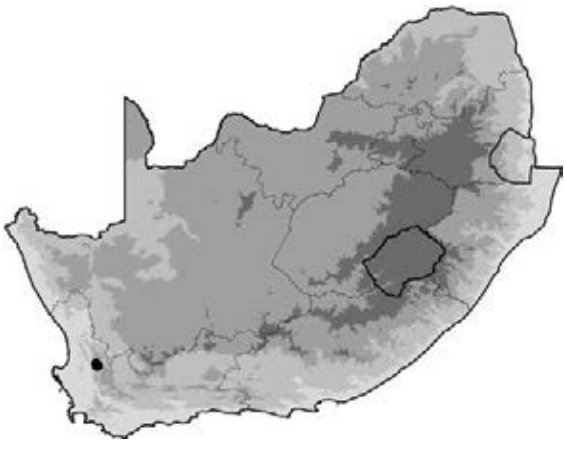
Plants 100–150 mm high excluding leaves. *Corm* globose-elliptic, ± 8 mm diam.; tunics light brown, concentric, splitting into vertical sections, drawn into short bristles above. *Stem* erect below, flexed outward above sheaths of upper 2 leaves, unbranched. *Leaves* 3, rarely 2, straight, terete with 4 narrow, longitudinal grooves, 0.5–1.0 mm diam., lowermost basal, longest, often exceeding spike, up to 300 mm long, uppermost leaf inserted in middle of stem. *Spike* flexuose, inclined with flowers on upper side, (1)2- or 3-flowered; bracts ± dry, light brown-translucent, 12–16 mm long, inner slightly shorter than outer, forked at apex. *Flowers* actinomorphic, cup-shaped, pale yellow, unscented; perianth tube funnel-shaped, 7–9 mm long; tepals narrowly ovate-elliptic, 18–25 × 6.0–8.5 mm. *Filaments* erect, equal, 12–14 mm long; anthers ± 5 mm long, yellow. *Style* dividing opposite upper ⅓ of anthers, branches ± 5 mm long. *Flowering time*: September.

Distribution and ecology: restricted to the lower eastern slopes and foot of the Piketberg in Western Cape, South Africa; on stony clay slopes in renosterveld or renosterveld–fynbos transition, flowering best after fire.



Diagnosis: spikes of 1 or 2, large, pale yellow, cup-shaped flowers and terete, four-grooved leaves set *Geissorhiza sufflava* apart in sect. *Angustifoliae*. It falls closest to the widespread, small-flowered *G. juncea* and the southwestern Cape endemic *G. furva*, both of which have similar foliage. *Geissorhiza furva* has deep yellow flowers with a perianth tube 3–5 mm long and tepals 15–22(–28) × 5–8(–9) mm, thus usually smaller than those of *G. sufflava*. The two species appear to differ in ecology and distribution, with *G. furva* from the Swartland south of the Piketberg, between Hermon and Paarl, occurring on stony, often seasonally waterlogged clay flats and slopes.

42. **Geissorhiza stenosiphon** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 358 (1985). Type: South Africa. [Western Cape], Cold Bokkeveld Mtns, Hexberg, SE slopes at ± 1 200 m, *Viviers 1300* (NBG, holo.; K, MO, NBG, S, WAG, iso.).

Plants slender, 100–300 mm high. *Corm* globose, 9–12 mm diam., tunics light brown, concentric to ± imbricate (?by distortion), regularly notched below, brittle-membranous to slightly woody, drawn into bristles above. *Stem* unbranched. *Leaves* 3, lower 2 basal, terete with 4 narrow longitudinal grooves, straight, reaching to ± middle of spike, second leaf cauline, sheathing stem below, uppermost leaf inserted on middle of stem, entirely sheathing, 15–22 mm long. *Spike* 1- or 2-flowered; bracts 15–20 mm long, outer pale green with upper margins membranous to dry, inner entirely

Distribution of ***Geissorhiza sufflava***.

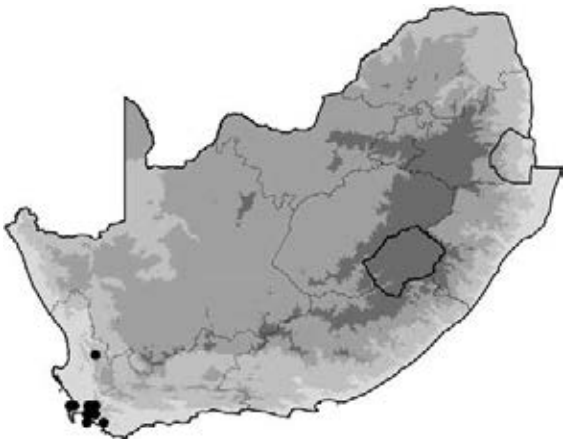
Distribution of ***Geissorhiza stenosiphon***.

membranous, ½–⅔ as long as outer. *Flowers* actinomorphic, salver-shaped, white, outside of tube and tepals pale pink to ± purple; perianth tube 40–50 mm long, cylindric throughout; tepals lanceolate, 12–14 × ± 4 mm, inner somewhat larger but shorter than outer. *Filaments* erect, equal, 2 mm long; anthers 2–3 mm long, white. *Style* dividing between apex of perianth tube and base of anthers, branches 2.0–2.5 mm long. *Capsules* ovoid, ± 10 mm long. *Flowering time*: December.

Distribution and ecology: restricted to the upper slopes of Hexberg in upper Elandskloof in the Cold Bokkeveld Mtns of Western Cape, South Africa; on stony, south and east trending, sandstone slopes.

Diagnosis: a remarkably long and slender perianth tube 40–50 mm long and narrow terete leaves make *Geissorhiza stenosiphon* unmistakable. Another unusual feature of the species is the style that divides at or below the base of the anthers. The flowers are actinomorphic with relatively small white tepals, 12–14 mm long, spreading horizontally. The vegetative morphology, especially the terete, 4-grooved leaves and apically dry floral bracts, is consistent with sect. *Angustifoliae* in which the short style and elongate perianth tube are unique.

Sect. 6. **Ixiopsis** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 359 (1985). Type: *Geissorhiza hesperanthoides* Schltr.



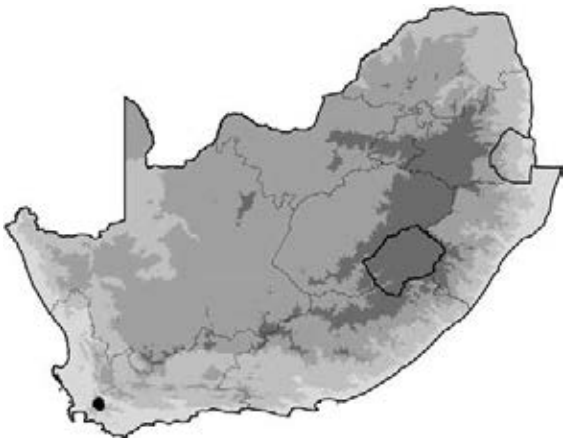
Corm tunics soft and membranous to fibrous and reticulate, leaves 3, the upper one or two sometimes bract-like and sheathing, the margins and midrib heavily thickened, linear, bracts herbaceous to membranous becoming dry above, flowers rotate to salver-shaped, actinomorphic, the tube either short, or reaching to the apex of, or well-exserted from the bracts, stamens equal.

Species 5: mountains of the southwestern Western Cape, South Africa.

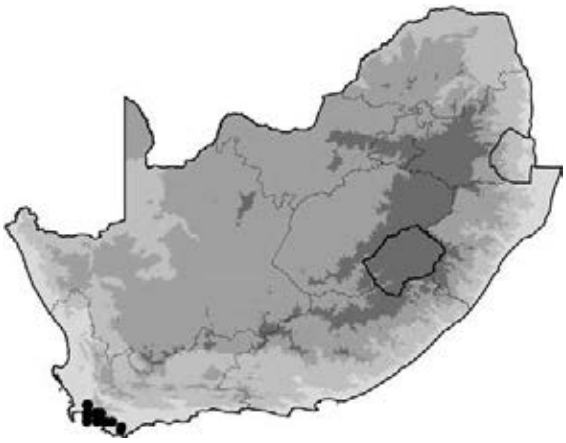
43. **Geissorhiza umbrosa** *G.J.Lewis* in Journal of South African Botany 7: 46 (1941); Goldblatt: 359 (1985). Type: South Africa, [Western Cape], wet rocks on Table Mtn, *Lewis 662* (SAM 54288, lecto., designated by Goldblatt: 359 (1985); BOL, PRE, isolecto.).

Plants 120–300 mm high. *Corm* globose, 3.5–6.0 mm diam., remains of older corms sometimes persisting below; tunics either membranous to soft papery and usually hardly accumulating, or composed of medium to fine netted fibres. *Stem* erect or inclined, simple (rarely 1-branched). *Leaves* 3, lower 2 basal, lowermost longest, second leaf shorter and sheathing lower part of stem for a short distance, linear (to subterete) to falcate, ⅓ to as long as stem, 1–2 mm wide, oblong in section, margins and main vein thickened, 2-grooved on each surface uppermost leaf inserted on lower ⅓ of stem, sheathing for at least ⅔ to almost entirely. *Spike* lax, 2- to 4(–10)-flowered; bracts 6–8(–10) mm long, green or becoming dry in upper half. *Flowers* actinomorphic, rotate, white, outer tepals often pink or reddish outside especially with age; perianth tube 2.5–4.0 mm long; tepals ± elliptic, 10–13 × 5–7 mm. *Filaments* erect, equal, 4–5 mm long; anthers 3–4 mm long, pale yellow. *Style* branching opposite upper ⅓ of anthers, branches ± 1.5 mm long. *Capsules* globose, 5–6 mm long. *Flowering time*: late October to December.

Distribution and ecology: mountains of Western Cape, South Africa, from the Cederberg and the Cape Peninsula eastward to the Riviersonderend Mtns; in sheltered, damp sites on stony sandstone slopes.



Distribution of ***Geissorhiza umbrosa***.



Diagnosis: an inconspicuous species, *Geissorhiza umbrosa* has small, white flowers with a perianth tube up to 4 mm long and tepals 10–13 mm long. The ± linear leaves have thickened margins and main vein and are 2-grooved on each surface, and the corm tunics range from soft and papery to fibrous. Its relationships are obscure.

44. **Geissorhiza alticola** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 361 (1985). Type: South Africa, [Western Cape], Louwshoek Peak, above Kaaimansgat, Villiersdorp, *Esterhuysen 35626* (MO, holo.; BOL, K, NBG, PRE, S, WAG, iso.).

Plants 200–300 mm high. *Corm* globose, symmetric 7–10 mm diam.; tunics papery, light brown, notched or torn below, not accumulating. *Stem* unbranched. *Leaves* (2)3, lowermost basal and longest, linear, 2–3 mm wide, with 2 narrow grooves on each surface, margins and midrib much thickened, second leaf

Distribution of ***Geissorhiza alticola***.

Distribution of ***Geissorhiza hesperanthoides***.

inserted near ground level, sheathing lower part of stem, with short free blade, uppermost leaf inserted in middle of stem, sheathing almost entirely. *Spike* flexuose, 3- to 5-flowered; bracts 7–10 mm long, dry and membranous above. *Flowers* actinomorphic, rotate, blue-violet; perianth tube funnel-shaped, 2–3 mm long; tepals obovate-elliptic, 11–13 × 5 mm, spreading. *Filaments* erect, equal, 4–5 mm long; anthers ± 4 mm long, yellow. *Style* dividing near apex of anthers. *Capsules* globose, 5–6 mm long. *Flowering time*: December to early February.

Distribution and ecology: a rare, high altitude endemic of the Du Toits Kloof–Wemmershoek–Stettynskloof Mtn complex of the Western Cape, South Africa; on stony sandstone ground above 1 500 m elevation.

Diagnosis: with a short perianth tube, ± 2.5 mm long but relatively long tepals, 11–13 mm long, *Geissorhiza alticola* appears to be allied to the *G. hesperanthoides* complex (including *G. nubigena* and *G. umbrosa* as well). It is similar to these species in general appearance and leaf morphology but has unbroken, papery rather than fibrous corm tunics. It can be distinguished from other high mountain species by its short, funnel-shaped perianth tube and fairly large blue-violet flower. Normally only the lowermost leaf is produced to any extent, while the two upper leaves sheath the stem for most or all of their length.

45. **Geissorhiza hesperanthoides** *Schltr.* in Botanische Jahrbücher für Systematik 27: 97 (1899); Goldblatt: 362 (1985). Type: South Africa, [Western Cape], summit of mtns near Vogelgat, *Schlechter 9555* (B, lecto., designated by Goldblatt: 362 (1985); B, BM, G, K, MO, PH, PRE, Z, isolecto.).

Plants 150–300 mm high. *Corm* globose, flattened on one side, 5–7 mm diam.; tunics of fine, pale reticulate fibres, sometimes with papery, fragmented layers between, fibres extending upward in a collar. *Stem* ± erect to inclined, smooth, rarely branched. *Leaves* (2)3, lowermost basal, longest, second inserted near ground level, sheathing lower part of stem, linear, 2–3 mm wide, margins and main vein much thickened, with 2 narrow grooves on each surface, occasionally sticky with adhering sand, uppermost leaf inserted in middle part of stem, sheathing or with short free apex. *Spike* flexuose, 1- to 3-flowered; outer bracts ± 10 mm long, reddish above, often with translucent apices, inner shorter and narrower. *Flowers* actinomorphic, rotate, tepals slightly cupped, blue to violet; perianth tube 5–8(–10) mm long, almost reaching apex of bracts, shortly exserted in old flowers; tepals oblanceolate, 12–18 × 6–8 mm. *Filaments* erect, equal, 7–10 mm long; anthers 4–5 mm long, yellow. *Style* dividing beyond anther apices, branches ± 3 mm long. *Capsules* globose, ± 6 mm long. *Flowering time*: late November to December (January at highest elevations).

Distribution and ecology: mountains of the Western Cape, South Africa, from Wellington Sneeukop and Victoria Peak south to the Bredasdorp Mtns; at middle to upper elevations, usually in damp, sometimes marshy sites and flowering in summer.

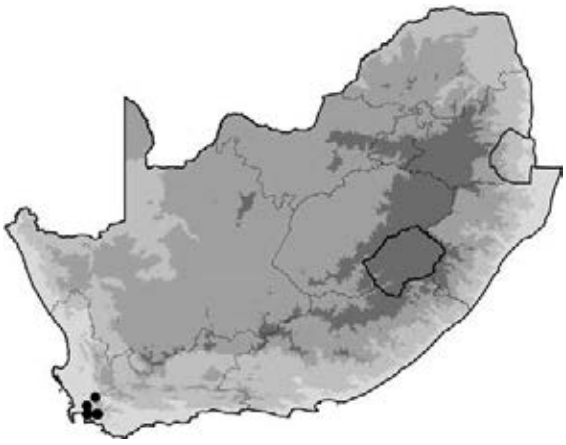
Diagnosis: *Geissorhiza hesperanthoides* is unusual in the genus in having fine, fibrous corm tunics, shared only with *G. nubigena* and *G. umbrosa* and evidently a specialised character in *Geissorhiza*, where hard woody concentric tunics are likely the ancestral state. Flowers of *G. hesperanthoides* have broad, somewhat cupped, violet-blue tepals and a perianth tube 5–8 mm long, extending to 7–10 mm in older flowers, and typically not or barely exserted from the bracts. *Geissorhiza nubigena*, with which *G. hesperanthoides* has been confused, has pink flowers with narrower tepals that extend at right angles to the longer tube, which is well exserted at anthesis and 10–18 mm long, becoming even longer in older flowers.

46. **Geissorhiza nubigena** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 366 (1985).

Type: South Africa, [Western Cape], southern slopes of Victoria Peak, *Goldblatt 6827* (MO, holo.; K, NBG, PRE, S, US, WAG, iso.).

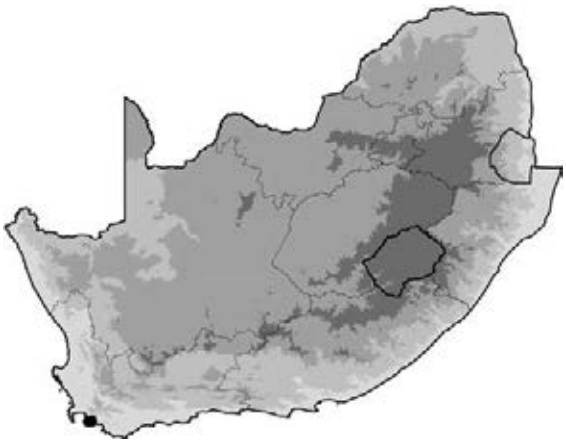
Plants 150–300 mm high. *Corm* globose, slightly flattened on one side, 5–9 mm diam.; tunics of fine, pale, netted fibres, sometimes with papery, fragmented layers between, fibres usually extending upward in collar. *Stem* rarely branched. *Leaves* (2)3, lowermost basal, longest, linear, 2–3 mm wide, margins and main vein much thickened and with 2 narrow grooves on each surface, second leaf inserted near ground level, sheathing lower part of stem for a short distance, uppermost leaf short, inserted in middle of stem, partly to entirely sheathing. *Spike* flexuose, 1- to 5-flowered; bracts ± 10 mm long, green, reddish above, often with translucent tips, inner shorter and narrower than outer. *Flowers* actinomorphic, salver-shaped, nodding, tepals spreading at right angles to tube, rose-pink; perianth tube cylindric, mostly 12–18 mm long, well-exserted from bracts when fully open; tepals oblanceolate-elliptic, 17–22 × 8–9 mm. *Filaments* 8–12 mm long; anthers 5–6 mm long, yellow. *Style* dividing beyond anther tips, branches 3–4 mm long. *Flowering time*: January.

Distribution and ecology: restricted to the higher mountains in the southwestern corner of Western Cape, South Africa, from Victoria Peak south through the Hottentots Holland Mtns to the Kogelberg; on grassy slopes at middle to upper elevations above 1 050 m, usually in sheltered or marshy sites.



Diagnosis: unusual in flowering in the summer, *Geissorhiza nubigena* is distinguished by the fibrous corm tunics, rose-pink flowers with a relatively long perianth tube, typically 12–18 mm long, exserted from the bracts when fully open. The flowers are held nearly horizontally, thus almost nodding with the tepals spreading at right angles to the tube. It is allied to the vegetatively similar *G. hesperanthoides*, which has violet to blue-purple flowers held upright with somewhat cupped tepals and a shorter perianth tube 5–8(–10) mm long. Both species have corms with fibrous tunics, and three leaves, the lowermost of which is longest, and blades with heavily thickened margins and main vein.

47. **Geissorhiza cataractarum** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 364 (1985). Type: South Africa, [Western Cape], above Betty's Bay, dripping south-facing cliffs in moss, *Goldblatt 5355* (MO, holo.; BR, E, K, NBG, NSW, PRE, S, US, WAG, iso.).



Plants 100–200(–300) mm high, often trailing. *Corm* ± ovoid, symmetric, 4–5 mm diam.; tunics light brown, firm to soft membranous, not normally accumulating. *Stem* suberect or trailing, unbranched. *Leaves* 3, lower 2 basal, up to 300 mm long, arching outward, trailing distally, linear, 1.0–1.5 mm wide, margins and main vein enlarged, thus 2-grooved on each surface, uppermost leaf inserted on lower ⅓ of stem, short, partly sheathing. *Spike* 1- to 5-flowered; bracts 6–9 mm long, membranous above. *Flowers* actinomorphic, rotate, pale blue-mauve, white in throat; perianth tube ± funnel-shaped, 4–6 mm long; tepals elliptic, 14–20 × 6–8 mm. *Filaments* erect, equal, ± 10 mm long; anthers 3(–4) mm long, white. *Style* dividing opposite upper ⅓ of anthers, branches ± 3 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: late November to mid-January.

Distribution and ecology: restricted to the mountains of southwestern Western Cape, South Africa between Betty's Bay and Hermanus; on wet, dripping, mossy south-facing cliffs and waterfalls.

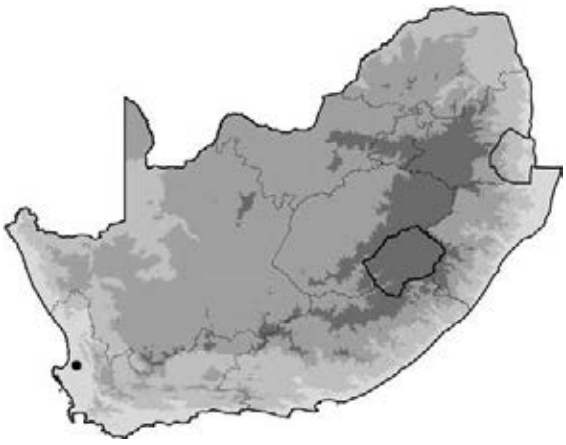
Diagnosis: *Geissorhiza cataractarum* is unusual in its habitat and in its particularly delicate, almost membranous corm tunics that seldom accumulate, instead decaying entirely within a year. The flowers are unremarkable, and typical of the genus in their blue-mauve colour, perianth tube 4–6 mm long, and spreading tepals. Plants have three leaves, the lower two longest and with trailing blades with thickened margins and main vein, thus are shallowly two-grooved on each surface.

Distribution of ***Geissorhiza nubigena***.

Distribution of ***Geissorhiza cataractarum***.

Sect. 7. **Engysiphon** *(G.J.Lewis) Goldblatt* in Annals of the Missouri Botanical Garden 72: 367 (1985). *Engysiphon* G.J.Lewis: 19 (1941). Type: *Geissorhiza exscapa* (Thunb.) Goldblatt, lecto., designated by Goldblatt: 367 (1985).

Corm tunics concentric, hard, woody; leaves sword-shaped to linear, either with heavily thickened margins and main vein or with margins raised and winged and curving around poorly thickened main vein, then appearing terete; spike few–several-flowered; outer bract green, inner membranous and usually < half as long as outer; flowers zygomorphic (actinomorphic in *G. helmei*) with stamens and style declinate (erect and included in *G. adriaanii*) and ; perianth tube short to elongate; stamens equal or 1 anther longer (*G. melanthera*).

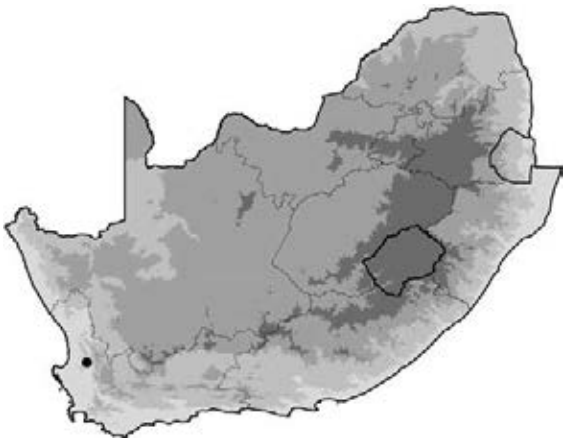


Species 10: southwestern western Cape, South Africa.

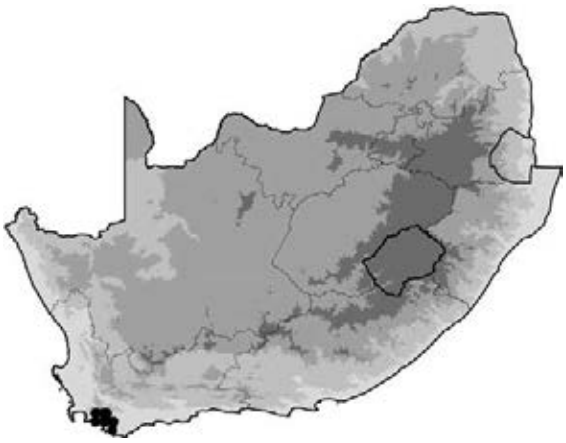
48. **Geissorhiza helmei** *Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 39: 135 (2009). Type: South Africa, Western Cape, Piketberg, Farm Kleigat, lower slopes SE of Melkhoutkop, above track to Farm Weltevrede, burned previous summer, 183 m, 26 Sept. 2006, *Helme 4200* (NBG, holo.).

Plants 80–150 mm high. *Corm* ovoid, 10–15 mm diam.; tunics concentric, light brown, fragmenting vertically into segments tapering above into short spines. *Stem* smooth, flexed above sheath of second leaf, suberect, usually 1-branched, flexed at base of spike. *Leaves* usually 3, lowermost basal, with long, linear blade, 10–15 × 3–4 mm, margins thickened and raised into wings extended at right angles and ciliate along edges, sticky outside with sand adhering, main vein also thickened with winged, ciliate edges, plane between margins and main vein, upper leaves smaller. *Spike* horizontal, lightly flexuose, with flowers borne on upper side, main spike 7- to 10-flowered; bracts suberect, held ± at right angles to axis, green with veins flushed red, margins membranous, outer ± 6 mm long, inner ± 1 mm shorter, forked apically. *Flowers* actinomorphic, pink, unscented; perianth tube funnel-shaped, ± 6 mm long; tepals subequal, oblong, ± 12 × 5 mm, spreading at right angles to tube. *Filaments* equal, erect, ± 6 mm long; anthers ± 4 mm long, forked at base, dark purple; pollen brown. *Style* dividing opposite middle ⅓ of anthers, branches ± 2 mm long. *Flowering time*: late August to mid-September.

Distribution and ecology: a narrow endemic of the lower northern slopes of the southern arm of the Piketberg Mtns in Western Cape, South Africa; in rocky ground in light sandy loam overlying clay, evidently flowering only after fire.



Diagnosis: in its general aspect *Geissorhiza helmei* recalls species of sect. *Engysiphon*, most members of which have fairly large corms with concentric tunics that fragment into sections that taper above into short bristles, and a single long basal leaf, always with thickened and winged margins and central vein, and with the surface of the margins glandular and with sand adhering to them. It and *G. adriaani* stand out in the section in having actinomorphic flowers, whereas other species have zygomorphic flowers with decumbent stamens and style. Most other members of the section also have flowers with a longer perianth tube although *G. brevituba* has a short tube, ± 8 mm long, thus comparable to the tube of *G. helmei*, ± 6 mm long. *Geissorhiza brevituba*, also endemic to the Piketberg, has larger flowers with tepals 25–30 mm long and spikes typically with only one to three flowers with the style dividing well beyond the anther tips. The main spikes of *G. helmei* have up to 10 flowers with tepals ± 10 mm long.



Distribution of ***Geissorhiza helmei***.

49. **Geissorhiza brevituba** *(G.J.Lewis) Goldblatt* in Annals of the Missouri Botanical Garden 72: 368 (1985). *Engysiphon brevitubus* G.J.Lewis: 24 (1941). Type: South Africa, [Western Cape], top of Piketberg Mtn, *H. Bolus 13651* (BOL, lecto., designated by Goldblatt: 368 (1985); BM, K, PRE, isolecto.).

Plants 12–200 mm high. *Corm* globose, 15–20 mm diam.; tunics woody, dark brown, concentric, breaking irregularly into sections, drawn into short points above. *Stem* usually inclined, flexed above sheath of uppermost leaf and at base of spike, usually unbranched. *Leaves* usually 3, lowermost ± basal, longest, as long or slightly exceeding spike, linear to narrowly sword-shaped, sticky and with sand adhering, margins expanded at right angles to blade, main vein also enlarged and winged, blade thus broadly 2-grooved on each surface, upper leaves shorter, uppermost inserted in middle of stem, sheathing for half its length. *Spike* flexuose, 1- to 3-flowered; outer bract 15–20 mm long, green, inner membranous, ± 12 mm long. *Flowers* zygomorphic, ± nodding, stamens and style declinate, pink with darker veins; perianth tube cylindric, ± 8 mm long, included in bracts; tepals obovate, 25–30 × 9–11(–13) mm, outer wider and shorter than inner. *Filaments* unilateral,

Distribution of ***Geissorhiza brevituba***.

Distribution of ***Geissorhiza schinzii***.

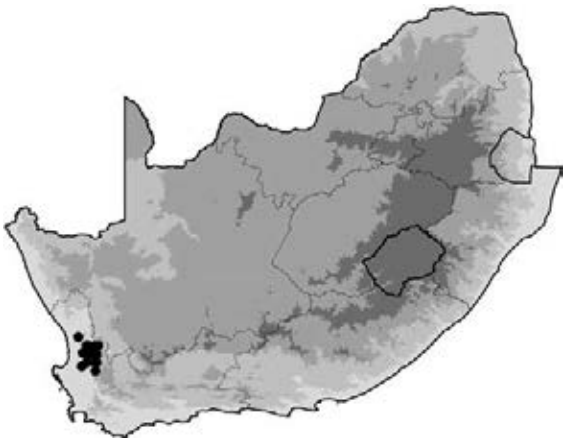
declinate, equal, ± 20 mm long; anthers unilateral, ± 6.5 mm long, dark purple; pollen brown. *Style* arching below filaments, dividing opposite upper ⅓ of anthers, branches ± 4 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: mainly September.

Distribution and ecology: endemic to the Piketberg Mtns of Western Cape, South Africa; on stony, sandstone slopes in low fynbos, especially abundant after fire.

Diagnosis: *Geissorhiza brevituba* is distinctive in sect. *Engysiphon* in the relatively short perianth tube, ± 8 mm long, substantially shorter than the floral bracts, these 15–20 mm long, relatively short for the section. Despite this the tepals are 25–30 mm long, in the normal range for the section. The leaves with thickened margins and main vein and large, more-or-less nodding, zygomorphic flower with declinate stamens and style are typical of sect. *Engysiphon.*

50. **Geissorhiza schinzii** *(Baker) Goldblatt* in Annals of the Missouri Botanical Garden 72: 368 (1985). *Acidanthera schinzii* Baker: 27 (1906). *Engysiphon schinzii* (Baker) G.J.Lewis: 22 (1941). Type: South Africa, [Western Cape], Houw Hoek, *Penther 587* (Z, lecto., designated by Goldblatt: 368 (1985), Z; K, isolecto.).

[*Gladiolus costatus* Eckl.: 38 (1827), invalid name without description.]



Plants (100–)150–200 mm high. *Corm* globose, asymmetric, flattened below on one side, 12–18 mm diam.; tunics concentric, woody, dark brown, breaking vertically into irregular sections, drawn into cusps ± 15 mm long above. *Stem* suberect, flexed above sheaths of upper 2 leaves, unbranched. *Leaves* usually 3, lowermost basal, longest, usually ± straight, lanceolate, usually slightly longer than stem, 4–6 mm wide, sticky below and on margins and midrib usually with sand adhering, margins enlarged and extending at right angles to blade, main vein also enlarged and winged, blade thus with 2 wide grooves on each surface, remaining leaves much shorter, uppermost inserted in middle of stem, sheathing for ± half their length. *Spike* flexuose, 1- to 4-flowered; outer bracts (20–)25–40 mm long, green, inner much shorter, concealed by outer. *Flowers* zygomorphic, with stamens and style declinate, tepals pale or deep pink with darker veins; perianth tube cylindric, 24–32 mm long, usually shortly exserted from bracts; tepals obovate, 35–40 × 9–15 mm, outer shorter and broader than inner. *Filaments* unilateral, declinate, equal, ± 20 mm long; anthers 6–7 mm long, purple; pollen brown. *Style* arching below filaments, dividing opposite or shortly beyond anther tips, branches ± 3.5 mm long. *Flowering time*: late August to early October.

Distribution and ecology: endemic to the southwestern corner of Western Cape, South Africa, extending from Houw Hoek near Grabouw to Napier and Baardscheerdersbos near Elim; mainly montane on stony sandstone slopes in fynbos, abundant after fire.

Diagnosis: fairly typical of sect. *Engysiphon, Geissorhiza schinzii* is distinguished by the relatively large, nodding flowers with a perianth tube of intermediate length, 24–32 mm long, and tepals 35–40 mm long, exceeding the length of the tube. The flowers are zygomorphic with unilateral, decumbent stamens and style. Like other species of the section, the leaves have thickened margins and main vein and are sticky, usually with sand adhering to the surface. The flowers are adapted for pollination by long-proboscid flies and the flower colour, perianth tube length, and brown pollen are all typical of that pollination strategy.

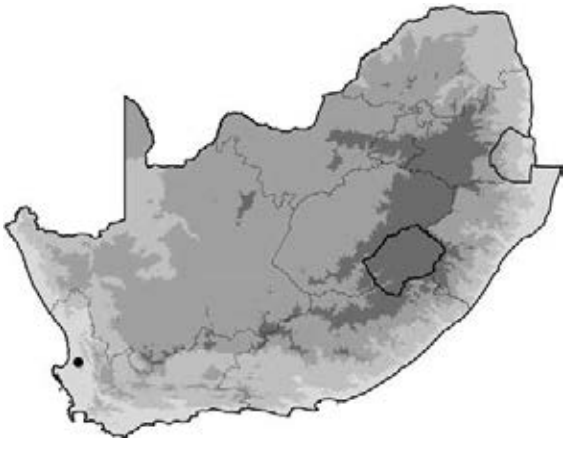
51. **Geissorhiza longifolia** *(G.J.Lewis) Goldblatt* in Annals of the Missouri Botanical Garden 72: 371 (1985). *Engysiphon longifolius* G.J.Lewis: 23 (1941). Type: South Africa, [Western Cape], Clanwilliam, Nieuwoudt Pass, *Leighton s.n.* (BOL 22558, holo.).

Plants 120–200 mm high. *Corm* ± globose, with oblique flattened base, 12–16 mm diam.; tunics woody, brown, concentric, breaking vertically into irregular section, drawn into points above. *Stem* inclined, flexed above

Distribution of ***Geissorhiza longifolia***.

sheath of uppermost leaf and at base of spike, occasionally with short branch. *Leaves* 2 or 3, lowermost basal, longest, up to 280 mm long, linear to narrowly sword-shaped, sticky on sheath, margins and main vein with sand adhering, margins expanded at right angles to blade, main vein also raised and winged, thus broadly 2-grooved on each surface, remaining leaves short, sheathing for half their length, uppermost inserted in middle of stem. *Spike* inclined to ± horizontal, flexuose, (2–)4- to 9-flowered; outer bracts (14–)16–25 mm long, green, inner membranous, ± half as long. *Flowers* zygomorphic, stamens and style unilateral and declinate, tepals white with pale pink veins, turning pink on fading; perianth tube cylindric, 14–20(–25) mm long, shortly exserted from bracts; tepals ± linear, 17–27 × (5–)7–9 mm, outer wider and shorter than inner. *Filaments* unilateral, declinate, equal, 10–15 mm long; anthers parallel, 4–6 mm long, dark purple. *Style* arching below filaments, dividing near apex of anthers, branches 2–3 mm long. *Capsules* ellipsoid to narrowly obovoid, 12–18 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: September to October.

Distribution and ecology: restricted to the interior mountains of the western half of Western Cape, South Africa, from the Gifberg in the north to Michell's Pass in the south; on stony sandstone or clay slopes, flowering mainly after fire.



Diagnosis: *Geissorhiza longifolia* is distinctive in sect. *Engysiphon* in its moderate-sized, white or pale pink flowers with a relatively short perianth tube 14–20(–25) mm long and narrow, often almost linear tepals 17–27 × 5–9 mm. It is sometimes confused with *G. confusa*, which is similar in overall appearance but is usually taller in stature and has larger, creamy white to beige flowers with the tube 25–40 mm long and mostly broader tepals 28–40 × 7–10 mm.

52. **Geissorhiza adriaanii** *Goldblatt & J.C.Manning*, new species. Type: South Africa, Western Cape, Piketberg, Aurora Mtn, Farm Grootplaat, 570 m, 26 Oct. 2019, *J.A. Van der Walt s.n.* (NBG, holo.).

Plants 200–300 mm high. *Corm* globose, asymmetric, ± flattened on one side and extending downward, 10–20 mm diam.; tunics woody, brown, concentric, fragmenting irregularly, drawn into short cusps above, accumulating. *Stem* ± erect, slender, unbranched. *Leaves* 3, lowermost basal, longest up to 350 mm long, linear to narrowly sword-shaped, 3–4 mm wide, sticky on sheath, margins and main vein with sand adhering, margins expanded at right angles to blade, main vein also raised and winged, thus broadly 2-grooved on each surface, ciliolate-scabridulous along margins and angles of midrib, drying or dry at flowering, remaining leaves short, sheathing for half their length, uppermost inserted in middle of stem. *Spike* suberect or slightly inclined, weakly flexuose, 4- or 5-flowered; outer bracts 8–10 mm long, green below but membranous in upper half or almost entirely so, inner membranous, slightly shorter. *Flowers* actinomorphic, slaver-shaped, tepals creamy white flushed salmon-pink on the reverse and dark pink in throat; perianth tube cylindric, 8–10 mm long, including stamens and style, shortly exserted from bracts; tepals linear, 18–28 × 2.5–3.0 mm, outer slightly wider and shorter than inner. *Filaments* included, 2 mm long, inserted 2 mm above base of tube; anthers included, 4 mm long, yellow, reaching to middle of tube. *Style* erect, very short, 2 mm long, reaching to base of filaments, with short branches ± 1 mm long. *Capsules* unknown. *Flowering time*: October.

Distribution and ecology: evidently a narrow endemic of the western end of the Piketberg Mtns in Western Cape, South Africa, known only from the type collection from Aurora Mtn; on the summit plateau in gravelly loam among restioid fynbos.

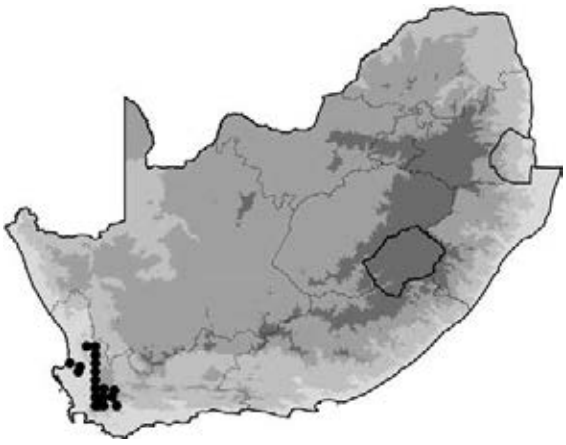
Diagnosis: a surprising find for the well-botanised western half of Western Cape, *Geissorhiza adriaanii* is named for Adriaan van der Walt who discovered the species in October 2019 at the southwestern end of the Piketberg Mtns. It is typical for sect. *Engysiphon* in its white to cream to pale pink perianth, relatively large, asymmetric corm, and somewhat sticky leaves to which sand adheres but is distinctive in its actinomorphic flower with the stamens

Distribution of ***Geissorhiza adriaanii***.

deeply included in the perianth tube, with the short filaments inserted 2 mm above the tube base. The relatively long, yellow anthers reach only to about the middle of the tube and the style is unusually short, reaching only to the base of the filaments. In general appearance *G. adriaanii* resembles *G. longifolia*, a species that extends from the Gifberg south to Michell's Pass, but that species has zygomorphic flowers with long, unilateral stamens with exserted filaments 10–15 mm long and purple anthers with brown pollen. The included stamens of *G. adriaanii* recall *G. esterhyuseniae* and *G. cedarmontana*, both subg. *Weihea* but not members of sect. *Engysiphon* and only distantly related to *G. adriaanii*.

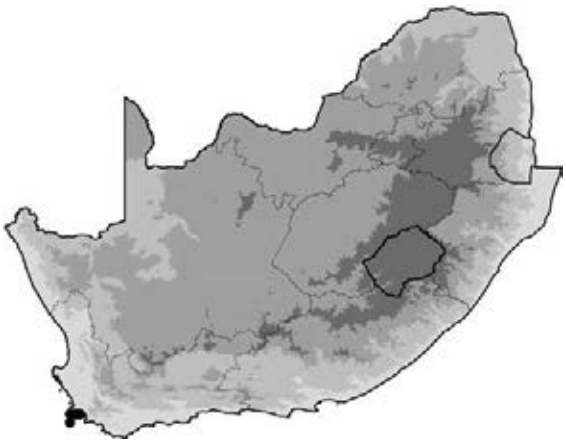
Of the 10 species in sect. *Engysiphon*, four are narrow endemics restricted to the Piketberg, viz. *G. adriaanii*, *brevituba, G. helmei* and *G. melanthera.*

53. **Geissorhiza confusa** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 373 (1985). Type: South Africa, [Western Cape], Bain's Kloof, *Schlechter 9162* (MO, holo.; G, K, iso.).



Plants 120–300 mm high. *Corm* globose, with oblique flattened base, 12–18 mm diam., tunics woody, brown, concentric, breaking vertically into irregular sections, drawn into points above. *Stem* ± erect, smooth, flexed at base of spike, rarely with a short branch. *Leaves* 2 or 3, lowermost basal, largest, usually shortly exceeding spike, up to 300 mm long, ± linear, straight or falcate, 3–7 mm wide, sticky on sheath, margins and main vein, with sand adhering, margins and main vein heavily thickened, blade thus broadly 2-grooved on each surface, remaining leaves short, sheathing for at least half their length, uppermost inserted in middle of stem. *Spike* inclined, flexuose, 1- to 4(–8)-flowered; outer bracts 30–60 mm long, green, inner membranous, ± half as long. *Flowers* zygomorphic, stamens and style declinate, creamy white to beige with pink veins, turning pink on fading; perianth tube cylindric, 25–40(–50) mm long, usually exserted up to 15 mm from bracts, curved near apex; tepals obovoid-elliptic, 28–40 × 7–10 mm, outer wider and shorter than inner. *Filaments* unilateral, declinate, equal, 20–22 mm long; anthers 6–8 mm long, dark purple; pollen brown. *Style* arching below filaments, dividing opposite or beyond anther tips, branches 3–4 mm long. *Capsules* ± cylindric, 15–23(–28) mm long. *Chromosome number* 2*n* = 26. *Flowering time*: October to December (to mid-January).

Distribution and ecology: extending through the interior mountains of the western half of Western Cape, South Africa, from the Gifberg in the north to Jonaskop in the Riviersonderend Mtns in the south; on stony sandstone slopes, most frequent after fire.



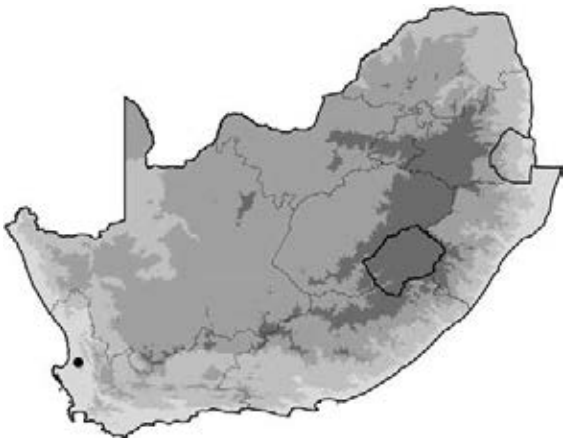
Diagnosis: with large creamy white or beige to almost yellow flowers, *Geissorhiza confusa* is one of the most conspicuous species in the genus. Vegetatively, the long basal leaf with thick margins and main vein and the large corm with woody tunics are typical of sect. *Engysiphon* but the perianth tube, mostly 35–50 mm long, is one of the longest in the section. The species has been much confused historically with *G. exscapa*, which has a comparably long perianth tube but usually pink flowers and different leaf morphology, the blades appearing terete but actually ± H-shaped in section with margins raised into wings that curve inward over the main vein, which is only slightly thickened.

54. **Geissorhiza bonaspei** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 375 (1985) [as *G. bonae-spei*]. Type: South Africa, [Western Cape], between Fish Hoek and Sun Valley, north-facing slopes after fire, *Goldblatt 5917* (MO, holo.; K, PRE, S, iso.).

Plants 120–200 mm high. *Corm* ± globose, asymmetric, one side obliquely flattened below; ± 8 mm diam.; tunics woody, brown, concentric, breaking vertically into irregular sections, drawn into points above. *Stem* ± erect, flexed above sheaths of upper 2 leaves, unbranched. *Leaves* 3, rarely 2, lowermost basal, longest, usually reaching to the apex of spike, linear, margins raised into wings held at right angles to blade and curving inward, thus blade evidently terete with 2 narrow longitudinal

Distribution of ***Geissorhiza confusa***.

Distribution of ***Geissorhiza bonaspei***.



grooves, main vein hardly thickened, sticky on sheath and blade and often covered with sand, remaining leaves much shorter, uppermost leaf inserted in middle of stem, sheathing for ½–⅔ its length, sometimes entirely. *Spike* flexuose, 1- to 5-flowered; outer bract green, 25–37 mm long, often dry toward apices, inner membranous, shorter than outer. *Flowers* zygomorphic with stamens and style declinate, pale pink, deeper pink outside and on veins; perianth tube cylindric, 20–30 mm long, reaching apex of bracts or shortly exserted; tepals narrowly obovate, obtuse, 24–27 × 5–7 mm, inner somewhat narrower and longer than outer. *Filaments* unilateral, declinate, equal, 14–16 mm long; anthers 4–5 mm long, dark purple; pollen brown. *Style* arching below filaments, dividing opposite middle ⅓ of anthers, branches 2–3 mm long. *Capsule* ± cylindric, 15–20 mm long, enclosed in bracts. *Chromosome number* 2*n* = 26. *Flowering time*: late September to mid-November.

Distribution and ecology: restricted to the southern Cape Peninsula in Western Cape, South Africa; on stony, sandstone soils on slopes and flats from Silvermine Plateau to Cape Point, blooming mainly after fire.

Diagnosis: *Geissorhiza bonaspei* is distinguished by the unusual leaf morphology and relatively large, pink flowers with a perianth tube 20–30 mm long and tepals 24–27 mm long and up to 7 mm wide. It is sometimes difficult to separate from closely allied to *G. tenella*, but that species has flowers white or faintly flushed pink, with a perianth tube 30–40 mm long and narrow tepals 14–22 × 3.0–4.5 mm. The leaves of both species are H-shaped in cross section with the margins raised into wings at right angles to the blade surface, the wings curving inward.

55. **Geissorhiza melanthera** *Goldblatt & J.C.Manning* in South African Journal of Botany 87: 22 (2013). Type: Western Cape, Piketberg, south-trending sandy slope northeast of Farm Kanariefontein [Barkatsfontein], 2 Oct. 2012, *Goldblatt & Porter 13850A* (NBG, holo.; MO, PRE, iso.).

Plants 140–185 mm high. *Corm* ± ovoid, 5–8 mm diam.; tunics concentric, woody, light brown, fragmenting vertically into elliptic segments, not accumulating. *Stem* suberect, flexed outward above sheaths of upper 2 leaves and at base of spike, suberect, simple or 1- or 2-branched from cauline leaf axils. *Leaves* usually (2)3, lowermost basal, suberect, 140–180 × ± 1.3 mm, blades ± square in outline, margins raised into wings extended at 90° to blade surface, sparsely ciliolate on edges, sticky outside with sand adhering, main vein hardly thickened, plane and paler green between margins and main vein, upper leaves smaller than basal. *Spike* inclined to ± horizontal, flexuose, with flowers borne on upper side, main spike 6- to 12-flowered; outer bract (12–)16–22 mm long, inner slightly shorter to ± ½ as long as inner, 2-keeled and forked apically. *Flowers* zygomorphic, nodding, unscented, pale beige-yellow, red at tepal bases and in tube, outside of tepals sometimes flushed red, anthers black; perianth tube ± cylindric, 10–14 mm long, constricted in lower

Distribution of ***Geissorhiza melanthera***.

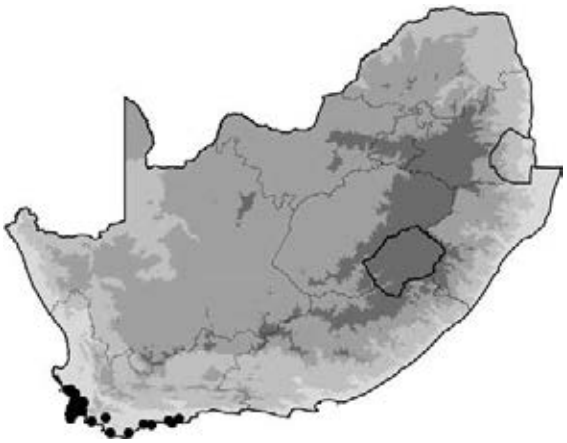
8–9 mm, wider distally; tepals narrowly obovoid-oblong, ± 24–26 × 7–8 mm, ultimately spreading at right angles to tube, inner slightly wider than outer. *Filaments* unequal, unilateral, declinate, ± horizontally, ± 5 mm long, red; anthers unequal, laterals 5–6 mm long, central 6.5–7.0 mm long, forked at base, ± black, remaining straight and rigid after dehiscence with white connective exposed; pollen dark purple. *Style* arching below filaments, dividing opposite upper ⅓ of anthers, ± 2.7 mm long. *Flowering time*: late September to mid-October.

Distribution and ecology: a narrow endemic of the western end of the Piketberg Mtns in Western Cape, South Africa; on gentle, south-trending slopes in deep sand, flowering best after fire.

Diagnosis: *Geissorhiza melanthera* is a particularly striking member of sect. *Engysiphon*. Its moderate-sized flowers recall smaller-flowered *G. helmei* (also a narrow endemic of the Piketberg) but *G. melanthera* has larger, beige-yellow flowers with perianth tube 10–14 mm long and spreading tepals 24–26 mm long. The flowers are zygomorphic with declinate stamens and style typical of the section but the anthers are black and slightly elliptic with the central anther slightly longer than the laterals. It has the smallest corms in sect. *Engysiphon*, only 5–8 mm in diameter.

The leaves are H-shaped in cross section, the margins bearing wings as wide as the leaf axis and held at right angles to the blade whereas the midrib is only slightly raised. This leaf type is characteristic of *G. exscapa*, which has larger flowers, and also pink-flowered *G. bonaspei* and white-flowered *G. tenella*. It is to these species that *G. melanthera* is immediately allied, all of which have a somewhat to significantly longer perianth tube at least 20 mm long and 40–80 mm in *G. exscapa*.

The anthers of *G. melanthera* are its most striking feature, unusual for the genus not only in their black colour but in retaining their elliptical shape after releasing their pollen, with a portion of the connective exposed and showing white between the thecae. In other species of the section the anthers lose their



shape, shrinking and becoming deformed after releasing pollen. The flowers are adapted for pollination by the bee-fly, *Magapalpus capensis*, a frequent pollinator of white-flowered *Pelargonium* species, but not known to pollinate other species of Iridaceae.

56. **Geissorhiza tenella** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 377 (1985), as new name for *Acidanthera rosea* Schinz: 222 (1894) [not *G. rosea* (Klatt) R.C.Foster (1941) = *G. heterostyla*]. *Engysiphon roseus* (Schinz) G.J.Lewis: 21 (1941). Type: South Africa, [Western Cape], 'Spitze des Teufelberges bei Capstadt,' ('montis Diaboli' on label), 3 300 ft [1 000 m], *Schlechter 75* (G, lecto., designated by Goldblatt: 377 (1985); B, K, isolecto.).

Acidanthera sabulosa Schltr.: 101 (1899) [not *G. sabulosa* Klatt (1885) = *G. imbricata* subsp. *imbricata*] Type: South Africa, [Western Cape], sand dunes near Eerste Rivier, *Schlechter 9025* (B, lecto., designated by Goldblatt: 377 (1985); BM, G, K, MO, isolecto.).

[*Gladiolus tenellus* Eckl.: 41 (1827), invalid name without description.]

Plants (100–)150–300 mm high. *Corm* globose, asymmetric, ± flattened on one side and extending downward, 7–10 mm diam.; tunics woody, brown, concentric, fragmenting irregularly, drawn into short cusps above. *Stem* ± erect, slender, usually unbranched. *Leaves* usually 3, ± terete, sticky on sheaths and sometimes on blades, margins expanded into wings raised at right angles to blade and curving inward (appearing terete with 2 narrow grooves on each surface), main vein hardly thickened, lowermost leaf longest, basal, reaching to base of spike, second leaf also basal, sheathing lower ⅓ of stem, uppermost leaf inserted on upper ⅓ of stem, sheathing for ± ⅔ of its length, often entirely sheathing. *Spike* (1)2- to 5-flowered; outer bract green, (20–)30–40(–50) mm long, inner membranous, half as long as outer. *Flowers* zygomorphic with stamens and style declinate, white to pale pink, flushed pink outside; perianth tube cylindric, (20–)30–40(–50) mm long, reaching to apex of bracts or exserted up to 15(–25) mm; tepals oblong to ± linear, acute, 13–23 × 2.0–4.5 mm. *Filaments* unilateral, declinate, equal, ± 14 mm long; anthers (2.5–)3.5–4.5 mm long, purple; pollen yellow. *Style* arching below filaments, dividing near apex of anthers, branches ± 3 mm long. *Capsules* ± cylindric, 12–20 mm long, enclosed in bracts. *Chromosome number* 2*n* = 26. *Flowering time*: October to November (to mid-December).

Distribution of ***Geissorhiza tenella***.

Distribution and ecology: restricted to coastal Western Cape, South Africa, extending from Yzerfontein in the north to Still Bay in the southeast; on sandy, seasonally wet flats and dunes, flowering well after fire.

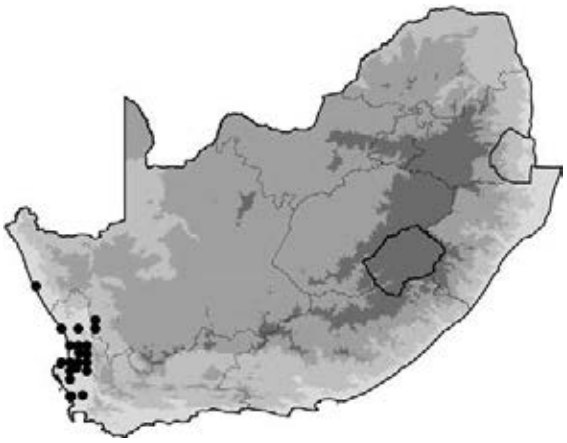
Diagnosis: distinguished by the white or pale pink flowers with unusually narrow tepals 13–23 × 2.0–4.5 mm, *Geissorhiza tenella* has a perianth tube remarkably variable in length, mostly 30–40 mm long but as short as 20 mm and occasionally as long as 50 mm. The leaf blades are H-shaped in cross section with the margins raised into broad wings held at right angles to the blade. It is allied to the long-tubed Atlantic Coast species *G. exscapa* and to the Cape Peninsula endemic *G. bonaspei*, with which it shares the distinctive leaf with winged margins and H-shaped in cross section. *Geissorhiza bonaspei* has slightly larger, deep pink flowers with relatively broad tepals mostly 24–27 × 5–7 mm.

Flower size is unusually variable in *G. tenella*. Plants from the east of its range, in the Caledon and Bredasdorp Districts as far east as Still Bay (as well as some from the Cape Flats), have a relatively short perianth tube, some 24–30 mm long and tepals 12–15 mm long. In contrast, most populations from the Cape Flats and along the Atlantic Coast usually have much larger flowers with a perianth tube 40–50 mm long and tepals up to 23 mm long. Such specimens approach *G. exscapa* in their flower size and this is probably related to their pollination biology. Both are pollinated by long-proboscid flies, which have particularly long mouth parts along the Atlantic Coast and comparatively short mouth parts on the south coast of Western Cape.

57. **Geissorhiza exscapa** *(Thunb.) Goldblatt* in Annals of the Missouri Botanical Garden 72: 378 (1985). *Gladiolus exscapus* Thunb.: 184 (1800). *Sphaerospora exscapa* (Thunb.) Klatt: 725 (1864). *Acidanthera exscapa* (Thunb.) Baker ex C.D.Bouché & Wittm.: 15 (1876). *Engysiphon exscapus* (Thunb.) G.J.Lewis: 23 (1941) [misapplied to *G. confusa*]. Type: South Africa, locality unknown, *Thunberg s.n.* '*Gladiolus exscapus* a' [UPS–THUNB 1022, lecto., designated by Goldblatt: 378 (1985)].

Gladiolus thunbergii F.Dietr.: 494 (1817), illegitimate superfluous name for *G. exscapus* Thunb. (1800). Type: uncertain, probably as for *G. exscapus* Thunb.

Acidanthera tubulosa Baker: 160 (1877), as a new name for *Ixia tubulosa* Houtt. (1780), not *I.*



tubulosa Burm.f. (1768). *Acidanthera tubulosa* N.E.Br.: 137 (1929), illegitimate homonym, not *A. tubulosa* Baker (1877). Type: South Africa, without precise locality or collector [G: Herb. Burman, specimen matching illustration in Houtt. (1780), lecto., designated by N.E.Br.: 137 (1929)].

Acidanthera picta R.C.Foster: 43 (1936). *Engysiphon pictus* (R.C.Foster) G.J.Lewis: 21 (1941) [misapplied to *G. bonaspei*]. Type: South Africa, without precise locality, or collector [G: Herb. Burman, lecto., designated by Goldblatt: 378 (1985)].

Engysiphon longitubus G.J.Lewis: 24 (1941). Type: South Africa, [Western Cape], Warm Baths, Clanwilliam, *Leipoldt s.n.* (BOL 20840, holo.).

[*Freesia costata* Eckl. ex Baker: 160 (1877), invalid name only in synonymy.]

Plants 180–320 mm high. *Corm* ovoid, 10–15 mm diam.; tunics brown, concentric, fragmenting irregularly, segments drawn into short cusps above. *Stem* sometimes very short, then sheathed almost entirely by leaves, flexed above sheath of second leaf and near base of spike, usually unbranched. *Leaves* 3, linear or appearing nearly terete, sticky on sheaths and blades, often with adhering sand, margins expanded into wings held at right angles to blade and curving inward (appearing nearly terete with 2 longitudinal grooves), midrib not or barely raised, lowermost leaf basal, largest, reaching to ± base of spike, upper leaves shorter, uppermost often largely sheathing, inserted in middle of stem. *Spike* inclined to horizontal, (1–)3- to 9-flowered, flexuose; outer bracts (30–)45–65 mm long, green, inner membranous, up to 20 mm long. *Flowers* zygomorphic, stamens and style declinate, tepals cream- to ivory-coloured or pink with darker veins, reddish outside, fading deep pink to ± red; perianth tube 40–80 mm long, usually well exserted from bracts, occasionally reaching only to apex of bracts, curved near throat; tepals narrowly obovate, 26–35 × 4.5–6.0 mm wide, outer wider and shorter than inner. *Filaments* unilateral, declinate, equal, held above lower tepal; anthers ± horizontal, 6–7 mm long, brown. *Style* arching below filaments, dividing near apex of anthers, branches ± 3 mm long. *Capsules* oblong-ellipsoid, up to 20 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: September to October.

Distribution of ***Geissorhiza exscapa***.

Distribution and ecology: extending along the Atlantic Coast of South Africa from near Hondeklipbaai in Northern Cape south to Blouberg near Cape Town in Western Cape, and inland in the Bokkeveld and Pakhuis Mtns; usually in deep alluvial coastal sands in sandveld vegetation, or inland in fynbos.

Diagnosis: *Geissorhiza exscapa* is recognised by the leaves with winged margins held at right angles to the blade but the main vein hardly raised, the leaf thus H-shaped in cross section, and by the large, cream-coloured to pink flowers with perianth tube 40–80 mm long, usually well exserted from the bracts, and narrowly obovate tepals, 26–35 × 4.5–6.0 mm. The stems are sometimes short and entirely sheathed by leaf bases. *Geissorhiza tenella* has a similar leaf morphology but usually smaller flowers with a perianth tube 20–40(–50) mm long and slightly shorter, narrower tepals 13–23 × 2.0–4.5 mm.

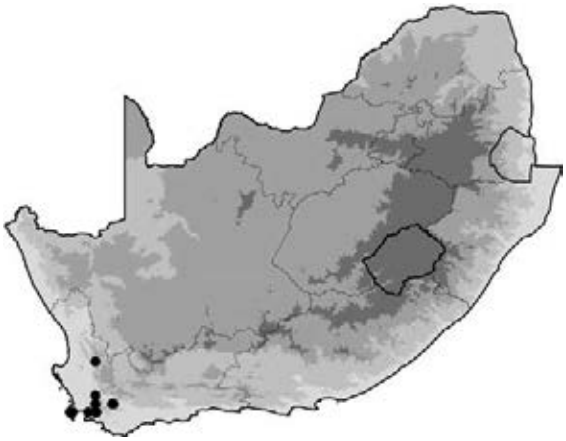
Plants from the Bokkeveld Mtns stand out in having bracts rather shorter than elsewhere, 30–35 mm long and matching those of *Geissorhiza confusa* but the leaves in these populations are quite typical of *G. exscapa*. Populations from the Pakhuis Mtns and some from the Piketberg have the perianth tube shortly exserted from the bracts, giving the specimens an unusual appearance. Again, the leaves are typical of the species and there seems no reason to treat them as separate taxa. In the absence of leaves, however, these plants can barely be distinguished from *G. confusa*, in which the tube may occasionally be up to 50 mm long.

Subg. 2. **Geissorhiza**

Corms with imbricate light to dark brown or blackish tunics, leaves lanceolate to sword-shaped or linear, plane, or with the margins and midrib and sometimes other veins thickened, or winged and ciliate-pubescent, stem smooth or ciliate-puberulous, spike few to several flowered, bracts herbaceous, often becoming dry above, rust-coloured in upper half (sects. *Ciliatae* and *Planifoliae*); flowers actinomorphic, rotate or salver-shaped or zygomorphic; tube shorter or as long as bracts; stamens equal or unequal with one filament somewhat to much shorter than other two.

Species 57.

Sect. 8. **Intermedieae** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 382 (1985) [as sect. *Intermedia*]. Type: *Geissorhiza scillaris* A.Dietr.



Corm tunics usually light brown; stem smooth; leaves with thickened margins and main veins; spike several flowered; bracts dry and membranous above; flowers actinomorphic, rotate; perianth tube short; stamens equal.

Species 2: southwestern Western Cape, South Africa.

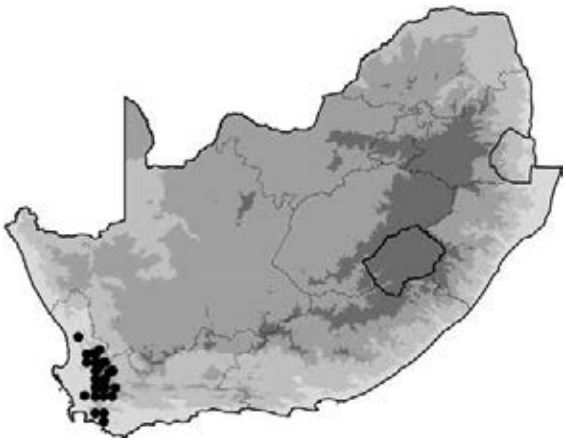
58. **Geissorhiza similis** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 382 (1985). Type: South Africa, [Western Cape], W slopes of Redhill, near the top, *Lewis 2493* (SAM, holo.; NBG., PRE, iso.).

Plants 120–250(–350) mm high. *Corm* ± symmetric, globose, 8–11 mm diam.; tunics imbricate, woody, light brown, incised below into triangular, acute to truncate sections. *Stem* ± erect, rarely branched. *Leaves* (2)3, lower 2 basal, lowermost longest, reaching to ± base of spike, occasionally exceeding stem, linear to falcate, 1–2 mm wide, margins and main vein thickened, 2-grooved on each surface, edges of margin and main vein often minutely ciliate to hispid, remaining leaves much shorter, uppermost leaf inserted in middle of stem, usually short and sheathing below, occasionally entirely sheathing, sheath ribbed, lower two leaves often sticky below especially on margins, with sand adhering even when dry. *Spike* slightly flexuose, (2)3- to 8-flowered; bracts green, translucent above, sometimes red-flushed, 4.5–7.0 mm long, inner shorter than outer. *Flowers* actinomorphic, rotate, white, outer tepals flushed pink outside, tepals spreading when fully open; perianth tube 2.5–3.0 mm long, shorter than bracts; tepals obovate-elliptic, 9–12 × 5–6 mm. *Filaments* erect, equal, 2–3 mm long; anthers 2–3 mm long, yellow. *Style* dividing opposite apex of anthers, branches up to 2 mm long. *Chromosome number* $2n = 26$. *Flowering time*: late August to October.

Distribution and ecology: occurring in the western half of Western Cape, South Africa, from Bain's Kloof to the Cape Peninsula and eastward to Jonas Kop in the Riviersonderend Mtns and with an isolated record from the Cederberg; in sandy mountain soil.

Distribution of ***Geissorhiza similis***.

Diagnosis: *Geissorhiza similis* is distinguished by the imbricate corm tunics that are brown rather than almost black as more typical of subg. *Geissorhiza*, white to creamy white flowers, and long basal leaf with thickened hispid margins and main vein, the remaining two leaves much shorter and largely sheathing. The leaf sheath and basal blade are sticky, and in this, as well as the white flowers, *G. similis* resembles the apparently unrelated *G. hispidula*, which has different corms with concentric tunics. Without corms it is difficult to separate the two species, although *G. hispidula* has well-developed blades on the cauline leaves and sticky floral bracts. Taller and more slender specimens of *G. similis* may also be confused with *G. umbrosa* (subg. *Weihea*) in the absence of corms, but that species normally has somewhat larger flowers and the leaves are smooth, without the ciliate to hispid and sticky margins.



59. **Geissorhiza scillaris** *A.Dietr.*, Species Plantarum 2: 587 (1833); Goldblatt: 384 (1985). *Ixia ramosa* Ker Gawl.: sub t. 549 (1802b), new name for *Ixia scillaris* Thunb.: 13 (1783), illegitimate homonym, not *I. scillaris* L. (1762) [not *G. ramosa* Ker Gawl. ex Klatt (1866)]. *Ixia phalangioides* Roem. & Schult.: 385 (1817), superfluous name for *Ixia ramosa* Ker Gawl. Type: South Africa, [Western Cape], without precise locality, *Thunberg s.n.* [UPS–THUNB 992 in part, lecto., designated by Goldblatt: 441 (1983)].

Plants slender, 120–350 mm high. *Corm* ± ovoid, 8–12 mm diam. (larger when old tunic layers accumulated); tunics woody, rarely papery, brown, imbricate, outer layers notched below into truncate segments, drawn into bristles above. *Stem* erect, flexed at base of spike, with membranous, green to white bract 7–12 mm long in upper ⅓, simple or rarely with short branch in axil of stem bract. *Leaves* 2, basal, lowermost free from base, straight to falcate, cross-shaped section, with strongly raised margins and midrib, thus with 4 grooves, sticky, often with adhering sand especially below, upper leaf sheathing almost entirely, enclosing stem in lower half or nearly to base of spike, free part 10–30 mm long. *Spike* 4- to 10(–20)-flowered; bracts green, becoming dry, transparent and pale or rarely brownish above, spreading distally, 6–8 mm long, inner shorter than outer. *Flowers* actinomorphic, rotate, white, pale grey-blue or blue with white centre; perianth tube funnel-shaped, 1.0–1.5 mm long; tepals elliptic, 7–9 × 3–4 mm wide. *Filaments* erect, equal, 2–3 mm long; anthers 2.5–3.5 mm, white; pollen creamy white. *Style* 5–6 mm long, dividing nearly opposite anther tips, branches ± 1 mm long. *Capsules* globose, 3–4 mm long, surrounded by bracts. *Chromosome*

number 2*n* = 26. *Flowering time*: mid-August to October (to December at high altitudes).

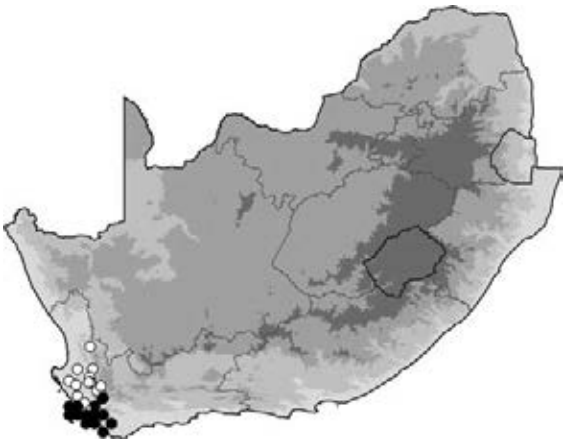
Distribution and ecology: a montane species, extending through the mountains of Western Cape, South Africa, from Pakhuis Pass and the Cederberg in the north to Shaw's Mtns in the Caledon District in the south; on stony sandstone slopes and plateaus, occasionally in seasonally wet sites, usually at elevations above 500 m.

Diagnosis: the distinctive *Geissorhiza scillaris* has imbricate corm tunics, small white to blue flowers, and just two foliage leaves, the lower with a long free blade and the upper sheathing the stem for most of its length. Plants usually have an inconspicuous green or transparent, sheathing bract a short distance below the spike. The blade of the lowermost leaf is terete with heavily thickened margins and main vein, thus cross-shaped in section and with 4 longitudinal grooves. Both the sheath and blade are sticky and usually have sand adhering to the surface. The star-like flowers are small, with a tube up to 1.5 mm long, spreading tepals 7–9 mm long, and usually white or pale grey-blue but some populations in the Cederberg and Cold Bokkeveld have clear blue flowers with a white centre. *Geissorhiza scillaris* has often been confused with *G. juncea*, which is broadly similar in appearance but with three foliage leaves, the lower two basal, slender and terete, and corm tunics of the concentric type. The two are not closely related.

Distribution of ***Geissorhiza scillaris***.

Sect. 9. Geissorhiza

Geissorhiza subsect. *Ventricosae* R.C.Foster: 27 (1941). Type: *G. imbricata* (D.Delaroche) Ker Gawl.



Corm tunics hard and woody, imbricate; stems smooth; leaves with margins and midrib and often other veins strongly thickened, sword-shaped to linear or terete; bracts green below, becoming dry above; flowers actinomorphic, rotate to salver-shaped, or zygomorphic; tube short or reaching to apex of bracts; stamens equal or unequal, unilateral and declinate in some species.

Species 10: southwestern Western Cape, South Africa.

60. **Geissorhiza imbricata** *(D.Delaroche) Ker Gawl.* in König & Sims, Annals of Botany 1: 224 (1804); Goldblatt: 387 (1985). *Ixia imbricata* D.Delaroche: 17 (1766). Type: South Africa, [Western Cape], Cape Peninsula, Lakeside, *Salter 7034* [BOL, neo., designated by Goldblatt & Barnard: 301 (1970)].

Plants 65–250(–300) mm high. *Corm* globose, 5–10 mm diam.; tunics blackish, imbricate, outer layers accumulating above, regularly notched below into segments. *Stem* simple or 1-branched, flexed above uppermost leaf sheath and at base of spike. *Leaves* 3, lower 2 basal, longest, reaching ± middle to apex of spike, sometimes longer, sword-shaped to ± linear, ribbed with (2–)4– several longitudinal grooves along entire length, 2–6(–10) mm wide, uppermost leaf inserted shortly above stem base, sheathing for ½ its length, sheath strongly ribbed and inflated. *Spike* flexuose, inclined, (2–)6- to 8(–14)-flowered; bracts green below, often becoming dry above, 6–12(–15) mm long, sometimes red above, inner narrower than outer. *Flowers* actinomorphic, rotate or tepals cupped, white to pale yellow, often red on outside of outer tepals, sometimes dark in centre; perianth tube ± funnel-shaped, 2–8 mm long, enclosed to shortly exserted from bracts; tepals elliptic, (9–)11–25(–30) × (4.5–)6.5–12.0 mm. *Filaments* erect, equal, 3–8(–10) mm long; anthers 3–7 mm long, pale yellow. *Style* dividing opposite upper ⅓ of anthers, branches 3–4 mm long. *Capsules* oblong-globose, 7–10 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: (August) September to October.

Distribution and ecology: extending from the Olifants River Valley in the north to Bredasdorp in Western Cape,

Distribution of ***Geissorhiza imbricata*** subsp. ***imbricata***, ●; subsp. ***bicolor***, ○.

South Africa; mainly on damp poorly drained, sandy or peaty flats, along streams or shallow marshes.

Diagnosis: *Geissorhiza imbricata* is distinguished mainly by the ribbed leaves, the uppermost with an inflated, ribbed sheath and actinomorphic flowers, usually white to creamy white but occasionally yellow and in some populations with a dark centre. Shorter-tubed populations are regarded as subsp. *imbricata* and those with longer tubes are segregated as subsp. *bicolor*.

Key to subspecies

1a Flowers white to cream-coloured without a dark centre, outer tepals often red or pink outside; perianth tube 2–4(–6) mm long; tepals 9–15(–17) mm long. . . . . 59a. subsp. *imbricata*
1b Flowers creamy white to pale yellow, occasionally with a dark centre, outer tepals sometimes red outside; perianth tube (4–)5–8 mm long; tepals (16–)20–30 mm long . . . . . .59b. subsp. *bicolor*

60a. subsp. **imbricata**

Geissorhiza wrightii Baker: 238 (1876). Type: South Africa, [Western Cape], Simons Bay, *Wright 243* (K, lecto., designated by Foster: 36 (1941); G, L, isolecto.).

Geissorhiza sabulosa Klatt: 203 (1885). Type: South Africa, [Western Cape], near Camps Bay, *Templeman sub MacOwan 2273* (S, lecto., designated by Goldblatt: 389 (1985); K, SAM, isolecto.).

Geissorhiza sulphurea var. *arenicola* R.C.Foster: 37 (1941). Type: South Africa, [Western Cape], Ceres Road (Wolseley), *Schlechter 8992* (B, holo.; BM, BOL, BR, E, G, H, K, L, MO, PRE, S, Z, iso.).

Spike mostly 6- to 8(–14)-flowered; bracts 6–8(–11) mm long: *Flowers* white to cream-coloured, with tepals spreading, outer tepals usually red outside; perianth tube 2–4(–6) mm long, enclosed in bracts; tepals 10–15(–17) × 4.5–7.0 mm wide, obtuse. *Filaments* (3–)4–5 mm long; anthers 3–5 mm long. *Capsule* oblong-globose, up to 10 mm long. *Flowering time*: (August to) September to October.

Distribution and ecology: fairly common in southern Western Cape, extending from the Cape Peninsula eastward to Caledon, Bredasdorp and north to the Tulbagh Valley and Worcester; on wet sandy flats, marshes and streambanks.

Diagnosis: subsp. *imbricata* is distinguished by the somewhat smaller flowers, either white or creamy white to pale yellow and always uniformly coloured. The tepals are mostly 10–15 mm long and the perianth tube 2– 4, rarely up to 6 mm long vs. mostly 5–8 mm long in subsp. *bicolor*. A certain amount of overlap in the flower features is to be expected between subspecies.

60b. subsp. **bicolor** (*N.E.Br.*) *Goldblatt* in Annals of the Missouri Botanical Garden 72: 390 (1985) [as (Thunb.) Goldblatt]. *Ixia bicolor* Thunb.: 3 (1803), illegitimate homonym, not *I. bicolor* (Thunb.) Ker Gawl. (1802a). *Geissorhiza bicolor* N.E.Br.: 44 (1928). Type: South Africa, [Western Cape], without precise locality, *Thunberg s.n.* (UPS–THUNB 921 '*Ixia bicolor* α', holo.).

Geissorhiza obtusata Soland. ex Ker Gawl.: t. 672 (1803). *G. imbricata* var. *obtusata* (Ker Gawl.) Baker: 157 (1892). Type: South Africa, without precise locality, cultivated in England, *Niven s.n.*, illustration in Ker Gawl.: t. 672 (1803).

Geissorhiza secunda var. *bicolor* Baker: 155 (1892). *G. imbricata* var. *concolor* Baker: 72 (1896). Type: South Africa, [Western Cape], near Somerset West, *H. Bolus 5567* (K, lecto., designated by Foster: 38 (1941); BOL, isolecto.).

Geissorhiza rubicunda R.C.Foster: 35 (1941). Type: South Africa, [Western Cape], Michell's Pass, *Schlechter 8931* (B, holo.; BM, BOL, BR, E, G, H, K, L, MO, P, PH, S, Z, iso.).

Geissorhiza bicolor var. *macowanii* R.C.Foster: 33 (1941). Type: South Africa, [Western Cape], near Malmesbury, *MacOwan s.n. sub Herb. Norm. Austr. Afr. 1568* (G, holo.; B, G, K, Z, iso.).

[*Ixia obtusata* Soland. ex Ker Gawl.: t. 549 (1802b), invalid name only in synonymy.]

[*Geissorhiza aurea* Eckl.: 21 (1827), invalid name, without description.]

Spike 2- to 4(–9)-flowered; bracts 10–12(–15) mm long. *Flowers* creamy to pale yellow, outer tepals often red to purple-flushed outside, with tepals somewhat cupped, occasionally dark in throat and tube usually also dark; perianth tube (4–)5–8 mm long, slightly shorter than, or reaching the apex of bracts, rarely exserted; tepals (16–)20–30 × 10–12 mm wide. *Filaments* 7–10 mm long; anthers 5–7 mm long. *Flowering time*: September to early October.

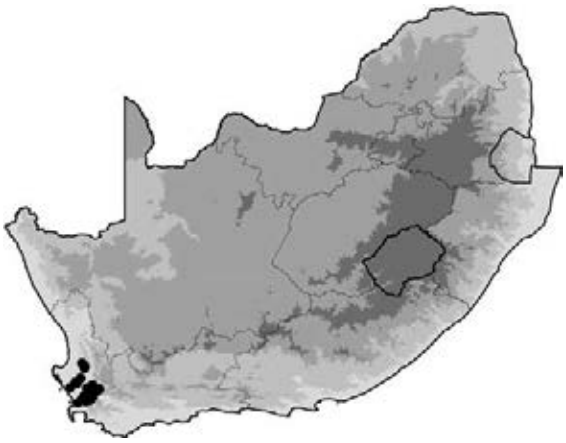
Distribution and ecology: Western Cape, South Africa, extending from the Olifants River Valley and Porterville to the Cape Flats.

Diagnosis: subsp. *bicolor* is distinguished from subsp. *imbricata* mainly by the larger flowers, the tepals (16–)20–30 mm long with a somewhat longer perianth tube, (4–)5–8 mm long and reaching nearly to the apex of or slightly exceeding the bracts. Plants usually have three fairly broad, several ribbed leaves and spikes of up to 9, but usually only 3 to 5 flowers.

The subspecies includes plants with pure yellow flowers as well as those with a dark centre, populations of the latter corresponding closely to the type collection of *Geissorhiza bicolor* and relatively rare, although recorded from Malmesbury to Stellenbosch in the south central part of the range of the subspecies. Such plants evidently differ in no other character from the type and similar collections of *G. rubicunda*, which was poorly

known when first described but has now been collected at many sites in the Tulbagh and Porterville Districts as well as in the Olifants River Valley to the north.

Subsp. *bicolor* may be confused with the southwestern Cape species *G. brehmii* and the two taxa can only be distinguished by their vegetative characteristics. The semi-aquatic *G. brehmii* has terete, somewhat succulent and inflated leaf blades with four narrow longitudinal grooves along their length. Often its lowermost leaf is much reduced, vestigial or even absent, while the uppermost leaf is largest and ribbed on the inflated sheath as in *G. imbricata*. Such specimens are especially difficult to separate from narrow-leaved individuals of subsp. *bicolor*. The white to creamy yellow flowers of *G. brehmii* also occasionally have a dark centre. Forms of subsp. *bicolor* with flowers with a dark centre may also be confused with *G. purpureolutea*, which has narrow two-grooved leaves, usually about 1.5 mm wide, and a smaller flower with tepals 10–17(–22) mm long and a short perianth tube, 2–4 mm long. The plants are also usually short, 60–120 mm high, although they may reach 170 mm. The two species grow in the same habitat and occasionally close to one another.



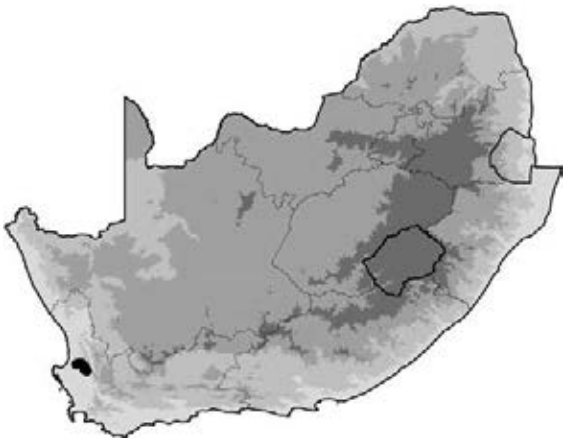
61. **Geissorhiza purpureolutea** *Baker* in Journal of Botany, British and foreign 14: 238 (1876); Goldblatt: 392 (1985). Type: South Africa, [Western Cape], between Paarl and Pont, *Drège 8476* (K, lecto., effectively designated by Foster: 33 (1941); G, L, isolecto.).

Geissorhiza sulphurea Schltr.: 99 (1899). Type: South Africa, [Western Cape], damp places near Ceres Road [Wolseley], *Schlechter 8981* (B, lecto., effectively designated by Foster: 36 (1941); BM, BOL, BR, E, G, H, K, MO, P, PH, PRE, S, Z, isolecto.).

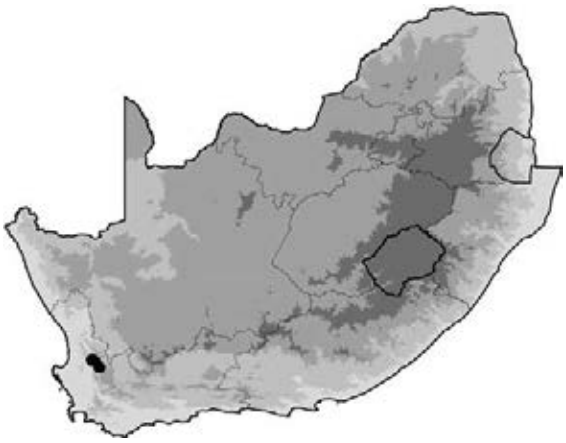
Plants 50–120(–170) mm high. *Corm* globose, ± symmetric, 5–7 mm diam.; tunics ± black, imbricate, notched below into sections. *Stem* usually unbranched. *Leaves* 3, linear to narrowly sword-shaped, 2- to 4-ribbed, margins thickened, lower 2 basal, uppermost cauline and largest, half as long to ± as long as spike, with inflated, strongly ridged sheath. *Spike* inclined, flexuose, (1–)3- to 5-flowered; bracts green, sometimes dry distally, 7–8 mm long. *Flowers* actinomorphic, rotate, pale yellow with dark brown or purple centre, tepals spreading, often flushed red outside; perianth tube funnel-shaped, 2–4 mm long; tepals ± elliptic, 10–17(22) × 7–8 mm. *Filaments* erect, equal, 5–6 mm long, often dark coloured in lower ½; anthers 4–6 mm long, yellow. *Style* dividing opposite apex of anthers, branches ± 2.5 mm long. *Flowering time*: mid-August to mid-September.

Distribution and ecology: restricted to the southwestern corner of Western Cape, South Africa, extending from Piketberg south to Tulbagh and Paarl; on wet sandy flats.

Diagnosis: relatively rare today, *Geissorhiza purpureolutea* has ribbed leaves with the uppermost leaf cauline and largest, and relatively small, pale to deep yellow flowers with a dark brown to purple centre. The perianth tube is 2–4 mm long and the tepals mostly 10–17 mm long. It is closely related to *G. imbricata* and almost identical with that species vegetatively but *G. imbricata* has larger flowers with a perianth tube 2–8 mm long and white to pale yellow tepals only occasionally with a dark centre.



Distribution of ***Geissorhiza purpureolutea***.



62. **Geissorhiza barkerae** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 393 (1985). Type: South Africa, [Western Cape], N of Piketberg, wet sites at the foot of Zebrakop, *Goldblatt 6391* (MO, holo.; K, NBG, PRE, S, WAG, iso.).

Plants 100–200 mm high. *Corm* ± ovoid-globose, ± symmetric, 7–11 mm diam.; tunics blackish, imbricate, regularly notched below into segments. *Stem* ± erect below, usually 1-branched, flexed above sheath of upper leaf and at base of spike. *Leaves* 3, linear-sword-shaped, 2–4 mm wide, (2–)4–several ribbed, ± as long as stem, lower 2 basal, uppermost largest, inserted near base or in lower part of stem, sheathing for half its length, sheath inflated and strongly ribbed. *Spike* inclined to ± horizontal, flexuose, (2–)4- to 10-flowered; bracts green, upper margins translucent, becoming dry and often red-flushed near apex, sometimes dry above at flowering, 10–13 mm long. *Flowers* zygomorphic, style and stamens declinate, held above ± deflexed lower tepal, pale yellow marked with purple to black in lower ⅓ of outer or all tepals, yellow in throat and tube, outer tepals often reddish outside; perianth tube funnel-shaped, 7–8 mm long; tepals lanceolate, 22–30 × 8–9 mm. *Filaments* unilateral, declinate, unequal, two longer, 15–20 mm long, one shorter, 10–14 mm long; anthers 5–6 mm long, yellow; pollen yellow. *Style* dividing opposite upper ⅓ of anthers, branches ± 5 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: mid-September to mid-October.

Distribution and ecology: endemic to the Piketberg area of Western Cape, South Africa, on the lower slopes and flats east and west of the range and on the lower slopes

Distribution of ***Geissorhiza barkerae***.

Distribution of ***Geissorhiza louisabolusiae***.

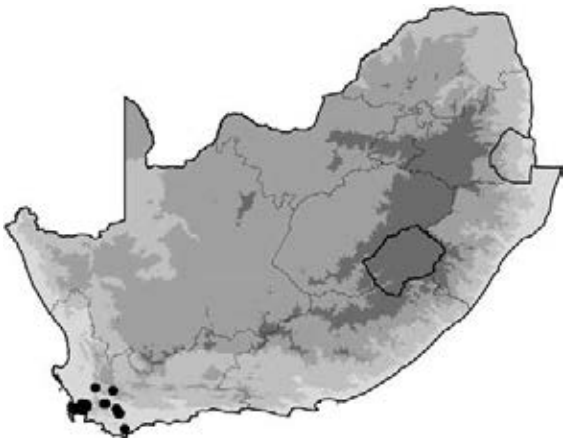
of the Olifants River Mtns; on seasonally wet to marshy flats, mainly on sandy ground.

Diagnosis: *Geissorhiza barkerae* is immediately recognised by the zygomorphic flowers borne on inclined to nearly horizontal spikes, the tepals remaining somewhat cupped even when the nodding flowers are fully open. The pale yellow flowers have large purple-black markings on the lower third of the outer or all tepals, a perianth tube 7–8 mm long, and tepals 22–30 mm long. The unilateral stamens are decumbent, thus held above the lowermost tepal and the filaments are unequal, one ± 5 mm shorter than the other two. It is evidently allied to and almost identical vegetatively to the more widespread *G. imbricate*, which has smaller, radially symmetric flowers.

63. **Geissorhiza louisabolusiae** *R.C.Foster* in Contributions from the Gray Herbarium of Harvard University 135: 34 (1941) [as *louisabolusae*]; Goldblatt: 395 (1985). Type: South Africa, [Western Cape], 6 miles [± 9 km] E of Graafwater, *Salter 2790* (K, holo.; BM, BOL, iso.).

Plants (100–)150–200 mm high. *Corm* ovoid, 7–9 mm diam.; tunics blackish, imbricate, notched into regular segments below. *Stem* flexed at base of spike, sheathed for ½–⅔ its length, occasionally 1-branched. *Leaves* 3, linear to nearly terete, reaching to ± base of spike, 1–2 mm wide, narrowly 4- to 6(–8)-grooved, lower 2 basal, uppermost basal or inserted shortly above ground, largest, sheathing stem below, sheath ribbed and inflated. *Spike* flexuose, inclined, 2- to 7-flowered; bracts green, margin often lined red above, usually becoming dry and membranous near apex, 8–10 mm long, inner shorter than outer. *Flower* actinomorphic, rotate, tepals somewhat cupped, bright yellow; perianth tube funnel-shaped, 4–6 mm long, nearly reaching apex of bracts; tepals elliptic, 18–28 × 7–9 mm. *Filaments* erect, unequal, two longer 7–9 mm long, shorter one 5–7 mm long; anthers 4.5–6.0 mm long, yellow; pollen yellow. *Style* dividing near apex of anthers, branches ± 2 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: late August to September.

Distribution and ecology: restricted to the Olifants River Valley and adjacent valleys to the west in Western Cape, South Africa; on seasonally wet, often waterlogged sandy flats or shallow marshy sites.



Diagnosis: a member of the *Geissorhiza imbricata* group, *G. louisabolusiae* has narrow, often almost terete, several ribbed and grooved leaves, the uppermost largest and with an inflated, strongly ribbed sheath. The flowers are uniformly bright yellow, have a short perianth tube 4–6 mm long, and usually slightly unequal stamens, two filaments ± 2 mm longer than the third.

64. **Geissorhiza brehmii** *Eckl. ex Klatt* in Linnaea 34: 653 (1866); Goldblatt: 396 (1985). *G. imbricata* var. *brehmii* (Eckl. ex Klatt) R.C.Foster: 38 (1941). Type: South Africa, [Western Cape], Hottentots Holland, near Somerset West, *Ecklon & Zeyher Irid. 295* (B, lecto., effectively designated by Foster: 38 (1941); FI, GH, isolecto.).

Geissorhiza teretifolia G.J.Lewis: 48 (1941). Type: South Africa, [Western Cape], Kenilworth Race Course, *Lewis 97* (SAM, holo.).

Geissorhiza louisabolusiae [as *louisabolusae*] var. *longifolia* R.C.Foster: 34 (1941). Type: South Africa, [Western Cape], road to Moorreesburg, Malmesbury [District], *Bachmann 1091* (B, holo.; Z, iso.).

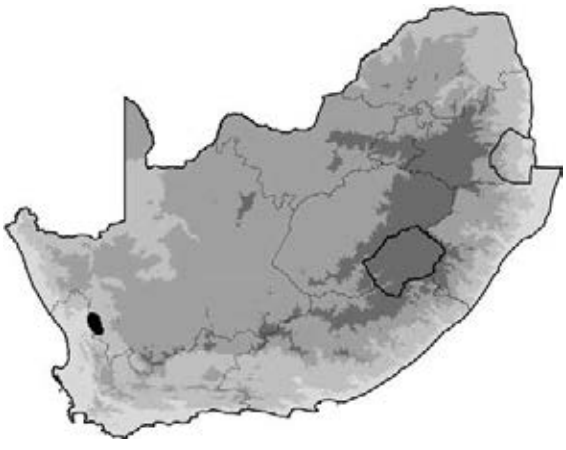
Plants 140–300 mm high. *Corm* ± globose, obliquely flattened below, 8–12 mm diam.; tunics blackish, imbricate, outer layers accumulating above, regularly notched below into angular segments, drawn into short bristles above. *Stem* often branched from uppermost leaf axil, and sometimes from base, flexed at base of spike. *Leaves* 2 or 3, lower 1 or 2 basal, lowermost small, often broken, or vestigial (occasionally lacking), second leaf ± as long as stem, usually terete (rarely few-ribbed), inflated or ± succulent with 4 very narrow longitudinal grooves, uppermost leaf usually cauline, inserted shortly above ground, with sheath ribbed and inflated, blade often as long as basal leaf (or leaves), ± 1.5 mm

Distribution of ***Geissorhiza brehmii***.

diam., terete or several-ribbed. *Spike* inclined, flexuose, 2- to 6-flowered; bracts often red distally, becoming dry and membranous near apex, 7–10(–15) mm long, inner ± 2 mm shorter, forked near apex. *Flowers* actinomorphic, ± cupped when fully open, white to creamy yellow, outer tepals sometimes flushed red to purple outside, occasionally dark coloured in throat and tube; perianth tube (3–)5–7(9) mm long, slightly shorter than, or reaching apex of bracts; tepals elliptic, 15–20(–26) × 6–9 mm, spreading. *Filaments* erect, equal, 5–9 mm long; anthers ± 5 mm long, creamy white or yellow. *Style* dividing opposite upper ⅓ to near apex of anthers, branches 2–4 mm long. *Capsules* globose, up to 6 mm long. *Flowering time*: (August to) September to October.

Distribution and ecology: extending in southern Western Cape, South Africa, from near Gouda to Malmesbury and the Cape Peninsula east to Caledon and Bredasdorp; in sandy ground, either marshy or seasonally flooded, or at edges of pools.

Diagnosis: the semi-aquatic *Geissorhiza brehmii* is recognised by the two or three leaves, all with terete, usually 4-grooved blades, the uppermost with an inflated and prominently ribbed sheath, a corm with imbricate tunics, and white to creamy yellow flowers, occasionally with a dark centre. The perianth tube is 5–9 mm long and the tepals 15–26 mm long. The leaf blades are typically slightly succulent and usually somewhat inflated and possibly hollow, and in most plants are terete but occasionally flattened and few-ribbed, these difficult to distinguish from narrow-leaved individuals of *G. imbricata*.



Gessirohiza brehmii has been confused at times with *G. hispidula* and with *G. geminata* but both these species have corms with concentric tunics. Also an aquatic species, *G. geminata* has two to four, well-developed basal leaves, plane when dry but possibly terete when alive, with a slightly thickened and raised main vein but without thickened margins. Capsules of *G. brehmii* appear to be unusually small, globose in shape and ± 6 mm long. Although poorly documented, capsules of *G. geminata* are obovoid and longer, mostly ± 8 mm long in dry specimens.

65. **Geissorhiza sulphurascens** *Schltr. ex R.C.Foster* in Contributions from the Gray Herbarium of Harvard University 135: 39 (1941); Goldblatt: 398 (1985). Type: South Africa, [Northern Cape], Bokkeveld W of Nieuwoudtville, *Marloth 7658* (B, holo.; PRE, iso.).

Plants 120–200 mm high. *Corm* ovoid, symmetric, 6–8 mm diam.; tunics blackish, imbricate, notched into regular segments below. *Stem* sheathed ± ⅔ its length, flexed above sheath of uppermost leaf, occasionally with 1 branch. *Leaves* 3, lower 2 basal, uppermost basal or inserted shortly above ground, largest, blades linear, ± 1 mm wide, reaching to between middle of stem and base of spike, margins and main vein thickened, 2-grooved on each surface, uppermost sheathing stem in lower ⅔, sheath inflated and several ribbed. *Spike* flexuose, inclined, 4- to 8(–10)-flowered; bracts green, upper margins often red, sometimes dry and brownish near apex with age, 7–9 mm long, inner shorter than outer. *Flowers* actinomorphic, rotate, tepals usually shallowly cupped, creamy white; perianth tube funnel-shaped, 3–4 mm long, enclosed in bracts; tepals ovate-elliptic, 13–18 × 5–7 mm. *Filaments* erect, equal, 5–8 mm long; anthers ± 6 mm long, pale yellow. *Style* dividing opposite apex of anthers, branches ± 2 mm long. *Capsules* ± globose, ± 5 mm long. *Flowering time*: late August and September.

Distribution and ecology: restricted to the Bokkeveld Mtns in southwestern Northern Cape, South Africa; in poorly drained, damp sandy ground, often waterlogged in winter.

Diagnosis: evidently somewhat isolated taxonomically, *Geissorhiza sulphurascens* has relatively small, creamy white to almost yellow flowers borne on relatively crowded spikes, the perianth tube 3–4 mm long and tepals 13–18 mm long. The leaves are linear with thickened margins and main vein, thus 2-grooved on each surface. The uppermost of the three leaves is usually largest and sheaths the lower ⅔ of the stem, the sheath

Distribution of ***Geissorhiza sulphurascens***.

somewhat inflated and several ribbed as are the upper leaves of all members of sect. *Geissorhiza*.

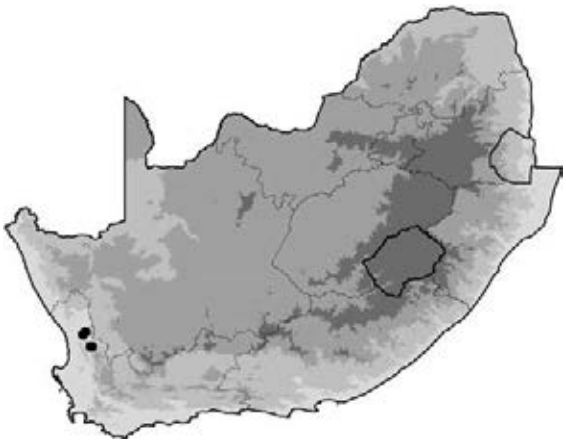
66. **Geissorhiza minuta** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 399 (1985). Type: South Africa, [Western Cape], Pakhuis Pass, *Esterhuysen 3193* (BOL, holo.; K, MO, iso.).

Plants 30–80(–120) mm high. *Corm* globose, symmetric, 5–6 mm diam.; tunics blackish, imbricate, notched into regular segments below. *Stem* flexed above sheath of uppermost leaf and at base of spike, occasionally with 1 branch from base. *Leaves* 3, lower 2 basal, uppermost basal or inserted shortly above ground, longer or shorter than lower leaves, blades, linear, ± as long as spike, ± 1 mm wide, margins and main vein thickened, thus 2-grooved on each surface, uppermost leaf sheathing lower ⅔ of stem, sheath ribbed and slightly inflated. *Spike* flexuose, inclined, 2- to 6-flowered; bracts green, upper margins often red, becoming dry and brownish from the apex with age, 4–5 mm long, inner ± as long as outer. *Flowers* actinomorphic, rotate, white, outer tepals flushed light to dark purple outside; perianth tube funnel-shaped, ± 1 mm long, enclosed in bracts; tepals elliptic, 7–8 × ± 2.5 mm. *Filaments* erect, equal, 2–3 mm long; anthers 2–3 mm long, pale yellow. *Style* dividing shortly beyond apex of anthers, branches ± 1.5 mm long. *Flowering time*: September to early October.

Distribution and ecology: restricted to the northwestern mountains of Western Cape, South Africa, on the Gifberg, Matsikamma and Pakhuis mtns; on wet sandstone pavement in shallow sandy ground, especially common after fire.

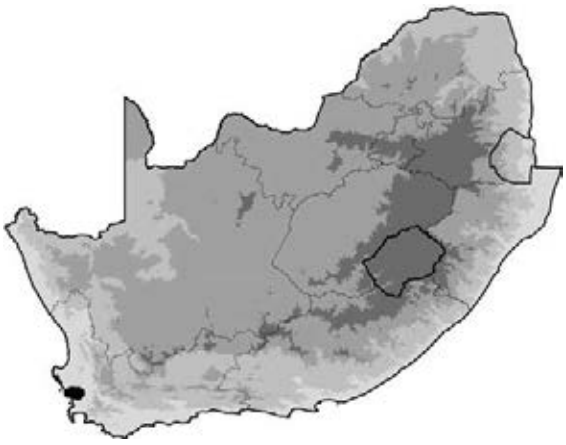
Diagnosis: the dwarf *Geissorhiza minuta* stands up to 120 mm high although is more often shorter than that. The white flowers are among the smallest in the genus, with a perianth tube ± 1 mm long and tepals 7–8 mm long. Although poorly documented, it is often common locally in suitable habitats in years of ample rainfall.

67. **Geissorhiza eurystigma** *L.Bolus* in South African Gardening and Country Life 21: 281 (1931); Goldblatt: 400 (1985). *G. mathewsii* var. *eurystigma* (L.Bolus) R.C.Foster: 27 (1941). Type: South Africa, [Western Cape], near Mamre, *L. Bolus s. n.* (BOL 19876, lecto., designated by Goldblatt: 400 (1985); K, isolecto.).



Ixia secunda D.Delaroche: 17 (1766). Type: South Africa, without precise locality or collector (L, holo.).

Ixia rocheana [as *rochensis*] var. *spithamaea* Ker Gawl.: t. 598 (1802c). Type: South Africa, [Western Cape], without precise locality, '*Ixia violacea*' *Masson s.n.* [BM, lecto., designated by Goldblatt: 400 (1985)].



[*Ixia violacea* Herb. Banks ex Ker Gawl.: t. 598 (1802c), invalid name only in synonymy.]

Plants 80–150(–200) mm high. *Corm* ovoid, ± symmetric, 8–11 mm diam., truncate at base; tunics imbricate, blackish, notched below into regular segments. *Stem* simple or 1- or 2-branched, flexed above sheath of upper leaf and at base of spike, rarely with a bract-like leaf in the upper half. *Leaves* 3, ± sword-shaped, several ribbed, reaching to base or middle of spike, 3–6 mm wide, lower 2 basal, uppermost inserted at base or in lower part of stem, sheath inflated, often as long and wider than lower leaves. *Spike* inclined, flexuose 2- to 5(–7)-flowered; bracts green, becoming dry and membranous from apex, often reddish on upper margins, 9–13 mm long, inner ± as long as outer. *Flowers* actinomorphic, tepals widely cupped, dark blue with red centre; perianth tube ± funnel-shaped, 6–9 mm long, exserted from bracts; tepals broadly elliptic, 16–24 × 9–13 mm. *Filaments* erect, equal, up to 9 mm long; anthers 4.5–5.5 mm long, yellow. *Style* dividing near apex of anthers, branches ± 4 mm long, broad, densely hairy. *Capsules* ovoid-oblong, ± up to 12 mm long. *Flowering time*: September to early October.

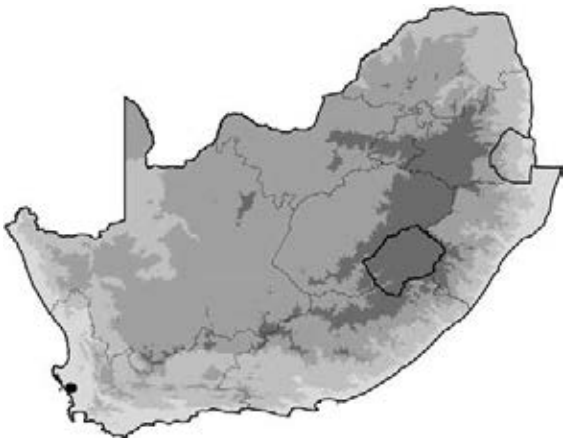
Distribution and ecology: restricted to southwestern Western Cape, South Africa, centred around Darling

Distribution of ***Geissorhiza minuta***.

Distribution of ***Geissorhiza eurystigma***.

and Mamre, and extending south to Kalabaskraal and Malmesbury; in gravelly sand.

Diagnosis: *Geissorhiza eurystigma* is recognised by the strikingly coloured flowers, dark blue with a deep red centre, and with broad, conspicuously hairy stigmas. The leaves are relatively broad and strongly multi-ribbed. *Geissorhiza radians*, which has similarly coloured flowers but with the red centre edged with a narrow white band, is immediately distinguished by its narrower leaves.



Geissorhiza eurystigma was confused in the past with *G. mathewsii* and was treated for a time as *G. eurystigma* subsp. *mathewsii.* The latter has similar blue flowers with a red centre and broad style branches but differs in its much shorter perianth tube, only ± 2.5 mm long, and anthers held above the style branches.

68. **Geissorhiza mathewsii** *L.Bolus* in Annals of the Bolus Herbarium 4: 42 (1926); Goldblatt: 402 (1985). Type: South Africa, [Western Cape], damp marshy places near Darling, in 1923 *Mathews s.n.* [BOL 18502, lecto., designated by Goldblatt: 402 (1985)].

Plants 80–180 mm high. *Corm* globose, ± symmetric, 7–10 mm diam., truncate at base; tunics imbricate, blackish, layers notched below into regular segments. *Stem* flexed above sheath of upper leaf and at base of spike, rarely with a bract-like leaf in upper half, simple or 1- to 3-branched. *Leaves* 3, lower two basal, reaching to base or middle of spike, 2–4 mm wide, sword-shaped, conspicuously several ribbed, lowermost smallest, uppermost leaf inserted at base or in lower part of stem, sheathing and inflated below, also several ribbed, longer than lower leaves. *Spike* secund, flexuose, 2- to 6-flowered; bracts green, becoming dry and membranous from apex, often reddish on upper margin, 6–12(–15) mm long, inner ± as long but narrower. *Flowers* actinomorphic, ± rotate when fully open, deep blue with a red centre sometimes edged with narrow white band; perianth tube funnel-shaped, 2–3 mm long, included in bracts; tepals obovate, 14–16 × 9–10 mm. *Filaments* erect, equal, 6.5–8.0 mm long; anthers ± 4.5 mm long, articulated and horizontal, lying over style branches, purple; pollen brown. *Style* dividing near anther bases, branches 2.0–3.5 mm long, broad, flat, evidently smooth, concealed by anthers. *Capsules* globose, up to 16 mm long. *Flowering time*: mid- to late September.

Distribution and ecology: a rare local endemic of the Darling area in southwestern Western Cape, South Africa; in seasonally wet, low lying ground.

Diagnosis: *Geissorhiza mathewsii* has been confused in the past with *G. eurystigma*, both of them with similarly coloured deep blue flowers with a red centre and broad style branches, and multi-ribbed leaves, but the structure of the flowers is quite different. Those of *G. mathewsii* have a short perianth tube 2–3 mm long, and anthers articulated on the filaments so that they lie almost horizontally and are held above the broad flat style branches.

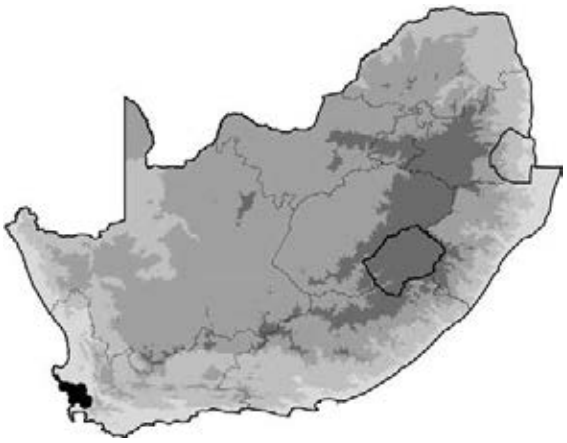
Distribution of ***Geissorhiza mathewsii***.

Geissorhiza eurystigma has flowers with a perianth tube 6–9 mm long and a long style with the broad style branches held above upright anthers. The style branches of *G. eurystigma* are conspicuously hairy, whereas those of *G. mathewsii* are evidently smooth, at least to the naked eye. The distinctive flower colouring of *G. eurystigma* is also found in *G. radians*, but that species is easily distinguished by the pitted markings on the tepals, narrower leaves up to 1.5 mm wide with 2-grooved blades, and a longer perianth tube 6–8 mm long.

69. **Geissorhiza radians** *(Thunb.) Goldblatt* in Nordic Journal of Botany 3: 441 (1983); Goldblatt: 404 (1985). *Ixia radians* Thunb.: 3 (1803). Type: South Africa, [Western Cape], without precise locality, *Thunberg s.n.* [UPS–THUNB 982, lecto., designated by Goldblatt: 441 (1983)].

Ixia rocheana [as *rochensis*] Ker Gawl.: t. 598 (1802c), superfluous name for *I. secunda* D.Delaroche (1766). *Geissorhiza rocheana* Ker Gawl.: 224 (1804) [as *rochensis*], as a new name for *I. rocheana. Rochea venusta* Salisb.: 322 (1812), as new name for *I. rocheana* Ker Gawl. *G. larochei* Loudon: 16 (1830), as new name for *I. larochei* Roem. & Schult.: 379 (1817), superfluous name for *I. secunda* D.Delaroche [= *G. eurystigma* L. Bolus]. Type: South Africa, without locality or collector, illustration in Ker Gawl.: t. 598 (1802c).

Geissorhiza monantha Sweet: 503 (1830), illegitimate homonym, not *G. monanthos* Eckl. [intended as new name for *Ixia secunda* Houtt.: 33 (1780), illegitimate homonym, not *I. secunda* D.Delaroche (1766)]. *G. rocheana* [as *rochensis*] var. *monantha* (Sweet) Baker: 156 (1892) [misapplied to *G. monanthos* Eckl.]. Type: South Africa, without locality, illustration in Houtt. t. 78, f. 1 (1780).



Geissorhiza tulipifera Klatt: 390 (1882). Type: South Africa, [Western Cape], near Paarl, *Drège 8486* (B: Herb. Lubeck, holo.; G, K, L, MO, P, S, iso.).

[*Ixia azurea* Herb. Banks ex Ker Gawl.: t. 598 (1802c), invalid name only in synonymy.]

[*Geissorhiza cyanea* Eckl.: 20 (1827), invalid name without description.]

Plants 80–160 mm high. *Corm* ovoid, symmetric, truncate below, 6–9 mm diam.; tunics blackish, imbricate, notched below into regular sections. *Stem* erect, flexed above sheath of upper leaf and at base of spike, simple or 1-branched. *Leaves* 3, lower 2 basal, uppermost inserted on lower part of stem, slightly longer or shorter than stem, linear, 0.5–1.5 mm wide, margins and main vein slightly thickened, thus narrowly 2-grooved on each surface, uppermost leaf with large, inflated, multi-ribbed sheath. *Spike* inclined, flexuose, 2- to 4(–6)-flowered; bracts green, 8–13(–16) mm long, inner shorter than outer. *Flowers* zygomorphic with stamens unilateral and declinate, tepals widely cupped, deep blue with glossy red centre edged with narrow white band, each tepal with a dark pit in midline; perianth tube funnel-shaped, usually exceeding bracts, 6–8 mm long; tepals obovate, 15–22 × 12–15 mm. *Filaments* unilateral, declinate, equal, ± 10 mm long, held above lowermost tepal, curving upward distally; anthers erect, ± parallel, 5–6 mm long, dark purple; pollen red-brown. *Style* arching beneath stamens, ± 2 mm long, branches 4 mm long. *Flowering time*: September to early October.

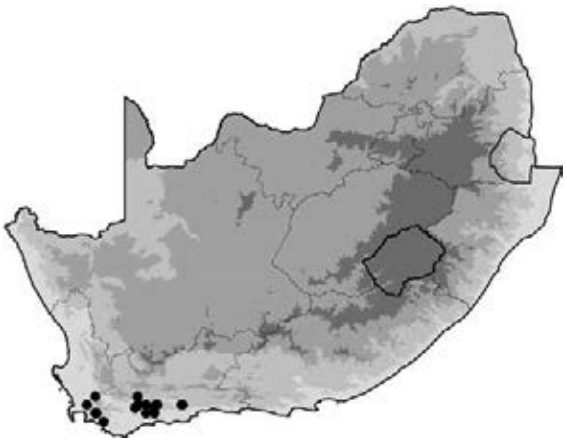
Distribution and ecology: restricted to low hills and flats along the West Coast of Western Cape, South Africa, extending from Yzerfontein and Darling south to Paarl and in the past to Somerset West; in seasonally damp sites in gravelly sand, often of decomposed granite.

Distribution of ***Geissorhiza radians***.

Diagnosis: one of the most striking species in the genus, *Geissorhiza radians* is immediately recognised by the large flowers with deeply cupped tepals, deep blue with red in the lower third edged with a narrow white band and each with a dark pit-like depression in the middle. The leaves are linear (sometimes almost terete) with thickened margins and main vein. The flowers are zygomorphic with the stamens unilateral and declinate, the style lying beneath them above the lowermost tepals. *Geissorhiza eurystigma* and *G. mathewsii* have similarly coloured flowers but lack the pitted tepal markings, and have unusual, broad style branches, and broader, ribbed leaves.

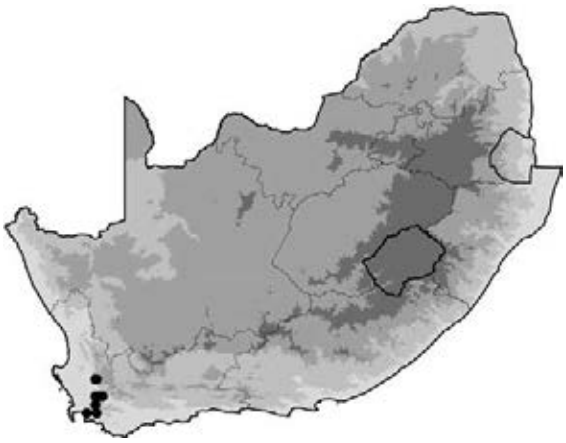
Sect. 10. **Monticolae** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 406 (1985) [as sect. *Monticola*]. Type: *Geissorhiza burchellii* R.C.Foster

Corm tunics hard and woody to fairly soft in texture; leaves sword-shaped to linear or terete, ± plane or with margins and main vein variously thickened; bracts green below, becoming dry above; flowers rotate to salver-shaped, actinomorphic or zygomorphic, perianth tube short or reaching to apex of bracts; stamens equal or more often strongly unequal, unilateral and declinate.



Species 10: southwestern Western Cape, South Africa.

70. **Geissorhiza burchellii** *R.C.Foster* in Contributions from the Gray Herbarium of Harvard University 135: 25 (1941); Goldblatt: 406 (1985). Type: South Africa, [Western Cape], Langeberg near Zuurbraak, *Schlechter 2160* (B, holo.; B, BM, BOL, BR, PRE, Z, iso.)



Plants 120–200 mm high. *Corm* ± ovoid, 7 mm diam.; tunics light brown, ± imbricate, papery, notched below into narrow sections, drawn into points above. *Stem* simple or 1- to 3-branched, with 1 to 3 short, sheathing, scale-like bracts, flexed at base of spike, dropping in bud. *Leaves* 2 to 4, lowermost basal, remaining inserted above base and sheathing stem for some distance, uppermost leaf sheathing for half its length, ± ½ to ± as long as stem, 1.5–3.0 mm wide, margins and main vein thickened, blade thus 2-grooved on each surface, often sticky below and with soil adhering. *Spike* flexuose, mostly 3- to 9-flowered; bracts flushed red above, outer (6–)8–10 mm long, inner slightly shorter. *Flowers* actinomorphic, ± rotate, tepals spreading when fully open, tepals sometimes reflexed with age, pale to deep purple or violet, pale yellow in throat and tube; perianth tube cylindric, 4–6 mm long; tepals elliptic, 12–18(–22) × 5–6 mm. *Filaments* erect, unequal; two longer 10–14 mm long, shorter one 6–10 mm long; anthers, 4.0–5.5 mm long, purple; pollen yellow. *Style* dividing opposite upper ⅓ of anthers, branches ± 4 mm long. *Capsules* ± globose, 5–7 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: December to January.

Distribution and ecology: a montane species of Western Cape, South Africa, extending from the Slanghoek Mtns south and east though the Hottentots Holland Mtns to the Langeberg; in stony, sandstone ground, mostly on south-facing slopes, blooming well only after fire.

Diagnosis: striking when in flower, *Geissorhiza burchellii* has relatively large deep purple to violet flowers with a short perianth tube, only 4–6 mm long and about one

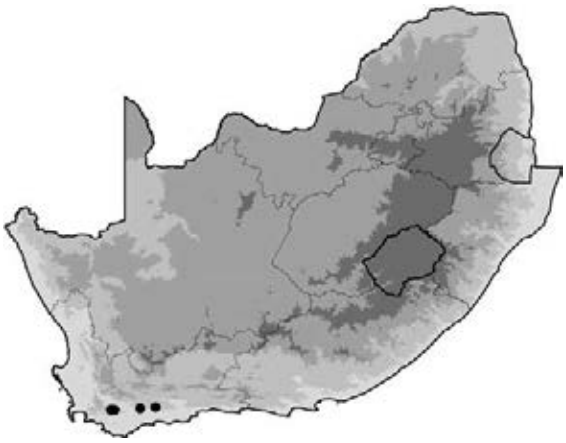
Distribution of ***Geissorhiza burchellii***.

Distribution of ***Geissorhiza grandiflora***.

third as long as the spreading to slightly reflexed tepals. The stamens are unequal, typical of the section, and the corm tunics are of the imbricate type but are of soft, papery rather than woody texture. The stems are hairless and usually branched and the leaves have the margins and main vein thickened, rendering the leaf surfaces two-grooved.

A collection from Grassy Dome in the Du Toit's Kloof Mtns is tentatively included in *G. burchellii.* The single specimen lacks leaves and corm and although the flowers match those of *G. burchellii* well, collection notes indicate that the flowers had white and dark red markings at the base of the tepals.

71. **Geissorhiza grandiflora** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 408 (1985). Type: South Africa, [Western Cape], N end of Limietberg, Bain's Kloof, ± 4 000 ft [1 200 m], *Esterhuysen 35832* (BOL, holo.; C, E, K, MO, NBG, PRE, S, US, WAG, iso.).



Plants mostly 200–350 mm high. *Corm* globose, 10–12 mm diam.; tunics brown, ± imbricate, papery, notched below into sections and drawn into short points above. *Stem* simple or 1- to 3-branched, flexed at base of spike, bearing in addition to cauline leaf, 1 or 2 short sheathing scale-like bracts. *Leaves* (2)3, lower 1 or 2 basal, reaching to ± base of spike, uppermost inserted on lower part of stem, sheathing for some distance, linear, 1.5–4.0 mm wide, margins and main vein thickened, surfaces thus 2-grooved, sometimes sticky below and with sand adhering. *Spike* flexuose, mostly 3- to 8-flowered; bracts green flushed red above, outer 13–16 mm long, inner slightly shorter. *Flowers* zygomorphic, ± salver-shaped, stamens and style declinate, pink with dark markings at bases of tepals, pale in tube; perianth tube cylindric, 15–18 mm long, slightly exceeding bracts; tepals ellipsoid, 22–30 × 6.5–9.0 mm. *Filaments* unequal, unilateral, declinate, two longer 11–18 mm long, shorter one 7–12 mm long; anthers 5–6 mm long, yellow; pollen yellow. *Style* dividing opposite upper ⅓ to apex of anthers, branches 4–5 mm long. *Capsules* obovoid to globose, 5–8 mm long, enclosed in bracts. *Chromosome number* 2*n* = 26. *Flowering time*: late November to early January.

Distribution and ecology: endemic to Western Cape, South Africa, extending from the Grootwinterhoek Mtns to the Hottentots Holland Mtns; in rocky, sandy ground at mid- to upper elevations, 900–1 500 m, flowering mainly after fire.

Diagnosis: *Geissorhiza grandiflora* has one of the largest flowers in the genus, comparable in size with those of some species of sect. *Engysiphon* (subg. *Weihea*). The flowers are deep pink and zygomorphic with stamens and style both unilateral and lying above the lowermost tepal. The light brown, imbricate corm tunics are papery in texture but otherwise match those of subg. *Geissorhiza* and are regularly notched along the lower margin. The unequal stamens and branched stems are characteristic of the sect. *Monticolae*, in which it most closely resembles *G. burchellii*, a generally smaller species with leaves with heavily thickened margins and midrib, and dark purple, radially symmetric flowers with a shorter perianth tube 4–6 mm long. The two species are occasionally sympatric or nearly so and both have been collected on the Cossacks and Slanghoek Mtns. A collection from the Grootwinterhoek mtns, provisionally assigned to *G. grandiflora*, has somewhat smaller flowers than are typical and their colour is uncertain.

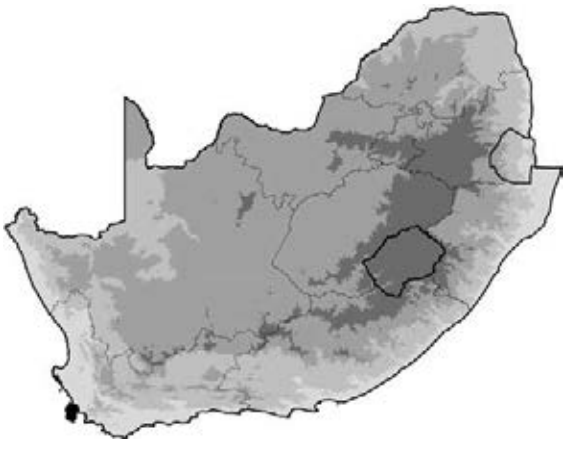
72. **Geissorhiza callista** *Goldblatt* in Flowering Plants of Africa 50: t. 1996 (1989). Type: South Africa, [Western Cape], Riviersonderend Mtns above Greyton, *Goldblatt 8680* (NBG, holo.; E, K, MO, PRE, S, US, WAG, iso.).

Plants 150–350 mm high. *Corm* ± ovoid, 4–7 mm diam.; tunics ± membranous, not accumulating, light to middle brown, probably imbricate. *Stem* suberect or inclined, simple or 1- or 2-branched, bearing a sheathing, bract-like leaf in upper ⅓. *Leaves* 3 or 4(5), lower 2 or 3 ± basal, reaching to ± base of spike, linear to falcate, with thickened margins and main vein, thus 2-grooved on

Distribution of ***Geissorhiza callista***.

each surface, uppermost leaf cauline, shorter than basal. *Spike* inclined, flexuose, mostly 3- to 5-flowered, bracts green below, flushed red to purple above, outer 10–13 mm long, inner slightly shorter. *Flowers* zygomorphic, nodding, with unilateral, declinate stamens and style, deep pink turning dark red-purple at tepal bases, pale in throat; perianth tube ± cylindric, widening near mouth, 22–25 mm long, well exserted from bracts; tepals oblanceolate, 24–26 × 9–12 mm, outer slightly longer than inner. *Filaments* unequal, unilateral, declinate; two longer 16–20 mm long, shorter one 13–17 mm long; anthers ± erect, ± 4.7 mm long, purple; pollen pale pink. *Style* arching below filaments, dividing ± 6 mm beyond anthers, branches ± 3 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: November and early December.

Distribution and ecology: restricted to the Riviersonderend Mtns and Langeberg in Western Cape, South Africa; on rocky sandstone slopes and cliffs often in wet mossy places, flowering well only after fire and evidently rare.



Diagnosis: with relatively large, pink flowers that are darker at the base of the tepals, *Geissorhiza callista* is recognised also by the elongate perianth tube 22–25 mm long and unilateral stamens and style. The stamens extend well beyond the mouth of the perianth tube, and the particularly long style divides up to 6 mm beyond the anther tips. The stem is usually inclined and the leaves falcate to trailing from steeply sloping ground. Like most members of sect. *Monticolae*, the leaves have thickened margins and main vein and are thus shallowly 2-grooved or channelled on each surface. The species was previously included in *G. grandiflora*, but that species differs in its erect stems and smaller flowers, the perianth tube up to 18 mm long and the tepals 20–22 mm long, a shorter style dividing opposite the upper third to apex of the anthers, and slightly longer style branches 4–5 mm long, contrasting with the longer style and shorter style branches, ± 3 mm long, in *G. callista*.

733. **Geissorhiza tabularis** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 410 (1985). Type: South Africa, [Western Cape], Table Mtn, between Skeleton and Window Gorges, *Goldblatt 6726* (MO, holo.; K, NBG, PRE, S, US, WAG, iso.).

Plants 250–350 mm high. *Corm* globose, tapering above, 7 mm diam.; tunics light brown, ± imbricate, papery in texture, cut below into narrow sections and drawn into points above. *Stem* simple or 1- to 3-branched, flexed at base of spike, bearing in addition to a cauline leaf, 1(2) short, sheathing scale-like bracts, flexed at base of spike. *Leaves* (2)3, lower 2 (or 1) basal, ½ to occasionally ± as long as stem, linear, 2–3 mm wide, with slightly thickened to winged margins and main vein, broadly 2-grooved on each surface, somewhat sticky below and with sand adhering, uppermost leaf cauline, sheathing for ½ its length. *Spike* nodding in bud, later becoming straight, 3- to 8-flowered, flexuose; bracts green, flushed red above, recurved above at flowering, outer 7–8 mm long, inner slightly shorter. *Flowers* actinomorphic, rotate, pale mauve to nearly white (usually white when dry); perianth tube ± cylindric, 1.5–2.0 mm long; included in bracts; tepals elliptic, 15–18 × 5–7 mm. *Filaments* suberect, unequal, two longer 5–6 mm long, shorter one 3–4 mm long; anthers 3.5–5.0 mm long, yellow. *Style* dividing opposite apex of anthers, branches ± 2.5 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: late October to mid-December.

Distribution and ecology: restricted to the lower plateau of Table Mtn on the Cape Peninsula in Western Cape, South Africa; in wet or marshy places in peaty sand, blooming rarely, if at all, except after fire.

Diagnosis: *Geissorhiza tabularis* was for many years included in the smaller-flowered *G. ramosa* and the two are no doubt closely related. *Geissorhiza tabularis* is distinguished by the larger flowers with tepals 15–18 mm long vs. 5–9 mm in *G. ramosa* and longer stamens. The two species share a smooth stem, often more highly branched in *G. ramosa*, a short perianth tube, and unequal filaments.

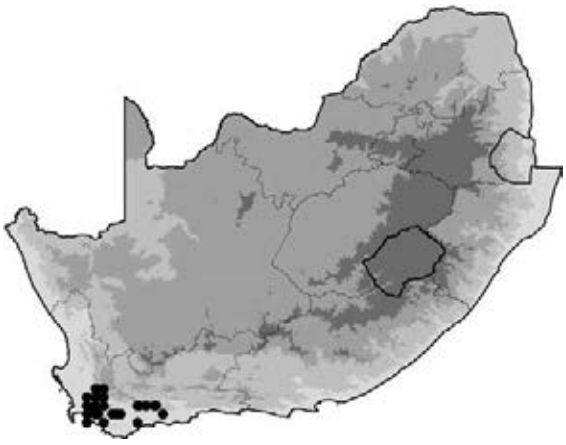
Distribution of ***Geissorhiza tabularis***.

74. **Geissorhiza ramosa** *Ker Gawl. ex Klatt* in Linnaea 34: 657 (1866); Goldblatt: 410 (1985). *G. secunda* var. *ramosa* (Ker Gawl. ex Klatt) Baker: 155 (1892). Type: South Africa, [Western Cape], 'Tulbaghskloof, Tulbaghsthal, am Fuss des Winterhoeksberg, am Witsenberg und bei Vogelvalei', *Ecklon & Zeyher Irid. 229* (77.11) (B, lecto., designated by R.C.Foster: 24 (1941); B, BM, E, FI, G, GH, L, LD, MO, P, PRE, SAM, W, Z, isolecto.).

Geissorhiza montana R.C.Foster: 55 (1941). Type: South Africa, [Western Cape], Genadendal Mtns, 3 000–4 000 ft [900–1 200 m], '*G. imbricata* a', *Drège s.n.* (B, holo.; BM, E, G, K, L, MO, S, iso.).

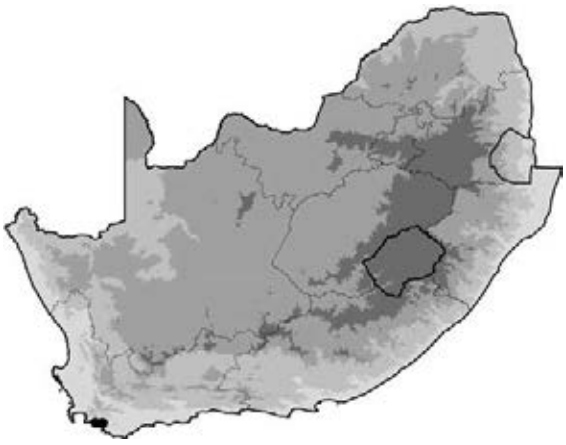
Plants 200–450 mm high. *Corm* ovoid, tapering above, 6–8 mm diam.; tunics brown, woody to ± papery in texture, incised below into regular sections. *Stem* 2- to 4-branched (rarely simple), with scale-like bracts subtending branches. *Leaves* 2 or 3(4), lower 1 or 2 basal, half as long to ± as long as stem, linear, 1.2–2.5 mm wide, margins and main vein thickened, narrowly 2-grooved on each surface, upper leaf (rarely two) cauline, sheathing stem below. *Spike* inclined, flexuose, few- to 11-flowered; bracts becoming dry and membranous from tips, outer 3.5–5.5 mm long, inner slightly shorter. *Flowers* rotate, actinomorphic, blue, purple, or violet (fading to pink then white when dry); perianth tube funnel-shaped, 2–3 mm long; tepals obovate-elliptic, (5–)7–9 × 3.3–4.5 mm. *Filaments* erect, unequal, two longer 3–4 mm long, shorter one 2.5–3.0 mm long; anthers 2.2–3.5 mm long, yellow. *Style* dividing opposite upper ⅓ of anthers, branches ± 1.5 mm long. *Capsules* globose to oblong, 3.5–5.0 mm long *Flowering time*: October to December (January at high elevations).

Distribution and ecology: occurring in the mountains of Western Cape, South Africa, from the Grootwinterhoek Mtns in the north to the Langeberg near Riversdale in the east; on stony sandstone ground, often in marshy or wet sites, most frequent after fires.



Diagnosis: *Geissorhiza ramosa* is recognised by the small, dark blue to violet or purple flowers with tepals 5–9 mm long and unequal stamens with anthers up to 3.5 mm long, and by its normally 2- to 4-branched, hairless stem. The unequal stamens are typical of most other species of sect. *Monticolae.* Depauperate plants may be less that 200 mm tall and without branches making identification uncertain.

75. **Geissorhiza bryicola** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 413 (1985). Type: South Africa, [Western Cape], Fernkloof Reserve, Hermanus, along path at Psoralea Drip, *Goldblatt 7032* (MO, holo.: K, NBG, PRE, S, WAG, iso.).



Plants 150–300 mm high. *Corm* subglobose, 5–8 mm diam.; tunics brown, brittle-membranous, imbricate, incised below into regular sections. *Stem* weak, inclined to trailing, simple or with 1(2) branches, sometimes with a scale-like bract in upper ⅓. *Leaves* usually 3(4), lower 2 basal, linear, weak and trailing, usually slightly longer than stem, 1.5–4.0 mm wide, nearly plane, margins and main vein lightly raised, upper leaf cauline, partly sheathing with short free apex. *Spike* inclined to horizontal, flexuose, (2–)5- to 10-flowered; bracts green below, membranous and translucent in upper half, outer 5–8 mm long, inner slightly shorter. *Flowers* actinomorphic, rotate, white; perianth tube funnel-shaped, ± 2.5 mm long; tepals 8–10 × ± 4 mm. *Filaments* suberect, unequal, two longer 4–6 mm long, shorter one 3.5–4.5 mm long; anthers ± 3 mm long, yellow; pollen yellow. *Style* dividing opposite apex of anthers, branches ± 5 mm long. *Capsules* globose, 3–5 mm long. *Chromosome number* $2n$ = 26 + 0–1b. *Flowering time*: late September to mid-November.

Distribution and ecology: restricted to the mountains above Betty's Bay and the Klein River Mtns, in Western Cape, South Africa; in cool shady sites, on damp cliffs near seeps or waterfalls, often in moss pads.

Distribution and ecology: Geissorhiza bryicola is recognised by the weak, inclined to trailing stem and inclined to horizontal spikes of up to 10 small white flowers

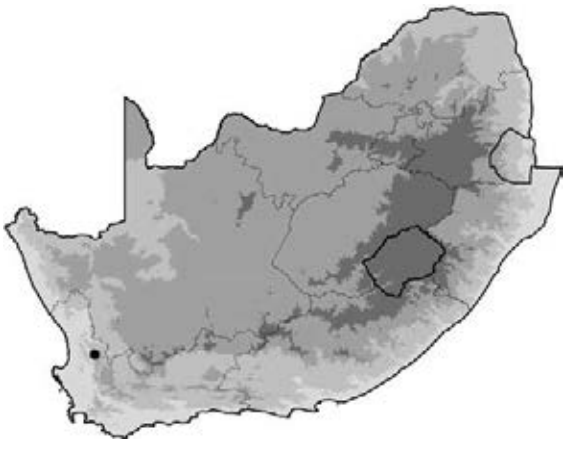
Distribution of ***Geissorhiza ramosa***.

Distribution of ***Geissorhiza bryicola***.

with tepals just 8–10 mm long. The stems are hairless and the stamens unequal. It bears the closest resemblance to the widespread montane species, *G. ramosa*, the two having similar small flowers with short unequal stamens but *G. ramosa* is a ± erect plant with 2- to 4-branched stems, blue to mauve or purple flowers, and leaves with strongly thickened margins and midrib.

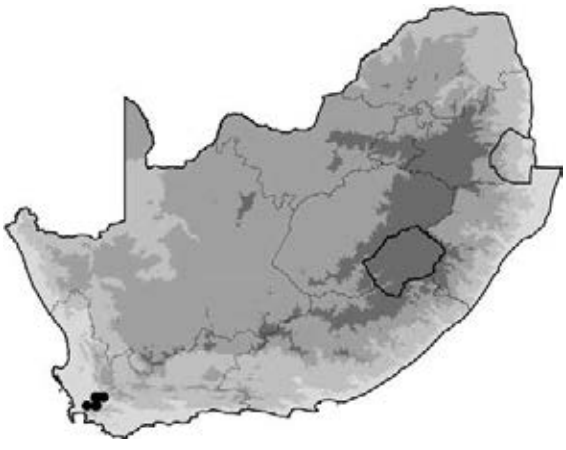
76. **Geissorhiza ciliatula** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 415 (1985). Type: South Africa, [Western Cape], Cederberg, Middelberg, 1 500 m, *Goldblatt 5144* (MO, holo.; K, NBG, S, iso.).

Plants 60–120 mm high. *Corm* globose, 3.5–5.0 mm diam.; tunics brown, ± imbricate, soft-textured, incised above and below. *Stem* suberect to inclined, minutely ciliate, unbranched, flexed above sheath of upper leaf. *Leaves* 2 or 3, linear and straight to falcate, up to 1 mm wide, oblong in section with margins and main vein strongly thickened, thus narrowly 2-grooved on each surface, lowermost leaf basal, longest, second also basal, but sheathing lower half of stem, free distally, uppermost leaf inserted on upper ⅓ of stem, sheathing for at least half its length (sometimes entirely sheathing and bract-like). *Spike* 1- to 4-flowered, flexuose; bracts 4–5 mm long, green below, membranous to dry and transparent above. *Flowers* actinomorphic, rotate, white, turning purplish on fading; perianth tube ± 1.5 mm long, included in bracts, flaring from base; tepals obovate, 6–7 × 3 mm. *Filaments* erect, equal, ± 2.5 mm long; anthers ± 2 mm long, yellow. *Style* dividing opposite apex of anthers, branches ± 1.3 mm long, recurved. *Capsules* globose, 3–4 mm long, included in bracts. *Chromosome number* 2*n* = 26. *Flowering time*: November.



Distribution and ecology: restricted to the Cederberg and Cold Bokkeveld Mtns of Western Cape, South Africa; growing above 1 200 m elevation in sheltered wet mossy places on cliffs and cracks in rocks, mainly south-facing, where shade and water are available late in the growing season.

Diagnosis: *Geissorhiza ciliatula* is distinguished by its low stature, up to 120 mm high, linear leaves with heavily thickened margins and midvein, minutely ciliate stems, and small white flowers with a perianth tube ± 1.5 mm long, tepals 6–7 mm long, and unequal stamens. The corm tunics are soft-textured and not firmly fixed in position but evidently imbricate.

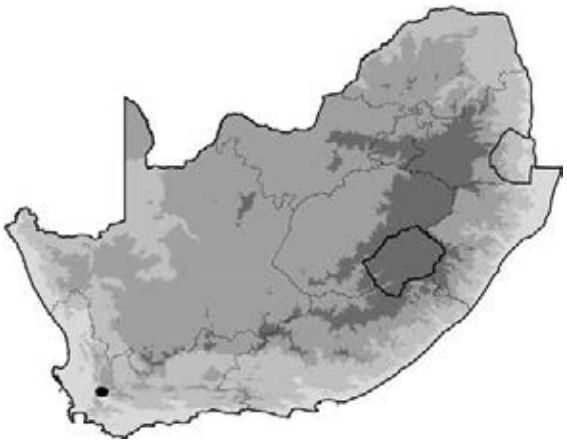


77. **Geissorhiza pseudinaequalis** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 415 (1985). Type: South Africa, [Western Cape], Witteberg, Slanghoek Mtns, wet overhung cliffs on S side, *Esterhuysen 22293* (BOL, holo.; K, MO, iso.).

Plants 180–300 mm high. *Corm* globose, symmetric, 5–9 mm diam., usually with numerous cormlets around base; tunics membranous-papery, ± imbricate, incised below, light brown, outer layers becoming irregularly broken. *Stem* bearing 1 or more green, sheathing bracts in upper half, often branched in upper axils, sometimes also from axil of uppermost leaf, flexed at base of spike. *Leaves* usually 3(4), linear, plane, margins and midrib slightly raised, occasionally sparsely ciliate on edges, 2–4 mm wide, usually ± as long as stem, lower 2 (or 3) leaves basal, uppermost inserted in lower ⅓ to middle of stem, sheathing below. *Spike* (2)3- to 7-flowered, flexuose; bracts 7–10 mm long, green, membranous on upper margins, occasionally ± dry above, rarely ± tawny. *Flowers* actinomorphic, rotate, blue to violet (or blue-mauve), usually pale in tube with throat ringed with darker colour; perianth tube 3–5 mm long, included in bracts; tepals obovate, 12–17(–20) × 5.0–6.5 mm. *Filaments* erect, unequal, two longer 8–10(–12) mm long, shorter one 4–6 mm long; anthers 3.5–5.0 mm long. *Style* dividing near or beyond tips of anthers, branches recurved. *Flowering time*: mid-October to January.

Distribution and ecology: restricted to middle and upper elevations in the mountains of Western Cape, South Africa in the Hex River Mtns and Bain's Kloof to Simonsberg; on damp, sheltered, south- or west-facing rock ledges and cliffs where shade and moisture are

Distribution of ***Geissorhiza ciliatula***.



Distribution of ***Geissorhiza pseudinaequalis***.

available in midsummer, flowering as late as January at higher elevations.

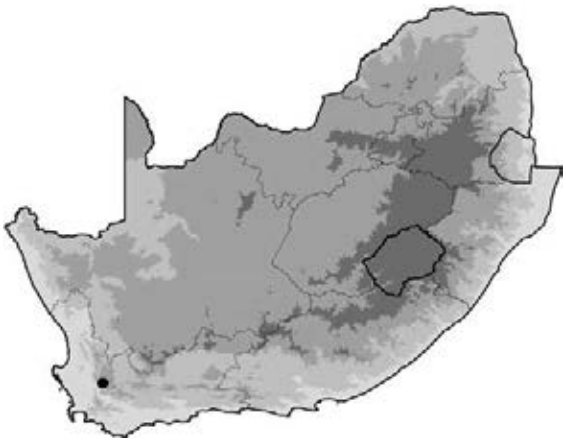
Diagnosis: one of several species of *Geissorhiza* that occupy specialised niches in the mountains of southwestern Western Cape, *G. pseudinaequalis* is distinguished by its papery corm tunics, smooth stem and markedly unequal stamens, with the longer two filaments 8–12 mm and shorter one 4–6 mm long. It also has relatively large, blue to violet (rarely blue-purple) flowers with tepals 12–17 mm, rarely up to 20 mm long. *Geissorhiza pseudinaequalis* is sometimes confused with *G. inaequalis* (sect. *Planifoliae*) because of its unequal stamens and flat leaves but that species has woody, imbricate tunics and puberulous stems. *Geissorhiza pseudinaequalis* is probably related to other montane species with similar soft-textured imbricate corm tunics, including *G. burchellii* and *G. tabularis*, both of which also have unequal stamens but differ in their larger size and in their leaves with strongly raised margins and midrib.

78. **Geissorhiza rupicola** *Goldblatt & J.C.Manning* in Novon 5: 158 (1995). Type: South Africa, [Western Cape], Mosterthoek Twins, Green Gullies Kloof, ± 1 250 m, 9 Dec. 1984, *Esterhuysen 36197* (BOL, holo.; NBG, MO, PRE, WAG, iso.).

Plants (100–)150–200 mm high. *Corm* globose, 9–12 mm diam.; tunics initially unbroken, soft and papery, becoming torn into narrow vertical strips, ultimately almost fibrous, accumulating with cataphylls as a fibrous collar around base. *Stem* ascending or trailing from cracks in steep rocks, unbranched. *Leaves* (2)3, lower 1 or 2 basal, linear, 1.5–3.0 mm wide, margins and main veins heavily thickened and raised into wings overarching blade surface, lowermost longest, reaching to between upper ⅓ of stem and base of spike, second basal leaf usually much shorter, sheathing in lower ½, uppermost leaf inserted on mid to upper part of stem, smaller than basal, sheathing for at least half its length, sometimes entirely. *Spike* (1)2- to 6-flowered, flexuose; bracts subequal, outer pale sometimes purple toward apex, 8–11 mm long, inner membranous, narrower than outer, 2-keeled, forked in upper 1–2 mm. *Flowers* salver-shaped, pale pink, unscented; perianth tube cylindric, (16–)19–23 mm long; tepals subequal, ovoid-oblong, spreading, 12–15 × 4.5–5.5 mm. *Filaments* suberect, equal, ± 8 mm long, exserted ± 6 mm from tube; anthers ± 3.5 mm long, cream-coloured; pollen yellow. *Style* dividing at or beyond anther tips, ultimately exceeding anthers by ± 4 mm, branches ± 2 mm long. *Capsules* globose, 4–6 mm long. *Seeds* prismatic with ridged angles, ± 1.5 mm long. *Flowering time*: November to early December.

Distribution of ***Geissorhiza rupicola***.

Distribution and ecology: known only from the Mosterthoek Twins at the western end of the Hex River Mtns in Western Cape, South Africa; confined to moist shady sites in thin soil on rocks, sometimes in cracks in steep cliffs.



Diagnosis: *Geissorhiza rupicola* stands out in the genus in its unusually long perianth tube, 16–23 mm long, slightly longer than the tepals. A tube of this length is also known in *G. grandiflora* but this species has longer tepals and unequal stamens with one filament shorter than the other two. The soft, papery corm tunics becoming torn into narrow vertical strips, ultimately almost fibrous, and accumulating with cataphylls as a fibrous collar around base are also distinctive for *G. rupicola*, the relationships of which are uncertain.

79. **Geissorhiza silenoides** *Goldblatt & J.C.Manning* in Novon 5: 156 (1995). Type: South Africa, [Western Cape], Ceres District, lower slopes of Gydo Pass, 20 Sept. 1993, *Goldblatt & Manning 9739* (NBG, holo.; K, MO, PRE, WAG, iso.).

Plants 200–300 mm high. *Corm* ± ovoid, one side flattened slightly below, 5–7 mm diam.; tunics woody, ± black, imbricate, layers breaking below into triangular points. *Stem* minutely scabrid-puberulous, unbranched, flexed above sheaths of upper 2 leaves, inclined above. *Leaves* 4, lower 2 basal and longest, reaching at least to middle of stem, sometimes to base of spike, linear, erect or trailing, 1.2–1.5 mm wide, oval in cross section with 2 narrow grooves on each surface, main vein thickened, margins raised and arched over surface, upper 2 leaves cauline, sheathing for at least ½ their length, sometimes only 9–12 mm long and entirely sheathing. *Spike* flexuose, drooping in bud, 4- to 7-flowered; outer bract pale green, upper margins pink-purple, 7–10 mm long, inner ± ⅔ as long, translucent with 2 green keels. *Flowers* actinomorphic, salver-shaped, pale pink, darker near tepal margins, white in throat, unscented; perianth tube cylindric, 15–17 mm long; tepals subequal, obovate, 12.5–14.0 × 6–7 mm, spreading when fully open. *Filaments* suberect, unequal, 4, 7 and 9 mm long; anthers ± 4.5 mm long, cream-coloured; pollen pale yellow. *Style* exceeding anthers by 2–4 mm, branches unusually long, 5–6 mm long. *Flowering time*: September to mid-October.

Distribution and ecology: known only from Gydo Pass in the Ceres District of Western Cape, South Africa; on south-facing slopes in loamy clay in *Protea laurifolia* fynbos.

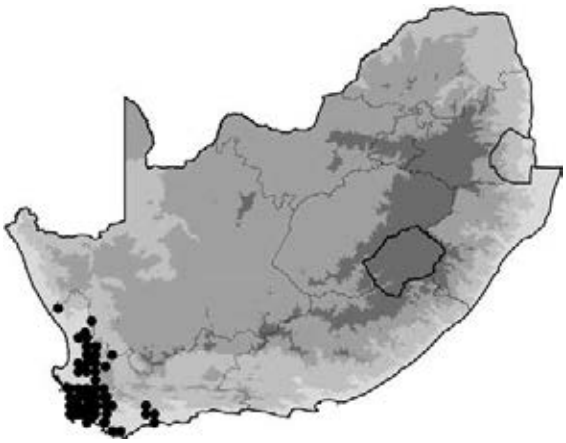
Diagnosis: with blackish imbricate corm tunics regularly notched below into blunt triangular segments, *Geissorhiza silenoides* is a typical member of subg. *Geissorhiza*, in which it stands out in the scabrid-puberulous stems, short leaves with heavily thickened margins and midribs, thus with two narrow grooves on each surface, and distinctive, pale pink flowers with long perianth tube, 15–17 mm long, and unequal stamens, each filament being of a different length. Unequal filaments are frequent in subg. *Geissorhiza*, but typically only one filament is shorter and the remaining two are equal. The combination of long perianth tube and unequal stamens are known only in sect. *Monticolae*, most members of which have soft-textured corm tunics. Sectional placement of *G. silenoides* is somewhat uncertain, but it has provisionally been included in sect. *Monticolae*.

