ovate, 3–4 mm diam. *Flowering time*: mid-August to late September.

Distribution and ecology: a rare endemic of the Overberg in Western Cape, South Africa, between Onrus and Bredasdorp; on damp shale slopes in renosterveld.



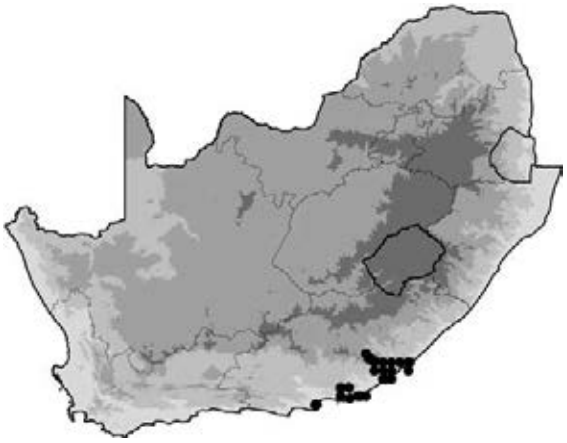
Diagnosis: distinctive in its small, tubular, pale greenish to white or yellowish flowers with strongly recurved tepals with tapering acuminate tips. The perianth tube 16–30 mm long is relatively long for so small a flower. The anthers are barely exserted from the perianth tube.

97. **Gladiolus stellatus** *G.J.Lewis* in Botaniska Notiser 119: 295 (1966), replacement name for *G. elongatus* Thunb.: 185 (1800), illegitimate homonym, not *G. elongatus* Salisb. (1796). Type: South Africa, [Western Cape], without precise locality, probably Oct. or Nov. 1772 or 1773, *Thunberg s.n.* (UPS-THUNB 1020, holo.; K, photo).

Geissorhiza patersoniae L.Bolus: 132 (1915). Type: South Africa, [Eastern Cape], Port Elizabeth District, Redhouse, Sept. 1912, *Paterson 47* (BOL, lecto., designated by Goldblatt & Manning: 204 (1998); GRA, K, isolecto.).

Plants 300–600 mm high. *Corm* globose, 9–15 mm diam., often with stolons from base; tunics of fine to fairly coarse fibres. *Stem* ± erect, inclined above sheath of uppermost basal leaf, usually with 1 or 2 branches. *Leaves* (4)6 to 9, lower 2 to 7 basal, shorter or slightly longer than stem, linear, (1–)2–3 mm wide, oval in section, margins not raised, cauline leaves shorter, usually entirely channelled. *Spike* slightly inclined, weakly secund, 5–12(–15)-flowered; bracts pale green, often becoming dry and light brown above, outer 10–15 mm long, inner slightly shorter. *Flowers* actinomorphic, star-like, white to cream-coloured or pale lilac, tepals with obscure narrow brown or purple median streak, reverse of tepals usually lightly feathered with greenish to brownish purple, intensely sweetly scented; perianth tube funnel-shaped, 5–7 mm long, included or shortly exserted from bracts; tepals subequal, spreading, elliptic, 14–20 × 5–8 mm. *Filaments* 5–7 mm long, exserted 3–4 mm from tube, parallel and contiguous; anthers (4–)5–6(–7) mm long, erect or diverging; pale yellow; pollen yellow. *Style* central, enclosed by filaments, dividing between base and upper ⅓ of anthers, branches 4–5 mm long. *Capsules* elongate-ellipsoid to oblong, 12–17 × 5 mm. *Seeds* ovate, ± 6 × 4 mm, broadly and evenly winged. *Flowering time*: mid-August to late October, occasionally in November; flowers opening ± 7:00 and closing 11:45 to 12:15.

Distribution and ecology: widespread along the southern coastal regions of South Africa, from just east of Swellendam in Western Cape to Bethelsdorp in Eastern Cape, extending inland in the Long Kloof; on stony ground in grassland and renosterveld shrubland, often on north-trending slopes. The flowers open only in the mornings, closing tightly at midday.



Distribution of ***Gladiolus stellatus***.

Diagnosis: distinctive in its drab white to pale lilac, radially symmetric flowers with a star-like perianth and erect, symmetrically arranged stamens and style. It is probably closely allied to *G. permeabilis* and *G. wilsonii*, both of which have bilabiate flowers with unilateral stamens.

98. **Gladiolus wilsonii** *(Baker) Goldblatt & J.C.Manning*, *Gladiolus* in southern Africa: 206 (1998). *Tritonia wilsonii* Baker: 38 (1886). *G. permeabilis* subsp. *wilsonii* (Baker) G.J.Lewis in Lewis et al.: 133 (1972). Type: South Africa, [Eastern Cape], vicinity of Port Elizabeth (grown in Britain by J. Wilson of St Andrews), June 1886, *Wilson s.n.* (K, holo.).

Gladiolus fredericii L.Bolus: 368, t. A (1931c). Type: South Africa, [Eastern Cape], Grahamstown, Commonage on left of Cradock road, cult. Cape Town, Oct.–Nov. 1929, *Dyer 1682* (BOL, holo.; GRA, K, PRE, iso.).

Plants (200–)300–600 mm high. *Corm* globose, 12–22 mm diam., often with small cormlets at base; tunics of fine to fairly coarse fibres. *Stem* erect, simple or with 1(2) branches, usually flexed above sheath of uppermost leaf. *Leaves* 6 to 8, lower 3 to 5 basal, reaching ± to base or slightly exceeding spike, linear, 1–3 mm wide, elliptic in section when alive, midrib area thickened, margins rarely lightly thickened, cauline leaves progressively smaller, uppermost entirely sheathing or with vestigial blade. *Spike* inclined, lightly flexuose, 4- to 12-flowered; bracts green or flushed purple above, outer 12–16(–20) mm long, inner shorter to ± as long, notched apically. *Flowers* white to cream-coloured or yellowish, reverse of upper tepals usually flushed pink to dull purple toward tips, sometimes also on midline, sometimes lower 3 tepals each with short, pale mauve streak, often sweetly scented; perianth tube obliquely funnel-shaped, 6–13 mm long, slender cylindric part

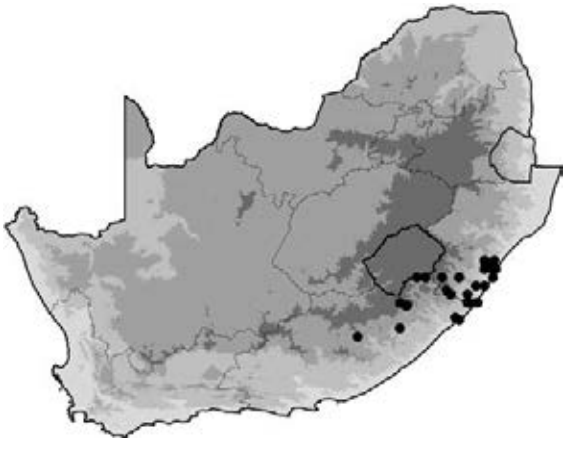
Distribution of ***Gladiolus wilsonii***.

3–6 mm long; tepals oblanceolate, unequal, dorsal largest, 20–26(–30) × 10–13(–18) mm, hooded over stamens, upper laterals 16–20(–23) × 8–9 mm long, curving outward distally, lower 3 tepals joined to upper laterals for 1–2 mm and together for ± 2 mm, lower laterals 16–20 × 6.5–13.0 mm, lower median ± as long or slightly shorter and wider or narrower than laterals. *Filaments* 10–13 mm long, exserted 6–8 mm from tube; anthers 6–9 mm long, purple; pollen cream-coloured. *Style* arching over stamens, dividing shortly below anther apices, branches 3.5–5.0 mm long. *Capsules* ellipsoid, 10–15 mm long. *Seeds* oblong, 5–6 × ± 3 mm, broadly but somewhat unevenly winged. *Flowering time*: mainly October to mid-November, occasionally in September.

Distribution and ecology: restricted to the coastal and near inland Eastern Cape, South Africa, from Jeffrey's Bay and Cape St Francis to Engcobo; in open grassland.

Diagnosis: recognised by the basal fan of linear leaves, 1–3 mm wide, with the midrib area thickened but not the margins, and the rather closed, white to greenish flowers with short perianth tube 6–13 mm long. *Gladiolus inandensis* from higher elevations and further north has very similar flowers produced in winter and spring at which time the current season's leaves are mostly dry and withered – the fresh leaves are subsucculent and distinctly oval in section.

99. **Gladiolus inandensis** *Baker*, Handbook of the Irideae: 207 (1892). Type: South Africa, [KwaZulu-Natal], Inanda, Aug., *Wood 237* (K, lecto., designated by Lewis et al.: 133 (1972); BM, K, GRA, isolecto.).



Tritonia teretifolia Baker: 194 (1892). Type: South Africa, [KwaZulu-Natal], foot of Table Mtn near Pietermaritzburg, Aug. 1840, *Krauss 430* (BM, holo.; G, K, OXF, iso.).

Gladiolus microphyllus Baker: 206 (1892). Type: South Africa, [KwaZulu-Natal], Suurberg Mtns near Kokstad, 5 500 ft [1 700 m], Oct. 1883, *Tyson 1852* (K, holo.; GRA, MO, SAM, iso.).

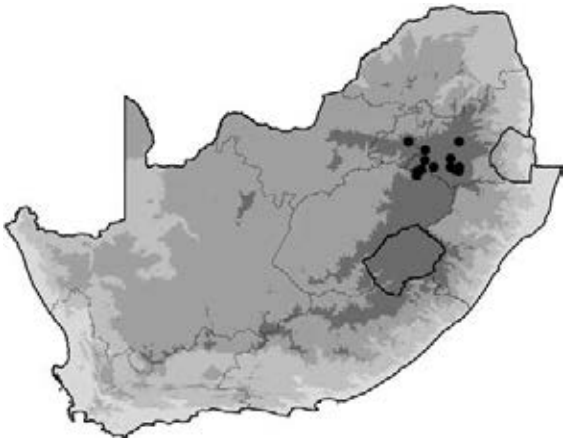
Gladiolus stenophyllus Baker: 282 (1897b), illegitimate homonym, not *G. stenophyllus* Schrank (1822). Type: South Africa, [Eastern Cape], Hangklip Mtn, Queenstown, Jan. 1894, *Galpin 1769* (K, holo.; BOL, GRA, PRE, iso.).

Gladiolus microsiphon Baker: 1006 (1904a). Type: South Africa, [KwaZulu-Natal], hills near Pinetown, 150 m, 12 Sept. 1893, *Schlechter 3167* (Z, probable holo.; BM, BOL, G, K, SAM, Z, iso.).

Plants 200–450 mm high, often growing in small clumps. *Corm* globose, 18–25 mm diam., usually with 1 or 2 large cormlets at base; tunics of fine, densely matted fibres. *Stem* erect or inclined, simple or with 1 branch, usually flexed above sheath of uppermost leaf. *Leaves* 4 to 6, lower 2 to 4 basal, usually ± dry at flowering (or burned and absent), reaching or exceeding spike, somewhat fleshy, oval in section when fresh but with midrib area thickened and prominent when dry, 1.5–2.0 mm diam., cauline leaves entirely sheathing or with vestigial blades; new leaves emergent at flowering, produced from separate shoots, ultimately 3 or 4 basal leaves produced in summer. *Spike* inclined, lightly flexuose, 4- to 12-flowered; bracts green, sometimes flushed purple, outer 11–16 mm long, inner shorter, notched apically. *Flowers* white to cream-coloured usually flushed pink to dull purple on reverse toward tips and sometimes also on midline, evidently without markings, unscented; perianth tube narrowly funnel-shaped, 9–12 mm long, slender cylindric part 5–8 mm long; tepals oblanceolate, unequal, dorsal largest, 22–23 × 11–15 mm, hooded over stamens, upper laterals 15–20 × 7–8 mm, curving outward distally, lower 3 tepals joined to upper laterals for 2–4 mm and together for 2–3 mm, lower laterals 14–16 × 6–7 mm, lower median 10–12 × 7 mm. *Filaments* 10–12 mm long, exserted 6–9 mm from tube; anthers 5–6 mm long, purple; pollen cream-coloured. *Style* arching over stamens, dividing opposite upper ⅓ of anthers, branches ± 3.5 mm long. *Capsules* narrowly ovoid-ellipsoid, (10–)12–15 mm long. *Seeds* ovate, 6–7 × 3.5–4.5 mm, broadly and evenly winged. *Flowering time*: August to September.

Distribution of ***Gladiolus inandensis***.

Distribution and ecology: extending from Queenstown in Eastern Cape, South Africa to southern Lesotho and to just inland of Durban in KwaZulu-Natal; largely restricted to sandstone outcrops in open grassland, with flowering delayed until winter and early spring when the leaves are usually dry and withered. Emergent leaves from the coming season's growth may be visible.



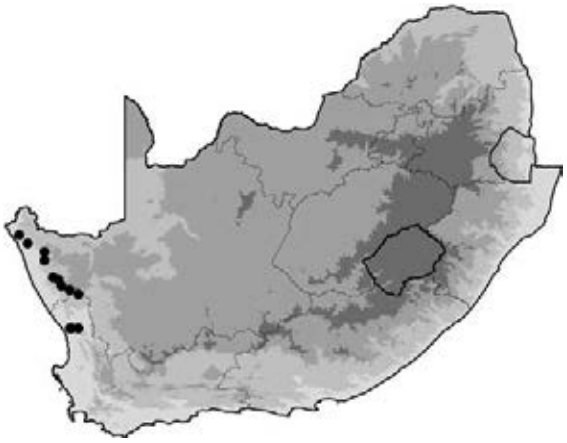
Diagnosis: an early-flowering species resembling *Gladiolus wilsonii* in the white to mauve flowers with short perianth tube 9–12 mm long but with subsucculent leaves, oval in section when fresh but largely withered at flowering.

100. **Gladiolus robertsoniae** *F.Bolus* in Journal of Botany, British and foreign 66: 13 (1928). Type: South Africa, [Free State], Frankfort, near Villiers, cult. Cape Town, *Robertson s.n.* as *BOL 15053* (BOL, lecto., designated by Lewis et al.: 181 (1972); GRA, K, isolecto.).

Plants 200–400 mm high. *Corm* globose, 14–18 mm diam.; tunics of somewhat wiry fibres. *Stem* erect, simple or with 1 branch, usually lightly flexed above sheaths of upper 2 leaves, 1.2–1.7 mm diam. below base of spike. *Leaves* 3(4), lower 2 linear to falcate, 80–160 mm long, 2–4 mm wide, main vein moderately thickened, margins lightly or not raised, cauline leaves shorter. *Spike* weakly inclined, ± straight, 4- to 8-flowered; bracts dark green sometimes flushed purple, outer 16–18 mm long, inner shorter to almost as long, notched apically. *Flowers* white or sometimes faintly flushed with violet toward tepal apices, reverse of tepal apices mauve in bud, reverse of tepals and tube becoming pale mauve on fading, lower side of throat with or without fine red lines decurrent on lower tepal bases, remaining open and carnation-scented day and night; perianth tube 28–44 mm long, straight and cylindric below, curving outward ± 6 mm below mouth and then flaring, 2.5 times as long as bracts; tepals broadly lanceolate to ovate, unequal, dorsal smallest, 18–24 × 12–16 mm, lightly inclined, broadly cordate above narrow base, upper laterals spreading gradually, 20–25 × 13–18 mm, lower 3 tepals joined to upper laterals for 4–6 mm, lower laterals 16–25 × 7.5–9.0 mm, lower median 14–22 × ± 11 mm. *Filaments* 8–9 mm long, included in upper part of tube or exserted up to 2 mm; anthers 5–9 mm long, white or light mauve; pollen yellow. *Style* arching over stamens, dividing between upper ⅓ and apex of anthers, branches 3.5–4.5 mm long. *Capsules* ± globose, 10–14 mm long. *Seeds* ovate, broadly winged, 5–6 × 3–4 mm. *Flowering time*: mostly October, occasionally to late November and rarely early December.

Distribution and ecology: scattered through the southern highveld of South Africa, from Ermelo in Mpumalanga to Frankfort and Villiers in eastern Free State; on dolerite outcrops and along drainage lines or seeps in moist grassland.

Diagnosis: recognised by the white or pale lilac flowers with long, narrow tube 28–44 mm long, with the filaments included or very shortly exserted, and ovate tepals with the dorsal smaller than the upper laterals.



Distribution of ***Gladiolus robertsoniae***.

Ser. **Deserticola** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus deserticola* Goldblatt

Plants from winter-rainfall region, often short. *Corm* tunics usually leathery to woody and clawed, rarely papery. *Leaves* green at flowering, often falcate, plane, firm-textured. *Spike* usually strongly inclined and scalloped. *Flowers* small to medium, zygomorphic or actinomorphic; perianth tube long or short, usually scented. *Capsules* ellipsoid and obtuse or obovoid and, lobed-retuse above.

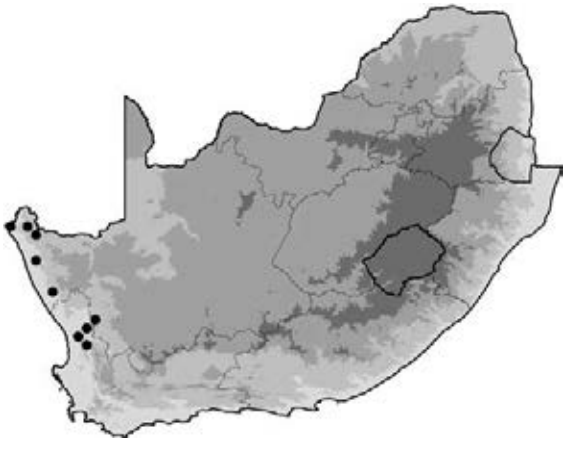
101. **Gladiolus arcuatus** *Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 338 (1882). Type: South Africa, [Western Cape], Mierenkasteel, 1830, *Drège 2629* (B, holo.; BM, G, P, S, iso.).

Plants (80–)120–200(–300) mm high. *Corm* depressed-globose, 12–20 mm diam.; tunics papery to dry-membranous. *Stem* erect or inclined, flexed outward above sheath of penultimate leaf, flexuose, usually simple or with a short branch. *Leaves* 5 or 6, lower 4 or 5 basal, reaching ± base of spike, narrowly lanceolate to falcate, 5–10(–12) mm wide, sheaths pubescent to velvety, main vein lightly thickened but not raised, margins and main vein pubescent, uppermost cauline leaf fairly short, diverging sharply from stem. *Spike* inclined, 4–7(9)-flowered; bracts pale green, outer (20–)25–35 mm long, inner slightly shorter but much narrower, minutely forked. *Flowers* dull greyish purple, brownish or dark purple, lower 3 tepals yellow in lower ⅔, papillose below and in throat, distal third dark purple fading to light grey-purple toward apices, tepals often partly yellowish on reverse but at least lower ½ of dorsal purple, with sweet fruity-herbal scent; perianth tube obliquely funnel-shaped, 10–15(–19) mm long; tepals with dorsal largest, arching forward, horizontal in upper ½, narrowed and ± claw-like in lower part, 26–32 mm long, claw ± 4.5 mm wide, limb ± 18 × 12–15 mm,

Distribution of ***Gladiolus arcuatus***.

upper laterals lanceolate, 25–26 × 10–12 mm, narrow and almost claw-like below, spreading in upper ⅓, windowed between bases of dorsal and upper laterals, lower tepals joined to upper laterals for 3–5 mm and together for 2–3 mm, free parts narrowed below into channelled claws 8–10 mm long, limbs lightly channelled, gently curving downward, ± 12–15 × 8–12 mm. *Filaments* 14–15 mm long, exserted ± 10 mm from tube; anthers 7–10 mm long, pale grey; pollen cream-coloured. *Style* arching over stamens, dividing opposite upper ⅓ of anthers, branches 3.5–5.0 mm long. *Capsules* broadly ellipsoid, 18–25 mm long. *Seeds* 8–9 × 7 mm, obliquely saucer-shaped, usually asymmetric with seed body closer to one side. *Flowering time*: late June to early August at low elevations, late August and September at higher elevations.

Distribution and ecology: scattered through high-lying parts of Namaqualand, South Africa, from near Steinkopf in Northern Cape to the central Olifants River Valley near Trawal in Western Cape; on gravelly or silty flats in open succulent shrubland, flowering in winter or early spring.



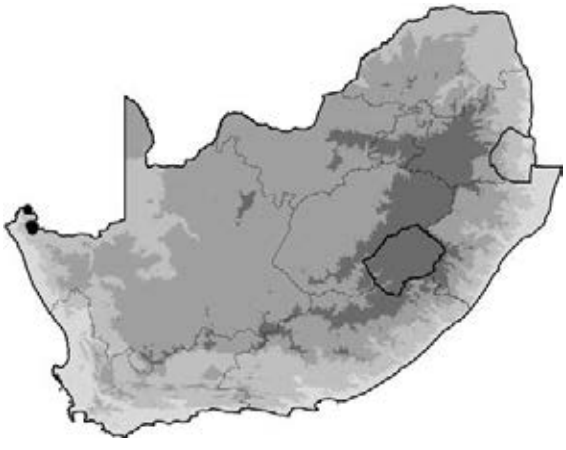
Diagnosis: distinguished from superficially similar species such as *Gladiolus scullyi* by its early flowering, softly papery or membranous corm tunics, and finely pubescent leaf sheaths and blade midrib and margins. The distinctive puberulous leaf sheaths are sometimes also encountered in *G. viridiflorus*, another winter-flowering species distinguished by its woody corm tunics, strikingly mottled cataphylls and often twisted leaves.

102. **Gladiolus viridiflorus** *G.J.Lewis* in Lewis *et* al. in Journal of South African Botany, Suppl. 10: 217 (1972). Type: South Africa, [Northern Cape], Calvinia District, between Nieuwoudtville and Kareebooms Farm, flowered at Kirstenbosch Gardens, 10 May 1963, *Lewis 6132* (NBG, holo.).

Plants 80–150(–300) mm high, with cataphylls mottled purple and white, rarely entirely purple, often puberulous. *Corm* globose to conic, 12–25 mm diam.; tunics of hard, woody layers divided into segments below or coarsely netted with claw-like ridges. *Stem* erect or slightly inclined below, flexed outward above sheath of second leaf and inclined, flexed at upper nodes, simple or with 1(2) branches, 1.3–2.0 mm diam. *Leaves* (3)4, lower 2 or 3 basal, erect to falcate, sheaths often puberulous, blades usually loosely twisted to lightly coiled, 2.7–6.0 mm wide, shorter than spike, up to 100 mm long, main vein evident but not thickened, margins not thickened, cauline leaves diverging sharply from stem. *Spike* lightly to strongly flexuose-scalloped, inclined to almost horizontal, (2)3- to 8-flowered; bracts green and slightly glaucous, outer (20–)25–40(–75) mm long, inner shorter, margins broadly transparent. *Flowers* greenish to yellowish brown with purple highlights, lower tepals with broad transverse yellow band in distal ⅓ outlined in purple and often dark near apices, strongly scented of freesia; perianth tube obliquely funnel-shaped, 12–17 mm long; tepals lanceolate, dorsal longest, 23–31 × 10–15 mm, inclined over stamens, upper lateral tepals 20–26 × 10–14 mm, narrowly windowed between dorsal and upper lateral tepals, lower tepals joined to upper laterals for 3–5 mm, and together for ± 2 mm, narrowly lanceolate, free parts 15–20 × 5–7 mm, arching downward. *Filaments* 12–15 mm long, exserted 6–8 mm from tube; anthers 6–9 mm long, greenish; pollen pale yellow. *Style* arching over stamens, dividing opposite middle of anthers, branches 3–4 mm long. *Capsules* broadly ellipsoid, acute, (12–)15–21 × ± 10 mm. *Seeds* broadly ovate, 10–12 × 8–10 mm, broadly and evenly winged. *Flowering time*: May to July.

Distribution and ecology: widespread through Namaqualand, South Africa, from near Clanwilliam in Western Cape to the Orange River near Alexander Bay in Northern Cape, and possibly extending into southern Namibia; on sandy or loamy flats in succulent karroid shrubland, flowering in winter.

Diagnosis: recognised by the purple and white mottled, often puberulous cataphylls and the relatively short, usually twisted leaves, sometimes with finely puberulous sheaths, and the hard corm tunics separating into



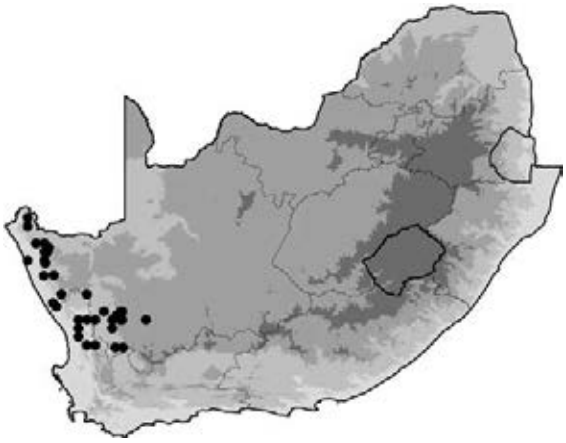
Distribution of ***Gladiolus viridiflorus***.

claws at the base. The flowers are dull green to yellowish brown with purple highlights and intensely fragrant.

103. **Gladiolus deserticola** *Goldblatt* in Journal of South African Botany 50: 457 (1984). Type: South Africa, [Northern Cape], Richtersveld, Stinkfontein Mtns, upper slopes of Cornellsberg, ridge south of beacon, ± 1 300 m, 6 Sept. 1977, *Oliver, Tölken & Venter 706* (PRE, holo.).

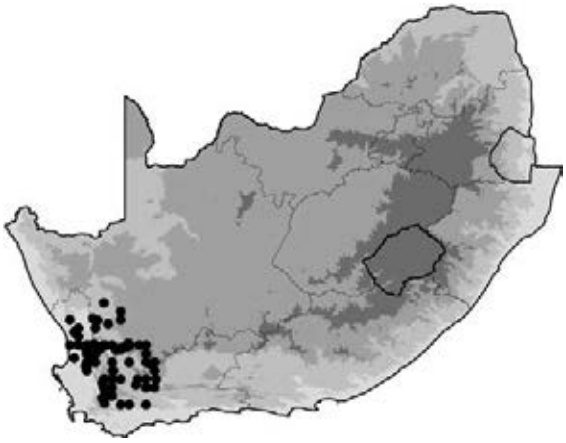
Plants 100–200(–270) mm high, with cataphylls purple mottled with white. *Corm* ± conic, base oblique, 6–12 mm diam.; tunics leathery becoming broken, somewhat fibrous and toothed below. *Stem* erect or inclined, erect below, sharply flexed above sheaths of leaves or above nodes when sheaths lacking, simple or with 1 or 2 branches. *Leaves* 4 (or 5 if stem with more than 1 branch), lower 2 basal and reaching to base of spike or exceeding it, linear, 1.5–2.5(–3.0) mm wide, usually twisted, erect or becoming trailing, main vein raised, second leaf sheathing lower ½ of stem, cauline leaves progressively shorter above, upper 1 or 2 not sheathing, diverging from stem. *Spike* flexed at base, usually inclined to horizontal, strongly flexuose-scalloped, 4- to 6-flowered; bracts green or brownish green, outer 12–20 mm long, inner slightly shorter, minutely forked. *Flowers* nearly actinomorphic but nectar guides only on lower tepals and stamens often unilateral, dark blue with lower lateral tepals or sometimes all 3 lower tepals cream-coloured in basal ⅓ edged with purple distally, weakly rose-scented; perianth tube narrowly funnel-shaped, ± 11 mm long, wider upper part only ± 1.5 mm long; tepals subequal, lanceolate, dorsal slightly longer and narrowed below, 14–21 × 4–5 mm, straight and usually upright, remaining tepals spreading from shortly above bases, 12–18 × 3.5–4.5 mm. *Filaments* symmetrical or unilateral, 6–9 mm long, exserted ± 4 mm from tube; anthers 4–5 mm long, pale yellow; pollen pale yellow. *Style* ± central, only slightly arcuate, dividing between middle and apex of anthers, branches ± 4 mm long. *Capsules* and *seeds* unknown. *Flowering time*: mid-August to mid-September, later at higher elevations.

Distribution of ***Gladiolus deserticola***.



Distribution and ecology: a narrow endemic of the Richtersveld in Northern Cape, South Africa, on the Stinkfontein Mtns and the Vandersterrberg; on cooler south-facing slopes in the lee of rocks or under shrubs, often along drainage lines.

Diagnosis: unmistakable in the almost regular, dark blue flowers on a scalloped, nearly horizontal spike, purple and white spotted upper cataphyll, and coarsely fibrous corm tunics. The lower lateral or all lower tepals are creamy white in the lower third.



104. **Gladiolus scullyi** *Baker*, Handbook of the Irideae: 244 (1892). Type: South Africa, [Northern Cape], Namaqualand, without precise locality, without date [probably 1890], *Scully s.n.* (K, holo.).

Plants (120–)200–350 mm high. *Corm* globose-conic, 12–15 mm diam., with small cormlets at base; tunics ± woody, fragmenting irregularly and often claw-like below, orange when young. *Stem* erect or inclined, flexed outward above sheaths of upper leaves, simple or often 1- or 2-branched. *Leaves* (5)6 to 8, lower 4 to 6 basal and usually in a 2-ranked fan, grey-green, often glaucous, reaching to base or sometimes middle of spike, narrowly lanceolate to linear, (2–)3–5 mm wide, fairly thick and succulent, main vein lightly raised, margins not raised, uppermost cauline leaf diverging from stem or sheathing only near base. *Spike* inclined, lightly flexuose, 5- to 8-flowered; bracts pale green, translucent on veins, occasionally dry near tips, outer 20–30(–35) mm long, inner shorter, acute or minutely forked. *Flowers* greenish cream-coloured to yellow-brown or beige, upper tepals sometimes flushed purple above, lower tepal limbs yellow basally and brown to purplish above, throat irregularly streaked with purple, strongly sweet-scented; perianth tube obliquely and narrowly funnel-shaped, 12–14 mm long, slender lower part 8–9 mm long; tepals lanceolate, dorsal largest, inclined over stamens, 25–35(–42) × 10–14(–16) mm, upper laterals arching outward, 22–28(–35) × 9–15 mm, windowed between dorsal and upper lateral tepals, lower 3 tepals united with upper laterals for 3–4 mm and together for 4–7 mm, narrowed into claws below, claws narrowly channelled, 4–6 mm long, limbs abruptly expanded and deflexed, sometimes with weakly developed auricles, 10–15(–20) × 8–12 mm. *Filaments* 12–16 mm long, exserted 9–12 mm from tube; anthers 6–9 mm long, light purple to cream-coloured; pollen cream-coloured. *Style* arching over stamens, dividing opposite or just below anther apices, branches 3.0–4.5 mm long. *Capsules* obovoid, trilobed-retuse above, 9–14 mm long. *Seeds* 5–6 × ± 5 mm, broadly and usually asymmetrically winged with seed body closer to one side. *Flowering time*: August and September.

Distribution and ecology: widespread though the high-lying parts of Namaqualand, South Africa, from Steinkopf in Northern Cape to Vanrhynsdorp in Western Cape and inland onto the Bokkeveld Escarpment to Calvinia; on stony granite and shale flats in succulent karroid and renosterveld shrubland.

Distribution of ***Gladiolus scullyi***.

Distribution of ***Gladiolus venustus***.

Diagnosis: recognised by the sweetly scented, dull yellowish to brownish flowers with the upper tepals windowed in profile, ± erect leaves, unspotted upper cataphylls and woody corm tunics clawed at the base and orange when young. The parapatric *Gladiolus venustus* has abruptly deflexed lower tepals with the lower laterals strongly auriculate at the base of the limbs and suberect upper lateral tepals not forming windows with the dorsal in profile. The two species intergrade along the Vanrhynsdorp–Calvinia axis and discrimination between them may be difficult there.

105. **Gladiolus venustus** *G.J.Lewis* in Journal of South African Botany 7: 56 (1941), replacement name for *G. formosus* Klatt in Linnaea 32: 692 (1864), illegitimate homonym, not *G. formosus* Pers. (1805). Type: South Africa, [Western Cape], Clanwilliam District, Olifants River at Brakfontein, Aug. [probably 1829], *Ecklon & Zeyher Irid. 140* (S, lecto., designated by Lewis et al.: 122 (1972); G, SAM, isolecto.).

Plants 120–350 mm high. *Corm* conic, 8–14 mm diam.; tunics hard, ± woody, fragmenting irregularly and often claw-like below, orange when young. *Stem* erect below, flexed outward above sheaths of upper leaves, then weakly inclined, frequently branched. *Leaves* 5 or 6, lower 3 to 5 basal, reaching to base or shortly exceeding spike, linear, 1.5–4.0(–9.0) mm wide, main veins but not margins lightly raised, cauline leaves shorter, uppermost diverging from stem or sheathing only near base. *Spike* inclined, flexuose-scalloped, 5- to 8-flowered; bracts pale green, apices sometimes becoming dry, veins transparent, attenuate, outer 20–30(–35) mm long, inner shorter to ± as long, minutely forked. *Flowers* blue-purple or bright pink, occasionally entirely dull yellow, lower 3 tepals bright yellow in lower ½, usually lightly rose-scented; perianth tube obliquely funnel-shaped, 12–17 mm long, lower cylindric part 8–11 mm long; tepals lanceolate, dorsal largest, lightly inclined, 30–37 × 10–16 mm, upper laterals slightly shorter than dorsal, suberect and extending at least partly behind dorsal, curving outward distally, lower 3 tepals united for 3–5 mm, free parts narrowed below into claws 2–4 mm long, deeply channelled, limbs sharply deflexed and pinched together at point of flexure with margins raised into ascending auriculate lobes, 15–22 × 9–11 mm, ± straight. *Filaments* 11–15 mm long, exserted 5–7 mm from tube; anthers 6–8 mm long, greyish or yellow; pollen yellow. *Style* arching over stamens, dividing opposite upper ⅓ of anthers, branches 2–3 mm long. *Capsules* globose, 3-lobed-retuse above, ± 10 mm long. *Seeds* 5–7 × ± 5 mm, broadly and usually asymmetrically winged with seed body closer to one side. *Flowering time*: August to mid-September, sometimes later at higher elevations.

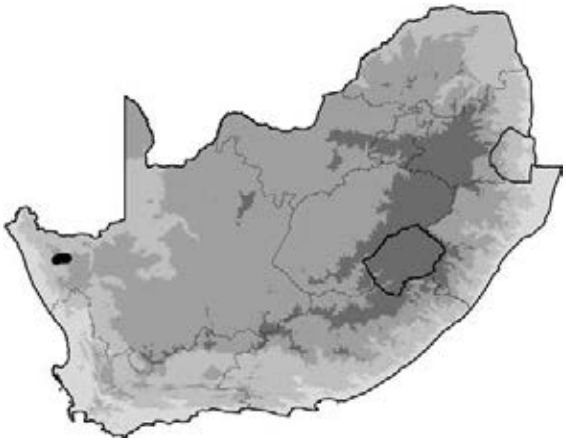
Distribution and ecology: extending through the interior valleys of the southwestern Western Cape, South Africa, from Vanrhynsdorp through the Olifants River Valley and the eastern Cederberg to Worcester and Robertson thence inland to Laingsburg and in the Northern Cape along the foothills of the Roggeveld to Calvinia; on stony shale and clay or sometimes sandstone flats and slopes, often along drainage lines.

Diagnosis: recognised by the fragrant, yellowish flowers tipped mauve to bright pink, the upper lateral tepals suberect and partially overlapping the dorsal tepal, the lower tepals abruptly deflexed and pinched together at the base and the lower laterals strongly auriculate at the base of the limbs. Most populations have the tepals tipped dull purple to mauve but populations in the Olifants River Valley and around Worcester have bright pink tips. The parapatric *Gladiolus scullyi* has the upper lateral tepals forming a more-or-less pronounced window with the dorsal tepal in profile, and the recurved lower tepals not strongly auriculate at the limb bases. The two species intergrade along the Vanrhynsdorp–Calvinia axis and discrimination between them is problematic there.

106. **Gladiolus salteri** *G.J.Lewis* in Lewis et al. in Journal of South African Botany, Suppl. 10: 127 (1972). Type: South Africa, [Northern Cape], Namaqualand, 28 km east of Springbok, 19 Sept. 1933, *Salter 3798* (BOL, holo.; BM, K, iso.).

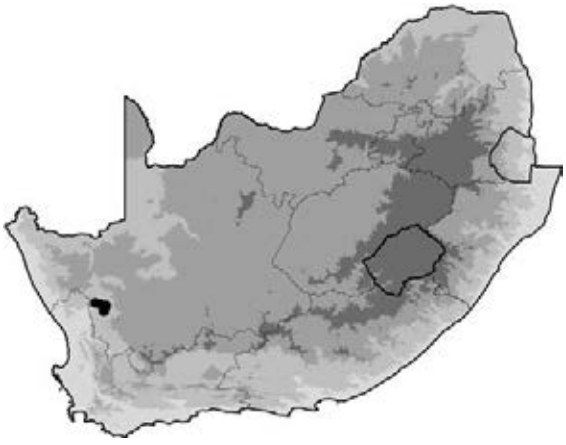
Plants 100–200 mm high. *Corm* globose-conic, 18–25 mm diam. or more, bearing a few cormlets around base; tunics coarsely fibrous, sometimes accumulating. *Stem* inclined, flexed above sheath of uppermost leaf, simple or with one or two branches. *Leaves* usually 4, lower 3 basal, falcate, all arching to one side, generally as long as spike, 4–7 mm wide, grey-green, uppermost leaf inserted in middle of stem. *Spike* inclined to nearly horizontal, flexuose, 5- to 8-flowered; bracts pale grey-green, dry and brown above, outer 15–20 mm long, inner slightly shorter. *Flowers* pale pink, lower tepals cream-coloured with deep pink markings in midline and toward apices, papillose on claws and lower throat, lightly rose-scented during day; perianth tube 18–22 mm long, narrowly and obliquely funnel-shaped, normally exserted from bracts, wider portion 3–4 mm long; tepals narrowed into claws below, dorsal longest, initially arcuate, erect distally with age, claw 28–32 mm long, slender, ± 8 mm at widest, upper laterals 20–22 mm long, claws ± 7 mm long, directed forward, limbs abruptly expanded, curving outward, lower tepals strongly clawed, united basally for 4–5 mm, channelled, free for ± 15 mm, limbs curving downward. *Filaments* ± 25 mm long, papillose toward bases, exserted 18–20 mm from upper part of tube; anthers ± 6 mm long, cream-coloured; pollen pale yellow. *Style* arching over stamens, dividing opposite lower ½ of anthers, branches ± 4 mm long. *Capsules* broadly ovoid, trilobed-retuse above, 9–11 × 10 mm. *Seeds* 4–5 × 3.5–4.0 mm, broadly winged with seed body asymmetrically placed. *Flowering time*: mid-August to mid-September.

Distribution and ecology: a local endemic from eastern Namaqualand in Northern Cape, South Africa, known only from east of Springbok at the western edge of Bushmanland; in gritty decomposed granite, often along drainage lines.



Diagnosis: recognised by the pale pink flowers with relatively narrow, spreading tepals, the upper ± 8 mm wide, lower tepals with cream-coloured and reddish markings, and relatively long filaments ± 25 mm long, well exserted from the perianth tube and papillose toward the base.

107. **Gladiolus lapeirousioides** *Goldblatt* in Journal of South African Botany 37: 229 (1971). Type: South Africa, [Northern Cape], Loeriesfontein District, along road to Kliprand, 23 Sept. 1970, *Goldblatt 540* (BOL, holo.; NBG, PRE, iso.).



Plants 80–140 mm high. *Corm* ± conic, 9–12(–15) mm diam., usually with a few cormlets at base on short stolons 5–8 mm long; tunics cartilaginous, breaking up into coarse fibres, yellow when young, sometimes accumulating in a dense mass. *Stem* erect below, strongly flexed outward above sheath of uppermost leaf, sometimes almost horizontal above, simple or 1- or 2-branched. *Leaves* 4 to 6, forming a basal fan, falcate and often all arching to one side, 3–5 mm wide, main vein and margins lightly thickened, only uppermost inserted on stem above ground, sheathing below. *Spike* nearly horizontal, lightly flexuose, (5)7- to 12-flowered; bracts green to green-grey, 15–20 mm long, inner shorter. *Flowers* creamy white, lower 3 tepals with yellow spot near base bordered with red, unscented; perianth tube cylindric, 35–40 mm long; tepals when fully open spreading at right angles to tube and all held in same plane, upper 3 narrowly elliptic, 20–22 mm long, lower tepals nearly linear, laterals 8–10 × 1.5–2.0 mm, lower median ± 15 × 4 mm. *Filaments* ± 8 mm long, exserted ± 4 mm from tube; anthers ± 3 mm long, purplish; pollen yellow. *Style* ± erect, dividing opposite anther apices, branches ± 2 mm long. *Capsules* obovoid, 3-lobed-retuse above, 8–12 mm long, lightly warty. *Seeds* ± 4 × 3 mm, broadly but unevenly winged with seed body eccentric. *Flowering time*: late August to early October.

Distribution and ecology: a narrow endemic known only from west of Loeriesfontein and the Agter Hantam in Northern Cape, South Africa; on low hills in stony shale, often along drainage lines.

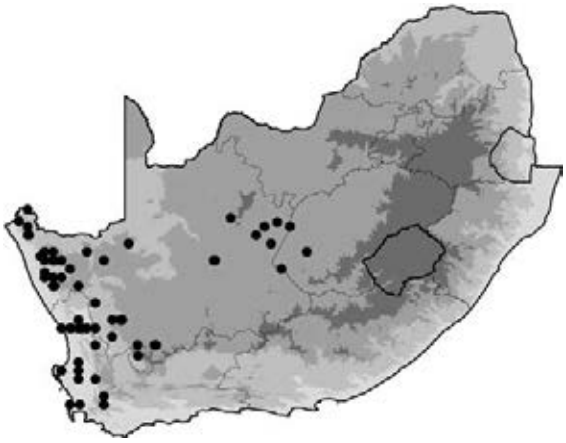
Diagnosis: recognised by the horizontal spikes of long-tubed, cream-coloured flowers with narrow, spreading tepals, the lower three with small yellow and red

Distribution of ***Gladiolus salteri***.

Distribution of ***Gladiolus lapeirousioides***.

markings near the base, the perianth tube long, straight and subcylindric, 35–40 mm long, and the filaments short, ± 8 mm long and exserted from the tube for about half their length.

Ser. **Hebea** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus alatus* L.



Plants mainly from winter-rainfall region, often short. *Corm* tunics papery to leathery. *Stem* sometimes flattened and winged. *Leaves* green at flowering, often falcate, plane or corrugate, firm-textured. *Spike* usually suberect, few-flowered. *Flowers* often large, strongly zygomorphic, perianth tube short, dorsal tepal arching or vertical, outer whorl widest, cordate and shortly clawed, sutures with glistening papillate ridges; filaments long and sometimes puberulous. *Capsules* ellipsoid and obtuse.

108. **Gladiolus orchidiflorus** *Andrews*, The Botanist's Repository 4: t. 241 (1802). *Hebea orchidiflora* (Andrews) Eckl. [as (Pers.) Eckl.]: 43 (1827). *Antholyza orchidiflora* (Andrews) Klatt: 733 (1864) [misapplied to *Tritoniopsis* species]. Type: South Africa, without precise locality, cultivated in England in 1802, *Niven s.n.*, illustration in Andrews: t. 241 (1802).

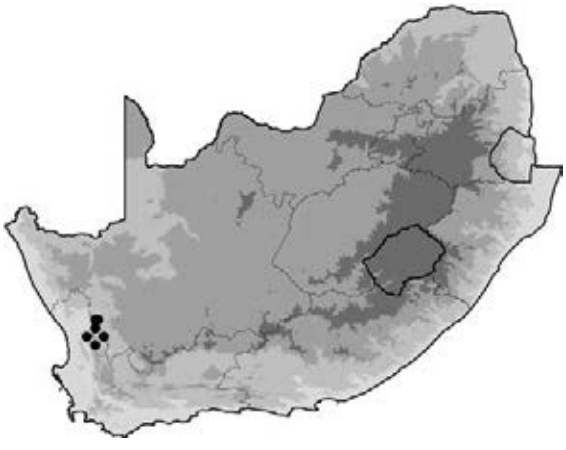
Gladiolus viperatus Ker Gawl.: t. 688 (1803d). Type: South Africa, without precise locality or collector, cultivated in Great Britain, illustration in Ker Gawl.: t. 688 (1803d).

Gladiolus dregei Klatt: 693 (1864). Type: South Africa, [Northern Cape], Namaqualand, between Pedroskloof and Leliefontein, 1830, *Drège 2631* (B, presumed holo.; G, K, P, S, iso.).

Plants (80–)180–450(–800) mm high. *Corm* globose to conic, 12–20 mm diam., producing numerous small cormlets at base; tunics moderately to very coarsely fibrous or thinly leathery to firmly papery. *Stem* erect below, flexed outward above sheaths of upper, simple or 1- or 2-branched. *Leaves* (4)5 to 8(10), lower 3 to 7 basal and often in a fan, reaching to ± middle of stem, narrowly lanceolate to linear, sometimes falcate, 2–7(–15) mm wide, soft-textured, sometimes somewhat fleshy, central and sometimes one or more secondary veins lightly thickened, margins occasionally lightly thickened, rarely lightly crisped. *Spike* inclined, lightly flexuose, flowers in 2 ranks, 5- to 12-flowered; bracts greenish or flushed purple-grey, outer (13–)18–23(–30) mm long, inner slightly shorter to ± as long, notched apically. *Flowers* greyish green to dull purple, lower 3 tepals with bright yellow to greenish transverse band in upper ⅓ edged distally darker purple, strongly scented of violets; perianth tube narrowly and obliquely funnel-shaped, 9–14 mm long; tepals with papillate ridges along sutures, dorsal longest, narrowly oblong-spathulate, strongly arched, 20–35 × 3–6 mm, upper laterals narrowly spade-shaped, with claws 2–4 mm wide, limbs triangular to lanceolate, 12–16 × 6–17 mm, curving outward distally, somewhat attenuate, lower 3 tepals joined to upper laterals for 2–4 mm and together for 1–2 mm, 11–20 mm long, arching downward, lower median slightly longer or shorter than laterals but ± twice as wide. *Filaments* strongly arched, 20–25 mm long, exserted 6–20 mm from tube; anthers 5–11 mm long, lilac to purple; pollen cream-coloured. *Style* arching over stamens, dividing opposite middle to upper ½ of anthers, branches 3.5–5.0 mm long. *Capsules* ellipsoid or occasionally globose, then ± 3-lobed and retuse, 10–23 mm long. *Seeds* ovate to rotund, 6–8 × 5–6 mm, broadly and evenly winged. *Flowering time*: August and September, occasionally in October or November in Kamiesberg.

Distribution of ***Gladiolus orchidiflorus***.

Distribution and ecology: widespread through the western near-interior of the winter-rainfall belt of southern Africa, from southern Namibia through the higher-lying parts of Namaqualand and Bushmanland in Northern Cape, South Africa southward along the Atlantic Coast and the Bokkeveld Escarpment to Cape Town and Worcester in Western Cape with outlying populations from Calvinia and Ladysmith, and then inland on the interior plateau from Fauresmith in Free State to Kimberley and Kuruman in North West; often on deep sandy soils in open shrubland, also on rocky slopes, sometimes in dolerite outcrops.



Diagnosis: recognised by the several plane leaves and characteristic greenish to purplish flowers with narrow, strongly arched dorsal tepal 3–6 mm wide, and broad, spade-shaped upper lateral and lower median tepals. Populations from the Atlantic Coast have almost turquoise green flowers but elsewhere the flowers are greyish to dull purple.

109. **Gladiolus watermeyeri** *L.Bolus* in South African Gardening and Country Life 17: 294 (1927b). Type: South Africa, [Northern Cape], Calvinia District, near Nieuwoudtville, Aug. 1913, *Marloth 5569* (BOL, holo.; PRE, iso.).

Plants (100–)160–350 mm high. *Corm* globose to depressed-globose, 15–22 mm diam.; tunics soft-papery to

membranous, not persisting, decaying irregularly. *Stem* erect below, flexed outward above sheathing part of third leaf and inclined above, occasionally robust plants with 1 branch. *Leaves* 4 or 5, lower 3 basal, lowermost longest and usually exceeding spike, others seldom reaching beyond middle of spike, narrowly lanceolate to linear, 3–11 mm wide, strongly 2- to 5-ribbed, margins thickened and raised, scabrid on veins, cauline leaves smaller, diverging from stem. *Spike* inclined, lightly flexuose, (1)2- to 6-flowered; bracts bright green, transparent along veins, outer 40–45 mm long, inner slightly shorter, not keeled, forked. *Flowers* greenish to creamy white, dorsal tepal grey-translucent but purplish along midline, upper lateral tepals conspicuously veined with maroon to purple or pink, lower 3 tepals dark olive-green, paler at tips and lightly veined, sutures between tepals thickened into iridescent papillose ridges, with strong freesia-like scent; perianth tube narrowly and obliquely funnel-shaped, 14–16 mm long, lower cylindric part ± 10 mm long, with sharp bend at base of flared part; tepals with upper laterals largest, dorsal hooded over filaments, boat-shaped, 27–35 × 10–15 mm, upper laterals spade-shaped, narrowed near base into short claws 1–2 mm long, curving outward from near base, 20–30 × 15–25 mm, lower 3 tepals united below for 2–4 mm, free parts 20–25 mm long, lower laterals channelled and narrowed below into claws, limbs narrowly boat-shaped, ± 9 mm long, lowermost triangular, narrowed below into a short claw, ± 22 mm wide. *Filaments* strongly arched, 20–22 mm long, exserted 15–16 mm from tube; anthers 9–13 mm long, dark green; pollen yellowish. *Style* arching over stamens, dividing between middle and apex of anthers, branches 4–8 mm long. *Capsules* broadly ellipsoid and 3-sided, (20–)27–35 mm long. *Seeds* broadly oval, (7–)9–11 × (5–)7–9 mm, light to dark pinkish brown, broadly and evenly winged. *Flowering time*: August to mid-September.

Distribution and ecology: a relatively local South African endemic, extending from the Bokkeveld Escarpment in Northern Cape to the Gifberg and the northern Cederberg near Wuppertal in Western Cape; on stony sandstone in seasonally moist sand in arid fynbos.

Distribution of ***Gladiolus watermeyeri***.

Diagnosis: recognised by the ribbed and scabridulous leaves, and the characteristic greenish to creamy white flowers with a translucent, boat-shaped dorsal tepal hooded over the stamens, and darkly veined, heart-shaped upper lateral tepals. The lower tepals are predominantly yellowish green except at the tips. The flowers are exceptionally cryptic and often most easily located by their strong and penetrating fragrance.

110. **Gladiolus virescens** *Thunb.*, Flora capensis: 196 (1811). Type: South Africa, [Western Cape], without precise locality, *Thunberg s.n.* (UPS-THUNB 1090, holo.).

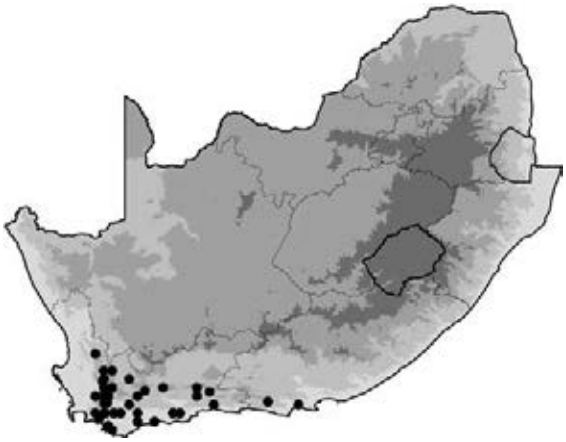
Gladiolus luridus Hornem.: 113 (1819). Type: South Africa, without precise locality or collector [possibly *C.P. Thunberg*] (C, holo.).

Gladiolus luteus Klatt: 694 (1864), illegitimate homonym, not *G. luteus* Lam. (1788). Type: South Africa, [Western Cape], Caledon District, without date [possibly 1831], *Ecklon & Zeyher Irid. 135* (C, holo.; BR, LD, P, PRE, S, Z, iso.).

Gladiolus pulchellus Eckl. ex Klatt: 693 (1864), illegitimate homonym, not *G. pulchellus* Salisb. (1796). *Hebea pulchella* Eckl. ex Baker: 178 (1877), as a synonym. *Gladiolus virescens* var. *lepidus* G. J.Lewis in Lewis et al.: 153 (1972), replacement name at varietal rank for *G. pulchellus* Eckl. ex Klatt. (1864). Type: South Africa, [Western Cape], Swellendam, without precise locality, Oct. 1831, *Ecklon & Zeyher Irid 137* (B, holo.; G, iso.).

Gladiolus bicolor Eckl. ex Baker: 178 (1877), illegitimate homonym, not *G. bicolor* Thunb. (1784). Type: South Africa, [Western Cape], near Caledon, *Ecklon s.n.* (S, holo.).

Gladiolus templemannii Klatt: 196 (1885). Type: South Africa, [Western Cape], Caledon District, Zwartberg near Hot Springs, Sept. 1884, *Templemann sub MacOwan 2608* (S, possible holo.; BM, BOL, K, SAM, iso.).



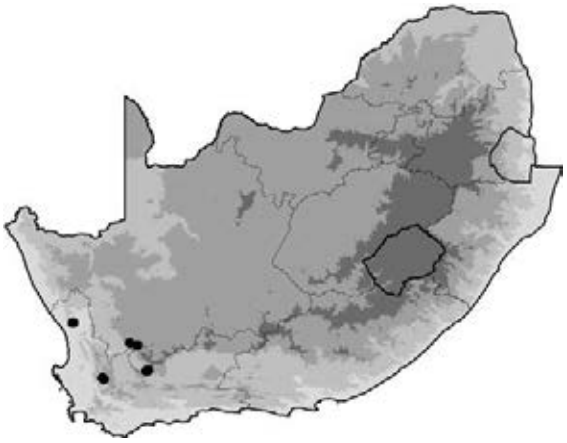
Gladiolus virescens var. *roseovenosus* G.J.Lewis in Lewis et al.: 153 (1972). Type: South Africa, [Western Cape], Worcester District, Kweekkraal near Brandvlei, 4 Sept. 1962, *Bayliss 642* (NBG, holo.).

Plants 120–200 mm high [excluding basal leaf]. *Corm* globose to depressed-globose, 12–15 mm diam.; tunics soft-papery becoming fibrous, seldom persisting. *Stem* ± erect below, flexed outward and inclined in middle but sometimes ± erect below spike, seldom branched. *Leaves* 3(5), lowest much longer and ± as long to twice as long as stem, linear to terete, 1–3 mm wide, oval to round in section with margins raised and edges arching toward main vein, main and often one other vein also raised, thus 2- or 3-grooved on each surface, remaining leaves short, lowermost sheathing lower half of stem, uppermost inserted in upper half of stem and distant from lower, usually bract-like without blade, sheaths

and sometimes blades sparsely to densely scabrid to pubescent on veins. *Spike* flexed at base, inclined, fairly straight or lightly flexuose, 3- to 7(12)-flowered; bracts green, veins ± transparent, outer 20–30 mm long, inner shorter and ± enclosed by outer. *Flowers* yellow to yellow-green or pink, upper 3 tepals flushed or feathered green, brownish purple or dark pink, lower 3 tepals with deep yellow to white band across base of limb, pale distally and sometimes mauve or pink apically, sutures between tepals thickened into densely papillose iridescent ridges, strongly violet-scented or unscented (some pink-flowered plants); perianth tube narrowly and obliquely funnel-shaped, 9–12(–15) mm long; tepals with dorsal longest, ± spathulate, straight and inclined or erect, margins sometimes recurved, 20–40(–48) × 10–16(–20) mm long, narrowed below and claw-like for ± 18 mm, upper ⅓ abruptly expanded and triangular, upper laterals spade-shaped, base narrow and claw-like for, 1–3 mm, limbs abruptly expanded, triangular, curving outward distally, 14–25(–30) mm long, lower 3 tepals joined to upper laterals for ± 5 mm and together for 1–3 mm, free parts 16–20(–30) mm long, clawed, narrow and grooved below, abruptly expanded into limbs 10–12(–20) mm long. *Filaments* strongly arched, 18–27 mm long, exserted for 15–22 mm; anthers 6–8 mm long, pale or dark; pollen yellow. *Style* arched over stamens, dividing opposite upper ⅓ of anthers, branches 4–6 mm long. *Capsules* oblong-ellipsoid, 18–25(–30) mm long. *Seeds* ovate to round, 5–7 × 5–6 mm, broadly and evenly winged. *Flowering time*: mid-August through September.

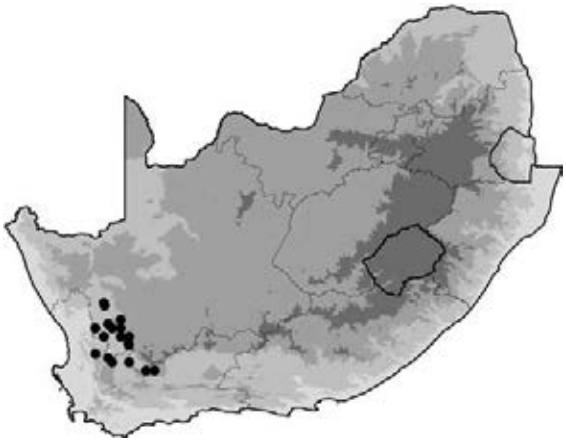
Distribution and ecology: widespread through southwestern and southern Western Cape, South Africa, from the Warm Bokkeveld and the Witteberg into the Breede River Valley and east of the Hottentots Holland Mtns to Bot River thence eastward into Eastern Cape near Humansdorp; on stony shale or sometimes alluvial fans in loamy, mostly in renosterveld shrublands.

Hybrids with *Gladiolus alatus* L. have been recorded near Rawsonville and Bot River.



Distribution of ***Gladiolus virescens***.

Diagnosis: recognised by the soft corm tunics, the ribbed or grooved and often scabrid leaves, the uppermost separated from and not overlapped by the leaf below it, thus exposing a portion of the stem, and the strongly veined flowers with suberect dorsal tepal. The flowers are variable in colour, usually yellowish to greenish with purple veins but sometimes pinkish with darker pink veins. Plants from the Swartruggens are unusually robust, with branched stems and relatively small, pinkish flowers. *Gladiolus ceresianus* has similar flowers but invariably three leaves, the lowermost terete and 4-grooved, the sheaths of all three leaves overlapping and completely concealing the lower part of the stem, and characteristically dark, fibrous corm tunics forming a neck around the base of the stem.



111. **Gladiolus ceresianus** *L.Bolus* in South African Gardening and Country Life 21: 368, t. B (1931c). Type: South Africa, [Western Cape], Ceres District, from the Ceres Wild Flower Show, 5 Oct. 1931, *Compton s.n.* (BOL [BOL 19883], holo.; K, iso.).

Plants 100–180(–300) mm high. *Corm* conical, 9–12 mm diam., with cormlets at base; tunics of dark, medium to coarsely textured fibres forming collar around base. *Stem* inclined throughout or erect below, flexed outward above sheath of uppermost leaf, unbranched. *Leaves* 3, always overlapping, lowermost longest and usually longer than stem, terete, 4-grooved, straight or falcate, 1–2 mm diam., second leaf sheathing lower ½ of stem and overlapping upper leaf sheath, reaching to ± middle of spike, third leaf shortest, sheathing only near base. *Spike* inclined, (1)2- to 4-flowered, lightly flexuose; bracts green or flushed reddish, outer 25–35(–40) mm long, inner slightly shorter, minutely notched. *Flowers* purplish brown or greenish grey, upper 3 tepals with dark purple veins radiating from midline, lower tepals greenish yellow in lower ⅔, sutures between tepals forming glistening papillose ridges, intensely sweetly scented; perianth tube narrowly and obliquely funnel-shaped, 12–16 mm long, slender basal part 8–10 mm long; tepals with dorsal longest, oblanceolate, 28–36(–45) × ± 11 mm, erect or inclined below and erect above, margins recurved, upper lateral tepals spade-shaped, bases abruptly narrowed into claws ± 4 mm long, limbs triangular, acuminate, curving outward above, 20–25 × 14–16 mm, lower 3 tepals united with upper laterals for 3–4 mm, free parts ± 16–25 mm long, clawed, narrow and channelled below, lower laterals with limbs 4–6 mm wide, lower median 9–10 mm wide. *Filaments* strongly arched, 20–22 mm long, exserted for ± 18 mm; anthers 8–9 mm long, light purple; pollen yellow. *Style* arching over stamens, dividing between middle and upper ⅓ of anthers, branches ± 6 mm long. *Capsules* and *seeds* unknown. *Flowering time*: mid-August to late September.

Distribution and ecology: centred in southwestern interior Western Cape, South Africa, in the Cold Bokkeveld and eastward to Matjiesfontein and the Klein Roggeveld and the Roggeveld in Northern Cape, with an outlying northern population at Hol River near Vredendal; on

Distribution of ***Gladiolus ceresianus***.

Distribution of ***Gladiolus uysiae***.

stony clay slopes, often along drainage lines, in succulent karoo and renosterveld shrubland.

Diagnosis: recognised by the dark, fibrous corm tunics, the three overlapping leaves concealing the stem between the second and third leaves, the lowermost leaf terete and 4-grooved, and the strongly purple-veined flowers with more-or-less erect dorsal tepal. *Gladiolus virescens* has similar flowers but the uppermost leaf is always slightly distant from the second leaf, thus exposing a section of stem, and the corm tunics are softly papery becoming finely fibrous.

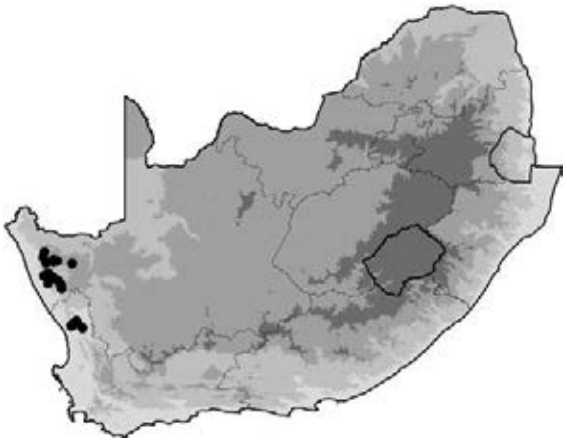
112. **Gladiolus uysiae** *L.Bolus ex G.J.Lewis* in Lewis et al. in Journal of South African Botany, Suppl. 10: 156 (1972). Type: South Africa, [Northern Cape], Calvinia District, without precise locality, cultivated at Nieuwoudtville, Sept. 1930, *Buhr s.n.* (BOL, holo.).

[*Gladiolus uysiae* L.Bolus: 367 (1931c), invalid provisional name.]

Plants 70–180 mm high. *Corm* depressed-globose, 10–14 mm diam., producing slender white stolons from base; tunics membranous to papery, not accumulating. *Stem* ± erect below, flexed outward and inclined in middle, rarely with short branch. *Leaves* 3, overlapping, lowermost longest, ± as long or slightly longer than stem, plane, somewhat fleshy, falcate, 3–6(–9) mm wide, main and 1 or 2 secondary veins evident but not thickened, remaining leaves reaching to between middle of stem and base of spike, uppermost usually mostly channelled. *Spike* flexed at base, inclined, 1- to 3-flowered, lightly flexuose; bracts green, outer 20–25 mm long, margins transparent, inner shorter and ± enclosed by outer. *Flowers* purple-pink but paler distally with strong purple to green veining, lower tepals with dark yellow-green band shortly below apex, sometimes purple-veined at tips, strongly and sweetly scented; perianth tube narrowly and obliquely funnel-shaped, 10–12 mm long; tepals with dorsal longest, straight and erect, oblanceolate, 28–35 mm long, widest in upper ⅓ with margins recurved, upper laterals spade-shaped, bases abruptly narrowed and claw-like for 2–3 mm, limbs triangular, acute, curving outward in upper ½, 15–18 mm long, lower 3 tepals joined to upper laterals for ± 1 mm and together for ± 1 mm, free for ± 15 mm long, clawed and narrow and channelled below, abruptly expanded into limbs 8–9 mm long, sutures between lower and upper lateral tepals thickened into iridescent papillose ridges. *Filaments* strongly arched, 20–25 mm long, exserted 18–20 mm from tube; anthers 6–8 mm long, purple; pollen yellow. *Style* arched over the filaments, dividing opposite upper third of anthers, branches 5–6 mm long. *Capsules* obovoid with rounded apices, obscurely 3-lobed, 12–18 mm long. *Seeds* round to broadly oval, ± 6 × 4–5 mm, broadly and evenly winged. *Flowering time*: mid-August to the end of September.

Distribution and ecology: restricted to the southwestern interior of South Africa, from the Bokkeveld Escarpment and Hantam to the Klein Roggeveld in Northern Cape and though the northern Cederberg and Tanqua Karoo basin to Touws River in Western Cape; on clay soils in renosterveld and succulent shrubland, forming extensive colonies through vegetative reproduction via stolons.

Diagnosis: recognised by the plane, subsucculent and usually ± falcate leaves, and the strongly purple-veined flowers with a large, suberect dorsal tepal. The production of slender, naked stolons is characteristic for the species. *Gladiolus ceresianus* and *G. virescens* have similar flowers but corrugate or grooved to terete leaves with thickened and raised veins and margins, and sessile or subsessile cormlets.



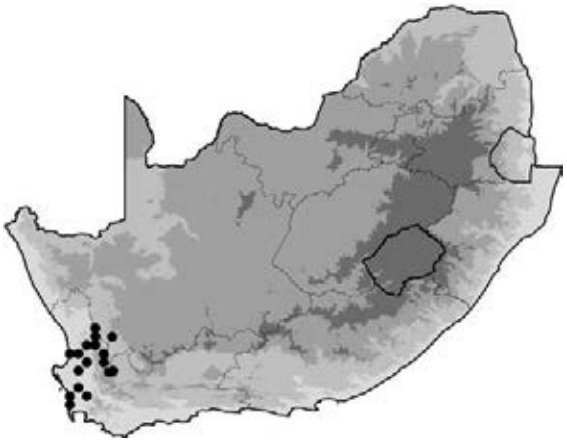
113. **Gladiolus equitans** *Thunb.*, Prodromus plantarum capensium: 186 (1800). Type: South Africa, Cape, without precise locality or collector, (UPS-THUNB 1021, holo.).

Gladiolus namaquensis Ker Gawl.: t. 592 (1802e). *G. alatus* var. *namaquensis* (Ker Gawl.) Baker: 177 (1877). Type: South Africa, without precise

locality, cult. in England from plants collected by J. Niven, illustration in Ker Gawl.: t. 592 (1802e), syn.; BM ['*Gladiolus namaquensis* Ker Gawler'], syn.).

Plants 150–300 mm high. *Corm* globose, 20–40 mm diam.; tunics firm-membranous to leathery, decaying irregularly, occasionally ± coarsely fibrous, often accumulating in a dense mass. *Stem* erect, compressed and ridged, usually 3-winged, with two wide and one narrow face, unbranched. *Leaves* 4(5), lower 2 or 3 ± basal and forming a 2-ranked fan, lowermost largest, reaching to just below base of spike, falcate, remaining leaves progressively shorter, 20–40 mm wide, obtuse-apiculate, margins heavily thickened, hyaline or reddish. *Spike* flexed at base and inclined, flexuose, nearly 2-ranked, 3- to 7-flowered; bracts prominently keeled with keels decurrent on stem angles, green with reddish keels and margins, outer 25–40(–50) mm long, 1-keeled, inner shorter, 2-keeled, minutely forked apically. *Flowers* orange to scarlet, lower lateral tepals yellow in lower ⅔, lower median tepal yellow in lower half, throat with glistening papillose ridges on sutures between tepals, lightly scented; perianth tube obliquely funnel-shaped, 10–15 mm long, entirely included in bracts; tepals dorsal largest, obovate-concave, hooded over stamens, 27–38 × 18–20 mm, upper laterals broadly heart-shaped, narrowed near base, curving gradually outward distally and spreading, 23–26 × 23–30 mm, lower 3 tepals united below for 3–5 mm, free parts ± 25 × 9–10 mm, clawed below, laterals channelled for most of length, lower median ± 18 × 12–15 mm. *Filaments* strongly arched, 17–25 mm long, exserted 13–20 mm from tube; anthers 8–14 mm long, cream-coloured with red on lines of dehiscence; pollen cream-coloured. *Style* arching over stamens, dividing opposite middle to upper ⅓ of anthers, branches 5–7 mm long. *Capsules* oblong-ellipsoid, 25–30 mm long. *Seeds* broadly ovate, 8–9 × ± 7 mm, broadly and evenly winged. *Flowering time*: mainly late August to mid-September, occasionally later, especially at high elevations.

Distribution and ecology: scattered through the highlands of Namaqualand, South Africa, in the mountains around Springbok and Okiep, and on the escarpment west of Kamieskroon and the Kamiesberg, all in Northern Cape, and in southern Namaqualand east of Bitterfontein as far south as Hol River near Vredendal in Western Cape; on rocky ridges, mainly in granite but also quartzite outcrops.



Distribution of ***Gladiolus equitans***.

Diagnosis: recognised by the broad, falcate lower leaves widest near the tips and with reddish, heavily thickened margins and large, bright orange to scarlet flowers with hooded dorsal tepal. The filaments are smooth.

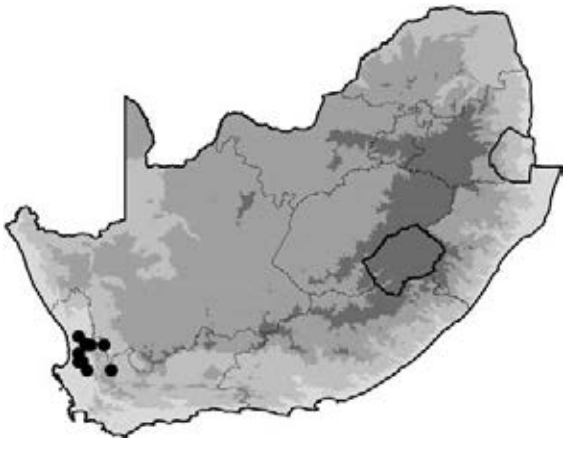
114. **Gladiolus speciosus** *Thunb.*, Flora capensis: 196 (1811). *Hebea speciosa* (Thunb.) Steud.: 724 (1840). *G. alatus* var. *speciosus* (Thunb.) G.J.Lewis in Lewis et al.: 167 (1972). Type: South Africa, without precise locality, probably Sept. 1773, *Thunberg s.n.* (UPS-THUNB 1071, holo.).

Plants (80–)120–200 mm high; *Corm* depressed-globose, 7–12 mm diam., with several long, slender, often branched stolons from base; tunics membranous to dry and softly papery, decaying irregularly. *Stem* erect below or inclined above ground, flexed outward above uppermost basal leaf and then inclined, compressed and 2-angled below, 3-sided and winged above, occasionally with a short branch. *Leaves* 4 to 6(8), lower 3 to 6 basal, lowermost about twice as long as stems, remaining leaves progressively shorter, linear to falcate, (2–)3–7 mm wide, midribs and sometimes 1 other pair of veins evident but not raised, margins sometimes slightly thickened, upper 2 or 3 leaves cauline, sheathing only at base. *Spike* inclined, lightly flexuose, 2- to 5(8)-flowered; bracts keeled, pale glaucous green usually red on keel and margins, outer 35–40(–50) mm long, inner shorter. *Flowers* predominantly orange, dorsal tepal whitish inside, upper laterals usually with large yellow blotch on reverse and orange or dull red to purple or yellowish inside, lower tepals yellow with orange apices, with iridescent papillose ridges at sutures between tepals, strongly herbaceous-scented; perianth tube obliquely funnel-shaped, 11–13 mm long; tepals dorsal largest, obovate to oblanceolate, concave, nearly horizontal, hooded over stamens, 25–40 × 18–26 mm, upper laterals broadly spade-shaped, strongly narrowed near bases into short claws 1–3 mm long, limbs triangular, 20–25 × 20–28 mm, gently curving outward distally, lower 3 tepals united with upper laterals for 3–5 mm, free parts 20–25 mm long, laterals spathulate, narrowed below into channelled claws 6–8 mm long, gradually expanding distally and 8–10 mm wide, lowermost with a claw ± 5 mm long, limb broadly triangular, 17–24 mm wide. *Filaments* ascending to arched, ± 22 mm long, exserted for ± 15 mm from tube, minutely pubescent toward base; anthers 8.5–10.0 mm long, dull greenish yellow, sometimes reddish to purple on lines of dehiscence; pollen yellowish. *Style* arching over stamens, dividing opposite middle third of anthers, branches ± 7 mm long. *Capsules* ellipsoid, 3-sided, often shortly beaked, (20–)30–35 × ± 11 mm, septa sometimes inflated and pithy. *Seeds* ovoid, sometimes

Distribution of ***Gladiolus speciosus***.

only 1 or 2 per locule with remaining ovules aborted, 9–12 × 8–11 mm, broadly and evenly winged. *Flowering time*: mid-September to mid-October.

Distribution and ecology: extending from the Bokkeveld Escarpment in Northern Cape, South Africa and Leipoldtville in Western Cape southward to Mamre; in deep sandy soils among Restionaceae.



Diagnosis: a relatively late-flowering species recognised by narrow, linear to falcate leaves with plane blades, and bright orange flowers, the upper laterals often predominantly yellow on the reverse, with hooded dorsal tepal arched over the stamens. The conspicuous, slender stolons are diagnostic among the small group of species with angled to winged stems and orange flowers. *Gladiolus pulcherrimus* with similar leaves, has flowers with a suberect dorsal tepal and conspicuously hairy filaments and the corm lacks stolons.

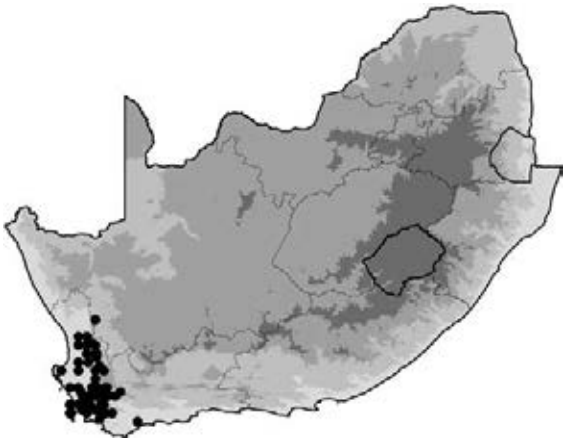
115. **Gladiolus pulcherrimus** *(G.J.Lewis) Goldblatt & J.C.Manning*, *Gladiolus* in southern Africa: 229 (1998). *G. alatus* var. *pulcherrimus* G.J.Lewis in Lewis et al.: 168 (1972). Type: South Africa, [Western Cape], Olifants River Valley 12 miles south of Klawer, 28 Aug. 1957, *Lewis 5220* (NBG, holo.).

Plants 200–400(–650) mm high. *Corm* depressed-globose, 10–15 mm diam.; tunics membranous, decaying irregularly. *Stem* erect below, flexed outward above sheaths of cauline leaves and inclined, compressed and 3-angled to 3-winged, usually with 1 or 2 branches. *Leaves* 5 to 7(8), lower 4 or 5 ± basal, lowermost sometimes slightly longer than others, reaching to ± base of spike, lanceolate to sword-shaped, (3–)6–12 mm wide, plane, main vein scarcely evident in fresh plants, margins lightly thickened, sometimes lightly crisped, grey-green with waxy bloom, uppermost leaf often ± bract-like. *Spike* inclined, flexuose, usually 5- to 8-flowered; bracts pale grey-green, glaucous, prominently keeled, outer 35–50 mm long, inner shorter, usually 2-keeled, minutely notched apically. *Flowers* salmon-pink to orange, upper 3 tepals feathered reddish below, dorsal often whitish on inside surface, lower 3 tepals pale greenish with salmon apices, sutures between tepals thickened into iridescent papillose ridges, lightly rose-scented; perianth tube obliquely funnel-shaped, ± 11 mm long, lower cylindric part ± 5 mm long; tepals with dorsal largest, initially arching over stamens but later ascending and curving upward distally, oblanceolate, ± 40 × 19 mm, narrowed below into a claw-like base ± 8 mm long, upper laterals ± spade-shaped, ± 27 × 23 mm, with narrow base 3–4 mm long, limb broadly triangular, spreading distally, lower 3 tepals united for ± 2–3 mm, free parts ± 24 mm long, lower laterals narrowly spathulate, narrowed below and channelled, gradually expanding above and ± 5 mm wide, lower median with a claw ± 8 mm long, limb narrowly triangular, ± 12 mm wide. *Filaments* strongly arched, ± 22 mm long, exserted ± 18 mm from tube, shortly pilose; anthers ± 8.5 mm long, dull greenish yellow, reddish on lines of dehiscence; pollen yellowish. *Style* arching over stamens, dividing opposite middle of anthers, branches ± 6 mm long. *Capsules* ellipsoid, 3-sided, (20–)25–40 mm long. *Seeds* ovate to fiddle-shaped, ± 8 × 6.5 mm, broadly and evenly winged. *Flowering time*: late August to mid-October.

Distribution and ecology: a relatively local endemic of the western part of Western Cape, South Africa, from the Olifants River Valley near Clanwilliam to Leipoldtville and the Gifberg; on deep sandy flats among Restionaceae.

Diagnosis: recognised by the plane leaves without thickened or raised veins, and salmon-pink to orange flowers with a suberect dorsal tepal and conspicuously hairy filaments. *Gladiolus speciosus*, with similar leaves, has a concave dorsal tepal that is strongly arched over the stamens, and almost glabrous filaments; it also produces characteristic long, slender stolons from the base of the corm. *Gladiolus alatus* has similar flowers but strongly ribbed or corrugate leaves.

Distribution of ***Gladiolus pulcherrimus***.



116. **Gladiolus alatus** *L.*, Plantae rariores africanae: 8 (1760). *Hebea alata* (L.) Eckl.: 42 (1827). Type: South Africa, Cape, without precise locality or collector [G: Herb. Burman, lecto., designated by Lewis et al.: 163 (1972)].

Gladiolus galeatus Burm.f.: 2 (1768). *Hebea galeata* (Burm.f.) Eckl.: 41 (1827). Type: South Africa, Cape, without precise locality or collector (G: Herb. Burman, holo.).

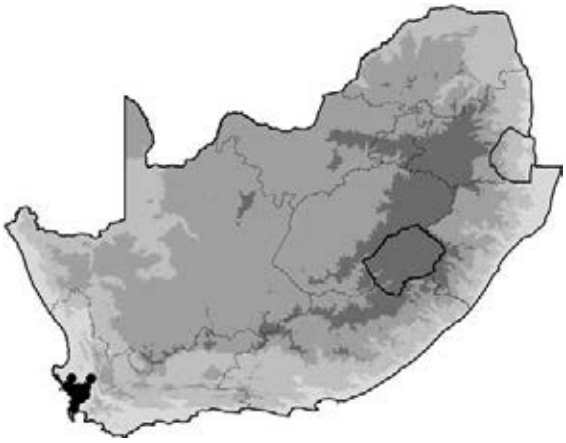
Gladiolus papilionaceus Licht. ex Roem. & Schult.: 408 (1817), illegitimate homonym, not *G. papilionaceus* Salisb. (1796). *G. alatus* var. *uniflorus* Klatt: 337 (1882), as a replacement name at varietal rank for *G. papilionaceus* [*G. uniflorus* Klatt mss cited in synonymy]. Type: South Africa, without precise locality, possibly collected by *M.H. Lichtenstein* (B: Herb. Willdenow 916, holo.).

Gladiolus alatus var. *algoensis* Herb.: t. 2608 (1825). *Gladiolus algoensis* (Herb.) Sweet: 397 (1826). Type: South Africa, said to be from the vicinity of Algoa Bay [Port Elizabeth], without collector, grown in England, illustration in Herb.: t. 2608 (1825).