Distribution of ***Geissorhiza silenoides***.

Sect. 11. **Planifoliae** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 417 (1985) [as sect. *Planifolia*]. Type: *Geissorhiza aspera* Goldblatt

Corm tunics blackish, hard and woody, leaves usually 3, blades plane, smooth, lanceolate to sword-shaped or linear, stem puberulous-ciliate, bracts herbaceous below, dry and rusty brown in the upper half, flowers rotate, actinomorphic or zygomorphic with unilateral stamens and style, perianth tube short, stamens equal or unequal.

Species 6: winter-rainfall Northern and Western Cape, South Africa.



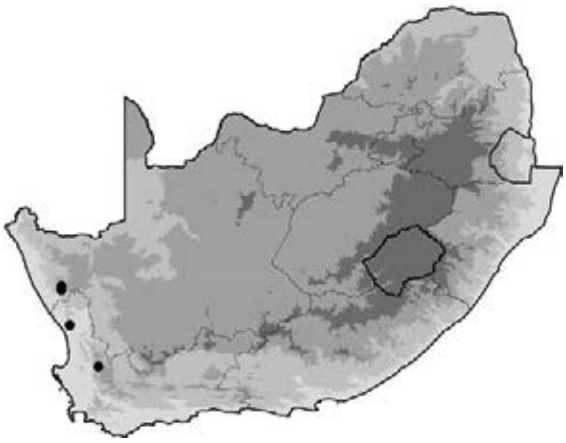
80. **Geissorhiza aspera** *Goldblatt* in Goldblatt & Barnard in Journal of South African Botany 36: 303 (1970); Goldblatt: 417 (1985). Type: South Africa, [Western Cape], Rondebosch Common, *Goldblatt 501* (BOL, holo.; K, NBG, PRE, iso.).

Gladiolus junceus Burm.f.: 2 (1768). Type: South Africa, without precise locality or collector, illustration in Plukenet: t. 187, f. 2 (1691) [not *Geissorhiza juncea* (Link) A.Dietr.].

Geissorhiza secunda Ker Gawl.: 224 (1804), as a new name for *Ixia secunda* P.J.Berg.: 6, & t. 360 (1767), illegitimate homonym, not *I. secunda* D.Delaroche (1766). Type: South Africa, without precise locality (Herb. Bergius).

Plants mostly 100–300 mm high. *Corm* ovoid-globose, 3–6 mm diam., with numerous cormlets at base; tunics dark, often blackish, imbricate, notched into sections below. *Stem* inclined or erect, simple or more often 1- to 3-branched, densely puberulous (slightly rough to touch), usually bearing a short leafy bract from upper node. *Leaves* usually 3, plane, linear to sword-shaped, erect to falcate, margins and main vein slightly raised, smooth or sparsely papillate to ciliate, ± as long as stem or somewhat longer, 2–5(–7) mm wide, lower 2 basal, upper basal or inserted shortly above ground, sheathing lower half of stem. *Spike* (1–)3- to 7-flowered, flexed below first flower, inclined; bracts green below, dry and brown in upper half, 6–12 mm long, spreading above, inner smaller, 6–8 mm long. *Flowers* rotate, often zygomorphic, usually deep blue to violet, or white or pale blue (rarely purple); perianth tube funnel-shaped, 1–2 mm long; tepals 11–15 × 4–6 mm. *Filaments* subequal or unequal, often declinate, 3–5 mm long, one usually shorter by up to 1 mm; anthers suberect or horizontal, (2.0)3.0–5.5 mm long, white to pale yellow. *Style* 7–8 mm long, branches up to 2 mm long. *Capsules* 5–6 mm long, ± ovoid. *Chromosome number* $2n = 26, 52$. *Flowering time*: August to September.

Distribution and ecology: widespread in Western Cape, South Africa, extending from the Cape Peninsula east to the Langeberg at Tradouw Pass and north through the Olifants River Valley as far as the Gifberg, with an isolated population in the high country west of Bitterfontein in Namaqualand; usually on sandy slopes and flats, sometime on granitic gravel.



Distribution of ***Geissorhiza aspera***.

Diagnosis: often locally common, *Geissorhiza aspera* is recognised by the minutely puberulous stem, plane leaves with slightly thickened margins, and typically glistening, dark blue (sometimes white) flowers with a greenish yellow throat, usually with slightly unequal filaments. The floral bracts are green in bud but as the flowers open they become dry and turn rusty brown at the tips. Plants vary greatly in size depending on soil fertility and available moisture, and may grow up to or even over 300 mm high, or be stunted and less than 100 mm. Although most often blue, plants in the Olifants River Valley and to the north often have partly or entirely white flowers. The stamens are sometimes described as being equal, but careful examination of live plants shows that one filament is usually slightly shorter, and in populations in the north of its range the filaments are clearly unequal.

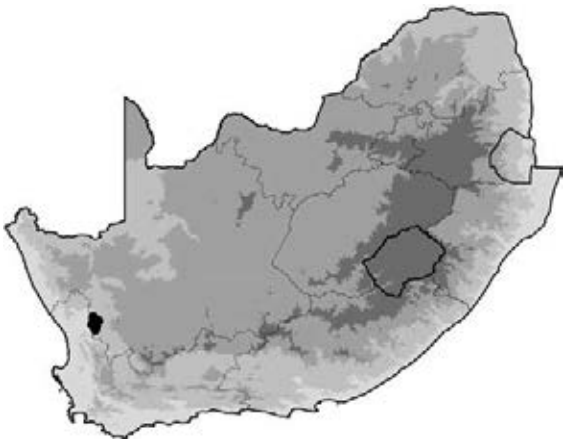
Geissorhiza aspera is unusual in the genus in being heteroploid with both diploid $2n = 26$ and polyploid $2n = 52$ populations. From the sample of seven populations so far examined, there is a pattern of diploids in the north of the range and tetraploids in the south, but both cytotypes have been recorded on the Cape Peninsula. *Geissorhiza aspera* is closely allied to *G. inaequalis*, which has larger, pale mauve or purple flowers but shares with *G. aspera* the characteristic puberulous stem and broad flat leaves. In *G. inaequalis* the short filament is about half as long as the other two and the bracts are green to membranous during flowering and unlike the typical dry, brown-tipped bracts of *G. aspera*. An unusual morph at the northern end of the Paardeberg near Malmesbury has purple flowers with a darker purple centre and the radially symmetric flowers are held almost upright in contrast to the nodding flowers of *G. aspera*. The two forms are parapatric and co-blooming near Malmesbury, where the purple-flowered morph grows on drier, more well-drained slopes than the typical, blue-flowered morph.

81. **Geissorhiza demissa** *Goldblatt & J.C.Manning* in Goldblatt *et al.* in Bothalia 39: 135 (2009). Type: South Africa, Northern Cape, upper southeastern slopes of Stalberg, 3 km S of Farm Welkom, among granite boulders, 1 370 m, 28 Oct. 2005, *Helme 3626* (NBG, holo.).

Plants delicate, 60–120 mm high, rarely with 1 short branch, stems puberulous but subglabrous below spike. *Corm* obliquely narrowly ovoid, ± 4 mm diam., with several cormlets at base, tunics woody, blackish, imbricate. *Leaves* 4, lower two basal, third leaf inserted shortly above ground, linear-falcate, reaching to ± base of spike, 0.7–1.0 mm wide, margins and main vein lightly thickened and narrowly winged, smooth, uppermost leaf cauline, largely to entirely sheathing. *Spike* 1- to 4-flowered; bracts green below, dry and brown in upper ½–⅔, outer ± 5 mm long, inner ± 4 mm long. *Flowers* actinomorphic, rotate, white with veins tinged blue below and reverse of outer tepals flushed blue in distal half; perianth tube funnel-shaped, ± 2.0 mm long; tepals subequal, obovate, 7–10 × 3.5 mm. *Filaments* erect, unequal, ± 3.5 mm long, uppermost 0.5 mm shorter, white; anthers 2–3 mm long; pollen ± white. *Style* dividing shortly beyond anthers, branches recurved, ± 0.5 mm long. *Flowering time*: late August to October, probably also in early November.

Distribution of ***Geissorhiza demissa***.

Distribution and ecology: recorded from the Kamiesberg in central Namaqualand, Northern Cape, South Africa, and in Western Cape on the plateau of the Gifberg near Vanrhynsdorp and in the Cold Bokkeveld; local and evidently uncommon in seasonally damp places in the shelter of granite boulders in the Kamiesberg or among sandstone rocks in the Western Cape mountains.



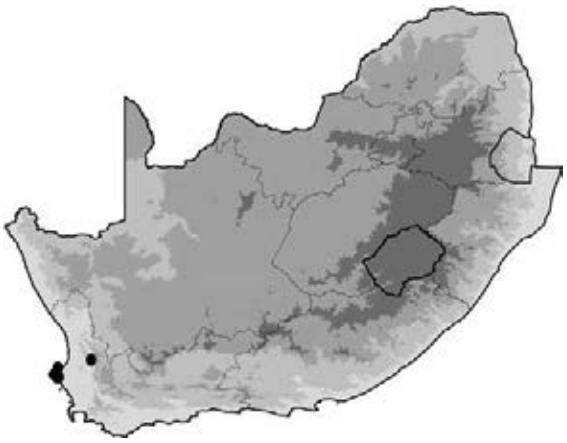
Diagnosis: closely allied to the common and widespread *Geissorhiza aspera*, *G. demissa* is a smaller plant rarely reaching 120 mm in height. It has the plane leaves with margins and main vein only lightly thickened, puberulous stem, and unequal stamens consistent with *G. aspera* but the smaller flowers have tepals only 7–10 mm long and anthers 2–3 mm long. The variable *G. aspera* typically has dark blue to violet flowers although northern populations from the Cederberg and Gifberg have white or bicoloured white and blue flowers. *Geissorhiza aspera* is typically larger in all respects and almost invariably branched, with leaf blades 2–7 mm wide, 2- to 7-flowered spikes, and stems that are puberulous up to the base of the spike, even in the northern, white-flowered populations. The unbranched stems of *G. demissa* are subglabrous below the spike and the leaves are never more than 1 mm wide. The flowers of the two species are similar in shape, but those of *G. aspera* are larger and nodding with horizontally oriented stamens and tepals 11–15 × 4–6 mm and anthers 2–5 mm long.

82. **Geissorhiza inaequalis** *L.Bolus* in South African Gardening and Country Life 20: 346 (1930); Goldblatt: 420 (1985). Type: South Africa, [Northern Cape], Klipkoppies 6 miles [± 9 km] from Nieuwoudtville, *L. Bolus s.n.* (BOL 19256, lecto., designated by Goldblatt 72: 420 (1985); BM, BOL, K, iso.).

Plants 120–250 mm high. *Corm* ovoid-globose, 6–8 mm diam., with several cormlets at base; tunics dark brown to ± black, imbricate, notched below. *Stem* ± erect or inclined, simple or 1- to 3-branched, lightly papillose-puberulous, usually bearing a short leafy bract from the upper node. *Leaves* usually 3, flat, sword-shaped, ± erect to falcate, margins and main vein slightly raised, smooth, shorter to somewhat longer than stem, 4–10 mm wide, lower two basal, third basal or inserted above ground and sheathing for some distance. *Spike* 2- to 7-flowered, usually flexed below first flower and secund; bracts green below, drying and becoming pale and membranous above, rarely ± brown at apex, 10–15(–18) mm long, spreading in upper ½, inner bract shorter than outer. *Flower* zygomorphic, light purple, white in throat and tube; perianth tube 2–3 mm long, funnel-shaped; tepals 20–23 × 4–6 mm wide. *Filaments* unilateral, declinate, unequal, two longer 8–10 mm long, shorter one 5–6 mm long; anthers inclined to horizontal, 5–6 mm long, one slightly shorter, white; pollen white. *Style* dividing near apex of anthers, branches ± 3 mm long, recurved. *Capsules* oblong, 5–8 mm long, ± 3.5 mm diam., shorter than bracts. *Chromosome number*, $2n = 52$. *Flowering time*: late August to early October.

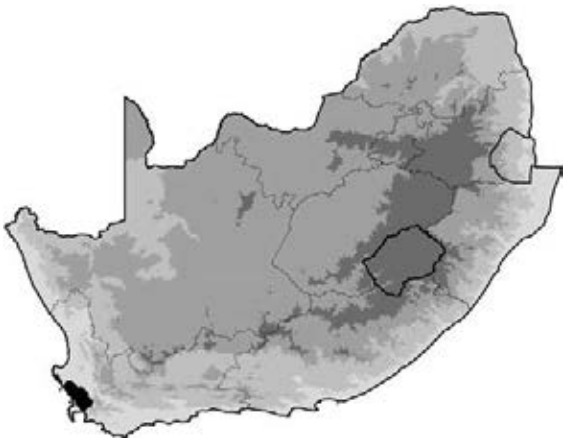
Distribution and ecology: known only from the vicinity of Nieuwoudtville in Northern Cape, South Africa; restricted to dolerite outcrops in heavy clay ground.

Diagnosis: *Geissorhiza inaequalis* is evidently closely related to common and widespread Western Cape species *G. aspera*, and they can be difficult to distinguish when dry. Both have a similar habit, flat, sword-shaped leaves and minutely velvety stems. *Geissorhiza aspera* typically has deep blue-violet, less often white or purple flowers, and at flowering time the upper parts of the floral bracts are often dry and rusty brown. The stamens are only slightly unequal or nearly equal, whereas *G. inaequalis* has larger, pale purple flowers, and green or pale, membranous bracts at flowering time, the brown colouration developing only after the flowers fade. It also has one filament about half as long as the others and even one anther may be slightly shorter then the other two. *Geissorhiza inaequalis* may also be confused with *G. heterostyla*, which is similar in habit and has one short filament. The latter, however, has leaves that are ciliate along the raised margins and main vein, and a short, dry scale-like bract in the upper part of the stem. Dry material must be examined carefully to avoid misidentification. *Geissorhiza inaequalis* is unusual in the genus in being tetraploid, $2n = 52$.



Distribution of ***Geissorhiza inaequalis***.

83. **Geissorhiza lewisiae** *R.C.Foster* in Contributions from the Gray Herbarium of Harvard University 135: 45 (1941); Goldblatt & Manning 145: 209 (1985). Type: South Africa, [Western Cape], Langebaan, 7 Sept. 1932, *Lewis s.n.* (K, holo.; BOL 20303, iso.).



Plants 150–300 mm high. *Corm* narrowly ovoid, ± 4 mm diam., with several cormlets at base. *Stem* puberulous, often 1- sometimes 2-branched. *Leaves* usually 4, lower 2 basal, blades ± linear, mostly 2–4 mm wide, margins and central vein somewhat thickened and narrowly winged, smooth or wing margins and secondary veins ciliate-hairy, uppermost cauline leaf sparsely hairy to smooth. *Spike* nodding in bud, flexuose, (1)2- to 5-flowered, branches with fewer flowers; bracts green below, dry and brown in upper ½–⅔, outer 10–17 mm long, inner 8–12 mm long. *Flowers* nodding, zygomorphic, glossy dark violet, yellow-green at base of tepals and in throat narrowly edged darker violet; perianth tube funnel-shaped, ± 2 mm long; tepals subequal, oblanceolate, outer 15–18 × 7–8 mm, inner longer and narrower, 17–20 × ± 5 mm. *Filaments* unilateral, declinate, unequal, 6–8 mm long, uppermost ± 1.5 mm shorter than lower 2, violet, sometimes pale yellow-green at base; anthers 5–6 mm long, declinate, pale violet; pollen white or mauve. *Style* declinate, dividing opposite anther tips, branches 3–4 mm long. *Flowering time*: late August to end of September.

Distribution and ecology: largely restricted to the Saldanha District of Western Cape, South Africa, extending from Steenberg Cove to the Posberg Peninsula, also local in the upper Olifants River Valley; in rocky sites, on limestone or granite.

Diagnosis: *Geissorhiza lewisiae* is recognised by the relatively large, dark, blue-violet flowers with a pale, yellow-green throat, tepals 15–20 mm long, and unilateral, decumbent stamens with unequal filaments. The stem is minutely puberulous but the leaves are smooth except for the raised margins, which are usually minutely ciliate. It appears to be most closely related to *G. aspera* with which it is sometimes sympatric, but it is always distinguished by the larger flower size, unilateral, declinate stamens and style and more intense blue-violet pigmentation than *G. aspera*, the nodding flowers of which have tepals 11–15 mm long, and shorter, horizontally oriented stamens. Both species have one filament slightly shorter than the other two. *Geissorhiza lewisiae* occurs in two disjunct sets of populations, a northern one around Citrusdal in the Olifants River Valley, and a western set along the Western Cape Coast, from Steenberg Cove on St Helena Bay to Saldanha Bay. Although typically associated with granite

Distribution of ***Geissorhiza lewisiae***.

Distribution of ***Geissorhiza monanthos***.

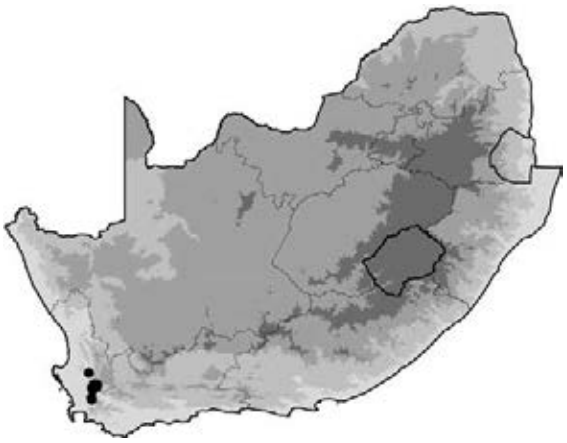
outcrops, it also occurs on limestone pavement and calcrete in the vicinity of Saldanha Bay. It has been included in *G. monanthos*, but this species has flowers with a pale, translucent centre surrounded by a dark blue to purple or red zone, and curved, bicoloured filaments that are pale in the lower half but dark violet distally. The median filament in *G. lewisiae* is always conspicuously shorter than the others by some 1.5 mm.

84. **Geissorhiza monanthos** *Eckl.* in Topographisches Verzeichniss der Pflanzensammlung von C.F Ecklon: 21 (1827); Foster: 39 (1941) [as *G. monantha* (Thunb.) Eckl.]; Goldblatt: 422 (1985, including *G. lewisiae*). *Ixia monanthos* Thunb.: 226 (1811), illegitimate name not *I. monanthos* D.Delaroche (1766) (= *Sparaxis* sp.). Type: South Africa. [Western Cape], exact locality unknown, *Thunberg s.n.* [UPS–THUNB 975, lecto., designated by Goldblatt: 422 (1982)].

Plants 100–160(–250) mm high. *Corm* narrowly ovoid, ± 3.5 mm diam., bearing several cormlets at base; tunics imbricate, black, notched below. *Stem* minutely puberulous, simple or 1(2 or 3)-branched. *Leaves* 3 or 4, lower 2 ± basal, ± linear to narrowly sword-shaped, slightly shorter than stem, blade narrowed below, 1.5–4.0 mm wide, ± plane with central vein and margins slightly thickened, glabrous, uppermost leaf inserted in upper ⅓ of stem, much shorter than basal leaves. *Spike* inclined, 1- or 2(–5)-flowered, branches 1(or 2)-flowered; bracts green, becoming dry and brown in upper half, outer 10–13 mm long, inner 7–10 mm long. *Flowers* nodding, zygomorphic, violet with glossy translucent white centre broadly edged with a band of intense violet or red; perianth tube ± 2 mm long; tepals subequal, obovate, 14–18 × 9–12 mm, sometimes narrowed below and tepals windowed near bases. *Filaments* unilateral, declinate, unequal; lower two (6–)8–10 mm long, uppermost ± 1.5 mm shorter, slightly thicker in middle, curving upward distally, white below, distal ⅔ violet; anthers 5–6 mm long, ascending, violet; pollen white or brown. *Style* dividing opposite anther tips, branches recurved, 3–4 mm long. *Flowering time*: late August to late September.

Distribution and ecology: restricted to the Atlantic coastal forelands of Western Cape, South Africa, extending from Darling south and east to Malmesbury, Klipheuwel and Joostenberg; usually on gravelly, granite-derived soils.

Diagnosis: usually low growing and seldom reaching more that 160 mm in height, *Geissorhiza monanthos* is recognised by the distinctively coloured flowers, violet with a glossy translucent white centre broadly edged with a band of darker violet or red, and filaments that are white below but violet in the upper ⅔. The flowers are nodding and zygomorphic with decumbent stamens strongly curving upward distally so that the anthers are suberect. As its name suggests, the inclined to horizontal spikes bear few flowers, often only one but occasionally up to four. *Geissorhiza monanthos* may be most closely related to *G. lewisiae*, a taller species with spikes of 2 to 5 flowers that are violet with the bases of the tepals and throat yellow-green to white. The stamens of *G. lewisiae* are unilateral but nearly straight, with the filaments uniformly coloured, thus very different from those of *G. monanthos.* In addition, the leaves of *G. monanthos* have slightly raised margins and midvein and are always smooth, whereas those of *G. lewisiae* have raised and narrowly winged margins and central veins. The pollen of *G. lewisiae* is pale mauve or ± white but *G. monanthos* usually has red-brown or occasionally white pollen.



85. **Geissorhiza tulbaghensis** *F.Bolus* in Annals of the Bolus Herbarium 2: 160 (1918); Goldblatt: 424 (1985). Type: South Africa, [Western Cape], Tulbagh, *L. Bolus s.n.* (*BOL14851*, lecto., designated by Foster: 40 (1941); K, PRE, isolecto.).

Plants 70–150 mm high. *Corm* ovoid, symmetric, truncate at base, 5–8 mm diam.; tunics imbricate, blackish, outer layers regularly notched below into truncate sections. *Stem* suberect below, inclined above, minutely puberulous, flexed above leaf sheaths, simple or 1- or 2-branched from axils of cauline or basal leaf. *Leaves* 3 or 4, lower 2 or 3 basal, 2 lowermost narrowed below and petiole-like, third leaf sheathing base of stem, uppermost leaf cauline, partly sheathing stem, sometimes

± scale-like), blades sword-shaped to lanceolate, plane, shorter to slightly longer than stem, 1.5–10.0 mm wide, often sticky below and with soil adhering. *Spike* flexed at base, inclined, flexuose, 1(2)-flowered; bracts green below, brown and dry above, outer 10–18 mm long, inner slightly shorter. *Flowers* zygomorphic, half nodding, stamens unilateral, declinate, held above lowermost tepal, tepals white with maroon-red to brownish markings toward base; perianth tube funnel-shaped, 4–5 mm long; tepals subequal, ovate, 18–22 × 10–13 mm, inner 8–11 mm wide. *Filaments* equal, unilateral, declinate, 10–12 mm long; anthers 3.0–4.5 mm long, ± erect, dark purple; pollen dark red-brown. *Style* arching below stamens, branches ± 5 mm long. *Capsules* ovate-oblong, 6–8 mm long, enclosed in bracts. *Chromosome number* 2*n* = 26 + 1b. *Flowering time*: August to mid-September.

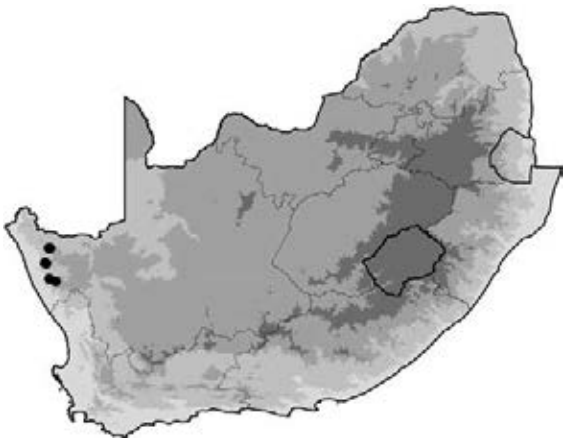
Distribution and ecology: restricted to the lower western slopes and foot of the Olifants River Mtns, Witzenberg and Bain's Kloof Mtns of Western Cape, South Africa, extending from the foot of Piekenierskloof Pass to Wellington and Tulbagh; on heavy, often stony clay soil in renosterveld.

Diagnosis: one of the most striking species of the genus, *Geissorhiza tulbaghensis* has large white flowers marked in the centre with maroon-red to brown. The flowers are half nodding and zygomorphic with the stamens and style unilateral and decumbent. Although similar vegetatively to *G. radians* and sharing with it very similar large zygomorphic flowers with declinate stamens and style, they are evidently unrelated: *G. tulbaghensis* has plane leaves and a puberulous stem typical of sect. *Planifoliae* whereas *G. radians* has the linear, 2-grooved leaves and ribbed leaf sheaths characteristic of sect. *Geissorhiza*. *Geissorhiza tulbaghensis* is distinctive not only in its flower coloration, but in the flat leaves with a slender petiole-like base. The flowers produce no nectar and are pollinated by the small horsefly, *Philoliche atricornis*, which also pollinates co-blooming species of Asteraceae.

Distribution of ***Geissorhiza tulbaghensis***.

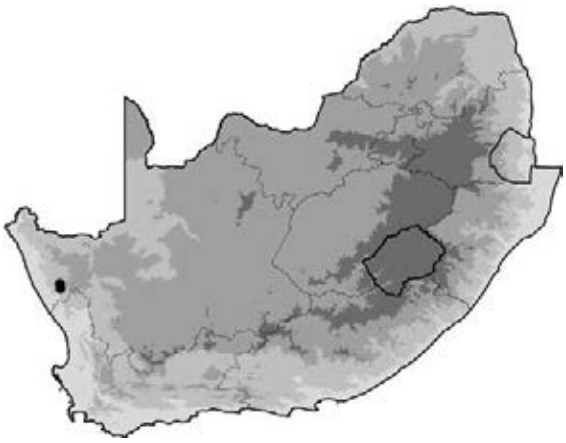
Hybrids have been recorded between *Geissorhiza tulbaghensis*, blue-flowered *G. aspera* and pale yellow-flowered *G. erosa* near Porterville. The hybrids are morphologically variously intermediate between the parents.

Sect. 12. **Ciliatae** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 426 (1985) [as sect. *Ciliata*]. Type: *Geissorhiza. inflexa* (D.Delaroche) Ker Gawl.



Geissorhiza subsect. *Pubescentes* Foster: 39 (1941). Type: *G. erosa* (Salisb.) Foster

Corm tunics woody with imbricate tunics, leaves with margins and main vein moderately to strongly raised and narrowly winged, edges ciliate-pubescent, sword-shaped to linear, bracts green below, dry and light brown to rust-coloured distally, flowers rotate to salver-shaped, actinomorphic, perianth tube short or long, reaching to apex of bracts, stamens equal or unequal.



Species 19: winter rainfall Northern and Western Cape, South Africa.

86. **Geissorhiza namaquensis** *W.F.Barker* in Flowering Plants of South Africa 18: t. 688 (1938); Goldblatt: 426 (1985). Type: South Africa, [Northern Cape], Namaqualand, Klipfontein, *Phillips s.n.* (BOL 22163, holo.).

Plants (80–)120–300 mm high. *Corm* globose, 8–10 mm diam., slightly asymmetric with one side obliquely flattened below and extended downward shortly, tunics dark brown, imbricate, notched below into ± regular segments, drawn into points above. *Stem* suberect or inclined, flexed at base of spike, minutely and sparsely puberulous below, sometimes with 1 branch. *Leaves* usually 3, sometimes 4, lower 2 basal, ± as long as stem, 2–4 mm wide, third leaf cauline, sheathing below, shorter than basal, fourth leaf, if present, shortest and becoming scale-like, blades evidently flat but margins raised and narrowly winged, main vein also raised, with margins, main and sometimes secondary vein edges ciliate. *Spike* inclined, flexuose, 2- to 8-flowered; bracts green, becoming dry, membranous and pale near apex, outer mostly 8–12 mm long, inner smaller, enclosed by outer. *Flowers* actinomorphic, salver-shaped, blue to blue-mauve; perianth tube cylindric, widening near throat, (7)8–11 mm long, reaching apex or just exceeding bracts; tepals elliptic, 14–18 × ± 4 mm. *Filaments* erect, equal, 5–6 mm long; anthers usually 4–6 mm long, yellow; pollen yellow. *Style* dividing opposite middle to upper ⅓ of anthers, often tilted downward, branches 2–3 mm long. *Capsules* globose, 6–8 mm long. *Flowering time*: mid-September to October.

Distribution of ***Geissorhiza namaquensis***.

Distribution of ***Geissorhiza namaquamontana***.

Distribution and ecology: endemic to Northern Cape, South Africa, extending from the southern Richtersveld to the Spektakel Mtns west of Springbok and on the escarpment west of Kamieskroon in central Namaqualand; on stony slopes often associated with shale or quartzite in renosterveld vegetation.

Diagnosis: one of three species of *Geissorhiza* endemic to Namaqualand, *G. namaquensis* is recognised by the well-developed perianth tube, mostly 8–11 mm long, minutely velvety stem, and leaves with raised, narrowly winged margins and main vein, both ciliate on the edges. The flowers are bright blue to blue-mauve with tepals 14–18 × 4 mm. Closely related *G. namaquamontana*, from the Grootberg and Kamiesberg, has smaller flowers with a perianth tube 6–7 mm long, tepals (6–)8–10 × 1.5–2.0 mm, and anthers 2–3 mm long. Long-tubed *G. kamiesmontana*, which is restricted to the Kamiesberg, has a longer perianth tube, 18–25 mm long, and dark violet flowers with longer, narrower tepals 16–20 × 3 mm.

87. **Geissorhiza namaquamontana** *Goldblatt & J.C.Manning* in South African Journal of Botany 111: 300 (2017). Type: South Africa, Northern Cape, Grootberg, 21 km SW of Kamieskroon, mid to upper southern slopes NE of Farm Naries, seasonally damp soils at base and between granite boulders, locally common, 700–860 m, 28 Sept. 2016, *Helme 8822* (NBG).

Plants 80–160(–250) mm high. *Corm* ± globose with oblique flattened side; tunics dark brown, imbricate. *Stem* puberulous, simple or 1- or 2-branched. *Leaves* 3 or 4, rarely 5 if plants with more than a single branch, lower 2 basal, ± as long as stem, 2–4 mm wide, remaining leaves cauline, sheathing below, shorter than basal, blades 1.5–3.0 mm wide, evidently flat but margins raised and narrowly winged, main vein also raised, with margins, main and sometimes secondary vein edges ciliate. *Spike* 1- to 3(5)-flowered; bracts green below, dry distally, often turning brown near tips, outer subacute, margins membranous, 7–10 mm long, inner slightly shorter. *Flowers* actinomorphic, salver-shaped, blue, base of tepals and throat white; perianth tube cylindric, widening near throat, 6–7 mm long, shortly exceeding bracts; tepals narrowly lanceolate (sublinear), (6–)8–10 × 1–2 mm. *Filaments* erect, equal, 4–5 mm long; anthers 2–3 mm long, white or yellow; pollen white or yellow. *Style* dividing opposite middle to apex anthers, often tilted downward, branches ± 1 mm long. *Capsules* ovoid?, 3(4) mm long. *Seeds* unknown. *Flowering time*: mid-September to mid-October.

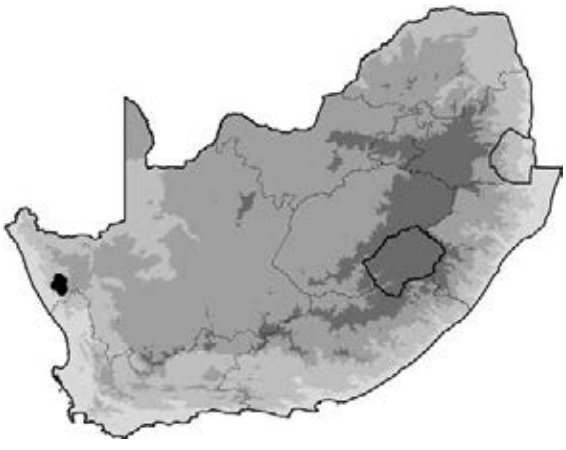
Distribution and ecology: endemic to Namaqualand in Northern Cape, South Africa, restricted to upper elevations above 700 m in the Kamiesberg near Leliefontein, on Rooiberg and on Grootberg to the west; in renosterveld vegetation on granite outcrops and granitic sands, sometimes in seeps on moss pads.

Diagnosis: like those of the other members of the *Geissorhiza namaquensis* group, the leaves of *G. namaquamontana* are narrowly sword-shaped to nearly linear, with the margins narrowly winged and ciliate and the main vein and sometimes a second pair of veins raised and similarly ciliate. There seems no difference in the leaves among the group except for overall size and number. Whereas four leaves are usual, some plants have only three leaves and one from Grootberg with multiple branches has a small fifth leaf. The point of division on the style seems to vary in *G. namaquamontana*, dividing opposite the middle to upper third of the anthers in the two Kamiesberg populations but opposite or shortly above the anther apices in the Grootberg plants which have white anthers and pollen. The style branches in both sets of populations are short, ± 1 mm long. A note on *Helme 3310* from the Kamiesberg states that the anthers and pollen are yellow. The differences between the Kamiesberg and Grootberg plants may simply be due to genetic drift or may signal that there are two separate taxa here. Additional field work in Namaqualand is needed.

88. **Geissorhiza kamiesmontana** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 427 (1985). Type: South Africa, [Northern Cape], Kamiesberg, E slopes of Rooiberg near Welkom, *Goldblatt 5770* (MO, holo.; K, NBG, PRE, WAG, iso.).

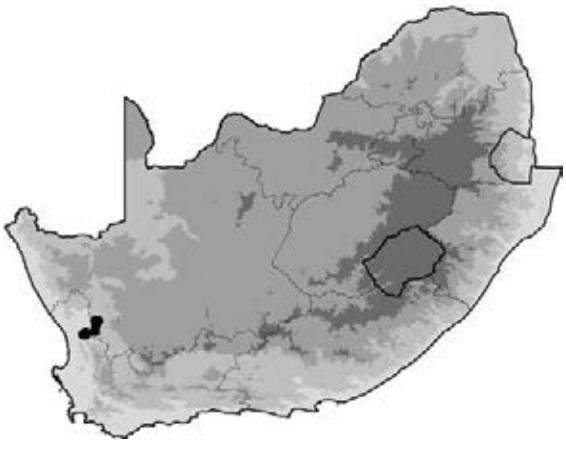
Plants mostly 150–300 mm high. *Corm* ± globose, somewhat asymmetric with one side flattened obliquely below, ± 10 mm diam.; tunics dark brown, imbricate, notched below into ± regular sections, drawn into points above. *Stem* minutely velvety, 1- or 2-branched. *Leaves* 3 or 4, lower 2 basal, upper 1 or 2 cauline, uppermost (when present) smallest, becoming scale-like, blades sword-shaped, reaching to ± base of spike, 2–3 mm wide, margins lightly raised and extending at right angles to blade, main vein raised and winged, velvety on edges of margins, main and secondary veins. *Spike* 1- to 4-flowered; bracts becoming dry from apex, turning brown above, outer 12–18(–21) mm long, inner enclosed by much longer outer bracts. *Flowers* salver-shaped, deep blue with pale throat and tube; perianth tube cylindric, widening near mouth, 18–25 mm long; tepals elliptic, 16–20 × ± 3 mm. *Filaments* suberect, equal, 8–10 mm long; anthers 3–4 mm long, yellow; pollen yellow. *Style* dividing opposite lower ⅓ of anthers, branches ± 2.5 mm long, reaching only to middle of anthers. *Capsules* ellipsoid, 6–9 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: September.

Distribution and ecology: restricted to the Kamiesberg of Namaqualand in Northern Cape, South Africa; at middle elevations on granite outcrops, often in moss pads in shallow soil near seasonal water sources.



Diagnosis: *Geissorhiza kamiesmontana* is distinguished by its deep blue flowers, paler in the throat, with an elongate perianth tube, 18–25 mm long, shortly exceeding the long floral bracts. The style is relatively short, dividing opposite the lower third of the anthers. The stem and leaves have a heavy, almost velvety, pale pubescence. Both *G. namaquensis* and *G. namaquamontana* are vegetatively similar, with puberulous stems and leaves with raised and winged margins, but their flowers are paler blue to blue-mauve, with a shorter perianth tube only 6–11 mm long.

89. **Geissorhiza divaricata** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 428 (1985). Type: South Africa, [Northern Cape], W of Nieuwoudtville, among rocks in fynbos, *Goldblatt 5838* (MO, holo.; K, NBG, iso.).

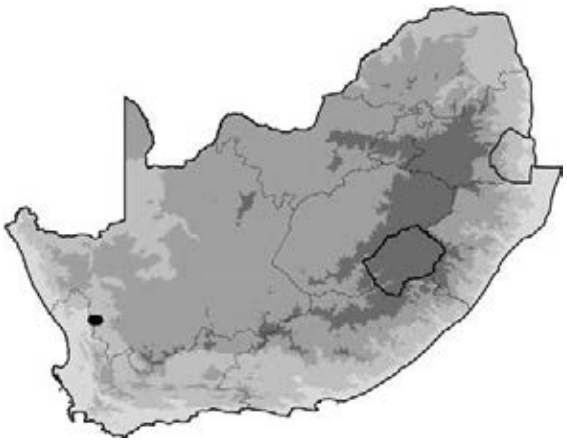


Plants (150–)220–450 mm high. *Corm* ± ovoid, obliquely flattened below, 10–12 mm diam.; tunics blackish, imbricate, notched below into sections. *Stem* usually bearing 1 or more short, dry, sheathing membranous scale-like bracts, usually branched from these nodes, also sometimes from cauline leaf axil, sharply flexed above nodes and at base of spike, sheathed at base by brown, persistent, fibrous leaf bases. *Leaves* 3, lower 2 basal, ½ to ± as long as stem, uppermost leaf inserted in middle of stem, sheathing upper half of stem for ½–⅔ its length, blades linear to sword-shaped, 2–3 mm wide, margins thickened and extended at right angles to blade, main vein also raised and winged, and one or two pairs of secondary veins enlarged, margin edges and veins ciliate-pubescent. *Spike* flexed at base, flexuose, inclined, (2)3- to 6-flowered; bracts dry-membranous, brown at flowering, flexed outward in upper half, outer ± 5.5 mm long, inner slightly shorter. *Flowers* actinomorphic, rotate, violet or white to pale mauve, reddish purple on reverse of outer tepals; perianth tube 1–2 mm long; tepals ovate-elliptic, ± 10 × 4 mm wide. *Filaments* erect, equal, ± 3 mm long; anthers 3–4 mm long. *Style* dividing opposite upper ⅓ of anthers. *Capsules* globose, 4–5 mm long. *Flowering time*: September.

Distribution and ecology: restricted to the Bokkeveld Mtns in Northern Cape, South Africa and the Gifberg in Western Cape; in rocky sandstone ground in fynbos.

Diagnosis: *Geissorhiza divaricata* is apparently very closely allied to *G. subrigida*, also restricted to the Bokkeveld Mtns. The two are distinctive in having a sheath of fibres

Distribution of ***Geissorhiza kamiesmontana***.



Distribution of ***Geissorhiza divaricata***.

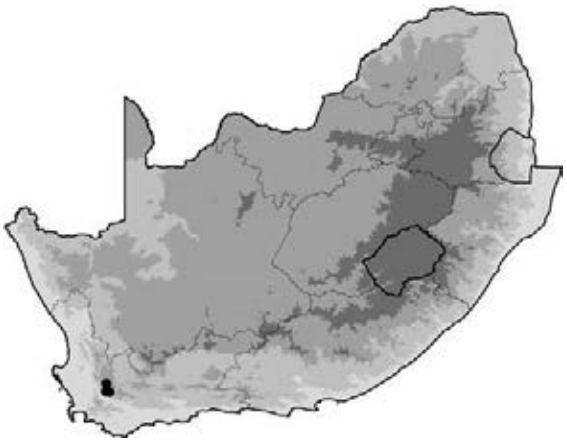
around the stem base, smooth stems, ciliate to pubescent and ribbed leaves, divaricate branching, and brown, membranous stem bracts. These shared similarities have tended to obscure their differences. *Geissorhiza divaricata* has small white to pale mauve or blue flowers with a perianth tube 1–2 mm long and tepals ± 10 mm, while *G. subrigida*, a shorter plant, has larger blue to violet flowers with perianth tube 3–4 mm long and tepals 12–17 mm long. Both grow in rocky sandstone ground but have not been recorded growing together. Plants included in *G. divaricata* from the Gifberg collected to date have either simple or 1-branched stems and lack the distinctive dry stem bracts found in those from the Bokkeveld Mtns.

90. **Geissorhiza subrigida** *L.Bolus* in South African Gardening and Country Life 22: 275 (1932); Goldblatt: 430 (1985). Type: South Africa, [Northern Cape], near Nieuwoudtville, ex hort. L. Bolus, Cape Town, *Buhr s.n.* (BOL 19995 [as 19943], holo.; K, PRE, iso.).

Plants 120–300 mm high. *Corm* ± ovoid, obliquely flattened below, 10–15 mm diam.; tunics blackish, imbricate, notched below into sections. *Stem* with a short, dry, membranous, sheathing scale-like bract in upper ⅓, usually branched at this node, also sometimes at axil of cauline leaf, flexed at nodes and base of spike, sheathed below by a fibrous collar of persistent leaf bases. *Leaves* 3, lower 2 basal, uppermost cauline, inserted in middle of stem, ½ to ± as long as stem, 3–6 mm wide, margins thickened and extending at right angles to blade, main vein also raised and winged and at least two other pairs of veins enlarged, ciliate to pubescent on veins and margin edges. *Spike* flexed at base, inclined, flexuose, (2)3-flowered; bracts ± dry, membranous and brown at flowering time, outer 6–10 mm long, flexed outward in upper half, inner slightly shorter. *Flowers* actinomorphic, rotate, violet, pale in throat and tube; perianth tube 2–3 mm long; tepals ovate-elliptic, 12–17 × 6–7 mm. *Filaments* erect, equal, ± 4 mm long; anthers 4–5 mm long. *Style* dividing opposite upper ⅓ of anthers, becoming decumbent. *Capsules* globose, ± 4 mm long. *Flowering time*: August to mid-September.

Distribution of ***Geissorhiza subrigida***.

Distribution and ecology: a narrow endemic of the Bokkeveld Mtns near Nieuwoudtville in Northern Cape, South Africa; on rocky sandstone ground, flowering well after fire.



Diagnosis: *Geissorhiza subrigida* stands out in its comparatively large blue to violet flowers, strongly ciliate-pubescent leaves, and a divaricate branching pattern. It is closely allied to the more widespread *G. divaricata*, which is similar in vegetative morphology, also with a divaricate branching pattern, but has smaller, white to pale mauve flowers. The leaves of *G. subrigida* and *G. divaricata*, with raised and flattened margins and the raised and winged midrib, both ciliate on their edges, are similar to several other species of sect. *Ciliatae*, in which the two species stand out in their divaricate branching, the presence of a bract-like scale on the stem, and equal stamens.

91. **Geissorhiza scopulosa** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 414 (1985). Type: South Africa, [Western Cape], Hex River Mtns, Milner Ridge Peak, 4 000–5 000 ft [1 200–1 500 m], *Esterhuysen 9328* (BOL, holo.; NBG, PRE, iso.).

Plants 80–150(–200) mm high. *Corm* globose, 8–10 mm diam.; tunics brown, firm to soft-membranous, imbricate, regularly notched below. *Stem* upright or inclined, simple, minutely ciliate-papillose, bearing a sheathing scale-like bract in upper ⅓. *Leaves* 3, lower 2 basal, lowermost longest, reaching at least to base of spike, sheath sticky and with sand adhering, second leaf sheathing lower part of stem for a short distance, uppermost inserted in upper part of stem, short, sheathing for at least ½ its length, blades linear, 1–2 mm wide, margins raised as narrow wings at right angles to lamina, main vein thickened. *Spike* inclined, flexuose, 2- to 5(–7)-flowered; bracts green in bud, becoming dry and membranous above, outer 3.5–5.0 mm long, inner slightly shorter. *Flowers* actinomorphic, rotate, pale blue-violet, creamy white in throat and tube; perianth tube funnel-shaped, 3–4 mm long, reaching or shortly exceeding bracts; tepals elliptic, 8–9 × ± 3 mm. *Filaments* suberect, unequal, longer two ± 3 mm long, shorter one ± 2 mm long; anthers ± 2.3 mm long, yellow. *Style* dividing opposite upper ⅓ of anthers, branches ± 1 mm long. *Capsules* globose, up to 4 mm long, included in bracts. *Seeds* unknown *Flowering time*: November.

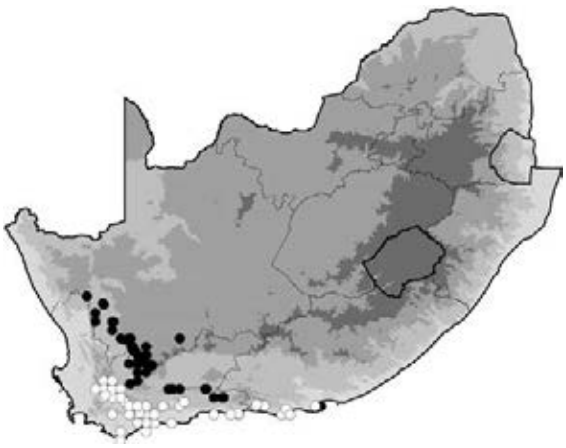
Distribution and ecology: restricted to high elevations in the Hex River Mtns of Western Cape, South Africa; in damp rocky sites, on cliffs and under boulders, usually south-facing at 1 200–1 800 m elevation.

Diagnosis: *Geissorhiza scopulosa* superficially resembles *G. ramosa* in the small, short-tubed flowers and general appearance but is a smaller plant with ciliate-papillose stems and is rarely branched, whereas *G. ramosa* has smooth stems and is almost invariably branched, sometimes with up to three or four branches.

Distribution of ***Geissorhiza scopulosa***.

Geissorhiza scopulosa is vegetatively more like the small-flowered species of sect. *Ciliatae*, in which most species also have ciliate-papillose to puberulous stems. The leaves of *G. scopulosa* have the margins raised into broad wings but the main vein hardly thickened, the blade thus H-shaped in section, a feature also consistent with several species of the sect. *Ciliatae*.

92. **Geissorhiza heterostyla** *L.Bolus* in South African Gardening and Country Life 20: 346 (1930); Goldblatt: 430 (1985). Type: South Africa, [Western Cape], near Whitehill, *L. Bolus s.n. BOL19148* (BOL, lecto., designated by Goldblatt: 430 (1985); BM, BOL, K, isolecto.).



Plants 120–450 mm high. *Corm* ovoid, symmetric, 9–12(–15) mm diam.; tunics blackish, woody, outer accumulating above, notched regularly into segments below. *Stem* puberulous to ciliate (subsp. *heterostyla*) or smooth (subsp. *rosea*), simple or more often branched, bearing membranous, often dry, sheathing bract-like leaf in upper part, usually branching from this axil, or also from axil of sheathing leaf. *Leaves* 3, linear to sword-shaped, lower 2 basal, ½ to ± as long as stem, 2–5 mm wide, I-shaped (to almost H-shaped) in section with margins raised at right angles to blade, ciliate on edges, midrib also raised and ciliate, uppermost basal or cauline, sheathing for most of its length, several ribbed on sheath. *Spike* mostly 3- to 7-flowered, flexed at base, inclined, flexuose; bracts 7–10(–15) mm long, initially pale green with hyaline margins, but drying from apex and becoming transparent, or flushed red or brown, inner shorter than outer. *Flowers* either zygomorphic, nodding, blue to violet (occasionally white) or actinomorphic and upright to half nodding, white, pale pink to pale mauve; perianth tube funnel-shaped, 1–2 mm long; tepals obovate to ellipsoid, 10–18(–22) × 6–9 mm. *Filaments* either unilateral, declinate or ascending, unequal, two longer usually 4–6 mm long, shorter one usually 3–4 mm long; anthers (2.5–)4.0–6.0 mm long, yellow or blue-black. *Style* usually long, dividing opposite upper half or beyond anther tips, branches usually long (rarely short, dividing opposite base of anthers and branches short). *Capsules* globose, 5–8 mm long. *Chromosome number* 2*n* = 26, 26 + 2b. *Flowering time*: August to early October.

Distribution and ecology: widespread through the Greater Cape Floristic Region, extending from the Langberg and Kubiskou Mtns in the western Karoo in Northern Cape, South Africa, through the Roggeveld and Witteberg in Western Cape and along the South Coast as far east as Port Elizabeth in Eastern Cape; on various soils, often on heavy clay or in stony sandstone ground in well-drained sites, also on limestone substrates.

Diagnosis: *Geissorhiza heterostyla* was based on plants from Whitehill in the western Karoo, individuals of which were variable for style length, hence the specific epithet. Plants had variously long styles dividing beyond the apex of the anthers, medium styles dividing at anther level, or short styles, dividing below the anthers. Other distinguishing features are the puberulous stem, submembranous sheathing, bract-like scale on the upper part of the stem, and leaves with raised, narrowly winged, ciliate margins (leaves I-shaped in section). Flowers are half to fully nodding and zygomorphic with the stamens unilateral and lying above the lower tepals or more-or-less upright with ascending, symmetrically arranged stamens. The stamens are consistently unequal, one filament 1–2 mm shorter than the other two, and the style arches downward to lie beneath the stamens.

Collections from near the type area and elsewhere either consist of plants with unequal styles or all plants in the population have long styles but otherwise match the species. Populations mixed or uniform for style length have now been collected across the western half of its range and while it appears likely that populations with uniformly long styles are the same species, the variation in style length is remarkable. All populations from the eastern end of the range examined have long styles.

The Witteberg, Ceres and Hex River Valley populations of *Geissorhiza heterostyla* are generally less robust than

Distribution of ***Geissorhiza heterostylya*** subsp. ***heterostyla***, ●; subsp. ***rosea***, ○.

plants from the western Karoo (though not invariably so), and match the type of *G. rogersii* (from the Hex River Mtns) in having leaves with less strongly raised margins and almost invariably smooth stems. One curious feature of the species is that the northern and usually larger-flowered populations have pollen grains with ancestral type apertures, whereas those from the south of its range have derived, complex apertures. This inconsistency plus the stems, which are not invariably hairy, renders the circumscription of *G. heterostyla* ambiguous. It seems useful to separate the smooth-stemmed plants as a separate subspecies, subsp. *rosea*.

Key to subspecies

1a Stems ciliate-papillate (rarely smooth); stamens unilateral and decumbent with blue-grey to white anthers; flowers usually blue to violet with white throat edged violet (rarely white to mauve) . . . . . 91a. subsp. *heterostyla*

1b Stems smooth (rarely sparsely ciliate-papillate); stamens mostly suberect with yellow anthers; flowers often uniformly white, or pale pink or pale mauve . . . . . 91b. subsp. *rosea*

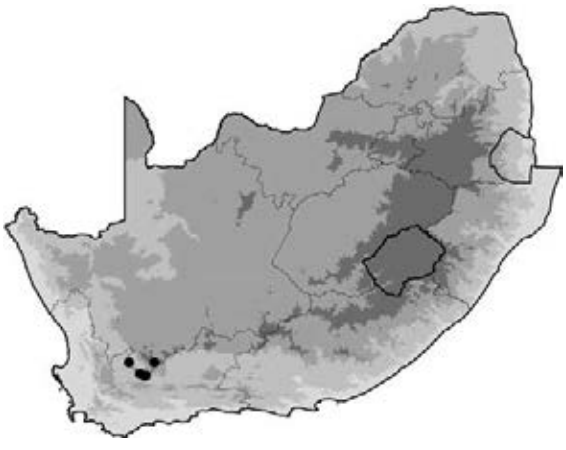
92a. subsp. **heterostyla**

Geissorhiza rogersii N.E.Br.: 452 (1931). Type: South Africa, [Western Cape], Worcester, between Osplaats and Tunnel Sidings, 600–900 m, *Rogers 16725* (K, lecto., designated by Goldblatt: 430 (1985); J, K, isolecto.).

Distribution and ecology: extending from the Langberg and Kubiskou Mtns west of Loeriesfontein across the Bokkeveld Plateau, Roggeveld and Klein Roggeveld in Northern Cape and across the Matjiesfontein-Witteberg Karoo to the Swartberg and Little Karoo; often in dolerite or shale-derived clay or sandstone.

Plants with stem minutely pubescent-papillate; flowers zygomorphic, nodding with decumbent stamens, tepals mostly blue to violet with yellow-green throat edged darker violet, less often pale blue or white; stamens and pollen mostly grey-blue (or white).

92b. subsp. **rosea** *(Klatt) Goldblatt & J.C.Manning* in South African Journal of Botany 106: 32 (2016). *Hesperantha rosea* Klatt: 395 (1882). *Geissorhiza rosea* (Klatt) Foster: 48 (1941), illegitimate homonym, not *G. rosea* Eckl. (1827) [= *G. erosa* (D.Delaroche) Ker Gawl.]. Type: South Africa, [Western Cape], Knysna, *Newdegate s.n.* (B: Herb. Lubeck, holo.).



Plants with stem smooth and hairless; flowers more-or-less actinomorphic, upright to half nodding with suberect stamens, tepals mostly white, then sometimes pink outside, or pale mauve to pale pink; stamens and pollen mostly yellow or white.

Distribution and ecology: extending across the southern coast and near interior of Western Cape, from Worcester and the Robertson Karoo to Knysna and along to Eastern Cape Coast from Plettenberg Bay to Port Elizabeth; mainly in clay or limestone.

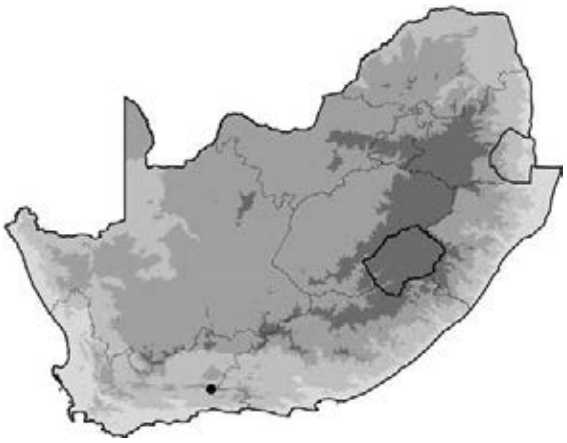
93. **Geissorhiza cantharophila** *Goldblatt & J.C. Manning* in Goldblatt et al. in Bothalia 39: 137 (2009). Type: Western Cape, Klein Roggeveld, 26.5 km north of N1 on road to Sutherland from Matjiesfontein, Farm Fortuin, 26 Aug. 2006, *Goldblatt & Porter 12704* (NBG, holo.; MO, PRE, iso.).

Plants 250–450 mm high. *Corm* ovoid, 8–10 mm diam.; tunics imbricate, blackish. *Stem* sparsely short-hairy, usually 1- to 3-branched, with a sheathing, bract-like scale up to 10 mm long in upper ⅓. *Leaves* 3, lower 2 with suberect to falcate blades, upper leaf sheathing stem but free distally, blades linear, margins raised into broad wings held at right angles to blade, main vein raised and bearing winged edges parallel to blade surface, ciliate on wing edges of margins and main vein. *Spike* inclined, flexuose, 3- to 6-flowered; outer bract dull grey-green in bud with submembranous margins, drying pale straw with age, ± 10 mm long, inner ± opaque-membranous with 2 dark green keels, ± 2 mm shorter than outer, apically forked. *Flowers* actinomorphic, rotate, bright, glistening pink (turning blue on drying) with a glossy, dark purple central zone, filaments and style also dark purple; perianth tube funnel-shaped, 2.0–2.5 mm long; tepals subequal, ovate, spreading, ± 15 × 7 mm. *Filaments* suberect, unequal, 4–5 mm long, one ± 1 mm shorter than other two; anthers 5–8 mm long, mauve-pink to purple; pollen pale pink (yellow when dry). *Style* slender, short, ± 3 mm long, dividing opposite lower ⅓ of filaments, branches ascending, ± 3 mm long, extending between anthers. *Capsules* subglobose, 3-lobed, 6–7 mm long. *Flowering time*: late August to mid-September, occasionally until early October; opening late morning and closing in late afternoon.

Distribution and ecology: restricted to the southern Roggeveld and Klein Roggeveld in Northern Cape and

Distribution of ***Geissorhiza cantharophila***.

adjacent Western Cape, South Africa; most often on south-trending slopes or flat ground on shale and clay.



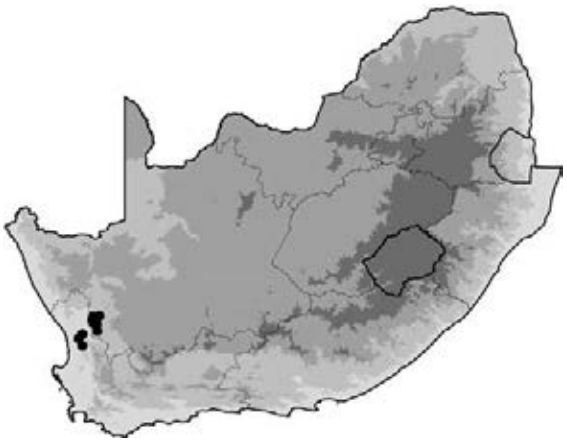
Diagnosis: with corms typical of subg. *Geissorhiza*, *G. cantharophila* is distinguished by the two basal leaves with narrowly winged margins and a raised and winged central vein exactly like those of its presumed immediate relative *G. heterostyla*, and it also has the derived pollen grains with complex aperture and operculum often found in that species. In living plants, the glistening purple-pink flowers with a dark purple centre, purple filaments and a short purple style are unmistakable. The style, ± 3 mm long, divides opposite the lower third of the filaments and the nearly straight style branches are unusual in the subgenus and probably associated with its pollination by hopliine beetles, species of which have been captured on the flowers.

Vegetatively almost identical, widespread *Geissorhiza heterostyla* is particularly difficult to distinguish from *G. cantharophila* in the herbarium but alive the blue to mauve or almost white flowers, pale yellow to green in the throat and tube usually edged in darker blue or mauve, and ± white stamens and style branches make it easy to separate the two species.

94. **Geissorhiza reclinata** *Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 39: 139 (2009). Type: Western Cape, Swartberg, Meiringspoort, SW trending slopes among sandstone rocks, 16 Aug. 2002, *Goldblatt & Porter 12057* (NBG, holo.; MO, PRE, iso.).

Plants 80–120 mm high. *Corm* ovoid, ± 8 mm diam.; tunics imbricate, dark brown, fragmenting below into tile-like sections. *Stem* sparsely short-hairy or sometimes ± smooth in upper ⅓, usually 1- to 3-branched, bearing sheathing scale-like bract up to 10 mm long in upper ⅓. *Leaves* mostly 3, lower 2 ± prostrate, blades linear, 80–120 × 1.5–2.0 mm, margins and main vein raised into narrow wings held at right angles to blade, wings sparsely ciliate, upper leaf sheathing stem below, free distally. *Spike* flexed at base and inclined, flexuose, 1- to 3-flowered; bracts unequal, green flushed purple above, margins membranous, outer ± 10 mm long, inner ± 8 mm long, apex entire. *Flowers* zygomorphic, held at ± 45° from vertical, blue-mauve (turning pale lilac on drying), greenish yellow in tube, upper 3 tepals dark blue-purple at base, filaments and style pale blue; perianth tube funnel-shaped, ± 2 mm long; tepals narrowly ovate, subequal, spreading, 14–16 × 7 mm. *Filaments* unilateral, declinate, unequal, two longer 10–12 mm long, shorter one 8–9 mm long; anthers 5–8 mm long, pale mauve-pink; pollen pale yellow (brown when dry). *Style* declinate, lying beneath filaments, dividing opposite anther tips, branches ± 1.5 mm long, extending above anthers. *Flowering time*: mid-August to mid-September, later at higher elevations.

Distribution and ecology: endemic to the eastern Swartberg in Western Cape, South Africa, where it is known only from Meiringspoort east of Oudtshoorn; on moist, peaty sand on southwest-trending slopes among sandstone rocks, flowering well after fire.



Distribution of ***Geissorhiza reclinata***.

Diagnosis: the dark brown, overlapping corm tunics and unequal filaments place *Geissorhiza reclinata* in subg. *Geissorhiza*, where it was initially compared with the Cape mountain species *G. pseudinaequalis* and *G. scopulosa* of sect. *Monticolae* partly because of the zygomorphic flowers with unilateral, declinate stamens and style and the upper tepals with dark markings near the base. However, it has pollen grains with specialised apertures known only in sect. *Ciliatae*, where it may be allied to *G. heterostyla* subsp. *heterostyla*, also with zygomorphic flowers. The sparsely short-hairy stems and leaves with the margins and central vein winged with ciliate wing edges likewise are consistent with *G. heterostyla* and other species of sect. *Ciliatae*. Unusual in subg. *Geissorhiza*, the basal leaves are prostrate and the stamens are unusually long, the two long filaments 10–12 mm long. The relatively large flowers have a perianth tube ± 2 mm long and tepals 14–16 mm long.

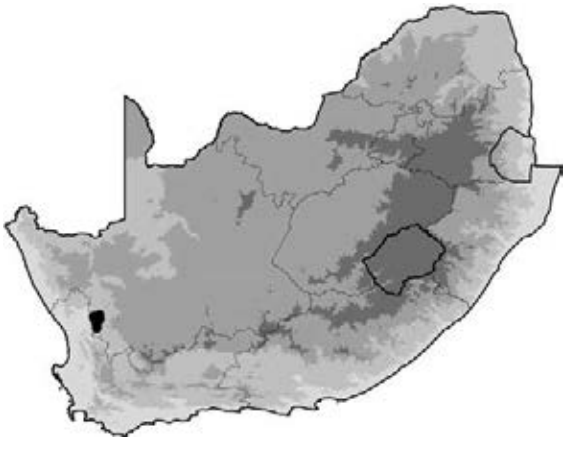
95. **Geissorhiza arenicola** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 434 (1985). Type: South Africa, [Northern Cape], sandy wet heathland west of Nieuwoudtville, *Goldblatt 7056* (MO, holo.; K, NBG, PRE, S, iso.).

Plants 120–260 mm high. *Corm* globose, symmetric, 6–10 mm diam.; tunics blackish, imbricate, woody, notched into regular segments below. *Stem* finely puberulous above third leaf, smooth below, occasionally with 1 branch, without a sheathing, bract-like cauline leaf. *Leaves* 3, narrow, linear, 1–2 mm wide, reaching to between middle of stem and base of spike, margins and main vein enlarged and thus 2-grooved on each surface, edges of margins and main vein minutely ciliate or evidently smooth, often sticky below with adhering sand, lower 2 leaves basal, uppermost inserted shortly above ground, often largest, sheathing stem for ⅔ of its length, sheath several ribbed, somewhat inflated. *Spike* flexuose, inclined, (1–)3- to 8-flowered; bracts green, margins

Distribution of ***Geissorhiza arenicola***.

often lined with red above, sometimes becoming dry and membranous from apex, 7–9 mm long, inner shorter and much narrower than outer. *Flowers* actinomorphic, rotate, deep blue-mauve with pale throat or white; perianth tube funnel-shaped, 1.5–2.0 mm long, enclosed in bracts; tepals elliptic, 10–15 × 4–8 mm. *Filaments* suberect, unequal, two longer 3–4 mm long, shorter one 2.0–2.5 mm long; anthers 3–5 mm long, white or pale yellow. *Style* dividing opposite or beyond anther tips, branches ± 2 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: September to mid-October.

Distribution and ecology: occurring on the Bokkeveld Mtns in Northern Cape and the Gifberg and northern Olifants River Mtns in Western Cape, South Africa; in stony sandstone ground.



Diagnosis: *Geissorhiza arenicola* is recognised by the puberulous stem (usually smooth below), two basal leaves with thickened margins and raised and thickened central vein, minutely ciliate on the edges and slightly sticky on the raised surfaces. The third leaf is largely sheathing, the sheath slightly inflated and distinctly ribbed. The flowers are usually deep blue and relatively large, with tepals mostly 12–15 mm long, and the filaments are unequal. Populations in the southern Bokkeveld Mtns are unusual in having uniformly white flowers. *Geissorhiza arenicola* is most easily confused with the more widespread and usually smaller-flowered *G. aspera* but is apparently related to the dark blue-flowered *G. splendidissima*, with which it shares a puberulous stem, a strongly ribbed and grooved upper leaf sheath, short perianth tube, and basal leaves with strongly raised margins and midrib, the edges of which are usually lightly ciliate.

96. **Geissorhiza splendidissima** *Diels* in Botanische Jahrbücher für Systematik 44: 117 (1909); Goldblatt: 435 (1985). Type: South Africa, [Western Cape], Oorlogskloof, *Diels 627* (B, holo.).

Plants 80–200 mm high. *Corm* ovoid, truncate at base, 7–10 mm diam.; tunics dark brown to black, imbricate, outer layers notched below into regular truncate sections. *Stem* suberect, densely minutely puberulous, simple or with 1(2) branch(es), with short sheathing scale-like bract in upper ⅓. *Leaves* 3, lower 2 basal, lowermost longest, shorter to slightly longer than stem, blades linear, mostly 1.5–2.0 mm wide, margins raised and extended at right angles to blade, main vein thickened, blade thus narrowly 2-grooved on each surface, edges of margins and midrib minutely ciliate, slightly sticky and with sand adhering, uppermost leaf inserted shortly above ground, sheathing below, with inflated sheath. *Spike* flexuose, flexed at base and inclined, mostly 2- to 5-flowered; bracts initially green, becoming dry and brown from apex, outer 16–20(–25) mm long, inner 8–16 mm long. *Flower* zygomorphic, glossy deep blue, darker toward base of tepals, yellow-green in throat, tepals widely cupped and tilted 30°, stamens unilateral and declinate, held above lowermost tepal; perianth tube funnel-shaped, 2–4 mm long; tepals broadly ovate, 15–22 × 9–14 mm, inner 8–12 mm wide. *Filaments* equal, unilateral, declinate, ± 5 mm long; anthers 7–8 mm long, horizontal; pollen red-brown. *Style* ± 10.5 mm long, lying beneath stamens, dividing opposite anther tips, branches 2 mm long. *Capsules* globose, ± 6–7 × 5 mm, enclosed in bracts. *Chromosome number* 2*n* = 26. *Flowering time*: late August to mid-September.

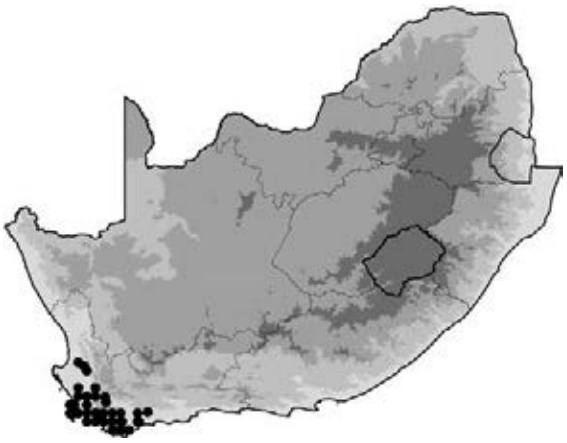
Distribution and ecology: restricted to the Bokkeveld Mtns and western Bokkeveld Plateau in Northern Cape, South Africa; on sandy to stony flats, mainly on tillite derived soils; flowering well only when the surrounding vegetation has been cleared or disturbed.

Diagnosis: immediately recognised by the glossy, dark blue flowers with dark red-brown pollen, *Geissorhiza splendidissima* has imbricate corm tunics typical of subg. *Geissorhiza*. Its affinities seem to be with sect. *Ciliatae* as it has similar leaf morphology, with strongly raised and winged margins ciliate on the edges. The puberulous stem is also consistent with the section, but the zygomorphic flowers with unilateral, declinate stamens and dark red-brown pollen are unusual, as is the somewhat ribbed sheath of the uppermost leaf. This

Distribution of ***Geissorhiza splendidissima***.

character is shared with the apparently allied *G. arenicola*, a character that sets these two species somewhat apart in the section.

97. **Geissorhiza inflexa** *(D.Delaroche) Ker Gawl.* in König & Sims, Annals of Botany 1: 224 (1804); Goldblatt: 436 (1985, including *G. erosa*). *Ixia inflexa* D.Delaroche: 15 (1766). *Hesperantha inflexa* (D.Delaroche) R.C.Foster: 77 (1941) [name misapplied to *H. vaginata*]. Type: South Africa, [Western Cape], Cape Peninsula, *Barker 3869* (BOL, neo., designated by Goldblatt & Barnard: 298 (1970); NBG, iso.).



Geissorhiza quinquangularis Eckl. ex Klatt: 654 (1866), illegitimate superfluous name for *G. rosea* Eckl. (1827). *G. hirta* var. *quinquangularis* (Eckl. ex Klatt) Baker: 155 (1892). *Hesperantha quinquangularis* (Eckl. ex Klatt) Klatt: 176 (1894). Type: South Africa, [Western Cape], Caledon Division, Swartberg, *Ecklon & Zeyher Irid. 214B* (B, 'type', designated by Foster: 55 (1941); G, isolecto.).

Geissorhiza graminifolia Baker: 155 (1892). Type: South Africa, [Western Cape], near Swellendam, *Drège 3496* (K, lecto., designated by Goldblatt: 438 (1985); B, E, G, L, MO, P, isolecto.).

Geissorhiza graminifolia var. *bicolor* Baker: 155 (1892). Type: South Africa, [Western Cape], Hout Bay, *MacOwan s.n. in Herb. Norm. Austr. Afr. 261* (K, lecto., designated by Goldblatt: 438 (1985); B, BOL, G, SAM, isolecto.).

Geissorhiza quinquangularis var. *atrofaux* R.C.Foster: 55 (1941). Type: South Africa, [Western Cape], Piketberg, *Schlechter 5210* (B, holo.; B, BM, G, K, SAM, W, Z, iso.).

Plants (50–)120–300(–400) mm high. *Corm* ± ovoid, 7–12 mm diam.; tunics blackish, imbricate, outer layers notched regularly below into sections. *Stem* smooth, sheathed below by uppermost leaf, rarely branched. *Leaves* 3, lower 2 basal, usually ½–⅔ as long as stem, sometimes exceeding spike, linear-sword-shaped, (1.5–)3.0–4.0(–10.0) mm wide, margins extended outward at right angles to blade, main vein also raised and winged, with wing edges minutely hairy, uppermost leaf basal or more often cauline, sheathing for most of its length, sheath ribbed and minutely hairy, slightly inflated. *Spike* (3)4- to 7-flowered, flexed at base; bracts usually ± dry at anthesis, reddish brown, occasionally greenish below, outer 8–16 mm long, inner somewhat smaller than outer. *Flowers* actinomorphic, rotate, creamy white to pale yellow, outer tepals usually flushed pink to red outside, sometimes dark at base of tepals and in throat; perianth tube short 1.5–2.0 mm long; tepals obovate-elliptic, (8–)10–15(–18) × 5–7 mm. *Filaments* suberect, equal, 4–5 mm long; anthers (2.5–)4.0–6.0 mm long. *Style* dividing near apex of anthers, branches ± 3 mm long, recurved above. *Capsules* globose-ellipsoid, 3–6 mm long. *Chromosome number* 2*n* = 26, 26 + 1b. *Flowering time*: August to September.

Distribution of ***Geissorhiza inflexa***.

Distribution and ecology: relatively common in southwestern Western Cape, South Africa, extending from Piketberg in the north to the Cape Peninsula and east to Bredasdorp and Swellendam in the east; mainly on clay slopes and flats.

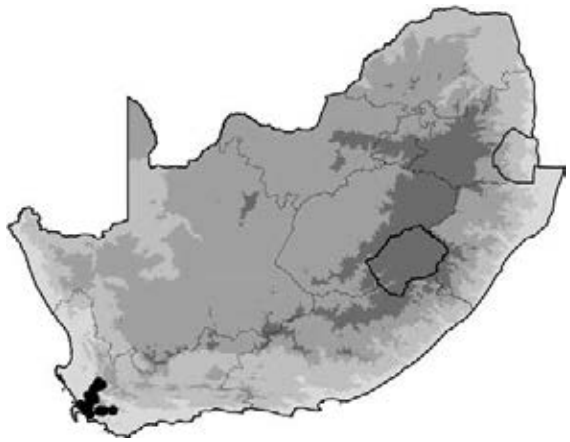
Diagnosis: *Geissorhiza inflexa* is recognised by the relatively small, creamy white flowers, often lightly flushed pink to red outside, inflexed stem, and narrowly sword-shaped leaves with raised and narrowly winged margins. The flowers have tepals mostly 10–15 mm long but exceptionally up to 18 mm in populations on the Cape Peninsula and nearby, and stamens with the anthers 4–6 mm long. The edges of the marginal wings, the main vein and sometimes secondary veins are ciliate to obviously hairy but the stem is quite smooth. *Geissorhiza inflexa* is closely allied to *G. erosa* and the two species have at times been united. The latter has larger, pink, red, purple or sometimes white flowers with tepals 18–24 × 8–10 mm, longer anthers 7–8 mm long, and usually broader leaves 5–10 mm wide.

98. **Geissorhiza erosa** *(Salisb.) R.C.Foster* in Contributions from the Gray Herbarium of Harvard University 135: 52 (1941); Goldblatt et al.: 142 (2009). *Ixia erosa* Salisb.: 36 (1796). Type: unknown (possible authentic material at G: Herb. De Candolle); South Africa, [Western Cape], Tulbagh, 9 Sept. 1945, *Lewis 5738* [NBG, neo., designated by Goldblatt et al.: 36 (2009)].

Ixia hirta Thunb.: no. 6 (1783), superfluous name for *I. inflexa* D.Delaroche (1766). *Geissorhiza hirta* Ker Gawl.: 224 (1804). Type: South Africa, [Western Cape], without date, *Thunberg s.n.* (UPS–THUNB, holo.).

Geissorhiza rosea Eckl.: 21 (1827). *Hesperantha ciliata* E.Mey. ex Klatt: 394 (1882), illegitimate superfluous name for *G. rosea* Eckl. Type: South Africa, [Western Cape], near Tulbagh, cultivated in Cape Town, without date, *Ecklon s.n.* [S, lecto., designated by Nordenstam: 282 (1972)].

Geissorhiza candida Eckl.: 21 (1827). Type: South Africa, [Western Cape], Hottentots Holland, *Zeyher s.n.* (S, holo.).



Hesperantha kermesina Klatt: 15: 395 (1882). *Geissorhiza erosa* var. *kermesina* (Klatt) R.C.Foster: 53 (1941). Type: South Africa, [Western Cape], between Paarl and Pont, without date, *Drège 8480* (B, effectively designated by Foster: 53 (1941); BM, G, K, L, MO, S, isolecto.).

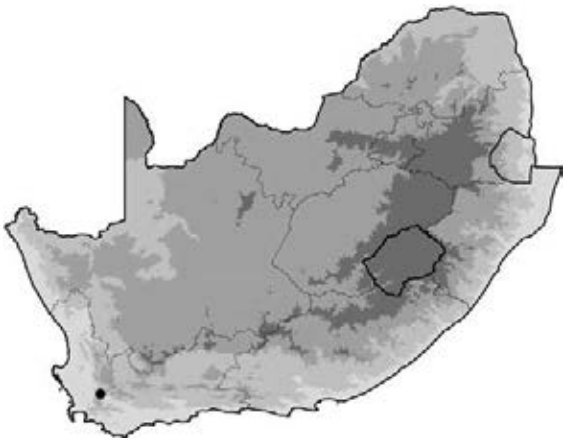
[*Ixia ciliaris* Salisb. ex Ker Gawl.: t. 549 (1802b), invalid name only in synonymy.]

[*Geissorhiza* (as *Gissorhiza*) *ciliaris* Salisb.: 321 (1812), invalid name without description.]

Plants 120–350 mm high. *Corm* ± ovoid, 7–12 mm diam.; tunics blackish, imbricate, outer layers notched regularly below into sections. *Stem* smooth, sheathed below by the uppermost leaf, rarely branched. *Leaves* 3, lower 2 basal, usually ½–⅔ as long as stem, sometimes exceeding spike, sword-shaped, 3–10 mm wide, margins extended outward at right angles to blade, main vein also raised and winged, edges of margins and main vein and sometimes secondary veins minutely hairy, uppermost leaf ± basal or cauline, sheathing for most of its length, sheath ribbed, minutely hairy, slightly inflated. *Spike* slightly flexed at base, flexuose, mostly 2- to 4(5)-flowered; bracts green or becoming dry distally, outer 18–20 mm long, inner ± 2 mm shorter. *Flowers* rotate, shallowly cupped, purple, pink, red, or white to pale yellow, unscented; perianth tube funnel-shaped, 1.5–2.0 mm long; tepals obovate to elliptic, 18–24 × 8–10 mm. *Filaments* suberect, equal, 5–7 mm long; anthers mostly 7–10 mm long; pollen yellow or white. *Style* dividing near apex of anthers, branches 3–4 mm long. *Capsules* globose to barrel-shaped, 4–6 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: mid-August to September.

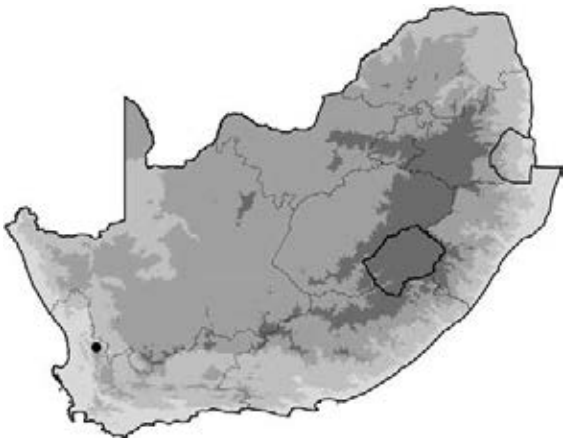
Distribution and ecology: occurring in the southwestern corner of Western Cape, South Africa, extending from Porterville and the Tulbagh Valley to Stellenbosch and Gordon's Bay; on clay or stony sandstone slopes, usually in renosterveld.

Distribution of ***Geissorhiza erosa***.



Diagnosis: the large-flowered *Geissorhiza erosa* is vegetatively almost indistinguishable from *G. inflexa*, but the spikes usually have fewer flowers, usually 2 to 4, with larger tepals, 18–24 × 8–10 mm, and often broader leaves. Consistent with the larger flower, the anthers are 7–10 mm long and the outer bracts are 18–20 mm long vs. tepals 10–15(–17) × 5–7 mm and anthers 4–6 mm long in *G. inflexa*. Generally the bracts of *G. inflexa* are dry and brown at flowering but in *G. erosa* the bracts are often green, turning light brown with age. The tepals are brilliant scarlet in popoulations from the upper Tulbagh Valley but pink to almost white or purple elsewhere.

99. **Geissorhiza exilis** *Goldblatt & J.C.Manning* in Goldblatt et al., Bothalia 39: 139 (2009). Type: Western Cape, Waaihoek Mtns, Farm Boesmansvlei, steep slopes above vineyards, SW-facing slopes among sandstone rocks, ± 390 m, 22 Sept. 2007, *Goldblatt & Manning 13014* (NBG, holo.; K, MO, PRE, iso.).



Plants 70–140 mm high. *Corm* 3–4 mm diam., ovoid, tunics imbricate, dark brown, fragmenting below into tile-like sections. *Stem* erect, smooth, usually 1- or 2-branched, bearing scale-like bract up to 10 mm long in upper ⅓ when second branch present. *Leaves* usually 3, lower 2 erect, blades linear or falcate, 30–40 × 1.5–2.5 mm, margins and main vein raised into narrow wings held at right angles to blade, wings prominently ciliate, upper leaf sheathing stem but free distally. *Spike* flexed at base and inclined, flexuose, 1- to 3-flowered, branches when present 1- or 2-flowered; bracts unequal, becoming dry and brown in upper half, outer 7–8 mm long, inner 5–6 mm long, 2-keeled and forked apically. *Flowers* actinomorphic, rotate, white with outer tepals flushed pale pink outside; perianth tube funnel-shaped, ± 1.5 mm long; tepals subequal, ± elliptic, spreading, ± 8 × 3–4 mm. *Filaments* suberect, equal, ± 2 mm long, anthers 3–4 mm long, white; pollen white. *Style* erect, dividing opposite upper ⅓ of anthers, branches ± 1.5 mm long, arching above anthers. *Flowering time*: September.

Distribution and ecology: known only from the slopes of the Waaihoek Mtns west of Worcester in Western Cape, South Africa; on fairly steep slopes in sandy ground among sandstone boulders, probably flowering only after fire.

Diagnosis: *Geissorhiza exilis* is identified by the narrow, sublinear to falcate leaves with the margins and central vein raised and extended into prominently ciliate wings, combined with a smooth stem, and flowers with equal filaments. Leaf morphology places the species in sect. *Ciliatae*, in which it appears to be most like *G. inflexa*. This species is an altogether larger plant with corms 7–12 mm diam., leaves mostly at least 3–4 mm wide, and flowers with tepals at least 8 mm long and more often 10–18 mm long. The stamens of *G. inflexa* are also larger, the filaments 4–7 mm long, the anthers

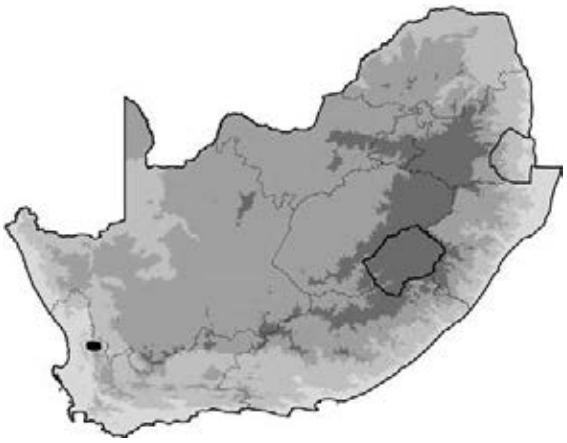
Distribution of ***Geissorhiza exilis***.

Distribution of ***Geissorhiza saxicola***.

mostly 3–6 mm long, and the style branches 4–5 mm long. Whereas *G. inflexa* favours clay or loam slopes and flats in renosterveld, *G. exilis* is a plant of sandy slopes in fynbos habitats.

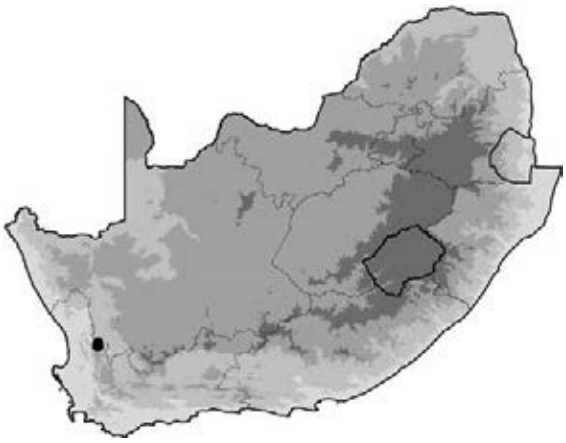
100. **Geissorhiza saxicola** *Goldblatt & J.C.Manning* in Goldblatt et al., Bothalia 39: 140 (2009). Type: South Africa, [Western Cape], Biedouw Valley, east-facing slopes above Biedouw Jeugkamp, damp sheltered places among sandstone rocks, 7 Sept. 1992, *Goldblatt & Manning 9404* (NBG, holo.; MO, iso.).

Plants 35–100 mm high. *Corm* unknown. *Stem* erect, pubescent, simple or rarely with a single short branch. *Leaves* 3, all basal or uppermost inserted on stem shortly above ground level, ± plane, falcate to trailing, lower 2 longest, exceeding stem, sublinear to narrowly sword-shaped, 1.5–4.0 mm wide, margins and main vein winged with marginal wings held at right angles to blade, wing edges prominently ciliate. *Spike* mostly 2- to 5-flowered, branch when present 1- or 2-flowered; bracts dry and brown in distal half, outer 7–8(–10) mm long, inner slightly shorter, 2-veined to 2-keeled, notched at apex. *Flowers* actinomorphic, rotate, white to pale pink, outer tepals pink to light purple outside, unscented; perianth tube funnel-shaped, 1.5–2.0 mm long; tepals 7–8 × 2–3 mm, spreading. *Filaments* suberect, unequal, two longer ± 3 mm long, shorter one ± 2 mm long; anthers 3.3–4.0 mm long. *Style* evidently erect, dividing opposite middle of anthers, branches 1.3–1.8 mm long. *Flowering time*: August to mid-October.



Distribution and ecology: poorly known, occurring in the northern Cederberg and Pakhuis Mtns of Western Cape, South Africa; in sandy soil, in moist shady sites in the shelter of sandstone rocks, sometimes locally abundant.

Diagnosis: *Geissorhiza saxicola* is recognised by the combination of a hairy stem, leaves with the margins and central vein winged with pilose wing edges, and small, white to pink flowers with unequal filaments. Its immediate relationships are uncertain although it evidently falls in sect. *Ciliatae*. Pollen grains with specialised, complex apertures place the species closest to *G. exilis* and *G. inflexa*, but the filaments of both these species are equal in length. The low stature and small flowers recall *G. minuta* of the Gifberg and Pakhuis Mtns, but that species has a smooth stem, equal stamens, and the thickened leaf margins and central vein lack the wings with ciliate edges of *G. saxicola*.



101 **Geissorhiza erubescens** *Goldblatt* in Annals of the Missouri Botanical Garden 72: 440 (1985). Type: South Africa, [Western Cape], Pakhuis Pass, shale slopes near top of pass, *Goldblatt 6396* (MO, holo.; K, NBG, PRE, S, WAG, iso.).

Plants 50–150 mm high. *Corm* ± globose, obliquely flattened below, 5–12 mm diam.; tunics blackish, imbricate, notched regularly below into sections. *Stem* suberect, ciliate to pubescent below third leaf, ciliate or smooth above, simple or 1-branched, sheathed below by fibrous collar of decayed leaf bases. *Leaves* 3, lower 2 basal, uppermost largest, inserted in middle of stem, blades linear, straight, ½–⅔ as long as stem, 2–3 mm wide, margins raised into wings extending at right angles to blade, main veins also raised and winged, minutely ciliate to visibly pubescent on wing edges, main veins and sometimes secondary veins. *Spike* flexed at base, flexuose, mostly 3- to 7-flowered; bracts membranous and greenish to transparent below, rust brown above, outer 6–8 mm long, flexed outward in upper ½, inner slightly shorter. *Flowers* actinomorphic, rotate, creamy white, outer tepals bright red outside; perianth tube funnel-shaped, 1.5–2.0 mm long, enclosed in bracts; tepals ovate-elliptic, 8–12 × 3–4 mm. *Filaments* suberect, equal, ± 3 mm long; anthers 2.5–3.0 mm long, creamy white; pollen creamy white. *Style* dividing opposite apex of anthers, branches recurved. *Chromosome number* 2*n* = 26. *Flowering time*: September.

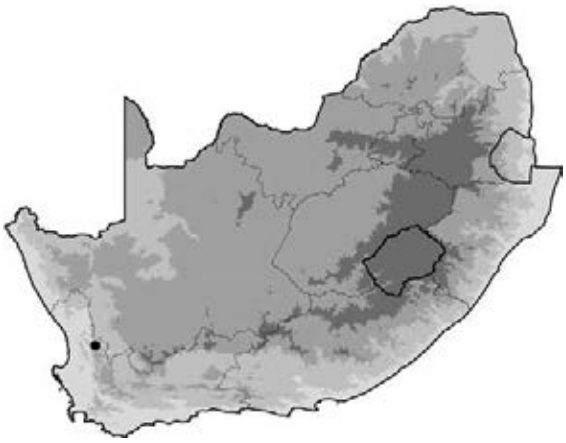
Distribution and ecology: known only from Pakhuis Pass in the Pakhuis Mtns of Western Cape, South Africa; common on the shale band, especially after fires.

Distribution of ***Geissorhiza erubescens***.

Distribution of ***Geissorhiza leipoldtii***.

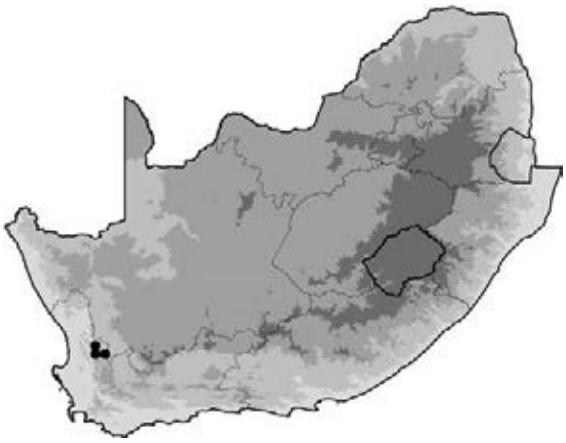
Diagnosis: a small-flowered species of sect. *Ciliatae*, *Geissorhiza erubescens* is recognised by the unusual collar of fibres around the stem base (at least in older individuals), strongly winged leaf margins, and relatively small flowers with tepals 8–12 mm long and equal stamens. The flowers are creamy white with the outer tepals bright red on the outside and the stem is ciliate-pubescent, less so in the upper half. It may be most closely allied to the smooth-stemmed southwestern Cape *G. inflexa*, or larger-flowered *G. leipoldtii* or *G. nutans*, the latter with unequal stamens and somewhat larger white flowers with tepals 14–16 mm long without the deep red markings on the reverse of the outer tepals characteristic of *G. erubescens*.

102. **Geissorhiza leipoldtii** *R.C.Foster* in Contributions from the Gray Herbarium of Harvard University 135: 47 (1941). Type: South Africa, [Western Cape], Pakhuis-Wuppertal road, *Leipoldt s.n. BOL20778* (K, holo.; BOL, SAM, iso.).



Plants mostly 200–350 mm high. *Corm* ovoid, symmetric, 5–8 mm diam.; tunics dark brown to blackish, imbricate, outer layers regularly notched below into sections. *Stem* sparsely ciliate, simple or 1- or 2-branched from axil of cauline leaf. *Leaves* 3, lower 2 basal, linear to sword-shaped, usually shorter than stem, 3–6 mm wide, apparently plane but margins raised into narrow, ascending wings ciliate along edges, main vein also slightly raised, winged and sparsely ciliate along edges, uppermost leaf cauline, sheathing for at least half its length. *Spike* flexed at base, mostly 3- to 6-flowered, flexuose; bracts ± membranous, dry and pale brown above, outer 12–16 mm long, inner smaller than outer. *Flowers* actinomorphic, upright to half nodding, shallowly cupped, stark white, greenish in throat (sometimes palest pink on fading); perianth tube funnel-shaped, 1.5–2.0 mm long; tepals narrowly obovate, 18–26 × 5–11 mm. *Filaments* suberect, equal (rarely upper filament slightly shorter), 7–8 mm long; anthers 6.5–8.0 mm long, bright yellow; pollen yellow. *Style* dividing opposite or slightly above anther tips, branches 4–6 mm long. *Capsules* globose, ± 5 mm long. *Flowering time*: late August to September.

Distribution and ecology: known only from hill slopes in the Biedouw Valley and near Wuppertal in Western Cape, South Africa; on seasonally moist, south-facing clay slopes.



Diagnosis: recognised by its ciliate stem and only two basal leaves, the margins with narrowly, ascending wings minutely ciliate on the edges, *Geissorhiza leipoldtii* has large, upright to slightly nodding, pure white flowers with tepals 19–26 × 7–11 mm. The stamens are relatively long and usually equal (or one filament slightly shorter) with anthers up to 8 mm long, bright yellow and bearing yellow pollen. In the past *G. leipoldtii* included plants from the Olifants River Valley and nearby with nodding flowers and markedly unequal filaments, but these are now recognised as *G. nutans*, as well as mauve-pink flowered *G. ixioides*, now also recognised as a separate species.

103. **Geissorhiza ixioides** *Schltr. ex R.C.Foster* in Contributions from the Gray Herbarium of Harvard University 135: 43 (1941). Type: South Africa, [Western Cape], 'Agtertuin, in collibus,' 15 Aug. 1897, *Schlechter 10866* (B, holo.; BM, BOL, BR, G, K, MO, P, PH, PRE, S, Z, iso.).

Plants (120–)160–300 mm high. *Corm* ovoid, symmetric, 5–8 mm diam.; tunics dark brown to blackish, imbricate, outer layers regularly notched below into sections. *Stem* sparsely ciliate, simple or 1(2)-branched. *Leaves* 3, lower 2 basal, linear to sword-shaped, usually shorter than stem, 3–5 mm wide, apparently plane, but margins raised at right angles to blade into wings ciliate along edges, main vein also slightly raised and winged, sparsely ciliate along edges, uppermost cauline, sheathing for at least ½ its length. *Spike* flexed at base, 2- to 6-flowered, flexuose; bracts ± membranous, dry and pale brown above, outer 10–12 × 4–4 mm, inner slightly smaller. *Flowers* actinomorphic, shallowly cupped, pale red-purple, dark in throat; perianth tube funnel-shaped,

Distribution of ***Geissorhiza ixioides***.

Distribution of ***Geissorhiza nutans***.

1.5–2.0 mm long; tepals narrowly obovate, (10–)12–16 × 5–7 mm. *Filaments* erect, equal, 3.5–4.5 mm long; anthers 5–7 mm long (4 mm after anthesis), light purple; pollen dull yellow. *Style* dividing opposite middle ⅓ of anthers, pale mauve (drying dark purple), branches 3–6 mm long. *Capsules* globose, ± 5.5 mm long. *Flowering time*: August to early September.

Distribution and ecology: a narrow endemic known only in the lower Doorn River Valley near Doornbos in Western Cape, South Africa; on stony, south- and east-facing slopes in rocky loamy clay ground.

Diagnosis: evidently allied to *Geissorhiza leipoldtii* and sharing with it a papillate to ciliate stem and three leaves, the lower two basal and the upper cauline and largely sheathing, *G. ixioides* is recognised by its mauve-pink flowers with a dark purple centre, relatively short, equal filaments, and short, purple style dividing opposite the middle third of the anthers. *Geissorhiza leipoldtii* has larger, pure white flowers with longer stamens with equal filaments 7–8 mm long and anthers 6.5–8.0 mm long. The species was included in *G. leipoldtii* by Goldblatt (1985) but later recognised as distinct (Goldblatt & Manning, 2016).

104. **Geissorhiza nutans** *Goldblatt & J.C.Manning* in South African Journal of Botany 106: 30 (2016). Type: South Africa, Western Cape, Olifants River to Algeria road, Farm Kriedouwkrans, moist, south-facing clay slope, 21 Aug. 2015, *Goldblatt & Porter 14094* (NBG, holo.; K, MO, PRE, iso.).

Plants mostly 150–240 mm high. *Corm* ovoid, symmetric, 5–8 mm diam.; tunics dark brown to blackish, imbricate, outer layers regularly notched below into sections. *Stem* sparsely ciliate, simple or 1-branched from axil of cauline leaf. *Leaves* 3, lower 2 basal, linear to sword-shaped, usually shorter than stem, 3–6 mm wide, apparently plane but margins with narrow, ascending wings ciliate along edges, main vein also slightly raised and winged, sparsely ciliate along edges, uppermost leaf cauline, sheathing for at least half its length. *Spike* flexed at base, 2- to 5-flowered, flexuose; bracts ± membranous, dry and pale brown above, outer 10–16 mm long, inner smaller than outer. *Flowers* zygomorphic with unilateral, decumbent stamens and style, shallowly cupped, white flushed mauve on reverse of outer tepals (often becoming pink or mauve with age); perianth tube funnel-shaped, 1.5–2.0 mm long; tepals narrowly obovate, 14–16 × 3–6 mm. *Filaments* unilateral, horizontal, unequal, two longer 5–7 mm long, shorter one ± 3 mm long; anthers 4.5–6.0 mm long, creamy white. *Style* dividing opposite upper ⅓ of anthers, branches 3–4 mm long. *Capsules* globose, ± 5 mm long. *Flowering time*: August to September.

Distribution and ecology: occurring in the Olifants River Valley and Cederberg in Western Cape, South Africa; usually on rocky clay ground, especially on south-facing, lightly wooded slopes.

Diagnosis: previously included in *Geissorhiza leipoldtii* (Goldblatt 1985), largely due to the limited material then available, *G. nutans* is readily distinguished from that species by the somewhat smaller flowers with narrower tepals 14–16 × 3–6 mm long vs. 18–26 × 5–11 mm in *G. leipoldtii* and shorter, markedly unequal stamens. Vegetatively the two are almost indistinguishable, having sparsely and minutely ciliate stems, and three leaves, the lower two basal and the upper one cauline and largely sheathing and the leaf blades with narrowly winged, ciliate margins and main vein. The flowers are nodding with the stamens unilateral and horizontal to drooping with white anthers 4.5–6.0 mm long and the filaments are markedly unequal, the longer two 5–7 mm long and the shorter ± 3 mm long. *Geissorhiza leipoldtii* has larger, upright to half nodding flowers with tepals 19–26 mm long and stamens symmetrically arranged with anthers 7–8 mm long and filaments ± 7 mm long (or one up to 0.5 mm shorter). The differences in the filament length in *G. nutans* are striking, the upper filament about half as long as the lower two, thus unmistakable. The anthers and pollen of *G. nutans* are white whereas those of *G. leipoldtii* are bright yellow.

INCOMPLETELY KNOWN

105. *Geissorhiza* sp. 1.

Plants up to 450 mm high. *Corm* ± ovoid, symmetric, ± 10 mm diam.; tunics blackish, imbricate, woody, notched into regular sections below. *Stem* smooth below, minutely ciliate in upper half but spike axis ± smooth, usually with 1 or 2 filiform branches, lower branch from cauline leaf axil and upper from axil of sheathing scale-like bract. *Leaves* 3, lower 2 basal, reaching to lower ⅓ or ± middle of stem, linear, ± 2 mm wide, margins expanded into broad wings raised at right angles to or arching over lamina, main vein slightly raised, thus H-shaped in section, edges of marginal wings and main vein ciliate; uppermost leaf inserted at or shortly above ground, sheathing for most of its length. *Spike* inclined, flexuose, several-flowered; bracts with broad membranous margins, becoming dry and rust-coloured distally at anthesis. *Flowers* actinomorphic, rotate, white or pale blue-mauve, white in throat often edged with darker blue, outer tepals flushed blue outside; perianth tube funnel-shaped, 1.5–2.3 mm long; tepals obovate-elliptic, outer 9(–12) × 3.5(–7) mm, inner slightly longer and narrower. *Filaments* unequal; two longer ± 3 mm long, shorter one ± 2 mm long; anthers ± 3.5 mm long, pale yellow; pollen ± white. *Style* dividing opposite middle to near apex of anthers, branches ± 1 mm long. *Flowering time*: mid-September to mid-October.

Distribution and ecology: to date only confirmed on the summit plateau of the Hantamsberg in the Calvinia District in Northern Cape, South Africa; in waterlogged or rocky clay or sandy ground.

Diagnosis: with corms typical of subg. *Geissorhiza*, this species remains incompletely known and keys out closest to *G. scopulosa* because of the minutely pubescent stem and leaf blades with broad marginal wings held at right angles to or arching over the surface, thus H-shaped in cross section. The radially symmetric flowers are pale grey-blue to white and have unequal stamens, the two longer filaments ± 3 mm long and the shorter one ± 2 mm long. Plants usually have one or two particularly slender, almost thread-like branches produced from the axils of the uppermost leaf and scale-like bract, this usually dry at flowering. *Geissorhiza scopulosa,* restricted to high elevations in the Hex River Mtns is a short plant, rarely exceeding 150 mm, is rarely branched and is also separated by its longer perianth tube 3–4 mm long. *G.* sp. 1 has also been confused with *G. heterostyla*, which also occurs on the Hantamsberg but only below the summit plateau, and has large, nodding, deep blue-violet flowers with decumbent stamens. It remains to be established whether *G.* sp. 1 occurs elsewhere.

21. **Hesperantha**

Hesperantha *Ker Gawl.* in König & Sims, Annals of Botany 1: 225 (1804a). Type: *H. falcata* (L.f.) Ker Gawl.

Schizostylis Backh. & Harv.: t. 5422 (1864); Goldblatt & Manning: 263 (1996). Type: *S. coccinea* Backh. & Harv. = *Hesperantha coccinea* (Backh. & Harv.) Goldblatt & J.C.Manning

Revisionary accounts: Goldblatt: 15–141 (1984), 390–443 (2003); Hilliard & Burtt: 407–438 (1986).

From the Greek, *hesperos*, evening, *anthos*, flower, for the night flowering of many species.

Deciduous perennials. *Rootstock* a corm, rarely a rhizome; corm globose to ovoid, often asymmetric with basal ridge from which roots emerge or bell-shaped; tunics woody, less often firm-papery, concentric or imbricate and then notched into sections below. *Stem* aerial or subterranean, simple or branched, terete, sometimes hairy or velvety. *Leaves* few to several, lower 2 or 3 cataphylls, these membranous or ± green above ground; foliage leaves unifacial, plane with a definite main vein or ± terete to oval in section, sometimes margins and/or main vein, sometimes hairy; margins with subepidermal sclerenchyma bundle and thin-walled epidermal cells. *Inflorescence* a spike with flowers usually spirally arranged, rarely flowers solitary; bracts green, soft-textured, inner slightly to significantly smaller than outer, notched apically. *Flowers* rotate to salver-shaped or nodding to ± pendent, diurnal or crepuscular, mostly white or pink, also yellow or blue to violet or red, usually actinomorphic, rarely weakly zygomorphic, often fragrant then usually in evenings, with nectar produced from septal nectaries; perianth tube cylindric, expanded near apex, short or long, sometimes curved; tepals subequal, spreading, sometimes recurved. *Stamens* symmetrically disposed or rarely unilateral and declinate; filaments inserted shortly below mouth of tube, sometimes very short, erect or drooping; anthers erect and facing inward or articulated on filament apices and horizontal, sometimes pendent, rarely included in tube. *Ovary* ± ellipsoid, sessile; style filiform, usually dividing at or just below mouth of tube, rarely above anthers, branches filiform, usually spreading (rarely suberect), stigmatic along most of their length. *Capsules* thin-walled, globose to oblong or ± cylindric, sometimes splitting open only in upper ⅓. *Seeds* globose to angular, flattened at chalazal end, sometimes slightly winged on angles or at opposite ends, smooth or rugulose, surface cells usually domed. *Pollen grains* monosulcate-operculate; operculum 2-banded, exine perforate-scabrate. *Basic chromosome number x* = 13.

Species ± 89, 87 in southern Africa with major centres in the winter-rainfall zone of South Africa and the Drakensberg and escarpment of eastern southern Africa, but extending through the tropical African highlands to Ethiopia and Cameroon.

As its name indicates *Hesperantha* was named for species with crepuscular flowers that open in the late afternoon, at which time they become fragrant, and close again during the night. *Hesperantha* has the highest proportion of moth-pollinated species in the family. The majority of species occur in the southern African winter-rainfall zone and have been found to be pollinated by settling moths of several lepidopteran families. Just a few species in the region have yellow, pink or purple flowers that open during the day and close at sunset, and these have different pollination strategies, notably *H. vaginata*, which has yellow tepals with dark brown markings and is pollinated by hopliine beetles. Species of eastern southern Africa show the opposite pattern, with most species having pink flowers with a diurnal pattern of opening and closing. Among these, species with short-tubed flowers are pollinated mainly by large-bodied bees and those with long-tubed flowers are pollinated only by long-proboscid flies, mostly nemestrinids. The few species of the area that have yellow or white flowers surprisingly also have a diurnal floral phenology.

The genus is recognised by ± woody corm tunics and flowers in which the style divides at or close to the mouth of the perianth tube into relatively long, laxly spreading style branches. The stamens are inserted just below the mouth of the tube or at the base of the tepals, the filaments are usually relatively short, and the anthers are articulated on the filaments and come to lie horizontally. Some striking exceptions include *Hesperantha cedarmontana*, in which the style divides in the lower part of the tube and both the style branches and stamens are included within the tube. In *H. kiarataylo-riae* the style divides above the mouth of the tube and the style branches are erect and coiled around themselves. Flowers of most species are radially symmetric, although *H. radiata* and its close allies have a perianth tube curved near the apex and the flowers are nodding or pendent and the stamens are unilateral, and *H. grandiflora* has zygomorphic flowers with unilateral, decumbent stamens oriented horizontally and lying above the lower tepals. Floral symmetry does not affect the pollination strategies in the genus.

The genus is divided into three sections with the majority of the species included in sect. *Concentricae*, with globose to ovoid corms with ± concentric corm tunics. The corms are slightly asymmetric and have a small flattened side from which the roots emerge. Sect. *Hesperantha* has bell-shaped corms with a broad, flat base and concentric tunics, in some species with the margins drawn into long spines. Sect. *Radiatae* has similar flat-based corms,

HESPERANTHA. H. coccinea: A, flowering plant. ***H. petitiana***: B, flowering plant; C, flower. ***H. brevistyla***: D, capsules; E, seed.

also sometimes with marginal spines, but stands out in having the outer floral bract margins united around the axis for some distance and most species have a curved perianth tube. *Hesperantha radiata* of the section has the widest range in the genus, extending from northern Namaqualand in the northwest to Eswatini in the east. Except for *H. radiata* both sect. *Hesperantha* and sect. *Radiatae* are restricted to the winter-rainfall part of southern Africa and most species of both are narrow endemics, several known only from one or a few populations. Exceptional in the genus, *H. coccinea* has a rhizomatous rootstock, the base producing narrow runners or stolons that develop into new plants. In some populations cormlets are produced in the stem axils. The species has red or pink, long-tubed flowers of typical *Hesperantha* structure, and although it was placed in the genus *Schizostylis* in the past there is no doubt that it is nested in *Hesperantha* and probably closely related to the long-tubed species of eastern southern Africa.

Molecular studies show that *Hesperantha* is most closely related to *Geissorhiza*, an association also indicated by morphology and cytology. Both genera have woody corm tunics, and slightly asymmetric corms (unless bell-shaped with a flat base), and both have the same basic chromosome number $x = 13$, unique in the subfamily. The genera differ in floral structure, the styles of *Geissorhiza* typically dividing well above the mouth of the perianth tube, usually opposite the anthers, and eccentric with short, recurved branches.

Keys to species

Note: For leaf number include the entirely sheathing leaves on the upper part of the stem and examine more than one plant since the character is, to a limited extent, variable. Measure leaf width in ± middle of one of lower leaves.

A. Species of the southern African winter-rainfall zone (SW Namibia and South Africa in Namaqualand, the western Karoo, and the southwestern and southern Cape as far east as Port Elizabeth)

1a Outer floral bract margins united around axis in lower part (sometimes only near base); corm bell-shaped to triangular in outline, tunics sometimes forming scalloped, concave segments (sect. *Radiatae*):
2a Stamens and style branches included in tube; flowers pink . . . . . 85. *H. elsiae*
2b Stamens and style branches exserted; flowers white to creamy yellow or pale to deep pink:
3a Anthers erect and cohering around style; style dividing near anther apices and branches ± erect and twisted around one another . . . . . 87. *H. kiaratayloriae*
3b Anthers ascending to decumbent, never cohering; style dividing near or opposite mouth of perianth tube and diverging:
4a Bract margins united only basally; perianth tube 6–8 mm long. . . . . 79. *H. brevifolia*
4b Bract margins united for at least 2 mm:
5a Flowers large with tepals 16–25 mm long and tube 15–25 mm long; perianth pale pink with darker veins 86. *H. muirii*
5b Flowers smaller with tepals 10–17 mm long and tube 5–12 mm long; perianth white or cream-coloured to yellow:
6a Leaves terete. . . . . 80. *H. juncifolia*
6b Leaves ± plane, often somewhat thicker in middle and occasionally weakly cross-shaped:
7a Bracts usually united around stem for 6–10 mm, i.e., ± half their length; spike straight with bracts parallel to axis; plants mostly 200–600 mm high with (1–)5 to 15 flowers per spike . . . . . 83. *H. radiata*
7b Bracts usually united around stem for ± ⅓ their length; spike flexuose with bracts diverging from axis; plants short, mostly 50–100 mm high, with 1 to 5 flowers per spike:
8a Corm base with prominent horizontal spines; bracts united around axis for up to 3 mm . . . . . 81. *H. marlothii*
8b Corm base without spines; bracts united around axis for 3–5 mm . . . . . 82. *H. decipiens*
1b Outer floral bract margins free to base; corm triangular to bell-shaped in outline, with a horizontal or oblique flat base OR globose to ovoid with rounded to pointed base and tunics imbricate to concentric, sometimes splitting into vertical sections tapering to points above (sect. *Concentricae* and sect. *Hesperantha*):
9a Corm bell-shaped to triangular in outline, with a horizontal or oblique flat base (sect. *Hesperantha*):
10a Plants acaulescent or almost so with aerial part of stem enclosed by leaf sheaths:
11a Flowers white with purple marking at bases of outer tepals. . . . . 76. *H. luticola*
11b Flowers deep pink to red-purple. . . . . 74. *H. latifolia*
10b Plants with aerial stem:
12a Style dividing at or below middle of perianth tube; style branches and sometimes anthers partly or completely included in perianth tube:
13a Anthers and style branches fully included in perianth tube. . . . . 72. *H. cedarmontana*
13b Anthers exserted; style branches reaching at least to mouth of tube or upper halves exserted:
14a Plants with 3 basal leaves and without cauline leaves; flowers pale watery yellow; upper half of style branches exserted; perianth tube 12–16 mm long . . . . . 67. *H. sufflava*
14b Plants with basal and cauline leaves; flowers white; style branches reaching only to mouth of tube; perianth tube 9–12 mm long. . . . . 78. *H. saldanhae*
12b Style dividing at or just below mouth of perianth tube; anthers and style branches fully exserted and filaments usually at least partly exserted from perianth tube:
15a Flowers small, erect or inclined on straight spike; perianth tube slightly curved, 4–6 mm long; tepals 4–7 mm long; leaves either plane and sometimes with crisped margins, or terete to ovoid in cross section and hollow; seeds with sharp angles (minute wings) and seed coat with whitish spongy cells. . . . . 77. *H. spicata*

15b Flowers small to large, upright, on straight or flexuose spike; perianth tube straight, (5–)7–14 mm long; tepals 6–18 mm long; leaves plane with straight margins; seeds globose or sides lightly flattened by pressure, seed coat dark brown:
16a Corm base usually with prominent radiating spines or margins toothed; flowers diurnal, closing in late afternoon; perianth pink to red-purple, rarely yellow:
17a Perianth tube 6–11 mm long; tepals 18–25 mm long, at least twice as long as tube; plants of Namaqualand and Bokkeveld Mtns . . . . . 73. *H. pauciflora*
17b Perianth tube 20–25 mm long; tepals ± 10 mm long about half as long as tube; plants of SW Namibia 75. *H. longistyla*
16b Corm base with small teeth or scarcely serrated and usually without prominent spines; flowers diurnal or crepuscular, opening in late afternoon or after sunset; perianth white, cream-coloured or yellow:
18a Plants with 2 basal foliage leaves and 1 or 2 smaller cauline leaves largely to entirely sheathing stem:
19a Basal leaves usually prostrate, semi-succulent, 4–5 mm wide; filaments < 1 mm long; style branches ascending, ± 2.5 mm long . . . . . 71. *H. laxifolia*
19b Basal leaves ± falcate, 2–6 mm wide, not noticeably succulent; filaments ± 3 mm long; style branches spreading, ± 12 mm long. . . . . 70. *H. eremophila*
18b Plants with 3 or more basal leaves, erect or falcate :
20a Tepals uniformly white on reverse, ascending and cupped when fully open; perianth tube 12–14 mm long, ± as long as tepals; leaves falcate to trailing. . . . . 69. *H. dolomitica*
20b Outer or all tepals flushed red to brown outside, spreading horizontally when fully open; perianth tube 4–12 mm long, shorter than tepals; leaves falcate to trailing:
21a Leaves narrow, 1–2 mm wide; perianth tube 10–12 mm; plants of shallow soils on sandstone pavement . . . . . 68. *H. lithicola*
21b Leaves broader, 4–8 mm wide; perianth tube 4–9 mm long; plants of deeper sandy soils or on clay ground . . . . . 66. *H. falcata*
9b Corm globose to ovoid with rounded or pointed base, often asymmetric with flattened side and tunics imbricate to concentric, sometimes splitting into vertical sections tapering to points above (sect. *Concentricae*):
22a Plants acaulescent or stem extending barely above ground but sheathed by leaf bases:
23a Flowers small, tepals 8–10(–12) mm long . . . . . 26. *H. hantamensis*
23b Flowers larger, tepals 13–25 mm long:
24a Flowers yellow; flowers crepuscular, opening at sunset. . . . . 28. *H. flava*
24b Flowers pink to red-purple; flowers diurnal, closing at night. . . . . 27. *H. humilis*
22b Plants with aerial stem:
25a Leaves pilose to scabrid ciliate on veins and margins, sometimes visible only microscopically (×10 magnification):
26a Leaves hollow or ± solid and with narrow longitudinal grooves; finely scabrid ciliate along groove edges:
27a Leaves ± round in cross section; flowers white to cream-coloured, crepuscular, opening in late afternoon, closing late at night . . . . . 13. *H. teretifolia*
27b Leaves oval in cross section; flowers pink, mauve or purple, diurnal, closing in early afternoon . . . . . 9. *H. pilosa*
26b Leaf blade flat sometimes with margins and main vein somewhat thickened or raised; pilose along sheath and blade margins and veins:
28a Plants dwarf, up to 50 mm high with spikes 1(2)-flowered; flowers magenta; leaves sparsely hairy (rarely evidently smooth) . . . . . 11. *H. glabrescens*
28b Plants mostly at least 100 mm high, with spikes usually with > 2 flowers; flowers white, blue, magenta or mauve; leaf blades and sheath of third leaf sparsely to densely hairy:
29a Leaves sword-shaped to oblong; scale-like leaf below spike mostly 12–20 mm long, often pilose. . . . . 10. *H. pseudopilosa*
29b Leaves linear to narrowly sword-shaped; scale-like leaf below spike 3–5(–10) mm long, usually smooth:
30a Leaves finely hairy; main vein and margins raised and thickened, margins forming wing-like ridges; flowers ± nodding; perianth white . . . . . 12. *H. secunda*
30b Leaves glabrous or hairy; margins sometimes raised and wing-like; flowers upright; perianth white or pink to violet:
31a Leaf blades usually conspicuously hairy; leaf tips usually acute (plants of open sandy slopes and flats) . . . . . 9. *H. pilosa*
31b Leaf blades sparsely hairy (often visible only under hand lens); leaf tips obtuse (plants of rocky cliffs) . . . . . 8. *H. malvina*
25b Leaves and stems smooth:
32a Flowers with perianth tube curved at apex, thus nodding to ± pendent . . . . . 35. *H. bachmannii*
32b Flowers with ± straight perianth tube, thus upright to half nodding:
33a Flowers predominantly shades of pink, mauve or purple:
34a Perianth tube elongate, 20–35 mm long, exceeding tepals:
35a Leaves linear, 2–3 mm wide; tube 25–30 mm long and filaments ± 8–10 mm long . . . . . 5. *H. oligantha*
35b Leaves sword-shaped, 7–10 mm wide; tube ± 20 mm long and filaments ± 2 mm long . . . . . 23. *H. purpurea*
34b Perianth tube 7–17 mm long, usually shorter than to ± as long as (or slightly longer) than tepals:
36a Basal leaves ovate, 12–20 × 4–8 mm, margins and main vein hardly thickened; stem with a short, scale-like leaf in upper part of stem . . . . . 22. *H. truncatula*
36b Basal leaves sword-shaped to linear or falcate, 40–100 × 2–4 mm; stem lacking a scale-like leaf in upper part of stem:
37a Perianth tube 7–10 mm long; leaf margins and often main vein somewhat to heavily thickened. . . . . 19. *H. fibrosa*

37b Perianth tube 13–17 mm long; leaf margins and main vein not noticeably thickened . . . . . 2. *H. namaquana*
33b Flowers predominantly white, cream-coloured or yellow (excluding pigment on reverse of outer tepals):
38a Perianth tube mostly 16–20 mm long, as long to slightly longer than tepals . . . . . 37. *H. pallescens*
38b Perianth tube 3–12(–17) mm long, shorter than to slightly longer than tepals:
39a Plants consistently with 2 basal leaves and a third usually cauline and partly to entirely sheathing lower part of stem:
40a Plants tiny, mostly 40–50 mm high; tepals 5–10 mm long; leaves linear, 1–2 mm wide:
41a Tepals 5–6 mm long; leaves linear-filiform, < 1 mm wide. . . . . 18. *H. minima*
41b Tepals ± 10 mm long; leaves linear, 1.4–2.0 mm wide . . . . . 4. *H. rupicola*
40b Plants small to moderate in size, usually at least 100–200 mm high; tepals 8–13 mm long; leaves linear to lanceolate and 1–7 mm wide:
42a Cataphylls dark chestnut-brown; sheathing leaf somewhat inflated and quadrangular in cross section; perianth tube 2–3 mm long; anthers 3–4 mm long . . . . . 15. *H. quadrangula*
42b Cataphylls pale; sheathing leaf not inflated nor noticeably quadrangular in cross section; perianth tube 5–12 mm long; anthers 4.5–6.0 mm long:
43a Perianth tube 6–10 mm long; leaves ± linear, up to 1.5 mm wide, fleshy and somewhat thicker in middle (plants of Namaqualand) . . . . . 17. *H. flexuosa*
43b Perianth tube ± 12 mm long; leaves lanceolate–falcate, 3–6 mm wide, plane and firm (plants of the western Karoo). . . . . 16. *H. filiformis*
39b Plants mostly with 4 (or more) leaves, sometimes uppermost ± scale-like:
44a Leaves elliptic to ± rectangular with squared margins in cross section and seemingly hollow (interior with large empty parenchyma cells), without thickened margins or main vein. . . . . 7. *H. rivulicola*
44b Leaves ± plane, not hollow, and with main vein and margins present, often slightly thickened:
45a Corms relatively large, mostly 10–15 mm diam.:
46a Flowers predominantly white (outer tepals often coloured outside):
47a Outer tepals usually glossy bright red outside (rarely glossy brown); filaments mostly 4–5 mm long; flowers opening 16:00–16:30 (or earlier), then intensely fragrant; plants of well-drained open habitats. . . . . 20. *H. cucullata*
47b Outer tepals dull grey-brown on outer midline; filaments ± 2 mm long; flowers opening after dark, ± 19:00–19:30, then odourless of faintly scented; plants of wet marshes. . . . . 21. *H. palustris*
46b Flowers predominantly or entirely yellow:
48a Plants up to 60 mm tall, sometimes almost acaulescent; flowers moderate in size, tepals ± 20 mm long, uniformly yellow . . . . . 25. *H. karooica*
48b Plants 120–180 mm tall, with well-developed aerial stem; flowers large with tepals 25–35 mm long, usually but not invariably marked with dark chocolate-brown . . . . . 24. *H. vaginata*
45b Corms fairly small, mostly 3–8 mm diam.:
49a Stem with a short, sheathing leaf in upper half . . . . . 3. *H. acuta*
49b Stem without a short, sheathing leaf in upper half:
50a Leaves (3)4 or 5, lower 3 basal, linear to sword-shaped and acute, always erect; perianth tube 8–10 mm long; flowers cream-coloured, occasionally white; plants of Western Cape Atlantic Coast, mostly on granite outcrops . . . . . 1. *H. erecta*
50b Leaves (3)4, lower 2 basal, oblong and obtuse, normally prostrate; perianth tube ± 12 mm long; flowers white; plants of montane habitats growing in rocky sandstone soil . . . . . 6. *H. montigena*

B. Species of eastern South Africa, Lesotho and Eswatini, extending from Eastern Cape, South Africa, east of Port Elizabeth to the Limpopo River (the summer-rainfall part of the subcontinent with a prolonged dry season in the winter and spring months)

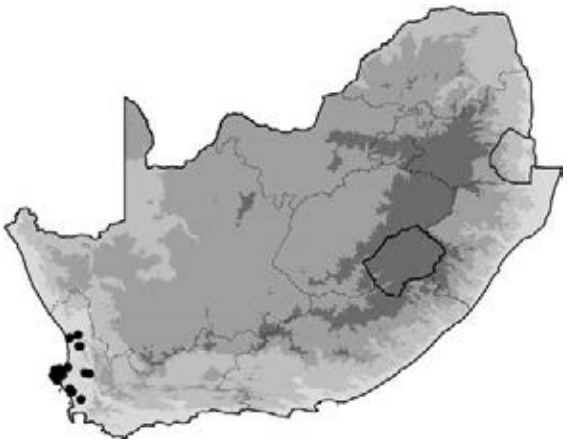
1a Perianth tube curved just below apex and flowers nodding to ± pendent; flowers white to cream-coloured, tepals often brown or dull red outside:
2a Outer bract margins free to base; corms ± globose . . . . . 36. *H. bulbifera*
2b Bract margins united around spike axis for up to half their length; corms ± bell-shaped with flat base:
3a Perianth tube 18–30 mm long; plants flowering in spring . . . . . 84. *H. longicollis*
3b Perianth tube 8–15 mm long; plants flowering in early to midsummer, mostly November to January . . . . 83. *H. radiata*
1b Perianth tube mostly straight, curved in two species with pink flowers; flowers variously pink to mauve, red, or white to creamy yellow, sometimes outer tepals shaded red to purple or brown outside:
4a Flowers produced in spring (dry season) when foliage leaves absent or partly emergent; leaves 1 or 2, fully developed after flowering and produced on separate shoots (occasionally old, partly to completely dry foliage leaves still attached to flowering stem at flowering):
5a Flowers borne close to ground level, raised above ground by perianth tube 9–14 mm long; tepals short, 6–7 mm long. . . . . 34. *H. crocopsis*
5b Flowers borne above ground on short flowering stem; perianth tube short or long; tepals 14–22 mm long:
6a Perianth tube 5–10 mm long; tepals white or pale pink inside; outer tepals lightly to strongly marked purple to brownish outside; leaves 2 or more, ± terete. . . . . 32. *H. schelpeana*
6b Perianth tube 20–27 mm long; tepals uniformly creamy white; leaf solitary, falcate, plane . . . . . 33. *H. altimontana*
4b Flowers produced in spring, summer or autumn (dry or rainy season) but always bearing fully developed foliage leaves on flowering stem:
7a Perianth tube (14–)18–60 mm long, sometimes curved near apex; seeds (where known) often with a prominent wing or thread-like appendage at one or both ends:

8a Perianth tube strongly curved near apex and tepals vertically oriented; stamens and style branches unilateral and declinate; anthers 8–13 mm long, dark brown . . . . . 60. *H. grandiflora*
8b Perianth tube straight or weakly curved above, tepals spreading horizontally or weakly ascending; stamens ascending to erect, and style branches spreading but not unilateral; anthers 3–9 mm long, yellow to whitish, or dark brown to black in three species:
9a Leaves and often stem weak and trailing; plants of cliffs and rock outcrops:
10a Plants with cormlets in lower leaf axils (sometimes lost when handled); leaves 4 to 6 (plants of Eastern Cape) . . . . . 61. *H. huttonii*
10b Plants without cormlets in lower leaf axils; leaves 4 or sometimes 3:
11a Flowers mauve-pink; perianth tube mostly 18–30 mm long; anthers 6–8 mm long (plants of Mpumalanga and Limpopo) . . . . . 63. *H. brevicaulis*
11b Flowers deep pinkish purple; perianth tube 18–42 mm long; anthers 3–6 mm long; (plants of KwaZulu-Natal and nearby):
12a Perianth tube 18–25 mm long; anthers 3–4 mm long. . . . . 64. *H. curvula*
12b Perianth tube mostly 30–42 mm long; anthers mostly 5–6 mm long. . . . . 65. *H. scopulosa*
9b Stem erect and leaves usually firm and upright; plants of grassland, open slopes, or streams and marshes:
13a Filaments 6–12 mm long:
14a Plants of streams, usually growing in water; rootstock a rhizome or vestigial, but producing slender underground rhizomes and sometimes axillary cormlets at aerial nodes; flowers pink or red, tepals spreading horizontally. . . . . 59. *H. coccinea*
14b Plants of grassland, rocky slopes or grassy marshes; rootstock a corm with woody tunics and stems lacking axillary cormlets; flowers pink to mauve-pink . . . . . 56. *H. woodii*
13b Filaments 3–6 mm long:
15a Leaves scabrid-pubescent; stamens erect and style branches evidently remaining suberect and noticeably shorter than anthers. . . . . 54. *H. pubinervia*
15b Leaves smooth; stamens and style branches ascending to spreading, style branches as long or longer than stamens:
16a Plants flowering in spring, August to October; flowers white, often pink outside . . . . . 31. *H. longituba*
16b Plants flowering in summer and autumn or winter, December to April or July; flowers pink to rosy purple:
17a Perianth tube mostly 45–60 mm long; anthers dark brown-black . . . . . 58. *H. stenosiphon*
17b Perianth tube mostly 14–25 mm long; anthers yellow or purple:
18a Style branches 18–20 mm long, exceeding anthers in closed flowers . . . . . 57. *H. mtamvunae*
18b Style branches 10–16 mm long, not exceeding anthers in closed flowers:
19a Spike with 5 to 11 flowers; leaves 3.0–5.5 mm wide; perianth tube 14–20 mm long; anthers and pollen yellow . . . . . 55. *H. pulchra*
19b Spike with (1)2 or 3 flowers; leaves 1.5–2.0 mm wide; perianth tube 16–23 mm long; anthers and pollen dark purple . . . . . 62. *H. hutchingsiae*
7b Perianth tube 3–15(–22) mm long, always straight; seeds (where known) globose or lightly angled, sometimes ridged on angles but not winged:
20a Plants flowering in spring, August to October, before main rainy season; flowers pale pink or white:
21a Perianth tube mostly 14–22 mm long; flowers crepuscular, white, opening in late afternoon and closing after dark . . . . . 31. *H. longituba*
21b Perianth tube mostly 4–12 mm long; flowers diurnal, white or pink to mauve-pink, outer tepals often flushed or feathered pink to mauve outside, closing in late afternoon:
22a Leaves usually 3 (rarely 4), lower 2 basal and with long, linear blades 2–3 mm wide, upper 1(or 2) largely or entirely sheathing; spike usually 2- or 3-flowered; plants of coastal KwaZulu-Natal and Transkei [northern Eastern Cape]. . . . . 51. *H. modesta*
22b Leaves usually 4, 2 basal, one subbasal and partly sheathing and a short, sheathing leaf in upper part of stem, basal leaves linear to oblong-lanceolate, 1–6 mm wide; spike mostly 1- to 6-flowered; plants of interior southern Africa, from southern Mpumalanga to Grahamstown in the south:
23a Leaves oblong-lanceolate, 2–6 mm wide; spike mostly 2- to 6-flowered; perianth tube (7–)9–12 mm long . . . . . 29. *H. candida*
23b Leaves linear, 1–2 mm wide; spike 1- or 2-flowered; perianth tube 4–6 mm long . . . . . 30. *H. debilis*
20b Plants flowering in wet season, summer and autumn, mainly mid-November to April, rarely earlier; flowers mostly pink to mauve or white to cream-coloured:
24a Plants growing on rocks, often on cliffs, stem weak and drooping; leaves ± linear:
25a Flowers pink, mauve or white; perianth tube 6–8 mm long; anthers 6.0–7.5 mm long; plants of KwaZulu-Natal . . . . . 53. *H. gracilis*
25b Flowers white, sometimes flushed pale pink on fading; perianth tube 7–11 mm long; anthers ± 4 mm long; plants of Mpumalanga. . . . . 48. *H. saxicola*
24b Plants not hanging from cliffs, stem erect:
26a Blades of lower leaves terete and grooved; flower mauve-pink. . . . . 14. *H. helmei*
26b Blades of lower leaves not terete, ± plane, sometimes with thickened and raised margins and veins; flowers white, pink or yellow:
27a Leaf blades with thickened margins, main and secondary veins; marginal and main vein thickenings with narrow wings arching over blade surface . . . . . 49. *H. hygrophila*
27b Leaf blades with or without thickened margins and main vein, but secondary veins not or hardly thickened and midrib and marginal thickenings rounded, not wing-like and arching over blade surface:
28a Flowers white to cream-coloured or palest yellow entirely or outer tepals pink or red outside:

29a Outer tepals speckled or uniformly bright red outside:
30a Stem usually 70–120 mm high (taller in cultivated plants); tepals 9.5–15.0 mm long; anthers 3–4 mm long; plants of KwaZulu-Natal . . . . . 43. *H. alborosea*
30b Stem usually 400–500 mm high; tepals 12–15 mm long; anthers 6–7 mm long; plants of Mpumalanga . . . . . 50. *H. rupestris*
29b Tepals uniformly white to cream-coloured, or sometimes faintly pink on outside of tepals, especially on fading:
31a Flowers tiny; tepals ± 5 mm long; perianth tube ± 4 mm long; anthers ± 2 mm long; leaves soft-textured . . . . . 52. *H. umbricola*
31b Flowers medium to large; tepals 12–20(–23) mm long; perianth tube (5.5–)6.5–8.5 mm long; anthers 5–8 mm long; leaves firm, with thickened margins and main vein:
32a Tepals uniformly cream-coloured to pale yellow, remaining cream-coloured on fading, 14–20(–23) mm long; filaments 3–4 mm long; anthers mostly golden-brown, dark when dry, 5–7 mm long . . . . . 46. *H. lactea*
32b Tepals uniformly white to cream-coloured or faintly flushed pink on outside of outer tepals especially on fading, 12–16 mm long; filaments 2.5–3.5 mm long; anthers creamy white, not darker on fading, mostly 6.5–8.0 mm long . . . . . 47. *H. inconspicua*
28b Flowers pink to mauve entirely:
33a Leaves mostly 0.7–2.0 mm wide, linear; perianth tube 3–6 mm long:
34a Stem slender and evidently soft; spike with 1 to 3 flowers widely spaced; tepals 6–8 mm long . . . . . 42. *H. exiliflora*
34b Stem slender but firm and wiry; spike mostly with 3 to 8 flowers; tepals 10–14 mm long:
35a Leaves usually 5 (unless plants depauperate), mostly 2–4 mm wide; tepals 13–16 mm long; anthers 4.0–4.5 mm long . . . . . 40. *H. schlechteri*
35b Leaves usually 4, mostly 1–2 mm wide; tepals 10–12 mm long; anthers 4.5–5.0 mm long . . . 39. *H. glareosa*
33b Leaves > 5 mm wide, falcate; perianth tube mostly 6–13(–15) mm long:
36a Leaves 4 or 5, lower 3 basal, often ± as long as stem or slightly longer; anthers 2.3–5.5 mm long and with white pollen; perianth tube 7–12(–15) mm long:
37a Tepals 7–9 mm long; perianth tube 7–9 mm long; anthers 2.3–3.0 mm long; style branches unusually short, suberect, reaching to base or lower ⅓ of anthers; outside of outer tepals pale greenish toward base and with darker green longitudinal veins . . . . . 44. *H. brevistyla*
37b Tepals 12–16 mm long; perianth tube 5–14 mm long; anthers 4–6 mm long; style branches 10–12 mm long, exceeding anthers in closed flower; outer tepals ± uniformly coloured outside:
38a Perianth tube mostly 12–14 mm long; anthers 4.5–5.5 mm long; perianth pale pink; stem and leaves weak and trailing . . . . . 41. *H. leucantha*
38b Perianth tube to 10 mm long; anthers 4–6 mm long; perianth middle to deep pink; stem and leaves ± erect . . . . . 40. *H. schlechteri*
36b Leaves normally 4, sometimes 3, with lower 2 basal, usually ± ½–⅔ as long as stem; anthers mostly 3–7 mm long and with yellow or white pollen; perianth tube (4.5–)6.0–12.0 mm long:
39a Spike with 1 or 2 flowers; tepals 10–12 mm long; uppermost leaf inserted in lower half of stem and not much distant from lower leaves . . . . . 45. *H. ingeliensis*
39b Spike with (2–)4 to many flowers; tepals 12–16 mm long; uppermost leaf often inserted in upper half of stem and distant from lower leaves . . . . . 38. *H. baurii*

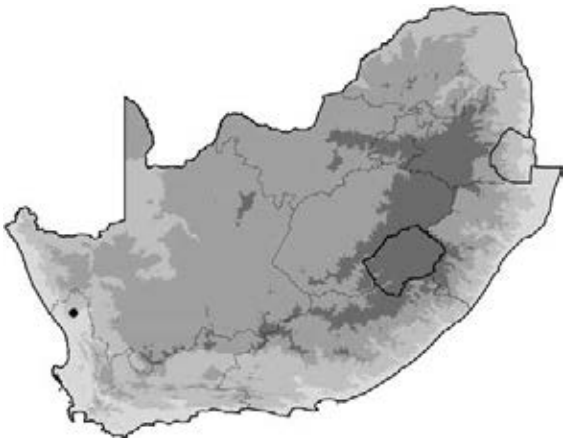
Sect. 1. **Concentricae** *Goldblatt* in Annals of the Missouri Botanical Garden 69: 375 (1982) [as sect. *Concentrica*]. Type: *Hesperantha pilosa* (L.f.) Ker Gawl.

Sect. *Imbricatae* Goldblatt: 376 (1982) [as sect. *Imbricata*]. Type: *Hesperantha humilis* Baker



Plants with small to large asymmetric corms, ± rounded at base, usually with a flattened lateral ridge; older corm tunics splitting from base into vertical segments or into overlapping layers notched at base. *Spike* with floral outer bract margins free to base. *Flowers* variously coloured, usually with a straight perianth tube (curved near apex in *H. bachmannii, H. bulbifera* and *H. grandiflora*).

Species 65: occurring across entire range of the genus from Western Cape, South Africa, to Ethiopia.



1. **Hesperantha erecta** *(Baker) Benth. ex Baker*, Handbook of the Irideae: 150 (1892); Goldblatt: 45 (1984). *Geissorhiza erecta* Baker: 238 (1876a). Type: South Africa, [Western Cape], Olifants R., July–Aug. 1830, *J. F. Drège 8468* (K, lecto., designated by Foster: 11 (1948); K, L, P, isolecto.).

Hesperantha semipatula R.C.Foster: 24 (1948). Type: South Africa, [Western Cape], Vogelfontein, *Schlechter 8521* (K, holo.; B, BOL, GRA, K, L, MO, PH, PRE, US, Z, iso.).

Plants (60–)120–220 mm high. *Corm* ovoid, with obliquely flattened side, 6–8 mm diam.; tunics dark brown, ± concentric layers fragmenting into elliptic segments. *Stem* unbranched, smooth. *Leaves* 3(5), linear to lanceolate, mostly basal, reaching ± to base of spike, (2)5–8 mm wide, soft-textured, main vein and

Distribution of ***Hesperantha erecta***.

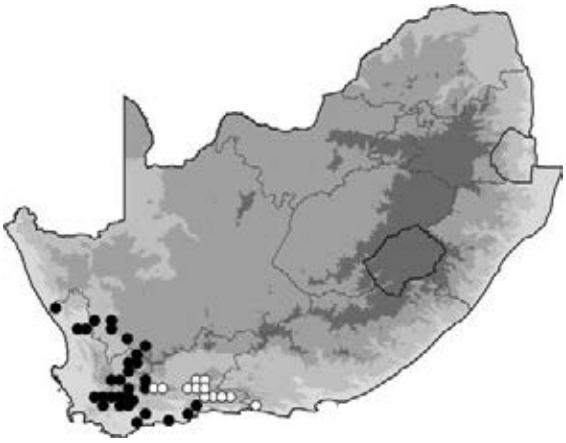
Distribution of ***Hesperantha namaquana***.

margins barely thickened, uppermost cauline and largely sheathing. *Spike* mostly 3- to 6-flowered; bracts 8–15 mm long. *Flowers* diurnal, white to creamy yellow, sometimes outer tepals flushed light brown to grey outside, slightly foetid-smelling; perianth tube funnel-shaped, 8–11 mm long; tepals spreading, narrowly ovate, 10–15 mm long. *Filaments* ascending, ± 5 mm long; anthers 4–6 mm long, pale yellow; pollen whitish. *Style branches* spreading, reaching nearly ± middle of anthers in closed flower. *Capsules* ovoid, 6–9 mm long. *Seeds* light brown, angular. *Chromosome number* 2*n* = 26. *Flowering time*: August to mid-September.

Distribution and ecology: restricted to the Atlantic Coast and near interior of Western Cape, South Africa, from near Mamre north to the Olifants River Valley near Klawer, especially common in the Saldanha Bay area; often on granite outcrops.

Diagnosis: an unspecialised species, *Hesperantha erecta* is recognised by the relatively short stature, rarely exceeding 150 mm, small corm with the tunics fragmenting into elliptical segments, and pale yellow to creamy white flower open during the day, the outer tepals only lightly pigmented grey to light brown outside. Although the flowers are white to creamy yellow, they are not, as might be expected in the genus, crepuscular as far as known and have been recorded opening ± midday and at 14:00 and closing at ± 16:00, thus before sunset.

2. **Hesperantha namaquana** *Goldblatt* in Journal of South African Botany 50: 47 (1984). Type: South Africa, [Northern Cape], Bitterfontein, Kareebergen, 24 July 1896, *Schlechter 8304/5* (K, holo.; B, BOL, PRE, iso.).



Plants 80–150 mm high. *Corm* ovoid, with obliquely flattened side, ± 9 mm diam.; tunics dark brown, ± concentric layers fragmenting into elliptic segments. *Stem* unbranched, smooth. *Leaves* 3(4), lower 2 basal, falcate, ± half as long as stem, 3–9 mm wide, main vein and margins barely thickened, upper 1 or 2 leaves cauline and largely sheathing. *Spike* mostly 2- to 5-flowered; bracts (12–)15–22 mm long. *Flowers* diurnal, ± salver-shaped, white to pale pink, outer tepals flushed pink to red outside; perianth tube funnel-shaped, 13–17 mm long, cylindric; tepals narrowly ovate-elliptic, 10–15 mm long, spreading. *Filaments* ascending, ± 3 mm long; anthers ± 6 mm long, pale yellow; pollen whitish. *Style branches* spreading, 8–10 mm long, exceeding anthers in closed flower. *Capsules* ovoid, 10–15 mm long. *Seeds* light brown, angular. *Flowering time*: late July to mid-August.

Distribution and ecology: a poorly documented and evidently very narrow endemic restricted to southern Namaqualand near Bitterfontein in Western Cape, South Africa; growing on sandy banks of watercourses.

Diagnosis: *Hesperantha namaquana* is recognised by the ovoid corm with prominently flattened side and relatively large pale pink to nearly white flowers with perianth tube 13–17 mm long and slightly shorter tepals 10–15 mm long.

3. **Hesperantha acuta** *(Licht. ex Roem. & Schult.) Ker Gawl.*, Genera Iridearum: 91 (1827); Goldblatt: 48 (1984). *Ixia acuta* Licht. ex Roem. & Schult.: 383 (1817). Type: South Africa, [Northern Cape], foot of the Roggeveld Mtns, Aug. 1805, *Lichtenstein s.n.* (B, holo.).

Plants mostly 100–250 mm high. *Corm* ovoid to globose, with obliquely flattened side, 6–8 mm diam.; tunics dark brown, ± concentric, layers fragmenting irregularly into sections. *Stem* unbranched, smooth. *Leaves* mostly 4, lower 2 basal, linear to lanceolate, reaching ± to base of spike, 2–3 mm wide, soft-textured, main vein slightly thickened, uppermost leaf cauline, often entirely sheathing. *Spike* 2- to 5(–8)-flowered; bracts mostly 8–15 mm long, often becoming dry above. *Flowers* crepuscular, salver-shaped, white or yellow, outer tepals flushed red to brown outside; perianth tube funnel-shaped, 8.5–15.0 mm long; tepals, narrowly ovate, 9.5–17.0 mm long, inner slightly shorted and wider, spreading. *Filaments* ± erect, 2.0–4.5 mm long; anthers 5.3–8.0 mm long, horizontal, pale yellow; pollen whitish.

Distribution of ***Hesperantha acuta*** subsp. ***acuta***, ●; subsp. ***tugwelliae***, ○.

Style branches ± 8 mm long, spreading, reaching middle of anthers or slightly exceeding them in closed flower. *Capsules* ovoid, 6–10 mm long. *Seeds* light brown, angular. *Chromosome number* 2*n* = 26. *Flowering time*: July to mid-September.

Distribution and ecology: a species of the dry interior of the South African winter-rainfall zone, extending from southern Namaqualand and the interior valleys of the Cederberg in Western Cape and the Roggeveld Mtns in Northern Cape though the Worcester–Robertson Karoo and the Little Karoo as far east as Joubertina in the Long Kloof in Eastern Cape.

Diagnosis: including both yellow- and white-flowered populations, *Hesperantha acuta* is recognised by the relatively large, rounded corms with obliquely flattened lateral ridge, this sometimes particularly prominent, and concentric tunics. Plants usually have four leaves, the uppermost, entirely sheathing. Flowers of both colour morphs, treated as separate subspecies, are crepuscular. The white-flowered populations occur in the west of its range and the yellow in the southeast. Flowers of white-flowered plants are slightly smaller that those with yellow flowers, with shorter filaments but longer style branches.

Key to subspecies

1a Flowers white, outer tepals usually red outside; filaments exserted ± 1.5–2.5 mm from tube . . . . . 3a. subsp. *acuta*

1b Flowers yellow, outer tepals yellow or sometimes light brown outside; filaments exserted ± 4 mm from tube . . . . . 3b. subsp. *tugwelliae*

3a. subsp. **acuta**

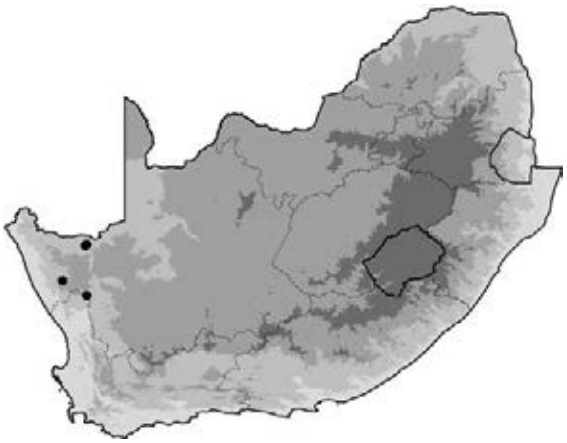
Hesperantha discolor N.E.Br.: 451 (1931). Type: South Africa, [Western Cape], Worcester, Osplaats–Tunnel Sidings, *Rogers 16740* (K, holo.; K, iso.).

Flowers white, outer tepals often red(brown) outside; perianth tube 8.5–12.0 mm long; tepals 9.5–16.0 mm long. *Filaments* exserted ± 1.5–2.5 mm; anthers 5.3–7.0 mm long. *Style* with branches reaching to ± upper ⅓ of anthers or shortly exceeding them in closed flower. *Flowering time*: August to mid-September.

Distribution and ecology: extending from the slopes of the Bokkeveld Mtns in the north though the Cederberg and Roggeveld and Worcester Karoo to Matjiesfontein and the western Little Karoo.

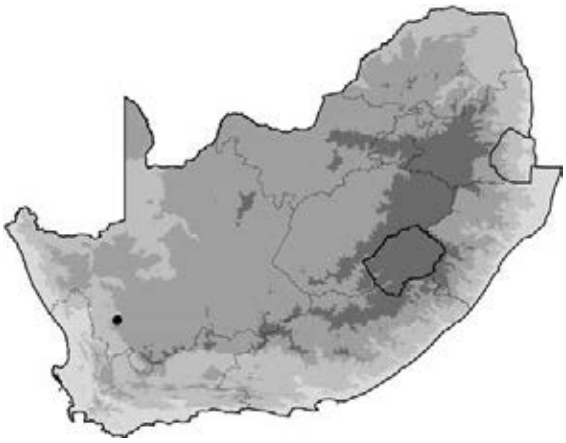
Diagnosis: distinguished from subsp. *tugwelliae* by the white flowers, the outer tepals usually bright red outside. The slightly smaller flowers have tepals 9.5–16.0 mm long and the filaments are exserted up to 2.5 mm.

3b. subsp. **tugwelliae** *(R.C.Foster) Goldblatt & J.C.Manning* in Bothalia 37: 182 (2007). *Hesperantha tugwelliae* R.C.Foster: 26 (1948). Type: South Africa, [Western Cape], Prince Albert, *Tugwell s.n.* as *Nat.Bot.Gard.1151/29* (K, holo.; BOL, MO, iso.).