Plants (80–)150–200 mm high. *Corm* depressed-globose, 12–16 mm diam.; tunics membranous, decaying irregularly or occasionally ± fibrous. *Stem* ± erect below, flexed outward above sheathing part of third leaf, slightly compressed, ridged to winged at least on 1 side, simple or rarely with 1 short branch, often with a small cormlet in subterranean leaf axils. *Leaves* 3 or 4(5), lower 2 or 3 ± basal, lowermost longest and reaching to ± top of spike, others progressively smaller, narrowly lanceolate to linear or falcate, 2–6(–9) mm wide, lightly (1)2–several-ribbed to markedly corrugate, often lightly scabrid-papillose on veins or surface, uppermost leaf often ± bract-like. *Spike* flexed at base and inclined, lightly flexuose, 2- to 5(8)-flowered; bracts strongly keeled, green with purple keel and margins, 25–35 mm long, inner slightly shorter, 2-keeled, acute. *Flowers* orange to scarlet, lower tepals light yellow-green with orange apices, upper lateral tepals feathered dark red in lower half, sutures between tepals thickened into iridescent papillose ridges, sweetly herbaceous-scented; perianth tube obliquely funnel-shaped, 10–14 mm long; tepals with dorsal largest, ascending to ± erect or weakly arching toward stamens, occasionally almost horizontal, broadly fiddle-shaped, 35–40(–50) × 16–25 mm, margins undulate below, upper laterals spade-shaped, 22–30 mm long, narrowed below into short claws 1–3 mm long, abruptly expanded into triangular limbs 18–28 mm wide, curving outward distally, lower 3 tepals united below for 3–5 mm, free for 20–26 mm, lower laterals narrowly oblanceolate, channelled below or throughout, 8–12 mm wide near apex, lowermost narrowed below into a claw-like base ± 8 mm long, limb broadly triangular, 12–18 × 16–19 mm, as wide or wider than both lower laterals. *Filaments* strongly arched, 20–26 mm long, exserted for ± 16–18 mm from tube, lightly to densely pubescent in upper half and minutely so below; anthers 6–10 mm long, dull green to yellowish with purple lines; pollen yellowish. *Style* arching over stamens, sparsely pilose, dividing near anther apices, branches ± 5 mm long. *Capsules* oblong-ellipsoid, 18–25 mm long. *Seeds* ovate to round, ± 8 × 6–8 mm, broadly and evenly winged. *Flowering time*: August and September, at higher elevations as late as early October.

Distribution of ***Gladiolus alatus***.

Distribution and ecology: widespread through the southwestern part of South Africa, from the Bokkeveld Escarpment in Northern Cape southward through the Cederberg, along the Atlantic Coast and east to Swellendam and the Potberg, and from Breede River Valley inland to Cabidu; mainly on stony sandstone or granite, often on thin or loamy soils.



Hybrids with *Gladiolus virescens* Thunb. have been recorded near Rawsonville and Bot River.

Diagnosis: distinguished among the species with ridged or winged stems and large, predominantly orange flowers with yellowish green markings on the lower tepals by the narrow, ribbed or corrugate leaves, suberect dorsal tepal, and pubescent filaments and style. *Gladiolus meliusculus* is vegetatively similar but typically has pink (rarely orange) flowers with broader, oblanceolate lower tepals with reduced yellow markings heavily edged with dark red, and shorter filaments ± 15 mm long.

117. **Gladiolus meliusculus** *(G.J.Lewis) Goldblatt & J.C.Manning*, *Gladiolus* in southern Africa: 232 (1998). *G. alatus* var. *meliusculus* G.J.Lewis in Lewis et al.: 166 (1972). Type: South Africa, [Western Cape], Malmesbury District, Ganzekraal road, 15 Sept. 1940, *Barker 2000* (NBG, holo.).

Plants 120–200(–270) mm high. *Corm* depressed-globose, 6–10 mm diam., usually producing 1 or 2 corm-

lets on short stolons up to 10 mm long; tunics membranous. *Stem* usually inclined from base or erect below, flexed outward above sheath of third leaf, unbranched, slightly compressed and 2-ridged to -winged below uppermost leaf, usually 3-ridged or -winged below first flower, usually with a small cormlet in subterranean axil. *Leaves* 4, lower 2 or 3 basal, lowermost longest, as long or longer than spike, linear, (1.8–)3.0–5.0 mm wide, strongly ridged, uppermost leaf usually bract-like and diverging from stem. *Spike* inclined, occasionally 2-, usually 3- to 6-flowered; bracts keeled, pale green with keel and margins red, 17–30 mm long, inner bracts shorter to ± as long, usually 2-keeled, minutely forked. *Flowers* pink to brick-red or orange, lower tepals yellow to greenish below narrowly to broadly edged with dark purple, throat with glistening papillose ridges on tepal sutures, sweetly honey-scented; perianth tube obliquely funnel-shaped, ± 11 mm long, mostly included in bracts; tepals with dorsal largest, oblanceolate, arching forward or ± erect when fully open, 30–38 × 15–18 mm, upper lateral tepals spade-shaped, shortly clawed for ± 2 mm, limbs abruptly expanded, 20–30 × ± 20 mm, spreading distally, lower tepals united for 3–4 mm, clawed below, laterals ± 23 mm long, claws channelled, limbs 12–16 × ± 12 mm, lower median with shorter claws, limbs 15–18 × 14–16 mm. *Filaments* strongly arched, ± 15 mm long, exserted ± 10 mm from tube, minutely pilose; anthers 5–7 mm long, purple or buff-coloured; pollen cream-coloured to yellow. *Style* arching over stamens, minutely pubescent, dividing between base and middle of anthers, branches ± 6 mm long. *Capsules* ovoid-ellipsoid, 20–26 mm long. *Seeds* oval, 6–8 × 5–6 mm, broadly and evenly winged. *Flowering time*: mid-August to early October.

Distribution of ***Gladiolus meliusculus***.

Distribution and ecology: a local endemic of the Atlantic coast of Western Cape, South Africa, historically recorded from the northern Cape Peninsula but now known only from near Philadelphia to Hopefield and Malmesbury and inland to Porterville; on loamy, seasonally waterlogged flats on granite or sandstone soils.

Diagnosis: recognised by the narrow, ribbed or corrugate leaves and pink to orange flowers with suberect dorsal tepal, oblanceolate lower tepals yellowish only toward the base edged with dark red, and relatively short, pubescent filaments ± 15 mm long and pubescent style. *Gladiolus alatus* has consistently orange flowers with narrower lower tepals yellowish for most of their length except at the extreme apices, and longer filaments 20–26 mm long.

Sect. 7. **Homoglossum** *(Salisb.) Goldblatt & J.C.Manning*, *Gladiolus* in southern Africa: 234 (1998). *Homoglossum* Salisb.: 143 (1866). Type species: *Gladiolus watsonius* Thunb.

Plants small to medium-sized. *Stem* unbranched. *Corm* tunics usually leathery to woody and clawed below, sometimes fibrous or membranous. *Leaves* 2 to 4, superposed with only lowermost basal, usually firm-textured, linear to terete, midrib and margins usually thickened and variously raised, sometimes X- or H-shaped, rarely plane with unthickened midrib and margins, usually less than 5 mm wide, sometimes reduced on flowering stem. *Spike* few-flowered; bracts glabrous, margins of inner bracts free. *Flowers* small to medium, weakly to strongly bilabiate, nectar guides various, usually streaks or spots on a pale background or a yellow transverse chevron edged in darker colour, usually strongly scented; perianth tube usually obliquely funnel-shaped, shorter than or much longer than dorsal tepal. *Anthers* never tailed. *Capsules* oblong-ellipsoid. *Seeds* broadly and evenly winged.

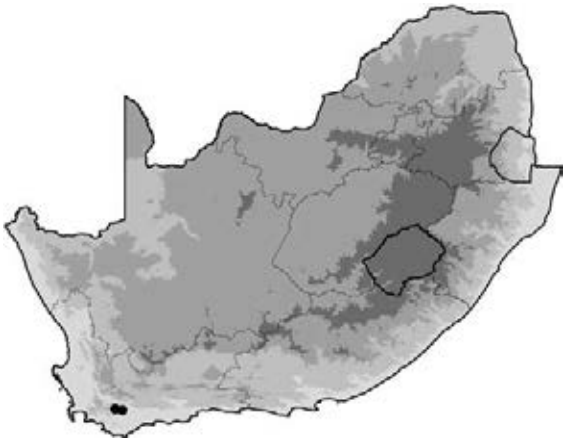
The section includes 52 species from southern Africa plus others from tropical Africa.

Ser. **Carinati** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus carinatus* Ait.

Plants from winter-rainfall region. *Corms* ovoid to subglobose; tunics papery to fibrous. *Cataphylls* sometimes purple mottled white above ground. *Leaves* green at flowering, linear, plane, firm-textured, midrib and margins lightly thickened. *Flowers* small to medium, bilabiate or rarely actinomorphic, perianth tube shorter than to ± as long as dorsal tepal, tepals acute to attenuate, lower tepals sometimes channelled below.

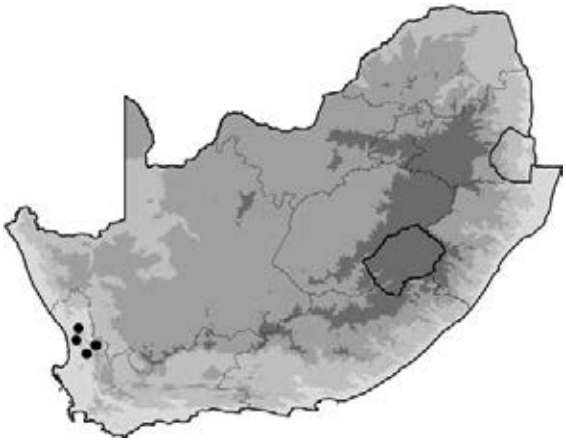
118. **Gladiolus atropictus** *Goldblatt & J.C.Manning*, *Gladiolus* in southern Africa: 235 (1998). Type: South Africa, Western Cape, MacGregor, pass to Die Galg, 25 July 1993, *Manning 2010* (NBG, holo.; PRE, iso.).

Plants 340–600 mm high. *Corm* conic, ± 15 mm diam.; tunics firm-papery, fragmenting into firm strips or



fairly coarse fibres. *Stem* erect, flexed outward above sheaths of upper 3 leaves, inclined in upper ⅓, unbranched. *Leaves* 4, lower 2 basal, lowermost sheathing lower ½ of stem, reaching to between middle and upper ⅓ of stem, linear, 1.5–2.0 mm wide, margins and main vein moderately thickened, second leaf sheathing stem to about upper third, blade shorter than basal, upper 2 leaves much shorter, lower margins united around stem. *Spike* flexuose, 1- or 2-flowered, inclined; bracts dull greenish grey with broad membranous margins, outer 26–35 mm long, inner slightly shorter, acute or minutely notched apically. *Flowers* deep mauve to violet, lower 3 tepals pale yellow in lower ½ feathered with dark violet, strongly scented of freesias and violets; perianth tube obliquely funnel-shaped, ± 13 mm long, lower cylindric part enclosed in bracts; tepals lanceolate-attenuate, upper 3 larger than lower, subequal or dorsal largest, dorsal 30–33 × ± 16 mm, horizontal and concave, upper laterals 28–30 × 12–14 mm, curving outward distally, lower 3 tepals joined to upper laterals for ± 10 mm, slightly narrowed and channelled in lower ½, lower laterals 18 × 8 mm, lower median longer than lower laterals, ± 21 × 9 mm, all curving outward distally. *Filaments* ± 12 mm long, exserted 5–8 mm from tube but concealed in flower; anthers 10–11 mm long, pale cream-coloured; pollen whitish. *Style* arching over stamens, branching just below anther apices, branches ± 3.5 mm long. *Capsules* and *seeds* unknown. *Flowering time*: mid-July to mid-August.

Distribution and ecology: a narrow endemic of the lower northern slopes and foothills of the Riviersonderend Mtns in Western Cape, South Africa; in loamy soil in sandstone outcrops.



Diagnosis: recognised by the ± conical corms with papery to somewhat fibrous corm tunics, four linear leaves with the margins and midrib moderately thickened, and deep mauve to violet, funnel-shaped flowers with darker streaks on the lower tepals. The thickened midrib and margins distinguish the species from *Gladiolus mutabilis*, which has characteristic subsucculent leaves without evidently thickened midrib and margins, and *G. inflexus* has just three leaves and subglobose corms with woody tunics.

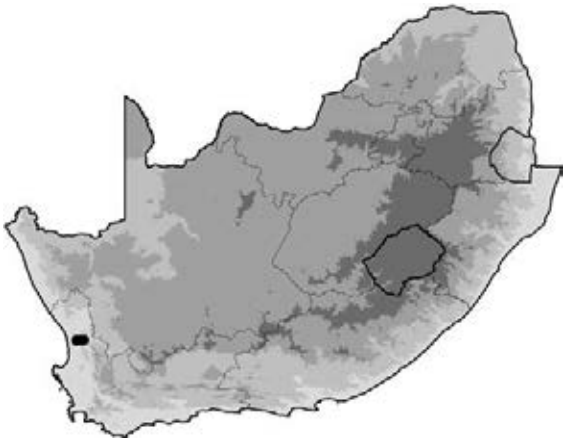
119. **Gladiolus violaceolineatus** *G.J.Lewis* in Lewis et al. in Journal of South African Botany, Suppl. 10: 233 (1972). Type: South Africa, [Western Cape], Clanwilliam District, Farm Alpha, west slope, 28 July, 1963, *Lewis 6142* (NBG, holo.; K, iso.).

Plants 300–500 mm high, with cataphylls sometimes minutely puberulous. *Corm* conic, 8–10 mm diam.; tunics cartilaginous to papery, fragmenting into firm strips or fairly coarse fibres. *Stem* erect, flexed outward above sheaths of upper 3 leaves, inclined in upper ⅓, unbranched. *Leaves* 4, lower 1 or 2 basal, lowermost sheathing lower ½ of stem, reaching to between upper ⅓ of stem and base of spike, linear, 1–2(–4) mm wide, straight, 3-angled, abaxial margin with raised edges extending outward at right angles to surface, main vein and adaxial margin not thickened or raised, remaining leaves progressively shorter, ± plane, lower margins united around stem. *Spike* inclined, flexuose, (1)2- to 4-flowered; bracts green to dark grey-green with broad membranous margins, outer (20–)28–33(–50) mm long, inner shorter, notched apically. *Flowers* pale blue streaked, speckled, and feathered with purple, lower 3 tepals white to yellow below and more strongly marked than upper, base of tepals and upper part of tube speckled with red spots, lightly sweet-scented; perianth tube obliquely funnel-shaped, 12–15 mm long, lower cylindric part enclosed in bracts; tepals narrowly lanceolate-attenuate, upper 3 larger than lower, dorsal usually largest, 26–39 × 9–18 mm, upper laterals ± 26–37 × 8–11 mm, curving outward distally, lower 3 tepals joined to upper laterals for ± 5 mm and together for ± 3 mm, slightly narrowed and deeply channelled in lower ½, lower laterals 18–30 mm long, lower median longer than laterals, 24–32 mm long, all curving outward above. *Filaments* 13–15 mm long, exserted 5–10 mm from tube but included in flower; anthers 9–11 mm long, pale grey; pollen whitish. *Style* arching over stamens, dividing between upper ⅓ and

Distribution of ***Gladiolus atropictus***.

Distribution of ***Gladiolus violaceolineatus***.

tips of anthers, branches ± 3.5 mm long. *Seeds* ovate, 7–8 × 5–6 mm, broadly and evenly winged. *Flowering time*: July to mid-August, occasionally later at higher elevations.



Distribution and ecology: a narrow endemic of the western mountains of Western Cape, South Africa, from Gifberg along the Pakhuis Mtns and Cederberg to Elandskloof near Citrusdal and on the Olifantsrivier Mtns near Clanwilliam; on cooler, south-facing rocky sandstone slopes.

Diagnosis: recognised by the conic corms, four leaves with unusual 3-angled blades with the adaxial margin winged at right angles to the blade proper, and distinctive purple-streaked flowers with attenuate tepals. The attenuate tepals and puberulous upper cataphyll suggest a relationship with yellow-flowered *Gladiolus comptonii* from the Heerenlogement Mtn near the coast.

120. **Gladiolus comptonii** *G.J.Lewis* in Lewis et al. in Journal of South African Botany, Suppl. 10: 235 (1972). Type: South Africa, [Western Cape], Heerenlogement Mtn, 26 July 1963, *Lewis 6144* (NBG, holo.; K, MO, iso.).

Plants 300–450 mm high, with cataphylls minutely puberulous. *Corm* globose-ovoid, 15–20 mm diam.; tunics leathery, fragmenting into coarse fibres. *Stem* erect, flexed outward above sheaths of 2 or 3 upper leaves and inclined in upper ⅓, unbranched. *Leaves* 4, lower 1 or 2 basal, lowermost sheathing lower ½ of stem, sheath minutely puberulous, reaching to base of spike, linear, 1.5–3.0 mm wide, straight, main vein and margins lightly raised, remaining leaves progressively shorter, lower margins united around stem. *Spike* inclined, flexuose, (1)2- or 3-flowered; bracts green to dark grey-green with broad membranous margins, attenuate, outer 35–60 mm long, inner shorter, lightly notched. *Flowers* bright yellow, upper tepals streaked and spotted reddish in lower ⅓, lower lateral tepals streaked and spotted with brown below, lightly sweet-scented; perianth tube obliquely funnel-shaped, 11–14 mm long, lower cylindric part enclosed in bracts; tepals narrowly lanceolate-attenuate, upper 3 subequal or dorsal slightly larger, dorsal 40–50 × 13–15 mm, upper laterals 36–44 mm long, curving outward distally, lower 3 tepals joined to upper laterals for ± 4 mm and together for ± 4 mm, slightly narrowed and deeply channelled below, lower laterals 33–40 × 8–9 mm, lower median slightly longer, 34–42 × 11–13 mm, all curving outward and downward distally. *Filaments* ± 13 mm long, exserted 8–10 mm from tube but hidden in flower; anthers 9–11 mm long, yellow; pollen yellow. *Style* arching over stamens, dividing between upper ⅓ and anther apices, branches 4–5 mm long. *Capsules* ellipsoid, subacute, 12–15 mm long. *Seeds* ovoid, 7–8 × 4–5 mm, broadly and evenly winged. *Flowering time*: mid- to late July, possibly also in late June.

Distribution and ecology: a winter-flowering species known only from the Heerenlogement Mtn near Graafwater in Western Cape, South Africa; on the cooler, upper southern slopes in rocky situations in fynbos at 600–700 m elevation.

Distribution of ***Gladiolus comptonii***.

Diagnosis: recognised by the four narrow leaves and the canary-yellow flowers with attenuate tepals, the upper laterals characteristically strongly recurved. The attenuate tepals and puberulous upper cataphyll suggest a relationship with mauve-flowered *Gladiolus violaceolineatus* from the Cederberg and adjacent mountains.

121. **Gladiolus roseovenosus** *Goldblatt & J.C.Manning*, *Gladiolus* in southern Africa: 238 (1998). Type: South Africa, [Western Cape], near Ruitersbos Forest Station, 1 Mar. 1982, *Vlok 347* (MO, holo.).

Plants 350–500 mm high, with cataphylls green or purple sometimes lightly mottled with white. *Corm* ± globose, ± 15 mm diam.; tunics firm-papery becoming fibrous. *Stem* erect, flexed outward above sheath of uppermost or upper 2 leaves, erect above, unbranched. *Leaves* 4, lowermost basal and reaching to between lower ⅓ and middle of stem, blade short to vestigial, up to 75 mm long, linear, 1.5–2.0 mm wide, margins and main vein lightly thickened, upper leaves progressively smaller, largely sheathing, uppermost with lower margins united around stem. *Spike* erect, lightly flexuose, 2- to 4-flowered; bracts pale green, outer 25–45 mm long, inner slightly shorter, forked apically. *Flowers* creamy pink mottled and streaked with dark pink on reverse, lower 3 tepals feathered with red on veins, sometimes becoming ± solid red below, unscented; perianth tube narrowly funnel-shaped, 36–44 mm long, curving forward and widened above, cylindric lower part 26–34 mm long, enclosed in bracts; tepals lanceolate, margins undulate, dorsal largest, arching over stamens, 34–37 × 18–26 mm, curving upward distally, upper laterals curving outward distally, 33–38 × 12–14 mm, lower 3 tepals joined to upper laterals for 9 mm and together for ± 2 mm, ± 27 × 11 mm, lower median slightly larger than laterals. *Filaments* 15–17 mm long, exserted 6–8 mm from tube; anthers 8–11 mm long, purple, reaching only

Distribution of ***Gladiolus roseovenosus***.

to middle of dorsal tepal; pollen cream-coloured. *Style* arching over stamens, dividing at or up to 5 mm beyond anther tips, branches 6–8 mm long. *Capsules* and *seeds* unknown. *Flowering time*: mid-February to April.

Distribution and ecology: a poorly known and local endemic of the southern foothills of the Outeniqua Mtns in Western Cape, South Africa, from the foot of Robinson's Pass near Mossel Bay to George; in peaty sandstone soil in grassy fynbos.

Diagnosis: an autumn-flowering species with short, linear leaves and large, pinkish flowers with relatively long perianth tube, 36–44 mm long and slightly longer than the dorsal tepal.

122. **Gladiolus carinatus** *Ait.*, Hortus Kewensis 1: 64 (1789). *G. odorus* Salisbury: 40 (1796), illegitimate superfluous name for *G. carinatus* Ait. Type: South Africa, without precise locality, ex Hort. Kew, 1781, *Masson s.n.* (BM, holo.).

Gladiolus tenellus Jacq.: 255 (1791). Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 248 (1792 [1788–1795]).

Gladiolus punctatus Jacq.: 160 (1791). Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 247 (1794 [1788–1795]).

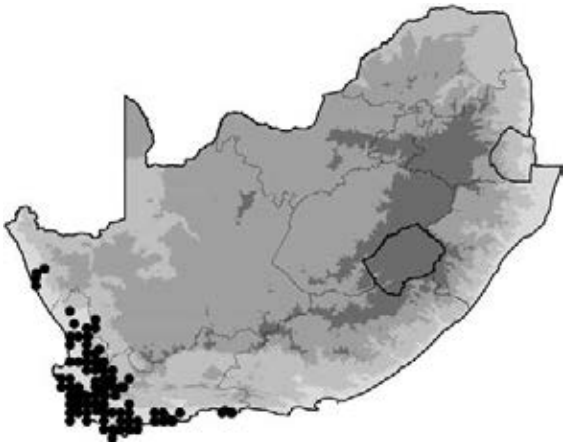
Gladiolus tristis var. *inodorus* Thunb.: 11 (1784). Type: South Africa, without precise locality, *Thunberg s.n.* (UPS-THUNB 1082, 1083, syn.).

Gladiolus laevis Thunb.: 184 (1800). Type: South Africa, without precise locality, *Thunberg s.n.* (UPS-THUNB 1038, holo.).

Gladiolus tristis var. *humilis* Thunb.: 8 (1784). Type: South Africa, without precise locality, *Thunberg s.n.* (UPS-THUNB 1075, holo.).

Gladiolus tristis var. *luteus* Thunb.: 8 (1784). Type: South Africa, without precise locality, *Thunberg s.n.* (UPS-THUNB 1076, holo.).

Gladiolus ringens Andrews: t. 27 (1798b) [as *G. ringens* var. *cinereo-odorata*]. *G. violaceus* Pers., illegitimate superfluous name for *G. ringens* Andrews. Type: South Africa, without precise locality or collector, illustration in Andrews: t. 27 (1798b).



Gladiolus suaveolens Zeyh. ex Klatt: 711 (1864), illegitimate homonym, not *G. suaveolens* Ker Gawl. (1827), illegitimate superfluous name. Type: South Africa, Western Cape, near Constantia, *Ecklon & Zeyher Irid. 150* (G, MO, S, syn.).

Gladiolus nivenii Baker: 210 (1892), as a replacement name at species rank for *G. ringens* var. *undulatus* Andrews: t. 275 (1803). Type: South Africa, without precise locality, *J. Niven s.n.* cult. Great Britain, illustration in Andrews: t. 275 (1803).

Gladiolus superans N.E.Br.: 467 (1932b). Type: South Africa, [Western Cape], Riversdale District, 1932, *Muir 4850* (K, holo.).

Plants 200–500(–1 000) mm high, with cataphylls purple mottled with white. *Corm* globose, 12–18 mm diam.; tunics leathery to ± woody, fragmenting into narrow strips or coarse fibres. *Stem* erect below, flexed outward above sheaths of 2 upper leaves, unbranched. *Leaves* 3, lowermost usually shortly exceeding spike, linear, (1–)3–9 mm wide, main vein lightly to moderately thickened, margins not or very little thickened, second leaf sheathing lower ½ of stem, channelled or with short blade, uppermost leaf inserted on upper ⅓ of stem, margins united below. *Spike* inclined, lightly flexuose, (1)4- to 6(10)-flowered; bracts pale green or greyish or flushed with purple, veins and margins translucent, outer 25–35(–65) mm long, inner shorter, lightly notched apically. *Flowers* pale to mid-blue to grey or pale yellow, rarely purple or pink, lower tepals with yellow band across upper third or yellow in lower ⅔, sometimes also streaked below and above with dark purple to blue, usually intensely scented of freesias or violets; perianth tube obliquely funnel-shaped, 13–16 mm long, lower cylindric part 5–7 mm long; tepals ovate to lanceolate, dorsal largest, arching forward, recurved apically, 24–30(–38) × (11–)17–20(–26) mm, upper laterals ± equal or slightly smaller, 22–34 × 14–18 mm, curving outward distally, lower 3 tepals joined to upper laterals for up to 5 mm and together for 4–6 mm, 18–25 × 7–13 mm, widest in upper ⅓, laterals deeply channelled below with margins ± vertical. *Filaments* 11–15 mm long, exserted 5–6 mm from tube; anthers 8–10 mm long, cream-coloured; pollen cream-coloured. *Style* arching over stamens, dividing near anther apices, branches 3–4 mm long. *Capsules* oblong to ellipsoid, acute, 20–25 mm long. *Seeds* oblong, 6–8 × 5–7 mm, broadly and evenly winged. *Flowering time*: June to mid-September.

Distribution and ecology: widely distributed through the southwestern part of Western Cape, South Africa, from the Bokkeveld Escarpment to near Knysna, and also recorded along the Namaqualand Coast at Hondeklipbaai and Kleinsee in Northern Cape; in deep sandy soils or alluvial washes among Restionaceae.

Distribution of ***Gladiolus carinatus***.

Distribution of ***Gladiolus griseus***.

Diagnosis: recognised by the conspicuously mottled cataphylls, three linear leaves with lightly thickened midrib, and relatively large, funnel-shaped flowers, usually pale to mid-blue but rarely pink or yellowish, the dorsal tepal 24–38 mm long. Blue-flowered plants are most common and are widespread through the coastal areas; yellow-flowered plants are largely restricted to montane and interior areas. Winter-flowering *Gladiolus griseus* from neutral and calcareous sands along the southwest coast has smaller, greyish flowers with perianth tube 6–10 mm long and dorsal tepal 16–26 mm long.

123. **Gladiolus griseus** *Goldblatt & J.C.Manning*, *Gladiolus* in southern Africa: 242 (1998). Type: South Africa, [Western Cape], Melkbos, 21 June 1959, *Horrocks 9* (NBG, holo., iso.).

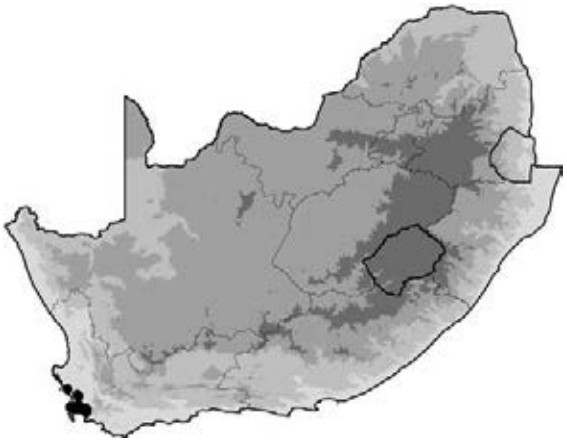
Gladiolus tristis var. *permeabilis* Thunb.: 13 (1784). *G. carinatus* subsp. *parviflorus* G.J.Lewis in Lewis et al.: 216 (1972), replacement name at subspecific rank [not *G. parviflorus* Jacq. (1771)]. Type: South Africa, [Western Cape], Paarden Island, Cape Peninsula, *Thunberg s.n.* (UPS-THUNB 1058, holo. [photo at BOL]).

Plants 200–800 mm high, with cataphylls purple mottled with white above ground. *Corm* globose, 8–15 mm diam.; tunics papery, decaying into soft-textured fibres. *Stem* erect below, flexed outward above sheaths of upper 2 leaves, unbranched. *Leaves* 3, lowermost usually shortly exceeding spike, linear, 2.0–7.5 mm wide, main vein lightly to moderately thickened, margins not or very little thickened, second leaf sheathing lower ½ of stem, blade fairly short, uppermost leaf shortest and inserted on upper ⅓ of stem, margins united below. *Spike* inclined, lightly flexuose, (3)6- to 15-flowered; bracts pale green or greyish green or flushed purple, veins and margins translucent, outer 25–35(–40) mm long, inner slightly shorter, minutely notched apically. *Flowers* greyish mauve to greenish grey, lower tepals with yellow band across upper ⅓ edged green and maroon, usually with light sweet scent; perianth tube obliquely funnel-shaped, 6–10 mm long, lower cylindric part 3–5 mm long; tepals with dorsal largest, arching forward, recurved apically, 16–26 × 11–17 mm, upper laterals ± equal or slightly smaller, 15–21 × 10–14 mm, scarcely curving outward distally, lower tepals joined to ± laterals for 2–3 mm and to one another for up to 3.5 mm, 13–16 × ± 6 mm, widest in upper ⅓, lower laterals deeply channelled below with margins ± vertical. *Filaments* 5–9 mm long, exserted 3–6 mm from tube; anthers 7.0–9.5 mm long, cream-coloured; pollen cream-coloured. *Style* arching over stamens, dividing between middle and upper ⅓ of anthers, branches ± 2 mm long. *Capsules* oblong to ellipsoid, acute, 15–20(–25) mm long. *Seeds* ovate, ± 7 × 4–5 mm, broadly and evenly winged. *Flowering time*: late May to July.

Distribution and ecology: a rare species of the Atlantic coast of Western Cape, South Africa, from St Helena Bay to False Bay; in neutral or calcareous sands in coastal scrub or sometimes among Restionaceae.

Diagnosis: a winter-flowering species with conspicuously mottled cataphylls, three linear leaves with lightly thickened main veins, and small, greyish flowers with short perianth tube 6–10 mm long and dorsal tepal 16–26 mm long. *Gladiolus carinatus* from acid sands along the coast and inland has larger, blue to pink or yellow flowers with a perianth tube 13–16 mm long, dorsal tepal 24–38 mm long and filaments 11–15 mm long.

124. **Gladiolus quadrangulus** *(D.Delaroche) Barnard* in Goldblatt in Journal of South African Botany 36: 300 (1970). *Ixia quadrangula* D.Delaroche: 16 (1766) [*I. quadrangularis* Burm.f.: 1 (1768), orthographic variant]. *Trichonema quadrangulum* (D.Delaroche) Sweet: 399 (1826). *Geissorhiza quadrangula* (D.Delaroche) Ker Gawl.: 88 (1827). Type: South Africa, [Western Cape], Cape Flats, Isoetes Vlei, waterlogged sandy soil, 22 Sept. 1970, *Goldblatt 525* (BOL, neo.; BOL, K, iso.).



Ixia linearis L.f.: 92 (1782). *Morphixia linearis* (L.f.) Ker Gawl.: 106 (1827). *Gladiolus linearis* (L.f.)

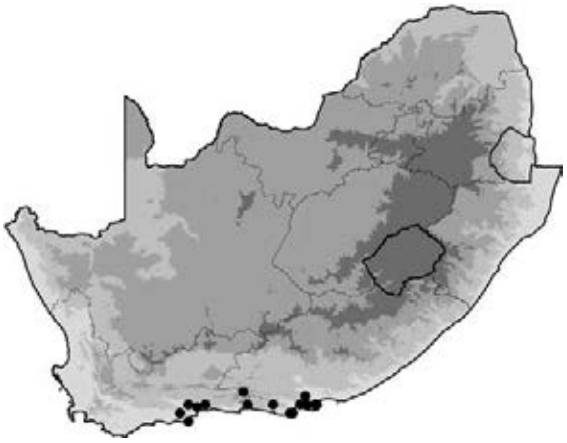
N.E.Br.: 48 (1928). Type: South Africa, Western Cape, flats between Cape Town and Stellenbosch, *Thunberg s.n.* (UPS-THUNB 964, holo.).

Gladiolus biflorus Klatt: 197 (1885), illegitimate homonym, not *G. biflorus* Thunb. (1784). Type: South Africa, [Western Cape], Cape Flats near Wynberg, seasonally flooded sandy ground, Sept. 1884, *MacOwan 2279* (S, ? holo.; B, BOL, G, K, P, SAM, UPS, iso.).

Plants 140–350(–450) mm high, with cataphylls purplish to dry and brown with white spots. *Corm* globose, 10–15 mm diam.; tunics firm-papery to softly leathery, fragmenting into narrow strips. *Stem* erect, unbranched, straight or lightly flexed above. *Leaves* 3, lower 2 basal, lowermost as long as or slightly longer than spike, linear, thickest in midline, margins not thickened or raised, 1–2 mm wide, second leaf sheathing lower half of stem, uppermost leaf inserted on upper ⅓ of stem, margins of sheathing part united around stem. *Spike* straight and erect, 2- to 5(8)-flowered; bracts pale green, veins and margins translucent, outer 27–33(–45) mm long, inner shorter. *Flowers* actinomorphic, star-like, pale pink, mauve, or white, tepals with darker veins and often with dark median streak toward base, lightly scented of narcissus, closing tightly in midafternoon; perianth tube narrowly funnel-shaped, 6–10 mm long, lower cylindric part filiform, 4–6 mm long, tightly enclosing style; tepals subequal or outer slightly larger than inner, ovate to broadly lanceolate, 18–25 × 7–12 mm. *Filaments* erect and symmetrically disposed, ± 5 mm long; anthers 7–8 mm long, yellow; pollen yellow. *Style* erect and central, dividing just below anther apices, branches 3–4 mm long. *Capsules* ellipsoid, 13–16 mm long. *Seeds* ovate, 4–6 × ± 4 mm, broadly and evenly winged. *Flowering time*: mid-August to mid-September, occasionally in early October.

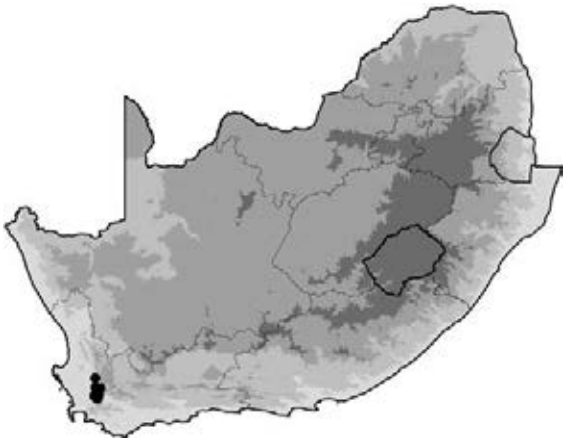
Distribution and ecology: a rare and local endemic of the coastal forelands around Cape Town in Western Cape, South Africa, from near Yzerfontein to Strand but locally extinct in parts of its range; in seasonal wetlands and vleis. The flowers close tightly in mid-afternoon.

Distribution of ***Gladiolus quadrangulus***.



Diagnosis: recognised by the conspicuously mottled cataphylls, three linear leaves with lightly thickened midrib, and radially symmetric, mauve to pink (rarely white) flowers with darker veins.

Ser. **Mutabili** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus mutabilis* G.J.Lewis



Plants from winter-rainfall region. *Corms* ovoid to subglobose; tunics papery to fibrous. *Leaves* green at flowering, often short, linear, plane, subsucculent or leathery, midrib and margins not at all thickened. *Flowers* medium, bilabiate, perianth tube shorter than to longer than dorsal tepal, tepals acute to attenuate, lower tepals sometimes channelled below.

125. **Gladiolus mutabilis** *G.J.Lewis* in Lewis et al. in Journal of South African Botany, Suppl. 10: 230 (1972), as a replacement name for *G. muirii* L.Bolus in Annals of the Bolus Herbarium 3: 181 (1924), illegitimate homonym, not *G. muirii* L.Bolus (1915). Type: South Africa, [Western Cape], Riversdale District, without precise locality, *Muir 1412* [BOL, lecto., designated by Lewis et al.: 230 (1972)].

Plants 250–500 mm high. *Corm* elongate-obconic, 8–10 mm diam.; tunics cartilaginous, decaying into firm strips and ultimately coarsely fibrous. *Stem* erect, flexed outward above sheaths of upper 2 or 3 leaves, unbranched. *Leaves* 4, lowermost basal, sheathing lower ⅓ of stem, ± linear, at least 50 mm long or reaching to top of spike, leathery or subsucculent, margins and main vein not thickened or raised, remaining leaves cauline, inserted between middle and upper ⅓ of stem, progressively shorter, all with short blades, imbricate and enclosing stem nearly to base of spike. *Spike* inclined, lightly flexuose, 2- to 5-flowered; bracts pale green, glaucous, outer elongate and attenuate, 25–40(–50) mm long, inner shorter. *Flowers* pale or dark blue, mauve, or brownish to cream-coloured shaded with brown, lower 3 tepals yellow across midline or in lower ⅔ and lightly and irregularly lined and spotted with purple to brown, sweetly scented of violets; perianth tube obliquely funnel-shaped, 13–17 mm long, usually completely enclosed in bracts; tepals with upper 3 larger than lower, obovate, lower laterals oblanceolate, margins undulate to crisped, dorsal arched to hooded over stamens, upper edges recurved, 25–32 × 14–16 mm, upper laterals curving outward distally, lower tepals united with upper laterals for 6–10 mm and together for 2–3 mm, lower laterals 16–28 × 7–9 mm, tapering and channelled below, lower median 16–25 × 12–14 mm. *Filaments* 10–15 mm long, exserted 4–5 mm from tube; anthers 9–11 mm long, lilac to cream-coloured; pollen pale yellow. *Style* arching over stamens, dividing just below to shortly above anther apices, branches ± 3 mm long. *Capsules* ellipsoid, ± 15 mm long. *Seeds* ovate, ± 5 × 3 mm, broadly evenly winged. *Flowering time*: May to July, rarely in August.

Distribution of ***Gladiolus mutabilis***.

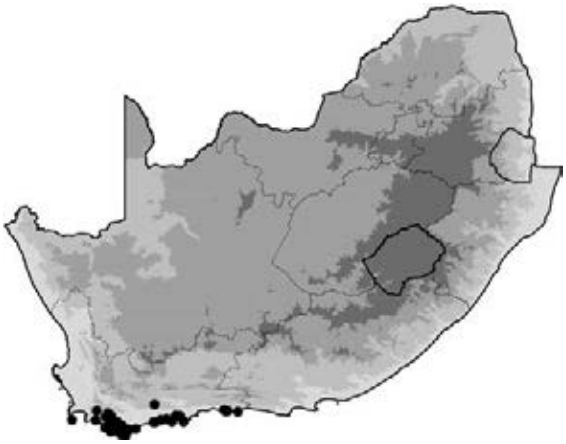
Distribution of ***Gladiolus exilis***.

Distribution and ecology: scattered along the south coast, from Albertinia to Mossel Bay in Western Cape, South Africa and further east from west of Humansdorp to Grahamstown in Eastern Cape; in loamy and stony sandstone soils.

Diagnosis: recognised by the elongate-obconic corm with four, linear, sometimes short-bladed, leathery or subsucculent leaves with the midrib and margins not thickened or raised, and the funnel-shaped flowers with perianth tube shorter than the dorsal tepal. *Gladiolus exilis* from the mountains on the West Coast has three leaves.

126. **Gladiolus exilis** *G.J.Lewis* in Lewis et al. in Journal of South African Botany, Suppl. 10: 229 (1972). Type: South Africa, [Western Cape], Wellington, near top of Bain's Kloof Pass, west-facing slopes, 20 May 1962, *Barnard s.n. NBG 62038* (NBG, holo.).

Plants 300–600 mm high. *Corm* ovoid, 12–15 mm diam.; tunics leathery, becoming finely fibrous. *Stem* slender, usually lightly flexed above sheaths of leaves and inclined above, unbranched. *Leaves* 3, lowermost basal, sheathing lower ½ of stem, reaching ± upper ⅓ of stem, blade linear, (50–)80–120 mm long, 1.0–1.5 mm wide, plane and slightly succulent, margins and main vein not thickened or raised, remaining leaves inserted on upper ⅓ of stem, much shorter than basal and slightly narrower. *Spike* inclined, weakly flexuose, 1- to 4-flowered; bracts greyish green, relatively soft-textured, outer 20–30 mm long, often attenuate and twisted, inner slightly shorter to ± as long, usually minutely forked apically. *Flowers* pale blue-mauve to whitish barely flushed with mauve, lower lateral tepals with narrow, pale yellow median streak in lower half, all 3 lower tepals irregularly streaked and speckled with dark mauve, usually lightly violet-scented; perianth tube obliquely funnel-shaped, 11–15 mm long, lower cylindric part 7–10 mm long; tepals lanceolate, dorsal 22–35 × 11–18 mm, extending ± horizontally over stamens, curved upward distally, upper laterals 22–33 × 10–15 mm, slightly spreading above, lower 3 tepals joined to upper laterals for 5–8 mm and together for 3–4 mm, laterals 16–28 × ± 6 mm, narrow below and becoming channelled toward base, lower median 18–28 × ± 9 mm. *Filaments* 11–12 mm long, exserted 5–7 mm from tube; anthers 8–10 mm long, pale mauve; pollen whitish. *Style* arching over stamens, dividing at or just beyond anther apices, branches ± 3 mm long. *Capsules* ellipsoid, 12–15 mm long. *Seeds* ovate, ± 6 × 4 mm, broadly and evenly winged. *Flowering time*: April and May.



Distribution and ecology: an early-flowering species restricted to the mountains northeast of Cape Town in Western Cape, South Africa, from the Groot Winterhoek Mtns and the Witzenberg to Bain's Kloof and the Slanghoek Mtns near Rawsonville; in loamy soils on rocky sandstone slopes.

Diagnosis: distinguished by the three, linear to almost filiform, short-bladed leathery leaves without thickened midrib and margin, and funnel-shaped pale blue to whitish flowers with the perianth tube shorter than the dorsal tepal. Related *Gladiolus mutabilis* from the south coast has four leaves.

127. **Gladiolus vaginatus** *F.Bolus* in Annals of the Bolus Herbarium 2: 103 (1917). Type: South Africa, [Western Cape], Albertinia, Apr. 1914, *Muir 1287* (BOL, holo.; K, iso.).

Gladiolus vaginatus var. *subtilis* Oberm. in Lewis et al.: 273 (1972). Type: South Africa, [Western Cape], 16 km west of Elim on road to Gansbaai, '*Gladiolus delicatus*,' Lewis ms., 15 Apr. 1962, *Lewis 5956* (NBG, holo.; MO, iso.).

Plants (220–)300–550(–1 050) mm high. *Corm* globose to slightly depressed-globose, 18–30 mm diam.; tunics thin and papery, decaying into fine fibres. *Stem* straight and erect, unbranched, continuing to elongate after flowering, remaining green for several months. *Leaves* 2, lowermost basal and entirely sheathing lower ⅔ of stem, blade completely suppressed, upper leaf reduced to sheathing scale 16–20 mm long, inserted above basal

Distribution of ***Gladiolus vaginatus***.

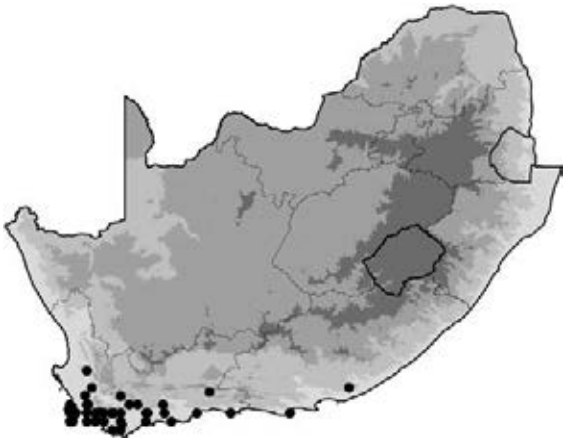
leaf, margins overlapping; leaves of non-flowering plants and seedlings solitary, linear, slightly succulent, 1.0–1.5 mm wide. *Spike* flexed at base and inclined, lightly flexuose, 2- to 6(12)-flowered; bracts grey to purplish green, outer 15–20 mm long, inner slightly shorter or ± as long, acute or minutely forked apically. *Flowers* pale blue, lower tepals streaked and dotted with purple on a cream-coloured to yellow background, throat yellow and minutely speckled with red-purple, usually with a light sweet scent; perianth tube obliquely funnel-shaped, 6.5–20.0 mm long, wider upper part 3–8 mm long; tepals with dorsal largest, ovate to lanceolate, arching over stamens to nearly horizontal, 18–27 × 8–13 mm, upper laterals spreading in upper ½, 17–23 × 6.5–10.0 mm, lower 3 tepals united with upper laterals for 2.5–4.0 mm and together for 3–6 mm, free parts lanceolate, 12–20 × 5–8 mm, narrowed and channelled below. *Filaments* 8–14 mm long, exserted 5–8 mm from tube; anthers 5.5–11.0 mm long, mauve; pollen pale mauve. *Style* arching over stamens, dividing opposite middle of anthers, branches 2–4 mm long. *Capsules* broadly ovoid, obtuse, 10–13 mm long. *Seeds* oblong, 7 × 4 mm, broadly and evenly winged. *Flowering time*: March and April.

Distribution and ecology: largely restricted to the coastal forelands of Western Cape, South Africa, from the southern Cape Peninsula to Knysna, extending inland to Villiersdorp; mostly on calcareous sands and limestone outcrops but also gravelly clay inland. The stem and sheathing leaves remain green and photosynthetic throughout the winter months.

Diagnosis: recognised by the two bladeless leaves, the lowermost sheathing the lower two thirds of the stem and the upper reduced to a sheathing bract or scale. The funnel-shaped flowers are pale blue to white, with a perianth tube shorter than to ± as long as the dorsal tepal.

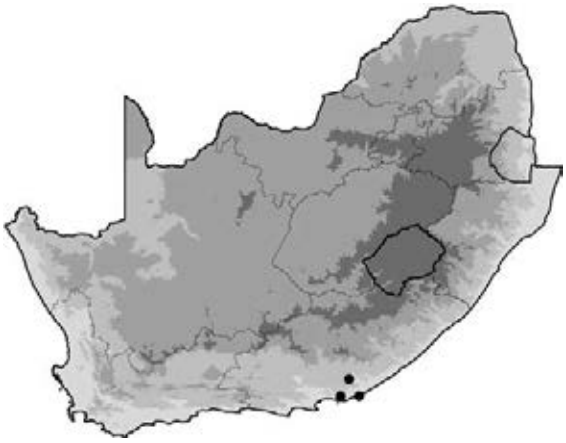
128. **Gladiolus maculatus** *Sweet*, Hortus britannicus: 397 (1826), replacement name at species rank for *G. versicolor* var. *tenuior* Ker Gawl.: t. 556 (1802a). *G. suaveolens* Ker Gawl.: 136 (1827), illegitimate superfluous name for *G. maculatus* Sweet [based on same type]. Type: South Africa, without precise locality, cult. Great Britain, illustration in Ker Gawl.: t. 556 (1802a).

Gladiolus versicolor var. *inaequalis* Ker Gawl.: t. 556 (1802a). *G. breynianus* Ker Gawl.: 135 (1827), replacement name at species rank and superfluous name for *G. pterophyllus* Pers. (1805). Type: South Africa, without precise locality, *Masson s.n.* [BM, lecto., designated by Lewis et al.: 260 (1972)].



Gladiolus versicolor var. *binervis* Ker. Gawl.: t. 1042 (1807). *G. binervis* (Ker Gawl.) Sweet: 397 (1826). Type: South Africa, without precise locality or collector, illustration in Ker. Gawl.: t. 1042 (1807).

Gladiolus vaginatus var. *fergusoniae* L.Bolus: 215 (1929b). Type: South Africa, [Western Cape], Riversdale District, Still Bay, May 1929, *Ferguson s.n. BOL 18922* (BOL, holo.).



Gladiolus hibernus Ingram: 9 (1931c). *G. maculatus* subsp. *hibernus* (Ingram) Oberm. in Lewis et al.: 263 (1972). Type: South Africa, without precise locality, *Ingram s.n.,* (BM, ?holo. [illustration]).

Plants 300–800 mm high. *Corm* globose, 10–20 mm diam.; tunics papery, becoming fibrous. *Stem* erect, lightly flexed above sheaths of upper 2 leaves, unbranched. *Leaves* 3 or 4, lower 2 basal, lowermost sheathing lower ½ of stem, short, rarely reaching above base of spike, linear, leathery or subsucculent, margins and main vein not raised or thickened, remaining leaves inserted between middle and upper ⅓ of stem, progressively shorter. *Spike* usually flexed at base and inclined, flexuose, 1–3(5)- flowered; bracts green or greyish to dull purple, soft-textured, outer 30–50(–65) mm long, inner shorter than to ± as long. *Flowers* dull yellow to lilac, densely to lightly speckled throughout with small to large, pale to dark brown or purplish spots, often darkest toward tepal apices, dorsal tepal ± transparent below apices on either side of midline, strongly and sweetly scented both day and night; perianth tube obliquely funnel-shaped, 23–35(–48) mm long, lower cylindric part 15–25 mm long, with papillose zones in lower throat opposite lower tepals; tepals lanceolate-attenuate, margins undulate, dorsal slightly larger, 25–33 × 13–19 mm, extending ± horizontally over stamens, upper laterals curving outward in upper ½, 25–33 mm long, lower 3 tepals joined to upper laterals for 5–7 mm and together for 1–2 mm, free parts 23–33 mm long, curving downward in upper ½. *Filaments* 13–16 mm long, exserted 4–6 mm from tube; anthers 8–11 mm long, brown to cream-coloured; pollen yellow. *Style* arching over stamens, dividing slightly below to slightly beyond anther apices, branches 2–3 mm long. *Capsules* ovoid-ellipsoid, ± 12 mm long. *Seeds* ovate, 5–6 × 3–4 mm, broadly and evenly winged. *Flowering time*: April to June, occasionally later.

Distribution and ecology: widespread through the southern coast and near interior of Western Cape, South Africa,

Distribution of ***Gladiolus maculatus***.

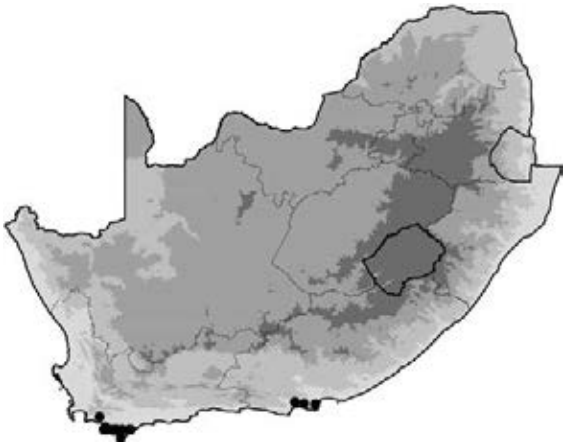
Distribution of ***Gladiolus albens***.

extending from the Cape Peninsula north to the Cederberg and east in Eastern Cape to Grahamstown and Alexandria; in clay or loamy soils in renosterveld shrubland or in transitional fynbos, flowering mainly in winter.

The species hybridises with *Gladiolus priorii* on the Cape Peninsula.

Diagnosis: recognised by the three or four linear leaves with short, subsucculent blades without thickened midrib and margins, and the fragrant, mottled flowers with narrowly funnel-shaped perianth tube 23–35(–48) mm long and longer than the dorsal tepal. The flowers are highly variable in colour and intensity of mottling *Gladiolus albens* from Port Elizabeth to Alexandria has unmarked white flowers with a mostly longer perianth tube (35–)45–65 mm long.

129. **Gladiolus albens** *Goldblatt & J.C.Manning*, *Gladiolus* in southern Africa: 250 (1998), as a new name at species rank for *G. maculatus* subsp. *eburneus* Oberm. in Lewis et al.: 263 (1972). Type: South Africa, [Eastern Cape], Alexandria, 8 May 1931, *Galpin s.n.* (BOL [*BOL 19568*], holo.; K, iso.).



Plants 250–500(–700) mm high. *Corm* globose, 10–20 mm diam.; tunics papery, becoming fibrous. *Stem* erect, lightly flexed above sheaths of upper 1 or 2 leaves, unbranched. *Leaves* 3(4), lower 2 basal, lowermost sheathing lower ⅓–½ of stem, short, rarely longer, linear, up to 100 mm long, 1–2 mm wide, leathery or subsucculent, with 3 equal veins, margins not raised or thickened, remaining leaves inserted between middle and upper ⅓ of stem, progressively shorter. *Spike* flexed at base and inclined, flexuose, 1–3(5)-flowered; bracts green or greyish, soft-textured, outer 27–40(–45) mm long, inner shorter to ± as long. *Flowers* cream-coloured to white, sometimes with small speckles or faint red-brown streaks in throat or on tepals, with light, somewhat metallic, dusty sweet scent; perianth tube narrowly and obliquely funnel-shaped, (35–)45–65 mm long, lower cylindric part 25–42 mm long, gradually expanding in upper part; tepals ovate, margins lightly undulate, subequal, dorsal slightly larger, 23–35 × 12–21 mm, extending ± horizontally over stamens, upper laterals curving outward distally, 23–39 × 9–14 mm, lower 3 tepals joined to upper laterals for 5–6 mm and together for 1–2 mm, free parts 21–31 × 1–13 mm, curving downward distally. *Filaments* 12–15 mm long, exserted 3–6 mm from tube; anthers 9–12 mm long, cream-coloured; pollen yellow. *Style* arching over stamens, dividing close to or shortly beyond anther apices, branches 3–5 mm long. *Capsules* and *seeds* unknown. *Flowering time*: March to May, occasionally in February.

Distribution and ecology: a narrow endemic of Eastern Cape, South Africa, from Port Elizabeth to Alexandria and inland to Somerset East; on grassy slopes.

Diagnosis: distinguished from *Gladiolus maculatus*, in which it was once included a subspecies, by the unmarked, white to cream-coloured flowers with mostly longer perianth tube, (35–)45–65 mm long and well exserted from the bracts.

130. **Gladiolus meridionalis** *G.J.Lewis* in Annals of the South African Museum 40: 127 (1954). *G. maculatus* subsp. *meridionalis* (G.J.Lewis) Oberm. in Lewis et al.: 262 (1972). Type: South Africa, [Western Cape], Caledon District, south slopes of mountains near Danger Point, 28 Apr. 1948, *Linley s.n.* (SAM [*SAM 60214*], holo.; BOL, K, iso.).

Plants 300–800 mm high. *Corm* globose, 10–20 mm diam.; tunics papery to leathery, becoming fibrous. *Stem* erect, lightly flexed above sheaths of upper 2 leaves, unbranched. *Leaves* 3, lower 2 basal, lowermost sheathing lower ½ of stem, short, rarely reaching base of spike, linear, leathery, margins and main vein not raised or thickened, cauline leaves inserted between middle and upper ⅓ of stem, progressively shorter. *Spike* flexed at base and inclined, flexuose, 1- or 2(3)-flowered; bracts green or greyish to dull purple, soft-textured, outer 36–50 mm long, inner shorter to ± as long. *Flowers* pale

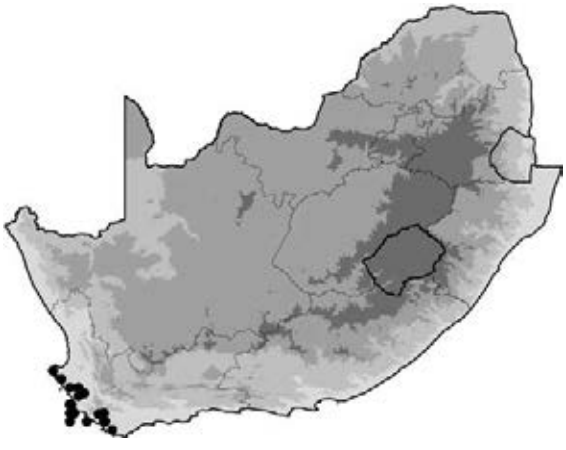
Distribution of ***Gladiolus meridionalis***.

to deep salmon-pink or cream-coloured, often with dark spots at base of lower tepals and in lower throat, faintly sweet-scented; perianth tube 40–48 mm long, slender and subcylindric below for ± 20 mm, upper part wide and cylindric; tepals ovate, subequal, dorsal 22–28 × 18–23 mm, extending ± horizontally over stamens, upper laterals 24–32 × 15–17 mm long, lower 3 tepals joined to upper laterals for 6–7 mm and to one another for ± 1 mm, free parts 20–28 mm long, curving downward in upper half. *Filaments* 28–40 mm long, exserted 3–4 mm from tube; anthers 9–10 mm long, light brown; pollen yellow. *Style* extending horizontally over stamens, dividing at or up to 5 mm beyond anther tips, branches ± 4 mm long. *Capsules* ovoid-ellipsoid, ± 12 mm long. *Seeds* ovate, ± 5 × 3 mm, broadly and evenly winged. *Flowering time*: April to June, occasionally in March or rarely later in year.

Distribution and ecology: with a highly discontinuous range in the southern part of South Africa, occurring between Gansbaai and Elim in Western Cape, and between Greenbushes and Bethelsdorp near Port Elizabeth in Eastern Cape; on sandstone slopes in fynbos near the coast.

Diagnosis: recognised by the three linear leaves with short, subsucculent blades without thickened midrib and margins, and the long-tubed, cream-coloured to pink flowers, the tube 40–48 mm long and slender and subcylindric in the lower half and widely cylindric in the upper half. Orange-flowered *Gladiolus priorii* from the west and southwest coast has narrower, oblong upper lateral and lower tepals 9–12 mm wide.

131. **Gladiolus priorii** *(N.E.Br.) Goldblatt & M.P.de Vos* in Adansonia 11: 421 (1990). *Antholyza priorii* N.E.Br.: 244 (1929b). *Homoglossum priorii* (N.E.Br.) N.E.Br.: 279 (1932a). Type: South Africa, [Western Cape], near Cape Town, open sites in scrub, July 1846, *Prior s.n.* (K, holo.).



Gladiolus hirsutus var. *tenuiflorus* Klatt: 713 (1864). Type: South Africa, [Western Cape], near Cape Town, without date, *Ecklon & Zeyher Irid. 152* (MO, syn.).

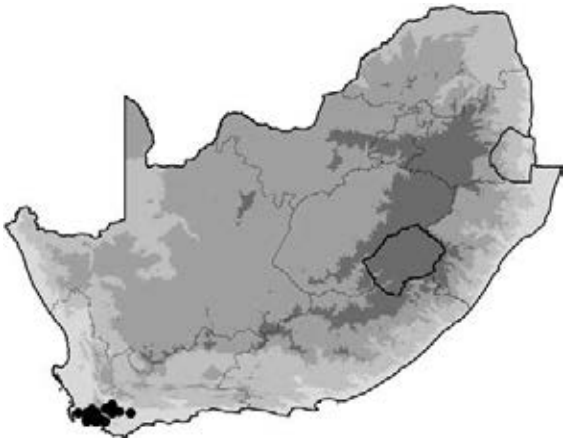
Plants 300–500(–700) mm high. *Corm* ovoid, 12–20 mm diam.; tunics papery, becoming softly fibrous. *Stem* erect, flexed outward above sheaths of upper 3 leaves, unbranched. *Leaves* (3)4, lowermost basal and sheathing lower ⅓–½ of stem, relatively short, rarely reaching base of spike, linear, up to 100 mm long, usually fairly fleshy, margins and main vein not raised or thickened, remaining leaves progressively shorter. *Spike* inclined, flexuose, 1- to 4(5)-flowered; bracts firm-textured, outer 25–40(–50) mm long, inner shorter to ± as long. *Flowers* scarlet, base of lower tepals and upper part of tube pale yellow or cream-coloured, unscented; perianth tube 30–46 mm long, slender and cylindric in lower 10–20 mm, abruptly expanded into a wider cylindric upper part 20–30 mm long; tepals lanceolate, dorsal largest, extending horizontally over stamens, 25–32 × 15–19 mm, upper laterals spreading ± from base, 22–32 × 10–12 mm, lower 3 tepals arching downward from base, 20–27 × 9–12 mm. *Filaments* 25–37 mm long, exserted 6–10 mm from tube; anthers 7.5–8.5 mm long, pale yellow; pollen yellow. *Style* extending horizontally over stamens, dividing between middle and upper ⅓ of anthers, 2.5–3.5 mm long. *Capsules* ellipsoid, acute, 12–15 mm long. *Seeds* ovate, 6–7 × ± 5 mm, broadly and evenly winged. *Flowering time*: May and June, occasionally in April or July.

Diagnosis and ecology: a species of rocky outcrops along the southwestern coast of Western Cape, South Africa, from Saldanha Bay to the Cape Peninsula, and east to Betty's Bay to Hermanus; often on granite but also sandstone ourcrops.

The species hybridises with *Gladiolus maculatus* on the Cape Peninsula.

Diagnosis: recognised by the three or four linear leaves with short, subsucculent blades without thickened midrib and margins, and the long-tubed, red to nearly orange flowers, the tube 30–46 mm long and slender and subcylindric in the lower half and widely cylindric

Distribution of ***Gladiolus priorii***.



in the upper half. With cream-coloured to salmon-pink flowers, *Gladiolus meridionalis* from the south coast has broader, ovate tepals 15–23 mm wide.

Ser. **Brevitubi** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus brevitubus* G.J.Lewis

Plants from winter-rainfall region. *Corms* subglobose; tunics fibrous. *Leaves* green at flowering, linear, midrib and margins lightly thickened, lower sheath scabridulous; bracts broadly ovate, obtuse. *Flowers* small, subactinomorphic, subrotate, perianth tube very short, tepals acute, lower tepals yellow at base.

132. **Gladiolus brevitubus** *G.J.Lewis* in Lewis et al. in Journal of South African Botany, Suppl. 10: 171 (1972), replacement name for *Tritonia ventricosa* Baker: 192 (1892) [not *G. ventricosus* Lam.]. Type: South Africa, [Western Cape], Appelskraal near Riviersonderend, Sept., *Zeyher 3793* (K, lecto., designated by Lewis et al.: 171 (1972), SAM, isolecto.).

Plants 120–400 mm high. *Corm* globose, 8–12 mm diam.; tunics of fine to medium-textured fibres, forming a short collar around base of stem. *Stem* erect or inclined, ± straight, unbranched. *Leaves* 3 or 4, lower 1 or 2 basal, lowermost usually somewhat longer than spike, sheath scabridulous, linear, 1.5–3.5 mm wide, main vein and margins lightly thickened, remaining leaves progressively shorter, upper 2 leaves largely to entirely sheathing. *Spike* inclined, flowers borne on upper side, lightly flexuose, 2- to 8-flowered; bracts green, broadly ovate and obtuse, margins often reddish, outer 10–13 mm long, inner slightly shorter to slightly longer. *Flowers* nearly actinomorphic, subrotate, orange to salmon or brick-red, lower lateral tepals yellow near base, with a light, sweet scent; perianth tube funnel-shaped, 2.5–4.0 mm long, papillate at throat; tepals subequal, outer whorl slightly larger than inner, ovate, 11–18 × 5.5–10.0 mm. *Filaments* unilateral, 2–3 mm long, reaching to ± mouth of tube, bases papillate; anthers 4–5 mm long, yellow; pollen yellow. *Style* straight, 4–5 mm long, dividing opposite base of anthers, branches 3–4 mm long. *Capsules* obovoid, 3-lobed apically and retuse, 8–11 mm long. *Seeds* oblong, 4.5–6.0 × 3.5–4.0 mm, broadly and evenly winged. *Flowering time*: late October and November, occasionally in early December.

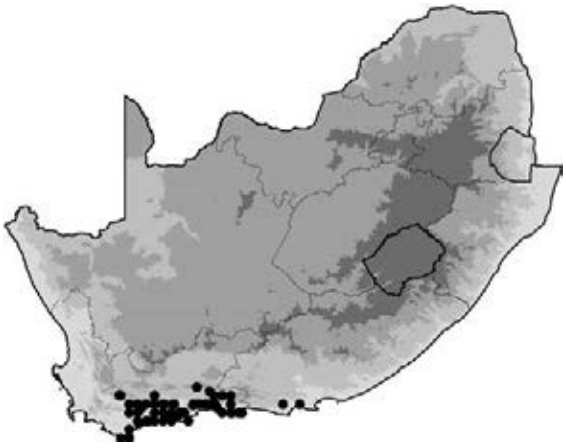
Distribution of ***Gladiolus brevitubus***.

Distribution and ecology: endemic to the southwestern mountains of Western Cape, South Africa, from the Hottentots Holland Mtns to the Riviersonderend and Kleinrivier Mtns in the east; on moist, south-facing sandstone slopes from 200 to 1 500 m elevation, flowering in late spring and early summer.

Diagnosis: a slender species with soft-textured, linear leaves, unusual ovate bracts, subequal tepals and subrotate, orange flowers with very short perianth tube, 2.5–4.0 mm long, enclosing the short, unilateral filaments.

Ser. **Graciles** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus gracilis* Jacq.

Plants from winter-rainfall region. *Corms* subglobose; tunics ± leathery and fragmenting into claws, or coarsely fibrous. *Leaves* green at flowering, linear, midrib and margins lightly thickened or margins winged and blade thus H-shaped. *Flowers* medium, zygomorphic, perianth tube usually shorter than dorsal tepal, tepals acute to attenuate or rarely obtuse, lower tepals usually streaked or spotted, sometimes blotched.



133. **Gladiolus rogersii** *Baker*, Handbook of the Ixideae: 208 (1892). Type: South Africa, [Western Cape], without precise locality (as Cape Flats), 1859, *Moyle Rogers s.n.* (K, holo.).

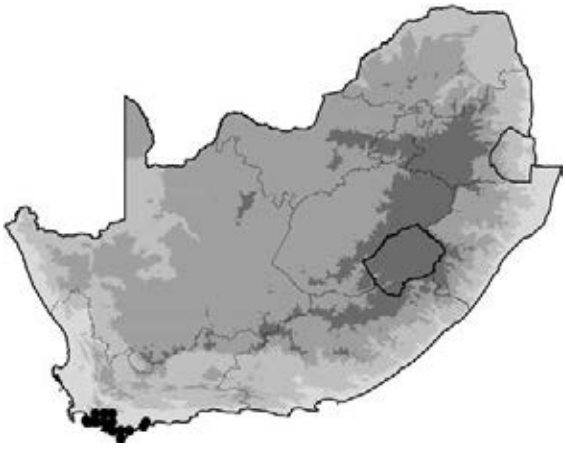
Gladiolus bolusii var. *burchellii* L.Bolus: 101 (1917). *G. burchellii* (L.Bolus) Ingram: 482 (1932). Type: South Africa, [Western Cape], Knysna District, west end of Groenvlei, 9 Aug. 1814, *Burchell 5631* (K, holo.).

Gladiolus rogersii var. *graminifolius* G.J.Lewis in Lewis et al.: 246 (1972). Type: South Africa, [Western Cape], Montagu District, Scheepersrus, 5 Aug. 1949, *Barker 5427* (NBG, holo.; BOL, iso.).

Gladiolus rogersii var. *vlokii* Goldblatt: 453 (1984). Type: South Africa, [Western Cape], Ruitersbos Forest Reserve in deep sand, 1 Mar. 1948, *Vlok 348* (NBG, holo.; MO, PRE, iso.).

Plants (200–)300–500(–650) mm high, with cataphylls purple or mottled with white or dry and dark brown, sometimes minutely velvety. *Corm* globose, 8–14 mm diam.; tunics usually papery or finely fibrous, occasionally fibres of medium texture, rarely coarse and claw-like below. *Stem* erect below, flexed outward above sheaths of 2 upper leaves and inclined above, unbranched. *Leaves* 3 or 4(5), lowermost or lower 2 reaching base or exceeding spike, linear (rarely ± ellipsoid in section), 1.5–4.0(–6.5) mm wide, straight, soft-textured to somewhat wiry, margins and main vein lightly to heavily thickened, cauline leaves inserted well above ground, progressively shorter, uppermost sometimes entirely sheathing,

Distribution of ***Gladiolus rogersii***.



margins usually united below. *Spike* inclined, (1)3- to 6-flowered; bracts green or flushed grey to purple with broad, transparent margins, diverging, outer 15–22 mm long, inner slightly smaller, minutely forked. *Flowers* inflated and bell-like, pale to dark blue or purple, darker on reverse of upper tepals, lower tepals lightly spotted with purple in lower ½ and with transverse or median yellow to white mark in upper ⅓ outlined or surrounded with dark blue to purple, usually lightly sweet-scented; perianth tube obliquely funnel-shaped, geniculate, 12–19 mm long, lower half erect and cylindric, upper half bent at right-angles and flaring outward; tepals with upper ovate, lower spathulate, dorsal largest, extending horizontally over stamens, obovate, 20–30 × 16–26 mm, upper laterals slightly shorter, curving slightly outward apically, lower 3 cupped with apices directed forward or downward, united for 5–9 mm with upper laterals, free parts 16–22 × 8–16 mm, not clearly divided into limb and claw, broadly obtuse or emarginate margins curved upward distally. *Filaments* 10–12(–15) mm long, exserted 5–8 mm from tube; anthers 5.5–9.0 mm long, blue; pollen cream-coloured. *Style* arching over stamens, dividing close to anther apices, branches ± 4 mm long. *Capsules* and *seeds* unknown. *Flowering time*: mainly late August to mid-October, occasionally to mid-November, exceptionally March to July.

Distribution and ecology: widespread along the southern coast of Soutb Africa, from the Agulhas Peninsula along the coastal plain and the Langeberg and Outeniqua Mtns in Western Cape to near Humansdorp in Eastern Cape, extending inland on Touwsberg; in fynbos on costal limestone flats and south-facing sandstone slopes up to 1 000 m elevation.

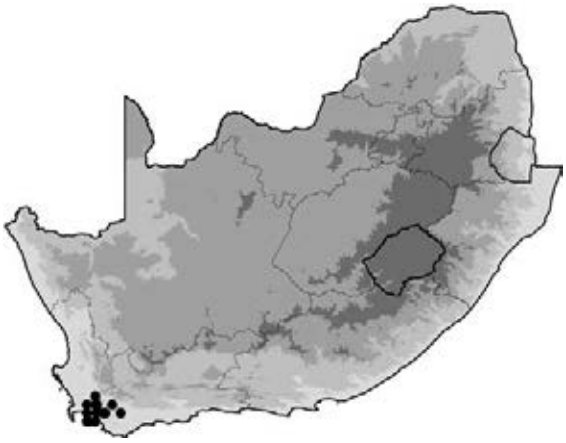
Diagnosis: a variable species with three to five linear leaves with the margin and midrib lightly thickened, rarely solidly oval in section, and inflated, bell-shaped, mauve to blue flowers with a short, sharply bent perianth tube 12–19 mm long. The lower tepals are typically marked with a white to yellow transverse band outlined with dark blue or purple.

134. **Gladiolus bullatus** *Thunb. ex G.J.Lewis* in Botaniska Notiser 119: 286 (1966) [as *G. bullatus* Thunb. ex N.E.Br.], replacement name for *G. spathaceus* Pappe ex Baker: 208 (1892), illegitimate homonym, not *G. spathaceus* L.f. (1782). Type: South Africa, [Western Cape], Caledon Swartberg, Sept. 1884, *MacOwan 2167* (also as *Herb. Norm. Austr. Afr. 282*) (K, lecto., designated by Goldblatt & Manning: 257 (1998); G, BOL, isolecto.).

Plants 450–1 000 mm high, with minutely puberulous cataphylls. *Corm* ovoid, 10–20 mm diam.; tunics hard and woody, usually splitting below into thick claw-like ribs. *Stem* erect and ± straight, lightly flexed outward above sheaths of upper 3 leaves and at base of spike, unbranched. *Leaves* (3)4, lowermost reaching to ± middle of stem, usually largely sheathing, linear, ± 2 mm wide, main vein heavily thickened, margins lightly thickened, thus oval in section with two narrow grooves on each surface, upper leaves progressively shorter, mostly sheathing, sheaths of all leaves overlapping. *Spike* inclined, 1- or 2-flowered; bracts brownish purple to grey, attenuate, lightly ridged along veins, outer 30–37(–70) mm long, inner similar but shorter. *Flowers* inflated and bell-like, often slightly flattened, blue to violet, darker on reverse of upper tepals, whitish within, lower tepals lightly spotted with purple in lower half, lower laterals with yellow marginal marks or transverse band in upper third, lowermost with yellow median streak, unscented; perianth tube 10–16 mm long, obliquely funnel-shaped, geniculate, erect and cylindric below for 5–8 mm long, bent at right angles in middle and flaring abruptly; tepals with upper broadly obovate, lower oblanceolate, dorsal largest, extended horizontally over stamens, 25–35 × 20–28 mm, upper laterals slightly shorter and curved slightly outward apically, lower 3 united with upper laterals for 4–10 mm and together for ± 2 mm, laterals 20–32 × 10–18 mm, cupped with apices directed forward, lower median slightly shorter, 18–22 × 12–16 mm. *Filaments* 12–14 mm long, exserted from tube for 3–6 mm; anthers 7–10 mm long,

Distribution of ***Gladiolus bullatus***.

reaching to middle of dorsal tepal, white to grey-blue; pollen cream-coloured. *Style* arching over stamens, dividing near anther apices, branches ± 3 mm long. *Capsules* narrowly ovoid, obtuse, 18–20 mm long, concealed in bracts. *Seeds* ovate, pointed at one end, 4–5 × 3 mm, broadly and evenly winged. *Flowering time*: mid-August to mid-September.



Distribution and ecology: restricted to the southern coastal mountains of Western Cape, South Africa, from Houw Hoek and Kogelberg to Bredasdorp and Potberg near Cape Infanta; on south-facing sandstone or rarely limestone slopes.

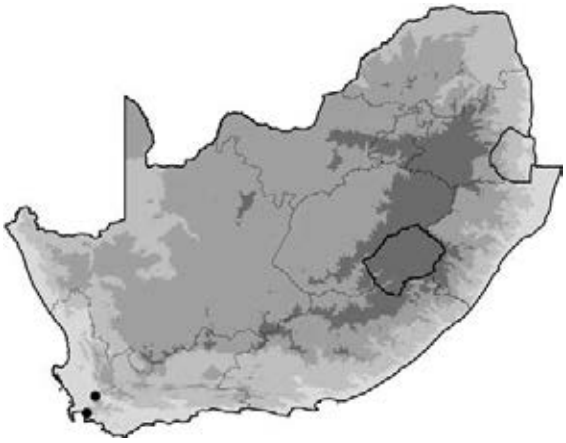
Diagnosis: distinctive in its four, rarely three, linear leaves with overlapping bases completely sheathing the stem to near the apex, the attenuate and ribbed bracts, and the one or two large, bell-shaped blue flowers with short, sharply bent tube 10–16 mm long. The lower tepals are marked with yellow lateral blotches or a transverse yellow band edged with purple.

135. **Gladiolus blommesteinii** *L.Bolus* in Annals of the Bolus Herbarium 3: 183 (1924). Type: South Africa, [Western Cape], without precise locality or collector, Caledon Wild Flower Show, 1915 [BOL (*BOL 14786*), lecto., designated by Lewis et al.: 218 (1972)].

Gladiolus blommesteinii var. *major* L.Bolus: 183 (1924). Type: South Africa, [Western Cape], without precise locality or collector, Caledon Wild Flower Show, 1915, *BOL 14791* (BOL, holo.).

Plants 300–600 mm high. *Corm* ovoid, 12–20 mm diam.; tunics hard and woody layers, splitting below into claw-like segments. *Stem* erect, flexed outward above sheaths of 3 upper leaves and weakly inclined above, unbranched. *Leaves* 4, lowermost basal, sheathing lower ½ of stem and reaching to between middle of stem and shortly above spike, linear, 1.0–1.5 mm wide, straight, margins and main vein lightly raised, upper leaves progressively shorter, usually sheathing for ½ their length, blades often slightly narrower, uppermost leaf usually reaching to middle of first flower. *Spike* inclined, (1)2- to 4-flowered; bracts green to dark grey-green, ridged along veins distally, outer 20–36 mm long, inner shorter, minutely forked apically. *Flowers* pale mauve-pink to pale blue-mauve, lower tepals yellowish below with streaks or lines of dark red, blue, or purple along veins, and with red spots and streaks in throat, lightly sweet-scented; perianth tube obliquely and narrowly funnel-shaped, 13–24 mm long, lower cylindric part 7–13 mm long, lower part enclosed in bracts and upper part reaching to ± apex of outer bract; tepals lanceolate, dorsal largest, 28–44 × 14–20 mm, ascending, upper laterals ± as long or somewhat shorter and slightly narrower, slightly ascending, lower 3 tepals joined to upper laterals for 4–6 mm and together for 2–3 mm, usually with a short tooth at point of union, narrowly lanceolate, not notably clawed below, free parts 20–35 × 8–10 mm, flexed outward in upper half. *Filaments* 12–14 mm long,

Distribution of ***Gladiolus blommesteinii***.



exserted 2–6 mm from tube but included in flower; anthers 8–11 mm long, whitish; pollen pale grey. *Style* arching over stamens, dividing opposite upper ⅓ of anthers, branches 3–4 mm long. *Capsules* and *seeds* unknown. *Flowering time*: August to mid-October.

Distribution and ecology: restricted to the southwestern mountains of Western Cape, South Africa, from Franschhoek Pass along the Hottentots Holland Mtns to Kogelberg and eastward to the Riviersonderend and Klein River Mtns; on south-facing sandstone slopes, flowering mainly after fire.

Diagnosis: recognised by the four linear leaves with slightly thickened main vein and margins, striate or ribbed bracts, and funnel-shaped, pink to mauve flowers with lanceolate-attenuate tepals, typically with darker veins and with purple-streaked nectar guides. *Gladiolus virgatus* has a slightly longer perianth tube, 22–27 mm long and ± abruptly flared above, and chevron-like red markings on the lower tepals.

136. **Gladiolus virgatus** *Goldblatt & J.C.Manning*, *Gladiolus* in southern Africa: 260 (1998). Type: South Africa, [Western Cape], west end of Du Toit's Peak, 16 Oct. 1949, *Esterhuysen 16061* (BOL, holo.; K, NBG, SAM, iso.)

Plants 400–500 mm high. *Corm* globose, ± 12–14 mm diam.; tunics hard and cartilaginous to woody, splitting below into claw-like segments. *Stem* erect below or inclined from base, flexed laterally above sheaths of upper 2 leaves, unbranched. *Leaves* 4, lower 2 basal, lowermost reaching to between base and slightly beyond apex of spike, sometimes sheathing stem up to middle, linear, 1.5–2.5 mm wide, main vein and margins lightly raised, remaining leaves progressively shorter and sheathing for ½ their length. *Spike* inclined, 2- to 4(6)-flowered; bracts green or flushed purple, ridged along veins 30–45(–50) mm long, inner slightly shorter, notched apically. *Flowers* pale to dark pink or nearly white, lower tepals with spear-shaped whitish median streak in lower half edged distally with dark pink V-shaped mark,

Distribution of ***Gladiolus virgatus***.

speckled pink in throat, unscented; perianth tube 22–27 mm long, slender below, abruptly expanded in upper 4–7 mm, slightly exceeding bracts; tepals lanceolate, unequal, margins usually undulate, dorsal largest, inclined over stamens, ± 30–37 × 18–19 mm, upper laterals ± as long, 14–16 mm wide, arching outward in upper ⅓, lower 3 tepals joined to upper laterals for 2–3 mm and together for ± 3 mm, gently to sharply flexed downward in middle, lower laterals 20–28 × 10–12 mm, lower median 25–28 × 10–12 mm. *Filaments* 12–16 mm long, exserted ± 8 mm from tube; anthers 8–9 mm long, light mauve; pollen whitish. *Style* arching over stamens, dividing between upper ⅓ and slightly beyond anther apices, branches ± 6 mm long. *Capsules* and *seeds* unknown. *Flowering time*: mid-September to early November, rarely as early as end of August.

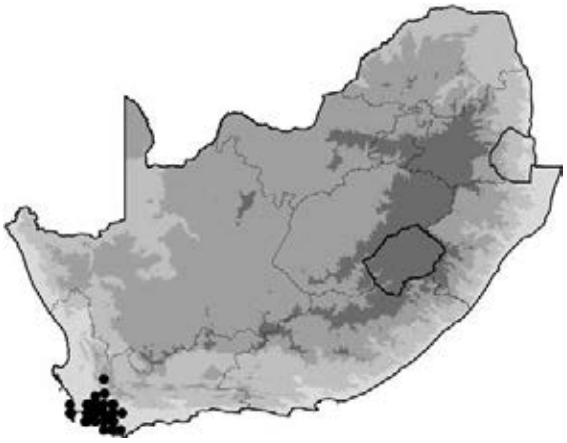
Distribution and ecology: a narrow endemic of the southwestern mountains of Western Cape, South Africa, from the Helderberg above Somerset West to Du Toit's Kloof; on south-facing sandstone slopes, flowering mainly after fire.

Diagnosis: recognised by the four linear leaves with lightly thickened main veins and margins, striate or ribbed bracts, and relatively long-tubed, pink flowers with lanceolate-attenuate tepals and red, chevron-shaped nectar guides on the lower tepals. Allied *Gladiolus blommesteinii* has a lightly shorter, gently flared perianth tube, 17–24 mm long, and streaked or spotted nectar guides on the lower tepals.

137. **Gladiolus debilis** *Sims* in Curtis's Botanical Magazine 52: t. 2585 (1825). Type: South Africa, without precise locality or collector, cultivated in Great Britain, illustration in Sims: t. 2585 (1825).

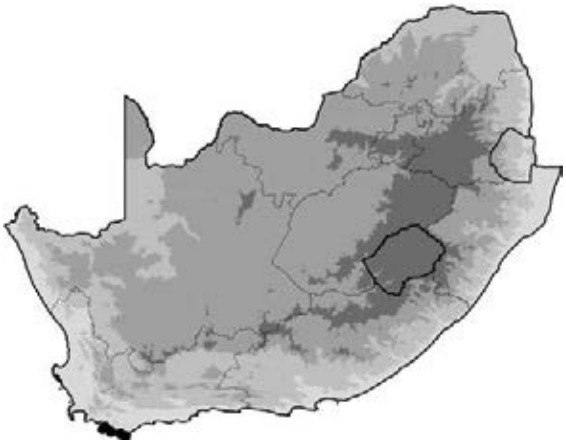
Gladiolus cochleatus Sweet: t. 140 (1832). *G. debilis* var. *cochleatus* (Sweet) G.J.Lewis in Lewis et al.: 186 (1972). Type: South Africa, without precise locality or collector, cultivated in Great Britain, illustration in Sweet: t. 140 (1832).

Gladiolus lambda Klatt: 708 (1864). Type: South Africa, Cape, without precise locality, *Reynaud s.n.* [S, lecto., designated by Lewis et al.: 186 (1972)].



[*Geissorhiza albens* E.Mey.: 187 (1843), invalid name without description.]

Plants (120–)250–450 mm high. *Corm* 8–15 mm diam.; tunics splitting into coarse wiry to ± woody claw-like segments. *Stem* flexed outward above sheaths of upper leaves, inclined above, unbranched. *Leaves* (3)4, lowermost basal and reaching to between upper ⅓ of stem and apex of spike, linear, 1–2 mm wide, main vein moderately thickened and margins usually also thickened and raised, upper leaves progressively shorter, sheathing for about ½ their length. *Spike* inclined, flexuose, 1- to 3-flowered; bracts light green to greyish, sometimes flushed dull purple, lightly ridged along veins, margins hyaline, 15–28 mm long, inner slightly shorter, minutely forked apically. *Flowers* white to pale pink, lower 3 tepals variously marked with red, often with a pair of large spots near base and a V- or spade-shaped distal mark, sometimes extending back along midline, lower part of throat speckled and streaked with red and filaments red, unscented; perianth tube cylindric, very slightly curved and expanded in upper 2 mm, (10–)15–22 mm long, slightly shorter to as long as bracts; tepals ovate to nearly orbicular, dorsal largest, inclined or erect, 17–27 × 10–18(–22) mm, upper laterals arching outward from base, spreading at right angles to tube, 15–27 × (9–)13–18 mm, lower tepals sometimes united basally for up to 3 mm, weakly flexed downward in upper ½, narrowed below, 15–24 mm long, subequal or lower median larger. *Filaments* 4–10 mm long, exserted 2–7 mm from tube, often reddish, or red abaxially; anthers 5–9 mm long, white above, purple below; pollen cream-coloured. *Style* dividing opposite to slightly beyond anther apices, branches 2–5 mm long. *Capsules* ellipsoid, subacute, (12–)14–18 mm long. *Seeds* ovate, 5–6 × ± 4 mm, broadly and evenly winged. *Flowering time*: September to early October.



Distribution and ecology: endemic to the southwestern mountains of Western Cape, South Africa, on the Cape Peninsula and from Bain's Kloof along the Hottentots Holland Mtns to the Kogelberg and eastward to Bredasdorp; on sandstone slopes, flowering mainly after fire.

Diagnosis: recognised by the mostly four (rarely three) linear leaves with lightly thickened midrib and margins, striate or ribbed bracts, and white flowers marked with red on the lower tepals and often flushed pinkish on the reverse, with a cylindric perianth tube (10–)15–22 mm long expanded only near the top. The markings on the lower tepals include chevrons, diamonds or streaks and lines in regular patterns, and the base of the throat is also marked with a ring of red.

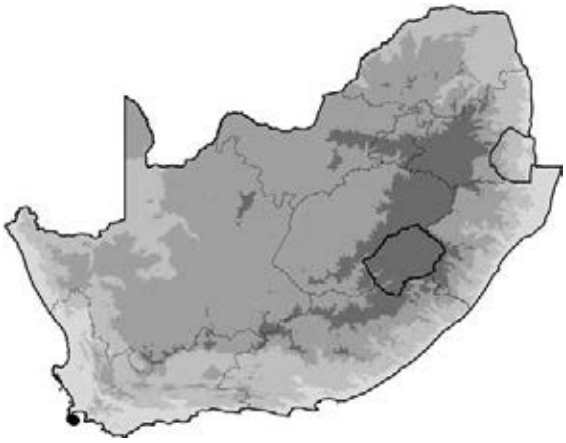
Populations from the Hottentots Holland Mtns have the smallest flowers, with the lower tepal marking reduced to a small red diamond; plants on the Cape Peninsula have flowers marked with V-shaped chevrons;

Distribution of ***Gladiolus debilis***.

Distribution of ***Gladiolus variegatus***.

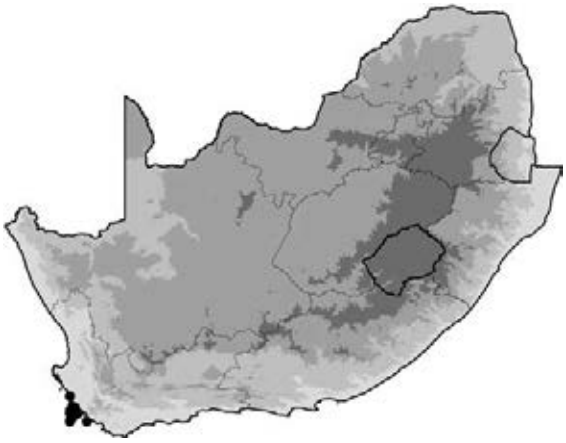
and those from Hermanus to Bredasdorp are marked with paired spots and streaks. *Gladiolus variegatus* from limestone hills on the Agulhas Peninsula has mostly three leaves, smooth bracts, and unevenly spotted lower tepals.

138. **Gladiolus variegatus** *(G.J.Lewis) Goldblatt & J.C.Manning* in Novon 6: 178 (1996). *G. debilis* var. *variegatus* G.J.Lewis in Lewis et al.: 188 (1972). Type: South Africa, [Western Cape], Bredasdorp District, Brandfontein, 14 Oct. 1951, *Esterhuysen 19087* (BOL, holo.; BOL, NBG, PRE, iso.).



Plants 200–400(–600) mm high. *Corm* conical, 10–15 mm diam.; tunics hard and woody, splitting into claw-like segments. *Stem* flexed outward above sheaths of upper 2 leaves, inclined and flexuose in upper ½, unbranched. *Leaves* 3(4), lower 2 basal, reaching to base or shortly exceeding spike, lowermost sheathing stem for a short distance, linear or falcate, 1.5–2.5 mm wide, main vein lightly raised, margins not thickened, second leaf sheathing lower ⅔ of stem, uppermost leaf sheathing for ½ its length. *Spike* lightly inclined, flexuose, 1- or 2(4)-flowered; bracts dark green, sometimes flushed greyish purple, smooth with narrowly hyaline margins, outer 25–40(–50) mm long, inner slightly shorter, minutely forked. *Flowers* white to pale pink, lower part of throat and lower 3 tepals with red spots irregularly spread on lower ⅔, unscented; perianth tube cylindric, very slightly curved and expanded in upper 3–4 mm, 14–20 mm long, shorter than bracts; tepals with dorsal largest, inclined, 25–30 × 16–22 mm, upper laterals arching outward from base and ultimately spreading at right angles to tube, 23–28 × 11–15 mm, lower tepals united with upper laterals for ± 2 mm and together for ± 2 mm, weakly arching downward in upper half, 24–27 × 10–13 mm, lower median slightly smaller than laterals. *Filaments* 12–15 mm long, exserted 5–6 mm from tube, often reddish, or red abaxially; anthers (7–)8–10 mm long, white above, dark purple below; pollen cream-coloured. *Style* dividing shortly below to beyond anther apices, branches ± 4 mm long. *Capsules* and *seeds* unknown. *Flowering time*: mid-September to mid-October.

Distribution and ecology: a narrow endemic of the south coast of Western Cape, South Africa, from near Gansbaai and Stanford to Cape Agulhas; on limestone outcrops, from near sea level to 250 m elevation.



Diagnosis: recognised by the mostly three (rarely four) linear leaves with lightly thickened main vein and margins, striate or ribbed bracts, and white to pale pink flowers irregularly spotted with red on the lower tepals, with a cylindric perianth tube 14–20 mm long expanded only near the top. *Gladiolus debilis* from sandstone slopes has mostly four leaves, ribbed bracts, and symmetrically marked lower tepals, mostly with diamond-, spade-, or chevron-shaped markings.

139. **Gladiolus vigilans** *Barnard* in Lewis et al. in Journal of South African Botany, Suppl. 10: 82 (1972). Type: South Africa, [Western Cape], Cape Point Nature Reserve, Vasco da Gama Ridge, Nov. 1939, *Lewis s.n.* (SAM [*SAM 54296*], holo.; PRE, iso.).

Plants 300–450 mm high. *Corm* 12–15 mm diam.; tunics hard and woody, splitting into claw-like segments. *Stem* flexed outward above sheaths of upper 2 leaves, inclined above, unbranched. *Leaves* 4, lower 2 basal and usually shortly exceeding stem, linear, 1.2–1.5 mm wide, margin and main vein moderately thickened, cauline leaves inserted in middle and upper ⅓ of stem respectively, progressively shorter, sheathing for ± ½ their length, uppermost channelled throughout. *Spike* inclined, flexuose, 1- to 3-flowered; bracts pale green, smooth with hyaline margins, outer 20–25 mm long, inner slightly shorter, minutely forked apically. *Flowers* pale pink, lower 3 tepals with median spade-shaped white mark edged in dark red, extending onto tube, base of upper part of tube with fine red lines from tepal sutures, unscented; perianth tube narrowly funnel-shaped, 35–40 mm long, straight and cylindric below for 30–35 mm, curved outward and flared in upper 5 mm, ± twice as long as bracts;

Distribution of ***Gladiolus vigilans***.

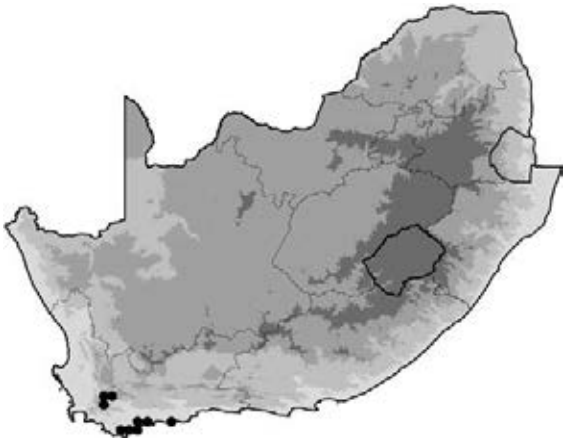
Distribution of ***Gladiolus ornatus***.

tepals with dorsal largest, inclined over stamens, ± 28 × 18 mm, upper laterals arching outward from base, ultimately spreading at right angles to tube, ± 25 × 17 mm, lower tepals united with upper laterals for ± 3 mm and together for ± 3 mm, narrowed below, downcurving distally, laterals ± 18 × 8 mm, lower median ± 22 × 6 mm. *Filaments* 12 mm long, exserted 6 mm from tube, white below, pink toward apices; anthers ± 6.5 mm long, dark purple; pollen cream-coloured. *Style* dividing between upper ⅓ and apex of anthers, branches ± 4 mm long. *Capsules* ellipsoid, 12–14 mm long. *Seeds* oblong, ± 5.5 × 3 mm, broadly and evenly winged. *Flowering time*: late October to early November.

Distribution and ecology: a local endemic of Western Cape, South Africa, known from low hills near Cape Point; on well-drained sandstone slopes.

Diagnosis: recognised by the mostly four linear leaves with lightly thickened midrib and margins, striate or ribbed bracts, and long-tubed, pale pink flowers with a cylindric perianth tube 35–40 mm long expanded only near the top. The lower lateral tepals are strongly marked with red, spade-shaped nectar guides. Somewhat similar *Gladiolus debilis*, which also occurs on the Cape Peninsula, has ribbed bracts and a shorter perianth tube, (10–)15–22 mm long.

140. **Gladiolus ornatus** *Klatt* in Transactions of the South African Philosophical Society 3: 198 (1885). Type: South Africa, [Western Cape], flats near Rondebosch, Oct. 1884, *MacOwan 2553* (G, S, SAM, syn.).



Plants 250–350 mm high. *Corm* globose, 9–12 mm diam.; tunics ± membranous, fragmenting irregularly. *Stem* flexed outward above sheathing parts of upper three leaves and inclined, unbranched. *Leaves* 3, lowermost basal and sheathing lower ⅓ of stem, linear, 1–2 mm wide, main vein lightly raised, margins lightly to heavily thickened, cauline leaves inserted on upper ½ of stem, progressively shorter, uppermost sheathing for ½ its length, channelled throughout. *Spike* inclined, flexuose, (1)2- or 3-flowered; bracts dull green or grey-purple, outer 27–32 mm long, inner ± as long or slightly shorter. *Flowers* pale to deep pink, lower tepals with spear–spade-shaped white median streak edged in dark pink, lower part of throat white, irregularly streaked dark pink, unscented; perianth tube obliquely funnel-shaped, 18–20 mm long, lower cylindric part ± 12 mm long, enclosed in bracts; tepals with dorsal largest, inclined, 30–33 × 18–21 mm, upper laterals outcurving in upper half, 28–31 × 15–17 mm, lower tepals united for ± 5 mm, curving downward in upper ⅓, 25–28 × 10–14 mm. *Filaments* 12–14 mm long, exserted 5–6 mm from tube; anthers ± 10 mm long, mauve to violet; pollen cream-coloured to mauve. *Style* arching over stamens, dividing opposite upper ⅓ of anthers, branches 4.0–5.5 mm long. *Capsules* ellipsoid, 16–20 mm long. *Seeds* unknown. *Flowering time*: late September to November.

Distribution and ecology: a narrow endemic of the extreme southwestern part of Western Cape, South Africa, from the Mamre hills to the Cape Peninsula and Jonkershoek; on seasonally moist or marshy sandy flats and slopes.

Diagnosis: recognised by the soft, membranous corm tunics, three linear leaves, and pink, broadly funnel-shaped flowers with moderately short tube, 18–20 mm long, the lower tepals each with a white lozenge-shaped marking outlined with red.

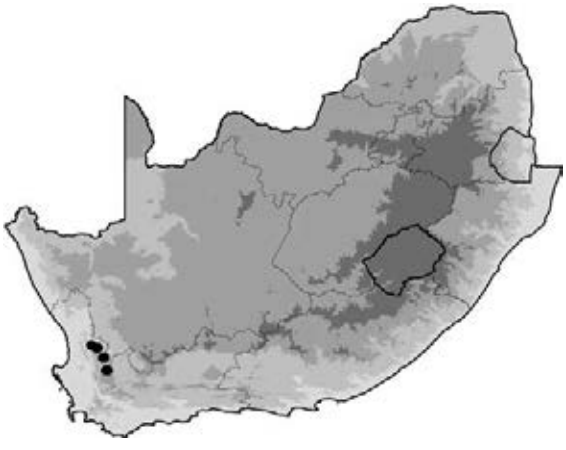
141. **Gladiolus inflexus** *Goldblatt & J.C.Manning*, *Gladiolus* in southern Africa: 266 (1998). Type: South Africa, [Western Cape], Worcester District, ± 8 km west of town in rocky alluvial ground with sandy loam, 27 July 1994, *Goldblatt & Manning 9888* (NBG, holo.; K, MO, PRE, iso.).

Plants (150–)200–350 mm high. *Corm* conic, 10–15 mm diam.; tunics hard and woody, splitting from below into claw-like segments. *Stem* sharply flexed outward above sheathing parts of each leaf, thus flexuose in upper ⅓.

Distribution of ***Gladiolus inflexus***.

Leaves 3, lowermost basal and sheathing lower ½–⅔ of stem, reaching or slightly exceeding apex of spike, linear, 1–2 mm wide, grey-green, main vein paler and slightly raised, margins not raised or hyaline, cauline leaves short, reaching to ± middle of spike, sheathing in lower ⅓–½. *Spike* flexuose, 1- to 3-flowered; bracts grey-green, margins transparent, apices often attenuate and twisted, outer 20–38 mm long, inner slightly longer or slightly shorter, lower margins broadly hyaline. *Flowers* pale to dull purple with base of tepals and throat cream-coloured, lower tepals speckled to blotched with purple in lower ⅔, sweetly scented; perianth tube obliquely funnel-shaped, 11–20 mm long; tepals broadly lanceolate, dorsal largest, 21–25 × 14–15 mm, spreading above, upper laterals as long but slightly narrower than dorsal, lower 3 tepals joined to upper laterals for 3–5 mm and together for 3–4 mm, 15–25 × 10 mm, narrowed below, curving outward and downward. *Filaments* 12–14 mm long, exserted 3–8 mm from tube but included in flower; anthers 6–7 mm long, light purple-grey; pollen cream-coloured. *Style* arched over stamens, dividing opposite or just below anther apices, branches 2–3 mm long. *Capsules* oblong-ellipsoid, 15–22 mm long. *Seeds* ovate, 6–7 × 4–5 mm, broadly and evenly winged. *Flowering time*: mid-to late July, rarely in early August.

Distribution and ecology: a local endemic with a scattered distribution in the southwestern corner of Western Cape, South Africa, between Worcester and Rawsonville and along the coast from Bredasdorp to Still Bay; in loamy soil on alluvial flats.



Diagnosis: recognised by the woody tunics, three linear leaves, and flexuose stem with purplish, narrowly funnel-shaped flowers, the lower tepals streaked and spotted. *Gladiolus gracilis* has similar flowers but mostly four leaves, these H-shaped in section with winged margins.

142. **Gladiolus taubertianus** *Schltr.* in Botanische Jahrbücher für Systematik 27: 103 (1899). Type: South Africa, [Western Cape], Cold Bokkeveld, 4 000 ft [1 200 m], 5 Sept. 1896, *Schlechter 8860* (BOL, lecto., designated by Goldblatt & Manning: 269 (1998); PRE, isolecto. [not *Schlechter 8860* in BM, G, K]).

Plants 180–500(–900) mm high, with cataphylls minutely puberulous above ground. *Corm* globose, ± 12 mm diam.; tunics hard and woody, splitting from below into claw-like segments. *Stem* flexed outward above sheathing parts of upper 2 or all 3 leaves, unbranched. *Leaves* 3, lowermost basal and sheathing lower ½ of stem, reaching to ± top of spike or exceeding it, linear, (1–)2–3 mm wide, main vein lightly raised and often a second vein pair also prominent and blade then flexed and L-shaped in section, margins barely thickened, second leaf sheathing lower ⅔ of stem, short, upper leaf inserted in upper ⅓ of stem, sheathing below, margins united around stem. *Spike* lightly inclined, and weakly flexuose, 1- to 3(5)-flowered; bracts grey-green, soft-textured, outer 20–35(–40) mm long, inner shorter, forked, twisted around to lie under outer. *Flowers* pale mauve to slate-blue, upper lateral and lower tepals lightly streaked with purple inside, lower laterals with pale yellow transverse band across middle, lightly sweet-scented; perianth tube obliquely funnel-shaped, 9–14 mm long, lower cylindric part 5–7 mm long; tepals ovate, dorsal largest, 20–26 × 11–16 mm, hooded over stamens, upper laterals curving outward above, 16–21 × 10–12 mm, lower 3 tepals joined to upper laterals for 2–5 mm, free parts 15–19 × 7–9 mm, ± straight and horizontal. *Filaments* ± 12 mm long, exserted ± 7 mm from tube, adpressed to dorsal tepal; anthers 6–9 mm long, pale lilac; pollen cream-coloured. *Style* arching over stamens, dividing opposite upper ⅓ of anthers, branches 4–5 mm long. *Capsules* and *seeds* unknown. *Flowering time*: mid-August to mid-September.

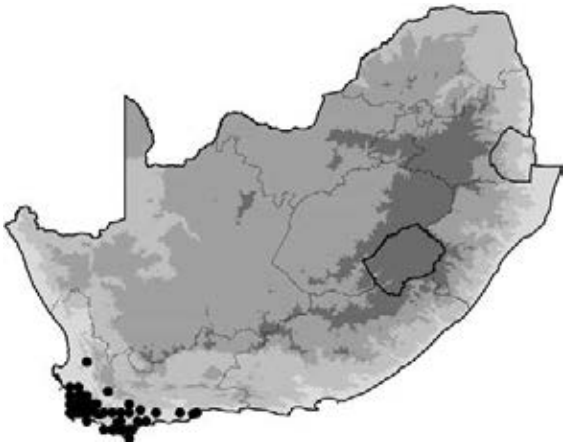
Distribution and ecology: endemic to the interior Cederberg and northern Cold Bokkeveld in Western Cape, South Africa; on relatively dry sandstone slopes.

Diagnosis: recognised by the woody tunics, three linear leaves, and small, purplish flowers with darker veins, the lower tepals streaked and spotted with purple on pale yellow nectar guides.

Distribution of ***Gladiolus taubertianus***.

143. **Gladiolus gracilis** *Jacq.*, Collectanea 4: 159 (1791). Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 246 (1794 [1788–1795]).

Gladiolus tristis var. *punctatus* Thunb.: 12 (1784). Type: South Africa, without precise locality, *Thunberg s.n.* (UPS-THUNB 1028, holo.).



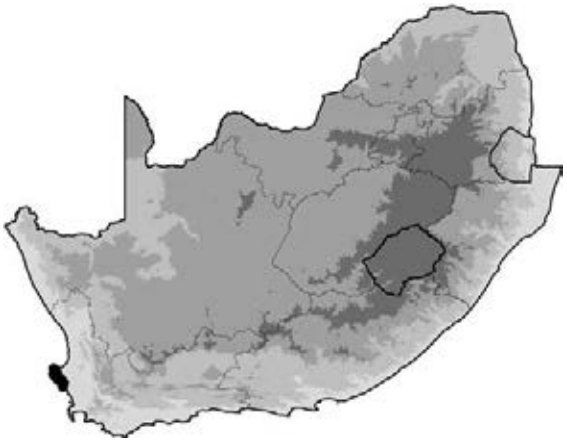
Gladiolus pterophyllus Pers.: 43 (1805). Type: South Africa, Western Cape, without precise locality or collector, cultivated in Austria, illustration in Jacq.: t. 244 (1794 [1788–1795]) '*Gladiolus tristis* var.'.

Gladiolus scaber Link: 70 (1820). Type: South Africa, without precise locality, *Lichtenstein s.n.* (B: Herb. Willdenow, holo.).

[*Gladiolus setifolius* Eckl.: 37 (1827), invalid name without description.]

Plants 250–500(–700) mm high. *Corm* 12–20 mm diam.; tunics hard and woody, splitting below into claw-like segments. *Stem* erect or inclined, upper portion inclined, flexed outward above sheaths of upper 3 leaves, unbranched. *Leaves* (3)4, lowermost basal and sheathing lower ½ of stem, often scabridulous below, reaching to between upper ⅓ of stem and middle of spike, linear and H-shaped in section, 1.5–2.5 mm wide, margins raised into broad wings arching over blade surface, margin usually scabrid to ciliate, cauline leaves progressively shorter and sheathing for at least ½ their length, sheaths closed. *Spike* inclined, flexuose, 2- to 5(7)-flowered; bracts grey-green or becoming dull purple, margins membranous, outer 17–35(–43) mm long, apices often attenuate and somewhat twisted, inner bract shorter. *Flowers* pale blue to grey, occasionally pink or dull yellow, lower 3 tepals and abaxial side of throat pale yellow to cream-coloured and marked irregularly with dark purple streaks and spots, usually delicately and sweetly scented, sometimes apparently unscented; perianth tube obliquely funnel-shaped, 12–18 mm long; tepals obovate, margins undulate, dorsal largest, 24–33 × 14–19 mm, curving outward in upper ½, upper laterals similar but slightly smaller, lower 3 tepals joined to upper laterals for 3–8 mm and together for a further 2–3 mm, narrowed below and shallowly channelled, sometimes ± claw-like, laterals 20–25 × 7–9 mm, arching downward distally, lower median 5–10 mm longer than lower laterals, up to 12 mm wide. *Filaments* 11–14 mm long, exserted 4–8 mm from tube; anthers 7–11 mm long, pale to dark blue; pollen cream-coloured or pale blue. *Style* arching over stamens, dividing shortly below to shortly beyond anther apices, branches 3–4 mm long. *Capsules* oblong-ellipsoid, acute, 12–18 mm long. *Seeds* ovate, 4.5–5.0 × ± 3 mm, broadly and evenly winged. *Flowering time*: mainly July and early August, sometimes in June.

Distribution and ecology: restricted to southwestern Western Cape, South Africa, from Aurora west of Piketberg along the coastal forelands to Albertinia; mainly on clay or granite flats and slopes in renosterveld shrubland.



Distribution of ***Gladiolus gracilis***.

Diagnosis: recognised by the narrow, marginally winged lower leaf blade, 1.5–2.5 mm wide and ± H-shaped in section with the margins curved inward over the midline, and the relatively short-tubed, funnel-shaped flowers with acute tepals, the lower streaked and spotted. *Gladiolus caeruleus* from coastal limestones on the Atlantic Coast, has broader leaves, 3–7 mm wide with the marginal wings at right angles to the blade, and pale blue flowers with obtuse tepals, the lower spotted with dark blue.

144. **Gladiolus caeruleus** *Goldblatt & J.C.Manning* in Novon 6: 179 (1996), replacement name at species rank for *G. gracilis* var. *latifolius* G.J.Lewis in Lewis et al.: 228 (1972) [not *G. latifolius* Lam. (1791)]. Type: South Africa, Western Cape, road to Donkergat, north of Churchhaven, 15 Aug. 1966, *Barker 10395* (NBG, holo.; K, iso.).

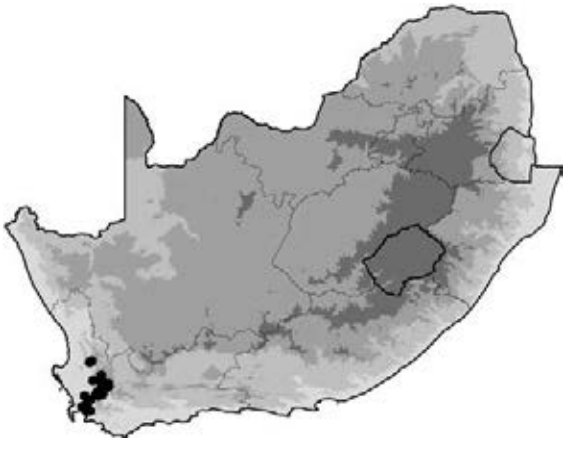
Plants 400–600 mm high. *Corm* 10–14 mm diam.; tunics hard and woody, splitting from below into claw-like segments. *Stem* erect or inclined below, upper portion inclined at ± 20°, flexed outward above sheaths of upper 2 leaves, unbranched. *Leaves* 4, lowermost basal and sheathing lower part of stem, sheath often scabrid below, reaching to between base and apex of spike, linear, 3–7 mm wide, margins raised at right angles to surface, thus H-shaped in section, edges smooth, main vein lightly raised, cauline leaves progressively shorter above and sheathing for at least ½ their length, sheaths closed. *Spike* (4)8- to 10(14)-flowered, flexed at base, weakly flexuose; bracts greyish green to dull purple-grey, with narrowly membranous margins, 25–35(–40) mm long, inner shorter, margins broadly membranous, barely notched at apex. *Flowers* pale blue, abaxial side of throat and lower ⅔ of lower tepals irregularly speckled with dark purple on a cream-coloured background, lightly scented; perianth tube obliquely funnel-shaped, ± 15 mm long; tepals obovate and obtuse, dorsal largest, 30–32 × ± 20 mm, curving outward distally, upper laterals spreading distally, ± 25 × 17 mm, lower 3 tepals joined to upper laterals for ± 6 mm and together

Distribution of ***Gladiolus caeruleus***.

for a further 2–3 mm, tapering toward bases, subequal, ± 20 × 8–10 mm, obtuse, arching gently outward. *Filaments* ± 12 mm long, exserted ± 6 mm from tube; anthers 9–10 mm long, pale blue; pollen cream-coloured or pale blue. *Style* arching over stamens, dividing opposite or shortly beyond anther apices, branches ± 4 mm long. *Capsules* ellipsoid, ± 15 mm long. *Seeds* ovate, 5–7 × ± 4 mm, broadly and evenly winged. *Flowering time*: August to mid-September.

Distribution and ecology: a narrow endemic of the Atlantic coast of Western Cape, South Africa, from Cape Columbine to Yzerfontein; on limestone outcrops and neutral sands in coastal scrub.

Diagnosis: recognised by the lower leaf blade, 3–7 mm wide with broad marginal wings, thus ± H-shaped in section, and the relatively short-tubed, pale blue flowers with obtuse tepals, the lower spotted with dark blue. *Gladiolus gracilis* from clay soils further inland has narrower leaves 1.5–2.5 mm wide with the marginal wings curved over the blade, and variously coloured flowers with acute tepals, the lower streaked and spotted.



145. **Gladiolus recurvus** *L.*, Mantissa plantarum 1: 28 (1767). *Watsonia recurva* (L.) Pers.: 43 (1805). *G. ramosus* Burm.f.: 2 (1768), illegitimate homonym and superfluous name for *G. recurvus* L. [based on same type]. Type: South Africa, without precise locality, illustration in Miller, Figures of plants 2: 157, t. 235, fig. 2 (1758).

Gladiolus modestus Ingram: 9 (1931c). Type: South Africa, [Western Cape], Breede River Valley, without date, *Ingram s.n.* (BM, colour illustration).

Plants 250–350 mm high. *Corm* globose, 10–14 mm diam.; tunics hard and woody, splitting from below into claw-like segments. *Stem* inclined above and flexed outward above sheath of each leaf, unbranched. *Leaves* 4, lowermost basal and sheathing lower ⅓ of stem, blade short or reaching to just below base of spike, 30–100 mm long, linear, ± 2 mm wide, margins raised into wings extended at right angles and arching inward over blade surface, edges lightly scabrid, main vein lightly raised but not thickened. *Spike* inclined, flexuose, 1- or 2(4)-flowered; bracts dull green to greyish brown, outer 30–40 mm long, apices somewhat twisted and with margins inrolled, inner shorter. *Flowers* dull cream-coloured to pale yellow, lower lateral tepals irregularly lined and spotted with dull purple, upper tepals sometimes lightly lined or spotted toward midline, lower margins of upper tepals transparent, with a strong, sweet cloying scent; perianth tube ± cylindric, curving outward and widening in throat, 27–36 mm long; tepals lanceolate-attenuate, upper margins undulate, apices twisted outward, dorsal largest, ascending, 22–30 × 14–18 mm, upper laterals 22–26 × 8–11 mm, spreading distally, lower 3 tepals joined to upper laterals for 4–7 mm and together for 2–3 mm, free parts ± 20 × 8–9 mm, spreading in upper ½. *Filaments* 14–15 mm long, exserted 4–5 mm from tube; anthers 8–10 mm long, dull grey to blackish; pollen pale yellow. *Style* arching over stamens, dividing just below to just beyond anther apices, branches 2.5–4.0 mm long. *Capsules* ovoid-ellipsoid, 14–16 mm long. *Seeds* ovate, ± 5 × 3 mm, broadly and evenly winged. *Flowering time*: mainly June to early August at low elevations, September to early October at higher elevations.

Distribution and ecology: endemic to the southwestern corner of Western Cape, South Africa, from the Cold Bokkeveld, Ceres and the upper Breede River Valley to Gouda and from Stellenbosch to Somerset West; on stony loam or clay in renosterveld.

Diagnosis: recognised by the narrow, marginally winged lower leaf blade, ± 2 mm wide and ± H-shaped in section with the margins curved inward over the midline, and the relatively long-tubed flowers with crisped, attenuate tepals, the lower streaked and spotted, and the perianth tube 27–36 mm long. *Gladiolus gracilis* has obliquely funnel-shaped blue, rarely pink, flowers with a shorter perianth tube, 12–18 mm long and ± acute tepals.

Distribution of ***Gladiolus recurvus***.

Ser. **Teretifolii** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus inflatus* Thunb.

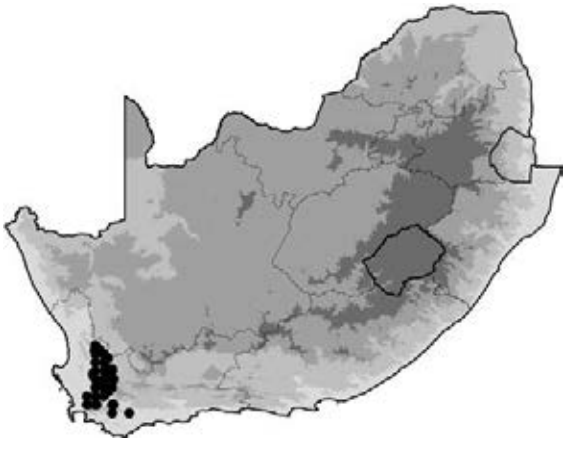
Plants from winter-rainfall region. *Corms* subglobose; tunics ± leathery to woody and splitting into claws, or coarsely fibrous. *Leaves* green or dry at flowering, usually three, terete and narrowly 4-grooved or X-shaped in section with midrib and margins thickened and raised. *Flowers* small to medium, zygomorphic, funnel- or bell-shaped, often scented; perianth tube usually shorter than dorsal tepal, lower tepals either with dark red median blotch or with ± transverse band of yellow outlined with dark red.

146. **Gladiolus inflatus** *(Thunb.) Thunb.*, Prodromus plantarum capensium: 185 (1800). *G. tristis* var. *inflatus* Thunb.: 12 (1784). Type: South Africa, without precise locality, *Thunberg s.n.* '*Gladiolus inflatus* a' (UPS-THUNB 1033, holo. [photo at BOL]).

Gladiolus tristis var. *hastatus* Thunb.: 13 (1784). *G. hastatus* (Thunb.) Thunb.: 185 (1800). Type: South Africa, without precise locality, *Thunberg s.n.* (UPS-THUNB 1032, holo.).

Gladiolus tristis var. *violaceus* Thunb.: 12 (1784). Type: South Africa, Western Cape, without precise locality, *Thunberg s.n.* (UPS-THUNB 1034, holo.).

Gladiolus bolusii Baker: 208 (1892). Type: South Africa, [Western Cape], Winterhoek Mtns near Tulbagh, Nov. 1879, *Bolus 5244* (K, holo.; BM, BOL, iso.).



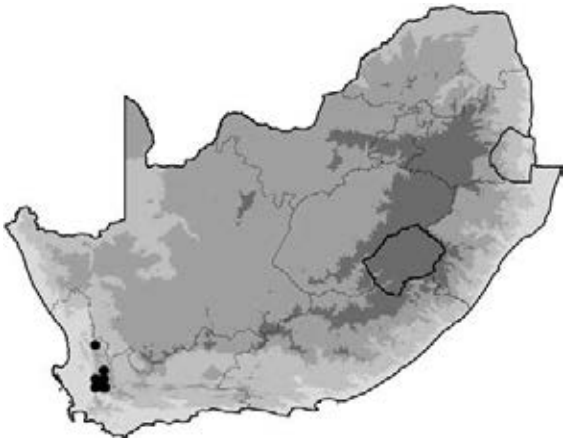
Gladiolus louiseae L.Bolus: 182 (1924). *G. inflatus* var. *louiseae* (L.Bolus) Oberm.: 241 (1972). Type: South Africa, [Western Cape], without precise locality, from the Ceres exhibit, Cape Town Wild Flower Show, Oct. 1921, *Guthrie s.n.* (BOL [BOL14195], holo.; BOL, K, iso.).

[*Gladiolus monostachyus* Thunb. ex Roem. & Schult.: 413 (1817), invalid name as a synonym.]

Plants (120–)200–450 mm high, with cataphylls sometimes scabrid above ground. *Corm* globose, 9–20 mm diam.; tunics usually ± woody, splitting below into claw-like ridges, sometimes cartilaginous becoming fibrous, sometimes forming slender collar around base of stem. *Stem* flexed outward above sheath of second leaf, unbranched. *Leaves* 3, lower 2 basal, lowermost sheathing stem only near ground or for a short distance, reaching to ± base of spike, sheath usually and blade sometimes retrorsely puberulous, terete to subterete with four hairline longitudinal grooves or rarely centric and cross-shaped in section with wide longitudinal grooves, straight or curving outward, ± 1 mm diam., second leaf sheathing lower ⅔ of stem, upper portion fairly short, sheath and blade sometimes puberulous, uppermost leaf sometimes reduced to a sheathing, bract-like scale 20–30 mm long, *Spike* flexed at base, lightly inclined, lightly flexuose, 2- or 3-flowered; bracts pale green to dull greenish grey, veins transparent, outer 18–26(–30) mm long, inner shorter to nearly as long as outer, acute. *Flowers* funnel- or slightly bell-shaped, deep pink to mauve, purple or violet, rarely white, lower tepals with dark spear- or ± spade-shaped purple to red marks in middle ⅓, sometimes throat ringed with red to purple, unscented; perianth tube obliquely funnel-shaped, 12–25(–30) mm long, lower cylindric part 5–12(–20) mm long; tepals with upper ovate, lower lanceolate to spathulate, dorsal largest, 22–27 × 12–17 mm, inclined to horizontal, upper laterals 20–24 × 12–14 mm, straight or recurved distally, lower 3 tepals united with upper laterals for 4–7 mm and sometimes together for ± 1 mm, 17–20 × 9–11 mm, straight or lightly curving downward distally. *Filaments* 12–18 mm long, exserted 5–11 mm from tube; anthers 7–9 mm long, grey-purple; pollen yellow. *Style* arching over stamens, dividing between middle and apex of anthers, branches 3–4 mm long. *Capsules* ellipsoid, subacute, 12–18 mm long. *Seeds* ovate, 5–6 × ± 4.5 mm, broadly and evenly winged. *Flowering time*: late September and October, sometimes to late November at higher elevations.

Distribution and ecology: relatively common in the mountains of southwestern Western Cape, South Africa, from the Cederberg and Cold Bokkeveld to Franschhoek Pass, the Hex River Mtns, Jonaskop in the Riviersonderend Mtns and possibly also the central Langeberg; on rocky sandstone slopes.

Diagnosis: recognised by the three leaves with narrow, terete blades and unscented, funnel-shaped flowers with perianth tube 12–25(–30) mm long, the lower tepals with dark spear- or spade-shaped markings. The species is variable for tube length. Late-flowering plants from the higher mountains around Ceres with pale pink flowers have the longest perianth tubes, up to 30 mm long. These may be confused with *Gladiolus cylindraceus* but this species has salver-shaped flowers with a cylindric perianth tube and shorter filaments, 7–8 mm long. *Gladiolus patersoniae* has consistently short-tubed, sweetly scented flowers with a sharply bent tube 10–12 mm long, the lower tepals with a transverse yellow band.

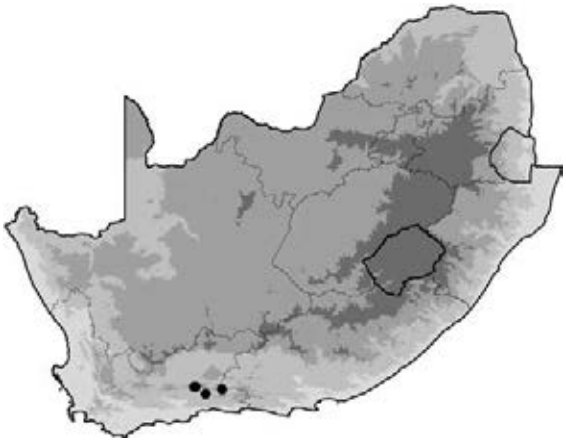


Distribution of ***Gladiolus inflatus***.

147. **Gladiolus cylindraceus** *G.J.Lewis* in Lewis et al. in Journal of South African Botany, Suppl. 10: 183 (1972). Type: South Africa, [Western Cape], Hansiesberg, Ceres District, 5 500–6 000 ft [1 700–1 800 m], 15 Dec. 1963, *Jones s.n.* (NBG, holo.).

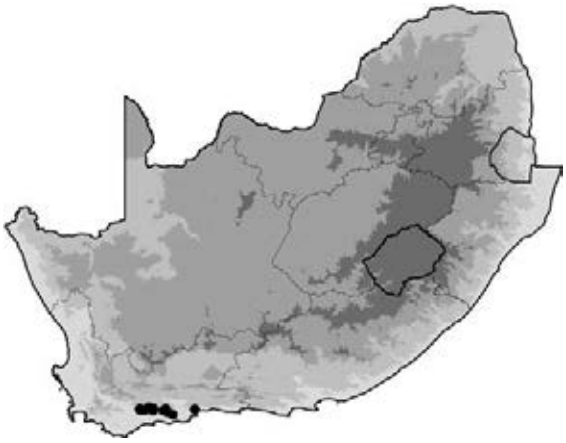
Plants 300–500 mm high. *Corm* globose, 12–20 mm diam.; tunics of medium-textured to moderately thick, ± wiry fibres, accumulating in a neck around base of stem. *Stem* flexed outward above sheaths of upper 1 or 2 leaves, unbranched. *Leaves* 3, lower 1 or 2 basal, lowermost sheathing stem for a short distance or only near ground, reaching to between base and apex of spike, suberect, main vein much raised thus cross-shaped in section, 2–3 mm diam., second leaf sheathing lower ½ of stem, overlapping uppermost leaf, blade fairly short with main vein less thickened than basal leaf, uppermost leaf inserted in middle to upper ⅓ of stem, mostly sheathing. *Spike* flexed at base and inclined, lightly flexuose, 5- to 8-flowered; bracts pale greenish grey, outer 18–28 mm long, inner shorter to nearly as long as outer, acute. *Flowers* salver-shaped, pale creamy pink to salmon-coloured, lower 3 tepals with reddish diamond-shaped mark in lower midline, sometimes with white to yellow centre, unscented; perianth tube cylindric, (25–)35–52 mm long, flared only near apex, half again as long to twice as long as bracts; tepals broadly lanceolate or dorsal ovate, dorsal largest, (18–)20–25 × 11–14 mm, lightly inclined or spreading at right angles to tube, upper laterals 18–25 × 9–12 mm, suberect or spreading, lower 3 tepals sometimes united with upper laterals for 1–2 mm and together for ± 2 mm, 15–21 × 7–8 mm, nearly straight, inclined. *Filaments* 7–8 mm long, exserted 3–4 mm from tube; anthers 5–8 mm long, white; pollen cream-coloured. *Style* ± straight, adaxial to stamens, dividing opposite upper third or shortly beyond anthers, branches 3–4 mm long. *Capsules* and *seeds* unknown. *Flowering time*: late November to late January.

Distribution and ecology: a narrow endemic of the western mountains in Western Cape, South Africa, from the Mostertshoek Peaks south of Ceres along the Witzenberg and Skurweberg ranges to the Krakadouwberge in the northern Cederberg; on rocky sandstone at high elevations above 1 500 m, flowering in summer.



Distribution of ***Gladiolus cylindraceus***.

Diagnosis: recognised by the three leaves with centric, X-shaped blade with four longitudinal grooves or furrows and unscented, salver-shaped flowers with cylindric perianth tube (25–)35–52 mm long, the lower tepals with dark diamond-shaped markings, and relatively short filaments 7–8 mm long. Related *Gladiolus inflatus* has funnel- or almost bell-shaped flowers with longer filaments 12–18 mm long and a shorter perianth tube.



148. **Gladiolus nigromontanus** *Goldblatt* in Journal of South African Botany 50: 456 (1984). Type: South Africa, [Western Cape], Swartberg Pass, Old Toll House, 950 m, 16 Mar. 1981, *Vlok 175* (MO, holo.; K, NBG, PRE, iso.).

Plants 300–400 mm high. *Corm* globose, ± 16 mm diam.; tunics of coarse fibres, accumulating in a collar around base of stem. *Stem* lightly flexed outward above sheaths of upper 2 or all leaves, inclined above, unbranched. *Leaves* 3, lowermost basal and sheathing lower ½ of stem, reaching middle or upper ⅓ of stem, relatively short, straight and erect, terete with 4 longitudinal grooves, ± 1 mm diam., cauline leaves entirely sheathing or with short free apices up to 20 mm long, lower of these fairly long and overlapped by sheath of basal leaf, uppermost short, inserted in upper ⅕ of stem, 40–55 mm long, sometimes overlapped by second leaf, margins of sheaths united around stem. *Spike* inclined, ± straight, 3- to 6-flowered; bracts pale green or flushed greyish purple, apices brown, 14–22 mm long, inner forked, slightly shorter. *Flowers* white to pale pink, lower 3 tepals with dark red longitudinal streaks or lozenge-shaped marks sometimes pale in centre, red in base of tube; perianth tube narrowly and obliquely funnel-shaped, (17–)20–25 mm long, exceeding bracts and emerging between them, curved outward beyond bracts, wider upper part ± 8 mm long; tepals with dorsal largest, obovate, inclined to hooded over stamens 20–24 × 14–16 mm, often recurved apically, upper laterals lanceolate, curving outward, becoming reflexed in upper ½, ± 20 × ± 12 mm, lower 3 tepals united below for ± 4 mm, free parts ± 15 mm long, forming horizontal, lightly channelled claws below, limbs 4–5 mm wide, recurving distally. *Filaments* 12–14 mm long, exserted 3–4 mm from tube; anthers ± 7 mm long, dark purple; pollen cream-coloured. *Style* arching over stamens, dividing 1–2 mm beyond anther tips, branches ± 4.5 mm long. *Capsules* obovoid, obtuse, ± 12 mm long (only immature capsules seen). *Seeds* unknown. *Flowering time*: February to early May.

Distribution and ecology: a narrow endemic of the Swartberg north of Oudtshoorn in Western Cape, South Africa; near perennial streams on sandstone slopes, flowering in midsummer and autumn.

Distribution of ***Gladiolus nigromontanus***.

Distribution of ***Gladiolus engysiphon***.

Diagnosis: recognised by the three leaves with relatively short, terete, longitudinally grooved blades and the white, narrowly funnel-shaped flowers with red median markings on the lower tepals, moderately long perianth tube, (17–)20–25 mm long, and purple anthers.

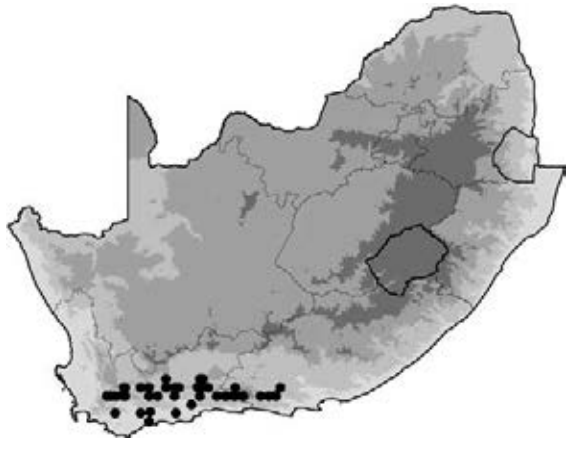
149. **Gladiolus engysiphon** *G.J.Lewis* in Lewis et al. in Journal of South African Botany, Suppl. 10: 266 (1972). Type: South Africa, [Western Cape], Riversdale District, foothills of the Langeberg at the Vette River, cultivated at Kirstenbosch Gardens, 22 Mar. 1934, *Ferguson s.n. Natl. Bot. Gard. 481/34* (SAM, holo.; BOL, PRE, iso.).

Plants 350–450 mm high. *Corm* ovoid, 9–12 mm diam.; tunics papery, becoming fibrous below. *Cataphylls* puberulous above ground. *Stem* lightly flexed outward above sheath of uppermost leaf, unbranched. *Leaves* 3, all largely or entirely sheathing, lowermost basal and sheathing lower ⅔ of stem, overlapping second leaf, cauline leaves inserted in upper ⅓ of stem, uppermost a bract-like scale 20–30 mm long, margins and main vein heavily raised and thickened, thus ± terete in section with four longitudinal grooves, ± 1 mm diam., sometimes lightly scabrid; non-flowering plants with solitary leaf. *Spike* flexed at base, inclined, straight, 2- to 6-flowered; bracts dull greenish grey to brown, 15–20(–27) mm long, inner slightly shorter to ± as long, forked apically. *Flowers* white or cream-coloured, occasionally lightly flushed with mauve, tube pinkish on reverse, upper lateral and lower 3 tepals with red streak in lower midline, sometimes cream-coloured to yellowish in centre of streak, upper part of tube lightly streaked with red, filaments pink to red or violet, unscented; perianth tube nearly cylindric or narrowly funnel-shaped, (22–)40–60 mm long, widening in upper 5–8 mm, sometimes rather abruptly; tepals narrowly lanceolate, dorsal largest, 16–20 × 9–10 mm, inclined over stamens, upper laterals 14–17 × 5–7 mm, spreading in upper ⅓, lower 3 tepals united with upper laterals for 3–4 mm, free parts 12–15 × 3–4 mm. *Filaments* 10–12 mm long, exserted 3–4 mm from tube; anthers 6–8 mm long, purple; pollen cream-coloured. *Style* arching over stamens, dividing opposite or up to 6 mm beyond anther apices, branches ± 3 mm long. *Capsules* obovoid, 10–14 mm long, 3-lobed above and retuse. *Seeds* oval, 4.5–5.0 × 3.5–4.0 mm, broadly and evenly winged. *Flowering time*: March to early April, occasionally as early as mid-February.

Distribution and ecology: a local endemic of Western Cape, South Africa, restricted to a narrow band along the southern foothills of the Langeberg from Swellendam to Riversdale and Herbertsdale; on clay loam or stony clay at the interface between shale and sandstone, flowering in the autumn.

Diagnosis: recognised by the three, largely sheathing and overlapping leaves with reduced blades, the lowermost sheathing the lower two thirds of the stem, and the white to cream-coloured flowers with long, slender tube (22–)40–60 mm long, produced in autumn.

150. **Gladiolus patersoniae** *F.Bolus* in Journal of Botany, British and foreign 66: 14 (1928). Type: South Africa, [Eastern Cape], Baviaanskloof Mtns, Sept. 1910, *Paterson 17* (GRA, holo.).



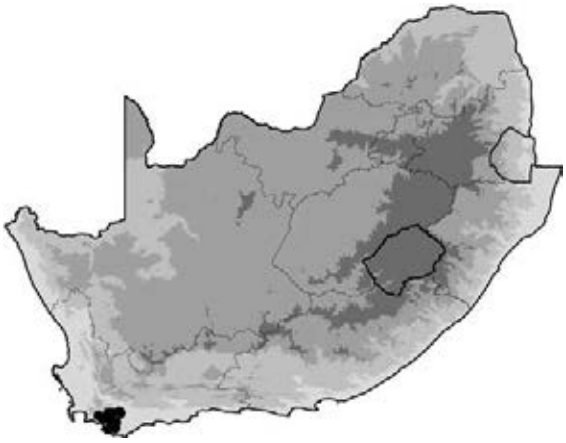
Gladiolus inflatus subsp. *intermedius* G.J.Lewis in Lewis et al.: 241 (1972). Type: South Africa, [Western Cape], Witteberg Mtns, 14 Oct. 1928, *Compton 3326* (BOL, holo.; K, iso.).

Plants 300–600(–1 000) mm high, with cataphylls sometimes puberulous above ground, often concealed by a thick mass of coarse fibres. *Corm* globose, 15–25 mm diam. or more; tunics of hard coarse fibres, usually thickened below into claw-like ridges, accumulating to form a thick collar around base. *Stem* flexed slightly in upper ⅓ above sheath of second leaf, unbranched. *Leaves* 3, lower 2 basal, lowermost usually sheathing only near base of stem, leaf longest, reaching or slightly exceeding spike, straight and ± erect, terete with 4 narrow longitudinal grooves, ± 2 mm diam., second leaf sheathing for most or all of its length, uppermost leaf largely to entirely sheathing and sometimes reduced to a grey-green scale 10–20 mm long, margins united in

lower ½. *Spike* inclined and flexuose, 2- to 4(5)-flowered; bracts greyish green, often flushed purple, margins hyaline, outer 18–37 mm long, inner shorter and enclosed by outer, forked apically. *Flowers* inflated and bell-like, pale to deep blue, slate, greyish, or cream-coloured, dorsal tepal usually more intensely coloured, lower 3 tepals with transverse yellow band or chevron across distal ⅓, usually outlined in dark blue or purple, strongly scented of apple and carnation; perianth tube obliquely funnel-shaped, geniculate, 10–12(–15) mm long, lower ½ erect and cylindric, upper ½ bent at right angles and flaring outward; tepals with upper broadly obovate, dorsal largest, hooded over stamens, 20–30 × 11–28 mm, upper laterals slightly shorter, curved slightly outward apically, lower 3 tepals united with upper laterals for 3–6(–10) mm and together for 2–3 mm, oblanceolate-spathulate, upper margins curving upward, 12–22 × 6–10(–14) mm, laterals slightly exceeding lower median. *Filaments* 10–16 mm long, exserted 6–8 mm from tube but enclosed in flower; anthers 6–8(–11) mm long, reaching to ± middle of upper tepal, whitish; pollen whitish. *Style* arching over stamens, dividing between middle and apices of anthers, branches ± 3.5 mm long. *Capsules* ovoid-ellipsoid, (14–)20–24 mm long. *Seeds* ± 7 × 5–6 mm, broadly and evenly winged. *Flowering time*: mid-August to mid-September at lower elevations, October and November at higher elevations.

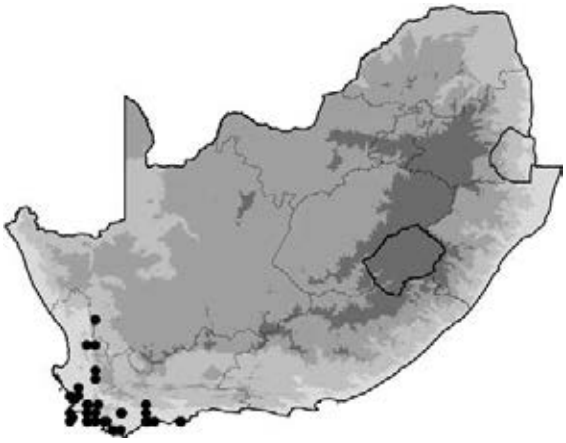
Distribution and ecology: endemic to Western Cape, South Africa and relatively widespread through the southern interior, from Worcester along the Hex River Mtns, Bonteberg and southern mountains to Baviaanskloof in Eastern Cape, and on the Potberg near Cape Infanta; on rocky sandstone slopes and alluvium in drier fynbos.

Diagnosis: recognised by the three leaves with narrow, terete blades and fragrant, bluish to grey or cream-coloured, bell-shaped flowers with sharply bent perianth tube 10–15 mm long, the lower tepals with a transverse yellow band outlined with darker colour. *Gladiolus inflatus* from the western and southwestern mountains has unscented, pink to mauve flowers with dark spear- or spade-shaped markings on the lower tepals and a curved perianth tube 12–30 mm long.



Distribution of ***Gladiolus patersoniae***.

151. **Gladiolus subcaeruleus** *G.J.Lewis* in Flowering Plants of Africa 29: t. 1158 (1953a). Type: South Africa, [Western Cape], Riviersonderend Mtns, southern foothills, Apr.–May 1950, *Lewis & Davis 2316* (SAM, holo.; K, SAM, iso.).



Plants 150–300 mm high, with cataphylls resembling leaves of flowering stem, puberulous above ground. *Corm* conic, 8–12 mm diam.; tunics firm-papery, decaying irregularly and becoming fibrous from the base, forming a fibrous collar around base. *Stem* erect below, flexed lightly above sheaths of upper 2 leaves, unbranched. *Leaves* 3(4), all entirely sheathing, lowermost sheathing lower ⅓–½ of stem, usually 60–80 mm long, second leaf inserted at ± middle of stem, slightly shorter than basal, sometimes just overlapping next leaf, uppermost leaf 20–40 mm long; foliage leaf produced after flowering, solitary, filiform, oval in section with 4 longitudinal grooves, with fine scattered deflexed hairs along groove edges. *Spike* lightly inclined, nearly straight, 3- to 5-flowered; bracts grey-green, outer 11–17 mm long, inner acute, slightly shorter to slightly longer. *Flowers* pale blue, lower lateral tepals with yellow transverse or spear-shaped median markings outlined in dark purple, lower median less prominently marked or unmarked, unscented or with a light metallic odour; perianth tube obliquely funnel-shaped, ± 15–17 mm long, lower cylindric part 8–10 mm long; tepals lanceolate to ovate, unequal, upper 3 largest, ovate, dorsal inclined over stamens, 20–24 × 10–12 mm, upper laterals directed forward, becoming patent in upper ⅓, ± 20 × 9–12 mm, lower 3 tepals united with upper laterals for ± 4 mm and together for ± 2 mm, lower laterals narrowed below into channelled claws ± 9 mm long, limbs ± 7 × 4.5 mm, lower median tepal lanceolate, not distinctly clawed, ± 15 × 7 mm, in profile lower tepals exceeding upper by ± 10 mm. *Filaments* 12–15 mm long, exserted 7–8 mm from tube; anthers 4.5–5.0 mm long, pale mauve; pollen cream-coloured. *Style* arching over stamens, dividing opposite anther apices, branches 2.0–3.5 mm long. *Capsules* obovoid, rounded apically, 10–12 mm long, mature capsules not seen. *Seeds* unknown. *Flowering time*: March and April.

Distribution and ecology: a narrow endemic of the Overberg in Western Cape, South Africa, extending from Bot River along the southern foothills of the Caledon Swartberg to Riviersonderend, southward to Napier and Elim; on clay and loam in renosterveld shrubland.

Diagnosis: an autumn-flowering species recognised by the fibrous corm tunics forming a collar around the base of the stem, three or rarely four, ± entirely sheathing leaves on the flowering stem, and pale blue, funnel-shaped flowers with transverse yellow bands or spear-shaped markings edged with purple on the lower tepals. The solitary foliage leaf, produced from a separate bud later in the season, is terete and 4-grooved, with scattered long hairs along the edges of the grooves. *Gladiolus martleyi* from sandy soils has softly papery or

Distribution of ***Gladiolus subcaeruleus***.

Distribution of ***Gladiolus martleyi***.

membranous corm tunics and pink to mauve flowers with slightly shorter perianth tube, 11–12 mm long, and a glabrous foliage leaf.

152. **Gladiolus martleyi** *L.Bolus* in South African Gardening and Country Life 23: 47 (1933a). Type: South Africa, [Western Cape], without precise locality, Banhoek, Stellenbosch, cultivated at Kirstenbosch Gardens, 29 Mar. 1932, *Martley s.n.* (BOL [*Natl. Bot. Gard. 371;32*], holo.; K, iso.).

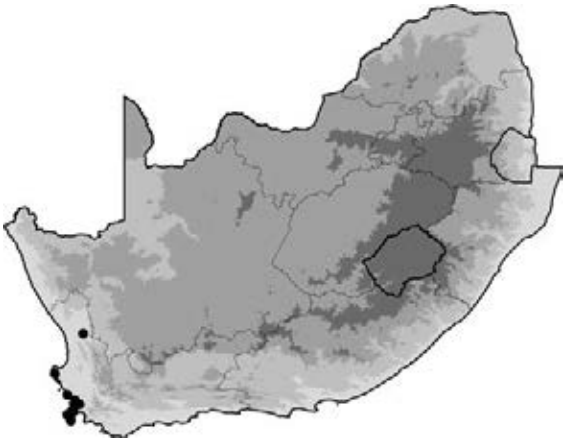
Gladiolus pillansii G.J.Lewis: 57 (1935). Type: South Africa, [Western Cape], Melkbosch road, 3 Apr. 1932, *Barnard s.n.* (BOL [*BOL 20518*], holo.; K, iso.).

Gladiolus pillansii var. *roseus* G.J.Lewis: t. 1159 (1953b). Type: South Africa, [Western Cape], Cape Peninsula, Scarborough, damp sandy ground near the vlei, 20 Feb. 1953, *Minicki s.n. SAM 60953* (SAM, holo.).

Plants (200–)300–600 mm high. *Corm* globose, 15–30 mm diam.; tunics softly papery or membranous, fragmenting irregularly or becoming somewhat fibrous. *Stem* erect below, inclined above, unbranched. *Leaves* 2 or 3, entirely sheathing, evenly spaced along stem or lowermost sometimes shortly overlapping one above, 50–150 mm long, progressively shorter, uppermost with margins free to base; foliage leaf produced after flowering, solitary, terete with four narrow longitudinal grooves, ± 1 mm diam. *Spike* weakly inclined, lightly flexuose, (3)5- to 11-flowered; bracts greyish to purplish green, outer 14–22 mm long, inner ± as long or slightly shorter, acute. *Flowers* pale to deep pink or lilac to mauve, lower lateral tepals with transverse band or spear-shaped to trilobed-spathulate yellow mark edged with darker pink or purple, often with strong sweet fragrance; perianth tube obliquely funnel-shaped, 11–12 mm long, cylindric lower part ± 7.5 mm long; tepals narrowly to broadly lanceolate, dorsal largest, inclined over stamens, curving upward distally, 22–27 × 11–12 mm, upper laterals recurving distally, 19–22 × 8.5–10.0 mm, lower 3 tepals united with upper laterals for 2–5 mm and together for 3–4 mm, free parts 15–19 mm long, gradually narrowed below into channelled claws, limbs arching downward, laterals ± 6 mm wide, lower median ± 8 mm wide. *Filaments* 12–13 mm long, exserted ± 8 mm from tube; anthers 6.0–8.8 mm long, dark purple-blue; pollen pale grey-blue. *Style* arching over stamens, dividing close to or slightly beyond anther apices, branches ± 3 mm long. *Capsules* narrowly ellipsoid, ± 12–20 mm long. *Seeds* oval, ± 7 × 4–5 mm, broadly and evenly winged. *Flowering time*: mainly March to April, occasionally in mid-February and as late as May.

Distribution and ecology: extending in Western Cape, South Africa, from the Gifberg in the north to Albertinia in the southeast; in deep sandy soils or sometimes loam in fynbos, flowering in autumn.

Diagnosis: an autumn-flowering species recognised by the softly papery or finely fibrous corm tunics, the foliage reduced to three, ± entirely sheathing leaves on the flowering stem, and pink to mauve, funnel-shaped flowers with transverse yellow bands or spear-shaped marking edged with red on the lower tepals. The solitary foliage leaf, produced from a separate bud later in the season, is terete and 4-grooved. *Gladiolus jonquilliodorus* from the Cape Peninsula and nearby Atlantic Coast has similar pale yellow or pearly grey flowers produced in midsummer, and two or three foliage leaves. *Gladiolus subcaeruleus* from clay soils has coarsely fibrous corm tunics forming a collar around the base of the stem and pale blue flowers with a slightly longer perianth tube, 15–17 mm long, and a thinly hairy foliage leaf.



153. **Gladiolus jonquilliodorus** *Eckl. ex G.J.Lewis* in Annals of the South African Museum 40: 124 (1954). Type: South Africa, [Western Cape], Cape Flats, damp places, Feb., *Zeyher 450* [SAM, lecto., designated by Lewis et al.: 287 (1972)].

Plants (250–)400–700 mm high, with dry, brown cataphylls. *Corm* globose, 20–40 mm diam.; tunics membranous to soft-papery, becoming finely fibrous. *Stem*

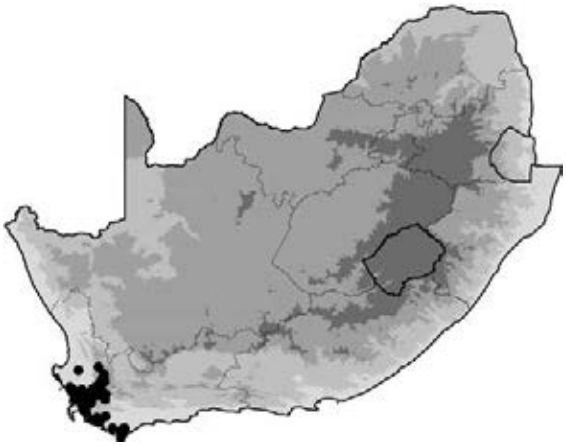
straight and erect, unbranched. *Leaves* 2 or 3, entirely sheathing, lowermost usually overlapping next; foliage leaves produced after flowering, 2 or 3, 300–500 mm long, terete with four narrow longitudinal grooves, ± 1 mm diam., dry and dead at flowering time, often lacking. *Spike* lightly flexed at base and inclined, (4)7- to 14-flowered; bracts soft-textured, yellowish green to grey, outer 14–18 mm long, inner slightly shorter. *Flowers* cream-coloured or pale yellow to pearly grey, sometimes flushed with pink or light mauve, lower 3 tepals or only lower laterals with transverse yellow band and often streaked with narrow purple lines below, sweetly scented during day, partially closing at night, then scentless; perianth tube obliquely funnel-shaped, 8–9 mm long, largely enclosed in bracts; tepals narrowly oblanceolate, unequal, dorsal ± 20 × 9 mm, extending horizontally over stamens, upper laterals slightly shorter, directed forward and twisted obliquely to overlap dorsal tepal, curving outward distally, lower tepals united to one another for ± 5 mm, free parts 8–10 mm long, narrowed below into claws, abruptly expanded into limbs ± 5 mm long, arching downward. *Filaments* ± 10 mm long, exserted ± 5 mm from tube; anthers ± 6 mm long, mauve; pollen pale yellow. *Style* arching over stamens, usually dividing at or just beyond anther apices, branches 1.0–1.5 mm long. *Capsules* ellipsoid, 16–19 mm long. *Seeds* ovate, ± 6 × 3.5 mm, broadly and evenly winged. *Flowering time*: mainly December to mid-January, occasionally in late November or early February.

Distribution and ecology: a rare and local endemic of the extreme southwestern corner of Western Cape, South Africa, from Saldanha to the southern Cape Peninsula but recently recorded southwest of Klawer; on sandy coastal flats and plateaus in fynbos, flowering in midsummer.

Diagnosis: a summer-flowering species recognised by the softly papery or finely fibrous corm tunics, leaves of the flowering stem only three and ± entirely sheathing and pale yellow to pearly grey, funnel-shaped flowers with a transverse yellow band on the lower tepals. The flowers close at night. The two or three foliage leaves, produced from a separate bud later in the season, are terete and 4-grooved. *Gladiolus martleyi* has similarly shaped but pink to mauve flowers produced in autumn and a solitary foliage leaf.

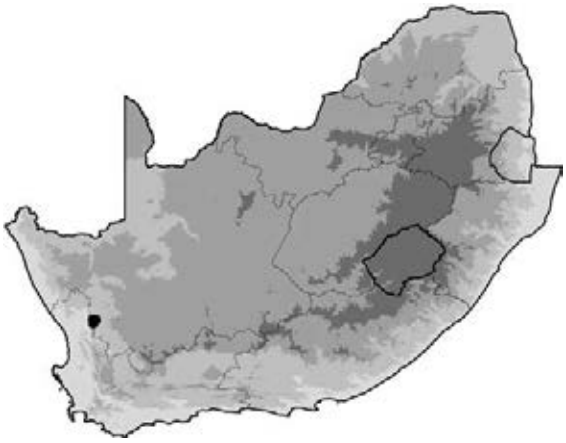
Distribution of ***Gladiolus jonquilliodorus***.

154. **Gladiolus trichonemifolius** *Ker Gawl.* in Curtis's Botanical Magazine 36: t. 1483 (1812). Type: South Africa, without precise locality, cultivated in Great Britain at Royal Botanic Gardens, Kew, *Masson s.n.* (BM, holo.).



Gladiolus citrinus Klatt: 340 (1882). Type: South Africa, [Western Cape], between Paarl Mtns and Paardeberg, 1840, *Drège 8457* (?B, holo.; BM, G, K, L, S, iso.).

Gladiolus erectiflorus Baker: 146 (1896), illegitimate homonym, not *G. erectiflorus* Baker (1895). Type: South Africa, [Western Cape], sandy places near Malmesbury, Oct. 1892, *Macowan 1548* (K, holo.; BOL, G, SAM, iso.).



Gladiolus symmetranthus G.J.Lewis: 122, t. 4 (1954). *G. trichonemifolius* f. *symmetranthus* (G. J.Lewis) Bullock: t. 357 (1960). Type: South Africa, Cape, near Koelenhof, between Stellenbosch and Muldersvlei, 14 Sept. 1950, *Lewis 2237* (SAM, holo.; K, PRE, iso.).

[*Ixia spathacea* Sol. ex Ker Gawl.: t. 1483 (1812), invalid name as a synonym.]

Plants 120–250 mm high. *Corm* globose, 7–12 mm diam.; tunics woody to leathery, splitting into claw-like segments. *Stem* erect below, flexed outward above sheaths of two upper leaves, unbranched. *Leaves* 3, lower 2 basal, lowermost sheathing lower ⅔ of stem, usually shortly exceeding spike, oval in cross-section to terete and longitudinally 4-grooved, margins and midribs heavily thickened, 1–2 mm diam., second leaf sheathing for ½ its length, reaching to ± base of spike, uppermost leaf inserted in upper ⅓ of stem, mostly sheathing. *Spike* inclined or erect, flexuose, 1- to 3(4)- flowered; bracts dark green, veins nearly transparent, attenuate, outer 30–40(–50) mm long, inner shorter. *Flowers* weakly zygomorphic or subactinomorphic, creamy-white to yellow, outer tepals often flushed purple on reverse, lower 3 tepals with paired brown lines either side of midline in lower half and deeper yellow across middle, sometimes purplish toward apices, mouth of tube edged with star-shaped purple band or base of tepals and upper part of tube with blackish star-shaped mark, often with a strong sweet freesia- or violet-like scent, or unscented; perianth tube straight or obliquely and narrowly funnel-shaped, 16–20 mm long; tepals with upper 3 slightly larger than lower 3, or subequal, or outer 3 slightly larger than inner, lanceolate-elliptic, 24–35(–40) mm long, dorsal 10–13(–18) mm wide, lower 3 usually united for 1–4 mm, 22–35(–44) × 7–9 mm, arching outward in upper half. *Filaments* 8–15 mm long, exserted ± 2 mm from tube; anthers 8–10 mm long, pale yellow; pollen cream-coloured. *Style* arching over stamens or occasionally nearly straight, dividing just below anther apices, branches 4–5 mm long. *Capsules* ovoid-ellipsoid, 12–15 mm long. *Seeds* ovate, 4–5

Distribution of ***Gladiolus trichonemifolius***.

Distribution of ***Gladiolus sufflavus***.

× ± 3.0–3.5 mm, broadly and evenly winged. *Flowering time*: August to mid-September, occasionally in late July or late September.

Distribution and ecology: restricted to the southwestern corner of Western Cape, South Africa, from Hopefield to Bredasdorp and inland to the Cold Bokkeveld; on seasonally marshy flats in loamy or sandy soils.

Diagnosis: recognised by the woody corm tunics, three leaves with slender, oval to terete and 4-grooved blades, and the creamy white to yellow, weakly zygomorphic flowers with funnel-shaped perianth tube 16–20 mm long and subequal tepals, the lower deeper yellow toward the base and with dark purple lines or streaks in the throat. White-flowered plants occur in the Hottentots Holland Mtns and around Bredasdorp.

155. **Gladiolus sufflavus** *(G.J.Lewis) Goldblatt & J.C. Manning*, *Gladiolus* in southern Africa: 287 (1998). *G. pritzelii* var. *sufflavus* G.J.Lewis in Lewis et al.: 250 (1972). Type: South Africa, [Northern Cape], Calvinia District, Glenridge Farm, Nieuwoudtville, 20 Aug. 1960, *Lewis 5730* (NBG, holo.; K, iso.).

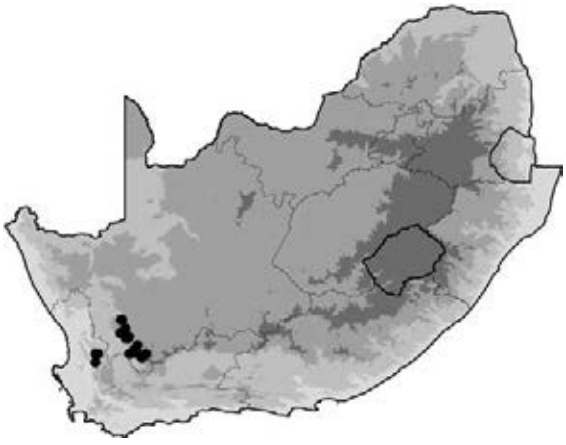
Plants 450–700 mm high, with cataphylls puberulous to villous above ground. *Corm* 18–25 mm diam.; tunics leathery, becoming ± fibrous, often accumulating in collar around base of stem. *Stem* erect, flexed outward above sheathing part of two upper leaves, unbranched. *Leaves* (3)4, lower 2 basal, sheathing only near base, reaching to between base and middle of spike, ± terete with 4 longitudinal grooves or cross-shaped in section, 2–3 mm diam., smooth on both sheath and blade, remaining leaves villous on sheaths, second leaf sheathing stem for most of its length, upper 2 leaves cauline and largely sheathing. *Spike* inclined, lightly flexuose, 4- to 6-flowered; bracts olive-green, outer 20–30 mm long, inner nearly as long. *Flowers* bell-shaped, pale yellow to greenish, lower tepals with obscure greenish, dark yellow or brown markings, with sweet lily-like fragrance; perianth tube obliquely funnel-shaped, geniculate, 14–15 mm long, lower half erect and cylindric, upper half bent at right angles and flaring outward; tepals with upper broadly ovate, lower spathulate, dorsal largest, arched to hooded over stamens, 18–20 × 13–16 mm, upper laterals slightly smaller, curving outward near margins, lower laterals united with upper laterals for 4–5 mm, forming a shallow spoon, ± 11 × 8 mm, not differentiated into claws below, curving upward below and deflexed apically. *Filaments* 13–14 mm long, exserted from tube for 7–8 mm but included in flower; anthers 6–7 mm long, purple; pollen cream-coloured. *Style* arched over stamens, dividing just below anther apices, branches ± 3.5 mm long. *Capsules* ovoid-ellipsoid, 17–21 mm long. *Seeds* ovate, 5–6 × 4 mm, broadly and evenly winged. *Flowering time*: late August and September.

Distribution and ecology: a local endemic of the Bokkeveld Escarpment near Nieuwoudtville in Northern Cape, South Africa; on sandstone along seasonal streams, ponds and seepages in arid fynbos.

Diagnosis: recognised by its stiffly erect stems with three or four leaves, the lowermost or lower two subbasal with a centric blade, terete or X-shaped in section and the remainder largely sheathing with softly villous sheaths, and nodding, pale yellow to yellow-green, bell-shaped flowers with a sharply bent perianth tube 14–15 mm long. *Gladiolus pritzelii* has bright yellow flowers, often conspicuously marked with brown on the lower tepals, and plane leaves with one or two raised veins but unthickened margins.

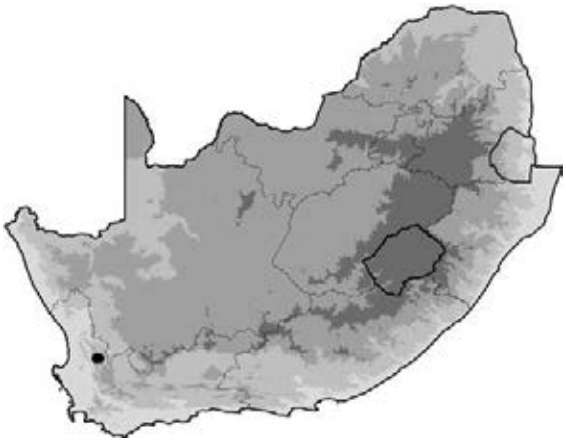
156. **Gladiolus pritzelii** *Diels* in Botanische Jahrbücher für Systematik 44: 118 (1909). Type: South Africa, [Northern Cape], Hantamsberg, Sept. 1900, *Diels & Pritzel 738* (B, holo. [photo at NBG, PRE]; Z, iso.).

Plants 200–600 mm high, with cataphylls often puberulous above ground. *Corm* globose, 15–20 mm diam.; tunics woody to leathery, splitting from below into coarse teeth or becoming fibrous. *Stem* ± erect throughout,



flexed above sheaths of upper two leaves, unbranched. *Leaves* 3, lowermost basal and reaching to ± base of spike, smooth or puberulous to villous, sheathing lower ⅓ of stem, linear, 1,0–3.5 mm wide, usually with 2 raised central veins, margins not noticeably thickened, second leaf sheathing stem to shortly below spike, blade short, third leaf inserted shortly below spike. *Spike* weakly inclined, flexuose, 1- to 3(5)-flowered; bracts pale to olive-green, margins membranous, outer 20–40 mm long, inner shorter, minutely forked. *Flowers* zygomorphic, bell-shaped, clear to dull yellow, upper lateral tepals sometimes with reddish markings, lower lateral tepals with bright yellow transverse band outlined in red to purple or brown, lower median with spade-shaped yellow mark outlined in red or purple, lower part of throat streaked with dark colour, sweetly fragrant; perianth tube obliquely funnel-shaped, geniculate, 11–12 mm long, lower ½ erect, cylindric for ± 6 mm, upper ½ bent sharply and flaring outward; tepals with upper 3 ovate, dorsal largest, arched over stamens, (16–)22–24 × 13–20 mm, upper laterals slightly smaller, recurving apically, lower 3 tepals united with upper laterals for 4–6 mm and together for 2–3 mm, scabrid in lower midlines, curving downward distally, laterals spathulate, 12–16 × ± 7 mm, lower median ± as long, lanceolate. *Filaments* 10–12 mm long, exserted 5–6 mm from tube but included in flower; anthers ± 8.5 mm long, reddish to brown; pollen yellow. *Style* arching over stamens, dividing shortly below anther apices, branches 3–4 mm long. *Capsules* and *seeds* unknown. *Flowering time*: late August and September.

Distribution and ecology: a montane species recorded from the southern Cederberg and Cold Bokkeveld in Western Cape, South Africa and inland in the Northern Cape from the Hantamsberg and the higher parts of the Roggeveld; on rocky sandstone slopes in fynbos or in the interior in dolerite outcrops in renosterveld.



Diagnosis: recognised by the three smooth to pubescent leaves with a pair of thickened and raised veins on one side but with the margins unthickened and bell-shaped, yellow flowers with short, sharply bent perianth tube 11–12 mm long. *Gladiolus delpierrei* has similar leaves but softly fibrous corm tunics and funnel-shaped, pale yellow to cream-coloured flowers with a very short perianth tube ± 8 mm long. *Gladiolus sufflavus* from the Bokkeveld Escarpment has X-shaped leaves with thickened margins and midrib, and greenish flowers.

157. **Gladiolus delpierrei** *Goldblatt* in Journal of South African Botany 45: 84 (1979). Type: South Africa, [Western Cape], Cederberg Mtns, Sneeuberg, 5 Jan. 1975, *Delpierre 456* (NBG, holo.).