Flowers yellow, outer tepals flushed brown outside; perianth tube 12.5–15.0 mm long; tepals 12.5–16.0 mm long. *Filaments* exserted ± 4 mm; anthers 6–8 mm long. *Style* with branches reaching to ± middle of anthers in closed flower. *Flowering time*: August to mid-September.

Distribution and ecology: occurring in the east of the range of *Hesperantha acuta*, along the northern foothills of the Swartberg Mtns, locally in the Kammanassie Mtns of the Little Karoo, and in the Long Kloof to the south in the vicinity Joubertina.



Diagnosis: subsp. *tugwelliae* is distinguished from subsp. *acuta* by the clear yellow flowers, often flushed brown outside, and with a strong, carnation-like scent. Relatively larger, the flowers have a perianth tube up to 15 mm long and tepals up to 16 mm long. The filaments are well exserted up to 4 mm from the mouth of the tube vs. up to 2.5 mm in subsp. *acuta*, and the style branches reach to ± the middle of the anthers in the closed flower whereas those of subsp. *acuta* reach close to or exceed the anther tips.

4. **Hesperantha rupicola** *Goldblatt* in Annals of the Missouri Botanical Garden 90: 403 (2003). Type: South Africa, [Northern Cape], Bushmanland, Farm Naab, E of Springbok, south-facing quartzite rocks, 14 Aug. 2000, *P. Desmet 3009* (NBG, holo.).

Plants 30–50 mm high. *Corm* globose with obliquely flattened side, 9–11 mm diam.; tunics dark brown, ± concentric layers. *Stem* unbranched, smooth. *Leaves* 3, all basal, spreading or drooping, ± as long to twice as long as stem, up to 90 mm long, ± linear to falcate, 1.4–3.5 mm wide, soft-textured, midrib and margins barely thickened. *Spike* 1-, occasionally 2- or 3-flowered; bracts

Distribution of ***Hesperantha rupicola***.

Distribution of ***Hesperantha oligantha***.

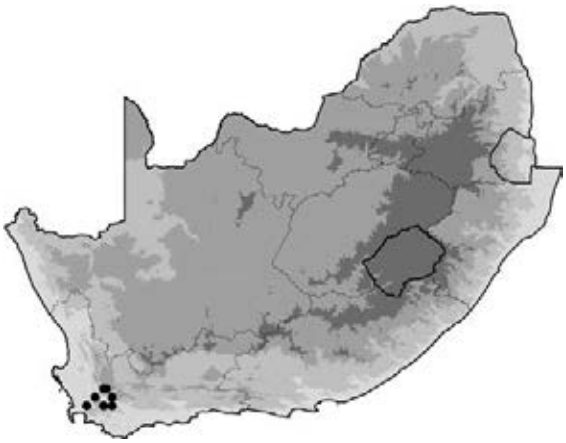
9–10 mm long, soft-textured, pale green or becoming membranous above, inner membranous with 2 green keels. *Flowers* white, outer tepals lightly flushed mauve outside; perianth tube funnel-shaped, ± 10 mm long; tepals ovate, ± 10 × 3–4 mm, obtuse, spreading. *Filaments* ± 4 mm long; anthers ± 5 mm long, shortly tailed, pale yellow; pollen whitish. *Style branches* spreading over tepals, reaching nearly to anther tips in closed flower. *Flowering time*: August.

Distribution and ecology: restricted to interior Namaqualand and western Bushmanland in Northern Cape, South Africa; in shade on south-facing slopes on cliffs and among boulders, in quartzite or granite rocks.

Diagnosis: *Hesperantha rupicola* can be distinguished by its short stature, up to 50 mm tall, soft-textured, spreading to drooping leaves, and a 1- to 3-flowered spike of moderate-sized white flowers. The relatively large corms have an oblique flat side and ± concentric tunics, and most closely resemble those of *H. acuta*, suggesting a possible relationship with this interior Western Cape and western Karoo species.

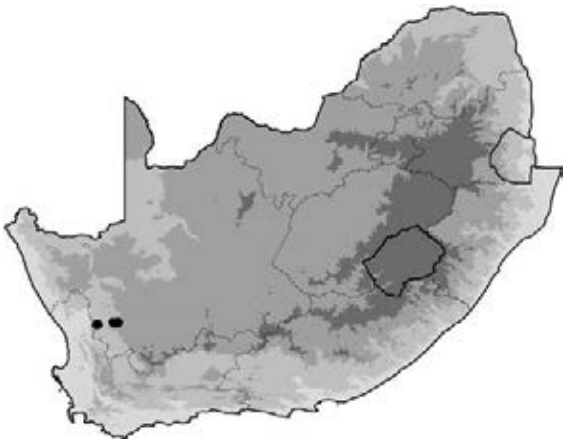
5. **Hesperantha oligantha** *(Diels) Goldblatt* in Journal of South African Botany 50: 87 (1984). *Lapeirousia oligantha* Diels: 117 (1909). Type: South Africa, [Northern Cape], Hantam Mtns, Oct. 1900, *F. Diels 725* (B, holo.; MO, iso.).

Plants mostly 60–80 mm high. *Corm* ovoid with obliquely flattened side, 4–5 mm diam.; tunics of dark brown, ± imbricate layers fragmenting into sections from base. *Stem* unbranched, sheathed below by membranous cataphyll. *Leaves* 3 or 4, all ± basal or uppermost cauline, falcate or ± straight, 30–70 × 2–3 mm, soft-textured, main vein slightly thickened. *Spike* (1)2- or 3-flowered; bracts 15–23(–30) mm long, inner concealed by outer. *Flowers* diurnal, salver-shaped, glossy red-purple; perianth tube cylindric, expanded neat apex, 25–35 mm long; tepals subequal, oblanceolate 15–18 × 3 mm, spreading. *Filaments* ± erect, 10 mm long; anthers ± 5 mm long, horizontal, pale yellow; pollen yellow. *Style branches* ± 10 mm long, spreading. *Flowering time*: October, probably also in late September.



Distribution and ecology: endemic to the summit plateau of the Hantamsberg above Calvinia in Northern Cape, South Africa; very local and restricted to shallow pools and streambanks.

Diagnosis: *Hesperantha oligantha* is unmistakable in its 2- or 3-flowered spikes of uniformly red-purple flowers with a perianth tube up to 35 mm long, and long, narrow tepals 15–18 × 3 mm. The plants are quite small, mostly less than 80 mm tall, with narrow, falcate leaves 2–3 mm wide. The flowers have the typical adaptations for pollination by long-proboscid flies of the genus *Prosoeca* (Manning & Goldblatt 1996).



6. **Hesperantha montigena** *Goldblatt* in Journal of South African Botany 50: 51 (1984). Type: South Africa, [Western Cape], Hex River Mtns, 11 Oct. 1980, *Esterhuysen 35528* (BOL, holo.; K, MO, iso.).

Plants 50–150(–250) mm high. *Corm* ovoid-elliptic with obliquely flattened side, 3–6 mm diam.; tunics dark brown, ± concentric, layers irregularly notched below. *Stem* unbranched. *Leaves* mostly 4, lower 2 basal, ± lanceolate, often prostrate, mostly 40–100 × 2–8 mm, soft-textured, main vein slightly thickened, upper 2 leaves cauline, largely to entirely sheathing. *Spike* 2- to 4(–8)-flowered; bracts mostly 9–15 mm long, often flushed red distally. *Flowers* crepuscular, salver-shaped, white, outer tepals usually flushed red outside; perianth tube ± cylindric, 12–15 mm long; tepals elliptic, 14–16 mm long, spreading. *Filaments* ± erect, 3–5 mm long; anthers 5–6 mm long, horizontal, white; pollen white. *Style branches* ± 8 mm long, spreading, reaching middle of anthers in closed flower. *Capsules* ovoid, ± 8 mm long. *Seeds* light brown, softly angular. *Chromosome number* $2n = 26$. *Flowering time*: October to late November.

Distribution and ecology: a montane species, occurring at high elevations,1 200–2 000 m, in the mountains of

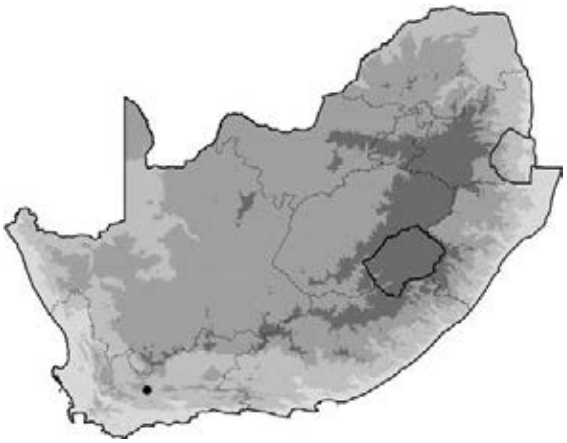
Distribution of ***Hesperantha montigena***.

Distribution of ***Hesperantha rivulicola***.

Western Cape, South Africa, from the Hex River Mtns and Keeromsberg south to the Riviersonderend and Groot Drakenstein Mtns; in stony sandstone-derived soils, flowering well only after fire.

Diagnosis: *Hesperantha montigena* is recognised by the moderate-sized crepuscular flowers, white with the outer tepals red outside, with tepals 14–16 mm long and as long as to slightly longer than the perianth tube. Plants bear four leaves, the lower two basal and largest, often prostrate or nearly so and the upper leaves small and sheathing the flowering stem. Plants mostly have two to four flowers per spike but plants with up to eight flowers are known.

7. **Hesperantha rivulicola** *Goldblatt* in Journal of South African Botany 50: 60 (1984). Type: South Africa [Northern Cape], Calvinia District, stream beds below the Hantamsberg, 16 Sept. 1980, *P. Goldblatt 5807* (MO, holo.; B, BOL, E, K, NBG, PRE, S, US, WAG, iso.).



Plants mostly 150–300 mm high. *Corm* ± ovoid with obliquely flattened side, 7–10 mm diam.; tunics dark brown, ± concentric, layers fragmenting irregularly into sections. *Stem* simple or 1- to 3-branched from base, sheathed below by membranous cataphyll. *Leaves* usually 3 or 4, lower 2 or 3 basal, ± linear, slightly inflated, reaching ± to base of spike, 2–3 mm wide, soft-textured, veins and margins not raised, uppermost leaf cauline, with elongate sheath and short free apex. *Spike* 2- to 5-flowered; bracts mostly 9–12 mm long, green or becoming dry above. *Flowers* crepuscular, salver-shaped, white, outer tepals flushed brown outside, sweetly scented; perianth tube cylindric, funnel-shaped, 7–10 mm long; tepals ± elliptic, 14–15 mm × 4–5 mm, inner slightly shorter and wider, spreading. *Filaments* ± erect, ± 3 mm long; anthers ± 6 mm long, horizontal, white; pollen white. *Style branches* ± 8 mm long, spreading. *Chromosome number* 2*n* = 26. *Flowering time*: mainly September.

Distribution and ecology: restricted to the Bokkeveld Mtns and Hantamsberg in the Calvinia District of Northern Cape, South Africa, occurring on several farms near Nieuwoudtville and on the Hantamsberg, both on the lower slopes and summit plateau; among rocks in seasonal watercourses on sandy, shale or dolerite substrates.

Diagnosis: although not particularly distinctive in its white, relatively large flowers, *Hesperantha rivulicola* is recognised by the small corms with concentric tunics and unusual, pale green leaves with slightly inflated blades without raised veins or margins. In cross section the leaves are oval to almost rectangular with rounded margins and internally have large, spongy cells. The uppermost leaf has an unusually long sheath, enclosing a good part of the stem with a short free apex. The flowers are pollinated by large anthophorine bees when they open after 16:00 and after dark by a range of settling moths.

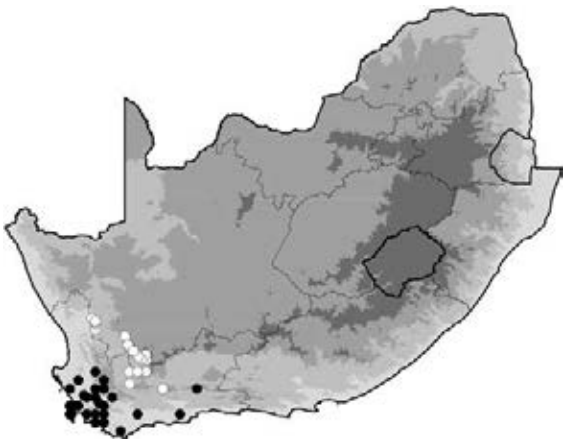
8. **Hesperantha malvina** *Goldblatt* in Annals of the Missouri Botanical Garden 90: 405 (2003). Type: South Africa, [Western Cape], Anysberg, Farm Tapfontein, W of Matjiesgoedkop, ledges on cliff face, 3 Sept. 1987, *Lloyd 1120* (NBG. holo.).

Plants 100–270 mm high, stem unbranched. *Corm* ovoid, ± 6 mm diam.; tunics woody, concentric. *Stem* unbranched, ?smooth. *Leaves* 4, lower 2 basal, linear-oblong, blades ± 2 mm wide, margins and main vein lightly thickened and sparsely long-hairy in lower ½, third leaf largely sheathing with short free apex, uppermost leaf entirely sheathing, partly membranous, 8–22 mm long, inserted shortly below spike. *Spike* 1- to 3-flowered; bracts 10–14 mm long, green or flushed purple, margins and apices membranous. *Flowers* mauve, diurnal; perianth tube cylindric below, expanded near apex, 8–9 mm long; tepals subequal, elliptic, 13–14 × 4–5 mm, spreading at right angles to tube. *Filaments* ± 3 mm long; anthers 5.5–6.0 mm long, yellow; pollen yellow. *Style branches* ± 7 mm long, reaching upper ⅓ of anthers in bud, spreading when mature. *Flowering time*: late September to early October.

Distribution of ***Hesperantha malvina***.

Distribution and ecology: restricted to the Anysberg in the Little Karoo, Western Cape, South Africa; on damp, south-facing sandstone cliffs and rocks.

Diagnosis: assigned to *Hesperantha pilosa* when first collected because it has sparsely hairy leaves, *H. malvina* actually bears little further resemblance to that species. The flowers are in general larger, with broadly elliptic tepals up to 14 mm long and 4–5 mm wide, while the leaves are linear-oblong and somewhat obtuse at the tips. In *H. pilosa* the tepals are seldom as long as 14 mm, rarely more than 3 mm wide, and the leaves are usually linear or linear-lanceolate and acute. The habitat, rocky sandstone cliffs, also differs from that of *H. pilosa,* which grows on granitic or sandy flats or lower slopes.



9. **Hesperantha pilosa** *(L.f.) Ker Gawl.* in König & Sims, Annals of Botany 1: 225 (1804a); Goldblatt: 54 (1984). *Ixia pilosa* L.f.: 92 (1782). Type: South Africa, [Western Cape], hills around Cape Town, Sept., *C.P. Thunberg s.n.* [UPS–THUNB 979, lecto., designated by Goldblatt: 54 (1984)].

Plants mostly 100–250 mm high. *Corm* ovoid, ± 6 mm diam.; tunics woody, concentric. *Stem* unbranched, usually sparsely hairy, with minute, scale-like bract in upper ⅓. *Foliage leaves* 3, lower 2 linear to narrowly sword-shaped, plane or with main vein and margins raised, or oval in cross section and ribbed, 1–4 mm wide, hairy to minutely ciliate, cilia horizontal on edges of ribs or margins, margins sometimes slightly winged, upper leaf partly sheathing lower half of stem, usually ribbed. *Spike* (2)3- to 5-flowered, bracts subequal, 8–10 mm long, outer green or becoming ± pale and membranous, inner membranous with 2 green keels, forked at apex or entire. *Flowers* ± salver-shaped, either diurnal and blue or deep pink (rarely white), with darker veins outside OR crepuscular and white to pale pink to lilac with outer tepals dark outside, unscented or with acrid, sour odour; perianth tube 6–8 mm long; tepals 9–16 × 2–5 mm, inner slightly shorter and wider than outer. *Filaments* 2.0–2.5 mm long; anthers (4)5–7 mm long, horizontal or ascending, pale yellow or white; pollen yellow to white. *Style branches* ultimately spreading, 5–9(11) mm long, reaching to middle to upper ⅓ of anthers, sometimes exceeding them, ± white, rarely purple. *Capsules* ± globose, 5–6 × 4–5 mm. *Seeds* angular, ± 1 mm long. *Chromosome number* 2*n* = 26. *Flowering time*: mid-August to late September.

Distribution and ecology: relatively widespread in the South African winter-rainfall region, extending from the Bokkeveld Mtns in Northern Cape to the Cape Peninsula and east to Cloete's Pass and the Swartberg Mtns in Western Cape; on a variety of soils, often in renosterveld.

Diagnosis: variable in flower colour and phenology, *Hesperantha pilosa* can readily be recognised by the sparsely hairy stem and three leaves, the lower two basal and the third largely sheathing the stem. The leaf blades are hairy to minutely ciliate and the stem, usually unbranched, bears a scale-like bract in the upper third. Usually plane and without raised margins, the leaf blades of some interior populations have raised margins or may be ± terete and grooved with minute cilia on the groove edges. Variation in flower pigmentation and timing of opening and closing has resulted in recognition of two subspecies. Subsp. *pilosa* has white (occasionally pale pink or lilac) flowers with dark markings on the reverse of the outer tepals and flowers are crepuscular, opening ± 18:00; and subsp. *bracteolata* has blue or deep pink (or rarely white) flowers often darkly veined on the reverse of the outer tepals and flowers are diurnal, opening in the morning and usually closing in early afternoon. The two subspecies have complimentary geographic ranges.

Hesperantha pilosa is closely related to *H. pseudopilosa* and the two are often so similar that the latter was originally described as subsp. *latifolia* of *H. pilosa.* Both have hairy stems and leaves but very different capsules and seeds and can also be distinguished by leaf width, up to

Distribution of ***Hesperantha pilosa*** subsp. ***pilosa***, ●; subsp. ***bracteolata***, ○.

10 mm in *H. pseudopilosa*, which also has a longer scale-like bract 8–20 mm long on the upper part of the stem.

Key to subspecies

1a Flowers crepuscular, usually white (creamy white) to pale pink or lilac, outer tepals darkly pigmented outside; anthers spreading horizontally over tepals; style branches 5–9 mm long, not reaching beyond middle of anthers in closed flower . . . . . 9a. subsp. *pilosa*

1b Flowers diurnal, usually blue or deep pink (rarely white), outer tepals not or faintly darker outside; anthers ascending; style branches (7)8–9(11) mm long, reaching to upper ⅓ of anthers or exceeding them in closed flower. . . . . 9b. subsp. *bracteolata*

9a. subsp. **pilosa**

Leaf blades plane, sometimes with main vein and margins slightly raised, linear to narrowly lanceolate, hairy to minutely ciliate on veins and margins. *Flowers* white (creamy white) to pale pink of mauve, outer tepals darkly pigmented outside, with sweet or acrid scent, opening ± 18:00 and closing after midnight; perianth tube 6–8 mm long; tepals 9–15 × 2–4 mm. *Filaments* 2.0–2.5 mm long; anthers (4)5–7 mm long, usually horizontal, lying over tepals, white; pollen white. *Style branches* 5–9 mm long, reaching to upper ⅓ of anthers, sometimes exceeding them, in closed flower, white.

Distribution and ecology: extending from the Cederberg to the Cape Peninsula and east along the Swartberg Mtns and Langeberg to near Herbertsdale; usually in sandy or loamy soil.

Diagnosis: subsp. *pilosa* is recognised by the crepuscular flowers, usually white but rarely pale pink to lilac, with the outer tepals darkly pigmented outside. The style branches are somewhat shorter than in subsp. *bracteolata*, 5–9 mm long and reaching only to the middle of the anthers in the closed flower. The leaves are typically plane with slightly raised margins and main vein.

A remarkable collection of what appears to be subsp. *pilosa* from the Hex River Mtns (*Esterhuysen 36196A*, BOL) flowering in December, consists of plants with only two leaves, the lower leaf linear-lorate and 4 mm wide, with an obtuse apex, and the second leaf sheaths the lower ⅔ of the stem. The margins, midrib and secondary veins all bear the long hairs that are diagnostic for *Hesperantha pilosa* but seem unusual in being slightly reflexed. The plants are taller than usual for *H. pilosa* and the spikes bear only one or two flowers. The style branches appear longer than those of any other white-flowered subsp. *pilosa* and in the closed flower reach the top of the anthers. The habitat, cool shaded slopes below a waterfall, is unusual for *H. pilosa*, which normally grows in light bush on exposed slopes and flowers in September and October. It seems possible that the habitat is responsible for the unusual morphology and late flowering time of the population, but it may equally represent a separate taxon.

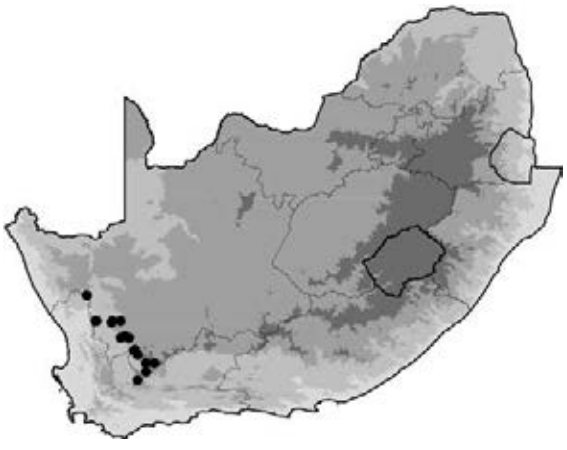
9b. subsp. **bracteolata** *(R.C.Foster) Goldblatt & J.C.Manning* in Bothalia 43: 149 (2013). *H. bracteolata* R.C.Foster: 6 (1948). Type: South Africa, [Northern Cape], Farm Uitkyk, *Marloth 9907* (B, holo.; PRE, iso.).

Hesperantha puberula Schltr. ex R.C.Foster: 22 (1948). Type: South Africa, [Northern Cape], Oorlogskloof, *Schlechter 10952* (B, lecto., designated by Goldblatt: 57 (1984); B, BOL, G, GRA, K, PRE, US, isolecto.).

Hesperantha ciliolata Goldblatt: 59 (1984). Type: South Africa. [Northern Cape], Roggeveld Escarpment, Farm Geelhoek, 21 Sept. 1953, *Acocks 17176* (PRE, holo.).

Leaf blades either linear to narrowly sword-shaped, blades plane or with main vein and margins raised, or oval in cross section and ribbed, 1–4 mm wide, pubescent or minutely ciliate, cilia horizontal on edges of ribs or margins, margins sometimes ± winged, upper leaf partly sheathing lower half of stem, usually ribbed. *Spike* (2)3- to 5-flowered. *Flowers* blue or pink to purple (rarely white), with slightly darker veining outside, unscented or with acrid, sour or musky odour, opening 10:00 to 11:00 and closing mid-to late afternoon; perianth tube 6–8 mm long; tepals (11–)12–16 × 3–5 mm. *Filaments* 2.0–2.5 mm long; anthers (4–)5–7 mm long, usually ascending to suberect, pale yellow or white; pollen yellow to white. *Style branches* (7)8–9(11) mm long, reaching to upper third of anthers, sometimes exceeding them, ± white, rarely purple.

Distribution and ecology: extending from the Bokkeveld Mtns northwest of Nieuwoudtville through the Roggeveld south into the Klein Roggeveld in Northern Cape and locally in the Voetpadsberg east of Touws River in Western Cape; usually in sandy, stony ground.



Diagnosis: distinguished from subsp. *pilosa* by the blue or deep pink (rarely white) perianth, the outer or all tepals not or only slightly more darkly pigmented on the reverse, subsp. *bracteolata* also usually has particularly long style branches, up to 11 mm long and reaching the upper third of the anthers when lined up together, or even exceeding them. Some plants may have relatively prominently ribbed leaves, the rib edges with short cilia directed horizontally as well as long hairs on the veins, a feature not seen in subsp. *pilosa*. Flowers are occasionally white or pale blue to almost white but are always diurnal, open during the morning and closing after 12:20, sometimes after 14:00. In contrast, flowers of subsp. *pilosa* are crepuscular, opening in the evening after 17:00 or at sunset, and then strongly scented and the tepals are white (creamy white), rarely pale mauve, with the outer or all tepals darkly pigmented red to brown or purple.

Hesperantha ciliolata was recognised on the basis of its straight, ribbed leaves, oval to terete in transverse section, with fine scabrid cilia on the rib edges.

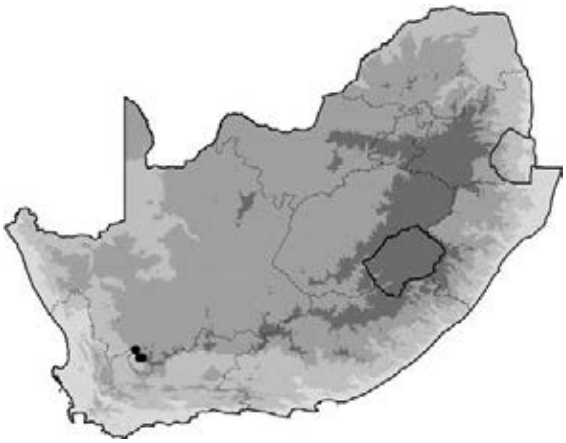
Similar populations with violet or mauve-pink flowers with such leaves are now also known, all with diurnal flowers. Intermediates between those with truly terete leaves and others with ± plane leaves have resulted in its reduction to synonymy. Plants from the Voetpadsberg east of Touws River have the same general appearance as subsp. *bracteolata* except that the leaves mostly have only two grooves on each surface, or sometimes a pair of secondary veins strongly raised with the edges of the raised parts ciliate-scabrid, as are the edges of the ribs of the sheathing upper leaf. The flowers closely resemble those of other populations of the subspecies in their blue colour but have a light, musky acrid scent. These plants seem best regarded as a minor variant of subsp. *bracteolata*.

10. **Hesperantha pseudopilosa** *Goldblatt* in Journal of South African Botany 53: 461 (1987) as new name for *H. pilosa* subsp. *latifolia* Goldblatt: 56 (1984) [not *H. latifolia* M.P.de Vos (1974)]. Type: South Africa, [Northern Cape], Roggeveld, slopes of Sneeukrans, 22 Sept. 1981, *Goldblatt 6339* (MO, holo.; K, NBG, iso.).

Plants mostly 120–320 mm high. *Corm* ovoid, 7–12 mm diam.; tunics woody, concentric. *Stem* unbranched, usually sparsely hairy, with scale-like leaf in upper third 8–20 mm long. *Foliage leaves* 3, lower 2 narrowly lanceolate, plane, hairy on veins and margins, usually shorter than stem, 4–10 mm wide. *Spike* 1- to 4(–6)-flowered; bracts 8–10 mm long, green or becoming ± pale and membranous distally. *Flowers* crepuscular, white, outer tepals brown to grey outside, salver-shaped, usually sweetly scented; perianth tube 8–11 mm long; tepals mostly 12–5 × 3–5 mm, inner slightly shorter and wider than outer. *Filaments* 2.0–2.5 mm long; anthers (4)5–7 mm long, spreading horizontally, white; pollen creamy white. *Style branches* spreading, 9–10 mm long, reaching upper ⅓ of anthers in closed flower. *Capsules* ± globose, 8–9 mm long. *Seeds* softly angular with loose testa, angles ridged, 2–3 mm long. *Flowering time*: mid-August to late September.

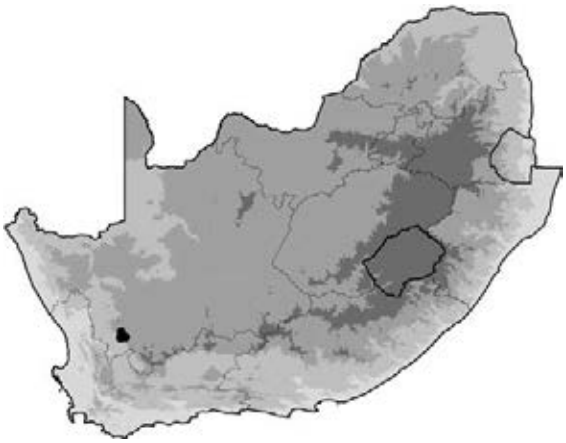
Distribution of ***Hesperantha pseudopilosa***.

Distribution and ecology: extending from interior Namaqualand near the Langberg and the Bokkeveld Mtns and western Karoo in Northern Cape, South Africa to the Laingsburg Karoo and interior of the Klein Swartberg in Western Cape; growing on well-drained, usually stony sand.



Diagnosis: *Hesperantha pseudopilosa* has the hairy leaves and stem of *H. pilosa* but differs in the broader foliage leaves, up to 10 mm wide, a longer scale-leaf 8–20 mm long. The larger capsules are 8–9 mm long and contain larger seeds, 2–3 mm long, with a loose testa. Capsules of *H. pilosa* are typically 6–8 mm long and the seeds are sharply angular and ± 1 mm diam. The crepuscular white flowers open relatively late in the day, mostly after 18:00, and then produce a strong sweet scent. They are visited by a range of settling moths, mostly of the family Noctuidae.

11. **Hesperantha glabrescens** *Goldblatt* in Annals of the Missouri Botanical Garden 90: 406 (2003). Type: South Africa, Northern Cape, farm Hottentotskloof, ± 15 km SW of Sutherland on Bo-Visrivier road, 2 Oct. 1999, *Goldblatt & Nänni 11190* (NBG, holo.; K, MO, iso.).



Plants 30–50 mm high. *Corm* ovoid, 4–6 mm diam.; tunics woody, concentric. *Stem* unbranched, smooth, bearing a scale-like bract shortly below spike. *Leaves* 3, lower 2 falcate, upper suberect, largely sheathing, blades 1.0–1.3 mm wide, margins and veins sparsely hairy, margins and main vein slightly thickened. *Spike* 1(2)-flowered; bracts ± 6 mm long, purplish, becoming dry and brown above. *Flowers* diurnal, rotate, magenta, unscented; perianth tube cylindric, expanded near apex, ± 3.5 mm long; tepals subequal, elliptic, 8 × 2 mm, spreading at right angles to tube. *Filaments* suberect, ± 2 mm long; anthers 3 mm long, yellow; pollen yellow. *Style branches* ± 3.5 mm long, purple, spreading. *Flowering time*: late September and early October.

Distribution and ecology: known only from the Roggeveld Escarpment SW of Sutherland in Northern Cape, South Africa; on moist clay flats along watercourses.

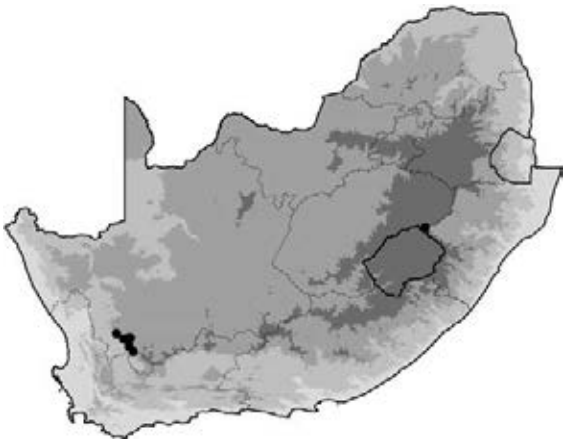
Diagnosis: closely related to the widespread *Hesperantha pilosa* and initially appearing to be a depauperate form of that species, *H. glabrescens* can be distinguished from its ally in several features. The leaves are sparsely hairy, unlike the fairly densely hairy or even downy leaves of *H. pilosa*, and the spikes are mostly 1- or rarely 2-flowered, whereas *H. pilosa* typically has several, sometimes up to 10 flowers per spike. Notable is the small size of the plants, only 30–50 mm high, shorter than recorded in *H. pilosa*. The flowers are magenta and quite small, with a perianth tube ± 3.5 mm long and tepals ± 8 mm long. Flowers of *H. pilosa* are always larger, usually white (subsp. *pilosa*) or blue or rarely deep pink (subsp. *bracteolata*), with a perianth tube mostly 6–8 mm long and tepals 9–16 mm long. The decision to recognise *H. glabrescens* was made in part because

Distribution of ***Hesperantha glabrescens***.

Distribution of ***Hesperantha secunda***.

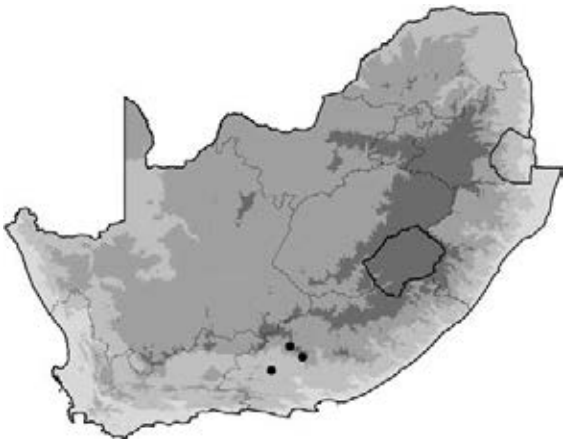
of the consistently different morphology from *H. pilosa* and because *H. pilosa* subsp. *bracteolata* grew nearby and was always taller, up to 120 mm high, and with 2 to 4 flowers per spike. These plants had plane, densely pilose leaf blades, in contrast to those of *H. glabrescens.* The flowers of the two species were, however, nearly identical in pigmentation and almost so in size at this site, although they could be distinguished by differences in perianth tube length.

12. **Hesperantha secunda** *Goldblatt & J.C.Manning* in Bothalia 43:150 (2013). Type: South Africa, [Northern Cape], Roggeveld Escarpment, 56 km from Calvinia on Blomfontein road to Middelpos, 17 Sept. 1980, *Goldblatt 5810* (NBG, holo.; K, MO, PRE, S, US, iso.).



Plants 100–200 mm high. *Corm* ovoid, 7–8 mm diam.; tunics woody, concentric. *Stem* unbranched, smooth, with minute, membranous, scale-like bract up to 3 mm long on upper third of stem. *Foliage leaves* 3, lower 2 basal, linear to narrowly sword-shaped, falcate or straight, finely hairy 2.5–4.0 mm wide, margins raised and winged at 90º to surface, main vein also raised with narrow wings parallel to surface, uppermost leaf sheathing lower part of stem for all or most of its length, several ribbed, finely hairy. *Spike* ± nodding, mostly 3- to 7-flowered; bracts subequal, 7–10 mm long, outer green or becoming ± pale and membranous, inner membranous with 2 green keels. *Flowers* nocturnal, creamy white, outer tepals grey-brown on reverse, nodding, tepals spreading at right angles to tube and vertical, strongly scented; perianth tube cylindric, curving outward, 6–7 mm long; tepals 10–11 × 2.5–3.5 mm, inner slightly shorter and wider than outer. *Filaments* ± 3 mm long; anthers 5–6 mm long, spreading almost parallel to tepals, white; pollen white. *Style branches* ascending, ± 4 mm long, reaching to base or lower fourth of anthers. *Flowering time*: September to mid-October.

Distribution and ecology: known from just three populations in Northern Cape, South Africa, two from the Roggeveld Escarpment west of Middelpos and the other from the southern slopes of the Keiskei Mtns southeast of Calvinia; growing in shallow, fine-grained soil over rocky (?sandstone) pavement.



Diagnosis: when first collected, *Hesperantha secunda* was referred to *H. pilosa* because of its pilose leaves and the scale-like bract in the upper third of the stem. However, its unusual, somewhat fleshy leaves with thickened to winged margins and thickened main vein, and nearly secund spike, prompted a reappraisal of its status and it is now regarded as a separate species, perhaps most closely allied to *H. pilosa*. In addition to its unusual leaves, the flowers are nodding on a curved perianth tube and have unusually short, ascending style branches, ± 4 mm long. *Hesperantha pilosa* has plane to ribbed leaves (or rarely terete or with slightly winged margins) and upright flowers with a straight perianth tube, tepals 9–16 mm long vs. 10–11 mm in *H. secunda* and longer style branches, 7–11 mm long, spreading laxly over the tepals. Flowers of *H. secunda* open at sunset, the tepals beginning to unfold at ± 17:00 and fully expanded by 18:00, remaining open until the early hours of the morning. The strong scent has a slightly unpleasant acrid component.

13. **Hesperantha teretifolia** *Goldblatt* in Journal of South African Botany 53: 460 (1987). Type: South Africa, [Northern Cape], Roggeveld Escarpment between Middelpos and Calvinia, 13 Oct. 1983, *Goldblatt 7090* (NBG, holo.; K, MO, PRE, S, STE, WAG, iso.).

Plants 250–500 mm high. *Corm* ± globose, ± 9 mm diam., asymmetric; tunics woody, concentric, splitting into elliptic sections. *Stem* slender, sometimes branched from near base, with short scale-like leaf shortly below spike. *Foliage leaves* 3, lower 2 basal, terete, shallowly grooved, ± half as long as stem, ± 2 mm diam., uppermost leaf sheathing ⅔ of stem with free blade up to 50 mm long. *Spike* flexuose, 6- to 10-flowered; bracts ± membranous, pale, often dry distally, 8–12 mm long. *Flowers* crepuscular, rotate, creamy white, outer tepals flushed brown outside; perianth tube straight, ± cylindric, ± 9.5 mm

Distribution of ***Hesperantha teretifolia***.

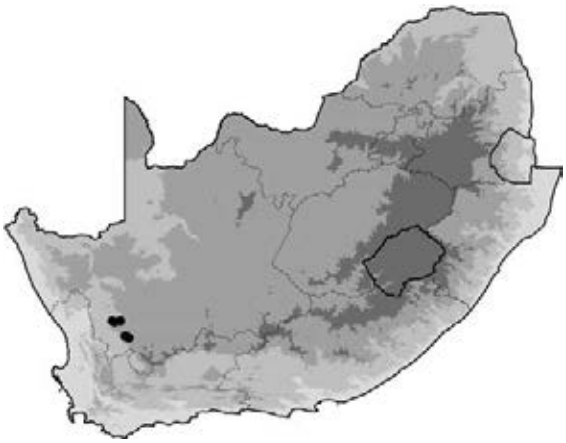
Distribution of ***Hesperantha helmei***.

long, slightly wider near apex; tepals subequal, elliptic, ovate, ± 13 × 4 mm, spreading. *Filaments* weakly diverging, ± 2.5 mm long; anthers 6–7 mm long, yellow; pollen yellow. *Style branches* ± 5 mm long, spreading over tepals. *Capsules* obovoid, 6–8 mm long. *Seeds* angular, with loose testa, ridged on angles, light brown. *Chromosome number* 2*n* = 26. *Flowering time*: September to mid-October.

Distribution and ecology: restricted to the Roggeveld Escarpment in Northern Cape, South Africa, and recorded from west of Middelpos and to the south on the farm Uitkyk; growing on rocky ground.

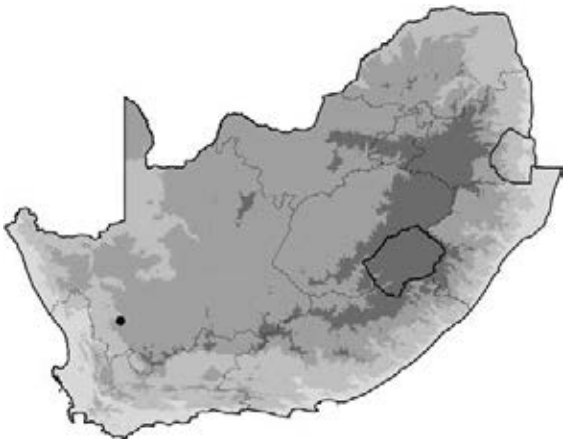
Diagnosis: *Hesperantha teretifolia* is distinctive in the centric, ± terete, minutely grooved, hollow leaves with the surface between the grooves densely covered by minute papillae or extremely short, cilia-like hairs (visible only at 10× magnification). The white flowers open late in the afternoon, mostly after 16:30, and are then sweetly scented. The flowers, typical of the genus in form, are creamy white with a perianth tube 9.5 mm long, slightly shorter than the elliptic tepals.

14. **Hesperantha helmei** *Goldblatt & J.C.Manning* in Bothalia 37: 179 (2007). Type: South Africa, Eastern Cape, ± 50 km E of Graaff-Reinet, upper northern slopes of Nardousberg, 1 km N of main peak, Annex Stijlfontein 250, 700 m, 19 Nov. 2004, *Helme 3144* (NBG, holo.).



Plants 180–250 mm high. *Corm* ± globose, ± 9 mm diam., asymmetric; tunics woody, concentric. *Stem* slender, unbranched, with short scale-like leaf in upper fourth. *Leaves* 3, lower 2 terete, strongly grooved, blades 8–15 × 1.2 mm, uppermost leaf sheathing lower ½–⅔ of stem. *Spike* 1- or 2-flowered; bracts green, ± 9 mm long, inner forked at apex. *Flowers* pale mauve, darker at mouth of tube, probably diurnal, outer tepals with broad purple streak on reverse; perianth tube straight, 6–8 mm long, slender, widening near apex; tepals subequal, narrowly ovate, ± 8.0 × 2.5 mm, outer slightly larger than inner, spreading slightly above horizontal. *Filaments* weakly diverging, exserted ± 2 mm; anthers ± 4 mm long, yellow; pollen yellow. *Style branches* ± 3.5 mm long, ascending, ultimately reaching to ± middle of anthers in closed flower. *Flowering time*: November and probably December.

Distribution and ecology: apparently restricted to the southern edge of the Great Escarpment around Graaff-Reinet in Eastern Cape, South Africa, where it has been recorded from the Onder-Sneeuberg and the Sneeuberg; in rocky grassland among dolerite boulders. The habitat burns regularly every few years during the dry season and is covered with snow in winter.



Diagnosis: *Hesperantha helmei* is distinctive in its terete, finely ribbed, smooth leaves, and relatively small, pale mauve flowers with a perianth tube 6–8 mm long and narrow tepals ± 8.0 × 2.5 mm. Another unusual attribute of the species is the small sheathing scale-like leaf in the upper part of the stem, a characteristic feature of a small group of species allied to *H. pilosa*. Among these species *H. helmei* is perhaps most closely related to *H. teretifolia*, which also has terete, prominently ridged leaves, the grooves lined with fine ciliate hairs, a feature lacking in *H. helmei*. The flowers of *H. teretifolia* are creamy white and larger than those of *H. helmei,* with a perianth tube ± 8 mm long and tepals ± 10 mm long but the two species are broadly similar in general appearance. The scale-like bract of *H. helmei* is 8–10 mm long vs. 2–4 mm in *H. teretifolia*.

15. **Hesperantha quadrangula** *Goldblatt* in Journal of South African Botany 50: 62 (1984). Type: South Africa, [Northern Cape], Hantamsberg, slopes below the summit cliffs, 16 Sept. 1980, *P. Goldblatt 5795* (MO, holo.; NBG, iso.).

Plants 100–300 mm high. *Corm* ± globose, 6–8 mm diam.; tunics woody, concentric, brown, outer layers breaking into irregular sections. *Stem* slender, unbranched, sheathed basally by brittle, dark brown cataphylls. *Leaves* 3, all ± basal, lower 2 up to 100 × 3–7 mm, plane, falcate or ± oblong, obtuse, uppermost leaf sheathing lower ½–⅔ of stem, quadrangular in

Distribution of ***Hesperantha quadrangula***.

Distribution of ***Hesperantha filiformis***.

section, free in upper 10 mm. *Spike* (1–)3- to 7-flowered; bracts green below, pale and membranous distally, 7–9 mm long. *Flowers* diurnal, ± rotate, white, outer tepals flushed or speckled dull pink to red outside, sweetly scented; perianth tube straight, 2–3 mm long, cylindric, included in bracts; tepals subequal, narrowly obovate, 9–12 × ± 3 mm, spreading. *Filaments* weakly diverging, ± 3 mm long; anthers 3–4 mm long, white; pollen white. *Style branches* ± 5 mm long, ascending, reaching to ± middle of anthers in closed flower. *Capsules* ± barrel-shaped, ± 6 mm long. *Seeds* unknown. *Flowering time*: late August and September.

Distribution and ecology: restricted to the western Karoo in Northern Cape, South Africa, and recorded only from the Hantamsberg at Calvinia and on the Roggeveld Escarpment northwest of Middelpos; on rocky dolerite or sandstone slopes and plateaus.

Diagnosis: *Hesperantha quadrangula* is reliably identified by the distinctive chestnut-brown cataphylls and white flowers with a particularly short perianth tube, 2–3 mm long. Plants consistently have two spreading, pale, relatively broad basal leaves and a largely sheathing upper leaf which is quadrangular in cross section. Observations on one population indicates that the flowers open at 16:00–16:30 and then produce a sweet, rose-like fragrance but the tepals close again at nightfall, and the flowers are completely closed by 19:30. The flowers are visited by a range of large-bodied bees and the occasional hopliine scarab beetle.

16. **Hesperantha filiformis** *Goldblatt & J.C.Manning* in Journal of South Africa Botany 98: 117 (2015). Type: South Africa, Northern Cape, Calvinia District, Farm Vanrhynshoek, Hantamsberg plateau, in wet red clay among dolerite boulders, 1 575 m, 25 Sept. 2014, *Goldblatt & Porter 14010* (NBG, holo.).

Plants 90–150 mm high, with short membranous sheathing cataphyll. *Corm* broadly ovoid, flattened on one side in lower ⅓, 8–10 mm diam.; tunics woody, dark brown, notched below into sections. *Stem* erect, simple. *Leaves* 3, lower 2 basal, lanceolate to falcate, up to 50 mm long, mostly 3–6 mm wide, firm, margins and main veins slightly thickened, appearing raised when dry, uppermost leaf subbasal, partly sheathing stem, free in upper half. *Spike* lax, 1- to 3-flowered, spaced 9–12 mm apart; bracts green with membranous upper margins, outer ± 10 mm long, inner slightly shorter. *Flowers* crepuscular, salver-shaped, white, reverse of outer tepals mottled grey-brown along midline, opening after 19:00, tepals then outspread, sweetly scented; perianth tube cylindric, ± 12 mm long, well exserted from bracts; tepals subequal, elliptic, ± 11 × 5 mm. *Filaments* erect, ± 2 mm long; anthers held horizontally, ± 5 mm long, white; pollen white. *Style branches* ± 4 mm long, ascending, reaching to ± middle of anthers in closed flower. *Capsules* ± ovoid-elliptic, obtuse, smooth, ± 11 mm long. *Seeds* unknown. *Flowering time*: September.

Distribution and ecology: known only from the Hantamsberg plateau near Calvinia, Northern Cape, South Africa; in moist red clay among dolerite boulders.

Diagnosis: small and inconspicuous *Hesperantha filiformis* stands up to 150 mm high and has lax spikes of 1 to 3 small flowers with a particularly slender perianth tube about 12 mm long and tepals about 11 × 5 mm. Plants consistently have only three leaves, the lower two basal and the uppermost inserted in the lower third of the stem and sheathing for about half its length. The white flowers are closed during daylight hours so that only the dull grey-brown reverse of the outer tepals is then visible. The flowers open after dark between 19:00 and 19:30 and then have a mild, sweet odour. The ovoid corms are slightly asymmetric, being flattened on one side, with the woody, dark brown tunics typical of sect. *Concentricae*. Its relationships are uncertain but possibly lie with the Namaqualand species *H. flexuosa*, which also consistently has three leaves, the uppermost partly sheathing the stem, but the somewhat fleshy leaves of this species are linear and no more than 1.5 mm wide. The firm-textured leaves of *H. filiformis* are 3–5 mm wide and have thickened margins and main vein, very

different from those of *H. flexuosa*. Capsules of *H. filiformis* are surprisingly long for so small a plant, 10–11 mm long, but seeds are so far unknown.

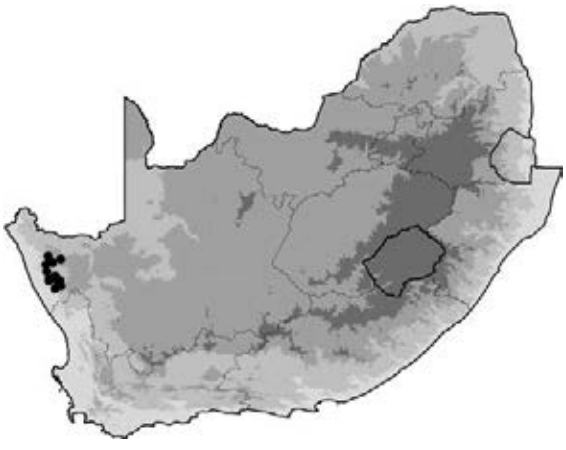
17. **Hesperantha flexuosa** *Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 394 (1882); Goldblatt: 63 (1984). Type: South Africa, [Northern Cape], Namaqualand, Kamiesberg, Elboogfontein, Aug.–Sept. 1830, *J. F. Drège 2639* (B: Herb. Lubeck, holo.; G, P, iso.).

Hesperantha namaquensis Baker: 149 (1892). Type: South Africa, [Northern Cape], 'Namaqualand', *Scully 50* (K, holo.).

Hesperantha bolusii R.C.Foster: 6 (1948). Type: South Africa, [Northern Cape], Namaqualand, near Nababeep, Sept. 1883, *H. Bolus s.n. sub Herb. Norm. Austr. Africae 694* (G, holo.; B, BOL, G, K, PRE, SAM, UPS).

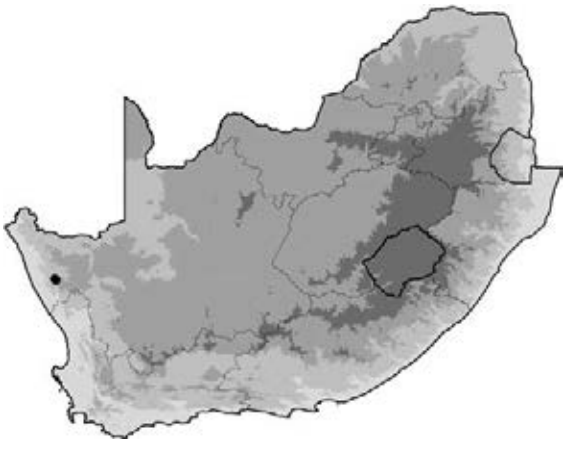
Plants (60–)100–200 mm high, slender. *Corm* ± ovoid, 3–6 mm diam., asymmetric with well-developed lateral ridge; tunics woody, dark brown, concentric, fragmenting vertically into elliptic sections. *Stem* slender, rarely with 1 branch. *Leaves* 3, lower 2 ± basal, linear, ± plane but wider in midline, up to half as long as stem, 0.5–1.5 mm wide, upper leaf cauline, lower half sheathing stem, with long free apex. *Spike* flexuose, 4- to 7-flowered; bracts ± membranous, often dry near tips, 7–10 mm long. *Flowers* crepuscular, ± rotate, white, outer tepals often flushed brown outside; perianth tube straight, 6–10 mm long, cylindric, wider near apex; tepals subequal, obovate, 8–13 × 3.5–5.0 mm, spreading. *Filaments* ± 3 mm long; anthers 4.5–6.0 mm long, held horizontally, white; pollen white. *Style branches* ± 7 mm long, ascending, reaching to ± middle of anthers in closed flower. *Capsules* ovoid, 5–6 mm long. *Seeds* angular-prismatic. *Chromosome number* 2*n* = 26. *Flowering time*: August to September, also October at higher elevations.

Distribution and ecology: relatively common and widespread in central and northern Namaqualand in Northern Cape, South Africa, extending from near Springbok in the north to middle elevations in the Kamiesberg; occurring on gritty, granitic sand on slopes and flats.



Diagnosis: white-flowered *Hesperantha flexuosa* is a relatively slender plant with somewhat succulent leaves with blades up to 1.5 mm wide. The lower two leaves are basal and have long blades and the upper leaf sheaths the stem in the lower half. The flowers are typical of the genus in the narrow, straight perianth tube with spreading tepals slightly longer than the tube. As with most white-flowered species of the genus from the winter-rainfall zone, the flowers are crepuscular, opening in the late afternoon and closing well after nightfall.

18. **Hesperantha minima** (*Baker*) *R.C.Foster* in Contributions from the Gray Herbarium of Harvard University 135: 77 (1941); Goldblatt: 65 (1984). *Geissorhiza minima* Baker: 239 (1876a). Type: South Africa, [Northern Cape], Namaqualand, Kamiesberg, 'Modderfonteinsberg,' Oct. 1830, *J. F. Drège 2632* (K, lecto., designated by Foster: 77 (1941); B, G, K, L, MO, P, S, isolecto.).

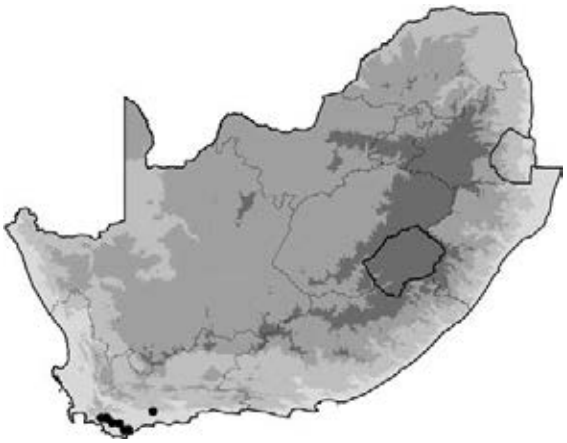


Plants 40–50 mm high. *Corm* ± ovoid, 4–5 mm diam., asymmetric; tunics woody, concentric, dark brown. *Stem* slender, sometimes 1-branched. *Leaves* 3, lower 2 ± basal, falcate, 20–30 × < 1 mm, upper leaf cauline, sheathing lower half of stem. *Spike* 1- to 3-flowered; bracts green, becoming pale and membranous distally, 3–5 mm long. *Flowers* crepuscular, ± rotate, white, outer tepals brown outside; perianth tube straight, 4–5 mm long, cylindric; tepals subequal, narrowly ovate, 5–6 × ± 2 mm, spreading. *Filaments* weakly diverging, ± 1 mm long; anthers 2–3 mm long, white; pollen white. *Style branches* ± 3 mm long, ascending, reaching to ± middle of anthers in closed flower. *Flowering time*: October and probably also early November.

Distribution and ecology: known only from the slopes of Sneeuberg in the Kamiesberg of Northern Cape, South Africa; growing in wet moss pads on granite pavement.

Diagnosis: immediately recognised by it small size, up to 50 mm high, and narrow leaves less than 1 mm wide,

Distribution of ***Hesperantha flexuosa***.



Distribution of ***Hesperantha minima***.

Hesperantha minima has white, crepuscular flowers about 12 mm diam. with a perianth tube 4–5 mm long and ± as long as the tepals. The tiny plants, smallest in the genus, have three leaves, the uppermost partly sheathing the stem. Its relationships are uncertain but the concentric corm tunics place the species in sect. *Concentricae*.

19. **Hesperantha fibrosa** *Baker*, Handbook of the Irideae: 149 (1892); Goldblatt: 66 (1984). Type: South Africa, [Western Cape], Klein River Mtns, Aug., *C.L. Zeyher 3960* (K, lecto., designated by Goldblatt: 66 (1984); B, G, S, SAM, W, Z, isolecto.).

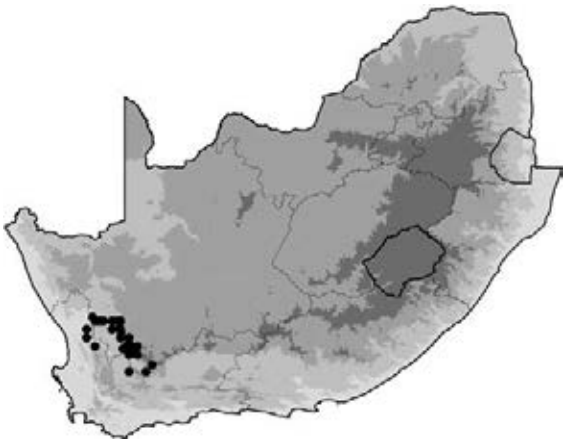
Plants 80–300 mm high. *Corm* ± ovoid, 8–12 mm diam., asymmetric with oblique flat side; tunics woody, concentric, dark brown, outer layers fragmenting into elliptic sections drawn into persistent fibres above, these forming a collar around base. *Stem* slender, unbranched, sheathed at base by ± dry, brown cataphylls and collar of fibres. *Leaves* 3, lower 2 ± basal, blades narrowly lanceolate, slightly succulent with main veins and margins thickened, ± half as long as stem, 2–4 mm wide, upper leaf cauline and sheathing lower half of stem. *Spike* flexuose, mostly 3- to 6-flowered; bracts green, 9–14 mm long. *Flowers* diurnal, ± salver-shaped, pale to deep pink to violet-purple; perianth tube straight, 7–10 mm long, cylindric, wider near apex; tepals subequal, elliptic, ± 10 × 3 mm, spreading. *Filaments* diverging, 3–4 mm long; anthers ± 4 mm long, light purple-brown; pollen ?yellow. *Style branches* ± 6 mm long, ascending, ultimately reaching to ± middle of anthers in closed flower. *Capsules* ovoid, 6–8 mm long. *Seeds* unknown. *Chromosome number* 2*n* = 26 *Flowering time*: mainly August and September, occasionally in early October.

Distribution and ecology: occurring in southern Western Cape, South Africa, extending from Houw Hoek in the west to Heidelberg in the east (a record from 'Elandskloof' in the Cold Bokkeveld to the north is erroneous); occurring on lower mountains slopes and hills in clay ground.

Distribution of ***Hesperantha fibrosa***.

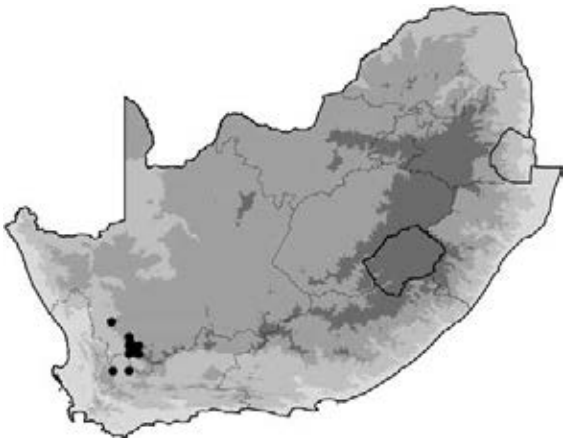
Diagnosis: fairly poorly known, the southern Cape *Hesperantha fibrosa* is recognised by the corm tunics extended upward as a collar of fibres around the base and by the somewhat fleshy leaf blades with thickened and raised margins that arch over the blade surface. Plants consistently have just three leaves, the lower two with long blades and the upper largely sheathing but with a short free apex. The flowers are typical of the genus but have relatively narrow tepals. The pale to deep pink or purple flowers are evidently diurnal.

20. **Hesperantha cucullata** *Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 393 (1882); Goldblatt: 72 (1984). Type: South Africa, [Northern Cape], Hantam Mtns, Aug., *H. Meyer 9* (B, lecto., designated by Goldblatt: 72 (1984); S, possible isolecto.).



Antholyza hantamensis Klatt: 228 (1894), as new name for *Hesperantha montana* Klatt: 393 (1882) [not *A. montana* (L.f.) Ker Gawl. (1804a)]. Type: South Africa, [Northern Cape], Hantam Mtns, *Meyer* 21 (B, lecto., designated by Goldblatt: 72 (1984); S, isolecto.).

Hesperantha buhrii L.Bolus: 13 (1931a). Type: South Africa, [Northern Cape], Nieuwoudtville, *L. Buhr s.n.* (BOL 18964, lecto., designated by Goldblatt: 72 (1984); GRA, K, isolecto.).



Plants (40–)150–300 mm high. *Corm* ± ovoid, mostly 7–14 mm diam., asymmetric with oblique base; tunics woody, imbricate, dark brown, regularly notched along lower margin. *Stem* simple or branched from near base (rarely also from axil of cauline leaf). *Leaves* 3 or 4 (more if branched), lower 2 or 3 ± basal, blades plane, sword-shaped to falcate, ± ⅓–½ as long as stem, 5–10 mm wide, upper leaf cauline, sheathing lower half of stem. *Spike* slightly flexuose, mostly 2- to 10-flowered; bracts green below, pale and membranous distally, 10–15 mm long. *Flowers* crepuscular, salver-shaped, white, outer tepals red (rarely glossy brown) outside, sweetly scented; perianth tube straight, ± 6–10(–12) mm long, cylindric, wider near apex; tepals subequal, obovate to elliptic, 12–20 × 4–10 mm, spreading. *Filaments* weakly diverging, mostly 4–5 mm long; anthers (4.0–)6.5–8.5 mm long, white or pale yellow; pollen white. *Style branches* 4–8 mm long, ascending, reaching to base or middle (rarely to tips) of anthers in closed flower. *Capsules* ovoid-ellipsoid, 10–12 mm long. *Seeds* dark brown, globose to softly angular. *Chromosome number* 2*n* = 26. *Flowering time*: mostly mid-August to late September, sometimes in October.

Distribution and ecology: relatively widespread in the western Karoo in Northern Cape, South Africa, extending from the Bokkeveld Mtns in the north to the Roggeveld and in the Tanqua and Doorn River basins, the northern Cederberg and Gifberg Mtns in Western Cape; in stony sandy or clay ground.

Diagnosis: *Hesperantha cucullata* is distinguished by the relatively large, white flowers mostly with the outer

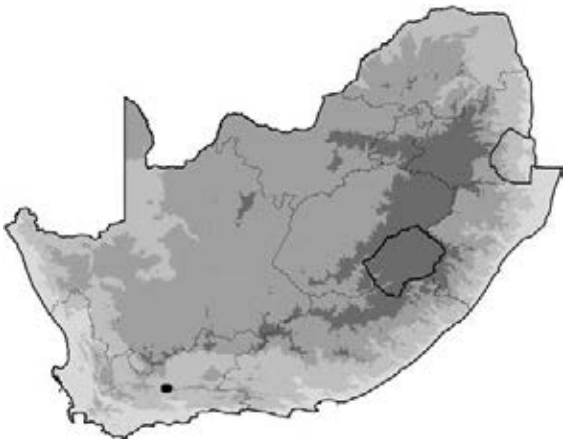
Distribution of ***Hesperantha cucullata***.

Distribution of ***Hesperantha palustris***.

tepals red outside and usually 12–20 × 6–10 mm, and the large asymmetric corms up to 14 mm diam. with imbricate tunics. The flowers are crepuscular, usually opening after 16:30 and then sweetly scented. Well-grown plants have at least four leaves, the lower three basal and with long, plane blades up to 10 mm wide.

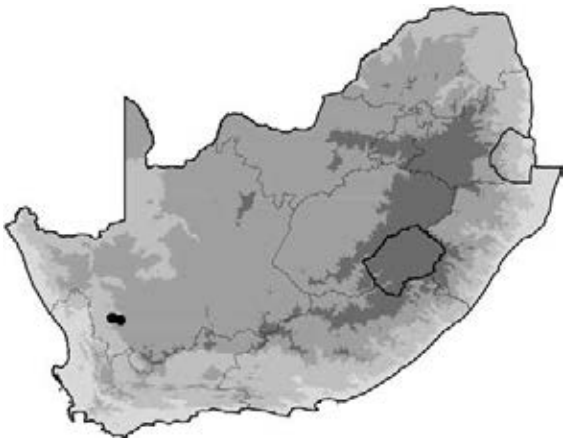
Populations from the Bokkeveld Mtns growing on sandstone pavement are often shorter in stature, with a slightly longer perianth tube, 10–12 mm vs. 6–10 mm, and shorter anthers, 4–5 mm vs. 6.0–8.5 mm, and perhaps merit taxonomic recognition. The style branches reach the tips of the anthers in these plants because the anthers are relatively short, whereas the style branches reach to between the base and middle of the anthers in other populations.

Plants from the southern Roggeveld with spikes of fewer flowers (mostly two or three) and the outer tepals brown outside (red elsewhere), and growing in wet habitats are referred to *Hesperantha palustris*.



21. **Hesperantha palustris** *Goldblatt & J.C.Manning* in Journal of South African Botany 98: 116 (2015). Type: South Africa, Northern Cape, Calvinia District, Tierkloof, *Bulbinella* marsh on dolerite sill NW of farm houses,), *Goldblatt & Porter 14040* (NBG, holo.; MO, PRE, iso.).

Plants 350–480 mm high, evidently lacking basal sheathing cataphylls at flowering. *Corm* broadly ovoid, flattened in lower ⅓ on one side, 12–14 mm diam.; tunics woody ± black, notched below into sections. *Stem* suberect, usually 2- or 3-branched from near base or simple, branches laxly arching outward. *Leaves* 4 or 5, mostly basal, ± linear, mostly 6–8 mm wide, soft and ± succulent, uppermost sometimes inserted shortly above ground, partly sheathing stem. *Spike* lax, 1- to 3-flowered, spaced 25–35 mm apart; bracts green, soft to ± membranous, 12–15 mm long, inner narrower, with membranous margins. *Flowers* crepuscular, rotate, white, middle ½–⅔ of outer tepals mottled grey-brown outside, opening after 19:00, tepals then outspread, evidently unscented [or faintly scented]; perianth tube ± cylindric, ± 8 mm long, reaching to ± top of bracts; tepals subequal, elliptic, 16 × 4 mm. *Filaments* erect, ± 6 mm long; anthers held horizontally, 6–7 mm long, white; pollen white. *Style branches* ± 5 mm long, ascending, reaching to lower ⅓ anthers in closed flower. *Capsules* ± ovoid-elliptic, obtuse, smooth, 12–14 × 6–7 mm. *Seeds* ± 2 mm long, irregularly angled by pressure, with light brown, loose testa. *Flowering time*: September to mid-October.



Distribution and ecology: extending from high elevations in the Hantamsberg near Calvinia through the Roggeveld to Verlatekloof, Northern Cape, South Africa; in a seasonal marshes and seeps, often among dense *Bulbinella* vegetation.

Diagnosis: *Hesperantha palustris* is distinctive in the marshy habitat, unique for the genus, and also stands out in its tall stature, up to 480 mm high, the long, linear, soft-textured leaves, and the unusually lax spikes of only one to three flowers. The flowers are white with the outer tepals coloured grey-brown in the middle section and the tepals are narrowly elliptic, ± 16 × 4 mm. Flowers open after dark, 19:00 and appear unscented or at best weakly scented. The capsules are unusually large, up to 14 mm long. *Hesperantha palustris* is perhaps most closely related to the widespread *H. cucullata*, a shorter species with firm to almost leathery leaves and the outer tepals of the white flowers usually bright, glossy red outside, with the dark pigment usually covering the entire outer surface. Flowers of *H. cucullata* open well before sunset, mostly 16:00–16:30, and then produce a strong, sweet odour. The tepals are relatively broader than in *H. palustris*, usually 12–16 mm long and at least a third to nearly half as wide.

22. **Hesperantha truncatula** *Goldblatt* in Journal of South African Botany 53: 461 (1987). Type: South Africa, [Western Cape], northern foothills of Klein Swartberg Mtns, Farm Vleiland, 10 Sept. 1983, *J.H.J. Vlok 662* (NBG, holo.; MO, PRE, iso.).

Distribution of ***Hesperantha truncatula***.

Distribution of ***Hesperantha purpurea***.

Plants 100–160 mm high. *Corm* ± ovoid, 7–9 mm diam., asymmetric; tunics woody, imbricate, dark brown. *Stem* slender, unbranched, with short scale-like leaf in upper fourth. *Leaves* 3, lower 2 ± basal, blades plane, unusually short and ± obtuse, 12–20 × 4–8 mm, upper leaf sheathing lower ½–⅔ of stem, 40–80 mm long, slightly inflated. *Spike* 1- to 5-flowered; bracts green below, pale and membranous distally, 8–12 mm long. *Flowers* crepuscular, ± rotate, pale blue-purple, pale in throat and tube, outer tepals with broad purple streak on reverse; perianth tube straight, ± 7 mm long, cylindric, wider near apex; tepals subequal, narrowly ovate, 11–13 × ± 5 mm, spreading. *Filaments* weakly diverging, ± 3 mm long; anthers 5.5–6.0 mm long, ?yellow; pollen ?yellow. *Style branches* ± 7 mm long, ascending, ultimately reaching to ± middle of anthers in closed flower. *Flowering time*: September and probably also late August.

Distribution and ecology: a narrow endemic of the northern foothills of the Klein Swartberg in Western Cape, South Africa; occurring on south-facing clay slopes and currently known only from the Farm Vleiland.

Diagnosis: *Hesperantha truncatula* is distinguished by its unusually short, relatively broad basal leaves with blades no more than 20 mm long and up to 8 mm wide. The upper, cauline leaf is slightly inflated, up to 80 mm long and sheaths the stem for its entire length. The stem also bears a short, scale-like bract shortly below the spike, a feature of *H. pilosa* and several related species, all of which differ from *H. truncatula* in their longer leaves, usually hairy or ciliate. The flowers, typical of the genus, have a relatively short perianth tube ± 7 mm long and tepals 1.5× as long as the tube. The pale blue-purple flowers are crepuscular, opening in the late afternoon and closing after dark.

23. **Hesperantha purpurea** *Goldblatt* in Journal of South African Botany 50: 85 (1984). Type: South Africa, [Northern Cape], Farm Perdekraal, NW of Calvinia, 12 Sept. 1981, *P. Goldblatt 6246* (MO, holo.; K, NBG, PRE, S, iso.).

Plants 80–250 mm high. *Corm* ± globose, 8–12 mm diam., asymmetric with oblique flat side; tunics woody, imbricate, dark brown, outer layers V-notched on lower margins. *Stem* slender, simple or 1-branched from near base. *Leaves* 4 or 5, all ± basal or uppermost cauline, blades plane, ± falcate, ± half as long as stem, 7–10 mm wide, uppermost leaf sheathing lower ⅓ of stem. *Spike* 1- to 3-flowered; bracts green, 15–20 mm long. *Flowers* diurnal, salver-shaped, dark red-purple, darker purple at bases of tepals, white in throat; perianth tube straight, ± 20 mm long, cylindric, wider near apex; tepals subequal, elliptic, 16–20 × 5–7 mm, spreading. *Filaments* suberect, ± 1.7 mm long; anthers 5–6 mm long, purple; pollen purple. *Style branches* 10–14 mm long, spreading, exceeding anthers in closed flower. *Capsules* ovoid-oblong, 10–14 mm long. *Seeds* unknown. *Chromosome number* 2*n* = 26 (also 39). *Flowering time*: August to mid-September.

Distribution and ecology: poorly documented and known for certain only from the farm Perdekraal, northwest of Calvinia in Northern Cape, South Africa; on dolerite outcrops in heavy red clay.

Diagnosis: *Hesperantha purpurea* is readily recognised by the red-purple flowers, the lower tepals with even darker markings, and slender perianth tube ± 20 mm long. The relatively large asymmetric corms with overlapping tunics suggest a relationship with *H. cucullata*. The flowers have the typical adaptations for pollination by long-proboscid *Prosoeca* flies.

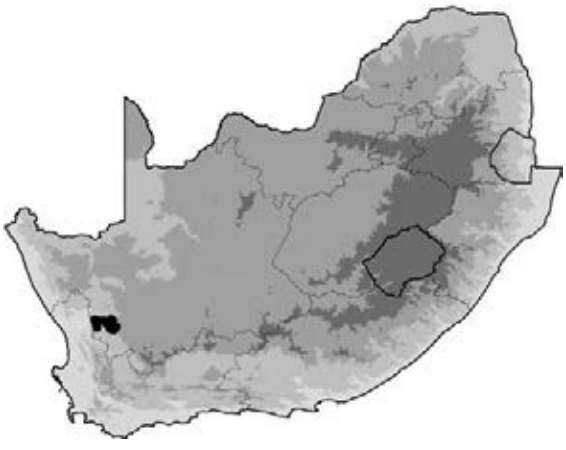
24. **Hesperantha vaginata** *(Sweet) Goldblatt* in Journal of South African Botany 36: 298 (1970); Goldblatt: 72 (1984). *Geissorhiza vaginata* Sweet: t. 138 (1836). Type: South Africa, without precise locality, Sweet: t. 138 (1836).

Hesperantha metelerkampiae L.Bolus: 114 (1927). Type: South Africa, [Northern Cape], near Nieuwoudtville, *Metelerkamp s.n.* (BOL 18555, holo.).

Hesperantha stanfordiae L.Bolus: 282 (1931b). *Hesperantha inflexa* var. *stanfordiae* (L.Bolus)

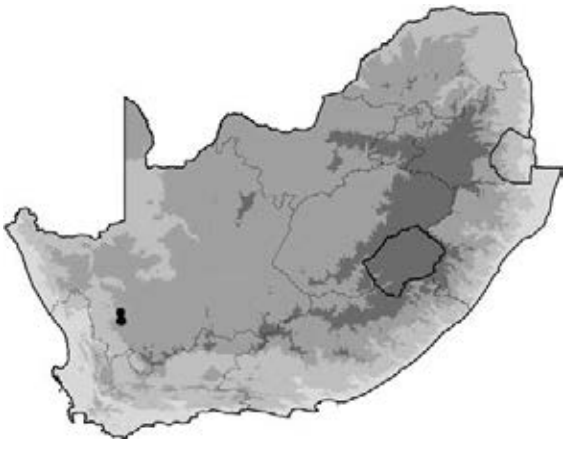
R.C.Foster: 17 (1948). Type: South Africa, [Northern Cape], near Nieuwoudtville, ex hort. Stanford, *Buhr. s.n.* (BOL [*BOL 19980*], lecto., designated by Goldblatt: 76 (1984); K, S, isolecto.).

Plants (50–)120–180 mm high. *Corm* ± globose, 10–14 mm diam., asymmetric with oblique flat side; tunics woody, imbricate, dark brown, outer layers V-notched on lower margins. *Stem* simple or 1- or 2(3)-branched from near base. *Leaves* 4 or 5, all ± basal or uppermost cauline, blades plane, ± falcate, ± half as long as stem, 7–10 mm wide, uppermost leaf sheathing lower ⅓ of stem. *Spike* 1- to 3-flowered; bracts green, 15–20 mm long. *Flowers* diurnal, rotate, yellow, usually with large ± black centre and dark brown on upper ⅓ of outer or all tepals, rarely uniformly yellow; perianth tube funnel-shaped, 5–8 mm long; tepals subequal, obovate-elliptic, 30–35 × 12–17 mm, widely cupped. *Filaments* suberect, ± 3 mm long; anthers 11–15 mm long, yellow; pollen yellow. *Style branches* ± 6 mm long, diverging, reaching ± middle of anthers in closed flower. *Capsules* ovoid-oblong, 9–10 mm long. *Seeds* softly angular, yellow-brown. *Chromosome number* 2*n* = 26. *Flowering time*: mid-August to mid-September.



Distribution and ecology: fairly widespread in the Bokkeveld Mtns and Plateau in Northern Cape, South Africa, from near Nieuwoudtville in the west to the slopes of the Hantamsberg at Calvinia in the east, to near Loeriesfontein in the north and to the south on the Keiskie Mtns and Driefontein-se-Berg; mostly on dolerite-derived red clay and among dolerite rocks, occasionally on sandy ground in the west of its range.

Diagnosis: *Hesperantha vaginata* is immediately recognised by the large yellow, cup-shaped flowers, in most populations strikingly marked with large brown markings on the tepals. Occasional populations are known with uniformly yellow flowers (matching the type of *H. stanfordiae*) or with both marked and unmarked flowers. The perianth tube is relatively short, 5–8 mm long, but the tepals, 30–35 × 12–17 mm, are among the largest in the genus. The tepals unfold in the early afternoon after 14:30 on warm sunny days and close about three hours later. Closely related *H. karooica* also has bright yellow flowers but never with contrasting markings, and the tepals are considerably smaller, ± 20 × 9–10 mm. Usually a smaller plant, *H. karooica* seldom exceeds 80 mm unless growing through bush, and has narrower leaves 3–4 mm wide vs. 7–10 mm in *H. vaginata*.

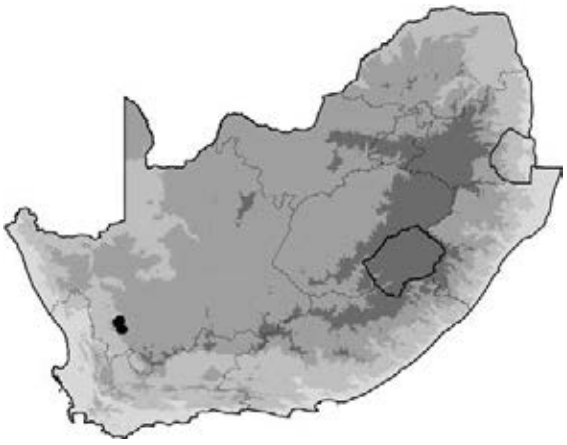


Hesperantha vaginata is the only species of the genus known to be pollinated exclusively by hopliine scarab beetles, Scarabaeidae: Hopliini. The unscented, yellow flowers are conspicuously patterned with chocolate-brown markings in most populations. In the Nieuwoudtville area, flowers are visited by *Clania glenlyonensis* beetles, which use the flowers as sites for assembly, mate selection, and copulation, but they also consume pollen, which does not seem to affect the reproductive success of the species as ample seeds are produced.

25. **Hesperantha karooica** *Goldblatt* in Journal of South African Botany 50: 79 (1984). Type: South Africa, Northern Cape, Calvinia, foot of the Hantamsberg, 25 Aug. 1968, *F.J. Stayner s.n.* (NBG 87606, holo.; NBG, iso.).

Plants 35–100(–160) mm high. *Corm* ± globose, 10–14 mm diam., asymmetric with oblique flat side; tunics woody, imbricate, dark brown, outer layers V-notched on lower margins. *Stem* simple or 1- or 2-branched from near base. *Leaves* 3 or 4, all ± basal or uppermost cauline and largely sheathing, blades plane, ± falcate, ± ½ as long as stem, 3–4 mm wide. *Spike* 1- or 2-flowered; bracts green, becoming pale and membranous above, 12–15 mm long. *Flowers* diurnal, rotate, yellow, outer tepals shaded brown outside; perianth tube funnel-shaped, 5–7 mm long; tepals subequal, obovate-elliptic, ± 20 × 9–10 mm, widely cupped. *Filaments* suberect, ± 3 mm long; anthers 9–10 mm long, yellow; pollen yellow. *Style branches* ± 9 mm long, diverging, reaching ± middle of anthers in closed flower. *Flowering time*: mid-August (to early September).

Distribution of ***Hesperantha vaginata***.



Distribution of ***Hesperantha karooica***.

Distribution and ecology: restricted to base of the Hantamsberg near Calvinia in Northern Cape, South Africa, recorded south and east of the range; in heavy red clay usually among dolerite rocks.

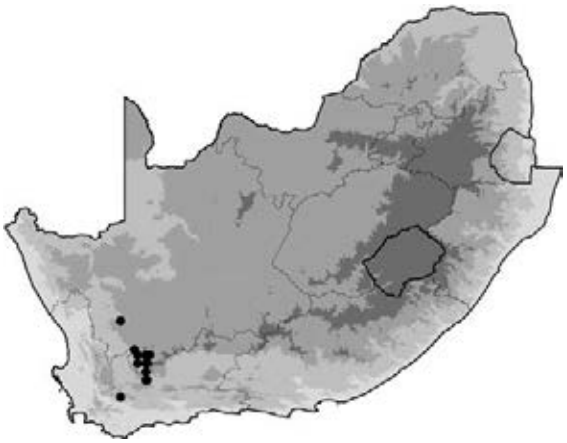
Diagnosis: still incompletely known, *Hesperantha karooica* is distinguished by the large, ± globose corm with overlapping tunics, a low stature, seldom exceeding 80 mm in open sites, narrow leaves, 3–4 mm wide, and relatively large, uniformly yellow flowers, with tepals ± 20 × 9–10 mm. The general appearance and yellow flowers recall *H. vaginata*, also restricted to the Calvinia District, but this taller species has broader leaves, 7–10 mm wide, and the flowers usually have large, dark brown makings on larger tepals, 30–35 × 12–17 mm.

26. **Hesperantha hantamensis** *Schltr. ex R.C.Foster* in Contributions from the Gray Herbarium of Harvard University 166: 15 (1948); Goldblatt: 84 (1984). Type: South Africa, [Northern Cape], Calvinia, dolerite hills, Aug. 1921, *R. Marloth 10262* (B, holo.; NBG, PRE, iso.).

Plants ± acaulescent, up to 60 mm high. *Corm* ± ovoid, 12–15 mm diam., asymmetric with oblique flat base; tunics woody, imbricate, dark brown, outer layers V-notched on lower margins. *Stem* rarely emerging above ground, simple or with one branch from near base, sheathing cataphyll often brown above ground. *Leaves* 3 or 4, all ± basal, plane, ± falcate, 20–40 × 5–6 mm. *Spike* 1- to 3-flowered; outer bract green, leaf-like, folded in midline, 15–25 mm long. *Flowers* crepuscular, salver-shaped, white, outer tepals shaded purple-brown outside, evidently odourless; perianth tube cylindric, filiform, 14–20 mm long, widening near apex; tepals subequal, ± elliptic, 8–12 × 4–5 mm, spreading. *Filaments* suberect, 3–5 mm long; anthers 5–6 mm long, held horizontally over tepals, white; pollen white. *Style branches* ± 9 mm long, spreading over tepals, slightly exceeding anthers in closed flower. *Capsules* ellipsoid, often flushed dull red, ± 12 mm long. *Seeds* softly angular, dull yellow. *Flowering time*: July to early August.

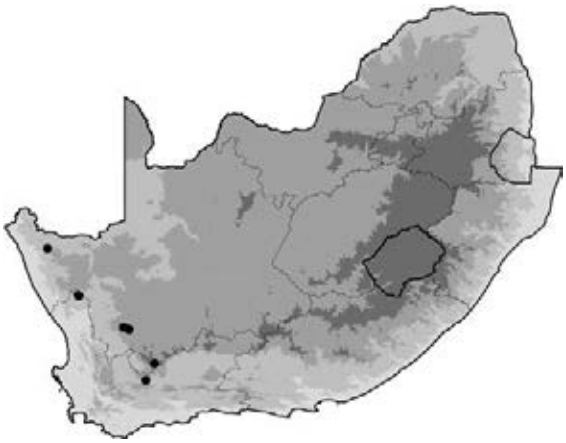
Distribution of ***Hesperantha hantamensis***.

Distribution and ecology: evidently a very narrow endemic, known from the southern and eastern foot and lower slopes of the Hantamsberg and the adjacent Keiskieberge near Calvinia, Northern Cape, South Africa; usually on heavy red clay on stony flats or along washes.



Diagnosis: one of three closely allied acaulescent species of the western Karoo, *Hesperantha hantamensis* has white flowers with a slender perianth tube 14–20 mm long and spreading tepals 8–12 mm long. The flowers are crepuscular, opening in the late afternoon, 16:30 and strongly fragrant, closing after dark. Related *H. flava* has larger, yellow flowers and *H. humilis* even larger, pink to rose flowers with a dark throat.

27. **Hesperantha humilis** *Baker* in Journal of Botany, British and foreign 14: 239 (1876a); Goldblatt: 80 (1984). Type: South Africa, [Northern Cape], Roggeveld near Jakkalsfontein, 7 Aug. 1811, *W.J. Burchell 1320* (K, holo.).



Plants mostly subacaulescent, 30–80 mm high. *Corm* ± obovoid, 12–16 mm diam., asymmetric with oblique flat side; tunics woody, imbricate, dark brown, outer layers V-notched on lower margins. *Stem* rarely emerging more than 20 mm above ground, simple or with one branch from near base, sheathing cataphyll often turning brown above ground. *Leaves* (2)3, all ± basal, plane, ± falcate, 20–70 × 6–8 mm. *Spike* 1- or 2(3)-flowered; bracts dimorphic, outer leaf-like, green, 20–30 mm long, inner ± half as long, concealed, membranous. *Flowers* diurnal, salver-shaped, pink, dark in throat, sometimes dark red at base of tepals, shaded dull red outside, unscented (when dry inner tepals often paler than outer); perianth tube cylindric, 17–24 mm long, occluded below by the style; tepals subequal, obovate-elliptic, 17–25 × 8–11 mm, spreading. *Filaments* suberect, 3–4 mm long; anthers 4.5–8.0 mm long, held horizontally over tepals, usually red-brown; pollen red-brown. *Style branches* 10–12 mm long, spreading over tepals. *Capsules* ellipsoid, 15–20 mm long. *Seeds* softly angular, dull yellow. *Chromosome number* $2n = 26$. *Flowering time*: July to August (to early September at higher elevations).

Distribution and ecology: extending from the slopes of the Hantamsberg at Calvinia through the Roggeveld in the western Karoo, Northern Cape, South Africa, to the high country between Whitehill and the Rooihoogte north of Koo in Western Cape; in rocky sites with thin soil, often in dolerite outcrops.

Diagnosis: *Hesperantha humilis* is readily recognised by the ± acaulescent habit and 1- to 3-flowered spike of deep pink flowers with an elongate perianth tube up to 24 mm long. The flowers are relatively large with tepals 17–25 mm long, the open flower thus up to 50 mm diam. As in other species of the genus with a similarly coloured perianth, the flowers are open during the day and close in the mid- to late afternoon. The long perianth tube suggests that the flowers are adapted for pollination by a

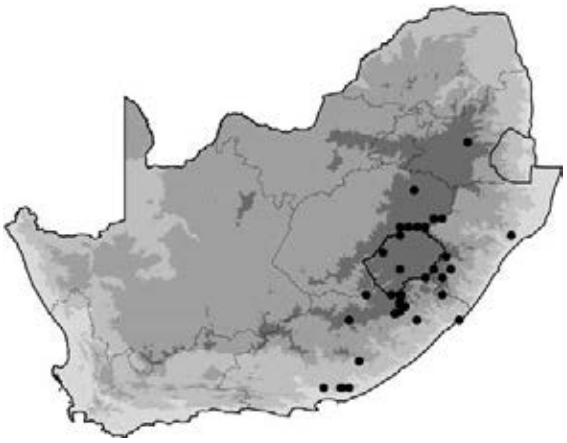
Distribution of ***Hesperantha humilis***.

Distribution of ***Hesperantha flava***.

long-tongued insect but the tube is very slender with the walls tightly clasping the style, leaving no room for an insect's tongue. The small quantity of nectar produced is forced into the top of the tube and is accessible to insect visitors, mostly large bees, with mouth parts no more than 5 mm long.

28. **Hesperantha flava** *G.J.Lewis* in South African Gardening and Country Life 23: 255 (1933); Goldblatt: 82 (1984). Type: South Africa, [Western Cape], Whitehill, 31 July 1937, *R.H. Compton 4276* (BOL, lecto., designated by Goldblatt: 82 (1984); K, isolecto.).

Plants mostly acaulescent, up to 60 mm high, including flowers. *Corm* ± ovoid, 12–15 mm diam., asymmetric with oblique flat side; tunics woody, imbricate, dark brown, outer layers V-notched on lower margins. *Stem* rarely emerging up to 12 mm above ground, unbranched. *Leaves* usually 2(3), basal, plane, ± falcate, obtuse at apex, lowermost 25–40 × 4–10 mm, upper 10–20 mm long. *Spike* 1- or 2-flowered; bracts dimorphic, outer leaf-like, green, 15–20 mm long, inner ± as long, concealed, membranous. *Flowers* crepuscular, salver-shaped, yellow, outer tepals dark brown outside, sweetly scented; perianth tube cylindric, 18–28 mm long; tepals subequal, obovate-elliptic, spreading, outer 13–15 × 5–8 mm, inner 1–2 mm shorter. *Filaments* suberect, ± 3 mm long; anthers 5–7 mm long, held horizontally, usually yellow; pollen yellow. *Style branches* 4–8 mm long, ascending. *Capsules* ellipsoid, 15–25 mm long. *Seeds* softly angular, dull yellow. *Chromosome number* 2*n* = 26. *Flowering time*: July to August.



Distribution and ecology: extending from northern Namaqualand and the margins of the western Karoo in Northern Cape, South Africa to the Laingsburg Karoo in Western Cape near Matjiesfontein, in a narrow band along the interior edge of the winter-rainfall zone; occurring mostly on clay soils.

Diagnosis: *Hesperantha flava* is readily recognised by the acaulescent habit and long-tubed, yellow flowers that open in the late afternoon. The flowers are relatively large with a perianth tube 18–28 mm long and outer tepals mostly 13–15 mm long. The large corms with overlapping tunics and the acaulescent habit are shared with *H. hantamensis* and *H. humilis*, both western Karoo species, the former having white flowers and the latter larger, pink to rose flowers. Vegetatively they are difficult to distinguish from one another but flower size, colour and phenology differ in all three.

29. **Hesperantha candida** *Baker*, Handbook of the Irideae: 151 (1892); Goldblatt: 410 (2003). Type: South Africa, [Free State], 1861, *Cooper 746* (K, holo.; E, G, NH, PRE, Z, iso.).

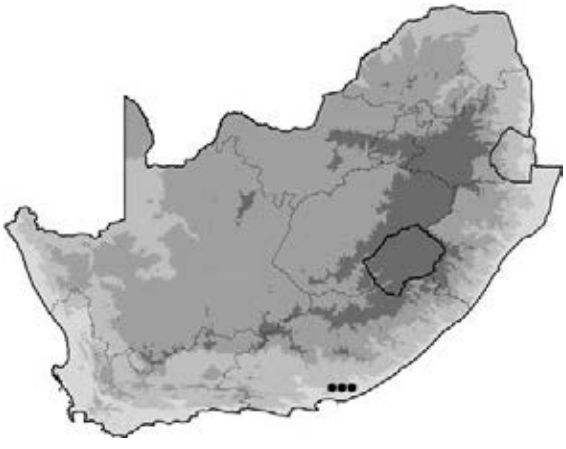
Hesperantha vernalis Hilliard & B.L.Burtt: 279 (1982); Hilliard & Burtt: 423 (1986). Type: South Africa, [KwaZulu-Natal], Estcourt, S side of Kamberg, 9 Sept. 1973, *F.B. Wright 1530* (E, holo.; MO, NU, iso.).

Plants 40–150(–300) mm high. *Corm* ovoid, slightly asymmetric, ± 10 mm diam.; tunics dark brown, ± concentric, splitting below into sections. *Stem* simple or branched from near base, weak, often curved. *Leaves* usually 4, lower 2 basal, third subbasal and uppermost short, entirely sheathing stem, blades lanceolate to ± ovate, usually ± as long as stem, sword-shaped to ± linear or falcate, mostly (2–)3–6 mm wide, leathery, main vein and margins thickened, often dry and broken (or burned) at flowering. *Spike* (1–)3- to 6-flowered; outer bract green, 8–18 mm long, inner bract partly membranous. *Flowers* diurnal, ± salver-shaped, pale pink, pale lilac or white, outer tepals flushed brown to greenish purple outside; scent not recorded; perianth tube cylindric, widening near mouth, mostly 7–12(–14) mm long; tepals mostly 15–20 mm long, elliptic, spreading. *Filaments* ± erect, ± 3 mm long; anthers 5.0–7.5 mm long, ?white; pollen ?white. *Style branches* spreading. *Capsules* oblong-ellipsoid, 7–10 mm long. *Seeds* light brown, softly angular, with loose testa. *Flowering time*: mostly August to October.

Distribution of ***Hesperantha candida***.

Distribution and ecology: with a relatively wide distribution in South Africa, extending from near Carolina in southern Mpumalanga through eastern Free State and adjacent KwaZulu-Natal to the Eastern Cape near Grahamstown and in Lesotho; in grassland, often stony sites.

Diagnosis: *Hesperantha candida* is recognised by the moderate-sized to fairly large usually pink to mauve-pink but occasionally white flowers with tepals mostly 15–20 mm long, perianth tube 7–12(–14) mm long, and anthers 5.0–7.5 mm long. At flowering time in late winter or early spring the leaves are sometimes dry at the tips or scorched by veld fires. The flowering time is important in distinguishing the species, although the somewhat fleshy leaves, often with obtuse tips, aid identification. *Hesperantha candida* is separated from the late winter–spring-blooming *H. longituba* by its shorter perianth tube and diurnal flowers. In *H. longituba* the perianth tube is 14–22 mm long and the apparently consistently white flowers are crepuscular. The leaves of *H. candida* are typically sword-shaped with a raised main vein and margins and an otherwise smooth surface but some collections from Eastern Cape have oblong to nearly ovate leaves that appear to lack thickened margins, whereas other collections from the area are intermediate, having the lowermost leaf sword-shaped and the other basal leaves oblong, leaving no doubt that broader-leaved plants are *H. candida*. Whatever the shape of the leaves, the surface between the margins and midrib is always plane and smooth, with secondary veins not visibly thickened. Plants from Grahamstown, at the southwestern extremity of the range, have the smallest flowers in the species, tepals ± 12 × 6 mm, and some specimens from there also have more flowers per spike than recorded elsewhere. They have 4 to 6 flowers per spike instead of the more usual 1 to 3 in populations further north. These plants are puzzling but more likely represent a southern and lower elevation morph of *H. candida* than an undescribed species.



The name *Hesperantha candida* has been mistakenly associated with the narrow-leaved but summer-blooming *H. leucantha*. This fairly slender, pale pink–mauve-flowered species of the Drakensberg and nearby has, like *H. candida*, diurnal but generally smaller flowers, with tepals 12–15 × 3–5 mm long and anthers 4.5–5.5 mm long, whereas those of *H. candida* have tepals mostly 15–20 × 6–9 mm and anthers 5.0–7.5 mm long. Leaves of *H. leucantha* are usually quite slender, mostly 1.5–2.5 mm wide, with only lightly thickened midribs and margins.

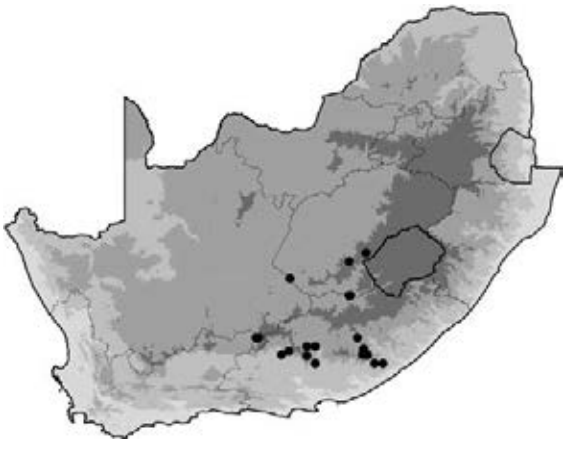
30. **Hesperantha debilis** *Goldblatt* in Annals of the Missouri Botanical Garden 90: 411 (2003). Type: South Africa, [Eastern Cape], Grahamstown Nature Reserve, W of Dassie Krantz, Oct. 1951, *A.R.H. Martin s.n. as RUH 9554* (GRA, holo.).

Plants 100–150 mm high. *Corm* ovoid, 4–5 mm diam.; tunics woody, concentric. *Stem* smooth, slender, usually branched at uppermost node, sometimes at next node below. *Leaves* 4, lower 2 basal, linear, third partly sheathing, free in upper half, uppermost largely sheathing, 15–20 mm long, inserted in upper ⅓ of stem, blades 1–2 mm wide, margins and midrib lightly thickened. *Spike* 1- or 2-flowered; bracts 8–11 mm long, green or flushed purplish, margins and apices membranous. *Flowers* ?crepuscular, rotate, white, outer tepals flushed red outside, scent unknown; perianth tube cylindric, expanded near apex, 4–6 mm long; tepals subequal, elliptic, spreading, 12–14 × ± 5 mm. *Filaments* 2.5–3.0 mm long; anthers ± 5 mm long, ?yellow; pollen ?yellow. *Style branches* ± 10 mm long, spreading, exceeding anthers by up to 2 mm in closed flower. *Capsules* globose, ± 3 mm long. *Seeds* unknown. *Flowering time*: October.

Distribution and ecology: restricted to the Suurberg and Grahamstown area of Eastern Cape, South Africa; occurring on sandy slopes.

Diagnosis: a slender, rather delicate plant, *Hesperantha debilis* is recognised by the small corms 4–5 mm diam., soft-textured, linear leaves 1–2 mm wide, and a slender, branched stem bearing one or two flowers per branch.

Distribution of ***Hesperantha debilis***.



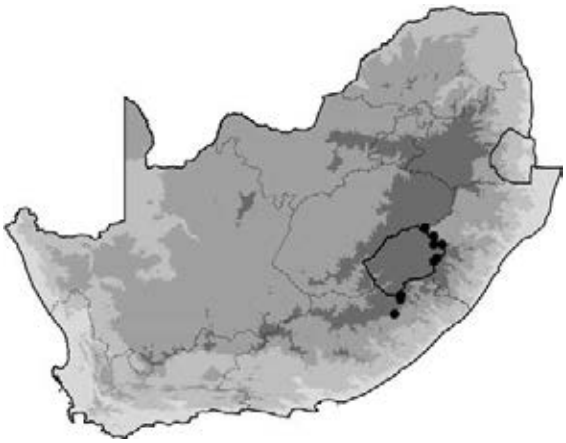
The white flowers have a short, straight perianth tube 4–5 mm long, and spreading tepals 12–14 mm long, thus more than twice as long as the tube. The relationships of *H. debilis* are uncertain.

31. **Hesperantha longituba** *(Klatt) Baker* in The Gardeners' Chronicle 7: 652 (1877); Goldblatt: 69 (1984). *Geissorhiza longituba* Klatt: 383 (1867). Type: South Africa, [Eastern Cape], Somerset East, date unknown, *J.H. Bowker s.n.* (K, lecto., designated by Goldblatt: 69 (1984); K, S, isolecto.).

Hesperantha candida var. *bicolor* Baker: 63 (1896). *H. bicolor* (Baker) R.C.Foster: 5 (1948). Type: South Africa, [Eastern Cape], Somerset East, Boschberg, *P. MacOwan s.n.* (K, lecto., designated by Foster: 5 (1948); BOL, G, GRA, M, WU, Z, isolecto.).

Plants (60–)150–300 mm high. *Corm* ± ovoid, 10–18 mm diam.; tunics of dark brown, overlapping fibres notched below into sections. *Stem* simple or 1-branched from near base, sometimes with a short, sheathing bract-like leaf in upper half. *Leaves* 3 or 4, all basal or uppermost inserted in lower ⅓ of stem and sheathing part of stem, blades ± lanceolate, reaching to ± base of spike, (3–)5–9 mm wide, leathery, often dry or torn distally, margins slightly raised, hyaline when dry. *Spike* lightly flexuose, (1)2- to 6-flowered; outer bract green, 12–20(–30) mm long, inner bract ± membranous, shorter than outer. *Flowers* crepuscular, salver-shaped, white, outer tepals flushed pink to red or brown outside, sweetly scented; perianth tube mostly 14–22 mm long; tepals elliptic, spreading, 15–22 × 8–10 mm. *Filaments* 5–8 mm long; anthers 8–12 mm long, ?white; pollen ?white. *Style branches* 12–16 mm long, spreading, reaching to near anther tips in closed flower. *Capsules* ovoid-elliptic, ± 8 mm long. *Seeds* unknown. *Flowering time*: (mid-July) August and September.

Distribution and ecology: largely a species of the southern Karoo and adjacent interior mountains of Eastern Cape, South Africa, extending from Somerset East, Murraysburg and Graaff-Reinet eastward to Grahamstown and into western Free State and as far north as De Aar in Northern Cape; flowering in spring in rocky grassland when the veld is usually dry.



Distribution of ***Hesperantha longituba***.

Diagnosis: recognised by the relatively large white flowers that open in the late afternoon and close after dark, *Hesperantha longituba* has tepals 15–22 mm long and a perianth tube usually 14–22 mm long. The leaves are broad and leathery with prominent, raised margins and midrib. The large corms, up to 18 mm diam., have overlapping tunics notched into segments below, like those of several western Karoo species, including *H. cucullata, H. humilis* and *H. vaginata* and on this basis *H. longituba* appears allied to these species rather than to those of eastern southern Africa.

Hesperantha longituba is sometimes confused with a second spring-flowering species from eastern southern Africa, *H. candida*, and has at times been included in that species. The two differ mainly in the length of the perianth tube, mostly 14–22 mm long in *H. longituba* vs. 10–12 mm long in *H. candida*. The flowers of the latter, as far as are known, are diurnal (confirmed by notes on some herbarium collections) whereas those of *H. longituba* are crepuscular. Plants from the Aliwal North and Stutterheim areas of Eastern Cape are intermediate in perianth tube length and make the distinction between the two species sometimes seem arbitrary but those from further west, at Cradock, Somerset East, and Graaff-Reinet always have a longer perianth tube, up to or even exceeding 22 mm.

32. **Hesperantha schelpeana** *Hilliard & B.L.Burtt* in Notes from the Royal Botanic Garden, Edinburgh 37: 302 (1979); Hilliard & Burtt: 434 (1986). Type: Lesotho, Black Mtns between Sani and Mokhotlong, 5 Nov. 1973, *Hilliard & Burtt 7075* (E, holo.; NU, iso.).

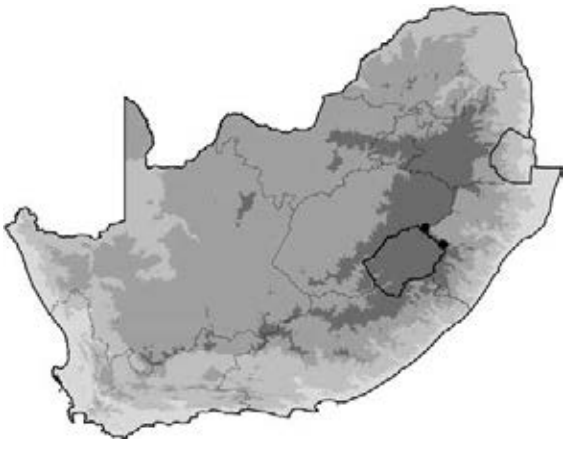
Plants 40–150 mm high, acaulescent, flowering without leaves. *Corm* ovoid-oblong, 10–15 mm diam.; tunics of relatively soft, brown, overlapping layers splitting above into slender cusps and below into segments. *Stem* underground, unbranched, sheathed. *Leaves* of flowering stem dry and often broken or lacking, foliage leaves produced after flowering on separate shoot, ultimately 2 or 3, basal leaf or leaves solitary or 2, falcate, ultimately 80–100 × 2–3 mm, probably centric and oval in section when alive, when dry main vein and margins appearing thickened, uppermost leaf entirely sheathing or with short unifacial tip. *Spike* 1- or 2(3)-flowered; bracts 10–22 mm long, green, often flushed purple. *Flowers* diurnal, salver-shaped, white to pink with dark throat, outer tepals sometimes tipped purple, feathered to uniformly red-purple to brown outside; perianth tube 5–10 mm long, narrowly funnel-shaped; tepals spreading, elliptic-ovate, 14–22 × 6–8 mm. *Filaments* erect, ± 1.5–3.0 mm long; anthers diverging, 6–8 mm long, yellow; pollen yellow. *Style branches* reaching to tips of anthers in closed flower. *Capsules* ovoid-oblong, 6–8 × 4–6 mm. *Seeds* flattened,

Distribution of ***Hesperantha schelpeana***.

narrowly winged, ± 2 × 1 mm. *Flowering time*: late September to mid-November.

Distribution and ecology: occurring in Lesotho and in South Africa in Eastern Cape, Free State and KwaZulu-Natal; in open places in wet turf and stony ground at higher elevations in the Drakensberg.

Diagnosis: *Crocus*-like *Hesperantha schelpeana* typically flowers on a short stem, the leaves of which are dry or absent, and is distinguished in addition by the short-tubed, relatively small flowers that appear in dry grassland. The perianth tube is up to 10 mm long and the tepals 14–22 mm long, thus ± twice as long as the tube. The flowers are usually white or pale pink with the outer tepals feathered red-purple outside but plants from The Sentinel on the Free State–Lesotho Border in the Drakensberg, at the northern limit of the species, have pink flowers, shading darker at the tips of the tepals and with the throat dark brown, providing a stark contrast to the deep yellow anthers and pollen. The reverse of the outer tepals is so strongly feathered with brown as to appear nearly uniformly pigmented.



New, green leaves are sometimes emergent at flowering, usually two in number and produced on a shoot separate from the flowers. The leaf blades are solid and oval in cross section when alive but appear flat with a prominent main vein when dry. The occasional presence of leaves at flowering time makes it possible to confuse *Hesperantha schelpeana* with *H. candida*, which flowers at the same time of year and has living, green leaves present on the flowering stem (unless destroyed by fire or grazing). Properly developed plants of *H. candida* have four leaves, two basal, a third subbasal and partly sheathing, and a short, sheathing leaf in the upper part of the stem. *Hesperantha schelpeana*, however, never has more than three leaves, the lowermost slender and exceeding the stem (when still present at flowering and then dry), the second much shorter, often largely sheathing, and a third, short, sheathing leaf usually present on the upper part of the stem. The leaf blades also differ, those of *H. candida* fairly broad and plane with thickened and raised margins and midrib.

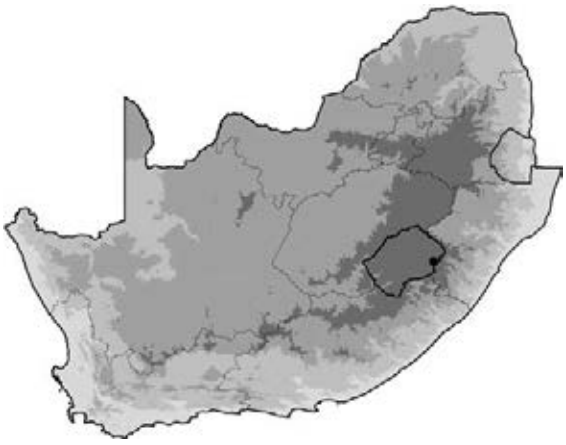
33. **Hesperantha altimontana** *Goldblatt* in Annals of the Missouri Botanical Garden 90: 414 (2003). Type: South Africa, [Free State], Drakensberg Mtns, The Sentinel, ± 2 500 m, 10 Oct. 1979, *G. Cubitt s.n.* (NBG, holo.).

Plants acaulescent, 100–120 mm high, flowering before leaves emerge. *Corm* ± globose, 10–15 mm diam.; tunics of relatively soft, imbricate layers. *Stem* unbranched, at flowering foliage leaves dry or lacking. *Leaves* (of the flowering stem) 2, entirely sheathing, 25–35 mm long; green foliage leaf produced later in season, solitary, falcate, 60–80 mm long, 3–4 mm wide, leathery, main vein hyaline but not raised when alive. *Spike* 1-flowered; bracts ± 20 mm long, green, flushed with purple, inner slightly shorter than outer. *Flowers* salver-shaped, uniformly creamy white, shading to pale yellow both inside and outside tube; perianth tube 20–27 mm long, cylindric, expanded near mouth; tepals spreading, elliptic-ovate, 20–23 × 9–10 mm, subacute. *Filaments* erect, ± 3 mm long; anthers diverging, ± 10 mm long, yellow; pollen yellow. *Style branches* ± 10 mm long, reaching to upper ⅓ of anthers in closed flower. *Flowering time*: October.

Distribution and ecology: occurring in Lesotho and in South Africa in Free State and KwaZulu-Natal; on stony, open ground in the high Drakensberg.

Diagnosis: *Hesperantha altimontana* is evidently allied to the two other southern African Drakensberg species that flower early in the season at which time the foliage leaves are dry or withered, with the new season's leaves appearing on separate shoots later in the year, *Hesperantha crocopsis* and *H. schelpeana*. It is most like *H. schelpeana* in its fairly large flowers but differs in having a perianth tube 20–27 mm long and uniformly creamy white perianth, whereas *H. schelpeana* has whitish or pink flowers with the outer tepals flushed to uniformly darker pink to purple on the outside, and a perianth tube 5–10 mm long. *Hesperantha crocopsis* has smaller flowers, the tepals only 6–7 mm long but a perianth tube 9–14 mm

Distribution of ***Hesperantha altimontana***.



long, and like *H. schelpeana*, the outer tepals are red to purple on the outside. Foliage leaves are lacking on flowering specimens, but plants from ridges west of Thaba Ntlenyana in Lesotho that appear to be *H. altimontana* have a distinctive, falcate leaf with a plane blade like no other known member of the genus.

34. **Hesperantha crocopsis** *Hilliard & B.L.Burtt* in Notes from the Royal Botanic Garden, Edinburgh 37: 302 (1979); Hilliard & Burtt: 435 (1986). Type: Lesotho, Mokhotlong District, above Mashai Pass, 7 Nov. 1977, *O.M. Hilliard & B.L. Burtt 10489* (E, holo.; NU, iso.).

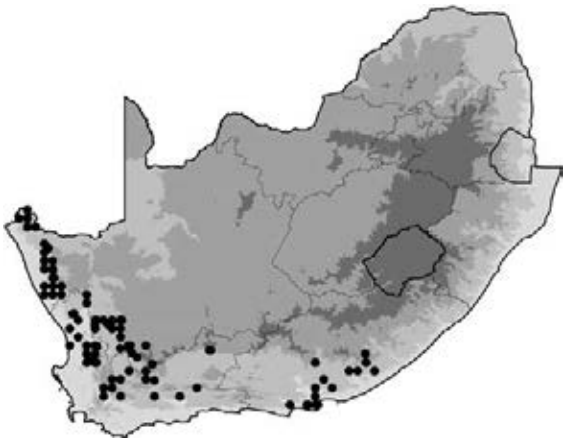
Plants acaulescent, up to 30 mm high at flowering, blooming with leaves emergent. *Corm* depressed-globose, ± 5 mm diam.; tunics papery, splitting above into narrow cusps and below into oblong sections. *Stem* unbranched, emerging above ground only in fruit, then up to 60 mm high, sheathed by membranous cataphylls, uppermost up to 55 mm long. *Leaves* 1 or 2, elongating after flowering, from separate shoot, blades linear, ultimately up to 70 × ± 1.5 mm; leaves of flowering stem dry and decayed at flowering. *Spike* 1(2)-flowered; bracts up to 5 mm long, united at base, membranous, hidden within cataphylls. *Flowers* diurnal, white with outer tepals pink to purple outside; perianth tube 9–14 mm long, cylindric, expanded near mouth; tepals spreading, elliptic-ovate, 6–7 × 2–3 mm. *Filaments* ± erect, 1.5–2.5 mm long; anthers diverging, 2.25–3.50 mm long, yellow. *Style branches* ± 4.5 mm long, reaching to lower ⅓ of anthers. *Capsules* oblong, ± 5 mm long. *Seeds* softly angular, ± 1.5 × 1 mm. *Flowering time*: November, probably also October.

Distribution and ecology: Lesotho and probably also adjacent Free State and KwaZulu-Natal in South Africa, in the high Drakensberg, 2 800–3 100 m; in stony, open sites on shallow ground in short, wet turf and silty streambanks.

Diagnosis: the *Crocus*-like *Hesperantha crocopsis* is one of three spring-blooming species of the genus from eastern southern Africa that have the flowers borne at ground level. It is distinguished by the small white flowers, the tepals 6–7 mm long and shorter than the perianth tube. The two leaves are emergent at flowering and are produced from a new shoot, ultimately reaching up to 70 mm long. Leaves of the short flowering stem are usually absent or represented by dry fragments attached to the stem. The two other species with this growth habit have considerably larger flowers with tepals 14–20 mm long in *H. schelpeana* and ± twice as long as the perianth tube, and tepals 20–23 mm long in *H. altimontana* and ± as long as the tube.

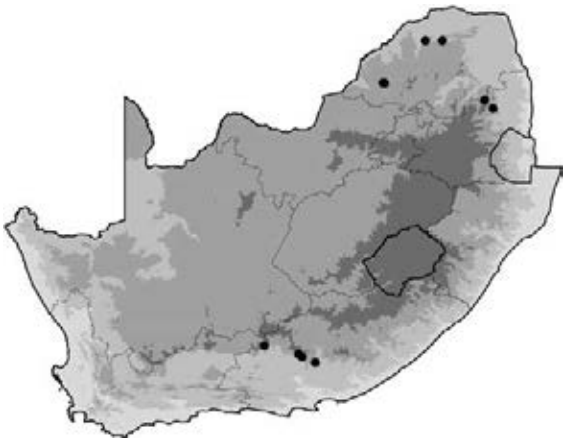
Distribution of ***Hesperantha crocopsis***.

35. **Hesperantha bachmannii** *Baker* in Bulletin de l'Herbier Boissier, sér. 2, 1: 863 (1901); Goldblatt: 90 (1984). Type: South Africa. [Western Cape], near Hopefield, Aug. 1885, *Bachmann 1177* (Z, lecto., effectively designated by Foster: 4 (1948) [not G as indicated elsewhere]; K, isolecto.).



[*Hesperantha virginea* Ker Gawl.: 225 (1804a), invalid name without description.]

[*Ixia virginea* Sol. ex Ker Gawl.: 225 (1804a), invalid name only in synonymy.]



Plants 150–300 mm high. *Corm* globose to ovoid, with flattened oblique base, 6–8 mm diam., bearing small cormlets at base; tunics woody, imbricate, splitting from base into sections. *Stem* simple or 1- or 2-branched from near base or aerial node. *Leaves* 3 or 4, lower 2 or 3 basal, with well-developed, soft-textured blades reaching to base of spike, plane, (2)3–7 mm wide, sword-shaped to falcate, upper leaf sheathing or unifacial distally, margins and main vein hardly thickened. *Spike* flexuose, mostly 3- to 7(–9)-flowered; bracts mostly 12–20 mm long, green with transparent margins. *Flowers* crepuscular, nodding to pendent, white, flushed red to purple outside, sweetly scented; perianth tube ± 10 mm long, cylindric, curved in upper half; tepals ovoid to elliptic, 14–20 × 5–8 mm, spreading to slightly reflexed. *Filaments* horizontal, 5–6 mm long; anthers 6–8 mm long, decumbent, yellow; pollen yellow. *Style branches* 7–8 mm long, reaching to upper ⅓ of anthers in closed flower. *Capsules* ± ovoid-oblong, ± 6 mm long. *Seeds* light brown, angular. *Chromosome number* 2*n* = 26. *Flowering time*: July to September, or in October in the east of its range and at higher elevations.

Distribution and ecology: widespread in South Africa, extending from the Richtersveld in Northern Cape though Western Cape to East London in Eastern Cape; most often on S-trending clay or clay loam slopes.

Diagnosis: the relatively common *Hesperantha bachmannii* is recognised by the unusually small corm, up to 8 mm diam., usually bearing several small cormlets at base, soft-textured leaves, and white flowers with a curved perianth tube ± 10 mm long. The flowers are thus nodding to almost pendent and have horizontally oriented stamens and nearly pendent style branches. Related

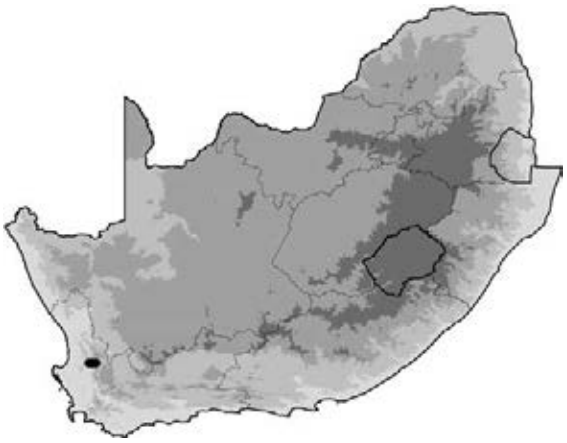
Distribution of ***Hesperantha bachmannii***.

Distribution of ***Hesperantha bulbifera***.

H. bulbifera has almost identical but somewhat to considerably larger flowers, with a perianth tube 9–15 mm long and tepals 16–20 mm long vs. tube ± 10 and tepals 14–20 mm long. In adition, *H. bulbifera* always has a conspicuous cormlet in some or all of the leaf axils, not present in *H. bachmannii*. The flowers produce a strong sweet fragrance when open after 16:00 or sometimes after 17:00.

36. **Hesperantha bulbifera** *Baker* in Journal of Botany, British and foreign 14: 183 (1876b); Goldblatt: 95 (1984). Type: South Africa, [Eastern Cape], Somerset East, Boschberg, Nov. 1876, *MacOwan 2215* (K, lecto., designated by Goldblatt: 95 (1984); BOL, G, K, PRE, WU).

Hesperantha sabiensis N.E.Br. ex R.C.Foster: 23 (1948). Type: South Africa, [Mpumalanga], Sabie, *Cunliffe s.n.* (K, lecto., designated by Goldblatt: 95 (1984); PRE, Z, isolecto.).



Plants 200–300 mm high. *Corm* globose with flattened oblique base, 8–10 mm diam.; tunics woody, imbricate, splitting from base into sections. *Stem* often inclined to trailing, simple or branched from axil of cauline leaf, bearing cormlets in some or all leaf axils. *Leaves* 3 to 5, lower 2 or 3 basal, with well-developed blades ± reaching spike apex, plane, sword-shaped to falcate, 3–7 mm wide, upper leaves cauline, sheathing or free and unifacial distally, soft-textured, margins and main vein hardly thickened. *Spike* flexuose, 2- to 6-flowered; bracts mostly 15–25(–30) mm long, green with transparent margins. *Flowers* evidently crepuscular, nodding to pendent, white, sweetly scented; perianth tube 9–15 mm long, cylindric, curved in upper half; tepals ovoid to elliptic, 16–20 × 5–8 mm, spreading to slightly reflexed. *Filaments* ± horizontal, 6–7 mm long; anthers ± 8 mm long, white; pollen white. *Style branches* 12–14 mm long, ± pendent, reaching close to anther tips. *Capsules* ± ovoid–oblong, 7–8 mm long. *Seeds* unknown. *Flowering time*: September and October in the south, May to July and October in the east and north of its range.

Distribution and ecology: with a widespread but scattered range in South Africa, recorded from the mountains above Somerset East in Eastern Cape to the Blouberg, Soutpansberg and Wolkberg in Limpopo; always in wet sites, usually on cliffs or near waterfalls.

Diagnosis: allied to the largely western southern African *Hesperantha bachmannii*, *H. bulbifera* has similar white flowers with curved perianth tube but these are somewhat larger, with a perianth tube 9–15 mm long and tepals 16–20 mm long vs. tube ± 10 mm long and tepals 14–20 mm long in *H. bachmannii*. In addition, *H. bulbifera* always has larger corms, 8–10 mm diam. vs. 6–8 mm, with a conspicuous cormlet in the lower leaf axils not present in *H. bachmannii*.

37. **Hesperantha pallescens** *Goldblatt* in Journal of South African Botany 50: 88 (1984). Type: South Africa, [Western Cape], below Piekenierskloof Pass, 3 Sept. 1980, *Goldblatt 5645* (MO, holo.; B, BOL, C, K, M, NBG, P, PRE, S, US, WAG, iso.).

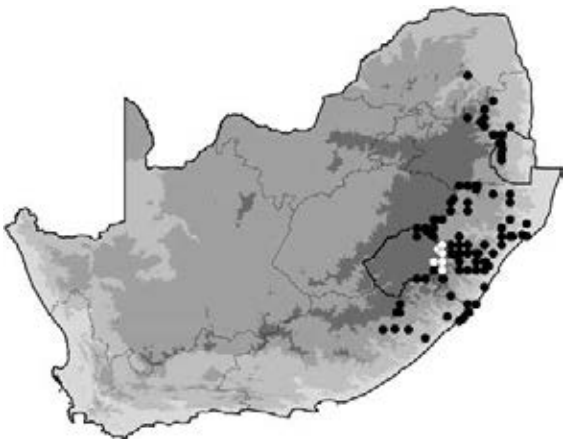
Plants 100–200 mm high. *Corm* globose to ovoid, with flattened oblique base, 3–6 mm diam., bearing small cormlets at base; tunics woody, imbricate, splitting from below into sections. *Stem* simple or 1- or 2-branched from axils of upper leaves. *Leaves* 4 or 5, lower 2 or 3 basal, with well-developed, soft-textured, ± flaccid blades reaching up to ± base of spike, plane, 2–3 mm wide, ± linear, upper 1 or 2 leaves cauline, uppermost largely sheathing, margins and main vein hardly thickened. *Spike* flexuose, mostly 2- to 4-flowered; bracts pale green, margins membranous, outer 12–16 mm long, inner slightly shorter. *Flowers* diurnal, salver-shaped, pale yellow, odourless; perianth tube (12–)16–22 mm long, cylindric, widening slightly above; tepals elliptic, 15–26 × ± 5.5 mm, slightly cupped. *Filaments* suberect, ± 5 mm long; anthers diverging, 5–6 mm long, yellow; pollen yellow. *Style branches* 10 mm long, ± spreading, reaching close to anther tips in closed flower. *Capsules* obovoid, ± 10 mm long. *Seeds* unknown. *Chromosome number* 2*n* = 26. *Flowering time*: August to mid-September.

Distribution of ***Hesperantha pallescens***.

Distribution and ecology: a narrow endemic, known only from the southwestern slopes of the Olifants River Mtns near Piekenierskloof Pass in Western Cape, South Africa; on clay banks and slopes in renosterveld.

Diagnosis: *Hesperantha pallescens* is distinguished by the pale yellow, diurnal flowers with a relatively long perianth tube mostly 16–22 mm long, and narrow tepals that remain slightly cupped even when fully open. The small corms, up to 6 mm diam. and with several small cormlets at the base, mostly closely resemble those of *H. bachmannii* and the two species also share soft-textured, slightly flaccid leaves. On this basis we consider them to be closely related. The crepuscular flowers of *H. bachmannii* are, however, very different, with white tepals and a curved perianth tube, thus facing toward the ground. The flowers of *H. pallescens* open shortly after 12:00 and close after 17:30, and have been found to be self-compatible, but pollination of the species remains to be studied.

38. **Hesperantha baurii** *Baker* in Journal of Botany, British and foreign 14: 182 (1876b); Hilliard & Burtt: 426 (1986). Type: South Africa. [Eastern Cape], Transkei, Baziya Mtn, Mar., *Baur 628* (K, holo.; BOL, iso.).



Plants mostly 150–500 mm high. *Corm* ± globose, slightly asymmetric with obliquely flattened side, 19–15 mm diam.; tunics woody, imbricate, splitting from base into truncate sections. *Stem* simple or sometimes branched from near base. *Leaves* usually 4, sometimes 5 or only 3, lower 2(3) basal, with well-developed blades reaching up to base of spike, (3)4–7 mm wide, sword-shaped to falcate, margins and main vein visibly thickened; upper 2 leaves cauline and largely or completely sheathing. *Spike* flexuose, mostly 3- to 12(–18)-flowered; bracts mostly 10–15 mm long, sometimes flushed red distally. *Flowers* diurnal, pale to deep pink, not scented; perianth tube (6.5–)8.0–12.5 mm long, cylindric, dilated at throat; tepals 12–21 × 5–6 mm, elliptic to obovate, spreading. *Filaments* ascending, ± 2.5 mm long, inserted at base of outer tepals; anthers 6–8 mm long, yellow; pollen yellow. *Style branches* 8–10 mm long, spreading, reaching to upper ⅓ or shortly beyond anthers in closed flower. *Capsules* ± ovoid–oblong, 8–9 × ± 5 mm. *Seeds* light brown, angular, angles narrowly ridged, pale. *Flowering time*: December to March.

Distribution and ecology: widespread in southern Africa, extending from northern Eastern Cape to Mpumalanga in South Africa, Lesotho and Eswatini; in well-watered grassland, mainly above 600 m.

Diagnosis: the tallest and most robust of the short-tubed, eastern southern Africa species of the genus, *Hesperantha baurii* is unusually variable. Populations from high elevations in the Drakensberg, with four (occasionally three) leaves, and spikes of up to 4(–6) large, deep pink (also described as magenta) flowers with tepals 12–21 mm long, up to 3 times as long as the tube, are recignised as subsp. *formosa.* Typical *H. baurii* has four or five leaves, and spikes of up to 12(–18) flowers with tepals 12–18 mm long, up to 1.5 times as long as the tube. The stems of subsp. *baurii* are up 400 mm tall and sometimes branched but those of subsp. *formosa* seldom reach 300 mm and are always unbranched. Populations at lower elevations in the Drakensberg may be intermediate between the two subspecies, a situation not unexpected in subspecies.

Hesperantha baurii can be recognised by the relatively short perianth tube, mostly 7–12 mm long, tepals 12–18(–21) mm long, and (three) four (five) leaves, the lower two largest and basal, the third leaf sheathing in the lower half, and the uppermost leaf usually short, inserted in the middle of the stem and entirely sheathing. Only the most robust individuals may have a single branch. The spike ranges from weakly to markedly flexuose and in subsp. *baurii* bears up to 15 flowers, occasionally more, and spikes with as many as 18 flowers have been recorded.

Hesperantha baurii is most easily confused with pale pink-flowered *H. leucantha*, but this is a more slender,

Distribution of *Hesperantha baurii* subsp. **baurii**, ●; subsp. **formosa**, ○.

often trailing plant, with spikes of 2 to 6 flowers, the the filaments inserted just below the mouth of the perianth tube and 4–5 mm long, ± as long as the anthers. In *H. baurii* the filaments are inserted at the base of the outer tepals and ± 2.5 mm long, thus less than half as long as the anthers, 6–8 mm long.

Key to subspecies

1a Tepals mostly 12–18 × 4–5 mm; foliage leaves mostly at least 200 mm long . . . . . 38a. subsp. *baurii*
1b Tepals mostly 15–21 × 5–9 mm; foliage leaves mostly 35–150 mm long . . . . . 38b. subsp. *formosa*

38a subsp. **baurii**

Hesperantha rubella Baker: 239 (1876a). Type: South Africa, [Free State], without precise locality, *Cooper 1027* (K 000320587, lecto., designated here; E, K isolecto.).

Hesperantha disticha Klatt: 393 (1882). Type: South Africa, [KwaZulu-Natal], valley near Botha's Hill, 2 000 ft [600 m], 6 Oct., *Wood 4543* (K, holo.; NH, iso.).

Hesperantha bifolia Baker: 865 (1901). Type: South Africa, [KwaZulu-Natal], mtns near Howick, 1 000 m, *Junod 374* (Z, holo.).

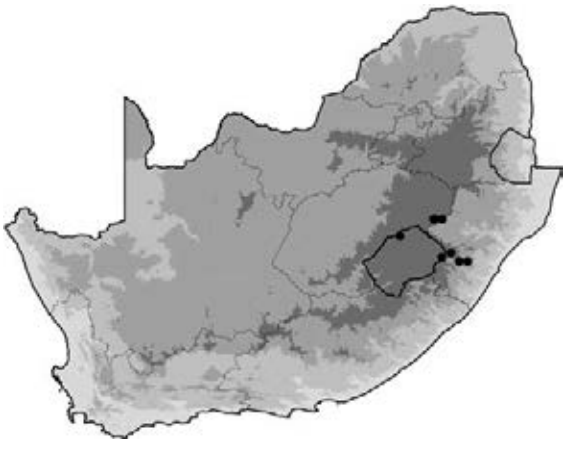
Plants up to 500 mm high. *Leaves* 4 or 5, lower 3 basal and longest, up to 200 mm long, upper 1 or 2 sheathing stem. *Spike* mostly 6- to 15(–18)-flowered; outer bract mostly 9–12 mm long. *Flowers* pale pink; perianth tube 6–10 mm long; tepals mostly 12–16(–18) × 4–5 mm.

Distribution and ecology: occurring throughout the range of the species but rare or absent above 3 500 m.

Diagnosis: subsp. *baurii* is usually taller than subsp. *formosa* and mostly 350–500 high, with slightly smaller bright pink flowers with tepals 12–18 mm long. The spikes also have several to many more flowers than subsp. *formosa*, as many as 15 to 18 vs. 2 to 6. Although intermediates between the two subspecies have been recorded, the presence of both at one site is puzzling indicating a need for additional research.

38b. subsp. **formosa** *Hilliard & B.L.Burtt* in Notes from the Royal Botanic Garden, Edinburgh 43: 430 (1986); Goldblatt: 416 (2003). Type: Lesotho, Sani Top, west of border post, 9 500 ft [2 900 m], 16 Jan. 1976, *O.M. Hilliard & B.L. Burtt 8829* (NU, holo.; E, MO, iso.).

Plants up to 300 mm high. *Leaves* usually 3(4), lower 2(3) basal and longest, 35–150 mm long, upper leaf sheathing stem. *Spike* mostly 2- to 4(–6)-flowered; outer bract 10–15 mm long. *Flowers* deep pink; perianth tube 7–11 mm long; tepals mostly 15–21 × 5–9 mm.



Distribution and ecology: high elevations in the Drakensberg of Lesotho and KwaZulu-Natal; in grassland.

Diagnosis: subsp. *formosa* is usually easily to distinguish from subsp. *baurii* by the spikes bearing 2 to 4(–6) flowers and normally only 2 basal leaves and a third, largely sheathing, cauline leaf. The slightly larger flowers have tepals 15–21 mm long vs. 12–16(–18) in subsp. *baurii*. Plants intermediate between the two subspecies have been recorded from slightly lower altitudes. A record of the co-occurrence at Sani Pass of subsp. *formosa* in fruit when subsp. *baurii* was in flower suggests that the current taxonomy may require revision.

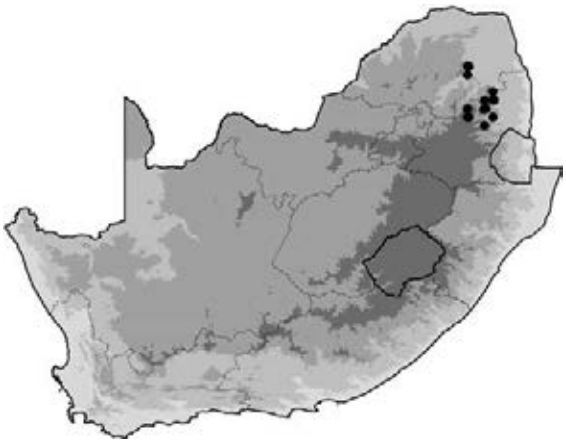
39. **Hesperantha glareosa** *Hilliard & B.L.Burtt* in Notes from the Royal Botanic Garden, Edinburgh 43: 424 (1986). Type: South Africa, [KwaZulu-Natal], Underberg, headwaters of Mlahlangubo River, 23 Jan. 1982, *O.M. Hilliard & B.L. Burtt 15367* (NU, holo.; E, iso.).

Plants 100–200 mm high. *Corm* ovoid, 10–12 mm diam.; tunics dark brown, overlapping, lower margin breaking into sections. *Stem* simple or 1-branched from near base. *Leaves* 4, lower 2 or 3 basal, upper 1 or 2 cauline, uppermost largely sheathing, blades of lower reaching to between middle and apex of stem, firm, upright or slightly falcate, mostly 0.8–2.0 mm wide, main vein thickened. *Spike* flexuose, (1)2- to 7-flowered; bracts 6.5–14.0 mm long, inner slightly shorter than outer. *Flowers* diurnal, deep pink, ?unscented; perianth tube, mostly 4–6 mm long; tepals 10.0–14.5 × 3.5–5.5 mm. *Filaments* 2–3 mm long; anthers 3–6 mm long. *Style branches* ± 7–8 mm long, reaching to upper ⅓ of anthers in closed flower. *Capsules* ellipsoid, 5–7 mm long. *Seeds* light brown, angular with narrow raised edges, ± 1 mm diam. *Flowering time*: December to early March.

Distribution and ecology: largely a species of the central Drakensberg in Lesotho and Free State and KwaZulu-Natal in South Africa but possibly extending north to southern Mpumalanga (specimens from there are provisionally assigned here); growing in damp turf and wet, rocky pavement.

Distribution of ***Hesperantha glareosa***.

Diagnosis: distinguished largely by the firm, narrow leaves up to 2 mm wide, and usually few-flowered spike, *Hesperantha glareosa* has deep rose-pink flowers with a short perianth tube 4–6 mm long, slightly less than half as long as the tepals, 10.0–14.5 mm long. It is easily separated from the superficially similar *H. baurii* by its habitat in wet ground in thin soil vs. grassland, smaller flowers (tube mostly 7–11 mm long and tepals 12–21 mm long in *H. baurii*) and narrow leaves. Specimens from Mpumalanga are very like some depauperate specimens of *H. glareosa* and may be this species, but it is impossible to determine if these very slender, one- or two-flowered plants (e.g., *Galpin 14329*, BOL, PRE; *Jacobsen 4780*, PRE) are depauperate, four-leafed *H. schlechteri* or truly *H. glareosa*. The flowers are moderate in size, the tepals 10.5–14.5 mm long, and perianth tube 5–7 mm long.



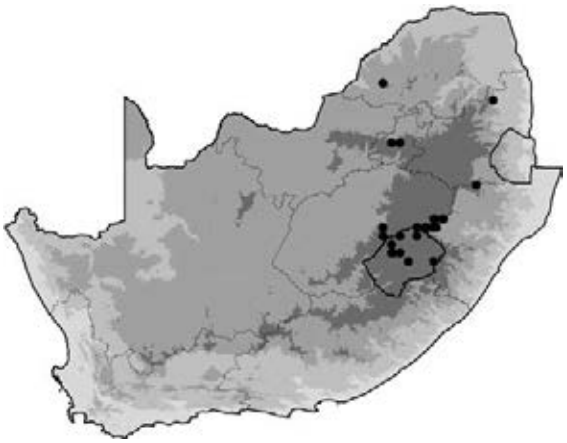
40. **Hesperantha schlechteri** *(Baker) R.C.Foster* in Contributions from the Gray Herbarium of Harvard University 114: 50 (1936); Goldblatt: 417 (2003). *Geissorhiza schlechteri* Baker: 863 (1901). Type: South Africa, [Limpopo], Woodbush, 27 Mar. 1894, *Schlechter 4701* (BOL, holo.; G, K, P, iso.).

Hesperantha similis R.C.Foster: 24 (1948). Type: South Africa, [Mpumalanga], Sabie District, Devil's Knuckles, Apr. 1887, *Wilms 1446* (K, holo.; B, Z, iso.).

Plants 180–300 mm high. *Corm* ovoid, 8–12 mm diam.; tunics woody, concentric. *Stem* usually unbranched, flexuose, often looped above sheaths of upper leaves. *Leaves* mostly (4)5, lower (3)4 basal or subbasal, largest, uppermost 1 or 2 inserted in middle of stem, sometimes entirely sheathing or with short free unifacial tip, blades of lower leaves linear, (1)2–4 mm wide, margins and main vein not or barely thickened when alive. *Spike* flexuose, mostly 4- to 8-flowered; outer bract mostly 9–12 mm long, green, inner bract ± ⅔ as long as outer. *Flowers* diurnal, pale to deep pink, outer tepals with a coppery brown flush outside; perianth tube cylindric below, widening near apex, 5–7(–10) mm long; tepals subequal, ± elliptic, 13–16 × 5.0–6.5 mm, spreading. *Filaments* 3–5 mm long; anthers 4–5(–6) mm long, yellow; pollen yellow. *Style branches* 10–12 mm long, laxly spreading, exceeding anthers by ± 2 mm in closed flower. *Capsules* oblong-obovoid, 7–9 mm long. *Seeds* subglobose or the sides flattened by pressure, ± 0.6 mm long. *Flowering time*: January to mid-March.

Distribution and ecology: occurring in Limpopo and Mpumalanga provinces of South Africa, along the escarpment from Woodbush in the north to Long Tom Pass in the south; on rocks and thin soil on sandstone or quartzite pavement.

Diagnosis: one of several pink-flowered species of the genus, *Hesperantha schlechteri* is recognised by the relatively short perianth tube, 5–7(–10) mm long, anthers mostly 4.0–4.5 mm long, and typically 5 leaves, the lower 3 with extended blades 2–4 mm wide. The flexuose stem has a pronounced loop above the sheaths of the upper leaves. Plants from Mariepskop with four or five leaves, the blades only about 1 mm wide, may not be correctly placed in *H. schlechteri.* Plants from near Mac-Mac Falls are also puzzling, the plants having blades of the lower leaves 4–6 mm wide, unusually broad for any *Hesperantha* species in Mpumalanga. The flowers are quite small, with tepals ± 7 mm long and a tube ± 5 mm long. They may be depauperate *H. schlechteri* or an undescribed species. A few other collections, including some from Dullstroom, also represent this variant.



Distribution of ***Hesperantha schlechteri***.

41. **Hesperantha leucantha** *Baker*, Handbook of the Irideae: 150 (1892). Type: South Africa, [KwaZulu-Natal], Oliviershoek Pass, 14 Jan. 1886, *J.M. Wood 3437* (K, holo.).

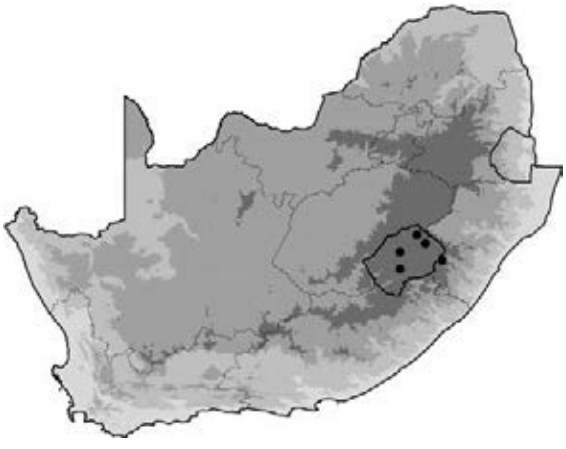
Geissorhiza macra Baker: 1005 (1904). Type: Lesotho, Mt. Machache, without date, *H. Jacottet 1937* (G, holo.).

Plants mostly 300–450 mm high. *Corm* ovoid, slightly asymmetric, ± 10 mm diam.; tunics dark brown, ± concentric, splitting below into sections and above into pointed cusps. *Stem* simple or branched from near base, weak, often curved or trailing. *Leaves* 4 or 5, lower 2 or 3 basal, reaching to ± base or middle of spike, sword-shaped to ± linear or falcate, often weak and trailing, mostly 1.5–5.5 mm wide, main vein and margins thickened, remaining leaves cauline, progressively shorter, uppermost entirely sheathing. *Spike* (1–)3- to 6-flowered; outer bract green, mostly 8–15 mm long, inner bract smaller, partly membranous. *Flowers* diurnal, salver-shaped, pale pink to pale mauve, rarely ± white, scent not recorded; perianth tube cylindric, widening near mouth, mostly 7–11 mm long; tepals spreading, mostly 9–13(–15) mm long. *Filaments* ± 5 mm long, inserted slightly below top of tube; anthers 4–5 mm long, white; pollen white. *Style branches* 10–15 mm long, exceeding anthers in closed flower. *Flowering time*: December to February.

Distribution of ***Hesperantha leucantha***.

Distribution and ecology: widespread and extending from Limpopo south through Gauteng, and Mpumalanga to Free State and KwaZulu-Natal in South Africa, also in western Lesotho; rocky grassland and trailing on cliffs.

Diagnosis: *Hesperantha leucantha* is recognised by its pale pink flowers with perianth tube usually 12–15 mm long and exserted from the bracts unless these are unusually long, and tepals 9–12(–15) mm long across its main range in interior Lesotho, eastern Free State and northern KwaZulu-Natal. The filaments are ± 5mm long and inserted shortly within the tube. Related *H. baurii* also has pink flowers but shorter filaments 2.0–2.5 mm long inserted at the base of the outer tepals. Plants from north of the Vaal River, in Gauteng and Northwest Province, placed in *H. leucantha* (as *H. candida*) by Hilliard & Burtt (1986), are somewhat atypical in their greater height and slender habit, but are currently included there.



Hesperantha leucantha is sometimes confused with *H. glareosa*, a species with deep pink flowers with a much shorter perianth tube, mostly 4–6 mm long, and tepals 10.0–14.5 mm long. *Hesperantha glareosa* also has four leaves, the lower three basal and with firm, narrow blades, mostly 1–2 mm wide.

42. **Hesperantha exiliflora** *Goldblatt* in Annals of the Missouri Botanical Garden 90: 419 (2003). Type: Lesotho, 3 km from New Oxbow Inn on road to Moteng Pass, subalpine grassland, 2 550 m, 3 Feb. 1987, *Killick 4477* (PRE, holo.; MO, iso.).

Plants mainly 120–250(–300) mm high. *Corm* obconic, ± 8 mm diam.; tunics woody, soon breaking into elliptic segments tapering above into short points. *Stem* slender, unbranched. *Leaves* usually 4, lower 2 basal and longest, reaching to between upper ⅓ of stem and apex of spike, ± linear, 1.2–2.3 mm wide, firm, erect, main vein and margins lightly raised, hyaline when dry, third leaf inserted shortly above ground, largely sheathing, uppermost leaf entirely sheathing, ± bract-like, 12–32 mm long, inserted in middle to upper ⅓ of stem. *Spike* mostly 1- to 3-flowered, lax, ± straight; outer bract 6.0–8.0(–9.5) mm long, green, upper margin transparent, inner bract slightly shorter, ± membranous with 2 green keels. *Flowers* diurnal, rotate, pink, pale yellow in throat; perianth tube funnel-shaped, 3.5–5.0 mm long; tepals elliptic, spreading, 6–8 × ± 2.5 mm. *Filaments* suberect, ± 2.5 mm long; anthers ascending, 2.5–3.3 mm long, shortly tailed, yellow; pollen yellow. *Style dividing* below mouth of tube, branches 3.0–3.5 mm long, diverging, reaching to between middle of anthers to just beyond tips in closed flower. *Flowering time*: January and February.

Distribution and ecology: known only from the central and eastern Drakensberg plateau of Lesotho but possibly also in KwaZulu-Natal, South Africa; in subalpine grassland, evidently in damp sites.

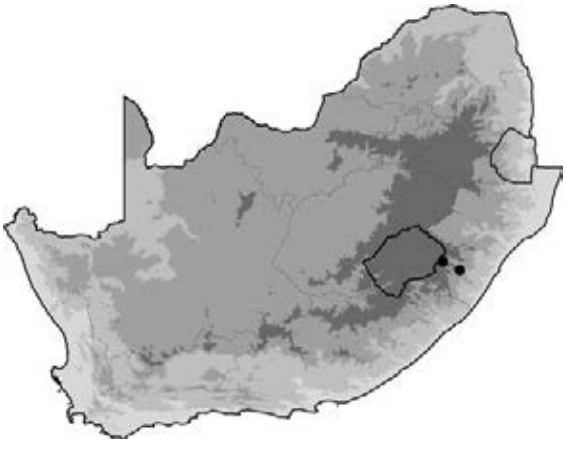
Diagnosis: the few known populations of *Hesperantha exiliflora* have remarkably small flowers, the perianth tube 3.5–5.0 mm long and the tepals 6–8 mm long, and it is distinguished largely by these features. The only other species of pink-flowered *Hesperantha* from eastern southern Africa with comparably small flowers, *H. ingeliensis*, has tepals mostly 10–12 mm long and broader, falcate leaves, 5.5–7.0 mm wide, unlike the straight, slender leaves up to 2.3 mm wide of *H. exiliflora*. *Hesperantha exiliflora* seems most closely allied to a second Drakensberg species, *H. brevistyla*, which has pale pink flowers with a tube 7–9 mm long, tepals ± 7 × 3.5 mm, short white anthers 2.5–3.5 mm long, and short style branches ± 6 mm long that reach to ± the lower third of the anthers at most. The flowers of *H. exiliflora* have yellow anthers and the style branches are 3.0–3.5 mm long, reaching to between the middle of the anthers or just beyond their tips in the closed flower. The tepals dry dark purple whereas those of *H. brevistyla* dry pink. Although collections of *H. exiliflora* were at first associated with the Drakensberg species *H. glareosa*, there seems no particular reason to consider them closely related. The straight stem and apparently consistently few-flowered

Distribution of ***Hesperantha exiliflora***.

spikes of *H. exiliflora* are unlike the rather wiry, flexuose spikes of *H. glareosa*, which has larger flowers with a tube 5–6 mm long and tepals 10–12 mm long.

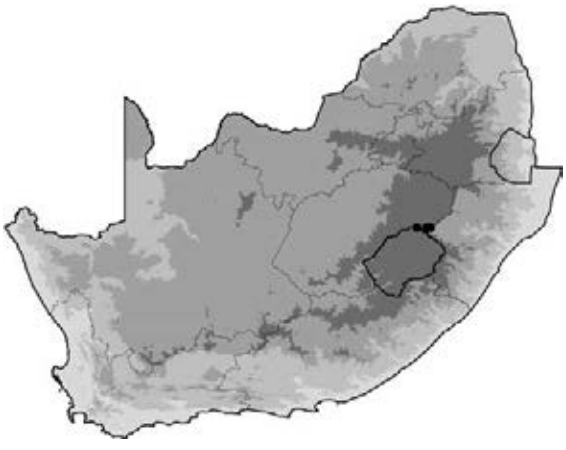
43. **Hesperantha alborosea** *Hilliard & B.L.Burtt* in Notes from the Royal Botanic Garden, Edinburgh 43: 421 (1986). Type: South Africa, [KwaZulu-Natal], Underberg, Cobham, Upper Polela Cave area, 7 800 ft [2 400 m], 13 Feb. 1979, *O.M. Hilliard & B.L. Burtt 15367* (E, holo.; NU, iso.).