Plants 550–650 mm high, with cataphylls lightly mottled above ground but dry and pale at flowering time. *Corm* globose, ± 20 mm diam.; tunics finely fibrous, forming thin collar around base. *Stem* unbranched. *Leaves* 3, lowermost basal and reaching to ± base of spike, linear, 3–4 mm wide, main vein and one other vein or vein pair moderately thickened and prominent, margins lightly thickened, sheaths of 2 lower leaves lightly scabrid on veins, remaining 2 leaves cauline, widely spaced, entirely sheathing, margins united below around stem. *Spike* lightly inclined, 5- to 7-flowered; bracts pale grey-green or flushed light purple, outer 18–20 mm long, inner slightly shorter. *Flowers* creamy yellow, upper lateral tepals reddish along midline toward base, lower tepals dark yellow in lower ⅓ with fine red lines or feathering at base, mouth of tube dark red; perianth tube narrowly funnel-shaped, ± 8 mm long; tepals with upper ovate, dorsal largest, ascending to inclined over stamens, ± 21 × 11 mm, upper laterals ± 17 × 8.5 mm, in profile sometimes narrowly windowed between dorsal and upper laterals, lower tepals lanceolate, joined to upper laterals for ± 3 mm, 12–13 mm long, narrowed below into channelled claws, limbs minutely puberulous in lower midline, recurved or sharply deflexed from middle, lowermost slightly longer than lower laterals. *Filaments* ± 12.5 mm long, exserted ± 9 mm from tube; anthers ± 8 mm long, light mauve; pollen cream-coloured. *Style* arching over stamens, dividing just below anther apices, branches 2–3 mm long. *Capsules* and *seeds* unknown. *Flowering time*: December and early January.

Distribution of ***Gladiolus pritzelii***.

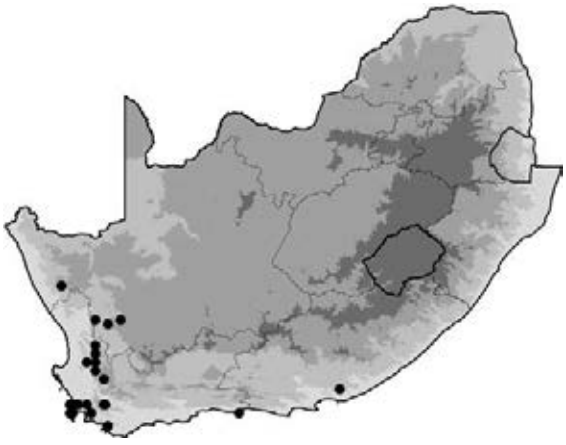
Distribution of ***Gladiolus delpierrei***.

Distribution and ecology: a local endemic of the Cederberg in Western Cape, South Africa, recorded only from the upper slopes of Sneeuberg; in seeps on sandstone, above 1 800 m elevation, flowering in midsummer.

Diagnosis: recognised by the three linear leaves, the lowermost with one or two veins thickened and raised and the margins lightly thickened, and small, funnel-shaped, pale creamy yellow flowers with a red throat and red streaks at the base of the upper and lower lateral tepals, with a very short perianth tube ± 8 mm long. *Gladiolus pritzelii* has similar leaves, with two veins thickened and raised and the lower tepals also puberulous in the lower midline, but coarsely fibrous tunics and bell-shaped, yellow flowers with a sharply bent perianth tube 11–12 mm long.

Ser. **Tristes** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus tristis* L.

Plants from winter- and summer-rainfall regions. *Corms* subglobose; tunics ± leathery to woody and splitting into claws, or coarsely fibrous. *Leaves* three, green at flowering, lowermost markedly longest, centric or linear with midrib and margins thickened and raised at right angles to blade thus with two furrows or grooves on each side. *Flowers* small to medium, zygomorphic or rarely subactinomorphic, usually trumpet-shaped and nocturnal with spicy scent, cream-coloured to brownish and variously mottled, rarely cup-shaped and pink, often hyaline along tepal sinuses and especially lower margins of dorsal tepal; perianth tube usually as long as or longer than dorsal tepal, rarely very short. *Capsules* oblong-ellipsoid or cylindric.



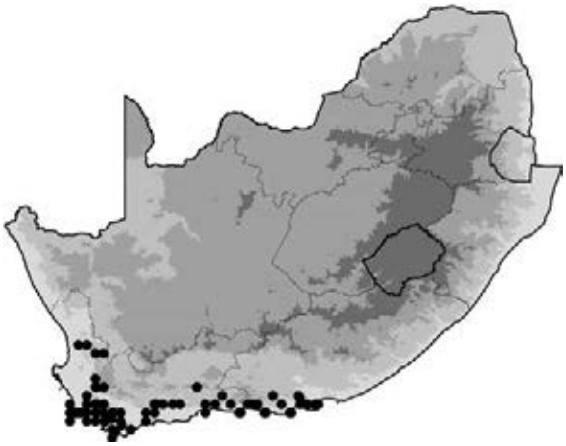
158. **Gladiolus hyalinus** *Jacq.*, Icones plantarum rariorum 2: conspectus tabularum, nec t. 242 (1795 [1788–1795]), replacement name for *G. strictus* Jacq.: 170 (1791), illegitimate homonym, not *G. strictus* Aiton (1789). Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 242 (1795 [1788–1795]).

Gladiolus confusus N.E.Br.: 31 (1928). Type: South Africa, [Western Cape], Devil's Peak near Mowbray, in rocks at foot of mountain, 300 ft [90 m], Aug. 1883, *H. Bolus 4890* (K, holo.; BOL, iso.).

Plants (120–)300–600 mm high. *Corm* globose-conic, 10–12 mm diam.; tunics ± woody, splitting below into claw-like segments. *Stem* erect below, flexed outward above sheaths of upper 2 leaves, unbranched. *Leaves* 3, imbricate, lowermost markedly longest, reaching to ± base of spike, linear, 1.7–2.5 mm wide, margins and main vein strongly thickened and raised, thus with two fairly wide grooves on each surface, second leaf sheathing lower ½ of stem, upper leaf sheathing for ± ½ its length. *Spike* inclined, ± straight, 1- to 3(6)-flowered; bracts pale green to greyish, sometimes long-attenuate, outer 36–50 mm long, usually exceeding perianth tube, inner slightly shorter, minutely forked. *Flowers* light to reddish brown on a pale cream-coloured background, tepals usually darker along midlines, lower ½ of dorsal tepal transparent on edges, abaxial part of throat transparent with dark spots and streaks, entire perianth becoming translucent after dark, unscented or rarely sweetly scented, especially at night; perianth tube 25–36 mm long, erect and cylindric below for 20–24 mm, abruptly bent and flared outward for 10–12 mm; tepals lanceolate to ovate, dorsal largest, arching over stamens, 23–30 × 12–16 mm, upper laterals 23–30 × 7–8 mm, lower 3 tepals united for 2–4 mm, lower laterals 14–20 mm long, curving obliquely away from lower median in upper ½, lower median ± straight, 16–25 × 5–6 mm. *Filaments* 12–16 mm long, exserted 2–5 mm from tube; anthers 9–11 mm long, cream-coloured; pollen yellow. *Style* arching over stamens, dividing at or shortly beyond anther apices, branches 2–3 mm long. *Capsules* elongate-ellipsoid, triangular in section, (20–)25–30 mm long, enclosed in bracts. *Seeds* ± ovate, 4–7 × 3–4 mm, broadly and evenly winged. *Flowering time*: June to mid-August, at higher elevations until late September, rarely in October.

Distribution and ecology: widely scattered through the South African winter-rainfall region, along the western escarpment from Steinkopf to Springbok, the Kamiesberg and Bokkeveld Mtns in Northern Cape, and south to the Cape Peninsula and Riviersonderend Mtns in Western Cape, with outlying records from near Mossel Bay, and Plettenberg Bay and Kenton-on-Sea in Eastern Cape; mostly on loamy or clay soils in renosterveld or transitional fynbos.

Diagnosis: *Gladiolus hyalinus* is recognised by the linear lower leaf with heavily thickened margins and midrib, and moderate-sized, dull-coloured flowers with upper tepals 23–30 mm long and perianth tube 25–36 mm long, with the lower lateral tepals obliquely twisted away from the lower median. The broad transparent lower edges of the dorsal tepal are striking. *Gladiolus liliaceus* has larger flowers, the upper tepals 40–45 mm long and the perianth tube 40–53 mm long, with the lower lateral tepals not obliquely twisted.



Distribution of ***Gladiolus hyalinus***.

159. **Gladiolus liliaceus** *Houtt.*, Natuurlijke historie 2, 12: 55, t. 79, f. 2 (1780). Type: South Africa, without precise locality or collector, cultivated in Holland, *Houttuyn s.n.* (G: Herb. Burman, holo.).

Gladiolus tristis var. *grandis* Thunb.: 12 (1784). *G. grandis* (Thunb.) Thunb.: 185 (1800). Type: South Africa, without precise locality, *Thunberg s.n.* (UPS-THUNB 1031, holo. [photo at BOL, K]).

Gladiolus versicolor Andrews: t. 19 (1798a). *G. versicolor* var. *major* Ker Gawl.: sub t. 556 (1802a). 8). Type: South Africa, without precise locality, *Pringle s.n.*, cultivated in Great Britain at Hammersmith, London, illustration in Andrews: t. 19 (1798a).

Plants 300–800 mm high. *Corm* globose, 12–18 mm diam.; tunics ± woody to leathery, splitting below into claw-like segments. *Stem* usually inclined below, sharply flexed outward above sheathing part of uppermost leaf and strongly inclined above, unbranched. *Leaves* 3, overlapping, 2 lowermost basal, lowermost markedly longest, reaching to between base and shortly beyond apex of spike, sheathing lower part of stem or only near base, second leaf sheathing lower ½ of stem, linear, (1.5–)2.0–4.0(–6.0) mm wide, margins and midribs strongly thickened and raised, thus with two narrow or broad grooves or furrows on each surface, margin and main vein edges minutely scabrid, uppermost leaf inserted between middle and upper ¼ stem. *Spike* inclined, lightly flexuose, 1- to 4(6)-flowered; bracts pale green or suffused dull grey, outer 55–80(–115) mm long, long-attenuate and often twisted above, especially lowermost, lower margins united around spike axis, inner shorter, twisted around to lie against outer, forked. *Flowers* light brown to dull pinkish red, tan, purplish or cream-coloured to greenish yellow, tepals darker along midlines, lower tepals pale yellow to cream-coloured in lower ⅓, abaxial ½ of throat speckled with dark brown, lower edges of dorsal tepal and sutures between tepals transparent, entire perianth changing colour after dark, becoming bluish to mauve and then intensely sweetly clove-scented; perianth tube narrowly and obliquely funnel-shaped, 40–45(–53) mm long, wider upper part 12–20 mm long, exserted between bracts, sometimes lightly pubescent in lower part of tube; tepals lanceolate-attenuate, slightly twisted in upper ½, margins undulate, sometimes crisped distally, dorsal largest, strongly inclined over stamens, curving upward distally, 38–45 × 14–20 mm, upper laterals 37–44 × 10–15 mm, arching outward from base, lower 3 tepals joined to upper laterals for 3–6 mm and sometimes together for up to 2 mm, curving outward distally, 31–40 × 10–15 mm. *Filaments* 15–25 mm long, usually exserted 1.5–5.0 mm from tube or sometimes only reaching top of tube, lightly pubescent below; anthers 11–16 mm long, brown or dull purple; pollen pale yellow or cream-coloured. *Style* arching over stamens, usually dividing opposite anther apices, branches ± 3 mm long. *Capsules* oblong-ellipsoid, triangular in section, 30–50 mm long. *Seeds* 4–5 × 3.0–3.5 mm, broadly and evenly winged. *Flowering time*: late August to mid-September at lower elevations, occasionally later especially at higher elevations; a late-blooming form blooms in November and December.

Distribution of ***Gladiolus liliaceus***.

Distribution and ecology: widespread through the winter-rainfall region of Western and Eastern Cape, South Africa, from the Cederberg to Bredasdorp and along the foothills of the coastal mountains to Port Elizabeth; in clay soils in renosterveld, mainly in lowland habitats.

Diagnosis: diagnosed by the linear lower leaf with heavily thickened and raised margins and midrib, and relatively large, dull, trumpet-shaped flowers with upper tepals 37–45 mm long and perianth tube 40–53 mm long. The lowermost bracts are conspicuously attenuate. Similar *Gladiolus hyalinus* has smaller flowers, the upper tepals 23–30 mm long and the perianth tube 25–36 mm long, with the lower laterals obliquely twisted away from the median. *Gladiolus tristis* has X-shaped leaves and mostly cream-coloured to yellowish flowers with shorter, acute to obtuse bracts up to 50 mm long.

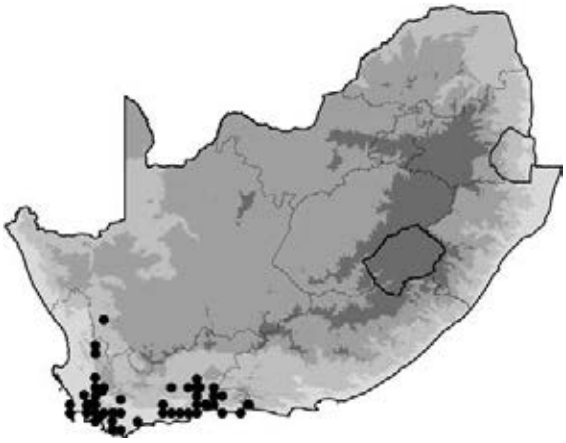
160. **Gladiolus tristis** *L.*, Species plantarum, edn. 2, 1: 53 (1762). Type: South Africa, without precise locality or collector, *Herb. Linn. 59.9* (LINN, holo.).

Gladiolus tristis var. *odorus* Thunb.: 11 (1784). Type: South Africa, without precise locality, *Thunberg s.n.* (UPS-THUNB 1080, holo.).

Gladiolus concolor Salisb.: t. 8 (1806). *G. tristis* var. *concolor* (Salisb.) Baker: 172 (1877). Type: South Africa, without precise locality, cultivated in Britain, figure in Salisb.: t. 8 (1806).

Gladiolus versicolor var. *longifolius* Ker Gawl.: sub. t. 556 (1802a). *G. spiralis* Pers.: 43 (1805). Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 245 (1792 [1788–1795]) '*G. tristis* var.' .

Gladiolus aestivalis Ingram: 301 (1930). *G. tristis* var. *aestivalis* (Ingram) G.J.Lewis in Lewis et al.:



195 (1972). Type: South Africa, Western Cape, Drakenstein Mtns, flowered in Britain, 1930, *Ingram s.n.* (location unknown, not at BM or K).

Gladiolus flavidus Ingram: 302, with fig. (1930). Type: South Africa, [Eastern Cape], Tsitsikamma, estuary of Groot River, 13 Nov. 1927, *Ingram s.n.* (location unknown, not at BM or K).

Gladiolus fulvescens Ingram: 301 (1930). Type: South Africa, Western Cape, dry ground near Elgin, 11 Oct. 1927, *Ingram s.n.* (location unknown, not at BM or K).

Plants (170–)400–1 200 mm high. *Corm* 12–18 mm diam.; tunics firm-papery or leathery, splitting from below into coarse fibres. *Stem* erect or inclined, usually flexed above sheaths of upper 2 leaves, unbranched. *Leaves* 3, rarely a fourth bract-like leaf below spike, lower 2 basal, lowermost markedly longest, reaching to base of spike or exceeding it, sheathing stem up to middle, 2–4 mm diam., X-shaped in section with main vein raised and margins slightly thickened, sometimes thickened edges of margins and main vein almost meeting and leaf thus appearing terete, upper 2 leaves largely to entirely sheathing. *Spike* lightly inclined, ± straight, mostly 3- to 5(11)-flowered; bracts pale to dark green, sometimes flushed grey above, outer (25–)40–50 mm long, inner slightly shorter to ± as long, acute or forked, twisted to lie against outer bract. *Flowers* pale to creamy yellow to greenish yellow, tepals darker coloured on midlines, or sometimes with purple to reddish median streaks, reverse of tepals usually dark grey-purple to reddish along midline and sometimes apices, sutures between tepals transparent for ± 10 mm, most conspicuously so between dorsal and upper laterals, weakly scented during day but strongly scented of carnation and cloves in early evening; perianth tube narrowly and obliquely funnel-shaped, 40–63 mm long, narrow cylindric part 20–30 mm long, lightly papillose in lower throat; tepals broadly lanceolate, unequal, dorsal largest, inclined to almost horizontal, 22–28 × 16–20 mm, upper laterals arching outward from base, 22–28 × 9–16 mm, lower tepals united with upper laterals for ± 2 mm and sometimes together for up to 2 mm, ± straight or curving outward distally, 16–22 × 9–12 mm. *Filaments* (15–)18–25 mm long, included or shortly exserted up to 2 mm; anthers 10–17 mm long, lower 4–5 mm included in tube, pale yellow to light purple; pollen pale yellow. *Style* arching over stamens, minutely scabridulous below, dividing between upper third and apex of anthers, branches (2–)4–6 mm long. *Capsules* ± oblong-ellipsoid, 34–36 mm long, ± as long or slightly longer than outer bract. *Seeds* oval, 5–7 × 4–5 mm, broadly and evenly winged. *Flowering time*: September to November, rarely in August, occasionally in December or early January at high elevations.

Distribution and ecology: widespread in the winter-rainfall parts of Northern, Western and Eastern Cape, South Africa, from the Bokkeveld Mtns to Bredasdorp and along the coastal forelands to Humansdorp and in the Swartberg; on damp sandy flats and marshes, seeps, streamsides and moist south-facing slopes in fynbos, flowering mainly in spring but summer-flowering forms occur at higher elevations.

Distribution of ***Gladiolus tristis***.

Hybrids with *Gladiolus caryophyllaceus* have been recorded in the Swartberg and were described as *G. lewisiae* [see Excluded Species].

Diagnosis: diagnosed by the ± x-shaped lower leaf with heavily thickened and raised main vein and thickened margins and relatively large, cream-coloured to pale yellowish, trumpet-shaped flowers, sometimes ± shaded with grey-brown on the reverse of the tepals, upper tepals 22–28 mm long and perianth tube 40–63 mm long. The bracts are relatively short and blunt, (25–)40–50 mm long. *Gladiolus liliaceus* has linear, grooved leaves and mostly brownish-mottled flowers with longer bracts, 55–115 mm long, those of the lower flowers always long-attenuate and much longer than the perianth tube. *Gladiolus longicollis* has shorter filaments, 5–13 mm long, and occurs mostly east of Port Elizabeth but also occurs in the Swartberg and Kammanassie Mtns.

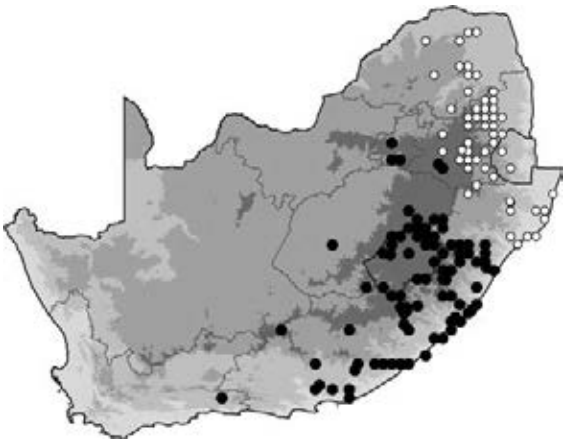
161. **Gladiolus diluvialis** *Goldblatt & J.C.Manning* in Bothalia 41: 290 (2011b), replacement name for *G. halophilus* [as *halophila*] Goldblatt & J.C.Manning: 791 (2011ab), illegitimate homonym, not *G. halophilus* Boiss. & Heldr. in Boiss. (1854). Type: Namibia, Keetmanshoop, tributary valley of Fish River S of Snyfontein, in saline seep at base of cliffs in dry river course, 10 Aug. 2010, *Mannheimer 4383* (WIND, holo.; EBH, K, MO, MSB, NBG, PRE, iso.).

Plants (150–)300–600(–1 000) mm high. *Corm* 15–20 mm diam., tunics firm-papery layers, splitting from below into coarse fibres. *Stem* stiffly erect or flexed slightly outward above second leaf, usually unbranched but very rarely with small branch in axil of uppermost leaf. *Leaves* 3, lower 2 basal, lowermost markedly longest, usually reaching at least to base of spike, 1.0–2.5(–3.0) mm diam., cross-shaped in section with midrib raised at right angles to blade, thus with two furrows ± 0.5 mm wide on each surface, second leaf largely or entirely sheathing

lower ± ⅔ of stem, sheath with hyaline longitudinal suture running entire length, uppermost leaf distant from second leaf, bract-like. *Spike* suberect, ± straight, 1- to 5(–7)-flowered; bracts pale green or flushed grey, outer 22–25 mm long, inner slightly shorter to slightly longer than outer, minutely notched. *Flowers* pale mauve or opalescent with darker mauve feathering along midline, especially on upper lateral tepals, mauve speckled on reverse, lower tepals white in basal half and in throat, yellow-green midline and spotted with purple, tube pale creamy yellow, weakly scented during day but strongly scented of carnations and cloves at night; perianth tube narrowly and obliquely funnel-shaped, 35–40 mm long, narrowly cylindric portion 25–30 mm long, minutely puberulous in lower throat; tepals broadly lanceolate-attenuate, unequal, dorsal largest, weakly hooded and ± horizontal over stamens, 25–30 × 10–12 mm, upper laterals arching or spreading distally, 25–30 × 8–10 mm, lower laterals united with upper laterals for 2–4 mm and together for 2 mm, recurved or deflexed distally, 23–25 × 6–8 mm. *Filaments* ± 14 mm long, included in tube or exserted for up to 1 mm; anthers ± 13 mm long, barely exserted, lilac with dark purple thecae; pollen pale yellow. *Style* arching over stamens, minutely puberulous below, dividing just below to just beyond anther apices, branches 3–4 mm long. *Capsules* oblong-ellipsoid, 35–40 × 6–7 mm, much longer than outer bracts. *Seeds* elliptic to oblong, 5.5–7.5 × 3.5–4.5 mm, broadly and unequally winged with wings broader at chalazal and micropylar ends. *Flowering time*: August.

Distribution and ecology: a narrow endemic of the Karas Region in southern Namibia, along the Fish River Canyon west of Keetmanshoop; in saline seeps and drainage lines among sedges. Flowers open shortly after sunset and wither the following evening. The species is self-compatible and facultatively autogamous.

Diagnosis: diagnosed by the ± X-shaped lower leaf with heavily thickened and raised margins and midrib, and the relatively large, pale mauve or opalescent, trumpet-shaped flowers that last only one day, the upper tepals 25–30 mm long and the perianth tube 35–40 mm long. The bracts are relatively short and blunt, 22–25 mm long. Similar *Gladiolus tristis* from the south-western South Africa has cream-coloured to pale yellow flowers lasting several days, a longer perianth tube, 40–63 mm long and longer filaments, (15–)18–25 mm long.



Distribution of ***Gladiolus diluvialis***.

162. **Gladiolus longicollis** *Baker* in Journal of Botany, British and foreign 14: 182 (1876a). *Acidanthera longicollis* (Baker) R.C.Foster: 42 (1936). Type: South Africa, [Eastern Cape], Baziya Mt, 3 000–4 000 ft [900– 1 200 m], Oct.–Nov., *Baur 505* (K, holo.; BOL, NU, iso.).

Plants (200–)300–500(–600) mm high. *Corm* conic, (7–)10–14 mm long, tunics of fairly fine to moderately coarse fibres, sometimes thickened and ± claw-like below. *Stem* erect, usually flexed outward just above sheathing part of second leaf, unbranched. *Leaves* 3, only lowermost with well-developed blade ± ⅔ as long as stem, X-shaped in section to terete with four narrow longitudinal grooves, second leaf sheathing stem for 100–150 mm, channelled throughout or with a short blade, third leaf inserted in upper ¼ of stem and largely sheathing. *Spike* 1- to 3(7)- flowered; bracts grey-green, outer shortly acuminate, 35–50(–65) mm long, inner shorter to slightly longer, acuminate or notched apically. *Flowers* white to pale yellow, often lightly to heavily mottled with brown, more densely so along midlines, outer tepals flushed and veined purplish to brown or green on reverse, tube obscurely lined with green or purple on veins, perianth expanding in evening or during misty weather, then scented of carnation and cloves, closing next morning; perianth tube slender and cylindric, ± horizontal and slightly curved above or erect below and curving outward above, (45–)50–110 mm long, 2–3 mm diam. in midline, papillose in lower throat; tepals subequal or unequal, outer whorl equal and larger than inner whorl, acute to acuminate or attenuate, dorsal nearly horizontal or curving upward distally, 25–32 × 12–17 mm, upper lateral 25–42 × 10–19 mm, lower tepals sometimes joined to upper laterals for up to 2 mm and together for up to 2 mm, lower lateral tepals 22–32 × 9–14 mm, lower median 25–32 × 12–14 mm. *Filaments* 5–13 mm long, usually included in tube or exserted 1–2 mm; anthers 9–15 mm long, included in tube for up to ½ their length or shortly exserted 1–2 mm beyond tube, green or purplish; pollen cream-coloured to yellow. *Style* arching over stamens, puberulous in lower half, dividing opposite upper third of anthers, branches 3–6 mm long. *Capsules* ellipsoid or subcylindric, 20–25 × ± 6 mm. *Seeds* ovate, 5–6 × 3.5–4.0 mm, broadly and evenly winged. *Flowering time*: October to mid-February.

Distribution and ecology: widespread through the south-eastern and eastern southern Africa, from the Swartberg in Western Cape, South Africa through Eastern Cape, KwaZulu-Natal, Lesotho, western Free State, Gauteng, Mpumalanga and Eswatini to Limpopo; in stony grassland. Flowering may take place over an extended period even within a single population.

Distribution of ***Gladiolus longicollis*** subsp. ***longicollis***, ●; subsp. ***platypetalus***, ○ .

Diagnosis: diagnosed by the ± X-shaped or terete lower leaf with heavily thickened and raised margins and midrib, and the long-tubed, trumpet-shaped flowers, cream-coloured or ± mottled with brown, the dorsal tepal 25–32 mm long and the upper laterals up to 45 mm long, and the perianth tube 45–110 mm long, with the filaments entirely or mostly included and 5–13 mm long. The bracts are relatively short and blunt, 35–65 mm long. *Gladiolus tristis* has longer filaments, (15–) 18–25 mm long, and occurs mostly west of Port Elizabeth but has also in the Swartberg Mtns.

Key to subspecies

1a Perianth tube 45–60(–65) mm long; tepals lanceolate and tapered distally; anthers entirely or mostly exserted; spike with 2 to 7 flowers . . . . . 162a. subsp. *longicollis*

1b Perianth tube 65–110 mm long; tepals broadly lanceolate to ovate, acute; anthers half-included; spike with 1 or 2(3) flowers . . . 162b. subsp. *platypetalus*

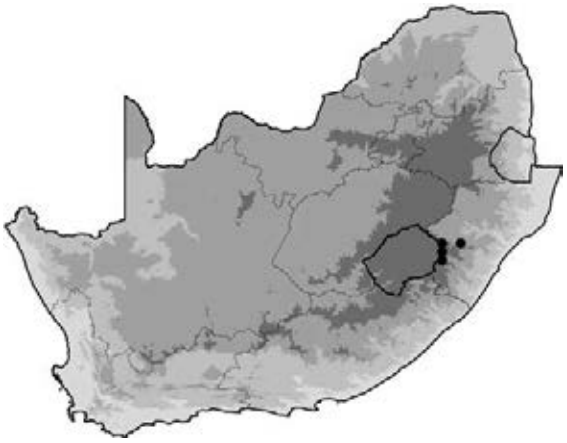
162a. subsp. **longicollis**

Gladiolus cygneus Ingram: 347, t. 144 (1931b), new synonym. Type: South Africa, [KwaZulu-Natal], Mont aux Sources, 9 500–10 000 ft [2 900–3 000 m], cultivated in Britain, 1930, *Ingram s.n.* (BM, holo.).

Spike (1)2–4(7)-flowered; bracts grey-green, outer 35–40 mm long, inner shorter. *Flowers* cream-coloured to yellow and variously speckled or mottled with brown; perianth tube usually erect below, curving outward above, 45–65 mm long, sometimes only shortly exserted from bracts; tepals lanceolate, attenuate, subequal, 30–35 × 8–12 mm. *Filaments* 10–12 mm long, reaching to mouth of tube; anthers ± 9 mm long, exserted or sometimes bases included in tube. *Style* dividing opposite anther apices, branches ± 3 mm long. *Flowering time*: October to November.

Distribution and ecology: extending from Gauteng, south western Mpumalanga and central KwaZulu-Natal through the eastern Free State, Lesotho and Eastern Cape to the Swartberg and Kammanassie Mtns in Western Cape.

162b. subsp. **platypetalus** *(Baker) Goldblatt & J.C.Manning*, *Gladiolus* in southern Africa: 197 (1998). *Acidanthera platypetala* Baker: 339 (1876b). *G. longicollis* var. *platypetalus* (Baker) Oberm. in Lewis et al.: 190 (1972). Type: Natal, Attercliffe, 30 Sept. 1860, *Sanderson 265* (K, holo.; BOL, probable iso.).



Gladiolus praelongitubus G.J.Lewis: 27 (1941). Type: South Africa, [Mpumalanga], Barberton District, Saddleback Range, 3 000–5 000 ft [900–1 500 m], Sept.–Oct. 1889, *Galpin 530* (SAM, holo.; BOL, K, PRE, iso.).

Spike 1- or 2(3)-flowered; bracts green or flushed purple, outer 45–55 mm long, shortly acuminate, inner shorter to slightly longer. *Flowers* white or cream-coloured, outer tepals flushed and veined purplish to brown or green on reverse, tube obscurely lined with green or purple; perianth tube slender and cylindric, ± horizontal and slightly curved, 65–110 mm long, well exserted from bracts; tepals lanceolate, outer whorl subequal and larger than inner whorl, dorsal 30–32 × 14–17 mm, upper lateral and lower median tepals 40–42 × 15–19 mm. *Filaments* 5–9 mm long, included in tube; anthers 11–13 mm long, lower half included in tube. *Style* dividing between middle and apex of anthers, branches 5–6 mm long. *Flowering time*: October to December, occasionally until mid-February.

Distribution and ecology: from central KwaZulu-Natal through Eswatini and Mpumalanga to Limpopo.

163. **Gladiolus symonsii** *F.Bolus* in Annals of the Bolus Herbarium 2: 99 (1917). Type: South Africa, [KwaZulu-Natal], Underberg District, Bushman's Peak, 9 500 ft [2 900 m], 8 Jan. 1915, *Symons 336* (BOL, holo.).

Plants 250–450 mm high. *Corm* globose, ± 10 mm diam.; tunics of fine to wiry fibres. *Stem* erect, unbranched, usually flexed outward just above sheathing part of second leaf. *Leaves* 3, lowermost markedly longest, sheathing lower ⅓ of stem, reaching to ± upper ⅓ of stem, 60–120 mm long, X-shaped in section with main vein raised and margins thickened, thus with 4 broad longitudinal grooves or furrows, remaining leaves without blades, second leaf sheathing stem for 80–150 mm, third leaf inserted near stem apex. *Spike* inclined, 2- to 4-flowered; bracts soft-textured, dull green, 20–30 mm long, inner shorter. *Flowers* subactinomorphic, with unilateral stamens and style, bright pink to pale rose, whitish in throat, lower 3 tepals feathered or streaked with fine red lines or spots at base, apparently unscented; perianth tube obliquely funnel-shaped, 8–12 mm long; tepals subequal, lanceolate, dorsal slightly larger, 20–25 × 10–13 mm, inclined over stamens, upper laterals suberect, slightly shorter than dorsal, lower 3 tepals

Distribution of ***Gladiolus symonsii***.

19–23 × 10 mm. *Filaments* ± 7 mm long, included or exserted up to 1 mm from tube; anthers 8–10 mm long, yellow; pollen yellow. *Style* arching over stamens, dividing opposite upper ¼ of anthers, branches ± 3.5 mm long. *Capsules* and *seeds* unknown. *Flowering time*: December to late January.

Distribution and ecology: a narrow endemic of the eastern Drakensberg in KwaZulu-Natal, South Africa and eastern Lesotho, extending from Bushman's Nek to Giant's Castle; in short grassland or on sandstone or basalt pavement, from 1 800 to 2 500 m.

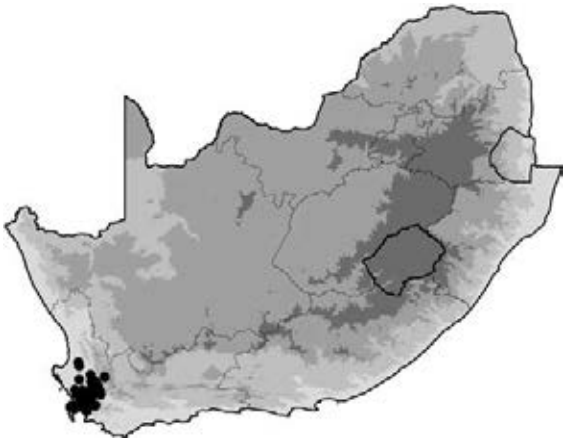
Diagnosis: diagnosed by the ± X-shaped lower leaf with heavily thickened and raised margins and midrib, and the pink, funnel-shaped flowers with subactinomorphic perianth with a very short tube, 8–12 mm long and short filaments ± 7 mm long scarcely exserted from the tube.

Ser. **Homoglossum** *Goldblatt & J.C.Manning*, new series. Type species: *Gladiolus watsonius* Thunb.

Plants mainly from winter-rainfall region. *Corms* subglobose; tunics ± leathery to woody and splitting into claws, or coarsely fibrous. *Leaves* three, green at flowering, lowermost markedly longest, centric or linear with midrib and margins thickened and raised at right angles to blade thus with two furrows or grooves on each surface. *Flowers* medium, zygomorphic, sometimes strongly so with lower tepals reduced, trumpet-shaped, mostly orange to red, unscented; perianth tube longer than dorsal tepal, dimorphic with slender, suberect lower part abruptly expanded into wider, ± horizontal, cylindric upper part. *Capsules* oblong-ellipsoid.

164. **Gladiolus watsonius** *Thunb.*, Dissertatio de Gladiolo no. 14 (1784). *Watsonia revoluta* Pers.: 42 (1805), replacement name for *G. watsonius* Thunb. (1784). *Antholyza watsonius* (Thunb.) Pax in Engler & Prantl.: 156 (1888) [as *watsoniana*]. *Homoglossum watsonium* (Thunb.) N.E.Br.: 278 (1932a). Type: South Africa, [Western Cape], 'Lions Rump and elsewhere on the Cape Peninsula', *Thunberg s.n* (UPS-THUNB 1092, holo.).

Gladiolus praecox Andrews: t. 38 (1798c) [as *G. praecox* var. *flore-rubro*]. *Watsonia praecox* (Andrews) Pers.: 42 (1805). *Homoglossum praecox* (Andrews) Salisb.: 325 (1812). Type: South Africa, without precise locality or collector, illustration in Andrews: t. 38 (1798c).



Homoglossum revolutum var. *gawleri* Baker: 161 (1877). *Gladiolus gawleri* (Baker) Klatt: 341 (1882). *Antholyza gawleri* (Baker) L.Bolus: 11 (1920). *Homoglossum gawleri* (L.Bolus) N.E.Br.: 278 (1932a). Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 569 (1802c) '*Gladiolus watsonius* var. ß, *corollis majoribus luteo-variegatus*'.

Antholyza acuminata N.E.Br.: 133 (1929a), replacement name for *Gladiolus recurvus* Houtt.: 49 (1782), illegitimate homonym, not *G. recurvus* L. (1767). *Homoglossum acuminatum* (N.E.Br.) N.E.Br.: 278 (1932a). Type: South Africa, without precise locality or collector, *Burman s.n.* (G: Herb. Burman '*Gladiolus recurvus*', holo.).

Homoglossum flexicaule N.E.Br.: 279 (1932a) [*Gladiolus watsonius* sensu Jacq.: t. 233 (1792 [1788–1795]). Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 233 (1792 [1788–1795]) '*Gladiolus watsonius*'.

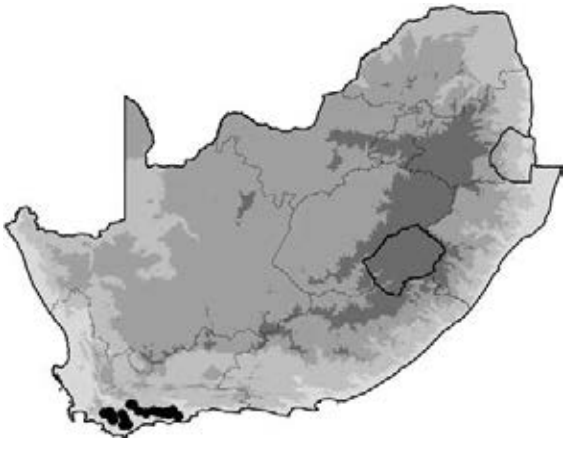
Gladiolus watsonius var. *maculosus* M.P.de Vos & Goldblatt: 421 (1990). Type: South Africa, [Western Cape], Kapteinskloof, Farm Banghoek, 22 Aug. 1989, *De Vos 2711* (NBG, holo., iso.).

Plants 300–700 mm high. *Corm* globose, 12–20 mm diam., often with numerous small cormlets around base; tunics ± woody to leathery, splitting below into claw-like segments. *Stem* barely flexed outward above sheath of terminal leaf, unbranched. *Leaves* 3, imbricate, lower 2 basal, lowermost sheathing lower thirds of stem and markedly longest, reaching to base or sometimes exceeding spike, linear, (1.5–)4.0–6.0 mm wide, midrib moderately thickened and raised, margins heavily thickened and forming wings extended at right angles to blade, thus with two grooves or furrows on each surface, second leaf sheathing stem for ⅔ of its length with a short blade, uppermost leaf inserted on upper ½ of stem, sheathing for ½ its length, lower margins united around stem. *Spike* erect and ± straight, (2)4- to 6(8)-flowered; bracts pale green or flushed light brown, outer (35–)40–55(–70) mm long, lower margins closed around stem, inner shorter to nearly as long. *Flowers* orange-red to scarlet, lower tepals often translucent, occasionally yellowish below and speckled dark red near base, dorsal tepal with edges translucent in lower ½, unscented; perianth tube 44–53 mm long, narrow and cylindric in lower 15–25 mm, abruptly expanded and curved outward into a wider cylindric, horizontal

Distribution of ***Gladiolus watsonius***.

upper part 30–38 mm long, 6–10 × 4–6 mm diam.; tepals broadly lanceolate, dorsal largest, extended horizontally over stamens, 26–33 × 12–18 mm, upper laterals 25–32 × 7–12 mm, ± spreading, lower 3 tepals arching outward from base, laterals 20–26 × 5–11 mm, lower median 23–32 × 6–12 mm. *Filaments* 32–40 mm long, exserted 8–13 mm from tube; anthers 7–10 mm long, dark purple; pollen cream-coloured to pale yellow. *Style* arching over stamens, dividing between upper ⅓ and apex of anthers, branches 4–6 mm long. *Capsules* elongate-ellipsoid, 40–45 × ± 14 mm. *Seeds* discoid, 6–9 × 5–6 mm, broadly and evenly winged. *Flowering time*: August to mid-September, occasionally in July.

Distribution and ecology: restricted to the southwestern forelands of Western Cape, South Africa, from Piketberg to the Cape Peninsula and inland to Worcester; on lower slopes and flats on clay and granite soils in renosterveld.

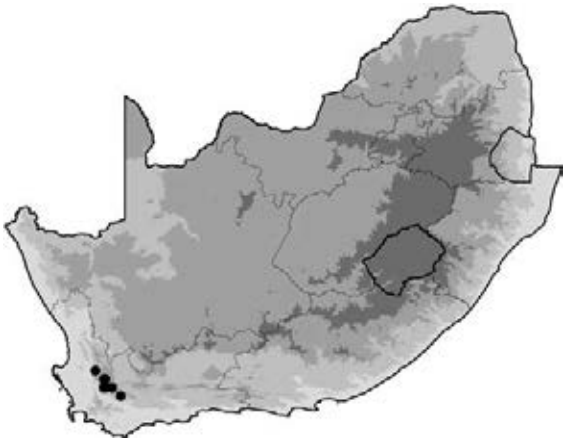


Diagnosis: distinguished from allied species in the series with similar flowers by the linear leaves, mostly 4–6 mm wide, with the main vein and margins heavily thickened, the blade thus with four longitudinal grooves. *Gladiolus teretifolius* from the Overberg has narrow, terete leaves 1–2 mm wide, and *G. quadrangularis* from inland near Ceres has centric blades x-shaped in section and softer corm tunics.

165. **Gladiolus teretifolius** *Goldblatt & M.P.de Vos* in Adansonia 11: 422 (1990), as a replacement name for *Antholyza muirii* L.Bolus: 12 (1920) [not *G. muirii* L.Bolus (1915)]. *Homoglossum muirii* (L.Bolus) N.E.Br.: 279 (1932a). Type: South Africa, [Western Cape], south slopes of the Langeberg behind Albertinia, 20 May 1914, *Muir 1348* (BOL, holo.; SAM, iso.).

Plants 400–700 mm high. *Corm* globose, 12–20 mm diam., often with numerous cormlets around base; tunics ± woody to leathery, splitting from below into claw-like segments. *Stem* usually slightly inclined above sheath of uppermost leaf, unbranched. *Leaves* 3, lower 2 basal, lowermost markedly longest, reaching ± the spike, 1–2 mm diam., oval to nearly terete in transverse section with margins and main vein thickened, thus with 2 narrow longitudinal grooves on each surface, second leaf sheathing stem for most of its length, blade 10–25 mm long, uppermost leaf inserted in upper ¼ of stem, almost entirely sheathing, overlapped by second leaf. *Spike* ± straight, 1- to 5(7)-flowered; bracts grey-green, sometimes flushed with purple, outer 35–45(–50) mm long, inner shorter. *Flowers* orange-red to scarlet (rarely cream-coloured), dorsal tepal translucent along lower edges, tube pale with red speckles and paired red lines from base of upper lateral tepals, unscented; perianth tube 35–45 mm long, straight and narrowly cylindric in lower 12–17 mm, abruptly expanded and curved outward into a wider cylindric upper part, 22–27 mm long, 6–7 mm diam.; tepals obovate, dorsal largest, 20–27 × 12–15 mm, extended horizontally, upper laterals patent, 16–25 × 10–12 mm, lower tepals arching outward and downward, laterals 12–18 × 8–12 mm, lower median 15–22 mm long. *Filaments* ± horizontal 32–38 mm long, exserted 9–12 mm from tube; anthers 7–9 mm long, dark violet; pollen yellow. *Style* arching over stamens, dividing opposite anther apices, branches ± 3.5 mm long. *Capsules* ovoid-ellipsoid, acute, ± 20 mm long. *Seeds* ovate, ± 4.5 × ± 3 mm, broadly and evenly winged. *Flowering time*: mid-July to end of August.

Distribution and ecology: restricted to the southwestern forelands of the Overberg in Western Cape, South Africa, from Bot River to east of Riversdale and the Langeberg near Albertinia; on lower slopes and flats on clay soils in renosterveld.



Diagnosis: distinguished from allied species in the series with similar flowers by the terete leaves, 1–2 mm diam., with the main vein and margins heavily thickened and thus with four fine longitudinal grooves. *Gladiolus watsonius* from west of the Hottentots Holland Mtns has linear leaves, mostly 4–6 mm wide with two furrows on each surface, and *G. quadrangularis* from inland near Ceres has centric blades that are x-shaped in section and 2.5–4.0 mm diam., and softer corm tunics.

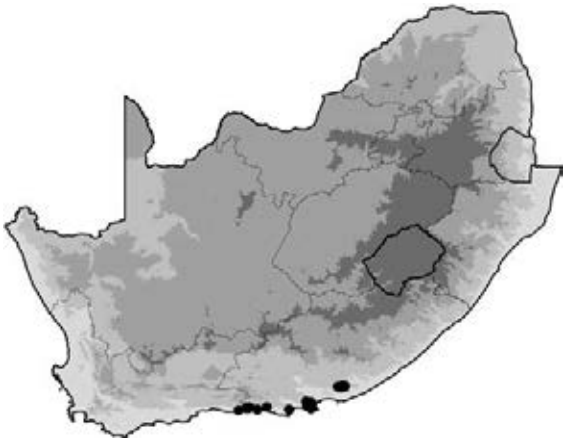
Distribution of ***Gladiolus teretifolius***.

166. **Gladiolus quadrangularis** *(Burm.f.) Ker Gawl.* in Curtis's Botanical Magazine 16: t. 567 (1802b) [misapplied to *G. abbreviatus* Andrews]. *Antholyza quadrangularis* Burm.f.: 1 (1768). *Anisanthus quadrangularis* (Burm.f.) Sweet: 397 (1826). *Petamenes quadrangularis* (Burm.f.) Salisb. ex J.W.Loudon: 42 (1841). *Homoglossum quadrangulare* (Burm.f.) N.E.Br.: 279 (1932a). Type: South Africa, without precise locality or collector, *Burman s.n.* (G: Herb. Burman, holo.).

Plants 350–700 mm high. *Corm* globose-conic, 12–20 mm diam.; tunics papery to leathery, decaying into fine or medium-textured vertical fibres below. *Stem* erect, flexed outward above sheaths of two upper leaves, unbranched. *Leaves* 3, lowermost markedly longest, reaching to between base and apex of spike, sheathing lower part of stem for 50–80 mm, erect or trailing above, centric, 2.5–4.0 mm wide, cross-shaped in section with midrib raised on either side of surface into wing-like ridges, edges of midrib wings and margins lightly thickened, second leaf sheathing stem for ± ⅔ of its length with a short blade, third leaf inserted shortly below spike, sheathing below. *Spike* erect, nearly straight, 4- to 8(11)-flowered; bracts green, outer 30–45 mm long, inner shorter, forked apically. *Flowers* scarlet to brick-red, rarely pink, dorsal and lower lateral tepals becoming transparent along lower edges, occasionally lower tepals orange toward bases, unscented; perianth tube (35–)43–55 mm long, lower part slender and cylindric (10–)12–22 mm, abruptly expanded and curved outward into a wider cylindric upper part (15–)24–32 mm long, 5–7 × 4–6 mm wide; tepals lanceolate, dorsal largest, extended horizontally over stamens, (20–)25–29 × (8–)12–15 mm, upper laterals spreading outward almost from base, (16–)20–28 × (6–)9–11 mm, lower tepals curving outward from base, laterals 10–15 × 4.5–6.5 mm, lower median (12–)15–20 × (3–)5–6 mm. *Filaments* ± horizontal 30–40 mm long, exserted (4–)6–10 mm from tube; anthers 9–11(–14) mm long, yellow; pollen yellow. *Style* extending horizontally over stamens, dividing between middle and apices of anthers, branches 3.5–4.5 mm long. *Capsules* ellipsoid, ± 25 mm long. *Seeds* unknown. *Flowering time*: mainly in late September, occasionally until late October at high elevations.

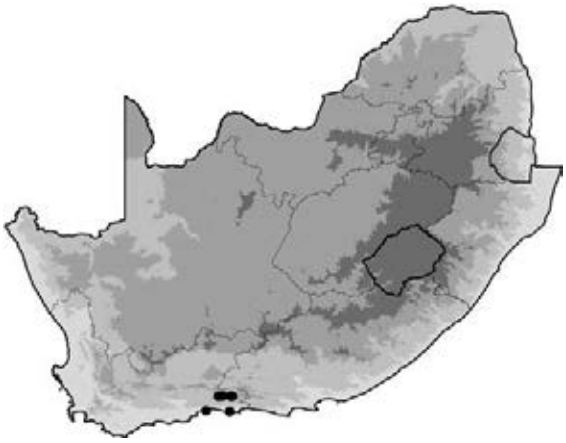
Distribution of ***Gladiolus quadrangularis***.

Distribution and ecology: centred in the Cold Bokkeveld in Western Cape, South Africa, extending from the southern Cederberg to Ceres; on slopes and plateaus on clay and loam soils in renosterveld shrubland.



Diagnosis: distinguished from allied species in the series with similar flowers by the softer corm tunics and centric leaves, 2.5–4.0 mm diam., x-shaped in section with main vein raised on either side of surface into wing-like ridges. *Gladiolus watsonius* from the western lowlands has linear leaves, mostly 4–6 mm wide with two furrows on each surface, and *G. teretifolius* from the Overberg has terete leaves, 1–2 mm diam., with the main vein and margins heavily thickened and thus with four fine longitudinal grooves. Both of these species have hard, clawed corm tunics.

167. **Gladiolus huttonii** *(N.E.Br.) Goldblatt & M.P.de Vos* in Adansonia 11: 422 (1990). *Homoglossum huttonii* N.E.Br.: 278 (1932a). Type: South Africa, [Eastern Cape], Albany District, without date, *Hutton s.n.* (K, holo.).



Homoglossum hollandii L.Bolus: 47 (1933a). Type: South Africa, [Eastern Cape], hills at Bethelsdorp, 4 miles from Port Elizabeth (bought from a flower seller), July 1931, *Bolus s.n.* (BOL [*BOL* 20077], lecto., designated by Goldblatt & Manning: 303 (1998); BOL, K, SAM, isolecto.).

Homoglossum hollandii var. *zitzikammense* L.Bolus: 47 (1933a). Type: South Africa, [Eastern Cape], flats at Ratelsbosch, Aug. 1905, *Fourcade 59* (BOL, holo., iso.).

Plants 200–450(–800) mm high. *Corm* globose, 8–12 mm diam.; tunics cartilaginous, splitting from below into coarse fibres or woody segments. *Stem* very lightly flexed above sheathing part of second leaf, unbranched. *Leaves* 3, lower 2 basal, lowermost markedly longest, sheathing only near ground, ± as long or slightly longer than spike, centric and cross-shaped in section with main vein raised into flanges up to 1.2 as wide as blade, 2–3 mm wide, second leaf sheathing lower ⅔ of stem, blade short, uppermost leaf inserted in upper ⅓ of stem. *Spike* erect or very slightly inclined, 3- or 4(8)-flowered; bracts green or flushed purple, outer 30–55 mm long, clasping stem below, seldom exceeding lower part of tube, inner slightly shorter, notched. *Flowers* orange-red, dorsal tepal with broad translucent edges in lower ½, lower tepals light orange to yellow in lower half, sometimes yellow on reverse, reverse of tube with deep red along tepal sutures, unscented; perianth tube 50–53 mm long, narrow and cylindric below for 20–32 mm, abruptly expanded into a tubular upper part 22–33 mm long, 5 × 6.5 mm wide, ascending; tepals broadly lanceolate, dorsal largest, ascending, 25–40 × 15–25 mm, upper laterals 22–32 × 12–18 mm, spreading in upper ½, lower 3 tepals much

Distribution of ***Gladiolus huttonii***.

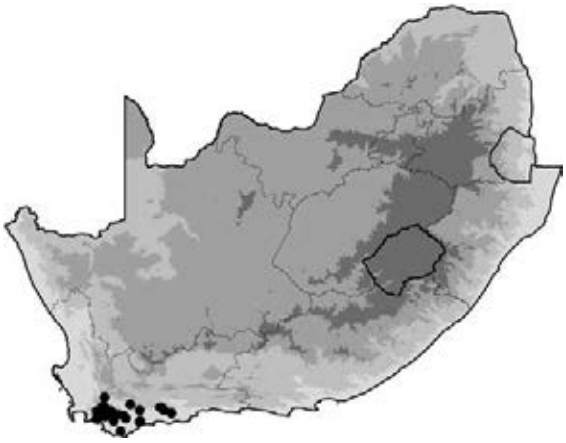
Distribution of ***Gladiolus fourcadei***.

smaller, lower laterals 12–20 × 10–14 mm, lower median 13–22 × 7–10 mm. *Filaments* 32–45 mm long, exserted 13–15 mm from tube; anthers 8–10 mm long, orange; pollen yellow. *Style* arching over stamens, dividing at or shortly beyond anther apices, branches ± 4 mm long. *Capsules* elongate–ellipsoid, 38–40 mm long, as long or slightly longer than outer bracts. *Seeds* oval, 5–6 × 3.5–4.5 mm, usually broadly and evenly winged. *Flowering time*: August to mid-September.

Distribution and ecology: restricted to the southern coastal plain of Eastern Cape, South Africa, from Plettenberg Bay to East London and inland to near Grahamstown; on loam or clay soils.

Diagnosis: recognised by the long lower leaf with x-shaped blade and the large, orange flowers with dimorphic tube 50–53 mm long marked with characteristic red longitudinal lines, and the reduced lower tepals ± half as large as the upper.

168. **Gladiolus fourcadei** *(L.Bolus) Goldblatt & M.P.de Vos* in Adansonia 11: 422 (1990). *Antholyza fourcadei* L.Bolus: 117–118 (1927a). *Homoglossum fourcadei* (L.Bolus) N.E.Br.: 279 (1932a). Type: South Africa, [Eastern Cape], near Uniondale, headwaters of Wagenboom River, 1 900 ft [580 m], Sept. 1922, *Fourcade 2337* (BOL, lecto., designated by Goldblatt & J.C.Manning: 305 (1998); K, NBG, isolecto.).



Plants 400–600 mm high. *Corm* globose-obconic, 10–12 mm diam.; tunics cartilaginous, splitting from below into soft fibres. *Stem* flexed outward above sheath of second leaf, then erect again, unbranched. *Leaves* (2)3, lower (1)2 basal, lowermost markedly longest, reaching to ± middle of spike, centric and cross-shaped in section, midrib raised into flanges up to half as wide as blade, margins and edges of midrib wings thickened, remaining leaves without blades, second leaf sheathing lower half of stem, uppermost leaf inserted on upper ⅓ of stem, largely or entirely sheathing, margins fused below. *Spike* erect and ± straight, 3- to 5-flowered; bracts pale brownish green, sometimes lightly flushed purple, outer 42–60 mm long, enclosing base of upper part of tube, inner bract shorter, minutely forked, twisted to lie against outer bract. *Flowers* yellow-green with upper tepals flushed and veined with dusky red, reverse of tepals and tube red, somewhat streaked on tepals, lower 3 tepals sometimes speckled with minute dark red spots in lower ½, unscented; perianth tube 35–46 mm long, slender and cylindric below for 15–18 mm, curving abruptly into a wider cylindric part 20–28 mm long, ± 5 mm diam., ascending to almost horizontal; tepals with dorsal ovate, ascending, 15–20 × ± 12 mm, upper laterals spreading, 14–15 × ± 10 mm, lower 3 tepals much smaller, patent, subequal, ± 9 × 7 mm, directed downward. *Filaments* 26–32 mm long, exserted 4–8 mm from tube; anthers 8–10 mm long, light purple; pollen yellow. *Style* extending horizontally over stamens, dividing opposite upper ⅓ of anthers, branches 4 mm long. *Capsules* and *seeds* unknown. *Flowering time*: occasionally in September, mostly October to November.

Distribution and ecology: a narrow endemic of Eastern Cape, South Africa, centred in the upper Long Kloof near Uniondale but recorded also near Knysna and on the southern slopes of the Kammanassie Mtns; in loam or clay soils.

Diagnosis: recognised by the long lower leaf with x-shaped blade and the relatively small flowers with dimorphic perianth tube 35–46 mm long, the upper tepals yellowish green flushed and veined with dusky red, and the smaller lower tepals ± half as long as the upper.

169. **Gladiolus abbreviatus** *Andrews*, The Botanist's Repository 3: t. 166 (1801). *Antholyza abbreviata* (Andrews) Pers.: 42 (1805). *Petamenes abbreviata* (Andrews) N.E.Br.: 276 (1932a). *Homoglossum abbreviatum* (Andrews) Goldblatt: 443 (1971). Type: South Africa, without precise locality or collector, cultivated in Great Britain at Hammersmith, London, illustration in Andrews: t. 166 (1801).

Plants 350–550 mm high. *Corm* globose-obconic, 10–12 mm diam.; tunics cartilaginous, splitting into fibres. *Stem* straight and erect, unbranched, often flushed red or purple. *Leaves* 3, lower 2 basal, lowermost markedly longest, reaching or shortly exceeding top of spike, centric, X-shaped in section, 3–4 mm wide, main raised into ridges up to half as wide as blade, margins lightly thickened, second leaf sheathing stem almost to base of spike and overlapping third leaf, with filiform blade up to 50 mm long, uppermost leaf inserted on upper ¼ of stem, entirely sheathing and bract-like, often dull purple. *Spike* erect, nearly straight, 4- to 6(9)-flowered; bracts greenish grey flushed dark red, or olive-green flushed brown or orange, outer 45–60(–70) mm long, inner much shorter, acute or barely notched apically. *Flowers* predominantly red to orange, dorsal tepal flushed brownish and pale to almost transparent on lower edges, upper lateral and lower tepals darker red, brown, or green, unscented; perianth tube 40–52 mm long, lower half narrow and cylindric, ascending, 17–25 mm long, abruptly expanded into a wide cylindric upper part, 24–30 mm long, ascending, 5–6 mm diam.; tepals with dorsal longest, elliptic, 16–31 × 11–15 mm, extended horizontally, upper laterals joined to dorsal for ± 3 mm, ovate-apiculate, 7–11 mm long, suberect, lower laterals deltoid, 5–6 mm long, lower median 3–4 mm long. *Filaments* 28–44 mm long, exserted 8–17 mm from tube; anthers 8–12 mm long, dull reddish; pollen yellow. *Style* arching over stamens, dividing opposite upper ⅓ of anthers, branches 4–6 mm long. *Capsules* elongate-elliptic, (20–)30–38 mm long. *Seeds* ovate, usually tapering at one end, 6–7 × ± 4 mm, broadly and evenly winged. *Flowering time*: mid-June to mid-August, occasionally in September.

Distribution of ***Gladiolus abbreviatus***.

Distribution and ecology: restricted to the lowlands of the Overberg in Western Cape, South Africa, from Villiersdorp and Bot River to Stormsvlei; on clay slopes in renosterveld.

Diagnosis: recognised by the long lower leaf with x-shaped blade and the obliquely tubular flowers with dimorphic perianth tube 40–52 mm long, the upper lateral tepals ± half the size of the dorsal and the lower tepals reduced to small triangular scales 3–6 mm long.

UNCERTAIN SPECIES

Gladiolus bakeri *Klatt* in Th.Durand & H.Schinz, *Conspectus florae africae* 5: 213 (1894), as a replacement name for *G. micranthus* Baker, Handbook of the Irideae: 212 (1892), illegitimate homonym, not *G. micranthus* Stapf (1885). Type: Botswana, Leshumo Valley, *Holub s.n.* (location unknown). Type not located and identity uncertain.

EXCLUDED SPECIES

[*Gladiolus aethiopicus* Drapiez ex Jackson, Index Kewensis 1: 1029 (1895), name without description. Published references to this name, either as *G. aethiopicus* Drapiez, *Dictionnaire classique des sciences naturelles* 5: 129 (1853) or as the combination *G. aethiopicus* (L.) Drapiez *ibid.* are incorrect as it does not appear in that publication.]

Gladiolus × *lewisiae* Oberm. in Flowering Plants of Africa 40: t. 1596 (1970). This is a natural hybrid *G. caryophyllaceus* × *G. tristis* and probably extinct.

Subtribe 2. **Melasphaerulinae**

Melasphaerulinae *Goldblatt & J.C.Manning*, new subtribe. Type: *Melasphaerula* Ker Gawl.

Corm bell-shaped with flat base, tunics firm-papery to woody, splitting radially from centre of base plate; stem well developed. *Leaf* margins with subepidermal sclerenchyma. *Inflorescence* a panicle of spikelets. *Flowers* zygomorphic; style branches undivided. *Capsules* depressed-cordate; seed epidermal cell outlines prominent; ovular vasculature intact; $x = 10$.

Genera 1, only *Melasphaerula*, 1 species: Greater Cape Floristic Region of southern Africa.

15. **Melasphaerula**

Melasphaerula *Ker Gawl.* in Curtis's Botanical Magazine 17: plate 615 (1803). Type: *M. graminea* (L. f.) Ker Gawl.

Phalangium Burm.f.: 3 (1768), illegitimate homonym, not *Phalangium* Miller (1754). Type: *P. ramosa* Burm.f. = *Melasphaerula graminea* (L.f.) Ker Gawl.

Diasia DC.: 151 (1803). Type: *D. graminifolia* DC. = *Melasphaerula graminea* (L.f.) Ker Gawl.

Aglaea Steud.: 21 (1821). Type: *A. graminea* (L.f.) Steud. = *Melasphaerula graminea* (L.f.) Ker Gawl.

From the Greek, *melas* = black, *sphaerulos* = small sphere, alluding to the cormlets in the basal leaf axils and sometimes also around the corm base.

Deciduous geophyte. *Corm* bell-shaped with flat base, axial in origin; tunics woody to firm-papery, concentric, splitting radially from centre of flat base into sharp, geniculate teeth, thus without a separate baseplate. *Cataphylls* 2, membranous becoming dry and papery. *Stem* aerial, erect or sprawling, terete and wiry, developing clusters of cormlets in axils of basal leaves, divaricately many-branched, branches laxly spreading. *Leaves* several, sword-shaped, mostly basal in a fan, plane with visible main vein, relatively soft-textured; marginal epidermis unspecialised. *Spikes* lax, few-flowered; bracts soft-textured with translucent margins, short, inner mostly membranous and strongly 2-veined, shorter than to ± as long as outer, notched apically. *Flowers* nodding, zygomorphic, long-lived, bilabiate, cream-coloured to yellow, all or at least lower 3 tepals with dark median streak, lightly scented, with nectar from septal nectaries; perianth tube obsolete; tepals with uppermost shorter and broader, lanceolate tapering to attenuate apices. *Stamens* unilateral and strongly arcuate; filaments inserted at mouth of perianth tube; anthers short. *Ovary* strongly obcordate and strongly 3-angled, locules with 2 or 3 pairs of ovules; style filiform, 3-branched distally, branches longitudinally folded. *Capsules* depressed-obcordate, deeply 3-lobed or winged, lobes apically auriculate, leathery, minutely papillate, dehiscing only along dorsal surface, few-seeded. *Seeds* subglobose, flattened at chalazal end, smooth, matte, testa cells domed. *Pollen grains* monosulcate-operculate, operculum 2-banded, exine perforate-scabrate. *Basic chromosome number* $x = 10$.

Species 1: coastal and near-inland southern Africa, mainly the winter-rainfall zone, in sheltered and moist, shady places.

The wiry, divaricately branched stems, the small, usually dull flowers with obsolete perianth tube and attenuate tepals, and the depressed-cordate, deeply lobed capsules are unmistakable. Although the bell-shaped corms with woody tunics of *Melasphaerula* bear a superficial resemblance to those of some species of *Geissorhiza* and *Hesperantha*, they decay in quite a different way, splitting radially into sharply bent teeth directly from the basal point rather than from the rim, thus without forming a separate baseplate as is found in other genera in the family with bell-shaped corms and woody tunics.

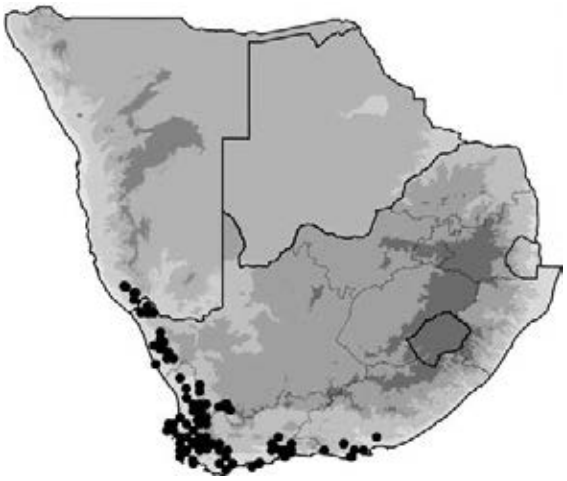
Melasphaerula is placed as sister to *Gladiolus* by molecular data, but the two show little resemblance to one another and are only distantly related to the remaining Crocoideae (Goldblatt & Manning 2008)

1. **Melasphaerula graminea** *(L.f.) Ker Gawl.* in Curtis's Botanical Magazine 17: t. 615 (1803). *Gladiolus gramineus* L.f.: 95 (1782). *Diasia graminifolia* DC.: 151 (1803), illegitimate superfluous name for *G. gramineus* L.f. (1782). *M. intermedia* Sweet: 399 (1826), illegitimate superfluous name for *M. graminea* (L.f.) Ker Gawl. (1803). *D. intermedia* (Sweet) Heynh.: 261 (1840). *Aglaea graminea* (L.f.) Steud.: 19 (1821). Type: South Africa, without precise locality, *Sparrman s.n. Herb. Linn. No. 59.23* [LINN, holo.—other type elements cited explicitly excluded in L.f.: 468 (Emendanda) (1782)].

   Phalangium ramosum Burm.f.: 3 (1768). *Melasphaerula ramosa* (Burm.f.) N.E.Br.: 138 (1929),

Melasphaerula graminea: A, flowering plant; B, flower; C, half-flower; D, capsules; E, seed.

illegitimate homonym, not *M. ramosa* (L.) Klatt (1894) [= *Ixia scillaris* L.]. Type: South Africa, without precise locality or collector, *Herb. Burman G0096635* [G, lecto., effectively designated by Brown: 138 (1929)].



Diasia iridifolia DC.: 151 (1803), as a new name for *Gladiolus gramineus* sensu Andrews: t. 62 [excluding synonyms]. Type: South Africa, without precise locality or collector, illustration in Andrews: t. 62 (1799).

[?*Phalangium obsoletum* Burm.f.: 3 (1768), invalid name without description —identity uncertain. based on: South Africa, without precise locality or collector, illustration in Plukenet, Phytographia 3: t. 187, f. 3 (1692).]

[*Melasphaerula iridifolia* Sweet: 399 (1826), invalid name without description.]

[*Melasphaerula parviflora* G.Lodd.: t. 1444 (1829), invalid name without description. *Diasia parviflora* G.Lodd. ex Steud.: 501 (1840), invalid name without descriotion.]

Plants 200–750(–1 000) mm high. *Corm* 8–15 mm diam.; tunics woody to firm-papery. *Stem* wiry, erect below but at length arching or sprawling, divaricately many-branched, branches horizontal or drooping, stem bracts awl-like. *Leaves* 5 or 6, mostly basal, narrowly lanceolate to lanceolate, (50–)100–200 × (3–)5–15 mm, cauline leaves 1 or 2, progressively smaller. *Spike* scalloped or flexuose, 1- to 8-flowered; bracts 2–5 mm long, ovate, gaping. *Flowers* nodding, cream-coloured to yellow, all or at least lower 3 tepals with maroon or purple median streak, weakly scented with sweet or musty odour; tube obsolete, < 1 mm long; tepals suberect, uppermost shortest, erect and hooded over the anthers, others lightly twisted, attenuate, uppermost ovate to lanceolate, 7–9 × 3–5 mm, others narrowly lanceolate, 9–15 × 1–2 mm. *Filaments* ± 2 mm long; anthers 1.0–1.5 mm long, yellow. *Style* dividing beyond anthers, branches 1.5–2.0 mm long. *Capsules* ± 4 × 8 mm, deeply 3-lobed. *Seeds* ± 2 mm diam. *Flowering time*: July to September.

Distribution of ***Melasphaerula graminea***.

Distribution and ecology: distributed widely through the winter- and aseasonal rainfall regions of southern Africa, from southern Namibia through Namaqualand and along the West Coast and the Roggeveld to Agulhas and eastward along the south coast and through the Little Karoo to near Humansdorp in South Africa; in sheltered and shaded, moist situations among rocks or at the foot of cliffs in a variety of soil types.

The small, dull flowers are pollinated by March flies (Bibionidae) (Goldblatt et al. 2005).

Diagnosis: readily recognised by its bell-shaped corm with the woody corm tunics splitting from the basal point; wiry, divaricately branched stem with spreading, scalloped spikes of small, cream-coloured to pale yellow flowers with lanceolate-attenuate tepals and an obsolete perianth tube; and distinctive depressed-cordate, deeply 3-lobed or -winged capsules with finely papillate surface.

The species was known until recently as *Melasphaerula ramosa* (Burm.f.) N.E.Br. but this is an illegitimate homonym for *M. ramosa* (L.) Klatt, which is a synonym of *Ixia scillaris* L.

Subtribe 3. **Freesiinae**

Freesiinae *Goldblatt* in Journal of South African Botany 37: 441 (1971). Type: *Freesia* Klatt

Corm tunics fibrous and reticulate; flowering stem well developed. *Leaf* margins with columnar epidermal cells and without subepidermal sclerenchyma. *Inflorescence* a spike or flowers solitary on branches. *Flowers* zygomorphic; style branches apically notched to deeply divided; seed epidermal cell outlines prominent or smooth (*Freesia*); ovular vasculature excluded (*Crocosmia, Devia*) or intact (*Freesia, Xenoscapa*); x = 11 (10).

Genera 4, mainly southern Africa; 20 species: *Xenoscapa* 3; *Freesia* 16; *Crocosmia* 7; *Devia* 1.

16. **Xenoscapa**

Xenoscapa *(Goldblatt) Goldblatt & J.C.Manning* in Systematic Botany 20: 172 (1995). *Anomatheca* sect. *Xenoscapa* Goldblatt: 88 (1972). Type: *X. fistulosa* (Spreng. ex Klatt) Goldblatt & J.C.Manning

Revisionary account: Manning & Goldblatt (2011): 283–288.

From the Greek, *xenos*, strange and *scapa*, flowering stem, because of the inflorescence, unusual for subfamily Crocoideae, bears solitary flowers on the main and lateral branches instead of spikes of multiple flowers.

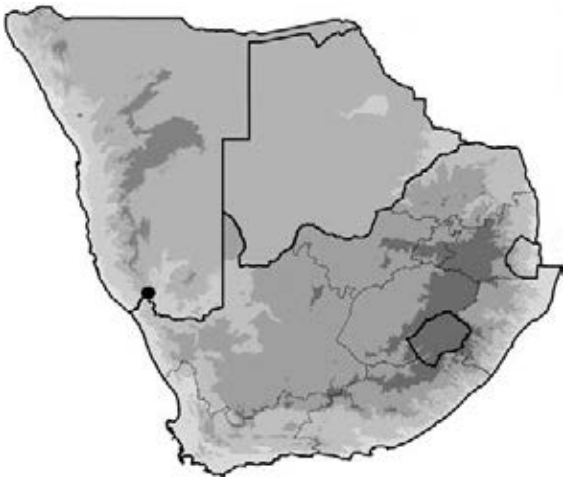
Small deciduous geophytes. *Corm* globose, axial in origin, tunics of finely netted fibres. *Cataphylls* 2 or 3, pale and membranous. *Stem* inclined to prostrate at base then stiffly erect, usually with 1–4 short branches each subtended by short cauline bract. *Leaves* 2 or 3, basal, prostrate, soft-textured, blade unifacial, oblong or falcate, plane with definite main vein; margin without vascular bundle, epidermal cells columnar and thickened. *Inflorescence* of solitary, sessile flowers terminal on axes; bracts leathery, green, inner slightly shorter or more often slightly longer than outer, strongly 2-veined, often notched apically. *Flowers* zygomorphic, long-lived, salver-shaped, either white and sweetly scented or pink with contrasting markings on lower tepals and unscented, with nectar from septal nectaries; perianth tube cylindric and elongate; tepals subequal, spreading or dorsal erect and slightly larger, spoon-shaped. *Stamens* unilateral and arcuate; filaments inserted shortly below top of perianth tube, shortly exserted. *Ovary* globose; style filiform, 3-branched distally, branches short and deeply divided, longitudinally folded, recurved. *Capsules* cartilaginous, ellipsoid to cylindric. *Seeds* strongly angled, with prominent chalazal crest, slightly wrinkled, matte, surface wrinkled, cells domed. *Pollen grains* monosulcate-operculate, operculum 1-banded, exine perforate-scabrate. *Basic chromosome number* x = 11.

Species 3: southern Namibia and western South Africa.

Xenoscapa fistulosa has a complex taxonomic history. It was described first in the genus *Ovieda* (a nomenclatural synonym of *Lapeirousia*) on account of the divided style branches and subsequently transferred in turn to *Lapeirousia*, *Anomatheca* and *Freesia* before being finally recognised as a separate genus, largely on account of its unusual inflorescence. Molecular DNA sequence data place the species as most closely related to *Freesia*.

Key to species

1a Flowers white or creamy white (rarely very pale pink), without contrasting nectar guides but perianth tube often flushed purple, fragrant; perianth tube 1.0–1.5 mm diam. at mouth; tepals 4–7 × 1–3 mm; anthers 1.0–2.5 mm long; capsules (8–)12–18 mm long . . . . . 3. *X. fistulosa*



1b Flowers lilac to dark pink or purple with contrasting nectar guides on lower tepals, unscented; perianth tube 1.5–2.0 mm diam. at mouth; tepals 6–14 × 2.0–5.5 mm; anthers 2–4 mm long; capsules 10–13 mm long:

2a Flowers dark pink; perianth tube 22–28 mm long; tepals 6–7 × 2–3 mm; anthers ± 2 mm long; plants from the Kamiesberg in central Namaqualand . . . . . 2. *X. uliginosa*

2b Flowers pale lilac; perianth tube 33–35 mm long; tepals 12–14 × 4.0–5.5 mm; anthers 3.5–4.0 mm long; plants from the Hunsberge in southern Namibia. . . . . 1. *X. grandiflora*

XENOSCAPA. X. fistulosa: A, flowering stem and capsule; B, dehisced capsule; C, seed. ***X. uliginosa***: D, flowering plant; E, detail of style branches; F, dehisced capsule.

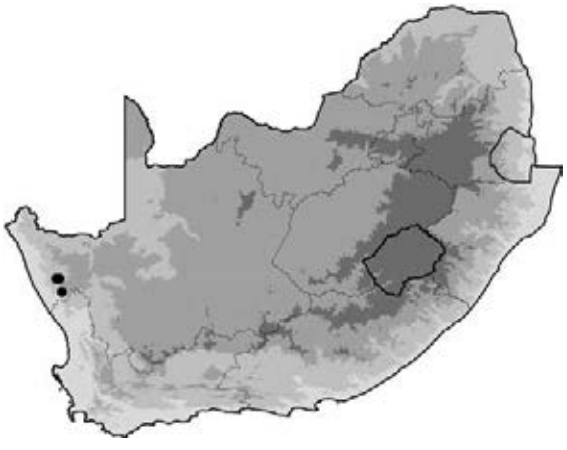
Distribution of ***Xenoscapa grandiflora***.

1. **Xenoscapa grandiflora** *Goldblatt & J.C.Manning* in Bothalia 41: 284 (2011). Type: Namibia, Hunsberge, Hohenzollern Peak, 1 July 2007 [fl. in cult. 13 July 2010], *E. van Jaarsveld sub J.C. Manning 3303* (NBG, holo.).

Plants 40–100 mm high, including flowers. *Corm* subglobose, 6–8 mm diam., tunics of coarse, netted fibres. *Leaves* 3, prostrate, oblong, lower two 45–60 × 15–20 mm, upper leaf ± half as large. *Stem* up to 45 mm long. *Spikes* 1-flowered; bracts green, 8–9 mm long, inner slightly longer and often shortly forked apically. *Flowers* zygomorphic with angle widest between upper and lower lateral tepals, pale lilac but darker on tube, lower 3 tepals each with pale creamy yellow patch at base outlined in purple, unscented; perianth tube cylindric, 33–35 mm long, wider and curved just below apex, 2 mm diam. at mouth; tepals subequal but inner slightly wider than outer, 12–14 × 4.0–5.5, dorsal erect, others spreading horizontally at right angles to tube. *Stamens* unilateral; filaments 3–5 mm long, exserted 2–4 mm from tube; anthers 3.5–4.0 mm long, dark purple; pollen grey-blue. *Style* dividing opposite anther bases, branches 4 mm long, deeply forked. *Capsule* oblong-cylindric, 10–13 × 3–4 mm. *Seeds* ± 1 mm diam. *Flowering time*: June to July.

Distribution and ecology: known only from the type collection from the summit of Hohenzollern Peak at the southern end of the Hunsberge in southern Namibia; wedged in crevices in the shelter of rock outcrops. Self-fertile and autogamous.

Diagnosis: distinguished from *Xenoscapa uliginosa* from the Kamiesberg by its larger, pale lilac flowers, with perianth tube 33–35 mm long and tepals 12–14 mm long. Additional collections are needed.

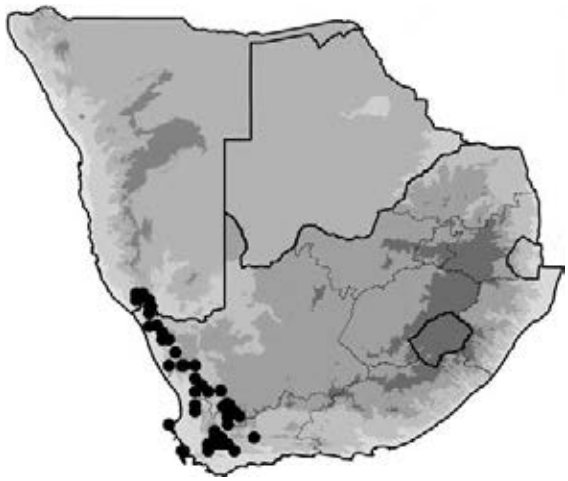


2. **Xenoscapa uliginosa** *Goldblatt & J.C.Manning* in Systematic Botany 20: 173 (1995). Type: South Africa, [Northern Cape], Namaqualand, Farm Modderfontein, lower east-facing slopes of Sneeukop, ± 1 400 m, 18 Sept. 1981, *Goldblatt [& Manning] 9244* (NBG, holo.; K, MO, PRE, iso.).

Plants 30–50 mm high, including flowers. *Corm* 5–8 mm diam.; tunics of fine, netted fibres. *Leaves* 3, prostrate, oblong, lower two 20–40 × 5–18 mm, upper leaf ± half as large. *Stem* up to 40 mm long. *Spikes* 1-flowered; bracts green, 6–7 mm long, inner slightly longer and often shortly forked apically. *Flowers* zygomorphic, dark pink or purple and darker on tube, lower 3 tepals each with pale creamy yellow patch at base outlined in purple, unscented; perianth tube cylindric, (20–)22–28 mm long, wider and curved just below apex, 1.5–2.0 mm diam. at mouth; tepals subequal but inner slightly wider than outer, 6–7 × 2–3 mm, dorsal erect or suberect and exposing anthers. *Stamens* unilateral; filaments 3–5 mm long, exserted ± 2 mm from tube; anthers ± 2 mm long, dark purple; pollen grey-blue. *Style* dividing opposite anther bases, branches 2 mm long, deeply forked. *Capsule* oblong, ± 10 × 3–4 mm. *Seeds* ± 1 mm diam. *Flowering time*: mid-September–October(early November).

Distribution and ecology: restricted to the Kamiesberg in central Namaqualand in Northern Cape, South Africa, on Sneeuberg and Rooiberg; along the margins of seasonal seeps and in rock flushes.

Hybrids with *Xenoscapa fistulosa* have been recorded on Sneeukop where the two species grow near one another (Manning & Goldblatt 2011). The flowers are adapted for pollination by long-proboscid flies (Manning & Goldblatt 1996).



Diagnosis: resembling *Xenoscapa grandiflora* in its unscented, moderately sized, pink flowers with contrasting darker nectar guides on the lower tepals, but distinguished by the dark pink perianth with shorter tube 20–28 mm long and tepals 6–7 mm long.

Distribution of ***Xenoscapa uliginosa***.

3. **Xenoscapa fistulosa** *(Spreng. ex Klatt) Goldblatt & J.C.Manning* in Systematic Botany 20: 172 (1995). *Ovieda fistulosa* Spreng. ex Klatt: 781 (1864). *Lapeirousia fistulosa* (Spreng. ex Klatt) Baker: 155 (1877). *Anomatheca fistulosa* (Spreng. ex Klatt) Goldblatt: 88 (1972). Type: South Africa, [Western Cape], Olifants River, Clanwilliam, without date, *Ecklon & Zeyher Irid. 254* (B, holo.; MO, PRE, iso.).