Plants 70–110 mm high. *Corm* ± ovoid, ± 15 mm diam.; tunics woody, dark brown, imbricate, lower margins breaking into sections and tapering above into short points. *Stem* erect, simple or sometimes 1-branched, somewhat flexuose, with upper cataphyll often turning dry and brown distally. *Leaves* usually 4, lower 2 basal and longest, reaching to between upper ⅓ of stem and shortly above apex of spike, ± sword-shaped, 2.0–4.5 mm wide, firm, erect, main vein and margins thickened and prominent, hyaline when dry, third leaf inserted shortly above ground, largely sheathing, uppermost leaf entirely sheathing, ± bract-like, 12–32 mm long, inserted in middle to upper ⅓ of stem. *Spike* mostly 3- to 10-flowered, weakly flexuose; outer bract 6.5–10.0 mm long, green with red tips, inner bract slightly shorter. *Flowers* diurnal, rotate, white, outer tepals flushed rose-pink outside; perianth tube funnel-shaped, 8–9 mm long; tepals elliptic, spreading, 12–15 × 4.0–5.5 mm. *Filaments* suberect, ± 3 mm long; anthers ascending, 3–4 mm long. *Style branches* ± 6.5 mm long, reaching to slightly beyond anthers tips in closed flower. *Flowering time*: January and February.



Distribution and ecology: recorded at elevations between 2 300 and 2 700 m in the southern KwaZulu-Natal Drakensberg, South Africa at Upper Polela Cave and Sani Pass; growing in wet situations such as rock flushes and wet gravel.

Diagnosis: among the white-flowered species of the genus from eastern southern Africa, *Hesperantha alborosea* is recognised by its short stature, up to 110 mm high, firm to rigid leaves with thickened margins and main vein, and flowers with a relatively short perianth tube, 6–9 mm long, the tepals about 1.5× as long. It most closely resembles *H. hygrophila*, also with white flowers but usually without pink on the reverse of the outer tepals, tepals usually ± twice as long as the tube, and longer anthers, 5–10 mm long.



44. **Hesperantha brevistyla** *Goldblatt* in Annals of the Missouri Botanical Garden 90: 420 (2003). Type: South Africa, Free State, Sentinel trail, rocky pavement below basalt cliffs on trail to the chain ladders, 5 Mar. 2002, *Goldblatt & Porter 11989* (NBG, holo.; MO, PRE, iso.).

Plants 40–100(–160) mm high. *Corm* obconic, ± 3 mm diam.; tunics woody, soon breaking into elliptic segments tapering above into short points. *Stem* unbranched. *Leaves* 4 or 5, lower 3 or 4 basal and longest, ± as long as spike, falcate to suberect, firm, 2–4(–5) mm wide, main vein and margins lightly raised, hyaline when dry, uppermost leaf inserted in ± middle of stem, partly or rarely entirely sheathing. *Spike* 1- to 4(5)-flowered, ± straight; bracts 9–13 mm long, green, inner 2-lobed at tip. *Flowers* diurnal, rotate, pale pink, cream-coloured in mouth of tube, outer tepals pale greenish with darker green veins outside; perianth tube funnel-shaped, 7–9 mm long; tepals spreading horizontally, elliptic, 7–8 × ± 3.5 mm, acute. *Filaments* ascending, 1.8–2.0 mm long; anthers ascending, 2.2–4.0 mm long, white; pollen white. *Style* dividing below mouth of tube, branches suberect, reaching to between the base and middle of anthers, ± 6 mm long. *Capsules* ellipsoid, 8–12 mm long. *Seeds* angular-prismatic, reddish brown, ± 1.3 × 1 mm, with membranous ridges at angles. *Flowering time*: February to mid-March.

Distribution and ecology: restricted to the northern Drakensberg of Free State and KwaZulu-Natal, South Africa, and probably also in northern Lesotho; on basalt slopes and rocky pavement in shallow damp soil.

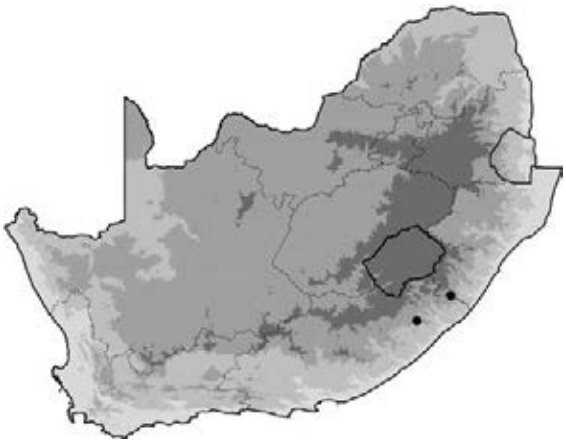
Distribution of ***Hesperantha alborosea***.

Distribution of ***Hesperantha brevistyla***.

Diagnosis: with small, pale pink flowers, the outer tepals pale greenish pink on the outside and veined dark green, *Hesperantha brevistyla* has unusually small white anthers, 2.2–4.0 mm long and remarkably short, suberect style branches that reach only to the base or middle of the anthers, unlike the longer, spreading style branches typical of the genus. *Hesperantha brevistyla* may be most closely allied to a second small-flowered Drakensberg species, *H. exiliflora*, which has pink flowers with a perianth tube 3.5–5.0 mm long, tepals 6–8 × ± 2.5 mm, yellow anthers 2.5–3.3 mm long, and style branches 3.0–3.5 mm long, reaching to between the middle of the anthers or just beyond their tips in the closed flower. The flowers of *H. exiliflora* dry purple whereas those of *H. brevistyla* dry pale pink.

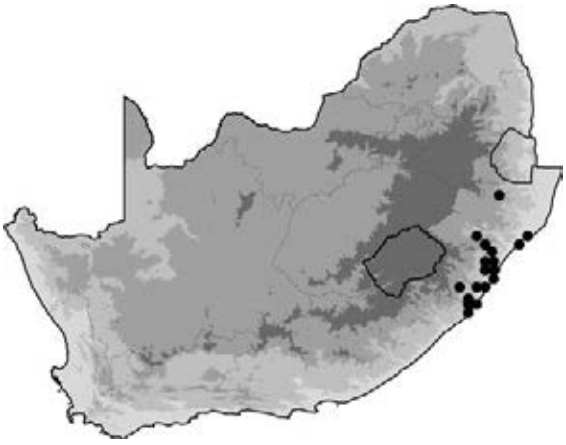
45. **Hesperantha ingeliensis** *Hilliard & B.L.Burtt* in Notes from the Royal Botanic Garden, Edinburgh 43: 424 (1986). Type: South Africa, [KwaZulu-Natal], Alfred District, Ngeli Mtn, ± 1 800 m, 4 Jan. 1969, *Hilliard & Burtt 5838* (NU, holo.; E, iso.).

Plants mostly 120–180 mm high. *Corm* ± globose, slightly asymmetric, ± 10 mm diam.; tunics woody, imbricate. *Stem* straight or arching toward ground, unbranched. *Leaves* 4, lower 2 basal, with well-developed blades reaching up to base of spike, (2)4–6 mm wide, sword-shaped to falcate, margins and main vein visibly thickened; upper 2 leaves cauline and largely or upper fully sheathing. *Spike* mostly 2-flowered; bracts green, outer 9–13 mm long, inner slightly shorter. *Flowers* diurnal, rotate, light purple to pink, evidently not scented; perianth tube 8–10 mm long, cylindric, dilated at throat; tepals subequal, elliptic, 9–12 × 4–5 mm, spreading. *Filaments* ± 2 mm long; anthers 4.5–5.5 mm long, yellow; pollen ?yellow. *Style branches* ± 8 mm long, shortly exceeding anthers in closed flower. *Capsules* and *seeds* unknown. *Flowering time*: January to March.



Distribution and ecology: poorly documented, known only from rocky sites on Ngeli Mtn in southern KwaZulu-Natal, South Africa and on Mjika, north of Mthatha in Eastern Cape; on wet cliffs and rocky flats at 1 400–1 800 m elevation.

Diagnosis: poorly known *Hesperantha ingeliensis* is distinguished from other eastern southern African pink–purple-flowered species of *Hesperantha* by the spike of only one or two flowers with an unusually short perianth tube, ± 5 mm long, and tepals ± twice as long. Its immediate relationships are uncertain, but it is possibly allied to *H. baurii*, from which it is distinguished by the spikes of mostly two flowers with shorter anthers.



46. **Hesperantha lactea** *Baker*, Handbook of the Irideae: 151 (1892); Hilliard & Burtt: 431 (1986). Type: South Africa, [KwaZulu-Natal], Verulam, Nov., *J.M. Wood 1118* [K, lecto., designated by Hilliard & Burtt: 431 (1986)].

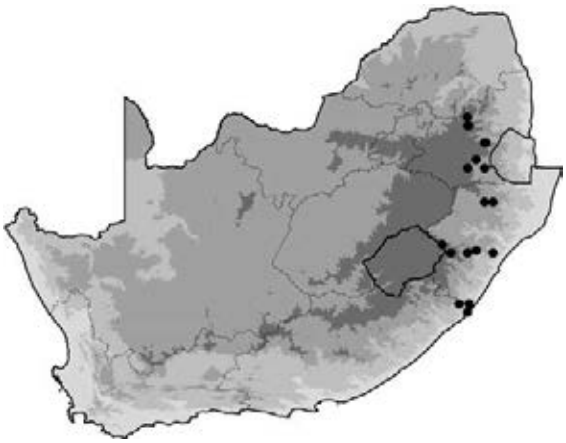
Plants mostly 200–500 mm high. *Corm* ± globose, slightly asymmetric with obliquely flattened side, 10–13 mm diam.; tunics woody, imbricate, splitting from base into sections. *Stem* simple or sometimes branched from near base. *Leaves* 4, lower 2 basal, with well-developed blades reaching up to base of spike, (2)4–6 mm wide, sword-shaped to falcate, margins and main vein visibly thickened; upper 2 leaves cauline and largely or upper fully sheathing. *Spike* flexuose, mostly 4- to 14(–18)-flowered; bracts 10–17 mm long, sometimes tipped red. *Flowers* diurnal, creamy yellow, evidently not scented; perianth tube 6.0–8.5 mm long, cylindric, dilated at throat; tepals 14–20 × 4–6 mm, ± elliptic, spreading. *Filaments* ascending, 3–4 mm long; anthers 5–7 mm long, dull yellow to brown; pollen brown or dull yellow. *Style branches* spreading, 7–10 mm long, reaching to ± apex of anthers. *Capsules* ± ovoid–oblong, 6–8 × ± 4 mm. *Seeds* light brown, angular, angles narrowly ridged, pale. *Flowering time*: November to February.

Distribution and ecology: largely a lowland and coastal species, extending from the coast of northern Eastern Cape north to Durban in KwaZulu-Natal, South Africa. Isolated records from Hlobane in the Vryheid District in

Distribution of ***Hesperantha ingeliensis***.

Distribution of ***Hesperantha lactea***.

northern KwaZulu-Natal assigned to this species may represent *H. inconspicua*.



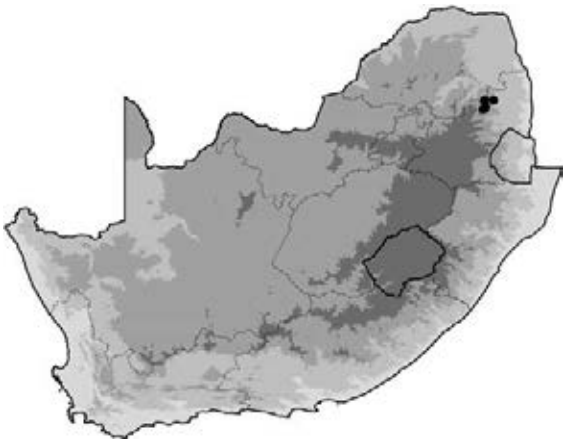
Diagnosis: *Hesperantha lactea* is a relatively tall species sometimes up to 500 mm high or more, with pale, creamy white to pale yellow flowers with a tube 6.0–8.5 mm long, and spreading tepals 14–20 mm long. The anthers, 5–7 mm long, are discolorous, usually brown or dull yellow, an unusual feature among white-flowered species of the genus. Like other white to pale yellow-flowered *Hesperantha* species of eastern southern Africa, the flowers are diurnal, with records of opening 11:45–12:30 and closing 16:40–17:15. This contrasts sharply with most white-flowered species of the genus from the southern African winter-rainfall zone, the flowers of which are crepuscular to nocturnal, opening in the late afternoon and closing after dark.

47. **Hesperantha inconspicua** *(Baker) Goldblatt* in Annals of the Missouri Botanical Garden 90: 422 (2003). *Gladiolus inconspicuus* Baker: 1005 (1904). Type: South Africa, [Mpumalanga as Transvaal], Donkerhoek, 4 Jan. 1894 but both locality, collection number and perhaps date are incorrect, *Schlechter 4188* (G, holo.).

Plants 25–45 mm high. *Corm* unknown. *Stem* smooth, often branched from the axil of third leaf. *Leaves* mostly 4, lower 3 basal or subbasal, leathery, narrowly sword-shaped to linear, mostly 3.0–4.5 mm wide, main vein and margins lightly thickened, midrib rounded, uppermost leaf inserted in middle of stem, partly to entirely sheathing, reaching to ± base of spike. *Spike* mostly 6- to 12-flowered; bracts green or purplish at tips, 10–15 mm long. *Flowers* white, sometimes faintly flushed pink on outside of outer tepals, often only on fading, unscented; perianth tube slender, expanded near apex, 7.0–8.5 mm long; tepals subequal, spreading at right angles to tube, 12–16(–18) × 6–8 mm. *Filaments* 2.5–3.0 mm long; anthers 6.5–8.0 mm long, creamy white; pollen yellow. *Style branches* reaching to apex of anthers in closed flower. *Capsules* subglobose, 4–7 mm long. *Seeds* angular-prismatic to ± ovoid, 1.5–1.8 × 1.2 mm. *Flowering time*: December to mid-March.

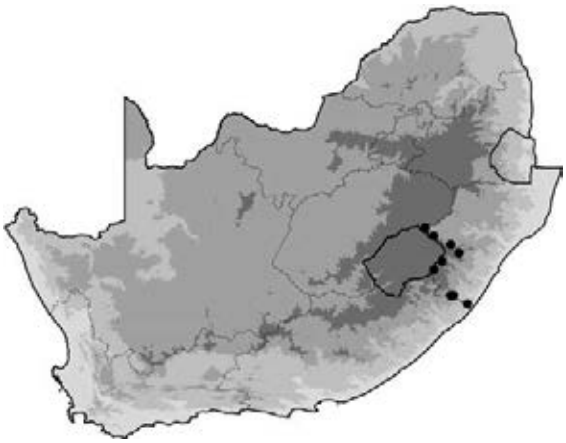
Distribution and ecology: South Africa, from the Blyde River hills and Lydenburg in Mpumalanga to the Mtamvuna River Gorge in southern KwaZulu-Natal.

Diagnosis: unexceptional in its vegetative aspect and flowers, *Hesperantha inconspicua* stands out among the eastern southern African species in its relatively tall stature, mostly 400–600 mm high, and white perianth (sometimes faintly flushed pink on the reverse of the outer tepals). Among the few other white- or cream-flowered species of eastern southern Africa, *H. inconspicua* can be confused with the coastal KwaZulu-Natal species *H. lactea*, which has creamy yellow flowers and dull yellow to brownish anthers and pollen. The leaves of the two species are virtually identical, both having thickened margins and a lightly raised, rounded midrib, with the other veins obscure and not visible when alive. The related *H. saxicola*, which also has white flowers, often fading pink, stands out both in its shorter stature and unusual habitat, rock outcrops and cliffs. These plants have drooping leaves and stems 100–180 mm long, and flexuose spikes of up to five large flowers with tepals mostly 15–16 × 7 mm and anthers ± 4 mm long. *Hesperantha inconspicua* often has smaller flowers with tepals 12–15 mm long but longer anthers, 6.5–8.0 mm long, and 6–12 flowers per spike. *Hesperantha hygrophila*, also with white flowers, has very different leaves with the margins thickened and main vein raised and flattened into wings held parallel to the blade surface.



Distribution of ***Hesperantha inconspicua***.

48. **Hesperantha saxicola** *Goldblatt* in Annals of the Missouri Botanical Garden 90: 423 (2003). Type: South Africa, [Mpumalanga], rocks at top of Mt. Anderson, Mar. 1933, *E.E. Galpin 13781* (PRE, holo.; BOL, K, iso.).



Plants 100–250 mm high. *Corm* ± globose, ± 9 mm diam.; tunics dark brown, extended upward as a collar of fibres around base. *Stem* trailing from cliffs, simple or branched. *Leaves* mostly 4, lower 3 basal or subbasal, reaching ± to base of spike, soft-textured, ± linear, mostly 1.5–2.2 mm wide, midrib and margins hardly thickened, uppermost leaf shorter, inserted in middle of stem, partly to entirely sheathing. *Spike* 2- to 4-flowered; bracts green, often drying at tips, 10–15 mm long, inner ⅔ as long to ± as long as outer. *Flowers* white, ?unscented; perianth tube funnel-shaped, expanded in upper half, (7–)11 mm long; tepals subequal, spreading, (11–)15–16 × 5.5–7.0 mm. *Filaments* 2.5–3.0 mm long; anthers ± 4 mm long, creamy white; pollen yellow. *Style branches* exceeding anthers by ± 1.8 mm in closed flower. *Flowering time*: March and April.

Distribution and ecology: local in Mpumalanga, and possibly also Limpopo Province, South Africa; on wet cliffs and rock seeps.

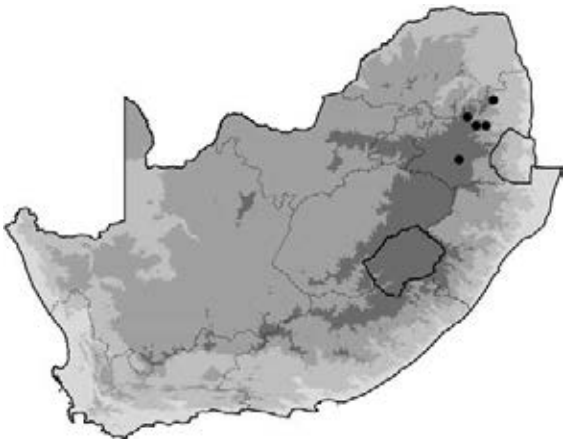
Diagnosis: *Hesperantha saxicola* is recognised by the trailing stems, linear leaves up to 2.2 mm wide, and spikes of only 2 to 5 white flowers with tepals 11–16 mm long.

Distribution of ***Hesperantha saxicola***.

Distribution of ***Hesperantha hygrophila***.

The stamens are comparatively short, with filaments up to 3 mm long and anthers about 4 mm long. *Hesperantha saxicola* has been confused with *H. leucantha*, which has upright stems and smaller, pale pink flowers. A collection from Mt. Sheba, a short distance to the north of Long Tom Pass, appears to belong here but the flowers have tepals lightly flushed with purple outside, leaves less than 1 mm wide, a perianth tube about 7 mm long and tepals ± 11 mm long, smaller than in populations to the south. Similar small-flowered plants with a white perianth from God's Window near Graskop (*Lötter 324*, NBG) may also be this species.

49. **Hesperantha hygrophila** *Hilliard & B.L.Burtt* in Notes from the Royal Botanical Garden, Edinburgh 40: 278 (1982); Hilliard & Burtt: 433 (1986). Type: South Africa, [KwaZulu-Natal], Alfred District, Ngeli Mtn, 2 Jan. 1969, *Hilliard & Burtt 5762* (E, holo.; NH, NU, iso.).



Plants 150–750 mm high. *Corm* ± obovoid, ± 10–12 mm diam.; tunics dark brown, imbricate, splitting into short spines above and into truncate sections below. *Stem* simple or 1-branched from near base. *Leaves* mostly 4, lower 2 basal, third inserted on lower part of stem, uppermost reduced, usually entirely sheathing, lower leaves ± linear, reaching ± to base or middle of spike, mostly 2–5 mm wide, main vein and margins thickened, raised and winged, secondary veins clearly visible. *Spike* ± straight, mostly 3- to 6-flowered; bracts pale green, outer 9.5–15.5 mm long, inner slightly shorter. *Flowers* diurnal, white, occasionally pale pink, unscented; perianth tube funnel-shaped, expanded in upper half, 5–7 mm long; tepals subequal, spreading, (9–)12–16 × 5.0–7.0 mm. *Filaments* 2–3 mm long; anthers 5–10 mm long, creamy white; pollen ± white. *Style branches* 8–9 mm long, exceeding anthers by ± 1.8 mm in closed flower. *Flowering time*: March and April.

Distribution and ecology: restricted to the Drakensberg and outlying ranges of KwaZulu-Natal, South Africa and Lesotho as far south as Ngeli Mtn; on wet to marshy slopes and flats usually among grasses and sedges.

Diagnosis: with unremarkable, white or sometimes pale pink flowers, *Hesperantha hygrophila* is recognised primarily by the distinctive pale green leaves with the main vein, margins, and a secondary pair of veins quite clearly thickened. The main vein is raised and flattened into wings that arch over the leaf surface and even the secondary veins are visibly thickened when seen alive. The flowers are diurnal with a record of opening between 8:30 and 9:00 and closing by 12:30. The species has been confused with white-flowered *H. inconspicua*, a generally more robust species with ± plane leaves and more flowers per spike (up to 16 in some plants), and sometimes with the stem branched in the axil of the third leaf. *Hesperantha hygrophila* may also be confused with the creamy white to pale yellow-flowered *H. lactea*, which grows in drier, well-drained grassland at altitudes of up to 800 m, rather than in wet habitats. *Hesperantha lactea* has dull yellow to light brown anthers that tend to dry dark brown, a feature which conveniently separates it from *H. hygrophila* in which the creamy white anthers remain pale when dry. The differences in leaf venation also separate the two but this feature is not always easy to see in dry specimens.

50. **Hesperantha rupestris** *N.E.Br. ex R.C.Foster* in Contributions from the Gray Herbarium of Harvard University 166: 23 (1948). Type: South Africa, [Mpumalanga], Waterval Boven, among rocks, 29 Mar. 1929, *C.E. Moss 17314* (K, holo.; PRE, iso.).

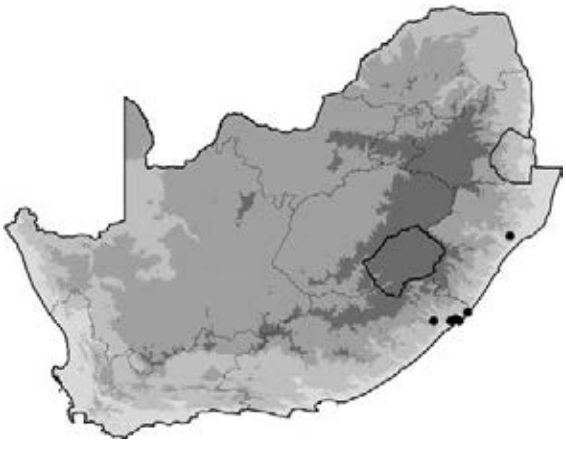
Plants 400–500 mm high. *Corms* globose, asymmetric with oblique flattened side, ± 10 mm diam.; tunics woody, imbricate, splitting from base into sections. *Stem* usually unbranched. *Leaves* 4, lower 2 basal and longest, 170–310 mm long, upper leaves cauline, progressively shorter, uppermost sheathing for half its length. *Spike* 6- to 9-flowered, lax, ± 2-ranked; bracts green with membranous tips, firm-textured, outer ± 12 mm long, with distinct keel, inner ± 7 mm long, 2-keeled and notched at tip. *Flowers* diurnal, white, outer tepals pink to red outside, presence of scent unknown; perianth tube ± 7 mm long; tepals elliptic, 12–15 × 2.5–3.0 mm.

Distribution of ***Hesperantha rupestris***.

Filaments ± 3 mm long; anthers 6–7 mm long. *Style branches* ± 10 mm long, reaching to ± apex of anthers in closed flower. *Flowering time*: February and March.

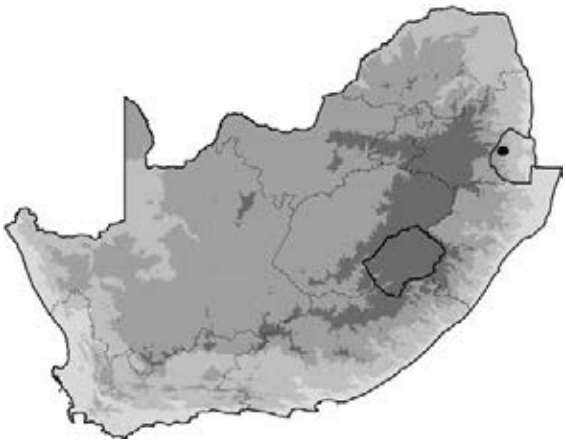
Diagnosis: restricted to the central Mpumalanga highlands in South Africa; in rocky grassland.

Diagnosis: a fairly robust species, sometimes standing 450–500 mm high, *Hesperantha rupestris* most closely resembles pink-flowered *H. baurii* in general aspect and is distinguished by the white to creamy white flowers with outer tepals flushed dark pink to red on the outside. Plants usually have four leaves, the lower two basal, narrowly lanceolate and reaching to about the base of the spike. The firm-textured blades have the margins and main vein thickened. As in other eastern southern African *Hesperantha* species with white flowers, these are diurnal and have been reported as opening in the morning.



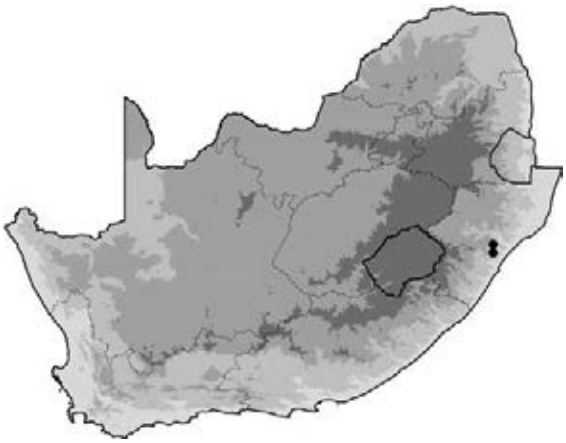
51. **Hesperantha modesta** *Baker*, Handbook of the Irideae: 150 (1892); Goldblatt: 425 (2003). Type: South Africa, [KwaZulu-Natal], Umlaas Location [or Bevaan River on the type at K, evidently in error], 17 July 1885, *Wood 3201* (K, holo.; NH, iso.).

?*Hesperantha subexserta* Baker: 62 (1896). Type: South Africa, [KwaZulu-Natal], valley near Botha's Hill, 2 000 ft [600 m], 6 Oct., *Wood 4543* (K, holo.; NH, iso.).



Plants mainly 150–250 mm high. *Corm* obconic, 7–9 mm diam.; tunics woody, soon breaking into elliptic segments tapering above into short points. *Stem* usually unbranched. *Leaves* 3 (rarely 4), lower 2 basal and longest, reaching to ± middle of stem, ± linear, 2–3 mm wide, firm-textured, main vein and margins lightly raised; upper 1 (or 2) leaves smaller, 45–60 mm long, inserted on lower ⅓ to middle of stem, sheathing for most of their length, with short free tip. *Spike* lax, mostly 2- or 3(4)-flowered; bracts green, 12–15 mm long, inner ± ⅔ as long as outer, translucent. *Flowers* diurnal, rotate, bright mauve-pink, pale yellow in mouth of tube; perianth tube 6–9 mm long, cylindric, expanded near apex; tepals spreading, elliptic, 10–15 × 3.5–5.0 mm, acute. *Filaments* suberect, ± 3 mm, inserted on tepals above mouth of tube; anthers ± 5 mm long, shortly tailed, yellow; pollen yellow. *Style branches* ± 10 mm long, laxly spreading, reaching to anther tips in closed flower. *Flowering time*: August to October.

Distribution and ecology: restricted to coastal KwaZulu-Natal and Eastern Cape, South Africa, mainly in the sandstone belt from Durban to Port St Johns, possibly also in Zululand near Eshowe; in marshy grassland, vlei edges and streambanks.



Diagnosis: sometimes confused with *Hesperantha baurii*, *H. modesta* is a late winter–spring-flowering species, usually with three leaves, the lower two basal and with well-developed linear blades of soft texture and the upper one (or two) cauline and largely sheathing (*H. baurii* usually has four, sometimes five leaves). The flowers are relatively large, in the middle of the range for *H. baurii*, but the available collections show it to be unusual in usually having only two to four flowers per spike. There is confusion about the type locality of *H. modesta* as the isotype at the KwaZulu-Natal Herbarium has the locality, Umlaas Location, whereas the sheet at K with the same number and date is purportedly from the Bevaan River, in the interior in the Vryheid District, which is evidently incorrect. *Hesperantha subexserta*, from Botha's Hill and also based on a Medley Wood collection, flowering in October, has provisionally been treated as a synonym of *H. modesta*. The type plants have two basal leaves, and one or two cauline, sheathing leaves of the soft texture typical of *H. modesta*, but the spike of one of the plants of the type collection has up to eight flowers and a short lateral branch in contrast to the two or three, or at most four flowers per spike of specimens of *H. modesta*. A collection from Eshowe, Zululand (*Lawn 1179*), well to the north of other collections of *H. modesta* is provisionally included here. The poor condition and crowded mounting of the specimens makes them difficult to identify for certain but the flowering time, October, and marshy habitat, suggest this species.

Distribution of ***Hesperantha modesta***.

Distribution of ***Hesperantha umbricola***.

Distribution of ***Hesperantha gracilis***.

52. **Hesperantha umbricola** *Goldblatt* in South African Journal of Botany 53: 459 (1987). Type: Swaziland, near Mbabane, among rocks, 21 Feb. 1982, *Goldblatt 6610* (MO, holo.; E, K, NBG, NU, PRE, S, iso.).

Plants 80–200(–250) mm high. *Corm* ± globose, 3–6 mm diam.; tunics dark brown, concentric, splitting into elliptic sections. *Stem* unbranched. *Leaves* 3 to 5, all basal or uppermost inserted on lower part of stem, reaching almost to base of 1.3–3.0 mm wide, main vein slightly thickened. *Spike* 2- to 6(–10)-flowered, weakly flexuose; bracts green with membranous tips, outer 5–9(–12) mm long, inner ± half as long, forked at apex. *Flowers* diurnal, rotate, white; perianth tube ± 5 mm long, expanded near apex; tepals elliptic, ± 6 × 2.5 mm. *Filaments* ± 2 mm long; anthers ± 3 mm long, white; pollen white. *Style branches* ± 6 mm long, reaching to ± apex of anthers in closed flower. *Capsules* obovoid, ± 4 mm long. *Seeds* angular, ± 0.6 mm long. *Flowering time*: February.

Distribution and ecology: known only from near Mbabane in Eswatini; growing in shade of granite boulders.

Diagnosis: *Hesperantha umbricola* is recognised by the unusually small, white flowers with a perianth tube about 5 mm long and tepals 6 mm long. The stamens are proportionately small, with filaments 2 mm long and anthers ± 3 mm long. The flowers are diurnal. The species may be allied to white-flowered *H. inconspicua* but its much smaller flowers that do not fade pink, and the narrow, soft-textured leaves make it easy to distinguish from that species, the flowers of which have tepals 12–18 mm long and often turn pale pink on fading.

53. **Hesperantha gracilis** *Baker*, Handbook of the Irideae: 149 (1892); Hilliard & Burtt: 422 (1986). Type: South Africa, [KwaZulu-Natal], base of perpendicular rocks at Isangwaan, Apr., *J.M. Wood 923* (K, holo.).

Plants 300–450 mm high. *Corm* ± globose, ± 10 mm diam.; tunics dark brown, concentric, splitting into elliptic sections tapering into short cusps above. *Stem* often curving downward, simple or 1- or 2-branched from near base, sheathed below by pale, membranous cataphyll. *Leaves* 4, lower 2 basal, upper 2 cauline, uppermost reduced, usually entirely sheathing; blades of lower leaves reaching to between middle of stem and apex of spike, 2–5 mm wide, fairly soft-textured, main vein and margins raised. *Spike* (2–)5- to 14-flowered; bracts green, outer 12–25 mm long, inner ± half as long. *Flowers* diurnal, white or mauve; perianth tube 6–8 mm long, cylindric, wider toward mouth; tepals subequal, elliptic, 14–21 × 4–6 mm, spreading. *Filaments* suberect, 2–3 mm long; anthers 6.0–7.5 mm long, ?white; pollen ?white. *Style branches* ± 9 mm long, reaching to ± apex of anthers in closed flower. *Capsules* ellipsoid-oblong, 5–8 mm long. *Seeds* ± light brown, ovoid, with loose testa, with persistent, slender funicle. *Flowering time*: February to April.

Distribution and ecology: poorly documented but evidently endemic to the hills between Durban and Pietermaritzburg in KwaZulu-Natal, South Africa; on wet, sandstone cliffs in moss and humus at 1 000–1 500 m elevation.

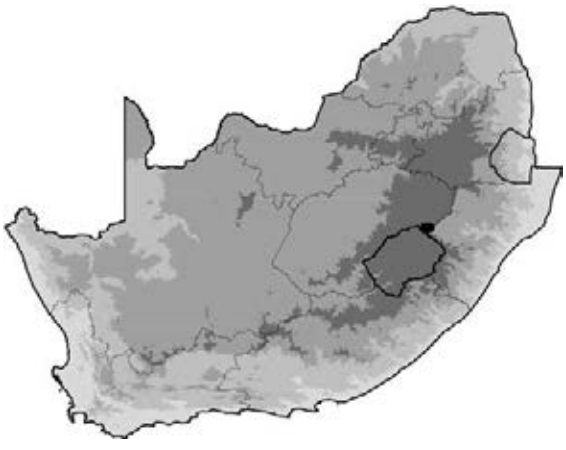
Diagnosis: a fairly slender plant, *Hesperantha gracilis* is recognised by the trailing stem, soft-textured, ± trailing leaves, and relatively large white to mauve flowers, with tepals 14–21 mm long and two to three times as long as the perianth tube, 6–8 mm long. *Hesperantha gracilis* may be most closely related to *H. leucantha* of interior eastern southern Africa, which has erect stems and pale pink to mauve or lilac flowers with a longer perianth tube mostly 9–16 mm long.

54. **Hesperantha pubinervia** *Hilliard & B.L.Burtt* in Notes from the Royal Botanical Gardens, Edinburgh 43: 419 (1986); Goldblatt: 426 (2003). Type: South Africa, [KwaZulu-Natal], Royal Natal National Park, Mont-aux-Sources, Feb. 1927, *Prescott-Decie s.n.* (BOL, holo.).

Plants 120–300 mm high. *Corm* conic, 7–9 mm diam.; tunics woody, dark brown, concentric, soon breaking

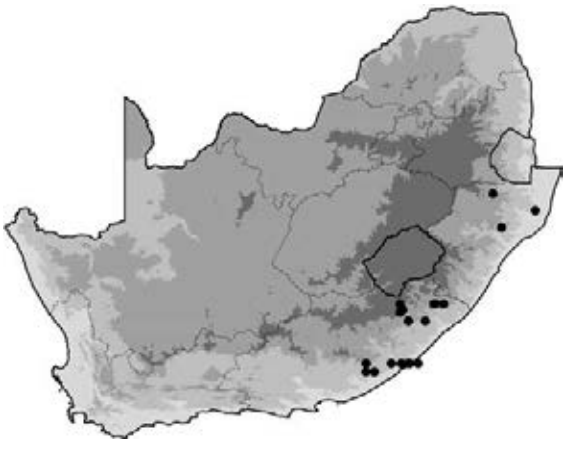
into elliptic segments tapering above into short points. *Stem* unbranched. *Leaves* 4, lower 2 basal, upper smaller and partly to entirely sheathing, blades ± linear, 2.5–3.5 mm wide, suberect, with scabrid hairs on margins, main vein and secondary veins, main vein prominently thickened, margins less so. *Spike* 1- to 3(4)-flowered; bracts 20–24 mm long, green. *Flowers* dull salmon-pink, pale yellow-green in mouth of tube edged in darker salmon; perianth tube 20–25 mm long, unusually slender, occluded by style almost to apex and without nectar; tepals spreading, 14–18 × 3.5 mm, subacute. *Filaments* erect, ± 5 mm long; anthers erect, ± contiguous, ± 4.5 mm long, yellow; pollen yellow. *Style branches* suberect in open flower, ± 6 mm long, reaching to ± upper ⅓ of anthers and extending between them. *Capsules* oblong, (10–)12–14 mm long. *Seeds* angular-prismatic, ± 1.2 × 1.0 mm, with membranous ridges on angles. *Flowering time*: February and March.

Distribution and ecology: known only from the high northern Drakensberg on the slopes below the Sentinel and on the Mont-aux-Sources Plateau, in Free State and adjacent KwaZulu-Natal, South Africa, and probably Lesotho; in rocky grassland on basalt.



Diagnosis: poorly known, *Hesperantha pubinervia* is readily recognised by the ± linear basal leaves scabrid-hairy on the margins and veins, and the relatively long-tubed flowers of an unusual dull salmon-pink colour. The perianth tube, 20–25 mm long, is unusually slender and completely occluded by the style. The flowers do not produce nectar and are evidently pollinated through deceit, offering no reward to its pollinator, a long-proboscis fly. *Hesperantha pubinervia* is also somewhat unusual in having relatively short, ascending style branches ± 6 mm long, rather than spreading over the tepals as in most species of the genus. The distinctively coloured flowers contrast markedly with the deep pink to magenta flowers of sympatric and co-blooming *H. baurii* and *H. scopulosa,* and with the pale pink flowers of *H. brevistyla* and *H. leucantha*.

55. **Hesperantha pulchra** *Baker*, Handbook of the Irideae: 150 (1892); Hilliard & Burtt: 413 (1986). Type: South Africa, [Eastern Cape], Transkei, Baziya Mtn, Apr., *Baur 159* (K, holo.; B, iso.).



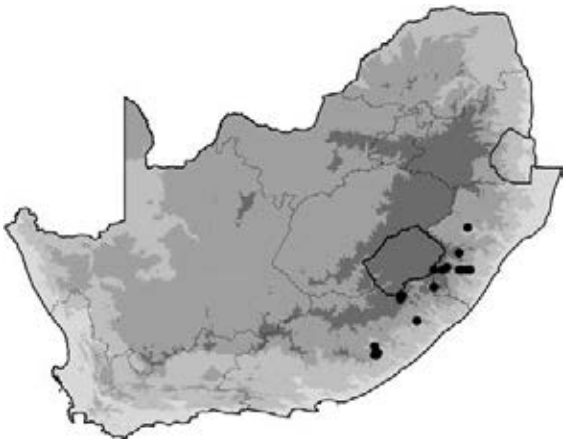
Plants 400–800 mm high. *Corm* ± globose, 15–20 × 12–16 mm; tunics dark brown, concentric, splitting into narrow elliptic sections narrowed distally into short cusps. *Stem* unbranched. *Leaves* 4, lowermost 1 or 2 basal, ± ⅔ as long as stem, 3.0–5.5 mm wide, remaining leaves cauline and shorter, uppermost largely sheathing and bract-like. *Spike* 5- to 11-flowered, straight or slightly flexuose; bracts green, outer 17–36 mm long, inner shorter. *Flowers* salver-shaped, diurnal, unscented; perianth tube ± cylindric, expanded near apex, 14–25(–28) mm long; tepals 14–24 mm long. *Filaments* (3)4–6 mm long; anthers 7–11 mm long, yellow; pollen yellow. *Style branches* 10–16 mm long, reaching to ± apex of anthers in closed flower. *Capsules* oblong, 10–17 mm long. *Seeds* globose, ± 1.3 mm diam. with short to well-developed wings. *Flowering time*: mainly March and April.

Distribution and ecology: extending from the Amatole Mtns of Eastern Cape, South Africa north to Naude's Nek; in rocky grassland.

Diagnosis: a late-flowering species, *Hesperantha pulchra* is recognised by the bright pink flowers with a perianth tube of intermediate length, mostly 15–20 mm long (14–28 mm), and relatively short filaments, 3–6 mm long. Plants from KwaZulu-Natal, north of the Tugela River, with a tube 15 mm long (*Gerstner 6713*, PRE) and ± 12 mm (*Fakude 3*, NH) fit uncomfortably in this otherwise Eastern Cape species. Plants from Mt Thomas, near Stutterheim in Eastern Cape (*McMaster s.n.,* NBG), collected in later flower on 11 February, with ripe capsules at the base of the spike, resemble *H. pulchra* except for the early flowering. These plants have narrowly elliptic capsules 25 mm long that contain large seeds, up to 4 mm long with the wings at either end ± 1 mm long and

Distribution of ***Hesperantha pubinervia***.

Distribution of ***Hesperantha pulchra***.



the seed body ± 2 mm long. Capsules of *H. pulchra* are described by Hilliard & Burtt (1986) as 10–17 mm long with seeds ± 1.25 mm diam., with weakly or strongly developed wings. We need to know more about both the Zululand and Mt Thomas plants. Additional collections, especially in fruit, will be helpful in understanding the range of variation in this species.

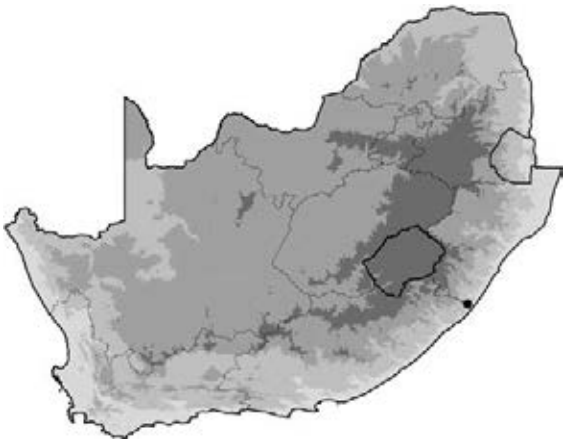
56. **Hesperantha woodii** *Baker*, Handbook of the Irideae: 150 (1892); Hilliard & Burtt: 413 (1986); Goldblatt: 427 (2003). Type: South Africa, [KwaZulu-Natal], Richmond District, Peak of Byrne, Apr. or May, 1883, *J.M. Wood 1868* (K, NH, syn.).

Hesperantha galpinii R.C.Foster: 13 (1948). Type: Lesotho, valley above Buffalo River falls, 14 Mar. 1904, *E.E. Galpin 6856* (BOL, lecto., designated by Goldblatt: 427 (2003); B, GRA, K, NH, PRE, SAM, isolecto.).

Plants 200–450 mm high. *Corm* conic, 8–10 mm diam.; tunics woody, layers soon breaking into triangular segments tapering above into short points. *Stem* unbranched. *Leaves* usually 4, lower 2 basal, longest, reaching to between middle of stem and apex of spike, linear, 2–3 mm wide, firm, upright, main vein prominently raised, margins lightly thickened, upper 2 leaves smaller and partly to entirely sheathing. *Spike* mostly 2- to 4-flowered; bracts 22–30 mm long, green, becoming dry and ± brown above. *Flowers* bright mauve-pink, pale yellow in throat; perianth tube (18–)22–38 mm long, cylindric, lightly curving toward apex, expanded near mouth; tepals weakly ascending, elliptic, 23–27 × 6.0–7.5 mm, acute. *Filaments* ascending, 6–8 mm long; anthers diverging, 9–10(–11) mm long, tailed in lower 2 mm, yellow; pollen yellow. *Style branches* 18–20 mm long, laxly ascending, exceeding anthers in closed flower. *Capsules* ± ellipsoid, 16–18 mm long. *Seeds* unknown. *Flowering time*: February to April, possibly in May.

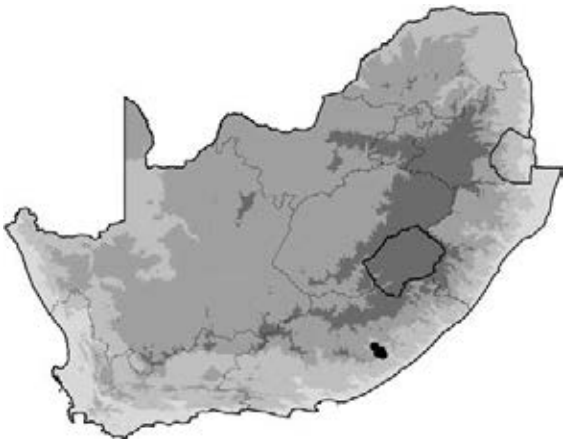
Distribution and ecology: restricted to the mountains of southern Lesotho and southern KwaZulu-Natal and adjacent Eastern Cape in South Africa as far south as Naude's Nek; on stony slopes and rocks, often near streams.

Distribution of ***Hesperantha woodii***.



Diagnosis: one of a handful of long-tubed, pink-flowered species of *Hesperantha* in eastern southern Africa, *H. woodii* is a relatively tall species, reaching up to 450 mm, with radially symmetric flowers, and is recognised by the perianth tube mostly 20–38 mm long, only slightly curved near the mouth, and the ascending rather that fully spreading tepals. Vegetatively similar *H. grandiflora* has a strongly curved perianth tube (26–)33–55 mm long, and zygomorphic flowers with vertically oriented tepals and unilateral stamens and style branches, and red-brown anthers and pollen, which are in marked contrast to the conventional yellow anthers and pollen in *H. woodii*.

57. **Hesperantha mtamvunae** *Goldblatt & J.C.Manning*, new species. Type: South Africa, KwaZulu-Natal, Port Edward, Umtamvuna Nature Reserve, Outeniqua Trail, 29 June 2017, *K.W. Grieve 2393* (NBG, holo. [2 sheets]).



Plants 500–750 mm high. *Corm* conic, ± 10 mm diam.; tunics woody, layers soon breaking into triangular segments tapering above into short points. *Stem* unbranched. *Leaves* 4, lowermost green or dry at flowering, lower 2 basal, longest, reaching to between middle of stem and apex of spike, linear, 1.5–2.5 mm wide, firm, upright, main vein prominently raised, margins lightly thickened, upper 2 leaves smaller and partly to entirely sheathing. *Spike* straight, 3- to 6-flowered; bracts 27–30 mm long, green, becoming dry and ± brown above. *Flowers* suberect, bright mauve-pink, pale yellow in throat; perianth tube 22–25 mm long, cylindric, straight or lightly curving toward apex, expanded near mouth; tepals weakly ascending, elliptic, 23–25 × 5–6 mm, acute. *Filaments* ascending, 5–6 mm long; anthers diverging, 11–12 mm long, tailed in lower 2 mm, brown; pollen brown (?rarely yellow). *Style branches* 18–20 mm long, laxly ascending, exceeding anthers in closed flower. *Capsules* ellipsoid, (12–)15–20 mm long. *Seeds* angular-prismatic, ± 2.5–3.5 × 1.5 mm, with broad membranous wings at both ends. *Flowering time:* June to July.

Distribution and ecology: known only from the Umtamvuna Nature Reserve in southern KwaZulu-Natal, South Africa; in open damp grassland and forest margins, on quartzite on fairly steep S- and SE-facing slopes below 400 m altitude.

Diagnosis: Hesperantha mtamvunae is recognised among the longer-tubed species of the genus in eastern southern Africa by its unusual height, 500–750 mm, and spikes of 3 to 6 pink flowers with the perianth tube 22–25 mm long and distinctive brown anthers, 11–12 mm long, thus twice as long as the filaments, 5–6 mm long. *Hesperantha woodii* from inland KwaZulu-Natal and the Eastern Cape has similar flowers but is a shorter plant up to 450 mm tall, usually with only 2 to 4 flowers per

Distribution of ***Hesperantha mtamvunae***.

Distribution of ***Hesperantha stenosiphon***.

spike, with bright yellow anthers, mostly 9–10 mm long, with proportionally longer filaments 6–8 mm long. *Hesperantha pulchra*, also with yellow anthers, has broader leaves 3.0–5.5 mm wide, and shorter style branches, 10–16 mm long, reaching only to the tips of the anthers in closed flowers.

Few other long-tubed, pink-flowered species of *Hesperantha* have brown anthers and sometimes pollen, notably *H. stenosiphon* (perianth tube 45–60 mm long and pollen yellow), *H. grandiflora* (perianth tube 40–55 mm long and flowers zygomorphic with stamens declinate, filaments 8–14 mm long), and *H. hutchingsiae* (perianth tube 21–23 mm long and spikes 2- or 3-flowered), and all are significantly shorter plants from inland at relatively high elevations, unlike the near-coastal *H. mtamvunae.* Additional collections are needed to better assess the species and its relationships.

58. **Hesperantha stenosiphon** *Goldblatt* in Annals of the Missouri Botanical Garden 90: 429 (2003). Type: South Africa. Eastern Cape, Bolo District, Moonstone Farm, steep grassy slope, 1 120 m, 20 Mar. 2001, *C. McMaster s.n.* (NBG, holo.; MO, PRE, iso.).

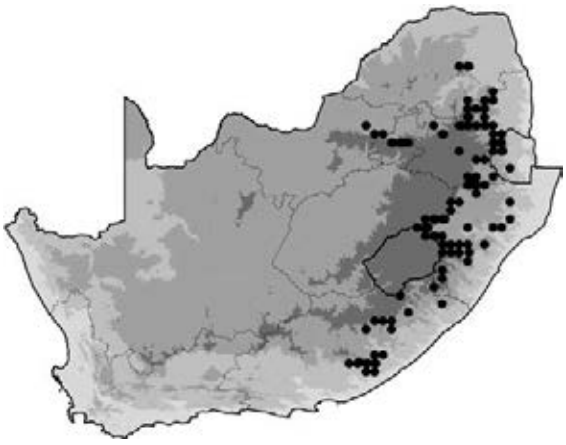
Plants 250–500 mm high. *Corm* globose, ± 12 mm diam.; tunics woody, layers soon breaking into vertical segments tapering above into short points. *Stem* usually unbranched. *Leaves* usually 4, lower 2 basal, longest, reaching to between middle of stem and apex of spike, ± linear, 2–3 mm wide, firm, erect, main vein and margins lightly thickened, upper leaves smaller and partly to entirely sheathing. *Spike* (2–)4- to 8(–12)-flowered; bracts 18–24 mm long, green, becoming dry and brown near tips. *Flowers* bright pink, white in mouth of tube; perianth tube 45–60 mm long, cylindric, slightly curved or straight, barely expanded near mouth; tepals ascending, elliptic, 18–21 × 7–8 mm, subacute. *Filaments* suberect, ± 3 mm long; anthers diverging, 9–10 mm long, dark brown to ± black; pollen yellow. *Style branches* ± 8.5 mm long, reaching to just below anther tips in closed flower. *Flowering time*: March and April.

Distribution and ecology: a narrow endemic of the Cathcart area of Eastern Cape, South Africa, known from just two localities; on hill tops among rocks partly shaded by bush and small trees or in open rocky grassland.

Diagnosis: among the elongate-tubed and pink-flowered species of *Hesperantha* of eastern southern Africa, *H. stenosiphon* stands out in the radially symmetric flowers with a nearly straight perianth tube 45–60 mm long, and dark brown to nearly back anthers but yellow pollen. The filaments are comparatively short, ± 3 mm long whereas the anthers are 9–10 mm long. It is probably most closely allied to long-tubed *H. grandiflora* and *H. woodii* and shares with them linear leaves with lightly to moderately thickened margins and midribs as well as the pink perianth. *Hesperantha grandiflora* has nodding flowers with vertically oriented tepals and unilateral, declinate stamens and style branches, filaments 8–14 mm long, and red-brown to purple anthers and pollen; and *H. woodii* has similarly large, but nearly upright, radially symmetric flowers with filaments 6–8 mm long and yellow anthers and pollen. The flowers of all three species have typical adaptations for pollination by long-proboscid flies, but pollination of *H. stenosiphon* has not been documented.

59. **Hesperantha coccinea** *(Backh. & Harv.) Goldblatt & J.C.Manning* in Novon 6: 263 (1996). *Schizostylis coccinea* Backh. & Harv.: t. 5422 (1864). Type: South Africa, without precise locality or collector, illustration in Back. & Harv.: t. 5422 (1864).

Schizostylis pauciflora Klatt: 380 (1867). Type: South Africa, without precise locality or collector, (K, holo.).



[*Schizostylis ixioides* Harv. ex Baker: 108 (1877), invalid name only in synonymy.]

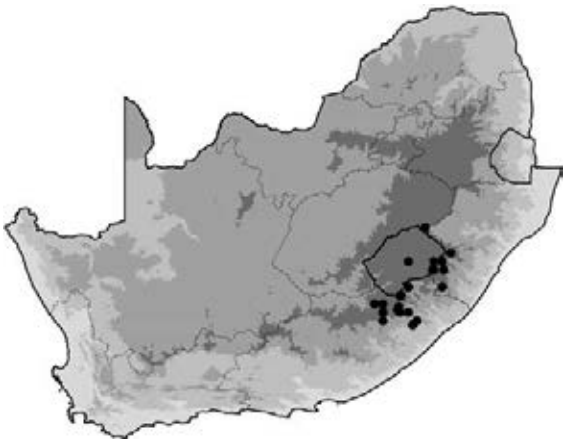
Plants up to 450 mm high. *Rootstock* a creeping rhizome. *Stem* usually unbranched, sometimes bearing cormlets in aerial axils. *Leaves* several, narrowly lanceolate to ± linear, somewhat fleshy, lower 3 or 4 basal and longest, reaching to about the base of the spike, 7–10 mm wide,

upper 3 or 4 leaves cauline and progressively shorter. *Spike* usually with 12 or more flowers; bracts green, outer 20–25 mm long, inner 2-keeled, ± ⅔ as long. *Flowers* salver-shaped, diurnal, red or pink, unscented; perianth tube ± 25 mm long, cylindric, expanded near apex; tepals elliptic, spreading, shallowly spooned, mostly 25–28 × 12–15 mm, inner slightly narrower than outer. *Filaments* ± 10 mm long; anthers ± 8 mm long, brown; pollen dull yellow. *Style branches* ± 20 mm long, laxly spreading over tepals, exceeding anthers in closed flower. *Capsules* club-shaped, 12–15 mm long. *Seeds* angular, ± 2 × 1.2 mm, with loose, translucent, light brown seed coat with a smooth outline, slightly ridged on angles. *Flowering time*: mainly March to May.

Distribution and ecology: relatively widespread in eastern southern Africa, extending from Hogsback in Eastern Cape, South Africa along the Great Escarpment and interior to Limpopo, as well as Lesotho and Eswatini, also recorded in eastern Zimbabwe; in marshes and along streams and drainage lines.

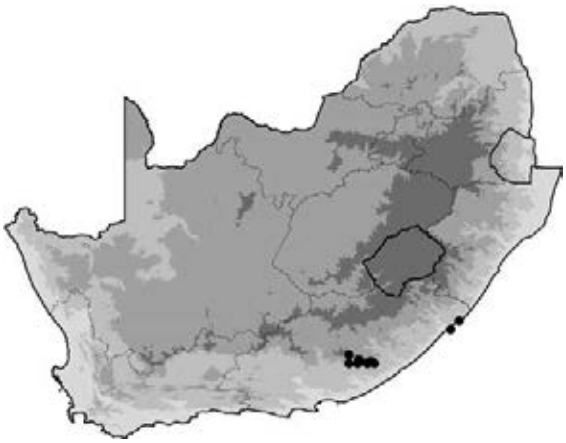
Diagnosis: with a flower structure exactly like that of *Hesperantha* species apart from the red colour of many populations, and virtually identical to that of long-tubed species like *H. pulchra* and *H. woodii*, there is little doubt that *H. coccinea* is correctly placed in the genus. While the flowers accord exactly with *Hesperantha* the rootstock differs in being a slender, branched rhizome. A plant of aquatic or semi-aquatic habitats, *H. coccinea* is thought to have lost its corm because this xeromorphic feature is not adaptive in such conditions. Small corms of the shape typical of *Hesperantha* are produced in the aerial leaf axils of some populations, supporting its assignment in the genus. There are two colour morphs of *H. coccinea*, the typical and more widespread red-flowered morph, which extends from the Amatole Mtns in Eastern Cape to Limpopo, and a pink morph local in the northern Drakensberg and Witwatersrand in Gauteng. Plants from there have been described as a separate species, *S. pauciflora*, because of its few-flowered spikes but probably represent depauperate plants or possibly a local variant. Mixed populations of red- and pink-flowered plants occur around Golden Gate in the Free State. The common red-flowered morph of *H. coccinea* is pollinated by large butterflies of the families Papilionidae and Satyridae but the pollination biology of the pink-flowered morph has not been studied.

Distribution of ***Hesperantha coccinea***.



Hesperantha coccinea is widely grown in gardens in North America and western Europe, and a range of named cultivars are available in the nursery trade, including at least one with white flowers.

60. **Hesperantha grandiflora** *G.J.Lewis* in Journal of South African Botany 7: 30 (1941) as new name for *Acidanthera tysonii* Baker: 187 (1892), not *H. tysonii* Baker (1892) [= *H. radiata* (Jacq.) Ker Gawl.]; Hilliard & Burtt: 410 (1986); Goldblatt: 431 (2003). Type: South Africa, [KwaZulu-Natal], waterfall near Mt Currie, Apr. 1883, *W. Tyson 1151* (*Herb. Norm. Austro-Afr. 895*) (K, holo.; BOL, NBG, PRE, iso.).



Plants 200–550 mm high. *Corm* conic, 12–15 mm diam.; tunics woody, ± imbricate, layers fragmenting into rectangular sections below and tapering into short cusps above. *Stem* unbranched. *Leaves* usually 4, lower 1 or 2 basal, longest, reaching to between middle of stem and apex of spike, ± linear, 2–3 mm wide, firm, ± erect, main vein prominently raised, margins lightly thickened, upper 2 leaves progressively smaller, uppermost partly to entirely sheathing. *Spike* mostly 2- to 5-flowered; bracts (20–)25–35(–42) mm long, green, inner slightly smaller than outer. *Flowers* diurnal, zygomorphic, pink, paler in throat; perianth tube 40–55 mm long, cylindric, curving outward distally, expanded near mouth; tepals ± vertically oriented, obovate-elliptic, (20–)25–37 × (6–)8–10(–12) mm. *Filaments* unilateral, declinate, 8–14 mm long; anthers ± parallel, facing dorsal tepal, 9–12 mm long, brown to purple; pollen brown to purple. *Style branches* arching below anthers, 15–25 mm long, exceeding anthers in closed flower. *Capsules* ± ellipsoid, 12–15 mm long. *Seeds* light brown, ± globose, 1.0–2.0 mm long, ± 1 mm diam., with narrow membranous wing at both ends. *Flowering time*: mainly late January to early March.

Distribution and ecology: relatively widespread in eastern southern Africa, extending from Lesotho and eastern Free State, South Africa near Witzieshoek through the KwaZulu-Natal Drakensberg to Eastern Cape at least as far south as Barkly Pass; in highland grassland.

Diagnosis: one of several long-tubed and pink-flowered species of *Hesperantha* in eastern southern Africa, *H. grandiflora* stands out in its zygomorphic, nodding flowers with the perianth tube, usually 40–55 mm long, curved outward near the apex and about 1.5× as long as the tepals, which are oriented ± vertically, while the stamens are unilateral and declinate, arching downward to lie above the lowermost tepal. The anthers are dark purple to red-brown, only rarely encountered in the genus. *Hesperantha stenosiphon*, with a similarly long perianth

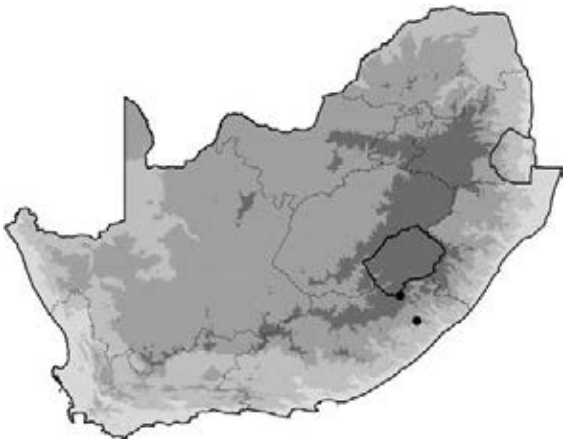
Distribution of ***Hesperantha grandiflora***.

Distribution of ***Hesperantha huttonii***.

tube but much smaller tepals, also has dark anthers, as does short-tubed *H. hutchingsiae*, but both have radially symmetric flowers. Like other long-tubed, pink-flowered species of *Hesperantha*, *H. grandiflora* is pollinated by long-proboscid nemestrinid flies.

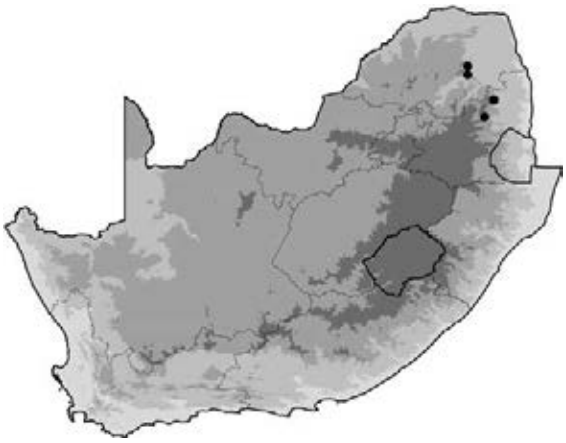
61. **Hesperantha huttonii** *(Baker) Hilliard & B.L.Burtt* in Notes from the Royal Botanic Garden, Edinburgh 40: 278 (1982); Hilliard & Burtt: 415 (1986); Goldblatt: 432 (2003). *Acidanthera huttonii* Baker: 339 (1876c). Type: South Africa, [Eastern Cape], Stockenstroom Division, Katberg, without date, *H. Hutton s.n.* (K, holo.).

Plants 200–500 mm high. *Corm* ± globose, 8–10 mm diam.; tunics dark brown, softly woody, overlapping, spitting below into truncate sections. *Stem* simple or occasionally 1-branched, erect or drooping. *Leaves* 5(6), lowermost 1 or 2 basal, up to 450 × 3–9 mm, soft-textured, flaccid, usually falcate, remaining leaves cauline, decreasing in size above, uppermost often entirely sheathing. *Spike* usually 4- to 7-flowered, ± straight; bracts 20–40 mm long. *Flowers* diurnal, salver-shaped, pink, unscented; perianth tube cylindric, expanded at apex, (15–)20–39 mm long; tepals elliptic, spreading, 15–24 × 5–8 mm. *Filaments* 6.0–7.5 mm long; anthers 7–10 mm long, yellow; pollen yellow. *Style branches* 18–20 mm long, exceeding anthers in closed flower. *Capsules* ± ellipsoid, 12–20 mm long. *Seeds* (1.5–)2.5–3.5 × 1.25 mm, with broad membranous wings at both ends ± 1.2–1.5 × 1 mm. *Chromosome number* 2*n* = 26. *Flowering time*: mostly February and March.



Distribution and ecology: occurring in Eastern Cape, South Africa, in the Amatole Mtns and Katberg to Adelaide and along the coast in the northern parts of the province; along forest margins, often in light shade, in clearings and on rock outcrops.

Diagnosis: *Hesperantha huttonii* is readily recognised by the pale pink flowers with an elongate perianth tube, typically 30–39 mm long, and large yellow anthers, 7–10 mm long. Plants have fairly broad, flaccid, drooping leaves, a suberect to drooping stem, and usually a cormlet in the axils of the lower leaves. The seeds of *H. huttonii* are distinctive, mostly 2.5–3.5 × ± 1.25 mm wide, with membranous wings at either end, the wings each ± half as long as the seed body which is up to 1.5 mm long. Plants from coastal northern Eastern Cape province, some 250 km to the east of the main range, best match the species, but one of the collections from there appears to lack axillary cormlets and has a perianth tube 23 mm long, while another collection has flowers with a tube only 15–17 mm long. The coastal plants are provisionally included in *H. huttonii* until more information becomes available. The long-tubed flowers are pollinated by long-proboscid flies.



62. **Hesperantha hutchingsiae** *Hilliard & B.L.Burtt* in Notes from the Royal Botanic Garden, Edinburgh 43: 414 (1986). Type: South Africa, [Eastern Cape], Transkei, Mhlahlane Forest Station, Mjika, ± 1 500 m, 21 Mar. 1985, *Hutchings & Plumstead 1621* (E, holo.).

Plants ± 300 mm high. *Corm* ± globose, ± 8 mm diam.; tunics dark brown, softly woody, imbricate. *Stem* simple, sheathed below by membranous, brown cataphyll. *Leaves* 4, lower 3 basal, linear, ½–⅔ as long as stem, 1.5–2.0 mm wide, main vein and margins thickened, prominent, uppermost leaf cauline, short, entirely sheathing. *Spike* 2- or 3-flowered; outer bract green flushed with dark purple, 16–20 mm long, inner smaller. *Flowers* diurnal, salver-shaped, rosy-purple, ?unscented; perianth tube cylindric, 21–23 mm long, expanded at throat; tepals subequal, ± 16 × 5.5 mm, spreading. *Filaments* ± 5 mm long; anthers 7.5 mm long, brown; pollen brown. *Style branches* ± 10 mm long, reaching to ± apex of anthers. *Flowering time*: March.

Distribution and ecology: so far known from two populations in the southern Drakensberg in Eastern Cape, South Africa, at Naude's Nek and to the southwest above Mhlahlane Forest Reserve near Mthatha; in wet depressions and marshes.

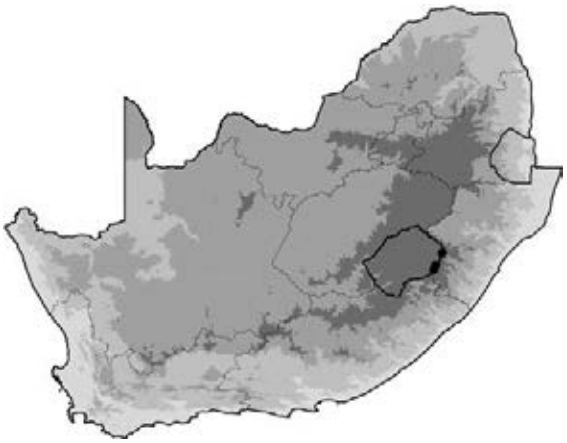
Distribution of ***Hesperantha hutchingsiae***.

Distribution of ***Hesperantha brevicaulis***.

Diagnosis: one of several species of eastern southern Africa with long-tubed, pink to purple flowers, *Hesperantha hutchingsiae* appears to be allied to the Eastern Cape and KwaZulu-Natal species *H. pulchra*. It is distinguished from that species by the shorter, narrower leaves 1.5–2.0 mm wide, 2- or 3-flowered spikes, and rosy-purple flowers. *Hesperantha pulchra* has leaves 3.0–5.5 mm wide, and spikes with mostly 5 to 11 bright pink flowers. *Hesperantha hutchingsiae* also stands out in the brown cataphyll sheathing the base of the stem, and in the dark brown anthers and pollen, both unusual in the genus, although dark brown to purple anthers also occur in the pink-flowered *H. grandiflora* and *H. stenosiphon*, both of which have flowers with a substantially longer perianth tube, 40–55 mm long in *H. grandiflora* and 45–60 mm long in *H. stenosiphon*; and in *H. mtamvunae*, with much longer anthers 11–12 mm long.

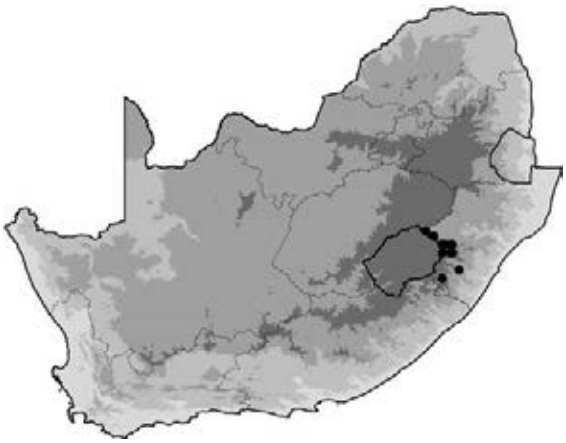
63. **Hesperantha brevicaulis** *(Baker) G.J.Lewis* in Journal of South African Botany 6: 30 (1941); Goldblatt: 433 (2003). *Acidanthera brevicaulis* Baker: 132 (1896). Type: South Africa, [Mpumalanga], Barberton, Devil's Bridge, Makwonga Range, Mar. 1891, *E.E. Galpin 1252* (K, holo.).

Plants 100–250 mm high. *Corm* conic, 7–9 mm diam.; tunics unknown. *Stem* usually inclined to sprawling, unbranched. *Leaves* 4, occasionally 5, lower 3 or 4 ± basal, with fairly soft-textured blades trailing distally, ± linear, 2–4 mm wide, main vein slightly raised, uppermost leaf cauline, largely to entirely sheathing. *Spike* mostly 2- or 3(4)-flowered; bracts green, soft-textured, outer 20–28 mm long, inner slightly shorter. *Flowers* mauve-pink, pale yellow in tube; perianth tube (13–)20–35 mm long, cylindric, curved toward apex, expanded near mouth; tepals spreading, 20–25 × 7–8 mm, subobtuse. *Filaments* ascending, (4–)5–8 mm long; anthers diverging, 7–10 mm long, yellow; pollen yellow. *Style branches* laxly spreading, 12–15(–20) mm long, exceeding anthers in closed flower. *Capsules* narrowly ovoid, 15–20 mm long, *Seeds* unknown. *Flowering time*: March to May, sometimes in February.



Distribution and ecology: South Africa, in Mpumalanga and Limpopo provinces along the Eastern Escarpment; on steep rocks and cliffs, growing in damp moss and rock crevices.

Diagnosis: one of several long-tubed, pink-flowered species of *Hesperantha* in eastern southern Africa, *H. brevicaulis* is distinguished by the soft-textured, trailing leaves, and short, usually trailing stem, 100–250 mm long. The comparatively large flowers typically have a perianth tube 18–35 mm long and tepals 20–25 mm long, the open flower thus 40–50 mm diam. The flowers are adapted for pollination by long-proboscid flies.



Plants from the Wolkberg and Serala in Limpopo apparently represent this species but flower earlier in the season, beginning to bloom as early as the middle of February. They also have flowers with a somewhat shorter perianth tube, 13–16 mm long. These shorter-tubed plants are provisionally included in *H. brevicaulis*. Plants from Serala, south of the Wolkberg, also differ from populations to the south in having anthers 5.0–6.5 mm long vs. 7–10 mm elsewhere.

Also puzzling are plants from Mt Prospect near Lydenburg, collected in early flower in mid-February. They have long-tubed mauve flowers with a tube 30–32 mm long, tepals ± 18 mm long, short filaments about 3 mm long, and anthers 6 mm long. The four leaves have well-developed blades and there is no sign of a largely sheathing upper leaf. The plants have blades with a firm texture, an apparently drooping flowering stem, and a spike of five flowers. The plant thus fits poorly in *Hesperantha brevicaulis* because of the firm leaves, absence of a sheathing upper leaf, spike with more than four flowers, short filaments, and relatively short anthers. Additional material of this plant is needed.

64. **Hesperantha curvula** *Hilliard & B.L.Burtt* in Notes from the Royal Botanic Garden, Edinburgh 43: 416 (1986). Type: South Africa. [KwaZulu-Natal], Underberg, Bushman's Nek, Thamathu Pass, 5 Feb. 1976, *Hilliard & Burtt 8981* (NU, holo.; E, MO, iso.).

Distribution of ***Hesperantha curvula***.

Distribution of ***Hesperantha scopulosa***.

Plants 120–300 mm high. *Corm* unknown. *Stem* usually simple or 1-branched, curving outward below, then ± erect. *Leaves* 4, lower 2 ± basal, ± half as long as stem, ± falcate, firm-textured, 1.5–4.0 mm wide, upper 2 leaves cauline, uppermost leaf largely to entirely sheathing. *Spike* mostly (1)3- to 5-flowered; bracts green or flushed purple distally, outer 14–21 mm long, inner slightly shorter. *Flowers* diurnal, magenta-rose, salver-shaped, ?unscented; perianth tube cylindric, curved toward apex, expanded near mouth, 18–25 mm long; tepals subequal, elliptic, spreading, 16–25 × 6–8 mm. *Filaments* ascending, (3–)4 mm long; anthers 7–9 mm long, yellow; pollen ?yellow. *Style branches* laxly spreading, 12–15(–20) mm long, exceeding anthers in closed flower. *Flowering time*: late January and February.

Distribution and ecology: a narrow endemic of the southern Drakensberg of KwaZulu-Natal, South Africa; occurring on wet turf ledges above Cave sandstone outcrops, ± 2 000–2 400 m elevation.

Diagnosis: recognised by the stem, curved outward above the base and then suberect, *Hesperantha curvula* has moderately long-tubed, bright magenta-pink flowers, the tube 18–25 mm long, with spreading tepals ± as long as the tube. *Hesperantha pulchra*, from lower elevation grassland in the Eastern Cape, has a comparably long tube but pale pink flowers and erect stems. *Hesperantha scopulosa*, which co-occurs with *H. curvula* in part of its range, has a longer perianth tube mostly 32–42 mm long.

65. **Hesperantha scopulosa** *Hilliard & B.L.Burtt* in Notes from the Royal Botanic Garden, Edinburgh 43: 417 (1986). Type: South Africa, [KwaZulu-Natal], Underberg, Bamboo Mtn, 8 Mar. 1977, *Hilliard & Burtt 10074* (NU, holo.; E, MO, iso.).

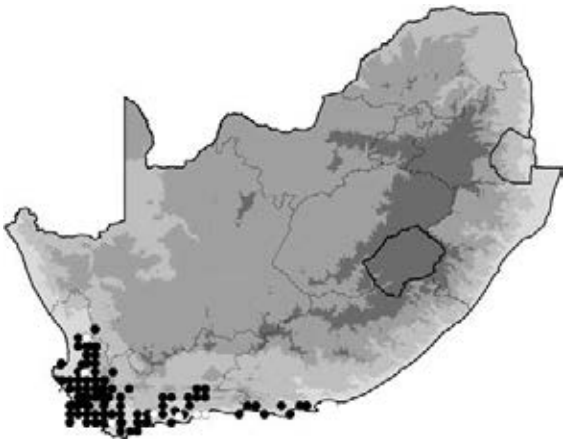
Plants mostly 140–250 mm high. *Corm* ± globose, 15–20 mm diam.; tunics dark brown, fragmenting below into truncate sections and drawn into short cusps above. *Stem* usually simple, rarely 1(2)-branched, curving outward distally, sometimes pendent. *Leaves* (3)4, lower 2 ± basal, ± usually longer than stem, falcate, soft-textured, (2.5–)4.5–10.0 mm wide, upper leaves cauline, shorter, uppermost largely to entirely sheathing. *Spike* mostly (1)3- to 8-flowered; bracts green or flushed purple distally, outer 20–35 mm long, inner slightly shorter. *Flowers* diurnal, salver-shaped, mauve-pink to magenta- pink, white in throat, unscented; perianth tube cylindric, curved toward apex, expanded near mouth, mostly 30–42 mm long; tepals subequal, elliptic, spreading, 16–25 × 5.5–7.2 mm. *Filaments* ascending, 3.0–4.4 mm long; anthers 4.5–7.0 mm long, yellow; pollen yellow. *Style branches* laxly spreading, 10–14 mm long, exceeding anthers in closed flower. *Capsules* ellipsoid, 8–13 mm long. *Seeds* ellipsoid-fusiform, lightly angled, 1.25–1.50 mm long, golden-brown, with thread-like funicle 2–3 mm long, pendent after capsule dehiscence. *Flowering time*: mostly mid-February to April.

Distribution and ecology: occurring at mid- to upper elevations of the Drakensberg of eastern Free State and KwaZulu-Natal, South Africa, probably also in Lesotho; on wet rock ledges and mossy rock faces, often on sandstone but also basalt.

Diagnosis: among the long-tubed *Hesperantha* species of the Drakensberg, *H. scopulosa* stands out in its rocky habitat, curved and often trailing stems, falcate leaves and mauve to magenta-pink flowers. The perianth tube is typically 30–42 mm long and 1.5–2.0× as long as the tepals, 16–25 mm long. Seeds of *H. scopulosa*, are striking in the genus, ovoid, ± 1.3 mm long, with a pale, irregularly twisted persistent funicle several times longer than the seed body. The chalazal end of the seed has what appears to be a vestigial wing. The flowers are pollinated by long-proboscid flies but flowers that have been examined show the tube lacks nectar and pollination visits depend on their resemblance to those of other species in the area that secrete nectar.

Sect. 2. **Hesperantha**

Plants with relatively large symmetrical, bell-shaped corms with flat, horizontal or oblique base; older corm tunics partly splitting from base. *Spike* with floral outer bract margins free to base. *Flowers* variously coloured, with straight perianth tube.



Species 13: restricted to the southern African winter-rainfall zone.

66. **Hesperantha falcata** *(L.f.) Ker Gawl.* in König & Sims, Annals of Botany 1: 225 (1804a); Goldblatt: 97 (1984). *Ixia falcata* L.f.: 92 (1782). Type: South Africa. Western Cape, hills around Cape Town, without date, *C.P. Thunberg s.n.* [UPS–THUNB 9052B, lecto., designated by Goldblatt: 97 (1984)].

Plants mostly 120–300 mm high. *Corm* bell-shaped with flat base, mostly 7–12 mm diam.; tunics overlapping, dark brown, outer layers splitting into sections below. *Stem* simple or 2- or 3-branched from near base, sometimes also from aerial axil. *Leaves* 4 or 5, lower 3 or 4 basal, usually reaching to ± base of spike, straight or falcate, mostly 4–8 mm wide, uppermost leaf shortest, sometimes entirely sheathing. *Spike* mostly 3- to 7-flowered; bracts green, often red later becoming dry distally, outer 7–12 mm long, inner slightly shorter. *Flowers* salver-shaped, white then with outer tepals red to brown outside and crepuscular, or yellow with outer tepals flushed brown outside and diurnal, sweetly scented when white; perianth tube cylindric, mostly 5–9 mm long, expanded near mouth; tepals (9–)12–16 mm long, elliptic, shallowly spooned. *Filaments* 3–4 mm long; anthers 3.5–7.5 mm long, ± horizontal, white or yellow; pollen white or yellow. *Style branches* ± 6 mm long, reaching to between middle and tips of anthers in closed flower. *Capsules* obovoid, 7–10 mm long. *Seeds* light brown, angular. *Chromosome number* 2*n* = 26. *Flowering time*: August and September, to mid-October in the south.

Distribution and ecology: South Africa, extending from the Bokkeveld Mtns in Northern Cape to the Cape Peninsula in Western Cape and east to Port Elizabeth in Eastern Cape; on sandy loam, stony sandstone slopes or on clay in renosterveld.

Diagnosis: one of the most common and widespread species of the genus in the winter-rainfall zone, *Hesperantha falcata* is recognised in sect. *Hesperantha* by the three or four, usually falcate, basal leaves and one more cauline and largely sheathing leaf, and white, creamy white or yellow flowers. Other white-flowered species of the section have smaller flowers, in *H. spicata* a perianth tube 4–6 mm long and tepals 4–7(–9) mm long. *Hesperantha laxifolia* has a similarly short perianth tube ± 5 mm long, only two foliage leaves (and one or two more entirely sheathing) and unusually short style branches ± 2.5 mm long. In *H. laxifolia* the style and style branches remain included in the perianth tube and in *H. cedarmontana* both style branches and stamens are included. In the rare white-flowered *H. dolomitica* from the Knersvlakte and *H. eremophila* from the Richtersveld, the narrow tepals remain half cupped in fully open flowers.

Distribution of ***Hesperantha falcata*** subsp. ***falcata***, ●; subsp. ***lutea***, ○.

The yellow-flowered populations, which occur mainly in the southern Cape and typically on clay or clay loam soils, are treated as a separate subspecies, distinguished by flower colour and diurnal flowering. Subsp. *falcata* remains relatively variable and some variants have been accorded specific rank, notably *H. trifolia*, recognised by its particularly large, creamy white flowers, almost always has three leaves and spikes with sometimes as few as two or three flowers, and the bracts are also rather soft-textured, often ± membranous but the presence of intermediates makes its recognition as a separate taxon seem unhelpful. These populations represent the northern race of the species. Plants from the east of the range of subsp. *falcata* have the smallest flowers of the species.

Key to subspecies

1a Flowers white, sometimes creamy white (rarely creamy yellow) and crepuscular, scented in the late afternoon and evening. . . . . 66a. subsp. *falcata*
1a Flowers pale to deep yellow and diurnal, never scented. . . . . 66b. subsp. *lutea*

66a. subsp. **falcata**

Hesperantha insipida G.J.Lewis: 56 (1941), as a new name for *Geissorhiza pauciflora* Baker: 1004 (1904) [not *H. pauciflora* G.J.Lewis, 1938]. Type: South Africa, [Western Cape], near Porterville, *R. Schlechter 4891* (B, BOL, G, K, W, Z, syn.).

Hesperantha pentheri Baker: 26 (1906). Type: South Africa, [Western Cape], Olifants River Valley, Clanwilliam, Aug. 1894, *A. Penther 686* [K, lecto., designated by Foster: 21 (1948)].

Hesperantha trifolia R.C.Foster: 26 (1948). Type: South Africa, [Western Cape], Bulshoek, 2 Aug. 1896, *R. Schlechter 8378* (B, holo.; BOL, G, K, MO, P, PH, PRE, US, Z, iso.).

[*Hesperantha maritima* Eckl.: 23 (1827), invalid name without description.]

[*Hesperantha pallida* Eckl.: 23 (1827), invalid name without description.]

Flowers nocturnal, white or creamy white, occasionally creamy yellow, outer tepals usually flushed red, sometimes brown outside, sweetly scented when open in later afternoon and evening; perianth tube 5–9 mm long; tepals (9–)12–16 mm long. *Flowering time*: August and September to early October in the southeast; flowers opening late afternoon, usually after 16:00 (but variable), closing after 21:00–21:30 or after 2:00, depending on population and weather conditions.

Distribution and ecology: occurring thoughout the range of the species, from the Bokkeveld Mtns to Port Elizabeth; on sandy flats and slopes, sometimes in seasonally wet places.

Diagnosis: the clear white to creamy white (sometimes almost pale yellow) flowers of subsp. *falcata* separate if from yellow-flowered subsp. *lutea.* As outlined above subsp. *falcata* remains variable, with the northern populations in the Olifants River Valley and nearby (described in the past as *H. pentheri* and *H. trifolia*) often having larger flowers, blooming earlier in the season, and often occurring in rocky, well-drained sites. Intermediates between this and the typical form make it impossible to consistently differentiate the two as separate taxa.

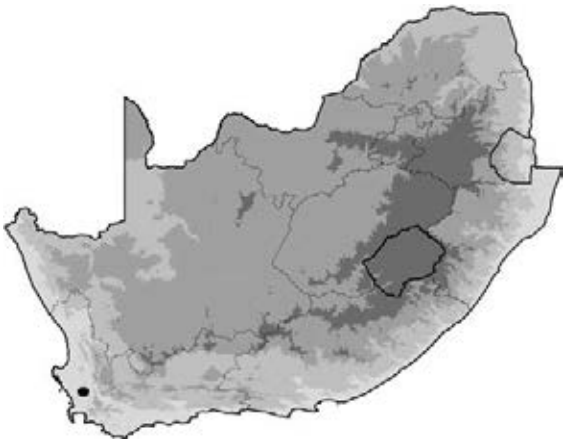
66b. subsp. **lutea** *(Benth. ex Baker) Goldblatt & J.C.Manning* in South African Journal of Botany 98: 119 (2015). *Hesperantha lutea* Benth. ex Baker [as *H. lutea* Benth.]: 149 (1892). Type: South Africa, [Western Cape], Caledon [District], without date, *C.L. Zeyher s.n.* (K, holo.).

Hesperantha lutea var. *luculenta* R.C.Foster: 19 (1948). Type: South Africa, [Western Cape], hills at Berg River Bridge, Piketberg, *R. Schlechter 5261* (GH, holo.; B, BOL, G, K, P, PRE, S, Z, iso.).

[*Geissorhiza lutea* Eckl.: 21 (1827), invalid name without description.]

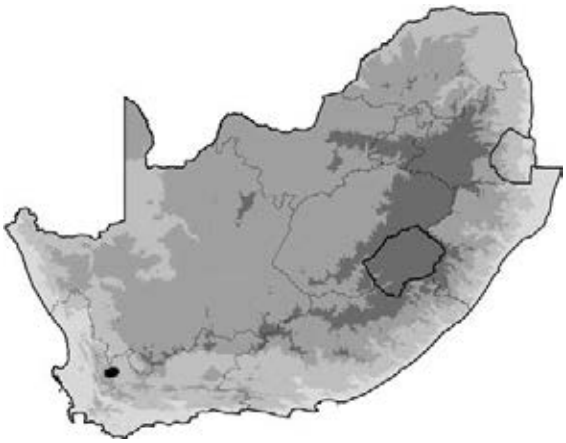
Flowers diurnal, clear pale or deep yellow, outer tepals usually flushed brown outside, unscented. *Flowering time*: mainly late August and September; flowers open late morning to shortly after midday and close ± 16:00.

Distribution and ecology: extending from near the Koebee Mtns to Porterville in the west and from Caledon to Mossel Bay in the south, Western Cape; on clay or clay loam slopes and flats.



Diagnosis: subsp. *lutea* is readily recognised in sect. *Hesperantha* by the clear yellow flowers. The northwestern populations have pale yellow flowers and those in the south deep yellow but the flowers are diurnal in both, opening in the late morning to shortly after midday and closing in the late afternoon. The subspecies occurs on clay soils in renosterveld, whereas subsp. *falcata* is most often found on sandy ground, sometimes in wet sites, or sandstone outcrops. The only other yellow-flowered populations in the section are a rare pale yellow-flowered morph of *H. pauciflora* from the Bokkeveld Mtns. *Hesperantha pauciflora* is distinguished from *H. falcata* by the corms bearing prominent lateral spines and typically pink to purple flowers. *Hesperantha sufflava* has pale, watery yellow flowers and differs in consistently having only three leaves, all basal, and the style dividing well within the perianth tube.

67. **Hesperantha sufflava** *Goldblatt* in Annals of the Missouri Botanical Garden 90: 435 (2003). Type: South Africa, Western Cape, Malmesbury, sandy gravel slopes in renosterveld, 14 Aug. 1999, *P. Goldblatt & I. Nänni 11087* (NBG, holo.; K, MO, PRE, S, WAG, iso.)



Plants mostly 80–150 mm high. *Corm* bell-shaped with flat base, 10–18 mm diam.; tunics woody, margins denticulate. *Stem* often branching from near base and from axil of uppermost leaf. *Leaves* 3, all basal or uppermost subbasal, lanceolate to falcate, reaching to ± middle or stem, 2–7 mm wide, slightly fleshy, main vein not visibly thickened, upper leaf sheathing stem with short free unifacial tip. *Spike* lightly flexuose, (2)3- to 7-flowered; bracts 10–14 mm long, green, often red along upper margins, divergent. *Flowers* salver-shaped, crepuscular, pale yellow, outer tepals flushed light brown outside; perianth tube slender, straight, 12–14(–16) mm long; tepals subequal, ovate, slightly spooned, 7–9(–10) × 4–5 mm, spreading ± at right angles to tube when fully open after 15:00. *Filaments* ± 2 mm long, inserted at tepal bases; anthers ± 4 mm long, erect, yellow; pollen yellow. *Style branches* ± 12 mm long, dividing in middle of tube, exserted ± 7 mm, then weakly diverging, reaching to ± upper ⅓ of anthers in closed flower. *Capsules* oblong-obovoid, (6–)7–9 × ± 4 mm. *Seeds* ± globose or weakly angled, ± 1.3 mm diam. *Chromosome number* 2*n* = 26. *Flowering time*: late July and August.

Distribution and ecology: local in the Malmesbury District of Western Cape, South Africa; in renosterveld on granitic gravel.

Diagnosis: *Hespernatha sufflava* at first appears to be intermediate between the common, usually white-flowered *H. falcata* and the rarer *H. spicata*, but at the type locality *H. spicata* grows together with *H. sufflava* and is obviously quite different in its secund spike of small, pure white flowers with slightly curved perianth tube 4–6 mm long and smaller tepals 4–7 mm long. Moreover, flowers of *H. spicata* open at about 18:30 when they release a strong, sweet, narcissus-like scent with a strong clove component. Flowers of *H. sufflava* are pale yellow and open at about 15:00 and have a quite different, slightly acrid, pyrethrum-like odour. Particularly unusual are the long style branches about 12 mm long

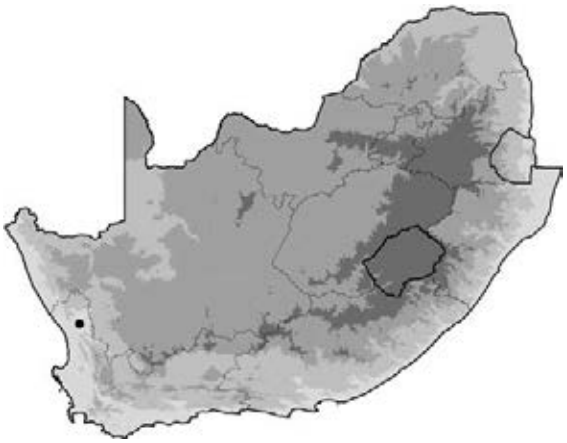
Distribution of ***Hesperantha sufflava***.

Distribution of ***Hesperantha lithicola***.

that divide in the middle of the perianth tube, with only the upper 7 mm exserted. In nearly all *Hesperantha* species the style divides just below the mouth of the tube and not within its narrow part.

Although easily confused with *Hesperantha falcata* the flowers of *H. sufflava* are somewhat smaller, with tepals 7–10 mm long but a substantially longer perianth tube, usually 12–16 mm long, and always longer than the tepals. In *H. falcata* the tepals are usually 12–18 mm long, exceptionally only 9–11 mm in southern Cape coastal populations, and the perianth tube is 4–9 mm long, thus usually shorter than the tepals. Apart from the flowers, *H. sufflava* is distinctive in always having only three leaves, all basal or the uppermost one subbasal, and the stem often has a branch produced from the axil of the upper leaf. Most populations of both *H. spicata* and *H. falcata* have three (rarely more) foliage leaves and one short, largely or entirely sheathing upper leaf.

68. **Hesperantha lithicola** *J.C.Manning & Goldblatt* in Bothalia 37: 180 (2007). Type: South Africa, Western Cape, Swartruggens, Farm Knolfontein, between Katbakkies Pass and Skitterykloof, in loam and leaf litter on sandstone pavement, 12 Sept. 2006, *P. Goldblatt & J.C. Manning 12817A* (NBG, holo.; MO, PRE, iso.).



Plants (40–)80–200(–290) mm high. *Corm* bell-shaped with flat base, 7–10 mm diam.; tunics breaking into segments below, margins fringed and often with radiating spines. *Stem* unbranched or rarely with one branch from near base. *Leaves* 4, lower 2 basal, suberect or falcate, often undulate or loosely coiled, (30–)50–100(–160) × 1–2 mm, main vein prominently raised and margins squared and minutely scabrid along both edges, uppermost leaf entirely sheathing. *Spike* 1- to 4-flowered; bracts green, flushed reddish, becoming dry apically, 11–20 mm long. *Flowers* salver-shaped, crepuscular, white, outer tepals red outside, with rosy citrus fragrance; perianth tube 10–12 mm long, cylindric, wider near apex; tepals subequal, elliptic, spreading, 10–15 × 4.0–6.5 mm, outer slightly larger than inner. *Filaments* slightly diverging, 3–5 mm, exserted 2–3 mm from tube; anthers horizontal, ± 6 mm long, pale yellow. *Style branches* 4.0–5.5 mm long. *Capsules* ellipsoid, 9–10 × 4 mm. *Seeds* subglobose, golden-brown, 1.0–1.5 mm diam., rugose, testa cells domed. *Flowering time*: September.

Distribution and ecology: restricted to the Swartruggens Mtns in the eastern Cold Bokkeveld of Western Cape, South Africa; on sandstone pavement in rock crevices or shallow humus, often in the shelter of small shrubs.

Diagnosis: *Hesperantha lithicola* is distinctive in its symmetrical, bell-shaped corm and narrow, often twisted or coiled leaves. It is evidently most closely allied to *H. falcata*, which it resembles in general appearance but from which it differs in its consistently narrower leaves, 1–2 mm wide vs. 4–8 mm in *H. falcata*, and longer perianth tube, 10–12 mm vs. 4–9 mm. The two species differ also in their habitats, with *H. lithicola* restricted to shallow soils on sandstone rock pavement, whereas *H. falcata* is a common and widespread species of seasonally moist, deeper clay or sandy soils. This ecological difference is evident at the type locality, where *H. falcata* occurs nearby on sandy flats not far from rocky outcrops where *H. lithicola* is found. *Hesperantha lithicola* is remarkably similar in general appearance to *H. acuta* but this species has a globose, asymmetrical corm with one side flattened and extended downward. Without corms, however, the two taxa are almost indistinguishable, although *H. acuta* does not occur on the Cold Bokkeveld and is typically found on clay soils, rarely limestone or in pockets of loam on sandstone outcrops.

69. **Hesperantha dolomitica** *Goldblatt & J.C.Manning* in Bothalia 43: 145 (2013). Type: South Africa, Western Cape, Vanrhynsdorp, Knersvlakte, Farm Varsche Rivier 260, 300 m north of Vars River, south-facing limestone crevices, ledges and moss pads, 76 m, 25 July 2012, *Helme 7424* [not *7425* in protologue] (NBG, holo.; MO, iso.).

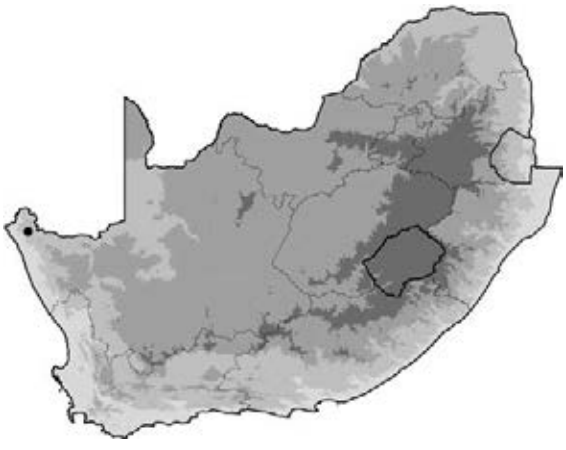
Plants mostly 180–250 mm high. *Corm* bell-shaped with flat base; tunics dark brown, softly woody, margins

Distribution of ***Hesperantha dolomitica***.

minutely toothed, outer layers irregularly broken. *Stem* unbranched, flaccid and inclined. *Leaves* 4, lower 2 basal, ± linear, flaccid, ± falcate, blades 60–80 × 3–4 mm, third leaf inserted shortly above ground and sheathing stem for most of its length, uppermost leaf bract-like, inserted on upper ⅓ of stem, entirely sheathing. *Spike* 2- to 4-flowered, bracts mostly 12–15 mm long, pale green, evidently becoming dry and pale straw-coloured during flowering, inner with 2 green keels, narrowed distally and tips sometimes recurved. *Flowers* evidently diurnal, white, tepals without darker colouring on reverse, remaining cupped when fully open, sweetly scented; perianth tube narrowly funnel-shaped, 12–14 mm long; tepals subequal, elliptic, 12–14 × 4 mm. *Filaments* ± 3 mm long; anthers 6–8 mm long, pale yellow; pollen yellow. *Style branches* ± 7 mm long, diverging. *Flowering time*: July, probably also August.

Distribution and ecology: local in the Knersvlakte in southern Namaqualand in Western Cape, South Africa, where it is restricted to limestone outcrops north of the Vars River; mostly wedged in cracks in the rocks, plants are also occasionally found in loamy, red soils at the base of the south-facing limestone cliffs.

Diagnosis: with bell-shaped corms with a flat base characteristic of sect. *Hesperantha*, *H. dolomitica* is recognised in the section by its relatively large, pure white flowers with tepals remaining cupped even when fully expanded and without darker pigmentation on the outside of the tepals. The perianth tube and tepals are about the same length, 12–14 mm long, relatively large for sect. *Hesperantha*. Additional observations are needed to confirm the ultimate orientation of the tepals which may not occur until after dark but they probably remain cupped.



70. **Hesperantha eremophila** *Goldblatt & J.C.Manning* in South African Journal of Botany 98: 119 (2015). Type: South Africa. Northern Cape, Richtersveld National Park, Vandersterrberg, on road to Koeskopfontein within the Venstervalle Valley, ± 3 km from Koeskopfontein, 13 Aug 2014, *P.C.V. van Wyk 477* (NBG, holo.; MO, iso.).

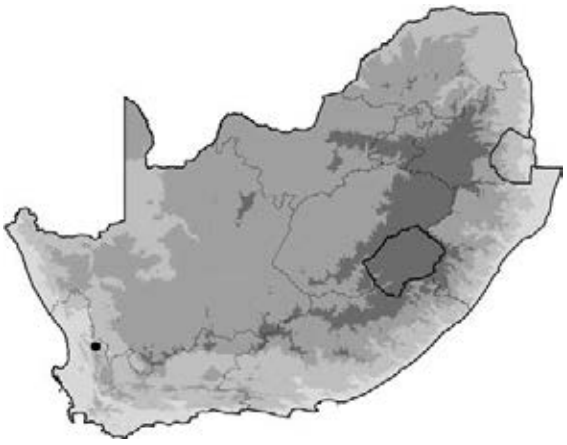
Plants mostly 150–350 mm high. *Corm* bell-shaped with flat base; tunics dark brown, softly woody, outer layers irregularly broken, margins minutely toothed. *Stem* unbranched. *Leaves* 3, lower 2 basal, falcate, blades 50–100 × 2–6 mm, bright green to slightly glaucous, with thickened, raised main vein, margins translucent-hyaline, uppermost leaf inserted shortly above ground, sheathing stem for most of its length with short blade up to 10 mm long. *Spike* flexuose, 1- or 2(3)-flowered, outer bract ± 12 mm long, pale green flushed red to purple at tip, inner slightly shorter, with 2 green keels, narrowed distally. *Flowers* crepuscular, rotate, white without darker colouring on reverse, dull yellow-green in throat and tube, tepals remaining cupped when fully open, with sweet, rose-like scent; perianth tube narrowly funnel-shaped, 5–6 mm long; tepals subequal, elliptic, 15–17 × 4–5 mm. *Filaments* ± 3 mm long, inserted ± 2 mm above base of tepals; anthers held horizontally, 7–8 mm long, pale yellow; pollen yellow. *Style* dividing 2 mm below mouth of tube, branches ± 12 mm long, diverging. *Flowering time*: August.

Distribution and ecology: restricted to the slopes of the Vandersterrberg in the Richtersveld National Park, Northern Cape, South Africa; in shaded, seasonally moist sites along seepages in rock crevices and at the foot of sandstone and conglomerate rock slabs.

Diagnosis: with a bell-shaped corm with a flat base, *Hesperantha eremophila* conforms to sect. *Hesperantha*, where it is distinguished by pure white flowers lacking dark colour on the reverse of the outer tepals, a funnel-shaped perianth tube 5–6 mm long, and tepals remaining cupped when fully open. The tepals, 15–17 mm long, are much longer than the perianth tube, and the long style branches, ± 12 mm long, are distinctive. The flowers are crepuscular, opening mid- to late afternoon and closing after midnight.

Among the white-flowered species of the section and genus only *H. dolomitica* has similarly cupped tepals also without colouring on the outside of the tepals, which suggests a possible relationship with *H. eremophila*.

Distribution of ***Hesperantha eremophila***.



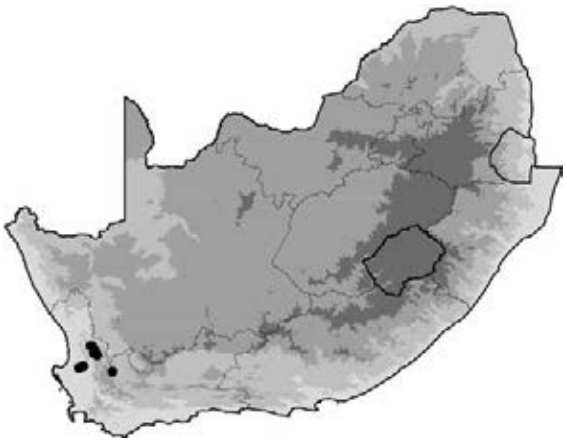
Flowers of *H. dolomitica* are larger, with a perianth tube 12–14 mm long and tepals about the same length, and style branches ± 7 mm long, just over half as long as those of *H. eremophila*.

71. **Hesperantha laxifolia** *Goldblatt & J.C.Manning* in Bothalia 43: 146 (2013). Type: South Africa, Western Cape, mtns north of Pakhuis Pass, occasional among sandstone rocks on S-facing slopes and banks, 12 Oct. 2012, *Goldblatt & Porter 13871* [not *13877*] (NBG, holo.; K, MO, PRE, iso.).

Plants 90–160 mm high. *Corm* bell-shaped with flat, sometimes oblique base, 10–15 mm diam.; tunics dark brown, inner layers ± woody, outer layers becoming soft and broken, margins minutely serrated. *Stem* unbranched, glabrous. *Leaves* 3(4), lower 2 leaves usually prostrate (suberect in deeply shaded sites), fleshy, flaccid, obtuse, 50–70 × 4–5 mm, with main vein raised, margins pale, slightly thickened, third leaf sheathing lower ⅓ of stem, slightly inflated, fourth leaf (when present) on upper part of stem, bract-like and entirely sheathing. *Spike* mostly 2- or 3(5)-flowered, outer bract 8–9 mm long, green flushed red distally, inner slightly shorter to ± as long, partly membranous with 2 green keels, notched apically. *Flowers* crepuscular, white, outer and sometimes inner tepals red to brown outside, rose-scented; perianth tube narrowly cylindric, slightly wider near apex, ± 5 mm long; tepals subequal, elliptic, ± 10 × 4 mm. *Filaments* ± 0.5 mm long; anthers ± 4 mm long, erect, pale yellow; pollen white. *Style branches* ± 2.5 mm long, arching upward, reaching to the lower ⅓ to slightly below middle of anthers in closed flower. *Capsules* and *seeds* unknown. *Flowering time*: September to late October.

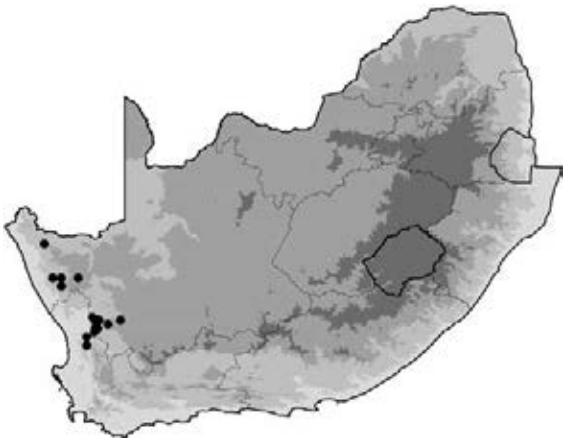
Distribution and ecology: known from a single, extended population in the Pakhuis Mtns of Western Cape, South Africa; in peaty and loamy sand in rocky sites, mainly in sheltered, shady situations on south-facing slopes.

Diagnosis: with white, crepuscular flowers typical of the genus, *Hesperantha laxifolia* is distinguished by its small flowers, with tepals ± 10 mm long and a particularly short perianth tube only half as long. Also unusual, the short stamens have filaments only about 0.5 mm long and anthers ± 4 mm long. The style divides just below the mouth of the tube into ascending style branches only 2.5 mm long, likewise unusually small for the genus and reaching only between the lower third and below the middle of the anthers in the closed flower. The two basal leaves are slightly succulent and spreading to ± prostrate, although the leaves may be ascending to suberect in deep shade. The flowers are crepuscular, opening at ± 18:00 and closing again between 21:00 and 21:30. The bell-shaped corms with the tunic margins finely toothed are typical of sect. *Hesperantha*, but within the section the relationships of *H. laxifolia* are uncertain. *Hesperantha montigena* also has prostrate leaves but much larger flowers with a perianth tube 12–15 mm long and tepals 14–16 mm long, thus ± as long as the tube, and the corms are asymmetric, placing it in sect. *Concentricae*.



Distribution of ***Hesperantha laxifolia***.

72. **Hesperantha cedarmontana** *Goldblatt* in Journal of South African Botany 50: 106 (1984). Type: South Africa, [Western Cape], Pakhuis Mtns W of Leipoldt's Grave, 27 Sept. 1981, *P. Goldblatt 6403* (MO, holo.; K, NBG, PRE, iso.).



Plants mostly 120–250(–450) mm high. *Corm* bell-shaped with flat base, ± 12 mm diam.; tunics dark brown, woody, margins minutely serrated, outer layers breaking into segments below. *Stem* unbranched, smooth, sheathing at base by membranous pale to brown cataphyll. *Leaves* usually 4, lower 2 basal, often prostrate, ± lanceolate, flaccid, ± blades 60–80(–150) × 2–8 mm, often obtuse, with slightly thickened main vein, third leaf inserted shortly above ground and sheathing stem for most of its length, uppermost leaf bract-like, inserted on upper third of stem, entirely sheathing. *Spike* (1–)3- to 8-flowered; bracts mostly 10–14 mm long, often flushed red. *Flowers* possibly crepuscular, salver-shaped, white, tepals flushed pink outside, carnation-scented; perianth tube ± cylindric, 10–13 mm long; tepals subequal, elliptic, 10–12 × ± 4 mm, spreading. *Filaments* included, inserted below mouth of tube, ± 0.5 mm long; anthers ± 3.5 mm long, pale yellow, included with apices barely emerging. *Style* short, dividing in lower ⅓ of tube, branches ± 3 mm long, seldom reaching base of anthers. *Capsules* narrowly ovoid, 10–15 mm long. *Seeds* unknown. *Chromosome number* $2n = 26$. *Flowering time*: July, probably also August.

Distribution and ecology: occurring in the mountains of Western Cape, South Africa, from Pakhuis Pass in the north to the Cold Bokkeveld and Swartruggens and locally in the Piketberg in the south; on sandstone outcrops, often in seasonally wet sites as on wet sandstone pavement.

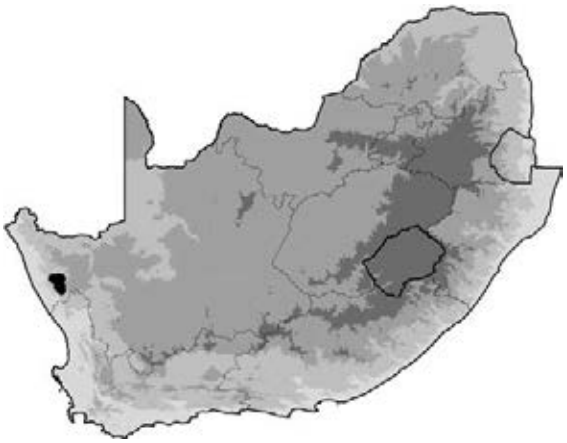
Diagnosis: *Hesperantha cedarmontana* is immediately distinguished by the white flowers with stamens, style and style branches included in the perianth tube. The tips of the comparatively short anthers, ± 3.5 mm long, just barely emerge from the mouth of the tube and the

Distribution of ***Hesperantha cedarmontana***.

Distribution of ***Hesperantha pauciflora***.

style branches reach no further than the bases of the anthers. The corms, fairly typical of sect. *Hesperantha,* are bell-shaped with the tunic margins minutely serrated. The two basal leaves have well-developed blades sometimes prostrate or flaccid but suberect when growing in dense vegetation. Flowers have been reported as beginning to open ± 12:30 and are fully open later in the day but the time of closing is not known.

73. **Hesperantha pauciflora** *G.J.Lewis* in Flowering Plants of Africa 18: t. 682 (1938); Goldblatt: 108 (1984). *Tritonia pauciflora* Baker: 193 (1892), illegitimate homonym, not *T. pauciflora* Klatt (1882). Type: South Africa, [Northern Cape], Namaqualand, near Naries, Sept. 1883, *H. Bolus 6622* [BOL, lecto., designated by Goldblatt: 108 (1984)].



Plants mostly 100–200 mm high. *Corm* bell-shaped with flat base, ± 10 mm diam.; tunics woody, margin with radiating spines. *Stem* simple or 1- or 2-branched from near base. *Leaves* 3 to 5, plane, ± lanceolate, ½–⅔ as long as spike, 3–7 mm wide. *Spike* flexuose, (1)2- to 4-flowered; bracts green or flushed red, becoming dry above, 9–14 mm long. *Flowers* diurnal, salver-shaped, pink to red-purple, sometimes white in throat (rarely uniformly yellow), outer tepals darker outside, occasionally scented; perianth tube 6–11 mm long, cylindric, widening near apex; tepals unequal, elliptic, spreading horizontally, outer 18–23(–26) × 7–9 mm, inner shorter and narrower. *Filaments* 2–8 mm long; anthers 5.5–9.0 mm long, ?purple (yellow when flowers yellow). *Style branches* 9–15 mm long, shorter than or exceeding anther tips in closed flower, laxly spreading. *Capsules* ovoid, 5–10 mm long. *Seeds* unknown. *Chromosome number* 2*n* = 26. *Flowering time*: mid-August and September.

Distribution and ecology: extending through northern Namaqualand from the southern Richtersveld near Kosies to the Kamiesberg and in the Bokkeveld Mtns in Northern Cape, South Africa; typically in deep sand or stony ground and sometimes very common in fallow or shallowly tilled fields.

Diagnosis: typical pink to purple-flowered *Hesperantha pauciflora* is recognised by the flat-based, bell-shaped corms with radiating marginal spines and an aerial stem up to 200 mm high. The flowers are large and attractive with tepals 18–26 mm long and a short perianth tube 6–11 mm long. Plants from Namaqualand have dark pink to purple flowers with a white throat, stamens with filaments 4–8 mm long, anthers 6.5–9.0 mm long, and the style branches reaching the anther tips or exceeding them by up to 2 mm in the closed flower. On the Bokkeveld Escarpment, ± 100 km south of the nearest Namaqualand populations, the flowers are either uniformly pale to deep pink, or often with darker pigmentation at the base of the tepals and in the throat, and the stamens in these populations have filaments only 2–3 mm long, with anthers 7–9 mm long, and the style branches barely reach the anther tips or up to 2 mm below them. Plants with pale yellow flowers from the south of its range at Papkuilsfontein south of Nieuwoudtville are included here, expanding the range of variation in *H. pauciflora*. They appear to differ in no other significant way from the pink-flowered populations and have identical bell-shaped corms with prominent radiating spines, spikes of only 2 to 4 flowers, and submembranous bracts, dry near the tips. The flowers also have the same daily opening and closing pattern.

The flowers of *Hesperantha pauciflora* open on warm days after 13:00 and close again after 17:00, during which time they are visited by a variety of bees and by hopliine beetles. Closely related *H. latifolia*, which is restricted to the Kamiesberg in Namaqualand, is acaulescent or nearly so and has similarly coloured red-purple flowers but with a longer perianth tube, 15–25 mm long, and is pollinated by long-proboscid flies.

74. **Hesperantha latifolia** *(Klatt) M.P.de Vos* in Journal of South African Botany 40: 252 (1974); Goldblatt: 111 (1984). *Syringodea latifolia* Klatt: 403 (1882). Type: South Africa, [Northern Cape], Kamiesberg, Ellenboogsfontein, Sept. 1830, *J.F. Drège 2633* (B, lecto., designated by De Vos: 252 (1974); P, S, isolecto.).

Distribution of ***Hesperantha latifolia***.

Hesperantha pearsonii R.C.Foster: 21 (1948). Type: South Africa, [Northern Cape], Namaqualand, Khomsoap Ravine, *Pearson 6539* (B, holo.; MO, iso.)

Plants mostly 60–100(–180) mm high, including leaves. *Corm* bell-shaped with flat base, ± 10 mm diam.; tunics woody, margin with radiating spines. *Stem* reaching shortly above ground or underground, sometimes 1- or 2-branched but always concealed by leaf bases. *Leaves* 3 to 5, plane, falcate or erect and lanceolate, 60–120 × (3–)4–7 mm. *Spike* 1- to 3-flowered; bracts pale green to ± membranous, 10–20 mm long, largely concealed by leaf bases. *Flowers* diurnal, salver-shaped, deep pink to purple, tepals darker outside; perianth tube (15–)20–25 mm long, cylindric, widening near apex; tepals subequal, elliptic, 15–23 × 4–9 mm, spreading horizontally. *Filaments* (4–)7–10 mm long; anthers 4–7 mm long, ?purple. *Style branches* 10–12 mm long, suberect, barely exceeding anthers in closed flower. *Capsules* ovoid, 6–10 mm long. *Seeds* unknown. *Chromosome number* 2*n* = 26. *Flowering time*: mid-August and September.

Distribution and ecology: restricted to higher elevations in the Kamiesberg of central Namaqualand in Northern Cape, South Africa; in shallow soils overlying granite pavement.

Diagnosis: typically a short plant, usually less than 80 mm high but up to 180 mm when growing through bush, *Hesperantha latifolia* is usually acaulescent or with a short aerial stem covered by the bases of the leaves, and has dark pink to red-purple flowers with a perianth tube mostly 20–25 mm long and elliptic tepals 15–23 mm long. The flowers are pollinated by the long-proboscid fly, *Prosoeca peringueyi*, which also pollinates several other long-tubed species with similarly coloured flowers in Namaqualand (Manning & Goldblatt 1996). *Hesperantha latifolia* is closely allied to a second pink–purple-flowered species, *H. pauciflora*, which has a short perianth tube, 6–11 mm long, and a well-developed aerial stem. The two species co-occur in the Kamiesberg, *H. pauciflora* growing in deep, sandy ground.

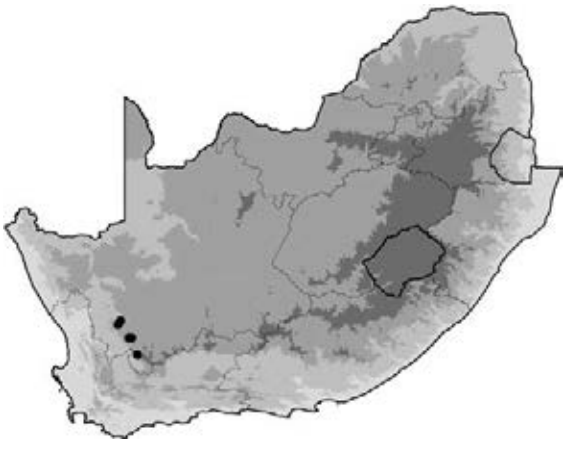
75. **Hesperantha longistyla** *J.C.Manning & Goldblatt* in Bothalia 37: 177 (2007). Type: Namibia, Witpütz, south of Sebrafontein, 1 400 m, 28 Aug. 2003, *P. Bruyns 9484A* (NBG, holo.).

Plants ± 30 mm high, including leaves. *Corm* bell-shaped with flat base, ± 10 mm diam.; tunics woody, margin with radiating spines. *Stem* reaching up to 10 mm above ground, unbranched. *Leaves* 3, plane, falcate, 30–50 × 2.5–3.0 mm. *Spike* 1- or 2-flowered; bracts green, 7–10 mm long, inner forked at apex. *Flowers* ?diurnal, purple, yellow in mouth of tube; perianth tube 20–25 mm long, slender, widening near apex; tepals subequal, narrowly ovate, ± 10 × 6 mm, outer slightly wider than inner, spreading horizontally. *Filaments* ± 4 mm long, exserted ± 3 mm from tube; anthers ± 5 mm long, ?yellow. *Style branches* ± 10 mm long, laxly spreading, exceeding the anthers in the closed flower. *Flowering time*: mid-August to early September.

Distribution and ecology: a montane species restricted to southwestern Namibia near Rosh Pinah, in the winter-rainfall part of the country; in crevices in dolomite rocks at high elevation.

Diagnosis: distinctive in its short stature, falcate leaves, and purple flowers with a relatively long perianth tube, 20–25 mm long, and disproportionately long style branches, *Hesperantha longistyla* has the bell-shaped corm with a flat base that characterises sect. *Hesperantha*. Among members of the section, the two purple-flowered species *H. latifolia* and *H. pauciflora*, both occurring in Namaqualand, are its most likely relatives, based on their similar flower colour and corms with radiating marginal spines. Also with a relatively long tube, *H. latifolia* differs in its smaller flowers, with tepals ± 10 mm long, and in the marked difference in the relative proportions of stamens and style. The filaments in *H. longistyla* are relatively short, 3–4 mm long and the style branches project ± 3 mm beyond the tips of the anthers, thus appearing unusually long. The flowers of *H. latifolia*, in contrast, are

Distribution of ***Hesperantha longistyla***.



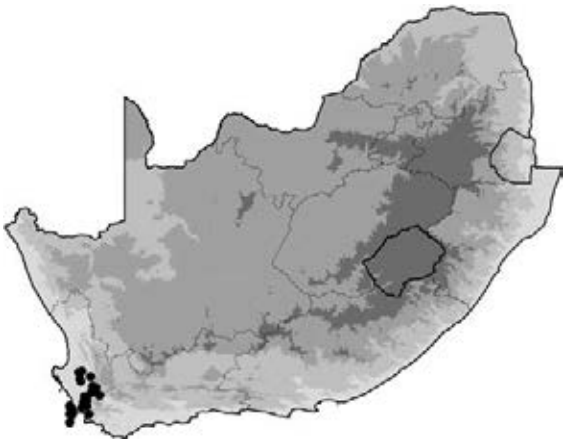
generally much larger, with tepals 15–23 mm long, filaments (4–)7–10 mm long and suberect style branches that barely extend beyond the tips of the anthers.

76. **Hesperantha luticola** *Goldblatt* in Journal of South African Botany 50: 113 (1984). Type: South Africa, [Northern Cape], between Middelpos and Calvinia, Farm Knechtsbank, 21 Aug. 1974, *M.F. Thompson 2529* (NBG, holo.; PRE, iso.).

Plants acaulescent, up to 100 mm high, including flowers. *Corm* ± bell-shaped flat base, 10–12 mm diam.; tunics of ± woody, overlapping layers, margins bearing short spines. *Stem* underground, sheathed at base by a pale, membranous cataphyll. *Leaves* 4 or 5, lanceolate to slightly falcate, 50–100 mm long, margins straight. *Spike* concealed by leaf sheaths, 1- or 2-flowered; bracts ± membranous, concealed by leaves 17–20 mm long. *Flowers* diurnal, borne at ground level, salver-shaped, white with large purple blotches at bases of outer tepals, lilac outside; perianth tube straight, cylindric, (15–)30–45 mm long, with thick walls tightly clasping style; tepals subequal, 10–15 × 4–6 mm long, spreading. *Filaments* diverging, ± 3 mm long; anthers horizontal, 3–5 mm long, yellow; pollen yellow. *Style branches* ± 12 mm long, laxly spreading. *Capsules* ovoid-oblong, (10–)15–25 mm long, raised above ground when mature. *Seeds* angular-prismatic. *Chromosome number* 2*n* = 26. *Flowering time*: July to mid-August.

Distribution and ecology: endemic to the western Karoo in Northern Cape, South Africa, extending from the Hantamsberg near Calvinia south along the Roggeveld Escarpment to Sneeukrans and the Farm Voëlfontein; in seasonally damp to waterlogged, shallow ground over rocky pavement, sometimes in standing water.

Diagnosis: *Hesperantha luticola* stands out in sect. *Hesperantha* as one of only two acaulescent species of the section. The white flowers have large purple blotches at the bases of the outer tepals and a remarkably long perianth tube, mostly 30–45 mm long. The tube has thick walls that tightly clasp the style so that nectar is forced into the top of the tube where it is accessible to insect visitors with short mouth parts. The corm, with short, radiating spines most closely resembles the corms of *H. latifolia* and *H. pauciflora* and it seems reasonable to infer that these are the closest relatives of *H. luticola*.



Distribution of ***Hesperantha luticola***.

77. **Hesperantha spicata** *(Burm.f.) N.E.Br.* in Bulletin of Miscellaneous Information, Kew 1929: 136 (1929); Goldblatt: 114 (1984). *Ixia spicata* Burm.f.: 1 (1768). *Ixia burmanni* F.Dietr.: 253 (1818), illegitimate superfluous name for *I. spicata* Burm.f. (1768). *Gladiolus burmanni* Schrank: 204 (1822), as a new name for *I. spicata* Burm.f. (1768) [not *G. spicatus* L.]. Type: South Africa. without precise locality or date, probably cultivated in Holland, *N.L. Burman s.n.* (G: Herb. Burman, holo.).

Plants 120–300(–500) mm high. *Corm* ± bell-shaped to obconic with flat base, 10–15 mm diam.; tunics of ± woody, overlapping layers, margins slightly flared, irregularly broken with edges frayed. *Stem* unbranched, sheathed at base by a pale, membranous cataphyll. *Leaves* usually 4, lower 2 ± basal, blades either terete and hollow or plane, straight, ± erect, falcate, sometimes with margins undulate to crisped, < half as long as stem, upper leaves cauline, shorter, the uppermost entirely sheathing. *Spike* straight, remote from leaves, up to 20-flowered; bracts green, often red-tipped, 5–7(–9) mm long, inner sometimes slightly longer than outer. *Flowers* crepuscular, ascending to half nodding, ± salver-shaped, white with outer tepals flushed red or brown outside; perianth tube straight, cylindric, 4–6 mm long; tepals subequal, obovate, 4–7(–9) mm long, spreading. *Filaments* diverging, ± 2 mm long; anthers spreading parallel to tepals, 3.5–4.5 mm long, white. *Style branches* ± 3 mm long, laxly spreading. *Capsules* narrowly ovoid, 7–9 mm long. *Seeds* angular-prismatic with ± white, spongy testa. *Chromosome number* 2*n* = 26. *Flowering time*: August to October.

Distribution and ecology: restricted to the southwestern corner of Western Cape, South Africa, extending from the Piketberg and Porterville to the Cape Peninsula and inland in the Tulbagh and Franschhoek Valleys; usually on sandy, stony ground, but also on clay loam substrates; especially common after fire.

Diagnosis: *Hesperantha spicata* is recognised by the relatively small, white flowers with perianth tube ± 4 mm long and tepals as long as to 1.5× as long. The anthers, articulated on the filament tips spread horizontally over the tepals. The corms, usually ± bell-shaped or obconic, often have a flared margin and sometimes lack the serrated or spiny margins common in sect. *Hesperantha*. The seeds are notable, having a white, spongy coat, not known in other species of the genus. Variation in leaf morphology, correlated to some extent with height and number of flowers per spike, led to recognition of three subspecies: subsp. *graminifolia* with plane leaves with straight margins and often a taller plant; subsp.

Distribution of ***Hesperantha spicata***.

fistulosa with terete, hollow leaves; and subsp. *spicata* with strongly falcate leaves with undulate to crisped margins, a shorter stature and fewer-flowered spikes. Recent records of subsp. *fistulosa* in full bloom growing in a wet seep and subsp. *spicata* in fruit nearby in deep sand expands our understanding of this plant. The situation seems inconsistent with separation at subspecies rank and an alternative treatment as a separate species for subsp. *fistulosa* seems equally acceptable.

Key to subspecies

1a Basal leaves terete, hollow, without evident main vein; spike with 4 to 9 flowers . . . . . 77c. subsp. *fistulosa*
1b Basal leaves plane with evident main vein; spike with 4 to 20 flowers:
2a Leaf blades plane, strongly falcate with margins undulate to crisped; flowers mostly 5 to 12 per spike . . . . . .77a. subsp. *spicata*
2b Leaf blades plane, narrowly lanceolate to weakly falcate with margins straight; flowers mostly 9 to 20 per spike . . . . . .77b. subsp. *graminifolia*

77a. subsp. **spicata**

Ixia cinnamomea L.f.: 92 (1782). *Hesperantha cinnamomea* (L.f.) Ker Gawl.: 225 (1804a). *H. spicata* var. *cinnamomea* (L.f.) R.C.Foster: 25 (1948). Type: South Africa, [Western Cape], 'in collibis Leeuwestaart, *Thunberg s.n.* (UPS–THUNB 937, lecto., designated by Goldblatt: 116 (1984); S, isolecto.).

Plants 120–200 mm high. *Leaves* usually 4, lower 2 ± basal, blades ± plane, strongly falcate, margins undulate to crisped, much shorter than stem, 5–12 mm wide. *Spike* mostly 5- to 12-flowered. *Tepals* 4–7 mm long, spreading.

Distribution and ecology: extending from the lower slopes of the Piketberg to the Tulbagh Valley and the northern Cape Peninsula; usually on stony clay or clay loam.

Diagnosis: subsp. *spicata*, often low in stature but up to 200 mm tall, has plane, strongly falcate leaves with undulate to crisped margins, and a spike with up to 12 flowers, but often fewer.

77b. subsp. **graminifolia** *(Sweet) Goldblatt* in Journal of South African Botany 50: 118 (1984). *Hesperantha graminifolia* Sweet: 9 (1818). Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 1254 (1810)

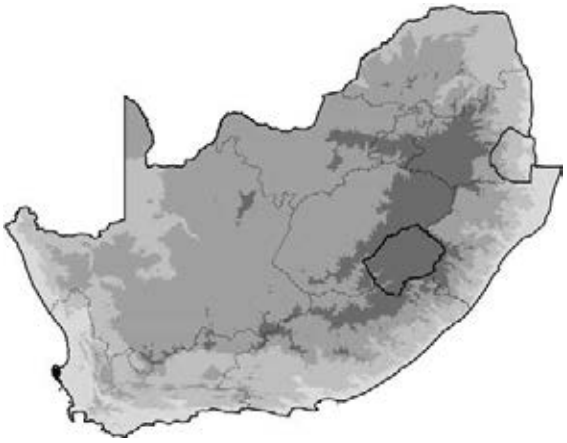
Plants mostly 200–500 mm high. *Leaves* usually 4, lower 2 ± basal, blades plane, narrowly lanceolate to weakly falcate, ± erect, margins straight, up to half as long as stem, 2–5(–8) mm wide. *Spike* mostly 9- to 20-flowered. *Tepals* 5–8(–9) mm long.

Distribution and ecology: extending from Malmesbury and Darling to the southern Cape Peninsula and inland to the Tulbagh Valley and Franschhoek Pass; on stony sandstone ground.

Diagnosis: a taller plant than subsp. *spicata*, standing usually up to 350 mm high, occasionally even taller, subsp. *graminifolia* has lanceolate to weakly falcate leaves with straight margins. The spikes bear 9 to 20 flowers, almost always more than in subsp. *spicata*, and the flowers are often slightly larger than in the other subspecies.

77c. subsp. **fistulosa** *(Baker) Goldblatt* in Journal of South African Botany 50: 119 (1984). *Hesperantha fistulosa* Baker: 1004 (1904). Type: South Africa, [Western Cape], near Porterville, 18 Aug. 1894, *Schlechter 4885* (G, lecto., designated by Foster: 12 (1948); B, BOL, GRA, K, SAM, WU, Z, isolecto.).

Plants up to 200 mm high. *Leaves* ?4, lower 2 basal, blades terete, hollow, without main vein, ± 2 mm diam. *Spike* 4- to 9-flowered; bracts 5–6 mm long. *Tepals* mostly 5–6 mm long. *Flowering time*: mid-August to late September.



Distribution and ecology: a rare endemic of the Western Cape forelands, recorded near Porterville south to Elandsberg Nature Reserve and near Paarl; occurring in seasonally wet sites, especially seeps and shallow marshes.

Diagnosis: subsp. *fistulosa* is recognised by the terete, hollow leaves without evident main veins but is otherwise very much like subsp. *spicata* in its low stature and spikes of relatively few flowers. The flowers appear exactly like those of subsp. *spicata*, the tepals usually 5–6 mm long, thus slightly smaller than in subsp. *graminifolia.*

Long thought to be a local endemic of the Porterville area, more recent records of subsp. *fistulosa* from Elandsberg Nature Reserve and south of Paarl show the subspecies to have a far wider range, but it remains rare. A population of subsp. *fistulosa* recorded in flower growing close to subsp. *spicata*, then in fruit and in sandy ground, throws some doubt on their current treatment as subspecies, which merits additional investigation.

78. **Hesperantha saldanhae** *Goldblatt* in Journal of South African Botany 50: 119 (1984). Type: South Africa, [Western Cape], granite rocks at Vredenburg, 8 Aug. 1962, *G.J. Lewis 5977* (NBG, holo.).

Plants 120–150 mm high. *Corm* ± bell-shaped with flat base, 10–12 mm diam.; tunics of ± woody, overlapping layers, margins irregularly broken with edges frayed. *Stem* unbranched, sheathed at base by a pale, membranous cataphyll. *Leaves* usually 4, lower 2 ± basal, blades plane, straight, ± erect, ± ⅓ as long as stem, upper leaves cauline, shorter, uppermost entirely sheathing. *Spike* straight, 5- to 8-flowered, secund; bracts green, 7–10 mm long, inner sometimes slightly longer than outer. *Flowers* ± nodding, ± salver-shaped, white; perianth tube straight, cylindric, 9–12 mm long; tepals subequal, narrowly obovate, 9–10 mm long, spreading. *Filaments* diverging, ± 1 mm long; anthers spreading, 2–3 mm long, ?white. *Style* dividing in middle of perianth tube, branches ± 4 mm long, reaching to just beyond mouth of tube to base of anthers. *Flowering time*: August.

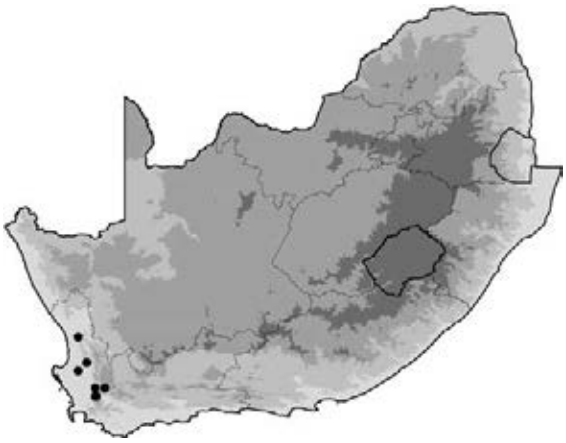
Distribution of ***Hesperantha saldanhae***.

Distribution and ecology: known only from the type collection, near Vredenburg in Western Cape, South Africa; on granite outcrops. Despite searches for the species it has never been recollected and may be extinct.

Diagnosis: readily mistaken for the more common and widespread *Hesperantha spicata*, *H. saldanhae* differs in its longer perianth tube, 9–10 mm long, thus ± twice as long as in *H. spicata*, filaments only 1 mm long and anthers 2–3 mm long, both shorter than in *H. spicata*. In addition, the style divides near the middle of the perianth tube with the short style branches barely reaching the mouth of the tube, and the base of the anthers. Flowers of *H. spicata* are fairly typical of the genus with the style dividing close to the mouth of the tube with the style branches spreading over the tepals.

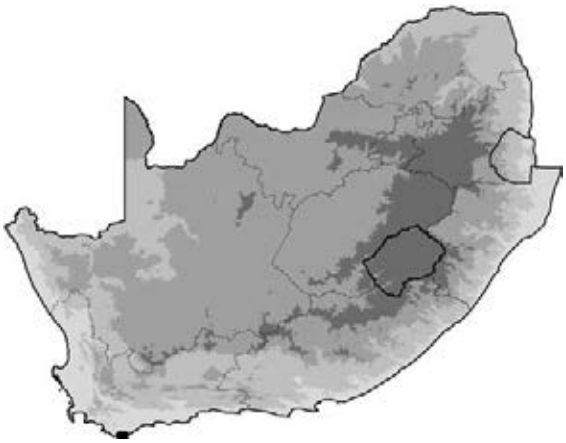
Sect. 3. **Radiatae** *Goldblatt* in Annals of the Missouri Botanical Garden 69: 377 (1982) [as sect. *Radiata*]. Type: *Hesperantha radiata* (Jacq.) Ker Gawl.

Plants with relatively large symmetrical, bell-shaped corms with a flat, horizontal or oblique base; tunics often scalloped below and fringed at the lower margins, older corm tunics not splitting from the base into segments but often the tunics forming scalloped, concave segments. *Spike* with floral outer bract margins united around the spike axis for up to half their length. *Flowers* white to creamy yellow or pink, most species with a strongly curved perianth tube, nearly straight in *H. brevifolia* and *H. juncifolia*.



Species 10, 9 in southern Africa: mainly in the winter-rainfall zone, but *H. radiata* extends from Namaqualand, South Africa in the west to Eswatini in the east; *H. longicollis* is eastern southern African extending north to Malawi; and *H. ballii* Wild is endemic to the Chimanimani Mtns of eastern Zimbabwe.

79. **Hesperantha brevifolia** *Goldblatt* in Journal of South African Botany 50: 121 (1984). Type: South Africa, [Western Cape], Piketberg, Zebrakop, 16 Dec. 1971, *E.E. Esterhuysen 35320* (MO, holo.; B, BOL, BR, C, E, K, M, NBG, P, PRE, S, US, iso.).



Plants (100–)150–400 mm high. *Corm* ± obconic with flat, oblique base, up to 6 mm diam.; tunics of ± woody, longitudinally ridged, overlapping layers, margins slightly flared and with edges frayed. *Stem* unbranched, sheathed by leaf bases and at base by a pale, membranous cataphyll. *Leaves* usually 4 or 5, lower 2 ± basal, blades plane, straight, ± erect, 20–30 mm long, upper leaves cauline, shorter, the uppermost entirely sheathing. *Spike* mostly 2- to 5-flowered, ± straight; bracts green, conspicuously veined, 10–14 mm long, outer with margins united around axis near base. *Flowers* upright to half nodding, ± salver-shaped, white with outer tepals flushed red outside; perianth tube 6–8 mm long, straight; tepals subequal, obovate, 8–13 × ± 4 mm, spreading to slightly reflexed. *Filaments* diverging, 3–5 mm long; anthers spreading, 5–6 mm long, white. *Style branches* 4–5 mm long, laxly spreading. *Capsules* narrowly ovoid, 6–8 mm long. *Seeds* light brown, angular-prismatic. *Flowering time*: late October to early December.

Distribution and ecology: endemic to Western Cape, South Africa, with a scattered distribution extending from the slopes of the Nardousberg, north of Clanwilliam to Tulbagh and the mountains north Bain's Kloof; evidently rare, usually flowering after fire.

Diagnosis: *Hesperantha brevifolia* is recognised in sect. *Radiatae* by the flexuose stem, leaves with unusually

Distribution of ***Hesperantha brevifolia***.

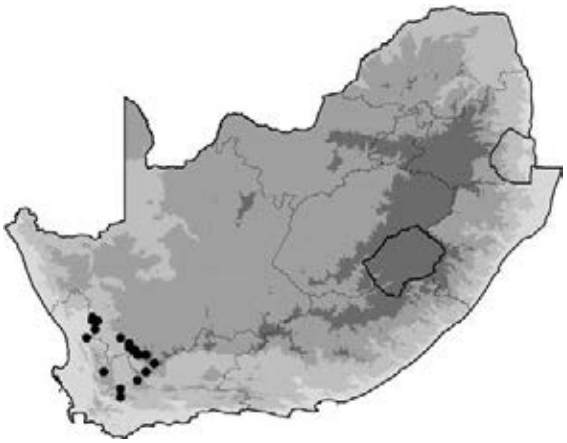
Distribution of ***Hesperantha juncifolia***.

short, plane blades, 20–30 mm long, and bract margins united around the axis only at the base. Unlike related *H. radiata*, the short perianth tube, 6–8 mm long, is ± straight rather than curved at the apex, and the flowers are thus suberect or half-nodding vs. nodding to almost pendent.

80. **Hesperantha juncifolia** *Goldblatt* in Journal of South African Botany 50: 135 (1984). Type: South Africa, [Western Cape], Bredasdorp, Ratelrivier, limestone flats, 29 Sept. 1970, *P. Goldblatt 403* (BOL, holo.).

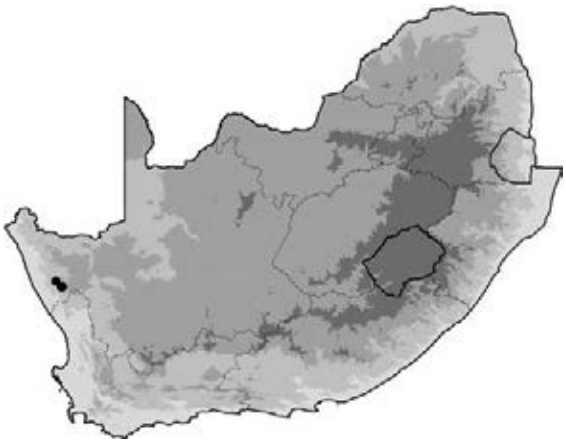
Plants 180–200 mm high. *Corm* ± bell-shaped, with flat, oblique base, up to 15 mm diam.; tunics of ± woody overlapping layers, fragmenting into segments with raised edges. *Stem* unbranched. *Leaves* usually 4, lower 2 basal, terete, straight, ± erect, shorter than stem, ± 1.5 mm diam., uppermost leaf sheathing stem nearly to base of spike. *Spike* mostly 5- to 8-flowered; bracts green below, membranous above, (10–)12–14 mm long, outer with margins united around axis in lower ⅓–½. *Flowers* crepuscular, half nodding, ± salver-shaped, white with outer tepals red outside, ± zygomorphic with anthers held against upper tepals and style branches pendent; perianth tube 5–6 mm long, straight; tepals subequal, obovate, 13–15 × 5–6 mm, spreading. *Filaments* ± 2 mm long; anthers ± 6 mm long, white. *Style dividing* at mouth of tube, branches ± 9 mm long, held against lower tepal. *Flowering time*: late September and October.

Distribution and ecology: a rare endemic restricted to the western coast of the Agulhas Peninsula in Western Cape, South Africa, recorded from Ratelrivier to Brandfontein; in wet depressions on limestone flats.



Diagnosis: *Hesperantha juncifolia* is readily recognised by the smooth, terete leaves, outer bracts united around the spike axis in the lower half to one third, and white flowers with a straight perianth tube only 5–6 mm long. The flat-based corm and bracts united around the spike axis are typical of sect. *Radiatae*. Related *H. radiata* has plane and often somewhat succulent leaves, the outer bracts united for ± half their length, and a longer perianth tube mostly 7–15 mm long, curved in the upper half. Unusual for white-flowered species of the genus and section, the flowers open early in the morning and close at ± 16:00.

81. **Hesperantha marlothii** *R.C.Foster* in Contributions from the Gray Herbarium of Harvard University 166: 20 (1948); Goldblatt: 130 (1984). Type: South Africa, [Northern Cape], Sutherland District, near Waterkloof, Sept. 1921, *Marloth 10412* (B, holo.; NBG, PRE, iso.).



Plants mostly 60–200 mm high. *Corm* ± obconic, with flat base 8–13 mm wide; tunics of woody, overlapping layers, base with laterally projecting spines. *Stem* usually unbranched, sheathed by leaves and at base by a membranous cataphyll. *Leaves* 3(4), straight, ± erect, linear, longest ± as long as stem, mostly 1.5–3.5 mm wide, uppermost leaf largely sheathing, sometimes ± bract-like, reaching nearly to base of spike. *Spike* (1)2- to 5-flowered; bracts green or often flushed red, 10–20 mm long, outer with margins united around axis at base or for up to 4 mm. *Flowers* nodding to ± pendent, creamy white, outer tepals red to brown outside; perianth tube 10–12 mm long, curved at or near apex; tepals subequal, narrowly ovate-elliptic, 10–15 × 4–5 mm, slightly reflexed when fully open. *Filaments* diverging, 4–6 mm long; anthers 4–6 mm long, yellow. *Style branches* 7–10 mm long, spreading. *Chromosome number* 2*n* = 26. *Flowering time*: late July to September; flowers opening near sunset.

Distribution and ecology: relatively widespread, extending along the Roggeveld Escarpment near Sutherland in Northern Cape, South Africa and in the Cold Bokkeveld and mountains east of Hex River Pass in Western Cape; usually on rocky, sandstone pavement in shallow, seasonally wet, sandy ground.

Diagnosis: closely allied to the more widespread *Hesperantha radiata* and easily confused with it, *H. marlothii*

Distribution of ***Hesperantha marlothii***.

Distribution of ***Hesperantha decipiens***.

is often a smaller plant, sometimes only 40 to 100 mm high vs. up to 600 mm in *H. radiata*, with spikes of up to 5 flowers, with the outer bracts united for up to 4 mm, about a third of their length. It can always be distinguished by the corms, the tunics of which bear prominent, radiating horizontal spines at the base. Corms of *H. radiata* lack these spines and have the outer bracts united around the axis for at least half their length.

82. **Hesperantha decipiens** *Goldblatt* in Annals of the Missouri Botanical Garden 90: 439 (2003). Type: South Africa, Northern Cape, Kamiesberg, northern slopes of Rooiberg, 19 Sept. 1991, *P. Goldblatt 9258* (NBG, holo.; K, MO, PRE, iso.).

Plants 100–150 mm high. *Corm* ovoid with oblique flat base, 8–12 mm diam.; tunics woody, concentric, ± scalloped into concave segments with fringed edges. *Stem* usually unbranched, smooth. *Leaves* 4, lower 3 ± basal and largest, blades linear, 1.2–2.0 mm wide, slightly fleshy, slightly thickened in midline, uppermost leaf inserted in middle of stem, sometimes entirely sheathing or with short free unifacial tip. *Spike* mostly 3- to 6-flowered, flexuose; bracts 10–15 mm long, green, becoming dry above, outer with margins united around stem for 3–5 mm, inner ± as long as outer. *Flowers* crepuscular, white to cream-coloured, outer tepals pale pink to reddish or brown outside, strongly scented of stocks when open; perianth tube slender, curved near apex, 10–13 mm long; tepals subequal, lanceolate, 12–14 × 2.5–3.5 mm, spreading ± at right angles to tube when fully open. *Filaments* ± 4 mm long; anthers 5–7 mm long, yellow; pollen white. *Style branches* ± 12 mm long, weakly spreading, slightly shorter or slightly longer than anthers. *Capsules* oblong-obovoid, 6–8 × ± 3.5 mm. *Seeds* angular, ± winged on angles, ± 1 mm long. *Flowering time*: August and September; flowers opening near sunset.

Distribution and ecology: extending from near Springbok in Northern Cape, South Africa through the Kamiesberg to the northern Knersvlakte in Western Cape; on thin, sandy gravel, often on granite pavement.

Diagnosis: poorly collected and often confused either with the widespread *Hesperantha radiata* or the related western Karoo species *H. marlothii*, *H. decipiens* is distinguished by the few-flowered, flexuose spike with the outer bract margins united around the axis only near the base, and corms without prominent lateral spines. *Hesperantha decipiens* has the flexuose, few(or several)-flowered spike of *H. marlothii* but the outer bract margins in that species are united for up to 4 mm, ± a third of their length. The corms in *H. marlothii* bear prominent lateral spines, whereas those of *H. decipiens* closely resemble *H. radiata* in their scalloped, lightly fringed lobes. Close examination of the flowers shows that the style branches of *H. decipiens* usually exceed the anthers by 1–2 mm and the anthers are 5–7 mm long. Robust specimens of *H. marlothii* have anthers 6–8 mm long and the style branches reach only to about the middle of the anthers. Less robust specimens have anthers 4.5–6.0 mm long but the style branches are still slightly short of the anther apices. *Hesperantha radiata* has the outer bract margins united for ± half their length, and a straight spike usually bearing >8 flowers.

83. **Hesperantha radiata** *(Jacq.) Ker Gawl.* in König & Sims, Annals of Botany 1: 225 (1804a); Goldblatt: 123 (1984); Hilliard & Burtt: 436 (1986). *Ixia radiata* Jacq.: 7 (1795 [1788–1795]). Type: South Africa, without precise locality, illustration in Jacq.: t. 280 (1794 [1788–1795]).

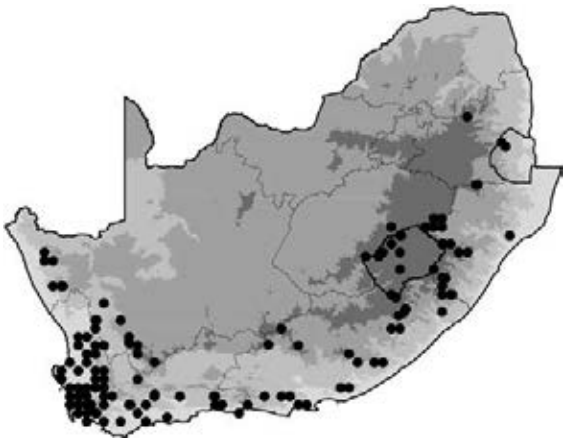
Gladiolus recurvus Thunb.: 9 (1784), illegitimate homonym, not *G. recurvus* L. (1767) [= *G. recurvatus* Thunb. ex Baker: 96 (1877), orthographic error]. *Hesperantha recurvata* Aschers. & Graebn.: 540 (1906), as a new name for *G. recurvus* Thunb. Type: South Africa, without precise locality, *Thunberg s.n.* (UPS–THUNB, holo.).

Ixia angusta Jacq.: 7 (1795 [1788–1795]), as a new name for *I. linearis* Jacq.: 183 (1791), illegitimate homonym, not *I. linearis* L.f. (1782). *Hesperantha angusta* (Jacq.) Ker Gawl.: 225 (1804a). *H. linearis* Fourc.: 77 (1932), as a new name for *I. linearis* Jacq. (1791), illegitimate homonym. Type: South

Africa, without precise locality or collector, illustration in Jacq.: t. 279 (1794 [1788–1795) '*I. linearis*'.

Ixia fistulosa Andrews: t. 59 (1799). *I. recurva* Vahl: 58 (1805), illegitimate superfluous name for *I. fistulosa* Andrews (1799). Type: South Africa, without precise locality or collector, illustration in Andrews: t. 59 (1799).

Hesperantha angustifolia Ker Gawl. ex J.W.Loudon: 91 (1841). Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 790 (1804b).



Hesperantha tysonii Baker: 151 (1892). Type: South Africa, [KwaZulu-Natal], streambanks near Kokstad, Oct. 1883, *W. Tyson 1585* (K, holo.; B, GRA, NH, SAM, iso.).

[*Hesperantha setacea* Eckl.: 23 (1827), invalid name without description.]

Plants (100–)200–500 mm high. *Corm* sometimes with collar of fibres around base, ± bell-shaped with flat, horizontal or oblique base, 7–14 mm diam.; tunics of dark brown overlapping layers, basal margin sometimes shortly toothed, outer layers splitting from base into segments often with fringed or acute edges. *Stem* usually erect, unbranched, sheathed at base by a dry membranous cataphyll. *Leaves* 5 or 6, lower 3 or 4 basal and longest, ± linear or falcate, often thicker in centre and somewhat succulent, reaching to between middle and near base of spike, 2.0–3.5 mm wide, uppermost 1 or 2 leaves often entirely sheathing and bract-like. *Spike* mostly 5- to 15-flowered, straight; bracts 10–15 mm long, sometimes overlapping the one above, outer with margins united around axis for at least half its length. *Flowers* nodding to half pendent, crepuscular, white, creamy white, dull yellow or sometimes brown, outer tepals red to purple outside, scented when open in late afternoon; perianth tube mostly 6–15 mm long, curved outward near apex; tepals 7–15(–17) × 2.5–5.0 mm. *Stamens* pendent; filaments 3–4 mm long; anthers 4.0–8.5 mm long, usually yellow; pollen yellow. *Style branches* mostly 5–11 mm long. *Capsules* ± cylindric, 10–18 mm long, apices exserted from bracts, splitting in upper ⅓. *Seeds* angular. *Chromosome number* 2*n* = 26. *Flowering time*: mainly August to November in winter-rainfall zone, November and December in summer-rainfall zone; flowers opening in late afternoon.

Distribution and ecology: widespread in southern Africa and extending from the Richtersveld of Northern Cape, South Africa through Western Cape into the mountains of Eastern Cape, KwaZulu-Natal and reaching Eswatini in the northeast; in a variety of habitats, both heavy clays and light, sandy soils and in well-drained and seasonally wet habitats.

Diagnosis: recognised in sect. *Radiatae* by the outer bracts united around the spike axis for at least half their length,

Distribution of ***Hesperantha radiata***.

Hesperantha radiata has nodding to half pendent flowers with a perianth tube of modest length, mostly 6–15 mm long, and tepals spreading to slightly reflexed when fully open near or after sunset. The leaves are unremarkable, although often slightly fleshy and thicker in the centre, sometimes even hollow near the midline. The corms, typical of the section in their horizontal to oblique flat base are somewhat variable, the outer layers splitting from the base into rounded to acute segments. Two subspecies are currently recognised: the taller, more robust subsp. *radiata* with broader leaves, larger flowers, and blooming in the winter-rainfall zone mainly in August and September; and subsp. *caricina*, usually a smaller plant, typically with a collar of fibres around the base, and a crowded spike of overlapping bracts 10–13 mm long, and blooming mainly from September to December in the winter-ranfall zone.

Populations from KwaZulu-Natal and nearby have been regarded as a separate species, *Hesperantha tysonii*, but plants cannot be distinguished from robust specimens of subsp. *radiata* from the winter-rainfall zone except by their provenance and sometimes slightly softer textured corm tunics.

Key to subspecies

1a Outer floral bract 11–15 mm long and not overlapping the one above; outer tepals 13–15 × 3–5 mm; style branches 8–11 mm long . . . . . .83a. subsp. *radiata*

1b Outer floral bract 10–13 mm long and shortly overlapping the one above; outer tepals 7–12 × 2.5–3.5 mm; style branches 5–6 mm long . . . . . .83b. subsp. *caricina*

83a. subsp. **radiata**

Corms without collar of fibres around base. *Leaves* 2.0–3.5 mm wide, uppermost leaf reaching close to base of spike. *Spike* crowded with outer bracts 11–15 mm long, not overlapping. *Flowers* cream-coloured to dull yellow, outer tepals reddish on reverse; perianth tube 8–14 mm long; tepals 13–15(–17) × 3–5 mm. *Filaments* mostly

± 4 mm long; anthers 5.0–8.5 mm long. *Style branches* mostly 8–11 mm long. *Flowering time*: late July to mid-September in the winter-rainfall zone; October to December in eastern southern Africa.

Distribution and ecology: extending from the Richtersveld of Northern Cape through Western and Eastern Cape to Eswatini; in a range of habitats, on both heavy clay and well-drained sandy soils.

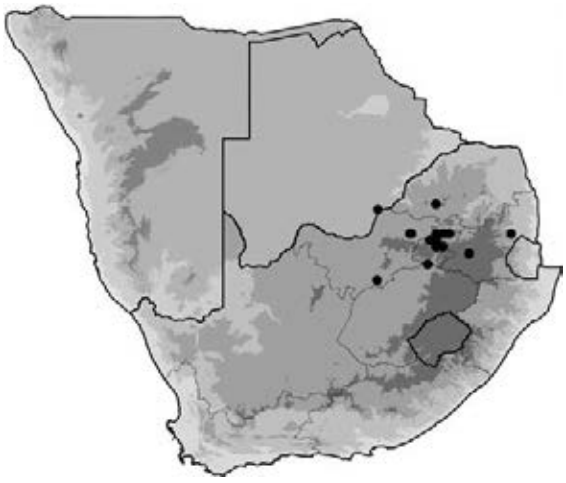
Diagnosis: subsp. *radiata* is readily distinguished by the key characters, including larger floral bracts 11–15 mm long, not overlapping the one above, and larger flowers with outer tepals 13–15 × 3–5 mm, anthers 5.0–8.5 mm long, and style branches 8–11 mm long. In Western Cape, where its range partly coincides with that of subsp. *caricina*, it always flowers earlier in the season.

83b. subsp. **caricina** *(Ker Gawl.) Goldblatt & J.C.Manning* in Bothalia 42: 139 (2012). *Hesperantha radiata* var. γ *caricina* Ker Gawl.: t. 790 (1804b). *H. tenuifolia* Salisb.: 321 (1812), as a new name for *H. radiata* var. *caricina* Ker Gawl. *H. caricina* (Ker Gawl.) Klatt: 395 (Erganz. 61) (1882), illegitimate superfluous name for *H. tenuifolia* (based on the same type). Type: South Africa, without precise locality or collector, Ker Gawl.: t. 790 (1804b).

Corms often with a collar of fibres around base. *Leaves* 1–2 mm wide, uppermost leaf entirely sheathing, often reaching close to base of spike, often dry at flowering. *Spike* crowded with outer bracts 10–13 mm long, imbricate. *Flowers* with perianth tube 6–10 mm long; tepals 7–12 × 2.5–3.5 mm. *Filaments* 4–5 mm long; anthers 4(–5) mm long. *Style branches* mostly 5–6 mm long. *Flowering time*: mostly late September and October, but until December at higher elevations.

Distribution and ecology: restricted to the southwestern corner of Western Cape, from Piketberg and Riebeeck Kasteel in the north to Hermanus in the southeast; often in sandy ground.

Diagnosis: subsp. *caricina* is usually recognised by the crowded spike of relatively small flowers, the tepals 7–12 × 2.5–3.5 mm and the perianth tube 6–10 mm long, and the shortly overlapping bracts 10–13 mm long are particularly distinctive. Plants are typically later flowering than subsp. *radiata*, usually in later September and October but have been recorded in bloom as late as December at high elevations. Populations of typical subsp. *radiata* occur throughout the range of subsp. *caricina* but invariably bloom earlier, from late July to mid-September, and have larger flowers, with tepals 13–15(–17) × 3–5 mm, perianth tube 8–14 mm long, and anthers mostly 4 mm long. The leaves of subsp. *caricina* are also somewhat narrower than in subsp. *radiata*, 1–2 mm wide, and often dry at flowering time vs. 2.0–3.5 mm wide and green at flowering.



84. **Hesperantha longicollis** *Baker* in Bulletin de l'Herbier Boissier, sér. 2, 4: 1004 (1904); Oberm.: t. 1810 (1980). Type: South Africa, [Gauteng, as Transvaal], Modderfontein, 11 Sept. 1898, *P. Conrath 600* (K, Z, syn.).

Hesperantha widmeri Beauverd: 990 (1905). Type: South Africa, [Gauteng], Modderfontein, *Widmer s.n.* (G, syn.).

Hesperantha matopensis L.S.Gibbs: 471 (1906). Type: Zimbabwe, Matopo Hills, banks of Malami R., *Gibbs 44* (BM, BOL, K, syn.).

Plants 300–500(–700) mm high. *Corm* ± bell-shaped, with flat base, ± 10 mm diam.; tunics of ± woody overlapping layers, fragmenting below into segments with minutely fringed margins. *Stem* simple or rarely with branch from near base, sheathed at base by membranous, pale or rarely brown cataphyll. *Leaves* usually 5, lower 2 or 3 basal and with long blades, linear, straight, often trailing, reaching to ± base of spike, wide, upper 2 leaves sheathing lower ⅔ of stem. *Spike* 3- to 6(9)-flowered, ± secund; bracts green, often flushed red distally, 12–25 mm long, outer with margins united around axis for 1–2 mm. *Flowers* nodding, ± white or creamy white, outer tepals brown to purplish outside; perianth tube 18–25 mm long, curved in distal half and becoming pendent; tepals subequal, narrowly ovate-elliptic, 14–18 × 5–6 mm, spreading. *Filaments* evidently unilateral, ± pendent, ± 6 mm long; anthers mostly 8–10 mm long, decumbent, purple-brown; pollen brown. *Style branches* 10–12 mm long, pendent, reaching ± to anther tips on closed flower. *Capsules* ovoid-oblong, 10–12 × 4 mm, enclosed in bracts, splitting in upper ⅓. *Seeds* unknown. *Flowering time*: October and November.

Distribution and ecology: widespread in central and eastern southern Africa, extending from near Douglas in Northern Cape through North West and Gauteng to Mpumalanga and Limpopo in South Africa, and in eastern Botswana, Zimbabwe and Malawi; mainly in

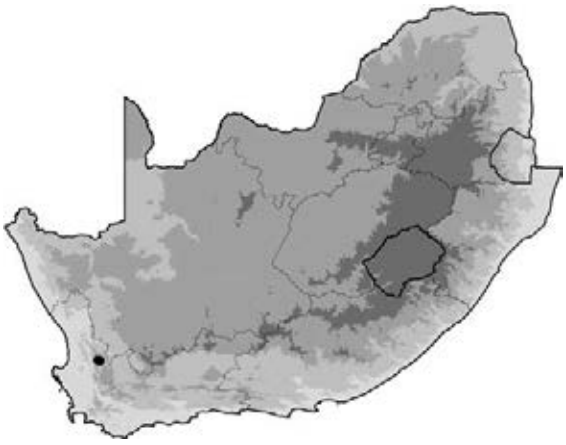
Distribution of ***Hesperantha longicollis***.

grassland, often in wet sites including marshes, vleis and streambanks.

Diagnosis: allied to *Hesperantha radiata* and sometimes mistaken for that species, *H. longicollis* is recognised by the outer bracts united around the spike axis barely at all or up to 2 mm at most, and the larger flower with a longer, strongly curved perianth tube, 18–25 mm long, the flower nodding to pendent, and the purple-brown anthers and brown pollen. *Hesperantha radiata* always has the outer bracts united around the spike axis for ± half their length, a shorter perianth tube 6–15 mm long, also curved distally, thus with the flower nodding to half pendent, and usually yellow anthers and pollen. The type of *H. matopensis,* from the Matopos, Zimbabwe, differs hardly at all from some collections of *H. longicollis* from South Africa.

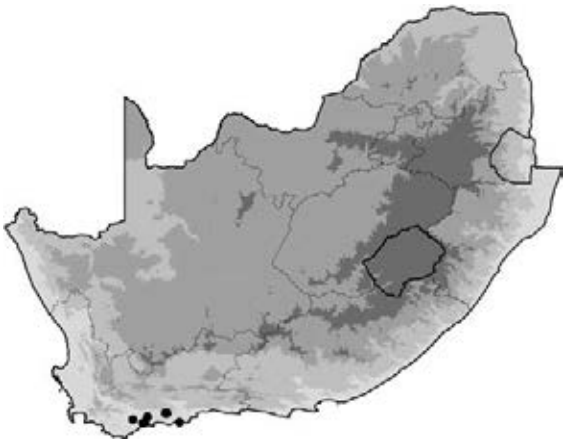
85. **Hesperantha elsiae** *Goldblatt* in Journal of South African Botany 50: 136 (1984). Type: South Africa, [Western Cape], Cederberg, Krom River Kloof, above Disa Pool, 11 Nov. 1979, *P. Goldblatt 5331* (MO, holo.; K, NBG, PRE, S, US, WAG, iso.).

Plants 250–300 mm high. *Corm* ± bell-shaped–ovoid, with oblique flat base, 10–12 mm diam.; tunics of ± woody overlapping layers, notched below into triangular segments. *Stem* unbranched, sheathed below by dry, brown cataphylls. *Leaves* ± 5, lower 2 longest, usually dry at flowering, soft and ± falcate, ± half as long as stem, ± 1 mm wide, upper 2 or 3 leaves short, largely to entirely sheathing. *Spike* (1)2- to 4-flowered; bracts ± membranous, drying from apex, often flushed red, 18–30(–40 mm long, outer with margins united around axis near base for ± 1 mm. *Flowers* half nodding, deep, glossy pink, unscented; perianth tube 13–21 mm long, cylindric, slightly curved toward apex; tepals subequal, lanceolate, laxly spreading, 13–55 × 5–7 mm, spreading. *Filaments* inserted in middle of tube, ± 1.5 mm long; anthers ± 5.5 mm long, included, yellow. *Style* dividing opposite base of anthers near middle of tube, branches ± 8 mm long, tips emerging from tube thus exceeding anthers. *Capsules* ovoid-oblong, ± 9 mm long. *Seeds* light brown, angular-prismatic. *Chromosome number* 2*n* = 26. *Flowering time*: December.



Distribution and ecology: known only from the southern Cederberg of Western Cape, South Africa; on sandstone slopes at ± 1 200 m elevation.

Diagnosis: the flat-based corm and outer bracts united near the base around the spike axis place *Hesperantha elsiae* in sect. *Radiatae*. It is remarkable in its flowers, deep pink with a perianth tube up to 21 mm long, the stamens included in the middle of the tube, and the style dividing at the level of the anthers with long style branches, ± 8 mm long, reaching the mouth of the tube with only the tips of the style branches visible outside the tube mouth. That series of features is unique in the section and rare in the genus. We suspect that *H. elsiae* has a wider range but it is currently known only from a single population.



86. **Hesperantha muirii** *(L.Bolus) G.J.Lewis* in Journal of South African Botany 7: 32 (1941); Goldblatt: 133 (1984). *Acidanthera muirii* L.Bolus: 195 (1915). Type: South Africa, [Western Cape], Riversdale District, Farm Plattekop, Oct. 1931, *J. Muir 1087* (BOL, holo.).

Hesperantha muirii var. *robusta* G.J.Lewis: 33 (1941). Type: South Africa, [Western Cape], Plattekop Farm, Riversdale, *Ferguson s.n.* (BOL, lecto., designated by Goldblatt: 133 (1984); K, iso.).

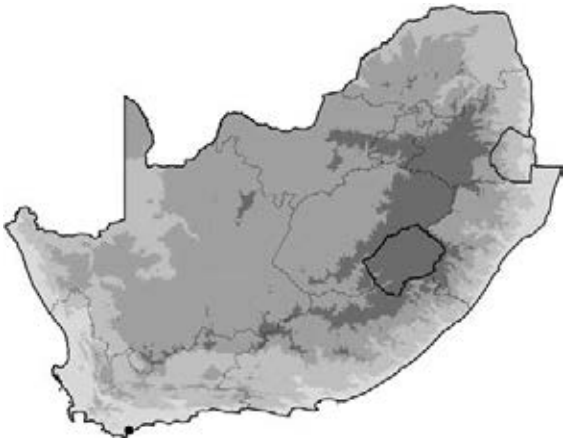
Plants 100–200 mm high. *Corm* ± bell-shaped, with flat, oblique base, 6–8 mm wide; tunics of ± woody overlapping layers, fragmenting into segments with minutely fringed margins. *Stem* unbranched, sheathed by leaves and at base by a brown cataphyll. *Leaves* 2 to 4, straight, ± erect, 30–80 mm long, 1.5–2.0 mm wide, uppermost leaf largely sheathing and reaching nearly to base of spike. *Spike* (1)2- or 3-flowered; bracts green, often flushed red, 18–30(–40 mm long, outer with margins united around axis for 2–3 mm. *Flowers* nodding,

Distribution of ***Hesperantha elsiae***.

Distribution of ***Hesperantha muirii***.

± white or pale pink especially with age, zygomorphic with unilateral stamens; perianth tube 15–25 mm long, curved toward apex; tepals subequal, narrowly ovate-elliptic, 15–25 × 6–9 mm, spreading. *Stamens* unilateral, pendent; filaments 8–10 mm long; anthers 6–10 mm long, white. *Style branches* 12–15 mm long, loosely twisted, pendent. *Chromosome number* 2*n* = 26. *Flowering time*: October and November.

Distribution and ecology: occurring on the coastal hills of southern Western Cape, South Africa, from north of Bredasdorp to near Albertinia; on clay and shale flats and slopes.



Diagnosis: largest-flowered species of sect. *Radiatae*, *Hesperantha muirii* has white to pale pink flowers with a perianth tube up to 25 mm long, curved at the apex, and spreading, ± vertically oriented tepals up to 25 mm long. The stamens are ± unilateral and pendent and the long style branches are twisted and sometimes tangled together, an unusual feature in the genus but one shared by pink-flowered *H. kiaratayloriae*, in which the style divides near the tips of the coherent anthers and the style branches are held erect.

87. **Hesperantha kiaratayloriae** *Goldblatt & J.C.Manning* in Bothalia 43: 211 (2013). Type: South Africa, Western Cape, Rûens Hills, northeast of Bredasdorp, Farm Plaatjieskraal, upper slopes of ridge in stony quartzite gravel over shale, 8 Nov. 2011, *Goldblatt & Porter 13729* (NBG, holo.; K, MO, PRE, iso.).

Plants 150–200(–300) mm high. *Corm* obliquely bell-shaped, 6–8 mm diam.; tunics ± woody, dark grey, fragmenting from lower margins into tile-like segments. *Stem* smooth, unbranched. *Leaves* several, dry at flowering time, linear, mostly 10–60 × 1.0–1.5 mm, uppermost 2 or 3 leaves sheathing for entire length. *Spike* 2- to 4(–7)-flowered, flexuose; bracts dry and brown at flowering, outer mostly 12–15 mm long with margins united near base for 1–2 mm sheathing spike axis, inner forked apically. *Flowers* diurnal, pink with white throat, unscented, anthers yellow, prominently displayed; perianth tube cylindric, slightly expanded at apex, 13–16 mm long, distal half exserted from bracts; tepals subequal, spreading, elliptic, ± 12 × 4–5 mm, outer slightly larger than inner. *Filaments* erect, 2.5 mm long, exserted ± 1 mm from tube; anthers ± 5 mm long, yellow, remaining coherent around style; pollen yellow. Style exserted, enclosed by stamens, dividing just below anther apices, branches ± 5 mm long, remaining erect, slightly twisted and often interlaced. *Capsules* subcylindric, 7–8 mm long. *Seeds* angular, ± 0.7 × 0.4 mm, with membranous raphal ridge expanded into a wing at micropylar end. *Flowering time*: (late October) November.

Distribution and ecology: known from a single population in the Bredasdorp District of Western Cape, South Africa; on a low, south-facing ridge in silcrete-quartzite stones over a shale substrate among tufts of grasses.

Diagnosis: unique in the genus, *Hesperantha kiaratayloriae* has the style extending well beyond the mouth of the perianth tube and overtopping the anthers, these also unusual in being parallel and contiguous. The stamens thus enclose the style, which divides immediately below the anther tips into upright, loosely twisted branches sometimes interlaced around one another. The margins of the floral bracts are united basally for up to 2 mm, and the bell-shaped corm with a flat base place the species in sect. *Radiatae*. Also unusual in the section for the pink flowers and leaves dry at flowering, *H. kiaratayloriae* mostly closely resembles *H. muirii*, which also has twisted style branches and relatively short leaf blades but larger, white or rarely pale pink flowers with the style dividing at the mouth of the perianth tube.

Distribution of ***Hesperantha kiaratayloriae***.

Subtribe 5. **Tritoniinae**

Tritoniinae *Goldblatt* in Journal of South African Botany 37: 441 (1971). Type: *Tritonia* Ker Gawl.

Subtribe *Babianinae* Goldblatt: 442 (1971). Type: *Babiana* Ker Gawl.

Corm tunics fibrous or sometimes papery. *Flowering stem* well developed or contracted and subterranean. *Leaf* margins either with a subepidermal sclerenchyma strand or with columnar epidermis. *Inflorescence* a spike. *Flowers* zygomorphic or actinomorphic; style branches simple or notched apically. *Seed* epidermis smooth with cell outlines obscure; ovular vasculature intact or excluded; x = ?11 (10, 7).

Genera 7, mainly southern Africa; ± 288 spp.: *Babiana* 93, *Chasmanthe* 3, *Sparaxis* 16, *Duthieastrum* 1, *Dierama* ± 45, *Tritonia* 30, *Ixia* 100.

22. **Babiana**

Babiana *Ker Gawl.* in Curtis's Botanical Magazine 16: t. 576 (1802a), name conserved against *Beverna* Adans. Type: *B. plicata* Ker Gawl. = *B. fragrans* (Jacq.) Ker Gawl. ex Steud.

Beverna Adans.: 20 (1763) [possibly a Latinised orthographic or typographic error for baviaan, a common name for the genus in the 18th century]. Type: not designated.

Anaclanthe N.E.Br.: 269 (1932a). Type: *A. plicata* (L.f.) N.E.Br. = *Babiana hirsuta* (Lam.) Goldblatt & J.C.Manning

[*Antholyza* L.: 37 (1753), in part, excluding the lectotype, *A. cunonia* L. = *Gladiolus cunonius* (L.) Gaertn., designated by Hitchcock & Green (1929).]

[*Acaste* Salisb.: 332 (1812), invalid name without description. Type: *A. venusta* Salisb. = *Babiana rubrocyanea* (Jacq.) Ker Gawl.]

Revisionary accounts: Lewis (1959); Goldblatt & Manning (2007).

From the Cape Dutch *babiaan*, baboon, for the fondness of this native African primate for *Babiana* corms.

Deciduous cormous perennials, corm rooting from below, basal in origin, tunics of tough closely fibrous layers, or sometimes netted. *Stem* aerial or subterranean, more-or-less terete, simple or branched, erect to arching outward, usually hairy to scabrid, or smooth, usually sheathed below by a collar of tough fibrous layers. *Leaves* several, lower 2 or 3 cataphylls; foliage leaves unifacial, blades pleated, with prominent veins at angles, without definite midrib, set obliquely to sheaths, sometimes nearly at right angles and thus held horizontally, rarely sheath extended upward as a pseudopetiole, ovate to linear, sometimes abruptly truncate, and then cuneate, sometimes undulate, sinuate or terete, usually pubescent or puberulous, or smooth, upper margins sometimes with long hairs; margin with marginal bundle and epidermal cells unspecialised. *Inflorescence* a spike, flowers few to many, often secund, or spiral or in two ranks; bracts paired, abaxial (outer) usually larger, short or long, green with dry brown apices, variously hairy or smooth, entirely dry in a few species, papery and translucent in 3 species, adaxial (inner) forked apically or to middle, or divided to base. *Flowers* usually zygomorphic and bilabiate or salver-shaped, or actinomorphic and with tepals spreading or cupped, usually shades of blue to violet, sometimes yellow, red, pink, purple, or white, when bilabiate usually with pale markings on lower lateral tepals, when actinomorphic centre often darker or lighter, often sweetly fragrant, usually with nectar from septal nectaries; perianth tube short to long, cylindric and straight to curved or funnel-shaped; tepals equal, subequal or unequal and dissimilar, then dorsal enlarged, hooded, reflexed or erect with margins involute and enclosing filaments, lower tepals sometimes clawed. *Stamens* unilateral and arcuate or symmetrically disposed and erect; filaments arising in mouth of tube; anthers linear and extrorse, or occasionally latrorse with connective very broad, exserted. *Ovary* smooth, hairy on ribs or densely hairy; style exserted or included, dividing opposite or beyond anther tips, or sometimes below level of anthers, style branches filiform or slightly to prominently expanded above. *Capsules* globose to ovoid, cartilaginous, hairy or smooth. *Seeds* pear-shaped, smaller at micropylar end, lightly wrinkled, surface smooth and usually shiny. *Pollen grains* monosulcate-operculate, operculum 2-banded, exine perforate-scabrate. *Basic chromosome number* x = 7.

Species 93, divided among three sections; mostly of the winter-rainfall zone of southern Africa, extending into the Upper Karoo, northeastern South Africa, Namibia, Zimbabwe and Zambia.

Babiana is easily recognised by the pleated leaves (sometimes almost terete but with several grooves) and presence of fine to prominent hairs on the leaves, stem and even bracts, the vestiture ranging from finely velvety to long-hairy. The floral bracts are usually green, often drying and rust-coloured at the tips with the inner notched at the tips or divided to the base or almost so, then evidently a pair. Rarely, as in the *B. scariosa* group, the bracts are dry and papery. Flowers are zygomorphic or in a few species radially symmetric, and most often shades of blue to violet but sometimes red, pink or other colours, and the style branches are undivided. The genus stands out in Crocoideae in its low basic chromosome number, $x = 7$ (other genera of subtribe Tritoniinae have $x = 11$ or 10). The genus is subdivided into three sections, mainly based on the nature of the inner floral bracts, notched at the tips (sect. *Teretifolieae*), divided to the base or almost so (sect. *Babiana*) or the bracts are short, divided to about the middle and the lower tepals specialised in being abruptly narrowed at the base and with ear-like lobes at the base of the limb (sect. *Antholyzoides*). Most species of sect. *Babiana* have a hairy ovary, a character rarely seen elsewhere in Iridaceae. Three species of sect. *Antholyzoides*, including *B. ringens*, have red flowers with elongate perianth tubes and are pollinated by sunbirds. Pollination is otherwise by large-bodied bees, or in several species of sect. *Babiana* and sect. *Teretifolieae* by long-proboscid flies. Pollination by hopliine beetles is indicated in species with radially symmetric flowers but has been little studied.

Within the sections, species are arranged in series, based on their morphology and important features, including perianth tube length, floral bract texture and presence and type of vestiture of the ovary.

Molecular phylogenetic studies have been remarkably unhelpful in assessing relationships in *Babiana*. Plastid and nuclear sequences differ substantially and neither is congruent with the classification based on morphology. We have not, therefore, been able to restructure the classification proposed by Goldblatt & Manning (2007). Sect. *Babiana* is broadly supported, but includes several species of the other two sections. There is no support for sect. *Antholyzoides*, but the red-flowered *B. ringens* group is retrieved as a clade; the remaining species of the section appear unrelated to one another and instead are linked to a range of species that appear very different morphologically. It seems unlikely that additional sequences will resolve the lack of congruency. That the zygomorphic flower is ancestral in *Babiana* is supported by molecular study, thus radial symmetry is derived, and according to both molecular evidence and morphology radial floral symmetry arose independently four times across the genus.

Key to sections

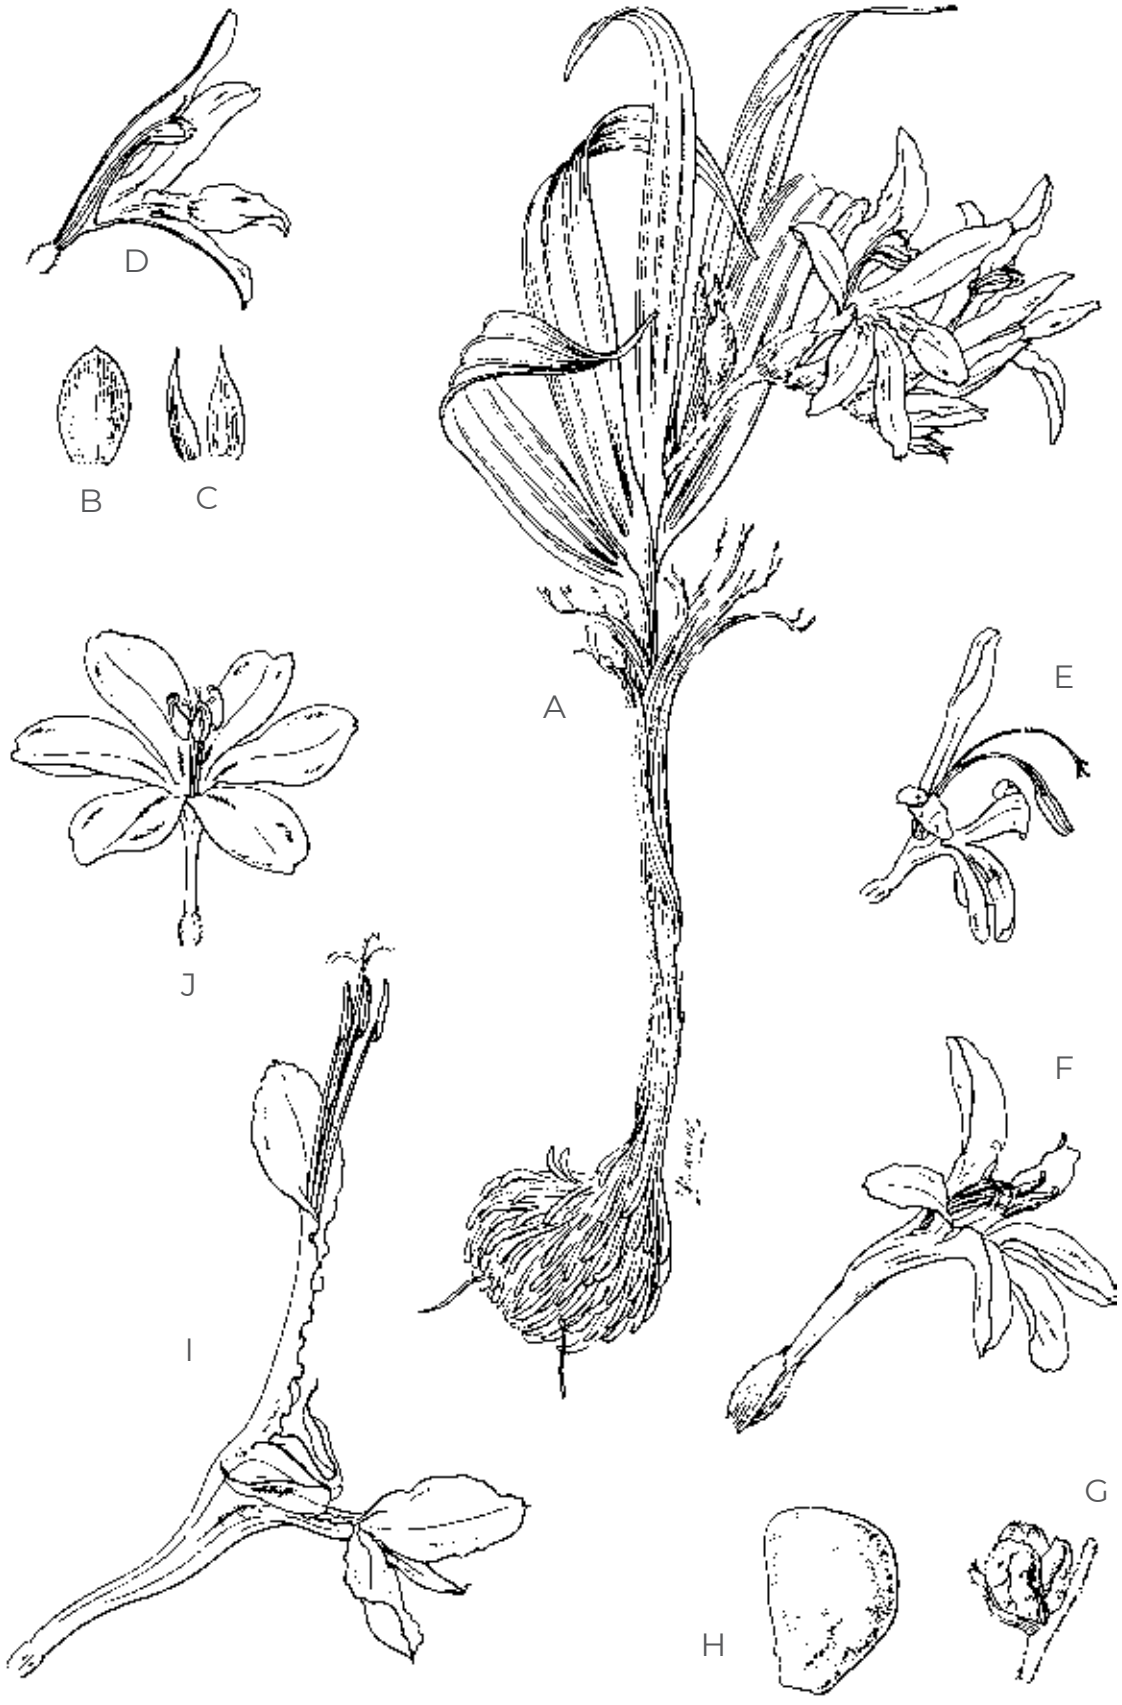
For leaf characters, examine only well-developed leaves; the lower leaves are often smaller than normal and upper leaves may grade into bracts. It is useful to examine more than one plant in a collection or population, as leaf characters are, to some extent, variable. Measure leaf width at ± the middle of a leaf. Measure bracts in the middle of the spike; the lower and upper flowers often have larger or smaller bracts than normal for a species.

Measure perianth tube length from the top of the ovary to the point at which the dorsal tepal separates from the upper lateral tepals. Thus not only the narrow lower portion of the tube is included in this measure, but also the wider, funnel-shaped portion. Inner floral bracts must be examined carefully to determine the point at which the apex is forked or if the inner bracts are divided to the base, thus evidently a pair.

A hand lens is useful for examining leaf and stem vestiture and the surface of the ovary.

1a Inner bracts divided to base or rarely close to base but then joined only by transparent membranous tissue; bracts green with dry brown or rust-coloured tips, or dry and brown, or completely papery and translucent; ovary often densely hairy (smooth or minutely hairy on ribs in a few species). . . . . Sect. 3. *Babiana*

1b Inner bracts forked at tips or divided in upper ⅓–½; bracts green with dry, light brown to rust-coloured tips, or sometimes brown throughout; ovary mostly smooth, rarely hairy:



2a Tepals narrowed below into claws, lower three abruptly so, with claw linear and limbs often with prominent auricular lobes at base; dorsal tepal initially arched, often curving upward and erect to recurving when fully open (margins curving forward and enclosing filaments in three species); bracts mostly 5–15 mm long, rarely to 22 mm; plants never acaulescent with spike borne at or below ground level. . . . . Sect. 2. *Antholyzoides*

2b Tepals not as above, limbs without prominent auricular lobes at base; dorsal tepal arched, erect, or fully patent, never initially arched and later curving back; bracts mostly 16–50 mm long, occasionally 13–15 mm; plants often acaulescent or nearly so with spike borne close to ground level or sometimes below ground . . . . Sect. 1. *Teretifolieae*

Keys to species

Sect. 1. *Teretifolieae*

1a Flowers actinomorphic, tepals ± equal and spreading horizontally or almost so; stamens erect, symmetrically arranged around central style:

BABIANA. B. toximontana: A, flowering plant; B, outer bract; C, inner bract divided to base; D, half-flower. ***B. sinuata***: E, flower; ***B. noctiflora***: F, flower. ***B. villosula***: G, dehisced capsule; H, seed. ***B. ringens*** subsp. ***ringens***: I, flower. ***B. melanops***: J, flower.

2a Stem aerial; flowers cream-coloured to pale yellow with brown to dull purple centre; leaves lanceolate to ovate; perianth tube 15–25 mm long; ovary sparsely hairy. . . . . 2. *B. pygmaea*
2b Stem subterranean; flowers blue or violet; leaves linear; perianth tube > 25 mm long; ovary hairless:
3a Flowers mauve-pink with red centre and throat; perianth tube 30–75 mm long; tepals 10–12 mm wide; anthers violet. . . . . 30. *B. radiata*
3b Flowers without red centre; perianth tube 45–75 mm long; tepals 5–7 mm wide; anthers white 36. *B. symmetrantha*
1b Flowers zygomorphic, tepals differentiated, with lower bearing contrasting markings and dorsal usually somewhat to much larger, often held apart, sometimes erect or recurved above; stamens arched or erect, unilateral with anthers parallel, rarely diverging, and facing lower tepals:
4a Leaves ± truncate with apex ragged and irregularly toothed:
5a Perianth tube funnel-shaped, widening toward throat, (18–)32–36 mm long:
6a Leaves and bracts softly long-hairy; leaf blades widest below apex; perianth tube ± 24 mm long; filaments straight; dorsal tepal erect to recurved . . . . . 6. *B. lanata*
6b Leaves and bracts smooth, scabrid or rarely roughly hairy; leaf blades widest at apex; perianth tube 18–36 mm long; filaments arching beneath ascending dorsal tepal . . . . . 21. *B. flabellifolia*
5b Perianth tube cylindric for most of length, 40–60 mm long:
7a Perianth tube sharply curved in upper 10 mm; plants of central Namaqualand . . . . . 24. *B. pubescens*
7b Perianth tube straight or nearly so; plants of Bokkeveld Mtns, Cold Bokkeveld and western Karoo:
8a Tepals spreading horizontally, 18–22 × 3.5–5.0 mm; filaments 8–9 mm long . . . . . 23. *B. praemorsa*
8b Tepals laxly ascending, straight or distally recurving, 26–32(–40) × 6–12 mm; filaments 15–18 mm long . . . . . 22. *B. cuneata*
4b Leaves acute to attenuate, sometimes pungent, or ± obtuse with rounded apex:
9a Stem and spike axis not reaching ground level, flowers arising below ground; bracts ± dry, membranous:
10a Flowers blue to violet with white markings on lower tepals; perianth tube 35–55(–70) mm long; dorsal tepal 30–50 mm long; filaments mostly 10–12 mm long; flowering mainly February to May . . . . . 44. *B. bainesii*
10b Flowers yellowish to buff-coloured (when dry, tepals often with broad purple median streak); perianth tube 30–40 mm long; dorsal tepal 24–40 mm long; filaments 15–18 mm long; flowering mainly July to September. . . . . 43. *B. hypogaea*
9b Spike always above ground, stem reaching shortly to well above ground level, flowers always arising above ground; bracts usually green, sometimes with dry tips, sometimes ± dry:
11a Perianth tube 22–105 mm long; perianth tube as long or up to three times as long as dorsal tepal:
12a Flowers pale pink, mauve, or white to yellow, suffused with mauve or pink, lower tepals sometimes with purple, pink or red marks in lower half:
13a Leaves smooth or at most with few scattered long hairs, deeply pleated or terete and grooved:
14a Leaves lanceolate, deeply pleated, stiff and pungent; perianth tube 25–52 mm long; tepals ± 10 mm long . . . . . 42. *B. lapeirousioides*
14b Leaves ± terete and with narrow longitudinal grooves; perianth tube 70–75 mm long; tepals 16–24 mm long:
15a Dorsal tepal ± 30 × 4 mm, remaining tepals twisted in propeller fashion; filaments ± 12 mm long and exserted ± 9.5 mm from the tube . . . . . 41. *B. teretifolia*
15b Dorsal tepal 20–24 × 6–8 mm, remaining tepals ± plane; filaments 4–5 mm long, exserted 1–3 mm from tube. . . . . 40. *B. brachystachys*
13b Leaves variously hairy, lanceolate to linear, plane or lightly pleated:
16a Leaves minutely hairy or almost hairless, with sparse scattered silky hairs on margins; blade loosely coiled in upper half and tips often recurved; plants of southern Namibia . . . . . 17. *B. longicollis*
16b Leaves velvety, usually lacking scattered silky hairs on margins; blade ± plane, straight or rotated for entire length; plants of South Africa:
17a Leaves lanceolate; perianth tube 40–65 mm long, less than twice as long as dorsal tepal; tube flaring gradually from base:
18a Flowers white, sometimes suffused with mauve; anthers 9–11 mm long . . . . . 31. *B. virginea*
18b Flowers yellow, sometimes suffused with mauve; anthers 7–8 mm long . . . . . 28. *B. vanzijliae*
17b Leaves linear to lanceolate or sword-shaped; perianth tube mostly 60–90 mm long, two to three times as long as dorsal tepal, narrow and cylindric in lower ⅔, flared, if at all, only toward apex:
19a Perianth tube 65–105 mm long, expanded in upper 5–10 mm into a wide gullet; dorsal tepal 30–34 mm long, lower tepals 18–23 × 8 mm; filaments 20–22 mm long, anthers 5–7 mm long; style branches ± 6 mm long . . . . . 38. *B. tubulosa*
19b Perianth tube (45–)60–100 mm long, straight and cylindric or nearly so, often slightly expanded in upper 5–7 mm; dorsal tepal 18–23 mm long, lower tepals 15–20 × 3–4 mm; filaments 13–16 mm long, anthers 4–5 mm long; style often dividing below (sometimes above) anther tips and branches 3–4 mm long. . . . . 39. *B. tubiflora*
12b Flowers shades of red, blue to violet, lower lateral tepals with white or yellow markings often edged in darker blue, violet or red:
20a Flowers red to purple with yellow markings on lower tepals and yellow in throat; filaments ± 40 mm long. . . . . 37. *B. carminea*
20b Flowers blue to violet with white to pale yellow splashes or streaks on lower lateral tepals; filaments 10–20 mm long:
21a Ovary hairy above base; filaments diverging above and anthers held widely apart; style dividing below anthers, style branches 11–13 mm long . . . . . 27. *B. geniculata*

21b Ovary hairless; filaments and anthers parallel and contiguous; style dividing opposite upper half of anthers or above them, style branches 3–6 mm long:
22a Leaves smooth, hairless, sometimes with prominent fibrous veins and margins (turning yellow on drying):
23a Perianth tube 45–70 mm long; leaves lanceolate, (5–)10–25 mm wide, with leaf tips hard and pungent . . . . . 33. *B. dregei*
23b Perianth tube 42–44 mm long; leaves linear, 5–10 mm wide, with leaf tips acute, not hard and pungent . . . . . 34. *B. rivulicola*
22b Leaves scabrid to velvety or long-hairy, lacking prominent fibrous veins and margins and leaf tips not or only weakly pungent:
24a Perianth tube 25–45 mm long; dorsal tepal ± as long as tube:
25a Leaves oblong-lanceolate, upright, subacute, soft-textured and weakly pleated; flowering June to July . . . . . 5. *B. pauciflora*
25b Leaves sword-shaped, rarely linear, often inclined toward ground, firm-textured and distinctly pleated; flowering (late July to)August . . . . . 25. *B. attenuata*
24b Perianth tube (30–)40–70 mm long; dorsal tepal ± as long to 3 times as long as tube:
26a Perianth tube slightly to sharply curved below throat; bract of lowermost flower never with blade-like, leafy tip; tepals unequal, dorsal 20–33 mm long:
27a Leaves usually arching toward ground, conspicuously hairy; perianth tube 36–43 mm long; dorsal tepal 20–23 mm long . . . . . 26. *B. curviscapa*
27b Leaves erect, sparsely short-hairy; perianth tube 60–70 mm long; dorsal tepal 23–33 mm long . . . . . 35. *B. framesii*
26b Perianth tube straight or nearly so, not curved below the throat; bract of lowermost flower with a blade-like, leafy tip; tepals nearly equal, dorsal (25–)30–45 mm long:
28a Flower bilabiate, lower tepals joined to upper laterals for 3–5 mm and to one another for ± 2 mm; dorsal tepal 35–43 mm long. . . . . 32. *B. rigidifolia*
28b Flower not noticeably bilabiate, lower tepals not joined to upper laterals for any distance; dorsal tepal 25–35 mm long . . . . . 29. *B. sambucina*
11b Perianth tube 12–30 mm long; dorsal slightly longer to twice as long as tube:
29a Flowers pale yellow sometimes flushed mauve, lower tepals yellow with paler edges . . . . . 28. *B. vanzijliae*
29b Flowers blue to violet or pink to magenta, lower tepals marked white to yellow:
30a Flowers magenta-pink, pale yellow on lower tepals (but see *B. nana*):
31a Leaf blades narrowly sword-shaped, borne on slender pseudopetioles; stem lightly retrorse-hairy; ovary rarely minutely hairy on ribs, or smooth . . . . . 4. *B. pilosa*
31b Leaf blades ovate to oblong, borne directly on sheaths and at nearly right angles to them, conspicuously long-hairy; stem densely long-hairy; ovary always smooth. . . . . 3. *B. rubella*
30b Flowers variously coloured, but not predominantly magenta-pink or yellow (but see *B. nana*):
32a Leaf margins undulate or crisped, and/or blade loosely coiled above middle:
33a Leaf blades broadly ovate, 30–40 × 20–25 mm, held at right angles to sheaths. . . . . 18. *B. cinnamomea*
33b Leaf blades linear to sword-shaped, 3–12 mm wide, erect or falcate:
34a Leaf blades with prominent central vein, margins undulate and crisped; bracts mostly 28–30 mm long . . . . . 10. *B. crispa*
34b Leaf blades less than 6 mm wide with two or more main veins, margins plane or undulate, rarely somewhat crisped; bracts mostly 17–27 mm long:
35a Flowers pale greyish green; leaf margins thickened . . . . . 14. *B. virescens*
35b Flowers pale blue, mauve or whitish; leaf margins usually unthickened:
36a Leaf blades lightly undulate, occasionally crisped in lower part, often twisted above; flowers violet; bracts lightly hairy, mostly 17–20 mm long. . . . . 15. *B. torta*
36b Leaf blades with margins plane, loosely coiled in upper half; flowers pale mauve to whitish; bracts smooth, 17–27 mm long . . . . . 16. *B. namaquensis*
32b Leaf margins plane, blades ± flat, sometimes twisted from base:
37a Flowers large, dorsal tepal 45–50 mm long; filaments ± 10 mm long . . . . . 7. *B. grandiflora*
37b Flower medium to large but dorsal tepal 25–40 mm long; filaments mostly 12–17 mm long:
38a Corm tunics not forming collar or rarely with short and sparse collar enclosing only below-ground portion of stem:
39a Perianth tube 12–17 mm long; tepals 25–30 mm long . . . . . 1. *B. nana*
39b Perianth tube 23–30 mm long; tepals 35–40 mm long . . . . . 9. *B. confusa*
38b Corm tunics forming well-developed collar enclosing stem below ground:
40a Anthers 7–9 mm long; ovary densely hairy above base. . . . . 8. *B. cedarbergensis*
40b Anthers 5–9 mm long; ovary smooth:
41a Perianth tube ± 14 mm long. . . . . 12. *B. tanquana*
41b Perianth tube 20–30 mm long:
42a Leaf blades lanceolate to linear, mostly 3–12 mm wide, erect or suberect:
43a Leaves shortly hairy or puberulous, more than twice as long as spike; filaments 10–11 mm long; flowers blue to violet . . . . . 13. *B. karooica*
43b Leaves softly long-hairy, ± as long as spike and mostly 3–6 mm wide, pleated at base; filament 15–17 mm long; flowers yellowish to reddish mauve . . . . . 11. *B. minuta*
42b Leaf blades broadly lanceolate to ± ovate, at least 13 mm wide, extended nearly horizontally, shallowly pleated along entire length:

44a Flowers lilac, inner tepals pale yellow edged lilac or entirely yellow; leaf blades 30–40 × 13 mm, smooth or upper margin sparsely long-hairy; perianth tube ± 25 mm long. . . . . 19. *B. horizontalis*
44b Flower greenish to grey-blue; leaf blades (40–)70–100 × 18–25 mm, scabrid on veins and margins; perianth tube 20–22 mm long . . . . . .20. *B. gariepensis*

Sect. 2. *Antholyzoides*

1a Flowers predominantly red; dorsal tepal erect, with margins curving inward, twice to three times as long as lower tepals; filaments enclosed by involute dorsal tepal, 25–60 mm long:
2a Main axis of spike and several lateral branches all bearing flowers; stem borne well above ground; leaves velvety hairy . . . . . 54. *B. hirsuta*
2b Main axis of spike sterile only lateral branches bearing flowers; stem extending shortly above ground; leaves smooth or minutely velvety:
3a Perianth tube 27–45 mm long, lower part not kinked and not abruptly expanded; dorsal tepal (18–)23–50 mm long; leaves firm to rigid, straight; style dividing between base and apex of anthers or exceeding anthers . . 55. *B. ringens*
3b Perianth tube 16–21 mm long with lower part kinked near apex and abruptly expanded; dorsal tepal 15–18 mm long; leaves relatively soft, falcate; style dividing below bases of anthers . . . . . 56. *B. avicularis*
1b Flowers variously coloured, but never predominantly red; dorsal tepal as long to 1.5× as long as lower tepals and ± plane; filaments mostly 6–20 mm long:
4a Stem and/or bracts hairy, hispid or velvety, at least above:
5a Leaf blades oblong, held nearly at right angles to sheath and stem, at least 12 mm wide and with 3 or 4 prominent veins; bracts sparsely hairy . . . . . 47. *B. lewisiana*
5b Leaf blades narrowly lanceolate or linear, blade not markedly oblique to sheaths and stem, mostly less than 8 mm wide; bracts minutely scabrid or smooth:
6a Bracts 8–10 mm long; anthers ± 4 mm long; leaves twisted to loosely coiled in upper half . . . . . 45. *B. spiralis*
6b Bracts mostly 14–20 mm long; anthers ± 6 mm long; leaves sword-shaped, not coiled above . . . . . 46. *B. stenomera*
4b Stem and bracts smooth or largely so:
7a Leaf margins strongly undulate and crisped; cataphylls and leaf sheaths cobwebby or woolly:
8a Anthers cohering; leaf margins and sheaths bearing scattered long hairs; lower lateral tepal limbs without auriculate lobes. . . . . 49. *B. sinuata*
8b Anthers free; leaves without hairs; lower lateral tepal limbs with prominent auriculate lobes at base . . . . 50. *B. striata*
7a Leaf margins not strongly undulate and never crisped; cataphylls and leaf sheaths sometimes cobwebby to woolly:
9a Bracts 12–20 mm long, hairless or sparsely hairy; flowers borne in erect or inclined spikes; sheaths and cataphylls cobwebby to woolly:
10a Leaf blades ascending, narrowly lanceolate or linear, blade not markedly oblique to the sheaths and stem, mostly less than 5 mm wide, loosely twisted in upper half . . . . . 48. *B. fimbriata*
10b Leaf blades borne obliquely to sheaths and stem, mostly more than 5 mm wide, hardly twisted in upper half, margins plane or lightly undulate . . . . . 51. *B. planifolia*
9b Bracts 4–7 mm long, hairless; flowers borne in horizontal spikes; sheaths and cataphylls smooth, not cobwebby to woolly:
11a Leaf blades ascending, not held markedly oblique to sheaths, narrowly lanceolate to linear, loosely twisted for entire length . . . . . 52. *B. lobata*
11b Leaf blades held nearly at right angles to sheaths, oblong to lanceolate, twisted distally and becoming erect. . . . . 53. *B. tritonioides*

Sect. 3. *Babiana*

1a Bracts entirely dry at flowering; outer bracts always smooth (series *Scariosae*):
2a Outer bract firm and solid in texture, tricuspidate with long central cusp . . . . . 62. *B. secunda*
2b Outer bract dry-membranous and translucent, clear or brownish, long-attenuate:
3a Flowers actinomorphic with stamens erect and symmetrically arranged around style; plants acaulescent or stem reaching just above ground. . . . . 78. *B. papyracea*
3b Flowers zygomorphic with stamens unilateral and arcuate, and perianth bilabiate; plants with well-developed aerial stem:
4a Perianth tube shorter than tepals, 12–20 mm long; flowers mauve with white or cream-coloured markings on lower tepals . . . . . 76. *B. scariosa*
4b Perianth tube longer than tepals, 35–45 mm long; flowers cream-coloured or lilac with red to purple markings on lower tepals . . . . . .77. *B. spathacea*
1b Bracts green in lower half or almost entirely, tips often dry and rust-brown, occasionally somewhat attenuate; outer bracts usually scabrid to hairy:
5a Tepals equal or subequal, symmetrically arranged and spreading with dorsal tepal not differentiated from others in size or colour; all tepals similarly marked; stamens symmetrically or asymmetrically arranged:
6a Tepals bicoloured deep blue with dark red base; anthers reddish brown, linear, less than 1 mm wide:
7a Stamens unilateral, facing base of spike; style dividing opposite middle of anthers, style branches widening into broad, glossy flattened stigmas; tepals narrowed below . . . . . 83. *B. rubrocyanea*
7b Stamens symmetrically arranged in centre of flower, enclosing style; style dividing below anthers, style branches filiform with apices not or barely expanded; tepals not narrowed below . . . . . 85. *B. regia*
6b Tepals either uniformly pink, red, purple, pale to dark blue, violet or mauve, or darker blue at bases and sometimes white in throat; anthers white, cream-coloured or blue to blackish, linear or arrow-shaped:

8a Anthers dark blue to blackish, either linear and less than 1.5 mm wide, or arrow-shaped with broad connective tapering to apex and 2–4 mm wide:
9a Flowers shades of pale to mid-blue or mauve, usually darker in centre; perianth salver-shaped with tepals narrowed into claws below; stem erect or nearly so . . . . . 92. *B. melanops*
9b Flowers shades or scarlet, purple or mauve-pink; perianth shallowly bowl-shaped; stem usually strongly arching outward. . . . . 93. *B. villosa*
8b Anthers white to cream-coloured, pale blue or turquoise, linear and less than 1 mm wide:
10a Bracts entirely green; leaf blades borne obliquely from stem; filaments ± 10 mm long . . . . . 88. *B. foliosa*
10b Bracts brown and scarious at apices; leaf blades not notably oblique:
11a Filaments 8–10 mm long, anthers well exserted from perianth tube; anthers and pollen white to pale yellow; flowers with darker centre . . . . . 84. *B. leipoldtii*
11b Filaments 5–8 mm long, anthers partly included within perianth tube; pollen mauve, blue or cream-coloured; flowers uniformly coloured or with white throat sometimes edged with dark pigment:
12a Flowers mauve to white; tepals oblong to obovate, 6–13 mm wide; style dividing between base and lower half of anthers . . . . . 86. *B. villosula*
12b Flowers pink; tepals obovate to suborbicular, 14–20 mm wide; style dividing below anthers . . . . . 87. *B. blanda*
5b Tepals subequal or unequal, but flower zygomorphic with unilateral stamens and dorsal tepal usually differentiated, often erect or arching over lower; tepals opposite dorsal with contrasting markings; stamens always asymmetrically arranged:
13a Ovary hairless or thinly hairy, sometimes only on ribs:
14a Underground part of stem without collar of fibres (or collar poorly developed); corm tunics of reticulate or netted fibres; stem reaching shortly or not at all above ground:
15a Leaf blades inclined toward ground, minutely hairy or evidently smooth; blades hardly pleated, usually borne on slender, terete pseudopetioles up to 140 mm long . . . . . 61. *B. petiolata*
15b Leaf blades suberect, usually obviously hairy; blades prominently pleated, borne directly on sheaths . . . . . 60. *B. ambigua*
14b Underground part of stem with well-developed collar of dry fibres; corm tunics of ± matted fibres not obviously netted; stem aerial or mostly underground:
16a Stem usually well developed, mostly 150–250 mm high and usually branched several times; perianth tube ± as long or longer than tepals, 25–30 mm long . . . . . 57. *B. fourcadei*
16b Stem often ± subterranean or extending above ground; perianth tube as long as or shorter than tepals, 10–20 mm long:
17a Bracts not noticeably rust-coloured at tips; inner bracts with broad membranous margins; ovary thinly hairy above or only on ribs . . . . . 71. *B. scabrifolia*
17b Bracts with conspicuous rust-coloured tips; ovary minutely hairy on ribs or smooth:
18a Perianth tube 10–14 mm long; stamens equal, filaments 12–14 mm long; inner tepals widest at or near apices. . . . . 58. *B. patula*
18b Perianth tube 17–20 mm long; stamens unequal in length, filaments 7–10 mm long; inner tepals widest near middle . . . . . 59. *B. montana*
13b Ovary hairy, often densely so:
19a Perianth tube 30–50 mm long, mostly 1.5–2.0× as long as dorsal tepal but at least 10 mm longer:
20a Perianth pale yellow; perianth tube narrow below, wide and tubular above, 35–50 mm long; tepals 27–32 mm long; flowers strongly scented . . . . . 75. *B. noctiflora*
20b Perianth shades of violet to mauve with either white or dark red or purple markings on lower tepals; tube slender, widening slightly in upper half; flowers unscented:
21a Aerial stem produced shortly above ground; spike horizontal . . . . . 65. *B. engysiphon*
21b Aerial stem produced well above ground; spike erect or slightly inclined:
22a Spike ± erect; perianth tube 35–47 mm long; tepals acute; outer bracts attenuate, 14–40 mm long; style branches slender . . . . . 73. *B. ecklonii*
22b Stem arching outward above and spike inclined; perianth tube 30–40 mm long; tepals obtuse (or obtuse-apiculate); outer bracts ± truncate, 10–30 mm long; style branches orbicular at tips and noticeably ciliate. . . . . 72. *B. latifolia*
19b Perianth tube shorter to ± as long as dorsal tepal, or if longer, then less than 32 mm long and less than 8 mm longer than dorsal:
23a Flowers blue or violet and inverted, with spike inclined; perianth tube recurved and dorsal tepal abaxial and ± horizontal, lower tepals suberect:
24a Tepals overlapping, forming cup, subequal, dorsal not held apart, 20–22 mm long; filaments 8–10 mm long. . . . . 81. *B. angustifolia*
24b Tepals not forming cup, dorsal held apart from others, 22–24 mm long; filaments 12–15 mm long. . . . . 82. *B. inclinata*
23b Flowers various colours, blue to violet, purple, red, cream-coloured, white or yellow, not inverted; perianth tube straight or arching forward and dorsal tepal erect or arching toward spike apex:
25a Anthers ovate or arrow-shaped, connective expanded below:
26a Perianth tube 10–18 mm long and shorter than to as long as dorsal tepal; style dividing below or opposite anther bases. . . . . 89. *B. nervosa*
26b Perianth tube 18–30 mm long and ± as long to slightly longer than dorsal tepal; style dividing opposite upper half of anthers:
27a Flowers pink to reddish purple; perianth tube 18–28 mm long . . . . . 90. *B. purpurea*

27b Flowers cream-coloured, pale pink or pale blue; perianth tube 20–30 mm long . . . . . 91. *B. patersoniae*
25b Anthers ± linear, connective not expanded below:
28a Perianth tube at least 18 mm long and ± as long as or longer than dorsal tepal:
29a Leaves strongly pleated, ± smooth or minutely hairy; dorsal tepal ± 32 mm long; style dividing below base of anthers. . . . . 70. *B. arenicola*
29b Leaves lightly pleated, hairy throughout; dorsal tepal 18–30 mm long; style dividing between base and apex of anthers:
30a Dorsal tepal 24–30 mm long; perianth tube 24–30 mm long . . . . . 80. *B. tubaeformis*
30b Dorsal tepal 18–22 mm long; perianth tube 18–20 mm long . . . . . 79. *B. fragrans*
28b Perianth tube 10–15(–25) mm long and ½ to nearly as long as dorsal tepal:
31a Flowers pale yellow, rarely light mauve, lower tepals deep yellow, highly fragrant; perianth tube 10–14(–15) mm long:
32a Plants with well developed ascending to suberect aerial stem; bracts 6–8 mm long . . . . . 67. *B. unguiculata*
32b Plants with stem extending shortly above ground and strongly inclined to horizontal; bracts 15–25 mm long . . . . . 74. *B. odorata*
31b Flowers blue to mauve with yellow markings on lower tepals, weakly scented or evidently unscented; perianth tube 9–25 mm long:
33a Plants flowering May to June rarely after mid-July; aerial stem short, seldom reaching more than 50 mm above ground; leaf blades broadly lanceolate to ovate, held nearly horizontally and ± at right angles to sheaths:
34a Leaves spreading at right angles to the sheaths, stiff-textured and straight; flowers smaller, the tube ± 9 mm long and the dorsal tepal ± 23 mm long; tepals spreading or recurved, with the lower lateral tepals mostly or entirely yellow; plants of quartz patches . . . . . 69. *B. salteri*
34b Leaves suberect and held at 45° to the sheaths, medium-textured and lightly coiled at the tips; flowers larger, the tube 12–14 mm long and the dorsal tepal 28–30 mm long; tepals suberect, with the lower lateral tepals blue with a median white marking; plants of sandy soils. . . . . 68. *B. toximontana*
33b Plants flowering (late July–)August to October; aerial stem short or well developed; leaf blades linear to lanceolate, ascending to erect:
35a Leaves narrow, deeply pleated, often rigid and almost pungent, mostly 2–8 mm wide; floral bracts 7–12 mm long; perianth tube 8–15 mm long. . . . . 64. *B. lineolata*
35b Leaves lanceolate, relatively firm but not rigid or pungent, shallowly to deeply pleated, mostly 8–20 mm wide; floral bracts 15–25 mm long; perianth tube (12–)15–18(–25) mm long:
36a Lower lateral tepals clawed and with prominent auriculate lobes at base of limb; inner bracts forked in upper ½–⅔ and membranous in lower midline. . . . . 66. *B. auriculata*
36b Lower lateral tepals not noticeably clawed and without auriculate lobes at base of limb; inner bracts divided to base. . . . . 63. *B. mucronata*

Sect. 1. **Teretifolieae** *G.J.Lewis* in Journal of South African Botany, Suppl. 3: 125 (1959), emended by Goldblatt & J.C.Manning: 15 (2007). Type: *Babiana brachystachys* (Baker) Ker Gawl.

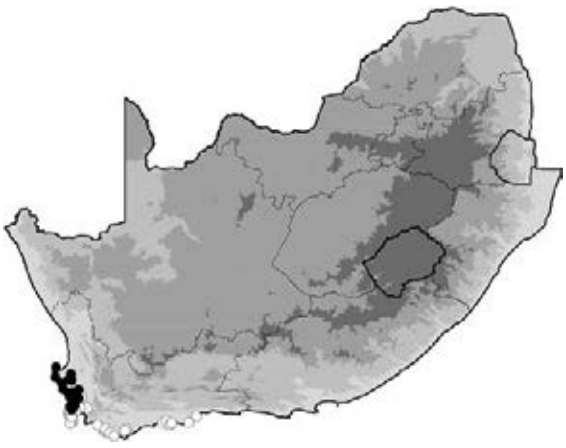
Stem often mostly or entirely underground, spike suberect to decumbent and borne shortly above, or sometimes shortly below ground level; bracts usually green, fairly large, lightly hairy, dry and light brown at tips, inner forked apically or to about middle. *Flowers* usually zygomorphic, rarely actinomorphic, usually shades of blue to mauve, occasionally white to pink, or yellow; perianth tube short or elongate; tepals not or scarcely clawed and dorsal not widely separated from others; anthers oblong-linear, without expanded connective. *Ovary* usually smooth, rarely sparsely hairy throughout or on ribs.

Species 44; occurring over the entire range of the genus, from southwestern Western Cape, South Africa, to northern Namibia, Zimbabwe and Zambia.

Ser. **Brevitubae** *Goldblatt & J.C.Manning*, new series. Type: *Babiana nana* (Andrews) Spreng.

Flowers zygomorphic or actinomorphic (*Babiana pygmaea, B. radiata*); perianth tube ⅓–⅔ as long as dorsal tepal, obliquely funnel-shaped or straight, slender, only slightly expanded at apex when flower radially symmetric.

1. **Babiana nana** *(Andrews) Spreng.*, Systema vegetabilium 1: 156 (1824); Lewis: 77 (1959); Goldblatt & Manning: 16 (2007). *Gladiolus nanus* Andrews: t. 137 (1801). Type: South Africa, without precise locality or collector, illustration in Andrews: t. 137 (1801).



Plants 60–150(–250) mm high. *Stem* reaching shortly above ground, often 1- or 2-branched. *Leaves* ovate to narrowly lanceolate to ± linear, 15–35 mm wide (subsp. *nana*) or 5–15 mm wide (subsp. *maculata*), densely soft-hairy, moderately to lightly pleated, suberect or held ± at right angles to sheaths. *Spike* suberect to weakly inclined, 2- to 6-flowered; bracts green, densely hairy, 16–30 mm long, inner slightly shorter than outer, forked apically. *Flowers* zygomorphic, blue or violet, rarely pale pink, with white markings on lower lateral tepals, usually strongly rosy violet-scented; perianth tube obliquely funnel-shaped, 12–17 mm long; tepals

subequal or upper 3 slightly larger, dorsal 25–30 mm long, lower 3 tepals united for a short distance, 22–25 mm long. *Stamens* unilateral; filaments arched, 10–14 mm long, sometimes shortly hairy at base; anthers 5.0–6.5 mm long. *Ovary* smooth (rarely shortly hairy on ribs); style usually dividing opposite or close to anther tips, branches 3(–5) mm long. *Flowering time*: mainly September, also in late August.

Distribution and ecology: South Africa, Western Cape, extending from the Piketberg and Hopefield in the north to Mossel Bay in the southeast; sandy flats and dunes along the coast, rarely a short distance inland.

Diagnosis: the moderate-sized blue, violet, or sometimes purple to pink flowers marked with white or pale yellow on the lower tepals of *Babiana nana* are a striking sight in spring along the coast of the Western Cape Province, and are rendered even more attractive at close range by their intense, rosy violet perfume. The species appears to have a combination of the most unspecialised characteristics of *Babiana,* including green floral bracts becoming dry at the tips, inner bracts forked only at the tips, and zygomorphic, bilabiate flowers. In addition, it is one of relatively few members of the sect. *Teretifolieae* that has an aerial (though short) stem that is often branched. The relatively short, funnel-shaped perianth tube and blue perianth are likewise ancestral features for the genus. A few other species of the section also have an aerial stem but appear specialised in their leaf morphology, notably *B. pilosa* and *B. rubella*.

Typical *B. nana* is the broad-leaved form common in deep sands along the coast north of Cape Town, while subsp. *maculata* includes the narrow-leaved southern populations that extend from the Cape Peninsula east of Cape Town to Mossel Bay. *Babiana confusa* (previously *B. nana* var. *confusa*), from between the Berg River and the sandy flats between Lambert's Bay and the Heerenlogement Cave, has an underground, unbranched stem, undulate to lightly twisted leaves, and larger flowers with a longer perianth tube, 23–30 mm long, and anthers 8–9 mm long (vs. a tube 12–17 mm long and anthers 5.0–6.5 mm long in *B. nana*).

Distribution of ***Babiana nana*** subsp. ***nana***, ●; subsp. ***maculata***, ○.

Babiana nana flowers relatively late in the season, mainly in September, while the superficially similar, but often fully acaulescent *B. ambigua*, which is often confused with *B. nana*, blooms in the same habitat in late July and August. *Babiana ambigua* has the inner floral bracts divided to the base, and also has narrowly sword-shaped or linear leaf blades like the southern *B. nana* subsp. *maculata*, and quite different from the relatively broad, oblong or lanceolate, soft-textured leaf blades of *B. nana* subsp. *nana*. Flowers of *B. nana* have the dorsal tepal suberect, whereas that of *B. ambigua* is arched over the stamens. A series of hybrids between *B. nana* and *B. ambigua* were discussed at length by Lewis (1959), who noted that the hybrids, intermediate between the parental taxa, tended to obscure the distinction between these two otherwise quite separate species.

Key to subspecies

1a Plants with broad, ovate to broadly lanceolate leaves 15–35 mm wide. . . . . 1a. subsp. *nana*
1b Plants with narrow, sword-shaped to linear leaves 5–12(–15) mm wide . . . . . .1b. subsp. *maculata*

1a. subsp. **nana**

Babiana sprengelii Baker: 182 (1882) [Baker: 165 (1877), invalid name]. Type: South Africa, [Western Cape], Saldanha Bay, *Zeyher s.n.* (B, ?holo.).

Babiana plicata var. *forsteri* Baker: 184 (1892). Type: South Africa, Western Cape, without precise locality, *Forster s.n.* (location of type not known).

[*Babiana fragrans* Eckl.: 31 (1827), invalid name without description.]

[*Babiana pygmaea* Spreng. ex Steud.: 176 (1840), invalid name only in synonymy.]

Plants with ovate to broadly lanceolate leaves (15–)20–35 mm wide, held obliquely or sometimes ± at right angles to sheaths, lightly pleated. *Flowers* shades of blue to violet; perianth tube mostly 14–17 mm long; dorsal tepal mostly 25–30 mm long.

Distribution and ecology: relatively common along the Atlantic Coast of Western Cape, South Africa, between Saldanha and Milnerton; on sandy coastal flats and dunes.

Diagnosis: subsp. *nana* is recognised by the broad leaves, held obliquely to the sheaths and often more-or-less horizontally. Flowering mainly in September, plants are often seen at the Hopefield and Darling wild flower shows where their form and wonderfully rich, violet-like scent can be admired comfortably. It is readily distinguished from the narrow-leaved subsp. *maculata* of the southern Cape coast by leaf shape.

1b. subsp. **maculata** *(Klatt) Goldblatt & J.C.Manning* in Strelitzia 18: 17 (2007). *Babiana maculata* Klatt: 349 (1882). *B. nana* var. *maculata* (Klatt) B.Nord.: 442 (1970). Type: South Africa, [Western Cape], Cape Flats, Doornhoogte, without date, *C.F. Ecklon & C.L. Zeyher Irid. 124* (B, K, S, syn.).

Babiana schlechteri Baker: 865 (1901). Type: South Africa, [Western Cape], littoral dunes at Muizenberg, *Schlechter 1277* (Z, holo.).

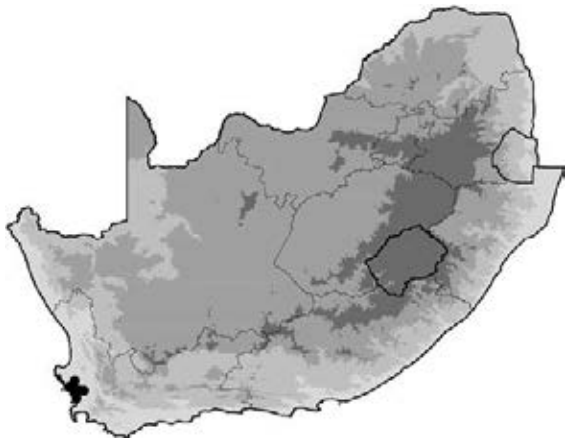
Babiana angusta N.E.Br.: 467 (1932b). Type: South Africa, [Western Cape], Riversdale Division, Aug. 1932, *J. Muir 4851* (K, holo.).

Babiana nana var *angustifolia* G.J.Lewis: 80 (1959). Type: South Africa, [Western Cape], Doornhoogte, *C.F.Ecklon & C.L.Zeyher Irid. 124* (B, holo.).

[*Babiana angustifolia* Eckl: 31 (1827), invalid name without description (based on *C.F.Ecklon & C.L.Zeyer Fud. 124*).]

Plants with lanceolate to sword-shaped leaves 5–15 mm wide, blades ascending to suberect, lightly pleated, usually overtopping flowers. *Flowers* shades of blue to violet; perianth tube 12–15 mm long, ± straight; dorsal tepal mostly 20–25 mm long.

Distribution and ecology: Western Cape, South Africa, extending from the Cape Peninsula to Mossel Bay; on sandy coastal flats and dunes.



Diagnosis: the narrow-leaved populations of *Babiana nana* are now recognised as a subspecies, both for the consistent difference in leaf width and orientation and the slightly smaller flowers, and for their largely separate range.

2. **Babiana pygmaea** *(Burm.f.) Baker* in Journal of the Linnean Society, Botany 16: 165 (1877), name misapplied to *B. nana*; Lewis: 32 (1959) [as *B. pygmaea* (Burm. f.) N.E.Br.]; Goldblatt & Manning: 17 (2007). *Ixia pygmaea* Burm.f.: 1 (1768) (as *I. pigmaea*). Type: South Africa, without precise locality or collector (G: Herb. Burman, holo.).

Babiana macrantha MacOwan: 394 (1890). Type: South Africa, [Western Cape], near Darling, Oct. 1877, *P. MacOwan sub Herb. Norm. Austr. Afr. 811* (SAM, holo.; B, K, P, iso.).

[*Gladiolus pygmaeus* (Burm.f.) Roem. & Schult.: 441 (1817), invalid name only in synonymy of *Ixia pygmaea* Burm.f.]

Plants up to ± 100 mm high. *Stem* erect, rarely branched, velvety hairy. *Leaves* lanceolate, 6–20 mm wide, pleated, softly hairy, spreading ± at right angles to sheaths. *Spike* erect, 2- to 5-flowered; bracts 30–36 mm long, velvety hairy, inner bract slightly shorter than outer, shortly forked or divided ± half its length. *Flowers* actinomorphic, yellow with a brown to dull purplish centre, unscented, tepals spreading when fully open;

Distribution of ***Babiana pygmaea***.

perianth tube cylindric, slightly expanded at throat, 15–25 mm long; tepals subequal, spreading when fully open, obovate, 23–33 × 14–20 mm. *Stamens* symmetrically arranged; filaments partly included, erect, enclosing style, 3–6 mm long; anthers 8–10 mm long. *Ovary* hairy above or on ribs; style dividing opposite middle of anthers, branches ± 3 mm long, rarely reaching anther tips. *Flowering time*: August to early September.

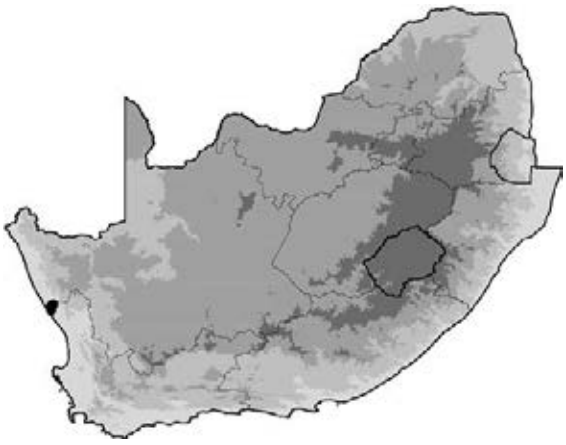
Distribution and ecology: restricted to the Atlantic coastal forelands of Western Cape, South Africa, between Hopefield and Darling; on sandy and gravel flats and lower slopes. Once relatively common, *Babiana pygmaea* has become increasingly rare in the last 20 years as its lowland habitat has become invaded by introduced *Acacia* species or reduced by expanding agriculture on the well-watered western coastal plain of Western Cape. Only a few small populations are now known near Hopefield, northeast of Malmesbury.

Diagnosis: the general aspect of *Babiana pygmaea* suggests an affinity with the *B. nana* group of species of sect. *Teretifolieae*, which have a similar vegetative morphology but conventional zygomorphic, more-or-less bilabiate blue to violet or purple flowers with the lower lateral tepals bearing nectar guides. One aspect of *B. pygmaea* that does not entirely accord with section *Teretifolieae* is the short, erect aerial stem and erect, rather than inflexed or decumbent spike. This feature may be associated with the actinomorphic flower, which is best displayed on an upright stalk. The apparently related *B. nana* also has a short, suberect aerial stem and only slightly deflexed spike. The bowl-shaped flowers of *B. pygmaea* are adapted for pollination by hopliine beetles. The pale yellow flowers with a dark centre and absence of scent are typical of this pollination strategy.

3. **Babiana rubella** *Goldblatt & J.C.Manning* in Strelitzia 18: 18 (2007). Type: South Africa, Northern Cape, Namaqualand, ± 8 km N of Kotzesrus, road to Hardevlei, 3 Sept. 2001, *P. Goldblatt & L.J. Porter 11825* (NBG, holo.; K, MO, PRE, US, iso.).

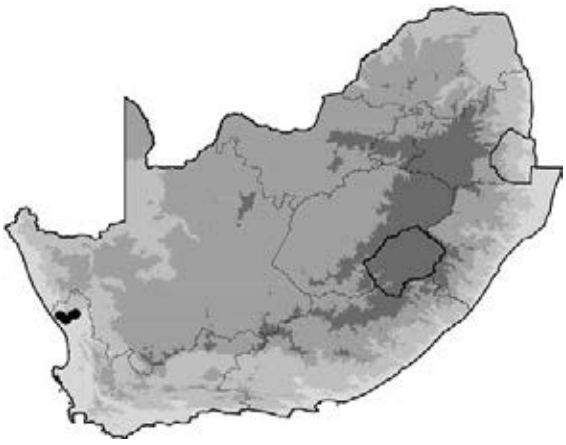
Plants 100–120 mm high. *Stem* extending above ground level and inclined, simple or with one branch, covered by leaf sheaths, densely long-hairy where exposed; sheathed below by a thick collar of fibres. *Leaves* broadly lanceolate to ovate, blade held obliquely to ± at right angles to short, broad, imbricate leaf sheaths, lightly plicate, veins and margins densely long-hairy, hairs up to 4 mm long, sheaths hairy or almost hairless. *Spike* suberect to inclined, (2)3- to 6-flowered; bracts green, densely hairy, apices dry and rust-brown, 15–24 mm long, inner ± as long as outer, forked apically or to ± middle, or transparent in upper mid-line. *Flowers* zygomorphic, bilabiate, pale to deep pinkish purple, lower lateral tepals yellow with pink tips, lightly rose-scented; perianth tube 12–15 mm long; dorsal tepal 28–30 × ± 8–9 mm, lower tepals joined to upper laterals for ± 5 mm and to one another for ± 3 mm, upper laterals ± 24 mm long, 23–25 mm long, lower margins crisped. *Stamens* unilateral; filaments arched, ± 14 mm long; anthers ± 4.5 mm long, pale blue; pollen white. *Ovary* smooth, ± 3 mm long; style arching over stamens. *Flowering time*: August to early September.

Distribution and ecology: known from a single locality on the southern coastal plain of Namaqualand north of Kotzesrus in Northern Cape, South Africa; on flats in deep sand.



Diagnosis: *Babiana rubella* is distinctive both in the densely long-hairy stem and leaves, and in the pink to light purple perianth with pale yellow lower lateral tepals. The flowers are of moderate size with a perianth tube 12–15 mm long, a dorsal tepal 28–30 mm long, and have a pleasant sweet, rose-like scent and the leaves have short, oblong-ovate blades held nearly horizontally to the sheaths. Superficially *B. rubella* resembles a second Namaqualand endemic, *B. horizontalis*, in the unusual pink flower colour, but that species has almost hairless leaves and bracts, and the stem reaches only shortly above ground. *Babiana pilosa* also has pink flowers and is densely hairy, though with retrorse hairs. Both *B. nana*, a species of coastal sandveld in Western Cape, and *B. rubella* may have a branched aerial stem, suberect to weakly inclined spikes, and relatively short, broad leaves, often held nearly at right angles to the sheaths but the flowers of *B. nana* are usually blue to violet with white markings.

4. **Babiana pilosa** *G.J.Lewis* in Journal of South African Botany, Suppl. 3: 87 (1959); Goldblatt & Manning: 19 (2007). Type: South Africa, [Western Cape], 15 miles west of Nuwerus, cultivated at Kirstenbosch Botanical Garden, 5 Aug. 1956, *H. Hall s.n. as Nat. Bot. Gard. 414/56* (NBG, holo.).



Plants 100–150 mm high. *Stem* erect, reaching well above ground, usually unbranched, with retrorse hairs above, with thick collar of fibres enclosing base. *Leaves* narrowly lanceolate, on long pseudopetioles, scarcely pleated, lightly retrorse-hairy. *Spike* decumbent, secund, 2- to 5-flowered; bracts green with dry rust-coloured tips, with short retrorse hairs, 20–30 mm long, inner slightly shorter than outer, forked apically and acuminate. *Flowers* zygomorphic, magenta-pink, lower lateral tepals with pale yellow markings; perianth tube 15–18 mm long; tepals unequal, dorsal 30–34 mm long, lower 3 tepals joined to upper laterals for ± 4 mm and forming a prominent lip, 20–28 mm long. *Stamens* unilateral; filaments ± 15 mm long; anthers ± 6 mm long. *Ovary* smooth, rarely sparsely hairy on ribs; style dividing opposite middle of anthers, branches ± 5 mm long. *Flowering time*: late July and August.

Distribution and ecology: restricted to southern Namaqualand south and west of Nuwerus in Western Cape, South Africa; on stony hills, often on quartzite patches.

Diagnosis: *Babiana pilosa* is readily recognised by the narrow leaves with a long pseudopetiole and the light magenta-pink perianth, an unusual colour in the genus. Both the stem, leaves and floral bracts bear slightly retrorse hairs, also rare in the genus. The pink flower colour is known in a few other species, notably the densely hairy *B. rubella*, also from Namaqualand, which has short, relatively broad leaves.

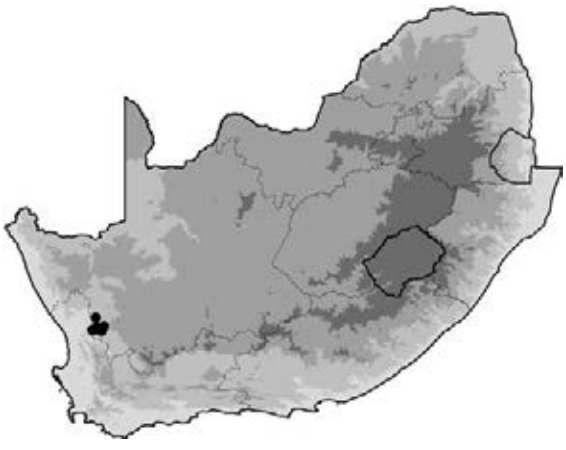
Distribution of ***Babiana rubella***.

Distribution of ***Babiana pilosa***.

5. **Babiana pauciflora** *G.J.Lewis* in Journal of South African Botany, Suppl. 3: 99 (1959); Goldblatt & Manning: 29 (2007). Type: South Africa, [Northern Cape], farm Menzieskraal, between Nieuwoudtville and Botterkloof, June 1953, *G.J. Lewis 2750* (SAM, holo.).

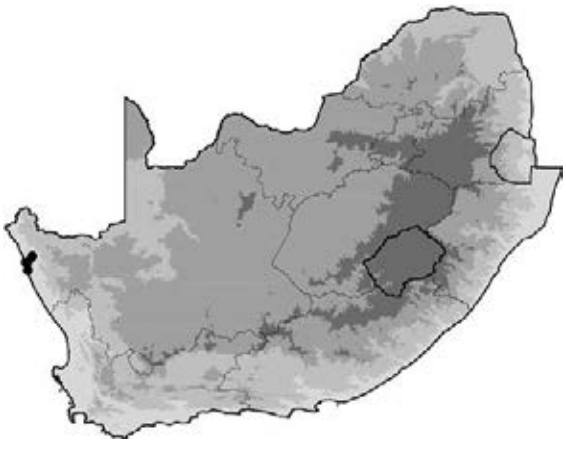
Plants up to 100 mm high. *Stem* short, unbranched, inclined above ground level, enclosed basally by collar of fibres. *Leaves* oblong-lanceolate, lightly pleated at base, hairy on veins. *Spike* compact, suberect, 2- to 4-flowered; bracts sparsely hairy above, green, 35–55 mm long, inner ± as long as outer, forked apically, strongly 2-keeled. *Flowers* zygomorphic, violet to deep purple, lower lateral tepals with bright yellow blotches outlined in lilac, sweetly rose-violet-scented, closing at night; perianth tube cylindric below, funnel-shaped above, 35–45 mm long; tepals unequal, dorsal 30–50 mm long, lower tepals joined basally for a short distance, 25–40 mm long. *Stamens* unilateral; filaments arched, 15 mm long; anthers 8 mm long. *Ovary* smooth; style dividing opposite anther apices, branches ± 4 mm long, tips expanded. *Flowering time*: June.

Distribution and ecology: poorly documented but evidently locally common, restricted to the Bokkeveld Mtns and Plateau of Northern Cape, South Africa; on stony clay flats.



Diagnosis: flowering in June, soon after the first winter rains have fallen, *Babiana pauciflora* is recognised by the violet flowers with relatively long perianth tube, 35–45 mm long, smooth ovary and large green bracts, 35–55 mm long, with the inner forked apically. It lacks any obvious specialisations that would help determine its possible relationships. The perianth tube, about as long as or slightly longer than the dorsal tepal, suggesting a possible relationship with the yellow-flowered *B. vanzijliae* of the section. Also from the Bokkeveld Mtns and Plateau, *B. vanzijliae* blooms later, in August and September, whereas *B. pauciflora* blooms in June.

6. **Babiana lanata** *Goldblatt & J.C.Manning* in Strelitzia 18: 20 (2007). Type: South Africa, Northern Cape, Namaqualand coast near Kleinzee, 2 Aug. 2001, *G.D. Duncan 447* (NBG, holo.).



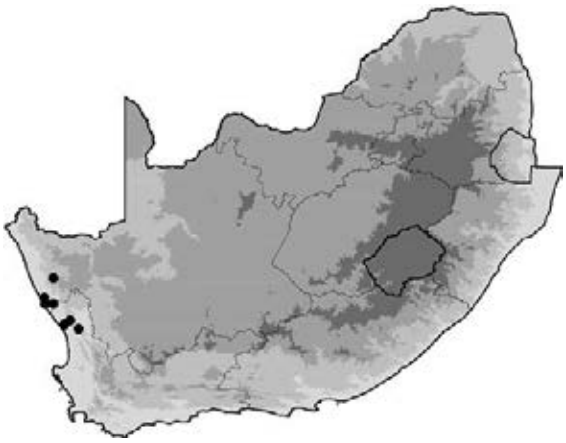
Plants 50–90 mm high, with deep-seated corm up to 20 mm diam. *Stem* erect, simple or 1-branched, reaching shortly above ground, enclosed at base by well-developed fibrous collar. *Leaves* 3 to 6, broadly lanceolate to ovate, 2–3 mm long, blade held very obliquely to overlapping leaf sheaths, lightly plicate, apex truncate, veins drawn into short teeth, with long silky hairs up to 3 mm long on veins and margins. *Spike* erect, long-hairy, 3- to 5-flowered; bracts green, silky-hairy, 12–16 mm long, inner ± as long as outer, forked apically, membranous in midline. *Flowers* zygomorphic, upper 3 tepals yellow or maroon with yellow margins, lower 3 tepals pale yellow with pale median maroon streak, presence of scent unknown; perianth tube narrowly funnel-shaped, ± 24 mm long; tepals spreading, lanceolate, dorsal ± 17 × 5 mm, lower tepals 15–17 mm long, channelled below. *Stamens* unilateral; filaments ± 14 mm long; anthers ± 5 mm, yellow; pollen yellow. *Ovary* smooth; style dividing opposite middle of anthers, branches ± 3 mm long. *Capsules* globose, ± 6 mm long. *Seeds* unknown. *Flowering time*: late July to early September.

Distribution and ecology: known from just three collections from the Namaqualand coastal plain at Kleinzee and near Port Nolloth in Northern Cape, South Africa; occurring on stony red sand.

Diagnosis: with relatively small flowers, although with a relatively long perianth tube, ± 24 mm long, *Babiana lanata* has a dorsal tepal ± 17 mm long and the lower tepals only slightly smaller. The upper three tepals are pale yellow or maroon with yellow edges, an unusual colour for the genus, while the lower tepals are pale creamy yellow with a pale maroon central streak. The most striking feature of the species is the leaf, the blade

Distribution of ***Babiana pauciflora***.

Distribution of ***Babiana lanata***.



abruptly truncate, widest about the middle and the apex serrated, with the surface covered with long silky hairs as are the spike axis and bracts. The truncate leaf blades recall those of *B. flabellifolia* and its immediate allies but *B. lanata* is probably not immediately related to this group of species, which always has fairly large, blue to mauve or purple flowers, less conspicuous vestiture, and leaves more obviously truncate, usually widest at the apex. The long silky pubescence and leaf blades set obliquely to the sheaths recall *B. rubella*, also from coastal Namaqualand, but that species is readily distinguished by its magenta-pink perianth, hooded dorsal tepal and acute leaf tips.

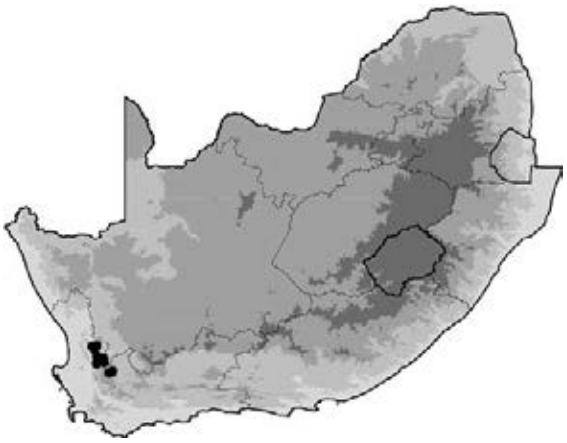
7. **Babiana grandiflora** *Goldblatt & J.C.Manning* in Strelitzia 18: 21 (2007). Type: South Africa, Northern Cape, 3.5 km east of Kotzesrus on road to Garies, 3 Sept. 2001, *P. Goldblatt & L.J. Porter 11823* (NBG, holo.; K, MO, PRE, iso.).

Plants 80–140 mm high, including leaves. *Stem* reaching shortly above ground or subterranean, densely hairy, occasionally with 1 or 2 branches. *Leaves* lanceolate to sword-shaped, lightly twisted, shortly velvety, 6–11(–15) mm wide. *Spike* decumbent, 2- to 5-flowered; bracts green with dry brown tips, velvety, 24–35 mm long, inner often slightly longer than outer, forked apically. *Flowers* zygomorphic, pale to deep blue with white splashes on lower tepals, strongly spicy-acrid scented with undertones of violet; perianth tube funnel-shaped, 18–20 mm long, lower part ± 12 mm long, thick-walled and blocked in lower half; tepals lanceolate, dorsal 45–55 × 13 mm, margins undulate, upper laterals joined to lower 3 tepals for ± 8 mm, lower tepals joined basally for ± 4 mm, ± 35 mm long. *Stamens* unilateral; filaments arched, ± 10 mm long, hairy at base, shortly exserted from upper part of tube; anthers 8–9 mm long, pale bluish; pollen off-white. *Ovary* smooth; style arching over stamens. *Flowering time*: late July to early September.

Distribution and ecology: restricted to the Namaqualand coastal plain between Soutfontein, south of Wallekraal in Northern Cape, to Koekenaap near the mouth of the Olifants River in Western Cape, South Africa; on sandy flats, usually in deep sand.

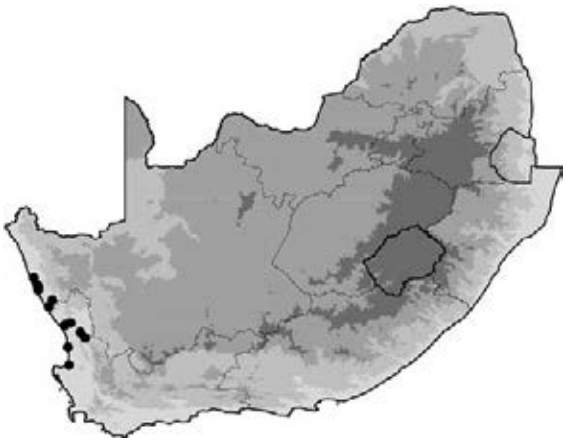
Diagnosis: currently included in sect. *Teretifolieae*, which comprises species with apically forked inner bracts, often a more-or-less underground flowering stem and a smooth ovary, *Babiana grandiflora* is distinctive mainly in its large flower, the perianth tube 18–20 mm long and dorsal tepal 45–55 mm long. The flowers have a strong odour of violets mixed with a spicy acrid odour, a common scent in the genus. Despite the large flowers, the stamens are disproportionately short, with the filaments ± 10 mm long, so that the anthers are held within the floral cup and largely hidden from view inside the funnel-shaped perianth. It may be most closely allied to the Western Cape coastal species, *B. nana*, but is easily distinguished from that species by the narrow, erect leaves with short, velvety pubescence and the mostly unbranched spikes borne at ground level and

Distribution of ***Babiana grandiflora***.



bearing 2 to 5 flowers. *Babiana grandiflora* has in the past been confused with the widespread *B. ambigua* of deep sands in coastal and inland sites in Western Cape, and although *B. grandiflora* resembles that species superficially, *B. ambigua* has inner bracts divided to the base, somewhat smaller flowers with the dorsal tepal 28–40 mm long and longer filaments 13–16 mm.

8. **Babiana cedarbergensis** *G.J.Lewis* in Journal of South African Botany, Suppl. 3: 82 (1959); Goldblatt & Manning: 23 (2007). Type: South Africa, [Western Cape], Cederberg, flats near Bushman's Cave, 23 Sept. 1930, *J.A. Lamb s.n. as Nat. Bot. Gard. 1613/30* (BOL, holo.; K, iso.).



Plants 40–60 mm high. *Stem* mostly underground, with collar of thick fibres around base. *Leaves* sword-shaped, rigid, almost pungent, pleated, 40–60 mm long, velvety hairy. *Spike* decumbent, 2- to 5-flowered; bracts green, outer often with a minute brown mucro at apex, 18–25 mm long, inner slightly shorter, forked in upper ⅓, margins membranous. *Flowers* zygomorphic, pale to deep violet with white markings outlined in dark blue on lower lateral tepals, lightly musk-scented; perianth tube obliquely funnel-shaped, 16–18 mm long; tepals unequal, dorsal largest, 28–35 mm long, lower tepals joined to upper laterals for ± 3 mm forming prominent lip, lower 3 tepals 21–27 mm long. *Stamens* unilateral; filaments arched, ± 13 mm long; anthers 7–9 mm long. *Ovary* hairy above base; style dividing at or beyond anther tips, branches ± 4 mm long. *Flowering time*: mainly in September.

Distribution and ecology: restricted to the Cederberg Mtns of Western Cape, South Africa; on rocky sandstone slopes and flats above 900 m elevation.

Diagnosis: superficially resembling the widespread and well-known *Babiana ambigua* in the narrow leaves and acaulescent habit, *B. cedarbergensis* has inner bracts divided only in the upper third, whereas *B. ambigua* has the inner bracts divided to the base. Other differences between these two species are the thick fibrous neck

Distribution of ***Babiana cedarbergensis***.

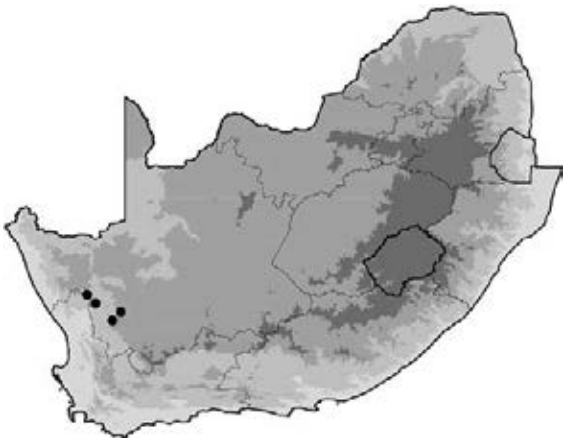
Distribution of ***Babiana confusa***.

around the base of the stem, stiff, straight leaves, and hairy ovary of *B. cedarbergensis*, whereas *B. ambigua* has a poorly developed neck of fibres around the base, firm but not rigid leaves, and a hairless ovary. The resemblance to *B. ambigua* is presumably convergent. *Babiana cedarbergensis* is restricted to higher elevations in the Cederberg and is endemic to the Northwest Centre of the Cape Floristic Region. The hairy ovary of *B. cedarbergensis* is unusual in section *Teretifolieae*.

9. **Babiana confusa** *(G.J.Lewis) Goldblatt & J.C.Manning* in Strelitzia 18: 23 (2007). *Babiana nana* var. *confusa* G.J.Lewis: 81 (1959). Type: South Africa, [Western Cape], near Berg River Station, July 1946, *G.J. Lewis 4798* (SAM, holo.).

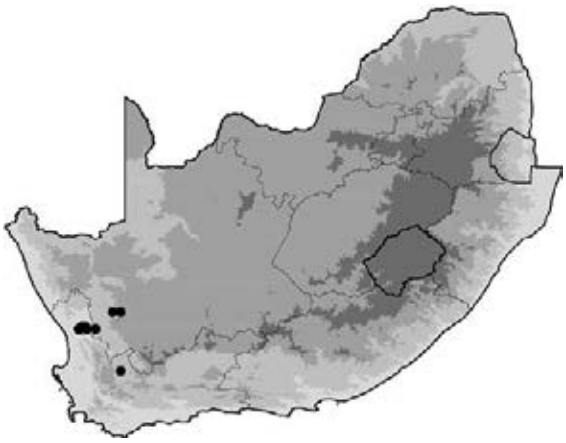
Plants 40–80 mm high. *Corm* globose, up to 20 mm diam.; tunics of fairly fine fibres. *Stem* usually mostly underground but sometimes reaching up to 10 mm above ground, unbranched, without well-developed collar of fibres around base, bearing cormlets in underground axils. *Leaves* ovate to broadly lanceolate, 8–14 mm wide, sparsely hairy to smooth except on margins, often somewhat glaucous, lightly pleated to almost plane, margins usually slightly raised. *Spike* suberect to inclined, 2- to 6-flowered; bracts green or becoming dry in upper half, sparsely hairy, 20–35 mm long, inner slightly longer than outer, forked apically. *Flowers* zygomorphic, white to pale blue with pale markings edged in blue on lower lateral tepals, scent unknown; perianth tube obliquely funnel-shaped, 23–30 mm long; tepals subequal or upper 3 slightly larger, dorsal 35–40 mm long, lower tepals joined to upper laterals for 4–5 mm and to one another for ± 2.5 mm, forming prominent lip, 25–28 mm long. *Stamens* unilateral; filaments arched, 12–15 mm long, sometimes shortly hairy at base; anthers 8–9 mm long. *Ovary* smooth; style usually dividing opposite or close to anther tips, branches ± 3 mm long. *Flowering time*: mid-June to August.

Distribution and ecology: South Africa, Western Cape, from the Atlantic Coast and near interior, extending from Koekenaap, Lambert's Bay and Heerenlogement Mtn to near Hopefield; on sandy flats and mountain plateaus.



Diagnosis: *Babiana confusa* is distinguished from *B. nana* by the larger flower with a longer perianth tube 23–30 mm long, subequal tepals, longer anthers, 8–9 mm long, and sparsely hairy to smooth, often glaucous leaves.

10. **Babiana crispa** *G.J.Lewis* in Journal of South African Botany, Suppl. 3: 84 (1959); Goldblatt & Manning: 24 (2007). Type: South Africa, [Western Cape], Clanwilliam to Doornbosch, Farm Langekraal, July 1933, *P. Ross Frames s.n.* (BOL 20837, holo.).



Plants 60–130 mm high, including leaves. *Stem* underground, sheathed a thick collar of fibres, unbranched. *Leaves* sword-shaped to linear, often slightly twisted, up to 13 × 3–6 mm, scarcely pleated, hairy, margins crisped and undulate. *Spike* short, suberect, 2- to 4-flowered; bracts with brown attenuate tips, outer hairy in upper half, 28–30 mm long, inner ± as long, forked apically. *Flowers* zygomorphic, pale blue, lower lateral tepals with white median markings, acrid-scented; perianth tube funnel-shaped, 14–20 mm long; tepals unequal, dorsal 25–30 mm long, lower tepals 16–18 mm long, margins crisped. *Stamens* unilateral; filaments arched, 15 mm long; anthers 6–7 mm long. *Ovary* smooth; style dividing opposite anther apices, branches ± 4 mm long. *Flowering time*: May to July.

Distribution and ecology: extending from the Langberg west of Loeriesfontein in Northern Cape to Biedouw Valley in Western Cape, South Africa; in hard clay and shale ground.

Diagnosis: *Babiana crispa* has relatively large flowers and large bracts, with the inner forked only at the tips, and is evidently allied to a group of early flowering species with short-tubed, scented flowers that extend across the dry northern interior of Western and Northern Cape

Distribution of ***Babiana crispa***.

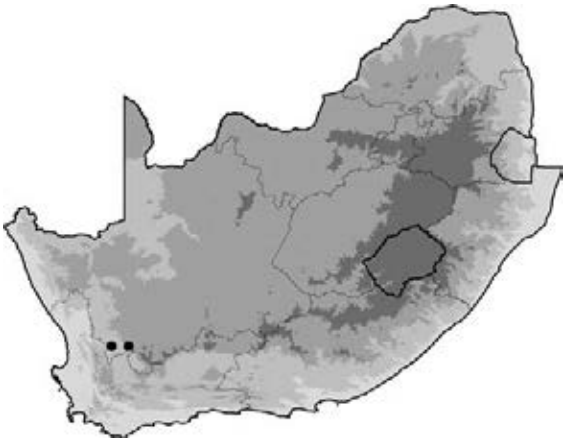
Distribution of ***Babiana minuta***.

from the western Karoo to northern Namaqualand. Among these species, all of which have few-flowered spikes borne at ground level, *B. crispa* can be recognised by the narrow leaves, 3–6 mm wide on mature flowering individuals, the blades undulate or lightly crisped, hardly or not at all pleated, and lightly twisted in the upper half.

11. **Babiana minuta** *G.J.Lewis* in Journal of South African Botany, Suppl. 3: 74 (1959). Type: South Africa, [Western Cape], near Vanrhynsdorp, July 1932, *T.M. Salter 2508* (BOL, holo., K, iso.).

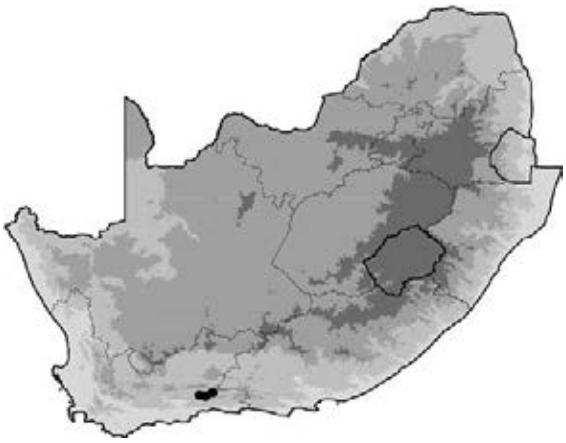
Plants mostly 40–60 mm high, often growing in tufts. *Stem* barely reaching above ground, decumbent above ground. *Leaves* often inclined toward ground, narrowly lanceolate to linear, mostly 3–6 mm wide, pleated at base, hairy, lightly twisted above; juvenile plants with linear, falcate leaves 1–2 mm wide. *Spike* short, horizontal, 1- to 3-flowered; bracts green with dry brown attenuate tips, 20–32 mm long, inner slightly shorter than outer, forked at apex. *Flowers* zygomorphic, yellow or mauve with reddish mauve to violet in centre of tepals, with yellow marks on lower lateral tepals, evidently unscented; perianth tube funnel-shaped, 20–22 mm long; tepals subequal, dorsal tepal 25–40 mm long, lower tepals joined for 2–4 mm, 20–25 mm long. *Stamens* unilateral; filaments arched, 15–17 mm long; anthers 5–6 mm long. *Ovary* smooth; style dividing opposite anther tips, branches ± 4 mm long, abruptly expanded apically. *Flowering time*: mainly June and July, rarely later.

Distribution and ecology: South Africa in Northern and Western Cape, extending from southern Namaqualand and the western Karoo to Karoopoort; in rock outcrops, either in shale, sandstone or marble.



Diagnosis: winter-flowering *Babiana minuta* remains poorly known and inadequately documented but is more widespread than originally believed and is even locally quite common. The reddish mauve to violet flowers are typical of the short-tubed species of sect. *Teretifolieae* and surprisingly large for the small leaves: a single open flower may be larger than the rest of the above ground parts of an individual. Plants grow in small tufts with adult, flowering individuals surrounded by the narrow juvenile leaves of young plants derived from cormlets produced from the base of mature corms.

12. **Babiana tanquana** *J.C.Manning & Goldblatt* in Strelitzia 18: 25 (2007). Type: South Africa, Western Cape, Tanqua Karoo, Farm De Syfer, among dolerite boulders, 3 July 2002, *J.C. Manning 2748* (NBG, holo.; K, MO, iso.).



Plants 60–120 mm high, including leaves. *Stem* largely subterranean or reaching up to 100 mm above ground, smooth, simple or with 1 or 2 branches produced close to ground. *Leaves* ascending, blades slightly oblique to sheaths and stem, lanceolate to narrowly ovate, 7–13 mm wide, shortly hairy on lamina, long-hairy on margins, rough to touch, hardly pleated but with 3 or 4 main veins. *Spike* decumbent or suberect, 3- to 6-flowered; bracts lightly striate, green with slender brown apices, slightly striate, lightly hairy above, outer 22–25 mm long, inner 2–5 mm longer than outer, forked apically. *Flowers* zygomorphic, upper tepals dark violet with pale lilac edges, lower laterals pale yellow in upper half, with acrid, spicy odour; perianth tube ± 14 mm long, slender below, curving outward and wider in upper 6 mm; tepals unequal, dorsal 25–30 mm long, arching over stamens, upper laterals joined to lower 3 for ± 4 mm, lower tepals 18–20 mm long. *Stamens* unilateral; filaments arched, ± 12 mm long; anthers ± 6 mm long. *Ovary* smooth; style arching over stamens, dividing opposite upper half of anthers, branches slender, ± 4 mm long. *Flowering time*: June and July.

Distribution and ecology: restricted to the Tanqua Karoo in interior Western Cape, South Africa; only in dolerite outcrops in clay soil.

Diagnosis: usually acaulescent *Babiana tanquana* is distinguished by the almost plane leaves with light pubescence on the blade surface and long-hairy on the margins, a spike borne at or shortly above ground level, and flowers with dark purple upper tepals, pale lilac on the

Distribution of ***Babiana tanquana***.

Distribution of ***Babiana karooica***.

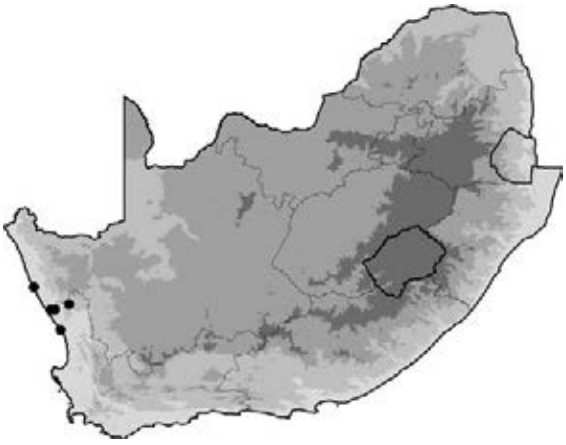
edges, and the pale yellow lower lateral tepals. The inner floral bracts are forked only near the apices and the ovary is hairless. *Babiana tanquana* most closely resembles the western Karoo *B. salteri* in general aspect, particularly the broad leaves held obliquely to the sheaths and short spike, but that species has inner bracts divided to the base and a densely hairy ovary. The attractive flowers have a distinctive acrid-musky scent characteristic of several other species of the genus. *Babiana tanquana* keys closest to *B. minuta*, the tepals of which also have pale margins, but this species has narrow leaves and the inner bracts shorter than the outer, whereas in *B. tanquana* the inner bracts exceed the outer by 2–5 mm. The species remains poorly documented.

13. **Babiana karooica** *Goldblatt & J.C.Manning* in Strelitzia 18: 26 (2007). Type: South Africa, Western Cape, ± 10 km W of De Rust, next to R62, locally abundant on Enon Conglomerate, 21 June 2006, *J.H.J. Vlok 2867* (NBG, holo.; K, MO, iso.),

Plants 120–200 mm high, including leaves. *Stem* reaching shortly above ground level, unbranched or rarely with a single branch, smooth. *Leaves* lanceolate to narrowly sword-shaped, 70–150 × 4–12 mm, shallowly pleated, shortly hairy but long-hairy at base and upper part of sheath; seedling leaves long-hairy. *Spike* decumbent, compact, 2- to 6-flowered; bracts (20–)25–30(–35) mm long, green with rust-coloured tips, long-hairy near margins otherwise sparely short-hairy or smooth, inner slightly shorter than outer, forked at apex. *Flowers* zygomorphic, blue to violet, lower lateral tepals each with a white median mark edged below in dark blue, intensely fragrant; perianth tube 20–35 mm long, curved and slightly flared at apex, tightly enclosing style below, puberulous in upper part, hairs extending onto bases of filaments; tepals subequal, dorsal 24–28 × ± 7 mm, suberect, lower 3 united basally for up to 4 mm, 20–22 mm long, extended horizontally. *Stamens* unilateral; filaments ± straight, 10–11 mm long, puberulous at base; anthers 6–7 mm long, lilac. *Ovary* smooth, those of lowermost flowers sometimes shortly stipitate; style dividing at apex or shortly beyond anthers tips, branches spreading, 3–6 mm long. *Capsules* subglobose, ± 8 mm long. *Flowering time*: late May to early July.

Distribution and ecology: a narrow endemic of southern Western Cape, South Africa, restricted to the central Little Karoo; on rocky slopes of Enon Conglomerate.

Diagnosis: an early flowering species, *Babiana karooica* is recognised in sect. *Teretifolieae* by the acaulescent habit, blue to violet flowers with perianth tube 20–35 mm long and puberulous in the throat, and violet anthers. The style divides beyond the anther tips. The species is easily confused with larger-flowered *B. sambucina*, which blooms later, mostly in August and September, but that species has a straight perianth tube 35–65 mm long and at least 1.5× as long as the dorsal tepal in length, and the tepals are broader, mostly 30–35 × 5–12 mm. In addition, the perianth tube is smooth inside, the anthers are cream-coloured to pale yellow, and the style typically divides opposite the base to middle of the anthers. *Babiana karooica* also lacks the distinctive leafy outer bract of the lowermost flower of the spike characteristic of *B. sambucina*.



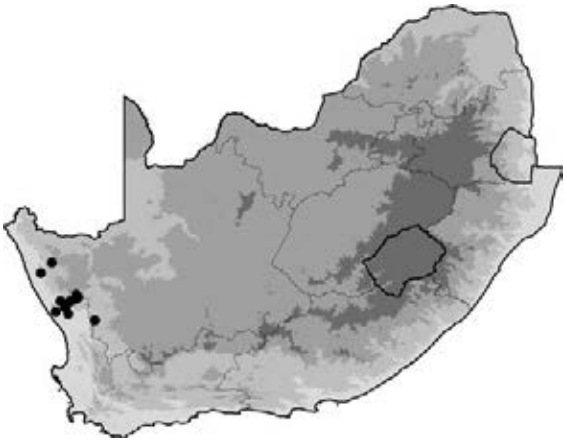
Babiana karooica may also be confused with *B. bainesii* but this species always has the spike underground, the flowers thus arising below ground level. A widespread species of the southern African summer-rainfall zone, *B. bainesii* typically flowers in late summer, mainly February to April, but later, in July and August in colder parts of the high mountains of the Great Karoo. *Babiana karooica* has broader and shorter leaves than *B. bainesii*, usually sparsely hairy on the veins and margins, slightly smaller flowers, and green floral bracts tipped rust-brown.

14. **Babiana virescens** *Goldblatt & J.C.Manning* in Goldblatt *et al.* Bothalia 38: 51 (2008). Type: Western Cape, Farm Kamagap, 1 km along Bitterfontein–Pofadder road, hillside on S side, 26 May 2007, *Manning 3093* (NBG, holo.; MO, iso.).

Plants 70–200 mm high. *Corm* with outer tunics of fine-textured, reticulate fibres. *Stem* reaching to ground level or up to 100 mm above ground, erect but strongly inflexed above uppermost leaf sheath, simple or with 1 short branch, glabrous below, becoming velvety near spike; sheathed by smooth cataphylls and leaf sheaths. *Leaves* 3 or 4, oblong to lanceolate, slightly twisted distally, blade suberect at ± 30° degrees, 40–100(–150) × (5–)10–18 mm, thinly velvety, lightly pleated, midrib and margins slightly thickened, margins hyaline, minutely hairy; seedling leaves linear-lanceolate and coiled, hairy. *Spike* 3- to 7-flowered, ± horizontal, secund; bracts green with brown tips, outer ovate, 20–30 mm long, margins narrowly hyaline, thinly and minutely velvety, especially distally, truncate or emarginate-apiculate, inner ± as long as outer, forked for 5–8 mm, with broad hyaline margins in lower half. *Flowers* zygomorphic, pale grey-green or flushed with greyish lilac, lower lateral tepals with yellowish green median blotches and purple streaks, with sweet, spicy scent; perianth tube obliquely funnel-shaped, hollow to base, 18–23 mm long; tepals unequal, narrowly lanceolate, margins crisped, dorsal suberect, recurving distally, 32–38 × 6.5–8.0 mm, upper laterals narrower, joined to lower tepals for 5–7 mm forming lip, lower tepals 25–30 × 4–5 mm. *Stamens* unilateral; filaments suberect, 12–16 mm long; anthers 7–8 mm long, whitish. *Ovary* smooth; style dividing opposite middle ⅓ of anthers, branches 4–6 mm long. *Capsules* subglobose, 8–9 mm long. *Flowering time*: late May to early June, fruiting in August to September.

Distribution and ecology: restricted to southern Namaqualand in Northern and Western Cape, South Africa, between Nuwerus and Bitterfontein; on gently sloping granite hills and valley bottoms in gravelly ground in open succulent karroid shrubland.

Discussion: *Babiana virescens* accords with sect. *Teretifolieae* in its apically forked inner floral bracts but is unusual in its well-developed aerial stem. The bilabiate flowers stand out in having particularly narrow, ± linear tepals, the dorsal 32–38 × 6.5–8.0 mm and the remaining tepals 4–5 mm wide. Although quite large, the greenish flowers are not conspicuous but have a characteristic spicy-acrid, chemical odour that is common in the genus. *Babiana virescens* may be most closely allied to *B. torta* and *B. namaquensis* on account of the slightly coiled leaves and early flowering but it is easily distinguished from them by its greenish flowers with particularly narrow tepals, and by the subglabrous or very short-hairy leaves and the aerial stem up to 100 mm high. The slightly thickened leaf margins are most evident in herbarium specimens, drying whitish or pale. Both blue-flowered *B. torta* and pale mauve–white-flowered *B. namaquensis* have distinctly hairy leaves without conspicuous margins and typically occur in rock outcrops, granite in the former but often limestone in the latter, with their corms wedged in crevices. *Babiana torta* typically occurs in granite rock outcrops, whereas *B. virescens* always occurs in open ground and relatively deep, loamy gravel. Both species have been collected within a few kilometres of one another east of Bitterfontein.



Distribution of ***Babiana virescens***.

15. **Babiana torta** *G.J.Lewis* in Journal of South African Botany, Suppl. 3: 86 (1959); Goldblatt & Manning: 27 (2007). Type: South Africa, [Northern Cape], ± 10 miles E of Kliprand to Brakfontein, 1 May 1958, *H. Hall s.n. as Natl. Bot. Gard. 385/54* (NBG, holo.).

Plants 40–80(–120) mm high. *Stem* largely underground or extending up to 10 mm above ground, unbranched. *Leaves* lanceolate, 7–12(–18) mm wide, soft-textured, undulate, sometimes lightly crisped, twisted above middle, margins and usually only one major vein prominently thickened, lying close to upper margin, softly hairy to ± smooth, juvenile leaves ± linear and loosely coiled, prominently hairy. *Spike* compact, at ground level, 1- to 3(–5)-flowered; bracts green with tips drying light brown, lightly hairy, 17–20 mm long, inner ± as long or slightly longer than outer, forked in upper ⅓. *Flowers* zygomorphic, pale slate-blue to mauve, or white, lower lateral tepals with pale yellow to white median blotch usually edged in dark blue, sweetly scented; perianth tube 20–22 mm long; tepals unequal, dorsal 30–34 mm long, lower tepals 22–25 mm long. *Stamens* unilateral; filaments arched, ± 15 mm long; anthers ± 6 mm long. *Ovary* smooth; style dividing opposite anther apices, branches ± 2 mm long. *Flowering time*: mainly May to mid-June.

Distribution and ecology: occurring across Namaqualand and extending from Springbok to Kliprand in Northern Cape, South Africa, to Nuwerus in Western Cape; mainly in crevices in granite outcrops or granitic gravel.

Diagnosis: *Babiana torta* flowers early in the season, mainly in late autumn, when little collecting is normally done. Plants are most often seen growing in cracks in granite outcrops with the narrow, coiled juvenile leaves mixed with the broader, less hairy leaves of mature individuals. Although plants usually have softly hairy leaves and bracts, the leaves may occasionally be almost smooth and the bracts sparsely hairy. Flowers are usually pale to mid-blue with white to pale yellow

Distribution of ***Babiana torta***.

Distribution of ***Babiana namaquensis***.

on the lower tepals, but may occasionally be white or even greenish mauve.

Babiana torta appears to be related to a group of early winter-flowering, dwarf species of Namaqualand and the adjacent western Karoo, including *B. crispa, B. minuta, B. namaquensis*, and *B. tanquana*. These all have few-flowered spikes borne at ground level and variously undulate, twisted or crisped leaves. Among this group, *B. torta* may be most closely related to *B. minuta*, also a species of rock outcrops and shallow soils that occurs in the western Karoo and adjacent southern Namaqualand. *Babiana torta* may also be confused with *B. namaquensis* and their differences are discussed in detail under the latter species.

16. **Babiana namaquensis** *Baker*, Handbook of the Irideae 181 (1892); Lewis: 76 (1959); Goldblatt & Manning: 28 (2007). Type: South Africa, [Northern Cape], sandy plains near Port Nolloth, Aug. 1883, *H. Bolus 6579* (K, holo.; BOL, iso.).

Babiana buchubergensis Dinter: 254 (1931). Type: Namibia, Buchuberg, on micaceous schist in a water ravine, 2 Aug. 1929, *M.K. Dinter 6569* (B, holo.).

Plants up to 80 mm high. *Stem* reaching ground level, usually with well-developed collar of fibres around base. *Leaves* narrowly lanceolate to linear, twisted to loosely coiled above, 1.5–3.5(–8.0) mm wide, not evidently pleated, smooth or with short or long hairs, margins and central vein prominently thickened. *Spike* borne at ground level, 1- to 3-flowered; bracts smooth, green with dry brown tips, 17–27 mm long, inner forked apically. *Flowers* zygomorphic, pale mauve to creamy white, flushed purple outside, lower lateral tepals white to yellow with mauve tips, sweetly scented; perianth tube funnel-shaped, 25–28 mm long; tepals unequal, dorsal 30–40 mm long, lower 3 shorter, 25–35 mm long, joined basally for short distance. *Stamens* unilateral; filaments arched, ± 12 mm long; anthers 5–6 mm long. *Ovary* smooth; style dividing opposite anther apices, branches ± 4 mm long. *Flowering time*: mainly June, sometimes in early July.

Distribution and ecology: occurring in southwestern Namibia and adjacent South Africa in the Richtersveld, extending from Buchuberg in southwestern Namibia to Eksteenfontein in Northern Cape; stony coastal and near interior flats and low hills, usually on weathered dolomite but also on micaceous schist, the corms often wedged in rock crevices.

Diagnosis: although surprisingly common in the Richtersveld, *Babiana namaquensis* is seldom seen for it flowers early in the season, mostly in June or July, when little plant exploration is undertaken. Leaf morphology of *B. namaquensis* is unusually variable. Younger plants produce narrow leaves, twisted or coiled above, while mature plants have narrowly lanceolate leaves loosely twisted distally. The leaf morphology recalls that of *B. torta*, a similarly acaulescent species of central and southern Namaqualand that also has coiled to twisted leaves. In *B. torta* the leaves are usually densely hairy, while the slate-blue or rarely white flowers have a perianth tube 20–22 mm long, and the bracts are prominently veined and silky hairy or rarely sparsely velvety. In contrast, *B. namaquensis* has sparsely hairy to smooth leaves, consistently smooth bracts, and a pale mauve to white perianth with a tube 25–28 mm long. *Babiana torta* appears to be confined to granitic substrates, mostly growing in cracks in granite outcrops, and it flowers mainly in May or early June, whereas *B. namaquensis* favours limestone substrates and flowers somewhat later, in late June or July.

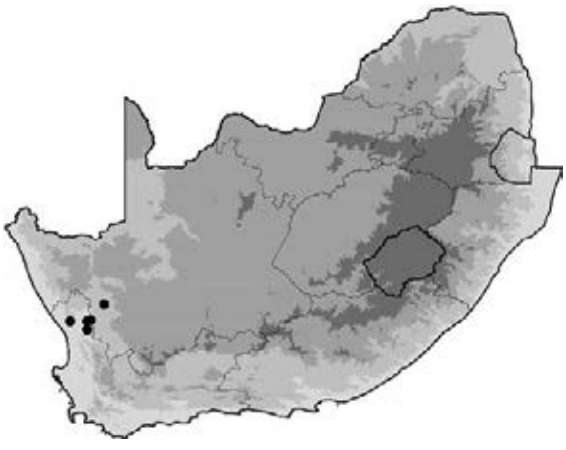
17. **Babiana longicollis** *Dinter* in Repertorium specierum novarum regni vegetabilis 29: 253 (1931); Lewis: 103 (1959). Type: Namibia, Klinghardt Mtns, 26 Sept. 1922, *M.K. Dinter 4007* (B, holo.).

Plants 100–150 mm high, including leaves. *Stem* reaching shortly above ground, sometimes branched, smooth.

Distribution of ***Babiana longicollis***.

Leaves sword-shaped to lanceolate, linear in juvenile plants, 60–100 × 4–10 mm, firm, lightly to strongly pleated, minutely hairy or almost hairless, loosely twisted in upper half and sometimes tip recurved, margins sparsely silky-hairy. *Spike* compact, decumbent, 3- to 5-flowered; bracts green with tips punctate and drying reddish brown, fairly prominently veined, smooth, 18–25 mm long, inner slightly longer than outer, forked apically, with dry attenuate tips. *Flowers* zygomorphic, purple to grey-mauve or greenish, lower tepals marked with white to pale yellow, scented of sweet pea; perianth tube (?32–)35–45 mm long; tepals unequal, dorsal 20–30 × (10–)15–20 mm, lower 3 tepals shortly united, 14–16 mm long. *Stamens* unilateral; filaments arched, ± 10 mm long; anthers 5–6 mm long. *Ovary* smooth; style dividing opposite anther bases, 3–4 mm long. *Flowering time*: mainly late June and July but sometimes in August.

Distribution and ecology: local in SW Namibia, from the Klinghardt Mtns to Rosh Pinah; in crevices in granite outcrops.



Diagnosis: known from a handful of collections from southern Namibia, *Babiana longicollis* has a stem produced shortly above the ground, relatively large flowers with a perianth tube 35–45 mm long and gradually widening in the upper half, and the dorsal tepal 20–30 mm long. Its relationships appear to lie with the northern Namaqualand species, *B. namaquensis*, which has identical leaves, ± 1.5–8.0 mm wide, loosely twisted in the upper half and weakly or not at all pleated, and pale mauve to whitish flowers with a substantially shorter perianth tube, mostly 25–28 mm long, compared to the longer tube of *B. longicollis*. The tepals of *B. longicollis* are smaller than to about the same size as those of *B. namaquensis*, the dorsal (15–)20–30 × (10–)15–20 mm. The style divides close to the bases of the anthers in *B. longicollis* but opposite the anther tips in *B. namaquensis*. Both species have hairless bracts.

18. **Babiana cinnamomea** *J.C.Manning & Goldblatt* in Strelitzia 18: 29 (2007). Type: South Africa, Western Cape, stony shale slope between Vanrhynsdorp and Grootdrif, foot of Vuurberg, rock crevices, 15 June 2002, *J.C. Manning 2744* (NBG, holo.).

Plants 40–60 mm high. *Stem* subterranean, unbranched, smooth. *Leaves* broadly ovate, held ± at right angles to sheaths, ± ovate, 30–40 × 20–25 mm, smooth, margins thickened, minutely papillate and crisped. *Spike* decumbent, short, 2- to 6-flowered; bracts green below, dry and translucent light brown toward tips, hairless, outer 17–19 mm long, inner 20–25 mm long, notched at apex. *Flowers* zygomorphic, pale yellow-green flushed with mauve, lower lateral tepals with white to cream-coloured median blotches, with sweet spicy scent; perianth tube funnel-shaped, narrow part hollow to base, 22–25 mm long; tepals unequal, dorsal ± 30 × 7–8 mm, upper lateral tepals joined to lower for ± 6 mm, forming a lip, lower tepals ± 20 mm long. *Stamens* unilateral; filaments ± 15 mm long; anthers 7–8 mm long. *Ovary* smooth; style dividing opposite anther tips, branches ± 3.5 mm long. *Flowering time*: early to midwinter, May and June.

Distribution and ecology: a fairly local endemic occurring along the base of the mountains stretching from east of Vanrhynsdorp to the Langberg west of Loeriesfontein in Western Cape, South Africa, and in the dry hills west of Nuwerus; on stony lower slopes usually in granite outcrops, also recorded on shale among quartzite pebbles.

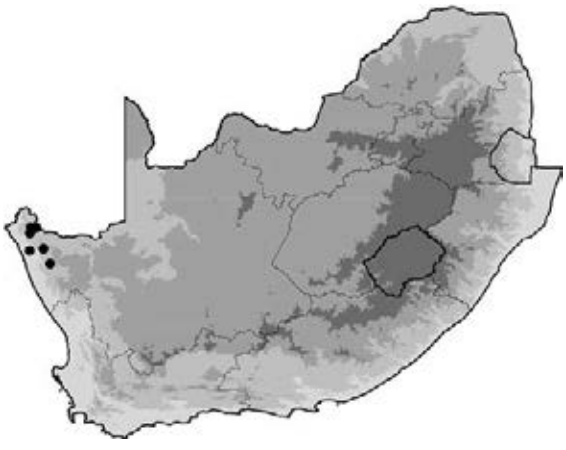
Diagnosis: a dwarf species, *Babiana cinnamomea* has distinctive, broadly ovate leaves with undulate and crisped margins unique in the genus, and the floral bracts are unusual in being largely dry, thinly papery in texture, and pale straw in colour with minute light brown flecks over the surface. Even in full bloom *B. cinnamomea* is inconspicuous, for the pale bluish green to pale yellow flowers are borne close to the ground and are easily overlooked.

Distribution of ***Babiana cinnamomea***.

The flowers have a particularly strong, sweet, spicy scent, reminiscent of cinnamon and clove, produced during the day and at night, a feature more noticeable than the drab flower colour and suggesting moth pollination. Like many other species of *Babiana* with highly modified leaves, the juvenile foliage is very different. Seedlings and plants with immature corms have slender, linear leaves that bear a few long soft hairs.

19. **Babiana horizontalis** *G.J.Lewis* in Journal of South African Botany, Suppl. 3: 90 (1959); Goldblatt & Manning: 31 (2007). Type: South Africa, [Northern Cape], Anenous Pass, June 1900, *E.G. Alston in Herb. Marloth 4568* (PRE, holo.).

Plants up to 50 mm high, including leaves. *Stem* reaching up to 30 mm above ground, unbranched, smooth, enclosed below by thick fibrous collar. *Leaves* lanceolate, blades held at right angles to short pseudopetioles 20–30 mm long, almost horizontal, 30–40 × 13 mm, scarcely plicate, smooth or sparsely long-hairy on upper margins, prominently 3- or 4-ribbed. *Spike* horizontal, (1)2- to 5-flowered; bracts green, smooth, closely striate, 25–70 mm long, inner shorter than outer, forked apically, tips pale and dry. *Flowers* zygomorphic, outer tepals lilac, occasionally yellow, inner tepals pale yellow; perianth tube ± 25 mm long, funnel-shaped; tepals unequal, dorsal ± 27 mm long, lower 3 tepals 20–23 mm long. *Stamens* unilateral; filaments 16–17 mm long; anthers ± 6 mm long, said to be declinate. *Ovary* smooth; style dividing just beyond anther tips, branches 3–4 mm long, expanded at tips. *Flowering time*: June and July.



Distribution and ecology: relatively poorly known, restricted to the southern Richtersveld, in Northern Cape, South Africa; evidently on granite outcrops.

Diagnosis: the dwarf *Babiana horizontalis* is easily recognised by the unusual leaves, borne on pseudopetioles sometimes up to 30 mm long, with the expanded, lanceolate to oblong blades prominently 3- or 4-ribbed, scarcely pleated, and held horizontally at right angles to the sheaths. The flowers typically have lilac outer and yellow inner tepals but may also be entirely yellow. The immediate relationships of *B. horizontalis* are uncertain, but it seems to be allied to the several dwarf, acaulescent species of Namaqualand, all of which have a smooth ovary and similar inner bracts forked at the apex.

20. **Babiana gariepensis** *Goldblatt & J.C.Manning* in Strelitzia 18: 31 (2007). Type: South Africa, Northern Cape, Richtersveld National Park, Koeskop, steep, south-facing rocky slope, Sept. 1995, *G. & F. Williamson 5776* (NBG, holo.).

Plants 120–200(–280) mm high. *Stem* usually largely subterranean, with 1 or 2 branches produced close to ground level, smooth. *Leaves* ascending-horizontal, borne obliquely to sheath and stem, blade broadly lanceolate, (40–)70–110 × 18–25 mm, exceeding spike, scabrid to papillate on veins and margins, rough to touch, obscurely plicate but with 3 to 5 main veins. *Spike* decumbent, close to ground level, congested, 3- to 5-flowered; bracts lightly striate, green with brown apices, shortly hairy on veins, 23–35 mm long, inner slightly shorter to ± as long as outer, forked apically. *Flowers* zygomorphic, bilabiate, pale grey-green, upper tepals each with slate-blue median streak, red-lined in throat, lower 3 tepals with white spear-shaped markings outlined in dull reddish maroon, sweetly violet-scented; perianth tube 20–24 mm long, slender below, curving outward and wider in upper 7 mm; tepals unequal, dorsal 28–32 × ± 5 mm, arching over stamens, upper laterals ± 28 × 4 mm, joined to lower for ± 5 mm, lower tepals 18–24 mm long. *Stamens* unilateral; filaments arched, ± 16 mm long; anthers ± 5 mm long, lilac; pollen grey-white. *Ovary* smooth; style dividing opposite lower ⅓ of anthers, branches ± 2 mm long. *Flowering time*: June and July.

Distribution and ecology: restricted to southern Namibia and Northern Cape, South Africa, from the Namuskluft near Rosh Pinah to Koeskop and Grasvlakte in the Richtersveld; on rocky open slopes and south-facing cliffs.

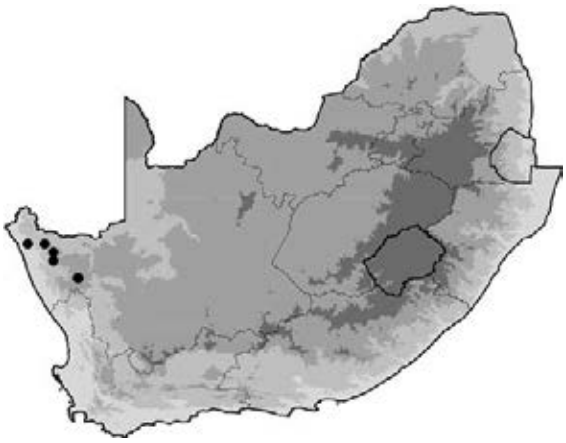
Distribution of ***Babiana horizontalis***.

Distribution of ***Babiana gariepensis***.

Diagnosis: *Babiana gariepensis* remains poorly collected and somewhat puzzling. The large bracts, 23–35 mm long, with the inner forked near the apex place *B. gariepensis* in sect. *Teretifolieae*. The broad, sparsely hairy, lightly plicate leaf and moderately long perianth tube, 20–22 mm long, with a sharp curve below the throat suggest a possible relationship with the central Namaqualand *B. attenuata*. The flowers seem distinctive also in the relatively long, narrow tepals, the dorsal 28–32 × 5 mm. Additional material in flower is needed to better understand this apparently rare southern Namibia and Richtersveld endemic.

Ser. **Cuneifolieae** *Goldblatt & J.C.Manning*, new series. Type: *Babiana cuneata* J.C.Manning & Goldblatt

Leaves abruptly truncate; flowers zygomorphic; perianth tube ⅓ as long to much longer than dorsal tepal, obliquely funnel-shaped or straight, slender, not or only slightly expanded at apex.



21. **Babiana flabellifolia** *Harv. ex Klatt* in Linnaea 35: 380 (1867); Goldblatt & Manning: 32 (2007). Type: South Africa, [Northern Cape], Namaqualand, without precise locality or date, probably near Modderfontein, west of Springbok, *H. Whitehead s.n.* (K, holo.).

Babiana cuneifolia Baker: 335 (1876). Type: South Africa, [Western Cape], Mierenkasteel, karroid slopes, Aug. 1830, *J.F. Drège 2627* (K, holo.; MO, P [2 sheets)], S, iso.).

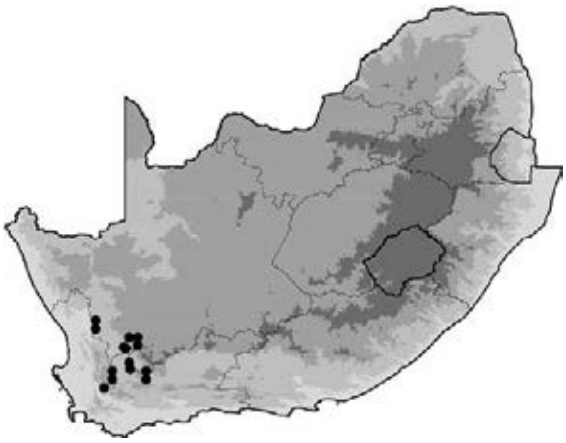
Babiana truncata G.J.Lewis: 100 (1959). Type: South Africa, [Northern Cape], 2 miles E of Springbok, 26 July 1950, *G.J. Lewis 2203* (SAM, holo.; SAM, iso.).

Plants up to 80 mm high. *Stem* short or entirely underground. *Leaves* crowded basally, abruptly truncate and wedge-shaped, pleated, smooth or finely hairy with shortly velvety margins, or rarely coarsely hairy with white hairs up to 2.5 mm long; juvenile leaves filiform and long-hairy. *Spike* borne at ground level, compact, 2- to several-flowered; bracts 15–30 mm long, ± membranous or green, smooth or papillate to finely hairy, inner bract forked at tip, tapering into slender awns. *Flowers* zygomorphic, pale mauve to violet, tube white to pale yellow and lower lateral tepals with pale yellow to white median markings, sweetly scented of rose or carnation, open day and night; perianth tube 12–36 mm long, cylindric, straight, dorsal tepal suberect or arching forward, 27–35 mm long, lower tepals slightly shorter, 25–27 mm long. *Stamens* unilateral; filaments arcuate, 15–18 mm long; anthers 6–8 mm long. *Ovary* smooth; style dividing near anther apices, branches 4–5 mm long, expanded apically. *Flowering time*: mainly June and July sometimes in early August.

Distribution and ecology: restricted to northwestern South Africa, extending from the Anenous Mtns of northern Namaqualand in Northern Cape to Koekenaap in the south in Western Cape, and locally inland on the Bokkeveld Plateau near Calvinia; in clay and granitic soils, in renosterveld and succulent karroid scrub.

Distribution of ***Babiana flabellifolia***.

Diagnosis: among the five species of *Babiana* with truncate, ± cuneate leaves, *B. flabellifolia* is distinguished by the sweetly scented flowers with subequal tepals and a perianth tube of short to moderate length, 12–36 mm long. The tube is largely or entirely included in soft-textured bracts 15–30 mm long. The flowers remain open at night and are then strongly scented of carnation. The relatively short perianth tube has comparatively thick walls in the lower half when the tube exceeds 20 mm, so that nectar is forced into the upper part of the tube where it is accessible to long-tongued solitary bees and moths, the presumed pollinators. Plants are often hairless, or sparsely hairy on the leaf margins or bracts, but the feature is variable, and some collections from near Springbok have lightly hairy leaves. The type collection of *B. flabellifolia* is somewhat puzzling because the leaves and bracts are conspicuously hairy. The exact origin of the type is unknown but Reverend Whitehead, who collected it, was stationed at the Anglican Mission at Modderfontein, close to Springbok and the presumption is that the type of *B. flabellifolia* was collected there or nearby. The long-hairy leaves and bracts of the type are not matched in any other specimen with truncate leaves and it is possible that they represent a taxon separate from the hairless or sparsely hairy plants that occur widely in southern Namaqualand as well as north of Springbok. More information on the variation in the type population and those growing nearby would be helpful in dealing more critically with the question about the status of the type of *B. flabellifolia* relative to other collections assigned to the species.



22. **Babiana cuneata** *J.C.Manning & Goldblatt* in Bothalia 34: 89 (2004); Goldblatt & Manning: 33 (2007). Type: South Africa, Western Cape, Cold Bokkeveld, Katbakkies Pass, 5 Sept. 2000, *P. Goldblatt & J.C. Manning 11457* (NBG, holo.; K, MO, PRE, iso.).

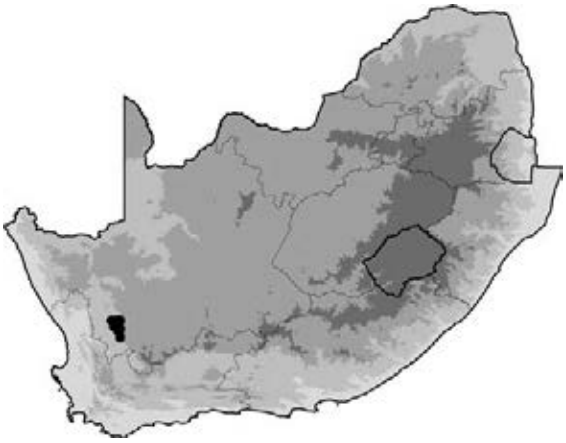
Plants 80–150 mm high, including leaves. *Stem* short, smooth. *Leaves* crowded basally, up to 6, oblong, (20–)30–100 × 8–18(–30) mm, leathery, pleated, abruptly truncate, smooth or finely velvety hairy. *Spike* compact, borne at ground level, 2- to 5(–7)-flowered; bracts green with brown attenuate tips, smooth or lightly hairy, 25–50 mm long, inner ± as long as outer, forked apically, basal margins sometimes fused around ovary for ± 2 mm. *Flowers* zygomorphic, pale blue to violet, lower lateral tepals with white median marks outlined dark violet to purple below, evidently odourless or sweetly scented; perianth tube 40–60 mm long, cylindric, straight, widening slightly in upper 8 mm; tepals spreading, subequal or upper three slightly larger, 26–32(–40) × 6–12 mm, upper laterals fused to lower for ± 2 mm. *Stamens* unilateral; filaments unilateral, 15–18 mm long, exserted 9–10 mm; anthers ± 6(–11) mm long, pale yellow to cream-coloured. *Ovary* smooth, lower flowers shortly stalked; style dividing opposite anther bases or opposite anther apices, branches ± 6 mm long, arching outward between or over anthers. *Flowering time*: August to mid-September.

Distribution and ecology: extending from the Bokkeveld Mtns and Klein Roggeveld in Northern Cape, South Africa, to the interior Cold Bokkeveld as far south as Karoopoort and the foot of the Witteberg between Matjiesfontein and Laingsburg in Western Cape; on dry rocky sandstone or dolerite slopes and flats in arid fynbos, renosterveld, or karroid bush.

Diagnosis: among the species with truncate foliage, *Babiana cuneata* is distinguished by the elongate perianth tube, 40–60 mm long, more-or-less equal, ascending tepals 26–30(–40) mm long, and a pale blue to violet, fragrant or apparently odourless flower. The stamens are openly displayed, with filaments 15–18 mm long and exserted 9–10 mm. The point of division of the style varies. In the type population the style branches opposite the base of the anthers but in plants to the south, below the Roggeveld Escarpment, it reaches the anther apices before branching. Flowering occurs from early August to late September. *Babiana flabellifolia* has, in contrast, strongly scented bilabiate flowers with an arched dorsal tepal more-or-less concealing the stamens, a perianth tube 18–36 mm long, and often dry, submembranous, or occasionally green, leafy bracts. In specimens where it is possible to see floral details, the style divides opposite the anther apices. Flowering in *B. flabellifolia* occurs from late June through July, rarely in early August in seasons when the rains are late or conditions are particularly cold. The flowers of *B. cuneata* closely resemble those of *B. sambucina*, which is widespread across the dry interior of the Cape Floral Region, but absent from the Roggeveld.

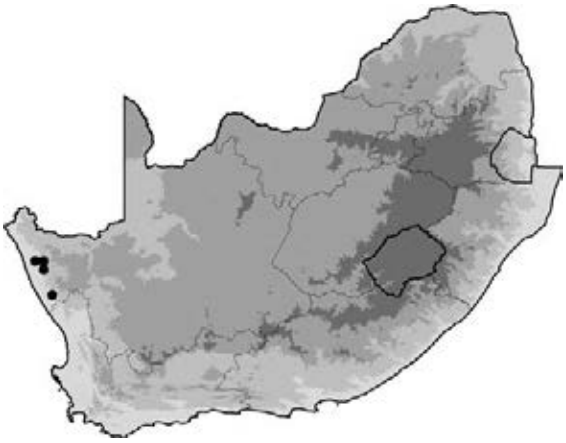
Plants at the southern end of the range, in the Klein Roggeveld south of Komsberg Pass, have unusually large flowers with the dorsal tepal ± 40 mm long, the anthers 9–11 mm long, and the style is also unusual in dividing opposite the anther apices rather than opposite their bases. Plants also seem unusual in the blue-grey colour of the leaves, often 20–30 mm wide, likewise exceptional for the species. At present, however, there appears no reason to recognise these as a separate taxon.

Distribution of ***Babiana cuneata***.



23. **Babiana praemorsa** *Goldblatt & J.C.Manning* in Bothalia 34: 90 (2004); Goldblatt & Manning: 35 (2007). Type: South Africa, [Northern Cape], Calvinia District, north of Bloukrans Pass, shale flats, 25 Aug. 1976, *P. Goldblatt 3935* (NBG, holo.; K, MO, iso.).

[*Babiana flabellifolia* sensu G.J.Lewis: 98 (1959), not of Harv. ex Klatt, misapplied name.]