Plants (50–)70–200 mm high, including flowers. *Corm* 5–8 mm diam.; tunics of fine to medium-textured, netted fibres. *Stem* up to 180 mm long. *Leaves* 3, prostrate, oblong, lower two 20–50(–70) × 5–18(–20) mm, upper leaf ± half as large. *Spikes* 1-flowered, sometimes a second inflorescence developing in axil of upper leaf; bracts green, 5–7 mm long, inner slightly longer and often shortly forked apically. *Flowers* zygomorphic, white or creamy white, rarely pale pink, flushed purplish on tube, unmarked, with sweet-spicy fragrance; perianth tube cylindric, 18–25(–33) mm long, wider and curved just below apex, 1.0–1.5 mm diam. at mouth; tepals subequal, 4–7 × 1–3 mm, dorsal ± erect but others spreading ± horizontally at right angles to tube. *Stamens* unilateral; filaments 3–5 mm long, exserted ± 2 mm from tube; anthers 1.0–2.5 mm long, dark purple; pollen grey-blue. *Style* dividing between base and middle of anthers, branches 2 mm long, deeply forked. *Capsule* oblong to cylindric, (8–)12–20 × 2.5–4.0 mm. *Seeds* ± 1 mm diam. *Flowering time*: August to October.

Distribution of ***Xenoscapa fistulosa***.

Distribution and ecology: widespread along the near interior of the southern African Atlantic Coast and the western Karoo, from Aurusberg and the southern edge of the

Plate 33: ***Xenoscapa fistulosa***, Clanwilliam, WC.

Huib-Hoch Plateau in southern Namibia through the higher-lying parts of the Richtersveld and Namaqualand of Northern Cape, South Africa to Montagu and the northern foothills of the Klein Swartberg, with isolated populations along the Western Coast from Vredenburg to the lower slopes of Lions Head on the Cape Peninsula in Western Cape; typically on shale or gneiss/granite substrates, from near sea-level to almost 1 300 m elevation, in cool, seasonally moist or wet and largely shaded situations in the lee of rocks or boulders.

Diagnosis: distinguished by the relatively small, fragrant, mostly white (rarely pale pink in the Richtersveld and southern Namibia) flowers without markings on the lower tepals and a slender perianth tube up to 1.5 mm diam. at the mouth. In most populations the main stem is relatively long, up to 180 mm, exceeding that of other species. *Xenoscapa fistulosa* is self-fertile and autogamous but hybridises with *X. uliginosa* in the Kamiesberg. The small, fragrant flowers appear to be otherwise adapted for pollination by settling moths.

17. **Freesia**

Freesia *Eckl. ex Klatt* in Linnaea 34: 672 (1866), name conserved against *Lomenia* Pourr. [= *Watsonia*] (Goldblatt 1980) and against *Anomatheca* Ker Gawl. (Goldblatt & Manning 1993). Lectotype: *F. refracta* (Jacq.) Klatt, designated by Goldblatt: 56 (1982).

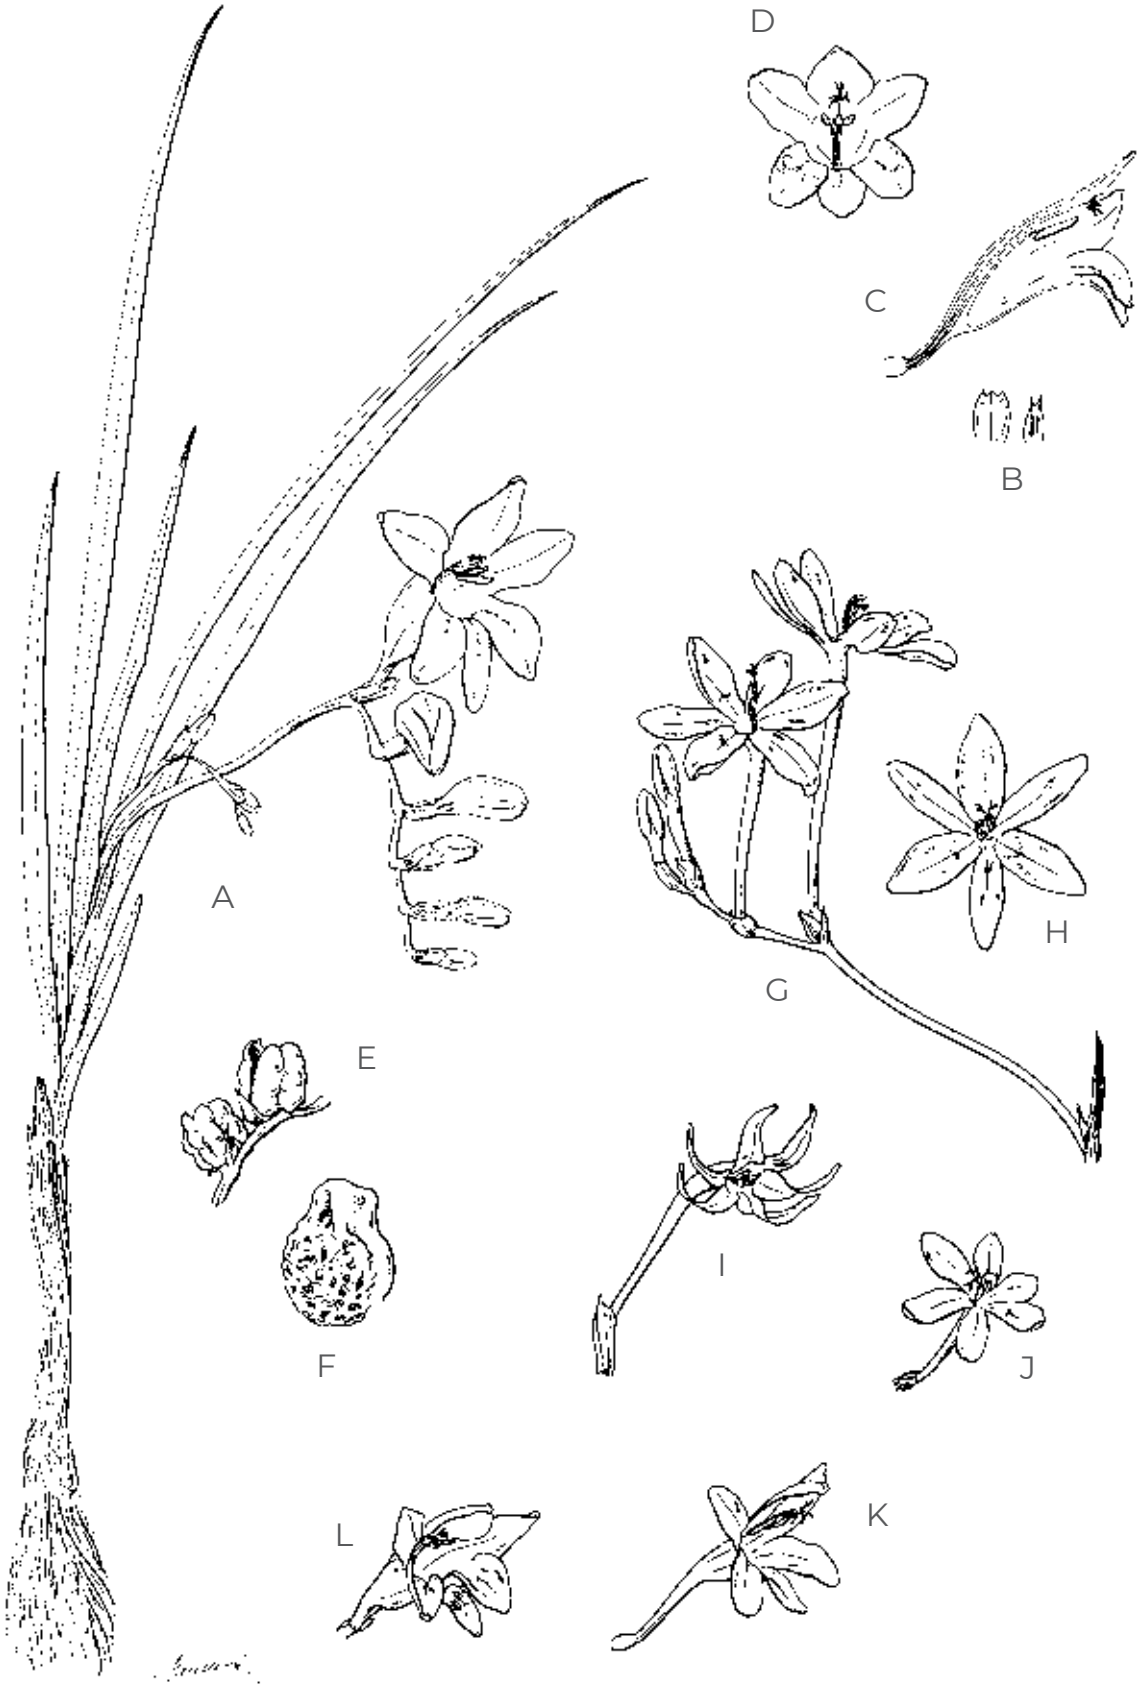
Anomatheca Ker Gawl.: 227 (1804). Type species: *A. juncea* Ker Gawl. = *Freesia verrucosa* (B.Vogel) Goldblatt

Nymanina Kuntze: 701 (1891), illegitimate superfluous name for *Freesia* Klatt. Type species: as for *Freesia*.

Revisionary accounts: Brown: 1–31 (1935); Goldblatt: 39–81 (1982); Goldblatt: 430–484 (1990); Manning & Goldblatt: 1–114 (2010).

Named after Dr Friedrich Heinrich Theodor Freese, a physician at Kiel, Germany, and friend of C.F. Ecklon, nineteenth century plant collector.

Small to medium-sized deciduous geophytes. *Corm* subglobose to narrowly conical, axial in origin; tunics of pale, fine to coarse, netted fibres. *Cataphylls* up to 3, papery. *Leaves* 4 to 13, lower 3 to 11 ± basal and suberect to prostrate, unifacial, linear-lanceolate to lanceolate, falcate or oblong, acute to obtuse, main vein lightly to moderately thickened, usually plane, rarely undulate or crisped (*F. viridis* subsp. *crispifolia*), uppermost 1 or 2 leaves cauline, usually without blade; margin without vascular bundle, epidermis cells columnar with thickened walls. *Stem* erect or shortly decumbent, usually terete but flattened and winged in *F. viridis*, often branched, smooth or sparsely to densely papillate. *Inflorescence* a spike, usually branched, rachis ± deflexed and inclined or horizontal, secund and ± scalloped; bracts either firm-textured and green with narrow, hyaline margin, or pale and papery or membranous and then usually tipped dark brown, acute, apiculate or tricuspidate, inner smaller and strongly 2-veined, forked apically. *Flowers* weakly to strongly zygomorphic, long-lived, either ± salver-shaped or funnel-shaped and bilabiate, mostly white or cream-coloured to pale yellow, often flushed purple on reverse but also pink, red or green to brown, lower tepals often with yellow to orange lateral nectar guides, often fragrant, nectar from septal nectaries; perianth tube either subcylindric and expanding slightly and evenly from base or near apex, or funnel-shaped and narrowly tubular below but ± abruptly expanded near middle into a broadly cylindric or flared distal part; tepals subequal or upper larger and sometimes hooded, oblong to lanceolate, inner tepals often oblong or ovate-cordate. *Stamens* unilateral, usually inserted at base of broader distal part of tube or near mouth of tube, usually included but sometimes exserted. *Ovary* ellipsoid; style filiform, 3-branched distally, branches deeply divided, longitudinally folded, recurved. *Capsules* cartilaginous, subglobose to oblong, 3-lobed, rough and papillate to verrucose in upper ½ or throughout. *Seeds* subglobose, sometimes with raphe and chalaza inflated, smooth or wrinkled, testa dry and glossy reddish brown, rarely bright orange to red when fresh. *Pollen grains* monosulcate-operculate, operculum 1- (*F. viridis* only) or 2-banded, exine perforate-scabrate. *Basic chromosome number x* = 11.



Species 16: mainly winter-rainfall southern Africa but extending into eastern subtropical and tropical Africa.

Freesia was initially restricted to the often highly fragrant species with funnel-shaped flowers but now includes several florally dissimilar species with salver-shaped flowers previously segregated as the genus *Anomatheca*. The genus is distinguished by the often narrowly conical corms with finely netted tunics, mostly soft-textured leaves with the marginal epidermal cells columnar and thickened, an inclined or horizontal and ± scalloped spike of flowers with deeply divided style branches, ± distinctive ± papillate or verrucose capsules, and subglobose seeds with a smooth, glossy testa.

The genus is popular in the cut-flower trade, with numerous named cultivars. These have all been derived from repeated crossing of colour forms of just the two species *Freesia corymbosa* and *F. leichtlinii* (subsp. *alba* and subsp. *leichtlinii*).

Key to species

1a Flowers ± salver- or trumpet-shaped with floral tube slender and cylindric throughout or widening gradually from base, 1–3 mm diam. at mouth; tepals subequal and ± spreading or recurved, without extensive yellow markings; stamens inserted in upper 5 mm of floral tube:
2a Stem 2-angled or -winged; floral tube sharply bent in upper part and mouth facing down; flowers green or brownish; anthers included. . . . . 9. *F. viridis*
2b Stem terete; floral tube straight or slightly curved, mouth facing sideways or upwards; flowers white, mauve, pink or red; anthers exserted:
3a Leaves < 100 mm long, much shorter than inflorescence, oblong, obtuse-apiculate; bracts 4.0–5.5 mm long; perianth tube 15–20 mm long; flowers pink . . . . . 5. *F. verrucosa*
3b Leaves usually > 100 mm long, often as long as or longer than inflorescence, linear-lanceolate to lanceolate, acute-apiculate; bracts (4–)5–20 mm long; perianth tube 20–40 mm long; flowers red, pink, pale blue or white:

FREESIA. F. fucata: A, flowering plant, B. outer bract (left) and inner bract (right); C, half-flower; D, flower front view; E, dehisced capsules; F, seed. ***F. laxa***: G, flowering branch; H, flower front view. ***F. viridis*** subsp. ***crispifolia***: I, flower. ***F. verrucosa***: J, flower. ***F. sparmannii***: K, flower. ***F. refracta***: L, flower.

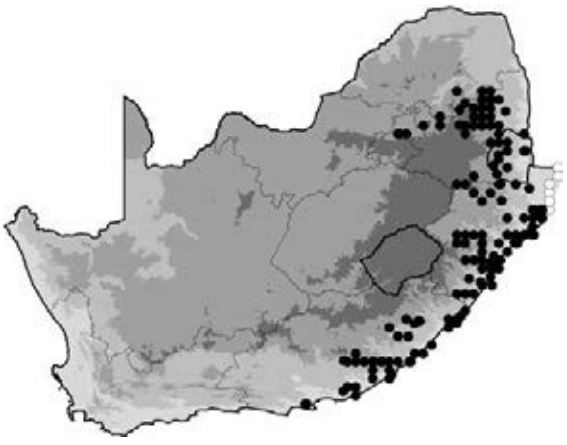
4a Perianth > twice as long as tepals; upper tepal 9–15 mm long; filaments 3–4 mm long, scarcely exserted . . . 1. *F. laxa*
4b Perianth tube ± as long as tepals or slightly longer; upper tepal 22–32 mm long; filaments 15–25 mm long, exserted 10–20 mm . . . . . 2. *F. grandiflora*
1b Flowers funnel-shaped, floral tube with narrowly tubular lower portion ± abruptly expanded into broadly cylindric distal portion, 5–15 mm diam. at mouth; stamens inserted near middle or in lower half of tube, at junction between lower and upper portions; lower tepals usually with extensive yellow markings:
5a Floral bracts thin-textured, membranous or papery, pale green or translucent and dry, usually with dark tips; stems smooth; seeds subglobose, without inflated raphe:
6a Bracts 7–13 mm long; flowers normally 50–65 mm long; filaments 18–32 mm long:
7a Leaves 100–200 mm long, acute; flowers white to cream-coloured, boldly marked with purple lines in throat; tepals ovate to elliptic; filaments 18–25 mm long . . . . . 3. *F. andersoniae*
7b Leaves 25–100 mm long, obtuse or subacute; flowers pale yellow, plain or with pale purple lines in throat; tepals suborbicular; filaments 27–33 mm long . . . . . 4. *F. speciosa*
6b Bracts 4–8 mm long; flowers normally 25–40 mm long; filaments 10–14 mm long:
8a Bracts uniformly pale; leaves usually ± as long as stem . . . . . 7. *F. refracta*
8b Bracts brown-tipped; leaves usually ± half as long as stem:
9a Leaves obtuse or subacute, (5–)7–18(–25) mm wide; bracts lightly tipped with dark brown; flowers white or cream-coloured, sometimes flushed pale lilac or mauve . . . . . 8. *F. occidentalis*
9b Leaves acute to acuminate, 2–7(–10) mm wide; bracts with pronounced dark brown tips; flowers usually pale yellow sometimes flushed dull purple, or pale to deep pink. . . . . 6. *F. corymbosa*
5b Floral bracts firm-textured or leathery, green with narrow membranous margins; stems puberulous or papillate, at least toward base; seeds obliquely globose, with inflated raphe:
10a Floral tube narrowly funnel-shaped, lower portion 12–15 mm long and ± as long as or slightly longer than upper portion; lower tepals 4–5 mm wide; flowers unscented . . . . . 10. *F. sparrmanii*
10b Floral tube funnel-shaped, lower portion ± half as long as upper portion; lower tepals 5–12 mm wide; flowers always fragrant:
11a Plants usually with deeply buried corms, bearing cormlets in one or more lower leaf axil; plants coastal in sandy soils . . . . . 15. *F. leichtlinii*
11b Plants with shallow corms, bearing cormlets at base of parent corm, never in leaf axils; plants inland in loamy or clay soils:
12a Corm tunics of soft, thin-textured fibres (< 0.1 mm diam.); flowers mostly with yellow or orange markings on lower median tepal only; flowering June to July . . . . . 14. *F. praecox*
12b Corm tunics of wiry, coarse-textured fibres (at least some > 0.2 mm diam.); flowers mostly with yellow or orange markings on all three lower tepals:
13a Flowers creamy yellow or bright yellow; number of leaves (5–)7 to 13; flowering (June) July to August . . . . . 16. *F. fergusoniae*
13b Flowers white; number of leaves 4 to 7(–9); flowering April to July:
14a Leaves erect, glaucous, acuminate, 4–5 mm wide . . . . . 11. *F. fucata*
14b Leaves erect or prostrate, green or glaucous, subacute to acute, 6–15(–20) mm wide:
15a Leaves medium-textured, with prominent main vein but no evident submarginal vein . . . 13. *F. caryophyllacea*
15b Leaves firm-textured and leathery, with inconspicuous main vein and prominent submarginal vein . . . . . 12. *F. marginata*

Subg. 1. **Freesia**

Anomatheca Ker Gawl. in König & Sims, Annals of Botany: 227 (1804). *Lapeirousia* subg. *Anomatheca* (Ker Gawl.) Baker: 173 (1892). *Freesia* subg. *Anomatheca* (Ker Gawl.) J.C.Manning & Goldblatt: 172 (2005). Type: *A. verrucosa* (B.Vogel) Goldblatt = *F. verrucosa* (B.Vogel) Goldblatt & J.C.Manning.

Plants small to medium-sized. *Stem* terete, smooth. *Leaves* erect to prostrate, lanceolate to oblong, plane, acute or obtuse. *Spike* suberect or inclined; bracts soft-textured, either soft-herbaceous and green throughout or drying from apex, or entirely membranous and translucent, often brown-tipped. *Flowers* either funnel-shaped and white or pale to deep pink or yellow with dark yellow or orange markings on lower tepals, or ± salver-shaped with straight tube and blue or pink to red with red markings on lower tepals. *Stamens* included or shortly to well exserted. *Seeds* subglobose or with inflated raphe, smooth or rugulose, reddish brown but sometimes orange to red when fresh.

Species 8: southern and tropical Africa.



1. **Freesia laxa** *(Thunb.) Goldblatt & J.C.Manning* in Systematic Botany 20: 171 (1995). *Gladiolus laxus* Thunb.: 50 (1823). *Lapeirousia laxa* (Thunb.) N.E.Br.: 24 (1928). *Meristostigma laxum* (Thunb.) A.Dietr.: 597 (1832). *Anomatheca laxa* (Thunb.) Goldblatt: 442 (1971). Type: South Africa, [Eastern Cape], without precise locality but probably Uitenhage District in December 1773, *Thunberg s.n.* (UPS-THUNB 1039, holo.).

Plants (150–)200–300(–500) mm high. *Corm* globose-conical, 10–15 mm diam., with cormlets at base; tunics

of fine-textured fibres. *Stem* erect, usually simple. *Leaves* 6 to 9, suberect, usually shortly overtopping spike, narrowly lanceolate, (40–)100–400 × 4–10(–15) mm, acute to acuminate, soft-textured with midrib moderately thickened. *Spike* slightly or moderately deflexed, (1)2 to 6(–14)-flowered; bracts ovate, (4–)5–8(–14) mm long, acute, soft-textured, green with reddish brown tips, inner slightly shorter. *Flowers* 25–40 mm long, red to pink, lilac or pale blue, rarely white, base of lower 3 tepals each with dark red, purple or violet blotch, unscented; perianth tube cylindric, expanded slightly near apex, (20–)25–35(–40) mm long, ± curved in upper 4 mm; tepals subequal but inner 3 broader, uppermost ± reflexed, others spreading, elliptic to obovate, 9–15 × 4–8 mm. *Filaments* erect, mostly 3–5 mm long, inserted 2 mm below mouth of tube, exserted 1–3 mm; anthers ± 4 mm long. *Style* dividing between base and apex of anthers. *Capsules* oblong-ovoid, 10–12(–15) × 8–10 mm, ± papillate. *Seeds* subglobose with highly inflated raphe, 2.5–3.0 mm diam., smooth and glossy, bright red when fresh but soon darkening to reddish brown. *Flowering time*: variable in any locality, from June to April, most often from October to December.

Distribution and ecology: widely distributed along the eastern seaboard of southern Africa from east of Port Elizabeth in South Africa through the Eastern Cape and KwaZulu-Natal Midlands to Mpumalanga and Eswatini; also southern Mozambique, Zambia, eastern Democratic Republic of the Congo, Tanzania, western Kenya, eastern Uganda and the Imatong Mountains in South Sudan; in small colonies in coarse sandy soil in coastal scrub and inland on the edges of bush and forest, often in rocky situations. Naturalised locally on waste ground in Australia around Sydney and the northern coast of New South Wales, in southern China, Mauritius, Réunion, Madeira, and USA in Florida and possibly other southern states; self-fertile and often autogamous.

Diagnosis: evidently closely allied to *Freesia grandiflora* and sharing subglobose-conical corms, suberect spikes of brilliant scarlet flowers (pale bluish in subsp. *azurea*), and seeds that are bright orange or red when fresh. Both species are restricted to forest or savanna in regions of summer rainfall. The flowers in *F. laxa* are generally smaller, with a relatively longer perianth tube more than twice as long as the tepals (9–15 mm long), and very short filaments, 3–4 mm long and scarcely exserted from the tube. The species reproduces vegetatively by sessile cormlets.

Distribution of ***Freesia laxa*** subsp. ***laxa***, ●; subsp. ***azurea***, ○.

Key to subspecies

1a Flowers pink to red (rarely white) with dark red markings on lower tepals; upper tepal 10–15 × 5–8 mm; style dividing at or above middle of anthers . . . . . 1a. subsp. *laxa*

1b Flowers lilac, pale bluish or white with violet or indigo markings on lower tepals; upper tepal 9–11(–12) × 4(–5) mm; style dividing below middle of anthers . . . . . 1b. subsp. *azurea*

1a. subsp. **laxa**

Anomatheca cruenta Lindl.: t. 1369 (1830). *Lapeirousia cruenta* (Lindl.) Baker: 173 (1892). *Freesia cruenta* (Lindl.) Klatt: 187 (1894). Type: South Africa, [Eastern Cape], without precise locality, *Lindley s.n.* (GCE, holo.).

Lapeirousia grandiflora Jacq.: 120 (1836), illegitimate superfluous name for *Anomatheca cruenta* Lindl. Type: illustration in Annales de flora et de Pomone 4: 122 (1836).

Lapeirousia graebneriana Harms: 366 (1901). Type: Tanzania, Iringa District, Uhehe, Ufuagi, 14 Mar. 1899, *Goetze 748* (B, holo.; BR, iso.).

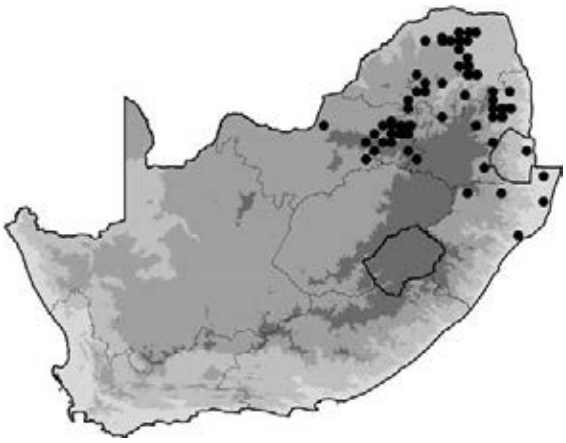
Flowers pink to red (rare white sports are known), usually paler on reverse, lower 3 tepals each with dark red blotch at base; perianth tube 20–35(–40) mm long; tepals 10–12(–15) × 4–8 mm. *Filaments* exserted 1.5–2.0 mm. *Style* dividing between middle and apex of anthers. *Flowering time*: August to January but peak flowering south of the equator is between November and January, and May to July north of the equator.

Distribution and ecology: widely distributed along the eastern coast and near interior of South Africa, from near Port Elizabeth through Eastern Cape and KwaZulu-Natal to Eswatini and Ohrigstad in Mpumalanga and Pretoria in Gauteng, and discontinuously through eastern tropical Africa to western Kenya, southern Tanzania, Zambia, eastern Uganda and southern Sudan but not recorded in Zimbabwe, northern Mozambique or southern Malawi; favouring rocky habitats on the edge of bush clumps and afrotemperate forest but also in coastal forest and bush near sea level in northern KwaZulu-Natal.

1b. subsp. **azurea** *Goldblatt & Hutchings* in Novon 3: 146 (1993). Type: Mozambique, Inhaca Island, 20 July 1980, *De Koning & Navunga 8312* (LMU, holo.; BR, K, MO, SRGH, iso.).

Flowers lilac, pale bluish or white, lower 3 tepals each with dark blue to violet blotch at base; perianth tube 25–35 mm long; tepals 9–11(–13) × 4(–5) mm. *Filaments*

exserted 1–3 mm. *Style* dividing between base and middle of anthers. *Flowering time*: June to September.



Distribution and ecology: restricted to coastal habitats between Richards Bay in northern KwaZulu-Natal and Massinga in central Mozambique; in coarse, sandy soils, either in exposed sites such as grassy dunes or in light shade.

2. **Freesia grandiflora** *(Baker) Klatt* in Th.Durand & H.Schinz, Conspectus florae africae 5: 187 (1894). *Anomatheca grandiflora* Baker: 337 (1876). *Lapeirousia grandiflora* (Baker) Baker: t. 6924 (1887), illegitimate homonym, not *L. grandiflora* Jacq. (1836) [= *F. laxa* (Thunb.) Goldblatt & J.C.Manning]. Type: Mozambique, mouth of Luabo [Luaua] River, 30 May 1858, *Kirk s.n.* [K, lecto., designated by Goldblatt: 53 (1993)].

Plants (120–)200–600 mm high. *Corm* globose-conical, 10–15 mm diam., producing thick, scaly rhizomes 20–40 mm long, tunics of fine fibres or ± papery. *Stem* erect, usually simple, rarely developing cormlets in axils of lower leaves. *Leaves* 6 to 9, suberect, usually reaching to base of spike or shortly above, lanceolate, (40–)100–300 × (6–)8–20 mm, acute, soft-textured with moderately thickened main vein. *Spike* suberect or weakly deflexed, becoming erect or suberect in fruit, 2- to 6-flowered; bracts ovate, soft and herbaceous, green with dark reddish brown tips, 10–20 mm long, acute, inner ⅔ as long. *Flowers* 30–50 mm long, usually red, rarely pinkish red or pink, base of lower 3 tepals with darker red blotch, unscented; perianth tube cylindric below, expanded and funnel-shaped near apex, 20–30(–35) mm long, straight or slightly curved above; tepals subequal with inner 3 slightly larger and uppermost largest, suberect below and spreading above, oblanceolate, upper tepals 22–32 × 7–10 mm, lower 21–26 mm long. *Filaments* erect and unilateral, (6–)15–25 mm long, inserted 3–4 mm below mouth of tube, exserted 12–20 mm; anthers 5.5–8.0 mm long. *Style* dividing between middle and apex of anthers. *Capsules* oblong, 8–10 × 7–8 mm, ± papillate. *Seeds* subglobose, 2.0–3.5 mm diam., with or without inflated chalaza and very short raphe, smooth or lightly wrinkled, deep orange or red when fresh but soon darkening. *Flowering time*: mainly January to April.

Distribution and ecology: scattered through the eastern, southern and tropical Africa, from north of Durban in KwaZulu-Natal through the northern provinces of South Africa as far west as Rustenburg and Zeerust, and through Eswatini and Mozambique to Zambia and southern Tanzania; typically in humus-rich soils in scrub, deciduous woodland or more rarely forest, sometimes along streams, also occasionally on anthills.

The production of rhizomes is unusual among southern African Crocoideae but is also found in *Crocosmia aurea*, another woodland or forest species. The flowers are evidently adapted for butterfly pollination and the seeds for bird dispersal.

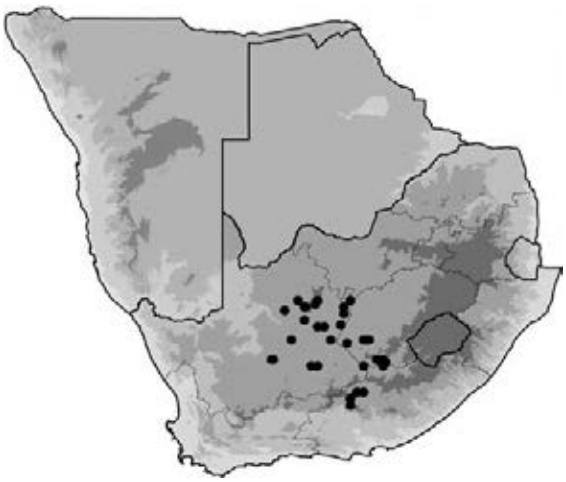
Distribution of ***Freesia grandiflora*** subsp. ***grandiflora***.

Diagnosis: allied to *Freesia laxa* but distinguished from it by the larger flowers with the dorsal tepal 22–32 mm long, relatively shorter tube at most only slightly longer than the dorsal tepal, and filaments typically 15–20 mm long and well exserted from the tube. The characteristic rhizomes are not developed in *F. laxa*, which produces sessile cormlets.

subsp. **grandiflora**

Tritonia graminifolia Baker: 195 (1892). *Lapeirousia graminifolia* (Baker) L.Bolus: 135 (1929b). Type: South Africa, [Mpumalanga], near Lydenburg, November 1874, *Bolus 2651* (K, holo.).

Freesia rubella Baker: 868 (1901). Type: Mozambique, Delagoa Bay [Maputo], 1890, *Junod 166* (Z, holo.).



Flowers usually bright red, rarely salmon-pink. *Filaments* 15–25 mm long, exserted 12–20 mm beyond tube. *Style* usually dividing between middle and apex of anthers, rarely below anthers.

Distribution and ecology: as for the species.

A second subspecies, subsp. *occulta* J.C.Manning & Goldblatt, with unusually short filaments, ± 6 mm long, occurs locally near Mocuba in Zambézia Province in north-central Mozambique.

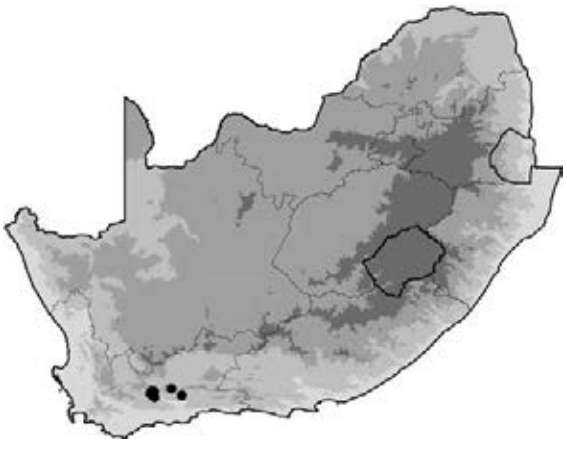
3. **Freesia andersoniae** *L.Bolus* in South African Gardening and Country Life 17: 337 (1927). Type: South Africa, [Northern Cape], Herbert District, September 1925, *Anderson 760* [BOL, lecto., designated by Goldblatt: 86 (1982)].

Plants 100–250(–300) mm high. *Corm* conical, 15–25 mm diam., tunics light brown, of medium–coarse-textured fibres. *Stem* erect, smooth but minutely verrucose on angles below each flower, usually simple. *Leaves* 10 to 14, inclined to suberect, ± as long as stem, narrowly lanceolate, 100–200 × 4–10 mm, acute to subattenuate,

Distribution of ***Freesia andersoniae***.

drying at flowering time. *Spike* deflexed, 2- to 5-flowered; bracts ovate, dry and membranous or papery, translucent with brown veins and rust-coloured speckling on apices, 7–10(–13) mm long, acute, inner up to 2 mm longer. *Flowers* 50–60 mm long, white to creamy white, base of lowermost tepal and inner edges of lower lateral tepals flushed orange, all three lower tepals with dark brownish midline and with dark chevrons in sinuses, strongly lily-scented; perianth tube funnel-shaped, 35–45 mm long with basal tubular portion 15–20 mm long, widening ± abruptly into cylindric-flared upper portion; tepals with dorsal largest, suberect, obovate, 12–16 × 10–12 mm, upper laterals broadly elliptic, lower tepals recurved, elliptic, 10–15 × 17–9 mm. *Filaments* arcuate, 18–25 mm long, inserted at base of widened upper portion, included; anthers 7–9 mm long. *Style* dividing between base and middle of anthers. *Capsules* shortly oblong or oblong-ovoid, (7–)10–12 × 8–10 mm, warty or papillate. *Seeds* subglobose or with chalaza slightly swollen, 2.5–3.0 mm diam., smooth, glossy dark or reddish brown. *Flowering time*: August to early October.

Distribution and ecology: scattered across the central plateau of South Africa in the drainage basins of the Orange and Vaal rivers, from the Kuruman Hills on the southern fringes of the Kalahari in the north to near Carnarvon in the west and to Aliwal North and the Sneeuberg near Middelburg in the east; typically along the lower, southern slopes of dolerite outcrops.



Diagnosis: *Freesia andersoniae* has an erect, almost smooth stem and thin-textured, membranous or papery bracts, and large, fragrant white flowers, 50–60 mm long, marked with characteristic purple chevrons in the tepal sinuses.

4. **Freesia speciosa** *L.Bolus* in South African Gardening and Country Life 19: 385 (1929a). Type: South Africa, [Western Cape], between Bonnievale and Barrydale (cultivated at the Karoo Garden, Whitehill), 22 Aug. 1929, *Archer s.n. BOL19027* (BOL, holo.).

Freesia sparrmanii [as *sparrmannii*] var. *flava* N.E.Br.: t. 11 (1921). *F. flava* (N.E.Br.) N.E.Br.: 27 (1935). Type: South Africa, [Western Cape], Ladismith District, 30 Oct. 1918 (fl. in cult. Pretoria 19 Sept. 1919), *Shand s.n. PRE 15786* (PRE, holo.).

Plants (80–)120–200(–300) mm high. *Corm* conic, 15–30 mm diam., tunics light brown, of medium–coarse-textured fibres. *Stem* erect, smooth but minutely verrucose on angles below each flower, usually simple. *Leaves* 5 or 6, inclined to suberect, usually ± half as long as stem, oblong, 25–100 × 14–20 mm, obtuse to subobtuse, apiculate, firm-textured or softer. *Spike* deflexed, 3- to 6-flowered; bracts ovate, membranous, green below when young but dry in upper ⅔, later translucent with brown veins and rust-coloured speckling on apices, 8–10 mm long, acute but lower bracts tricuspidate, inner up to 1 mm longer. *Flowers* 50–70 mm long, pale creamy yellow, base of lowermost tepal and inner edges of lower lateral tepals flushed orange, all three lower tepals with brown midline, strongly lily-scented, with sour or bitter note during day; perianth tube funnel-shaped, 35–50 mm long with basal tubular portion 15–20 mm long, widening ± abruptly into cylindric-flared upper portion; tepals with dorsal largest, suberect, broadly ovate to suborbicular, 15–18 × 14–15 mm, upper laterals elliptic, lower tepals recurved, lower laterals broadly elliptical to suborbicular, 14–15 × 11–12 mm, lower median oblong, 14–15 × 7–8 mm. *Filaments* arcuate, 27–33 mm long, included; anthers 6–7 mm long. *Style* dividing at or slightly beyond anther apices. *Capsules* short-oblong or oblong-ovoid, 9–13 × 8–10 mm, warty or papillate. *Seeds* globose, 2.5–3.0 mm diam., smooth or finely wrinkled, glossy dark or reddish brown. *Flowering time*: mid-August to September.

Distribution and biology: endemic to the western Little Karoo in Western Cape, South Africa, from Anysberg to Calitzdorp; on cooler, south-trending stony slopes in

Distribution of ***Freesia speciosa***.

open shrubland, typically in loam or alluvium, or with the corms wedged in cracks on south-facing sandstone cliffs in humus.

Diagnosis: a distinctive species with obtuse, often somewhat succulent leaves and large, pale creamy yellow flowers, 50–70 mm long, with broadly elliptical or suborbicular lower lateral tepals, 11–12 mm wide, and elongate filaments 27–33 mm long.

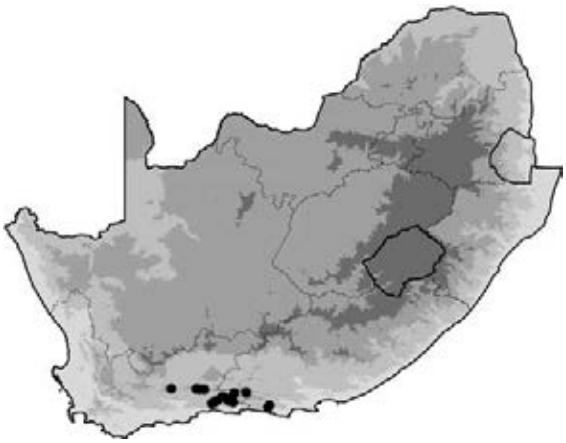
5. **Freesia verrucosa** *(B.Vogel) Goldblatt & J.C.Manning* in Systematic Botany 20: 171 (1995). *Ixia verrucosa* B.Vogel in Trew: t. 24, f. 2 (1784). *Anomatheca verrucosa* (B.Vogel) Goldblatt: 442 (1971). Type: without precise locality, figure in Trew, Plantae Rariores 3: 8, t. 24, f. 2 (1784).

Gladiolus junceus L.f.: 94 (1782), illegitimate homonym, not *G. junceus* Burm.f. (1768) [= *Geissorhiza aspera* Goldblatt]. *Lapeirousia juncea* Ker Gawl.: t. 606 (1802). *Anomatheca juncea* (Ker Gawl.) Ker Gawl.: 227 (1804). *Peyrousia juncea* (Ker Gawl.) Poir.: 364 (1826). *Meristostigma junceum* (Ker Gawl.) Steud.: 130 (1841). *Freesia juncea* (Ker Gawl.) Klatt: 187 (1894). Type: [South Africa], without precise locality, *Thunberg s.n. LINN59.25* [as *Gladiolus falcatus*] (LINN, holo.).

Ixia emarginata Lam.: 342 (1789). Type: South Africa, without precise locality, Herb. Lamarck (P, holo.).

Gladiolus amabilis Salisb.: 41 (1796). Type: unknown.

Gladiolus pulchellus Salisb.: 39 (1796). Type: unknown.



Gladiolus polystachyus Andrews: t. 66 (1799). *G. paniculatus* Pers.: 45 (1805), illegitimate superfluous name for *G. polystachyus* Andrews. Type: illustration in Andrews: t. 66 (1799).

Ixia elliptica Thunb.: 4 (1803). Type: [South Africa], without precise locality, *Thunberg s.n.* (UPS-THUNB 897, holo.).

Gladiolus excisus Jacq.: 46 (1804). Type: illustration in Jacq.: t. 491 (1804).

Ixia gawleri Schrad.: 67 (1810), illegitimate superfluous name for *Gladiolus amabilis* Salisb. [= *F. verrucosa* (B.Vogel) Goldblatt & J.C.Manning]. Type: illustration in Ker Gawl.: t. 606 (1802).

Plants 80–200 mm high. *Corm* conic, 10–15 mm diam., tunics of fine–medium-textured fibres. *Stem* suberect, smooth, usually branched. *Leaves* 7 to 10, suberect, usually ± ⅓ as long as stem, oblong, (15–)20–80 × 3–9 mm, obtuse-apiculate, margins sometimes slightly undulate, soft-textured with moderately thickened main vein. *Spike* slightly deflexed to horizontal, (4–)8- to 10(–15)-flowered; bracts obovate, soft-textured, herbaceous, 4.0–5.5 mm long, green below but soon becoming pale, flushed pinkish distally with reddish veins, inner slightly shorter. *Flowers* 25–30 mm long, bright pink, lower 3 or only median tepal with whitish or pale yellowish blotch at base outlined with dark pink, unscented or lightly scented; perianth tube subcylindric, 15–20 mm long, straight or slightly curved in upper 5 mm; tepals subequal or upper 3 slightly larger, spreading, elliptic to oblanceolate, 8–11 × 3–4 mm. *Filaments* arcuate, 6–7 mm long, inserted 4–5 mm within tube, shortly exserted; anthers ± 3 mm long. *Style* dividing opposite middle of anthers. *Capsules* short-oblong to subglobose, 6–7 × 6 mm, papillate. *Seeds* subglobose, 1.5–2.0 mm diam., smooth, glossy reddish brown. *Flowering time*: late August to October.

Distribution of ***Freesia verrucosa***.

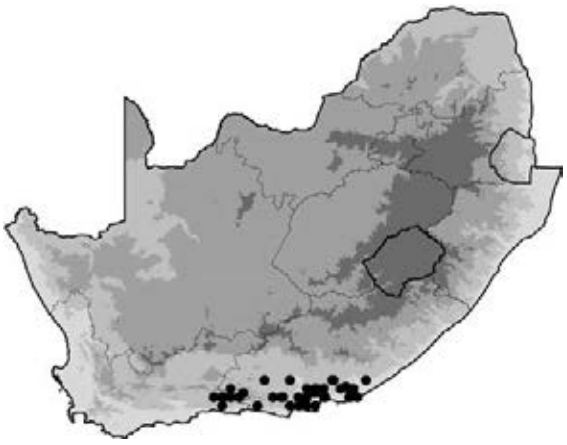
Distribution and ecology: restricted to the Little Karoo and Long Kloof between Ladismith in Western Cape and Willowmore in Eastern Cape; in stony clay soils in open renosterveld shrubland and washes.

Diagnosis: recognised by the spreading or prostrate fan of short, obtuse leaves, and the declinate or horizontal spike of pink, ± salver-shaped flowers with slender tube 15–20 mm long and short bracts 4.0–5.5 mm long.

6. **Freesia corymbosa** *(Burm.f.) N.E.Br.* in Bulletin of Miscellaneous Information, Kew 1929: 132 (1929). *Gladiolus corymbosus* Burm.f.: 2 (1768). Type: South Africa, without precise locality (cultivated in Europe), *Burman s.n.* (G-Herb. Burman, holo.).

Freesia odorata Eckl. ex Klatt: 672 (1866), illegitimate superfluous name for *F. sparrmanii*. *F. refracta* var. *odorata* Baker: 167 (1892). Type: South Africa, [Eastern Cape], heights between the Bushmans and Kariega Rivers, *Ecklon & Zeyher Irid. 108* (GH, holo.; K, LD, MO, P, PRE, iso.).

Freesia aurea Hend. ex Gumbl.: 392 (1896). *F. corymbosa* var. *aurea* (Hend. ex Gumbl.) N.E.Br.: 16 (1935). Type: [South Africa], without locality or date, *Gumbleton s.n.* (K, holo.).



Freesia armstrongii W.Watson: 195 (1898). Type: South Africa, [Eastern Cape], Humansdorp Distr. (cultivated at Royal Botanic Gardens, Kew), *Armstrong s.n.* (K, holo.).

Freesia metelerkampiae L.Bolus: 337 (1927). Type: South Africa, without precise locality (cultivated in Cape Town), July–August 1927, *Metelerkamp s.n.* (BOL, holo.).

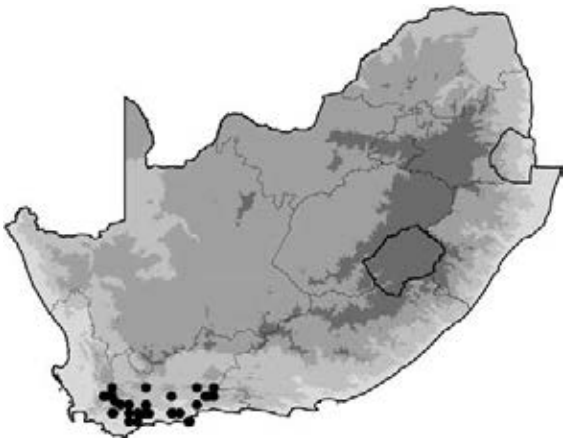
Freesia brevis N.E.Br.: 263 (1933), illegitimate superfluous name for *F. metelerkampiae* L.Bolus. Type: illustration in South African Gardening and Country Life 17: 336 (1927) (a figure of the type of *F. metelerkampiae* when alive).

[*Tritonia odorata* G.Lodd.: t. 1820 (1832), invalid name without description. *Waitzia odorata* G.Lodd. ex Heynh.: 854 (1841), invalid name without description.]

Plants (120–)150–400(–600) mm high. *Corm* conic or globose, 12–30 mm diam., tunics light brown, of medium-textured to coarse fibres, sometimes forming collar. *Stem* suberect, smooth, usually branched. *Leaves* 7 to 10, erect, usually ± half as long as stem, narrowly lanceolate, (40–)60–200 × 2–7(–10) mm, acute, rarely oblong-lanceolate and obtuse. *Spike* horizontal or deflexed, (3–)6- to 10-flowered; bracts oblong to oblanceolate, membranous becoming dry, 4–8 mm long, translucent or flushed pale pinkish, with brown veins and dark brown tips, obtuse or rarely apiculate, inner slightly shorter to slightly longer, with dark brown tips. *Flowers* 25–35(–40) mm long, usually pale to deep yellow, pale to deep pink, or rarely white, with base of tube, lowermost tepal and inner margins of lower lateral tepals bright yellow to orange, lower tepals with brownish midline running into tube, unscented or weakly scented; perianth tube funnel-shaped, 20–25(–35) mm long with basal tubular portion 5–10(–20) mm long and strongly curved at tip, widening abruptly into flared upper portion; tepals with dorsal largest, suberect, broadly ovate-cordate, 8–12 × 7–10 mm, upper laterals ovate, lower tepals recurved, lower laterals broadly ovate-cordate with margins strongly upcurved, 7–11 × 8–10 mm, lower median ovate, 7–10 × 4–8 mm. *Filaments* arcuate, 13–15 mm long, included; anthers 5–6 mm long. *Style* dividing at or slightly beyond anther apices. *Capsules* subglobose or oblong, 6–8 × 6–8 mm, papillate. *Seeds* globose with flattened chalaza, slightly wrinkled, glossy reddish brown, 2.0–3.5 mm diam. *Flowering time*: (May) late August to October.

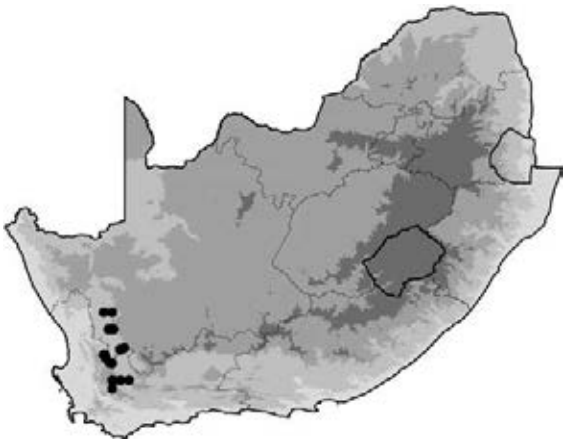
Distribution of ***Freesia corymbosa***.

Distribution and ecology: fairly widespread in southern South Africa, from near Uniondale in Western Cape through the Long Kloof and adjacent valleys to Grahamstown, King William's Town and Butterworth in Eastern Cape; in loamy or sandy soils in rocky conglomerate, sandstone or shale, in open scrub or grassy fynbos.



The flowers are typically pale yellow with a darker throat and lower tepals but are deep yellow around Port Elizabeth, and rose- or deep pink-flowered populations occur in the Long Kloof, near Haarlem, Joubertina and Zuurbron, and near Hankey. The lower part of the perianth tube is exceptionally long, 15–20 mm long, in plants from the southern foothills of the Zuurberg, near Enon.

Diagnosis: resembling both *Freesia refracta* and *F. occidentalis* in its bracts and flowers but distinguished by the usually obtuse bracts prominently tipped with dark brown for up to 0.5 mm, and often more brightly coloured flowers, mostly pale to deep yellow but also pink, or rarely white.



7. **Freesia refracta** *(Jacq.) Klatt* in Linnaea 34: 673 (1866). *Gladiolus refractus* Jacq.: t. 241 (1795). *Tritonia refracta* (Jacq.) Ker Gawl.: 228 (1804). *G. resupinatus* Pers.: 45 (1805), illegitimate superfluous name for *G. refractus* Jacq. *Waitzia refracta* (Jacq.) Heynh.: 855 (1841). *Montbretia refracta* (Jacq.) Endl. ex Heynh.: 418 (1847). *Nymanina refracta* (Jacq.) Kuntze: 701 (1891). Type: illustration in Jacq.: t. 241 (1795).

Freesia hurlingii L.Bolus: 112 (1933a). Type: South Africa, [Western Cape], Bonnievale, 23 August 1931, *Hurling & Neil s.n.* (BOL, lecto., designated by Goldblatt: 74 (1982); BOL, isolecto.).

Plants (80–)150–400(–600) mm high. *Corm* conic or ± globose, 12–30 mm diam., tunics light brown, of fine–medium-textured fibres, forming short neck. *Stem* suberect, smooth, usually branched. *Leaves* 7 to 10, usually erect, half as long to ± as long as stem, narrowly lanceolate-attenuate, (60–)100–300 × 2–7(–10) mm, acute, sometimes glaucous, rarely with prominent marginal vein. *Spike* horizontal or deflexed, (4)5- to 10(–12)-flowered; bracts oblong to oblanceolate, membranous becoming dry, translucent or flushed pale pinkish with brown veins, 4–8 mm long, obtuse to apiculate, inner slightly shorter to slightly longer. *Flowers* 25–35 mm long, pale greenish yellow or dull white, ± purplish on reverse and base of tube, lowermost tepal and inner margins of the lower lateral tepals bright orange, all

Distribution of ***Freesia refracta***.

Distribution of ***Freesia occidentalis***.

3 lower tepals with dark brownish midline, either unscented or strongly scented of rose and violet with spicy undertones; perianth tube funnel-shaped, 16–25 mm long with basal tubular portion 5–8(–9) mm long, widening abruptly into flared upper portion; tepals with dorsal largest, suberect, broadly ovate-cordate, 8–12 × 7–10 mm, upper laterals ovate, lower tepals recurved, laterals broadly ovate-cordate, margins strongly upcurved, 7–11× 8–10 mm, lower median ovate, 7–10 × 4–8 mm. *Filaments* arcuate, 10–14 mm long, included; anthers 5–6 mm long. *Style* dividing at or slightly beyond anther apices. *Capsules* subglobose or oblong, 6–10 × 6–8 mm, papillate. *Seeds* globose with flattened chalaza, 2.0–2.5 mm diam., lightly wrinkled, glossy reddish brown. *Flowering time*: mid-July to early September.

Distribution and ecology: relatively common in the southwestern Western Cape, South Africa, from Genadendal along the coast to Gouritz River Mouth and from the Hex River Valley and Breede River Valley through the Little Karoo to De Rust; in drier, stony soils in shrubland and coastal thicket.

Diagnosis: distinguished from *Freesia corymbosa* and *F. occidentalis*, which it resembles in its bracts and flowers, by its mostly dull yellowish or greenish perianth, uniformly pale bracts without brown tips, and leaves mostly as long as the stem.

8. **Freesia occidentalis** *L.Bolus* in South African Gardening and Country Life 23: 266 (1933c). Type: South Africa, [Western Cape], Nieuwefontein, precise locality not given, September 1932, *Compton 4723* (BOL, lecto., designated by Goldblatt: 77 (1982); K, isolecto.).

Freesia framesii L.Bolus: 245 (1934). Type: South Africa, [Northern Cape], Calvinia District (cultivated in Cape Town), September 1934, *Ross Frames ex Skaife BOL21366* (BOL, holo.).

Plants 80–300(–600) mm high. *Corm* conic, 15–20 mm diam., tunics light brown, of medium-textured to coarse fibres, forming collar. *Stem* suberect, smooth, usually branched. *Leaves* 7 to 10, erect or inclined, ± half as long to as long as stem, oblong to lanceolate, 40–120(–300) × (5–)7–18(–25) mm, obtuse to subacute, apiculate. *Spike* horizontal or deflexed, (3–)6- to 9-flowered; bracts oblanceolate to oblong, membranous becoming dry, translucent or flushed pale pink with brown veins and tips, 5–8 mm long, apiculate, inner slightly shorter to slightly longer, with brown tips. *Flowers* 30–35 mm long, white to yellow, sometimes flushed mauve or pink, base of tube sometimes bright orange, lowermost tepal and inner margins of lower lateral tepals bright yellow, all three lower tepals with dark brownish midline, strongly rosy violet-scented with peppery overtones; perianth tube funnel-shaped, 20–25 mm long with basal tubular portion 6–11 mm long and strongly curved at tip, widening abruptly into flared upper portion; tepals unequal, dorsal largest, suberect, broadly ovate-cordate, 8–12 × 7–10 mm, upper laterals ovate, lower tepals recurved, lower laterals broadly ovate-cordate with margins strongly upcurved, 7–11 × 8–10 mm, lower median ovate, 7–10 × 4–8 mm. *Filaments* arcuate, 13–15 mm long, included; anthers 5–6 mm long. *Style* dividing at or slightly beyond anther apices. *Capsules* subglobose or oblong, 6–10 × 6–8 mm, papillate. *Seeds* globose with flattened chalaza, 2.0–2.5 mm diam., lightly wrinkled, glossy reddish or purplish brown. *Flowering time*: August to September.

Distribution and ecology: restricted to the western edge of the Tanqua Karoo and nearby, from southwest of Calvinia in Northern Cape, South Africa, to Karoopoort and along the foot of the Bonteberg to Pieter Meintjies siding in Western Cape; in arid fynbos, transitional fynbos–renosterveld or succulent karoo, in loamy soils, in rocky alluvium, or shale outcrops, on south-trending slopes or drainage lines.

Diagnosis: distinguished from the similar *Freesia refracta* and *F. corymbosa* by its obtuse or subacute leaves, typically shorter than the flowering spike, flowers with rather blunt tepals, and brown-tipped bracts.

Subg. 2. **Viridibractea**

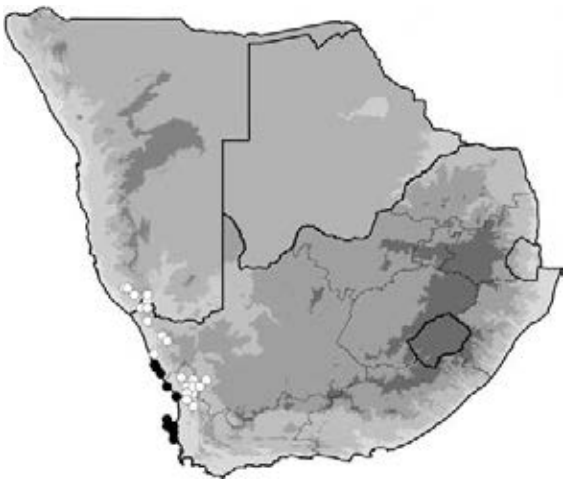
Subg. **Viridibractea** *(Goldblatt) J.C.Manning & Goldblatt* in Strelitzia 27: 50 (2010). *Freesia* sect. *Viridibractea* Goldblatt: 56 (1982). Type: *F. alba* (G.L.Mey.) Gumbl. = *F. leichtlinii* subsp. *alba* (G.L.Mey.) J.C.Manning & Goldblatt

Plants small to medium-sized. *Stem* either winged in section and smooth, or terete and puberulous, at least below. *Leaves* erect to prostrate, blades lanceolate to oblong, plane or undulate-crispulate, acute or obtuse. *Spike* inclined or horizontal; bracts firm-textured, herbaceous and green with narrow, translucent margin. *Flowers* either funnel-shaped and white or pale to deep yellow with dark yellow or orange markings on lower tepals, or ± tubular with tepals ± recurved and yellowish green or brownish. *Stamens* included or shortly exserted. *Seeds* subglobose or with inflated raphe, smooth or rugulose, reddish brown.

Species 8: South Africa.

Sect. 1. **Alatae** *J.C.Manning & Goldblatt* in Novon 15: 172 (2005). Type: *Freesia viridis* (Aiton) Goldblatt & J.C.Manning

Stem compressed and laterally winged. *Leaves* erect or suberect, falcate, acute to attenuate, plane or undulate-crispulate. *Flowers* green to brownish or maroon, scented or evidently unscented at night, tubular, tube sharply curved apically, tepals ± equally recurved, lanceolate. *Filaments* inserted near top of tube, included. Seeds subglobose, without inflated raphe. Pollen operculum 1-banded.



Species 1: West Coast and near interior Western and Northern Cape, South Africa.

9. **Freesia viridis** *(Aiton) Goldblatt & J.C.Manning* in Systematic Botany 20: 172 (1995). *Gladiolus viridis* Aiton: 481 (1789). *Tritonia viridis* (Aiton) Ker Gawl.: 231 (1804). *Waitzia viridis* (Aiton) Kreysig: 52 (1829). *Montbretia viridis* (Aiton) Voigt: 610 (1845). *Lapeirousia viridis* (Aiton) L.Bolus: 276 (1932). *Anomatheca viridis* (Aiton) Goldblatt: 443 (1971). Type: South Africa, [Western Cape], Swartland, without exact locality or date, *Masson s.n.* (BM, holo.).

Plants 100–300(–500) mm high. *Corm* conic, 10–30(–40) mm diam., tunics of fine-textured to coarse fibres, sometimes extending as collar. *Stem* erect, flattened and 2-winged, usually simple. *Leaves* 4 to 8, suberect or sometimes prostrate, half as long as to slightly longer than stem, narrowly lanceolate to oblong or falcate, (30–)50–150(–200) × 4–15(–25) mm, acute to attenuate, rarely obtuse-acuminate, margins plane or undulate to crisped, soft-textured or leathery with moderately thickened midrib. *Spike* deflexed, (3)4- to 10-flowered; bracts ovate, herbaceous and firm-textured, green, often flushed pinkish at tips, 5–10(–25) mm long, obtuse, inner slightly shorter. *Flowers* 20–40 mm long, yellowish green to olive-green or ± strongly flushed with brown or maroon, unscented or rose-scented at night; perianth tube subcylindric, expanding gradually from base to apex, 15–25 mm long, curved sharply downward in upper 5–7 mm with oblique mouth; tepals subequal with upper 3 slightly larger, recurved from base, lanceolate and obtuse to linear-lanceolate and attenuate, 6–15 × 1–2 mm. *Filaments* arcuate, 5–7 mm long, at bend in tube, included or very shortly exserted; anthers shortly protruding from tube, ± 3 mm long. *Style* dividing at base of anthers. *Capsules* oblong or subglobose, 3-lobed, 10–15 × 8–10 mm, rough or papillate when fresh. *Seeds* globose, 2.0–3.0 mm diam., wrinkled, glossy reddish brown. *Flowering time*: mid-May to mid-August (October).

Distribution and biology: widely scattered along the West Coast and near-interior winter rainfall region, from southern Namibia and the Richtersveld and Namaqualand of Northern Cape, South Africa, through the Olifants River Valley to Mamre north of Cape Town in Western Cape; mostly in coastal thicket and succulent Karroo shrubland, rarely in arid fynbos. The species is self-fertile and facultatively autogamous.

Diagnosis: a highly distinctive species with several vegetative and floral specialisations, notably the flattened and winged stems, the small, greenish or brown flowers

Distribution of ***Freesia viridis*** subsp. ***viridis***, ●; subsp. ***crispifolia***, ○.

with strongly curved perianth tube and included stamens, and the one-banded pollen operculum.

Key to subspecies

1a Leaves narrowly lanceolate to lanceolate, mostly 4–10 mm wide, plane; tepals (6–)10–18 mm long . . . . . 9a. subsp. *viridis*
1b Leaves lanceolate to falcate, up to 25 mm wide, margins ± crispulate or undulate; tepals 6–10 mm long. . . . . 9b. subsp. *crispifolia*

9a. subsp. **viridis**

Leaves narrowly lanceolate to lanceolate, (2–)4–10(–15) mm wide, plane. *Flowers* yellowish green, or green flushed with dark purple; tepals oblong-lanceolate to narrowly lanceolate and attenuate, (6–)10–18 mm long.

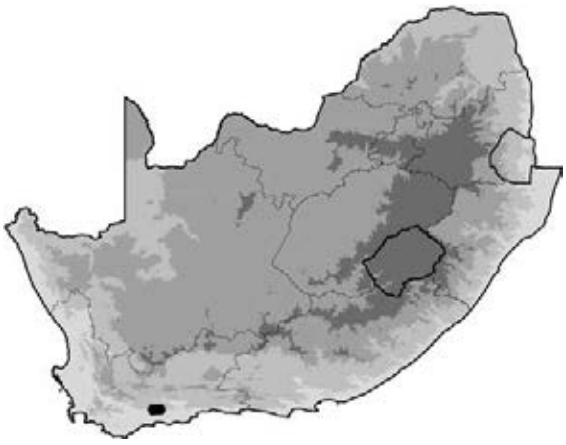
Distribution and ecology: essentially coastal, from Yzerfontein to south of the Olifants River Mouth in Western Cape but occurring in isolated populations in Namaqualand at Brand-se-Baai, Groen River Mouth and near Hondeklip Bay in Northern Cape; in pockets of loam or rock cracks in coastal thicket.

9b. subsp. **crispifolia** *(Goldblatt) J.C.Manning & Goldblatt* in Strelitzia 27: 55 (2010). *Anomatheca viridis* subsp. *crispifolia* Goldblatt: 87 (1972). Type: South Africa, [Western Cape], Clanwilliam, July 1894, *Leipoldt 161* (BOL, holo.; NBG, PRE, iso.).

Leaves oblong-lanceolate to falcate, 5–10(–25) mm wide, margins weakly undulate to crisped. *Flowers* dull green or brownish to maroon; tepals oblong-lanceolate to lanceolate, 6–10 mm long.

Distribution and ecology: distributed along the near interior of the West Coast from Clanwilliam in Western Cape, through the Knersvlakte and central Namaqualand in Northern Cape as far north as the Auros Mountains in southern Namibia; on a wide variety of substrates from near the coast to just over 100 km inland, often in crevices in rock outcrops.

Populations from the Richtersveld and southern Namibia in the extreme north of the range are characterised by short, ± inclined leaves with weakly undulate margins.



Sect. 2. **Viridibractea** *Goldblatt* in Journal of South African Botany 48: 56 (1982). Type: *Freesia alba* (G.L.Mey.) Gumbl. = *F. leichtlinii* subsp. *alba* (G.L.Mey.) J.C.Manning & Goldblatt

Stem terete, sparsely to densely papillate. *Leaves* erect, inclined or prostrate, acute or obtuse. *Flowers* funnel-shaped with upper tepal largest and erect, white or pale to deep yellow with dark yellow or orange markings on lower tepals. *Filaments* inserted at base of widened upper portion, included. *Seeds* obliquely subglobose, with inflated raphe.

Species 7: southwestern and south-coastal Western and Eastern Cape.

10. **Freesia sparrmanii** *(Thunb.) N.E.Br.* in Flowering Plants of South Africa 1: t. 11 (1921). *Gladiolus sparrmanii* [as *sparrmannii*] Thunb.: 191 (1814). *Ixia sparrmanii* (Thunb.) Roem. & Schult.: 285 (1822). *Meristostigma sparrmanii* (Thunb.) Steud.: 130 (1841). Type: South Africa, [Western Cape], exact locality unknown but probably at or near Grootvadersbosch, September–October 1775, *Sparrman s.n.* (S, lecto., designated by Goldblatt: 63 (1982); S, isolecto.).

Plants (100–)150–250 mm high. *Corm* conical, 10–25 mm diam., tunics pale, of fine-textured fibres. *Stem* erect or flexed outward above uppermost sheath and then suberect, minutely papillate in lower half, usually branched. *Leaves* 5 to 9, erect, ± as long as the stem, linear to narrowly lanceolate, tapering above, 70–200 × (2–)3–8(–9) mm, acute. *Spike* deflexed, (3–)5- to 8(–11)-flowered; bracts obovate, herbaceous and firm-textured, green with hyaline margins, flushed purple apically, (3–)4–6(–7) mm long, inner slightly shorter. *Flowers* (30–)35–40 mm long, white, flushed dull purple on reverse of tepals, base of lower median tepal with oblong yellow-orange mark in midline, unscented; perianth tube narrowly funnel-shaped, 20–27 mm long with basal narrow part 12–15 mm long, expanded into wider, flared upper portion; tepals unequal, dorsal largest and suberect, ovate, 10–11 × ± 7 mm, upper laterals slightly narrower, lower tepals recurved, narrowly ovate, 7–8(–10) × 4–5 mm. *Filaments* arcuate, 10–14 mm long, included; anthers 4.0–4.5 mm long. *Style* dividing ± 2 mm beyond anther apices. *Capsules* oblong or subglobose,

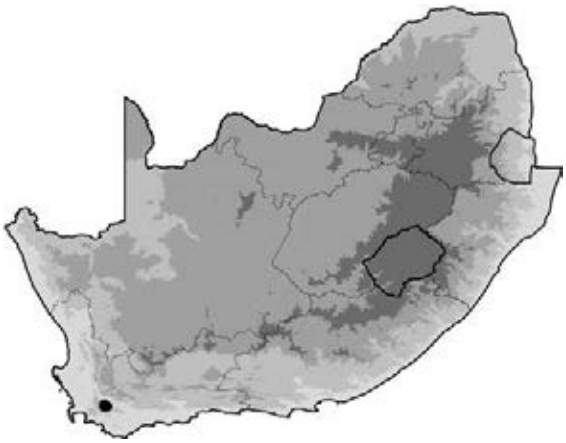
Distribution of ***Freesia sparrmanii*** .

10–12 × 8–10 mm, papillate. *Seeds* obliquely subglobose with inflated chalaza and raphe, 2.0–2.5 mm diam., smooth, glossy reddish brown. *Flowering time*: late September to late October.

Distribution and ecology: a local endemic along the southern foothills of the Langeberg between Suurbraak and Grootvadersbosch in Western Cape, South Africa; forest margins and clearings on the forest floor.

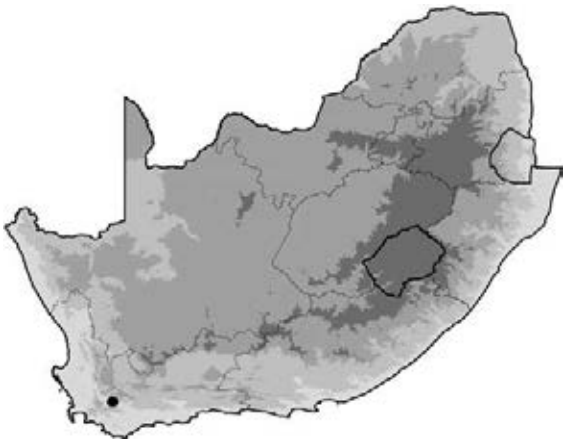
Diagnosis: distinguished from other gullet-flowered species by its slender, white flowers with narrow tepals up to 5 mm wide and narrowly funnel-shaped tube with the slender, lower portion 12–15 mm long and ± as long as or slightly longer than the upper part.

11. **Freesia fucata** *J.C.Manning & Goldblatt* in Bothalia 31: 189 (2001). Type: South Africa, Western Cape, Villiersdorp District, 5.5 km along Doornrivier Road, Farm Die Hoek, 10 July 2000, *Manning 2271* (NBG, holo.).



Plants 150–300 mm high. *Corm* conic, 15–20 mm diam., tunics pale, of medium-textured fibres, accumulating with age and forming collar. *Stem* flexed outward above uppermost sheath and then suberect, minutely papillate, usually 1- or 2-branched. *Leaves* 5 or 6, inclined to suberect, usually ± as long as stem, linear-lanceolate, 80–250 × 4–5 mm, tapering above, acute. *Spike* lightly deflexed, 4- to 9-flowered; bracts obovate, herbaceous and firm-textured, green with hyaline margins, 6–10(–13) mm long, tricuspidate, inner slightly shorter. *Flowers* (30–)35–47 mm long, white flushed dull purple on reverse of tepals, base of lower tepals marked yellow-orange with dark midline, strongly violet-scented; perianth tube funnel-shaped, 20–30 mm long with tubular lower portion 6–7 mm long, widening ± abruptly into flared upper portion; tepals unequal, dorsal largest, suberect, ovate, 11–18 × 8–11 mm, upper laterals oblong, lower tepals recurved, lower laterals narrowly ovate, 10–14 × 6–8 mm, lower median oblong, 10–16 × 5–6 mm. *Filaments* arcuate, 13–15 mm long, included; anthers 7–8 mm long. *Style* dividing at or slightly beyond anther apices. *Capsules* oblong, (6–)9–12 × (6–)7–10 mm, papillate. *Seeds* obliquely subglobose with inflated chalaza and raphe, 2.5–3.0 mm diam., wrinkled, glossy reddish brown. *Flowering time*: July.

Distribution and biology: a local endemic of the Hoeksrivier Valley north of Villiersdorp in Western Cape, South Africa; in clay soils in open renosterbos shrubland or stony washes.



Diagnosis: distinguished from other early-flowering species of sect. *Viridibractea* by its narrow, glaucous, almost grass-like leaves, 4–5 mm wide, and 3-toothed bracts.

12. **Freesia marginata** *J.C.Manning & Goldblatt* in Novon 15: 168 (2005). Type: South Africa, Western Cape, between Worcester and Robertson, 25 May 2002, *Manning 2734* (NBG, holo.).

Plants 40–100 mm high, usually ± prostrate. *Corm* conic, 15–20 mm diam., tunics of pale, medium-textured fibres, accumulating with age and forming long collar. *Stem* flexed outward above uppermost leaf sheath and then prostrate or horizontal, densely puberulous, usually simple. *Leaves* (4)5 or 6(7), prostrate or rarely erect, slightly shorter than to half as long as stem, oblong to lanceolate, 20–50(60) × 6–15 mm, acute, leathery and ± glaucous, with prominent submarginal vein. *Spike* declinate, 4- to 10-flowered; bracts obovate, herbaceous and firm-textured, green with hyaline margins, 5–7 mm long, tricuspidate or upper bracts obtuse with prominent central cusp tipped rusty brown, inner slightly longer. *Flowers* (30–)33–37 mm long, white usually lightly flushed purple on reverse of tepals, base of lower tepals marked yellow-orange and usually with dark midline, strongly violet-scented; perianth tube funnel-shaped, 18–25 mm long, with tubular basal portion 6–10 mm long, widening ± abruptly into flared upper portion; tepals unequal, dorsal largest, erect, obovate, 12–15 × 7–8 mm, upper laterals oblong-lanceolate, lower tepals recurved, oblong-lanceolate, 11–13 × 4.0–5.5 mm. *Filaments* arcuate, 15–17 mm long, included;

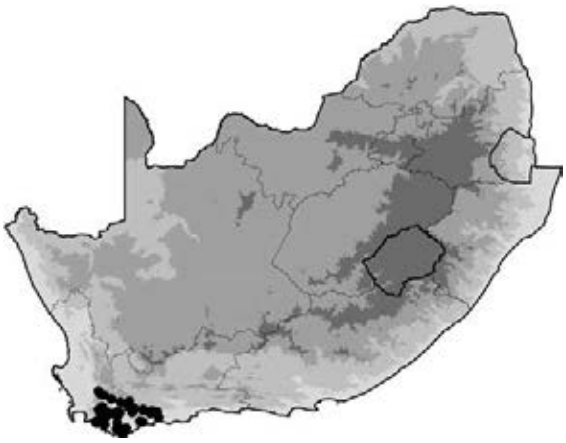
Distribution of ***Freesia fucata***.

Distribution of ***Freesia marginata***.

anthers 5.0–5.5 mm long. *Style* dividing below or opposite anther apices. *Capsules* oblong or subglobose, (5–)6–10 × 5–10 mm, minutely papillate when fresh. *Seeds* obliquely subglobose with slightly to moderately inflated chalaza and raphe, 2.0–3.0 mm diam., slightly wrinkled, glossy reddish or purplish brown. *Flowering time*: late May to early June.

Distribution and ecology: a highly local endemic of the Breede River Valley in Western Cape, South Africa, between Worcester and Robertson; in gravelly or stony washes in decaying sandstone in open succulent karoo shrubland.

Diagnosis: resembling *Freesia caryophyllacea* in its prostrate, ± obtuse leaves and early flowering but distinguished by the ± glaucous leaves with inconspicuous main vein but prominent submarginal vein, clearly visible in both fresh and dried leaves as a translucent line ± 0.5 mm in from the leaf margin.



13. **Freesia caryophyllacea** *(Burm.f.) N.E.Br.* in Bulletin of Miscellaneous Information, Kew 1929: 134 (1929). *Ixia caryophyllacea* Burm.f.: 1 (1768). *Antholyza caryophyllacea* (Burm.f.) Roem & Schult.: 448 (1817). *Anisanthus caryophyllaceus* (Burm.f.) Klatt: 344 (1882). Type: South Africa, without locality (cult.), *Burman s.n.* (G, holo.).

Gladiolus xanthospilus DC. in Redouté 3: t. 124 (1805). *Freesia xanthospila* (DC.) Klatt: 673 (1866). *Tritonia xanthospila* (DC.) Ker Gawl. ex Spreng.: 154 (1824). *Waitzia xanthospila* (DC.) Heynh.: 855 (1841). *Montbretia xanthospila* (DC.) Heynh.: 418 (1847). Type: South Africa, without precise locality, cultivated in France, illustration in Redouté: t. 124 (1805).

Freesia parva N.E.Br.: 9 (1935). Type: South Africa, [Western Cape], near Elim, 24 Apr. 1896, *R. Schlechter 7727* (K, lecto., designated by Goldblatt: 65 (1982); BOL, isolecto.).

Freesia elimensis L.Bolus: 168 (1933b). Type: South Africa, [Western Cape], 8 miles [13 km] from Bredasdorp on Elim road, 22 April 1933, *W.F. Barker & L. Bolus NBG697/33* (BOL, holo.; BOL, iso.).

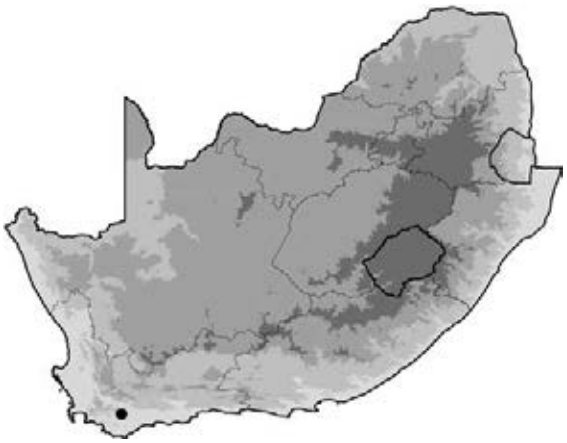
Plants 30–100 mm high, usually ± prostrate. *Corm* conic, 10–15 mm diam., tunics of pale, medium-textured fibres, sometimes accumulating with age and forming long collar. *Stem* flexed outward above uppermost leaf sheath and then prostrate or horizontal, rarely suberect, densely puberulous, usually simple. *Leaves* 5 to 7(–9), prostrate or rarely erect, usually slightly shorter than stem, oblong to lanceolate, (20–)30–100(–120) × 6–15(–20) mm, subacute or obtuse, thin-textured or leathery. *Spike* declinate, 3- to 10-flowered; bracts obovate, herbaceous and firm-textured, green with hyaline margins, 5–8 mm long, inner slightly shorter. *Flowers* 30–40(–60) mm long, white flushed purple on reverse of tepals, base of lower tepals marked yellow-orange and usually

Distribution of ***Freesia caryophyllacea***.

with dark midline, unscented or violet-scented; perianth tube funnel-shaped, 20–30 mm long with basal tubular portion 5–8(–12) mm long, widening ± abruptly into flared upper portion; tepals with dorsal largest, erect, elliptical to obovate, 17–25(–30) × 8–12 mm, upper laterals oblong-lanceolate, lower tepals recurved, oblong-lanceolate, 14–20 × 6–8 mm. *Filaments* arcuate, 13–20 mm long, included or slightly exserted; anthers 4–6 mm long. *Style* dividing at or just beyond anther apices. *Capsules* oblong or subglobose, 8–10 × ± 10 mm, papillate. *Seeds* obliquely globose with inflated chalaza and raphe, 2.0–3.0 mm diam., wrinkled, glossy reddish brown. *Flowering time*: mid-April to early June.

Distribution and ecology: relatively common in the lowlands of southwestern Western Cape, South Africa, from Wolseley through the Breede River Valley to Heidelberg in the east, and from the foothills of the Riviersonderend Mtns near Greyton, through Caledon and Napier to Bredasdorp, with a westerly extension along the coast to Hermanus and outlying populations near Grabouw; typically in gravelly clay soils in renosterveld shrubland although also in sandy loam in fynbos or coastal scrub.

Diagnosis: mostly readily recognised by its relatively short, blunt or subacute leaves, often borne in a prostrate fan, and by its ± horizontal inflorescence, typically with rather large bracts. The white flowers are flushed with purple and marked on some or all of the lower tepals with golden-yellow blotches that turn brown as the flowers age, and appear in late autumn or winter, from April to June, rarely into July.



Forms with narrower, suberect leaves and flowers with just the median lower tepal marked with yellow occur on coastal limestones around Bredasdorp and may represent introgression with *Freesia leichtlinii* subsp. *leichtlinii*. Similar plants from coastal outcrops at Onrus and Hermanus have been treated in *F. leichtlinii* subsp. *alba* but they lack the characteristic axillary cormlets of that species. Individuals in these populations with very narrow leaves approach *F. praecox* but tend to have fewer leaves than that species.

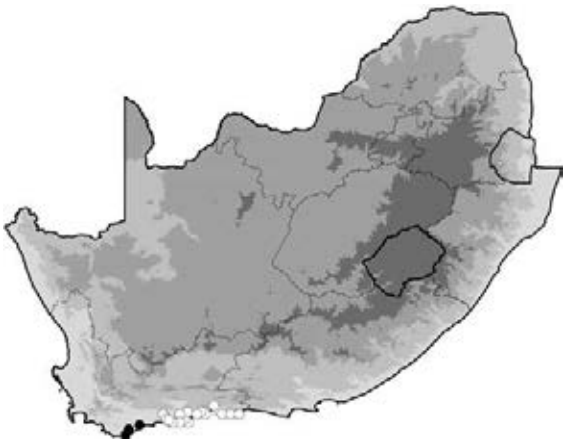
14. **Freesia praecox** *J.C.Manning & Goldblatt* in Strelitzia 27: 65 (2010). Type: South Africa, Western Cape, Riviersonderend, hill north of town, 15 June 2004, *J.C.Manning 2921* (NBG, holo.; K, MO, PRE, iso.).

Plants 60–300 mm high. *Corm* conic, 10–20 mm diam., tunics pale, of medium-textured fibres, accumulating with age but not forming collar. *Stem* flexed outward above uppermost sheath and then suberect, minutely puberulous, usually simple. *Leaves* 6 to 9(–11), prostrate or suberect, usually slightly longer than stem, narrowly lanceolate, 50–200(–250) × 4–10(–14) mm, tapering-attenuate. *Spike* lightly flexed to horizontal, 3- to 8-flowered; bracts obovate, herbaceous, green with hyaline margins, 5–10(–12) mm long, acute or lower weakly tridentate, inner slightly shorter. *Flowers* (30–)35–45 mm long, white, usually flushed dull purple on reverse of tepals, base of lower median tepal (rarely lower laterals also) marked yellow-orange, lower tepals, especially laterals, with purple or mauve veins in basal half, strongly violet-scented; perianth tube (15–)20–30 mm long with basal narrow part 5–9 mm long, widening abruptly into wider, flared upper portion; tepals with dorsal largest, suberect, oblong-elliptic, 13–22 × 6–10 mm, upper laterals slightly narrower, oblong, lower tepals recurved, lower laterals oblong-elliptic, 15–20 × 6–8 mm, lower median oblong, 12–20 × 5–7 mm. *Filaments* arcuate, 15–20 mm long, included; anthers 4–6 mm long. *Style* dividing at or slightly beyond anther apices. *Capsules* ovoid, 11–12 × 8–9 mm, papillate-verrucose. *Seeds* obliquely globose with inflated chalaza and raphe, 2.0–3.0 mm diam., finely wrinkled, glossy reddish brown. *Flowering time*: mid-June to mid-July.