Plants 50–150 mm high. *Stem* short, suberect or decumbent, rarely reaching 20 mm above ground. *Leaves* several in a spreading fan, oblong-cuneate, abruptly truncate, pleated, minutely hairy, in a spreading fan; juvenile leaves linear, ± 1 mm wide, silky hairy. *Spike* congested, 5- to 6-flowered; bracts green, minutely hairy, outer 25–50 mm long, inner slightly shorter, forked apically, with acuminate tips. *Flowers* weakly zygomorphic, dark violet with white to cream-coloured spear-shaped marks often edged with red or dark blue on lower lateral tepals, unscented or rarely lightly sweet-scented; perianth tube 40–60 mm long, cylindric, straight; tepals subequal, spreading horizontally, mostly 18–22 × 3.5–5.0 mm. *Stamens* unilateral; filaments suberect, 8–9 mm long, exserted 4–5 mm; anthers 5–6 mm long, violet or yellow. *Ovary* smooth; style dividing opposite upper half of anthers or shortly beyond them, branches 2–3 mm long. *Flowering time*: August to mid-September.

Distribution and ecology: endemic to the Calvinia Distinct in Northern Cape, South Africa, and extending from the Hantamsberg and Bloukrans Pass westward to near Nieuwoudtville; in dolerite outcrops, often in rock crevices.

Diagnosis: one of five species of *Babiana* with abruptly truncate, wedge-shaped leaves, *B. praemorsa* is recognised by its flowers with a straight, cylindric perianth tube 40–60 mm long and firm, narrow, spreading tepals, 18–22 mm long. The perianth is deep violet rather than

Distribution of ***Babiana praemorsa***.

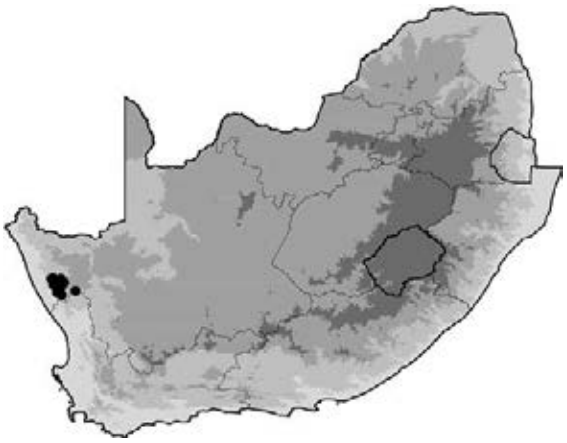
Distribution of ***Babiana pubescens***.

blue as in the apparently related long-tubed *B. pubescens* of the central Namaqualand. *Babiana praemorsa* can be distinguished from it and *B. cuneata*, the other long-tubed species with wedge-shaped leaves, by its short filaments, 8–9 mm long, exserted 4–5 mm from the perianth tube, tepals spreading at right angles from the nearly straight tube of uniform diameter, and short style branches ± 3 mm long.

24. **Babiana pubescens** *(Lam.) G.J.Lewis* in Annals of the South African Museum 40: 131 (1954); Lewis: 110 (1959), excl. syn. *B. cuneifolia* Baker; Goldblatt & Manning: 36 (2007). *Gladiolus pubescens* Lam.: 119 (1791). Type: South Africa, [Northern Cape], without precise locality or date, *F. le Vaillant s.n.* (P: Herb. Lamarck, holo.).

Plants 60–100 mm high. *Stem* short, decumbent, rarely extended above ground, simple or 1- or 2-branched. *Leaves* crowded basally, abruptly truncate and wedge-shaped, lightly pleated, usually finely hairy. *Spike* congested, 6- to 10-flowered; bracts ± smooth to velvety, 20–38 mm long, inner slightly shorter than outer, forked apically. *Flowers* zygomorphic, blue to violet with white median marks often edged red on lower lateral tepals; perianth tube elongate, sharply bent below apex, ± 50 mm long; tepals unequal, dorsal largest and held somewhat apart, ± 20 mm long, lower tepals joined to upper laterals for short distance and to one another for ± 2 mm, forming a lip, 15–17 mm long. *Stamens* unilateral; filaments ± 15 mm long, well exserted from tube; anthers 6–7 mm long. *Ovary* smooth; style dividing opposite lower half of anthers; style ± 4 mm long. *Flowering time*: late July to early September.

Distribution and ecology: occurring in central Namaqualand, Northern Cape, South Africa, extending from Komaggas in the north to Garies; on stony slopes in coarse granitic gravel.



Diagnosis: *Babiana pubescens* is readily distinguished among the species with truncate leaves by the slender perianth tube, ± 50 mm long, sharply bent below the apex, and the relatively narrow tepals 15–20 mm long and 5–7 mm wide. Although said by Lewis (1959) to occur from Garies southward to Mierenkasteel (near Nuwerus) in southern Namaqualand, *B. pubescens* has only been reliably reported from Komaggas, southwest of Springbok, and in the vicinity of Garies. Despite being increasingly threatened by overgrazing and especially the heavy stocking of goats, *B. pubescens* remains relatively common locally. The attractive, blue to violet, long-tubed flowers are pollinated by the long proboscid fly, *Prosoeca peringueyi*, an important insect pollinator of species with long-tubed flowers in Namaqualand.

Ser. **Longitubae** *Goldblatt & J.C.Manning*, new series. Type: *Babiana sambucina* (Jacq.) Ker Gawl.

Flowers zygomorphic or actinomorphic (*Babiana symmetrantha*); perianth tube as long as or longer than dorsal tepal, slender, not or only slightly expanded at apex.

25. **Babiana attenuata** *G.J.Lewis* in Journal of South African Botany, Suppl. 3: 102 (1959); Goldblatt & Manning: 36 (2007). Type: South Africa, [Northern Cape], foot of the Kamiesberg near Kamieskroon, 29 July 1957, *G.J. Lewis 4414* (SAM, holo.; NBG, iso.).

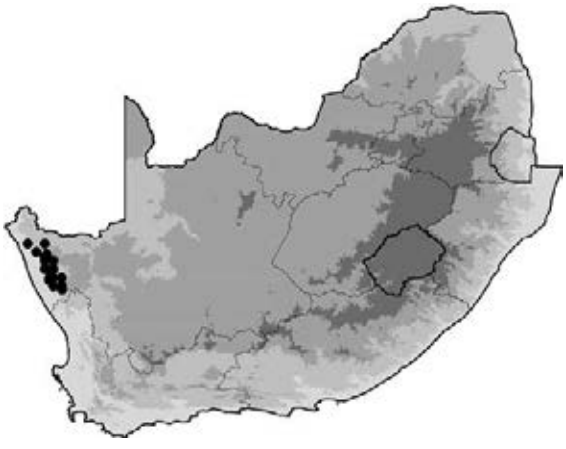
Plants up to 80 mm high. *Stem* mostly or entirely underground, softly hairy. *Leaves* sword-shaped to lanceolate, rarely linear, plicate, softly hairy, often twisted and arching toward ground. *Spike* decumbent, 4- to 9-flowered; outer bract 20–30 mm long, velvety, inner ± as long, forked apically, attenuate. *Flowers* zygomorphic, bilabiate, blue to violet with white to yellow marks on lower lateral tepals, strongly scented of violets; perianth tube narrowly funnel-shaped, 25–35 mm long, bent near apex; tepals unequal, dorsal (20–)26–35 mm long, lower tepals slightly shorter. *Stamens* unilateral; filaments arching under dorsal tepal, ± 15 mm long; anthers 5–7 mm long. *Ovary* smooth; style arching over stamens, dividing opposite anther tips, branches ± 2.5 mm long. *Flowering time*: late July to early September.

Distribution of ***Babiana attenuata***.

Distribution and ecology: restricted to central Namaqualand, in the Kamiesberg and the highlands between Kamieskroon and Garies in Northern Cape, South Africa; on rocky and gravel slopes.

Diagnosis: *Babiana attenuata* has attractive blue-violet flowers borne on crowded horizontal spikes close to ground level. It is most easily recognised by the moderately long perianth tube, 25–35 mm long, about as long as or slightly longer than the bracts and tepals, and the strong sweet violet floral fragrance. It is easily confused with the vegetatively virtually identical *B. curviscapa*, which extends from Steinkopf in the north to Bitterfontein in the south, thus including the entire range of *B. attenuata*. They are separated primarily by the length of the perianth tube, substantially longer in *B. curviscapa* and usually 36–43 mm vs. 25–35 mm in *B. attenuata*. Flowers of *B. attenuata* are always strongly fragrant and have tepals usually 26–35 mm long, whereas the flowers of *B. curviscapa* are only faintly scented or lack a floral odour completely and the shorter tepals are 20–23 mm long. In the north of its range *B. curviscapa* has magenta to cherry-red flowers but elsewhere they are blue as in *B. attenuata*. Despite its relatively long perianth tube, *B. attenuata* is pollinated by anthophorine bees with mouthparts about 10 mm long.

Plants from the southern Kamiesberg with erect, linear leaves up to 150 mm long and conspicuously long-hairy, appear rather different to other populations of *B. attenuata* and may represent a local variant or possibly a separate species but the flowers match those of other populations of the species in critical details.



26. **Babiana curviscapa** *G.J.Lewis* in Journal of South African Botany, Suppl. 3: 107 (1959); Goldblatt & Manning: 37 (2007). Type: South Africa, [Northern Cape], Nababeep, 5 Sept. 1951, *W.F. Barker 7431* (NBG, holo.; K, iso.).

Babiana framesii var. *kamiesbergensis* G.J.Lewis: 98 (1959). Type: South Africa, [Northern Cape], Kamiesberg, ex hort. Kirstenbosch, 30 Sept. 1943, *C.L. Leipoldt s.n.* as *Natl. Bot. Gard. 981/39* (NBG, holo.).

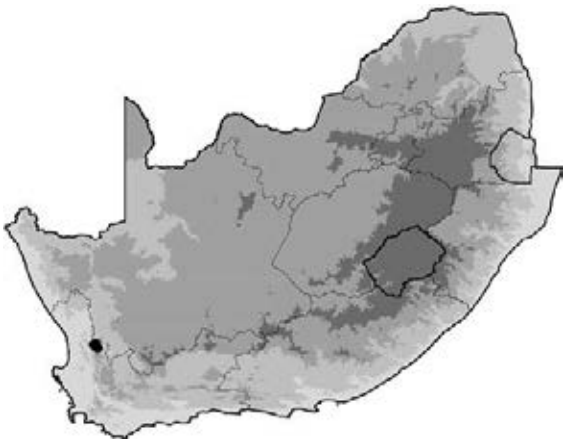
Plants mostly acaulescent, 80–150 mm high, including leaves, often growing in tufts. *Stem* short, mostly underground, smooth or hispid to long-hairy, with up to 3 branches. *Leaves* several, lanceolate, pleated, velvety hairy, rarely long silky hairy, blades held apart, not forming a fan, loosely twisted, mostly 5–8 mm wide, rarely up to 15 mm. *Spike* horizontal, 5- to 12-flowered; bracts green with dry brown tips, velvety, 25–35 mm long, inner ± as long as outer, forked at apex. *Flowers* zygomorphic, deep red-purple or violet to deep blue, with white markings on lower lateral tepals, odourless or faintly violet-scented; perianth tube elongate-cylindric, 36–43 mm long, bent near apex; tepals unequal, dorsal 20–23 mm long, lower tepals 17–19 mm long. *Stamens* unilateral; filaments 12–14 mm long; anthers 4–6 mm long, white. *Ovary* smooth; style dividing opposite upper ⅓ of anthers, branches ± 4 mm long. *Flowering time*: late August to September.

Distribution and ecology: extending from the southern Richtersveld near Steinkopf to the Kamiesberg in Northern Cape, South Africa, and to Bitterfontein in Western Cape; on stony granitic flats and granite outcrops.

Diagnosis: the most common long-tubed species of *Babiana* in Namaqualand, *B. curviscapa* blooms from late August to the end of September, depending on elevation, plants on the Kamiesberg flowering the latest. It appears to be most closely allied to *B. attenuata*, which is vegetatively virtually indistinguishable in its short, somewhat twisted leaves but with strongly scented violet flowers with a shorter perianth tube, 25–35 mm long, and adapted for pollination by large-bodied long-tongued anthophorine bees, whereas the longer-tubed flowers of *B. curviscapa* are pollinated by long-proboscid flies. Although the two species flower at a slightly different time, *B. curviscapa* mainly in September and *B. attenuata* from late July to late August, flowering times may overlap at some sites, creating the possibility for hybridisation. Possible interspecific crossing between

Distribution of ***Babiana curviscapa***.

the two species is the reason they can sometimes be difficult to distinguish.



27. **Babiana geniculata** *G.J.Lewis* in Journal of South African Botany, Suppl. 3: 109 (1959); Goldblatt & Manning: 38 (2007). Type: South Africa, [Western Cape], Wuppertal, Boontjiesrivier, 25 Aug. 1896, *R. Schlechter 8666* (BOL, holo.; B, MO, S, iso.).

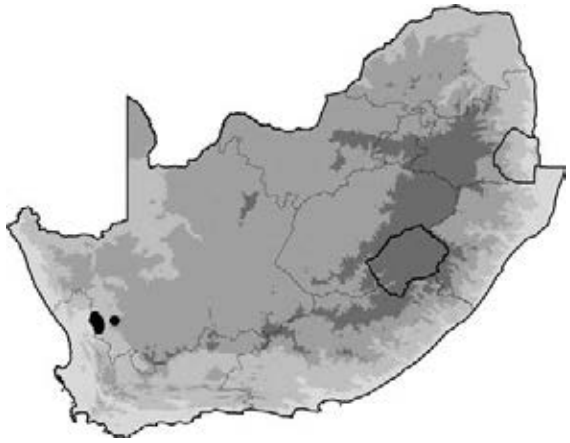
Babiana velutina var. *nana* Schltr.: 100 (1899). Type: South Africa, [Western Cape], Boontjiesrivier, 25 Aug. 1896, *R. Schlechter 8666* (B, BOL, MO, S, syn.).

Plants 20–60 mm high. *Stem* reaching just above ground, usually unbranched, velvety-hairy, enclosed below in thick collar of fibres. *Leaves* lanceolate, pleated, usually inclined toward ground, velvety-hairy. *Spike* compact, decumbent, 4- to 9-flowered; outer bract 25–35 mm long, green with dry acuminate apices, densely hairy, inner ½–⅔ as long, forked in upper ⅓. *Flowers* zygomorphic, violet, lower lateral tepals with white median streaks, unscented; perianth tube 35–45 mm long, cylindric, sharply bent near apex; tepals unequal, dorsal 23–29 mm long, lower tepals joined to upper laterals for ± 3 mm and to one another for 2–3 mm, forming a prominent lip, 15–22 mm long. *Stamens* unilateral; filaments arcuate, diverging distally, 13–15 mm long; anthers ± 7 mm long, held widely apart. *Ovary* hairy above base; style dividing opposite middle of filaments, branches slender 11–13 mm long. *Flowering time*: August.

Distribution and ecology: endemic to the northern Cederberg, Pakhuis and Biedouw Mtns in Western Cape, South Africa; on rocky sandstone slopes in dry fynbos.

Diagnosis: low-growing and virtually acaulescent, *Babiana geniculata* is distinctive in its flowers with a long slender perianth tube 35–45 mm long and bent at a sharp angle just below the apex, the ovary hairy above the base, and the divergent rather than parallel filaments with the anthers held well apart from one another. The style is also unusual in dividing opposite the middle of the filaments, thus below the bases of the anthers. The style branches, the longest in the genus, 11–13 mm long, are slender and barely expanded at the tips. The flowers are adapted for pollination by long-proboscid flies.

Distribution of ***Babiana geniculata***.



The inner bracts, forked in the upper third, are consistent with sect. *Teretifolieae* in which the inner bracts are usually forked only near the apex, whereas superficially similar *Babiana ecklonii* is a taller plant with the inner bracts divided to the base, a feature diagnostic for sect. *Babiana*. *Babiana curviscapa* from Namaqualand, also with short leaves and a decumbent spike of long-tubed flowers with the perianth tube sharply bent below the apex, has conventional arcuate and parallel stamens, a hairless ovary, and the style divides close to the anther apices into short branches, ± 4 mm long. The relationships and sectional position of *B. geniculata* remain uncertain.

28. **Babiana vanzijliae** *L.Bolus* in Annals of the Bolus Herbarium 4: 27 (1925); Lewis: 85 (1959) [as *B. vanzyliae*]; Goldblatt & Manning: 38 (2007). Type: South Africa, [Northern Cape], Nieuwoudtville District, without precise locality, flowered in Cape Town, Sept. 1924, *Van Zijl s.n.* (BOL 17698, holo.).

Plants 40–120 mm high. *Stem* reaching shortly above ground level, velvety, rarely with 1 or 2 branches borne at ground level, base enclosed by thick collar of fibres. *Leaves* sword-shaped to lanceolate, pleated, velvety-hairy. *Spike* compact, decumbent, 3- to 5-flowered; bracts green, becoming dry at tips, 25–40 mm long, inner slightly shorter than outer, forked at apex. *Flowers* zygomorphic, usually yellow, occasionally pale blue-mauve, lower lateral tepals with whitish median blotches, strongly scented; perianth tube narrowly funnel-shaped, (18–)25–50 mm long; tepals unequal, dorsal arching forward, 30–38 mm long, lower tepals joined to upper laterals for short distance forming oblique lip, 25–30 mm long. *Stamens* unilateral; filaments arcuate, 15–17 mm long; anthers 7–8 mm long. *Ovary* smooth or shortly hispid on ribs; style arching over stamens, dividing opposite anther tips, branches ± 4 mm long. *Flowering time*: early August to mid-September.

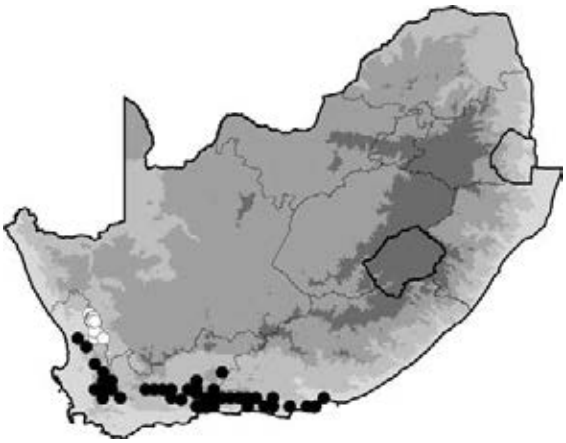
Distribution and ecology: a narrow endemic of the Bokkeveld Mtns in Northern Cape, South Africa, extending from the northern end of the range to Lokenberg south of Nieuwoudtville; on rocky sandstone- and tillite-derived soils in fynbos and renosterveld.

Diagnosis: one of just a handful of yellow-flowered species of *Babiana*, *B. vanzijliae* is recognised primarily by the yellow flowers with a long perianth tube mostly 25–50 mm long. In the south, at Papkuilsfontein and Lokenberg, the perianth may be a dull creamy yellow or flushed pale bluish mauve and the perianth tube is often shorter, 18–25 mm long. The shorter-tubed plants with

Distribution of ***Babiana vanzijliae***.

mauve flowers may be the result of introgression due to occasional crossing with short-tubed, violet-flowered *B. mucronata* because both species may be pollinated by bees and *Prosoeca* flies with mouthparts up to 12–14 mm long. In the north the longer tube may be the result of pollinator selection by flies with longer probosces.

29. **Babiana sambucina** *(Jacq.) Ker Gawl.* in König & Sims, Annals of Botany 1: 234 (1804); Lewis: 92 (1959); Goldblatt & Manning: 39 (2007). *Gladiolus sambucinus* Jacq.: 15 (1797). Type: South Africa, without precise locality, collector or date, illustration in Jacq.: t. 15 (1797).



Plants 80–300 mm high, including leaves. *Stem* mostly underground, smooth, sometimes branched. *Leaves* lanceolate to linear, rarely subterete, strongly pleated to nearly flat, shortly hairy or hispid, occasionally ± smooth, or long-hairy and silky at base and upper part of sheath or throughout. *Spike* compact, several-flowered; bracts mostly 25–40 mm long, green with rust-coloured tips, variously scabrid to sparsely long-hairy, inner slightly shorter than outer, forked at apex, sometimes united basally around ovary; lowermost outer bract extended and leaf-like above, up to 60 mm long. *Flowers* zygomorphic, violet to blue, lower lateral tepals each with a white median mark edged below in dark blue to red, or sometimes with solid red centre, intensely fragrant or rarely evidently odourless; perianth tube 35–55(–65) mm long, straight, slightly flaring above, hollow throughout or with thick walls below tightly enclosing style; tepals subequal, (20–)30–35 × 5–12 mm, lower 3 tepals sometimes basally united for up to 2 mm. *Stamens* unilateral; filaments ± straight, 10–20 mm long; anthers 7–10 mm long, white. *Ovary* smooth, lowermost sometimes shortly stalked; style usually dividing between middle and apex of anthers, branches 3–4 mm long. *Flowering time*: mainly mid-August and September.

Distribution and ecology: a widespread species extending from the Bokkeveld Mtns in Northern Cape, South Africa, though interior Western Cape to Uitenhage and Addo in Eastern Cape; usually stony slopes and flats or rock outcrops, in dry fynbos and renosterveld, most often on sandstone-derived soils.

Diagnosis: *Babiana sambucina* is recognised by the smooth spike borne at ground level, a distinctive lowermost outer floral bract that is extended upward into a short blade, and flowers with a long, straight perianth tube and nearly equal tepals. The leaves and bracts are often almost hairless or at best velvety but are sometimes sparsely long-hairy, and with silky pubescence at the top of the leaf sheaths. The perianth is pale to deep blue or violet and the lower lateral tepals each have a prominent white mark edged in dark blue and sometimes red. The tepals are relatively large, usually 30–35 mm long, only slightly shorter than the tube, mainly 35–55 mm long, or sometimes equalling the tube. Flowers of most populations are strongly and sweetly scented of violets, a particularly characteristic feature of the species.

Despite the length of the tube, flowers of typical *B. sambucina* are pollinated by long-tongued bees, mostly large *Anthophora* species, with tongues no more than 10 mm long. Bees readily reach the nectar because it is held in the upper 10 mm of the tube, the lower portion being thick-walled and tightly enclosing the style. The elongate tube thus functions largely as a pseudopedicel, raising the flowers above the ground.

Of the three unusual sets of populations that Lewis (1959) formally recognised as varieties of *Babiana sambucina*, one of them, var. *undulato-venosa*, from the southeastern part of the range of the species, has short lanceolate leaves sometimes not overtopping the flowers, a perianth tube 55–60 mm long, and the lower bract has a weakly developed blade. It is no longer formally recognised taxonomically. More distinctive, var. *longibracteata* has long narrow leaves 2–6 mm wide, densely covered in long white silky hairs, and is currently treated as a separate subspecies. The third variety, var. *unguiculata*, is now considered a separate species, *B. rigidifolia*.

Distribution of ***Babiana sambucina*** subsp. ***sambucina***, ●; subsp. ***longibracteata***, ○.

Babiana sambucina can be confused with the widespread *B. bainesii* (long misidentified as *B. hypogaea*) of summer-rainfall southern Africa. The latter differs most significantly in the spike being borne just below the ground so that the flowers arise at about ground level, whereas in *B. sambucina* the spike is carried slightly above the ground. The leaves of *B. bainesii* are longer and normally narrower than in *B. sambucina*, usually 3–10 mm wide, and roughly hairy, but the degree and type of leaf pubescence is variable in both species. The perianth tube of *B. sambucina*, normally 35–55 mm long, is similar to that of *B. bainesii*, but the tepals, 20–60 × 6–12 mm, are proportionally narrower than in *B. sambucina* and do not overlap one another in the lower half as in *B. sambucina*. In addition, the perianth tube of *B. bainesii* has a wide throat and the lower tepals are joined to the upper laterals, forming a prominent lip not found in *B. sambucina*, which has the tube cylindric or gradually expanded from the base and the tepals arise at more-or-less the same level.

Among the species of the southern African winter-rainfall zone, *Babiana sambucina* may be most closely allied to *B. framesii* of the Bokkeveld Plateau and we find it difficult to separate the two when dry. *Babiana framesii* has, like *B. sambucina*, a long straight perianth tube, although somewhat curved below the throat, but the somewhat smaller tepals are proportionally narrower and spread almost at right angles to the tube, and the flowers are at most only lightly scented.

Key to subspecies

1a Leaves linear to sword-shaped, mostly 6–12 mm wide, occasionally subterete and ± 2.5 mm wide, variously velvety, pubescent, scabrid, or smooth; perianth tube 30–65 mm long, usually hollow only near apex; flowers usually strongly scented; usually growing in tufts in rocky ground . . . . . 29a. subsp. *sambucina*

1b Leaves linear, 2–6 mm wide, with long white-silky hairs; perianth tube 40–55 mm long, hollow to base; flowers lightly scented or unscented; usually growing singly in sandy ground . . . . . 29b. subsp. *longibracteata*

29a. subsp. **sambucina**

Babiana undulato-venoso Klatt: 350 (1882). *B. sambucina* var. *undulato-venoso* (Klatt) G.J.Lewis: 96 (1959). Type: South Africa, [Eastern Cape], Humansdorp, Company's Drift, Sept. 1922, *H.G. Fourcade 2311* (SAM, neo., designated by Lewis: 96 (1959); BOL, iso.).

Babiana mucronata var. *longicollis* Baker: 183 (1892). Type: South Africa, ex hort. Hibbert, England, without precise locality, illustration in Ker Gawl.: t. 638 (1803c).

Babiana stellata Schltr.: 99 (1899). Type: South Africa, [Western Cape], Cold Bokkeveld, *R. Schlechter 8856* (B, holo.).

Babiana gawleri N.E.Br.: t. 2710 (1905). Type: South Africa, [Western Cape], Olifants River, ex hort. Hibbert, England, without precise locality, illustration in Ker Gawl.: t. 638 (1803c).

Leaves lanceolate to linear or subterete, short or long-hairy or hispid, sometimes glabrescent. *Spike* with bracts mostly 25–40 mm long, green with rust-coloured tips, variously scabrid to long-hairy. *Flowers* with lateral tepals occasionally with red in throat, intensely to lightly fragrant, rarely evidently odourless; perianth tube 30–50(–60) mm long, gradually flaring, straight; tepals subequal, (20–)30–35 × 6–12 mm or dorsal slightly longer. *Filaments* 10–20 mm long.

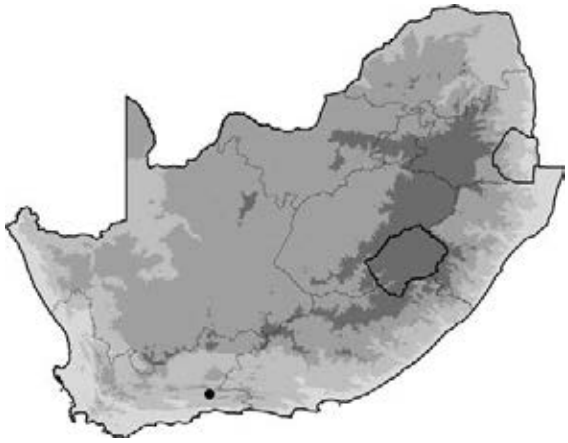
Distribution and ecology: extending from the Cold Bokkeveld in Western Cape, South Africa, to Uitenhage and Addo in Eastern Cape; in rocky, usually sandstone-derived ground. Plants from the Great Escarpment east of Sutherland probably also belong here.

Diagnosis: always acaulescent, with spikes produced at ground level, subsp. *sambucina* varies considerably in leaf form and perianth tube length across its wide range. Particularly noteworthy is a narrow-leaved variant from the Anysberg and nearby ranges in the western Little Karoo. While the flowers are exactly like those of typical *B. sambucina* from the nearby Klein Swartberg and Groot Swartberg, the leaves have heavily thickened veins and nearly terete blades, and seem at first to be significantly different from subsp. *sambucina*, but these plants grow together with others with broader leaves that have identical flowers, suggesting that they do not merit taxonomic recognition.

A second variant includes plants from shale and limestone slopes in the Cango Valley of the Little Karoo. These resemble *Babiana sambucina* in vegetative form but have unscented or at best weakly scented flowers. The bases of all the tepals and the throat are dark red, while the perianth tube is uniformly wide and hollow throughout, and contains nectar in the base. The floral adaptations of this plant seem to us exactly those for long-proboscid fly pollination, although we have not seen insects visiting them. In addition, the pubescence of the leaves is very short, which contrasts with the dense, fairly long vestiture of most Little Karoo and Swartberg populations of *B. sambucina*. The degree of hairiness in *B. sambucina* does, however, vary across its range, and differences thus seem not particularly significant. Future study will show whether these populations merit taxonomic recognition, but for the present we regard them as a divergent race of *B. sambucina*.

29b. subsp. **longibracteata** *(G.J.Lewis) Goldblatt & J.C.Manning* in Strelitzia 18: 41 (2007). *B. longibracteata* G.J.Lewis: 243 (1932). *B. sambucina* var. *longibracteata* (G.J.Lewis) G.J.Lewis: 95 (1959). Type: South Africa, [Northern Cape], Grasberg Road, 10 miles [16 km] N of Nieuwoudtville, Sept. 1930, *L. Bolus s.n.* (BOL 19803, holo.; K, iso.).

Plants like subsp. *sambucina* but leaves mostly nearly flat, linear, 11–30 × 2–6 mm, with spreading or appressed long, silky hairs. *Spike* with bracts except for lowermost, 35–40 mm long, long silky hairy. *Flowers* with perianth tube 40–55 mm long, hollow throughout, with nectar at base, lightly scented or unscented. *Filaments* 15–20 mm long.



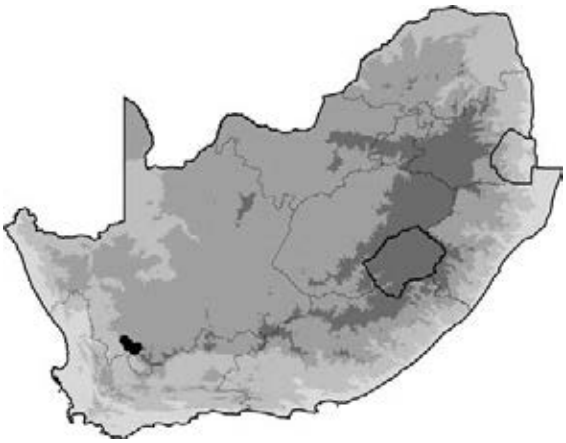
Distribution and ecology: restricted to the Bokkeveld Mtns in Northern Cape, South Africa; in rocky sandstone ground.

Diagnosis: subsp. *longibracteata* is distinguished by the long, silky hairs on the leaves and bracts, and flowers with a perianth tube hollow to the base and with a faint scent or lacking scent entirely, this in stark contrast to subsp. *sambucina*. The nearest populations of subsp. *sambucina* occur well to the south, in the Cold Bokkeveld. Subsp. *longibracteata* could equally be regarded as a separate species but the infraspecific rank recognises its close affinity with *B. sambucina*, of which it perhaps represents a series of populations in the process of evolving into a separate species evidently driven by a shift in pollination from large-bodied bees to long-proboscid flies.

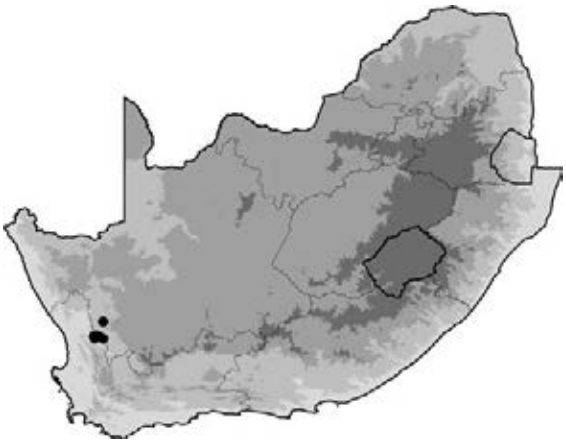
30. **Babiana radiata** *Goldblatt & J.C.Manning* in Strelitzia 18: 41 (2007). Type: South Africa, Western Cape, Little Karoo, near De Rust, Farm Mons Ruber, sandy flats at foot of Enon Conglomerate ridge, 18 Sept. 2002, *P. Goldblatt & L.J. Porter 12187* (NBG, holo.; K, MO, PRE, WAG, iso.).

Plants 100–180 mm high, including leaves. *Stem* subterranean, mostly unbranched, sheathed by collar of coarse, brittle, fibres. *Leaves* in basal tuft, narrowly lanceolate to ± linear, up to 180 mm long and exceeding spike, 2–4(–7) mm wide, nearly plane, finely hairy. *Spike* inclined, 4- to 6-flowered; bracts pale green, dry and light brown at tips, shortly attenuate, finely hairy, 25–35 mm long, inner ± as long as outer, forked at apex. *Flowers* actinomorphic, salver-shaped, tepals forming shallow bowl, pink-purple with red centre and throat, sometimes with median white, linear to diamond-shaped median mark in red zone, sweetly scented during day; perianth tube 30–37 mm long, cylindric, straight or slightly curved, flared outward in upper 6 mm, with thick walls tightly enclosing style, upper quarter containing nectar; tepals lanceolate to spathulate, ascending below, spreading distally, subequal, 28–37 × 10–12 mm. *Stamens* symmetrically arranged, erect; filaments ± 9 mm long, purple; anthers 8–10 mm long, diverging, violet; pollen whitish. *Ovary* smooth; style erect, purple, dividing opposite lower ⅓ of anthers, branches 4–5 mm long. *Flowering time*: mid-August to mid-September.

Distribution and ecology: a very narrow endemic from near De Rust in the central Little Karoo in Western Cape, South Africa; on sandy flats in succulent karoo vegetation.



Distribution of ***Babiana radiata***.



Diagnosis: *Babiana radiata* is recognised by the radially symmetric flower with a pink-purple perianth, the tepals forming a shallow bowl, and short style with the branches extending between the lower parts of the anthers. The stem is subterranean, only the spike is held above ground, and the linear leaves are 2–4(–7) mm wide, usually bearing fine long hairs. The large soft, pale green floral bracts, the inner of which is forked apically, and smooth ovary place the species in sect. *Teretifolieae*, where it may be most closely related to the widespread *B. sambucina*. That species has broader, noticeably pleated leaves, usually shortly hairy to scabrid leaves and zygomorphic flowers, usually blue to violet with the lower lateral tepals boldly marked in the centre with white blotches outlined in darker blue or rarely red-purple. The radially symmetric flower of *B. radiata* is an independent development in the section.

31. **Babiana virginea** *Goldblatt* in Journal of South African Botany 45: 82 (1979); Goldblatt & Manning: 42 (2007). Type: South Africa, [Northern Cape], Roggeveld Escarpment west of Middelpos, farm Rooiwal, Sept. 1974, *M. Thomas* sub *P. Goldblatt s.n.* (MO, holo.; K, NBG, PRE, S, iso.).

Plants 100–180 mm high, including leaves. *Stem* subterranean or barely raised above ground, usually unbranched. *Leaves* lanceolate, pleated, finely hairy, exceeding the flowers. *Spike* 2- to 4-flowered; bracts mostly 25–45 mm long, but lowermost up to 80 mm, densely hairy, green with brown, attenuate tips, inner forked at apex. *Flowers* zygomorphic, white or pale mauve with pale yellow or cream-coloured blotches on lower lateral tepals, intensely fragrant; perianth tube 45–65 mm long, gradually flaring from base, straight; tepals unequal, dorsal 35–40 mm long, lower directed forward, 30–35 mm long. *Stamens* unilateral; filaments arched, 15 mm long; anthers 9–11 mm long, pale yellow. *Ovary* smooth; style dividing opposite anther tips, branches spreading, ± 5 mm long, expanded at tips. *Flowering time*: mainly September.

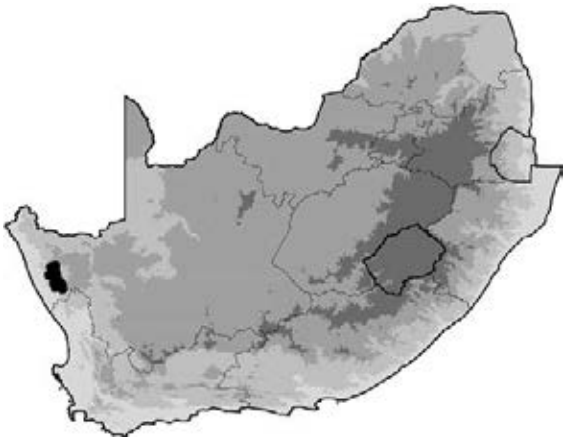
Distribution of ***Babiana virginea***.

Distribution of ***Babiana rigidifolia***.

Distribution and ecology: centred on the Roggeveld Escarpment in Northern Cape, South Africa, extending from near Middelpos southward to Matjiesfontein in Western Cape; in stony ground, often in dolerite outcrops with the corms wedged in cracks.

Diagnosis: an acaulescent species, *Babiana virginea* has densely hairy, lanceolate leaves exceeding the typically white but sometimes pale mauve flowers. The flowers are large, with a tube up to 65 mm long and dorsal tepal 35–40 mm long, and have a strong, clove-like fragrance suggesting moth pollination. *Babiana virginea* is perhaps most closely related to the widespread, blue-flowered *B. sambucina*, also acaulescent, and can be distinguished from that species by the leaf vestiture, usually almost smooth or sparsely scabrid. The lowermost outer floral bract in *B. sambucina* is produced upward as a small leaf, a feature sometimes weakly developed in *B. virginea*.

32. **Babiana rigidifolia** *Goldblatt & J.C.Manning* in Strelitzia 18: 44 (2007), as new name for *B. sambucina* var. *unguiculata* G.J.Lewis: 95 (1959) [not *B. unguiculata* G.J.Lewis]. Type: South Africa [Western Cape], top of Botterkloof Pass, 20 Sept. 1952, *G.J. Lewis 2650* (SAM, holo.).



Plants 150–200 mm high, including leaves. *Stem* reaching up to 100 mm above ground level, ± erect, simple or 1- or 2-branched, smooth, sheathed below by dense collar of coarse fibres. *Leaves* sword-shaped to lanceolate, attenuate, usually exceeding spike, mostly 9–16 mm wide, pleated, softly hairy to glabrescent, apices firm and pungent, on drying veins and margins prominent and hyaline. *Spike* compact, several-flowered; bracts green, becoming brown at tips, minutely velvety, attenuate, outer 25–45 mm long (but lowermost often longer), lightly keeled, inner 2-keeled, slightly shorter than outer, forked apically. *Flowers* zygomorphic, violet, lower lateral tepals with narrow median white streak or blotch, unscented; perianth tube elongate, 45–55 mm long, slightly curved upward; tepals unequal, markedly narrowed in lower half, dorsal tepal 35–43 × 8–12 mm long, slightly longer than lower 3, lower tepals joined to upper laterals for 3–5 mm and to one another for ± 2 mm, forming a prominent lip, 27–40 × 6–10 mm. *Stamens* unilateral; filaments 18–20 mm long; anthers ± 8 mm long. *Ovary* smooth; style usually dividing opposite anther tips, branches ± 4 mm long. *Flowering time*: late August and September.

Distribution and ecology: restricted to the Bokkeveld–Stinkfontein Mtn complex between Nieuwoudtville and Botterkloof in Northern Cape, South Africa; in crevices in sandstone outcrops and rocky pavement.

Diagnosis: striking in its deep violet flowers, *Babiana rigidifolia* is recognised by the elongate perianth tube, 45–50 mm long, lower tepals joined to the upper laterals and forming a prominent lip 5–7 mm long, and rigid, velvety to almost smooth leaves with pungent tips. The leaves are fairly broad, up to 16 mm wide, strongly pleated and are held in a tight, erect fan. With their firm tips the leaves recall those of the Namaqualand *B. dregei*, but that species has smooth to glabrescent leaves with cartilaginous hyaline veins and margins and a particularly horny, pungent tip. The flowers are similar but somewhat smaller, with the dorsal tepal 18–28 × 8–10 mm, and the lower lateral tepals have prominent white median blotches. On drying, the major veins and margins of the leaves of *B. rigidifolia* appear prominent and hyaline, plants then even more closely resembling those of *B. dregei*.

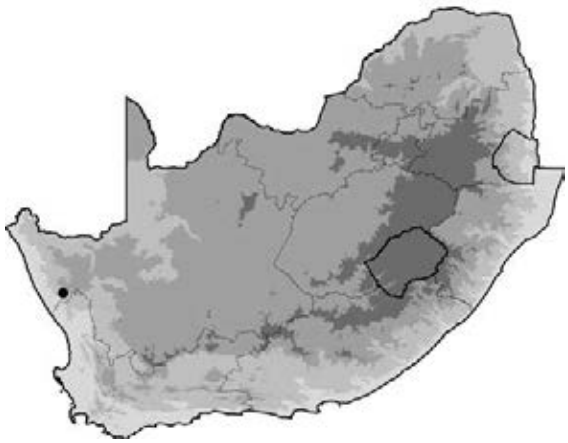
33. **Babiana dregei** *Baker* in Journal of Botany, British and foreign 14: 336 (1876); Lewis: 106 (1959); Goldblatt & Manning: 44 (2007). Type: South Africa, [Northern Cape], Namaqualand, Uitkomst, Oct. 1830, *J.F. Drège 2628* (K, holo.; B, MO, P [3 sheets], iso.).

Plants ± 120–350 mm high, including leaves. *Stem* aerial, reaching shortly to well above ground, arching outward below spike, usually branched, sometimes repeatedly, angular, smooth (or minutely hairy on spike axis). *Leaves* sword-shaped to lanceolate in a tight fan, (5–)10–20(–

Distribution of ***Babiana dregei***.

25) mm wide, pleated, smooth, with prominently thickened veins and margins (these turning pale yellow on drying), apices hard and pungent. *Spike* compact, several-flowered; bracts green or with dry tips, minutely puberulous, or velvety, outer 35–60 mm long, keeled, inner 5–10 mm shorter, forked apically. *Flowers* zygomorphic, dark blue to violet or magenta purple with white splashes edged in darker colour on lower lateral tepals, unscented; perianth tube elongate, (45–)50–65(–70) mm long, straight or slightly curved near throat; tepals unequal, dorsal 18–28 mm long, lower three slightly shorter, joined to upper laterals for 2 mm in a lip. *Stamens* unilateral; filaments 11–15 mm long; anthers ± 8 mm long. *Ovary* smooth; style usually dividing between middle and shortly beyond anther tips, branches 3–4 mm long. *Flowering time*: mainly late August and September.

Distribution and ecology: centred in the Kamiesberg highlands of Namaqualand, Northern Cape, South Africa, extending from Mesklip, south of Springbok, to Garies; always in granite outcrops.



Diagnosis: the very distinctive *Babiana dregei* has striking, hard-textured, lanceolate leaves with a prominent, spiny, piercing apex and is a robust species, plants reaching up to 350 mm in height and producing numerous flowers on branched stems. The leaves have prominent, pale fibrous veins at the angles of the folds or pleats and are usually smooth but sometimes finely hairy. The flowers, with an elongate perianth tube, typically 50–65 mm long, are pollinated by the long-proboscid fly, *Prosoeca peringueyi*.

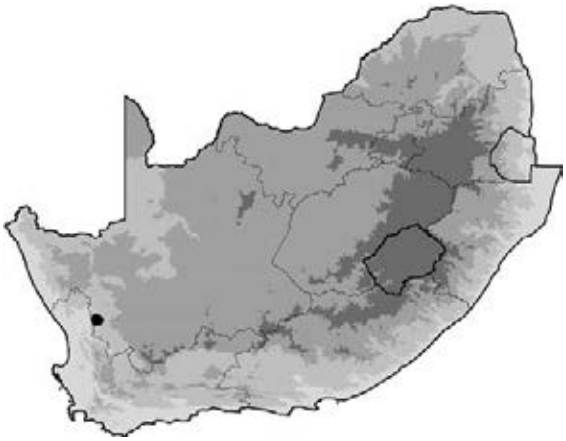
34. **Babiana rivulicola** *Goldblatt & J.C.Manning* in *Bothalia* 42: 137 (2012). Type: Northern Cape, southern Kamiesberg, Long Kloof, ± 20 km from Doringkraal turnoff from N7, Farm Nartjiesdam, in crevices in rocky bed of perennial stream, 22 Sept. 2010, *Goldblatt & Porter 13572* (NBG, holo.; K, MO, PRE, iso.).

Plants up to 300 mm high, excluding longer leaves, growing in dense clumps. *Stem* simple or 1- or 3-branched, slightly angled. *Leaves* mostly 6 or 7, linear, 250–450 × 5–10 mm, exceeding stem, firm but arching toward ground, shallowly pleated to almost flat, smooth. *Spike* flexed outward with flowers initially in two ranks, mostly 6- to 9-flowered; bracts green below, dry and light brown toward tips, outer mostly up to 35 mm long but lowermost much longer, attenuate, inner ± ⅔ as long as outer, 2-keeled, forked apically, tips attenuate. *Flowers* zygomorphic, pale blue to blue-mauve, paler in throat, lower 3 tepals with central, white, lanceolate blotch and darker violet marks near base, darkly lined on abaxial side of throat, lightly sweet-scented; perianth tube funnel-shaped, 42–44 mm long, lower part cylindric, upper ± 10 mm expanded into wide throat; tepals lanceolate, unequal, dorsal ± 30 × 8 mm, lower 3 tepals united with upper laterals for ± 3 mm, arching outward, 25 × 6 mm. *Stamens* unilateral; filaments straight, suberect, ± 15 mm long, included in floral cup; anthers ± 5 mm long, pale mauve; pollen white. *Ovary* smooth; style dividing opposite or slightly beyond anther tips, branches ± 5 mm long, recurved distally. *Flowering* mid- to late October.

Distribution and ecology: known only from the southern Kamiesberg in Northern Cape, South Africa; in cracks in granite bedrock in streams.

Diagnosis: *Babiana rivulicola* most closely resembles a second, more widespread Namaqualand endemic, *B. dregei*, both species having an aerial stem, smooth leaves, stem and bracts, and flowers with a long perianth tube. The leaves of *B. dregei* are broadly lanceolate and rigid with sharply pungent tips and the short stem is concealed among the leaves, whereas the stem reaches up to 300 mm high in *B. rivulicola* and the linear leaves are longer and relatively softly textured, with acute but not pungent tips. The flowers of the two species are broadly similar, ± funnel-shaped with the lower two thirds of the perianth tube cylindric, but *B. dregei* has a ± cylindric perianth tube (45–)50–65(–70) mm long, curved just below the apex, unlike the shorter, funnel-shaped perianth tube of *B. rivulicola*, 42–44 mm long. Additional floral differences include the longer anthers, ± 8 mm

Distribution of ***Babiana rivulicola***.



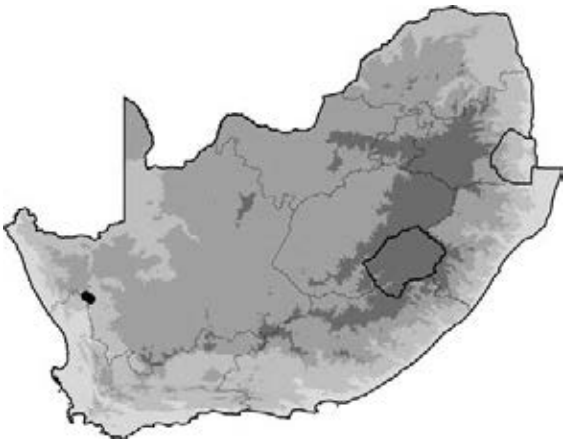
long and shorter style branches, 3–4 mm long in *B. dregei* vs. anthers ± 5 mm long and style branches ± 5 mm long in *B. rivulicola*. *Babiana dregei* occurs on dry, stony slopes close to sites where *B. rivulicola* grows but is in fruit when *B. rivulicola* comes into flower.

35. **Babiana framesii** *L.Bolus* in South African Gardening and Country Life 22: 276 (1932b); Lewis: 97 (1959); Goldblatt & Manning: 45 (2007). Type: South Africa, [Northern Cape], near Nieuwoudtville [as Klawer], cultivated at Kirstenbosch Gardens, September 1927, *P. Ross Frames s.n. as Natl. Bot. Gard. 1244/26* (BOL, holo.).

Plants 100–200 mm high. *Stem* short, reaching up to 20 mm above ground, simple or often with 1 or 2 short branches, sheathed below by thick collar of compact fibres. *Leaves* crowded basally, lanceolate, pleated, shortly hairy. *Spike* compact, suberect, 4- to 8-flowered; bracts green with dry tips turning brown with age, with short and long silky hairs, 40–50 mm long, inner ± as long as outer, forked apically. *Flowers* zygomorphic, dark blue-purple, lower lateral tepals with arrow-shaped white markings in midline, lightly sweet-scented; perianth tube 60–70 mm long, cylindric, slightly curved below throat; tepals subequal or dorsal up to 3 mm longer, 23–33 × 5–9 mm, spreading nearly horizontally. *Stamens* unilateral; filaments suberect, 10–12 mm long; anthers 7–9 mm long. *Ovary* smooth; style dividing opposite upper ⅓ of anthers, branches ± 4 mm long. *Flowering time*: August to mid-September.

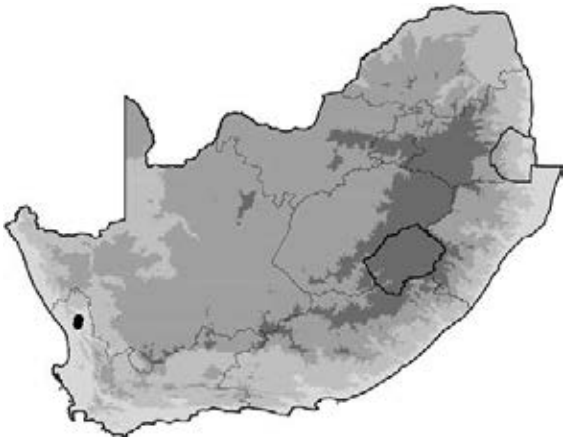
Distribution and ecology: restricted to the Bokkeveld Plateau in the vicinity of Nieuwoudtville in the western Karoo, Northern Cape, South Africa; in dolerite rock outcrops in karroid scrub.

Diagnosis: *Babiana framesii* is most easily identified by its short stem, reaching no more than 20 mm above ground, tight fan of basal leaves, and ± erect spike with silky bracts 40–50 mm long. The flowers are deep violet-blue and have an elongate perianth tube 60–70 mm long, slightly curved at the throat. The lower tepals have bold white markings in the midline outlined in darker blue or red and the tepals are relatively narrow, 5–9 mm wide, and spread almost at right angles to the tube when the flowers are fully open. The stamens are held erect with the filaments exserted ± 10 mm from the tube and the anthers are 7–9 mm long. *Babiana framesii* is well known from the immediate vicinity of Nieuwoudtville, where it is often difficult to distinguish from the long-tubed *B. sambucina* subsp. *longibracteata*. The latter has a straight perianth tube, broader tepals mostly 8–12(–16) mm wide, and even when the flowers are fully open, the tepals may overlap one another and remain slightly ascending, unlike the outspread, widely separate tepals of *B. framesii*. The perianth tube of *B. sambucina* subsp. *longibracteata* is 30–55 mm long, shorter than that of *B. framesii*.



Distribution of ***Babiana framesii***.

Namaqualand plants treated by Lewis (1959) as *Babiana framesii* var. *kamiesbergensis* are now included in *B. curviscapa*, which also has the stem produced shortly above ground and, unless growing under shrubs, has the spike strongly arched toward the ground. The perianth tube is shorter than that of *B. framesii*, 36–43 mm long, and is sharply curved below the apex.



36. **Babiana symmetrantha** *Goldblatt & J.C.Manning* in Goldblatt *et al*., Bothalia 38: 49 (2008). Type: South Africa, Western Cape, Loeriesfontein, summit plateau of the Langberg among dolerite boulders, 5 Sept. 2006, *Goldblatt & Porter 12772* (NBG, holo.; K, MO, PRE, S, iso.).

Plants 100–200(–300) mm high, including leaves, often in small clumps. *Corm* with fibrous tunics. *Stem* subterranean or reaching above ground when growing through vegetation, producing slender cormlets in lower axils, simple or 1-branched, enclosed below by collar of brittle fibres. *Leaves* linear, exceeding flowers, up to 200 × 2–5(–8) mm, flat, sparsely pubescent. *Spike* 2- or 3-flowered; bracts green, becoming dry and brown at tips, 30–35 mm long, finely hairy, long-attenuate, inner slightly shorter than outer, 2-keeled, forked apically. *Flowers* actinomorphic, salver-shaped, tepals spreading when fully open, violet with darker violet marks near tepals bases, sometimes lower lateral tepals marked white outlined violet, sweetly scented of violets; perianth tube cylindric, 45–60(–75) mm long, straight, slightly expanded in upper 10 mm, hollow above but with thick walls tightly enclosing style in lower half; tepals subequal, lanceolate, (22–)28–35 × 5–7 mm, inner tepals narrower than outer. *Stamens* symmetrically arranged, erect; filaments ± 10 mm long, exserted ± 7 mm, purple; anthers ± 6 mm long, contiguous at tips, white; pollen white. *Ovary* smooth; style erect, purple, dividing below base of anthers, branches 4–5 mm long, expanded in upper ⅓, arching between anthers. *Flowering time*: mid-August to mid-September.

Distribution and ecology: a narrow endemic of the summit plateau of the isolated Langberg at ± 1 000 m

Distribution of ***Babiana symmetrantha***.

Distribution of ***Babiana carminea***.

elevation, west of Loeriesfontein in Northern Cape, South Africa; in heavy red clay among dolerite boulders.

Diagnosis: *Babiana symmetrantha* is recognised by the radially symmetric, violet flowers with spreading subequal tepals and an elongate perianth tube up to 75 mm long. Plants are ± acaulescent when growing in open ground and have a hairless ovary, and inner floral bracts forked at the apex. It is one of just three species of the section with a radially symmetric perianth, the others being *B. pygmaea* and *B. radiata* but *B. symmetrantha* appears only distantly related to these species and is more likely allied to the *B. framesii–B. sambucina* group, which also has an underground stem and elongate perianth tube, but a zygomorphic perianth. *Babiana symmetrantha* is also unusual in its linear, almost plane leaves that show little hint of the characteristic pleating of most *Babiana* species. The long-tubed flowers appear to be adapted for pollination by long-proboscid flies.

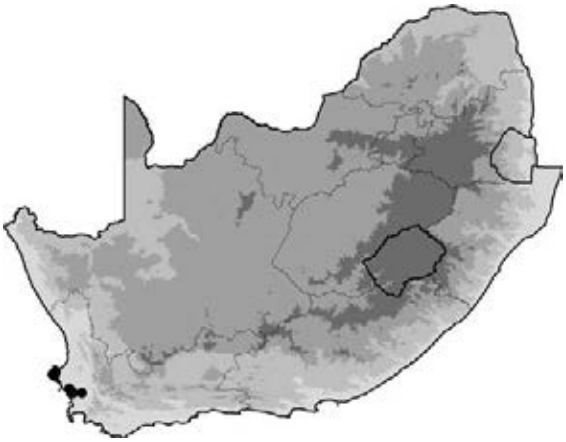
37. **Babiana carminea** *J.C.Manning & Goldblatt* in Strelitzia 18: 46 (2007). Type: South Africa, Western Cape, Vanrhynsdorp, Knersvlakte, Farm Quaggaskop, limestone ridge, 13 Aug. 1997, *P. Goldblatt & J.C. Manning 10662* (NBG, holo.; K, MO, PRE, iso.).

Plants ± acaulescent, 50–100 mm high, including leaves. *Stem* reaching shortly above ground level, unbranched, sheathed below by collar of coarse fibres. *Leaves* erect, narrowly lanceolate, up to 100 mm long, exceeding flowers, shallowly pleated, finely hairy. *Spike* decumbent, 2- to 5-flowered; bracts pale green with dry light brown tips, finely hairy, 40–50 mm long, inner slightly longer than outer, forked apically. *Flowers* zygomorphic, carmine red to red-purple, lower lateral tepals with broad, spear-shaped creamy yellow blotches, unscented; perianth tube slightly curved, 56–60 mm long, ± cylindric below, 36–40 mm long, widening abruptly and curving outward, upper 17–20 mm ± horizontal, cylindric, ± 6 mm diam.; tepals unequal, dorsal 40–48 × 9–13 mm, lower 3 tepals united basally for 2–4 mm, 35–40 × 10 mm. *Stamens* unilateral; filaments somewhat enlarged below, ± 40 mm long, exserted ± 20 mm from tube, dark pink; anthers ± 9 mm long. *Ovary* smooth; style usually dividing between base and middle of anthers, branches ± 6 mm long. *Capsules* ovoid, 10–14 mm long; mature seeds unknown. *Flowering time*: late July and August.

Distribution and ecology: a narrow endemic of the Knersvlakte in southern Namaqualand, in Western Cape, South Africa; confined to limestone outcrops, the corms tightly wedged in crevices in the rock.

Diagnosis: evidently most closely related to the other long-tubed *Babiana* species of sect. *Teretifolieae*, *B. carminea* has a spike borne at ground level, finely and shortly hairy leaves, floral bracts 40–50 mm long, and flowers with an elongate perianth tube, 56–60 mm long. The primary distinction between the long-tubed species of this alliance is in the flowers, which closely reflect their pollination ecology. *Babiana dregei* and *B. framesii* have dark blue to violet flowers with white markings, and a slender, straight or curved perianth tube of narrow diameter and both are pollinated by long-proboscid flies. In contrast, the flowers of *B. carminea* are red to reddish purple with a perianth tube that is slender below and wide and cylindric above, features typically associated with pollination by sunbirds, *Nectarinia* species. Pollination by sunbirds is an unusual strategy in the genus, shared only with the apparently distantly related *B. avicularis, B. ringens* and *B. hirsuta*. The presence of pale markings on the tepals such as found in *B. carminea* is unusual in bird-pollinated flowers, and may reflect a relatively recent shift from long-proboscid fly to avian pollination and the persistence of a feature no longer of adaptive value.

38. **Babiana tubulosa** *(Burm.f.) Ker Gawl.*, Genera iridearum 154 (1827); G.J.Lewis: 118 (1959), excluding var. *tubiflora*; Goldblatt & Manning: 47 (2007). *Ixia tubulosa* Burm.f.: 1 (1768). Type: South Africa, without precise locality or date, *N.L. Burman s.n.* (G: Herb. Burman, syn. [two sheets of four so-named]).



Gladiolus tubatus Jacq.: 6 (1795 [1788–1795]). *Babiana tubata* (Jacq.) Sweet: 396 (1826). Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 264 (1793 [1788–1795]).

Gladiolus longiflorus Andrews: t. 5 (1797), illegitimate homonym, not *G. longiflorus* P.J.Berg. (1767). Type: South Africa, without precise locality, illustration in Andrews: t. 5. (1797).

Plants 70–150 mm high. *Stem* extending shortly to up to 100 mm above ground, then lightly hairy to velvety, with a poorly developed fibrous collar around base. *Leaves* narrowly sword-shaped, 8–12 mm wide, pleated, hairy. *Spike* inclined to ± horizontal, mostly 6- to 10-flowered; bracts green with dry, brown tips, velvety, 20–40 mm long, inner ± half as long as outer, forked apically. *Flowers* zygomorphic, creamy white, pink to red outside, with triangular to spear-shaped red markings on lower lateral tepals, tepal claws ascending with limbs spreading, odourless; perianth tube 65–105 mm long, cylindric below widening in upper 15–21 mm into a distinct gullet, tepals unequal, narrowed below and ± clawed, dorsal ± 30–34 mm long, lower 3 tepals 18–23 × 8 mm. *Stamens* unilateral; filaments 20–22 mm long; anthers 5–7 mm, purple; pollen white. *Ovary* smooth; style dividing opposite or shortly above anther tips, branches ± 6 mm long. *Flowering time*: mid-September to mid-October.

Distribution and ecology: a fairly narrow endemic of Western Cape, South Africa, extending from the Saldanha Peninsula to the hills between Mamre and Darling and inland on the Paardeberg south of Malmesbury; on well-drained granite-derived slopes, granite outcrops, occasionally on limestone, or on coastal dunes.

Diagnosis: *Babiana tubulosa* is recognised by the creamy white to creamy pink flowers, usually flushed pink to red outside, with prominent red markings on the lower tepals, and the elongate perianth tube 65–105 mm long, usually expanded in the upper 8–20 mm in a wide gullet. It is often confused with white (or creamy white to pink)-flowered *B. tubiflora*, a widespread coastal species that typically has narrow, ± linear, pilose leaves, a similarly elongate perianth tube, mostly 60–80 mm long but slender throughout or only slightly expanded in the upper 5–7 mm; in addition, it has shorter filaments 13–16 mm long, a short style usually dividing opposite the base to middle of the anthers (sometimes exceeding the anther tips), and style branches 3–4 mm long. The larger flowers of *B. tubulosa* have filaments 20–22 mm long and style branches ± 6 mm long prominently displayed above the anthers.

Distribution of ***Babiana tubulosa***.

The flowers have the typical adaptations for pollination by long-proboscid flies, but floral ecology of *B. tubulosa* has not been studied.

39. **Babiana tubiflora** *(L.f.) Ker Gawl.* in Curtis's Botanical Magazine 18: t. 680 (1803e); Goldblatt & Manning: 48 (2007). *Gladiolus tubiflorus* L.f.: 96 (1782). *G. elongatus* Salisb.: 40 (1796), illegitimate superfluous name for *G. tubiflorus* L.f. *Babiana tubulosa* var. *tubiflora* (L.f.) G.J.Lewis: 120 (1959). Type: South Africa, [Western Cape], without precise locality (as Swartland), *Thunberg s.n.* (UPS–THUNB 1085, holo.).

Plants 70–150 mm high, including leaves. *Stem* ± acaulescent or reaching up to 50 mm above ground, densely white-velvety, without collar of fibres around stem base, often producing slender stolons. *Leaves* linear to sword-shaped, 3–6 mm wide (subsp. *tubiflora*) OR lanceolate, 8–12 mm wide (subsp. *saxicola*); shallowly pleated, smooth to lightly to densely hairy. *Spike* inclined to decumbent, 6- to 16-flowered; bracts with dry brown tips, velvety, 35–60 mm long, inner mostly ¼ to ½ as long, forked apically. *Flowers* zygomorphic, white, with or without small pink or red median markings on lower lateral or all 3 lower tepals (subsp. *tubiflora*) OR creamy pink to creamy white, with small pink to red markings on lower tepal (subsp. *saxicola*), tepals ascending below or spreading from base, odourless; perianth tube (45–)60–80(–100) mm long, ± straight, cylindric throughout or slightly wider in upper 5–7 mm; tepals subequal, narrowed below and ± clawed, dorsal only slightly larger, 18–23 mm long, lower 3 tepals 3–4 mm wide. *Stamens* unilateral; filaments arched, 13–16 mm long; anthers 4–5 mm, usually white. *Ovary* smooth; style dividing between lower ⅓ to shortly above anther tips, branches 3–4 mm long. *Flowering time*: mostly August to mid-September, occasionally early October.

Distribution and ecology: largely a coastal species of Western Cape, South Africa, extending from Lambert's Bay in the north to Still Bay in the southeast; on sandy, mainly coastal flats and dunes, rarely a short distance inland.

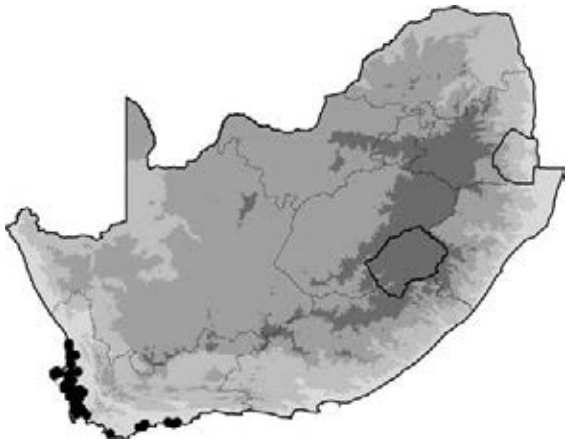
Diagnosis: usually a small plant, typical *Babiana tubiflora* is recognised by the relatively small, white to creamy white flowers, often with small red or pink markings at

the base of the lower tepal limbs, an elongate perianth tube, and often narrow, linear leaves. The perianth tube is uniformly slender or very gradually expanded toward the apex and usually 60–80 mm long but sometimes shorter or longer. The filaments are 13–16 mm long and the style branches are 3–4 mm long and often not reaching the anther tips. *Babiana tubiflora* is closely related to a second long-tubed species, *B. tubulosa*, and often confused with it. This local endemic of the Atlantic Coast and near interior of Western Cape has creamy beige to pink flowers usually flushed pink outside, prominent red markings on the lower tepals limbs, and a perianth tube 65–105 mm long that is expanded distally into a wider gullet 5–12 mm long. The longer stamens have filaments 20–22 mm long with longer anthers, and the style divides opposite or slightly beyond the anther tips with the style branches ± 6 mm long. The flowers of both species are adapted for pollination by long-proboscid flies.

Typically a plant of sandy flats and dunes, *Babiana tubiflora* flowers mainly in August and early September, but populations from granite outcrops in the Saldanha District flower later, from mid-September to late October, and have broader leaves, often longer stems and sometimes pink flowers. Flowers of these plants are flushed reddish on the outside of the tepals and have the short style branches typical of *B. tubiflora* but the style is often longer, dividing up to 4 mm beyond the anther tips. The ascending tepals, ± 20 × 3–4 mm, have weakly defined claws and the dorsal is hardly if at all differentiated from the remaining tepals. The leaves in these plants are relatively broad, up to 12 mm wide and softly hairy. These populations differ significantly from the typical white-flowered populations and are recognised as a separate subspecies.

Key to subspecies

1a Plants acaulescent or stem up to 50 mm high; leaves linear to sword-shaped, 3–6 mm wide; style dividing between base and middle of anthers; anthers usually white to pale blue-mauve . . . . . 39a. subsp. *tubiflora*



1b Plants with stems often 120–180 mm high; leaves lanceolate 8–12 mm wide; style usually dividing 2–4 mm above anther tips (or opposite lower half of anthers); anthers dark purple. . . . 39b. subsp. *saxicola*

39a. subsp. **tubiflora**

Gladiolus angustifolius Lam.: 119 (1791), as new name for *G. plicatus* Lam.: 119 (1791), illegitimate homonym, [not *G. plicatus* (L.) L. (1762)]. Type: South Africa, without precise locality or collector (P: herb. Lamarck, holo.).

Gladiolus inclinatus DC. in Redouté: t. 44 (1803), illegitimate superfluous name for *G. tubiflorus* L.f. Type: South Africa, without precise locality or collector, illustration in Redouté: t. 44 (1803).

Plants 70–150 mm high, with stem acaulescent or extending 50 mm above ground, densely pale velvety hairy. *Leaves* linear to sword-shaped, 3–6 mm wide; shallowly pleated, smooth to lightly hairy. *Spike* inclined to decumbent, mostly 6- to 12-flowered; bracts velvety, 35–60 mm long, inner ¼ to ± ½ as long as outer. *Flowers* white to creamy white, with small pink to red markings at base of lower tepal limbs; perianth tube (45–)60–80(–100) mm long, cylindric, slightly wider in upper 5–7 mm; tepals subequal, lanceolate, narrowed below and ± clawed, dorsal only slightly larger, 18–23 mm long, lower 3 tepals 3–4 mm wide. *Filaments* 13–16 mm long, exserted 7–10 mm from tube; anthers 4–5 mm long, usually white or pale blue-mauve). *Style* usually dividing opposite lower to middle ⅓ of anthers, branches 3–4 mm long. *Flowering time*: mostly August to mid-September.

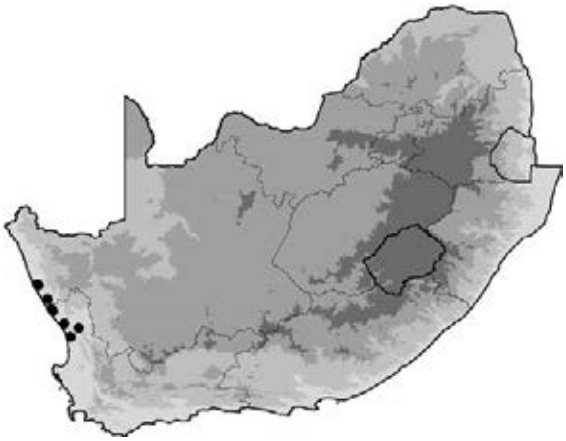
Distribution of ***Babiana tubiflora*** subsp. ***tubiflora***, ●; subsp. ***saxicola***, ○.

Distribution and ecology: as for the species; always in deep sandy ground on flats and dunes.

Diagnosis: subsp. *tubiflora* is distinguished by the white to creamy white flowers, the lower tepals clawed and often with small pink to red marks at the bases of the limbs. The anthers are white to pale mauve and the style usually divides opposite the lower to middle third of the anthers. Sample populations of subsp. *tubiflora* have proved to be self-compatible and autogamous—almost all capsules produce full complements of seeds when isolated from potential pollinators.

A local small-flowered variant from Jacobsbaai on the Atlantic Coast north of Saldanha has an unusually short tube, 40–45 mm long, and short tepals, 12 × 6 mm, not narrowed below into claws. Associated with the short tepals, the filaments are ± 6 mm long. As in typical subsp. *tubiflora*, the style divides opposite the lower third of the anthers. Only two populations of this morph are known, both comprising less than 100 plants and growing in deep sand on the foredunes. These plants have not been recognised taxonomically and we provisionally regard them to be merely a local sport or mutant. The flower dimensions are not included in the description of the species.

39b. subsp. **saxicola** *Goldblatt & J.C.Manning*, new subspecies. Type: South Africa, Western Cape, nature reserve at Langebaan, hill top among granite rocks, 8 Oct. 2014, *Goldblatt & Porter 14077* (NBG, holo., MO, PRE, iso.).



Plants 150–300 mm high, with stem extending shortly to up to 180 mm above ground, densely pale velvety hairy. *Leaves* mostly lanceolate, 8–12 mm wide, softly hairy. *Spike* inclined, mostly 10- to 16-flowered; bracts velvety, 20–45 mm long, inner ± half as long as outer, united basally around ovary. *Flowers* creamy pink to ± beige, pink to red outside, with triangular to spear-shaped red markings in middle of lower tepals and small red streaks at bases; perianth tube 65–75 mm long, cylindric slightly wider toward mouth, tepals subequal, lanceolate, dorsal and lower laterals slightly wider, obscurely narrowed below, ± 20 × 3–4 mm, lower median smallest. *Filaments* ± 12 mm long, exserted 5–6 mm from tube; anthers ± 4 mm long, dark purple; pollen pale purple. *Style* dividing 2–4 mm beyond anther tips (rarely opposite lower half of anthers), branches 2.5–3.5 mm long. *Flowering time*: mid-September to late October.

Distribution and ecology: local in the Saldanha District of Western Cape, South Africa, near Langebaan and in the West Coast National Park; on granite outcrops, corms wedged in rocks.

Diagnosis: subsp. *saxicola* is recognised in *B. tubiflora* by the stems usually extended well above ground, and by the lanceolate leaves up to 12 mm wide and softly hairy. The flowers are creamy pink to pale pink with tepals and tube flushed reddish outside, and have the short style branches typical of *B. tubiflora* but the style is often longer, dividing up to 4 mm beyond the anther tips. The tepals, ± 20 × 3–4 mm, are more-or-less straight and the dorsal is hardly if at all differentiated from the remaining tepals. The late flowering time and habitat in granite outcrops also differ from subsp. *tubiflora*, which grows on sandy ground.

40. **Babiana brachystachys** *(Baker) G.J.Lewis* in Flowering Plants of South Africa 14: 338 (1934a); Goldblatt & Manning: 48 (2007). *Acidanthera brachystachys* Baker: 338 (1876). Type: South Africa, [Western Cape], without precise locality [collected in 'Clanwilliam District'] or date, *P.A. Mader sub P. MacOwan 2183* (K, holo.).

Plants 200–300 mm high. *Stem* mostly underground or very short, often branched, sheathed by long-hairy to somewhat cobwebby cataphylls. *Leaves* leathery, linear to ± terete with longitudinal grooves, smooth, sheaths ciliate on margins, cobwebby below. *Spike* horizontal, 5- to 10-flowered; bracts green, drying brown at tips, smooth, 22–35 mm long, inner ± as long as outer, forked in upper ⅓. *Flowers* weakly zygomorphic, pale pink, lower tepals with red triangular marks on lower midline, darker pink outside, odourless; perianth

Distribution of ***Babiana brachystachys***.

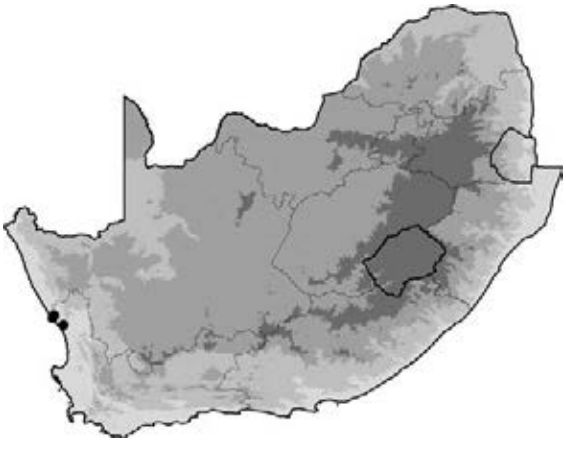
tube cylindric, 70–75 mm long, slightly curved toward apex; tepals subequal, spreading at right angles to tube, 16–24 mm long. *Stamens* unilateral; filaments 4–5 mm long; anthers ± 5 mm long. *Ovary* smooth; style dividing opposite anther apices, branches ± 2.5 mm long. *Flowering time*: September and October.

Distribution and ecology: western South Africa, extending from Wallekraal in Namaqualand, Northern Cape, to near Lambert's Bay in Western Cape; on sandy slopes and dunes inland of the coast.

Diagnosis: unmistakable in the linear to nearly terete leaves with narrow longitudinal grooves, and the horizontal spikes bearing pale pink flowers with an elongate, slender perianth tube 70–75 mm long, *Babiana brachystachys* is a remarkable plant. The unusual flowers suggest pollination by long-proboscid flies, which pollinate flowers of several species with this shape and colour. Apart from the evident close relationship to *B. teretifolia*, its affinities are uncertain and we suggest that it may be allied to the large group of *Babiana* species with a similar largely underground stem, decumbent spike and inner bracts divided in the upper third. The cobwebby to woolly cataphylls of *B. brachystachys* are remarkable for the sect. *Teretifolieae* and recall the predominantly Namaqualand sect. *Antholyzoides*. Although known originally only from the sandveld east of Hondeklipbaai near Wallekraal, *B. brachystachys* has since been recorded at several localities to the south, including near the Groen River Mouth, Brand-se-Baai, Vredendal and Lambert's Bay.

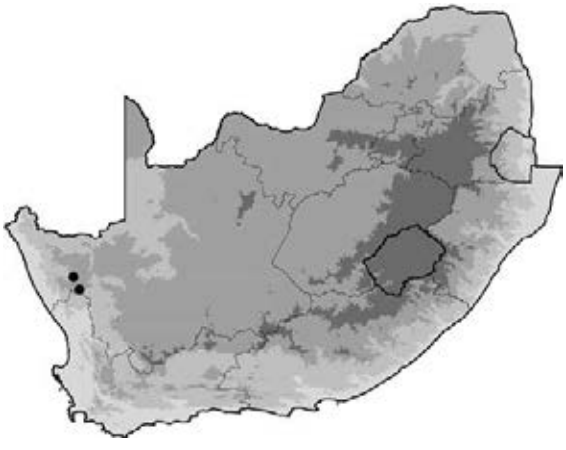
41. **Babiana teretifolia** *Goldblatt & J.C.Manning* in Bothalia 40: 51 (2010). Type: Western Cape, Vanrhynsdorp, southern Namaqualand, Farm Kommandokraal, NW of Vredendal, 10 Sept. 2008, *Goldblatt & Porter 13101* (NBG, holo.; MO, iso.).

Plants acaulescent, up to 300 mm high, including leaves. *Stem* smooth or sparsely hairy, usually 1- or 2-branched, occasionally reaching shortly above ground, with cata-



phylls and dry leaf sheaths forming a collar around base. *Leaves* ± 8, oval to round in section, ± 2 × 1.3–1.6 mm, narrowly 2-grooved on wider surfaces, 1-grooved on narrow surfaces, margins sparsely hairy below. *Spike* decumbent, crowded, secund in 2 ranks, up to 10-flowered; bracts green with rust-brown at tips, acute-attenuate, 18–25 mm long, inner ± as long as outer, forked apically for 3–4 mm. *Flowers* zygomorphic, predominantly pink, beige toward tepal bases, lower 3 tepals with narrow diamond-shaped markings in lower midline, red in throat, tepals ± uniformly pink outside; perianth tube cylindric, slender, 65–70 mm long, hollow, slightly curved; tepals narrowly linear and twisted, spreading with dorsal held slightly apart from upper laterals, ± 30 × 4 mm, upper lateral and lower tepals ± 26 × 2.5 mm. *Stamens* unilateral; filaments ± 12 mm long, inserted ± 2.5 mm below mouth of tube; anthers 5.5–6.0 mm long, white; pollen white. *Ovary* smooth; style arching over stamens, dividing at or shortly beyond anther tips, branches ± 5 mm long, notched apically. *Flowering time*: September.

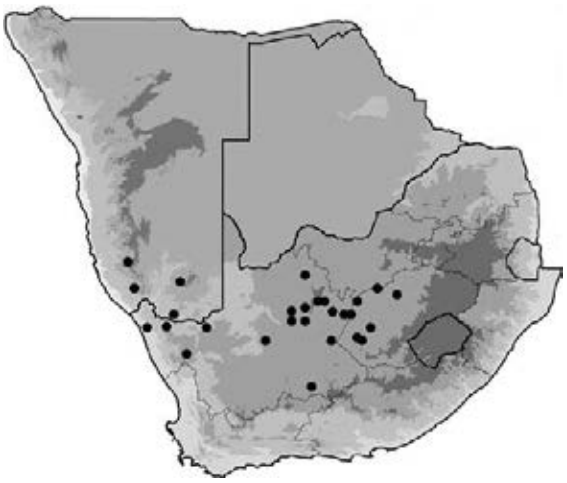
Distribution and ecology: known from a single extended population on the Farms Kommandokraal and Skilpadvlei near Lutzville, Western Cape, South Africa; in deep sand in coastal sandveld.



Diagnosis: in its subterete leaves and crowded, decumbent spikes of extremely long-tubed flowers, *Babiana teretifolia* superficially appears to be merely a variant of *B. brachystachys*, a species centred in coastal Namaqualand and extending south to near Lambert's Bay in Western Cape. The flowers, however, differ in several respects, especially in the remarkably narrow, channelled, spreading and twisted tepals, with the dorsal tepal hardly differentiated from the remaining five. The dorsal tepal is ± 30 × 4 mm and the remaining tepals ± 26 × 2.5 mm, whereas typical *B. brachystachys* has oblong-lanceolate, ± plane tepals, the dorsal tepal 20–24 × 6–8 mm and the lower three tepals 15–18 × 4–6 mm. These differences extend to the stamens: in *B. teretifolia* the filaments are ± 12 mm long and exserted ± 9.5 mm from the tube and the anthers are 5.5–6.0 mm long and white, as is the pollen, whereas *B. brachystachys* has filaments 4–5 mm long, exserted 1–3 mm, and anthers 4–5 mm long and usually pale violet to purple when fresh, as is the pollen, but occasionally white. In addition, the style of *B. teretifolia* divides opposite the anther tips so that the style branches, ± 5 mm long, arch above the anthers and can readily be seen to be notched at the tips. In *B. brachystachys* the style divides opposite the upper third of the anthers and the style branches are only ± 2.5 mm long. Added to the floral differences are the sparsely hairy leaf sheaths and flowers spaced ± 1.5 mm apart, in contrast with the woolly leaf sheaths and flowers set 3–6 mm apart in most populations of *B. brachystachys*. The extraordinarily long, linear and twisted tepals, compared to the more conventional oblong-lanceolate tepals of *B. brachystachys*, mark *B. teretifolia* as a specialised, geographic segregate of its already highly specialised sister species. The flowers of both species are adapted for pollination by long-proboscid flies.

42. **Babiana lapeirousioides** *Goldblatt & J.C.Manning* in Strelitzia 18: 49 (2007); Goldblatt & Manning: 143 (2012). Type: South Africa, [Northern Cape], without precise locality, as 'Gariep,' 30 Sept. 1943, *C.L. Leipoldt s.n.* (NBG, holo.).

Plants (50–)100–200 mm high, including leaves. *Stem* reaching up to 70 mm above ground, usually simple, rarely with 1 branch. *Leaves* narrowly sword-shaped, 50–150 × 5–9 mm, rigid, plicate, pungent, smooth, primary veins thickened, pale when dry. *Spike* compact, 2- to 4-flowered; bracts (17–)20–25(–35) mm long, smooth or minutely scabrid above, closely veined, dry and brown near apex, inner slightly shorter than outer, forked apically. *Flowers* zygomorphic, white, lower tepals with red or purple markings near base, unscented; perianth tube (25–)35–43(–52) mm long, cylindric, straight, flaring slightly toward mouth; tepals subequal or upper three slightly larger, spreading, narrowly oblanceolate, (10–)14–20 × 3–4 mm. *Stamens* unilateral; filaments erect, 7–8 mm long; anthers 4.5–5.5 mm, creamy white. *Ovary* smooth; style dividing from near base of anthers to shortly beyond anther tips, branches ± 2.5 mm long. *Flowering time*: late September to early October.



Distribution of ***Babiana teretifolia***.

Distribution of ***Babiana lapeirousioides***.

Distribution and ecology: restricted to the dry eastern foothills of the Kamiesberg in Namaqualand, Northern Cape, South Africa; in rock outcrops.

Diagnosis: *Babiana lapeirousioides* was described from fragmentary type material said to be from 'Garip', then thought to be the Garip Hills in the western Richtersveld, but has now been recollected at Vaalputs, in the eastern foothills of the Kamiesberg at the transition into Bushmanland. It is readily recognised by the white flowers with red V-shaped markings on the lower tepals, a straight, nearly cylindric perianth tube 22–40 mm long, and long, narrow leaves with sharp, pungent tips. The flowers are typical of those adapted for pollination by long-proboscid flies. When not in flower the stiff, sharply pungent leaves of *B. lapeirousioides* are easily confused with young plants of blue-flowered *B. dregei*, which grows in similar habitats in granite outcrops at higher elevations in the Kamiesberg.

Distribution of ***Babiana hypogaea***.

43. **Babiana hypogaea** *Burch.*, Travels in the interior of southern Africa 2: 589 [415 in reprinted edition] (1824); Goldblatt & Manning: 49 (2007). *Antholyza hypogaea* (Burch.) Klatt: 345 (Ergänzungen 11) (1882). Type: South Africa, [Northern Cape], Pellat Plains near Takun (or Litakun), 24 Aug. 1812, *W.J. Burchell 2241* (K, lecto., designated by Goldblatt & Manning: 92 (2004); B, P, isolecto.).

    Babiana falcata G.J.Lewis: 115 (1959). Type: South Africa, [Northern Cape], 20 miles E of Springbok, red sand flats, 8 Sept. 1950, *W.F. Barker 6671* (NBG, holo.).

    Babiana flavida G.J.Lewis: 117 (1959). Type: South Africa, [Northern Cape], Warrenton, Dec. 1922, *C.G. Adams 819* (BOL, holo.).

Plants acaulescent, 50–80 mm high, often growing in tufts with leaves up to 150 mm long. *Stem* subterranean or barely reaching above ground, simple or with short or vestigial lateral branches. *Leaves* linear to falcate or sword-shaped, often bent near base, sometimes inclined toward ground or evidently prostrate, lightly pleated, sparsely hairy to finely long-hairy, 25–150 × 1.5–3.0 mm, with firm tips. *Spike* usually arising below ground, 2- to 6-flowered; bracts 30–35 mm long, smooth, ± membranous below, green above ground level in upper ⅓, outer 25–50 mm long, inner as long or slightly longer, forked apically, attenuate. *Flowers* zygomorphic, greenish yellow to buff-coloured or ± white, flushed with light brown or blue-mauve outside, tepals darker in midline especially when dry, lower tepals marked with purple in lower half or reddish arrow-shaped marks near base and with dark reddish streaks in throat, strongly scented; perianth tube emerging from below ground level, cylindric, widening at throat, 30–40 mm long; tepals unequal, dorsal 35–42 mm long, lower tepals joined to upper laterals for up to 6 mm, forming a prominent lip, 30–35 mm long. *Stamens* unilateral; filaments 15–18 mm long; anthers 8–11 mm long. *Ovary* smooth, lower flowers of the spike shortly stalked; style dividing close to anther apices, branches ±3–4 mm long. *Flowering time*: mainly June to September, occasionally at other times depending on rainfall.

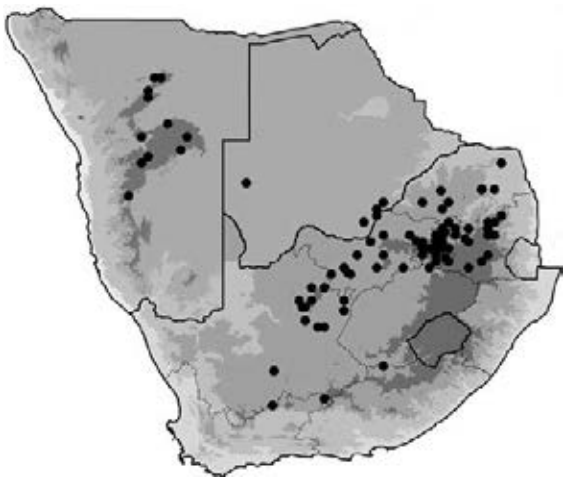
Distribution and ecology: relatively widespread, extending from southeastern Namibia to Northern Cape and Free State, South Africa, where it occurs in Bushmanland and the Upper Karoo; mostly in red sand plains.

Diagnosis: both *Babiana hypogaea* and *B. bainesii* are acaulescent plants with the long-tubed flowers arising below the ground, but those of *B. hypogaea* have a tube 30–40 mm long and shorter, often sparsely hairy to almost smooth leaves, sometimes with inclined to prostrate blades. The blades are often visibly constricted and apparently flexible at the base, which suggests an inclined to prostrate orientation even when they appear upright in pressed specimens. In contrast, *B. bainesii* has larger, blue-mauve to violet flowers with prominent white markings on the lower lateral tepals edged in darker blue, as well as nearly erect, usually densely hairy leaves, mostly 15–25 mm long. The flowers also have a tube (40–)50–60(–70) mm long, contrasting with the shorter tube of *B. hypogaea*. The shortly stipitate ovary of *B. hypogaea* and *B. bainesii* are typical of species of several genera of Iridaceae with an inflorescence borne at or below ground level and occur in other acaulescent species of *Babiana*, notably *B. sambucina*.

44. **Babiana bainesii** *Baker* in Journal of Botany, British and foreign 14: 335 (1876); Lewis: 115 (1959) [as *B. hypogea* (sic.)]; Goldblatt & Manning: 51 (2007). Type: South Africa, 'South African Goldfields', in 1870, *J.T. Baines s.n.* [K, lecto., designated by Goldblatt & Manning: 92 (2004)]. *Note:* The type was cited by Baker (1876) as having been collected in South Africa ('Transvaal') although the locality 'South

African Goldfields', given by the collector Thomas Baines, is not explicit.

Babiana bakeri Schinz: 712 (1906), as new name for *B. schlechteri* Baker: 1005 (1904), illegitimate homonym, not *B. schlechteri* Baker (1901). Type: South Africa, [Mpumalanga], near Middelburg, 22 Dec. 1893, *R. Schlechter 4055* (Z, ?holo.).



Babiana hypogea var. *ensifolia* G.J.Lewis: 114 (1959). Type: South Africa, [Eastern Cape], near Murraysburg, Aug. 1879, *W. Tyson 312* (SAM, holo.; K, SAM, iso.).

Babiana hypogea var. *longituba* G.J.Lewis: 115 (1959). Type: South Africa, [Limpopo], Mount Myorul, 29 Mar. 1894, *R. Schlechter 4729* (BOL, holo.; K, iso.).

Plants mostly 150–250 mm high (leaves only), sometimes growing in tufts. *Stem* underground, often branched. *Leaves* linear to sword-shaped, pleated, much exceeding flowers, 15–25 × 3–10 mm, densely hairy, scabrid, rarely ± smooth. *Spike* compact, at or shortly below ground level, with lower flowers shortly stalked, 2- to 8-flowered; bracts membranous to papery, with dry, rust-coloured tips or dry and rust-coloured throughout, lightly hairy, outer mostly 35–60 mm long, inner slightly shorter, forked at apex. *Flowers* zygomorphic, blue to violet or mauve, tepals paler (rarely white) toward edges, lower lateral tepals with white markings often edged in dark blue, usually sweetly scented; perianth tube mostly 40–60(–70) mm long, cylindric with expanded throat; tepals unequal, dorsal 40–50 mm long, upper laterals joined to lower tepals for ± 6 mm in a lip, lower tepals 25–40 mm long. *Stamens* unilateral; filaments 10–15 mm long; anthers 8–10(–12) mm long. *Ovary* smooth, lower flowers shortly stipitate; style usually dividing close to anther tips, branches ± 6 mm long. *Flowering time*: mainly in summer, February to April, occasionally in December or January; Upper Karoo populations in August or September.

Distribution and ecology: Botswana, Namibia, South Africa, Zimbabwe and Zambia, across summer-rainfall southern Africa from Murraysburg and Carnarvon in the Upper Karoo to southern Zambia in the northeast and northern Namibia in the northwest; on stony or sandy slopes and flats in dry grassland and bush.

Diagnosis: *Babiana bainesii* is recognised by the subterranean stem and inflorescence, the flowers thus arising shortly below ground level, and by its narrow, upright leaves, associated with blue-mauve to violet flowers with white markings on the lower lateral tepals edged in darker blue. The flowers have a perianth tube 40–55(–70) mm long and subequal tepals, the dorsal usually about as long as the tube, or slightly shorter when the tube exceeds 50 mm. The narrow leaves are linear to sword-shaped, erect and 15–25 mm long, thus much exceeding the flowers. Plants are often difficult to see among the grass where they grow, but when in bloom can often be located by their particularly strong sweet scent. Available evidence indicates that the flowers are pollinated by large-bodied bees.

Distribution of ***Babiana bainesii***.

A peculiar feature of this and the allied *Babiana hypogaea* is the underground inflorescence, a spike but with the lower flowers borne on short stalks, these sometimes resembling lateral branchlets, each bearing one or two flowers. As discussed under the preceding species, this feature is not particularly significant. Lewis (1959) treated *B. bainesii* as a synonym of the earlier *B. hypogaea*, misinterpreting the type of the latter, which flowered in winter and evidently had pale yellowish to buff-coloured flowers. That Burchell (1924) described the flower colour of *B. hypogaea* as blue was perhaps the result of basing the description on his pressed specimens in which the tepals have a dull mauve cast, as do all dry specimens of the species. This is the result of the mauve pigmentation on the outside of the tepals masking the dull yellow colouring of the inside of the tepals when dry.

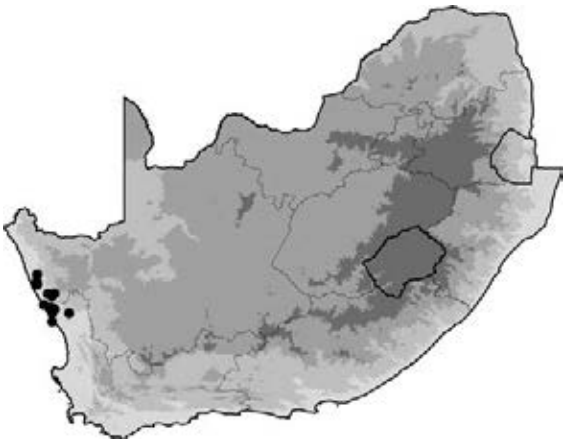
Of the two varieties of the species, var. *longituba* from the mountains of Limpopo, South Africa, was distinguished largely by an elongate perianth tube up to 70 mm long and is now included in *B. bainesii.* The long tube in these plants likely represents the extreme of a range that includes many plants with a tube 55–65 mm long. The second variety, var. *ensifolia* has comparatively short, broad leaves 50–140 × 10–14 mm, unlike the narrow, sparsely to densely hairy, narrowly sword-shaped to linear leaves, mostly 15–25 × 3–10 mm, of typical var. *bainesii.* It broadly resembles the largely southern Cape species *B. sambucina* but has the entirely subterranean inflorescence, short lateral branchlets and rust-coloured bracts typical of *B. bainesii*. These plants flower in early spring, August and September. Var. *ensifolia* is poorly documented and requires additional study before its status can be established. It is provisionally included in *B. bainesii.*

Sect. 2. **Antholyzoides** *Benth. & J.D.Hook.*, Genera plantarum 3: 707 (1883); Goldblatt & Manning: 53 (2007). Type: *Babiana ringens* (L.) Ker Gawl., lecto., designated by Goldblatt & Manning: 53 (2007).

Babiana subg. *Antholyzoides* Baker: 166 (1877), Baker: 107 (1896). Type: *Babiana ringens* (L.) Ker Gawl., lecto., designated by Goldblatt & Manning: 53 (2007).

Babiana sect. *Exohebeoides* G.J.Lewis: 126 (1959). Type: *Babiana striata* (Jacq.) G.J.Lewis

Stem well-developed, smooth or velvety hairy (*B. spiralis, B. stenomera*), main axis erect with short, horizontal lateral branches, sterile in *B. avicularis* and *B. ringens*. *Leaves* usually smooth, sometimes scabrid or long-hairy on margins. *Spike* with bracts relatively short, usually hairless, dry in upper ⅓, apiculate-attenuate, inner forked to ± middle, 2-keeled. *Flowers* zygomorphic, dorsal tepal widely separated from others, curving back and erect when fully unfolded, distinctly clawed, lower tepals usually united for some distance in a lip, clawed, lower lateral tepals with limb abruptly expanded and usually bearing a lobe or auricle on either side of base. *Stamens* unilateral; filaments arcuate; anthers oblong-linear, fused together in *B. sinuata*. *Ovary* smooth.



Species 12, mainly Namaqualand, with *B. sinuata* extending south into northern Western Cape.

Ser. **Exohebeoides** *(G.J.Lewis) Goldblatt & J.C.Manning*, name at new rank. *Babiana* sect. *Exohebeoides* G.J.Lewis: 126 (1959). Type: *B. striata* (Jacq.) G.J.Lewis

Flowers zygomorphic, shades of blue to violet or yellow, dorsal tepal longer than perianth tube and ultimately erect or recurved.

45. **Babiana spiralis** *Baker*, Handbook of the Irideae: 111 (1892); Lewis: 132 (1959); Goldblatt & Manning: 53 (2007). Type: South Africa, [Northern Cape], Namaqualand, without precise locality or date, collector uncertain, as Herb. Forsyth s.n. (K, syn. [2 sheets]).

Plants (150–)250–550 mm high. *Stem* erect, usually 2- to 6-branched, shortly velvety. *Leaves* narrowly lanceolate to linear, pleated, 1.5–2.5 mm wide, loosely to fairly tightly twisted above, often with pronounced pseudopetiole sometimes up to 40 mm long, sparsely scabrid on veins, sheath margins and upper edge of blade usually long-hairy, not cobwebby on sheaths. *Spike* 5- to 8-flowered; bracts green below, dry in upper ⅓, ± attenuate, obscurely hairy to hispid on lower midline, outer 8–10 mm long, inner slightly shorter, forked to ± middle. *Flowers* zygomorphic, blue-mauve to pink, lower tepals yellow with blue-mauve or pink tips, with strong freesia-like scent; perianth tube funnel-shaped, 8–10 mm long; tepals unequal, clawed, dorsal initially arched, later erect, 18–21 mm long, upper laterals joined to lower for ± 4 mm, lower 3 united for short distance, lower laterals abruptly expanded at top of claw, limb bases with prominent auriculate lobes. *Stamens* unilateral; filaments arched, ± 15 mm long; anthers 4 mm long. *Ovary* smooth; style dividing opposite middle of anthers, branches ± 3 mm long, spreading. *Flowering time*: August, September.

Distribution of ***Babiana spiralis***.

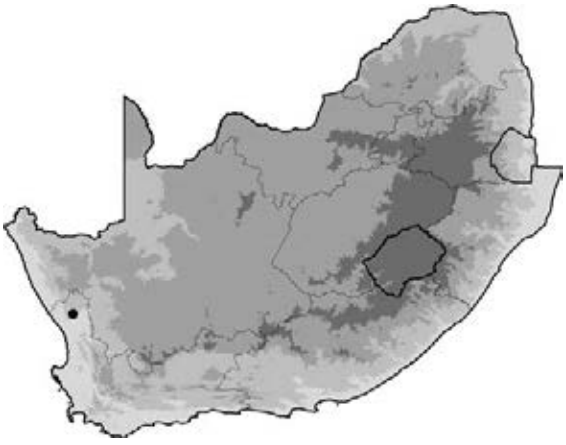
Distribution and ecology: extending from near Garies and Hondeklip Bay in Northern Cape, South Africa, south to Trawal and the Nardouw foothills in the Olifants River Valley, Western Cape; usually on sandy ground.

Diagnosis: *Babiana spiralis* is perhaps most closely related to *B. fimbriata* of central Namaqualand and it has often been confused with that species. The brightly coloured, attractive flowers, velvety hairy stem, and leaves twisted or coiled above and hairless except for a few long hairs on the margins distinguish it from *B. fimbriata*, which has dull coloured flowers, somewhat rigid, only weakly twisted leaves, a sparsely hairy or smooth stem, and upper lateral tepal limbs curving inward, very different from the ± patent tepals of *B. spiralis*. The lower lateral tepals of *B. fimbriata* also lack the auriculate lobes at the base of the limbs characteristic of most species of series *Exohebeoides*, including *B. spiralis*. Instead, the lower lateral tepals are obscurely lobed at best. The leaf sheaths and cataphylls of *B. spiralis* are not woolly or cobwebby as they are in *B. fimbriata*, and the leaf blades may have fairly well-developed terete pseudopetioles, sometimes up to 40 mm long with the broad part of the blade abruptly expanded. The ranges of the two species overlap in central Namaqualand, but *B. spiralis* has the wider distribution, extending westward to the sandy coast south of Hondeklipbaai and south to the Nardouw Mtns in Western Cape.

46. **Babiana stenomera** *Schltr.* in Botanische Jahrbücher für Systematik 27: 100 (1899); Lewis: 127 (1959); Goldblatt & Manning: 53 (2007). Type: South Africa, [Western Cape], Kareebergen, near Nuwerus, 1 200 ft [± 380 m], 17 July 1896, *R. Schlechter 8185* (B, BOL, K, MO, P, PRE, S, syn.).

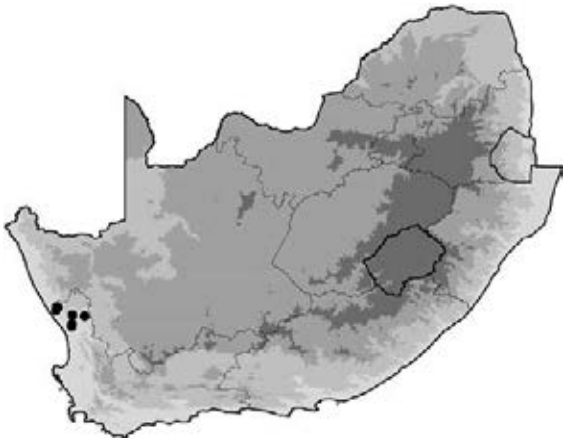
Plants 80–120 mm high. *Stem* short, erect, densely hairy above, simple or with 1 or 2 short branches, sheathed below by a thick collar of fibres; cataphylls and bases of leaf sheaths evidently smooth. *Leaves* sword-shaped, reaching ± to top of spike, mostly 4.0–5.5 mm wide, scarcely plicate, hairless or sparsely hairy on veins and sheath margins. *Spike* erect, 5- to 8-flowered; bracts evidently green with brown tips, mostly 15–20 mm long, inner shortly hairy near base and on keels, divided near apex, sometimes for almost ⅓ their length. *Flowers* zygomorphic, blue-mauve with yellow markings on lower lateral tepals; perianth tube 12–14 mm long; tepals unequal, shortly clawed, dorsal tepal 22–24 mm long, lower tepals joined to upper laterals for ± 4 mm and to one another for ± 2 mm, ± 15 mm long. *Stamens* unilateral; filaments ± 15 mm long; anthers ± 6 mm long. *Ovary* smooth; style evidently dividing opposite middle of anthers, branches ± 4 mm long. *Flowering time*: July.

Distribution and ecology: a narrow endemic of the Kareeberge near Nuwerus in southern Namaqualand, Western Cape, South Africa; on granite hills at ± 380 m elevation.



Diagnosis: *Babiana stenomera* is recognised by the floral bracts 15–20 mm long, the inner of which does not have rust-coloured, acuminate tips, and the ascending leaves are 4.0–5.5 mm wide. *Babiana stenomera* is evidently most closely related to a second Namaqualand species, *B. fimbriata*, but that species has narrower leaves, up to 3.5 mm wide, tapering and lightly twisted in the upper half, a smooth or at best sparsely hairy stem, and prominent long hairs on the edges of the leaf sheaths. The bracts of *B. stenomera* in particular, mostly 15–20 mm long, are beyond the expected range for *B. fimbriata* or for the related *B. spiralis* which has narrow, coiled leaves.

47. **Babiana lewisiana** *B.Nord.* in Botaniska Notiser 123: 436 (1970); Goldblatt & Manning: 55 (2007). Type: South Africa, [Western Cape], Vredendal, Hol River, on quartzite slope, 28 July 1962, *B. Nordenstam 787* (S, holo.; K, M, MO, NBG, iso.).



Plants 70–150 mm high. *Stem* simple or with one branch, softly hairy above, sheathed below by smooth cataphylls. *Leaves* with short pseudopetioles, blades oblong, held almost at right angles to sheaths, 10–15 mm wide, strongly ribbed but scarcely plicate, hairless or minutely hairy on margins. *Spike* 3- to 8-flowered; bracts sparsely hairy, green with attenuate, dry brown tips, often torn at apex, 15–20 mm long, inner slightly shorter than outer, forked to ± middle. *Flowers* zygomorphic, greenish yellow with purple tips; perianth tube funnel-shaped, ± 10 mm long; tepals unequal, dorsal oblong, ± 25 mm long, lower tepals joined to upper laterals for short distance, with short, well-developed claws, ± 20 mm long. *Stamens* unilateral; filaments arcuate, ± 15 mm long; anthers 5–6 mm long. *Ovary* smooth; style dividing opposite anther apices, branches ± 2.5 mm long. *Flowering time*: July and August.

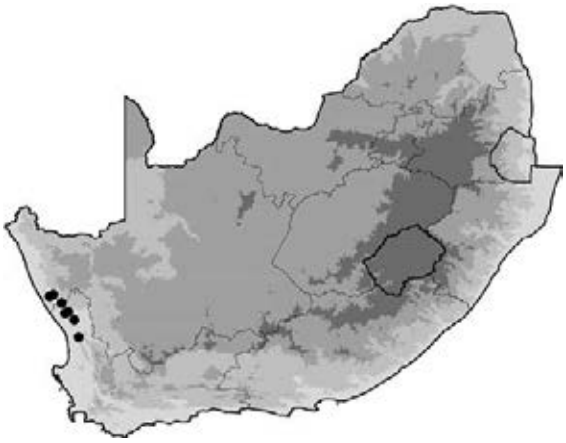
Distribution and ecology: a rare endemic of the Knersvlakte in Western Cape, South Africa, near Vredendal; on stony quartzite ground near Hol River.

Diagnosis: distinctive in the short, oblong leaf blades held at right angles to the short, erect pseudopetioles, a softly hairy stem of short stature, up to 150 mm high, and relatively long, sparsely hairy floral bracts 15–20 mm long. The greenish yellow flowers have a short perianth tube, 10 mm long, a dorsal tepal ± 25 mm long, and lower tepals ± 20 mm long with short, well-developed claws. *Babiana salteri*, also with short spreading leaves, has hairy, soft-textured leaves, inner bracts divided to the base, and a densely hairy ovary. The similarity of the short leaf blades held nearly at right

Distribution of ***Babiana stenomera***.

Distribution of ***Babiana lewisiana***.

angles to the sheaths is best seen as convergent. *Babiana lewisiana* is most likely allied to the group of species in sect. *Antholyzoides* that have a pubescent stem and lack the cobwebby to woolly hairs on the cataphylls and lower leaf sheaths. These include *B. spiralis* and *B. stenomera* but it should not be confused with either of these species because of the plane leaves with broad, oblong blades extending almost horizontally, unlike the narrow, distally coiled leaves of the latter two species.



A collection, in fruit, from granite slopes S of Kotzesrus in Northern Cape may be this species and if so would represent a significant range extension. These plants conform with *Babiana lewisiana* in the virtually hairless leaves, hairless ovary, and absence of cobwebby hairs on the cataphylls.

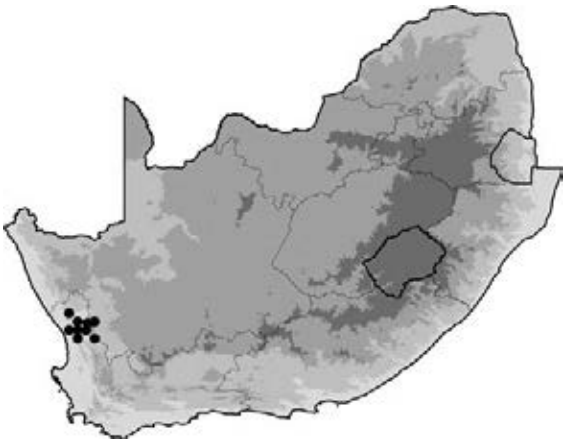
48. **Babiana fimbriata** *(Klatt) Baker* in Journal of the Linnean Society, Botany 16: 166 (1877); Lewis: 132 (1959) [including *B. spiralis*]; Goldblatt & Manning: 55 (2007). *Antholyza fimbriata* Klatt: 299 (1867). Type: South Africa, [Northern Cape], southern Namaqualand, between the Swartdoorn and Groen River, Aug. 1830, *J.F. Drège 2619* (B, holo.; K, MO, P [3 sheets], S [2 sheets]; a second sheet of *Drège 2619* at K may be *B. planifolia*).

Plants 120–200 mm high. *Stem* erect, simple or with short lateral branches, smooth or sparsely hairy in lines below bracts, sheathed below by cobwebby to woolly cataphylls. *Leaves* linear, pleated, as long as or shortly exceeding spike, 3–4 mm wide, loosely twisted above, sparsely short- or long-hairy on lightly undulate margins. *Spike* short, erect, 5- to 7-flowered; bracts smooth, green, dry and brown toward apices, 12–14 mm long, inner forked in upper ⅓, membranous in lower midline. *Flowers* zygomorphic, dull reddish purple to red-brown, greenish outside, lower lateral tepals yellow-green with purple tips, sweetly scented of freesia and vanilla; perianth tube funnel-shaped, 10–12 mm long; tepals unequal, clawed, dorsal initially arched, becoming erect, (18–)21–25 mm long, upper lateral tepals directed forward and arching slightly inward, lower tepals joined to upper laterals for ± 5 mm and to one another for ± 2.5 mm, lower laterals with conspicuous auriculate lobes at limb bases, 10–12 mm long. *Stamens* unilateral; filaments arched, 13–15 mm long; anthers 5–6 mm long, usually lilac; pollen creamy white. *Ovary* smooth; style dividing between middle and upper ⅓ of anthers, branches ± 2.5 mm long. *Flowering time*: late July to mid-September.

Distribution and ecology: a Namaqualand endemic, extending from Garies in Northern Cape, South Africa, to Nuwerus and the Knersvlakte north of Vanrhynsdorp in Western Cape; occurring on stony granite or quartzitic slopes.

Diagnosis: distinguished by the hairless or nearly hairless stem and the woolly or cobwebby cataphylls and bases of the leaf sheaths, *Babiana fimbriata* has leaves

Distribution of ***Babiana fimbriata***.



3–4 mm wide with the blades slightly twisted. The dark purple to almost brown flowers have greenish yellow lower lateral tepals with prominent auriculate lobes at the limb bases. The upper lateral tepals of *B. fimbriata* are directed forward or are slightly curved inward in the proximal half, a feature unique in the genus. *Babiana spiralis*, which has been confused with *B. fimbriata*, has smooth cataphylls and leaf sheaths, a velvety stem, and bright pink or blue flowers, also with auriculate lobes on the lower tepal limbs. The upper lateral tepals of *B. spiralis* curve outward shortly above the base in conventional subpatent orientation.

Babiana fimbriata is a fairly narrow endemic of central Namaqualand, whereas the relatively widespread *B. spiralis* favours deep sandy soils, and extends from Garies to Klawer in the south and west to the Atlantic Coast between Groen River Mouth and Kotzesrus.

49. **Babiana sinuata** *G.J.Lewis* in Journal of South African Botany, Suppl. 3: 128 (1959); Goldblatt & Manning: 56 (2007). Type: South Africa, [Western Cape], 10 miles [16 km] S of Klawer, 10 Sept. 1950, *W.F. Barker 6710* (NBG, holo.; BOL, K, SAM, iso.).

[*Babiana namaquana* Schltr. ms. Vuurfontein (?Zuurfontein), *Schlechter 10979* (B, K).]

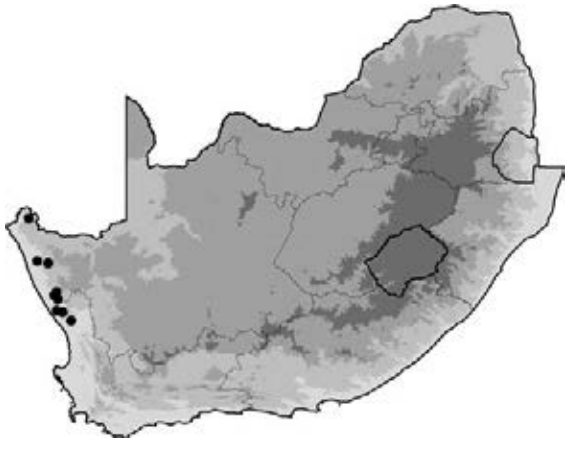
Plants 120–250 mm high. *Stem* smooth, erect, mostly 2- to 6-branched, sheathed basally by woolly or cobwebby cataphylls. *Leaves* lanceolate, with sheaths often woolly or cobwebby, blades ± plane with few prominent veins, reaching to ± base of spike, loosely twisted, undulate and crisped, margins of sheath and upper margin of blade long-hairy, margins thickened, dark green. *Spike* inclined, lax, several-flowered; bracts smooth, green below, dry and brown in upper half, 8–10 mm long, inner as long as outer, forked to ± middle. *Flowers* zygomorphic, pale blue-mauve, lower tepals yellow with pale blue tips, lower laterals also with dark violet median mark, sweetly scented; perianth tube funnel-shaped, 8–9 mm long; tepals unequal, clawed, dorsal tepal held

Distribution of ***Babiana sinuata***.

apart from others, initially arcuate, later erect, ± 28 mm long, lower 3 shortly united, 12–14 × 3 mm. *Stamens* unilateral; filaments arcuate, 20 mm long; anthers connate, ± 7 mm long. *Ovary* smooth; style mostly dividing opposite upper half of anthers, sometimes beyond anther tips, branches ± 1.5 mm long. *Flowering time*: late August to mid-September.

Distribution and ecology: extending from southern Namaqualand to Bulshoek north of Clanwilliam and in the lower Doorn River Valley east of the Nardouw Mtns, Western Cape, South Africa; on stony shale slopes.

Diagnosis: one of the most distinctive species of the genus, *Babiana sinuata* can be recognised immediately by the twisted and broadly undulate leaves with thickened, crisped margins and woolly to cobwebby cataphylls and leaf sheaths; the upper (adaxial) margins also bear fine long hairs. The moderate-sized, pale blue-mauve flowers have the upper tepals at first arching over the stamens but later becoming erect and the lower median tepal has a prominent violet central mark on a pale yellow background. Most remarkable, however, are the long, arched stamens with anthers joined together, a feature unique in the genus. The woolly cataphylls and crisped, undulate, and twisted leaves suggest a close relationship with *B. striata*, with which it has been confused. Flowering earlier in the year, *B. striata* is easy to distinguish by the more compact inflorescence of smaller flowers with the anthers parallel but not joined together, and the corm tunics of particularly coarse fibres.



50. **Babiana striata** *(Jacq.) G.J.Lewis* in Journal of South African Botany, Suppl. 3: 129 (1959), excl. var. *planifolia*; Goldblatt & Manning: 56 (2007). *Gladiolus striatus* Jacq.: 5 (1795 [1788–1795]). *Waitzia striata* (Jacq.) Heynh.: 855 (1841), illegitimate name, genus invalid. *Montbretia striata* (Jacq.) Voigt: 610 (1845). *Antholyza striata* (Jacq.) Klatt: 346 (1882). Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 260 (1793 [1788–1795]).

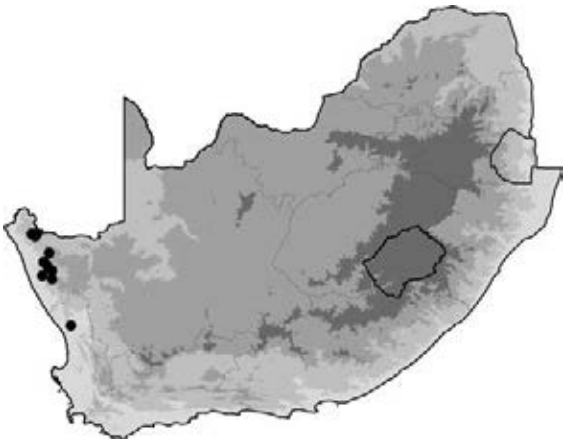
Gladiolus formosus Pers.: 44 (1805), illegitimate superfluous name for *G. striatus* Jacq. *Hebea formosa* Eckl.: 42 (1827) illegitimate name. Type: Unknown, probably illustration in Jacq.: t. 260 (1793 [1788–1795]).

Plants 80–150 mm high. *Corm* globose; tunics coarsely fibrous. *Stem* smooth, inclined, smooth, 1- or 2-branched, enclosed below ground by a thick collar of fibres and sheathed by cobwebby to woolly cataphylls. *Leaves* sword-shaped to lanceolate, margins broadly undulate and lightly crisped, twisted above, with prominent midrib, hairless or ciliate on margins, sometimes only near tips. *Spike* inclined to horizontal, 3- to 5-flowered in 2 ranks; bracts smooth, 8–15 mm long, inner forked in upper ⅓. *Flowers* zygomorphic, pale mauve or dull yellow, lower lateral tepals darker yellow-green in midline, lower median with spear-shaped, purple mark, evidently unscented; perianth tube ± 7 mm long; tepals unequal, abruptly narrowed below into claws, dorsal largest, widely arched, later curving back, 20–25 mm long, lower tepals joined to upper laterals for 3–4 mm and to one another for 3–6 mm, with prominent auriculate lobes above base of limbs, 12–14 mm long. *Stamens* unilateral; filaments ± 15 mm long; anthers 4.5–6.0 mm long. *Ovary* smooth; style dividing opposite anther bases, branches ± 2 mm long. *Flowering time*: June to late July.

Distribution and ecology: widespread in Namaqualand, Northern Cape, South Africa, extending from the southern Richtersveld to Nuwerus; on stony and gravel slopes at lower elevations, evidently uncommon.

Diagnosis: winter-flowering *Babiana striata* is recognised primarily by the unusual inclined leaves with undulate and tightly crisped margins, smooth or at most ciliate on the margins with the entire blade loosely twisted. The fairly small flowers are borne on an inclined to horizontal spike facing the spike axis, and the tepals are pale yellow, flushed light purple outside. Like most species of sect. *Antholyzoides*, the cataphylls and leaf bases are cobwebby. The species is most often confused

Distribution of ***Babiana striata***.



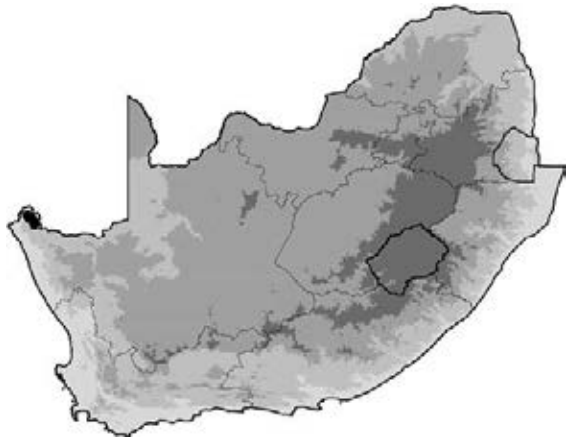
with blue-flowered *B. sinuata*, which also has similar undulate and twisted leaves but is otherwise very different. The leaves of *B. sinuata* differ in having long hairs on the margins of the sheath and upper margin of the blade, the flowers are larger, with the dorsal tepal ± 28 mm long (versus 20–25 mm in *B. striata*), and are pale blue with pale yellow lower tepals with pale blue tips, and the lower laterals have a conspicuous dark violet median mark. Even more distinctive are the stamens of *B. sinuata*, which have filaments ± 20 mm long and connate anthers, a feature that persists even in pressed specimens. The stamens of *B. striata* have filaments ± 15 mm long and the anthers free from one another. Surprisingly, given their dull colouration, the flowers of *B. striata* appear unscented, at least in the live plants examined from near Kotzesrus.

51. **Babiana planifolia** *(G.J.Lewis) Goldblatt & J.C.Manning* in Bothalia 35: 10 (2005), 57 (2007). *B. striata* var. *planifolia* G.J.Lewis: 130 (1959). Type: South Africa, [Northern Cape], 9 miles [14.5 km] W of Steinkopf, 30 June 1935, *T.M. Salter 5554* (BOL, holo.).

Plants 120–350 mm high. *Corm* globose; tunics finely fibrous. *Stem* erect, usually smooth, simple or with 1 or more short lateral branches, enclosed below ground by thick fibrous collar, cataphylls and base of leaf sheaths cobwebby to woolly. *Leaves* lanceolate to sword-shaped, plane or lightly undulate in proximal half, loosely twisted distally, blades (4–)8–16 mm long, sparsely short-hairy, often long-hairy on adaxial margins. *Spike* erect, sometimes sparsely hairy, with 3 to 8 flowers spirally arranged; bracts smooth or sparsely short-hairy, 12–24 mm long, inner forked to middle, tips attenuate. *Flowers* zygomorphic, mauve, lower lateral tepals yellow-green with mauve to purple tips; perianth tube 8–16 mm long, slender below, expanded toward apex; tepals unequal, clawed, dorsal arched, later recurving, 23–28 mm long, lower lateral tepals joined to upper laterals for 4–5 mm and to one another for ± 2 mm, 15–20 mm long. *Stamens* unilateral; filaments arched, ± 15 mm long; anthers ± 6 mm long. *Ovary* smooth; style dividing opposite middle to upper ⅓ of anthers, branches ± 3 mm long. *Flowering time*: May and June, occasionally in July.

Distribution and ecology: a Namaqualand endemic, *Babiana planifolia* extends from the southern Richtersveld to Garies and Soebatsfontein in Northern Cape, South Africa, to the northern Knersvlakte in Western Cape; on stony slopes, mainly on fine-grained soils.

Diagnosis: *Babiana planifolia* has nearly plane leaves, occasionally lightly undulate toward the base, and corm tunics of relatively fine texture. Plants have cobwebby to woolly cataphylls and lower leaf sheaths and the leaf blades are sparsely long-hairy on the veins or are virtually hairless. Like *B. striata* the stem and bracts are usually hairless and the lower lateral tepals appear to lack the prominent auriculate lobes typical of most other species of sect. *Antholyzoides*, including *B. striata*.



Distribution of ***Babiana planifolia***.

Plants from the Eksteenfontein area of the southern Richtersveld are included in *Babiana planifolia* although they have short, broad, lightly undulate leaves 35–50 × 15–20 mm, twisted in the upper half. These plants also seem to consistently differ in their short stature and long, soft, almost silky hairs on the leaf margins and upper sheaths, sometimes very conspicuous. Corms, cataphylls, and the lower leaf sheaths of the Richtersveld plants are not known and these plants are thus provisionally included in *B. planifolia*. When more specimens become available they may be found to constitute a separate taxon.

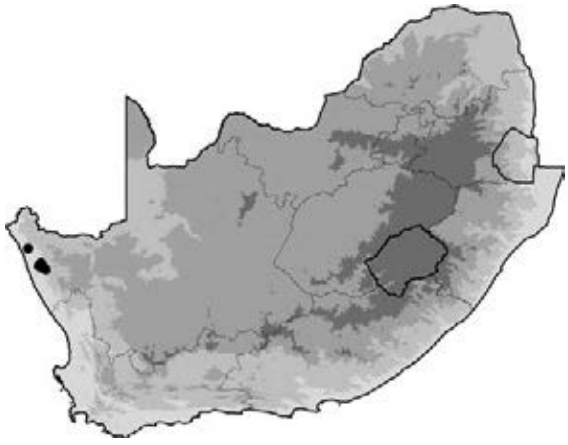
52. **Babiana lobata** *G.J.Lewis* in Journal of South African Botany, Suppl. 3: 135 (1959); Goldblatt & Manning: 58 (2007). Type: South Africa, [Northern Cape], as 'near Garies' [but certainly from the Richtersveld], 29 July 1937, *I.C. Verdoorn 1892* (PRE, holo.).

Plants 120–250 mm high, hairless throughout, with depressed globose corm up to 15 mm diam. *Stem* simple or few-branched, sometimes ± dichotomously with branches widely diverging, sheathed by smooth cataphylls, old dry leaves coiled around stem base. *Leaves* narrowly linear–sword-shaped, reaching or shortly exceeding spike, 2.5–4.0 mm wide, scarcely plicate, smooth, slightly twisted, veins thickened, prominent when dry. *Spike* inclined to ± horizontal, (4–)7- to 12-flowered; bracts subequal, smooth, dry and rust-coloured in upper ⅓, 5–8 mm long, inner ± as long or slightly longer than outer, forked apically or in upper ⅓. *Flowers* pale blue-mauve to violet, limbs of lower lateral tepals pale yellow or with mauve tips, with light acrid-metallic scent; perianth tube 7–9 mm long, funnel-shaped; tepals unequal, dorsal 18–23 × 4–5 mm, erect, later curving back in distal ⅓, lower lateral tepals joined to upper laterals for ± 5 mm and to one another for ± 3 mm, abruptly clawed at base, claws ± 2 mm long, limbs with conspicuous auriculate lobes at bases, margins lightly crisped. *Stamens* unilateral; filaments ± 15 mm long; anthers ± 4 mm long, purple; pollen cream-coloured. *Ovary* smooth; style dividing between base and middle of anthers, branches tangled

Distribution of ***Babiana lobata***.

in anthers. *Capsules* depressed-globose, ± 6 × 7–8 mm. *Flowering time*: July and August.

Distribution and ecology: endemic to the Richtersveld of Northern Cape, South Africa, extending from Armanshoek in the Richtersveld National Park to the foot of the Stinkfontein Mtns; on rocky lower slopes and flats.



Diagnosis: with blue flowers with yellow markings on the lower tepals, *Babiana lobata* is recognised by the simple or dichotomously branched stem with flowers borne on the upper side of horizontal spikes, the lower tepals with auricular lobes at the bases of the limbs. The plants are hairless throughout and the floral bracts are short, 5–8 mm long, dry distally with the inner forked in the upper third. Somewhat unusual, the dry remains of past season's leaves are twisted around the base of the stem. *Babiana lobata* has been associated with two related species, *B. fimbriata* and *B. spiralis* from central Namaqualand, both also with auriculate lobes on the lower lateral tepal limbs. *Babiana fimbriata* has leaves twisted distally, woolly–cobwebby cataphylls, and lightly hairy bracts 12–14 mm long, much exceeding those of *B. lobata*. The related *B. spiralis* has velvety hairy stems but smooth cataphylls and leaf sheaths, and bracts 8–10 mm long. The hairless habit, short floral bracts, and more-or-less divaricate branching suggest that *B. tritonioides* is most closely related to *B. lobata*. Centred in the Komaggas area of northwestern Namaqualand, *B. tritonioides* has short, relatively broad leaves, the blades borne at right angles to the sheaths and twisted or folded back on themselves in concertina fashion and is typically a shorter plant, 100–150 mm high.

53. **Babiana tritonioides** *G.J.Lewis* in Journal of South African Botany, Suppl. 3: 134 (1959); Goldblatt & Manning: 59 (2007). Type: South Africa, Northern Cape, between Brakwater and Komaggas, 31 July 1953, *W.F. Barker 6699* (NBG, holo.).

Plants 100–150(–350 under bushes) mm high. *Stem* sharply inclined, simple or with 1 or 2 widely diverging branches, sheathed by smooth cataphylls, with collar of fibres around base. *Leaves* oblong to lanceolate, blades held ± at right angles to sheaths, 40–60 × 6–10(–18) mm, scarcely plicate, undulate in concertina fashion, twisted above and erect, smooth, veins lightly thickened. *Spike* horizontal, flexuose, 7- to 10-flowered; bracts smooth, 4.0–6.5 mm long, inner forked to ± middle. *Flowers* zygomorphic, blue-mauve, lower lateral tepals yellow, sweetly scented; perianth tube narrowly funnel-shaped, 6–8 mm long; tepals unequal, clawed, dorsal 23–27 mm long, lower tepals joined to upper laterals for 3–5 mm and to one another for ± 2 mm, 12–14 mm long, lower laterals with conspicuous auriculate lobes just above limb base. *Stamens* unilateral; filaments 15–17 mm long; anthers ± 5 mm long. *Ovary* smooth; style dividing opposite middle to upper ⅓ of anthers, branches 3–4 mm long. *Flowering time*: late July to early September.

Distribution and ecology: local in northern Namaqualand in Northern Cape, South Africa, from Komaggas to Kosies, but also recorded in the southern Richtersveld from the Oograbies (or Ugrabies) Hills northeast of Port Nolloth, although this record remains to be confirmed; on stony granitic slopes.

Diagnosis: the short floral bracts, 6–8 mm long, strongly inclined, secund spike and flowers with narrow tepals suggest that *Babiana tritonioides* is closely allied to the Richtersveld species, *B. lobata*, and the two seem somewhat isolated taxonomically within sect. *Antholyzoides*. The species is especially distinctive in the ± horizontal and distally twisted leaf blades, but the lower tepals have auriculate lobes above the base characteristic of the section. Based on morphology, *B. lobata* and *B. tritonioides* appear closely related and evidently represent a northern species pair of sect. *Antholyzoides*. The short leaves of *B. tritonioides* with relatively broad blades, mostly 40–60 × 6–10 mm, held nearly at right angles to the sheaths and twisted or folded back on themselves in concertina fashion, and short stature make the species easy to distinguish from the taller *B. lobata*, which has stems 120–250 mm high and erect, linear to

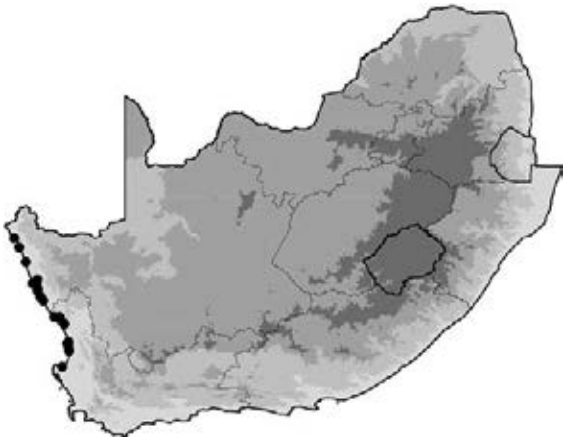
Distribution of ***Babiana tritonioides***.

narrowly sword-shaped leaves 2.5–4.0 mm wide, only lightly twisted in the upper half.

Ser. **Antholyzoides** *Goldblatt & J.C.Manning*, new series. Type: *Babiana ringens* (L.) Ker Gawl.

Flowers zygomorphic, predominantly red, lower tepals with yellow or green markings, dorsal tepal longer than perianth tube, erect and enclosing filaments.

54. **Babiana hirsuta** *(Lam.) Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 38: 53 (2008). *Antholyza hirsuta* Lam.: 201 (1783). *Gladiolus sulcatus* Lam.: 119 (1791), illegitimate superfluous name for *A. hirsuta* Lam. Type: without locality or collector, 'antholyza hirsuta. encycl.' as written on herbarium sheet, (P: Herb. Lamarck, holo.).



Babiana thunbergii Ker Gawl.: 233 (1804), as a new name for *Antholyza plicata* L.f.: 96 (1782) [not *B. plicata* Ker Gawl. 1802a]; Goldblatt & Manning: 60 (2007). *Anaclanthe plicata* (L.f.) N.E.Br.: 269 (1932a). *Gladiolus mollis* Vahl: 119 (1805), as a new name for *Antholyza plicata* L.f. [not *G. plicatus* L. (1762)]. Type: South Africa, [Western Cape], dunes near the coast below Verlorenvlei, Oct. 1774, *C.P. Thunberg s.n.* (UPS–THUNB 1104, holo.).

Anaclanthe namaquensis N.E.Br.: 269 (1932a). *Antholyza namaquensis* (N.E.Br.) Goldblatt: 444 (1971). Type: South Africa, [Northern Cape], dunes near Port Nolloth, Sept. 1883, *H. Bolus* sub *Herb. Norm. Austr. Afr. 669* (BOL, K, syn.).

[*Antholyza hirta* Pers.: 42 (1805), invalid name only in synonymy.]

Plants 400–700 mm high. *Stem* erect, densely hairy, with several, short, horizontal branches. *Leaves* lanceolate, firm, pleated, minutely hairy or scabrid. *Spikes* horizontal, crowded, many-flowered; bracts smooth or minutely hairy, green with dry brown tips, outer 18–30 mm long, inner slightly shorter, divided to ± middle, transparent in midline, prominently 2-veined. *Flowers* zygomorphic, facing spike apex, bright red, lower tepals yellow marked with green to black at base, unscented; perianth tube narrowly funnel-shaped, expanded in upper half, curving upward away from spike apex, 30–40 mm long; tepals unequal, ± clawed, dorsal 16–20 mm long, erect, margins curving inward enclosing filaments, lower tepals united with upper laterals for ± 6 mm in a prominent lip, lower and upper laterals ± 8 mm long. *Stamens* unilateral; filaments straight, erect, unilateral, 37–40 mm long, enclosed by upper tepal; anthers 5–7 mm long. *Ovary* smooth; style dividing between base and middle of anthers, branches ± 4 mm long. *Flowering time*: mainly July to October.

Distribution and ecology: common along the Atlantic Coast of Northern and Western Cape, South Africa, from the mouth of the Orange River southward to Britannia Bay near Saldanha but so far not recorded further north in adjacent southwestern Namibia; on sandy coastal flats and dunes, often common and making a striking display when in full bloom.

Distribution of ***Babiana hirsuta***.

Diagnosis: one of the most robust species of the genus, *Babiana hirsuta* is usually 0.35–0.50 m high but may reach 1 m when growing through low bush. The bright red flowers are distinctive in the large, erect dorsal tepal with the margins loosely curving together and enclosing the filaments and style. The anthers and style extend beyond the tepal apex, and the upper lateral and lower 3 tepals are partly united in an extended lower lip with the lower tepal lobes short and inconspicuous. The flowers broadly resemble those of *B. ringens* but are considerably smaller.

The flowers are clearly adapted for sunbird pollination and both dusky and malachite sunbirds are recorded visitors. The species is known locally as the *sandlelie* (sand lily).

55. **Babiana ringens** *(L.) Ker Gawl.* in König & Sims, Annals of Botany 1: 233 (1804); Baker: 114 (1896); Goldblatt & Manning: 61 (2007), 50 (2010). *Antholyza ringens* L.: 37 (1753). Type: South Africa, without precise locality or date, illustration in Commelin: 81, t. 41 (1697).

Plants 120–400 mm high. *Stem* with main axis sterile, velvety, with 1(2) horizontal branches borne shortly above ground. *Leaves* linear-lanceolate to almost terete, stiff, pungent, deeply pleated, usually smooth or minutely hairy. *Spike* decumbent, borne close to ground, 2- to 10-flowered; bracts green with dry rust-coloured tips, smooth or minutely hairy below, 20–50 mm long, inner forked in upper ⅓. *Flowers* zygomorphic, red with yellow throat, unscented; perianth tube narrowly funnel-shaped, expanded in upper ⅓, curving upward away from spike apex, 27–45 mm long; tepals unequal, dorsal longest, 18–50 mm long, channelled below with margins overlapping and enclosing filaments and style, lower tepals shortly united with upper laterals,

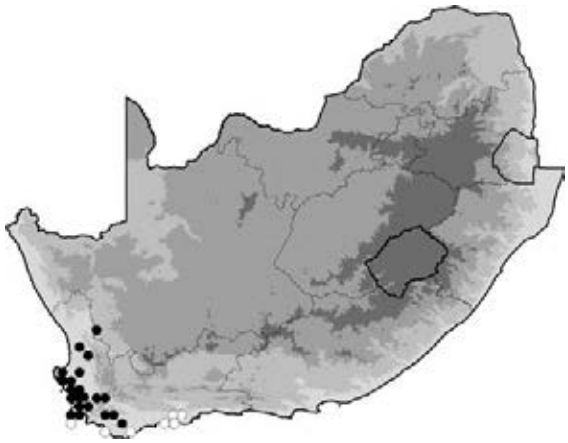
22–25 mm long. *Stamens* unilateral; filaments straight, erect, unilateral, 24–60 mm long; anthers 4.0–7.5 mm long, purple. *Ovary* smooth; style dividing opposite base of anthers (subsp. *australis*) or between middle of anthers or shortly beyond them, branches 2–5 mm long. *Flowering time*: late July to October.

Distribution and ecology: extending in South Africa from the Bokkeveld Mtns in Northern Cape south and east to Albertinia in Western Cape; on sandy flats and slopes in strandveld and fynbos, mainly along the coast up to 500 m elevation but also inland locally up to 600 m.

Diagnosis: the unusual flower of *Babiana ringens*, one of the most distinctive species in the genus, is adapted for sunbird pollination. Its specialisations include the red colour, stiff stamens and style, and elongate perianth tube with a wide throat.

Apart from the flower itself, the most striking adaptation of *Babiana ringens* is the sterile main stem, which acts as a perch for visiting sunbirds. Closely related, but smaller-flowered *B. avicularis*, shares this feature but differs from *B. ringens* in the falcate leaves elliptic in section and in the smaller flowers with a perianth tube 16–21 mm long, with the narrow basal part 4 mm long and kinked at the apex and dorsal tepal 15–18 mm long vs. tube 22–45 mm long and dorsal tepal 18–50 mm long but mostly 20–45 mm in *B. ringens*. The two species are allied to *B. hirsuta*, which has similar red flowers with a channelled dorsal tepal enclosing the filaments and style, but a multi-branched stem, the main axis of which bears a typical spike of several flowers. Variation across the range of *B. ringens* is considerable and populations from southern Western Cape with smaller flowers and a shorter style are segregated as subsp. *australis*.

Key to subspecies



1a Style dividing opposite middle to tips of anthers or beyond them; dorsal tepal 25–50 mm long . . . . . 55a. subsp. *ringens*

1b Style dividing at or below base of anthers; dorsal tepal 18–30 mm long . . . . . 55b. subsp. *australis*

55a. subsp. **ringens**

Sterile stem 150–400 mm long. *Spike* mostly 4- to 10-flowered. *Flowers* with perianth tube 28–40 mm long, slender lower part 15–20 mm long and upper wider part 12–15 mm long; dorsal tepal 25–45(–50) mm long, upper lateral and lower median tepals narrowly lanceolate, 20–25 mm long, attenuate and mucronate, lower lateral tepals clawed with ovate blade. *Filaments* 37–70 mm long, exceeding apex of dorsal tepal; anthers 5.0–7.5 mm long. *Style* dividing opposite middle of anthers or shortly beyond them, branches 4–5 mm long. *Flowering time*: August to October.

Distribution: most common along the western coastal belt of Western Cape from Graafwater to the northern Cape Peninsula but extending inland in the Breede River Valley south of Worcester and on the Bokkeveld Escarpment at Botterkloof Pass; on deep sandy soils.

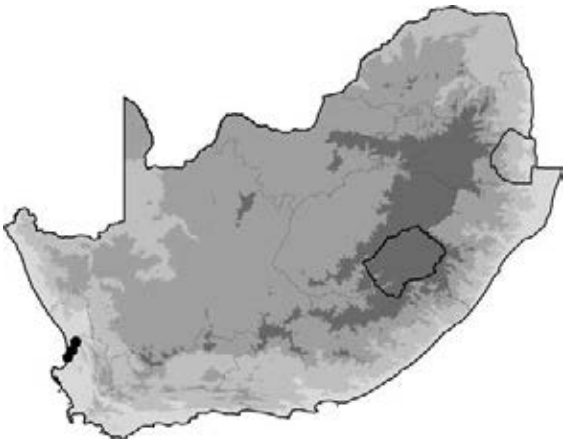
Distribution of ***Babiana ringens*** subsp. ***ringens***, ●; subsp. ***autralis***, ○.

55b. subsp. **australis** *Goldblatt & J.C.Manning* in Bothalia 40: 50 (2010). Type: Western Cape, Bredasdorp, Frikkiesbaai, 24 Aug. 1946, *Compton 18185* (NBG, holo.).

Sterile stem up to 120 mm long. *Spike* 2- to 4-flowered. *Flowers* with perianth tube 27–35 mm long, slender lower part 15–20 mm long and upper wider part 12–15 mm long; dorsal tepal 18–30 mm long, upper lateral and lower median tepals narrowly lanceolate, 20–25 mm long. *Filaments* 24–34 mm long, not reaching apex of dorsal tepal; anthers 4.0–5.5 mm long, reaching or sometimes exceeding apex of dorsal tepal. *Style* dividing at or 1–2 mm below base of anthers; branches 2–4 mm long. *Flowering time*: mainly mid-July to late August.

Distribution and ecology: extending along the southern coast of Western Cape, from Albertinia in the east to the Agulhas Peninsula, with outlying populations on the southern Cape Peninsula south of Red Hill; on sandy ground in coastal fynbos, flowering well after fire.

Diagnosis: subsp. *australis* stands out from typical *Babiana ringens* in its generally smaller size and 2- to 4-flowered spike of markedly smaller flowers, with tube 27–35 mm long, and smaller tepals, the dorsal 18–30 mm long. In comparison, subsp. *ringens* has spikes of (3–)6 to 10 flowers, a perianth tube 28–40 mm long, and a dorsal tepal 25–45(–50) mm long. In keeping with the longer perianth tube, the filaments are 37–70 mm long, and the anthers are 5.0–7.5 mm long vs. filaments 24–34 mm long and anthers 4.0–5.5 mm long in subsp. *australis*. The style of subsp. *australis* divides at or below the base of the anthers and the style branches are relatively short, 2–4 mm, compared with a style usually dividing beyond the anther tips (rarely opposite the middle of the anthers) in subsp. *ringens* and the style branches are 4–5 mm long. Both subspecies occur on



the Cape Peninsula, with subsp. *australis* recorded from the southern Peninsula and subsp. *ringens* in the north: their ranges do not overlap.

Two northern populations of subsp. *ringens* from the immediate vicinity of Graafwater have unusually small flowers for the subspecies, with a perianth tube 31–40 mm long and a dorsal tepal ± 25 mm long, but unlike subsp. *australis* they have anthers 5.0–5.5 mm long, a style dividing opposite the middle to upper third of the anthers, and style branches 4–5 mm long. These populations occur close to others with larger flowers, typical of subsp. *ringens*, and may represent a local race or possibly reflect poor growing conditions in a particular year.

56. **Babiana avicularis** *Goldblatt & J.C.Manning* in Bothalia 40: 47 (2010). Type: South Africa, Western Cape, coast south of Elands Bay, ± 30 km north of Rocher Pan, sandy flats, 11 Sept. 2008, *Goldblatt & Porter 13109* (NBG, holo.; K, MO, PRE, S, iso.).

Plants up to 120 mm high, excluding leaves. *Stem* with main axis suberect and sterile, usually with two decumbent branches borne close to ground, minutely velvety. *Leaves* 6 to 8, linear, up to 300 × 2–3 mm, firm, ± oval in cross section, closely pleated, usually with 2 or 3 folds on each surface, smooth. *Spike* horizontal, ± 2-ranked, mostly 8- to 12-flowered; bracts minutely scabrid, green with dry brown apices, outer 14–22 mm long, with prominent mucro, inner ± half as long, divided ± to base, joined by transparent tissue at ovary level. *Flowers* zygomorphic, facing spike apex, ± red, paler in throat, lower part of tube yellow, lower 5 tepals with pale green limbs sometimes fading to pink near tips, darker green in midline, unscented; perianth tube compressed-funnel-shaped, lower part ± 4 mm long, cylindric and kinked near apex, abruptly expanded into flared upper part 12–17 mm long; tepals unequal, outer whorl prominently mucronate, dorsal 15–18 × 2.5–3.5 mm, ascending, channelled below, margins curving inward enclosing filaments and style, expanded to 3 mm wide and recurved in upper 5 mm, lower 3 tepals united with upper laterals for ± 4 mm in prominent lip, directed forward, lower and upper laterals ± 8 × 1.5 mm, lower median 3–7 × 1–2 mm. *Stamens* unilateral; filaments suberect, 25–32 mm long, enclosed below by dorsal tepal, reaching apex of dorsal tepal; anthers 3.5–5.0 mm long, purple. *Ovary* smooth; style dividing shortly below base of anthers, branches 4–5 mm long, recurved. *Capsules* barrel-shaped, ± 11 × 8.5 mm, showing outline of seeds. *Flowering time*: mid-August to late September.

Distribution and ecology: restricted to the Atlantic Coast and near interior of Western Cape, South Africa, with just four populations known, two from sandy flats between Elands Bay and Rocher Pan, a short distance inland from coastal dunes adjacent to the beach; a third is from the Olifants River Valley north of Clanwilliam, also on sandy ground; and the fourth, the earliest record, is from coastal fynbos close to Leipoldtville; always in sandy ground.

Distribution of ***Babiana avicularis***.

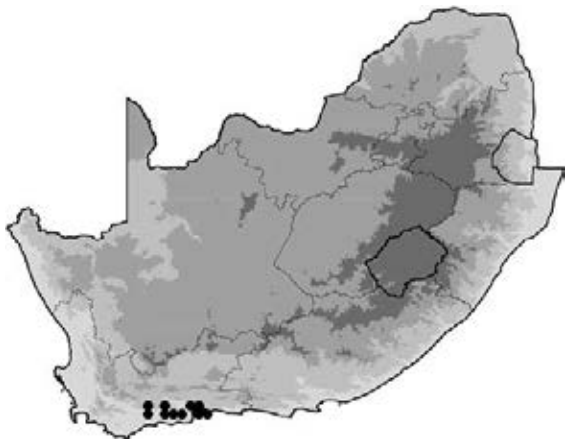
Diagnosis: flowers of *Babiana avicularis* resemble those two other predominantly red-flowered species of the genus, *B. hirsuta* and *B. ringens*, except that they are almost half the size. Like *B. ringens*, the main axis is sterile and, as in *B. ringens* it serves as a perch for birds taking nectar from the flowers but their flowers differ in some important respects apart from their smaller size. Flowers of *B. ringens* subsp. *ringens* have a perianth tube 28–40 mm long, a dorsal tepal 25–45(–50) mm long, enlarged lower lateral tepals ± 20 mm long, and the upper tepals are recurved. In addition, the filaments are 37–70 mm long, the anthers 5.0–7.5 mm long, and the style divides opposite the upper half of the anthers or shortly beyond their tips. Subsp. *australis* has slightly smaller flowers with the dorsal tepal 18–30 mm long and filaments 24–34 mm long. In contrast, flowers of *B. avicularis* have a tube 16–21 mm long and distinctive in the lower cylindrical part of the tube 4 mm long and kinked below the apex. All three lower tepals are pale green and directed forward. In both species, as well as in *B. hirsuta*, the margins of the dorsal tepal curve inward and enclose the filaments and style with only the distal third or quarter expanded and slightly recurved. The filaments of *B. avicularis* are 25–32 mm long, the anthers 3.5–5.0 mm long and the style divides below the bases of the anthers. The leaves of *B. ringens* are lanceolate to sublinear but firm to rigid in texture with almost pungent tips, in contrast to the longer, linear, arching, softer leaves of *B. avicularis*. Like its two relatives, flowers of *B. avicularis* are adapted for pollination by sunbirds.

The floral bracts of *Babiana avicularis* are notable in two respects: they are rust-coloured at the tips and prominently mucronate, and the shorter inner bracts are divided for about ¾ of their length, with the two halves strongly divergent, whereas in both *B. hirsuta* and *B. ringens*, the inner bracts are divided in the upper third to half and do not notably diverge. The two coastal populations of *B. avicularis* are sympatric and co-blooming with *B. hirsuta*, but no hybrids have been recorded at either site.

Sect. 3. **Babiana**

Babiana sect. *Acastae* Salisb. ex Benth. & Hook.f.: 707 (1883). Subg. *Acaste* (Salisb. ex Benth.) Baker: 166 (1877) & 107 (1896). Type: *Babiana angustifolia* Sweet [lecto., designated by Goldblatt & Manning: 61 (2007)].

Plants with the aerial stem well developed or acaulescent, usually velvety hairy, sometimes smooth, main axis erect or decumbent, branched or not. *Leaves* usually velvety; bracts often relatively short, usually hairy, green with dry rust-coloured tips or entirely dry, inner divided to base (or almost so), each half with prominent central vein. *Flowers* zygomorphic or actinomorphic, dorsal tepal seldom widely separated from other tepals when flower zygomorphic, lower tepals usually united for some distance in a lower lip. *Stamens* symmetrically arranged or unilateral, sometimes dark blue to blackish; anthers oblong-linear or with connective expanded and then anthers arrow-shaped. *Ovary* densely hairy or sometimes smooth.



Species 37, mainly Western Cape but *B. patersoniae* extends into Eastern Cape and *B. mucronata* and *B. unguiculata* occur to the north in the Bokkeveld Mtns of Northern Cape.

Ser. **Patulae** *Goldblatt & J.C.Manning*, new series. Type: *Babiana patula* N.E.Br.

Flowers zygomorphic, with smooth or mostly smooth ovary.

57. **Babiana fourcadei** *G.J.Lewis* in Pillans in South African Gardening and Country Life 24: 268 (1934); Lewis: 92 (1959); Goldblatt & Manning: 62 (2007). Type: South Africa, [Western Cape], hills east of Great Brak River, Sept. 1932, *H.G. Fourcade 4765* (BOL, holo.; BOL, iso.).

Plants (70–)150–250 mm high. *Stem* erect, usually with 3 to 5(–7) short lateral branches, rarely unbranched, long-hairy, enclosed below by a tough fibrous collar (occasionally in overgrazed or poor conditions subacaulescent). *Leaves* usually ± falcate or lanceolate, (5–)9–20(–30) mm wide, lightly pleated, shortly hairy, usually crowded basally, reaching to base or middle of spike. *Spike* lax to ± compact, (4–)6- to 10-flowered; bracts green with dry rust-coloured tips, softly hairy, 12–20 mm long, inner shorter than outer, divided to base. *Flowers* zygomorphic, pale to deep blue to violet, lower lateral tepals white to pale yellow edged toward base with small violet marks, intensely sweet-spicy scented; perianth tube narrowly funnel-shaped, abruptly curved outward in upper 6 mm, 20–30 mm long; tepals unequal, dorsal 25–30 × ± 10 mm, flaring gradually from base, lower 3 tepals joined to upper laterals for 3–5 mm and to one another for ± 2 mm, lower tepals 18–24 mm long. *Stamens* unilateral; filaments arched, 15–18 mm long; anthers 5–8 mm long, pale mauve. *Ovary* smooth; style usually dividing opposite upper ⅓ of anthers, rarely slightly beyond tips; style 4–5 mm long, abruptly expanded apically. *Flowering time*: September to mid-October.

Distribution of ***Babiana fourcadei***.

Distribution and ecology: restricted to southern Western Cape, South Africa, extending from Swellendam to George, south of the Langberg–Outeniqua Mtn axis; occurring on lower mountain slopes and coastal hills.

Diagnosis: *Babiana fourcadei* is distinguished by the well-developed aerial stem, smooth ovary, and outer bracts dark rusty brown at the tips and rather irregularly lobed or torn. Among the species of series *Patulae*, *B. fourcadei* is recognised by the well-developed and usually repeatedly branched stem, and fairly large pale blue to violet flowers with a perianth tube, 20–30 mm long, dorsal tepal 25–30 mm long, and the completely smooth ovary. *Babiana patula*, often confused with *B. fourcadei*, always has a shorter, ± decumbent stem, and thus seldom exceeds 100 mm in height, and the ovary in most populations is minutely hairy on the ribs (plants with a completely hairless ovary are unusual but are reported in the literature). The perianth of *B. patula* ranges from either pale blue to mauve, purple, or pale yellow to white, typically with large yellow or cream-coloured markings on the lower lateral tepals. The flowers are slightly smaller, the tube 10–14 mm long, the dorsal tepal mostly 20–25 mm long, and the bracts acute and often only light brown.

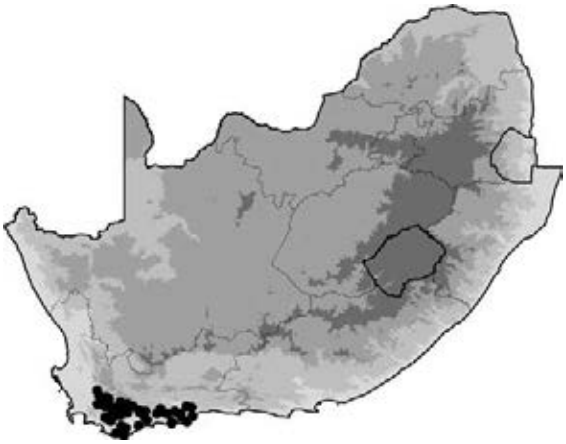
58. **Babiana patula** *N.E.Br.* in The Gardener's Chronicle ser. 3, 92: 466 (1932b); Lewis: 62 (1959); Goldblatt & Manning: 62 (2007). Type: South Africa, [Western Cape], near Riversdale, 30 Aug. 1932, *J. Muir 4852* (K, holo.).

Plants mostly 60–100 mm high. *Stem* usually reaching shortly above ground level, sometimes up to 150 mm high, flexed outward above, velvety-hairy, simple with up to 4 short, ascending branches. *Leaves* lanceolate,

pleated, usually widely divergent, velvety to pilose. *Spike* decumbent, 3- to 9-flowered; bracts green with dry, rust-coloured apices, hairy, 10–15(–20) mm long, outer truncate to trifid, inner slightly shorter than outer, divided to base. *Flowers* zygomorphic, mauve to blue, occasionally purple, yellow or white, lower laterals and sometimes lower median yellow, tipped with mauve or entirely yellow, intensely fragrant often of rose or violet; perianth tube narrowly funnel-shaped, 10–14 mm long; tepals unequal, dorsal mostly 20–25 mm long, lower tepals joined to upper laterals for ± 2.5 mm and to one another for ± 2 mm, forming a lip, lower tepals 15–25 mm long. *Stamens* unilateral; filaments arched, 12–14 mm long; anthers ± 6 mm long. *Ovary* minutely hairy on ribs (or evidently smooth); style dividing between middle and apex of anthers, branches 3–4 mm long. *Flowering time*: August and September.

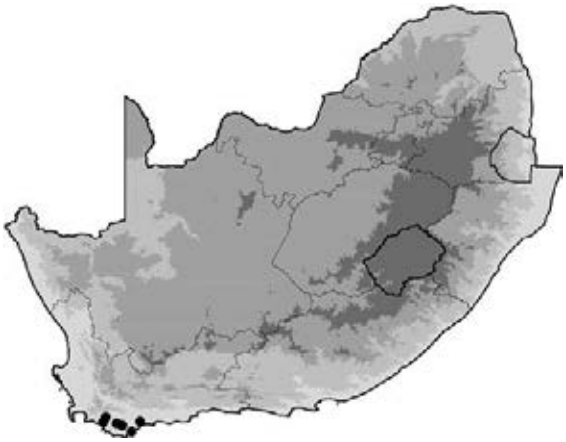
Distribution and ecology: extending from near Wolseley in the Breede River Valley to Albertinia in Western Cape, South Africa, also in the Little Karoo near Montagu; on clay or stony flats and lower slopes.

Diagnosis: distinctive in the relatively small, strongly fragrant flowers, *Babiana patula* is typically low growing and often has an unusually coloured perianth. While the flowers may be white to creamy yellow, they are more often violet or light mauve to purple with the lower lateral tepals deep yellow and tipped with purple or mauve. The affinities of *B. patula* seem to lie with the southern Cape *B. fourcadei*, a taller plant with blue to violet flowers marked with white, a longer perianth tube 20–30 mm long, often a quite different, spicy acrid fragrance, and a completely smooth ovary. The ovary of *B. patula*, unusual in sect. *Babiana* but typical of other members of series *Patulae,* is usually sparsely hairy on in the ribs. The character readily separates it from the superficially similar *B. odorata*, which also has strongly scented, cream-coloured and yellow flowers, sometimes flushed with mauve, but always has a densely hairy ovary.



Babiana patula may also be confused with *Babiana ambigua*, a typically acaulescent or short plant of sandy habitats. Flowers of *B. ambigua* are dark blue, rarely mauve, and have white nectar guides. The ovary of *B. ambigua*, like that of *B. patula,* is smooth or sparsely hairy on the ribs, but the outstanding difference is that *B. ambigua* lacks a well-developed fibrous collar around the stem base present in *B. patula*.

59. **Babiana montana** *G.J.Lewis* in Journal of South African Botany, Suppl. 3: 63 (1959); Goldblatt & Manning: 64 (2007). Type: South Africa, [Western Cape], Kleinrivier Mtns, Aug., *C.L. Zeyher 4003* (BOL, holo.; K, P, SAM, S [2 sheets], Z, iso.).



Plants 60–100 mm high, including leaves. *Corm* with tunics of coarse, matted fibres. *Stem* short, suberect, sometimes with short lateral branch, hairy, sheathed below by collar of tough fibres. *Leaves* lanceolate, pleated, hairy. *Spike* 4- to 5-flowered, crowded; bracts green with dry rust-coloured acute tips, densely hairy, 25–30(–38) mm long, inner ± 5 mm shorter than outer, divided to base. *Flowers* 2 to 5 in deflexed spike, zygomorphic, mauve, lower lateral tepals with yellow median blotch edged below in dark purple; perianth tube narrowly funnel-shaped, 17–20 mm long; tepals unequal, dorsal 25–35 mm long, lower tepals 22–30 mm long. *Stamens* unilateral; filaments unequal, median longer, 7–10 mm long; anthers 7 mm long. *Ovary* smooth; style dividing opposite upper half of anthers, branches ± 3 mm long, tips flattened and orbicular. *Flowering time*: June to August.

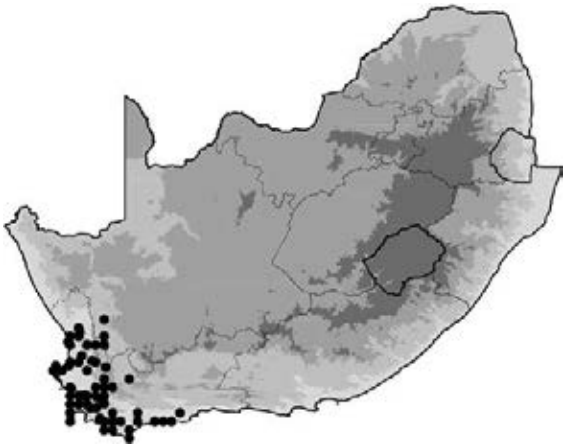
Distribution and ecology: extending from Caledon to Bredasdorp in Western Cape, South Africa; on sandstone and limestone slopes.

Diagnosis: readily recognised by the unusual, coarsely fibrous corm tunics that form a distinctive hard, cylindric collar around the stem base, *Babiana montana* has blue-mauve flowers with unequal filaments, the median one longer than the other two. In addition, the style branches have prominent orbicular tips, a character rare in the genus. The smooth ovary also stands out in

Distribution of ***Babiana patula***.

Distribution of ***Babiana montana***.

sect. *Babiana* but this feature is shared with a few other species, including *B. ambigua* and *B. fourcadei*. *Babiana montana* can also be distinguished from *B. ambigua* by the thick collar of fibres about the underground part of the stem, a feature lacking in the latter, as well as the unequal stamens. Plants from limestone habitats west of Bredasdorp have smaller bracts than is usual, 12–14 mm long, and smaller flowers about 40 mm long, but have the unequal stamens typical of the species.



60. **Babiana ambigua** *(Roem. & Schult.) G.J.Lewis* in Journal of South African Botany, Suppl. 3: 64 (1959); Goldblatt & Manning: 64 (2007). *Gladiolus ambiguus* Roem. & Schult.: 446 (1817), as a new name for *G. mucronatus* Lam.: 119 (1791), illegitimate homonym, not *G. mucronatus* Jacq. (1791). Type: South Africa, [Western Cape], without precise locality or date, collector unknown (P: Herb. Lamarck, holo.).

Babiana obliqua E.Phillips in Flowering Plants of South Africa 9: t. 357 (1929); Lewis: 67 (1959). Type: South Africa, [Western Cape], Lambert's Bay, ± 20 yards [18 m] from high water mark, flowered at National Herbarium, Pretoria, July 1929, *J.J. van Nouhuys s.n.* (PRE 8180, holo.; K, iso.).

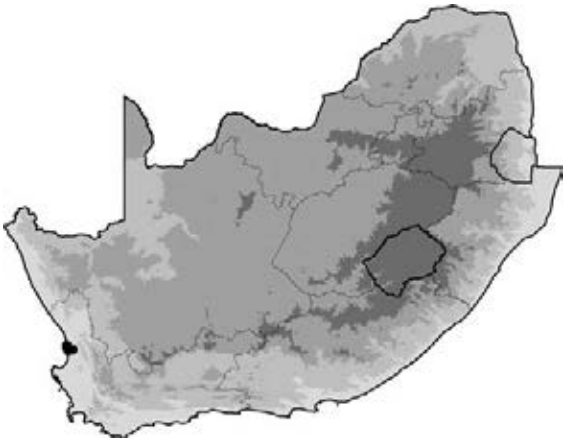
Plants 50–80(–160) mm high, including leaves. *Corm* with fibrous, netted tunics, with small cormlets at base; non-flowering plants with long, unbranched stolons with terminal corms or young plants. *Stem* underground or reaching shortly above ground level, without basal fibrous collar, suberect or inclined, lightly hairy, often with cormlets in underground axils. *Leaves* linear to lanceolate, exceeding stem, usually fairly narrow, 3–10(–15) mm wide, pleated, softly hairy. *Spike* crowded, decumbent, 2- to 4-flowered; bracts usually entirely green or with brown tips, finely to velvety hairy, 15–30(–40) mm long, inner ± as long as or slightly shorter than outer, divided to base. *Flowers* borne close to ground level, zygomorphic, blue to mauve, occasionally lilac, with white to cream-coloured markings on lower lateral tepals edged in darker blue to purple, sweetly or spicy fragrant; perianth tube obliquely funnel-shaped, 10–19 mm long; tepals unequal, dorsal 28–45 × 10–12 mm, lower tepals joined to upper laterals for 2–4 mm and to one another for 2–4 mm, 20–30 mm long. *Stamens* unilateral; filaments arcuate, 13–16 mm long; anthers linear, 6–8 mm long. *Ovary* smooth or sparsely hairy on ribs distally; style dividing opposite anther tips; style 4–6 mm long, expanded in upper ⅓. *Flowering time*: late July to September.

Distribution and ecology: fairly widespread in southwestern South Africa, extending from Botterkloof in Northern Cape and the Gifberg in Western Cape in the north to Riversdale in the south; mostly in deep coastal sands or stony or sandy mountain slopes and plateaus.

Diagnosis: *Babiana ambigua* is distinguished by the acaulescent habit, stem lacking a collar of fibres around the base, rather soft-textured fibrous corm tunics and

Distribution of ***Babiana ambigua***.

floral bracts divided to the base. The relatively large flowers are predominantly dark blue to violet with white to creamy white markings and have a sweet or spicy scent. It is often confused with a second coastal species, *B. nana*, and the two sometimes occur together, *B. nana* flowering somewhat later in the season than *B. ambigua*. Hybrids between the two species have been described by Lewis (1959) from the Cape Peninsula and on the Atlantic Coast to the north. Although similar in general appearance, *B. nana* usually has a short aerial stem and larger and more intensely fragrant flowers, the perianth often a deeper colour and, most importantly, the inner bracts are undivided. Lewis (1959) also reported hybrids between *B. ambigua* and the related and similar *B. scabrifolia* from the Olifants River Valley. *Babiana grandiflora* is also easily confused with *B. ambigua*, but this species from coastal Namaqualand has the inner floral bracts only notched apically, and considerably larger flowers with the dorsal tepal 45–55 mm long vs. 28–40 mm in *B. ambigua*.



61. **Babiana petiolata** *Goldblatt & J.C.Manning* in Strelitzia 18: 65 (2007). Type: South Africa, Western Cape, south of Lambert's Bay, strandveld above the beach, flowered in Portland, Oregon, USA, May 2004, *Goldblatt & Porter 12301a* (NBG, holo.).

Plants acaulescent, up to 50 mm high, including leaves. *Corm* with fibrous, netted tunics. *Stem* reaching to ground level, smooth, simple or 1- or 2-branched, without collar of fibres around base, with small cormlets at first node above corm. *Leaves* lanceolate to sword-shaped, shallowly pleated, lightly papillate-scabrid to virtually smooth, usually with terete pseudopetiole 5–40 mm long, blades arching forward and concave with margins facing toward ground and often thickened. *Spike* decumbent, 4- to 6-flowered; bracts 15–20 mm long, keeled above and sparsely hairy on keel and margins, obtuse, with broad membranous margins, divided to base. *Flowers* zygomorphic, violet, lower tepals with pale yellow markings reddish proximally, with light iris-like scent; perianth tube obliquely funnel-shaped,

± 11 mm long, lower cylindric part ± 7 mm long; tepals unequal, dorsal held slightly apart, ± 30 × 8 mm, upper laterals smaller, lower 3 tepals joined to upper laterals for ± 5 mm and to one another for ± 3 mm, lower median narrowed below into channelled claw. *Stamens* unilateral; filaments arcuate, ± 12 mm long; anthers ± 6 mm long, light violet; pollen cream-coloured. *Ovary* smooth, ± 4 mm long; style arching over stamens, dividing opposite anther apices, branches ± 5 mm long, expanded at tips. *Flowering time*: late June and July.

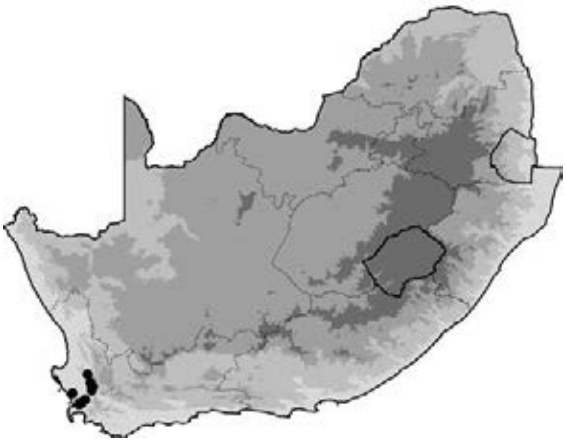
Distribution and ecology: poorly documented but locally fairly common on the Atlantic Coast of Western Cape, South Africa, between Lambert's Bay and Velddrif; on flat sandy ground in strandveld not far inland of the coast.

Diagnosis: so named for the leaf blades narrowed below into a terete, petiole-like base above the sheaths, the remainder of the blades of *Babiana petiolata* are oblong to lanceolate. The distinctive leaves are inclined toward the ground and the blades are concave, especially when young or on immature plants, which have only one or two leaves versus three or four in mature individuals. The species is evidently most closely related to the widespread *B. ambigua* and is readily confused with this species. Both have the inner floral bracts divided to the base, and smooth ovary, and the underground part of the stem lacks a collar of fibres. It is distinguished from *B. ambigua* by the consistently pseudopetiolate leaves with smooth or sparsely papillate to scabrid blades, small flowers with a perianth tube ± 11 mm long, a pleasing *Iris*-like scent, and its early flowering time, mainly late June and July. Leaves of *B. ambigua* often appear petiolate but the apparently narrow base of the blade is actually the leaf sheath extending upward, and is normally clasping the leaf above; the blades are also obviously pleated and usually prominently hairy. The larger flowers have a tube 12–19 mm long and a spicy, acrid scent with undertones of violet. *Babiana ambigua* extends from Strandfontein north of Lambert's Bay to Riversdale in the southern Cape and co-occurs with *B. petiolata* near Lambert's Bay and then their differences become evident.

Distribution of ***Babiana petiolata***.

Ser. **Secundae** *Goldblatt & J.C.Manning*, new series. Type: *Babiana secunda* (Thunb.) Ker Gawl.

Spike with dry floral bracts; flowers inverted; perianth tube shorter than dorsal tepal; ovary smooth.



62. **Babiana secunda** *(Thunb.) Ker Gawl.*, Genera iridearum 154 (1827); Lewis: 57 (1959); Goldblatt & Manning: 66 (2007). *Gladiolus secundus* Thunb.:186 (1800). Type: South Africa, [Western Cape], without precise locality or date, *Thunberg s.n.* (UPS–THUNB, holo. [K, drawing]).

Babiana reflexa Eckl.: 33 (1827). *B. stricta* var. *reflexa* (Eckl.) Baker: 113 (1896). Type: South Africa, without precise locality, cult. Cape Town, *Ecklon s.n.* [S, lecto., designated by Nordenstam: 290 (1972)].

Plants 150–350 mm high. *Stem* flexed nearly horizontally, often with widely diverging branches, lightly velvety at least below. *Leaves* lanceolate, pleated, velvety. *Spike* inclined, secund, many-flowered; bracts initially green but usually completely dry and brown at flowering, smooth, 10–13 mm long, outer tricuspidate with long central awn, inner shorter than outer, divided to base. *Flowers* zygomorphic, inverted, with perianth tube recurved and facing spike apex, dorsal tepal horizontal, unilateral stamens curved back to lie above dorsal tepal and lower tepals suberect, blue with yellow or white markings on lower lateral tepals; perianth tube narrowly funnel-shaped, 6–8 mm long; tepals unequal, dorsal largest, 18–20 mm long, lower shortly joined below, 14–17 mm long. *Stamens* unilateral; filaments arching over dorsal tepal, 12–14 mm long; anthers facing spike apex, ± 6 mm long, yellow; pollen yellow. *Ovary* smooth; style dividing opposite anther tips, branches 3–4 mm long. *Flowering time*: mainly October to mid-November.

Distribution and ecology: extending from Hopefield and Porterville to Mamre and Paarl in Western Cape, South Africa; on clay and stony flats and lower slopes in renosterveld.

Diagnosis: *Babiana secunda* is one of a handful of species of *Babiana* with inverted flowers, that is, with the spike inclined and the flowers facing upward, with the dorsal tepal and the unilateral stamens facing the spike apex. It can be distinguished by the smooth, dry, often torn floral bracts, the outer tricuspidate with a long central awn and hairless ovary, the latter unusual for sect. *Babiana*. *Babiana secunda* blooms unusually late in the season, usually in October or November. In the other species with inverted flowers, *B. angustifolia, B. inclinata*, and *B. rubrocyanea*, the ovary is densely hairy, the bracts remain partly green at flowering, are usually velvety and lack a pronounced awn although they do tend to be tricuspidate. The anthers and pollen are pale to deep blue or violet (or sometimes white) in *B. angustifolia* and *B. inclinata*, whereas the anthers and pollen of *B. secunda* are yellow.

Distribution of ***Babiana secunda***.

The relationships of *Babiana secunda* remain uncertain hence its isolated position within sect. *Babiana* alone in series *Secundae*. DNA-based phylogenetic studies are not informative about the relationships of *B. secunda* although it is retrieved in an isolated position among species of sect. *Babiana*.

Ser. **Mucronatae** *Goldblatt & J.C.Manning*, new series. Type: *Babiana mucronata* (Jacq.) Ker Gawl.

Flowers zygomorphic; perianth tube shorter or longer than dorsal tepal; ovary variously hairy.

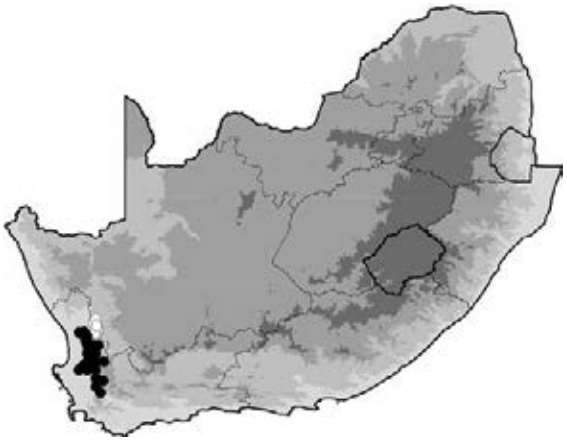
63. **Babiana mucronata** *(Jacq.) Ker Gawl.* in König & Sims, Annals of Botany 1: 234 (1804); Lewis: 58 (1959); Goldblatt & Manning: 67 (2007). *Gladiolus mucronatus* Jacq.: 162 (1791b). Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 253 (1794 [1788–1795]).

Plants 50–180 mm high. *Stem* suberect or flexed outward, simple or with 2 or 3 branches, velvety-hairy, enclosed below by thick fibrous collar. *Leaves* sword-shaped to broadly lanceolate, 7–15(–20) mm wide, usually reaching ± middle or top of spike, exceeding stem in dwarf plants, pleated, shortly hairy with margins velvety and sometimes prominent. *Spike* suberect, compact, mostly 4- to 12-flowered; bracts green with dry and rust-coloured tips, outer obtuse to truncate or tridentate, (11–)15–25 mm long, inner ± half as long to only slightly shorter than outer, divided to base. *Flowers* zygomorphic, pale to dark blue-violet, lower lateral tepals with white to cream-coloured or pale yellow with violet edges, usually acrid-scented, occasionally evidently odourless; perianth tube narrowly funnel-shaped, (10–)12–18(–25) mm long; tepals unequal, dorsal 25–35 mm long, lower joined to upper laterals for 3–5 mm and to one another for ± 2.5 mm, forming a prominent lip, lower 15–18 mm long. *Stamens* unilateral; filaments arched, 13–16 mm long; anthers 5–7 mm long, violet or pale turquoise. *Ovary* densely hairy; style dividing between middle and apex of anthers, branches 3–4 mm long. *Flowering time*: late July to September.

Distribution and ecology: extending from the Bokkeveld Mtns in Northern Cape, South Africa, in the north to Tulbagh in Western Cape in the south; on rocky sandstone or stony clay slopes and flats and rock outcrops.

Diagnosis: one of the most common species of the interior valleys and lower mountain slopes of the western half of Western Cape, *Babiana mucronata* is recognised among species of sect. *Babiana* with a densely hairy ovary by the pale to deep violet flowers with white to pale yellow blotches on the lower lateral tepals. The anthers are pale yellow to lilac or sometimes turquoise and the flowers usually have an acrid to metallic odour or occasionally apparently odourless. Most other blue-flowered species of sect. *Babiana* from this area are more-or-less acaulescent, have leaves taller than the stem, and a smooth or sparsely hairy ovary, except for the relatively tall *B. lineolata*, which favours wet sandy ground and is easily separated by the rigid, narrow, deeply pleated leaves and short floral bracts, mostly 7–10 mm long.

Babiana mucronata is typically a fairly tall plant with a branched, aerial stem, and lightly pleated, softly hairy leaves. In the north of its range, on the Gifberg and Bokkeveld Escarpment, however, plants are consistently dwarfed, with a stem extending only a short distance above the ground, and flowers with a perianth tube about 12 mm long, whereas the taller southern populations have a tube 15–25 mm long. The northern plants are segregated as subsp. *minor*, being both geographically and morphologically distinct from subsp. *mucronata*. Plants from Elandskloof described by Lewis (1959) as var. *longituba* seem to represent no more than a slightly longer-tubed form of typical *B. mucronata* and are now included in subsp. *mucronata*. Longer-tubed populations of subsp. *mucronata* occur in a seemingly random pattern across the range of the taxon.



Key to subspecies:

1a Plants tall, usually 150–350 mm high, spike usually exceeding leaves; perianth tube 15–18(–25) mm long. . . . . 63a. subsp. *mucronata*
1b Plants dwarf, mostly 70–100 mm high, spike usually overtopped by leaves; perianth tube 10–14 mm long. . . . . 63b. subsp. *minor*

63a. subsp. **mucronata**

Babiana mucronata var. *longituba* G.J.Lewis: 60 (1959). Type: South Africa, [Western Cape], Elandskloof, 29 Sept 1944, *W.F. Barker 3090* (NBG, holo.).

Plants with well-developed aerial stem, mostly 150–350 mm high, suberect, usually branched. *Leaves* lanceolate, 7–15(–20) mm wide, usually reaching to ± middle or top of spike, margins not thickened. *Spike* 6- to 12-flowered; bracts 15–25 mm long. *Flowers* violet, lower

Distribution of ***Babiana mucronata*** subsp. ***mucronata***, ●; subsp. ***minor***, ○.

lateral tepals with white or pale yellow markings edged violet; perianth tube mostly 15–18(–25) mm long; dorsal tepal 25–35 mm long, lower tepals joined to upper laterals 3–5 mm and to one another for ± 2.5 mm, forming a lip, lower 15–18 mm long. *Filaments* 13–16 mm long; anthers 5–7 mm long. *Flowering time*: August and September.

Distribution and ecology: extending from the Olifants River Mtns and Pakhuis Pass to Tulbagh and Piketberg in Western Cape, South Africa; mostly on rocky sandstone slopes, occasionally on gravelly shale, conspicuous after fire.

Diagnosis: unless dwarfed by poor seasonal rains, subsp. *mucronata* is an erect plant with an aerial stem usually at least 150 mm high. It grows in a variety of habitats, and may be found on sandstone outcrops, stony clay slopes, and sometimes on the shale band of the Table Mountain series of the Cape System.

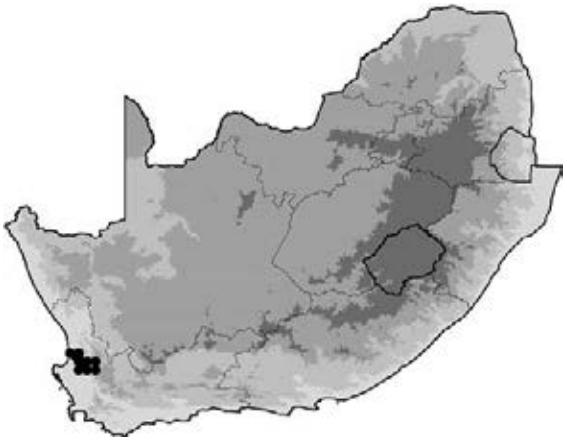
63b. subsp. **minor** *(G.J.Lewis) Goldblatt & J.C.Manning* in Strelitzia 18: 68 (2007). *Babiana mucronata* var. *minor* G.J.Lewis: 60 (1959). Type: South Africa, [Western Cape], Gifberg Plateau, 21 Sept. 1948, *J.H.P. Acocks 14905* (PRE, holo.; K, iso.).

Babiana klaverensis G.J.Lewis: 72 (1959). Type: South Africa, [Western Cape], Klawer, higher plateau in front of mountains, not rare, flowers mostly eaten or faded, corms often dug out by baboons, 250 m, 1 Aug. 1920, *H.K.C. Andreae 505* (PRE, holo.).

Plants mostly 70–100 mm high, including leaves. *Stem* reaching up to 40 mm above ground level, suberect or decumbent, simple or 1- or 2-branched, velvety. *Leaves* sword-shaped, firm, lightly to strongly pleated, finely hairy, margins occasionally thickened and prominent. *Spike* compact, 3- to 6-flowered; bracts 11–15 mm long. *Flowers* violet or blue-mauve; perianth tube 10–14 mm long; dorsal tepal 25–30 mm long, lower tepals joined to upper laterals for short distance and to one another for ± 1.5 mm, lower 20–25 mm long. *Filaments* ± 13 mm long; anthers ± 6 mm long. *Flowering time*: mid-July to mid-September.

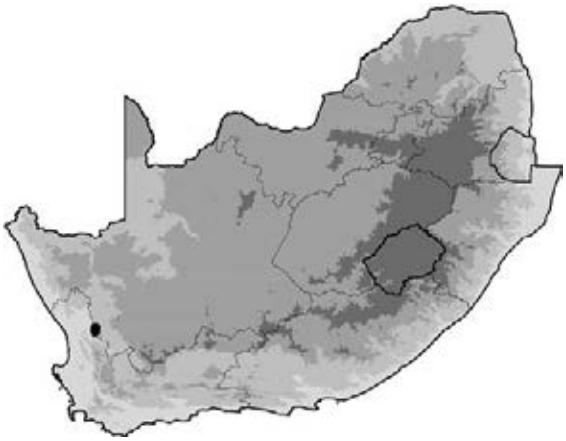
Distribution and ecology: extending from the Bokkeveld Mtns in Northern Cape, South Africa, to the Gifberg in Western Cape; on rocky sandstone slopes and sandstone pavement.

Diagnosis: consistently short in stature, subsp. *minor* also has slightly smaller flowers than subsp. *mucronata*, with a slightly shorter perianth tube ± 12 mm long, dorsal tepal ± 25 mm long, and the lower and upper lateral tepals are joined for up to 2.5 mm into a lip. In contrast, subsp. *mucronata* has a perianth tube 15–25 mm long, dorsal tepal 25–35 mm long, and lower tepals joined for 5–7 mm long. Associated with the short perianth tube, subsp. *minor* has floral bracts 11–15 mm long.



64. **Babiana lineolata** *Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 347 (Ergänzungen 13) (1882); Lewis: 51 (1959). Type: South Africa, [Western Cape], Olifants River Valley near Brakfontein, Sept., *C.F. Ecklon & C.L. Zeyher 76.9* (Irid. 132) (B, holo.; P [2 sheets], Z, iso.).

Babiana parviflora Brehm ex Klatt: 350 (1882). Type: South Africa, [Western Cape], without precise locality or date, *J.F. Drège 1825* (B "Herb. Lubeck", holo., not seen and evidently destroyed; P, S, iso.).



Gladiolus stenophyllus Schrank: 212 (1822), as a new name for *G. plicatus* var. *angustifolius* Jacq.: 4 (1791b). Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 238 (1791 [1788–1795]).

Babiana stenophylla Baker: 866 (1901). Type: South Africa, [Western Cape], *Ecklon & Zeyher Irid. 132* (Z, holo.; B, P, iso.).

Plants 130–250 mm high. *Stem* erect, usually with several short lateral branches, velvety hairy. *Leaves* sword-shaped, 2–6(–10) mm wide, rigid, deeply pleated, finely hairy. *Spike* erect, secund, compact, 4- to 12-flowered; bracts green with rust-coloured attenuate tips, softly hairy, outer 7–14 mm long, inner ± ⅔ to nearly as long as outer, divided to base. *Flowers* zygomorphic, pale to deep blue, lower lateral tepals white to pale yellow, tipped with blue, evidently odourless; perianth tube narrowly funnel-shaped, 10–16 mm long; tepals unequal, tapering below, dorsal 18–24 mm long, lower tepals joined to upper laterals for 3–4 mm and to one another for ± 2 mm, 14–20 mm long. *Stamens* unilateral; filaments arched, 12–17 mm long; anthers 4.5–6.0 mm long. *Ovary* densely hairy; style dividing opposite middle of anthers, branches 3–4 mm long. *Flowering time*: September and early October.

Distribution of ***Babiana lineolata***.

Distribution of ***Babiana engysiphon***.

Distribution and ecology: extending from the Cold Bokkeveld and southern Olifants River Valley to the Piketberg in Western Cape, South Africa; mainly on seasonally wet sandy flats.

Diagnosis: *Babiana lineolata* can be recognised in sect. *Babiana* by the rigid, narrow, suberect, deeply plicate leaves, several-branched stem with short bracts, and zygomorphic, markedly bilabiate flower with the dorsal tepal erect and the lower tepals united below to form a prominent lip. Plants typically grow in dense colonies in damp sandy sites where the pale blue-mauve flowers make a display unusual for the genus. The fairly short-tubed flowers are adapted for pollination by anthophorine bees and *Apis mellifera* workers, which visit the flowers for their nectar.

Babiana lineolata is evidently most closely related to *B. mucronata* and it is easily confused with this species. The paler coloured flowers with a perianth tube 8–15 mm long and bracts 7–12 mm long, easily separate it from the taller subsp. *mucronata* which has a tube 15–25 mm long, bracts 15–25 mm long, and broader, more softly textured leaves 7–15(–20) mm wide. The shorter *B. mucronata* subsp. *minor* is not likely to be confused with *B. lineolata*.

65. **Babiana engysiphon** *J.C.Manning & Goldblatt* in Strelitzia 18: 69 (2007). Type: South Africa, Northern Cape, Calvinia, Moedverloor road, ± 28 km from Doornbos, 4 Sept. 2004, *P. Goldblatt & J.C. Manning 12388* (NBG, holo.; K, MO, PRE, iso.).

Plants 60–100 mm high, including leaves. *Stem* reaching shortly above ground level, flexed at ground level and inclined, simple or 1(2)-branched, velvety. *Leaves* mostly 5 to 7, ± linear to narrowly sword-shaped, 3–4 mm wide, widest in upper ⅓, shallowly pleated to almost flat, minutely velvety. *Spike* horizontal, compact, (2–)4- to 8-flowered; bracts green, with light brown attenuate tips, velvety to lightly hairy, outer 15–25 mm long, lightly keeled, inner ± ⅔ to ± as long as outer, margins membranous, divided to base or almost so, or joined in lower ⅓ by transparent membranous tissue. *Flowers* zygomorphic, dark violet, lower lateral tepals with broad white to pale yellow blotch near base, odourless; perianth tube elongate, (30–)35–40 mm long, gently upcurving, cylindric, slightly expanded at apex; tepals unequal, dorsal largest, 22–27 × 7–8 mm, recurved in upper half, lower 3 tepals joined to upper laterals for 4–5 mm and to one another for ± 2 mm in a prominent lip, 15–16 × 6 mm. *Stamens* unilateral; filaments 10–12 mm long, well exserted; anthers 5–6 mm long. *Ovary* softly hairy; style dividing opposite anther tips, branches ± 3 mm long, filiform throughout. *Flowering time*: late August and September.

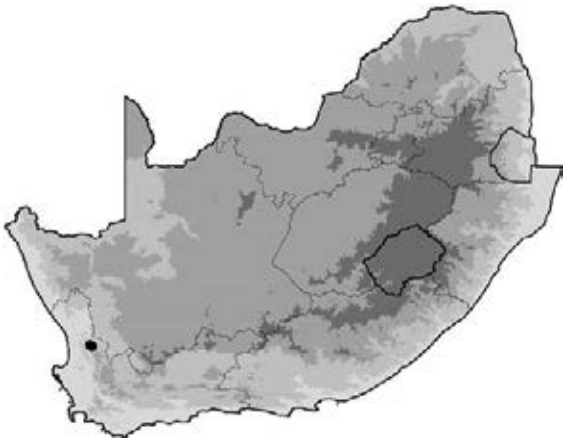
Distribution and ecology: a narrow endemic of the Stinkfontein and southern Bokkeveld Mtns near Moedverloor in Northern Cape, South Africa; in sandy and stony sandstone ground in fynbos with restiads.

Diagnosis: a dwarf plant, seldom reaching more than 100 mm above the ground, *Babiana engysiphon* is recognised by its elongate perianth tube, mostly 35–40 mm long, violet perianth with large white markings on the lower lateral tepals and horizontal spike. The several leaves, narrow and almost linear to narrowly sword-shaped and usually lightly pleated or nearly plane and velvety, arch toward the ground and are often close to horizontal. Its immediate relationships are uncertain. The softly hairy ovary and bracts divided to the base or nearly so conform to ser. *Mucronatae* of sect. *Babiana*.

Plants co-occur in some places with *Babiana mucronata* subsp. *minor*, which has short-tubed, scented flowers adapted for pollination by anthophorine bees, whereas the odourless flowers of *B. engysiphon* are pollinated by long-proboscid flies. Despite the difference in pollination system, some hybridization between the two is evident. These plants have a tube of intermediate length and pale yellow rather than white markings on the lower tepals. *Babiana engysiphon* also co-occurs with *B. rigidifolia*, but this more robust, broad-leaved plant grows in a different habitat, with the corms wedged in

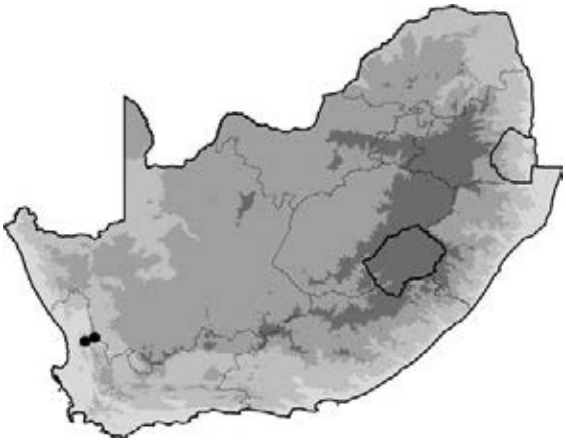
crevices in sandstone pavement. Although their flowering times overlap, no hybrids have been recorded between the two, despite both evidently being pollinated by long-proboscid flies.

66. **Babiana auriculata** *G.J.Lewis* in Journal of South African Botany, Suppl. 3: 88 (1959); Goldblatt & Manning: 71 (2007). Type: South Africa, [Western Cape], Pakhuis Pass, Sept. 1947, *G.J. Lewis 1878* (SAM, holo.).



Plants 40–100 mm high. *Stem* short, often with 1 or 2 short branches, deflexed, lightly hairy. *Leaves* lanceolate, pleated, with short and long silky hairs, apex shortly cuspidate. *Spike* inclined to horizontal, secund, 3- to 8-flowered; outer bracts green, dry and rust-coloured in upper ⅓, softly hairy, 13–25 mm long, inner slightly shorter than outer, forked for ± ⅔ and membranous in lower midline, margins hyaline. *Flowers* 3 to 8 nodding, zygomorphic, dorsal tepal and stamens facing spike apex, blue-mauve, lower lateral tepals with pale yellow markings outlined in dark violet; perianth tube funnel-shaped, 15–20 mm long; tepals unequal, dorsal 20–28 mm long, lower tepals joined to upper laterals for short distance, forming a lip, lower narrowed into claws ± 5 mm long, limbs 10–15 mm long, lower laterals with auriculate lobes at base. *Stamens* unilateral; filaments arched, 15–18 mm long; anthers 4–6 mm long. *Ovary* hairy on ribs; style dividing opposite upper half of anthers, branches ± 3 mm long. *Flowering time*: September.

Distribution and ecology: known only from the Pakhuis Mtns in Western Cape, South Africa; in crevices in sandstone outcrops.



Diagnosis: *Babiana auriculata* is distinguished by the strongly deflexed stem and blue-mauve flowers with yellow markings on the lower tepals and auricular lobes at the base of the lower lateral tepal limbs. Although included in sect. *Babiana* because of the ovary hairy on the ribs, the inner bracts are not divided to the base but are joined in the lower third by membranous tissue. At first *B. auriculata* appears to be a smaller form of *B. mucronata*, but that species has the inner bracts clearly divided to the base, a densely hairy ovary, and the lower tepals lack auricular lobes. The auricular lobes of the lower tepals recall sect. *Antholyzoides* but the partly hairy ovary is inconsistent with that section, as are the membranous inner bract margins and midline. Apart from their incomplete separation, the inner bracts are otherwise typical of sect. *Babiana* in their membranous margins and rust-coloured tips. The narrow claws of the lower tepals suggest that *B. auriculata* is most closely allied to *B. unguiculata*, which also has narrowly clawed lower tepals. The nearly horizontal spike axis with the flowers facing the stem apex is another striking feature of *Babiana auriculata*, and one shared with a few other species of section *Babiana*.

67. **Babiana unguiculata** *G.J.Lewis* Journal of South African Botany, Suppl. 3: 131 (1959); Goldblatt & Manning: 71 (2007). Type: South Africa, [Western Cape], Nardouw Pass, Sept. 1941, *T.P. Stokoe 8482* (SAM, holo.; BOL, iso.).

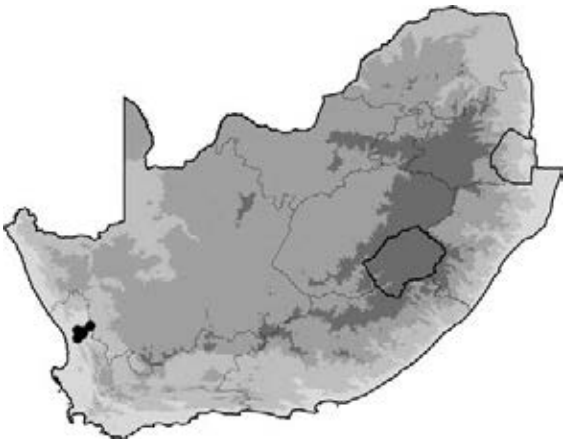
Plants 100–200 mm high. *Stem* erect, sometimes with 1 or 2 short branches in upper ⅓, velvety, enclosed below by thick collar of fibres. *Leaves* sublinear to sword-shaped, reaching to ± middle of spike, 4–7 mm wide, sometimes lightly twisted, strongly pleated, usually shortly hairy (in cultivation smooth except for a line of long hairs on adaxial margins). *Spike* suberect, 4- to 12-flowered; bracts green, dark brown at tips, softly hairy, 7–15 mm long, inner slightly shorter or longer than outer, forked mostly to base (rarely for half their length with membranous midline). *Flowers* zygomorphic, pale creamy yellow, lower lateral tepals deep yellow; perianth tube 10–12 mm long; tepals unequal, dorsal ± 25 mm long, arching over stamens, later erect, lower tepals joined to upper laterals for ± 5 mm and to one another for 3–4 mm in a prominent lip, lower laterals with narrow claws ± 2 mm long, abruptly widening into broad limbs ± 15 × 7 mm. *Stamens* unilateral; filaments arched, 12–15 mm long; anthers 5–6 mm long, yellow; pollen white. *Ovary* lightly hairy, mostly

Distribution of ***Babiana auriculata***.

Distribution of ***Babiana unguiculata***.

on ribs; style dividing between middle and apex of anthers, branches 3–4 mm long. *Flowering time*: August to mid-September.

Distribution and ecology: extending from the Bokkeveld–Stinkfontein Mtn complex south of Nieuwoudtville in Northern Cape south to the Nardouw Mtns in Western Cape, South Africa (but poorly documented and known from just two sites); in seeps and locally wet sandstone pavement.

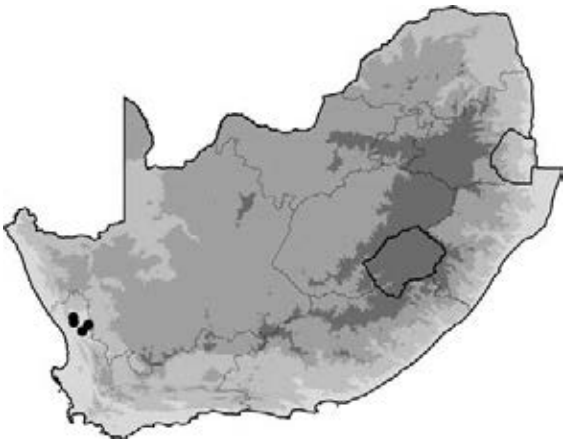


Diagnosis: the fairly small, yellow flowers, hairy ovary, and inner bracts divided almost to the base of *Babiana unguiculata* are consistent with sect. *Babiana*. In the type collection the narrow leaf blades are tightly pleated, appearing to be ribbed, but other collections have softer-textured leaves, only moderately pleated, densely short-hairy but long-hairy along the adaxial margins. The general appearance of the flowers and the short floral bracts recall *B. auriculata* and *B. lineolata* in particular but both have blue rather than pale yellow flowers. Flowers of *B. unguiculata* lack the auriculate lobes on the lower tepal limbs so characteristic of *B. auriculata*.

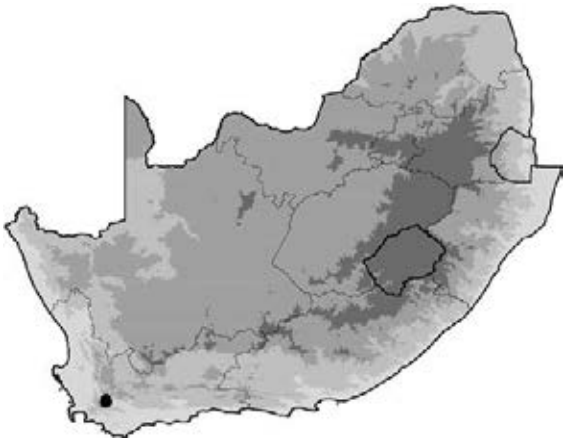
68. **Babiana toximontana** *J.C.Manning & Goldblatt* in Strelitzia 18: 73 (2007). Type: South Africa, Western Cape, flats below Matsikamma along road near foot of Gifberg Pass, 18 July 2005, *J.C. Manning* et al. *2979* (NBG, holo.; K, MO, iso.).

Plants 80–150 mm high. *Stem* reaching shortly above ground, velvety, strongly inflexed and horizontal, few-branched. *Leaves* 5 or 6, lanceolate, lightly coiled distally, held at ± 45° to sheaths, 50–100 × 7–18 mm, velvety, lightly pleated. *Spike* horizontal, secund, mostly 5- to 10-flowered; bracts green with brown tips, velvety, truncate, outer 14–20(–30) mm long, inner 11–15(–20) mm long, divided to base. *Flowers* zygomorphic, pale to deep blue, lower lateral tepals with white median blotches and wine-red streaks, with sweet spicy scent; perianth tube funnel-shaped, 12–14 mm long; tepals unequal, dorsal 28–32 × 6–8 mm, upper lateral tepals joined to lower for ± 5 mm, forming a lip, lower tepals ± 20 mm long. *Stamens* unilateral; filaments ± 15 mm long; anthers 7 mm long, lilac. *Ovary* densely hairy; style dividing opposite anther tips, branches ± 4 mm long. *Flowering time*: June to mid-July.

Distribution and ecology: a local endemic of the foothills of the Matsikamma and Gifberg Mtns between Vanrhynsdorp and Klawer, in Western Cape, South Africa; on sandy flats and stony lower slopes in arid fynbos.



Diagnosis: distinctive in the spreading, velvety leaves, lightly coiled at the tips, *Babiana toximontana* typically has short, branched stems with horizontally arching, secund spikes, and fairly truncate bracts, the inner divided to the base. The flowers are moderately sized and pale to deep blue marked with white blotches and red streaks on the lower tepals. It is evidently closely allied to *B. salteri*, which also has oblique, rather spreading leaves and dense, horizontal spikes and also flowers early in the season, in late June and July. *Babiana salteri* has broader, more widely spreading leaves that are firm-textured and never twisted or coiled at the tips, and smaller flowers (tube ± 9 mm vs. 12–14 mm long and dorsal tepal 23 mm vs. 28–30 mm long) with the lower lateral tepals mostly or entirely yellow and the upper lateral tepals narrower and recurved. The two species favour different habitats, with *B. salteri* restricted to quartz patches on clay soils in succulent karoo scrub, and *B. toximontana* favouring sandstone-derived soils in arid fynbos. *Babiana salteri* is known for certain only NE of Vanrhynsdorp, whereas *B. toximontana* occurs in several populations in the foothills and lower slopes of Gifberg and Matsikamma.



Distribution of ***Babiana toximontana***.

69. **Babiana salteri** *G.J.Lewis* in Journal of South African Botany, Suppl. 3: 73 (1959); Goldblatt & Manning: 73 (2007). Type: South Africa, [Western Cape], 16 miles [± 24 km] NE of Vanrhynsdorp on road to Calvinia, 14 June 1938, *T.M. Salter 7318* (SAM, holo.).

Plants 70–100 mm high. *Stem* reaching shortly above ground, usually with 1 to 3 short branches, shortly hairy above, base enclosed by thick fibrous collar. *Leaves* lanceolate-oblong with blades held ± at right angles to sheaths and stem, pleated, minutely hairy, mostly 20–40 mm long. *Spike* compact, 2-ranked, 5- to 10-flowered; bracts green with dry tips, lightly hairy, 10–13 mm long, inner ± as long as outer, divided to base. *Flowers* zygomorphic, pale blue-mauve with white to yellow markings on lower lateral tepals; perianth tube funnel-shaped, ± 9 mm long; tepals unequal, tapering toward base, dorsal ± 23 mm long, lower 3 tepals joined to upper laterals for short distance and to one another for ± 2 mm, 13–15 mm long. *Stamens* unilateral; filaments ± 1.3 mm long; anthers ± 7 mm long. *Ovary* densely hairy; style dividing opposite middle of anthers, branches ± 3 mm long. *Flowering time*: June to late July.

Distribution of ***Babiana salteri***.

Distribution of ***Babiana arenicola***.

Distribution and ecology: extending from the southern Knersvlakte and lower slopes of the Bokkeveld and Koebee Mtns in Western Cape, South Africa; on dry stony flats and lower mountain slopes.

Diagnosis: the dwarf *Babiana salteri* is recognised by the low stature, up to 100 mm high, and leaves with broadly lanceolate to ovate blades held almost at right angles to the sheaths enclosing the erect stem. The relatively small, pale blue-mauve flowers have a short perianth tube ± 9 mm long, dorsal tepal ± 23 mm long and lower tepals 13–15 mm long tapering toward the base, although not distinctly clawed. The short, horizontally oriented leaves recall those of the Richtersveld endemics, *B. gariepensis* and *B. horizontalis*, as well as those of the southern Namaqualand *B. lewisiana* but none of these species has bracts divided to the base.

70. **Babiana arenicola** *Goldblatt & J.C.Manning* in Strelitzia 18: 74 (2007). Type: South Africa, [Western Cape], Brandvlei, south of Worcester, half a mile before the hot spring, 18 Sept. 1974, *A.A. Mauve & I. Oliver 757* (PRE, holo.; MO, NBG, iso.).

Plants 60–140 mm high, including leaves. *Stem* reaching 20–40 mm above ground level, lightly hairy, enclosed below by collar of dark brown fibres. *Leaves* narrowly sword-shaped to linear, shortly exceeding stem, mostly 3–6 mm wide, firm to rigid, deeply pleated and veins thickened, sparsely short-hairy, mainly on veins. *Spike* erect, 2- to 6-flowered; bracts green with dry rust-brown tips, ± smooth above, shortly to silky hairy below, outer 22–30(–45) mm long, inner ± ⅔ as long, shortly attenuate, divided to base. *Flowers* zygomorphic, blue with white markings on lower lateral tepals edged toward throat in dark blue or red, sweetly scented; perianth tube straight, cylindric below, widening gradually in upper ⅓, ± 30 mm long; tepals subequal, dorsal ± 32 × 12 mm, upper laterals ± 32 × 10 mm, lower tepals 28–30 × 10 mm. *Stamens* unilateral; filaments suberect, unilateral, ± 15 mm long, exserted ± 8 mm from mouth of tube; anthers linear, 6–7 mm long, yellow; pollen white. *Ovary* sparsely to densely shortly hairy; style dividing ± 2 mm below base of anthers, branches 5–6 mm long, slender, hardly expanded at tips. *Flowering time*: mid-August to late September.

Distribution and ecology: local in the vicinity of Brandvlei, between Worcester and Villiersdorp in Western Cape, South Africa; in sand among sandstone rocks.

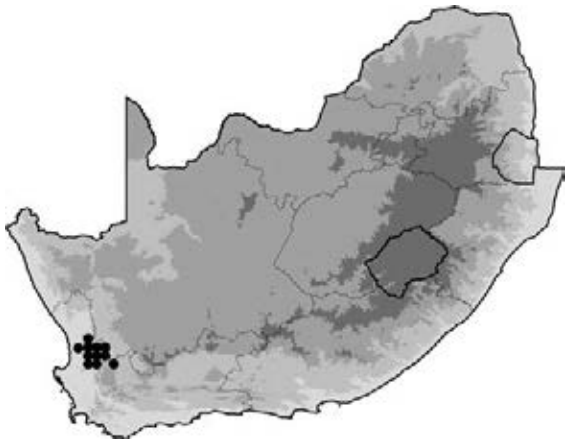
Diagnosis: a puzzling species of sect. *Babiana*, plants are nearly acaulescent and have blue flowers borne close to ground level, thus broadly resembling *B. ambigua*, from which *B. arenicola* differs markedly in having a fairly prominent hairy ovary, narrow, deeply pleated, stiff leaves 3–6 mm wide, and straight perianth tube, ± 30 mm long. The style is also unusual in dividing below or shortly above the base of the anthers into slender branches 5–6 mm long. By contrast, *B. ambigua* has firm, but less rigid leaves, 3–10 mm wide, a curved perianth tube, 10–19 mm long, wider in the throat, arched filaments, and the style dividing opposite the anther tips. *Babiana arenicola* is included in ser. *Mucronatae* because of the shortly hairy, almost bristly ovary, and linear, yellow anthers and pollen.

71. **Babiana scabrifolia** *Brehm ex Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 349 (Ergänzungen 15) (1882); Lewis: 68 (1959); Goldblatt & Manning: 75 (2007). Type: South Africa, [Western Cape], Clanwilliam District, Langevallei, July 1830, *J.F. Drège 2623* (K, lecto., designated by Lewis: 68 (1959); P, iso. [two sheets]).

Babiana occidentalis Baker: 183 (1892). Type: South Africa, [Western Cape], Clanwilliam, without precise locality, *Mader in Herb. Macowan 2169* (K, holo.).

Babiana subglabra G.J.Lewis: t. 545 (1934b). Type: South Africa, [Western Cape], Olifants River Valley near Clanwilliam, ex hort. Kirstenbosch, *G.J. Lewis s.n. as Natl. Bot. Gard. 1812/32* (BOL, holo.).

Babiana adpressa G.J.Lewis: 1 (1938). Type: South Africa, [Western Cape], Nardouw Pass, ex hort. Kirstenbosch, *T.M. Salter s.n. as Natl. Bot. Gard. 1159/33* (BOL, holo.).



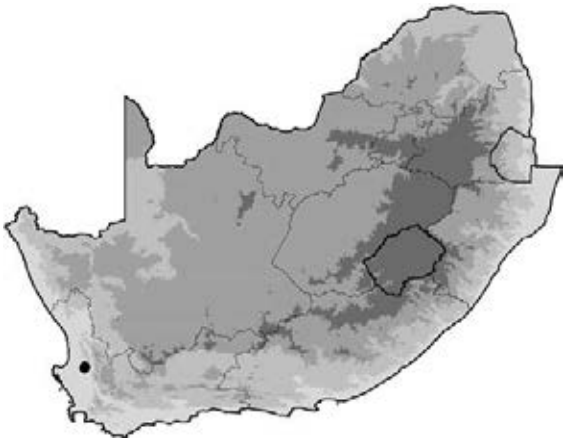
Babiana scabrifolia var. *acuminata* G.J.Lewis: 70 (1959). Type: South Africa, [Western Cape], Olifants River Valley at Bulshoek Barrage, 2 Aug. 1950, *G.J. Lewis 2192* (SAM, holo.; SAM, iso.).

Babiana scabrifolia var. *declinata* G.J.Lewis: 71 (1959). Type: South Africa, [Western Cape], between Brandewyn River and Doorn River, in sand, 25 Aug. 1950, *G.J. Lewis 2207* (SAM, holo.).

Plants 50–150 mm high, including leaves. *Stem* ± underground, with thick collar of fibres around base, often forming tufts, simple or branched at ground level, hairy above ground. *Leaves* lanceolate to oblong, exceeding stem, 6–20 mm wide, usually inclined toward ground, soft-textured and lightly pleated, shortly hairy or nearly smooth, narrow and twisted in young plants. *Spike* congested, ± horizontal, 4- to 8-flowered; bracts green, sparsely hairy, 20–32 mm long, inner slightly shorter than outer, divided to base (rarely shortly above base), with wide transparent margins. *Flowers* zygomorphic, mostly pale blue to pale lilac, lower lateral tepals with broad white to cream-coloured splashes in upper half outlined in dark blue to violet, sweetly scented, often of narcissus; perianth tube narrowly funnel-shaped, 12–18 mm long; tepals unequal, dorsal 30–45 × 7–10 mm, lower tepals joined to upper laterals for up to 4 mm and to one another for ± 4 mm, forming a prominent lip, 20–30 mm long, margins of lower laterals undulate, lightly crisped in lower half. *Stamens* unilateral; filaments arched, 13–18 mm long; anthers 6–8 mm long; pollen white. *Ovary* thinly hairy above or on ribs, rarely smooth; style dividing between middle and apex of the anthers, branches 4–5 mm long, expanded at tips. *Flowering time*: June to August.

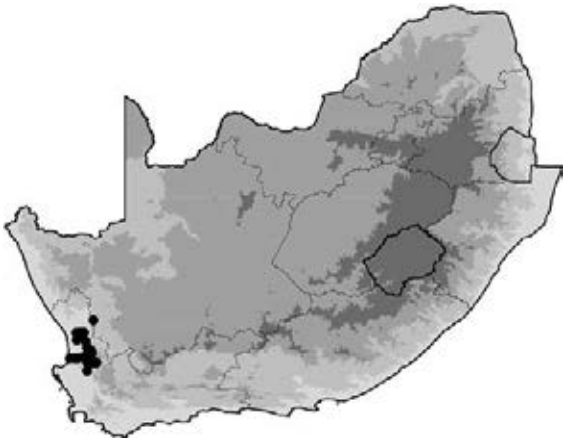
Distribution and ecology: centred in the Olifants River Valley in Western Cape, South Africa and on lower slopes of the surrounding mountains; on stony soils in dry fynbos or karroid scrub.

Diagnosis: *Babiana scabrifolia* is most easily recognised by the underground stem, often branched at ground level, and usually forming small tufts, and the fairly large, pale blue to blue-mauve flowers, which have a pleasing sweet scent and contrast both in the scent and large size with those of *B. mucronata*, which is also common in the Olifants River Valley. That species typically has an erect, usually well-developed aerial stem, while the flowers have a densely hairy ovary and produce a rather harsh acrid-spicy odour. Young plants do not have the narrow, twisted to coiled immature leaves of *B. scabrifolia* that surround the parent plants. It reproduces amply by cormlets and it is common to see mature flowering plants with their broad, soft-textured leaves surrounded by the linear, twisted to coiled leaves produced by immature plants.



Distribution of ***Babiana scabrifolia***.

Babiana scabrifolia is unusually variable in leaf shape, size and pubescence, and what are now thought to be ecological variants were described in the past as the separate species *B. subglabra* and *B. adpressa*. The variants are often simply individuals growing in more shaded, or wetter, or more exposed sites. Hybrids between *B. scabrifolia* and *B. mucronata* occur locally where they are sympatric, and have overlapping flowering times and share the same pollinators, anthophorine bees and honey bees.



Babiana scabrifolia is broadly similar in habit to *B. ambigua* and the two occasionally grow fairly close to one another. The latter is most easily distinguished by the absence of a collar of fibres around the underground part of the stem and by the tepals with more-or-less straight margins that contrast with the undulate to crisped tepal margins of *B. scabrifolia*. While *B. scabrifolia* has a sparsely thinly ovary, sometimes only on the ribs, *B. ambigua* typically has a smooth ovary, occasionally sparsely hairy on ribs.

72. **Babiana latifolia** *L.Bolus* in South African Gardening and Country Life 17: 377 (1927); Goldblatt & Manning: 76 (2007). *B. ecklonii* var. *latifolia* (L.Bolus) G.J.Lewis: 105 (1959). Type: South Africa, [Western Cape], foot of the Piketberg, flowered at Kirstenbosch Gardens, 16 Sept. 1927, *D. van Zijl s.n. as Natl. Bot. Gard. 625/1927* (BOL, holo.).

Plants 100–250 mm high. *Stem* inclined, usually 2- to 4-branched, densely hairy. *Leaves* lanceolate, to 20 mm wide, soft and lightly pleated, softly hairy. *Spike* several-flowered; bracts green with brown tips, densely long-hairy, 15–25 mm long, outer obtuse-acuminate, inner slightly shorter than outer, divided to base. *Flowers* zygomorphic, violet with whitish or pale violet median streaks on lower lateral tepals; perianth tube cylindric, curved near apex, 30–40 mm long; tepals unequal, dorsal suberect, 22–26 mm long, lower tepals obtuse to obtuse apiculate, 17–21 mm long, joined to upper laterals for ± 4 mm, forming a fairly prominent lower lip. *Stamens* unilateral; filaments arcuate, ± 12 mm long;

Distribution of ***Babiana latifolia***.

Distribution of ***Babiana ecklonii***.

anthers ± 6 mm long, dark blue black. *Ovary* densely hairy; style dividing opposite upper thirds of anthers, branches ± 4 mm long, tips unusually large and undulate, overtopping anthers. *Flowering time*: August to early September.

Distribution and ecology: known only from the eastern base and lower slopes of the Piketberg in Western Cape, South Africa; on loamy sandstone-derived soils.

Diagnosis: *Babiana latifolia* differs from *B. ecklonii* in its unusual style branches conspicuously enlarged at the tips, purple flower colour with narrow white nectar guides on the lower lateral tepals, blue-black anthers, and obtuse apiculate tepal tips. Flowers of *B. ecklonii* are violet with broad white to pale yellow nectar guides, the anthers are pale violet, and the tepals are narrow and acute. The style divides opposite the anther apices in *B. latifolia* and the style branches are ± 4 mm long with the tips unusually broad and undulate. In *B. ecklonii* the point of division of the style and length of style branches is variable, in different individuals, dividing variously below the anthers and ± 2 mm long, or opposite the middle or close to the anther apices and up to 4 mm long, but in both cases the style branches are slender, widening gradually toward the tips. Vegetatively the two also differ: in *B. latifolia* the leaf and stem pubescence is velvety but in *B. ecklonii* the pubescence is longer and sparser, and the erect stem is largely sheathed by the leaf bases, whereas the stem of *B. latifolia* arches outward and is free of the leaf bases for at least half its length. As expected from its long perianth tube, flowers of *B. latifolia* are pollinated by the long-proboscid flies.

73. **Babiana ecklonii** *Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 348 (Ergänzungen 14) (1882); Lewis: 104 (1959); Goldblatt & Manning: 76 (2007). Type: South Africa, [Western Cape], without precise locality or date, *Ecklon & Zeyher 133* [G, lecto., designated by Lewis: 105 (1959)].

Babiana velutina Schltr.: 100 (1899). Type: South Africa, [Western Cape], Gifberg, near Windhoek, 1 Aug. 1897, *R. Schlechter 8364* (BM, K, MO, P, PRE, Z, syn.).

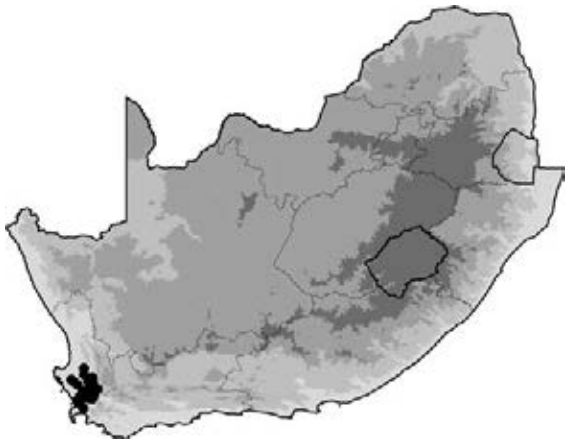
Babiana fastigiata L.Bolus: 377 (1927). Type: South Africa, [Western Cape], said to be from George, cultivated at Piketberg, Aug., *D. van Zyl s.n.* (BOL 17823, holo.).

Plants 100–300 mm high. *Stem* ± erect, often weakly flexed below spike, usually 2- to 4-branched, softly hairy, mostly sheathed by leaves. *Leaves* lanceolate to sword-shaped, in a tight fan, usually relatively soft-textured and lightly pleated, somewhat silky hairy. *Spike* 2-ranked, closely 4- to many-flowered; bracts green with dry, brown, attenuate tips, densely hairy, outer 14–25 mm long, inner ± ⅔ as long as outer, divided to base or almost so. *Flowers* zygomorphic, violet with large cream-coloured to pale yellow marks on lower lateral tepals, unscented; perianth tube cylindric, usually sharply curved below apex, 35–47 mm long, widening and arching outward in upper 6–8 mm; tepals unequal, dorsal suberect, 23–27 mm long, lower 3 tepals joined to upper laterals for 5–7 mm and often to one another for a short distance, forming a pronounced lower lip, lower 3 tepals 12–17 mm long, extending horizontally below, arching outward and downward above. *Stamens* unilateral; filaments arcuate, 14–16 mm long, diverging after anther dehiscence; anthers 5–7 mm long, pale blue or violet. *Ovary* hairy above or throughout, rarely hairy only on ribs; style usually dividing opposite middle of anthers, occasionally below anther bases or opposite anther tips, branches ± 4 mm long (or when style short, branches ± 2 mm long), stigmatic lobes barely expanded. *Flowering time*: August and September.

Distribution and ecology: South Africa, Western Cape, from the Gifberg and Heerenlogement Mtn in the north to Elandskloof and Piekenierskloof in the south; on mountain slopes up to 500 m elevation and flats in stony, sandstone-derived soils, often in rock crevices.

Diagnosis: although typical of sect. *Babiana* in its branched, aerial stem and inner bracts divided to the

base, *B. ecklonii* is remarkable for its tall stature when well grown, the stem largely sheathed by the bases of the erect leaves, and for its elongate perianth tube, 35–47 mm long. The blue-violet flowers have large white markings on the lower lateral tepals and unusual stamens, which are initially parallel, but after dehiscence the filaments diverge, leaving the anthers widely separated from one another.



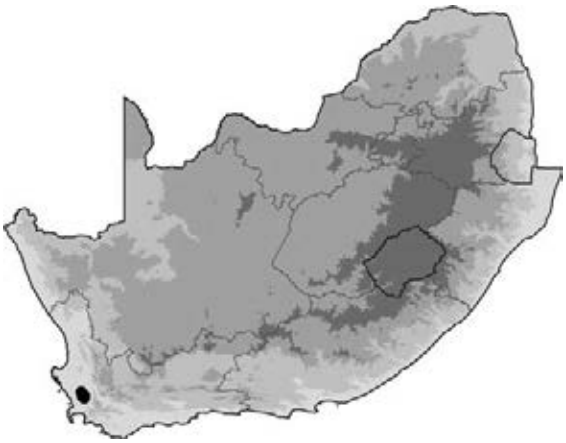
Variation across the range of *Babiana ecklonii* is puzzling. It is fairly uniform in the Olifants River Mtns, where it has blue-violet flowers with very discrete and prominent white to pale yellow nectar guides on the lower lateral tepals, an erect stem, fairly attenuate floral bracts, and style branches terminating in small stigmatic lobes. At the northern edge of its range, at Klawer and on the Gifberg, plants have narrower, more densely pilose leaves and also have flexed and inclined stems. While the type form of *B. ecklonii* has the ovary densely hairy above the base, plants from sites west of the Olifants River Mtns may have the ovary hairy only on the ribs.

A feature of *Babiana ecklonii*, evidently unique in the genus, is variation in style and style branch length within populations. At sites in the Olifants River Valley and near Algeria in the Cederberg, the style in some plants is short, dividing below the anther bases and with style branches ± 2 mm long, but in others the style divides opposite the middle or upper third of the anthers and the branches are ± 4 mm long. The flowers are pollinated by long-proboscid flies.

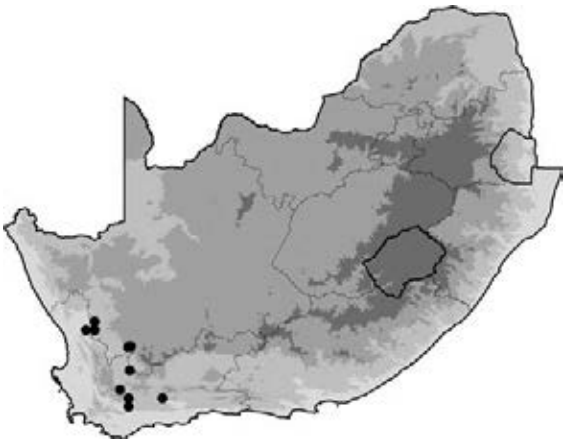
74. **Babiana odorata** *L.Bolus* in South African Gardening and Country Life 22: 243 (1932a); Lewis: 60 (1959); Goldblatt & Manning: 77 (2007). Type: South Africa, [Western Cape], near Porterville, 4 August 1897, *R. Schlechter 10725* (BOL, lecto., designated by Lewis: 61 (1959); K, S, isolecto.).

Plants 50–150 mm high, ± acaulescent. *Stem* inclined, usually with short lateral branches, velvety. *Leaves* lanceolate, pleated, softly hairy. *Spike* inclined, 3- to 8-flowered; bracts green with dry rust-coloured tips, softly hairy, 15–25 mm long, inner slightly shorter than outer, divided to base. *Flowers* zygomorphic, usually creamy yellow with deep yellow blotches on lower tepals, sometimes upper tepals flushed pale mauve, spicy violet-scented; perianth tube narrowly funnel-shaped, 10–14 mm long; tepals unequal, dorsal largest, 26–34 mm long, lower joined to upper laterals for ± 3 mm and to each another for 2–3 mm, forming a prominent lip, 20–22 mm long. *Stamens* unilateral; filaments arched under dorsal tepal, 14–17 mm long; anthers 5–6 mm long, blue or turquoise. *Ovary* densely hairy; style usually dividing opposite anther apices, branches 4–5 mm long, expanded apically. *Flowering time*: late July to early September.

Distribution and ecology: restricted to the southwestern corner of Western Cape, South Africa, extending from Porterville and Piketberg to the Tygerberg near Cape Town; mainly on gravelly granite-derived soils, occasionally on sandstone, at low elevations in renosterveld.



Distribution of ***Babiana odorata***.



Diagnosis: the attractive *Babiana odorata* is a common species of the loamy clay or granitic soils of the Swartland north of Cape Town and is a pleasant sight in lightly disturbed renosterveld in early spring around Malmesbury and Moorreesburg. Plants have short, velvety stems or are almost stemless, the flowers then borne close to ground level. The flowers may be pale creamy yellow with bright yellow lower tepals or rarely flushed pale mauve, but are always intensely fragrant, with a spicy to pleasant violet odour, the scent varying with ambient temperature and age of the flowers, which each last three days. *Babiana odorata* is most easily confused with the vegetatively similar *B. patula*, which occurs in similar habitats to the east, in the Breede River Valley and across the low hills of the southern Cape. Most readily distinguished by the ovary smooth or lightly hairy on the ribs vs. densely hairy in *B. fragrans*, *B. patula* has dull yellowish or white or more often pale mauve to blue or dull purple flowers with yellow markings and a particularly strong fragrance, often of violet or freesia.

75. **Babiana noctiflora** *J.C.Manning & Goldblatt* in Strelitzia 18: 78 (2007). Type: South Africa, Western Cape, Slent Farm, SE end of Paardeberg, granite outcrops, 28 Sept. 1999, *P. Goldblatt 11172* (NBG, holo.; K, MO, NBG, PRE, iso.).

Plants 180–300 mm high. *Stem* usually with 2 to 4 branches, flexed outward above, velvety to silky hairy. *Leaves* lanceolate, pleated, softly hairy, reaching to ± middle of spike. *Spike* inclined, 4- to 8-flowered; bracts green with dry rust-coloured tips, silky hairy, 12–15 mm long, inner slightly shorter than outer, divided to base. *Flowers* zygomorphic, creamy yellow, lower lateral tepals deep yellow, violet-scented; perianth tube 35–50 mm long, slender and cylindric below, with long wide throat, 15–25 mm long; tepals unequal, dorsal 27–32 mm long, inclined toward ground, lower tepals joined to upper laterals for ± 5 mm, lower three

Distribution of ***Babiana noctiflora***.

Distribution of ***Babiana scariosa***.

22–25 mm long. *Stamens* unilateral; filaments arched, 28–30 mm long; anthers 6–7 mm long. *Ovary* densely hairy; style dividing below or opposite base of anthers, branches ± 4.5 mm long, expanded at apex. *Flowering time*: late September to mid-October.

Distribution and ecology: a narrow endemic of the Paardeberg between Malmesbury and Agter-Paarl, in Western Cape, South Africa; on granite outcrops in fynbos.

Diagnosis: resembling *Babiana odorata* in the relatively broad leaves and pale yellow flowers, *B. noctiflora* has a taller but inclined stem, up to 300 mm long, and inclined spike. The flowers stand out in having an elongate perianth tube 33–50 mm long, compared with 10–14 mm in *B. odorata*. It is also late flowering, from mid-September until mid-October, which contrasts with the early spring flowering of *B. odorata* in July and August. The flowers have the typical features of ser. *Mucronatae*, having inner bracts divided to the base, a densely hairy ovary and linear anthers. The flowers are adapted for pollination by night-flying moths and they remain open and scented all night.

Ser. **Scariosae** *(G.J.Lewis) Goldblatt & J.C.Manning*, name at new rank. *Babiana* sect. *Scariosae G.J.Lewis* in Journal of South African Botany, Suppl. 3: 122 (1959). Type: *B. spathacea* (L.f.) Ker Gawl.

Floral bracts dry and membranous; flowers zygomorphic or actinomorphic, dorsal tepal shorter or longer than perianth tube; ovary smooth.

76. **Babiana scariosa** *G.J.Lewis* in Journal of South African Botany, Suppl. 3: 122 (1959); Goldblatt & Manning: 80 (2007). Type: South Africa, [Northern Cape], between Oorlogskloof and Papkuilsfontein, Sept. 1939, *C.L. Leipoldt 3043* (BOL, K, syn.).

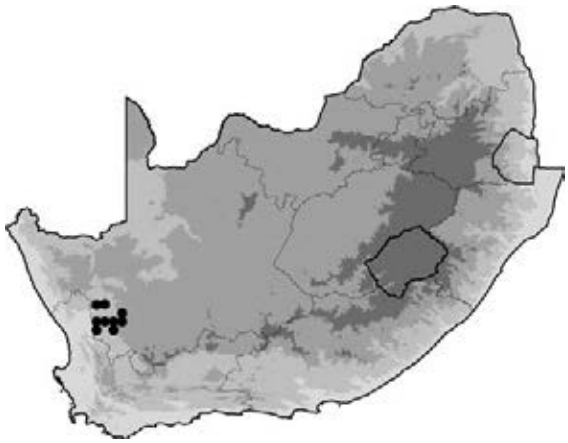
Plants mostly 300–600 mm high, occasionally up to 800 mm. *Stem* erect, smooth, usually with several short branches held close to axis. *Leaves* linear-lanceolate, pleated, shortly velvety. *Spike* erect, congested, many-flowered; bracts dry-papery, smooth, brown or ± translucent with brown flecks, attenuate, 20–24 mm long, inner bract divided for ± ⅔ its length. *Flowers* zygomorphic, blue to mauve with white to pale yellow markings on lower tepals; perianth tube narrowly funnel-shaped, 11–20 mm long; tepals unequal, dorsal largest, 23–27 × 6–11 mm, lower tepals joined to upper laterals for ± 5 mm, shortly clawed, 17–20 × 6–8 mm. *Stamens* unilateral; filaments arched, 12–14 mm long; anthers 5–7 mm long, yellow. *Ovary* smooth; style dividing opposite middle of anthers, branches 3–4 mm long. *Flowering time*: August to mid-October.

Distribution and ecology: extending from the Bokkeveld Mtns and Roggeveld Escarpment in Northern Cape, South Africa, to the Hex River Mtns and western Little Karoo near Montagu and the Touwsberg in Western Cape; on dry sandstone or clay slopes, in arid fynbos or karroid scrub.

Diagnosis: *Babiana scariosa* is readily recognised by the blue flowers with white to yellow markings, a perianth tube of intermediate length, mostly 12–15 mm (but up to 20 mm in the type) combined with distinctive dry, brown to translucent floral bracts. Plants can be relatively tall for the genus, up to 500 or even 800 mm but plants from the Bokkeveld Plateau are consistently shorter, mostly ± 300 mm tall. *Babiana scariosa* is most closely allied to acaulescent *B. papyracea*, which has a radially symmetrical, short-tubed flower, but similar dry, membranous floral bracts. It may also be related to *B. spathacea* of the western Karoo, which also has similar floral bracts, but the flowers of this species are creamy beige with red markings on the lower tepals and have an elongate perianth tube. Hybrids between this species and *B. scariosa* may be found where the two co-occur on the Bokkeveld Plateau south of Nieuwoudtville.

77. **Babiana spathacea** *(L.f.) Ker Gawl.* in Curtis's Botanical Magazine 17: t. 638 (1803c), name misapplied to *B. sambucina*; Lewis 3: 124 (1959); Goldblatt & Manning: 80 (2007).

Gladiolus spathaceus L.f.: 96 (1782). Type: South Africa, [Northern Cape], without precise locality, as Bokkeveld "Bockland" and Hantam, Nov. 1774, *Thunberg s.n.* (UPS–THUNB 1070, holo.).



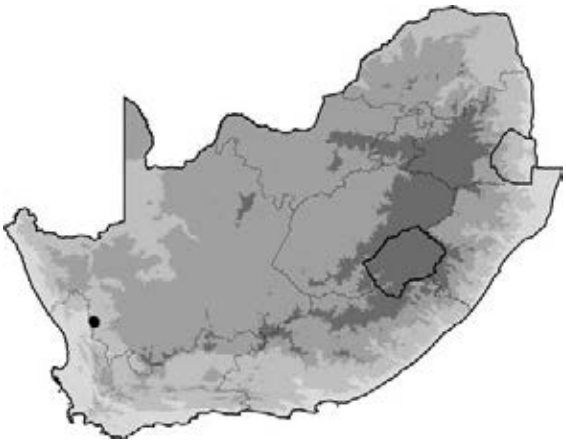
Gladiolus paleaceus Vahl: 118 (1805). Type: South Africa, without precise locality, collector unknown (C: ex Herb. Royen, presumed holo.).

Babiana densiflora Klatt: 348 (1882). Type: South Africa, [Northern Cape], Hantam Mtns, *Meyer 1869* (B, holo.).

Plants mostly 250–400 mm high. *Stem* erect, smooth, usually with several short branches held close to main stem, smooth. *Leaves* linear-lanceolate, pleated, shortly hairy. *Spike* congested, erect, many-flowered; bracts dry-membranous, pale brown or ± transparent with brown flecks, attenuate, 25–50 mm long, inner slightly shorter than outer, divided for ⅔ its length, rarely completely, but often torn at anthesis and appearing divided to base. *Flowers* zygomorphic, creamy beige to white, sometimes pale lilac outside, or bluish white to lilac, lower tepals and lower half of throat with small red or purple markings, odourless; perianth tube cylindric, sharply curved above, (30–)35–45 mm long; tepals unequal, dorsal 20–23 × 6 mm, ovate-spathulate, upper laterals curved backward, lower 3 joined together for a short distance, directed forward, ± 15 mm long. *Stamens* unilateral; filaments weakly arched, ± 10 mm long; anthers 4–6(–7) mm long, usually violet or purple. *Ovary* smooth; style dividing opposite anther tips, branches usually short, 1.8–2.5(–4.0) mm long. *Flowering time*: mostly from mid-September to early November.

Distribution and ecology: restricted to the western Karoo of Northern Cape, South Africa, extending from Loeriesfontein in the north to Calvinia and near Nieuwoudtville in the south; stony clay soils, often in dolerite outcrops, in karroid scrub and renosterveld.

Diagnosis: *Babiana spathacea* is immediately recognised by the long-tubed, usually creamy beige to ± white flowers with dark red to purple markings near the bases of the lower three tepals, a perianth tube 35–45 mm long and dorsal tepal ± 25 mm long. The dry, membranous, long-cuspidate floral bracts, which prompted the name *spathacea*, are distinctive only in combination with the perianth characters. Two other species also have similar floral bracts, *B. scariosa*, which has bilabiate, blue flowers with a relatively short perianth tube, 12–20 mm long, and the acaulescent *B. papyracea*, which has large, radially symmetric flowers. South of Nieuwoudtville plants included in *B. spathacea* are unusually variable, some having pale lilac-blue flowers with purple markings, a somewhat smaller perianth with the tube 30–36 mm long and the dorsal tepal 13–23 mm long. These plants also sometimes have longer style branches, up to 4 mm long, unusual for the species, in which 1.8–2.0 mm long is typical.



Distribution of ***Babiana spathacea***.

It seems likely that hybridisation with *Babiana scariosa*, which also grows there and in the same habitat, is the source of the bluish colouring, shorter perianth tube, and longer style branches. Closer to Nieuwoudtville plants have white flowers with red markings, flushed lilac on the tube and reverse of the tepals, and the anthers and pollen are dark purple. Flowers are smaller and have a tube ± 30 mm long and a dorsal tepal ± 15 mm long, but the style branches in these plants are 2.0–2.5 mm long, which is typical of *B. spathacea*. The shift in flower colouring and perianth size is puzzling but so striking that this distinctive race of *B. spathacea* probably deserves taxonomic recognition. The pattern of variation needs additional study before an informed decision can be reached.

78. **Babiana papyracea** *Goldblatt & J.C.Manning* in Strelitzia 18: 81 (2007). Type: South Africa, Northern Cape, Glenlyon farm, S of Nieuwoudtville, tillite flats, 4 Oct. 2000, *P. Goldblatt 11611* (NBG, holo.; K, MO, PRE, iso.).

Plants up to 150 mm high, including leaves. *Stem* short or subterranean, closely 2- to 4-branched, usually forming small tufts. *Leaves* several in basal tuft, linear, pleated, shortly velvety, 2–4 mm wide. *Spike* congested, 3- to 8-flowered; bracts dry, membranous, pale with brown flecks, 30–35 mm long, tapering to attenuate, awn-like tips, with brown central vein, inner ± as long as outer, usually divided for ± ⅔ its length. *Flowers* actinomorphic, pale or deep blue-purple (rarely white), tepals often darker toward base and with white markings, throat usually white, unscented; perianth tube filiform, straight, 35–45 mm long, thick walled and tightly enclosing style; tepals subequal, narrowly lanceolate, 26–32 × 5–6 mm, spreading at ± 70° from vertical when fully open. *Stamens* symmetrically arranged; filaments erect, surrounding style, ± 7 mm long; anthers ± 8 mm long, straight, weakly diverging, later arching inward, light mauve; pollen cream-coloured. *Ovary* smooth; style dividing opposite lower half of anthers, branches slender, ± 2.5 mm long. *Flowering time*: late September and October.

Distribution of ***Babiana papyracea***.

Distribution and ecology: a narrow endemic of the Bokkeveld Plateau in Northern Cape, South Africa, only known from near Nieuwoudtville and a short distance to the south of the town; on stony clay ground in renosterveld.

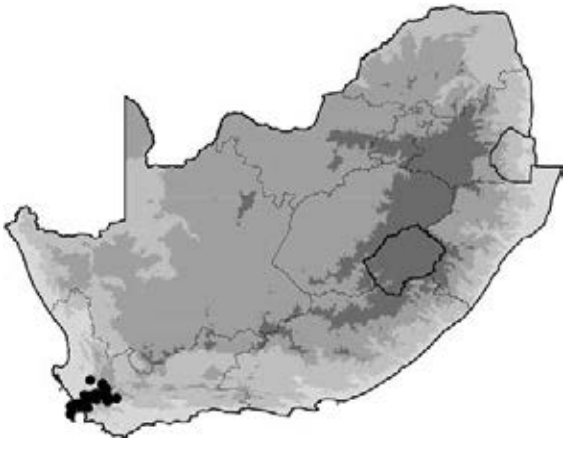
Diagnosis: *Babiana papyracea* is recognised by the ± acaulescent habit, and radially symmetric, blue-mauve flowers with dry, membranous floral bracts with attenuate awn-like tips. It is most closely related to the taller, short-tubed *B. scariosa*, which has bilabiate flowers but similar dry floral bracts, also shared with long-tubed *B. spathacea*, both of which also occur in the immediate vicinity of Nieuwoudtville. The radially symmetric flower of *B. papyracea* is a striking contrast to the zygomorphic flowers of its two relatives. The flowers of *B. papyracea* appear to be adapted for pollination by hopliine beetles.

Ser. **Babiana**

Flowers mostly zygomorphic, shades of blue to violet or yellow, dorsal tepal usually longer than perianth tube; ovary variously hairy.

79. **Babiana fragrans** *(Jacq.) Steud.*, Nomenclator botanicus, edn. 2, 1: 176 (1840); Goldblatt & Manning: 83 (2007). *Gladiolus fragrans* Jacq.: t. 14 (1797). Type: South Africa, without precise locality or collector, cultivated in Vienna, illustration Jacq.: t. 14 (1797).

Babiana plicata Ker Gawl.: t. 576 (1802a), illegitimate superfluous name for *Gladiolus fragrans* Jacq. (1797). Type: South Africa, without locality, illustration in Ker Gawl.: t. 576 (1802a).



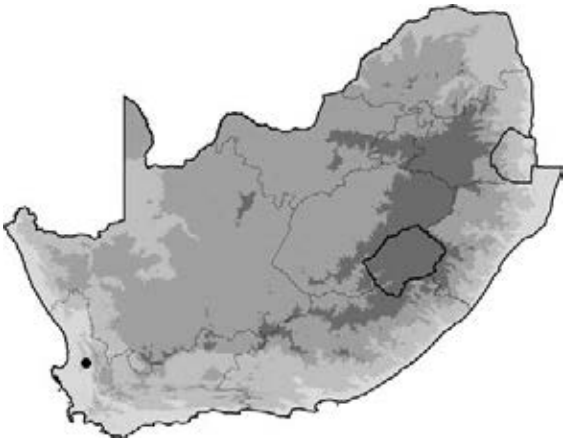
Babiana disticha Ker Gawl.: t. 626 (1803b). *Gladiolus distichus* (Ker Gawl.) Roem. & Schult.: 440 (1817). Type: South Africa, without precise locality, illustration in Ker Gawl.: t. 626 (1803b).

Babiana lilacina Eckl.: 31 (1827). Type: uncertain, possibly from Devils Peak, Cape Town, *Ecklon 123* '*Babiana lilicina*' (location unknown).

Plants 70–200 mm high. *Stem* erect, often branched, velvety. *Leaves* lanceolate to oblong, ascending, up to 20 mm wide, lightly pleated, shortly hairy. *Spike* ± erect, 4- to 10-flowered; bracts green with dry rust-coloured tips, usually densely hairy, 12–18 mm long, inner usually slightly shorter than outer, divided to base. *Flowers* zygomorphic, pale deep violet, occasionally creamy yellow, lower lateral tepals usually with narrow median streak or blotch, and with dark blue or purple markings near base, lightly to intensely fragrant; perianth tube narrowly funnel-shaped, 18–20 mm long; tepals subequal, dorsal ascending, 18–22 mm long, lower tepals joined to upper laterals for 2–3 mm, lower ± 18 mm long. *Stamens* unilateral; filaments suberect, 12–16 mm long; anthers 6–7 mm long, mid- to dark blue. *Ovary* densely hairy; style dividing between base and middle of anthers. *Flowering time*: mainly late August and September.

Distribution and ecology: South Africa, Western Cape, extending from Ceres and Malmesbury to the Cape Peninsula; occurring on sandstone, granite and occasionally clay slopes.

Diagnosis: seemingly relatively unspecialised in the section, *B. fragrans* is recognised by the subequal, spreading tepals, the dorsal only slightly longer than the lower, and small pale markings edged in darker blue or purple on the lower tepals. The perianth tube is about as long as or slightly longer than the dorsal tepal and the erect, usually branched stem bears spikes of up to 10 flowers. The suberect stamens are unilateral and the anthers parallel and contiguous, and usually dark blue. The soft-textured, hairy leaves are lightly pleated and often oblong rather than the usual sword-shape in sect. *Babiana*. The flowers have a strong, pleasant scent, likened to carnations. Somewhat variable across its range, *B. fragrans* from the interior southwestern Cape has a more strongly bilabiate flower with the dorsal tepal up to 5 mm longer than the lower and the upper lateral tepals are united for a short distance with the lower, thus forming a more pronounced lip than is evident in plants from the Cape Peninsula and nearby.



Distribution of ***Babiana fragrans***.

80. **Babiana tubaeformis** *Goldblatt & J.C. Manning* in Goldblatt et al. in Bothalia 38: 53 (2008), as a new name for *B. longiflora* Goldblatt & J.C.Manning: 94 (2004) & 84 (2007), illegitimate homonym, not *B. longiflora* (L.f.) Steud.: 686 (1840) [= *Tritonia cooperi* subsp. *cooperi*]. Type: South Africa, Western Cape, 3218 (Clanwilliam): ± 28 km north of Piketberg, 31 Aug. 2002, *P. Goldblatt & L.J. Porter 12129* (NBG, holo.; MO, iso.).

Babiana stricta var. *grandiflora* G.J.Lewis: 46 (1959). Type: South Africa, [Western Cape], 18 miles north of Piketberg, 28 July 1950, *G.J. Lewis 2197* (SAM, holo.; SAM, iso.).

Plants mostly 150–200 mm high. *Stem* erect, often branched, velvety hairy. *Leaves* lanceolate to oblong, mostly 9–12 mm wide, lightly pleated, fairly soft-textured, sparsely hairy. *Spike* suberect, 6- to 10-flowered; bracts green with dry rust-coloured tips, outer ± obtuse to bilobed at apex, densely hairy, mostly 16–20 mm long, inner slightly shorter than outer, divided to base. *Flowers* zygomorphic, lilac to deep mauve or violet, lower tepals white in centre with spear-shaped reddish basal mark, or with narrow median white stripe, lightly rose-scented; perianth tube slender, straight, widening in upper ⅓, 25–30 mm long; tepals subequal, ascending, 20–24 mm long, dorsal mostly 1–3 mm longer than lower 3, upper laterals joined to lower tepals for ± 2 mm. *Stamens* unilateral; filaments weakly arched, mauve, ± 15 mm long; anthers ± 6 mm long, dark purple, with narrow connective visible. *Ovary* densely hairy; style dividing between middle and apex of anthers, branches 3–4 mm long, expanded and densely ciliate at tips, exceeding anthers. *Flowering time*: mainly mid-August to mid-September.

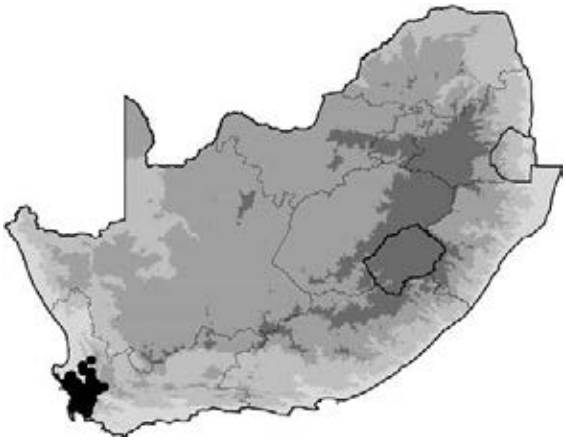
Distribution and ecology: poorly collected, *B. tubaeformis* is known only from flats at the foot of the Piketberg and Porterville Mtns in Western Cape, South Africa; on stony sandstone ground in transitional fynbos–renosterveld.

Distribution of ***Babiana tubaeformis***.

Diagnosis: *Babiana tubaeformis* has been collected several times at the same locality or close by north of Piketberg. It differs from *B. nervosa* in its longer tubed flowers and particularly in the fairly broad, soft-textured leaves arranged in a spreading fan, unlike the fairly rigid, narrow, deeply pleated, ± erect, shortly hairy leaves of *B. nervosa*. Possibly most closely related to *B. fragrans*, which has comparable, soft-textured, long-hairy, fairly broad leaves and large floral bracts rust-coloured only at the tips. *Babiana tubaeformis* is recognised in sect. *Babiana* by the elongate perianth tube 25–30 mm long and the dark violet stamens reaching to about the middle of the dorsal tepal. Other long-tubed species of sect. *Babiana*, *B. ecklonii* and *B. latifolia*, are unlike *B. tubaeformis* in their odourless, dark violet flowers with a slender perianth tube 30–47 mm long, curved at the apex, and the lower tepals joined to one another for at least 4 mm (5–7 mm in *B. ecklonii*), thus forming a strongly bilabiate perianth with horizontally extended lower tepals and the dorsal erect. *Babiana fragrans* also has strongly scented flowers with a perianth tube 18–20 mm long, broader usually light blue (rarely pale yellow) tepals, and the style dividing opposite the lower third of the anthers.

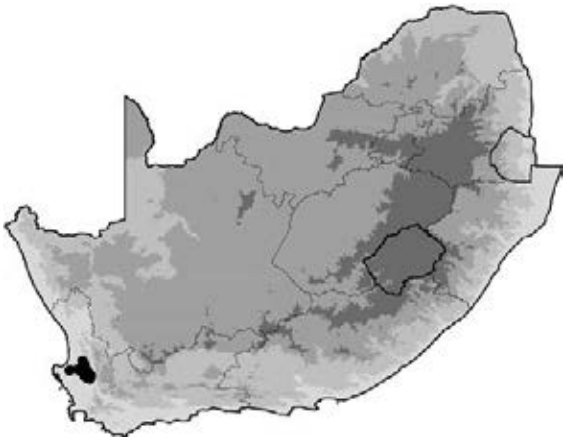
81. **Babiana angustifolia** *Sweet*, Hortus Britannicus: 396 (1826), as a new name for *B. stricta* var. α Ker Gawl.: t. 637 (1803d); Goldblatt & Manning: 85 (2007). *B. stricta* var. *angustifolia* (Sweet) Baker: 166 (1877). *B. pulchra* G.J.Lewis: 48 (1959), illegitimate superfluous name for *B. angustifolia* Sweet. Type: South Africa, without precise locality or date, illustration in Ker Gawl.: t. 637 (1803d).

Babiana atrocyanea Eckl.: 33 (1827). Type: South Africa, [Western Cape], without precise locality, ?*Ecklon s.n.* (S, holo.).



Babiana atrodeltoidea Eckl.: 33 (1827). Type: South Africa, [Western Cape], without precise locality, ?*Ecklon s.n.* [S, lecto., designated by Nordenstam: 289 (1972)].

Babiana stellata Eckl.: 32 (1827). Type: South Africa, [Western Cape], without precise locality, ?*Ecklon s.n.* (S, holo.).



Babiana intermedia L.Bolus: 276 (1932b). Type: South Africa, between Darling and Yzerfontein, Sept 1932, *H.M.L. Bolus s.n.* (BOL 20167, holo.).

[*Acaste pulchra* Salisb.: 332 (1812), illegitimate name, genus invalid.]

Plants mostly 100–150 mm high. *Stem* velvety, usually unbranched, strongly deflexed. *Leaves* lanceolate, strongly pleated, stiffly erect, minutely velvety, inclined. *Spike* inclined, secund, 2- to 8-flowered; bracts green, rust-coloured at tips, velvety, 12–14 mm long, outer ± tricuspidate or trilobed apically, inner often slightly shorter than outer, divided to base. *Flowers* zygomorphic, inverted with perianth tube recurved, dorsal tepal horizontal, unilateral stamens curved back to

Distribution of ***Babiana angustifolia***.

Distribution of ***Babiana inclinata***.

lie above dorsal tepal and lower tepals suberect, dark blue to violet or purple, lower 3 tepals with black or red spear-shaped markings; perianth tube curved, narrowly funnel-shaped, 11–17 mm long; tepals subequal, cupped, 20–22 mm long, dorsal hardly different from others, up to 12 mm wide. *Stamens* unilateral; filaments arching over dorsal tepal, 8–10 mm long; anthers linear, facing spike apex, 4.5–6.0 mm long, blackish. *Ovary* densely hairy; style arching beneath stamens, dividing opposite anther apices, branches 4–5 mm long, with cuneate tips. *Flowering time*: August and September.

Distribution and ecology: extending from Porterville in the north to Somerset West in the south, in Western Cape, South Africa; on damp to seasonally wet sandy or loamy flats and lower slopes.

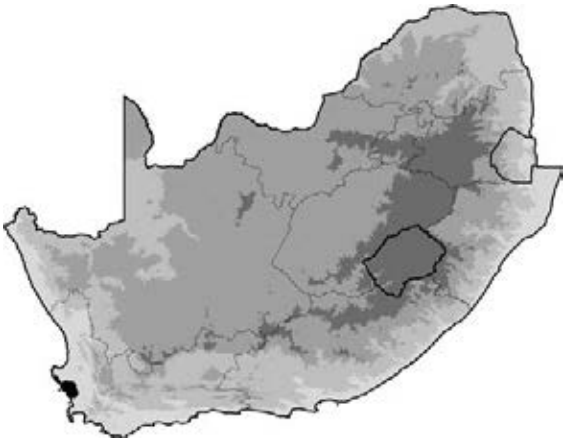
Diagnosis: *Babiana angustifolia* is recognised by the dark blue perianth with relatively broad, subequal tepals held in a shallow cup enclosing the stamens and style. The perianth is inverted so that the dorsal tepal and arched stamens face the spike apex, unusual in *Babiana*, shared with few other species. The lower tepals of the darkly pigmented perianth have blackish or occasionally dark red spear-shaped marks in the lower midline and this together with the blackish anthers gives the flowers a distinctive appearance. The flowers are often visited by hopliine scarab beetles, sometimes seen resting for long periods in the base of the floral cup, and these beetles may be the primary pollinators of *B. angustifolia*.

82. **Babiana inclinata** *Goldblatt & J.C.Manning* in Strelitzia 18: 86 (2007). Type: South Africa, Western Cape, flats at the foot of the Piketberg, north of town, 27 Sept. 2001, *P. Goldblatt & J.C. Manning 11931* (NBG, holo.; MO, PRE, iso.).

Plants mostly 150–300 mm high. *Stem* strongly inclined, velvety, usually branched. *Leaves* lanceolate, closely pleated, velvety, in loose basal fan. *Spike* inclined, secund, several–many-flowered; bracts green with rust-coloured tips, outer 9–12 mm long, obtuse or bilobed at tip, inner slightly shorter to ± as long as outer, divided to base. *Flowers* zygomorphic, inverted, with perianth tube recurved, dorsal tepal horizontal, unilateral stamens curved back to lie above dorsal tepal and lower tepals suberect, blue to violet, lower tepals often and dorsal sometimes cream-coloured, lower with black or reddish markings in lower ⅓, unscented; perianth tube curved, narrowly funnel-shaped, ± 10 mm long; tepals unequal, oblong-oblanceolate, dorsal held somewhat apart, 22–24 mm long, lower tepals joined to upper laterals for ± 2 mm, 18–20 mm long. *Stamens* unilateral; filaments arched over dorsal tepal, 12–15 mm long; anthers linear, facing spike apex, 5–6 mm long, often with narrow portion of connective visible between thecae; anthers and pollen purple, lilac or white. *Ovary* densely hairy; style dividing opposite middle of anther level, branches ± 3.5 mm long, expanded apically. *Flowering time*: mid-August and September.

Distribution and ecology: restricted to the southwestern corner of Western Cape, South Africa, extending from Porterville and Gouda to Piketberg and Hopefield; occurring on damp clay flats and lower slopes.

Diagnosis: *Babiana inclinata* has been confused with the vegetatively similar *B. angustifolia*, which also has inverted flowers, but *B. inclinata* has a more widely cupped flower, unequal tepals that do not form a cup, a dorsal tepal 22–24 mm long and held well apart from the others, and the anthers are purple to lilac or white rather than almost black. The lower tepals are shortly united with the upper laterals for about 2 mm to form a distinct lower lip, and the free parts are 12–15 mm long. While the anthers of *B. inclinata* are the same size as in *B. angustifolia*, 5–6 mm long, the filaments are longer, 12–15 mm versus 8–10 mm in *B. angustifolia*. The tepals of *B. angustifolia* are ± equal, 20–22 mm long and overlap one another forming a cup and the filaments are 12–15 mm long. In the inverted flowers of the two species the unilateral stamens lie above the dorsal tepal and face the top of the spike.



83. **Babiana rubrocyanea** *(Jacq.) Ker Gawl.* in König & Sims, Annals of Botany 1: 234 (1804); Lewis: 36 (1959); Goldblatt & Manning: 87 (2007). *Ixia rubrocyanea* Jacq.: 268 (1791a). *Ixia cyanea* Pers.: 49 (1805), either an orthographic error or if new then a superfluous name for *I. rubrocyanea* Jacq. *Gladiolus rubrocyaneus* (Jacq.) Vahl: 98 (1805). *Acaste venusta* Salisb.: 332 (1812), illegitimate superfluous name for *B. rubrocyanea* (Jacq.) Ker Gawl. *B. stricta* var. *rubrocyanea* (Jacq.) Baker: 165 (1877). [*Babiana rubro-coerulea* Pritz.: 134 (1854) orthographic error for *rubrocyanea*]. Type: South Africa, without precise locality, illustration in Jacq.: t. 285 (1791 [1788–1795]).

[*Ixia africana* Hornem. ex Roem. & Schult.: 424 (1817), invalid name only in synonymy.]

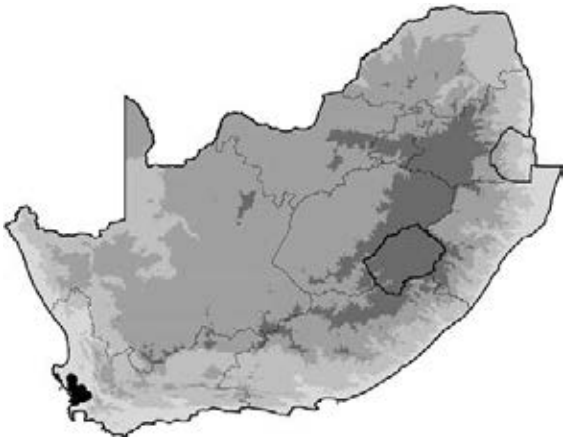
Plants 50–150 mm high. *Stem* strongly flexed outward and inclined, usually branched. *Leaves* lanceolate, pleated, hairy. *Spike* inclined, 5- to 10-flowered; bracts green with brown tips, velvety, outer trilobed at apex, 18–30 mm long, inner slightly shorter than outer, divided to base. *Flowers* subzygomorphic with only stamens and style unilateral, deep blue with red centre outlined in white, odourless; perianth tube narrowly funnel-shaped, 15–20 mm long; tepals subequal, symmetrically disposed, widely cupped, 20–24 mm long. *Stamens* unilateral (possibly sometimes symmetrically arranged); filaments arching over lower tepals, 10–13 mm long; anthers 6–7 mm long, facing spike apex, reddish brown; pollen brown. *Ovary* hairy above base; style dividing opposite middle of anthers, branches short, ± 2 mm long, with broad, flattened tips. *Flowering time*: August to mid-September.

Distribution and ecology: local between Darling and Mamre in Western Cape, South Africa; on stony and sandy granitic slopes in renosterveld.

Diagnosis: *Babiana rubrocyanea* is readily recognised by the deep blue flowers with a dark red centre, and unusual red-brown anthers and pollen. The tepals are subequal and symmetrically arranged but the stamens and style are usually unilateral with the anthers facing the spike apex. The style also has unusually short style branches with very broad tips. *Babiana regia* has superficially similar, dark blue flowers with a red centre but the stamens are symmetrically arranged in the centre of the flower, and the style banches below the anthers into filiform branches that are not or barely expanded apically.

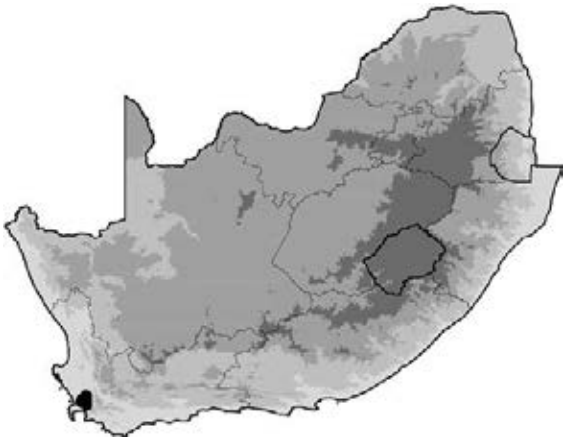
Distribution of ***Babiana rubrocyanea***.

Babiana rubrocyanea is most likely allied to the *B. angustifolia* group of species and possibly most closely to *B. angustifolia*. That species has similarly cupped, subequal tepals, flowers borne on a strongly inclined stem, and outer floral bract bidentate with a central mucro. The latter recall the trilobed to obscurely tricuspidate bracts of *B. rubrocyanea*. Also, the unilateral stamens with the anthers facing the spike apexes of *B. rubrocyanea* have exactly the same orientation in *B. angustifolia*.



Both hopliine beetles and the horsefly, *Philoliche atricornis*, have been recorded visiting *B. rubrocyanea*.

84. **Babiana leipoldtii** *G.J.Lewis* in Journal of South African Botany, Suppl. 3: 33 (1959); Goldblatt & Manning: 87 (2007). Type: South Africa, [Western Cape], between Mamre and Darling, 4 Aug. 1940, *C.L. Leipoldt s.n.* (SAM 55686, holo.).



Plants 100–180 mm high. *Stem* usually erect or slightly inclined, often branched, velvety-hairy. *Leaves* lanceolate, pleated, hairy, usually reaching to ± base of spike. *Spike* erect or inclined, 4- to 8-flowered; bracts green with dry, rust-coloured tips, velvety, 20–35 mm long, inner slightly shorter than outer, divided to base. *Flowers* actinomorphic, blue-violet, somewhat darker in centre, lower tepals sometimes with small red markings in lower ⅓, usually lightly scented of violets; perianth tube funnel-shaped, flared in upper half, 15–20 mm long, walls thick and tightly enclosing style below; tepals subequal, spreading, 25–30 mm long, oblong-ovate. *Stamens* symmetrically arranged; filaments erect, surrounding style, 7–9 mm long; anthers linear, 6–8 mm long, white or yellow. *Ovary* densely hairy above; style dividing between base and middle of anthers, branches ± 4 mm long, expanded at tips. *Flowering time*: late July to mid-September.

Distribution and ecology: a relatively rare endemic of the coastal forelands of Western Cape, South Africa, extending from near Hopefield to Darling and Klipheuwel; on damp sandy or stony flats. The wet, poorly drained sandy flats where it grows are rapidly disappearing under the plough or are being invaded by alien *Acacia* species so that little of its former range remains.

Diagnosis: *Babiana leipoldtii* is distinctive in its actinomorphic flowers with erect, symmetrically arranged filaments enclosing the style and bearing linear, white or

Distribution of ***Babiana leipoldtii***.

Distribution of ***Babiana regia***.

yellow anthers. It may be most closely allied to *B. villosula*, which also has radially symmetric flowers and the two are easily confused. *Babiana villosula* has pale blue to mauve flowers with a small white centre, and usually bluish to mauve anthers, whereas *B. leipoldtii* has violet flowers darker in the centre and white or yellow anthers that contrast with the perianth colour. Both species have short filaments included in the upper part of the perianth tube and the anthers held at the mouth of the tube. Apart from the flowers, *B. leipoldtii* is distinguished from most other species with an actinomorphic flower by the relatively tall, aerial stem and somewhat lax spike. Related species have the stem extended only a short distance above the ground.

85. **Babiana regia** *(G.J.Lewis) Goldblatt & J.C.Manning* in Bothalia 34: 94 (2004) & 88 (2007). *B. stricta* var. *regia* G.J.Lewis: 45 (1959). Type: South Africa, [Western Cape], Bottelary Road near Stellenbosch, Sept. 1950, *G.J. Lewis & D.K. Davis 2216* (SAM, holo.; PRE, SAM, iso.).

Plants 50–120 mm high. *Stem* velvety, strongly flexed outward, simple or branched. *Leaves* narrowly lanceolate, deeply pleated, fairly stiff, shortly rough-hairy. *Spike* ascending, 4- to 10-flowered; bracts green, rust-coloured at tips, velvety-hairy, 12–22 mm long, inner ± as long as outer, divided to base. *Flowers* actinomorphic, deep blue with red centre sometimes edged with diffuse white zone, unscented; perianth tube narrowly funnel-shaped, 10–12 mm long, filiform near base, wider above; tepals subequal, obovate, 18–20 × 8–10 mm. *Stamens* symmetrically arranged; filaments erect, ± 8 mm long; anthers erect, 4–5 mm long, linear, reddish brown. *Ovary* densely hairy; style dividing ± 2 mm below anther bases, branches slender, ± 2 mm long, extending between filaments. *Flowering time*: mainly September to early October.

Distribution and ecology: restricted to the extreme southwestern corner of Western Cape, South Africa, in lowlands between Malmesbury and Stellenbosch; in seasonally damp, well-drained sandy and gravelly slopes and flats. Its habitat is largely given over to agriculture and it is now limited to only a few, small sites that no longer represent viable habitats.

Diagnosis: *Babiana regia* is easily recognised by its actinomorphic flower with broad, ovate, overlapping tepals that form a shallow cup, and coloured dark blue with a deep red centre. The stamens are arranged symmetrically around the short style that divides below the level of the linear anthers and the anthers bear reddish brown pollen. It was initially regarded merely as a colour form of *B. nervosa*, but that species has a zygomorphic flower with blue to mauve, white or cream-coloured, spreading tepals, the lower distinguished from the upper by different markings, unilateral stamens, sagittate anthers with an expanded connective and a style dividing at the base of the anthers. *Babiana rubrocyanea* from Darling, also with bowl-shaped purple flowers with a red centre, is distinguished by its mostly unilateral stamens with the anthers facing the spike apex, and the unusually short style branches with very broad tips. Flowers of *B. regia* produce no detectable nectar and are pollinated by hairy hopliine scarab beetles, of which the common southwestern Cape *Anisonyx ursus* was the most frequent visitor recorded at the one site.

86. **Babiana villosula** *(J.F.Gmel.) Ker Gawl. ex Steud.*, Nomenclator botanicus 1: 371 (1821); Lewis: 28 (1959); Goldblatt & Manning: 88 (2007). *Ixia villosula* J.F.Gmel.: 110 (1796). *B. obtusifolia* Ker Gawl.: 234 (1804), illegitimate superfluous name for *Ixia villosula* J.F.Gmel. *B. stricta* var. *obtusifolia* Baker illegitemate name: 166 (1877). Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 284 (1791 [1788–1795]) '*Ixia villosa*'.

Ixia plicata L.: 4 (1756). *Gladiolus plicatus* (L.) L.: 53 (1762) [not *Babiana plicata* Ker Gawl. (1802a)]. Type: South Africa, without precise locality or collector (type, ?LINN) [name misapplied by Thunb.: 20 (1784) to *B. fragrans*].

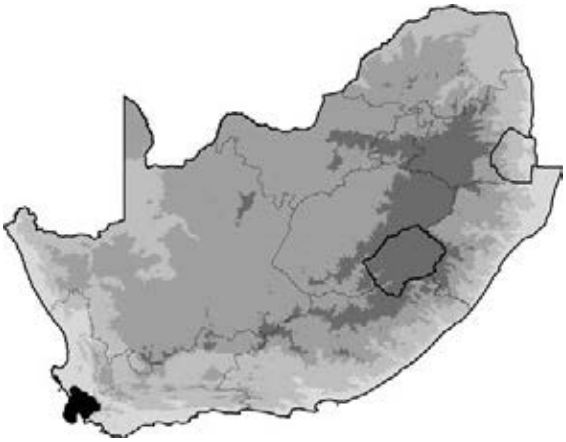
Ixia caerulescens Pers.: 48 (1805). Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 284 (1791 [1788–1795]) '*Ixia villosa*'.

Babiana orthosantha Baker: 27 (1906). Type: South Africa, [Western Cape], as 'Olifants River Valley, October' but incorrect, *Penther 941* (K, syn.).

Babiana hiemalis L.Bolus: 243 (1932a). Type: South Africa, [Western Cape], Wynberg Hill, Aug. 1932, *H.M.L. Bolus s.n.* (BOL 20151, holo.).

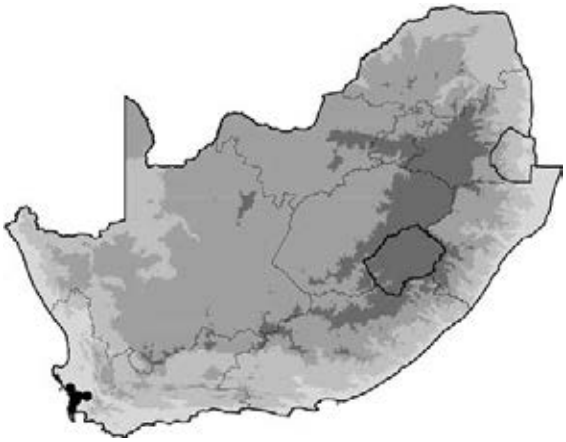
Plants 60–150 mm high, ± acaulescent. *Stem* short, often mostly subterranean, simple occasionally or with 1 or 2 branches, velvety hairy. *Leaves* lanceolate, pleated, softly hairy. *Spike* congested, erect, 2- to 8-flowered; bracts green with dry rust-coloured tips, 18–40 mm long, inner shorter than outer, margins hyaline, divided to base. *Flowers* actinomorphic, white or pale blue to mauve (rarely mauve-pink) with white at tepal bases and throat edged in darker blue, lightly acrid- or violet-scented; perianth tube 18–25(–30) mm long, erect, widening at throat; tepals subequal, 20–30 × 8–13 mm. *Stamens* symmetrically arranged; filaments erect, surrounding style, 3.5–6.0 mm long; anthers 4–6 mm long, divergent, pale blue, mauve, or whitish, linear or connective wider toward base. *Ovary* densely hairy; style dividing opposite base or lower ⅓ of anthers, branches filiform ± 4 mm long, tips hardly expanded. *Flowering time*: May to July, rarely in August.

Distribution and ecology: local in the southwestern corner of Western Cape, South Africa, from Darling and Malmesbury to Gordon's Bay and the Cape Peninsula; on stony sandstone flats and lower slopes in fynbos.



Diagnosis: *Babiana villosula* is recognised by the radially symmetric flowers typically with a pale blue perianth and white throat, or rarely uniformly white (or mauve-pink), short stamens with filaments up to 6 mm long, and usually pale blue or mauve (rarely whitish) anthers held in the mouth of the tube that contrast with the white throat. The anthers are usually linear with parallel lobes but occasional populations have the connective slightly expanded below and the lobes slightly diverging. The flowers are lightly scented with a perfume suggesting violets, usually combined with a light, acrid, somewhat unpleasant chemical component. Flowering early in the season, when few other geophytes are in bloom, *B. villosula* is pollinated by native honey bees foraging for the traces of nectar in the perianth tube as well as pollen.

87. **Babiana blanda** *(L.Bolus) G.J.Lewis* in Journal of South African Botany, Suppl. 3: 30 (1959); Goldblatt & Manning: 89 (2007). *B. macrantha* var. *blanda* L.Bolus: 276 (1932b). Type: South Africa, [Western Cape], near Melkbosstrand, cultivated at Kirstenbosch, Sept. 1932, *O.A. Eaton s.n. as Natl. Bot. Gard. 1110/26* (BOL, holo.).



Plants 80–150 mm high. *Stem* erect, velvety-hairy, rarely 1- or 2-branched. *Leaves* oblong-lanceolate, pleated, hairy, blades held ± at right angles to sheaths. *Spike* suberect, 3- to 6-flowered; bracts green with dry rust-coloured tips, outer 24–35(–45) mm long, inner slightly shorter, divided to base. *Flowers* actinomorphic, pale to deep rosy pink, sometimes white in centre, unscented; perianth funnel-shaped, 20–27 mm long; tepals subequal, obovate or suborbicular, 23–33 × 14–20 mm, forming a shallow bowl. *Stamens* symmetrically arranged; filaments erect, surrounding style, 5–8 mm long; anthers linear, 7–9 mm long, pale pink, diverging. *Ovary* silky hairy above; style dividing below anther bases, branches 3–4 mm long, expanded apically. *Flowering time*: late August to September.

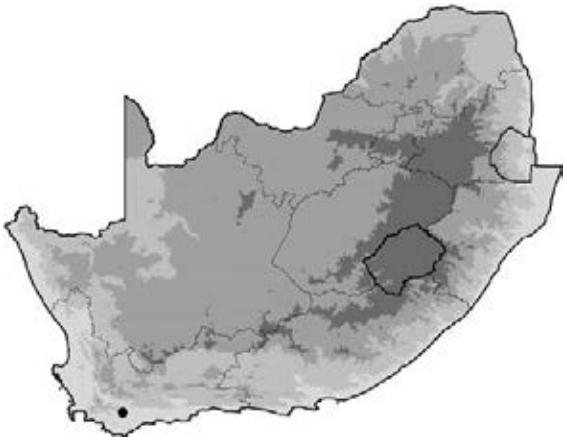
Distribution and ecology: local in Western Cape, South Africa, extending along the Atlantic Coast from Darling to Milnerton and near Agter-Paarl; in seasonally wet, sandy or loamy flats.

Diagnosis: the large-flowered *Babiana blanda* with its bright rosy pink, radially symmetric perianth is now unfortunately on the brink of extinction in the wild.

Distribution of ***Babiana villosula***.

Distribution of ***Babiana blanda***.

Never common, its specialised, seasonally wet habitat has now all but disappeared, and the remaining known wild plants are seriously threatened by encroachment of alien *Acacia* species and pasturage. It appears to be most closely related to *B. villosula*, which has similar, though generally smaller, radially symmetric flowers but blooms earlier in the season. The two may be distinguished by flower size and colour, the tepals of *B. villosula* are 20–30 × 8–13 mm and blue to blue-mauve (rarely white) with a small white centre, whereas those of *B. blanda* are 23–33 × 14–20 and rosy pink, and unscented, unlike *B. villosula*. The style branches of *B. villosula* are filiform with small expanded tips, whereas those of *B. blanda* have prominent, broad apices. The leaf blades of *B. blanda* also tend to be oriented more obliquely to the sheaths than in related species, but this character is variable and cannot be relied upon alone.



Lewis (1959) described several hybrids between *B. blanda* and *B. villosula*. Populations that we have seen on low sandstone outcrops between Klipheuwel and Joostenberg are variable between the two species in flower colour, tepal shape and style length, and presumably represent hybrid swarms.

88. **Babiana foliosa** *G.J.Lewis* in Journal of South African Botany, Suppl. 3: 35 (1959); Goldblatt & Manning: 90: (2007). Type: South Africa, [Western Cape], Riviersonderend, 4 Aug. 1951, *W.F. Barker 7343* (NBG, holo.).

Plants up to 100 mm high. *Stem* reaching shortly above ground level, simple or with 1 or 2 branches. *Leaves* lanceolate, pleated, hairy. *Spike* congested, 2- to 5-flowered; bracts velvety hairy, entirely green, 20–30 mm long, inner slightly shorter than outer, margins hyaline, divided to base. *Flowers* actinomorphic, mauve with cream-coloured markings; perianth tube straight, ± 20 mm long, widening toward throat; tepals subequal, 20–24 × 8–12 mm. *Stamens* symmetrically arranged; filaments surrounding style, ± 10 mm long; anthers 5–6 mm long. *Ovary* densely hairy; style dividing opposite anther bases, branches ± 4 mm long, with broad expanded tips. *Flowering time*: August.

Distribution and ecology: South Africa, Western Cape, near Riviersonderend; presumed to grow on clay-loam flats.

Diagnosis: known only from the type, *Babiana foliosa* is a puzzling plant, with radially symmetric flowers closely resembling those of winter-flowering *B. villosula* from west of the Hottentots Holland Mtns. At first it seems merely to be an eastern form of that species but its flowers have substantially longer filaments, ± 10 mm long vs. 4–6 mm in *B. villosula*, and a stouter perianth tube. The more numerous leaves, for which the species was named, and green bracts without dry rust-coloured tips, also make it easy to distinguish *B. foliosa* from other species of sect. *Babiana* with actinomorphic flowers.

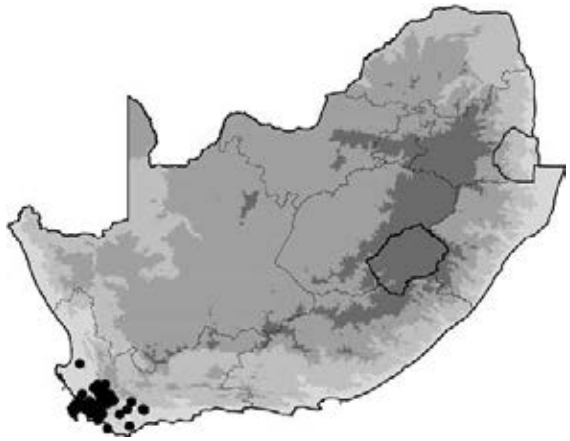
Distribution of ***Babiana foliosa***.

Ser. **Strictae** *Goldblatt & J.C.Manning,* new series. Type: *Babiana nervosa* (Lam.) Goldblatt & J.C.Manning

Flowers zygomorphic or actinomorphic, variously coloured; anthers usually dark purple to black and linear or arrow-shaped with visible connective; ovary densely hairy.

89. **Babiana nervosa** *(Lam.) Goldblatt & J.C.Manning* in Bothalia 44: 47 (2014). *Gladiolus nervosus* Lam.: 724 (1788). Type: South Africa, without precise locality, attributed to *Sonnerat s.n.* (P: Herb. Lamarck, holo.).

Babiana stricta (Aiton) Ker Gawl.: t. 621 (1803a); Lewis: 40 (1959); Goldblatt & Manning: 90 (2007). *Gladiolus strictus* [Sol. in] Aiton: 63 (1789). Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 621 (1803) [neo., designated by Goldblatt & Manning: 94 (2004)].



Babiana erectifolia G.J.Lewis: 3 (1938). *B. stricta* var. *erectifolia* (G.J.Lewis) G.J.Lewis: 43 (1959). Type: South Africa, [Western Cape], Brand Vlei, near Worcester, Sept. 1932, *G.J. Lewis s.n. as Natl. Bot. Gard 2686/32* (BOL, holo.).

Gladiolus ringens Thunb.: 186 (1800), illegitimate homonym, not *G. ringens* Andrews (1798). Type: South Africa, without precise locality, *Thunberg s.n.* (UPS–THUNB, syn.).

?*Babiana caesia* Eckl.: 32 (1827). Type: South Africa, without precise locality, ?*Ecklon s.n.* (location unknown, not at S).

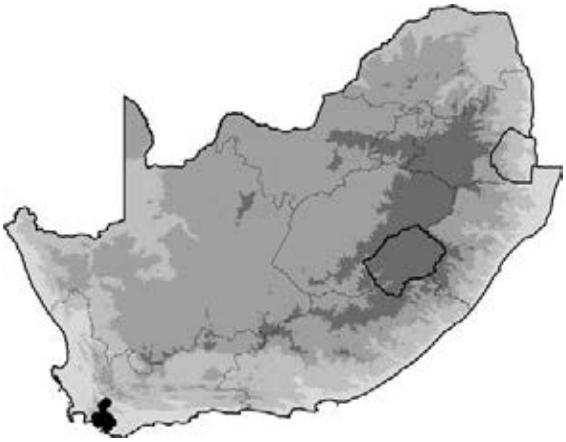
Babiana flavocaesia Eckl.: 32 (1827). Type: South Africa, vicinity of Stellenbosch, ?*Ecklon s.n.* (S, holo.).

Plants 120–200 mm high. *Stem* slender, suberect to flexed outward, velvety, simple or branched. *Leaves* sword-shaped to almost linear, 4–7(–11) mm wide, fairly rigid and deeply pleated, shortly hairy. *Spike* ± erect

Distribution of ***Babiana nervosa***.

or weakly flexed, 4- to 9-flowered; bracts green with dry and brown apices, mostly 8–12(–15) mm long, inner divided to base. *Flowers* weakly zygomorphic, mauve to violet-blue, white or pale yellow, often with contrasting marks at base of lower tepals, apparently unscented or lightly violet-scented; perianth tube narrowly funnel-shaped, 8–18 mm long, widening in upper 3–4 mm; tepals subequal, 15–25 mm long. *Stamens* unilateral; filaments weakly arched or erect, 8–13 mm long; anthers arrow-shaped with broad connective wider at base, 4–7 mm long, usually dark blue-black. *Ovary* hairy; style usually dividing below anther bases, branches 3–4 mm long, expanded toward tips. *Flowering time*: mostly mid-August to early October.

Distribution and ecology: extending from the Cape Peninsula eastward to Worcester and Swellendam in Western Cape, South Africa; in damp to waterlogged clay or gravelly soils in renosterveld or fynbos.



Diagnosis: *Babiana nervosa* is recognised by the several, narrow, deeply pleated, suberect leaves, a blue-mauve, purple-pink, or cream-coloured to pale yellow perianth and a narrow, but partly hollow perianth tube that usually contains nectar. The stamens are unilateral and suberect with sagittate anthers that have the connective expanded in the lower half, and a short style that divides opposite the base of the anthers. Although the tepals are subequal, the lower (adaxial three) have contrasting markings and the lower lateral tepals, and, sometimes along with the dorsal, may be cream-coloured, in contrast to the other tepals which may be bluish.

90. **Babiana purpurea** *Ker Gawl.* in Curtis's Botanical Magazine 26: sub. t. 1019 (1807a), new name for *Ixia purpurea* Jacq.: 268 (1791a), illegitimate homonym, not *I. purpurea* Lam. (1789); Lewis: 47 (1959); Goldblatt & Manning: 91 (2007). *I. flabelliformis* Salisb.: 37 (1796), new name for *I. purpurea* Jacq. and illegitimate superfluous name for *I. villosa* Aiton. *Gladiolus purpureus* (Ker Gawl.) Willd.: 198 (1797). *G. purpureus* (Jacq.) Vahl: 114 (1805), illegitimate homonym, not *G. purpureus* (Ker Gawl.) Willd. (1797). *B. stricta* var. *purpurea* (Ker Gawl.) Ker Gawl.: (1807b) [name misapplied to *B. villosa* (Aiton) Ker Gawl.]. Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 286 (1792 [1788–1795]).

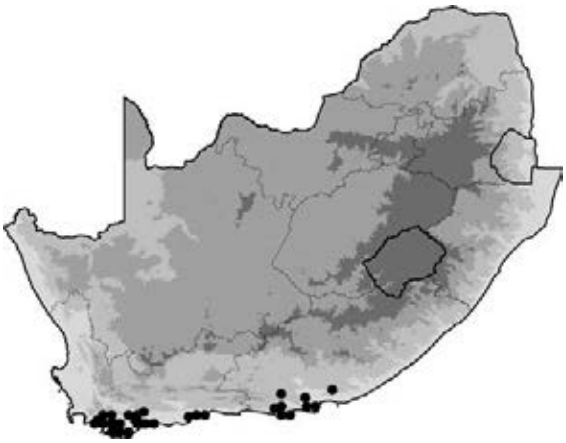
Plants 100–200 mm high. *Stem* velvety, simple or 1- to 3-branched, often flexed outward, with prominent collar of fibres around base. *Leaves* narrowly lanceolate, firm, pleated, hairy. *Spike* velvety, suberect, 4- to 10-flowered; bracts green with rust-coloured tips, 15–25 mm long, inner divided to base. *Flowers* weakly zygomorphic, pink to reddish purple, lower tepals with darker markings near base, lightly fragrant; perianth tube straight, cylindric below, slightly expanded above, 18–28 mm long; tepals subequal, spreading, 18–25 mm long. *Stamens* unilateral; filaments nearly straight, 10–14 mm long; anthers arrow-shaped, parallel, connective not or hardly exposed, facing lower tepals, 6–8 mm long, purple. *Ovary* hairy; style arching behind filaments, exceeding anthers, branches slender, ± 4 mm long, with broad, bilobed tips. *Flowering time*: August and September.

Distribution and ecology: extending from Botrivier to Robertson and Bredasdorp in Western Cape, South Africa; on clay flats and slopes in renosterveld.

Diagnosis: *Babiana purpurea* has pink or purple flowers that at first glance appear to be radially symmetric but the stamens are unilateral and erect and the anthers are parallel, facing the lower tepals, which usually have contrasting markings near the base. The dark blue to blackish anthers are arrow-shaped, suggesting a relationship with *B. nervosa* and *B. villosa* of sect. *Babiana*. Unlike these species, however, the anther connectives are not visibly expanded. The flowers are evidently adapted for pollination by large anthophorine bees that visit the flowers in search of nectar, quantities of which are secreted from septal nectaries into the base of the perianth tube. It can be distinguished from *B. nervosa* by the pink to red-purple perianth colour, perianth tube 18–28 mm long, and unusual style branches, broadly

Distribution of ***Babiana purpurea***.

lobed at the tips and held above the anther apices. *Babiana nervosa* has white to creamy yellow or blue to blue-mauve flowers with creamy white markings on the lower lateral tepals, a perianth tube 10–18 mm long, and fairly short style branches up to 3 mm long, less prominently expanded at the tips, and usually dividing opposite the lower half to middle of the anthers. Although Lewis (1959) described the flowers of *B. purpurea* as sometimes having symmetrically disposed stamens, this condition is evidently rare and not representative of the species.



Babiana purpurea is sometimes confused with a second species of clay soils in the southern Cape, *B. patersoniae*, which extends from Napier and Riviersonderend to Port Elizabeth and Alexandria in Eastern Cape. That species has flowers with a longer perianth tube, 20–30 mm long, lightly flared from the base and curved near the apex, a bluish or mauve to nearly white perianth, and a strong sweet fragrance with a strong clove component. Flowers of *B. patersoniae* may be adapted for pollination by moths, for unlike most species of the genus, the flowers remain open at night when the intense fragrance seems most powerful. The style branches of *B. patersoniae* are also expanded at the tips but the style itself normally divides below the anther apices, in contrast to that of *B. purpurea* which divides at or beyond the anther tips.

91. **Babiana patersoniae** *L.Bolus* in South African Gardening and Country Life 21: 282 (1931); Lewis: 55 (1959); Goldblatt & Manning: 92 (2007). Type: South Africa, [Eastern Cape], Swartkops near Port Elizabeth, cultivated in Cape Town, Sept. 1931, *F.M. Paterson 39* (BOL, holo.; K, iso.).

[*Babiana caerulescens* Eckl.: 32 (1827), invalid name without description.]

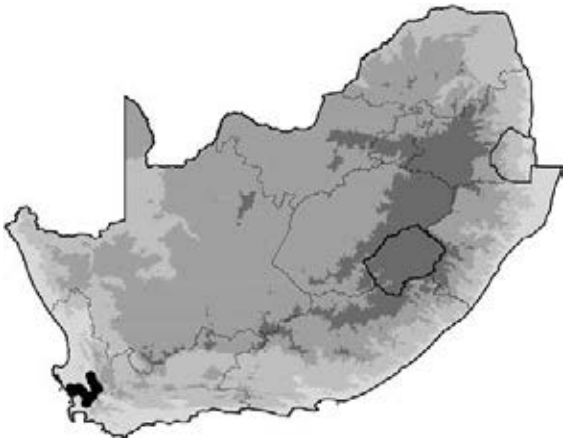
Plants 150–250 mm high. *Stem* suberect, usually with 1 or 2 short branches, velvety. *Leaves* sword-shaped, firm, pleated, closely hairy. *Spike* erect, 2- to 5-flowered; bracts green with dry brown apices, lightly hairy, 12–30 mm long, inner slightly shorter to ± half as long as outer, divided to base. *Flowers* zygomorphic, white to pale blue to mauve, lower lateral tepals partly cream-coloured to yellow, with darker red to purple markings near base, usually strongly scented of cloves, especially at night; perianth tube nearly cylindric, lightly flared in upper half, 20–30 mm long, tepals subequal, dorsal 16–25 × 8–11 mm, lower tepals joined to upper laterals for 1–2 mm, 15–22 mm long. *Stamens* unilateral; filaments arched, 8–12 mm long; anthers 4–5 mm long, blue to blackish, linear to ± arrow-shaped with connective expanded below; pollen cream-coloured. *Ovary* hairy in upper half; style dividing between base and middle of anthers, branches ± 4 mm long, with prominent, spathulate tips. *Flowering time*: August to October.

Distribution and ecology: widespread across southern Western Cape from near Caledon eastward to Alexandria in Eastern Cape, South Africa; most often on clay and loamy slopes in grassland or renosterveld.

Distribution of ***Babiana patersoniae***.

Diagnosis: *Babiana patersoniae* is recognised by a combination of zygomorphic flowers with a moderately long, slender perianth tube 20–30 mm long, dark blue, usually arrow-shaped anthers (sometimes linear) and a densely hairy ovary. The flowers are pale blue to mauve, sometimes largely white, with the lower lateral tepals partly cream-coloured to yellow. The floral bracts range from 12–18 mm in plants from the west to up to 30 mm long in the east where it may possibly be confused with long-tubed but acaulescent *B. sambucina* (section *Teretifolieae*) but *B. patersoniae* always has the inner bracts divided to the base. In the west, *B. patersoniae* may be confused with *B. purpurea*, which also has dark anthers and inner bracts divided to the base but a pink to purple perianth, and longer tepals relative to the tube, which is narrow below and only wider in the upper third, whereas the tube of *B. patersoniae* has a wider diameter and is gradually flared in the upper half. Confusion is also possible with *B. fourcadei*, which also has bracts divided to the base, but a smooth ovary, and is often a more robust plant, usually bearing 3 to 5 short lateral branches. The intensely fragrant flowers of *B. fourcadei* have white lower lateral tepals edged distally in pale blue, long slender style branches not so obviously expanded at the tips, and a generally larger flower with the dorsal tepal 25–30 mm long.

Flowers of *Babiana patersoniae* are thought to be adapted for pollination by settling moths as they remain open at night when the pale colour is easily seen and the sweet clove fragrance is particularly intense. *Babiana patersoniae* is one of only two species of the genus that ranges across the southern coast of South Africa into Eastern Cape.



92. **Babiana melanops** *Goldblatt & J.C.Manning* in Strelitzia 18: 93 (2007). Type: South Africa, Western Cape, east-facing hill slope north of Mamre, on Darling road, 22 Aug. 1999, *P. Goldblatt & I. Nänni 11095* (NBG, holo.; K, MO, PRE, iso.).

Plants mostly 160–200 mm high. *Stem* velvety hairy, usually branched, suberect, strongly deflexed in fruit,

sheathed below ground with thick collar of fibres. *Leaves* lanceolate, pleated, densely hairy, fairly softly textured. *Spike* erect, mostly 6- to 10-flowered; bracts green with dry rust-coloured tips, outer 16–26 mm long, inner slightly shorter, divided to base. *Flowers* actinomorphic, blue or pale mauve, tepals darker in lower ⅓, unscented or scented of lemon; perianth tube slender, 16–27 mm long, filiform below, slightly flared in upper ⅓; tepals subequal, spreading, narrowed and claw-like below, 20–27 mm long. *Stamens* symmetrically arranged; filaments erect, 8–9 mm long, blue; anthers arrow-shaped to linear, with connective expanded and widest at base, blackish to dark purple, sometimes partly turquoise, 7–8 mm long. *Ovary* densely hairy; style dividing just below anther bases. *Flowering time*: August to early September.

Distribution and ecology: centred along the Atlantic Coast of Western Cape, South Africa, between Darling and Mamre, and from Wellington and the Tulbagh Valley; on granitic gravel slopes in renosterveld.

Diagnosis: *Babiana melanops* has long been confused with related *B. villosa*, which also has radially symmetric flowers and prominent, blackish stamens with arrow-shaped anthers but it differs in its suberect stem, tepals spreading horizontally when fully open, and narrowed at the base more-or-less into claws so that the perianth has small windows between the bases of adjacent tepals. The flowers of typical *B. melanops* are either dark blue or mauve with a dark, almost black centre. Plants from the hills near Mamre have sweetly scented flowers, and the perianth tube, 16–17 mm long, contains nectar but other populations, such as those near Darling, have odourless flowers with a longer tube, 20–27 mm long, and only traces of nectar at the top of the tube that is blocked internally by the style. The flowers of the Mamre plants are pollinated by a combination of apid bees, especially *Apis mellifera* foraging for nectar, and by hopliine beetles that assemble on the flowers and sometimes sleep in the flowers, which close at night. The unscented flowers of other populations are evidently pollinated exclusively by hopliine beetles.

Distribution of ***Babiana melanops***.

Plants assigned to *Babiana melanops* from near Wellington and in the Tulbagh Valley, growing on a sandy loam, sometimes in alluvial fans of sandstone rocks, lack the characteristic dark centre of the species and may represent a separate species..

93. **Babiana villosa** *(Aiton) Ker Gawl.* in Curtis's Botanical Magazine 16: t. 583 (1802b); Lewis: 37 (1959); Goldblatt & Manning: 94 (2007). *Ixia villosa* [Sol. in] Aiton: 58 (1789). *Belamcanda villosa* (Aiton) Moench: 214 (1802). *Gladiolus villosus* Vahl: 145 (1805), illegitimate homonym, not *G. villosus* Burm.f. (1768). *B. stricta* var. *villosa* (Aiton) Baker: 166 (1877). Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 583 (1802b) [neo., designated by Goldblatt & Manning: 94 (2007)].

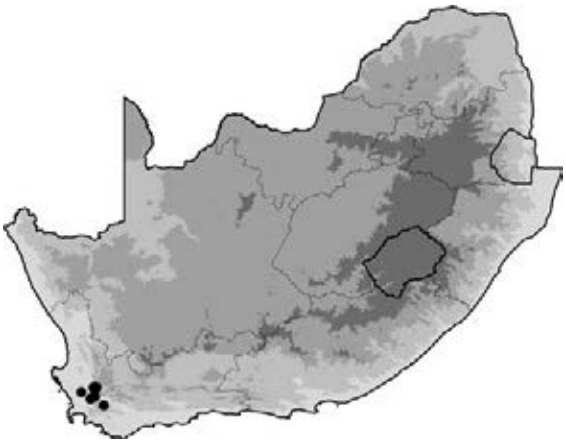
Ixia punicea Jacq.: 8 (1795 [1788–1795]). *Gladiolus puniceus* (Jacq.) Vahl: 114 (1805), illegitimate homonym, not *G. puniceus* Lam. (1788).Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 287 (1794 [1788–1795]).

Gladiolus latifolius Lam.: 49 (1791). Type: South Africa, without precise locality, as Ile de France, *Commerson s.n.* (P: Herb. Lamarck, holo.).

Babiana punicea Eckl.: 32 (1827). Type: South Africa, without precise locality, ?*Ecklon s.n.* (S, holo.).

Babiana villosa var. *grandis* G.J.Lewis: 39 (1959). Type: South Africa, [Western Cape], commonage at Malmesbury, 30 Aug. 1957, *G.J. Lewis 5230* (NBG, holo.; K, iso.).

[*Babiana rosea* Eckl.: 32 (1827), invalid name without description.]



Plants 100–200 mm high. *Stem* usually strongly deflexed, velvety hairy, sometimes branched. *Leaves* lanceolate, pleated, hairy. *Spike* ascending, 3- to 8-flowered; bracts green with dry brown tips, outer, 13–24(–28) mm long, inner ½–⅔ as long, divided to base. *Flowers* actinomorphic, scarlet, purple or mauve-pink, unscented; perianth tube slender, 16–28(–36) mm long; tepals subequal, ovate, 28–33 × 12–15 mm, partly cupped even when fully open. *Stamens* symmetrically arranged; filaments erect, surrounding style, 8–15 mm long; anthers arrow-shaped with prominent connective wider in lower ⅓, dark purple to blackish, 7–9 mm long, up to 3 mm wide, ± latrorse. *Ovary* hairy; style dividing shortly below or opposite anther bases, branches 2–3 mm long. *Flowering time*: August and September.

Distribution and ecology: local in Western Cape, South Africa, in the Tulbagh and Malmesbury Districts; on clay or granitic gravel flats and slopes in renosterveld.

Diagnosis: *Babiana villosa* is recognised by the radially symmetric flowers with large black or purple, arrow-shaped anthers with a broad connective, widest in the lower third. The flowers range in colour from

brilliant scarlet-red to dark purple or deep pink, with a moderately long, slender perianth tube, mostly 16–28 mm long but in some populations up to 36 mm, and an unusually short style, dividing opposite the anther bases. Scarlet-flowered plants are restricted to the upper Tulbagh Valley but elsewhere flowers are deep purple, or on the Paardeberg near Malmesbury to the west, are pink. The latter plants have the longest tube in the species, up to 30–36 mm long.