Distribution and ecology: a highly localised endemic from the lower end of Olifantskloof and surrounding hills at Riviersonderend in Western Cape, South Africa; in loamy soils in cracks in sandstone outcrops.

Diagnosis: a poorly defined species resembling *Freesia leichtlinii* subsp. *alba* in its finely fibrous corm tunics, numerous, relatively narrow, tapered leaves, and flowers with usually just the lower median tepal marked with yellow but lacking the axillary cormlets diagnostic of that species, and flowering several months earlier, in June and July rather than August and September.

Distribution of ***Freesia praecox***.



Freesia praecox is most likely to be confused with narrow-leafed forms of *F. caryophyllacea* but tends to have more numerous leaves, usually 6 to 9 and up to 11, with gradually tapering, narrowly lanceolate-attenuate blades that are distinctly longer than the flowering stem.

15. **Freesia leichtlinii** *Klatt* in Regel, Gartenflora 23: 289 (1874). *Nymanina leichtlinii* (Klatt) Kuntze: 701 (1891). *F. xanthospila* var. *leichtlinii* (Klatt) N.E.Br.: 22 (1935). Type: illustration in Regel: t. 808 (1874).

Plants 60–250 mm high (rarely up to 500 mm under bushes). *Corm* conic, 10–15(–20) mm diam., sometimes deeply buried, tunics pale, of fine–medium-textured fibres. *Stem* erect or flexed upward above uppermost sheath and then suberect, minutely papillate, at least toward base, usually simple, producing cormlets in lower, subterranean leaf axils and later at base of corm. *Leaves* 5 to 9, inclined to suberect or rarely prostrate, less than half as long to ± as long as stem, narrowly lanceolate to linear-lanceolate, 40–140(–300) × (3–)6–12 mm, acute. *Spike* deflexed or horizontal, (2–)4- to 9-flowered; bracts obovate, herbaceous and firm-textured, green with hyaline margins, 4–7(–12) mm long, inner slightly shorter. *Flowers* (25–)30–45 mm long, white to cream-coloured or pale yellow, usually ± flushed dull purple on reverse of tepals, base of all 3 lower tepals or only lower median tepal marked yellow to orange, strongly violet-scented; perianth tube funnel-shaped, (15–)20–25(–40) mm long with basal tubular portion (5–)6–9(–20) mm long, widening ± abruptly into flared upper portion; tepals subequal or unequal with dorsal largest, suberect, ovate, 13–18 × 8–14 mm, upper laterals slightly narrower, lower tepals recurved, 12–14 × 6–12 mm. *Filaments* arcuate, (12–)15–18(–22) mm long, included; anthers 6–9 mm long. *Style* dividing at or slightly beyond anther apices. *Capsules* oblong, 10–12 × 8–10 mm, papillate or rugulose. *Seeds* obliquely subglobose with inflated chalaza and raphe, 2.5–3.0 mm diam., wrinkled or smooth, glossy reddish brown. *Flowering time*: August to October.

Distribution and ecology: distributed along the South Coast of South Africa, from Agulhas in Western Cape to Plettenberg Bay in Eastern Cape; in lime-enriched sands or calcareous loam in bush, thicket or restioid fynbos. Naturalised in the winter-rainfall parts of Australia and north of Nice in France.

Diagnosis: distinguished by its deeply buried corms with finely fibrous corm tunics and suberect leaves with the lower always bearing cormlets in their axils along the subterranean portion of the stem. The white to pale

Distribution of ***Freesia leichtlinii*** subsp. ***leichtlinii***, ●; subsp. ***alba***, ○.

yellow flowers are produced in spring, mainly between August and late September.

Key to subspecies

1a Flowers pale yellow or creamy white, lightly flushed purple outside, with base of lower 3 tepals marked deep yellow to orange; perianth tube (15–)20–25 mm long with basal narrow part 5–9 mm long; plants from Agulhas to St Sebastian Bay . . . . . 15a. subsp. *leichtlinii*

1b Flowers uniformly white, or white to creamy white flushed purple outside, usually with base of only lower median tepal marked yellow to orange; perianth tube (15–)20–40 mm long with basal narrow part 5–20 mm long; plants from Still Bay to Plettenberg Bay. . . . . 15b. subsp. *alba*

15a. subsp. **leichtlinii**

Freesia muirii N.E.Br.: 467 (1932). Type: South Africa, [Western Cape], Mossel Bay Division, without exact locality or date, *F. Muir 4849* (K, syn.), *4849A* (K, PRE, syn.).

Freesia gentilis N.E.Br.: 20 (1935). Type: South Africa, cultivated at Botanical Gardens, Cape Town, from corms said to have been collected by G. Alston at Vanwyksvlei, *SAM20966* (SAM, holo.).

Plants mostly 100–200 mm high. *Leaves* usually prostrate or inclined and ± half as long as flowering stem. *Flowers* cream-coloured to pale yellow, usually lightly flushed dull purple on reverse of tepals, base of lower 3 tepals marked deep yellow to orange; perianth tube (15–)20–25 mm long with basal narrow part (5–)6–9 mm long; tepals unequal, dorsal largest, 13–18 × 8–14 mm, lower tepals 12–14 × 8–12 mm. *Seeds* wrinkled. *Flowering time*: August to September.

Distribution and ecology: from Agulhas to St Sebastian Bay in Western Cape; in sandy or calcareous loam in open scrub or coastal thicket.

15b. subsp. **alba** *(G.L.Mey.) J.C.Manning & Goldblatt* in Strelitzia 27: 70 (2010). *Freesia refracta* var. *alba* G.L.Mey: 37 (1881). *F. alba* (G.L.Mey.) Gumbl.: 392 (1896). *F. sparrmanii* [as *sparrmannii*] var. *alba.* (G.L.Mey.) N.E.Br.: t. 11 (1921). Type: illustration in Zeitschrift des Schweizerischen Gartenbauvereins 1, t. 3 (Meyer 1881).

Freesia middlemostii W.F.Barker: 112 (1933). Type: South Africa, [Western Cape], Bredasdorp, Aug. 1932, *A.J. Middlemost s.n.* (BOL, holo.).

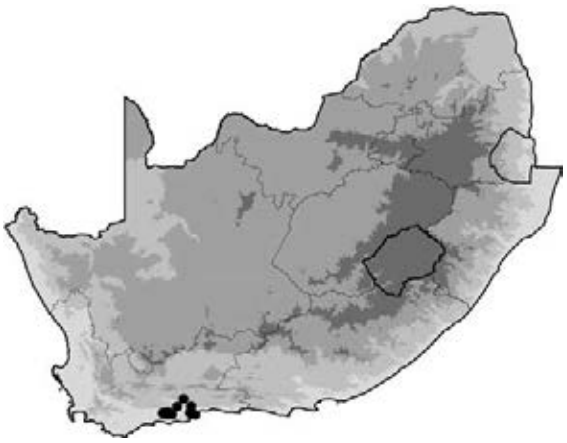
Freesia picta N.E.Br.: 21 (1935). Type: South Africa, [Western Cape], Beaufort West [?Cult.], August 1933, *Black s.n. NBG1558/13* (BOL, holo.).

[*Freesia lactea* Fenzl ex N.E.Br. [as Fenzl ex Klatt]: 23 (1935), invalid name without description.]

Plants mostly 200–500 mm high. *Leaves* usually inclined or suberect and ± as long as flowering stem. *Flowers* white to cream-coloured and flushed dull purple on reverse of tepals, or pure white, usually only lower median tepal marked with yellow to orange; perianth tube (15–)20–40 mm long, basal narrow part 5–20 mm long; tepals subequal or unequal then dorsal largest, 13–18 × 8–12 mm, lower tepals 12–14 × 6–10 mm. *Seeds* smooth or slightly wrinkled. *Flowering time*: late July to early October.

Distribution and ecology: from west of Still Bay in Western Cape to Plettenberg Bay in Eastern Cape; in coarse sandy or calcareous soils, often in crevices in rocky outcrops, or in light shade along the margins of coastal scrub or forest patches.

The finest form of the species, with large, pure white flowers 50 mm long with subequal tepals and the lower part of the perianth tube 15–20 mm long, occurs on the Robberg Peninsula at Plettenberg Bay and is the form associated with the species in cultivation. The original freesia of horticulture, subsp. *alba* was hybridised in the late 19th Century with *F. corymbosa* to produce the more robust and larger flowered strains available today in the horticultural trade. In early literature, *F. leichtlinii* and especially subsp. *alba* was misidentified as *F. refracta*, which was never used in the breeding of *Freesia* cultivars.



16. **Freesia fergusoniae** *L.Bolus* in South African Gardening and Country Life 17: 337 (1927). Type: South Africa, [Western Cape], Riversdale, Aug. 1926, *Ferguson s.n.* (BOL, holo.).

Plants 60–200(–300) mm high. *Corm* conic, 15–20 mm diam., tunics of pale, coarse-textured fibres, accumulating. *Stem* erect or flexed upward above uppermost sheath and then suberect, minutely papillate at least toward base, usually simple. *Leaves* (5–)7–13, prostrate to inclined, oblong to lanceolate, usually < half as long as stem, 40–140(–200) × 6–16 mm, obtuse to subacute. *Spike* deflexed or horizontal, (2–)4 to 8(–12)-flowered; bracts obovate, firm-textured, green with hyaline margins, 4–7(–10) mm long, inner slightly shorter. *Flowers* (25–)30–45 mm long, pale yellow to cream-coloured

(± white), ± flushed dull purple on reverse of tepals, base of lower tepals marked orange, strongly violet-scented; perianth tube funnel-shaped, (15–)20–25 mm long with basal tubular portion 5–9 mm long, widening ± abruptly into flared upper portion; tepals unequal, dorsal largest, suberect, ovate, 13–18 × 8–14 mm, upper laterals slightly narrower, lower tepals recurved, 12–14 × 8–12 mm. *Filaments* arcuate, 14–20 mm long, included; anthers 6–8 mm long. *Style* dividing at or slightly beyond anther apices. *Capsules* oblong, 10–12 × 8–10 mm, papillate. *Seeds* obliquely subglobose with inflated chalaza and raphe, 2.5–3.0 mm diam., wrinkled, glossy reddish brown. *Flowering time*: July to August.

Distribution and ecology: locally common along the southern foothills of the Langeberg between Heidelberg and Riversdale in Western Cape, South Africa, extending inland along the Gourits River to the Rooiberg and the northern end of Robinson's Pass; in clay soils in renosterveld, flowering best in cleared or burned sites.

Diagnosis: usually readily recognised by the fragrant, pale yellow flowers with prominent orange markings on the lower tepals. The spikes are held well above the leaves, which are typically prostrate and obtuse but in some populations may be suberect and acute. Erect-leaved plants of *Freesia fergusoniae* are most likely to be confused with yellow-flowered *F. leichtlinii* subsp. *leichtlinii*, but that species is restricted to coastal sands or sandy loam and has deeply buried corms with fine to medium-textured tunics, and produces axillary cormlets along the subterranean portion of the stem.

Distribution of ***Freesia fergusoniae***.

Populations from Soetmelksrivier, southeast of Riversdale with cream-coloured or white flowers and a prostrate flower spike are easily confused with *Freesia caryophyllacea*, but the more numerous leaves (9 to 12 vs. 5 to 7) and later flowering (mid- to late July) are consistent with *F. fergusoniae*.

UNCERTAIN SPECIES

[*Freesia curvifolia* Klatt in Th.Durand & H.Schinz, Conspectus florae africae 5: 187 (1894), invalid name without description and identity unknown.]

Freesia herbertii Klatt ex N.E.Br. in Journal of South African Botany 1: 14 (1935). Type: locality and collector unknown, cultivated specimen (B, holo.). Probably a species of sect. *Viridibractea* but otherwise unknown. Brown (1935) took the name from *Sparaxis herbertii,* a name without nomenclatural status that was listed in the synonymy of *F. xanthospila* by Klatt: 673 (1866), regarded as a synonym of *F. caryophyllacea*.

18. **Crocosmia**

Crocosmia *Planch.* in Flore des Serres et des Jardins de l'Europe 7: 161, t. 702 (1851). *Tritonia* sect. *Crocosmia* (Planch.) Baker: 163 (1877b), as *'Crocosma'*. Type: *C. aurea* (Pappe ex Hook.f.) Planch.

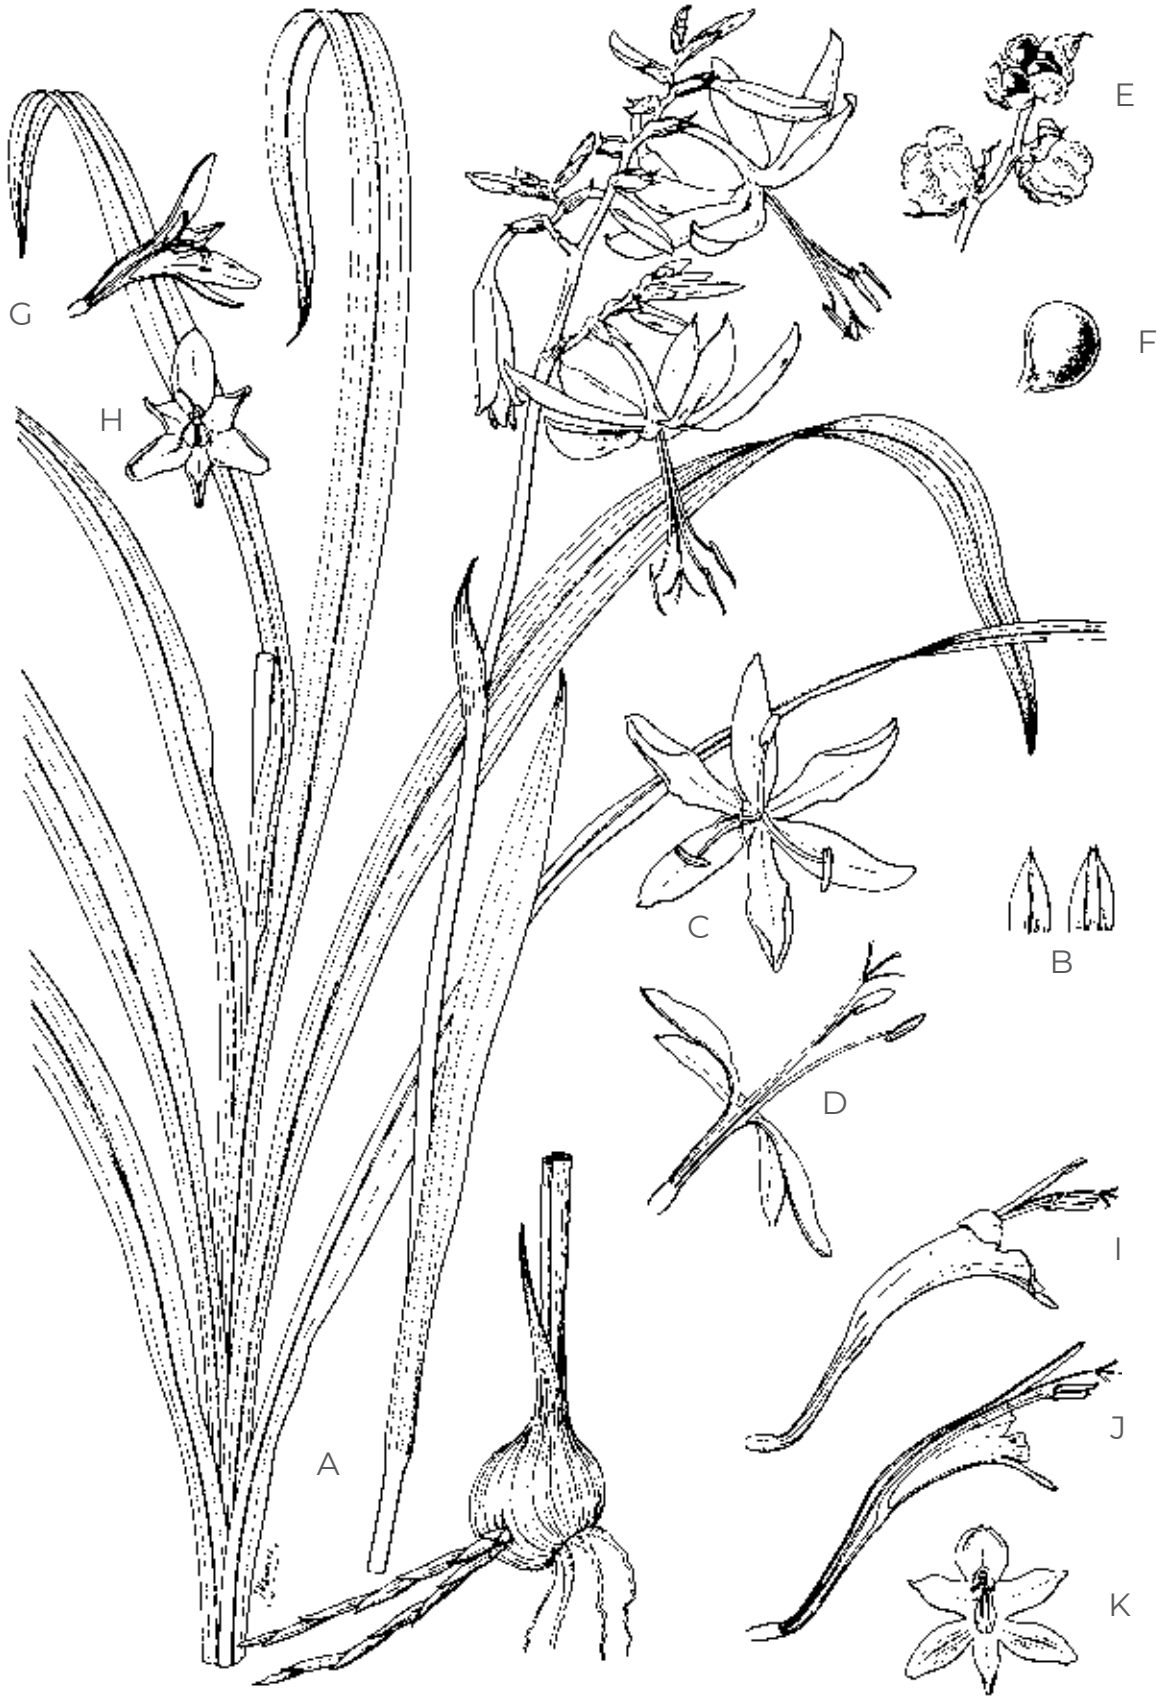
Curtonus N.E.Br.: 270 (1932). Type: *Curtonus paniculatus* (Klatt) N.E.Br. = *Crocosmia paniculata* (Klatt) Goldblatt

[*Crocanthus* Klotzsch ex Klatt in Peters: 516 (1864), invalid name without description.]

Revisionary accounts: De Vos: 474 (1984); Goldblatt et al.: 63 (2004).

From the Greek *krokos,* that is, crocus, the source of the culinary herb saffron, and *osme,* scent, thus 'smelling of saffron'; the grammatically more correct form *Crocosma* was often used in the 19th century, but *Crocosmia* is now firmly established. The flowers also produce an orange, saffron-coloured dye.

Deciduous geophytes. *Rootstock* a depressed-globose corm rooting from below, those of past seasons often not resorbed, producing thin rhizomes from base in some spp., tunics firm-papery, sometimes becoming fibrous with age. *Stem* smooth, rarely ridged, simple or branched, sometimes repeatedly and strongly flexuose. *Leaves* several, firm-textured, either plane with prominent main vein, or pleated with prominent vein at each fold, mostly basal and forming a 2-ranked fan, lanceolate to sword-shaped, cauline few and reduced; leaf margins without marginal vein, epidermal cells columnar with thickened walls. *Inflorescence* a spike, flowers either arranged in 2 ranks or lying on one side of axis, usually many and crowded, axes often strongly flexuose; bracts small, green, becoming dry at tips, firm-textured, inner ± as long as outer and notched apically. *Flowers* zygomorphic, funnel-shaped to tubular or actinomorphic and pendent, shades of yellow or orange to scarlet, lower tepals sometimes with contrasting markings or green, unscented, with nectar from septal nectaries; perianth tube cylindric or funnel-shaped, widening gradually and flared or tubular above; tepals equal or unequal, then dorsal largest. *Stamens* unilateral and arched, sometimes lying against dorsal tepal, or symmetrically disposed and central; filaments included to well exserted; anthers parallel, subversatile. *Ovary* ovoid, enclosed by bracts; style exserted, ascending or arching over stamens or pendent, branches filiform or expanded apically, notched at tips. *Capsules* depressed-globose, 3-lobed, leathery, often warty above, sometimes reddish to orange inside. *Seeds* globose or angular and prismatic, 2 to several per locule, brown or reddish to black, either shiny and smooth when fresh, coat at least sometimes fleshy and wrinkled on drying, or soft and spongy, the raphal vascular trace excluded. *Pollen grains* monosulcate-operculate, operculum 2-banded, exine perforate-scabrate. *Basic chromosome number x* = 11.



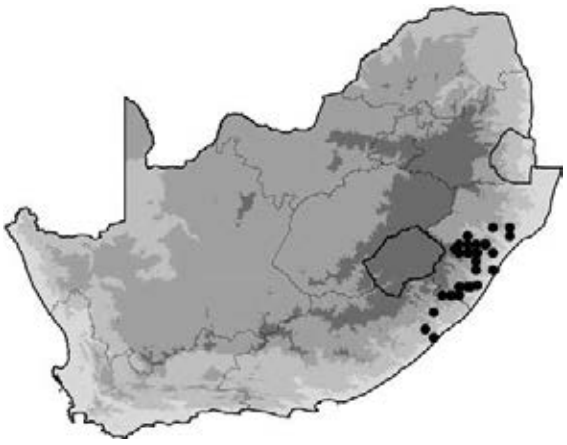
Species 8: confined to Africa south of the Sahara and Madagascar (1 sp.), mostly eastern southern Africa, including Lesotho, South Africa, Eswatini and Mozambique; 1 endemic to Namaqualand, Northern Cape. The disjunct distribution between the northwestern coast of southern Africa, an area of moderate to low winter rainfall, and summer-rainfall eastern southern Africa and tropical Africa, is remarkable.

Crocosmia closely resembles the larger southern and tropical African genus *Tritonia,* which has some 30 species often with orange flowers and short, dry floral bracts. The resemblance is misleading, however, and DNA sequence data from several chloroplast genes show that *Crocosmia* is most closely related to *Devia,* a local endemic with a single species of the Roggeveld Plateau near Sutherland in South Africa. These two genera together are related to *Freesia*. Similarities between *Crocosmia* and *Chasmanthe* in flower form and general habit, long thought to indicate close relationship, are likewise not supported. *Chasmanthe* is related to *Tritonia,* though not, according to available molecular data, its immediate ally. Similarities between *Crocosmia* and *Chasmanthe* are probably associated with their pollination systems. Flowers of three species are adapted for pollination by sunbirds (*Nectarinia*), and like many bird-pollinated flowers they have reddish to orange pigmentation, long stamens and an elongate, relatively wide perianth tube. Flowers of other species are adapted for pollination by butterflies or bees.

Some species and a range of hybrids of *Crocosmia*, sometimes referred to as *Montbretia*, are widely grown, and new cultivars are frequently introduced, both for garden display and for the cut flower trade.

Key to species

1a Leaves sword-shaped and plane, with a prominent central vein:
  2a Flowers actinomorphic and pendent, all tepals spreading from the base; filaments well exserted from the tube and directed downward. . . . . 2. *C. aurea*
  2b Flowers zygomorphic and secund or half-nodding, the dorsal tepal somewhat to much larger and the stamens unilateral; filaments largely exserted from the tube, suberect or horizontal:



CROCOSMIA. C. aurea: A, flowering plant; B, outer bract (left) and inner bract (right); C, flower front view; D, half-flower; E, dehiscing and undehisced capsules; F, seed. ***C. mathewsiana***: G, half-flower; H, flower front view. ***C. fucata***: I, flower side view; J, half-flower; K, flower front view.

3a Perianth tube elongate and widely cylindric in the upper half; the dorsal tepal extended more-or-less horizontally . . . . . 3. *C. fucata*
3b Perianth tube funnel- or salver-shaped, the upper part flaring and widest at the mouth:
4a Filaments 8–12 mm long; flowers funnel-shaped with the tepals directed forward (plants of southern Africa) . . . . . 1. *C. pottsii*
4b Filaments 15–40 mm long; flowers salver-shaped with the tepals spreading in the upper half (plants cultivated or weedy). . . . . *C. ×crocosmiiflora*
1b Leaves lanceolate and pleated, with several veins more-or-less equally prominent:
5a Perianth tube 15–25 mm long, upper part funnel-shaped and flaring; filaments well exserted from the flower, 13–35 mm long:
6a Flowering stem usually unbranched; spike arching outward to nearly horizontal; dorsal tepal 20–30 mm long; filaments 30–35 mm long . . . . . 4. *C. masoniorum*
6b Flowering stem somewhat to much branched; dorsal tepal 14–22 mm long; filaments 13–20 mm long:
7a Flowering stem branched repeatedly; spikes drooping; dorsal tepal about 14 mm long; filaments 13–15 mm long . . . . . 5. *C. mathewsiana*
7b Flowering stem with just a few branches; spikes arching outward; dorsal tepal 22 mm long; filaments 17–20 mm long . . . . . *C. ×crocosmoides*
5b Perianth tube 33–45 mm long, upper part wide and cylindric or weakly flaring; filaments 25–50 mm long:
8a Dorsal tepal 14–18 mm long; plants often growing in clumps; flowering stem divaricately branched and the branches often also branched; spike axes strongly flexuose . . . . . 6. *C. paniculata*
8b Dorsal tepal 20–30 mm long; plants usually solitary; flowering stem simple or few-branched; spike axes hardly flexuose or straight . . . . . 7. *C. pearsei*

1. **Crocosmia pottsii** *(McNab ex Baker) N.E.Br.* in Transactions of the Royal Society of South Africa 20: 264 (1932); Goldblatt et al.: 69 (2004). *Montbretia pottsii* McNab ex Baker: 424 (1877a). *Tritonia pottsii* (McNab ex Baker) Baker: sub t. 6722 (1883). Type: South Africa, [KwaZulu-Natal], without precise locality or collector, ex hort M. Leichtlin (in Baden-Baden, Germany) (K, holo.).

Plants 70–1 100 mm high. *Corm* subglobose, ± 25 mm diam., producing stolons from base; tunics papery, light brown, becoming fibrous with age. *Stem* with 2–several well-developed, suberect, ascending branches. *Leaves* several in basal fan, reaching ± to base of spike, blades sword-shaped, up to 15 mm wide, medium-textured, plane with prominent main vein, often with a pair of secondary veins ± midway between main vein and margins. *Spike* arching outward, with up to 30 flowers in 2 rows; bracts brown at tips, becoming entirely brown, 4–8 mm long, outer ± acute, inner forked. *Flowers* zygomorphic, nodding, funnel-shaped, scarlet, often paler outside, yellow in throat, unscented; perianth tube obliquely funnel-shaped, 14–20 mm long, narrow lower part ± 7 mm long, ± abruptly expanded; tepals directed forward, spreading in upper ½, dorsal largest, hooded over stamens, 11–15 mm long, lateral and lower tepals 8–12 mm long. *Filaments* unilateral, 10–12 mm long; anthers parallel, 6–7 mm long, yellow; pollen yellow. *Style* arching over stamens, dividing opposite anther tips or up to 2 mm beyond them, branches diverging, 2–3 mm long, notched at tips. *Capsules* ovoid to globose, broadly 3-lobed, 7–8 mm long. *Seeds* angular-prismatic, up to 8 per locule, 24 per capsule, light to midbrown, with a spongy coat. *Chromosome number* 2*n* = 22. *Flowering time*: mainly mid-December to January.

Distribution of ***Crocosmia pottsii***.

Distribution and ecology: occurring in eastern South Africa and extending from near Umtata in Eastern Cape through KwaZulu-Natal as far north as Melmoth; along streams and in light bush along the banks of rivers.

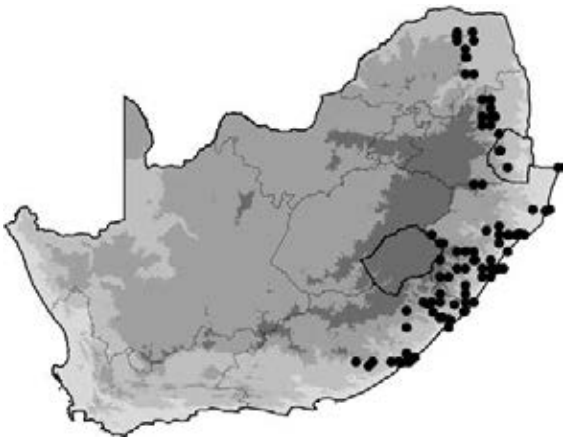
Diagnosis: *Crocosmia pottsii* is distinguished by the small, funnel-shaped flowers with a perianth tube 14–20 mm long, and a dorsal tepal up to 15 mm long. The leaves are sword-shaped and plane, with a prominent main vein.

Plants of *C. pottsii* grown at the nursery of Victor Lemoine in Nancy, France were crossed there with the related *C. aurea* in the late 1870s and the hybrid progeny first flowered in the summer of 1881. Initially called *'Montbretia crocosmaeflora', C. ×crocosmiiflora* was widespread in gardens by the 20th century and is now naturalised in many parts of the world.

2. **Crocosmia aurea** *(Pappe ex Hook.f.) Planch.* in Flore des Serres et des Jardins de l'Europe 7: 161 & t. 702 (1851); Goldblatt et al.: 69 (2004). *Tritonia aurea* Pappe ex J.D.Hook.: t. 4335 (1847). *Babiana aurea* (Pappe ex J.D.Hook) Klotzsch: 293 (1851). Type: South Africa, without precise locality, as 'George', *Pappe s.n.* (K, holo.; SAM, iso.).

Crocosmia aurea var. *maculata* Baker: 407, 565 and f. 80 (1888). *C. maculata* (Baker) N.E.Br.: 264 (1932). Type: South Africa, without locality, cultivated in Britain, September 1888, ex hort. J. O'Brien, Harrow, England; thought to have come from near Algoa Bay, Eastern Cape (K, holo.).

[*Crocanthus mossambicencis* Klotzsch ex Klatt in Peters: 516 (1864), invalid name only in synonymy.]



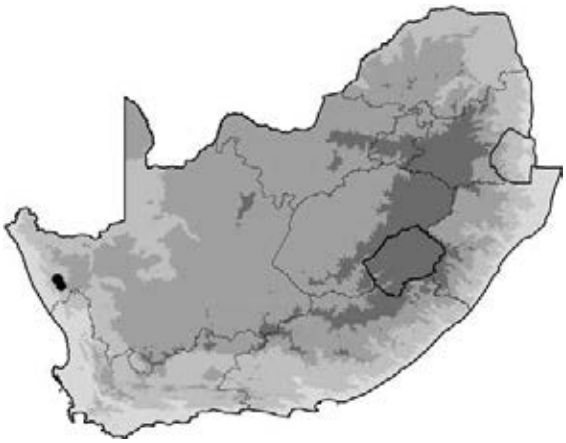
subsp. *auzea*

Plants 400–700 mm high. *Corm* subglobose, 15–20 mm diam., producing long, slender stolons up to 200 mm long terminating in new plants; tunics papery, soft-textured. *Stem* usually 2- to 4-branched. *Leaves* sword-shaped, reaching ± to base of spike, (10–)20–30 mm, wide, fairly soft-textured, plane with prominent main vein, margins not raised. *Spike* arching toward ground, fairly lax, up to 10-flowered; bracts straw-coloured to pale orange, becoming dry, 7–15 mm long. *Flowers* actinomorphic, pendent, salver-shaped with tube arching toward ground, orange, pale in throat, occasionally tepals marked darker orange to brown above base, unscented; perianth tube slender, widening slightly toward mouth, 18–27 mm long; tepals spreading or slightly recurved, 30–35(–40) × 8–12 mm. *Filaments* clasping style below, diverging above, usually white, 20–35 mm long; anthers 7–10 mm long, light orange; pollen orange or yellow. *Style* directed toward ground, mostly 30–45 mm long, dividing opposite anthers, branches diverging, 4–8 mm long. *Capsules* depressed-globose, 3-lobed, showing outline of seeds, orange inside. *Seeds* globose, up to 4 per locule, ± 4 mm diam., dark brown to blackish, coat initially slightly fleshy, wrinkled when dry. *Chromosome number* $2n = 22$. *Flowering time*: mainly February to April.

Distribution and ecology: extending from Eastern Cape to Limpopo in South Africa, also in Lesotho and Eswatini; in tropical Africa in Angola, Zambia, Uganda and Central African Republic; mostly in shade in forest margins.

Diagnosis: a most attractive plant, *Crocosmia aurea* is readily distinguished by the radially symmetric, pendent, orange flowers with narrow perianth tube and subequal tepals. The unusually long filaments are well-exserted from the perianth tube and hang downward. The leaf blades are plane, the ancestral condition in the genus.

Two subspecies are recognised, the widespread subsp. *aurea* and small-flowered subsp. *pauciflora* centred in Angola and western Zambia but extending to Congo and Uganda. A smaller plant, subsp. *pauciflora* often has unbranched stems, flowers with a perianth tube 10–15 mm long, tepals 15–18 mm long and anthers ± 3.5 mm long. The description above applies only to subsp. *aurea* in southern Africa.



Distribution of ***Crocosmia aurea*** subsp. ***aurea***.

The flowers are adapted for pollination by large swallowtail butterflies (*Papilio*) and perhaps other large butterflies. The large, shiny, almost black seeds contrast with the pale, often orange or even reddish inner surface of the capsules. Resembling a small blackberry, they are dispersed by birds.

3. **Crocosmia fucata** *(Herb.) M.P.de Vos* in Journal of South African Botany 50: 494 (1984); Goldblatt et al.: 77 (2004). *Tritonia fucata* Herb.: t. 35 (1838). *Antholyza fucata* (Herb.) Baker: 180 (1877b). *Chasmanthe fucata* (Herb.) N.E.Br.: 274 (1932). *Petamenes fucata* (Herb.) E.Phillips: 44 (1941). Type: South Africa, without precise locality or collector, illustration in Herbert: t. 35 (1838).

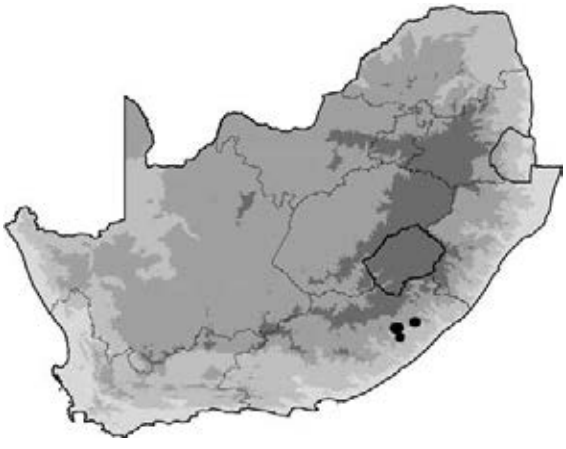
Plants 1.3–1.9 m high, forming large tufts of up to 10 plants. *Corm* globose, 30–50 mm diam., older corms persisting in series under current corm. *Stem* ± erect, bearing up to 3 cauline leaves, inclined more than 60° above basal leaves, 2- to 4-branched, flushed purplish. *Leaves* ± 10, lower 7 basal in 2-ranks, reaching to ± base of spike, sheaths forming a false stem below, blades lanceolate, 300–400 × (11–)20–26 mm, soft-textured, with prominent main vein, margins not raised. *Spike* 2-ranked, main axis up to 22-flowered, lateral spikes up to 16-flowered; bracts membranous below, dry and papery above, outer ± 8 mm long, acute, inner slightly longer to slightly shorter, 2-keeled, forked apically. *Flowers* orange-scarlet, lower 3 tepals usually reddish orange and with narrow red median streak, tube yellow beneath, unscented; perianth tube trumpet-shaped, curved upward at base and suberect, 40–50 mm long, cylindric and slender in lower 20–25 mm, gradually expanded and curved outward, upper ± 20 mm long, ± straight, horizontal, ± 6.5 × 4 mm wide; tepals lanceolate, dorsal

Distribution of ***Crocosmia fucata***.

largest, extended horizontally, ± 16 × 8 mm, upper laterals spreading, ± 12 × 5 mm, lower 3 tepals ± 12 × 5 mm, spreading. *Filaments* 32–34 mm long, exserted ± 10 mm from tube; anthers ± 7 mm long, dark red; pollen yellow. *Style* horizontal, adaxial to stamens, dividing opposite upper ⅓ of anthers, branches ± 2 mm long, minutely notched. *Capsules* subglobose to depressed-globose, 3-lobed, rugose to papillate, 8–9 × 10 mm. *Seeds* globose, 4–5 mm diam., glossy reddish brown, coat loose and wrinkled when dry. *Chromosome number* 2*n* = 22. *Flowering time*: late October and November.

Distribution and ecology: a local endemic of the northern Kamiesberg in Namaqualand, Northern Cape, South Africa, where it is known only from the slopes of Sneeukop and the valleys to the west; in locally moist habitats, thus along drainage lines on cool south-facing slopes and streambanks in light shade in gritty, granite-derived loam.

Diagnosis: *Crocosmia fucata* is a tall plant with fairly narrow, plane leaves, and a flowering stem usually with 2 to 4 branches diverging at a wide angle from the main axis and a strongly arching spike. The flowers are predominantly scarlet with the lower 3 tepals each with a narrow red median streak and the tube yellow in the underside and in the throat.



The long-tubed flowers are similar to those of species like *C. paniculata* and *C. pearsei,* with a narrow cylindric lower portion and a wider, also cylindric upper part but both of these species have strongly pleated leaves. In detail, the flowers can be seen to be somewhat different from those of *C. paniculata,* which has the outer whorl of tepals noticeably smaller than the inner three, and a slight but unmistakable pouch where the lower part of the perianth tube expands into the wider upper portion. The flowers are adapted for pollination by sunbirds.

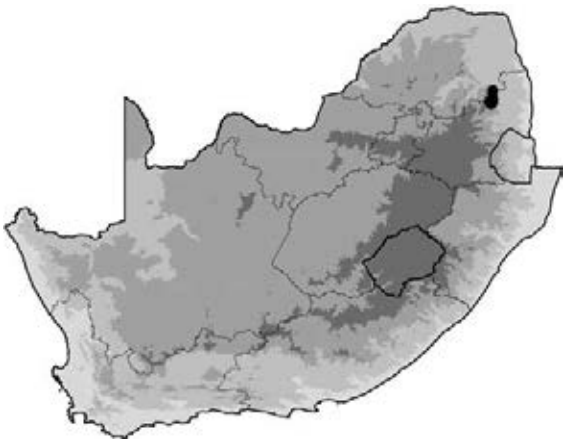
4. **Crocosmia masoniorum** *(L.Bolus) N.E.Br.* in Transactions of the Royal Society of South Africa 20: 264 (1932); De Vos: 484 (1984); Goldblatt et al.: 81 (2004). *Tritonia masoniorum* L.Bolus: 43 (1926) [as *masonorum*]. Type: South Africa, [Eastern Cape], Tembuland, Engcobo Mtn, 4 500 ft [1 400 m], 20 Jan. 1896, *H. Bolus 10303* (BOL, lecto., designated by De Vos (1984); K, isolecto.).

Plants mostly 500–800 mm high. *Corm* globose, persistent in series under main corm, ± 25 mm diam., with cormlets at base and on short rhizome-like stolons; tunics brown, fibrous, soon disintegrating. *Stem* suberect or inclined to drooping, sometimes with 1 or 2 short branches. *Leaves* several in a basal fan, ± lanceolate, tapering to narrow, petiole-like base, pleated, usually shorter than stem, 25–50 mm wide. *Spike* flexed at base and ± horizontal, with numerous flowers borne on upper side facing spike apex; bracts soft-textured, green, becoming dry from tips, outer 5–10 mm long, inner shorter than outer, forked apically. *Flowers* zygomorphic, bright orange (rarely yellow), unscented; perianth tube obliquely funnel-shaped, curving upward, 18–25 mm long, lower ½ narrow and cylindric, widening above to 10 mm at mouth; tepals spreading when fully open, dorsal largest, 20–30 mm long, suberect, others 18–26 mm long, curving outward, outer 5–7 mm wide, inner 7–12 mm wide. *Filaments* 30–35 mm long; anthers 7–9 mm long, reaching apex of dorsal tepal. *Style* exserted from tube, 42–45 mm long, dividing opposite anther tips, branches ± 3.5 mm long, bilobed to forked at tips. *Capsules* depressed-globose, 3-lobed, ± 10 × 9 mm. *Seeds* ± 4 mm diam., ovoid-angular, lightly wrinkled, dark brown, 2 or 3 per locule. *Chromosome number* 2*n* = 22. *Flowering time*: December to January.

Distribution and ecology: known from only a handful of sites in the mountains north of Engcobo and Umtata in Eastern Cape, South Africa, but probably more common than the records suggest; in rocky sandstone outcrops, often on cliffs, or on streambanks.

Diagnosis: perhaps the loveliest of all *Crocosmia* species, *C. masoniorum,* the swan crocosmia, is recognised by the

Distribution of ***Crocosmia masoniorum***.

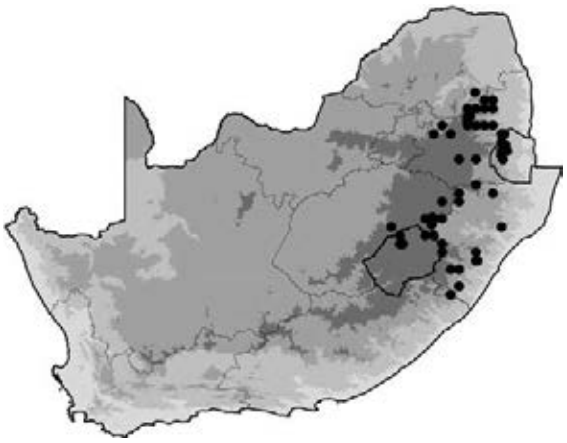


broad, pleated leaves, and the brilliant orange flowers borne on inclined stems with crowded spikes held horizontally. The flowers have a perianth tube 18–25 mm long and spreading, somewhat flaccid tepals, with the rather stiff, diverging stamens prominently displayed.

5. **Crocosmia mathewsiana** *(L.Bolus) Goldblatt ex M.P.de Vos* in Journal of South African Botany 50: 488 (1984); Goldblatt *et al.*: 85 (2004). *Tritonia mathewsiana* L.Bolus: 76 (1921). Type: South Africa, [Mpumalanga, as Transvaal], Pilgrim's Rest District, near Graskop, ex hort. Kirstenbosch, *Wood s.n.* (BOL, holo.).

Plants 1 500–2 000(–2 500) mm high. *Corm* globose, 30–50 mm diam., old corms persisting under current one; tunics of unbroken papery layers, becoming fibrous with age. *Stem* erect or inclined, 4- to 7-branched, lower branches sometimes 1- or 2-branched. *Leaves* several, in basal fan, reaching to ± base of spike, lanceolate, pleated, firm, up to 35 mm wide. *Spikes* drooping in bud, becoming horizontal as flowers open, 2-ranked, main spike 18- to 30-flowered, lateral spikes with fewer flowers; bracts firm-textured, purple below, apices dry and brown, outer apiculate or obscurely trifurcate, 5–7 mm long, inner usually slightly shorter than outer, shortly forked. *Flowers* zygomorphic, bright orange, facing to nodding or half-pendent, unscented; perianth tube trumpet-shaped, 16–20 mm long, slightly arched; tepals ± symmetrically disposed with dorsal slightly larger, inner tepals oval-elliptic, 15–16 × ± 9 mm, outer tepals narrowly deltoid, ± 14 × 5 mm. *Filaments* 13–15 mm long, exserted ± 3 mm; anthers parallel, contiguous, 6–7 mm long, yellow; pollen yellow. *Style* arching adaxial to filaments, 20–23 mm long, dividing just below anther bases, branches 5–10 mm long, laxly spreading, forked apically. *Capsules* depressed-globose and 3-lobed, 6–7 × 8 mm diam. *Seeds* angular-prismatic, dark red-brown, ± 3 mm long, mostly 1 or 2(3) per locule. *Flowering time*: late January to March.

Distribution: a narrow endemic of the lower escarpment of the northern Drakensberg between Graskop and Mariepskop in Mpumalanga, South Africa; in light shade along the edges of elfin forest, sometimes within evergreen forest, in well-drained sandy ground among boulders in Black Reef Quartzite.



Diagnosis: *Crocosmia mathewsiana* is readily identified by the combination of strongly pleated leaves, multibranched flowering stem, drooping, flexuose spikes, and relatively short-tubed, brilliant orange-scarlet flowers. We assume its relationships lie with the three other pleated-leaved species of the genus, and it is perhaps most closely allied to *C. paniculata,* which also has a multibranched flowering stem and strongly flexuose spikes. Vegetatively the two are almost indistinguishable, although the stem and branches of *C. mathewsiana* are more slender and strongly nodding in bud. The spikes are also less prominently flexuose and the flowers of the two species differ considerably, those of *C. paniculata* having an elongate perianth tube 33–40 mm long (vs. 20 mm), and are adapted for pollination by sunbirds in contrast to pollination by large bees in *C. mathewsiana.*

Distribution of ***Crocosmia mathewsiana***.

6. **Crocosmia paniculata** *(Klatt) Goldblatt* in Journal of South African Botany 37: 444 (1971); De Vos: 490 (1984); Goldblatt *et al.*: 88 (2004). *Antholyza paniculata* Klatt: 379 (1867). *Curtonus paniculatus* (Klatt) N.E.Br.: 270 (1932). Type: South Africa, without precise locality, as 'Natal and Zululand', circa 1864, *W.T. Gerrard 1530* (K, holo.; BOL, NH (as *W.T. Gerrard and M.J. McKen*), iso.).

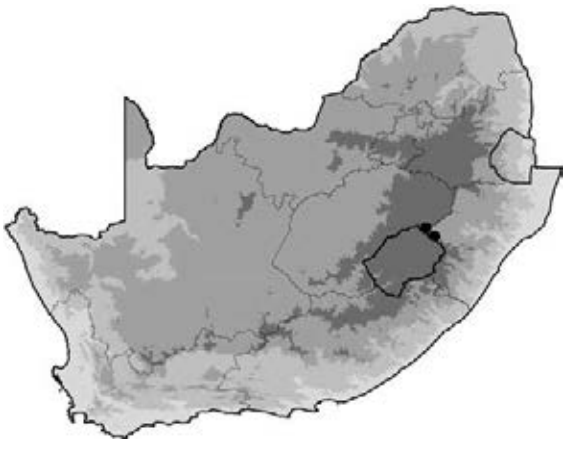
Plants mostly 1 200–1 500 mm high. *Corm* globose, persisting short chains, 30–35 mm diam.; tunics brown, papery or becoming fibrous with age. *Leaves* several in basal fan, reaching to base of spike, ± lanceolate, pleated, mostly 35–50 mm wide. *Stem* erect or somewhat inclined, with 3 to 6 diverging branches, these sometimes also branched. *Spike* arching outward, ± horizontal, with 18–25 flowers borne on upper side in 2 rows facing outward; bracts firm-textured, purplish green, becoming dry from tips, outer 6–10 mm long, sometimes obscurely 3-fid, inner 2-veined, forked at tip, slightly shorter than outer. *Flowers* zygomorphic, deep orange to orange-brown, sometimes shaded with reddish brown outside, yellowish in tube, lower 3 tepals marked in lower third with a dark red median streak decurrent on tube, ± trumpet-shaped, dorsal tepal extended horizontally, remaining tepals spreading, unscented; perianth tube narrow below, abruptly widened into a cylindric upper part, curved in middle, mostly 33–40(–50) mm long, upper part 15–25 mm long; tepals unequal, dorsal largest, inclined to ± horizontal, 14–18 × 8–10 mm, united with upper laterals for ± 5 mm, upper laterals narrowly deltoid, ± 10 × 5 mm, lower lateral tepals narrowly ovoid to oblong, 11–14 × 5–6 mm, lower median narrowly deltoid, directed downward, ± 10 × 4 mm. *Filaments* 25–40 mm long, exserted 12–18 mm from tube; anthers parallel, contiguous, ± 6 mm long, dull red or yellow, red on lines of dehiscence; pollen yellow. *Style* mostly 50–65 mm long, dividing opposite base to middle of anthers, branches 5–7 mm long, forked apically for < 1 mm, arching forward, shortly exceeding anther

Distribution of ***Crocosmia paniculata***.

apices. *Capsules* depressed-globose, 3-lobed, 5.5 × 8 mm, flushed dull red to purple, slightly rough to touch. *Seeds* globose or sides slightly flattened by pressure, lightly wrinkled, ovoid-angular, 1–3 per locule, ± 3 mm long, dark red-brown. *Chromosome number* 2*n* = 22. *Flowering time*: mainly December to mid-February.

Distribution and ecology: extending in eastern southern Africa from the northern highlands near Blyde River Canyon and Graskop in Mpumalanga, South Africa through Eswatini and interior Mpumalanga and north-eastern Free State into Lesotho and locally in the foothills of the KwaZulu-Natal Drakensberg (also recorded in the eastern highlands of Zimbabwe but probably introduced there); in moist places, along streams, drainage lines and in marshes.

Diagnosis: the tallest species in the genus, *Crocosmia paniculata* reaches well above 1 m sometimes almost 2 m tall and has broad, deeply pleated leaves and erect several-branched stems. The spikes arch outward, becoming almost horizontal so that the bright to dull orange or reddish flowers are displayed above the spike axes, forming two rows facing outward. The flowers have an elongate perianth tube 33–40 mm, narrowed in the lower portion, and large dorsal tepal 15–18 mm long, well exceeding the lateral and lowermost tepals, only 6–12 mm long. The flowers are pollinatwed by sunbirds.



Plants from the KwaZulu-Natal Midlands, for example, near Hilton, Howick and Nottingham Road, have dark red flowers with a shorter perianth tube, only 26–28 mm long. They are seldom seen in truly wild situations but are either cultivated in gardens or found near abandoned dwellings, road verges and ditches. The first record of this form appears to have been collected at Pietermaritzburg in 1909, and it it possibly an old cultivar no longer available in the trade, although similar plants appear to be wild in the Karkloof. It is fertile and appears to breed true from seed.

7. **Crocosmia pearsei** *Oberm.* in Bothalia 13: 450 (1981); De Vos: 493 (1984); Goldblatt et al.: 93 (2004). Type: South Africa, [KwaZulu-Natal], Drakensberg, summit of Mnweni Pass, 1 Apr. 1977, *R.O. Pearse 34* (PRE, holo.).

Plants mostly 800–1 000 mm high. *Corm* globose, persisting series forming chains, ± 25 mm diam.; tunics brown, fibrous. *Stem* suberect or inclined to horizontal, simple or with 1 or 2 short branches. *Leaves* few in basal fan, ± lanceolate with narrow, petiole-like base, pleated, shorter than stem, decreasing in size above, 35–70 mm wide. *Spike* arching outward, ± horizontal, with many flowers borne on upper side in 2 rows facing outward; bracts soft-textured, purplish green, becoming dry from tips, outer 8–10 mm long, inner bifid and shorter than outer. *Flowers* zygomorphic, deep orange, ± trumpet-shaped, dorsal tepal horizontal, remaining tepals arching outward and spreading in upper ½, unscented; perianth tube narrow below, wider and cylindric above, 40–45 mm long; tepals unequal, dorsal largest, 20–30 × 10–12 mm, remaining tepals 14–20 × 7–8 mm. *Filaments* 45–50 mm long; anthers 6–7 mm long. *Style* 50–60 mm long, dividing opposite upper ½ of anthers, ultimately branches exceeding anther tips, 3.5 mm long, bilobed to shallowly forked at tips. *Capsules* depressed-globose, 3-lobed, 6 × 8 mm, green, often flushed dull red, drying brown. *Seeds* ± globose, dull reddish brown. *Flowering time*: mainly December to early February.

Distribution and ecology: originally known from a few inaccessible sites in the high Drakensberg near Cathedral Peak in KwaZulu-Natal, South Africa, but now recorded as far north as Basuto Gate, north of The Sentinel in Free State, and almost certainly also in adjacent eastern Lesotho; in basalt outcrops and cliffs, mostly on cooler slopes at elevations above 2 000 m.

Diagnosis: *Crocosmia pearsei* is recognised by the slender stem seldom reaching 1 m in height, often unbranched or at most with 1 or 2 short branches, unlike the strongly branched *C. paniculata* with which it may be confused. The spikes in both species are strongly flexuose, with the flowers borne in two opposed rows,

Distribution of ***Crocosmia pearsei***.

facing away from one another. The flowers of *C. pearsei* are larger, some 60–70 mm long, with a perianth tube 40–45 mm long and a dorsal tepal ± 20 mm long, whereas typical *C. paniculata* has flowers with a perianth tube 33–40 mm long and a dorsal tepal 14–18 mm long. The two species occupy quite different habitats, *C. paniculata* being a plant of wet sites, growing in deep, rich soils at moderate elevations, unlike the high-altitude, well-drained basalt slopes and cliffs favoured by *C. pearsei*. The flowers of both species are pollinated by sunbirds.

FORMALLY NAMED HYBRIDS

Crocosmia ×crocosmiiflora *(Lemoine) N.E.Br.* [as *C. crocosmiflora*] in Transactions of the Royal Society of South Africa 20: 264 (1932); De Vos: 497 (1984); Goldblatt et al.: 100 (2004). *Montbretia ×crocosmiiflora* Lemoine, The Garden 18: 188 (21 August 1881) [as *M. crocosmiaeflora*]. *Tritonia ×crocosmiiflora* (Lemoine) Nicholson, Illustrated Dictionary of Gardening 4: 94 (1888) [as *T. crocosmiflora*]. Type: illustration in Morren, La Belgique Horticole 31: t. 14 (1881), neo., designated by Goldblatt et al.: 100 (2004).

Plants 350–600(–900) mm high. *Leaves* plane, narrowly lanceolate, ± ⅔ as long as stem, 8–15 mm wide. *Stem* laxly branched, branches ascending and arching outward. *Spike* lightly flexuose, mostly 6- to 10-flowered; bracts reddish with dry brown tips, 6–10 mm long. *Flowers* zygomorphic with radially symmetric perianth but unilateral stamens, bright orange, paler in throat, unscented; perianth tube funnel-shaped, slightly curved forward, 12 mm long, ± 5 mm wide at mouth; tepals subequal, mostly 15–22 mm long. *Filaments* 15–22 mm long; anthers 6–8 mm long, yellow. *Style* arching over stamens, dividing well beyond anther tips, branches ± 4 mm long, forked at tips. *Capsules* globose, showing outline of seeds. *Seeds* often aborted or ± globose, reddish brown.

Crocosmia ×crocosmiiflora is remarkably vigorous, disease resistant and easily propagated primary hybrid between *C. aurea* and *C. pottsii,* made in 1879 in Nancy, France. The flowers are perfectly intermediate between the two species. The taxon remains widely cultivated today because it is so easy to grow, is undemanding of care and soil, and thrives in a wide range of habitats and climate zones. It has been superseded in the nursery trade by larger-flowered or more colourful cultivars. Because of its vigour and rapid vegetative reproduction it persists in abandoned gardens and slowly spreads into meadows, roadsides and eventually into undisturbed vegetation. It is a serious weed in many parts of the world, including Hawaii, North and Central America, Madagascar, Australia, New Zealand, the Philippines and tropical Asia in general.

Crocosmia ×crocosmoides *(Leichtlin ex J.N.Gerard) Goldblatt* in Goldblatt et al., *Crocosmia* and *Chasmanthe*: 103 (2004). *Antholyza ×crocosmoides* Leichtlin ex J.N.Gerard, Garden and Forest 10: 315–316 (1897), as *'A. crocosmoides'*. Type: of cultivated origin, released commercially in The Netherlands by the Van Tubergen bulb company in 1895, and herbarium specimens sent to the Royal Botanic Gardens, Kew, in 1904 (K, neo.).

Crocosmia ×latifolia N.E.Br.: 264 (1932) [as *C. latifolia*]; De Vos: 483 (1984). Type: of cultivated origin, released commercially in the Netherlands by the Van Tubergen bulb company in 1895, and herbarium specimens sent to the Royal Botanic Gardens, Kew, in 1904 (K, syn.).

Plants 500–1 000 mm high. *Leaves* lanceolate, lightly pleated and with multiple major veins, ± ⅔ as long as stem, 20–40 mm wide. *Stem* laxly branched, branches ascending and arching outward. *Spike* flexuose, with many flowers; bracts reddish brown with dry brown tips, 10–15 mm long. *Flowers* zygomorphic, orange-red; perianth tube trumpet-shaped, slightly curved forward, 15–25 mm long, widening gradually from base to mouth, ± 5 mm wide at mouth; tepals unequal, dorsal largest, up to 22 mm long, lateral and lower tepals 12–18 mm long. *Filaments* 17–20 mm long; anthers 7–8 mm long, yellow. *Style* arching over stamens, dividing opposite anthers, branches ± 5 mm long, shortly forked. Capsules and seeds not produced.

Crocosmia ×crocosmoides is the result of a deliberate cross between *C. aurea* and *C. paniculata*, *and* was made available circa 1890. The plants have leaves only lightly pleated but with multiple veins toward the base, rather than a single prominent main vein, which indicates one parent species with pleated leaves and the other with plane leaves. Brown (1932) described it as *C. latifolia,* evidently accepting the plant as a naturally occurring species, and unaware of the valid name *Antholyza ×crocosmoides* Leichtlin ex J.N.Gerard.

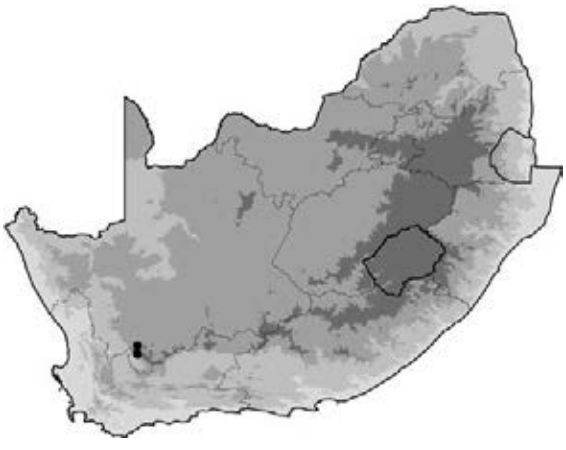
19. Devia

Devia *Goldblatt & J.C.Manning* in Annals of the Missouri Botanical Garden 77: 362 (1990); Goldblatt: 148–150 (1999). Type: *D. xeromorpha* Goldblatt & J.C.Manning

Named in honour of the South African botanist and specialist in the Iridaceae, M.P. de Vos.

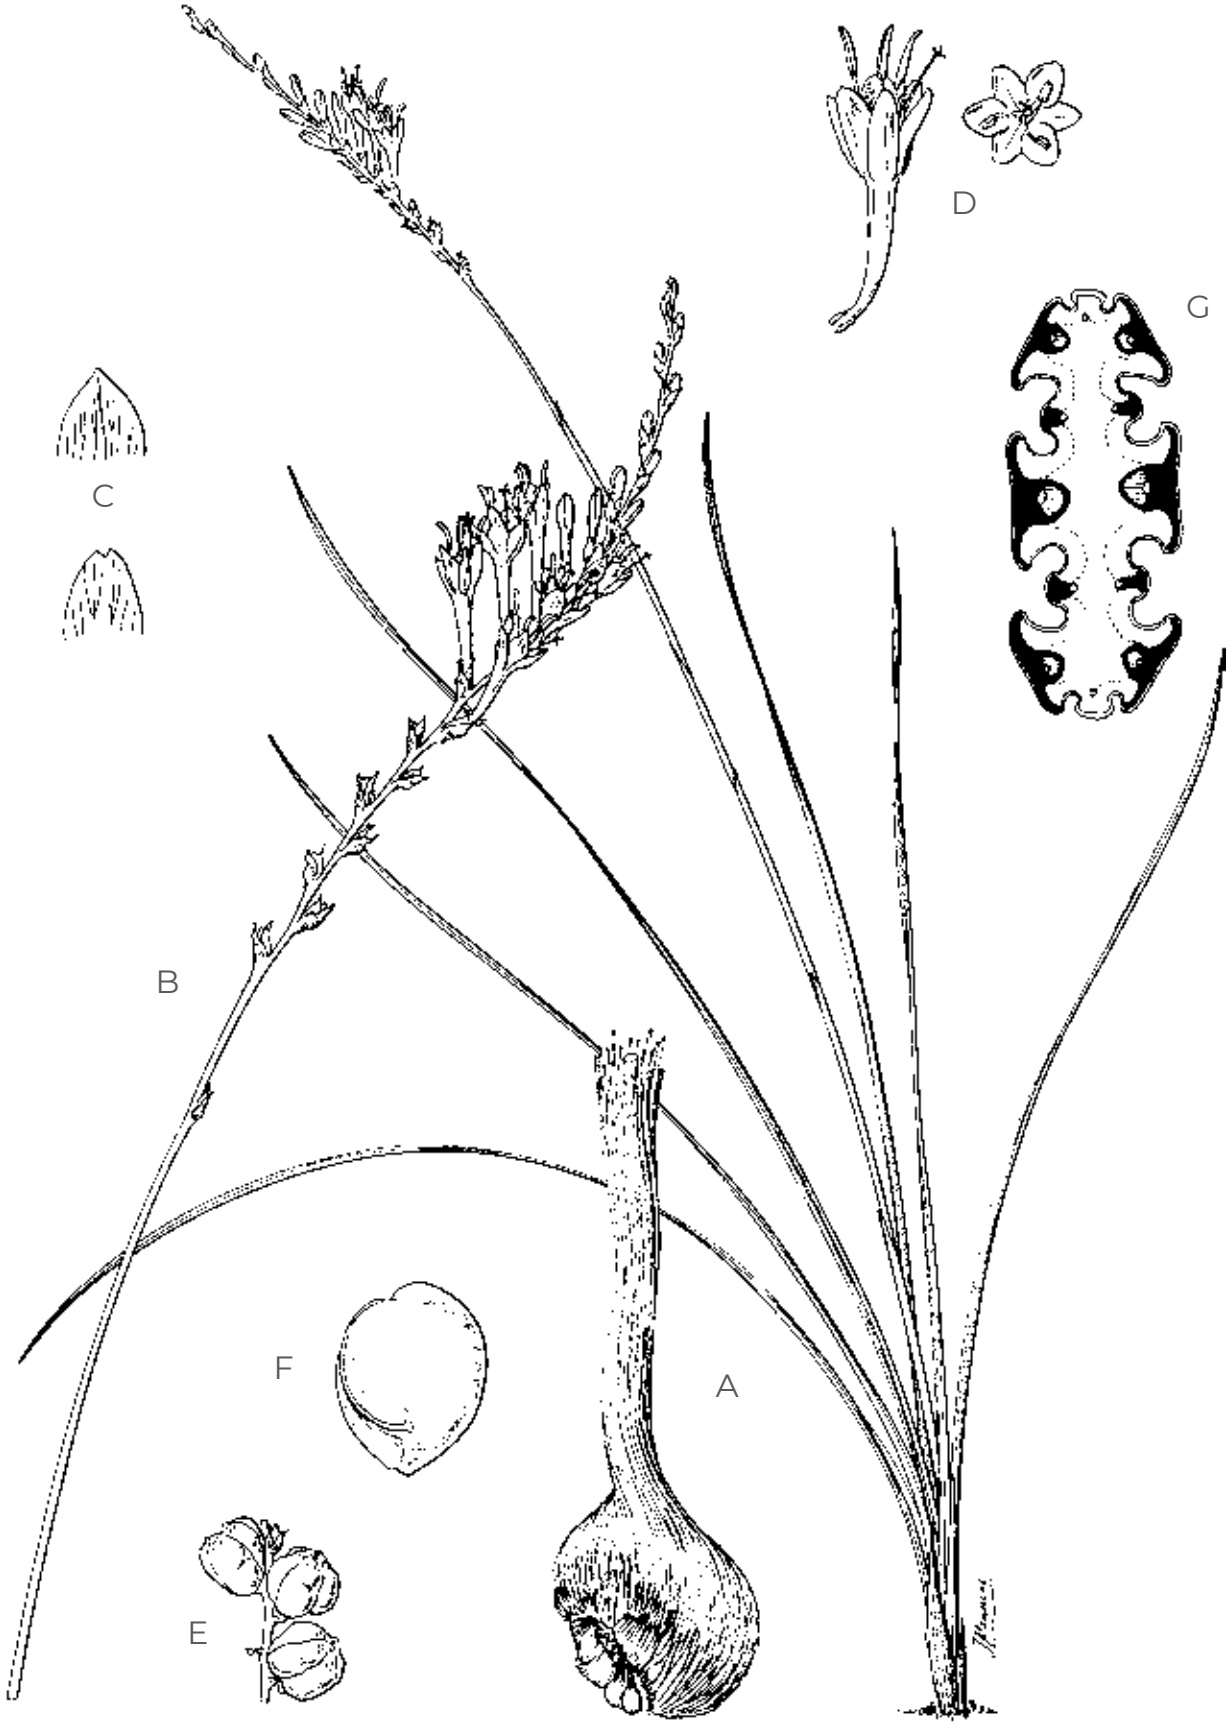
More-or-less evergreen geophyte. *Corm* depressed-globose, axial in origin, rooting from below; tunics of coarse fibres. *Stem* round in section, sheathed below by a thick collar of coarse fibres, usually branched. *Leaves* several, mostly basal, dry or becoming dry at flowering time, linear, oval in cross section, with main and second pair of veins heavily thickened, thus with two narrow longitudinal grooves on each surface, cauline leaves few and reduced; margins unthickened and with columnar epidermal cells. *Inflorescence* a many-flowered, secund spike; bracts leathery, dry at anthesis, inner about as long as outer, notched apically. *Flowers* actinomorphic, salver-shaped, pink, with nectar from septal nectaries; perianth tube narrowly funnel-shaped; tepals subequal, ascending. *Stamens* symmetrically disposed, rotated anticlockwise; filaments slender; anthers lying opposite inner tepals, splitting longitudinally. *Ovary* globose; style eccentric, branches short, notched apically. *Capsules* globose, cartilaginous, slightly warty above. *Seeds* globose, flattened at the chalazal end, hard and shiny, up to 2 per locule, smooth, surface cell outlines prominent; ovular vascular trace excluded. *Pollen grains* monosulcate-operculate, operculum 2-banded, exine perforate-scabrate. *Basic chromosome number x* = 10.

Species 1, only *D. xeromorpha*: a local endemic of the high rocky central Roggeveld Escarpment in the western Karoo, Northern Cape.



The strange-looking *Devia* has a tuft of grass-like leaves ± dry at flowering and a spike of small, dusty pink flowers with the stamens rotated anticlockwise. The genus is allied to the largely eastern southern African *Crocosmia* of subtribe Freesiinae and shares with this taxon smooth seeds with an excluded vascular trace. Both the internal leaf anatomy and capsule and seed characters are consistent with those of *Crocosmia*. Molecular sequences of several plastid DNA regions confirm the close relationship of *Devia* and *Crocosmia*, retrieving them as sister genera, together forming a clade allied to *Freesia* and *Xenoscapa*.

1. **Devia xeromorpha** *Goldblatt & J.C.Manning* in Annals of the Missouri Botanical Garden 77: 362 (1990) & :149 (1999).Type: South Africa, Northern Cape, Roggeveld Escarpment, Farm Vierfontein, *Snijman & Manning 1194* (NBG, holo.; K, MO, PRE, iso.).



Plants 500–700 mm high, forming dense clumps. *Corm* depressed-globose, 20–27 mm diam.; tunics of coarse fibres accumulating in a dense mass. *Stem* sheathed below by a thick collar of coarse fibres, simple or 1- to 3-branched. *Leaves* ± dry at flowering, linear, mostly 6, all ± basal, oval in cross section, main and second pair of veins heavily thickened, thus with two narrow longitudinal grooves on each surface, apex pungent, margins unthickened, edged by narrow grooves, cauline leaves few and reduced. *Spike* 18- to 26-flowered, secund in 2 ranks, branches with fewer flowers; bracts dry, 2.4–4.0 mm long. *Flowers* actinomorphic, salver-shaped with tepals ascending forming a narrow cup including filaments, dusty dull pink, unscented; perianth tube narrowly funnel-shaped, ± 9 mm long; tepals subequal, ovate-elliptic, ± 6 × 3.5 mm. *Stamens* rotated anticlockwise width of 1 tepal; filaments ± 9 mm long; anthers ± 4 mm long, yellow. *Style* ± 16 mm long, eccentric, dividing opposite middle to upper ⅓ of anthers, ± 0.5 mm long, notched apically. *Capsules* 5–6 mm long, warty above. *Seeds* globose, (0)1 or 2 per locule, smooth, surface cell outlines prominent. *Flowering time*: November and December.

Distribution and ecology: as for the genus, restricted to the central Roggeveld Escarpment in Northern Cape, South Africa; on rocky slopes at close to 2 100 m elevation, usually in dolerite outcrops in mountain renosterveld, flowering late in the season in November and December.

Diagnosis: *Devia xeromorpha* is recognised by the several, linear leaves dry at flowering time and a slender spike of small, relatively inconspicuous, dusty pink flowers. Plants are moderate in size, 500–700 mm high, and form dense tussocks resembling associated clump-forming grasses. The flowers are radially symmetric except that the style is twisted to lie off-centre

Distribution of ***Devia xeromorpha***.

Devia xeromorpha: A, flowering plant and corm; B, inflorescence; C, outer bract (top) and inner bract (bottom); D, flower side view (left) and front view (right); E, capsules; F, seed; G, tissue plan of leaf transection.

while the stamens are rotated anticlockwise, a feature unknown elsewhere in the family. The leaves are unusual in having a pair of narrow longitudinal grooves on each surface, and the margins have columnar epidermal cells with thickened walls. The subglobose capsules are lightly warty and each locule usually contains two rounded to lightly angled seeds which have the ovular vascular trace excluded. The inconspicuous flowers are visited by long-proboscid bee-flies (family Bombyliidae), which may be their legitimate pollinators.

Subtribe 4. **Hesperanthinae**

Hesperanthinae *Goldblatt* in Journal of South African Botany 37: 439 (1971). Type: *Hesperantha* Ker Gawl.

Corm with rounded or flat base (rarely a slender rhizome), tunics hard and woody or less often papery or fibrous; stem well developed or contracted and subterranean. *Leaf* margins with columnar epidermal cells and without subepidermal sclerenchyma. *Inflorescence* a spike, sometimes contracted. *Flowers* mostly actinomorphic, less often zygomorphic with stamens unilateral and decumbent; style branches undivided, sometimes extremely long; seed epidermal cell outlines prominent; ovular vasculature intact; $x = 11$ (10).

Genera 2, Africa, mainly southern Africa; 193 species: *Geissorhiza* 104; *Hesperantha* 89, 87 in southern Africa.

20. **Geissorhiza**

Geissorhiza *Ker Gawl.* in Curtis's Botanical Magazine 18: t. 672 (1803). Type: *G. obtusata* Soland. ex Ker Gawl. = *G. imbricata* subsp. *bicolor* (Thunb.) Goldblatt

Sphaerospora Klatt: 725 (1864), illegitimate homonym, not *Sphaerospora* Sweet ex Loudon (1841). Type: *S. exscapa* (Thunb.) Klatt (lecto., designated by Goldblatt: 303 (1985) = *Geissorhiza exscapa* (Thunb.) Goldblatt

Engysiphon G.J.Lewis: 19 (1941). Type: *E. schinzii* (Baker) G.J.Lewis (lecto., designated by Goldblatt: 303, 1985) = *Geissorhiza schinzii* (Baker) Goldblatt

[*Anomaza* Laws. ex Salisb.: 323 (1812), invalid name without description (also applied to *Freesia* sect. *Anomatheca*).]

[*Rochea* Salisb.: 322 (1812), invalid name without description.]

[*Weihea* Eckl.: 22 (1827), invalid name without description.]

Revisionary accounts: Goldblatt: 277–447 (1985); Goldblatt et al.: 123–152 (2009).

From the Greek *geisson*, tile, *rhizon*, root, for the tiled appearance of the overlapping, segmented corm tunics of subg. *Geissorhiza* (but not of subg. *Weihea*).

Deciduous perennial geophytes. *Corm* globose to ovoid, asymmetric or bell-shaped, usually with a basal ridge from which the roots emerge, axial in origin; tunics woody, or rarely membranous to fibrous, concentric or imbricate, then notched below. *Stem* aerial, simple or branched, terete in section, smooth or minutely hairy or scabrid. *Leaves* few to several, unifacial, usually with a definite main vein, blades plane to terete or I- or H-shaped in section with margins and or main vein raised and winged, occasionally hairy or sticky; margins with subepidermal sclerenchyma bundle and thin-walled epidermal cells. *Inflorescence* a spike, flowers usually spirally arranged, rarely solitary on branches; bracts green and soft-textured to membranous, inner smaller than outer and forked at apex. *Flowers* star-like or funnel–salver-shaped, sometimes with tube elongate, variously coloured, often blue to violet, also pink, yellow, cream-coloured, purple, red or bicoloured, mostly actinomorphic, zygomorphic in some species, faintly scented or unscented, with nectar from septal nectaries; perianth tube short to long, funnel-shaped or cylindric; tepals subequal, inner usually shorter than outer, cupped or spreading from base. *Stamens* symmetrically arranged or unilateral and arching downward (declinate); filaments filiform, equal or unequal with one shorter than other two, exserted, rarely included and inserted well inside tube; anthers erect or ascending, rarely included. *Style* filiform, eccentric or unilateral and held below stamens, usually exserted, the branches usually slender and recurved, rarely broadly expanded above. *Capsules* globose to oblong or cylindric, cartilaginous to bony. *Seeds* ± globose, flattened at chalazal end, sometimes lightly wrinkled, matte, surface cells domed or areolate. *Pollen grains* mostly monosulcate-operculate, usually with 2-banded operculum or with more complex apertures, exine perforate-scabrate (rarely grains with complex, multiple apertures and lacking operculum). *Basic chromosome number* $x = 13$.

Species ± 104: divided among two subgenera; restricted to the winter-rainfall zone of South Africa, extending from northern Namaqualand in Northern Cape through the western Karoo and southwestern Western Cape and east to Grahamstown in Eastern Cape.

A large genus, *Geissorhiza* shows relatively limited floral variation, most species having moderate-sized, radially symmetric flowers with a short perianth tube, a long style dividing opposite the anthers but eccentric in position, and slightly asymmetric corms with woody, rarely fibrous or papery tunics. The corm structure is

the basis for recognition of two subgenera: in subg. *Weihea* the tunics are concentric, fragmenting vertically into sections drawn into points at the top and bottom; whereas the tunics of subg. *Geissorhiza* are imbricate, the older tunics being displaced upward by new tunics and spitting into sections at the base, the corms then appearing to be covered with overlapping tiles.

Leaf morphology is surprisingly diverse. A plane surface is the ancestral condition, but the margins and main veins are often thickened rendering the leaf either oval or terete in section as the thickened areas form ridges occluding most of the surface. Such terete leaves with four longitudinal grooves characterise the *G. juncea* group of subg. *Weihea*. In several species the margins are raised into wing-like flanges held at right angles to the surface, this rendering the leaf I-shaped in section. In the most extreme examples, the marginal wings are nearly as wide and the leaf surface over which they arch, thus rendering the leaf H-shaped in section. Surprisingly, such leaves have evolved in both subgenera, notably in sect. *Engysiphon* of subg. *Weihea* and the *G. heterostyla* group of subg. *Geissorhiza*. Leaves or leaf sheaths are sticky in many species, resulting in the accumulation of sand grains, but neither the source of the sticky substance nor its adaptive value has been investigated.

In an unusual development for Iridaceae, the stamens are unequal in several species of subg. *Geissorhiza*, in which the upper filament is shorter than the lower two but the anthers are of equal length. The character is most frequent in sections *Ciliatae* and *Planifoliae* of the subgenus. *Geissorhiza melanthera* is unique in the genus in having anthers of unequal length and an unusual purple-black colour. Flowers are typically upright and radially symmetric (barring the eccentric style) but nodding, zygomorphic flowers with decumbent, unilateral stamens and style characterise several species of both subgenera, features poorly preserved in pressed herbarium specimens.

Molecular studies in *Geissorhiza* have so far been limited to single species comparisons with other genera of Iridaceae and confirm its immediate relationship with *Hesperantha*, an alliance first proposed on the basis of similar asymmetric corms, woody corm tunics, and shared basic chromosome number $x = 13$.

Key to subgenera

1a Plants with concentric corm tunics, old tunics completely enclosed by new ones and layers splitting vertically from base or apex, tunics usually brown and ± woody to papery or ± fibrous; stamens usually equal in length, rarely one filament shorter or longer ..... 1. subg. *Weihea*
1b Plants with overlapping corm tunics, old tunics pushed upward and fragmenting into tile-like segments from base, usually blackish and woody; stamens equal or unequal with one filament shorter than other two. ... 2. subg. *Geissorhiza*

Subg. *Weihea*

1a Stamens and style included in lower half of perianth tube:
2a Leaf margins winged, lower leaf sticky with adhering sand grains; perianth tube 8–10 mm long; tepals linear 18–28 × 2.5–3.0 mm ..... 52. *G. adriaanii*
2a Leaves plane or margins thickened, not sticky; perianth tube 10–16 mm long; tepals ovate, 12–15 ×6–7 mm:
3a Leaves plane, 3–5 mm wide; bracts 12–14 mm long; flowers white ..... 29. *G. esterhuyseniae*
3b Leaves with margins and central veins heavily thickened, 1.5–2.0 mm wide; bracts 7–11 mm long; flowers pink with dark markings at bases of tepals ..... 30. *G. cedarmontana*
1b Stamens and style, or at least style branches, exserted from perianth tube:
4a Foliage leaf solitary and stem with scale-like, membranous bract in upper half ..... 38. *G. unifolia*
4b Leaves 2 or more in addition to scale-like bracts in upper half of stem:
5a Leaf blades spirally twisted; style usually dividing opposite base of anthers; flowering stems each with a single (rarely 2) flower:
6a Flowers yellow; perianth tube ± 3 mm long ..... 25. *G. corrugata*
6b Flowers mauve; perianth tube 4–5 mm long ..... 26. *G. spiralis*
5b Leaf blades ± straight or falcate but not spirally twisted; style dividing opposite or beyond anthers; flowering stems with one to several flowers:
7a Corm tunics entirely of fibrous layers or softly membranous, either not accumulating or becoming fibrous with age:
8a Perianth tube 2–4 mm long; tepals 10–13 mm long:
9a Flower white to pale mauve-pink ..... 43. *G. umbrosa*
9b Flowers deep blue to mauve or violet ..... 44. *G. alticola*
8b Perianth tube 5–18 mm long; tepals 12–22 mm long:
10a Tepals 17–22 long; perianth tube 9–18 mm long, exserted from or included in bracts:
11a Perianth tube 10–18 mm long, well exserted from bracts; corm tunics of fine, netted fibres, leaves linear, 2-grooved on each surface with margins and central vein heavily thickened; plants of open rocky slopes ..... 46. *G. nubigena*
11b Perianth tube 9–13 mm long, not or barely exserted from bracts; corm tunics soft-textured, soft-papery, not becoming fibrous; leaves linear, ± plane with margins and central veins thickened; plants of waterfalls and wet, shaded rocks ..... 6. *G. uliginosa*
10b Tepals 12–18 mm long; perianth tube 5–8(–10) mm long, not or barely exserted from bracts:
12a Perianth pink; plants 60–120 mm high; lower leaves prostrate, 20–50 × 2.5–6.0 mm, ± plane with thickened margins; flowering January ..... 10. *G. altimontana*

GEISSORHIZA. G. silenoides: A, flowering plant; B, flower. ***G. rupicola***: C, flowering plant. ***G. imbricata***: D, capsule; E, seed.

12b Perianth mauve to violet; plants 100–300 mm high; leaves linear, 1–3 mm wide, 2-grooved on each surface with margins and central vein heavily thickened; flowering mostly late November and December:
13a Corm tunics finely fibrous; leaves 2–3 mm wide; flowers without pale throat; perianth tube 5–8 (–10) mm long. . . . . 45. *G. hesperanthoides*
13b Corm tunics membranous; leaves 1.0–1.5 mm wide; flowers with a pale throat; perianth tube 4–6 mm long . . . . . .47. *G. cataractarum*
7b Corm tunics firm-papery to woody in texture, often drawn into bristles above:
14a Leaves not plane, either strongly ridged, or margins and main vein heavily thickened, or blade terete with 5 narrow longitudinal grooves:
15a Flowers moderate in size to large, tepals (14–)17–40 mm long, mostly whitish or creamy white to beige or pink, usually darker pink on reverse; stamens unilateral and declinate; bracts acute (mostly sect. *Engysiphon*):
16a Leaves not sticky, terete with hairline longitudinal grooves; perianth tube 12–20 mm long; tepals 20–30 mm long; plants of exposed rock outcrops only seasonally moist. . . . . 5. *G. fourcadei*
16b Leaves sticky, sometimes only sheaths, blades always with the margins strongly thickened or raised but if 4-grooved then grooves clearly visible:
17a Leaf blades with margins raised and winged but central vein hardly thickened, thus appearing H-shaped in cross section, marginal wings often curving inward and blade thus often evidently terete:
18a Tepals linear or narrowly lanceolate, 3.0–4.5 mm wide, usually uniformly white. . . . . 55. *G. tenella*
18b Tepals oblong to obovate, 4.5–8.0 mm wide, usually beige to whitish flushed with pink or uniformly pink:
19a Stamens unequal in length, one anther longer than other two; anthers dark purple-black . . . . . 54. *G. melanthera*
19b Stamens equal in length; anthers yellow or pink, never purple-black:
20a Perianth tube 15–30 mm long; spike borne on well-developed stem, (1)2- to 4(5)-flowered . . . . . 53. *G. bonaspei*
20b Perianth tube 40–80 mm long; spike borne on a disproportionately short stem, sometimes spike virtually at ground level, (1–)3- to 9-flowered . . . . . 56. *G. exscapa*
17b Leaf blades terete to linear or falcate, with both central vein and margins thickened and winged but visibly with 2 narrow grooves on each surface:
21a Perianth tube ± 8 mm long, included in bracts and about a third as long as tepals . . . . . 49. *G. brevituba*
21b Perianth tube 20–50 mm long, reaching at least to bract apices or exceeding bracts and about as long as or longer than tepals:
22a Tepals 17–27 mm long, white or barely flushed with pink. . . . . 51. *G. longifolia*
22b Tepals 28–40 mm long, pink or cream-coloured, becoming flushed with pink with age:
23a Tepals slightly longer than perianth tube, 9–15 mm wide. . . . . .50. *G. schinzii*
23b Tepals shorter than perianth tube, 7–10 mm wide . . . . . 52. *G. confusa*
15b Flowers small to moderate in size, tepals mostly 6–25(–30) mm long, either white to yellow, or blue or deep pink (whitish flushed pink in two species); stamens either symmetrically arranged or unilateral and declinate; bracts obtuse:
24a Leaf blade terete with four hairline longitudinal grooves:
25a Perianth tube elongate, 40–80 mm long. . . . . 42. *G. stenosiphon*
25b Perianth tube short, 2–9 mm long:
26a Flowers small, white to creamy white or yellow, tepals cupped or outspread when fully open, 8–14 mm long . . . . . .39. *G. juncea*
26b Flowers moderate in size, pale to golden yellow, tepals often remaining cupped when fully open, 15–25 mm long:
27a Tepals golden-yellow and spreading when fully open; perianth tube 3–5 mm long . . . . . .40. *G. furva*
27b Tepals lemon-yellow and cupped when fully open; perianth tube 7–9 mm long. . . . . 41. *G. sufflava*
24b Leaf blade linear to falcate with two visible, narrow to relatively wide longitudinal grooves on each surface:
28a Flowers mauve, blue, purple or pink:
29a Perianth tube 7–8 mm long; spike 1- to 4-flowered. . . . . 31. *G. lithicola*
29b Perianth tube 3–6 mm long; spike 4- to 10-flowered:
30a Plants 150–350 mm tall; flowers pale mauve. . . . . 32. *G. purpurascens*
30b Plants 80–140 mm tall; flowers pale pink (darkening when dry) . . . . . 48. *G. helmei*
28b Flowers white to cream-coloured or yellow:
31a Stem minutely hairy in upper half. . . . . .37. *G. intermedia*
31b Stem smooth:
32a Flowers small, tepals 7–9 mm long. . . . . .36. *G. pappei*
32b Flower moderate in size, tepals 10–22 mm long:
33a Flowers whitish to cream-coloured, outer tepals usually flushed reddish outside; tepals 10–15 mm long and perianth tube 3–4 mm long . . . . . 35. *G. hispidula*
33b Flower pale or bright yellow, not normally flushed red on reverse; tepals 16–26 mm long and perianth tube 5–11 mm long:
34a Bracts not normally sticky; perianth tube 9–11 mm long; filaments 8–9 mm long; flowers pale yellow with dark centre . . . . . .34. *G. darlingensis*
34b Bracts sticky and usually with sand adhering; perianth tube 5–8 mm long; filaments 3–8 mm long; flowers bright or pale yellow, with or without dark tube . . . . . .33. *G. humilis*
14b Leaves plane or nearly so, margins and central veins only slightly raised:
35a Flowers zygomorphic with stamens and style unilateral and declinate:

36a Flowers purple or blue; tepals 12–18 mm long:
37a Leaves prostrate, soft-textured; flowers blue-mauve; perianth tube ± 3 mm long . . . . . 12. *G. monticola*
37b Leaves upright, firm-textured; flowers purple; perianth tube (5–)6–8 mm long . . . . . 27. *G. karooica*
36b Flowers pink with darker markings; tepals 22–32 mm long:
38a Stems and leaves trailing; leaf blades soft-textured; perianth tube 10–13 mm long . . . . . 4. *G. outeniquensis*
38b Stems and leaves erect; leaf blades firm-textured; perianth tube 8–10 mm long. . . . . 3. *G. roseoalba*
35b Flowers actinomorphic with stamens symmetrically arranged:
39a Leaves linear to narrowly sword-shaped or terete, mostly 1–2(–4) mm wide, never hairy even on margins; spike sometimes with only 1 or 2 flowers:
40a Perianth tube 6–8 mm long, usually exserted from bracts; flowers white to creamy white, rarely pale yellow:
41a Leaf blades plane however narrow; plants 40–80 mm high; stem rarely branched, never dichotomously . . . . . 15. *G. setacea*
41b Leaf blades terete; plants usually more than 120 mm high; stem usually dichotomously branched . . . . . 20. *G. geminata*
40b Perianth tube 2–5 mm long, included in bracts; flowers white, yellow or lilac:
42a Flowers clear yellow; corms pointed at base or bell-shaped with flat base:
43a Flowers cup-shaped; filaments 7–10 mm long; tepals 13–25 mm long; perianth tube ± 4 mm long . . . . . 18. *G. malmesburiensis*
43b Flowers rotate when fully open; filaments 2–4 mm long; tepals (6–)8–15(–18) mm long; perianth tube 2–3(–4) mm long:
44a Style branches 2–3 mm long, filiform, ciliolate with hairs shorter than width of style branch; tepals (6–)8–15(–18) mm long; anthers 3–6 mm long . . . . . 17. *G. ornithogaloides*
44b Style branches ± 1.5 mm long, linear, densely ciliate with hairs longer than width of style branch; tepals 6–7 mm long; anthers ± 1.5 mm long . . . . . 19. *G. platystigma*
42b Flowers white or lilac; corms pointed at base:
45a Flowers tiny, tepals 3–6 mm long; perianth tube 1.0–2.5 mm long . . . . . 14. *G. nana*
45b Flowers somewhat larger, tepals 6–12 mm long; perianth tube 2–5 mm long:
46a Flowers pale lilac or purple; perianth tube 2–3 mm long; leaves soft-textured, spreading or prostrate . . . . . 11. *G. delicatula*
46b Flowers white; perianth tube 2–5 mm long; leaves firm, ascending to erect, plane or terete:
47a Perianth tube 3–5 mm long; outer tepals rarely flushed red or purple outside; leaves ± sword-shaped, 2–9 mm wide. . . . . 13. *G. bracteata*
47b Perianth tube 2.0–2.5 mm long; outer tepals red outside; leaves up to 1 mm wide, linear-falcate, exceeding the spike. . . . . 16. *G. lapidosa*
39b Leaves sword-shaped, lanceolate or ovate, (2–)3–10 mm wide, smooth or hairy, sometimes only on margins; spike often with more than 2 flowers:
48a Basal leaves ± upright:
49a Perianth tube 8–10 mm long; flowers pale pink. . . . . 2. *G. elsiae*
49b Perianth tube 2–6 mm long; flowers white, pink, or blue to violet:
50a Plants branching mainly at base; flowering stems mostly 1- or 2(3)-flowered; flowers white, sometimes flushed red on reverse. . . . . 13. *G. bracteata*
50b Plants branching above ground level, or unbranched; flowering stems usually with at least 3 flowers and as many as 7:
51a Flowers blue; leaf sheaths and sometimes proximal parts of blades and margins minutely hairy to pubescent . . . . . 28. *G. pusilla*
51b Flowers never blue; leaves smooth entirely or minutely hairy on margins:
52a Leaves ½–⅔ as long as spike; flowers white or violet; tepals mostly 8–11 mm long, sometimes longer . . . . . 1. *G. inconspicua*
52b Leaves less than a third as long as spike; flowers mauve, pink or yellow to orange; tepals 13–17 mm long:
53a Flowers deep yellow to orange, dark brown-maroon in centre . . . . . 8. *G. tricolor*
53b Flowers pink or mauve, without dark centre:
54a Perianth tube 4–5 mm long; style branches ± 3 mm long . . . . . 7. *G. foliosa*
54b Perianth tube 2–3 mm long; style branches 4–5 mm long . . . . . 9. *G. nigromontana*
48b Basal leaves prostrate or inclined toward ground:
55a Perianth tube 10–30 mm long, as long as or longer than tepals; leaves usually broadly ovate and minutely velvety along margins. . . . . 24. *G. ovata*
55b Perianth tube 1.5–8.0 mm long; leaves narrowly ovate to lanceolate, usually hairless:
56a Leaves firm-textured; cormlets never produced in aerial leaf axils:
57a Perianth tube 3–4 mm long; flowers creamy white to pale yellow; spike mostly 3- to 6-flowered . . . . . 23. *G. parva*
57b Perianth tube 2.5–3.0 mm long; flowers white; spike 1- or 2-flowered. . . . . 13. *G. bracteata*
56b Leaves soft-textured, often flaccid; cormlets borne in aerial leaf axils:
58a Flowers solitary on each flowering stem, lilac or blue. . . . . 11. *G. delicatula*
58b Flowers usually more than one per flowering stem, white to pale yellow:
59a Stem either without or with only one cauline leaf; flowers fertile, capsules developing rapidly after flowering. . . . . 21. *G. ovalifolia*
59b Stem bearing 2 or more cauline leaves; flowers sterile, and cormlets produced in bract axils in place of capsules after flowering . . . . . 22. *G. bolusii*

Subg. *Geissorhiza*

1a Stem minutely hairy, puberulous or pilose, sometimes only in lower part (hand lens usually needed):
2a Perianth tube (5–)8–25 mm long:
3a Flowers pink; perianth tube 15–17 mm long; one filament shorter than other two . . . . . .78. *G. silenoides*
3b Flowers blue to violet; filaments equal:
4a Perianth tube 18–25 mm long; filaments 8–10 mm long. . . . . 87. *G. kamiesmontana*
4a Perianth tube 5–11 mm long; filaments 5–6 mm long:
5a Tepals 14–18 × 3–6 mm; anthers 5–7 mm long. . . . . .85. *G. namaquensis*
5b Tepals (6–)8–10 × 1.5–2.0 mm; anthers 2–3 mm long . . . . . 86. *G. namaquamontana*
2b Perianth tube < 4 mm long:
6a Leaves ± plane with margins and central vein slightly to moderately thickened, but not obviously winged; margins and central vein smooth or minutely ciliate:
7a Perianth predominantly purple, pale in throat; short filament at least 4 mm shorter than long filaments; tepals 18–23 mm long. . . . . 81. *G. inaequalis*
7b Perianth predominantly blue to violet or white with pale throat OR purple with dark purple throat; short filament no more than 2 mm shorter than long filaments; tepals 7–20 mm long:
8a Flowers radially symmetric except for eccentric style; tepals 7–11 mm long; flowers violet to pale blue, purple or predominantly white:
9a Tepals blue with white throat or partly to entirely white; tepals mostly 11–14 × 4–6 mm; main spike mostly with 3–7 flowers; anthers 3–5 mm long . . . . . .79. *G. aspera*
9b Tepals white, sometimes flushed dull purple outside and tepal tips light violet, 7–10 × 3.5–4.0 mm; main spike with 1–4 flowers; anthers 2–3 mm long. . . . . 80. *G. demissa*
8b Flowers zygomorphic with unilateral stamens and style; tepals 14–20 mm long; flowers predominantly violet with pale throat or pale centre edged in dark pigment:
10a Flowers with large pale, translucent centre edged with dark violet or red; filaments curved and slightly thickened in middle; spike with 1 or 2(–5) flowers; pollen usually red-brown (or white) . . . . . 83. *G. monanthos*
10b Flowers violet with pale throat; filaments straight and filiform throughout; spike with 2–5 flowers; pollen pale mauve or white. . . . . 82. *G. lewisiae*
6b Leaves with raised and winged margins, wings held ± at right angles to blade or arching inward; wing edges smooth or ciliate to long-hairy:
11a Flowering stem with a short, membranous, scale-like bract in upper third sometimes subtending a branch:
12a Style always short, dividing below level of anthers; flowers glossy pink to purple with dark centre; filaments, style and style branches dark purple . . . . . .92. *G. cantharophila*
12b Style usually at least reaching to middle of anthers (occasional short-styled plants may occur in some populations); flowers blue to violet, mauve or white with pale centre, often edged with darker colour, style and style branches white to pale blue or mauve:
13a Leaf margins raised into broad wings, blade thus H-shaped in cross section; tepals 8–9 mm long; anthers ± 2.5 mm long . . . . . 90. *G. scopulosa* (see also 105. *G. sp. 1.*)
13b Leaf margins raised into narrow horizontal or ascending wings, blade ± I-shaped (not H-shaped) in cross section; tepals at least 12 mm long; anthers at least 4 mm long:
14a Long filaments 10–12 mm long; basal leaves prostrate . . . . . .93. *G. reclinata*
14b Long filaments 4–6 mm long; basal leaves erect to falcate . . . . . 91. *G. heterostyla*
11b Flowering stem without a scale-like bract in upper third:
15a Plants rarely higher than 80 mm; tepals 7–8 × 2–3 mm . . . . . 99. *G. saxicola*
15b Plants (120–)160–300 mm high; tepals 12–14 × 4–5 mm:
16a Flowers white to pale pink or pale mauve; stamens unilateral and horizontal to drooping; long filaments 6–7 mm long . . . . . 103. *G. nutans*
16b Flowers usually blue (or white); stamens symmetrically disposed; long filaments 3–4 mm long . . . .94. *G. arenicola*
17a Leaves plane with margins and central vein slightly thickened but not winged; flowers zygomorphic with stamens and style unilateral and declinate; anthers and pollen brown:
18a Flowers white with reddish to brown, patterned centre . . . . . 84. *G. tulbaghensis*
18b Flowers glossy dark blue-violet, pale in throat . . . . . 95. *G. splendidissima*
17b Leaves with margins significantly thickened and/or raised into horizontal or ascending wings; flowers radially symmetric except for eccentric style; anthers and pollen not brown, usually white to yellow:
19a Leaf margins and central vein heavily thickened rendering blades 2-grooved on each surface; margins smooth not ciliate . . . . . 75. *G. ciliatula*
19b Leaf margin edges raised into horizontal or ascending wings; marginal wing edges minutely ciliate:
20a Flowers small; tepals 6–8 mm long; anthers ± 2.5 mm long . . . . . 100. *G. erubescens*
20b Flowers larger; tepals 12–28 mm long; anthers 6–8 mm long
21a Flowers white with yellow-green throat; filaments ± 7 mm long; style dividing opposite or shortly beyond anther tips. . . . . 101. *G. leipoldtii*
21b Flowers mauve-pink with dark centre; filaments 4–5 mm long; style dividing opposite middle of anthers . . . . . 102. *G. ixioides*
1b Stem smooth:
22a Stamens unequal, one at least 0.5 mm and usually more than 2 mm shorter than others; leaf margins lightly to moderately thickened but never raised into wings extended at right angles to surface:
23a Flowers small, with tepals 7–11 mm long:

24a Stem inclined to trailing, usually 1-branched, occasionally 2-branched; flowers white . . . . . 74. *G. bryicola*
24b Stem erect, simple or usually 2- or 3-branched; flowers white or blue to violet:
25a Flowers blue to violet . . . . . 73. *G. ramosa*
25b Flowers white, outer tepals often flushed blue to purple outside . . . . . 65. *G. minuta*
23b Flowers moderate in size to large, tepals (12–)14–30 mm long:
26a Flowers white or creamy yellow with or without dark centre:
27a Flowers pale yellow with blackish centre; tepals 22–30 mm long; stamens unilateral and declinate, longer filaments 15–20 mm long . . . . . 61. *G. barkerae*
27b Flowers uniformly creamy yellow; tepals 18–28 mm long; stamens symmetrically arranged, longer filaments 7–9 mm long . . . . . 62. *G. louisabolusiae*
26b Flowers white, blue, purple, mauve, or pink:
28a Perianth tube short, up to 3 mm long
29a Corm tunics ± soft-papery in texture; tepals 15–18 mm long; plants of the Cape Peninsula . . . . . 72. *G. tabularis*
29b Corm tunics hard and woody; tepals 10–18(–22) mm long; plants of the South Coast, Worcester to Port Elizabeth . . . . . 91. *G. heterostyla*
28b Perianth tube 4–25 mm long:
30a Leaf blades plane . . . . . 76. *G. pseudinaequalis*
30b Leaf blades with margins and central vein moderately to heavily thickened:
31a Perianth tube 4–6 mm long. . . . . 69. *G. burchellii*
31b Perianth tube 10–25 mm long:
32a Tepals 12–15 mm long. . . . . 77. *G. rupicola*
32b Tepals 22–30 mm long:
33a Perianth tube 10–18 mm long; anthers and pollen yellow . . . . . 70. *G. grandiflora*
33b Perianth tube 22–25 mm long; anthers purple and pollen ± pink. . . . . 71. *G. callista*
22b Stamens equal in length; leaf margins either only lightly to moderately thickened or raised into wings held at right angles to surface and minutely hairy to hispid along edges:
34a Leaf blades minutely to velvety hairy on veins and margins; bracts ± dry and rust distally at anthesis:
35a Leaf blades with the margins and central vein raised and winged, minutely hairy to pubescent on edges; stem without scale-like bract in upper half:
36a Plants small, 70–120(–140) mm high; tepals ± 8 × 3–4 mm . . . . . 98. *G. exilis*
36b Plants mostly 150–250 mm high; tepals (8–)10–24 × 6–10 mm:
37a Flowers white to cream-coloured; tepals (8–)10–18 × 6–7 mm; anthers 4–6 mm long. . . . . 96. *G. inflexa*
37b Flowers white to pink, red or purple; tepals 18–24 × 8–10 mm; anthers 7–8 mm long . . . . . 97. *G. erosa*
35b Leaf blades ± ribbed and velvety; stem with 1 or 2 scale-like bracts in upper half:
38a Flowers ± white, outer tepals flushed reddish or mauve on reverse or uniformly blue; tepals ± 10 mm long . . . . . 88. *G. divaricata*
38b Flowers blue to mauve; tepals 12–17 mm long . . . . . 89. *G. subrigida*
34b Leaf blades not visibly hairy or minutely hairy; bracts remaining green or dry and pale distally:
39a Leaf blades of lower 2 leaves linear or terete, margins and central veins moderately to heavily thickened, grooves between raised parts sometimes very narrow:
40a Foliage leaves 2, upper one sheathing lower half of stem and with short free blade; stem bearing short, membranous, scale-like bract in upper half . . . . . 58. *G. scillaris*
40b Foliage leaves 3, sometimes the lowermost lost by flowering time; stem without a scale-like bract in upper half:
41a Leaf blades terete with 4 hair-like longitudinal grooves. . . . . 63. *G. brehmii*
41b Leaf blades with central vein and margins separated by wide grooves. . . . . 59. *G. similis*
39b Leaf blades of lower 2 leaves with two or more ribs (including central vein):
42a Flowers white to pale yellow, sometimes with dark central mark:
43a Tepals mostly 11–25 mm long and perianth tube mostly 4–8 mm long; tepals often flushed reddish on reverse, often without dark centre . . . . . 59. *G. imbricata*
43b Tepals mostly 10–16 mm long and perianth tube 2–4 mm long; tepals seldom flushed red on reverse and with dark centre:
44a Spikes mostly 2- or 3-flowered, rarely more; perianth cream-coloured to yellow with a dark brown to purplish centre . . . . . 60. *G. purpureolutea*
44b Spikes mostly at least 5-flowered; perianth uniformly white or cream-coloured . . . . . 64. *G. sulphurascens*
42b Flowers blue-violet with red centre:
45a Stamens and style unilateral and declinate; style branches linear-filiform; flower with red centre edged in white . . . . . 68. *G. radians*
45b Stamens and style symmetrically arranged; style branches ovate-spathulate, about 2–3 × 2 mm; flower with red centre not edged in white:
46a Perianth tube 6–9 mm long; anthers erect, borne below style branches . . . . . 66. *G. eurystigma*
46b Perianth tube up to 2.5 mm long; anthers arching inward, borne above style branches . . . . . 67. *G. mathewsii*

Subg. 1. **Weihea**

Subg. **Weihea** *(Eckl. ex Baker) Goldblatt* in Annals of the Missouri Botanical Garden 72: 309 (1985). *Geissorhiza* sect. *Weihea Eckl. ex* Baker: 95 (1877); Foster: 39 (1941). Type: *G. ovata* (Burm.f.) Aschers. & Graebn. (as *G. excisa* (Thunb.) Ker Gawl.), lecto., effectively designated by Foster: 39 (1941).

[*Weihea* Eckl.: 309 (1827), invalid name without description.]

Plants with corm tunics concentric, ± woody, splitting vertically into ± elliptic sections, or ± papery to fibrous. *Leaves* lanceolate to sword-shaped, linear, blades plane or with margins and main vein thickened, then sometimes terete with narrow longitudinal grooves, smooth rarely ciliate-pubescent. *Stem* smooth, rarely ciliate. *Spike* with bracts green, sometimes becoming dry above, rarely rusty brown. *Flowers* actinomorphic, rotate to salver-shaped zygomorphic and declinate; perianth tube ± as long as bracts, very short, or extremely long (sect. *Engysiphon*), stamens equal, rarely included in the tube.

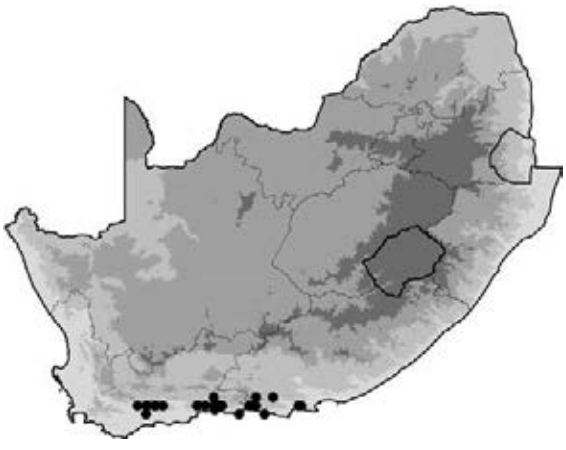
Species 57.

Sect. 1. **Weihea** *Eckl. ex Baker* in Journal of the Linnean Society, Botany 16: 95 (1877). Type: *Geissorhiza ovata* (Burm.f.) Aschers. & Graebn.

Geissorhiza subsect. *Foliosae* R.C.Foster: 55 (1941). Type: *G. foliosa* Klatt

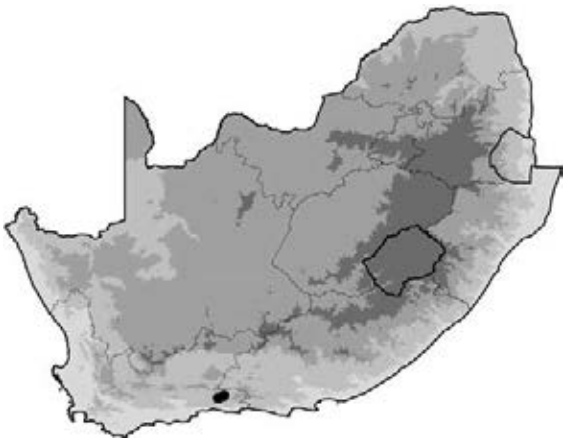
Corm tunics woody to soft in texture; leaves lanceolate to sword-shaped or linear, blades plane, smooth, occasionally terete and 4-grooved; stem smooth; spike 1–several-flowered, bracts green, sometimes becoming dry above; flowers rotate to salver-shaped, radially symmetric or zygomorphic, tube ± as long as bracts or up to twice as long; when zygomorphic stamens and style declinate.

Species 24: Core Cape Floristic Region, South Africa.



1. **Geissorhiza inconspicua** *Baker* in Bulletin of Miscellaneous Information, Kew 1906: 26 (1906); Goldblatt: 309 (1985). Type: South Africa, [Western Cape], George, Montagu Pass, *Penther 713* (K, holo.).

   Geissorhiza violacea Baker: 26 (1906). Type: South Africa, [Western Cape), Knysna, 'Blau Krantz' River, *Penther 677* (K, holo.).



Plants 100–180(–300) mm high. *Corm* globose, asymmetric with obliquely flattened side extending downward, 5–8 mm diam.; tunics concentric, dark brown, outer layers sometimes ± papery and soft, fragmenting irregularly into sections. *Stem* simple or more often 2- to 5-branched from base and upper nodes. *Leaves* 3 to 5, usually erect, lower 2 or 3 basal, largest, 2.5–6.0 mm wide, sword-shaped to linear, ± ½–⅔ as long as stem, upper leaves smaller, sometimes entirely sheathing, uppermost often bract-like. *Spike* (1–)3- to 7-flowered; bracts 6–8 mm long, ± membranous above, often reddish on margins, inner ± as long as outer. *Flowers* rotate, either blue to purple or white with outer tepals pink outside; perianth tube 4–5(–6) mm long, cylindric, reaching ± to apex of bracts; tepals obovate, 8–11(–15) × 5–6 mm wide. *Filaments* equal, 4–6(–8) mm long; anthers 3–4 mm long; pollen yellow. *Style* dividing opposite apex of anthers, branches ± 2 mm long. *Capsules* obovoid, 5–7 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: October to November at low altitudes, occasionally to February at highest altitudes.

Distribution and ecology: extending from the Langeberg near Swellendam in Western Cape, South Africa to Port Elizabeth in Eastern Cape; montane or on flats along the coast.

Diagnosis: *Geissorhiza inconspicua* can usually be distinguished by its 3 to 5 comparatively short leaves clustered at the base of the plant and typically well-branched stems with several-flowered spikes held well above the leaves. Flowers are either white or violet to purple. It is sometimes difficult to separate from the Langeberg species, *G. foliosa*, but this species has shorter and often relatively broad leaves in contrast to the longer, narrowly sword-shaped to linear leaves of *G. inconspicua*, and larger flowers with tepals 13–17 mm long and anthers 4–6 mm long vs. tepals mostly 8–11 mm long (rarely up to 15 mm) and anthers 3–4 mm long in *G. inconspicua.*

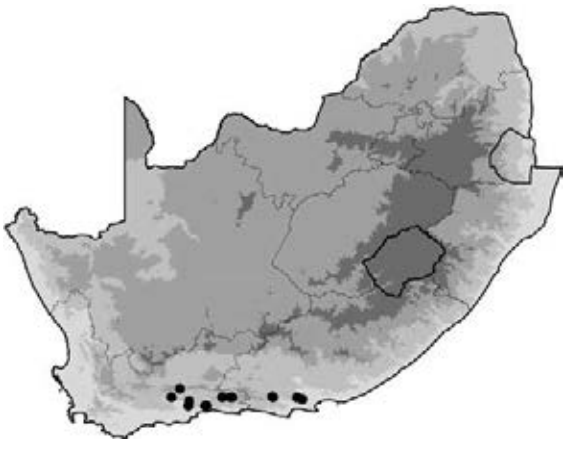
Distribution of ***Geissorhiza inconspicua***.

Distribution of ***Geissorhiza elsiae***.

2. **Geissorhiza elsiae** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 311 (1985). Type: South Africa, [Western Cape], Kammanassie Mtns, Mannetjiesberg, 4 000–5 000 ft [1 200–1 500 m], southern slopes, *Esterhuysen 6412* (BOL, holo.; BOL, K, PRE, iso.).

Plants 140–250 mm high. *Corm* globose with one side flattened below, 7–10 mm diam.; tunics concentric, dark brown. *Stem* ± erect, simple or branched from upper 1 or 2 nodes. *Leaves* (3)4 or 5, erect to falcate, at least lower 3 basal, (2–)3–6 mm wide, sword-shaped to ± linear, reaching base of spike or only ½–⅓ as long as stem, upper leaf cauline, smaller than basal, sometimes ± bract-like. *Spike* 2- to 4-flowered; bracts 12–14 mm long, soft-textured, becoming reddish distally and on veins, inner usually shorter than outer. *Flowers* ± salver-shaped, purple with darker markings in lower midline of tepals (± colourless when dry); perianth tube 6–10 mm long, cylindric, initially reaching to ± apex of bracts, later shortly exserted; tepals obovate, 15–20 × 7–8 mm. *Filaments* equal, 6–11 mm long; anthers 5–6 mm long; pollen yellow. *Style* dividing opposite apex of anthers, branches up to 3 mm long. *Capsules* 7–9 mm long, ovoid. *Flowering time*: late October to mid-November.

Distribution and ecology: a narrow endemic of the Kammanassie Mtns in the Little Karoo in Western Cape, South Africa; on south-facing slopes in cool damp sites.



Diagnosis: *Geissorhiza elsiae* is distinguished by its large, purple flowers with tepals 15–20 mm long, 1- to 4-flowered spike, and few-branched habit; branches, when present, are produced from the upper nodes rather than from near the base. It is probably most closely allied to the more widespread southern Cape species, *G. inconspicua* which has smaller flowers, usually violet or white in colour.

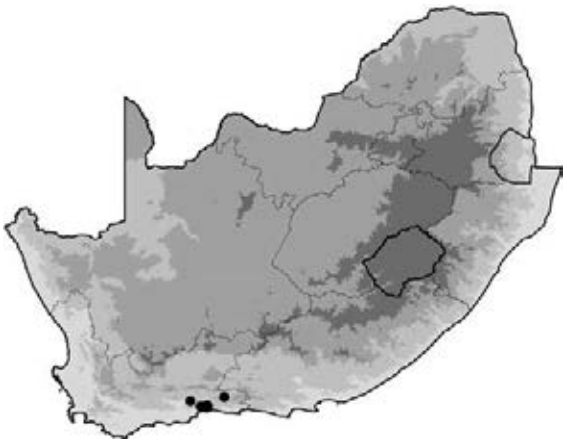
3. **Geissorhiza roseoalba** *(G.J.Lewis) Goldblatt* in Annals of the Missouri Botanical Garden 72: 312 (1985). *Acidanthera roseoalba* G.J.Lewis: 266 (1933). *Engysiphon roseoalbus* (G.J.Lewis) G.J.Lewis: 24 (1941). Type: South Africa, [Western Cape], Doorn River, George, *Fourcade 4744* (BOL, holo.; BOL, NBG, iso.).

Plants 150–200 mm high. *Corm* globose, ± asymmetric with an oblique flat side, 8–10 mm diam.; tunics concentric, dark brown, woody, fragmenting irregularly into sections. *Stem* simple or 1-branched from upper node. *Leaves* 3 to 5, erect to falcate, lower 2 or 3 basal, upper cauline and progressively smaller, sometimes uppermost bract-like, 3–6 mm wide, sword-shaped to ± linear, longest usually reaching to ± base of spike or shorter. *Spike* 1- to 3-flowered; bracts 14–18(–25) mm long, becoming membranous above, often reddish on margins, inner equal to or somewhat shorter than outer. *Flowers* zygomorphic, tepals held ± vertically, whitish inside with red markings near base of tepals, flushed reddish outside; perianth tube 8–10 mm long, cylindric, initially included in bracts, or becoming shortly exserted; tepals obovate to elliptic, 22–32 × 10–15 mm wide. *Filaments* equal, unilateral and declinate, 12–20 mm long; anthers 6–8 mm long; pollen yellow. *Style* dividing opposite apex of anthers, branches 3–4 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: August to September.

Distribution and ecology: extending from near Calitzdorp in the Little Karoo in Western Cape, South Africa, east through the Long Kloof and Baviaanskloof to the Great Winterhoek Mtns near Uitenhage in Eastern Cape; mainly on stony sandstone slopes in dry fynbos vegetation, flowering mainly after fire.

Diagnosis: distinguished by the concentric corm tunics, zygomorphic flowers with vertically oriented tepals and unilateral, declinate stamens, *Geissorhiza roseoalba* has relatively large white to pink-flushed tepals, the lower with pink to red markings near the base. At one stage included in the genus *Engysiphon*, now sect. *Engysiphon*, *G. roseoalba* differs markedly from the other species of that section in having three to five fairly soft-textured

Distribution of ***Geissorhiza roseoalba***.



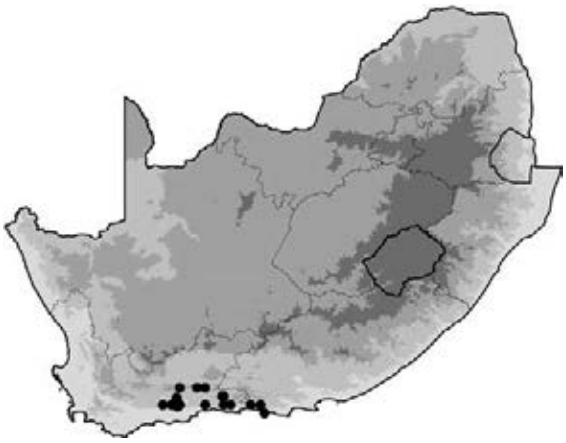
leaves with a plane blade in contrast to the one to two firm leaves with heavily thickened and viscid margins of species of sect. *Engysiphon*.

4. **Geissorhiza outeniquensis** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 313 (1985). Type: South Africa, [Western Cape], George, Outeniqua Mtns, Jonkersberg, wet rocky streambanks and waterfalls, *Esterhuysen 19379* (BOL, holo.; K, PRE, iso.).

Plants 200–500 mm long, usually decumbent or trailing, forming clumps. *Corm* depressed-globose, symmetric, 6–8 mm diam., forming short runners terminating in new plants; tunics apparently concentric, light brown, soft-papery, decaying readily and not accumulating. *Stem* decumbent, unbranched. *Leaves* 4–several, decumbent to trailing, at least lower 2 basal, upper cauline and progressively smaller, sometimes bract-like, 3–6 mm wide, linear, usually reaching base of spike, sometimes longer. *Spike* 2- to 4-flowered; bracts 16–20(–24) mm long, green, becoming submembranous above, inner slightly shorter than outer. *Flowers* zygomorphic, declinate, pink to purple with dark pink markings near base of lower tepals, purple outside; perianth tube 10–13 mm long, cylindric, ± as long or slightly longer than bracts; tepals ellipsoid, 26–32 × 10–14 mm. *Filaments* equal, unilateral, declinate, 15–20 mm long; anthers 6–8 mm long; pollen yellow. *Style* dividing opposite apex of anthers, branches 3–4 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: December to mid-January.

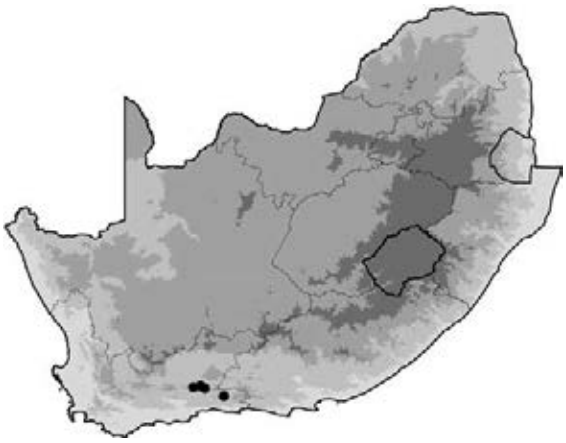
Distribution and ecology: restricted to the Outeniqua Mtns immediately around George in Western Cape, South Africa; along streams and waterfalls in moist shady kloofs.

Diagnosis: a member of sect. *Weihea* and evidently most closely related to *Geissorhiza roseoalba*, *G. outeniquensis* has, like that species, a zygomorphic flower with declinate stamens and style. The flowers have a perianth tube 10–13 mm long vs. 8–10 mm in *G. roseoalba* and it also differs in its riverine habitat, soft-textured corm tunics and four to several, soft-textured, often trailing leaves. *Geissorhiza outeniquensis* has an unusual caespitose habit: the main plants produce short runners which sprout to form new stems and leaf clusters close to the parent plant. It seems to have lost the deciduous habit of the genus and does not die back and become dormant during the later summer and autumn.



Distribution of ***Geissorhiza outeniquensis***.

5. **Geissorhiza fourcadei** *(L.Bolus) G.J.Lewis* in Journal of South African Botany 7: 32 (1941); Goldblatt: 315 (1985). *Acidanthera fourcadei* L.Bolus: 118 (1927). Type: South Africa, [Eastern Cape], Humansdorp, southern slopes of Witte Els Berg, *Fourcade 2968* (BOL, lecto., designated by Goldblatt: 315 (1985); BOL, MO, PRE, S, isolecto.).



Plants 150–300 mm high. *Corm* ± ellipsoid, 6–10 mm diam., corms of previous seasons persistent and accumulating below current corm; tunics brown, woody to soft-papery, concentric but sometimes imbricate by displacement especially when soft, fragmenting irregularly from base and apex, outer layers sometimes ± fibrous, extending upward in a collar with decaying leaf bases. *Stem* erect, smooth, simple or 1- or 2-branched, bearing 2 or 3 dry sheathing bracts below spike. *Leaves* 3 to 5, lower 2 to 4 leaves basal, terete or nearly so, margins and main vein much enlarged, thus narrowly 4-grooved, ± ½ to as long as stem, uppermost cauline, short, partly to entirely sheathing. *Spike* 1-flowered on main axis and lateral branches; bracts drying near apex, (12–)16–30 mm long, inner as long, or slightly shorter than outer. *Flowers* salver-shaped, pink to purple; perianth tube (8–)17–20 mm long, cylindric, widening gradually near apex, reaching almost to tips of bracts or shortly exserted; tepals oblanceolate-elliptic, 25–30 × ± 11 mm. *Filaments* equal, 13–20 mm long; anthers 10–12 mm long, brown; pollen brown. *Style* eccentric, dividing opposite or beyond anther tips. *Flowering time*: mid-January to early May.

Distribution and ecology: widespread but fairly rare in the mountains of southern Western Cape, South Africa and recorded from the Great Swartberg between Swartberg Pass and Meiringspoort, the Kammanassie Mtns and the Outeniqua and Tsitsikamma mtns from Robinson's Pass to Witte Els Berg; in stony sandstone ground, evidently in damp situations, including seeps and streambanks. The late summer to autumn blooming habit is unusual and related to its pollination by long proboscid flies that are on the wing at this time of year.

Diagnosis: *Geissorhiza fourcadei* is distinctive in the genus in the persistent bases of leaves and cataphylls which accumulate in a collar around the stem base and in the spike and its branches always bearing just one flower. It is also notable in having the corms of past seasons often persist instead of decaying, so that a series of old corms accumulate behind the current one. *Geissorhiza fourcadei* seems isolated in the subgenus but is best referred to sect. *Weihea* in which there is a tendency

Distribution of ***Geissorhiza fourcadei***.

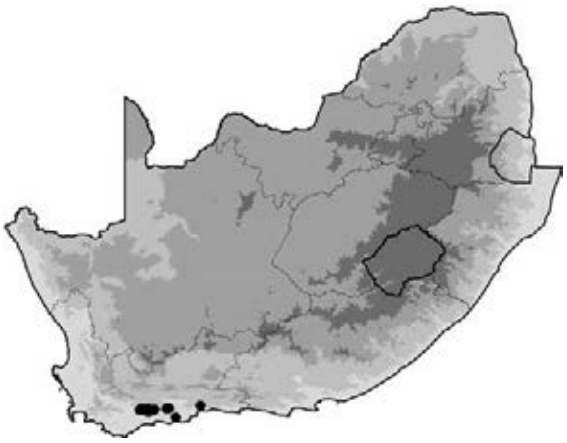
Distribution of ***Geissorhiza uliginosa***.

for the reduction of the number of flowers in the spike. It is also distinctive here in its terete, 4-grooved leaf.

Some collections from the Swartberg stand out in having unusually short bracts (12–15 mm long) and a short perianth tube (± 8 mm long) but otherwise match *G. fourcadei* well. They may represent a depauperate population as other collections from the Swartberg are more-or-less typical and accord with those from the Outeniqua Mtns, or they may represent local adaptation to shorter-tongued pollinators.

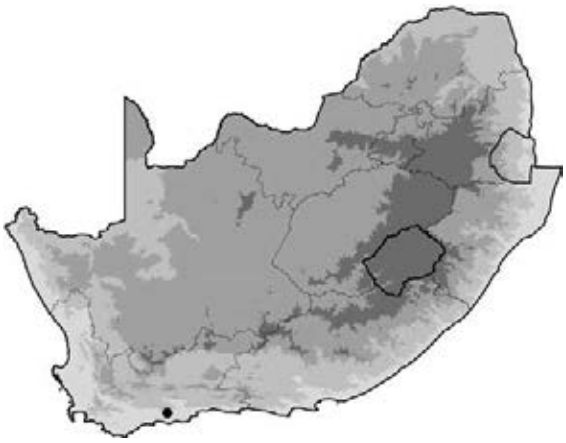
6. **Geissorhiza uliginosa** *Goldblatt & J.C.Manning* in Novon 5: 159 (1995). Type: South Africa, [Western Cape], Oudtshoorn District, Swartberg Mtns, stream east of Gouekrans Hiking Trail hut, 15 Jan. 1989, *Vlok 2075* (NBG, holo.; MO, iso.)

Plants 150–300 mm high. *Corm* much reduced, 3–5 mm diam.; tunics light brown, soft-textured, not accumulating with age. *Stem* trailing, usually with at least 1, sometimes up to 4 branches. *Leaves* usually at least 5, lower 3 basal and longest, usually shorter than stem but trailing, plane with lightly thickened margins and main vein, cauline leaves shorter than basal, largely or entirely sheathing. *Spike* 1-flowered; bracts green, margins often red, outer 16–20 mm long, inner ± as long or slightly shorter than outer. *Flowers* zygomorphic, funnel-shaped, pale pink to purple, creamy white in throat, base of tepals dark pink; perianth tube narrowly funnel-shaped, 9–13 mm long; tepals ovate-elliptic, subequal, 20–22 × 9–11 mm, subpatent when fully open. *Filaments* equal, unilateral, declinate, 12–14 mm long; anthers 7–9 mm long, dark brown; pollen brown. *Style* declinate, extended below filaments, branches ± 4 mm long. *Flowering time*: December and January.



Distribution and ecology: restricted to the Great Swartberg in southern Western Cape, South Africa; in wet sites on cliffs, streambanks and waterfalls.

Diagnosis: *Geissorhiza uliginosa* is distinguished by the branched stems, each branch bearing just a single flower, a small corm with soft corm tunics and plane, trailing leaves. The pink flowers are zygomorphic and have a short perianth tube 9–13 mm long and subequal tepals 20–22 mm long. The single-flowered branches and unilateral declinate stamens recall *G. fourcadei*, but this has a longer perianth tube, (8–)17–20 mm long, xeromorphic, terete, 4-grooved leaves and larger corms with persistent firm-papery corm tunics.



7. **Geissorhiza foliosa** *Klatt* in Linnaea 34: 658 (1866); Goldblatt: 317 (1985). Type: South Africa, [Western Cape], Swellendam, 'Berge bei Puspasvlei,' *Ecklon & Zeyher Irid. 218* (70.10) (B, lecto. effectively designated by Foster: 62 (1941); B, BM, E, FI, K, L, LD, MO, P, PRE, S, SAM, W, Z, isolecto.).

[*Geissorhiza nigromontana* Eckl.: 21 (1827), invalid name without description.]

Plants 80–200(–300) mm high. *Corm* globose, asymmetric with an obliquely flattened side extending shortly downward, 5–10 mm diam.; tunics concentric, dark brown, hard and woody, fragmenting irregularly into sections. *Stem* simple or 1- or 2-branched either from base or from upper nodes. *Leaves* 5 to several, at least lower 3 or 4 basal, erect to falcate, 3–6 mm wide, lanceolate to sword-shaped, typically short and seldom > ⅓ as long as stem, upper leaves cauline, progressively smaller, uppermost often entirely sheathing. *Spike* 2- to 5-flowered; bracts 9–12(–15) mm long, evidently green, becoming dry-membranous above, often reddish along margins, inner usually slightly shorter than outer. *Flowers* actinomorphic, rotate, pale pink to purple, rarely white; perianth tube ± 5 mm long, cylindric, included in bracts; tepals obovate, 13–17 × 6–7 mm. *Filaments* equal, 4–5 mm long; anthers 4–6 mm long; pollen yellow. *Style* dividing opposite apex of anthers, branches 3–4 mm long. *Capsules* 7–9 mm long, narrowly ovoid. *Chromosome number* 2*n* = 26. *Flowering time*: September to early November.

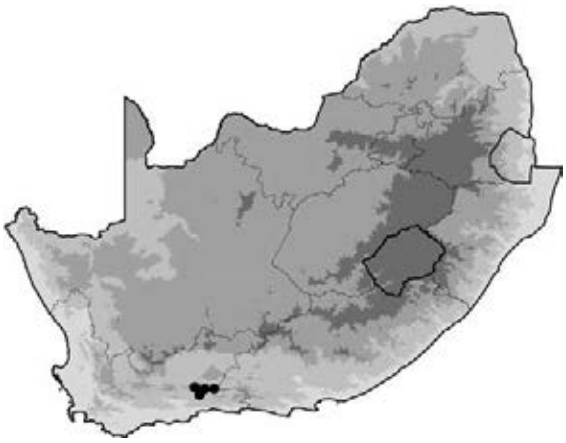
Distribution of ***Geissorhiza foliosa***.

Distribution of ***Geissorhiza tricolor***.

Distribution and ecology: local in southern Western Cape, South Africa along the southern slopes and foothills of the Langeberg between Swellendam and Riversdale; on clay or clay loam slopes and flats.

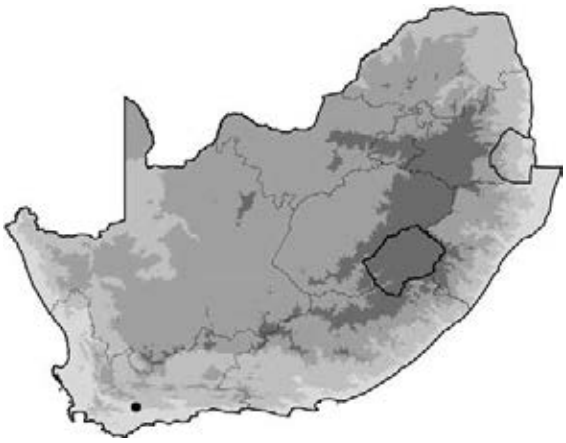
Diagnosis: distinguished by its 5 to 7, characteristically short, lanceolate leaves, *Geissorhiza foliosa* has relatively large pink to purple flowers with tepals 13–17 mm long and a short perianth tube ± 5 mm long. It is perhaps most easily confused with *G. inconspicua* but this species has smaller, violet to purple or white flowers, with shorter tepals mostly 8–11 mm long and longer leaves reaching at least to the base of the spike.

8. **Geissorhiza tricolor** *Goldblatt & J.C.Manning* in Goldblatt et al., *Bothalia* 39: 127 (2009). Type: Western Cape, Werner Frehse Nature Reserve, south of N2, east of Riversdale, pebbly ferricrete in renosterveld-fynbos transitional vegetation, 6 Oct. 2006, *Manning 3071* (NBG, holo.; MO, PRE, iso.).



Plants 100–150(–200) mm high. *Corm* obliquely globose, asymmetric and flattened slightly below on one side, 5–6 mm diam., tunics concentric, brown, hard and woody, fragmenting irregularly into sections. *Stem* erect, simple or 1- or 2-branched, either from base or from upper nodes. *Leaves* 6 to 8, lower 4 or 5 basal and largest, lanceolate to sword-shaped, short and mostly < ⅓ as long as stem, 15–50 × (2–)3–5 mm, upper decreasing progressively in size, uppermost bract-like and often without blade. *Spike* (1)2- or 3-flowered; bracts green, flushed reddish distally, elliptic, (12–)15–18 mm long, subequal, inner not notched apically. *Flowers* rotate, golden-yellow with glossy blackish maroon eye covering basal ¼ of tepals, yellowish green in tube, outer tepals flushed reddish on reverse, unscented; perianth tube funnel-shaped, 3–4 mm long; tepals broadly obovate-quadrate, margins irregularly crenulate in distal half, 15–18 mm long, outer 10–11 mm wide, inner 12–14 mm wide. *Filaments* equal, ± 3 mm long, exserted for ± 1 mm, dark maroon; anthers ± 5 mm long at anthesis; pollen yellow. *Style* eccentric, ± 6 mm long, dark maroon, exserted ± 1 mm, dividing opposite lower ½ of anthers, branches 2.5–3.0 mm long. *Flowering time*: September and early October.

Distribution and ecology: a narrow endemic of the hills southeast of Riversdale in Western Cape, South Africa, with the largest population in the small Werner Frehse Nature Reserve; in pebbly ironstone (ferricrete) at the transition between renosterveld and fynbos-thicket.



Diagnosis: *Geissorhiza tricolor* is recognised by its deep yellow flowers with exceptionally broad tepals and a dark, maroon-black central eye. The perianth tube, 3–4 mm long, is relatively short in comparison to the tepals, 12–15 mm long. The species recalls *G. inconspicua* and *G. foliosa* in vegetative morphology, but the flowers are larger than in both of these species and very different in colour. *Geissorhiza foliosa* has pink to light purple flowers with a tube ± 5 mm long and tepals 13–17 mm long, and *G. inconspicua* has blue-violet, pink or white flowers with a perianth tube 4–6 mm long and tepals 8–11, rarely up to 15 mm long. The flowers of *G. tricolor* closely resemble those of orange-flowered *Ornithogalum dubium* (Hyacinthaceae), which blooms together with it at the type locality, and both species are assumed to be pollinated by the same suite of hopliine beetles, but no potential pollinators have so far been recorded.

9. **Geissorhiza nigromontana** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 318 (1985). Type: South Africa, [Western Cape], Great Swartberg, Blesberg at Tierkloof, along stream, *Vlok 93* (MO, holo.; NBG, SAAS, iso.).

Plants 100–160 mm high. *Corm* globose, asymmetric with obliquely flattened side extending downward, ± 6 mm diam.; tunics ± concentric, light brown, outer layers apparently brittle-papery. *Stem* usually prostrate below, upright above, simple or branched from base or upper nodes, bearing cormlets at lower nodes. *Leaves* 3 to 6, falcate, at least lower 2 basal, 4–10 mm wide, ⅓–⅔ as long as stem, upper leaves cauline and progressively smaller, uppermost often entirely sheathing. *Spike* 2- or

Distribution of ***Geissorhiza nigromontana***.

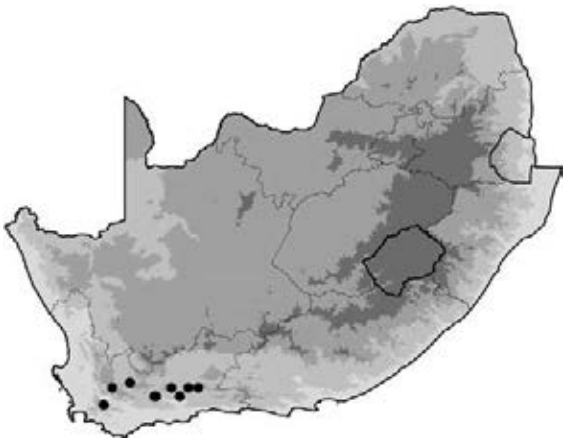
Distribution of ***Geissorhiza altimontana***.

3-flowered; bracts 8–10 mm long, green, ± membranous above, inner slightly shorter than outer. *Flowers* rotate, blue-purple; perianth tube 2–3 mm long, cylindric, included in bracts; tepals obovate, 14–16 × ± 6 mm wide. *Filaments* equal, ± 6 mm long; anthers ± 5 mm long; pollen yellow. *Style* dividing ± opposite middle of anthers, branches 4–5 mm long. *Flowering time*: January to February.

Distribution and ecology: local in the Great Swartberg in Western Cape, South Africa; along streams in shade at ± 1 800 m elevation, flowering near the end of summer.

Diagnosis: distinctive in its short-tubed blue-purple flowers, the perianth tube 2–3 mm long and much longer tepals 14–16 mm long, *Geissorhiza nigromontana* has spikes of only 2 or 3 flowers. The style branches are unusually long, 4–5 mm long, and the corm tunics are softly papery. Notably the stem is prostrate at the base and becomes abruptly erect above. It is most probably closely related to *G. foliosa*, a species of the Langeberg foothills, which blooms mainly in October and November and it has the broad flat leaves typical of that species, but *G. foliosa* has a perianth tube 5–6 mm long, a spike of up to 7 flowers and style branches up to 3 mm long. *Geissorhiza nigromontana* is also distinctive in bearing cormlets in the lower stem axils, a feature rare in the genus.

10. **Geissorhiza altimontana** *Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 39: 129 (2009). Type: South Africa, Western Cape, Langeberg, upper slopes of Leeuriviersberg, 300 m east of peak, 1 550 m, 15 Jan. 2006, *Helme 3778* (NBG, holo.).



Plants 60–120 mm high, including flowers, base sheathed underground by a collar of dry, persistent fibrous leaf bases, and above ground by dry cataphylls. *Corm* ovoid, 4–6 mm diam.; tunics soft-textured, light brown, evidently concentric, becoming fibrous, not accumulating with age. *Stem* sometimes horizontal at ground level for a short distance, erect above, unbranched, smooth. *Leaves* 5 or 6, lower 4 basal, spreading horizontally and ± prostrate, blades lanceolate, leathery, 20–50 × 2.5–6.0 mm, margins moderately thickened, upper 1 or 2 cauline and shorter, sheathing for ½ their length. *Spike* erect, ± straight, 1- or 2-flowered; bracts with red tips, 7–10 mm long, outer obtuse, inner notched apically. *Flowers* radially symmetric with tepals ascending, pink but ± greenish in throat, unscented; perianth tube ± cylindric, 7–8 mm long; tepals subequal, oblong, ± 14 × 6 mm, ascending and forming a wide cup. *Filaments* equal, ± 8 mm long; anthers ± 4 mm long, sagittate at base for ± 1 mm, yellow; pollen yellow. *Style* dividing opposite anther apices, branches ± 1.3 mm long. *Flowering time*: January.

Distribution and ecology: known from just one collection on Leeuriviersberg (Grootberg) west of Swellendam, in Western Cape, South Africa; high in the Langeberg at ± 1 550 m elevation in unburned veld, on damp, mossy ledges on steep, south-trending slopes.

Diagnosis: with its five or six relatively short leaves, the basal with horizontally spreading blades, low stature and 1- or 2-flowered spikes, *Geissorhiza altimontana* appears most closely allied to the Swartberg species, *G. nigromontana* and *G. uliginosa*. *Geissorhiza uliginosa* is essentially aquatic, growing in streams and waterfalls, and has reduced corms, but *G. nigromontana* has a similar habitat to *G. altimontana*, viz.; damp, mossy ledges in shallow soil and south-facing slopes, and both species flower in the summer months of January and February. The longer perianth tube, 7–8 mm long, and tepals ± 14 mm long, readily separate *G. altimontana* from *G. nigromontana*, which has a very short perianth tube, 2–3 mm long, and tepals 14–16 mm long.

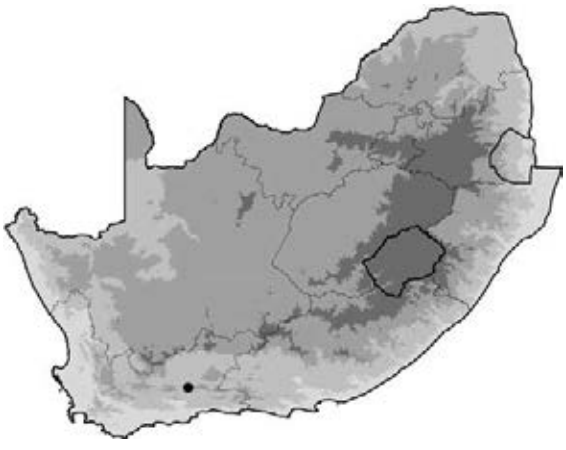
11. **Geissorhiza delicatula** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 319 (1985). Type: South Africa, [Western Cape], shady mountainside, Seven Weeks Poort, *Compton 4016* (NBG, holo.; BOL, iso.).

Plants 30–90(–120) mm high. *Corm* globose, asymmetric with obliquely flattened side extending downward,

Distribution of ***Geissorhiza delicatula***.

3–8 mm diam.; tunics concentric, brown, firm to softly membranous, fragmenting irregularly into sections. *Stem* simple or 1- to 3-branched from base or upper nodes. *Leaves* 3 to 6, at least lower 2 or 3 basal, often prostrate or erect to falcate, 1.5–4.5 mm wide, linear to sword-shaped, half as long as stem, upper cauline and progressively becoming shorter, uppermost often entirely sheathing. *Spike* usually 1(rarely 2 or 3)-flowered; bracts 4–8 mm long, becoming membranous and dry above, sometimes reddish on margins, inner ± as long as outer. *Flowers* rotate, pale lilac-purple, cream-coloured in throat and tube; perianth tube cylindric, 2–3 mm long, included in bracts; tepals obovate, 7–12 × 2.5–4.5 mm. *Filaments* equal, erect, 3–5 mm long; anthers 2.5–3.5 mm long, white; pollen yellow. *Style* dividing toward apex of anthers, branches up to 1.5 mm long. *Capsule* narrowly obovoid, 4–7 mm long. *Seeds* light brown, angular. *Flowering time*: August to September in drier sites, November to December at higher elevations.

Distribution and ecology: local in the mountains of southern Western Cape, South Africa, from Jonas Kop in the west to Swartberg Pass in the east; in stony ground in sheltered often shady sites.



Diagnosis: a small, delicate plant mostly 30–90 mm high, *Geissorhiza delicatula* has simple or 1- or rarely 2-branched, slender stems and small flowers, with tepals 7–12 mm long and a short perianth tube, 3–4 mm long, included in the bracts. It is apparently related to *G. inconspicua* and *G. foliosa*, both larger plants with larger flowers and spikes typically with at least 3 and up to 7 flowers. The plane leaves are soft-textured leaves and often prostrate or decumbent.

12. **Geissorhiza monticola** *Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 39: 129 (2009). Type: South Africa, Western Cape, Western Cape, Swartberg, road to Gamkasloof, 10 Sept. 2001, *Goldblatt & Porter 11872* (NBG, holo.; MO, iso.).

Plants 100–160 mm high. *Corm* globose, asymmetric with oblique, flattened side, ± 10 mm diam.; tunics concentric, dark brown, fragmenting into vertical sections. *Stem* filiform, flexuose, with up to four branches from axils of cauline leaves. *Leaves* 4 to 7, soft-textured, lower 2 or 3 basal and ± half as long as stem, spreading to prostrate, linear to falcate, plane with slightly thickened and raised main vein, 2–3 mm wide, upper leaves cauline, progressively decreasing in size, partly to entirely sheathing. *Spike* 1-flowered on main axis and branches; bracts green, soft, flushed purple, margins membranous, ± transparent, 8–10 mm long, inner slightly shorter. *Flowers* zygomorphic, nodding with tepals held vertically, blue-mauve with greenish cream-coloured throat edged with dark blue; perianth tube funnel-shaped, slightly curved, ± 3 mm long; tepals narrowly oblong, obtuse, spreading at right angles to tube, 14–18 × 4.0–5.5 mm, inner slightly narrower than outer. *Filaments* unilateral, declinate, 7–9 mm long, exserted 7–8 mm; anthers 3–4 mm long, dull pink. *Style* dividing near apex of anthers, branches 3–4 mm long. *Flowering time*: September.

Distribution and ecology: known only from the central Swartberg, west of Swartberg Pass in Western Cape, South Africa; on south-trending, rocky sandstone slopes in pockets of peaty sand.

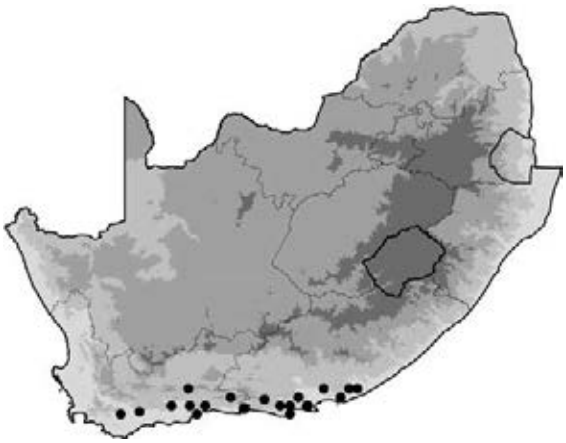
Diagnosis: distinguished by its large, zygomorphic flowers solitary on the branches, *Geissorhiza monticola* has a nodding blue perianth and well-exserted, declinate stamens The flowers have a short perianth tube ± 3 mm long and tepals 14–18 mm long. The plane leaves are prostrate with slightly thickened margins and main veins. Its relationships presumably lie with *G. delicatula* of the Langeberg and Swartberg and its allies, with which it shares an oblique corm, several plane leaves with the marginal vein set slightly away from the margin itself, and solitary flowered spikes. *Geissorhiza delicatula* has much smaller, cup-shaped flowers held upright, with elliptical or obovate, pale mauve tepals mostly 7–10 mm long, erect stamens with filaments 3–5 mm long, and a central style of similar length with short style branches

Distribution of ***Geissorhiza monticola***.

up to 1.5 mm long, thus less than half as long as in *G. monticola*. *Geissorhiza nigromontana* may also be confused with *G. monticola*, but it has a stem ± prostrate toward the base, a spike of 2 or 3 flowers (flowers always single in *G. monticola*), bears cormlets in the leaf axils, shorter leaves with blades 4–10 mm wide vs. 2–3 mm in *G. monticola*, and the flowers are, as far as known, upright and radially symmetric.

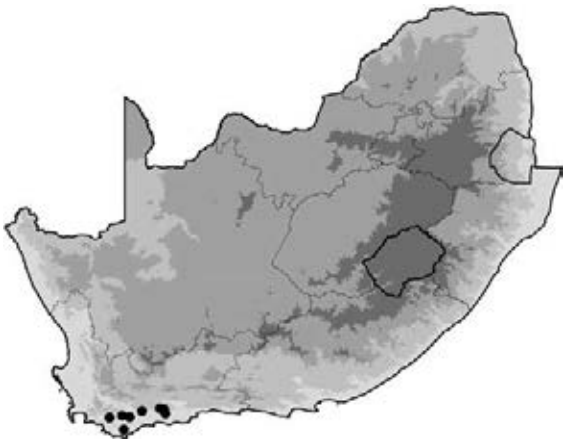
13. **Geissorhiza bracteata** *Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 391 (1882); Goldblatt: 319 (1985). Type: South Africa, [Eastern Cape], Olifantshoek, Uitenhage, *Ecklon & Zeyher s.n.* (B: Herb. Lubeck, holo.; probable isotypes *Ecklon & Zeyher Irid. 221* (10.9), B, BM, E, FI, G, LD, MO, PRE, S, W, Z).

[?*Weihea elatior* Eckl.: 22 (1827), invalid name without description. *Geissorhiza tabularis* var. *elatior* Eckl. ms. *Ecklon & Zeyher Irid. 221* (10.9)].



Plants (40–)60–180 mm high. *Corm* ovoid, asymmetric with oblique flat side directed downward, 4–6 mm diam.; tunics pale to dark brown, concentric, outer layers fragmenting irregularly into elliptic sections drawn into points above. *Stem* simple or 2- to 5-branched from base, occasionally also from cauline node. *Leaves* (3)4 to several, lower 2 or 3 basal, sword-shaped, ⅓–½ as long as stem, often prostrate, 2–9 mm wide, upper leaves cauline, progressively smaller, sometimes entirely sheathing. *Spike* usually 1(rarely 2 or 3)-flowered; bracts often reddish along margins, 6–10 mm long, inner usually slightly shorter than outer. *Flowers* actinomorphic, rotate, white, outer tepals sometimes red-flushed outside; perianth tube funnel-shaped, 2.5–5.0 mm long, flared from base; tepals obovate, (5–)8–12 × 4.5–6.0 mm. *Filaments* erect, equal, 5–7 mm long; anthers 2.0–3.5 mm long; pollen yellow. *Style* dividing opposite apex of anthers. *Capsules* narrowly ovoid, 7–9 mm long. *Chromosome number* 2*n* = ± 52. *Flowering time*: September to mid-October.

Distribution and ecology: widespread in southern South Africa, from Montagu and Touws River in Western Cape to Grahamstown in Eastern Cape; in clay or loamy sand in fynbos or forest edges.

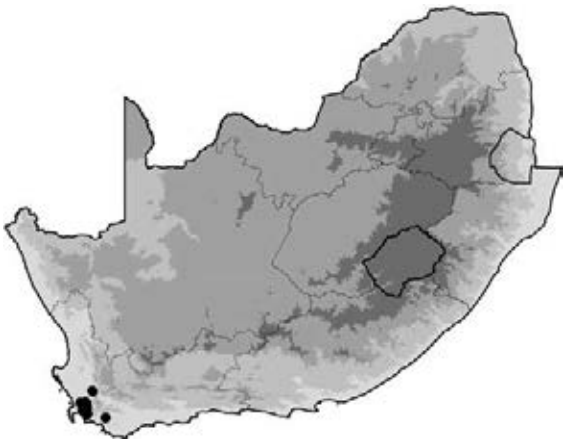


Diagnosis: *Geissorhiza bracteata* is recognised by its relatively small size, several plane leaves often inclined toward the ground or even prostrate, and small white flowers mostly 1 or 2, rarely 3 per spike. Branches, when present, are typically produced from the base of the stem. The flowers have a perianth tube up to 5 mm long and tepals up to 12 mm long. Based on studies of a single population from Hankey in Eastern Cape, *G. bracteata* is polyploid, 2*n* = ± 52, and in the greenhouse proved to be autogamous, which is unusual in the genus.

14. **Geissorhiza nana** *Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 391 (1882); Goldblatt: 321 (1985). Type: South Africa, [Western Cape], 'Rivierzondereinde,' Swellendam, *Ecklon & Zeyher 3967* (90.9) (as *3969*) (B: Herb. Lubeck, holo.; B, FI, G, K, SAM, W, Z, iso.).

Plants tiny, 25–40(–80) mm high. *Corm* narrowly ovoid, asymmetric, with oblique flat side, 35 mm diam.; tunics middle brown, concentric, drawn into bristles above. *Stem* simple, or up to 3-branched, branches produced from near base, rarely also from aerial node. *Leaves* (3)4 to 6, usually all basal, or uppermost inserted on lower part of stem, plane, half as long, to slightly longer than stem, 1–2 mm wide, narrowly sword-shaped. *Spike* 1- or 2(3)-flowered; bracts 4–6 mm long, sometimes red along margins. *Flowers* actinomorphic, tiny, rotate, white, pale red-brown on outside of outer tepals; perianth tube 1.0–2.5 mm long, nearly cylindric; tepals obovate, 3–6(–8) mm long. *Filaments* erect, equal, ± 2 mm long; anthers 1.2–1.8 mm long, white; pollen creamy-white. *Style* dividing at mid-anther level, branches < 1 mm long. *Capsules* 4–6 mm long, obovoid, usually slightly exceeding bracts. *Chromosome number* 2*n* = 26. *Flowering time*: September to early October.

Distribution of ***Geissorhiza bracteata***.



Distribution of ***Geissorhiza nana***.

Distribution and ecology: restricted to the Caledon, Bredasdorp and Swellendam Districts of Western Cape, South Africa; on clay flats and slopes in renosterveld.

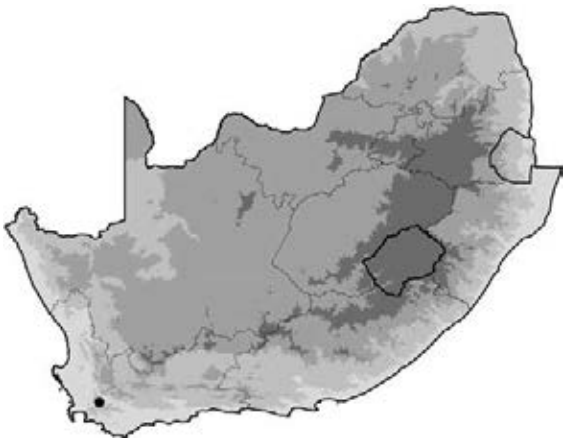
Diagnosis: a dwarf species, *Geissorhiza nana* rarely reaches up to 80 mm high and has tiny creamy white flowers with a perianth tube 1.0–2.5 mm long and spreading tepals 3–6(–8) mm long. It is closely allied to and easily confused with *G. bracteata,* which has somewhat larger flowers with a perianth tube 2.5–5.0 mm long and tepals 8–12 mm long, rarely smaller. *Geissorhiza setacea* is very similar in general appearance to *G. nana* but is larger in all features, having flowers with a tube ± 6 mm long and tepals mostly 8–12 mm long.

15. **Geissorhiza setacea** *(Thunb.) Ker Gawl.* in König & Sims, Annals of Botany 1: 224 (1804); Goldblatt: 322 (1985). *Ixia setacea* Thunb.: 146 (1783). Type: South Africa, [Western Cape], without precise locality, *Thunberg s.n.* (UPS–THUNB 995, lecto., designated by Foster: 64 (1941); S: Herb. Osbeck, S: Herb. Alstroemer, S: Herb. Montin, isolecto.).

Plants small, 40–80 mm high. *Corm* globose, asymmetric, one side flattened below and extending downward in a fan-like ridge, 3–4 mm diam.; tunics concentric, outer layers irregularly fragmented. *Stem* occasionally 1(rarely 2)-branched from base. *Leaves* usually 4, lower 3 basal, ± half as long as stem, erect to falcate, linear to narrowly sword-shaped, 1.0–2.5 mm wide, plane, uppermost leaf cauline, smaller than basal leaves, lower half sheathing stem. *Spike* 1(rarely 2)-flowered; bracts 5–7 mm long, upper margins sometimes reddish, inner slightly longer than outer. *Flowers* actinomorphic, salver-shaped, creamy white or pale yellow with a dark centre, flushed red to purple on outside of outer tepals; perianth tube ± 6 mm long, narrowly funnel-shaped; tepals obovate, (8–)10–12 × 6–8 mm. *Filaments* erect, equal, 3–4 mm long; anthers 2.5–4.0 mm long. *Style* dividing opposite apex of anthers. *Flowering time*: July to August (to September).

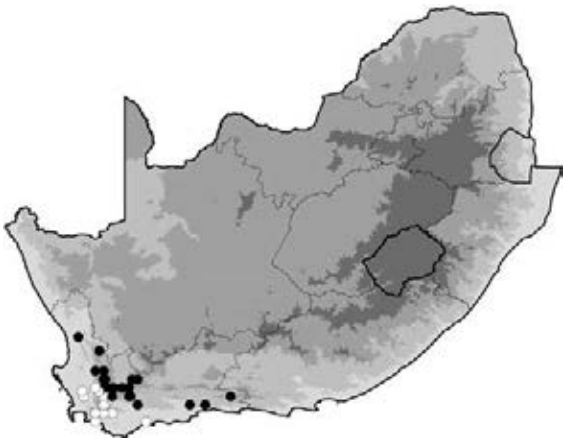
Distribution of ***Geissorhiza setacea***.

Distribution and ecology: restricted to the southwestern corner of Western Cape, South Africa, extending from near Gouda in the north to the Cape Peninsula, the foot of the Hottentots Holland Mtns and possibly Caledon in the south; on wet sandy or loamy clay flats.



Diagnosis: a dwarf species 40–80 mm tall, *Geissorhiza setacea* is most easily recognised by its fairly large, relatively long-tubed flowers usually borne singly on short stems. The flowers are usually white and have a perianth tube ± 6 mm long and tepals 8–12 mm long. Also short in stature, *G. nana* has similar but smaller flowers with a perianth tube 1.0–2.5 mm long and tepals 3–6(–8) mm long. Although usually white-flowered, populations of *G. setacea* have pale yellow flowers with a blackish centre in the north of its range at Elandsberg Nature Reserve near Gouda. These plants appear to differ in no other characters from the typical white-flowered plants.

16. **Geissorhiza lapidosa** *Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 39: 131 (2009). Type: South Africa, Western Cape, Du Toit's Kloof Mtns, Goudini Sneeukop, western and southern edges of shale band, 1 700–1 730 m, seasonally damp, shallow moss and shale-derived silt overlying sandstone shelf, rare and localised, 9 Nov. 2008, *Helme & Turner 5747* (NBG, holo.).



Plants ± acaulescent, 20–40 mm high. *Corm* obliquely ovoid with narrow flat side, 4–5 mm diam., tunics woody, dark, blackish, concentric. *Stem* smooth, flushed red, not or barely extending above ground, unbranched. *Leaves* 4, lower 2 basal, third leaf inserted at or shortly above ground, linear-falcate, exceeding spike, 0.5–1.0 mm wide, thick and leathery, elliptic in section when fresh, glaucous with margins often reddish, uppermost leaf cauline, entirely sheathing. *Spike* 1- or 2-flowered; bracts leathery and glaucous flushed reddish but submembranous and finely flecked with brownish red on margins, outer truncate or obscurely tricuspidate, 4–5 mm long, inner as long or slightly shorter, notched at apex. *Flowers* actinomorphic, rotate, white with outer tepals reddish pink outside; perianth tube funnel-shaped, 2.0–2.5 mm long; tepals oblanceolate, ± 6 × 2 mm. *Filaments* erect, equal, 3.5–4.0 mm long; anthers 1.5–2.0 mm long, ± white; pollen white. *Style* dividing opposite lower ½ of anthers, branches 1.5–2.0 mm long. *Flowering time*: November.

Distribution and ecology: restricted to Goudini Sneeukop in the Du Toits Kloof Mtns in Western Cape, South Africa; along a narrow band of sandstone pavement at the edge of cliffs in moist seeps draining from a shale sponge overlying the sandstone, a very restricted habitat less than 4 m wide, unusual for the genus. The two known colonies are about 800 m apart in an area regularly covered by snow in winter and spring.

Diagnosis: distinguished by its small size and underground stem, *Geissorhiza lapidosa* has a corm with

Distribution of ***Geissorhiza lapidosa***.

Distribution of ***Geissorhiza ornithogaloides*** subsp. ***ornithogaloides***, ●; subsp. ***flava***, ○.

concentric tunics and smooth, ± plane, falcate leaves. It differs from other dwarf species of subg. *Weihea* in its high mountain habitat and unusual leathery, falcate leaves at most 1 mm wide. The short-tubed, white flowers have an unusually short style dividing opposite the lower half of the anthers. Similar flowers are found in *G. nana* and *G. setacea*, both lowland species: *G. nana* occurs in renosterveld vegetation in the Overberg between Caledon and Swellendam and has broader, thin-textured leaves up to 2 mm wide and even smaller flowers with the tepals mostly 3–6 mm long, and very short filaments ± 2 mm long; *G. setacea* grows in seasonally wet places on flat sandy or loamy ground in Western Cape between Gouda and Caledon and has similarly narrow but linear leaves, 0.5–1(–2) mm wide but larger flowers with tepals 6–8 mm long, a longer tube ± 6 mm long, and the style branching opposite the tips of the anthers.

17. **Geissorhiza ornithogaloides** *(Licht. ex Roem. & Schult.) Klatt* in Linnaea 34: 656 (1866); Goldblatt: 323 (1985). *Ixia ornithogaloides* Licht. ex Roem. & Schult.: 376 (1817). *Trichonema ornithogaloides* (Licht. ex Roem. & Schult.) A.Dietr.: 583 (1833). Type: South Africa, [Western Cape], Cold Bokkeveld, *Lichtenstein s.n.* (B, holo.).

Plants small, 40–70(–100) mm high. *Corm* either ± ovoid or bell-shaped with broad flat base, 4–6 mm at widest diam.; tunics medium brown, concentric, either fragmenting into elliptic or irregular sections when bell-shaped and lower margins minutely serrated. *Stem* ± erect, usually branching from cauline leaves. *Leaves* usually 4, lower 2 basal, linear to lanceolate, erect to falcate, 1–3 mm wide, flat, upper two leaves cauline and sheathing below, sheaths often inflated. *Spike* 1(rarely 2)-flowered; bracts green, becoming dry above, 7–10 mm long. *Flowers* actinomorphic, clear yellow, rotate; perianth tube 2–4(–5) mm long, included in bracts; tepals obovate, (6–)8–15(–18) × 3.5–6.0 mm. *Filaments* erect, equal, 2–4 mm long; anthers 3–6 mm long, yellow; pollen yellow. *Style* dividing opposite apex of anthers, branches 2–3(–4) mm long. *Capsules* obovate, 7–9 mm long, usually exceeding bracts. *Chromosome number* 2*n* = 26. *Flowering time*: mid-August to early October.

Distribution and ecology: extending in Western Cape, South Africa from the Koudeberg near Wuppertal in the northern Cederberg south to Paarl and eastward through the Worcester District and interior southern Cape to Companies Drift in the Long Kloof in Eastern Cape; on stony sandstone and clay flats and slopes.

Diagnosis: a dwarf and typically slender species, *Geissorhiza ornithogaloides* is recognised by the mostly solitary, bright yellow flowers, unusual in the genus. It is morphologically variable and even within populations plants may be more robust and have much larger flowers than others, the extremes seemingly almost different species. The vegetative morphology is, however, quite uniform, with plants always having spikes with either one or two flowers, two narrow, plane, basal leaves and two cauline and partly sheathing leaves. The corms are of two types: the interior and eastern populations, subsp. *ornithogaloides*, have small ellipsoid corms with concentric tunics of the type characteristic of subg. *Weihea*, whereas the southwestern populations, subsp. *flava*, have bell-shaped corms with a flat base and minutely serrated margins. The two sets of populations otherwise appear identical.

Geissorhiza ornithogaloides is most closely related to *G. malmesburiensis*, which is broadly similar to subsp. *flava* in the yellow flowers and bell-shaped corms, but differs in having somewhat larger, cupped flowers, the perianth tube ± 4 mm long, tepals mostly 18–20(–25) mm long and filaments 7–10 mm long.

Key to subspecies

1a Corm ± ellipsoid, tapering at both ends, not campanulate in outline; lower margins of tunics not or rarely slightly serrated. . . . . 17a. subsp. *ornithogaloides*
1b Corm bell-shaped with flat base; lower margins of the tunics minutely serrated . . . . . 17b. subsp. *flava*

17a. subsp. **ornithogaloides**

Geissorhiza marlothii R.C.Foster: 66 (1941). *G. ornithogaloides* subsp. *marlothii* (R.C.Foster) Goldblatt: 325 (1985). Type: South Africa, [Western Cape], Cold Bokkeveld, Houdenbeck, 850 m, *Marloth 10612* (B, holo.; NBG, PRE, iso.); [Western Cape], Schoongesig, Ceres, *Hanekom 1222* [NBG, epi., designated by Goldblatt & Manning: 7 of 9 (2014)].

Corm ovoid-ellipsoid, tapering at both ends, obliquely flattened on one side, 3–5 mm diam.; tunics concentric, fragmenting vertically into elliptic segments. *Flowers* sometimes very small, with tepals (6–)8–12(–15) mm long. *Filaments* 2–4 mm long; anthers 3–4 mm long. *Flowering time*: late August to October.

Distribution and ecology: extending from Wuppertal and the Cold Bokkeveld in the northeast through the Warm Bokkeveld and the Witteberg and Voetpadsberg, with outlying populations in the Little Karoo, the Albertinia District and the upper Long Kloof in Eastern Cape; on sandy and stony clay slopes and flats.

Diagnosis: subsp. *ornithogaloides* is distinguished from subsp. *flava* only by the corms, ovoid-ellipsoid and tapering at both ends, this typical of subg. *Weihea* and the ancestral type in *Geissorhiza ornithogaloides*. The bell-shaped corm of subsp. *flava* is specialised and derived. In all other features, the two subspecies are essentially identical, although there are several populations of subsp. *ornithogaloides* on the edges of the range of this subspecies that have smaller flowers than any found in subsp. *flava*.

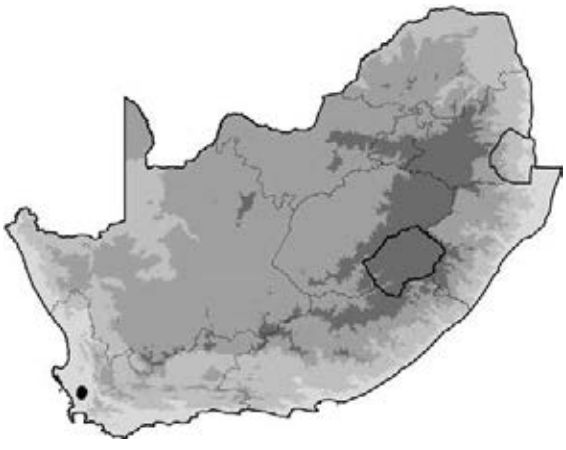
17b. subsp. **flava** *(Klatt) Goldblatt & J.C.Manning* in Bothalia 44: 7 of 9 (2014). *Geissorhiza flava* Klatt: 392 (1882). *G. ornithogaloides* var. *flava* (Klatt) R.C.Foster: 68 (1941). Type: South Africa, [Western Cape], without precise locality, *Breutel s.n.* (B, holo.).

[*Waitzia flava* Reichb. in Klatt: 392 (1882), invalid name only in synonymy.]

[*Geissorhiza romuleoides* Eckl.: 27 (1827), invalid name without description.]

Corm bell-shaped obliquely flattened base, 4–6 mm diam.; tunics medium brown, concentric, lower margins minutely serrated. *Flowers* with tepals 8–12(–18) mm long. *Filaments* 2.5–4.0 mm long; anthers 3–6 mm long. *Flowering time*: September and October.

Distribution and ecology: extending in Western Cape from near Paarl east to Worcester and the Hex River Valley and south to the Caledon District; on stony sandstone and clay flats and slopes.



Diagnosis: subsp. *flava* differs from subsp. *ornithogaloides* almost exclusively by its bell-shaped corms with flat base and minutely serrated lower margins. In other features the two subspecies are virtually identical, although some populations of subsp. *ornithogaloides* have smaller flowers than any found in subsp. *flava*.

18. **Geissorhiza malmesburiensis** *R.C.Foster* in Contributions from the Gray Herbarium of Harvard University 135: 66 (1941); Goldblatt: 327 (1985). Type: South Africa, [Western Cape], hill near Malmesbury, 300 m, *Schlechter 1654* (B, holo.; B, BOL, BR, L, MO, PRE, Z, iso.).

Plants small, 50–80 mm high. *Corm* bell-shaped with flat base, 4–6 mm diam.; tunics medium brown, concentric, lower margins minutely serrated. *Stem* erect, simple or branched from upper leaves. *Leaves* usually 4, lower 2 or 3 basal, linear-filiform, ± erect, 0.8–1.1 mm wide, plane, upper 1 or 2 leaves cauline, sheathing part inflated. *Spike* 1-flowered; bracts pale green with hyaline margin, becoming dry above, 7–11 mm long. *Flowers* actinomorphic, cup-like, clear yellow; perianth tube ± 4 mm long, included in bracts; tepals obovate, 13–25 × 4–7 mm. *Filaments* erect, equal, 7–10 mm long; anthers 4–5 mm long, yellow; pollen yellow. *Style* dividing between middle and apex of anthers, branches ± 4 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: September to early October.

Distribution and ecology: restricted to the immediate vicinity of Malmesbury and the northern end of the Paardeberg in Western Cape, South Africa, where it is currently known from just three sites, one surrounded by wheat fields; on gravelly soils in renosterveld.

Diagnosis: with a bell-shaped corm with a somewhat oblique, flat base with toothed margins, *Geissorhiza malmesburiensis* closely resembles *G. ornithogaloides* subsp. *flava* in habit, corm and leaves. The pale yellow flowers are, however, somewhat larger, with a perianth tube ± 4 mm long, tepals mostly 15–25 × 4–7 mm and remaining cupped when fully open, and longer filaments, 7–10 mm long. *Geissorhiza ornithogaloides* has smaller flowers with the perianth tube 2–3(4) mm long, tepals (6–)8–15 mm long, rarely up to 18 mm, and

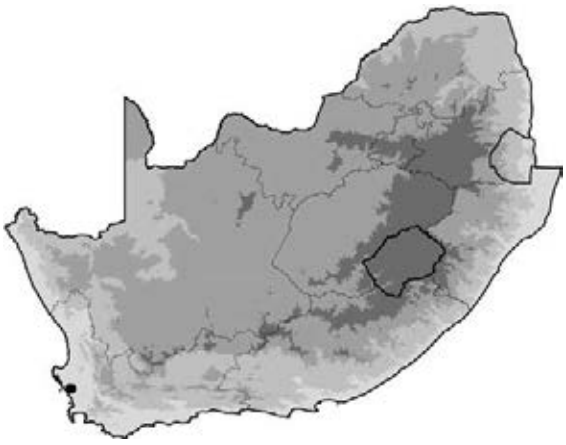
Distribution of ***Geissorhiza malmesburiensis***.

shorter filaments, 2–4 mm long. Also, robust plants of *G. ornithogaloides* are often branched and have spikes of more than one flower each.

19. **Geissorhiza platystigma** *Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 39: 132 (2009). Type: South Africa, Western Cape, gravelly, north-facing slopes in Darling Nature Reserve, 22 Sept. 1999, *Goldblatt & Nänni 11162A* (NBG, holo.; MO, iso.).

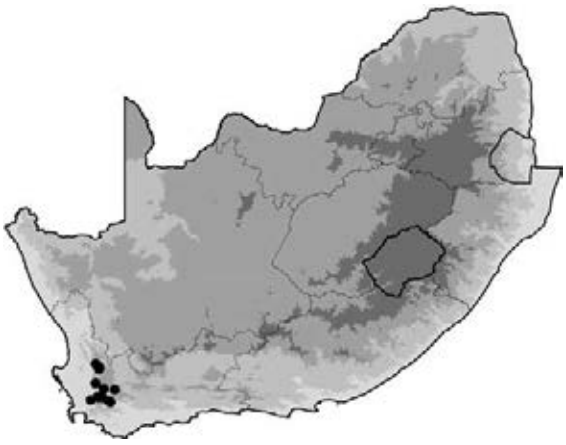
Plants 25–50 mm high. *Corm* bell-shaped, ± 3 mm diam., with minutely toothed margins; tunics light brown, concentric, woody. *Stem* usually 1- or 2-branched from near base. *Leaves* usually 3, linear, ± 1 mm wide, sheaths inflated, plane, ± as long as stem. *Spike* 1-flowered; bracts sometimes flushed purple distally, outer ± 8 mm long, inner ± 6 mm long, not forked at apex. *Flowers* actinomorphic, rotate, pale yellow, unscented; perianth tube funnel-shaped, ± 1.5 mm long; tepals narrowly ovate, 6–7 × ± 3 mm. *Filaments* erect, equal, ± 2 mm long; anthers ± 1.5 mm long, pale yellow. *Style* erect, dividing opposite upper third of anthers, branches ± 1.5 mm long, with prominent hairs longer than width of branch. *Capsules* barrel-shaped, ± 5 mm long. *Flowering time*: September, probably also in late August.

Distribution and ecology: known only from the Darling Nature Reserve in the hills above Darling in Western Cape, South Africa; in granite-derived soils on east-trending slopes in open ground or in the shade of low shrubs in renosterveld.



Diagnosis: one of the most inconspicuous species of *Geissorhiza*, *G. platystigma* stands just 25–50 mm high with the main stem and branches each bearing a single small flower. The style branches, its most distinctive feature, are short, ± 1.5 mm long, broad and densely covered in prominent hairs much longer than the width of the branches. The corm closely resembles that of *G. ornithogaloides* subsp. *flava* in its bell shape with flat base and minutely serrated margins. Seemingly immediately allied to this widespread species of the southern Cape and interior, *G. platystigma* differs from it in flower size and details; *G. ornithogaloides* has a perianth tube 2–3(–4) mm long, tepals (6–)7–12(–18) mm long, much larger anthers 3–6 mm long, and the style branches are slender, 2–3 mm long, and thread-like as is typical of the genus.

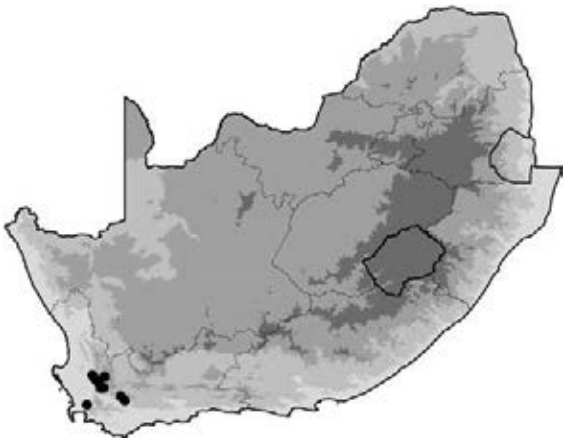
20. **Geissorhiza geminata** *E.Mey. ex Baker*, Handbook of the Irideae: 159 (1892); Goldblatt: 327 (1985). Type: South Africa, (Western Cape], between 'Slangenheuwel, Franschehoek und Donkerhoek', *Drège s.n.* '*G. geminata* EM. a' (K, lecto., designated by Goldblatt: 327 (1985); B, BM, E, G, K, L, MO, P, S, isolecto.).



Ixia geminata Vahl: 68 (1805). Type: unknown, assigned here by G.J.Lewis: 189 (1962).

[*Geissorhiza geminata* Drège ms. in E.Mey.: 119–187 (1844), invalid name without description.]

Plants (120–)160–300 mm high. *Corm* globose, ± symmetric, obliquely flattened below; tunics concentric, light brown, fragmenting irregularly into segments, drawn into short bristles above. *Stem* often branched, then dichotomously so, or simple, sometimes with a small scale-like leaf in upper third. *Leaves* 3 to 5, lower 2 or 3 basal, lowermost shortest, others shorter or longer than stem, 1–2 mm wide, plane when dry with slightly raised main vein, possibly inflated and terete when live in some populations, upper leaves cauline and partly sheathing, uppermost entirely sheathing, often vestigial. *Spike* (1)3- or 4-flowered, branches 1- to 3-flowered; bracts green, hyaline or reddish along margins, 6–8 mm long, inner ± as long, or longer than outer. *Flowers* actinomorphic, white (to creamy white), often yellow in throat, rotate to cup-like, outer tepals usually flushed deep pink or purple outside; perianth tube 6–8 mm long, exceeding bracts by 1–2 mm or more; tepals 8–15 × ± 6 mm. *Filaments* erect, equal, 3–5 mm long; anthers 3–5 mm long, white; pollen creamy white. *Style* dividing opposite or above apex of anthers, branches 3–4 mm long. *Capsules* ± ovoid, 7–8 mm long. *Flowering time*: September to November.



Distribution of ***Geissorhiza platystigma***.

Distribution of ***Geissorhiza geminata***.

Distribution and ecology: a narrow endemic of Western Cape, South Africa, extending from the Cold Bokkeveld and upper Tulbagh Valley in the north to Brandvlei near Worcester in the south; semi-aquatic, in sandy marshes, ponds and vleis, often in standing water.

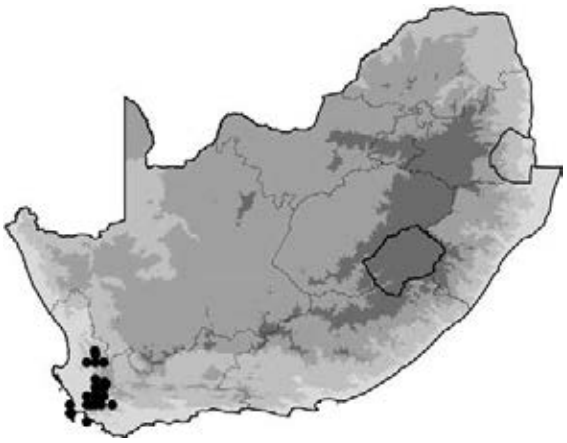
Diagnosis: recognised by the wetland habitat, white flowers, and corms with concentric tunics, *Geissorhiza geminata* also has an unusual branching pattern: when branched, the stem forks into two ± equal axes, thus in dichotomous fashion, the main stem then hardly different from the branch. *Geissorhiza geminata* is superficially similar to *G. brehmii*, which is also semi-aquatic and has fairly large white flowers, but *G. brehmii* has the imbricate corm tunics of subg. *Geissorhiza* and also differs in having terete leaves, whereas *G. geminata* has plane or possibly hollow terete leaves without visible or raised margins.

Distribution of ***Geissorhiza ovalifolia***.

21. **Geissorhiza ovalifolia** *R.C.Foster* in Contributions from the Gray Herbarium of Harvard University 135: 58 (1941); Goldblatt: 329 (1985). Type: South Africa, [Western Cape], 'Drakensteinsbergen, 4 000–5 000 ft [1 200–1 500 m]', Oct., *Drège s.n.* (B, holo.; G, S, iso.).

Plants small, 30–70(–90) mm high. *Corm* ovoid, ± 2 mm diam., tunics concentric, soft-papery. *Stem* usually prostrate near base, upright distally, rarely 1-branched. *Leaves* 4 or 5, lower 3 or 4 basal, prostrate, plane, lanceolate-oblong, or ovate, acute, 10–40 × 2–5 mm wide, uppermost cauline, entirely sheathing, with a cormlet in axil of 1 or more basal or rarely cauline leaves. *Spike* 1 to 4(–6)-flowered, flexuose; bracts soft, ± membranous above, 4–7 mm long, inner usually slightly shorter than outer. *Flowers* actinomorphic, rotate, white, yellow in throat; perianth tube 2–3 mm long, flaring from base; tepals ovate, 6–8 × ± 3.5 mm. *Filaments* erect, equal; 2–3 mm long; anthers 1.5–3.0 mm long, white. *Style* dividing opposite apex of anthers, branches 1.2–2.0 mm long. *Capsules* ovoid, 3–5 mm long. *Flowering time*: late September to mid-November.

Distribution and ecology: mountains of Western Cape, South Africa, from Twenty Four Rivers Mtns in the north to Franschhoek in the south; usually in shaded sites in damp moss on rock outcrops and cliffs.



Diagnosis: the diminutive and small-flowered *Geissorhiza ovalifolia* is distinguished by the stem prostate at the base and erect distally, and four or five plane leaves, at least the lower three or four prostrate and ovate to oblong. Plants often produce a cormlet in the axils of the basal and even cauline leaves. The flowers are white with a pale yellow throat and have a perianth tube 2–3 mm long and tepals 6–8 mm long. It is often confused with the more widespread and common *G. bolusii*, which occurs in similar habitats in the Western Cape mountains. *Geissorhiza ovalifolia* is evidently sexually fertile, and capsules develop rapidly after blooming whereas the triploid *G. bolusii* is sexually sterile and reproduces by the production of cormlets in all basal and cauline leaf axils as well as in the axils of the floral bracts after flowering. The two can sometimes also be distinguished by the number of cauline sheathing leaves, one in *G. ovalifolia* but usually several in *G. bolusii*, however the difference does not always hold.

22. **Geissorhiza bolusii** *Baker*, Handbook of the Irideae: 158 (1892); Goldblatt: 330 (1985). Type: South Africa, [Western Cape], Du Toits Kloof, 2 300 ft [700 m], *H. Bolus s.n.* (*BOL 5247* in K, lecto., effectively designated by Foster: 57 (1941); BOL, isolecto.).

Geissorhiza rupestris Schltr.: 98 (1899). Type: South Africa, [Western Cape], mtns above Bain's Kloof, 2 400 ft [730 m], *Schlechter 9167* (B, lecto., designated by Foster: 139 (1941); B, BM, BOL, E, G, H, K, L, MO, PH, PRE, Z, isolecto.)

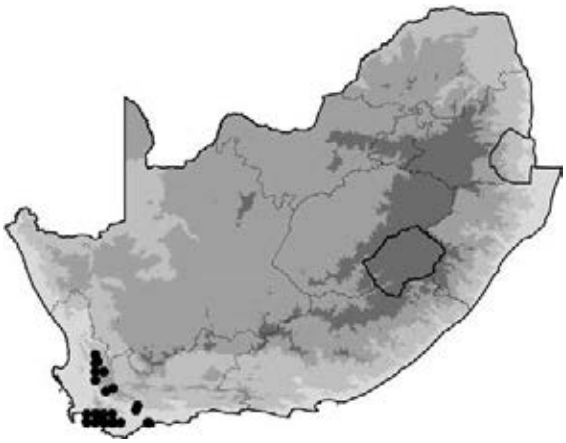
Geissorhiza dregei Baker: 158 (1892). Type: South Africa, [Western Cape], Paarl mtns, *Drège s.n.* '*G. secunda* fl. Ker a' (K, lecto., effectively designated by Foster: 139 (1941), K; BM, E, G, K, L, MO, isolecto.).

Plants 30–80(–110) mm high. *Corm* ± ellipsoid, 2–4 mm diam.; tunics brown, concentric, brittle-papery, notched below into sections, and drawn into points above. *Stem* usually prostrate at base, erect above, occasionally branched, bearing a small cormlet in each axil. *Leaves* mostly 3 to 5, basal, sword-shaped to lanceolate, acute, usually prostrate, plane, stem also bearing small, sheathing leaves. *Spike* 2- to 8-flowered, or flowers all aborted but floral bracts subtending cormlets; bracts 3–6(–10) mm long, inner ± as long or longer than outer when subtending flowers, smaller when flowers aborted, a cormlet produced in axil of each sterile bract and after flowering also in axils of floral bracts. *Flowers* actinomorphic, rotate, white (or not produced); perianth tube funnel-shaped, 3–4 mm long, reaching apex of bracts or shortly exserted; tepals spreading, ovate, 7–10 × 2–3 mm. *Filaments* erect, equal, 3–4 mm long; anthers 2–3 mm long, white. *Style* dividing near apex of anthers, branches ± 1.5 mm long. *Capsules* and *seeds* never developed. *Chromosome number* $2n = 39$. *Flowering time*: October to December (to January).

Distribution of ***Geissorhiza bolusii***.

Distribution and ecology: mountains of Western Cape, South Africa, from the northern Cederberg to the Cape Peninsula and east to the western end of the Riviersonderend Mtns; on shady south-facing slopes, cliffs and damp rocks, often in moss pads.

Diagnosis: diminutive, white-flowered *Geissorhiza bolusii* is unusual in the genus mainly in the several plane, more-or-less sword-shaped leaves usually prostrate or arching toward the ground, the several, small cauline, sheathing leaves, and the presence of two kinds of stems. Some produce no flowers but develop a cormlet in the axil of each flower bract, while others bear small white flowers but no capsules, and a cormlet later develops in place of each aborted bloom. Most populations comprise plants of both kinds, including the type collections of *G. bolusii* and its synonym, *G. rupestris*. The species is also cytologically unusual, being triploid, $2n = 39$ (counts from five populations from different parts of its range), and it never reproduces by seed. Reproduction is exclusively by the small axillary cormlets. *Geissorhiza bolusii* is probably most closely related to *G. ovalifolia*, which grows in similar habitats and also has small, white flowers but usually has none or only one cauline leaf or bract and produces one or few cormlets in its leaf axils. Fruit development is evidently fairly rapid and immature capsules can be seen in some collections in which fading blooms are present at the tips of spikes.



23. **Geissorhiza parva** *Baker* in Bulletin of Miscellaneous Information, Kew 1906: 26 (1906); Goldblatt: 331 (1985). Type: South Africa, [Western Cape], Houw Hoek, *Penther 723* (K, holo.).

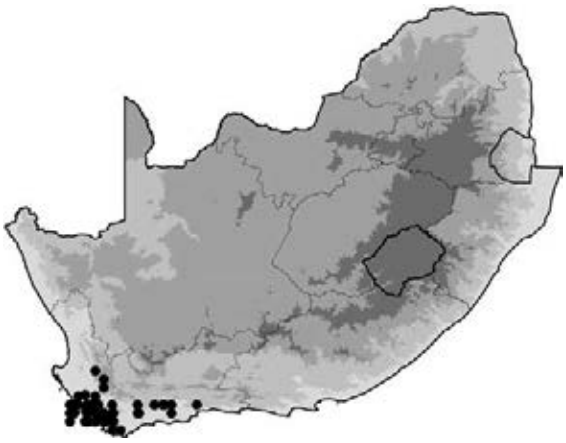
[*Geissorhiza dregei* sensu Baker: 158 (1892) & :74 (1896), in part (excluding type but including *G. bolusii* Baker).]

Plants small, 40–70(–120) mm high. *Corm* ovoid-conic, asymmetric, obliquely flattened toward base, flat part extending downward, 3–5 mm diam.; tunics dark brown, concentric, firm-woody, fragmenting irregularly. *Stem* smooth, often prostrate at base, erect above, simple or rarely branched, flexed above cauline leaf. *Leaves* 3 or 4, all basal or uppermost cauline, 15–20(–45) mm long, prostrate or inclined, much shorter than stem, sword-shaped to oblong, sometimes ± ovate, rarely linear, usually minutely dotted or streaked with red, acute or obtuse, margins occasionally ciliate to papillose toward apex. *Spike* (1)2- to 6-flowered; bracts usually red on margins, 4–6(–8) mm long, inner slightly shorter than outer. *Flowers* actinomorphic, rotate, creamy white to pale yellow; perianth tube 3–4 mm long, included or just exserted from bracts, gradually widening from base; tepals spreading, ± ovate, 6–8 × 2.5–3.5 mm. *Filaments* erect, equal, ± 2 mm long; anthers 2.0–2.5 mm long; creamy white; pollen yellow. *Style* dividing opposite apex of anthers, branches 1.5–2.0 mm long. *Capsules* globose to oblong, 3–7 mm long. *Flowering time*: mid-August to October (to early December at high elevations).

Distribution and ecology: endemic to the Western Cape, South Africa, extending from the Cederberg in the north to the Langeberg near Swellendam in the east; mainly montane at middle to upper elevations but occasionally at low elevations near the coast in the Caledon District, either in open ground or more often on wet rocky pavement in sand or damp moss pads.

Diagnosis: a small plant, *Geissorhiza parva* is recognised by the creamy white to pale yellow flowers with a perianth tube 3–4 mm long, tepals 6–8 mm long and by the three or four, short, inclined to prostrate leaves mostly up to 20 mm long (but occasionally up to 45 mm). Populations occurring north of the Hex River Mtns can often be distinguished by having four leaves, in contrast to the southern populations, which normally have only three, but the difference is not without exception. Some northern populations of *G. parva* can be difficult to distinguish from the related *G. ovalifolia*, but this species has white flowers, softer-textured leaves and usually an axillary cormlet in one or more of the lower leaf axils. Hybrids have been recorded between *G. parva* and the taller and larger-flowered *G. ovata* near Caledon, and are intermediate between the two species.

Distribution of ***Geissorhiza parva***.



24. **Geissorhiza ovata** *(Burm.f.) Aschers. & Graebn.*, Synopsis der Mitteleuropäischen Flora 3: 540 (1906). *Ixia ovata* Burm.f.: 1 (1768); Goldblatt: 333 (1985). Type: South Africa, precise locality not known, *Burman s.n.* (G: Herb. Burman, holo.).

Type: South Africa, precise locality unknown, *Thunberg s.n.* (UPS–THUNB 951 '*Ixia excisa* α', lecto., effectively designated by Brown (1928); S: Herb. Montin, S: Herb. Castrom, S: Herb. Swartz, isolecto.).

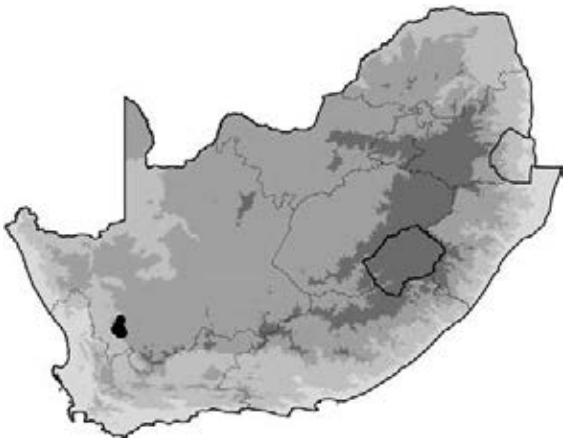
[*Weihea elatior* Eckl.: 22 (1827), invalid name without description.]

Plants 60–150 mm high. *Corm* ± ovoid, asymmetric, obliquely flattened below; tunics brown, concentric, drawn into points above. *Stem* often prostrate for a short distance at base, erect above, rarely branched. *Leaves* 2 or 3, lower 2 basal, prostrate or inclined, much shorter than stem (10–)15–30(–60) mm long, 5–12(–14) mm wide, ovate-oblong, acute or obtuse, sometimes ciliate-pubescent on veins (rarely throughout), frequently minutely brown-pellucid dotted, margins thickened, usually ciliate, often reddish, uppermost inserted on upper part of stem, often entirely sheathing. *Spike* (1)2- to 6-flowered; bracts firm, often brown dotted, 7–10(–12) mm long, inner slightly shorter than outer. *Flowers* actinomorphic, salver-shaped, white or pale pink above with red marks at tepal bases, dark red (to brown) outside; perianth tube cylindric, 10–18(–30) mm long, well exserted from bracts; tepals spreading, ± elliptic, (7–)10–13 × (3.5–)5.0–7.0 mm. *Filaments* erect, equal, 5–7 mm long; anthers 2–4 mm long, white; pollen white. *Style* dividing at or near apex of anthers, branches 1.5–2.5 mm long. *Capsules* globose, 6–8 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: (late July) August to October.

Distribution and ecology: extending from the Cape Peninsula north to the Olifants River Mtns and east to the Langeberg at Garcia's Pass in Western Cape, South Africa; mainly montane at middle to upper elevations but also at low elevations near the coast, in stony sandstone soils, usually very common after fires.

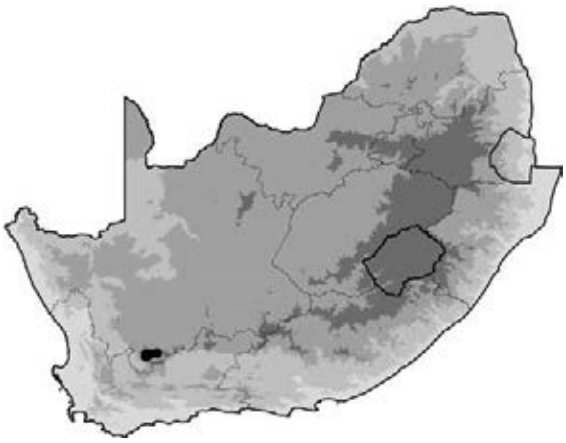
Distribution of ***Geissorhiza ovata***.

Diagnosis: easily recognised by the pair of ovate or oblong basal leaves, prostrate or nearly so, and the stem prostrate near base, *Geissorhiza ovata* has long-tubed white flowers marked with red in the centre and red to brown on the reverse of the tepals. The perianth tube, mostly 10–18 (rarely up to 30) mm, is well exserted from the bracts and the spreading tepals are typically 10–13 mm long. It is allied to *G. parva*, a smaller species with a similar habit with short, prostrate or semi-prostrate leaves but smaller yellow to creamy-white flowers, with a perianth tube 3–4 mm long. *Geissorhiza ovata* is quite variable as to height and flower size, and although the perianth tube is typically 10–18 mm long it is up to 30 mm long in plants from the Klein River Mtns. Plants from near the eastern end of its range near Swellendam have the smallest flowers with tepals ± 7 mm long, although the perianth tube is of normal length. None of these variants seems worth taxonomic recognition.



Sect. 2. **Tortuosae** *R.C.Foster* in Contributions from the Gray Herbarium of Harvard University 135: 69 (1941). Type: *Geissorhiza corrugata* Klatt

Leaves linear to subterete, all basal, straight or twisted; stem smooth, short; spike 1(2)-flowered; flowers actinomorphic or zygomorphic with stamens and style declinate (*G. karooica*), the style shorter than or reaching to the apex of the anthers.



Species 3: western Karoo, South Africa.

25. **Geissorhiza corrugata** *Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 391 (1882); Goldblatt: 336 (1985). Type: South Africa, [Northern Cape], Hantam Mtns, *Meyer 24* (B, holo.).

Plants small, up to 50 mm high, including flowers. *Corm* asymmetric, ovoid with an oblique flat side extending downward as a prominent ridge, 5–7 mm diam.; tunics brown, concentric. *Stem* single or 2 or 3 produced from base. *Leaves* 3 or 4, all basal, ± 30 mm long, 1–2 mm wide, laxly twisted spirally, margins lightly thickened, the uppermost sheathing the stem below and ± straight. *Spike* 1(2)-flowered; bracts green to ± membranous, 12–15 mm long, pale or flushed red and spreading distally, inner slightly shorter than outer. *Flowers* actinomorphic, ± rotate, yellow; perianth tube funnel-shaped, ± 3 mm long; tepals ovate, 12–15 × 4–6 mm, outer wider

Distribution of ***Geissorhiza corrugata***.

Distribution of ***Geissorhiza spiralis***.

than inner. *Filaments* erect, equal, 4–5 mm long; anthers ± 5 mm long, yellow; pollen yellow. *Style* 6–7 mm, dividing ± opposite base of anthers, branches up to 6 mm long, ± spreading to laxly recurved. *Capsules* globose to ovoid, 8–10 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: mainly August to mid-September.

Distribution and ecology: a local endemic of the Calvinia District of the western Karoo in Northern Cape, South Africa; on seasonally wet, poorly drained clay flats.

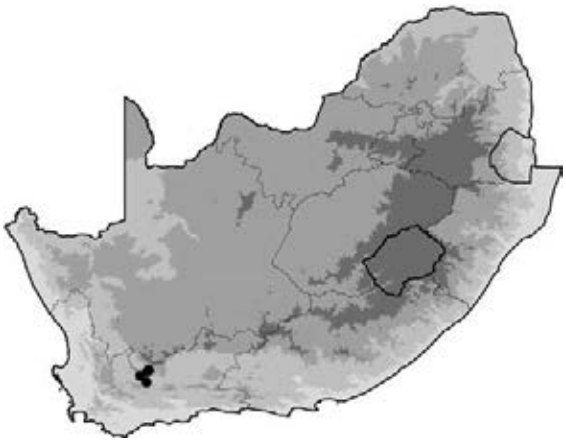
Diagnosis: *Geissorhiza corrugata* stands out in its small size, up to 50 mm tall, including the flowers, and in its loosely spirally coiled leaves. The bright yellow flowers and borne singly on the stems, and have a short perianth tube up to 3 mm long, spreading tepals, and a style dividing ± opposite the bases of the anthers. It shares these distinctive leaf and style features with *G. spiralis*, which has purple to deep pink flowers with a longer perianth tube. Greenhouse-grown plants have shown that flowers of *G. corrugata* are self-compatible and autogamous. The short style and spreading branches facilitate self-fertilization. Plants are often exceedingly common locally and can make a striking display, the yellow blooms visible from a considerable distance.

26. **Geissorhiza spiralis** *(Burch.) M.P.de Vos ex Goldblatt* in Annals of the Missouri Botanical Garden 72: 337 (1985). *Trichonema spirale* Burch.: 260 (1822). *Romulea spiralis* (Burch.) Baker: 90 (1877). *Bulbocodium spirale* (Burch.) Kuntze: 700 (1891). Type: South Africa, [Northern Cape], Roggeveld, Jakkalsfontein–Renosterrivier, *Burchell 1356* (K, holo.).

Plants 25–45 mm high, including flowers. *Corm* ovoid, asymmetric with an oblique flat side below, extending downward shortly, 4–7 mm diam.; tunics brown, concentric. *Stem* single or 2 or 3 produced from base, partly or entirely concealed by leaf bases. *Leaves* usually 4, basal, coiled or twisted distally, uppermost sometimes straight and usually sheathing part or all of stem, 0.5–2.0 mm wide, margins and main vein lightly thickened. *Spike* 1-flowered; bracts 10–13 mm long, membranous, pale green flushed purple above, inner slightly shorter than outer. *Flowers* actinomorphic, shallowly cup-shaped, purple to deep pink with white heart-shaped markings at tepal bases edged with dark red-purple, throat and tube pale yellow; perianth tube funnel-shaped, 4–5 mm long; tepals broadly ovate, 13–15 × 8–10 mm, outer wider than inner. *Filaments* erect, equal, ± 4 mm long; anthers 5–6 mm long, yellow. *Style* 6–7 mm long, dividing near base of anthers; branches ± 5 mm long, laxly spreading. *Flowering time*: September.

Distribution and ecology: a rare species, evidently restricted to the southern Roggeveld near Sutherland in Northern Cape, South Africa; on rocky slopes in sandy ground.

Diagnosis: *Geissorhiza spiralis* is distinguished by its four (rarely three) twisted leaves, solitary-flowered spikes, and style dividing opposite the base of the anthers. These features are also characteristic of *G. corrugata*, which has bright yellow flowers with a perisanth tube ± 3 mm long whereas *G. spiralis* has purple to deep pink flowers marked white and red-purple at the base of the tepals and a perianth tube 4–5 mm long.



27. **Geissorhiza karooica** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 338 (1985). Type: South Africa, [Western Cape], near Matjiesfontein, foot of Ghaap Kop, *Goldblatt 6371* (MO, holo.; BOL, K, NBG, PRE, S, UC, US, WAG, iso.).

Plants 30–60 mm high. *Corm* globose, ± 5 mm diam.; tunics light brown, concentric, outer layers fragmenting into unequal vertical sections. *Stem* simple or 2- or 3-branched from base. *Leaves* 4 to 6, all basal, linear, 1.0–1.8 mm wide, ± as long as stem, upper 2 or 3 sheathing stem below, erect or becoming falcate, plane, margins not thickened. *Spike* 1-flowered; bracts 8–12 mm long, membranous, ± dry, brown above, inner ± as long or slightly shorter than outer. *Flowers* zygomorphic, salver-shaped, half nodding, dark violet-purple, yellow

at base of tepals and in throat; perianth tube 5–8 mm long, ± cylindric, exserted from bracts; tepals subequal, lanceolate, obtuse, 12–15 × 4–5 mm, spreading at right angles to tube. *Filaments* unilateral, declinate, equal, 8–10 mm long; anthers 2.5–3.3 mm long, white; pollen white. *Style* dividing between base and middle of anthers, branches 1.2–2.0 mm long. *Capsules* ± oblong, 8–11 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: August to September.

Distribution and ecology: margins of the western Karoo between Matjiesfontein and Whitehill in Western Cape, South Africa, and in the Klein Roggeveld in Northern Cape; on coarse, broken shale flats and slopes.

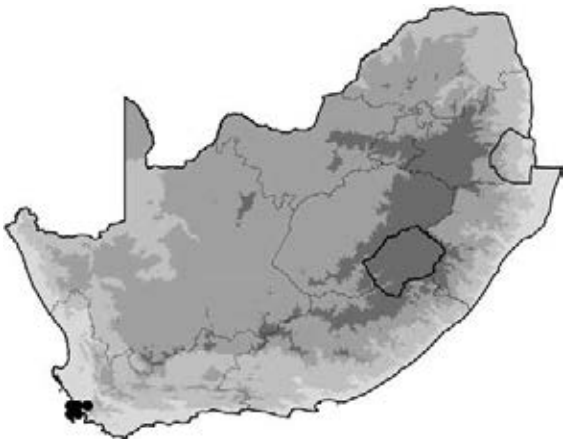
Diagnosis: a dwarf species, *Geissorhiza karooica* is distinctive in having half nodding flowers solitary on stems or branches, of which up to four may be produced on each plant. The glossy violet-purple flowers are large and attractive and unusual in being zygomorphic with unilateral, declinate stamens, while the tepals are subequal and symmetrically arranged. Plants have four to six narrow, linear leaves inserted at the base, up to 1.8 mm wide. *Geissorhiza karooica* appears to be allied to two western Karoo species, *G. corrugata* and *G. spiralis*, which have radially symmetric flowers also borne singly on each branch but with spirally coiled leaves, and are also distinctive in having the style dividing near the anther bases into unusually long branches.

Distribution of ***Geissorhiza karooica***.

Sect. 3. **Pusillae** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 339 (1985) [as sect. *Pusilla*]. Type: *Geisshoriza pusilla* (Andrews) Klatt

Corm with woody tunics; leaves narrowly sword-shaped, ± plane, minutely hairy on margins and lower part of blade; stem smooth; spike few flowered, bracts green below, dry and ferrugineous in upper half; flowers actinomorphic, rotate; perianth tube very short.

Species 1: southwestern Western Cape, South Africa.



28. **Geissorhiza pusilla** *(Andrews) Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 392 (1882); Goldblatt: 339 (1985). *Ixia pusilla* Andrews: t. 245 (1802). *G. secunda* var. *pusilla* (Andrews) Baker: 155 (1892). Type: South Africa, [Western Cape], exact locality unknown, illustration in Andrews: t. 245 (1802).

Geissorhiza pubescens Wolley-Dod: 171 (1900). Type: South Africa, [Western Cape], Signal Hill, *Wolley-Dod 1602* (K, lecto. effectively designated by Foster: 50 (1941); B, BM, BOL, iso.).

[*Geissorhiza nigromontana* Eckl., unpublished manuscript name.]

Plants small, (70–)120–300 mm high. *Corm* globose, evidently asymmetric with a down-pointing ridge on one side, 4–10 mm diam.; tunics light brown, concentric. *Stem* simple or 1- or 2-branched. *Leaves* 2 to 4, lower 2 or 3, or all basal, reaching to ± base of spike, lanceolate, erect or falcate, 3–8 mm wide, margins and often sheaths and lower parts of blades softly long-hairy, margins often ciliate, upper leaves smaller, usually mostly sheathing stem, uppermost shortest and often entirely sheathing. *Spike* (1)2- to 6-flowered; bracts below, brown and dry and spreading in upper half, 5–8 mm long, inner shorter than outer. *Flowers* actinomorphic, rotate, pale to deep blue or blue-mauve; perianth tube funnel-shaped, 1–2 mm long; tepals elliptic, 7–10 × 3–4 mm. *Filaments* erect, equal, ± 2 mm long; anthers ± 3 mm long, yellow. *Style* 4–5 mm long, branches ± 1 mm long. *Capsules* obovoid to subglobose, 5–7 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: (late August) September to early October.

Distribution and ecology: a narrow endemic of the Cape Peninsula and nearby hills in Western Cape, South

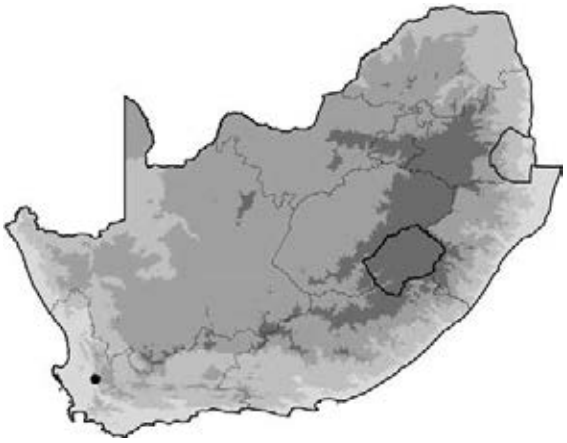
Distribution of ***Geissorhiza pusilla***.

Africa, possibly extending to Caledon; damp, often shady places, mainly montane at low to middle elevations, usually on shale or granite-derived soils.

Diagnosis: evidently taxonomically isolated, *Geissorhiza pusilla* stands out in subg. *Weihea* in its plane, softly hairy leaves with ciliate margins and small blue to blue-mauve flowers. It closely resembles the common *G. aspera*, which has ± black, imbricate corm tunics characteristic of subg. *Geissorhiza*, a puberulous stem and usually unequal stamens with one shorter filament. *Geissorhiza pusilla* has light brown concentric corm tunics, a hairless stem, and the stamens are equal in length.

Sect. 4. **Includantherae** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 340 (1985) [as sect. *Includanthera*]. Type: *Geisshoriza cedarmontana* Goldblatt

Corm with tunics woody, concentric; leaves linear, plane or with margins and midrib thickened; spike few flowered; flowers salver-shaped; perianth tube elongate, exserted from bracts; stamens and style short, included in lower half of tube.



Species 2: mountains of the West Coast, South Africa.

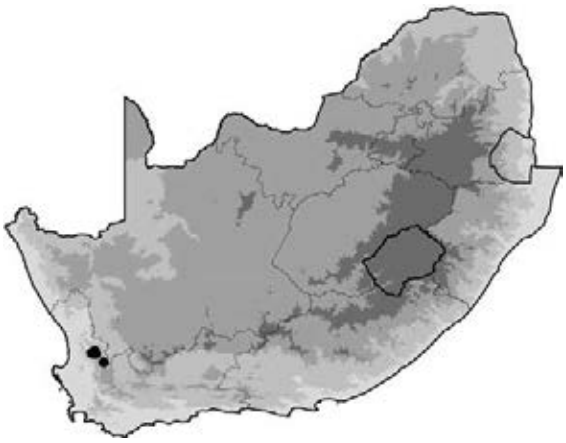
29. **Geissorhiza esterhuyseniae** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 341 (1985). Type: South Africa, [Eastern Cape], Great Winterhoek Mtns, crevices in cliffs and rocky ledges, *Esterhuysen 28519A* (BOL, holo.).

Plants 70–180 mm high. *Corm* unknown. *Stem* apparently inclined to trailing from sloping to inclined rocks. *Leaves* (3)4, plane, (2)3 basal or third inserted in lower part of stem, ± falcate, ± half as long as stem, 3–5 mm wide, ± plane, obtuse, margins lightly thickened, uppermost inserted on upper half of stem, entirely sheathing. *Spike* 1- to 3-flowered; bracts green, becoming pale and membranous above, 12–14 mm long, inner ± as long or shorter than outer. *Flowers* actinomorphic, salver-shaped, white, fragrant; perianth tube cylindric, 10–16 mm long, including stamens and style, well-exserted from bracts; tepals obovate 13–15 ± 7 mm. *Filaments* included, ± 3 mm long, inserted 2.5 mm above base of tube; anthers ± 4.5 mm long, not reaching top of tube. *Style* ± 0.5 mm long, dividing below base of filaments, branches 2 mm long. *Flowering time*: October.

Distribution and ecology: known only from a single collection from high elevations in the Groot Winterhoek Mtns of Western Cape, South Africa; trailing from cliffs and steep slopes.

Diagnosis: one of the most remarkable species in the genus, *Geissorhiza esterhuyseniae* has both stamens and style included within a relatively long perianth tube up to 16 mm long. This set of characters is known elsewhere in *Geissorhiza* in the northern Cederberg species, *G. cedarmontana*, and in *G. adriaanii* (sect. *Engysiphon*) from Piketberg. Corms are not known for *G. esterhuyseniae* and it is included in subg. *Weihea* because of its morphological similarity to *G. cedarmontana*. This species has a perianth tube 13–15 mm long, comparable with that of *G. esterhuyseniae*, but shorter filaments 1 mm long and the white flowers have red at the tepal bases, whereas *G. esterhuyseniae* has uniformly white flowers with filaments ± 3 mm long. Both species grow in similar sheltered, south-facing rocky situations.

Distribution of ***Geissorhiza esterhuyseniae***.



30. **Geissorhiza cedarmontana** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 341 (1985). Type: South Africa, [Western Cape], Cederberg, Middelberg, *Goldblatt 5145* (MO, holo.; K, NBG, PRE, S, WAG, iso.).

Plants (70–)120–350 mm high. *Corm* globose, symmetric, ± 10 mm diam., tunics concentric, pale brown, notched below into segments and drawn into bristles above. *Stem* erect or inclined, unbranched. *Leaves* 2 or 3, usually lower 2 well developed, basal, upper of these sheathing stem for some distance, linear, shorter or ± as long as stem, 1–2 mm wide, margins and midrib heavily thickened, thus with 2 longitudinal grooves on each surface, uppermost leaf cauline, sometimes entirely sheathing. *Spike* flexuose (1)2- to 5-flowered; bracts 7–11 mm long, green, margins hyaline, outer obtuse, inner membranous, slightly shorter than outer. *Flowers* actinomorphic, salver-shaped, pale to deep pink, with red spot at base of each tepal; perianth tube cylindric, 13–15 mm long, well-exserted from bracts, including stamens and style; tepals ovate, spreading, 12–14 × 6–7 mm, outer wider than inner. *Filaments* included, ± 1 mm long, inserted ± 1.8 mm above base of perianth tube; anthers ± 3 mm long, reaching to middle of tube. *Style* short, < 1 mm long, dividing below base

of filaments, branches short, ± 1 mm long. *Capsules* obovoid, 5–6 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: mid-October to November.

Distribution and ecology: restricted to the northern Cederberg in Western Cape, South Africa; on south-facing slopes, in rock outcrops or under boulders at ± 1 200 m elevation.

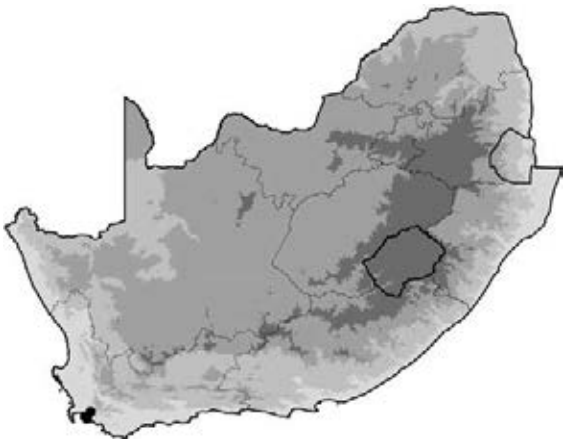
Diagnosis: *Geissorhiza cedarmontana* and the poorly known *G. esterhuyseniae* stand out in the genus in having stamens and style branches included within the relatively long perianth tube. *Geissorhiza cedarmontana* is recognised by its very short filaments, ± 1 mm long, inserted ± 2 mm above the base of the perianth tube, and a similarly short style less than 1 mm long, with three short poorly defined branches. The pink to almost white flowers have a red mark at the base of each of the spreading tepals. The leaves are also modified, having much thickened margins and main veins, thus with two longitudinal grooves running the length of each leaf surface. In contrast, *G. esterhuyseniae* has uniformly white flowers with filaments ± 3 mm long, inserted ± 2.5 mm above the base of the perianth tube, and better developed style branches some 2 mm long. The leaves of *G. esterhuyseniae* are flat, with only slightly raised margins and main veins.

Distribution of ***Geissorhiza cedarmontana***.

Sect. 5. **Angustifoliae** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 343 (1985) [as sect. *Angustifolia*]. Type: *Geisshoriza humilis* (Thunb.) Ker Gawl.

Geissorhiza subsect. *Filiformes* Foster: 18 (1941). Type: *G. juncea* (Link) A.Dietr.

Corm tunics mostly hard and woody, occasionally soft and papery; leaves with margins and main vein heavily thickened, narrowly sword-shaped to linear, sometimes terete; bracts green, often membranous and dry above; flowers usually rotate, actinomorphic; perianth tube short, reaching to apex of bracts, or elongate, exceeding bracts.



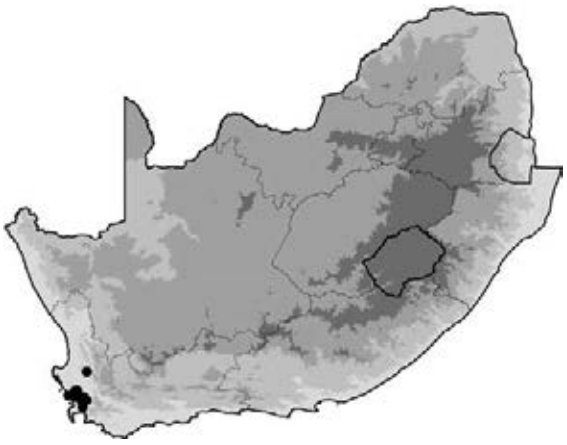
Species 12: southwestern Western Cape, South Africa.

31. **Geissorhiza lithicola** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 343 (1985). Type: South Africa, [Western Cape], between Kogelberg and Steenbras, *Esterhuysen 35262* (BOL, holo.; K, MO, PRE, S, WAG, iso.).

Plants 150–300 mm high. *Corm* ± globose, flattened obliquely below, 6–10 mm diam.; tunics hard, woody, light brown, splitting into vertical sections, drawn into points above. *Stem* smooth, unbranched. *Leaves* usually 3, lower 2 basal and longest, ± half as long to as long as stem, ± 2 mm wide, sheaths sticky, with sand adhering, margins and main veins much thickened, with edges ciliate, upper leaf cauline and sheathing in lower half. *Spike* flexuose, mostly 2- to 4-flowered; bracts becoming dry and membranous near tips, inner shorter and narrower than outer. *Flowers* actinomorphic, rotate, purple; perianth tube funnel-shaped, 7–8 mm long; tepals ellipsoid, 15–20 × 7–9 mm. *Filaments* erect, equal, 6–7 mm long; anthers ± 5 mm long, yellow; pollen yellow. *Style* dividing opposite anther tips, branches 2–3 mm long. *Flowering time*: October.

Distribution and ecology: a poorly documented, narrow endemic of the Kogelberg in Western Cape, South Africa; in stony, sandstone ground, seen only after fire.

Diagnosis: *Geissorhiza lithicola* is distinguished by the hard woody corm tunics, and large, violet-purple flowers with tepals 15–20 mm long and relatively short perianth tube 7–8 mm long. The anthers are yellow. Plants typically have three leaves, the lower two basal and with linear blades with the margins and main veins heavily thickened.



Distribution of ***Geissorhiza lithicola***.

32. **Geissorhiza purpurascens** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 345 (1985). Type: South Africa, [Western Cape], Mamre road, *Barker 808* (NBG, holo.).

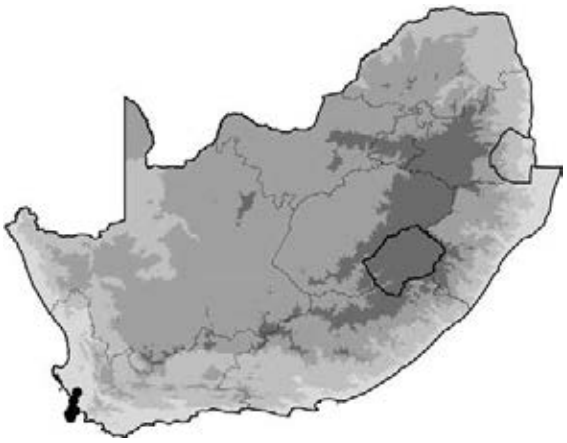
Plants (140–)180–300 mm high. *Corm* asymmetric, globose, with one side flattened below and extending downward, 6–8 mm diam.; tunics concentric, light brown, fragmenting irregularly, drawn into points above. *Stem* simple or 1-branched, flexed above sheathing part of leaves. *Leaves* 3, lower two basal, lowermost longest, ± half as long as stem, sometimes longer, 2–3(–5) mm wide, sticky and with adhering sand, linear, margins and main vein thickened, broadly 2-channelled on each surface, margins and edges of main vein ciliate, second leaf shorter, sheathing stem below, upper leaf inserted in middle of stem, partly to entirely sheathing. *Spike* flexed at base, flexuose, inclined to horizontal with flowers on upper side, 4- to 10-flowered; bracts 6–9 mm long, margins hyaline, becoming pale and dry above, inner shorter than outer. *Flowers* actinomorphic, rotate, pale to deep mauve (darker when dry); perianth tube funnel-shaped, 3–4(–6) mm long; tepals elliptic, 0–16 × 6–8 mm. *Filaments* erect, equal, 4–6 mm long; anthers 3.5–4.5 mm long, yellow; pollen yellow. *Style* dividing near apex of anthers, branches ± 2.5 mm long. *Flowering time*: September to early October.

Distribution and ecology: rare and local in southwestern Western Cape, South Africa, between Paarl Mtn and the coast near Mamre and Darling but with an isolated population on the south slopes of the Piketberg; in deep quartzitic sands, often in seasonally wet sites.

Diagnosis: *Geissorhiza purpurascens* is distinguished by the hard, woody, concentric corm tunics, three narrow leaves, the lower two with thickened margins and main vein, and ciliate edges, and light to dark purple flowers borne on an inclined, flexuose spike. The leaves are ± oblong in cross section with two broad channels on each surface between the margins and main vein. It is perhaps most closely related to *G. juncea*, but that species has somewhat smaller, white to yellow flowers and terete leaves. Plants from well-drained, stony, south-trending slopes of the Piketberg appear to belong here but are unusual in having broader leaves, up to 5 mm wide, and flowers with a somewhat longer perianth tube, ± 6 mm long, compared to populations to the south and west, which have leaves only 2–3 mm wide and a perianth tube 3–4 mm long.

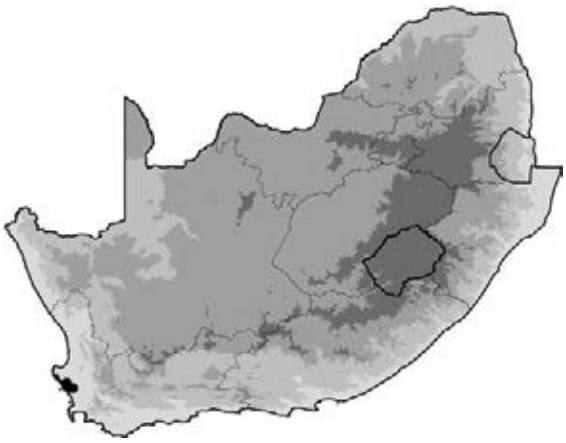
Distribution of ***Geissorhiza purpurascens***.

33. **Geissorhiza humilis** *(Thunb.) Ker Gawl.* in König & Sims, Annals of Botany 1: 242 (1804); Goldblatt: 346 (1985). *Ixia humilis* Thunb.: 8 (1783). Type: South Africa, [Western Cape], hills around Cape Town, *Thunberg s.n.* (UPS–THUNB 959 '*I. humilis* α', lecto., effectively designated by Brown: 47 (1928); S: Herb. Montin, S: Herb. Casstrom, isolecto.).



Geissorhiza humilis var. *grandiflora* Baker: 153 (1892). Type: South Africa, [Western Cape], fields near Claremont, *H. Bolus 4602* (K, lecto., designated by Goldblatt: 346 (1985); BM, BOL, SAM, isolecto.).

[*Trichonema humile* Ker Gawl. ex Steud.: 702 (1841), invalid name only in synonymy.]



Plants short, 80–140 mm high. *Corm* ± ovoid, asymmetric, obliquely flattened below; tunics light brown, concentric, fragmenting irregularly, drawn into bristles above. *Stem* inclined, flexed above base, rarely with a single branch. *Leaves* 2 or 3, lowermost basal, longest, falcate, exceeding stem, 1–3 mm wide, margins and midrib thickened and with 2 narrow grooves on each surface, second leaf smaller, uppermost usually cauline, sheathing below, ribbed, sometimes much reduced mostly to entirely sheathing, sticky, with sand adhering. *Spike* 2- to 8-flowered, flexuose; bracts 8–12 mm long, lightly ribbed, truncate, margins hyaline, inner as long but narrower than outer, sticky. *Flowers* actinomorphic, rotate, tepals spreading, bright or pale yellow, rarely with dark tube; perianth tube ± narrowly funnel-shaped, 5–8 mm long, barely to shortly exserted from bracts; tepals obovate-ellipsoid, 16–22 × 12–14 mm. *Filaments* erect, equal, 5–8 mm long; anthers ± 5 mm long, yellow. *Style* dividing opposite upper third of anthers, branches 3–4 mm long. *Capsules* oblong-cylindric, (8–)10–12 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: late August to October.

Distribution and ecology: a narrow endemic of Western Cape, South Africa, extending from the Cape Peninsula to Stellenbosch and Riverlands near Mamre Road; on coarse sandy ground, flowering well only after fire.

Diagnosis: *Geissorhiza humilis* is recognised by the relatively large, bright or pale yellow flowers with tepals 16–22 mm long, and three leaves, the blades with thickened margins and midribs, thus narrowly 2-grooved on each surface. Both the leaves and the floral bracts are sticky and usually have grains of sand adhering to them. Populations on the Cape Peninsula always have

Distribution of ***Geissorhiza humilis***.

Distribution of ***Geissorhiza darlingensis***.

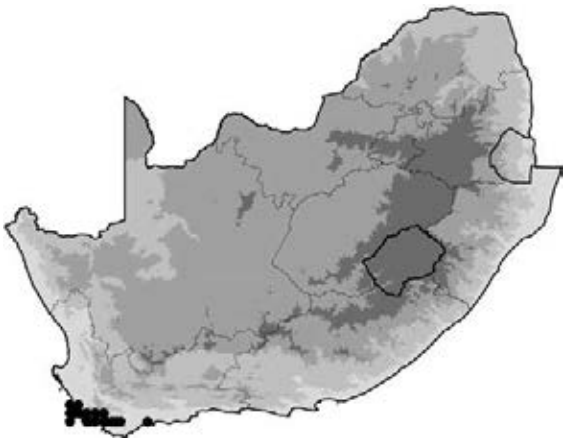
bright, golden yellow flowers but elsewhere the species may have pale yellow flowers, with or without a green or dark tube.

Geissorhiza humilis and the related but smaller flowered *G. hispidula* grow together at several sites on the Cape Peninsula, and often flower at the same time, when it is clear that they are quite different species although vegetatively they are almost identical. Not surprisingly, they have often been confused and their taxonomic history is intertwined. *Geissorhiza hispidula* can be distinguished by the smaller, creamy white flowers with short perianth tube 3–4 mm long and tepals 10–15 mm long, the outer marked red on the reverse, and spikes usually with 2 to 5 flowers, often fewer than in *G. humilis*. *Geissorhiza darlingensis*, restricted to the Darling area to the north of Cape Town, is closely allied to *G. humilis* and also vegetatively almost identical but has somewhat larger flowers with tepals 23–26 mm long, a tube 9–11 mm long vs. 5–8 mm in *G. humilis*, and longer filaments 8–9 mm long. The flowers also have a conspicuous dark centre.

34. **Geissorhiza darlingensis** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 348 (1985). Type: South Africa, [Western Cape], Tienie Versfeld Flower Reserve, Darling, ex hort. Kirstenbosch, *Roux s.n.* (NBG, holo.; MO, iso.).

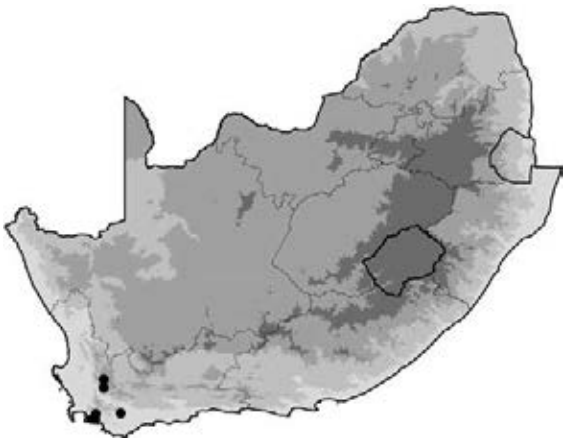
Plants 70–150 mm high. *Corm* ± ovoid, nearly symmetric, 5–8 mm diam.; tunics pale brown, breaking irregularly into vertical sections, drawn into points above. *Stem* flexed above sheath of cauline leaf and inclined, simple or with 1 or 2 branches. *Leaves* 3, lower 2 basal, linear, 2–3 mm wide, lowermost exceeding spike, second leaf shorter, margins and main vein much enlarged, ciliate along edges, with 2 wide grooves on each surface, sticky, often with sand adhering, uppermost leaf cauline, with inflated sheath, shorter than basal. *Spike* flexed at base, 2- to 5-flowered; bracts green, 10–15 mm long, ± truncate, inner smaller. *Flowers* actinomorphic, ± cupped, pale yellow with dark purple-black centre; perianth tube ± cylindric, 9–11 mm long, usually shortly exserted from bracts; tepals 23–26 × ± 12 mm. *Filaments* erect, equal, 8–9 mm long; anthers ± 5 mm long, yellow. *Style* dividing opposite upper third to shortly beyond anthers, branches ± 3 mm long. *Capsules* oblong-ellipsoid, truncate, 10–12 mm long. *Flowering time*: late September to mid-October.

Distribution and ecology: restricted to the immediate vicinity of Darling, north of Cape Town in Western Cape, South Africa; on damp sandy ground.



Diagnosis: a striking species, *Geissorhiza darlingensis* has large pale yellow flowers with a purple-black centre. Allied to *G. humilis* of the Cape Peninsula and adjacent West Coast, it has a longer perianth tube 9–11 mm long and tepals 23–26 mm long vs. perianth tube 5–8 mm long and tepals mostly 16–22 mm long in *G. humilis*. Both species have linear leaves with thickened margins and midribs and are sticky, usually with sand adhering to the surface. The ciliate edges of the leaf margins and main vein of *G. darlingensis* are evidently lacking in *G. humilis*. The distinction between the two species is not always clear where their ranges approach.

35. **Geissorhiza hispidula** *(R.C.Foster) Goldblatt* in Annals of the Missouri Botanical Garden 72: 349 (1985). *G. humilis* var. *hispidula* Foster: 19 (1941). Type: South Africa, [Western Cape], Cape Flats, *Zeyher 1599* (K, holo.; B, G, K, SAM, iso.).



Geissorhiza humilis var. *bicolor* Baker: 153 (1892). Type: South Africa, [Western Cape], Muizenberg, *MacOwan in Herb. Norm. Austr. Afr. 257* (K, lecto., designated by Goldblatt: 349 (1985); B, BOL, G, SAM, isolecto.).

[*Geissorhiza striata* Eckl.: 21 (1827), invalid name without description.]

Plants small, 70–150(–250) mm high. *Corm* ± ovoid, asymmetric, obliquely flattened on one side, 5–7 mm diam.; tunics concentric, woody, brown. *Stem* ± erect or inclined, smooth, rarely branched. *Leaves* 3, lower 2 basal, longest,

Distribution of ***Geissorhiza hispidula***.

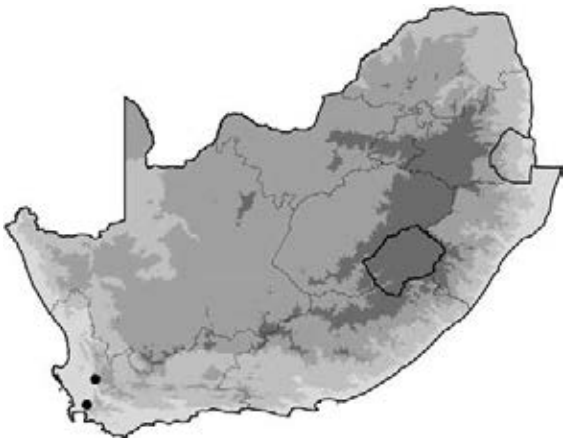
Distribution of ***Geissorhiza pappei***.

linear, erect to falcate, 1–2 mm wide, slightly longer than stem, margins and midrib much enlarged, with 2 narrow grooves on each surface, edges of margin and main vein smooth or minutely ciliate, usually sticky, with sand adhering, uppermost leaf cauline, short and sheathing below or entirely, sheath ribbed. *Spike* 2- to 5-flowered, flexuose; bracts with hyaline or reddish margins, 7–9 mm long, sticky, inner shorter than outer. *Flowers* actinomorphic, rotate, white to creamy white, often with outer tepals pink to red outside, tepals spreading; perianth tube 3–4 mm long, not or barely exceeding bracts; tepals narrowly elliptic, 10–15 × 5–8 mm. *Filaments* erect, equal, 3–4 mm long; anthers ± 3 mm long, yellow. *Style* dividing ± opposite apex of anthers, branches ± 2.5 mm long. *Capsules* ± obovoid-oblong, 5–8 mm long, exserted from bracts. *Chromosome number* 2*n* = 26. *Flowering time*: August to September.

Distribution and ecology: widespread in southern Western Cape, South Africa, extending from the Cape Peninsula eastward to Albertinia; in sandy ground, usually on flats or mountain plateaus and flowering only after fire.

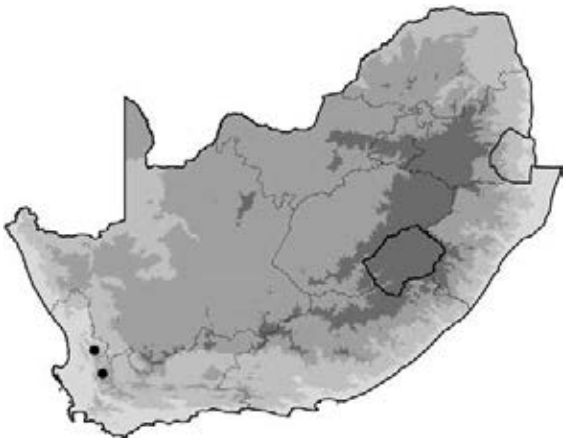
Diagnosis: *Geissorhiza hispidula* has small corms with concentric tunics, just three leaves, these with a sticky surface and thickened margins and main veins, and relatively small, creamy white flowers with a narrow perianth tube 3–4 mm long and narrowly elliptic tepals 10–15 × 5–8 mm. It has often been confused with *G. humilis*, with which it sometimes grows and flowers and then their differences are quite evident. *Geissorhiza humilis* has bright yellow flowers with broader tepals, 16–22 × 12–14 mm and a perianth tube 5–6 mm long.

36. **Geissorhiza pappei** *Baker*, Handbook of the Irideae: 154 (1892); Goldblatt: 351 (1985). Type: South Africa, [Western Cape], Zonder Einde Mtns [Riviersonderend Mtns], *Zeyher 3965* (K, lecto., designated by Foster: 20–21 (1941); B, SAM, isolecto.).



Plants small, 50–100 mm high. *Corm* ovoid, asymmetric, with base obliquely flattened on one side, 5–7 mm diam.; tunics concentric, soft and papery, light brown. *Stem* suberect, rarely branched. *Leaves* 3, lower 2 basal, linear and erect to falcate, lowermost longest, shortly exceeding stem, 0.5–1.3 mm wide, margins and main vein somewhat to much enlarged, then with 2 narrow grooves on each surface, edges of margins and main vein evidently smooth, often sticky and with sand adhering; uppermost cauline, short and sheathing below or entirely, sheath ribbed. *Spike* flexuose, 1- to 4-flowered; bracts green, hyaline above, 3–6 mm long, inner shorter than outer. *Flowers* actinomorphic, rotate, white to creamy white, tepals spreading; perianth tube 2.5–3.5 mm long, not or barely exceeding bracts; tepals narrowly obovate-elliptic, 6–9 × 2.5–4.0 mm. *Filaments* erect, equal, ± 2 mm long; anthers ± 2 mm long, yellow. *Style* dividing opposite apex of anthers, branches up to 0.7 mm long. *Flowering time*: September to early October.

Distribution and ecology: a rare and local endemic of southwestern Western Cape, South Africa, known from near Ceres, Highlands near Caledon and the Riviersonderend Mtns in the east; in sandy ground.



Diagnosis: evidently closely allied to *Geissorhiza hispidula* and very similar in leaf morphology, *G. pappei* is a smaller plant with smaller, white flowers with a perianth tube 2.5–3.5 mm long and tepals 6–9 mm long. The larger, usually creamy white flowers of *G. hispidula* have a perianth tube 3–4 mm long and tepals 10–15 long. *Geissorhiza pappei* is poorly known and requires additional study.

37. **Geissorhiza intermedia** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 352 (1985). Type: South Africa, [Western Cape], Banhoek, Spitzkop, 4 000 ft [1 200 m], *Esterhuysen 11887* (BOL, holo.).

Plants small, 50–120 mm high. *Corm* ovoid, 5–7 mm diam.; tunics concentric, firm textured, light brown. *Stem* ± erect, minutely and densely ciliate above uppermost leaf, rarely branched. *Leaves* 3, lower 2 basal, erect, sword-shaped to falcate, lowermost ± as long as

Distribution of ***Geissorhiza intermedia***.

Distribution of ***Geissorhiza unifolia***.

stem, 1.5–3.5 mm wide, often slightly sticky below and on sheath, with sand adhering, margins and midrib enlarged; with 2 broad grooves on each surface, margins and edges of main vein evidently smooth (rarely sparsely and minutely ciliate), uppermost leaf cauline, smallest. *Spike* flexuose, 1- to 3-flowered; bracts green, membranous above, 6–9 mm long, inner 1–2 mm shorter than outer. *Flowers* actinomorphic, rotate, white; perianth tube 2–3 mm long, not reaching apex of bracts; tepals narrowly obovate-elliptic, 8–10 × ± 4 mm. *Filaments* equal, erect, ± 4 mm long; anthers 2–3 mm long, yellow. *Style* dividing opposite apex of anthers, branches ± 2 mm long. *Flowering time*: September to October.

Distribution and ecology: a rare and local endemic of the southwestern mountains of Western Cape, South Africa, recorded from the Twenty Four Rivers Mtns, Banhoek and Simonsberg; in sandy ground.

Diagnosis: a small, inconspicuous plant, *Geissorhiza intermedia* stands out in its densely ciliate stem, an unusual character in subg. *Weihea* and is otherwise undistinguished in its white flowers with a short perianth tube 2–3 mm long and narrow leaves with strongly raised margins and main vein. It can easily be mistaken for the similar and probably closely related *G. hispidula*, which has a largely lowland distribution, and has narrower, sticky leaves and bracts and invariably a smooth stem. *Geissorhiza intermedia* may also be confused with *G. similis*, which is alike in general appearance but has imbricate corm tunics, a longer perianth tube, and also has smooth stems.

38. **Geissorhiza unifolia** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 353 (1985). Type: South Africa, [Western Cape], N Cederberg, peak at Koupoort, *Esterhuysen 12159* (BOL, holo.; MO, iso.).

Plants small, 50–100 mm high. *Corm* globose, ± 5 mm diam.; tunics brown, brittle papery, ± concentric, notched below, drawn into bristles above. *Stem* erect, flexed above leaf sheath, minutely papillate-ciliate especially below, unbranched. *Leaves* 2(3), lower basal, sheathing stem below, ± falcate, 0.5–1.3 mm wide, margins and main vein thickened, uppermost leaf entirely sheathing. *Spike* flexuose, 1- to 5-flowered; bracts 3.5–5.0 mm long, green below, dry and transparent to light brown above. *Flowers* actinomorphic, rotate, tiny, white, outer tepals purple-pink outside; perianth tube ± cylindric, 1.5–2.0 mm long; tepals ± elliptic, 3.5–5.0 × ± 2 mm. *Filaments* equal, erect, ± 2 mm long; anthers 1.0–1.8 mm long. *Style* dividing ± opposite middle of anthers, branches ± 1 mm long. *Capsules* globose, ± 4 mm long, shorter than bracts. *Flowering time*: October.

Distribution and ecology: a rare endemic of the Cederberg and Cold Bokkeveld Mtns of Western Cape, South Africa; at high elevations, 5 500–6 000 m, on thin soils over damp, rocky pavement, mostly on south-facing slopes.

Diagnosis: *Geissorhiza unifolia* is easily recognised by its single basal foliage leaf, minutely ciliate stem 50–100 mm high, and tiny flowers with tepals up to 5 mm long. The remaining one or two leaves are short and largely to entirely sheathing. The leaf sheath and cataphyll are sticky and have sand adhering to them. The papery, rather than woody corm tunics are concentric and fairly typical of subg. *Weihea*. The relationships of *G. unifolia* are uncertain but the ciliate stem recalls *G. intermedia*.

39. **Geissorhiza juncea** *(Link) A.Dietr.*, Species plantarum 2: 587 (1833); Goldblatt: 353 (1985). *Ixia juncea* Link: 50 (1821). *G. humilis* var. *juncea* (Link) Baker: 153 (1892). Type: South Africa, locality unknown: cultivated in Berlin, *Link 1205* [B, lecto.; effectively designated by Foster: 21 (1941)].

Geissorhiza secunda var. *setifolia* Eckl. ex Baker: 155 (1892). Type: South Africa, [Western Cape], between Paarl and Pont, *Drège 8460* [K, lecto., designated by Goldblatt: 354 (1985)].

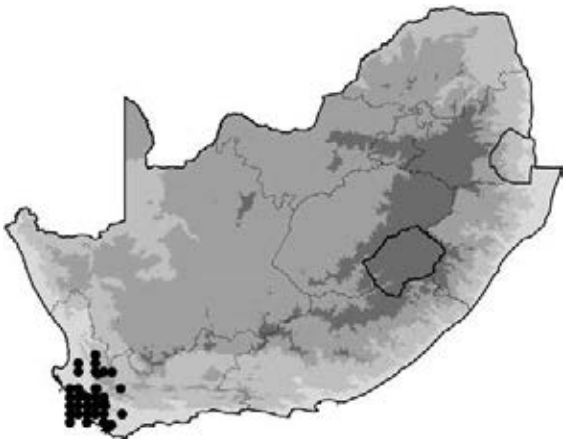
Geissorhiza filifolia Baker: 238 (1876). Type: South Africa, [Western Cape], precise locality unknown, *Prior s.n.* (BM, holo. [GH, photo.]).

Geissorhiza pallidiflora Schltr.: 98 (1899). *G. juncea* var. *pallidiflora* (Schltr.) R.C.Foster: 23 (1941). Type: South Africa, [Western Cape], flats between Bain's Kloof and Wolseley (Ceres Road), *Schlechter 9088* (B, lecto., designated by Goldblatt: 354 (1985); B, BM, BOL, isolecto.).

Hesperantha subulata Baker: 864 (1901). Type: South Africa, [Western Cape], Cape Flats, *Rehmann 1850* (Z, lecto., designated by Goldblatt: 354 (1985); BM, BR, isolecto.).

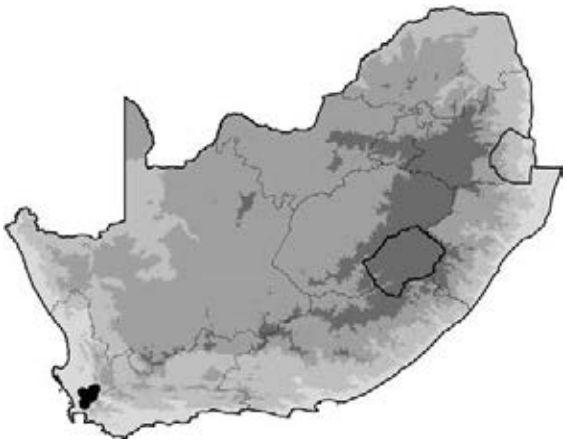
[*Geissorhiza setifolia* Eckl.: 22 (1827), invalid name without description.]

Plants slender, mostly 150–350 mm high. *Corm* globose, 5–9 mm diam., tunics light brown, concentric, woody, outer layers breaking irregularly, drawn into bristles above. *Stem* slightly inclined, flexed at base of spike, and sometimes above sheath of cauline leaf, rarely 1-branched. *Leaves* 3, lower 2 basal, terete, ± erect, reaching to ± middle of spike, with 4 narrow longitudinal grooves, uppermost leaf cauline, sheathing stem for ± half its length, 20–40 mm long, sheaths of lower leaves usually sticky. *Spike* inclined, 3- to 8(–13)-flowered; bracts 5–8 mm long, pale green to brown below, membranous above, curving outward in upper half, inner shorter than outer. *Flowers* actinomorphic, rotate, white to pale yellow, outer tepals often reddish or brown outside; perianth tube funnel-shaped, 2–3 mm long; tepals elliptic, mostly 8–12 × 3.0–5.5 mm. *Filaments* erect, equal, 2–3(–5) mm long; anthers 2–4 mm long, white or pale yellow. *Style* 6–12 mm long, dividing above apex of anthers, branches 1.2–2.5 mm long. *Capsules* ± globose, 3.3–4.5 mm long. *Chromosome number* $2n = 26$. *Flowering time*: August to October (to November at high elevations).



Distribution and ecology: extending throughout the western half of Western Cape, South Africa, from the northern Cederberg at Pakhuis Pass to the Cape Peninsula and Caledon; mostly in stony sandstone ground, also on loamy clay or granite-derived soils, often in seasonally wet and even marshy sites.

Diagnosis: the fairly common *Geissorhiza juncea* is recognised by its slender habit, with two basal leaves, the blades terete but with thickened margins and main vein and four narrow grooves between them, and small, white to pale yellow, star-like flowers with a perianth tube 2–3 mm long and tepals typically 8–12 mm long. It is is allied to a group of species including *G. humilis* and *G. hispidula* which have small corms with hard concentric tunics and narrow leaves with raised and thickened margins and midribs but can be readily distinguished from these species by its terete leaves and particularly short perianth tube. It is perhaps most closely allied to *G. furva*, with similar narrow, terete leaves but larger, deep yellow flowers with tepals 15–22(–28) mm long. This is also typically a shorter plant than *G. juncea*, mostly 60–120(rarely to 180) mm high, and the flowers are distinctive when dry as they turn an unusual blackish colour with age.



40. **Geissorhiza furva** *Ker Gawl. ex Baker*, Handbook of the Irideae: 155 (1892); Goldblatt: 356 (1985). Type: South Africa, [Western Cape], between Paarl and Pont, *Drège 8478* (K, lecto., designated by Goldblatt: 305 (1985); G, L, iso.).

[*Ixia furva* Banks ex Ker Gawl.: 224 (1804), invalid name without description.]

Plants small to medium, 70–120(–180) mm high. *Corm* globose, ± symmetric, obliquely flattened below, 7–9 mm diam.; tunics light brown, concentric, layers fragmenting irregularly, drawn into bristles above. *Stem* ± erect below, flexed above leaf sheaths and at base of spike, smooth. *Leaves* (2)3, lower 2 basal, terete and narrowly 4-grooved, usually sticky on sheaths and with sand adhering, lowermost longest, usually shortly exceeding stem, uppermost cauline, sheathing stem below, terete above, sometimes entirely sheathing. *Spike* inclined with flowers in upper side, flexuose, mostly 2- to 6-flowered; bracts 6–12 mm long, dry and papery above, inner slightly smaller than outer, sometimes longer. *Flowers* actinomorphic, rotate, deep yellow (becoming blackish when dry); perianth tube funnel-shaped, 3–5 mm long; tepals ± elliptic, 15–22(–28) × 10–2 mm.

Distribution of ***Geissorhiza juncea***.

Distribution of ***Geissorhiza furva***.

Filaments erect, equal, 7–13 mm long; anthers 5–6 mm long, yellow. *Style* dividing near or shortly beyond anther tips, 4–5 mm long. *Flowering time*: September to mid-October.

Distribution and ecology: restricted to the western coastal lowlands of Western Cape, South Africa, extending from Mulder's Vlei near Stellenbosch to Elandsberg Nature Reserve; on stony or sandy flats and slopes.

Diagnosis: *Geissorhiza furva* is a relatively short specuies, rarely exceeding 120 mm in height, with terete, 4-grooved leaves, and large deep, golden-yellow flowers. The flowers are unusual in turning a blackish colour on drying. The small corms, up to 9 mm diam., with concentric tunics that fragment vertically into irregular sections are typical of subg. *Weihea*. *Geissorhiza furva* is probably mostly closely related to the more common and widespread *G. juncea*, which has smaller, white to pale yellow flowers, the tepals mostly 8–12 × 3.0–5.5 mm.

41. **Geissorhiza sufflava** *Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 39: 133 (2009). Type: South Africa, [Western Cape], Piketberg, lower slopes of Versfeld Pass, light stony clay in renosterveld, 22 Sept. 1992, *Goldblatt & Manning 9468* (NBG, holo.; MO, PRE, iso.).