Flowers of *Babiana villosa* are pollinated primarily by the hopliine scarab beetles, *Anisonyx ursus* and *A. ditus* in the Malmesbury District, and *Lepithrix ornatella* and *Peritrichia rufotibialis* in the Tulbagh Valley. Plants from the Darling–Mamre areas north of Cape Town with violet flowers with a dark centre are now treated as *B. melanops.*

Distribution of ***Babiana villosa***.

23. **Chasmanthe**

Chasmanthe *N.E.Br.* in Transactions of the Royal Society of South Africa 20: 273 (1932). Type species: *C. aethiopica*.

Revisionary accounts: De Vos: 253–261 (1985); Goldblatt et al.: 48–62 (2004).

From the Greek, *chasme*, gaping, *anthos*, flower, alluding to the widely gaping mouth of the flower.

Deciduous geophytes. *Corm* depressed-globose rooting from below; tunics firm-papery, sometimes becoming coarsely fibrous with age. *Stem* round in cross section, simple or branched. *Leaves* several, foliage leaves in a basal 2-ranked fan, blades unifacial, with prominent central vein and numerous fine, closely spaced parallel secondary veins, sword-shaped, plane; cauline leaves few and reduced; marginal anatomy with thickened columnar epidermal cells and without marginal vein. *Inflorescence* a spike, flowers either arranged in 2 opposed ranks or on one side of axis (secund), usually many and crowded; bracts small, green, becoming dry at tips, inner as long or shorter than outer and notched apically. *Flowers* zygomorphic, orange, lower tepals with contrasting markings (rarely yellow) or lower laterals entirely green, unscented, with nectar from septal nectaries; perianth tube elongate, cylindric below and sometimes spirally twisted, expanded abruptly and horizontal above; tepals unequal, dorsal largest, extended forward and ± horizontal and concave, remaining tepals much smaller, directed forward or reflexed. *Stamens* unilateral, arched beneath dorsal tepal, lower (median) filament slightly longer than other 2; anthers parallel, subversatile, slightly diverging from ± middle. *Style* elongate, arching behind stamens; style branches slightly expanded at tips. *Capsules* globose, 3-lobed, leathery, sometimes purple inside, smooth or lightly warty outside. *Seeds* globose, 2 to 4 per locule, orange, shiny and smooth when fresh, coat sometimes fleshy, then wrinkled on drying, raphal vascular trace excluded. *Pollen* monosulcate-operculate, operculum 2-banded; exine perforate-scabrate. *Basic chromosome number* $x = 10$.

Species 3; South Africa, in Northern Cape, Western Cape and Eastern Cape, extending from coastal central Namaqualand and the Bokkeveld Plateau in the northwest to East London and Kentani in the east, usually in bush, or forest margins.

Evidently taxonomically isolated, *Chasmanthe* has often been associated with *Crocosmia* (subtribe *Freesiinae*) because of their similar vegetative appearance, including large corms and a fan of large, relatively soft-textured leaves, and mostly long-tubed orange to red flowers adapted for bird pollination. Differences in chromosome number, $x = 10$ in *Chasmanthe* but $x = 11$ in *Crocosmia*, cast doubt on an immediate relationship and molecular studies provide even stronger evidence for a distant relationship. Current evidence suggests that *Chasmanthe* is allied to *Babiana* ($x = 7$), but we see no support for this relationship based on morphology. Future phylogenetic study may yield additional information on the relationships of *Chasmanthe.*

All three species have flowers adapted for pollination by sunbirds, and the orange seeds, sometimes with fleshy seed coats, are believed to be distributed by birds. This mode of seed dispersal is rare in Iridaceae and may explain the relatively wide ranges of two of the species.

Key to species

1a Stem curved at base of an inclined to horizontal spike and flowers borne on the upper side of axis, usually in one rank; slender part of perianth tube spirally twisted; seeds fleshy when first exposed, later becoming dry and wrinkled; inside of capsule reddish to purple. . . . . 3. *C. aethiopica*

1b Stem and spike erect, often branched and flowers borne in two ranks; slender part of perianth tube not spirally twisted; seeds dry, shiny, with a hard seed coat; inside of capsule straw-coloured:

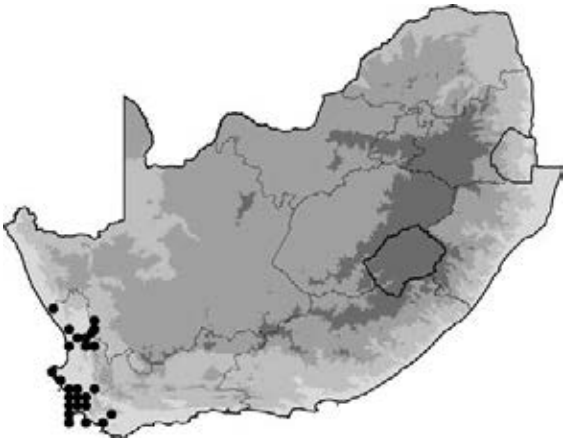
2a Tepals orange to scarlet, the lower ± spreading, except lower median; capsules warty and with nipple-like apex; upper tepal arising 3–7 mm beyond lower tepals . . . . . 1. *C. floribunda*

2b Upper and lower medial tepals orange to scarlet but lower laterals green, all directed forward; capsules smooth, rounded at apex; tepals all arising at ± same level. . . . . .2. *C. bicolor*

1. **Chasmanthe floribunda** *(Salisb.) N.E.Br.* in Transactions of the Royal Society of South Africa 20: 274 (1932); De Vos: 258 (1985); Goldblatt *et al.*: 58 (2004). *Antholyza floribunda* Salisb.: 324 (1812). *Petamenes floribunda* (Salisb.) E.Phillips: 44 (1941). Type: South Africa, without precise locality or collector, illustration in Sims: t. 561 (1802).

Antholyza praealta Delile in Redouté: t. 387 (1813). Type: South Africa, without precise locality or collector, illustration in Redouté: t. 387 (1813).

Chasmanthe floribunda var. *duckittii* G.J.Lewis in L.Bolus: 47 (1933). Type: South Africa, [Western Cape], near Darling, ex hort. Kirstenbosch, *F. Duckitt s.n. as Nat. Bot. Gard. 419/27* (BOL, holo.).



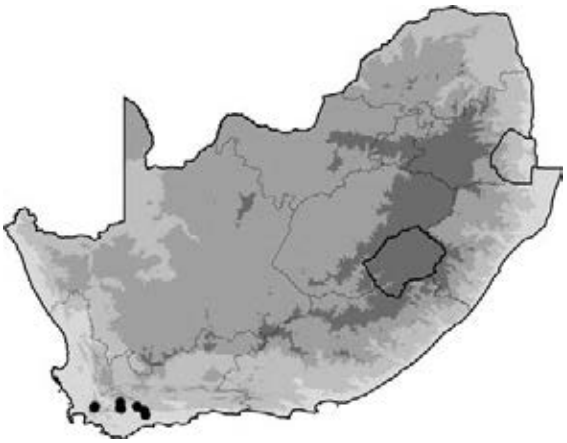
CHASMANTHE. C. aethiopica: A, flowering plant; B, half-flower; C, capsules. ***C. floribunda***: D, flower side view; E, capsule; F, seed.

Plants 500–1 200 mm high. *Corm* depressed-globose, 60–70 mm diam. when mature, with tunics firm-papery, becoming fibrous with age. *Stem* erect, usually branched, branches ascending. *Leaves* sword-shaped, medium-textured, with a prominent main vein, mostly 25–35 mm wide, occasionally barred light purple on sheaths. *Spike* erect, with flowers in two ranks, mostly 30- to 40-flowered; bracts (9–)13–15 mm long, green, flushed red on margins or entirely. *Flowers* deep orange to scarlet (rarely yellow), lower half of tube paler orange or yellow, unscented; perianth tube trumpet-shaped, slender below for (5–)7–8 mm, spirally twisted, abruptly expanded into a wide, cylindric upper part 20–25 mm long, slightly pouched at base, arching outward and horizontal above; tepals unequal, dorsal largest, (21–)24–26 × 6.5–8.0 mm, spathulate, spooned, upper lateral tepals ± 12 mm long, lower laterals ± 15 × 6 mm, lower median ± 10 mm long. *Filaments* with median 4–6 mm longer; anthers 6–7 mm long, parallel, median extending beyond dorsal tepal apex, purple; pollen purple. *Style* arching adaxial to filaments, usually dividing opposite middle of lateral anthers (or anther bases), branches 7–10 mm long. *Capsules* depressed-globose, 3-lobed, showing outline of seeds, 10–15 mm long, tapering to a nipple-like point, surface slightly warty. *Seeds* up to 4 per locule (up to 12 per capsule), globose or weakly angled by pressure, ± 5 mm diam., chalazal end flattened or concave, bright orange, coat hard and shiny. *Chromosome number* 2*n* = 20. *Flowering time*: July to September.

Distribution and ecology: extending in the South African winter-rainfall zone from coastal central Namaqualand in Northern Cape to the Cape Peninsula and east to Hermanus in Western Cape, also inland on the Bokkeveld Mtns near Nieuwoudtville; most common along the coast and coastal mountains, favouring sandstone and granite substrates but in dolerite outcrops in the western Karoo.

Diagnosis: readily distinguished from its congeners by the relatively large flowers, branched stem and erect spike, *Chasmanthe floribunda* has uniformly coloured, bright orange-scarlet flowers borne in an erect, two-ranked spike. It has long been confused with *C. aethiopica*, a shorter plant with an unbranched flowering stem and inflexed spike, either strongly inclined or nearly horizontal, with the flowers borne in a single row on the upper surface of the flowering axis.

Distribution of ***Chasmanthe floribunda***.



The Bokkeveld populations represent a distinct race of *C. floribunda* with some unusual features, most obviously the purple banding on the leaf sheaths and the pale orange perianth. The flowers are also slightly smaller than the coastal form, notably in their shorter perianth tube, up to 25 mm long, dorsal tepal ± 21 mm long, and style dividing below the anther bases, when more typically it divides opposite the middle of the anthers. An attractive, yellow-flowered variant, called var. *duckittii*, is descended from a single plant or small colony found in the 1920s near Darling, north of Cape Town.

Like all species of *Chasmanthe,* the flowers of *C. floribunda* are adapted for pollination by sunbirds. The Malachite Sunbird, *Nectarinia famosa,* is the most frequent visitor, but the Lesser Double-collared Sunbird, *Cinnyrus chalybeus*, may also be seen visiting the flowers.

2. **Chasmanthe bicolor** *(Gasp.) N.E.Br.* in Transactions of the Royal Society of South Africa 20: 273 (1932); De Vos: 259 (1985); Goldblatt et al. 55 (2004). *Antholyza bicolor* Gasp.: 118 (1832). *A. aethiopica* var. *bicolor* (Gasp.) Baker: 179 (1877). *Petamenes bicolor* (Gasp.) E.Phillips: 44 (1941). Type: South Africa, without precise locality or collector, illustration in Morren, La Belgique horticole 2: t. 25/1 (1852), neo. [as lecto.], designated by M.P.de Vos: 259 (1985).

   Antholyza aethiopica var. *minor* Lindl.: t. 1159 (1828). Type: South Africa, without precise locality or collector, illustration in Lindley: t. 1159 (1828).

Plants 700–900 mm high. *Corm* lightly depressed-globose, 20–25 mm diam., tunics thin-papery. *Stem* erect, usually with 1 to 3 short branches, spike strongly drooping in bud and early flowering. *Leaves* several in a basal fan, sword-shaped, with a prominent main vein, reaching ± base of spike, 17–33 mm wide. *Spike* erect, 2-ranked, mostly 18- to 28-flowered; bracts with dry tips, 6–10 mm long. *Flowers* nodding, orange-scarlet, lower lateral tepals green, tube yellow inside, unscented; perianth tube trumpet-shaped, slender below for 6–10 mm, abruptly expanded into a wide, cylindric upper part mostly 20–25 mm long, arching outward and horizontal above; tepals all arising ± at same level, unequal, dorsal largest, 27–40 mm long, spathulate, folded along midline, upper lateral and lowermost tepals directed forward, 5–8 mm long, lower laterals spreading to half-recurved, ± 8 mm long. *Filaments* 45–60 mm long; anthers 6–7 mm long, median usually exceeding dorsal tepal, purple; pollen purple. *Style* arching below filaments, dividing opposite middle of anthers, branches ± 3 mm long. *Capsules* ± ovoid, 3-lobed, showing outline

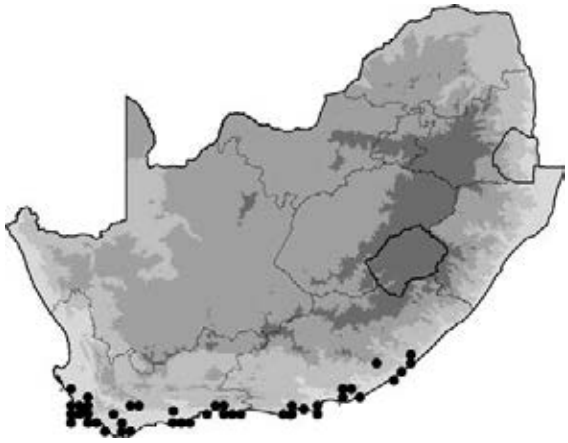
Distribution of ***Chasmanthe bicolor***.

of seeds, 15–20 mm long, smooth. *Seeds* globose, 2 per locule, 3.5–4.0 mm long, yellowish to orange, coat hard, semi-matte. *Flowering time:* July to August.

Distribution and ecology: a narrow endemic of Western Cape, South Africa, occurring near Robertson and MacGregor, and near Swellendam; along streams in the shade of evergreen riverine woodland and bush [records from Franschhoek evidently represent cultivated plants].

Diagnosis: *Chasmanthe bicolor* is recognised by the globose corm, unlike the almost disk-like corm of its two congeners, the slender flower with small lateral and lower tepals, the green colour of the lower lateral tepals and the yellow underside of the tube, and the short style branches, ± 3 mm long. The strongly drooping apex of the spike, evident even after the lower flowers have opened, is also distinctive. The spike is usually straight before the first flower buds open in *C. aethiopica* and *C. floribunda*. *Chasmanthe bicolor* appears to be most closely related to the more robust *C. floribunda*, which has a particularly large corm, and larger, bright orange-scarlet flowers with style branches 7–10 mm long.

3. **Chasmanthe aethiopica** *(L.) N.E.Br.* in Transactions of the Royal Society of South Africa 20: 273 (1932); De Vos: 256 (1985); Goldblatt et al.: 50 (2004). *Antholyza aethiopica* L.: 863 (1759). *Gladiolus stoloniferus* Salisb.: 41 (1796), illegitimate superfluous name for *A. aethiopica* L. *Petamenes aethiopica* (L.) Allan: 305 (1940). Type: South Africa, without precise locality or collector (LINN 60.3, holo.).



Antholyza ringens Andrews: t. 32 (1798), illegitimate homonym, not *A. ringens* L. (1753). *A. aethiopica* var. *ringens* Baker: 167 (1896). Type: South Africa, without precise locality or collector, illustration in Andrews: t. 32 (1798).

Antholyza vittigera Salisb.: 324 (1812). *A. aethiopica* var. *vittigera* (Salisb.) Baker: 167 (1896). *Chasmanthe vittigera* (Salisb.) N.E.Br.: 274 (1932). *Petamenes vittigera* (Salisb.) E.Phillips: 44 (1941). Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 1172 (1809).

Antholyza aethiopica var. *immarginata* Thunb. ex Baker: 230 (1892). *A. immarginata* (Thunb. ex Baker) N.E.Br.: 17 (1928). Type: South Africa, without precise locality, *Thunberg s.n.* (UPS–THUNB 1100, holo.).

Chasmanthe peglerae N.E.Br.: 273 (1932). *Petamenes peglerae* (N.E.Br.) E.Phillips: 44 (1941). Type: South Africa, [Eastern Cape], Kentani division, near Black Rock Cove, July 1902, *A.M. Pegler 500* (K, holo.; BOL, PRE, iso.).

Plants 400–650 mm high. *Corm* depressed-globose, 30–45 mm diam.; tunics papery to fibrous. *Stem* unbranched. *Leaves* several in a basal fan, sword-shaped, medium-textured, with prominent main vein, mostly 12–20 mm wide. *Spike* arching outward to almost horizontal, 10- to 16-flowered, flowers borne on upper side of axis; bracts green or flushed red on margins or entirely, 8–12(–15) mm long, inner minutely forked at tip. *Flowers* facing to side or toward base of spike, bright orange to scarlet, tube often yellowish on underside, unscented; perianth tube trumpet-shaped, slender below for (5–)7–10(–15) mm, twisted through 360°, abruptly expanded into a wide, cylindric upper part 16–25 mm long, lightly 3-pouched at base, arching outward; tepals unequal, dorsal largest, (22–)25–35 × 7–10 mm, spathulate, spooned distally, upper and lower lateral tepals mostly 10–15 mm long, spreading or half-reflexed, lowermost smallest, directed ± forward. *Filaments* arching under dorsal tepal, 40–50 mm long, median one 3–4 mm longer; anthers 5–7 mm long, median reaching ± to apex of dorsal tepal, light purple; pollen purple. *Style* horizontal, dividing opposite upper ⅓ of anthers, often ultimately exceeding them, branches 4–5 mm long. *Capsules* ovoid to barrel-shaped, 3-lobed, smooth, dark red to purple-black inside on opening. *Seeds* up to 3 per locule, more often 1 or 2 (3 to 9 per capsule), globose, initially 6–7 mm diam., bright orange, coat fleshy and smooth, becoming wrinkled on drying and 5–6 mm

Distribution of ***Chasmanthe aethiopica***.

diam. *Chromosome number* 2*n* = 20. *Flowering time*: April to June, sometimes as late as July.

Distribution and ecology: mainly in the winter-rainfall zone of southern Africa, extending from Darling, north of Cape Town in Western Cape, along the southern coast to Kei Mouth and Kentani in Eastern Cape; in coastal bush and along forest margins in a variety of soils.

Diagnosis: *Chasmanthe aethiopica* is readily recognised by its comparatively short stature, the spike seldom reaching more than 500 mm in height, unbranched flowering stem, and inclined to almost horizontal spike. The 10 to 16 flowers are borne in a single congested row on the upper side of the spike axis. The flowers are distinctive in the perianth tube being abruptly expanded above the narrow cylindric lower part, the wider upper part of the tube is lightly expanded into three pouches, and the lower part of the tube is twisted through 360°. Although all *Chasmanthe* species have orange seeds, only those of *C. aethiopica* have a fleshy coat when first exposed after the capsule walls split. The seed coat later becomes dry and wrinkled. The inside of the capsules is often flushed reddish to purple. Thus both vegetatively and in flower and fruit *C. aethiopica* stands apart in the genus. The confused taxonomic history of *C. aethiopica* and closely related *C. floribunda* is detailed by Goldblatt et al. (2004).

The long-tubed flowers are adapted for pollination by sunbirds, of which the Lesser Double-collared Sunbird, *Cinnyrus chalybeus*, is the most frequently recorded visitor. The Malachite Sunbird, *Nectarinia famosa*, is also recorded as a visitor to the flowers.

24. **Sparaxis**

Sparaxis *Ker Gawl.* in Sims, Curtis's Botanical Magazine 15: sub. t. 548 (1802) & in König & Sims, Annals of Botany 1: 225 (1804a). Type species: *S. bulbifera* (L.) Ker Gawl.

Synnotia Sweet: t. 150 (1826a) [as *Synnetia*], corr. *Synnotia* by Sweet: 501 (1826b). *Sparaxis* sect. *Synnotia* (Sweet) Goldblatt: 57 (1991). Type: *Synnotia variegata* Sweet = *Sparaxis variegata* (Sweet) Goldblatt

Streptanthera Sweet: t. 209 (1827). Type: *Streptanthera elegans* Sweet = *Sparaxis elegans* (Sweet) Goldblatt

Anactorion Raf.: 34 (1838 as 1836). Type: *A. bicolor* (Thunb.) Raf. = *Sparaxis villosa* (Burm.f.) Goldblatt

Revisionary account: Goldblatt & Manning (2013).

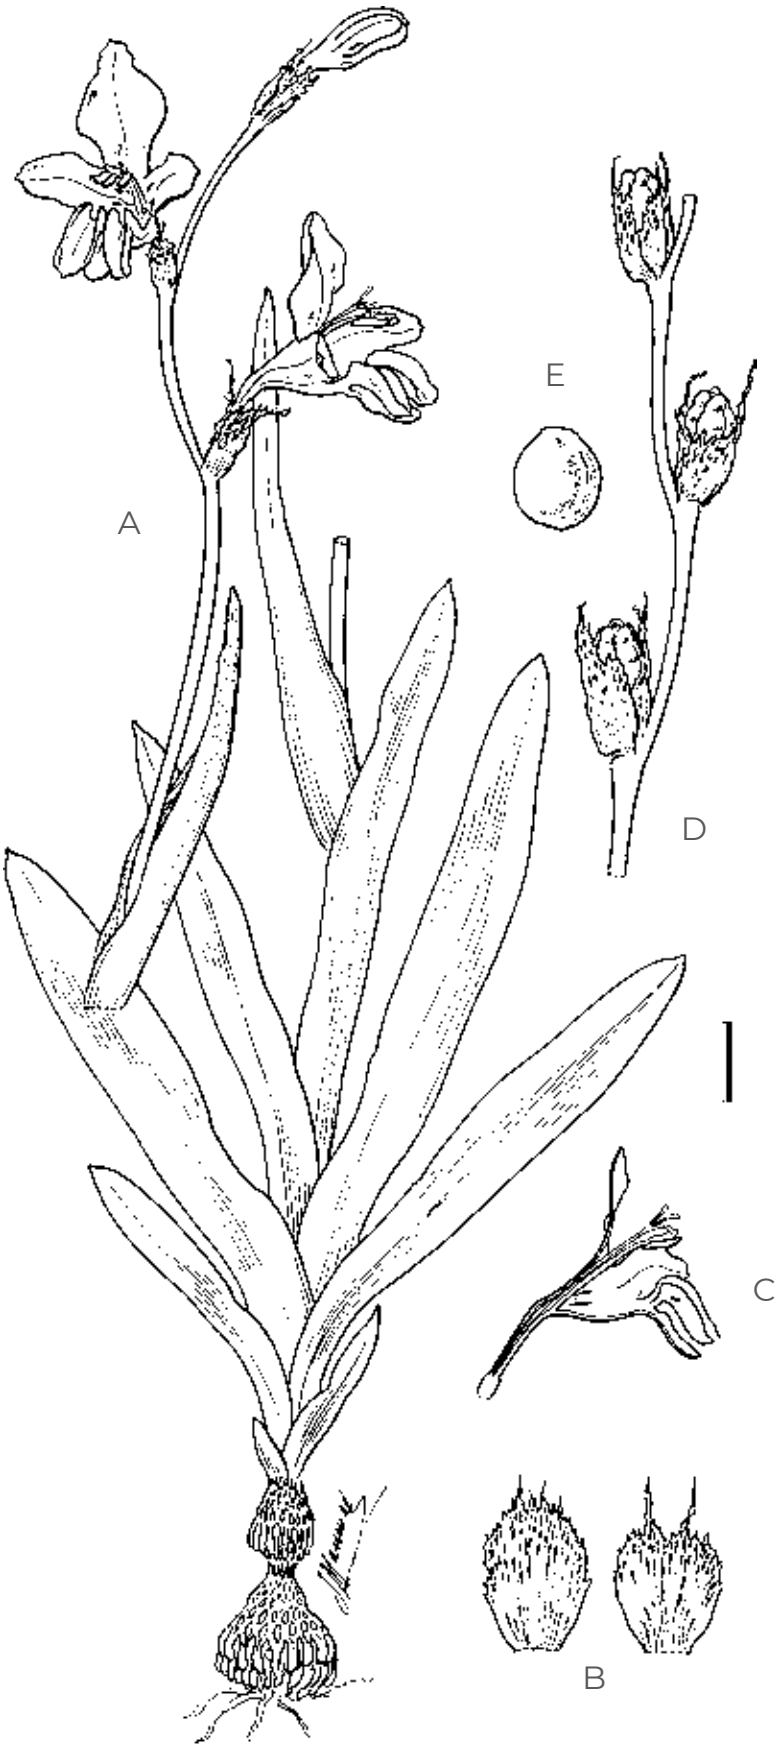
From the Greek, *sparasso*, to tear, for the tattered appearance of the floral bracts.

Deciduous geophytes. *Corm* globose to conical, rooting from base; corm tunics of fine to moderately fine netted fibres or of coarse hard fibres often thickened below into claw-like ridges. *Stem* firm and relatively thick, ± erect, smooth, simple or branched, then either from near base or well above ground, sometimes with few, moderate-sized axillary cormlets below, or many small cormlets in all axils. *Leaves* several, mostly basal, sometimes also cauline, lowermost 2 or 3 membranous and sheathing (thus cataphylls), foliage leaves green, with blades lanceolate to linear or falcate, obtuse to acute, often obliquely acuminate, smooth, often with many closely set fine secondary veins, with prominent central vein, margins sometimes thickened; marginal anatomy with thickened columnar epidermal cells and without marginal vein. *Inflorescence* a spike, (1-) few- to several-flowered, lax, 2-ranked in bud, loosely spiral or nearly secund in bloom; bracts dry and crinkled, pale-translucent with brown streaks, ± entire to lightly lacerate, or outer (abaxial) with 3 long tapering cusps, inner (adaxial) smaller than outer, with 2 long tapering cusps. *Flowers* actinomorphic or zygomorphic, then with either only stamens and style asymmetrically arranged or perianth also asymmetric and ± bilabiate with upper (adaxial) tepal larger and often hooded and lower 3 tepals smaller, with contrasting marking and ± horizontal or directed downward; perianth tube short to long, funnel-shaped (cylindric below and expanded above), sometimes obliquely so, or elongate, much exceeding bracts and dimorphic with lower part cylindric and abruptly bent and widened above; tepals subequal in radially symmetric flowers or, in zygomorphic flowers, dorsal largest; lanceolate to obovate or spathulate, acute to obtuse. *Stamens* symmetrically or asymmetrically disposed; filaments straight, surrounding style, or curved outward with abaxial stamen twisted to lie opposite adaxial tepal, or all filaments ± parallel and opposite adaxial tepal; anthers straight, curved or spirally coiled, sub-basifixed, extrorse or functionally introrse. *Style* straight and erect or unilateral, branches either short, often with expanded tips, or long and filiform. *Capsules* barrel-shaped to ± globose, firm-membranous, showing outline of seeds. *Seeds* globose, relatively large, smooth, usually glossy, (2–)4 to 15 per locule. *Pollen* monosulcate-operculate with 2-banded operculum; exine perforate-scabrate. *Basic chromosome number x* = 10.

Species 16; restricted to the winter-rainfall zone of South Africa; centred in southwestern Western Cape but extending north to the southern margin of Namaqualand and the western Karoo in Northern Cape.

Although a small genus by the standards of southern African Iridaceae, *Sparaxis* is surprisingly diverse in floral morphology, associated pollination strategies and even compatibility relations. Flowers range from the short-tubed, actinomorphic and brightly coloured *S. tricolor* and *S. elegans* adapted primarily for pollination by hopliine beetles to those species with two-lipped, long-tubed purple and white or yellow flowers adapted for pollination by long proboscid nemestrinid flies. The less striking, small-flowered *S. villosa* and *S. parviflora* are pollinated by bees. Both the latter and *S. meteler-kampiae* are autogamous in the absence of pollinators. Floral zygomorphy is most likely ancestral in the genus, and the radially symmetric flowers of *S. fragrans* and *S. maculosa* and those of the *S. tricolor* group evidently represent two independent reversals.

Species of *Sparaxis* with zygomorphic flowers were previously treated as the genus *Synnotia*, but morphological, cytological and molecular studies have shown that the genus has no merit.



The relationships of *Sparaxis* are most likely with *Tritonia* and the monospecific *Duthiastrum*, with which leaf marginal anatomy is consistent. Basic chromosome number is *x* = 10 in both *Sparaxis* and *Duthiastrum* but *x* = 11 in most *Tritonia* species. The dry, papery and often torn floral bracts are reminiscent of *Dierama* and to a lesser extent *Ixia* and *Tritonia*.

Key to species

1a Perianth zygomorphic, with adaxial (upper) tepal largest, erect and often hooded and lower 3 tepals usually smaller and ± horizontal; stamens unilateral and arcuate with anthers parallel and ± contiguous:
2a Narrow lower part of perianth > 25 mm long, well exserted from bracts; tube bent abruptly (geniculate) at top of slender part into wide throat:
3a Flowers with upper tepal 25–30 mm long; anthers 5–7 mm long; style reaching at least to apex and sometimes exceeding anthers; style branches 4–7 mm long and spreading beyond anthers. . . . . 15. *S. variegata*
3b Flowers with upper tepal 14–17 mm long; anthers 3–4 mm long; style not reaching anther apices; style branches 2–3 mm long and tangled in anthers . . . . . 16. *S. metelerkampiae*
2b Narrow part of perianth tube < 25 mm long, exserted or included in bracts; tube gently to sharply curved at top of narrow part:
4a Corm tunics of fine fibres; flowers smaller, dorsal tepal < 10 mm long; filaments 4.5–8.0 mm long:
5a Flowers 32–36 mm long from base of perianth tube to tip of dorsal tepal . . . . . 4. *S. calcicola*
5b Flowers ± 18 mm long from base of perianth tube to tip of dorsal tepal. . . . . 5. *S. parviflora*
4b Corm tunics either of fine or coarse fibres thickened into claws below; flowers usually larger, dorsal tepal at least 15 mm long; filaments 10–20 mm long:
6a Corm tunics of hard, claw-like fibres not extending upward in a neck; upper tepal directed forward and somewhat hooded over stamens; filaments 12–13 mm long:
7a Upper tepal ± 16 mm long; throat ± unmarked; base of leaves unmarked; style dividing opposite lower half of anthers, branches ± 2 mm long . . . . . 14. *S. villosa*
7b Upper tepal 22–24 mm long; throat boldly marked with dark stripes; base of leaves lightly speckled with purple (not visible in dry material); style dividing near anther apices, branches ± 5 mm long 13. *S. caryophyllacea*
6b Corm tunics of fine fibres, usually extending upward in a neck; upper tepal erect or directed backwards; filaments 15–20 mm long:
8a Cylindric lower part of perianth tube < 8 mm long; leaf bases spotted red to purple (sometimes fading when dry. . . . . 12. *S. galeata*
8b Cylindric lower part of perianth tube 15–25 mm long:
9a Leaf bases speckled, blades with prominent submarginal vein; perianth tube ± 18 mm long. . . . .10. *S. auriculata*
9b Leaf bases unmarked, blades without prominent submarginal vein; perianth tube 20–25 mm long . . . . . 11. *S. roxburghii*
1b Perianth radially symmetric; stamens either symmetrically disposed around central style or abaxial stamen lying opposite adaxial tepal, and style eccentric and inclined opposite adaxial tepal:
10a Bracts 18–30 mm long, entire to slightly lacerate, always without discrete cusps; stamens symmetrically disposed around erect style; style branches 2–3 mm long:
11a Anthers spirally coiled and reaching only to apex of style; style branches greatly expanded. . . . . 3. *S. elegans*
11b Anthers straight or slightly twisted and curved, extending well beyond style branches; style branches not greatly expanded:
12a Anthers straight, yellow to ochre-coloured; spikes 2- to 5-flowered; tepals orange, marked with yellow and black . . . . . 1. *S. tricolor*
12b Anthers incurved, slightly twisted, red to brown; spikes (2-)5- to 10-flowered; tepals rose pink, marked with yellow and red to purple . . . . . .2. *S. pillansii*
10b Bracts 10–20 mm long, deeply lacerate with discrete cusps ± as long as or longer than rest of bract; stamens symmetrical or asymmetrical; style branches > 4 mm long:
13a Lateral margins of outer bracts irregularly serrate (or ± fringed); stamens symmetrically arranged around style; style branches ± 5 mm long:
14a Tepals with large black markings at base, 27–35 × 8–10 mm; leaves oblong to lanceolate, 9–12 mm wide and obliquely apiculate. . . . . 9. *S. maculosa*
14b Tepals unmarked, 18–25 × 5–8 mm; leaves linear to narrowly lanceolate, 2–5(–9) mm wide and acute . . . 8. *S. fragrans*
13b Lateral margins of outer bracts ± entire, not serrate or fringed; stamens and style unilateral, thus asymmetrically disposed; style branches 6–10 mm long:
15a Stem usually branched in middle of stem and bearing one or more cauline leaves; many small cormlets produced after flowering at all nodes . . . . . .7. *S. bulbifera*
15b Branches, if present, produced from base and stem lacking a cauline leaf; cormlets never produced above ground. . . . . 6. *S. grandiflora*

Sect. 1. **Streptanthera** *(Sweet) Goldblatt & J.C.Manning* in Strelitzia 32: 20 (2013). *Streptanthera* Sweet: t. 209 (1827). Type: *Streptanthera elegans* Sweet = *Sparaxis elegans* (Sweet) Goldblatt

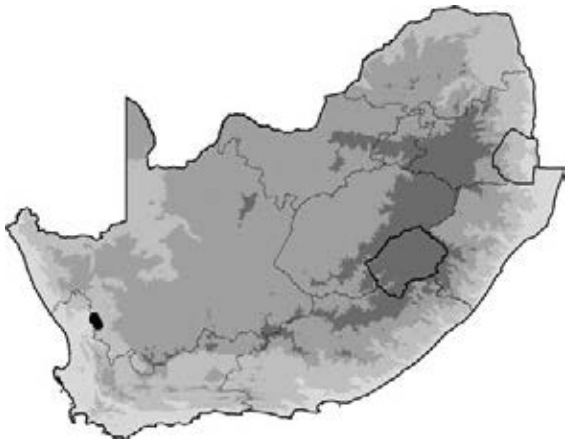
Plants with corm tunics of fine fibres. *Spike* with floral bracts without cusps, the inner deltoid and acute, becoming lacerate with age. *Flowers* radially symmetric with tepals variously coloured, predominantly orange, red, salmon or white; perianth tube short, funnel-shaped, up to 12 mm long. *Stamens* symmetrically arranged around central style; anthers straight or S-shaped, then coiled around style.

Sparaxis villosa: A, flowering plant; B, outer bract (left) and inner bract (right); C, half-flower; D, capsules; E, seed.

Species 3: northern Western Cape and southwest Northern Cape, South Africa.

1. **Sparaxis tricolor** *(Schneev.) Ker Gawl.* in König & Sims, Annals of Botany 1: 225 (1804a); Goldblatt & Manning: 20 (2013). *Ixia tricolor* Schneev.: t. 39 (1794). *Streptanthera tricolor* (Schneev.) Klatt: 390 (1882). Type: South Africa, without precise locality or collector, illustration in Schneev.: t. 39 (1794).

Ixia tricolor Curtis: t. 381 (1797), illegitimate homonym, not *I. tricolor* Schneev. (1794). Type: South Africa, without precise locality or collector, illustration in Curtis: t. 381 (1797).



Sparaxis blanda Sweet: 398 (1826b). *S. tricolor* var. *blanda* (Sweet) Baker: 99 (1877). Type: South Africa, without locality or collector, illustration in Ker Gawl.: t. 1482, δ, *floris subroseo-albida* (1812).

Sparaxis griffinii Sweet: 398 (1826b). *S. tricolor* var. *griffinii* (Sweet) Baker: 99 (1877). Type: South Africa, without locality or collector, illustration in Ker Gawl.: t. 1482, γ, *floris violaceo-purpurea* (1812).

Sparaxis versicolor Sweet: t. 160 (1826c). *S. tricolor* var. *versicolor* (Sweet) Baker: 99 (1877). Type: South Africa, without precise locality or collector, illustration in Sweet: t. 160 (1826c).

Sparaxis lineata Sweet: t. 131 (1832). *S. grandiflora* var. *lineata* (Sweet) Baker: 99 (1877). *Streptanthera lineata* (Sweet) Klatt: 390 (1882). Type: South Africa, without precise locality or collector, illustration in Sweet: t. 131 (1832).

Plants mostly 300–400 mm high, with 1 to 3(–5) branches from base. *Corms* 10–20 mm diam., tunics of fine, pale, netted fibres. *Leaves* 5 to 10 in a basal fan, narrowly sword-shaped, acuminate, reaching ± to base of spike, 10–20 mm wide, closely veined with prominent main vein. *Spike* suberect, ± straight, 2- to 5-flowered, initially 2-ranked but ultimately subsecund; bracts dry, crinkled, light translucent brown with darker streaks, without visible veins, outer 20–30 mm long, narrowly deltoid, entire, later upper margins lacerate, inner usually slightly shorter, forked apically. *Flowers* radially symmetric, bright orange-scarlet, yellow in centre broadly edged with dark red-brown, unscented; perianth tube funnel-shaped, 9–12 mm long, lower narrow part ± 4.5 mm; tepals subequal, broadly lanceolate-ovate, 25–35 mm, outer 15–20 mm wide, inner 13–16 wide. *Stamens* symmetrically arranged; filaments 6–7 mm long, closely surrounding style, yellow; anthers linear, 8–9 mm long, weakly diverging, pale yellow; pollen white. *Style* dividing opposite lower ⅓ of anthers, branches 2–3 mm long, expanded in distal ⅓, notched at apex. *Capsules* ± barrel-shaped, 6–7 mm long, showing outline of seeds. *Seeds* globose, glossy reddish brown, ± 2.0–2.5 mm diam., 4 to 8 per locule. *Chromosome number* 2*n* = 20. *Flowering time*: September, rarely in late August.

Distribution of ***Sparaxis tricolor***.

Distribution and ecology: restricted to the northern end of the Bokkeveld Escarpment in Northern Cape, South Africa, where it is known from just a few farms northwest and south of Nieuwoudtville; in seasonally wet sites in loamy sand or among rocks along seasonal watercourses. Naturalised in parts of Australia.

Diagnosis: *Sparaxis tricolor* is recognised but its ± cup-shaped, radially symmetric, brilliant orange flowers with a yellow centre edged in dark red-brown to almost black. The dark markings enclosing the yellow extend as a narrow line almost to the base of the tepals. The yellow stamens are erect and surround the style, which divides opposite the lower third of the anthers into short branches 2–3 mm long. The ± narrowly deltoid-ovate bracts of *S. tricolor* and allied *S. elegans* and *S. pillansii* differ from those of other species in the genus in lacking obvious veins, and the outer are initially entire and acute, later becoming irregularly torn. The bracts, also crinkled and flecked with dark brown streaks, are quite different to the cuspidate bracts of other species of the genus. The radially symmetric flower is derived in *Sparaxis*, evidently an adaptation to hopliine beetle pollination. The contrasting markings on the bright orange flowers with dark brown edged yellow in the centre of *S. tricolor*, also called the harlequin flower, represent beetle marks that attract pollinating hopliine beetles. The horsefly *Philoliche atricornis* also visits the flowers and like the related *S. elegans*, *S. tricolor* evidently has a bimodal pollination system using both beetles and short-proboscid horseflies.

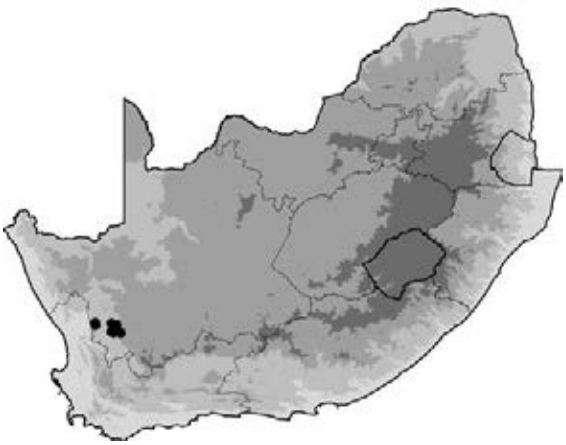
2. **Sparaxis pillansii** *L.Bolus* in South African Gardening and Country Life 22: 57 (1932a); Goldblatt & Manning: 23 (2013). Type: [Northern Cape], near Nieuwoudtville, Sept. 1931, *L. Bolus s.n.* (BOL 19182, holo.).

Plants 250–650 mm high, unbranched or with 1 to 3 branches from base. *Corm* 10–25 mm diam., tunics of moderately fine, netted fibres, often with fairly large cormlets in leaf axils. *Leaves* 8 to 10, all basal, reaching to ± middle of stem, lightly veined with central vein prominent. *Spike* suberect, lax, 4- to 9-flowered; bracts

dry, translucent with dark brown streaks, outer narrowly deltoid, with single main vein, sometimes torn distally, 24–29 mm long, inner shorter to ± as long, often forked apically for up to 6 mm. *Flowers* radially symmetric, old rose-coloured fading to dull pink, tepals each with a heart-shaped yellow base edged in dark red to purple-brown, yellow in tube, unscented; perianth tube funnel-shaped, 7–9 mm long, lower slender portion ± 3 mm long; tepals subequal, lanceolate, subacute, 22–29 × 12–14 mm, slightly cupped or spreading horizontally when fully open. *Stamens* symmetrically arranged; filaments erect, ± 7.5 mm long, white, clasping style; anthers arcuate or slightly twisted in upper half, 7–8 mm long, red-purple or white with red-purple on adaxial surface. *Style* slender, white or red distally, dividing opposite middle of anthers, branches 2–3 mm long, slender, often slightly wider and bilobed distally, dark red, extending between anthers. *Capsules* ± barrel-shaped, ± 7 mm long. *Seeds* globose, glossy reddish brown, ± 2.5 mm diam., 4 to 6 per locule. *Chromosome number* unknown. *Flowering time*: late September to mid-October.

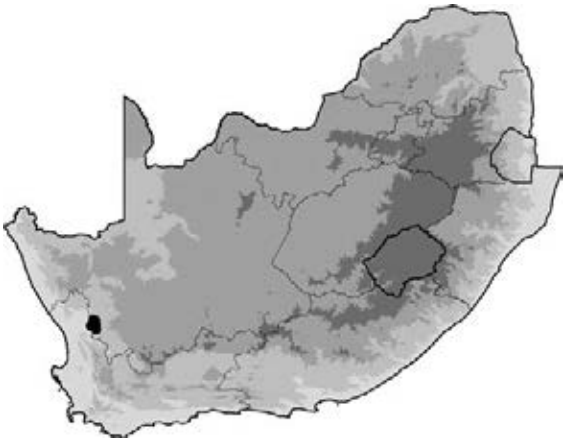
Distribution and ecology: endemic to the Calvinia District in Northern Cape, South Africa, and best known in the dolerite hills east of Nieuwoudtville but extending as far east as Calvinia and the Keiskie Mtns southeast of Calvinia; usually in heavy red clay waterlogged for much of the growing season, sometimes in pools of standing water among dolerite boulders, but also in broken shale along seasonal washes and watercourses.

Diagnosis: usually a tall plant, sometimes reaching 650 mm, *Sparaxis pillansii* has lax spikes of large flowers coloured old rose to dull pink with a small yellow centre edged with red to purple. The shape of the radially symmetric flowers closely resembles that of *S. tricolor,* a shorter plant seldom exceeding 350 mm with bright orange flowers with a larger yellow centre. Molecular phylogenetic analysis shows *S. pillansii* and *S. tricolor* to be immediately related and sister to *S. elegans*. The species occupy very different soil types and their ranges complement one another. In some populations the anthers are very slightly twisted, a feature otherwise unknown in the genus, except for the exaggerated twisting of the anthers of *S. elegans*.



Pollination biology is the same as in the closely related *Sparaxis elegans* and *S. tricolor*, the flowers being visited by various hopliine beetles and also by the short-proboscid horse fly, *Philoliche atricornis*. Small empidid flies are also often seen in the flowers and no doubt are able to accomplish cross pollination as their bodies bear visible loads of the whitish pollen of *S. pillansii*.

3. **Sparaxis elegans** *(Sweet) Goldblatt* in Journal of South African Botany 35: 233 (1969); Goldblatt & Manning: 25 (2013). *Streptanthera elegans* Sweet: t. 209 (1827). Type: South Africa, without precise locality or collector, figure in Sweet: t. 209 (1827).



Streptanthera cuprea Sweet: t. 122 (1831) [Sweet: 501 (1830) invalid name]; Baker: 86 (1896); Pole-Evans: t. 320 (1928). *Sparaxis cuprea* (Sweet) Klatt: 378 (1867). Type: South Africa, without precise locality or collector, figure in Sweet: t. 122 (1831).

Streptanthera cuprea var. *non-picta* L.Bolus: 276 (1932b). Type: [Northern Cape], Nieuwoudtville, *Buhr s.n.* (BOL 19443, holo.).

Plants 100–300 mm high, stem usually simple or branching from base. *Corm* 10–17 mm diam., tunics of moderately fine, pale fibres. *Leaves* 5 to 9, ± as long as stem, 5–14 mm wide, closely veined with midrib prominent. *Spike* flexed at base of first flower, mostly 3- to 5-flowered; bracts dry, crinkled, pale-translucent with brown streaks, without visible veins, outer 18–22 mm long, deltoid, entire or lacerate apically, inner 16–20 mm long, forked apically. *Flowers* radially symmetric, predominantly salmon-pink or white, purple in centre edged with a violet transverse band containing yellow transverse marks and a pale streak in centre of each tepal, rarely without markings, unscented; perianth tube funnel-shaped, 6–10 mm long, narrow basal

Distribution of ***Sparaxis pillansii***.

Distribution of ***Sparaxis elegans***.

part 2–3 mm long; tepals subequal, ovate, spreading horizontally when fully open, 18–32 × 14–21 mm. *Stamens* symmetrically arranged; filaments 5–7 mm long, purple; anthers tightly S-shaped and twisted around style, ± 4 mm long, maroon; pollen red-brown. *Style* yellow below, purple distally, dividing opposite anthers, branches ± 2 mm long, strongly broadened distally and ± 2 wide, bilobed at tips. *Capsules* globose, mostly 6–8 mm long, enclosed by bracts. *Seeds* usually 6 per locule, globose, glossy dark reddish brown, ± 2 mm diam. *Chromosome number* 2*n* = 20. *Flowering time*: September.

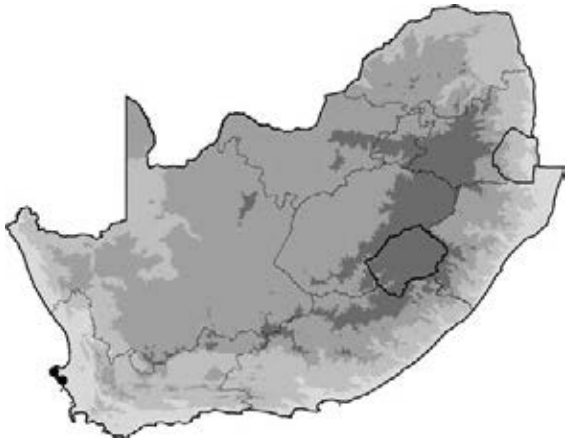
Distribution and ecology: restricted to the western Bokkeveld Plateau and the Bokkeveld Mtns of Northern Cape, South Africa, and in the Klein Koebee in Western Cape to the south; on stony, tillite-derived soils in the north and on clays in the south but always in renosterveld.

Diagnosis: *Sparaxis elegans* is easily recognised by the distinctively marked flowers, purple anthers coiled around the style, red-brown pollen, and unusually broad style branches. The common form with salmon-pink flowers occurs in the Nieuwoudtville area, with the white-flowered form in the south of its range. The two colour morphs usually occur in pure stands, but white morphs mixed with the salmon-coloured are known from a few sites. The shift from salmon- to white-flowered populations is abrupt. Occasional orange-flowered populations in the northern Bokkeveld lack the characteristic markings in the centre of the flowers and were described as var. *non-picta*.

The strikingly coloured and patterned flowers are pollinated by hopliine beetles and the short-proboscid horsefly, *Philoliche atricornis*; the former using the flowers for sites of assembly and copulation, and the latter seeking the minute traces of nectar that the flowers produce

Sect. 2. **Sparaxis**

Sparaxis sect. *Synnotia* (Sweet) Goldblatt in Contributions from the Bolus Herbarium 13: 57 (1991). *Synnotia* Sweet: t. 150 (1826a, as *Synnetia*), corr. *Synnotia* by Sweet: 501 (1826b). Type: *Synnotia variegata* Sweet = *Sparaxis variegata* (Sweet) Goldblatt subsp. *variegata*



Plants with corm tunics of fine or coarse fibres. *Spike* with floral bracts with prominent cusps, these often brown. *Flowers* zygomorphic or radially symmetric, with tepals yellow often marked with purple, white, or purple; perianth tube funnel-shaped, short, up to 20 mm long or elongate and ± cylindric. *Stamens* unilateral or symmetrically arranged around central style; anthers straight.

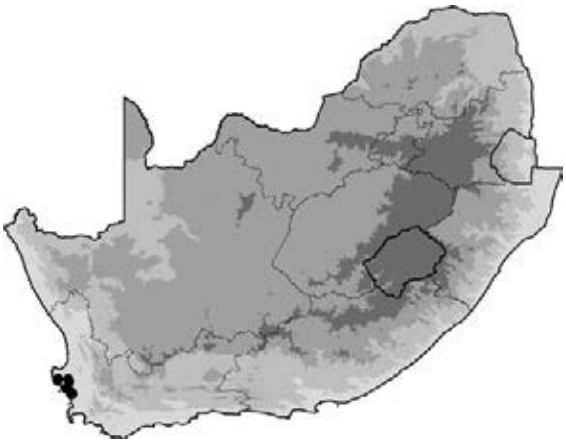
Species 13: western half of Western Cape, South Africa.

4. **Sparaxis calcicola** *Goldblatt & J.C.Manning* in Strelitzia 32: 28 (2013). Type: Western Cape, Vredenburg, Jacobsbaai, crevices in limestone pavement, 25 Aug. 2007, *Goldblatt, Manning & Porter 12894* (NBG, holo.; K, MO, PRE, S, iso.).

Plants mostly 120–220 mm high. *Corm* 8–14 mm diam., tunics of pale, fine fibres, often matted together. *Stem* usually unbranched or with 1(2) branches from base, occasionally also from middle of stem, without cormlets in lower axils. *Leaves* 5 to 8, obtuse to acute or obliquely apiculate, usually reaching to ± base of spike or sometimes shortly exceeding it, (3–)5–10 mm wide, with prominent main vein, sometimes with thickened margins. *Spike* 3- to 5-flowered, branches with fewer flowers, weakly flexuose, suberect; bracts dry, wrinkled, pale with dark brown streaks below, rust-brown above, outer 12–14 mm long, irregularly lacerate with 3 prominent cusps, inner 10–12 mm long, 2-cusped. *Flowers* zygomorphic, upper tepals creamy white, upper lateral and lower tepals yellow with dark mark at limb base, lightly lemon-scented; perianth tube obliquely funnel-shaped, curving outward above, 13–15 mm long; tepals unequal, dorsal largest, erect, 20–22 × 8–10 mm, widest in midline, upper laterals spreading at right angles to tube, 14–16 × ± 6 mm long, lower tepals united in lower 2–3 mm, narrowed at base of free part into claws ± 3 mm long, expanding abruptly into oblong limbs ± 10 mm × ± 5 mm, channelled in lower half, spreading horizontally. *Stamens* unilateral; filaments arched, ± 8 mm long, white; anthers ± 4 mm long; pollen creamy yellow. *Style* arching above filaments, white, dividing opposite anther tips, branches diverging to weakly recurved, ± 3 mm long, expanded apically and ciliate on margins, convolute below apex. *Capsules* barrel-shaped, (7–)9–11 mm long. *Seeds* 4 to 6 per locule, globose, yellowish brown, 2.2–2.5 mm diam. *Flowering time*: early August to mid-September.

Distribution and ecology: restricted to the rocky limestone hills and coast immediately north and west of

Distribution of ***Sparaxis calcicola***.



Saldanha Bay in Western Cape, South Africa; in loamy soil in limestone pavement and in calcrete, in low scrub dominated by *Osteospermum moniliferum* L. (Asteraceae) and among several other, mainly edaphic endemics of the Saldanha coast.

Diagnosis: *Sparaxis calcicola* is readily recognised by the bilabiate flower with a suberect dorsal tepal larger than the upper laterals, the short, arcuate stamens, and corms with tunics of fine, netted fibres. The flower is most like that of the more widespread *S. villosa*, which is, however, restricted to clay soils and has smaller flowers, the dorsal tepal somewhat hooded over the stamens, and corm tunics of coarse, claw-like fibres. The finely fibrous tunics and similarly oriented suberect dorsal tepal of *S. calcicola* recall *S. parviflora*, and the two species have been shown in molecular studies to be closely related, sharing a clade with *S. bulbifera* and *S. grandiflora*. *Sparaxis parviflora* has much smaller flowers, less than half the size of those of *S. calcicola*, the dorsal tepal 9–10 mm long and the tube 8–9 mm long.

The moderate-sized but brightly coloured and fragrant flowers are pollinated by honey bees, *Apis mellifera*, and possibly other large bees, which are rewarded by the small quantity of nectar secreted in the base of the tube.

5. **Sparaxis parviflora** *(G.J.Lewis) Goldblatt* in Annals of the Missouri Botanical Garden 79: 155 (1992); Goldblatt & Manning: 30 (2013). *Synnotia parviflora* G.J.Lewis: 140 (1956). Type: South Africa, [Western Cape], between Darling and Mamre, Sept. 1953, *Lewis 3556* (SAM, holo.; K, iso.).

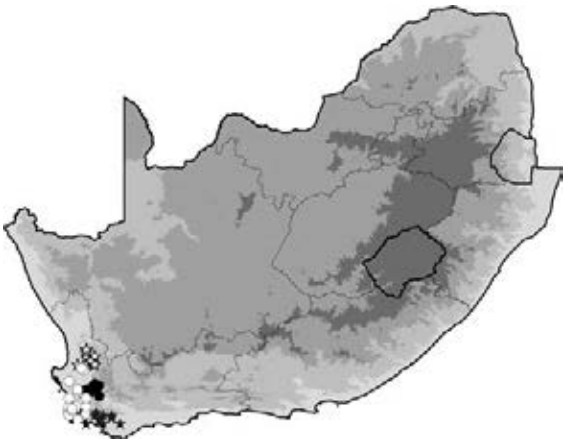
Plants 120–200 mm high. *Corm* 10–15 mm diam., tunics of fine, pale, ± matted fibres. *Stem* simple or branched from near base. *Leaves* 5 to 7, obliquely apiculate, basal except uppermost, this inserted shortly above ground level, 7–14 mm at widest, sheathing lower part of stem. *Spike* (1–)3- to 5-flowered, weakly flexuose, secund; bracts pale below with whitish veins, becoming irregularly marked with brown distally, 10–15 mm long, outer obscurely 3–5-lobed, central lobe always longest, inner ± as long as outer, 2–4-lobed, but with 2 prominent, acute central lobes. *Flowers* zygomorphic, upper 3 tepals mauve or creamy yellow and lower 3 yellow with mauve or white tips, often with dark spots at base, abaxial half of throat darkly streaked, with weak spicy-sweet or rosy scent; perianth tube narrowly funnel-shaped, lower part clasping style, upper part curving outward, 8–9 mm long; tepals unequal, upper 3 largest, dorsal erect, 9–10 × ± 5 mm, upper laterals spreading at right angles to tube, ± 8.0 × 5.5 mm, lower 3 tepals united for ± 2 mm, lower laterals broadly channelled, horizontal with tips curving upward, ± 8.0 × 3.5 mm, lowermost held somewhat below lower laterals, 8 × 5 mm. *Stamens* unilateral, arcuate; filaments ± 4.5 mm long, reaching mouth of tube, white; anthers ± 4 mm long, purple when upper tepals

Distribution of ***Sparaxis parviflora***.

mauve or white with violet lines on locule sutures; pollen ± white. *Style* arched adaxial to filaments, white, dividing ± opposite anther bases, branches diverging, recurved distally, ± 3.5 mm long, channelled, ciliate along margins ± to base, slightly wider in upper half. *Capsule* barrel-shaped, 9–10 × ± 7 mm. *Seeds* (4)5 or 6 per locule, dark reddish brown, 2.4–2.8 mm diam. *Chromosome number* $2n = 20$. *Flowering time*: mid-August to mid-September.

Distribution and ecology: restricted to the coastal plain between Mamre and Saldanha Bay on the Atlantic Coast of Western Cape, South Africa; in sandy ground or in gritty, granite-derived soil, often in granite outcrops.

Diagnosis: *Sparaxis parviflora* is immediately recognised by its tiny flowers, the smallest in the genus, with white or mauve upper tepals and yellow lower tepals with white or mauve tips, and the finely fibrous corm tunics. The small flowers have a dorsal tepal 9–10 mm long, and the three lower ± 8 mm long. The plants are also fairly small, usually less than 150 mm tall and more often less than 100 mm, and the leaves are seldom more than 12 mm wide. In contrast, the seeds are the largest in the genus, up to 2.8 mm in diameter. In shape and colour the flowers are most like those of *S. calcicola*, but this species has much larger flowers, 20–22 mm long. Some forms of *S. villosa* have particularly small flowers, the upper tepal ± 10 mm long, and confusion between them is best avoided by examination of the corm tunics, those of *S. villosa* being coarsely fibrous and ± clawed below, contrasting starkly with the finely fibrous tunics of *S. parviflora*. Based on chromosome counts for a single population, *S. parviflora* is tetraploid with $2n = 40$, the only known polyploid in the genus in which the other 10 species counted are diploid.



Flowering occurs fairly early in the season and plants are usually in fruit by mid-September. *Sparaxis parviflora* is facultatively autogamous, not surprising in a plant with such small, inconspicuous flowers. In the wild the weakly scented flowers are often visited by honey bees.

6. **Sparaxis grandiflora** *(D.Delaroche) Ker Gawl.* in König & Sims, Annals of Botany 1: 225 (1804a); Baker: 116 (1896); Goldblatt & Manning: 32 (2013). *Ixia grandiflora* D.Delaroche: 23 (1766). Type: South Africa, [Western Cape], near Tulbagh Road Station, 9 Sept. 1968, *Goldblatt 303* (BOL, neo., designated by Goldblatt: 239 (1969); MO, iso.).

Plants mostly 120–300 mm high. *Corm* globose, 6–15 mm diam., tunics of fine, pale netted fibres. *Stem* simple or 1- to 3(–5)-branched from base. *Leaves* 6 to 10, in basal fan, ± lanceolate to weakly falcate, mostly ½–⅔ as long as stem, (4–)7–12 mm wide, obtuse-acuminate or acute, with prominent main vein and numerous fine secondary veins. *Spike* suberect or inclined, mostly 2- to 6-flowered; bracts dry, crinkled, pale, usually with brown streaks, 12–16(–20) mm long including cusps, outer ± lacerated distally, with 3 prominent, twisted dark brown cusps, inner slightly smaller, with 2 prominent cusps. *Flowers* with radially symmetric perianth but unilateral stamens, white to pale or deep yellow with outer tepals often flushed purple outside, often with dark marks at tepal bases, or violet or dark plum-purple but pale in tube, usually unscented but sometimes faintly sweet-scented or strongly scented of *Freesia*; perianth tube funnel-shaped, 10–14 mm long, narrow basal part 3–5 mm long; tepals subequal or outer 3 slightly larger, 22–45 × 10–18(–25) mm. *Stamens* unilateral but diverging, abaxial stamen twisted to lie against adaxial tepal; filaments 7–10 mm long; anthers facing inward, 7–12(–14) mm long, white. *Style* unilateral, slender, white, lying against adaxial tepal, dividing opposite middle of anthers or up to 2 mm beyond anther tips, branches filiform, 6–9 mm long. *Capsules* ± barrel-shaped, 6–10 mm long, *Seeds* 7 or 8 per locule, ± 1.8 mm diam. *Chromosome number* 2*n* = 20. *Flowering time*: August and September.

Distribution and ecology: relatively widespread in the southwestern Western Cape, South Africa, extending from Clanwilliam (and possibly Graafwater) in the northwest to Bredasdorp in the southeast; at low elevations and usually on heavy clay soils, but occasionally found on sandy ground, often waterlogged in winter.

Diagnosis: *Sparaxis grandiflora* is readily recognised by a combination of the unilateral orientation of the stamens but radially symmetric perianth and the branching produced only from the base, typically below ground level. Unlike other Iridaceae with unilateral stamens, the filaments are not parallel with contiguous anthers but are divergent and held well apart from one another. Only *S. bulbifera* has similarly unilateral stamens and a radially symmetric perianth, but it always bears cauline leaves and branches arise on the upper part of the stem. After flowering in *S. bulbifera*, numerous small cormlets are produced at the aerial nodes in addition to larger cormlets at the underground nodes. The tepals are also consistently ovate-elliptic in *S. bulbifera* but are often slightly spathulate in *S. grandiflora*.

Distribution of ***Sparaxis grandiflora*** subsp. ***grandiflora***, ●; subsp. ***acutiloba***, ☆; subsp. ***fimbrimarginata***, ○; subsp. ***violacea***, ★.

Sparaxis grandiflora is unusually variable in flower colour and tepal shape and as a result four allopatric subspecies are recognised. Although finely circumscribed, each subspecies seems to represent a separate race of the species, geographically isolated by mountain ranges and associated edaphic barriers. Bright yellow-flowered plants in the Olifants River Valley have relatively narrow tepals and represent subsp. *acutiloba*. Distributed west and southwest of the Olifants River Mtns, subsp. *fimbriata* has white to pale yellow flowers, often with dark markings at the bases of the tepals. Also tentatively included here is a collection of purple flowered plants said to have been collected near Graafwater. The populations with pale yellow flowers in the hills north and west of the Piketberg have the broader tepals of subsp. *fimbriata* and are included in that subspecies but are obviously intermediate in perianth colour between typical subsp. *fimbriata* and yellow-flowered subsp. *acutiloba*.

In the Tulbagh Valley the typical form of *Sparaxis grandiflora*, mostly with intensely pigmented, plum-purple flowers and slightly spathulate tepals, is largely isolated from subsp. *fimbriata* by the Elandskloof Mtns. Plants from the Caledon District east of the Hottentots Holland Mountains treated as subsp. *violacea* have pale violet or white flowers with markedly obtuse and often spathulate tepals. Populations examined in bloom have flowers strongly scented of freesia, but flowers of other subspecies have at best only a faintly flowery scent or no scent at all.

Key to subspecies

1a Flowers dark plum-purple (rarely white mutants present); tepals spathulate; plants from Tulbagh Valley, rarely westward to Gouda . . . . . 6b. subsp. *grandiflora*

1b Flowers white, yellow or pale violet to light purple; tepals spathulate to narrowly ovate:

2a Flowers clear, deep yellow; tepals narrowly ovate, acute or subacute; plants from Olifants River Valley. . . . . 6c. subsp. *acutiloba*

2b Flowers white, pale yellow, cream-coloured or pale violet; tepals ovate to spathulate, obtuse:
3a Tepals spathulate, white, sometimes marked with violet or uniformly pale violet; usually strongly scented of freesia; plants from east of Hottentots Holland Mtns. . . . . .6d. subsp. *violacea*
3b Tepals narrowly ovate, usually white to pale yellow, often mauve on reverse of tepals (?rarely purple), not obviously scented; plants from west of Olifants River-Hottentots Holland Mtn axis . . . . . .6a. subsp. *fimbriata*

6a. subsp. **fimbriata** *(Lam.) Goldblatt* in Journal of South African Botany 35: 242 (1969); Goldblatt & Manning: 35 (2013). *Ixia fimbriata* Lam.: 339 (1789). *Sparaxis fimbriata* (Lam.) Ker Gawl.: 226 (1804a). Type: South Africa, without precise locality or collector, illustration in Miller: t. 237, fig. 1, 2 (1758).

Ixia sparsa Mill.: 7 (1768). Type: uncertain, possibly illustration in Miller: t. 237, fig. 1,2 (1758).

Ixia liliago DC. in Redouté: t. 109 (1805). *Sparaxis grandiflora* var. *liliago* (DC.) Ker Gawl.: t. 258 (1818). *S. liliago* (DC.) Sweet: 398 (1826b). Type: South Africa, without precise locality or collector, illustration in Redouté: t. 109 (1805).

Sparaxis grandiflora var. *striata* Sweet: 501 (1830). Type: South Africa, without precise locality or collector, illustration in Ker Gawler: t. 779 (Oct. 1804b).

[*Ixia lacera* L. ex Ker Gawl.: t. 548 (1802) et Roem. & Schult.: 398 (1817), invalid name only in synonymy (based on *LINN58*/18 & *58/19*). *Sparaxis lacera* L. [as Herb. Banks] ex Ker Gawl.: 226 (1804a), invalid name only in synonymy.]

Plants up to 300 mm high. *Leaves* ± sword-shaped, lowermost sometimes falcate, obtuse–acute-acuminate, ⅔ to ± as long as stem. *Flowers* mostly white, cream-coloured or pale yellow (?rarely purple), yellow in throat, bases of tepals each with small to prominent dark-purple-black spot, flushed grey-mauve to purple on reverse of outer tepals; tepals obovate or elliptic, 28–40(–45) × (8–)10–16(–23) mm, obtuse or subacute. *Stamens*: anthers 9–10 mm long. *Style* dividing between middle and apex of anthers, branches (5–)7–9 mm long.

Distribution and ecology: extending in Western Cape, South Africa, from the Cape Peninsula and Somerset West in the south through the Boland and Swartland to the Piketberg in the north (including an outlying population with purple flowers said to have been collected north of Graafwater); on clay flats and slopes.

Diagnosis: subsp. *fimbriata* is distinguished by the white to cream-coloured or pale yellow flowers with ovate tepals mostly 28–40 mm long (a collection included here, known only from a poorly localised site north of Graafwater has atypical purple flowers but appears otherwise to conform to subsp. *fimbriata*, although the tepals are unusually narrow, 8–9 mm wide). Particularly large-flowered plants occur near Darling, with tepals up to 45 mm long and up to 23 mm wide. Populations at low elevations east and west of the Piketberg have pale yellow flowers with the tepals sometimes acute at the tips and thus approach subsp. *acutiloba*. Subsp. *fimbriata* is seldom seen in gardens today, which is a pity, for it makes an attractive rock garden and container subject.

6b. subsp. **grandiflora**

Ixia uniflora L.: 27 (1767). Type: South Africa, without precise locality or collector (*LINN58/19*, holo.).

Ixia holosericea Jacq.: 9 (1797). Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 17 (1797).

Ixia aristata var. *atropurpurea* [Ker Gawl in] Andrews: t. 87 (1800). Type: South Africa, without precise locality or collector, illustration in Andrews: t. 87 (1800).

Sparaxis meleagris Eckl.: 27 (1827). Type: unknown.

Sparaxis stellaris D.Don in Sweet: t. 383 (1837). *S. grandiflora* var. *stellaris* (D.Don) Baker: 99 (1877). Type: South Africa, without precise locality or collector, illustration in Sweet: t. 238 (1837).

Sparaxis atropurpurea Klatt: 389 (1882), illegitimate superfluous name for *Ixia holosericea* Jacq. Type: South Africa, [Western Cape], Tulbaghskloof, *Zeyher s.n.* [B: Herb. Lubeck, lecto., designated by Goldblatt: 240 (1969)].

Plants mostly 150–200 mm high. *Leaves* lanceolate, acute to acuminate, up to 10 mm wide, lower sometimes falcate. *Flowers* deep red-purple but white in throat and tube (rarely whitish, sometimes flushed or speckled purple inside and outside); tepals spathulate, obtuse, 25–30 × 8–18(–25) mm, spreading ± horizontally when fully open. *Stamens*: anthers 10–12 mm long. *Style branches* ± 7 mm long.

Distribution and ecology: largely restricted to the Tulbagh Valley, South Africa, with a single collection from Voëlvlei just west of the Elandskloof Mtns and outside the Tulbagh Valley; in heavy clay at low elevations in habitats now largely given over to agriculture, burning or clearing of the veld stimulates flowering.

Subsp. *grandiflora* is recognised by the plum-red flowers white in the throat and tube (occasional white-flowered morphs have been recorded in some populations) with spathulate tepals broadest in the upper third. The flowers have been reported to be pollinated by hopliine beetles: flower colour and radially symmetric perianth with a pale throat is consistent with this pollination system. Vegetatively subsp. *grandiflora* closely matches subsp. *fimbriata*, which occurs in similar habitats on the coastal plain west of the mountains that isolate the Tulbagh Valley. The two subspecies appear to intergrade around Voëlvlei near Gouda at the western foot of the Elandsberg Mtns.

6c. subsp. **acutiloba** *Goldblatt* in Journal of South African Botany 35: 245 (1969) [description], Flora of Southern Africa 7(2), part 1: 163 (1999) [citation of type material]; Goldblatt & Manning: 37 (2013). Type: [Western Cape]: 8 miles [± 12 km] south of Clanwilliam, wet clay, 28 Aug. 1968, *Goldblatt 264* (BOL, holo.; MO. iso.).

?*Ixia monanthos* D.Delaroche: 21 (1766). *Sparaxis monanthos* (D.Delaroche) N.E.Br.: 135 (1929). Type: South Africa, without precise locality or collector (G—Herb. Burman, holo.).

Sparaxis lutea Eckl.: 28 (1827). Type: South Africa, without precise locality, ex Hort. Ludwig, *Ecklon s.n.* (S, holo.).

Plants mostly up to 350 mm high, rarely up to 450 mm. *Leaves* sword-shaped to almost linear, acute to acuminate, ± ⅔ as long as stem, mostly 6–10 mm wide. *Flowers* bright yellow, bases of tepals with a small to prominent purple-black spot, sometimes flushed mauve on reverse of tepals, especially outer, faintly sweet-scented; tepals narrowly oblanceolate to obovoid, acute to subobtuse, 24–30 × 12–14 mm. *Stamens*: anthers 9–10 mm long. *Style* dividing opposite lower to upper ⅓ of anthers, branches ± 6 mm long.

Distribution and ecology: found only in the Olifants River Valley in Western Cape, South Africa, and extending from the central part of the valley near Citrusdal to some 10–12 km south of Clanwilliam; at fairly low elevations along the valley bottom in exposures of Bokkeveld shales in this area of predominantly Cape Sandstone-derived soils.

Diagnosis: subsp. *acutiloba* is recognised by the bright, clear yellow flowers with comparatively narrow, oblanceolate to narrowly obovate tepals mostly 24–30 × 12–14 mm and the relatively narrow leaves, mostly 6–10 mm wide. The tepals remain ascending and the flower thus remains cup-like even when fully open.

6d. subsp. **violacea** *(Eckl.) Goldblatt* in Journal of South African Botany 35: 244 (1969); Goldblatt & Manning: 38 (2013). *Sparaxis violacea* Eckl.: 27 (1827). Type: South Africa, [Western Cape], Bot River, *Ecklon & Zeyher Irid 114* (SAM, lecto., designated by Goldblatt: 244 (1969); MO, isolecto.).

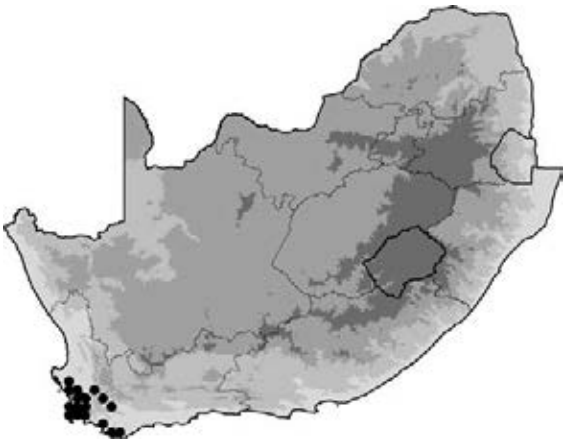
Sparaxis cana Eckl.: 28 (1827). Type: South Africa, without precise locality, ex Hort. Ludwig, Cape Town, *Ecklon s.n.* (S, holo.).

Plants rarely more than 200 mm high, sometimes only 60 mm high, usually unbranched. *Leaves* often markedly falcate to lanceolate, ± ⅓–½ as long as stem, obtuse acuminate or acute, 6–12 mm wide, margins slightly thickened and sometimes turning purple. *Flowers* pale violet with white throat and tube or ± white, then often with violet spots at tepal bases, tepals flushed grey-mauve on reverse, especially outer tepals, strongly scented of freesia; tepals spathulate, obtuse, 22–37 × 7–16 mm. *Anthers* up to 7 mm long.

Distribution and ecology: occurring across the low, rolling hills of the Overberg of Western Cape, South Africa, extending from Bot River in the west to Fairfield near Napier in the east; on clay slopes and flats in renosterveld.

Diagnosis: subsp. *violacea* is recognised by the pale violet to white flowers with markedly spathulate tepals. Generally less robust than the other subspecies, plants seldom exceed 200 mm high. The leaves are somewhat shorter and broader than in other subspecies and have notably thickened margins. The strong freesia-like odour of the flowers is unique among the subspecies, which have unscented or at best very faintly scented blooms.

7. **Sparaxis bulbifera** *(L.) Ker Gawl.* in König & Sims, Annals of Botany 1: 226 (1804a); Baker: 116 (1896, excluding *S. grandiflora* subsp. *violacea* as var. β, *violacea*); Goldblatt & Manning: 39 (2013). *Ixia bulbifera* Mill. ex L.: 4 (1756). *Belamcanda bulbifera* (L.) Moench: 214 (1802, as *Belemcanda*). *Pardanthus bulbiferus* (L.) Klatt: 551 (1862). Type: South Africa, without precise locality or collector [LINN 58/16, neo., designated by Goldblatt: 237 (1969)].



Ixia alba L.: 862 (1759). Type: unknown, said by Lewis: 185 (1962) to be *Sparaxis bulbifera* without explanation.

Ixia bulbifera Mill.: (1768), illegitimate homonym, not *I. bulbifera* L. (1756). Type: South Africa, without precise locality or collector, illustration in Miller: t. 236, f. 2 (1758).

Sparaxis albiflora Eckl.: 28 (1827). Type: South Africa, without precise locality, *Zeyher s.n.* [SAM, lecto, designated by Goldblatt: 237 (1969)].

Sparaxis miniata Klatt: 389 (1882). Type: South Africa, without precise locality, *Drège 3968* (S, holo.).

Plants 150–300(–500) mm high. *Corm* 9–15 mm diam., tunics of fine pale fibres. *Stem* usually with up to three branches from aerial nodes, after flowering bearing several small cormlets at each aerial node as well as below ground. *Leaves* 5 to 9, narrowly sword-shaped, acute, both basal and cauline, reaching to ± base of spike, 4–11 mm wide, closely veined with prominent main vein. *Spike* fairly lax, flexed below base of first flower, mostly 2- to 4-flowered; bracts dry, crinkled, uniformly pale or streaked with brown, outer mostly 14–16 mm long, with 3 subequal cusps slightly longer than body of bract, loosely twisted, inner bracts similar but slightly shorter, 2-cusped. *Flowers* with radially symmetric perianth but unilateral stamens, white but yellow in throat and tube, sometimes with small black spot at base of each tepal, outer tepals often purple outside, usually faint sweet rose-scented; perianth

Distribution of ***Sparaxis bulbifera***.

tube funnel-shaped, 14–16 mm long, narrow basal part 5–7 mm long; tepals subequal, narrowly ovate to lanceolate, 25–28 × ± 12 mm. *Stamens* unilateral but not parallel, abaxial stamen twisted to lie against adaxial tepal; filaments 7–8 mm long; anthers facing inward, 7–8 mm long, white; pollen white. *Style* unilateral, lying against adaxial tepal, white, dividing at or up to 2 mm beyond anthers tips, branches filiform, ± 10 mm long. *Capsules* ovoid to oblong, usually barrel-shaped, ± 8 × 6 mm with 9 or 10 seeds per locule, or oblong, ± 11 × 5 mm long with 11 or 12 seeds per locule. *Seeds* globose, ± 2 mm diam., glossy brown. *Flowering time*: mainly September to mid-October, occasionally in August.

Distribution and ecology: widespread in southwestern Western Cape, South Africa, extending from Hopefield and Saldanha Bay in the west to Bredasdorp in the east; on flats and the lower slopes of hills and mountains, mainly in sandy ground, usually waterlogged in winter, but on wet clay soils, often in disturbed sites.

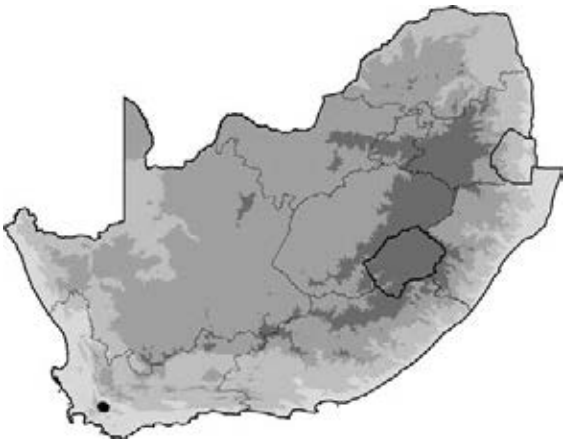
Diagnosis: the large white flowers of *Sparaxis bulbifera* are easily confused with those of white flowered *S. grandiflora* subsp. *fimbriata*, and they are indeed strikingly similar in their radially symmetric perianth but unilateral stamens and unilateral style with long slender style branches. The tepals of *S. bulbifera* are narrowly ovate to lanceolate, whereas those or *S. grandiflora* subsp. *fimbriata* tend to be broader, usually widest in the upper third and sometimes spathulate. The two species are more easily distinguished by vegetative features: *S. grandiflora* produces branches from the base; thus close to or below ground level, whereas branching in *S. bulbifera* is aerial and even when unbranched, the stems of this species have one or more aerial nodes, each bearing a leaf, and after flowering a cluster of small cormlets. Differences in habitat also help separate the two: *S. grandiflora* favours clay ground, sometimes waterlogged in winter but relatively well drained, whereas *S. bulbifera* is rarely encountered away from wet, sandy flats. The two species are evidently immediately related and, not surprisingly, hybrids between the two have been recorded where their habitats overlap.

Pollination of *Sparaxis bulbifera* is generalist: hopliine beetles, halictid bees and honey bee workers are frequently seen visiting the flowers.

8. **Sparaxis fragrans** *(Jacq.) Ker Gawl.* in König & Sims, Annals of Botany 1: 225 (1804a); Baker: 117 (1896); Goldblatt & Manning: 42 (2013). *Ixia fragrans* Jacq.: 7 (1795 [1788–1795]). *Romulea fragrans* (Jacq.) Eckl.: 19 (1827). *Gladiolus odorus* Schrank: 206 (1822), as a new name for *I. fragrans* Jacq. (1795) not *G. fragrans* Jacq. (1797) and also an illegitimate homonym, not *G. odorus* Salisb. (1796). Type: South Africa, Western Cape, without precise locality, illustration in Jacq.: t. 274 (1794 [1788–1795]).

   Ixia sordida Hornem.: 6 (1819). Type: South Africa, without precise locality, cultivated in Copenhagen, Denmark, *Horneman s.n.* (C, holo.).

   Synnotia stenophylla Baker: 865 (1901). Type: South Africa, [Western Cape], *Ecklon & Zeyher Irid. 118* (Z, holo. [with misplaced flower of *S.* cf. *metelerkampiae*]; PRE, SAM, TCD, iso.).



Plants mostly 100–200 mm high. *Corm* globose, ± 15 mm diam., tunics of fine, pale fibres extending upward as collar around stem base. *Stem* unbranched or with a branch produced from base, with small cormlets in underground leaf axils. *Leaves* 6 to 10, all ± basal, reaching to ± base of spike, narrowly sword-shaped to sublinear, 2–9 mm wide, obtuse, obliquely apiculate, closely veined with ± prominent central vein. *Spike* slightly inclined, 1- to 3(4)-flowered, weakly flexuose, flowers spirally arranged; bracts dry, crinkled, translucent with light brown streaks, 15–18 mm long, lateral margins fimbriate, distally drawn into long tapering cusps, outer 3-veined and 3 prominently 3-cusped, inner 2-veined and 2-cusped, cusps often twisted or coiled. *Flowers* radially symmetric, pale to deep yellow to pale beige, often flushed brown or grey-purple on reverse of outer tepals, occasionally with small black spot near tepal bases, sweetly or unpleasantly sour smelling; perianth tube funnel-shaped, 6–8 mm long, narrow basal part ± 4 mm long; tepals subequal, ± oblong, 18–25 × ± 7 mm. *Stamens* symmetrically arranged; filaments erect, ± 6 mm long, enclosing style; anthers contiguous below, diverging above, 6–9 mm long, pale yellow. *Style* dividing opposite upper ⅓ of anthers, branches filiform below, gradually expanded and recurved in distal half, ± 5 mm long, extending outward between anthers. *Capsules* ± globose, 9–10 × ± 7 mm. *Seeds* light brown, up to 6 per locule, ± 2 mm diam. *Chromosome number* 2*n* = 20. *Flowering time*: mid-August to late September.

Distribution and ecology: endemic to the Caledon District in southwestern Western Cape, South Africa, extending from Bot River and Villiersdorp in the west to the eastern end of the Caledon Swartberg; favouring clay flats and slopes, often waterlogged in the winter months.

Diagnosis: *Sparaxis fragrans* is recognised by the small yellow to buff-coloured, mostly unpleasantly scented

Distribution of ***Sparaxis fragrans***.

Distribution of ***Sparaxis maculosa***.

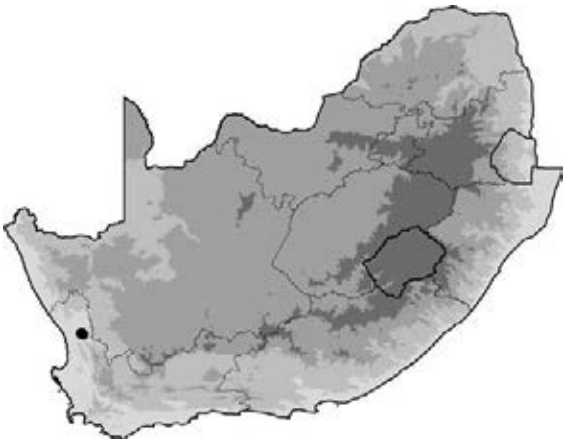
flowers borne in few-flowered spikes, symmetrically disposed stamens and narrow, acute leaves. It shares virtually identical, fringed bract margins and radially symmetric flowers with *S. maculosa*, evidently its closest relative, but the latter has larger, unscented blooms boldly marked at the base of the tepals with large maroon-purple markings divided longitudinally by a pale yellow line. The flowers are pollinated by a range of small insects, including halictid bees, native honey bee workers and hopliine beetles.

9. **Sparaxis maculosa** *Goldblatt* in Annals of the Missouri Botanical Garden 79: 153 (1992); Goldblatt & Manning: 44 (2013). Type: South Africa, [Western Cape], Farm Stettyn, between Worcester and Villiersdorp, 8 Sept. 1988, *Perry & Manning 3603* (NBG, holo.; K, MO, NBG, PRE, iso.).

Plants 100–200(–300) mm high. *Corm* globose, ± 15 mm diam., tunics of fine pale closely matted fibres. *Stem* simple or 1- or 2-branched from base. *Leaves* 7 to 9, ± basal, ± ⅔ as long as spike, lanceolate(–oblong), 9–12 mm wide, abruptly expanded adaxially above sheath, obliquely apiculate, closely veined with ± prominent central vein. *Spike* 1- or 2(3)-flowered, weakly flexuose, flowers spirally arranged; bracts dry, crinkled, translucent with brown streaks, lateral margins fimbriate, 15–20 mm long, distally drawn into long tapering cusps, outer with 3 prominent veins, 3-cuspidate, inner with 2 prominent veins and 2-cuspidate. *Flowers* actinomorphic, bright yellow, tepals each with dark maroon-purple, heart-shaped mark with central yellow streak in lower ⅓, unscented; perianth tube funnel-shaped, 6–7 mm long, narrow basal part ± 2.5 mm long; tepals subequal, ± oblong, 27–35 × 8–10 mm. *Stamens* symmetrically arranged; filaments erect, 6–7 mm long; anthers linear, diverging, contiguous below, 9.5–11.0 mm long, pale yellow. *Ovary* globose, ± 2.5 mm long; style dividing opposite the lower ⅓ of anthers, branches filiform, 4.5–5.0 mm long, extending outward between upper ⅓ of anthers. *Capsules* ± globose, shortly stipitate on stalks ± 1 mm long, 6–9 × 5–6 mm, not splitting at apex, walls eventually fragmenting by horizontal cracks. *Seeds* reddish brown, up to 8 per locule, ± 2 mm diam. *Flowering time*: late August and September.

Distribution and ecology: known from just a few farms in the Stettyn area of the Hoeksrivier drainage north of Villiersdorp in Western Cape, South Africa; in heavy clay in renosterveld. *Sparaxis maculosa* evidently originally consisted of a single extended population, but just three fragmentary colonies of the species are known today.

Diagnosis: *Sparaxis maculosa* is recognised by the radially symmetric yellow flowers with a dark centre and long-cuspidate bracts with the lateral margins slightly and irregularly serrated. The bracts are almost identical to those of *S. fragrans*, which also has a radially symmetric flower, leaving no doubt that the two are immediately related. *Sparaxis fragrans* is consistently a more slender plant with linear to narrowly lanceolate (or falcate) leaves, 2–8 mm wide and predominantly yellow to buff-coloured flowers with narrower tepals, ± 7 mm wide, sometimes with small dark marks at the tepal bases. The flowers of *S. fragrans* mostly have a slightly unpleasant, acrid odour, whereas those of *S. maculosa* lack scent. It is likely that the flowers are adapted for hopliine beetle pollination, given the conspicuous dark markings of the flowers and their lack of scent, but there are no observations on pollination of the species. Compatibility relations are likewise unknown. Molecular-based phylogenies show the species pair to be phylogenetically isolated within sect. *Sparaxis*.



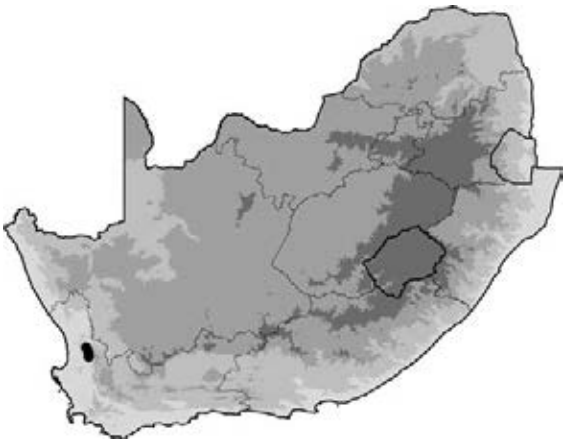
10. **Sparaxis auriculata** *Goldblatt & J.C.Manning* in Bothalia 29: 59 (1999); Goldblatt & Manning: 46 (2013). Type: South Africa, [Western Cape], Farm Keurlandshoek (Colinshoek), slopes of the Gifberg, 7 Aug. 1998, *Goldblatt & Manning 10966* (NBG, holo.; K, MO, PRE, S, iso.).

Plants 150–400 mm high, stem usually 1- or 2-branched from axils of cauline leaves, inclined above. *Corm* globose-conical, 12–14 mm diam., tunics of medium-textured fibres mostly oriented vertically. *Leaves* 5 to

8, mainly basal, uppermost inserted in middle of stem, reaching to between middle of stem and base of spike, narrowly lanceolate, acute, mostly 10–15 mm wide, with prominent submarginal vein, margin thus appearing somewhat thickened, sheathing parts of leaves speckled with purple (often fading when dry). *Spike* mostly 5- to 7-flowered, weakly flexuose, ± secund; bracts pale below with whitish veins, becoming streaked with light brown above, 15–20 mm long, lightly lacerate with prominent central cusp, inner bracts slightly shorter, with 2 terminal cusps. *Flowers* zygomorphic, bilabiate, pale yellow, dorsal tepal usually pale mauve, lower tepals deep yellow fading to white at tips, abaxial half of throat obscurely lined with grey-purple, unscented; perianth tube obliquely funnel-shaped, distal part curving outward, ± 18 mm long, lower tepals united for 6–7 mm, basal cylindric portion narrow and clasping style; tepals unequal, dorsal largest, broadly ovate, erect, ± 25 × 18–20 mm, upper lateral tepals oblong-ovate, ± 20 × 10–12 mm, spreading distally, lower 3 tepals abruptly deflexed and pinched together at bases, directed downward, ± 18 × 8 mm, strongly channelled, lower laterals with prominent auricular lobes at base. *Stamens* unilateral and arcuate; filaments ± white, ± 18 mm long; anthers 7–8 mm long, creamy white, exserted; pollen creamy white. *Ovary* 3.5 mm long, oblong-trigonous; style arching over stamens, white, ± 4 mm long, dividing just below anther tips, branches filiform, diverging and recurved in distal half, slightly wider toward apex. *Capsules* ± barrel-shaped, trilobed, ± 6(–7) × ± 6 mm, showing outline of seeds. *Seeds* 3 or 4 per locule, ± 2.2 mm diam., glossy light brown. *Flowering time*: August to early September.

Distribution and ecology: a local endemic of the Gifberg–Matsikamma Mtn complex in the Vanrhynsdorp District of northern Western Cape, South Africa; recorded in rocky sites on sandstone at low to middle elevations and locally common among rocks and in cleared places on bush-covered sandstone slopes.

Diagnosis: the flowers of *Sparaxis auriculata* resemble those of the common southwestern Cape *S. villosa* in general appearance but are substantially larger in all respects. In *S. auriculata* the dorsal tepal is ± 25 × 18–20 mm and the anthers 7–8 mm long, compared with a dorsal tepal 14–19 × 10–12 mm and anthers 3–4 mm in *S. villosa*. Furthermore, the style in the latter species divides near the anther bases, the style branches are ± 3 mm long, rarely reaching beyond the middle of the anthers, and the lower tepals are inclined slightly below the horizontal and without auriculate basal lobes, whereas *S. auriculata* has longer anthers, style branches dividing just below the anther tips, ± 4.5 mm long and exceeding the anthers. The downward-directed lower tepals bear unusual prominent auriculate lobes above the base. *Sparaxis auriculata* can also be distinguished by vegetative features: the corms are narrowly conic with tunics of medium-textured fibres, the leaf sheaths are liberally spotted with dark purple, and the leaf blades are unique in *Sparaxis* in the prominent submarginal vein that makes the margins appear thickened. The corms of *S. villosa* differ substantially being globose with coarse,



Distribution of ***Sparaxis auriculata***.

netted fibres, the vertical elements of which are thickened into claw-like ridges below, and the leaves lack the dark spotting so marked in *S. auriculata*.

The narrow, conical corms and soft corm tunics are characteristic of only two other species of *Sparaxis*, *S. galeata* and *S. roxburghii*, both occurring in northern Western Cape. The underground part of the stem is enclosed by a thick collar of fine fibres and the leaves have speckled sheaths but the two differ from *S. auriculata* in floral details. *Sparaxis galeata* has short-tubed, extremely sweetly fragrant flowers with a reflexed dorsal tepal, and prostrate, obtuse leaves, and it favours dry, stony, clay flats and slopes. The rare *S. roxburghii* has long-tubed flowers (perianth tube 20–25 mm long), otherwise resembling those of *S. galeata*, and is known from a few populations in the mid-Olifants River Valley on stony slopes. Neither species has the submarginal vein of *S. auriculata*. Molecular phylogenies place *S. roxburghii* as immediately related to *S. auriculata*. The flowers share the common pollination system of the genus, large-bodied, long-tongued bees that visit the flowers to forage for nectar.

11. **Sparaxis roxburghii** *(Baker) Goldblatt* in Annals of the Missouri Botanical Garden 79: 156 (1992); Goldblatt & Manning: 48 (2013). *Synnotia bicolor* var. *roxburghii* Baker: 198 (1892); 135 (1896). *Synnotia roxburghii* (Baker) G.J.Lewis: 146 (1956). Type: South Africa, [Western Cape], 15 miles [± 22 km] N of Citrusdal, 26 Aug. 1957, *Lewis 5207* (NBG, neo., designated by Goldblatt: 156 (1992); MO, iso.). [The location of the original type, without precise locality, *Roxburgh s.n.*, is unknown].

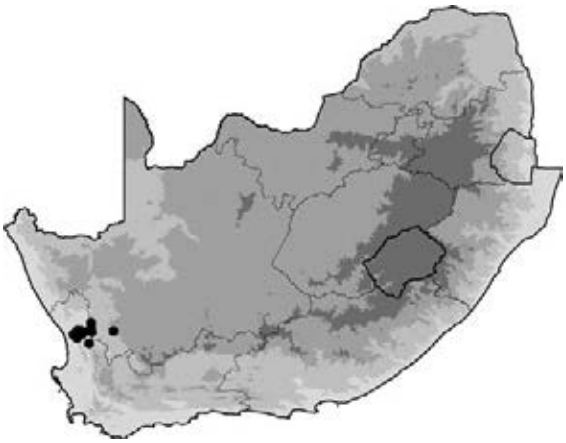
Plants 280–450 mm high, stem often with 1(2) branches from aerial nodes. *Corm* 25–30 mm diam., tunics of fine, netted fibres, extending upward in collar around stem base. *Leaves* 7 to 9, all basal except uppermost, narrowly lanceolate, ± ½ as long as stem, 8–15 mm wide. *Spike* subsecund, mostly 5- to 7-flowered; bracts 15–20(–25) mm long, pale with brown streaks, margins lightly lacerate, outer with long central cusp, inner ± as

Distribution of ***Sparaxis roxburghii***.

long as outer, with 2 long cusps. *Flowers* zygomorphic, mauve to lilac, dorsal tepal darker than upper laterals, lower tepals yellow in lower ⅔, tipped purple; perianth tube 20–30 mm long, cylindric part 13–23 mm long, curved and expanding gradually distally, upper part funnel-shaped; tepals unequal, dorsal largest, lanceolate, 22–28 × 10–12 mm, upper laterals 18–20 × ± 8 mm, lower 3 smallest, joined for 6–7 mm, ± 13 mm × ± 5.5 mm. *Stamens* unilateral, arcuate; filaments 15–20 mm long; anthers 4–5 mm long; pollen yellow. *Ovary* ± 4 mm long; style dividing near anther bases, branches ± 4 mm long, spreading outward, filiform. *Capsules* ± globose, 5–6 × ± 5 mm. *Seeds* 3(4) per locule, size unknown. *Flowering time*: late August to mid-September.

Distribution and ecology: known with certainty from a few small populations in the Olifants River Valley between Citrusdal and Clanwilliam in Western Cape, South Africa, a short distance south of the Farm Kriedoukrans; in stony clay ground in dry fynbos.

Diagnosis: the finely fibrous corm tunics forming a neck around the stem base and the erect to reflexed, rather than hooded, upper tepal suggest that *Sparaxis roxburghii* is most closely related to *S. galeata*, from which it is distinguished by the elongate perianth tube, 20–30 mm long vs. ± 15 mm in *S. galeata*. Molecular studies, however, suggest that *S. roxburghii* is most closely related to *S. auriculata*, which has a funnel-shaped rather than largely cylindric perianth tube ± 18 mm long. All three species have unusually small and nearly globose capsules containing only 2 to 4 seeds per locule.



The long-tubed flowers are almost certainly adapted for pollination by a long-proboscid fly.

12. **Sparaxis galeata** *Ker Gawl.* in König & Sims, Annals of Botany 1: 225 (1804a), as a new name in *Sparaxis*. *Gladiolus galeatus* Jacq.: 167 (1791), illegitimate homonym, not *G. galeatus* Burm.f.: 1768 (= *G. alatus* L.); Goldblatt & Manning: 50 (2013). *Synnotia galeata* (Ker Gawl.) Sweet: 398 (1826a); Lewis: 143 (1956). *Hebea galeata* (Ker Gawl.) Eckl.: 41 (1827). *Anactorion galeatum* (Ker Gawl.) Raf.: 34 (1838). Type: South Africa, [Western Cape], without precise locality or collector, illustration in Jacq.: t. 258 (1794 [1788–1795]).

Plants 120–200(–350) mm high. *Corm* 16–22 mm diam.; tunics of pale, fine fibres accumulating in thick mass extending upward to ground level in collar around base. *Stem* branching only from base or unbranched. *Leaves* 5 to 7, narrowly lanceolate, obtuse to acute, obliquely apiculate, usually inclined toward ground, ± half as long as stem, 10–18 mm wide, speckled purple on sheaths. *Spike* ± secund, 4- to 7-flowered, branches with fewer flowers, weakly flexuose, straight or inclined; bracts pale with dark brown streaks, becoming brown above, somewhat lacerate, outer 13–16 mm long, 3-cusped with central cusp more prominent, inner slightly shorter than outer, 2-cusped. *Flowers* zygomorphic, upper tepals violet or dull yellow-brown, lower tepals deep yellow shading to violet at tips, upper laterals fading to pale yellow distally, throat streaked purple and yellow on abaxial side, with heavy, sweet slightly spicy odour; perianth tube obliquely funnel-shaped, 12–15 mm long; tepals unequal, dorsal largest, erect, 25–30 × 14–15 mm, widest in midline, upper laterals recurved, ± 22 mm long, lower tepals united with upper lateral for ± 5 mm and to each other for ± 2 mm, free parts ± 17 × 5–6 mm, narrowly clawed at base, limbs channelled, flexed downward. *Stamens* unilateral, arcuate; filaments 18–20 mm long, translucent purple; anthers 5–6 mm long before dehiscence, shrinking to ± 3 mm; pollen yellow. *Style* arched above filaments, purple, dividing opposite middle to apex of anthers, branches weakly recurved, 4–5 mm long, filiform, slightly expanded and forked at tips. *Capsules* barrel-shaped to subglobose, 5–8 mm long. *Seeds* ± 2.2 mm diam., yellow-brown, 2 or 3(4) per locule. *Chromosome number* $2n = 20$. *Flowering time*: early August to mid-September.

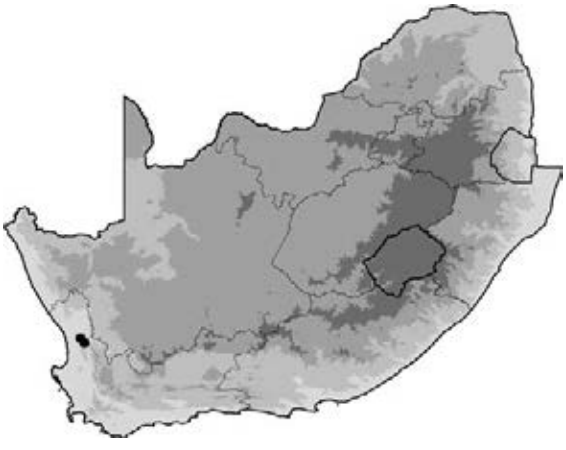
Distribution and ecology: occurring in the lower Olifants River Valley between the Nardouws Mtns and the foot of the Matsikamma Mtns and Kobee Valley in Western Cape and in the Bokkeveld Mtns near Lokenberg in Northern Cape, South Africa (an isolated record from the Farm Driefontein southwest of Calvinia requires confirmation); on dry arid stony clay flats and slopes.

Diagnosis: *Sparaxis galeata* is recognised by the large flowers with a particularly large, erect dorsal tepal, 20 × 12 mm, held vertically above the small, spooned and down-curved lower tepals. The flowers are usually strongly scented. The finely fibrous corm tunics accumulate in a dense mass around the corm and base of the stem, and the somewhat obtuse leaves are speckled with red to purple at the base. The capsules are unusually small for the genus, 5–8 mm long and contain at most 4 seeds per locule (compared with as many as 8 to 10 per locule in *S. villosa* and 10 to 12 in *S. metelerkampiae*). Based on morphology alone, *S. galeata* has been considered most closely allied to *S. roxburghii*, which

Distribution of ***Sparaxis galeata***.

has similar finely fibrous corm tunics that form a collar around the stem base, usually speckled leaf bases, and a prominent, erect dorsal tepal. Flowers of *S. roxburghii* are differently coloured, and have a perianth tube 20–30 mm long compared to 12–15 mm in *S. galeata*. The molecular-based phylogeny suggests that *S. roxburghii* is more closely allied to *S. auriculata*, but all three species are clearly related and share unusually small, rounded capsules with up to four seeds per locule.

A population on the southern slopes of Mauwerskop near Vanrhynsdorp has somewhat smaller, rather dull beige flowers, the dorsal tepal yellow-brown and only 16–20 mm long (vs. 25–30 mm in other populations), but the shape of the flower and all other features correspond with typical *S. galeata*. Flowers of this population have filaments ± 18 mm, anthers ± 6 mm, and notably a shorter style dividing opposite the middle of the anthers rather than at their apices.



The large, brightly coloured and strongly fragrant flowers are adapted for pollination by large, long-tongued bees, which visit the flowers to forage on the small quantity of nectar secreted in the base of the tube. The flowers are self-incompatible and strongly protandrous. The stigmatic tips of the style branches recurve late in the flowering cycle and then come in contact with pollen, but self-pollination rarely occurs.

13. **Sparaxis caryophyllacea** *Goldblatt* in Annals of the Missouri Botanical Garden 79: 156 (1992); Goldblatt & Manning: 53 (2013). Type: [Western Cape], middle slopes of the Nardouw Mtns, north of Clanwilliam, 13 Aug. 1976, *Goldblatt 3851* (NBG, holo.; K, MO, PRE iso.).

Plants 120–300 mm high. *Corm* 13–18 mm diam.; tunics of hard, coarse, vertical fibres, often thickened below into claw-like ribs. *Stem* often with 1 or 2 branches produced in axils of cauline leaves. *Leaves* 5 to 7, mostly basal, upper 1 or 2 cauline, inserted in mid-part of stem, broadly oblanceolate, reaching ± middle of stem, 10–15 mm wide, usually obtuse, apiculate, sometimes obliquely so, lower leaves usually speckled with red to purple (fading on drying), often inclined (leaves of juvenile plants usually ± prostrate). *Spike* straight or barely flexuose, 2- to 4-flowered, ± secund, lateral spikes when present with fewer flowers; bracts pale below with whitish veins, becoming light brown above, outer 12–14 mm long, lacerate, with prominent central cusp, inner 2-cusped. *Flowers* zygomorphic, pale yellow with dorsal tepal shading to violet in distal half, upper later tepals cream-coloured above base, lower tepals deep yellow, fading to cream-coloured at tips, throat yellow with prominent dark streaks, sweetly carnation-scented; perianth tube funnel-shaped, curving outward distally, ± 20 mm long; tepals unequal, dorsal erect to slightly hooded, 24–28 × 12–14 mm, upper laterals ± 16 × 8–9 mm, directed forward, lower tepals united for 3 mm, ± horizontal proximally, ± 12 × 6–7 mm, flexed downward and channelled distally. *Stamens* unilateral and arcuate; filaments ± 12 mm long, whitish; anthers ± 4.5 mm long, white, only partially exserted; pollen ± white. *Ovary* ± 3.5 mm long, ovoid-trigonous; style arched over filaments, dividing shortly below anther apices, branches ± 6 mm long, recurved distally between anthers, conduplicate below, becoming narrowly channelled toward upper ⅓. *Capsule* broadly ovoid, 10–11 × 6–7 mm. *Seeds* globose, glossy brown, 1.8–2.2 mm diam., usually 10 per locule. *Chromosome number* 2*n* = 20. *Flowering time*: August.

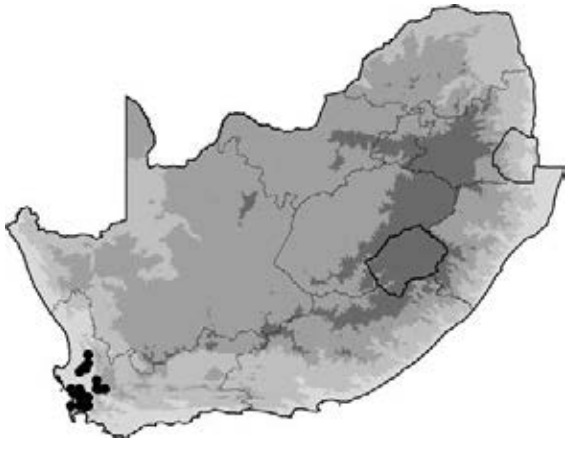
Distribution and ecology: a very local endemic known only from the western slopes at the northern end of the Nardouw Mtns in Western Cape, South Africa; growing in stony clay, below the contact line with the lowermost band of Table Mountain Sandstone that caps the Nardouw range.

Diagnosis: the flowers of *Sparaxis caryophyllacea* most closely resemble those of *S. villosa*, but the similarity may be because this is the ancestral flower type in the genus rather than an indication of close relationship. It can be distinguished by the relatively large flower size alone, the dorsal tepal 24–28 mm long compared with 12–16 mm in *S. villosa*, and in addition the pale yellow perianth is conspicuously striped with black in the throat

Distribution of ***Sparaxis caryophyllacea***.

and strongly carnation scented. Another diagnostic feature is the red to purple speckling on the sheaths of the lower leaves. This character is also present in *S. galeata*, presumably due to convergence, for the two do not seem immediately related. In the molecular phylogeny based on plastid and nuclear gene sequences, *S. caryophyllacea* is retrieved as sister to the *S. tricolor* clade (but with weak statistical support) and together with these three species comprises a clade sister to the remaining species of *Sparaxis*. However, in the nuclear gene-based phylogeny, *S. caryophyllacea* is retrieved in an entirely different position, as sister to a clade including *S. villosa* plus the two long-tubed species, *S. metelerkampiae* and *S. variegata*. This clade shares one notable synapomorphy, coarsely fibrous corm tunics. In light of the nuclear gene-based phylogeny and the shared coarsely fibrous corm tunics *S. caryophyllacea* is provisionally regarded as allied to the *S. villosa–variegata* species group.

Sparaxis caryophyllacea is self-compatible and sets full capsules, containing ± 30 seeds, when hand pollinated with its own pollen and is sometimes autogamous in the greenhouse. In nature the species is most likely normally outcrossing, and is pollinated by large-bodied anthophorine bees.



14. **Sparaxis villosa** *(Burm.f.) Goldblatt* in Annals of the Missouri Botanical Garden 79: 156 (1992); Goldblatt & Manning: 55 (2013). *Gladiolus villosus* Burm.f.: 2 (1768). *Synnotia villosa* (Burm.f.) N.E.Br.: 133 (1929); Lewis: 142 (1956). Type: South Africa, [Western Cape], without precise locality, illustration in Breyne: t. 8, f. 2 (1739) [lecto., effectively designated by Brown: 133 (1929)].

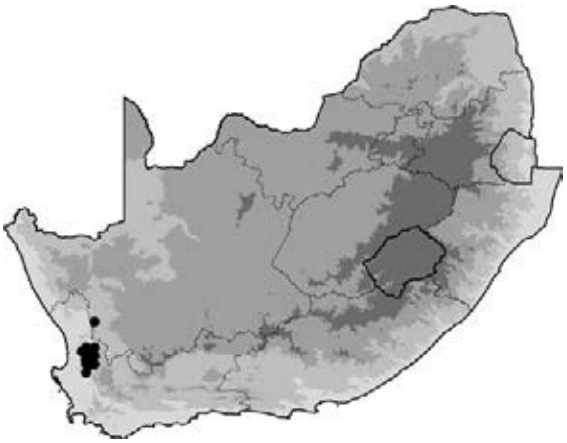
Gladiolus bicolor Thunb.: no. 16, t. 2, f. 1 (1784). *Ixia bicolor* (Thunb.) Ker Gawl.: t. 548 (1802). *Sparaxis bicolor* (Thunb.) Ker Gawl.: 225 (1804a). *Synnotia bicolor* (Thunb.) Sweet: 398 (1826b); Baker: 134 (1896), excl. syn. *Gladiolus galeatus* and var. *roxburghii*. *Hebea bicolor* (Thunb.) Eckl.: 42 (1827). *Anactorion bicolor* (Thunb.) Raf.: 34 (1838). Type: [Western Cape], Groene Kloof, *Thunberg s.n.* (UPS–THUNB, syn. [two sheets]).

Plants 150–350 mm high. *Corm* 9–15 mm diam., tunics of hard, coarse fibres, netted above, thickened and vertical below, often forming claw-like ridges. *Stem* simple or with 1 branch from axil of cauline leaf. *Leaves* 5 to 7, mostly in a basal fan, uppermost inserted in middle of stem, narrowly lanceolate, obliquely apiculate, reaching to between middle of stem and base of spike, 5–15 mm wide, sheathing lower part of stem. *Spike* weakly flexuose, subsecund, 2- to 4-flowered; bracts pale below with whitish veins, becoming irregularly streaked light brown above, outer 15–25 mm long, ± 3 cuspidate with central cusp prominent, becoming irregularly lacerate, inner ± as long as outer, with 2 prominent cusps. *Flowers* zygomorphic, creamy yellow with dorsal tepal violet in upper half and lower tepals deep yellow fading to cream-coloured at tips, abaxial half of throat streaked yellow and violet, unscented; perianth tube obliquely funnel-shaped, upper part curving outward, (12–)15–16 mm long; tepals unequal, dorsal largest, erect to slightly hooded, (10)15–16 × 9–10 mm, upper laterals ± 12 mm long, directed forward, lower 3 tepals united basally for ± 2 mm, ± horizontal below, ± 10 mm long, channelled and flexed downward distally. *Stamens* unilateral, arcuate; filaments ± 13 mm long, white; anthers violet above, cream-coloured below, ± 3 mm long, fully exserted; pollen ± white. *Ovary* 4–5 mm long, oblong-trigonous; style arched over filaments, purple, dividing just below or opposite anther bases, branches ± 2 mm long, ascending, recurved distally, ciliate along margins ± to base, slightly expanded distally. *Capsules* barrel-shaped, ± 12 × 6–7 mm. *Seeds* 1.7–2.1 mm diam., light brown, (8)9 or 10 per locule. *Chromosome number* $2n = 20$. *Flowering time*: mid-August to late September.

Distribution and ecology: scattered through the western forelands of the Western Cape, South Africa, from the Cape Peninsula northward along the West Coast and through the Tulbagh and Olifants River Valleys as far north as Piketberg and Citrusdal; in renosterveld on heavy clay and granite-derived soils, often in rocky sites but also under low shrubs where it blooms more erratically than in open habitats. Naturalised in the Mt Lofty Range of South Australia.

Diagnosis: *Sparaxis villosa* is recognised by its comparatively small flowers with an erect to slightly hooded, dorsal tepal usually ± 16 mm long, much exceeding the yellow lower tepals, ± 10 mm long. The distinctive coarse corm tunic fibres are also shared with the rare *S. caryophyllacea*, but this species has larger flowers, the dorsal tepal ± 20 mm long. The two long-tubed species, *S. metelerkampiae* and *S. variegata*, also have similar corm tunics but the long perianth tube immediately sets them apart. These distinctive corm tunics define the lineage comprising these four species. A particularly small-flowered variant of *S. villosa* occurs on granite outcrops at Vredenburg, the dorsal tepal ± 10 mm long and perianth tube ± 12 mm long. These plants might easily be misidentified as *S. parviflora* were it not for the distinctive woody tunics.

Distribution of ***Sparaxis villosa***.



The modest-sized and fairly inconspicuous flowers appear likely to be insect pollinated but the species is self-compatible. Plants from two populations have proven to be autogamous in the greenhouse. The anthers shed pollen directly onto receptive stigmas. Selfing results in the production of full capsules with (8)9 or 10 seeds per locule (typically 27 to 30 seeds per capsule), the normal complement for the species. The autogamous habit may account for the comparatively wide range of *S. villosa*. Hybrids between *S. villosa* and *S. metelerkampiae* have been recorded at the foot of Piekenierskloof Pass. Although mostly separated geographically and edaphically, the ranges of the two species overlap for a short distance and at this locality they co-occur on loamy soils at the shale-sandstone interface.

15. **Sparaxis variegata** *(Sweet) Goldblatt* in Annals of the Missouri Botanical Garden 79: 157 (1992); Goldblatt & Manning: 58 (2013). *Synnotia variegata* Sweet: t. 150 (1826b); Lewis: 147 (1956), in part excluding var. *metelerkampiae*. Type: South Africa, without precise locality or collector, illustration in Sweet: t. 150 (1826a).

Sparaxis wattii Harv.: 330 (1838). Type: South Africa, [Western Cape], without precise locality, *Watt s.n.* (TCD, holo.; GH, K, iso.).

Plants 100–180(–300) mm high. *Corm* 12–22 mm diam.; tunics of coarse, hard fibres, with thickened vertical strands in lower half. *Stem* simple or sometimes branched near middle. *Leaves* several in a tight fan, inclined or appressed to ground, 100–150 × 8–14 mm. *Spike* secund in 2 ranks, 3- to 8-flowered, branches always with fewer flowers than main spike; bracts pale with brown streaks, margins irregularly toothed, outer 20–25 mm long, inner ± as long, divided distally into 2 long cusps. *Flowers* zygomorphic, bilabiate, either pale yellow with dorsal tepal violet and lower laterals purple at tips or less often upper three tepals violet, throat yellow to white with longitudinal purple streaks, unscented; perianth tube cylindric below, abruptly bent at right angles into wide horizontal part, cylindric part 30–32 mm long, ± 2 mm diam., upper part ± 12 mm long, slightly inflated, ± 12 mm wide at mouth; tepals unequal, dorsal longest, ± erect, lanceolate-ovate, 25–30 × 16–18 mm, upper laterals ± 20 × 10 mm, recurving in distal half, lower tepals united basally for 5–7 mm, ± clawed, limbs channelled, ± 12 × 4.5 mm. *Stamens* unilateral and arcuate; filaments ± 20 mm long; anthers parallel, white, striped purple on locule sutures, 6–7 mm long. *Ovary* ovoid, ± 3 mm long; style dividing near anther tips, branches recurving gradually, 4–5 mm long, channelled and broader in distal ½. *Capsules* oblong, 9.0–11.5 × ± 6 mm. *Seeds* globose, brown, ± 2 mm diam., (5–)8 or 9(10) per locule. *Flowering time*: late August to mid-September.

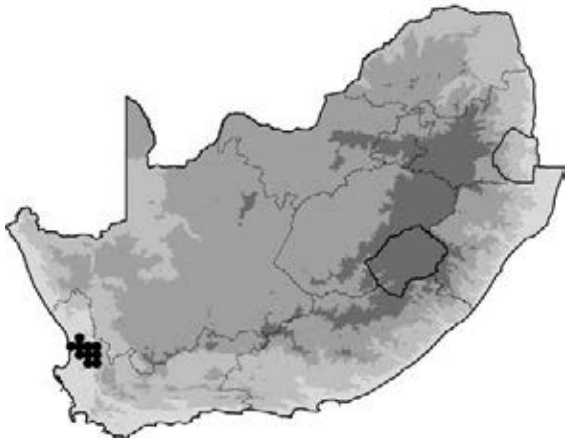
Distribution and ecology: centred in the lower Olifants River Valley between Clanwilliam and Bulshoek in Western Cape, South Africa; on rocky, often south-trending sandstone slopes, sometimes along the courses of temporary streams.

Distribution of ***Sparaxis variegata***.

Diagnosis: the large flowers of *Sparaxis variegata* are either yellow with the dorsal tepal pale violet or predominantly violet with the lower tepals either yellow or white, tipped with violet and the throat white streaked with purple lines. The typical violet-flowered form occurs in the south of the range, notably at Rondegat, south of Clanwilliam. The larger size of the flowers, including the tepals and anthers, a style that divides near the anther apices, and often the predominantly yellow perianth, distinguish *S. variegata* from closely allied *S. metelerkampiae*. The longer style with the branches arched above the anthers makes self-pollination unlikely, but in any event, the species is genetically self-incompatible. The capsules, up to 11.5 mm long, typically contain 8 to 10 seeds per locule. Like its close relative *S. metelerkampiae*, *S. variegata* has corms with coarsely fibrous tunics and flowers with a long perianth tube with a strong bend at the apex of the slender, cylindric part of the tube.

Both *Sparaxis variegata* and *S. metelerkampiae* are pollinated by long-proboscid flies, but flowers are also occasionally visited by large, long-tongued bees. The bees cannot reach nectar in the lower part of the tube and reported visits are either exploratory and may be part of a bimodal pollination system utilising both bees and flies. Some interbreeding and introgression may occur with *S. metelerkampiae* in the large population of *S. variegata* on south-trending slopes near Rondegat. Flower size is unusually variable at this locality and the predominantly purple colouration may be derived through hybridisation with *S. metelerkampiae* growing nearby.

16. **Sparaxis metelerkampiae** *(L.Bolus) Goldblatt & J.C.Manning* in Bothalia 29: 61 (1999). *Synnotia metelerkampiae* L.Bolus: 77 (1923). *Sparaxis variegata* var. *metelerkampiae* (L.Bolus) G.J.Lewis: 148 (1956). *Sparaxis variegata* subsp. *metelerkampiae* (L.Bolus) Goldblatt: 158 (1992). Type: South Africa, [Western Cape], Eendekuil, *Metelerkamp s.n.* (BOL16039, holo.; K, PRE iso.).



[*Sparaxis orchidiflora* G.Lodd.: t. 1099 (1826), invalid name without description.]

[*Sparaxis luteoviolacea* Eckl.: 27 (1827), invalid name without description (based on *Ecklon & Zeyher 76.8*: C, E, G, GH, P).]

Plants 120–300 mm high. *Corm* 10–16 mm diam., tunics of coarse netted fibres usually thickened below into claw-like ridges. *Stem* simple or 1(2)-branched from aerial part of stem, inclined above leaf sheaths. *Leaves* 5 to 7, lanceolate, obtuse to acute, apiculate, sometimes obliquely so, basal except uppermost, this inserted in middle of stem, ± ½–⅔ as long as stem, 7–12 mm wide, sheathing lower part of stem, often inclined toward ground. *Spike* ± secund, 2- to 5-flowered; bracts pale or irregularly streaked with brown, slightly crinkled, outer 15–18 mm long, 3-cuspidate, central cusp more prominent, inner slightly shorter, with 2 prominent cusps. *Flower* violet-purple with cream-coloured to yellow (rarely reddish) markings on lower tepals; perianth tube with cylindric lower part 35–40 mm long, upper part 10 mm long, 6–7 mm wide at mouth; tepals unequal, dorsal largest and erect with margins incurved, 15–20 mm long, 8–11 mm wide, upper laterals 12 mm long, ± 5 mm wide, directed forward below and outward distally, lower tepals united with upper lateral for ± 3 mm and to each another for ± 4 mm, limbs channelled below and flexed downward in distal half, ± 12 × 4–5 mm. *Stamens* unilateral, arcuate; filaments 10–12 mm long, purple, reaching top of tube or exserted up to 3 mm; anthers 3–4 mm long, purple, median anther extending beyond tips of laterals; pollen pale yellow. *Style* usually dividing opposite lower ⅓ of anthers or below them (possible hybrids have style dividing opposite or beyond anther tips), purple, branches diverging, 2–3 mm long, extending between anther bases. *Capsule* cylindric-trilobed, 12–15 mm long, 5 mm wide. *Seeds* glossy brown, globose, 1.3–1.6 mm diam., 10 to 12 per locule. *Chromosome number* 2*n* = 20. *Flowering time*: August to mid-September.

Distribution and ecology: extending through the northern part of Western Cape, South Africa, from the Gifberg in the north, through the Olifants River Valley and adjacent mountains to Piekenierskloof and Eendekuil in the south and to Leipoldtville in the west (an early record from Oorlogskloof on the southern Bokkeveld Mtns requires confirmation); in sandy and stony ground, always in well-drained situations.

Diagnosis: *Sparaxis metelerkampiae* has long-tubed, purple flowers with the lower tepals each with a white longitudinal streak, at the centre of which is a pale yellow or reddish mark. The tepals are smaller than those of immediately related *S. variegata*, the dorsal tepal 15–20 mm long vs. 25–30 in *S. variegata*, and the style is short, dividing below or opposite the lower third of the anthers and has branches 2–3 mm long. In *S. variegata* the longer style divides close to the anther tips and the branches are 4–5 mm long. The shorter style of *S. metelerkampiae* results in the style branches and anthers coming into contact during anthesis, ensuring self-pollination if insect-mediated pollen transfer fails. The species has been treated as a variety or subspecies of *S. variegata* on the basis of intermediates between the two but they are usually easy to distinguish and have quite different compatibility relations. Some of the variation in perianth size in both species may be due to growing conditions and possibly to hybridisation locally, as both share the same pollinator.

Distribution of ***Sparaxis metelerkampiae***.

Greenhouse studies have shown that the species is fully self-compatible and autogamous. Flowers consistently set full capsules with 10 to 12 seeds per locule without hand pollination and in the absence of insect visitors. The flowers are, however, adapted for pollination by long-proboscid flies and often receive visits from these flies. *Sparaxis metelerkampiae* appears to hybridise with *S. variegata* south of Clanwilliam and hybrids with *S. villosa* have been recorded at the foot of Piekenierskloof Pass.

NATURAL HYBRIDS (see Goldblatt & Manning 2013).

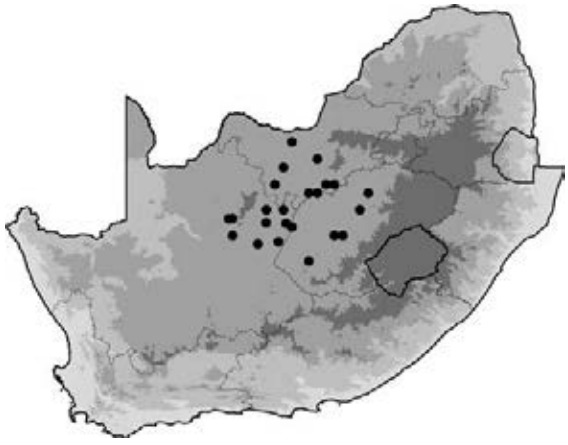
25. **Duthiastrum**

Duthiastrum *M.P.de Vos* in Journal of South African Botany 41: 91 (1975), as a new name for *Duthiella* M.P.de Vos: 301 (1974), illegitimate homonym, not *Duthiella* C.Mueller Hal. ex Broth. in Engl. & Prantl.: 1009 (1908). Type: *Duthiella linifolia* (Phillips) M.P.de Vos = *Duthiastrum linifolium* (Phillips) M.P.de Vos

Revisionary accounts: De Vos: 301–309 (1974); De Vos: 139–141 (1999).

Named for the pioneering South African botanist, Miss A.V. Duthie (1881–1963), combined with the Latin, *aster*, star.

Deciduous geophytes. *Corm* globose, axial in origin; tunics of fine, netted fibres. *Cataphylls* 2 or 3, membranous or papery. *Leaves* several, unifacial, linear to narrowly sword-shaped, mostly basal, in a tight 2-ranked fan, blades plane, with a definite main vein, leathery; margin without vascular bundle, epidermal cells columnar with thickened walls. *Stem* subterranean, branched below ground. *Inflorescence* subterranean, branched, of 1(2) sessile flowers terminal on axes; bracts oblanceolate, membranous, concealed by leaves, inner 2-veined and slightly shorter than outer, notched apically. *Flowers* actinomorphic, long-lived, salver-shaped, yellow (rarely orange), unscented, with nectar from septal nectaries; perianth tube elongate, cylindric; tepals subequal, spreading, lanceolate. *Stamens* symmetrically disposed, erect; filaments inserted shortly below top of perianth tube; anthers suberect, yellow. *Ovary* subterranean, club-shaped and conspicuously stalked; style filiform, 3-branched distally, branches narrowly oblanceolate, longitudinally folded. *Capsules* borne at ground level, ellipsoid, conspicuously stalked, cartilaginous. *Seeds* globose, flattened at chalazal end, hard, smooth and shiny, testal cells obscured by thick cuticle; ovular vascular trace excluded. *Pollen grains* monosulcate-operculate, operculum 2-banded, exine perforate-scabrate. *Basic chromosome number* $x = 10$.



Species 1, central South Africa.

A distinctive, monospecific genus recognised by its contracted, subterranean stem, basal fan of sword-shaped leaves with anatomically specialised margins, mostly solitary, yellow flowers with an elongate perianth tube, and subterranean, conspicuously stalked ovary and capsules. Several of these states, notably the branched inflorescence with 1(2) flowers per branch, long-tubed flowers with the floral tube largely blocked by the style and thus functioning as a pseudostalk, and stalked capsules, are correlated with the stemless habit and are thus not independent. The finely netted corm tunics are characteristic of several related genera including *Ixia* and *Sparaxis*. Among them, similar, derived seeds with a smooth, glossy testa and excluded vascular bundle and the specialised leaf margin anatomy are found also in *Chasmanthe*, *Sparaxis* and *Tritonia*, and molecular data place *Duthiastrum* as sister to *Sparaxis*. The two genera share the basic chromosome number $x = 10$.

1. **Duthiastrum linifolium** *(E.Phillips) M.P.de Vos* in Journal of South African Botany 41: 91 (1975). *Syringodea linifolia* E.Phillips: 125 (1913). *Duthiella linifolia* (E.Phillips) M.P.de Vos: 306 (1974). Type: South Africa, [Northern Cape], without precise locality or collector *SAM 20664* (SAM, holo.).

Plants 60–150 mm high. *Corm* 10–15 mm diam.; tunics of fine, netted fibres. *Stem* up to 100 mm long, subterranean, branched. *Leaves* 6 to 9, mostly basal, linear to narrowly lanceolate, 40–120 × (1.5–)3.0–6.0 mm, with prominent main and secondary veins. *Spike* 1- or 2-flowered; bracts 25–60 mm long, membranous and pellucid, inner as long as or shorter than outer. *Flowers* bright yellow (rarely dull orange with yellow star in centre), outer tepals veined or flushed brownish purple beneath, unscented, opening midday and closing at dusk; perianth tube 40–80 mm long, ± 1 mm diam., occluded by style but widening gradually to 2 mm in upper 10 mm; tepals spreading, elliptic, 12–25 × 4–8 mm. *Filaments* 4–6 mm long; anthers 5–7 mm long, incurved apically, yellow. *Ovary* with stalk 1.5–15.0 mm long; style dividing opposite anthers, branches 3–6 mm long. *Capsules* ellipsoid, 20–25 mm long, stalked. *Seeds* 2–3 mm diam. *Flowering time*: March to May (June).

Distribution and ecology: scattered through central South Africa in the Vaal–Orange drainage basin, from Kimberley in Northern Cape to Mmbatho in Northwest

Distribution of ***Duthiastrum linifolium***.

Duthiastrum linifolium: A, flowering plant; B, dehiscing capsules; C, seed.

and eastward to Kroonstad in Free State, with a recent unconfirmed sight record from Devon near Heidelberg in Gauteng of a population with dull orange flowers. The species is locally common in alluvial washes, mainly in limey silt or on chalky flats.

The flowers open in the early afternoon around 13:00 and close shortly after dark each day. The perianth tube, although elongate, has a relatively thick wall and functions as a pseudo-pedicel: the interior is occluded by the long style except near the apex where the tube widens slightly. The little nectar that is produced is forced by capillary action into the top of the tube where it is accessible to a range of insects with short mouthparts, including various bees, the most likely pollinators. The capsules protrude above ground level at maturity, carried up to the surface by elongation of the stem.

26. **Dierama**

Dierama *K.Koch,* Index Seminum Hortus Berolinensis 1854, Appendix 10 (1855). Type: *Dierama ensifolium* K.Koch & C.D.Bouché = *D. pendulum* (L.f.) Baker

From the Greek, *dierama*, a funnel, describing the shape of the flower.

Revisionary account: Hilliard & Burtt (1991).

Evergreen perennials, solitary or growing in clumps. *Rootstock* a depressed-globose corm rooting from below and axial in origin, persisting; tunics of coarse, netted fibres, often accumulating in a dense mass. *Stem* aerial, slender and wiry, often drooping above, rarely erect, usually several-branched, subtending bracts dry and thread-like. *Leaves* several, often without a definite midrib in mature plants, plane, linear, leathery and fibrotic; with marginal vascular bundle and unspecialised epidermal cells. *Spikes* pendent or erect, axes wiry; bracts dry, usually papery and translucent, occasionally solid and herbaceous or leathery in centre or lower part, becoming torn above, usually brown-streaked or -spotted, outer with prominent main vein and numerous smaller lateral veins, acute or attenuate, inner smaller than outer, 2-veined, forked apically. *Flowers* actinomorphic, bell-shaped, long-lived, usually nodding, mostly pink to mauve but also maroon or purple, yellow or white, with dark markings near tepal bases, unscented, with nectar from septal nectaries; perianth tube funnel-shaped, relatively short; tepals subequal, cupped or spreading distally, often enclosing stamens and style. *Stamens* symmetrically disposed, central; filaments slender; anthers linear, dehiscing longitudinally. *Ovary* globose, sessile; style filiform, surrounded by stamens, usually included in floral cup, branches short, slender, slightly expanded above and recurved. *Capsules* globose, cartilaginous. *Seeds* globose or lightly angled, flattened at the chalazal end, smooth, hard, often shiny, ovular vascular trace excluded. *Pollen* monosulcate-operculate, operculum 2-banded, exine perforate-scabrate. *Basic chromosome number* $x = 10$.

Species ± 45, southern and eastern tropical Africa, centred in eastern southern Africa with 37 species in the region, and six species restricted to tropical Africa from Zimbabwe through Malawi, Tanzania and Kenya to Ethiopia; mainly montane but also coastal in South Africa, favouring rocky grassland but also in marshes and along streams. Primarily a genus of highland grassland but extending to near the coast along the temperate eastern seaboard of South Africa, most diverse in KwaZulu-Natal with 26 species (Hilliard & Burtt, 1991).

Dierama is recognised by the mostly evergreen habit, tough, fibrous leaves, and slender, wiry stems with drooping spikes of radially symmetric, funnel-shaped flowers subtended by large, dry, papery or sometimes partly herbaceous floral bracts, generally pale with brown streaks and veins. A few species are exceptional in having semi-erect spikes with nearly upright flowers. The adult leaves are distinctive in lacking a prominent central vein, although this is present in the juvenile state.

Dierama is one of a small group of allied genera with more-or-less dry floral bracts and specialised seeds with a smooth, glossy testa and a vascular bundle that is excluded from the seed body during development. Within this group it is most closely allied to *Tritonia* and *Ixia*, where the unusually flexible, wiry stems, ancestrally actinomorphic flowers, and basic chromosome number $x = 10$ suggest a likely sister relationship with *Ixia*, which is evidently derived in possessing 3-veined and often tricuspidate outer bracts, and pollen with a 1-banded operculum.

The flowers are pollinated by solitary bees that forage for nectar and pollen. The genus shows only modest floral variation, confined to size, colour and degree of spreading of the tepals.

Almost all the species merit horticultural attention, but few are available in the trade, where they are often misidentified as *D. pendulum*, for many years the only named species.

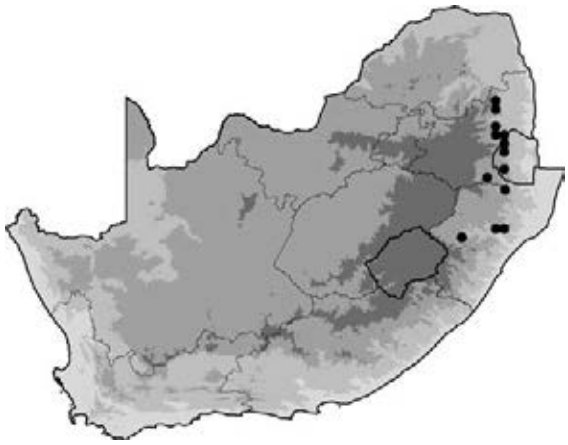
The taxonomy of *Dierama* is still far from adequately understood despite the monograph by Hilliard & Burtt (1991). Many of the taxa recognised at species level by Hilliard & Burtt (1991) were considered by them to have 'multiple relationships with one another', and more work is clearly required to analyse this further. As it is, species recognition in the genus is difficult, both because of the lack of critical diagnostic features and the frequent introgression between species. The following identification key serves to discriminate typical examples. The original keys to the species provided by Hilliard & Burtt (1991) should also be consulted.

Key to species

1a Foliage leaves produced on separate shoot alongside flowering stem and often not fully formed at flowering; plants flowering early spring, August to September:
2a Flowering stem lacking conspicuous basal internode and without axillary cormlets; tepals suberect, flaring distally, ± twice as long as perianth tube . . . . . 3. *D. nixonianum*

2b Flowering stem with conspicuous basal internode and with axillary cormlets in lowermost leaf axil; tepals spreading widely from near base, ± three times as long as perianth tube . . . . . 4. *D. trichorhizum*
1b Foliage leaves produced at base of flowering stem and fully formed at flowering; plants flowering in spring and summer, September to February or later:
3a Bracts with solid patch of hard tissue in lower ½–⅔, this often drying pale buff-coloured or uniform brown:
4a Plants solitary or few in small tufts, with pendulous inflorescences; leaves 2–6 mm wide; co-florescences 2 to 5; flowers funnel- or bell-shaped. . . . . 26. *D. insigne*
4b Clump-forming species with erect or suberect inflorescences; leaves 6–12 mm wide; co-florescences ± 10; flowers subrotate. . . . . 27. *D. erectum*
3b Bracts membranous or with solid patch of tissue only at extreme base:
5a Inflorescences erect and suberect; bracts whitish to orange-buff-coloured and lightly flecked all over:
6a Flowering stems 1 000–1 500 mm tall; leaves 450–1 000 mm long; lateral spikes mostly 6- to 13-flowered; perianth tube mostly 6–8 mm long; plants from central KwaZulu-Natal to Mpumalanga . . . . . 1. *D. galpinii*
6b Flowering stems 450–850 mm tall; leaves 300–600 mm long; lateral spikes mostly 4- to 7-flowered; perianth tube mostly 5–6 mm long; plants from southern KwaZulu-Natal . . . . . .2. *D. tysonii*
5b Inflorescences ± pendulous; bracts various:
7a Bracts entirely white or so lightly flecked as to appear white:
8a Flowers white to pale yellow, rarely pale pink:
9a Terminal spike 3- to 6-flowered; bracts 24–32 mm long; perianth 30–50 mm long . . . . . .34. *D. luteoalbidum*
9b Terminal spike mostly 6- to 12-flowered; bracts 14–25 mm long; perianth 13–30(–35) mm long:
10a Perianth 18–35 mm long . . . . . 33. *D. argyreum*
10b Perianth 14–18 mm long. . . . . .35. *D. pallidum*
8b Flowers pink to purple:
11a Perianth 14–18 mm long, often shorter than the bracts; anthers 5–6 mm long . . . . . .28. *D. dubium*
11b Perianth (17–)20–33 mm long, much longer than the bracts; anthers 7–10 mm long:
12a Flowering stems solitary or up to three in small tufts; leaves 3–6 mm wide . . . . . .29. *D. reynoldsii*
12b Flowering stems forming large clumps; leaves (5–)6–15 mm wide . . . . . .30. *D. latifolium*
7b Bracts ± evidently flecked with brown:
13a Flowers white to pale yellow:
14a Leaves almost needle-like, 1.0–2.5 mm wide; bracts heavily flecked and almost solidly coloured throughout except along margins . . . . . 37. *D. pumilum*
14b Leaves 3–9 mm wide; bracts moderately to heavily flecked toward base with paler shoulders:
15a Anthers 5–7 mm long; plants from KwaZulu-Natal. . . . . 36. *D. sertum*
15b Anthers 7–9 mm long; plants from Eswatini . . . . . 17. *D. elatum*
13b Flowers pink to purple or dark wine-red:
16a Flowers dark wine-red, rarely purple but then perianth less than 35 mm long:
17a Perianth 22–31 mm long:
18a Plants 1 200–2 100 mm high; terminal spike 8- to 18-flowered; plants from Mpumalanga to Northern KwaZulu-Natal . . . . . 31. *D. tyrium*
18b Plants 750–1 250 mm high; terminal spike mostly 4- to 8-flowered; plants from Eastern Cape . . . . 32. *D. atrum*
17b Perianth 15–23 mm long:
19a Bracts reddish brown with paler shoulders, with 4 or 5 main veins each side of the midvein; lateral spikes often borne on strikingly long peduncles, usually 90–230 mm long . . . . . 25. *D. mobile*
19b Bracts dark brown with sharply contrasting white shoulders, with 6 to 8 main veins each side of the midvein; lateral spikes on shorter peduncles 60–125 mm long . . . . . 24. *D. pictum*
16b Flowers pale to magenta-pink or mauve, rarely purple but then perianth 35–54 mm long:
20a Small, mostly clump-forming plants 300–600 mm tall with leaves 1–4 mm wide; terminal spike 1- to 4(5)-flowered; bracts bright rusty brown with 6 to 8 main veins each side of the midvein; flowers bright pink or reddish . . . . . .23. *D. pauciflorum*
20b Not as above:
21a Flowering stems forming large clumps; perianth 15.5–20.5 mm long with stigmas held 3.5–7.5 mm below top. . . . . 15. *D. floriferum*
21b Not as above:
22a Plants from Western and Eastern Cape, Free State or southern and central KwaZulu-Natal:
23a Perianth 28–50 mm long and plants from west of the Kei River:
24a Tips of tepals ± folded together and twisted giving them a pointed appearance . . . . . .7. *D. grandiflorum*
24b Tips of tepals not folded and twisted:
25a Flowers funnel-shaped with widely flaring tepals; plants from west of Grahamstown . . . 5. *D. pendulum*
25b Flowers ovoid in shape with suberect or weakly spreading tepals; plants from east of Grahamstown. . . . . .6. *D. pulcherrimum*
23b Perianth up to 30(–35) mm long and plants from east of the Kei River:
26a Perianth mostly 26–35 mm long with tube 8–13 mm long; anthers mostly 8–12 mm long . . 9. *D. robustum*
26b Perianth mostly 15–28 mm long with tube 5–8 mm long; anthers 5–8 mm long:
27a Main veins 6 to 9 each side of the midvein with well-developed intermediate veins, all coalescing to form a solid base . . . . . .10. *D. ambiguum*
27b Main veins 4 to 6 each side of the midvein, intermediates well developed or not but never coalescing:
28a Plants forming clumps:
29a Flowers pale mauve; perianth 25–28 mm long with tepals 8–12 mm wide. . . . . 13. *D. jucundum*

DIERAMA. D. longistylum: A, leaf and flowering stem; B, outer bract; C, half-flower. ***D. plowesii***: D, flowering plant; E, outer bract; F, half-flower.

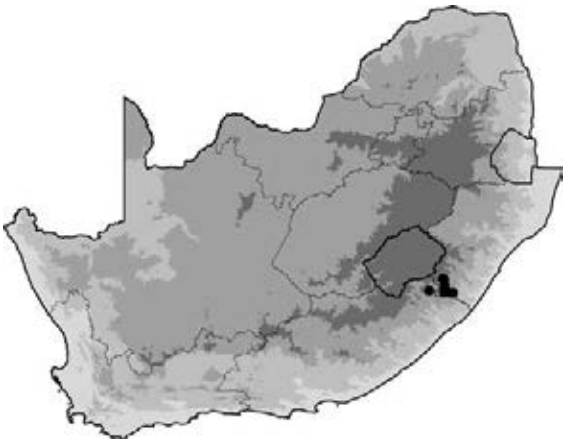


29b Flowers mostly pink to red, rarely mauve; perianth up to 23 mm long with tepals 5–8 mm wide . . . . . 14. *D. dracomontanum*
28b Plants solitary or few in tufts:
30a Bracts two internodes long, with 6 main veins on each side of the midvein, all veins closely contiguous and parallel. . . . . 12. *D. cooperi*
30b Bracts usually shorter than two internodes long, with 4 to 6 main veins on each side of the midvein, all veins not closely contiguous and parallel:
31a Flowers pale pink or almost white; bracts drab; plants coastal from Durban southward 8. *D. igneum*
31b Flowers and bracts more richly coloured; plants from Drakensberg foothills and lower slopes . . . . . .11. *D. dissimile*
22b Plants from northern KwaZulu-Natal, Gauteng, Mpumalanga, Limpopo or Eswatini:
32a Perianth 26–37 mm long with tube (6.5–)8.0–12.0 mm long; leaves (4–)6–10 mm wide . . . . 16. *D. formosum*
32b Perianth 13–25(–27) mm long with tube 4.0–7.5 mm long; leaves 1.5–5.0 mm wide:
33a Bracts with 6 to 8 main veins each side of midvein:
34a Bracts dark brown with contrasting white shoulders; perianth pink to wine-red, 15–23 mm long . . . . . 24. *D. pictum*
34b Bracts chestnut-brown with paler brown shoulders; perianth pink, 20–29 mm long . . . . .22. *D. nebrownii*
33b Bracts with 3 to 5 main veins each side of midvein:
35a Lateral spikes 6 to 8. . . . . 20 *D. adelphicum*
35b Lateral spikes mostly up to 5:
36a Bracts delicately veined, with 3 or 4 faint main veins restricted to basal half . . . . . .21. *D. gracile*
36b Bracts more strongly and heavily veined:
37a Bracts < 2 internodes long; perianth mostly 19–25 mm long; anthers mostly 6–7 mm long . . . . . .18. *D. mossii*
37b Bracts 2 internodes long or longer; perianth mostly 13–18 mm long; anthers mostly 4.5–6.0 mm long . . . . . 19. *D. medium*

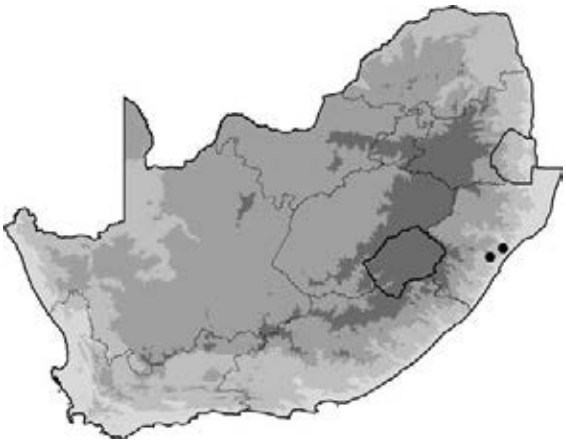
1. **Dierama galpinii** *N.E.Br.* in Journal of the Royal Horticultural Society 54: 200 (1929). Type: South Africa, [Mpumalanga], near Barberton, Saddleback Range, Sept.–Oct., *Galpin 527* (K, holo.; BOL, PRE, iso.).

Plants 1.0–1.5 m high, stems few in small tufts. *Corm* ± 25–40 mm diam. *Stem* with lowermost peduncle 35–90 mm long. *Foliage leaves* several, mostly 450–1 000 × 4–8 mm; reduced sheathing leaves 4 to 6. *Spikes* erect or suberect, terminal 6- to 14-flowered, laterals 5 to 10, suberect, (4)6- to 13-flowered; bracts lanceolate to oblanceolate, acuminate and usually with 2 lateral cusps, 10–20 × 3–5(–6) mm, 2 internodes long or longer, lightly flecked all over, midline often uniformly orange-brown, lateral veins 3 to 5 each side of main vein, 2 veins flanking midvein sometimes running almost to apex. *Flowers* funnel-shaped with tepals widely flaring, pale to bright magenta-pink, rarely white; perianth tube (5.5–)6.0–8.0 mm long; tepals 12–17 × 4–8 mm. *Anthers* (5.5–)6.0–8.0 mm long. *Stigmas* held 2.0–7.5 mm below top of perianth. *Flowering time*: mainly August to November (April).

Distribution and ecology: extending from Kaapsche Hoop in southern Mpumalanga, South Africa, through western Eswatini to Estcourt in northern KwaZulu-Natal, South Africa; in grassland, from ± 600–1 600 m elevation.



Diagnosis: a tufted species with erect inflorescences 1.0–1.5 m tall of pale to deep pink flowers with perianth 17–25 mm long, and translucent, lightly flecked bracts. *Dierama tysonii* from southern KwaZulu-Natal with similar inflorescences is more strongly clump-forming, with shorter stems up to 8.5 m tall, and fewer flowers on the lateral spikes, mostly 4 to 7.



Distribution of ***Dierama galpinii***.

2. **Dierama tysonii** *N.E.Br.* in Journal of the Royal Horticultural Society 54: 200 (1929). Type: South Africa, [KwaZulu-Natal], grassy slopes near Kokstad, *Tyson 1558* (K, holo.; BOL, iso.).

Plants ± 450–850 mm high, in small clumps. *Corm* ± 20–40 mm diam. *Stem* with lowermost peduncle 45–120 mm long. *Foliage leaves* several, 300–600 × 3.5–8.5 mm; reduced sheathing leaves 3 or 4. *Spikes* erect, terminal 6- to 9-flowered, laterals 4 to 8, 4- to 7-flowered; bracts lanceolate to oblong-lanceolate, acuminate, 14–20 × 4–6 mm, ± 2 internodes long, lightly flecked all over and midline often uniformly orange-brown, especially in upper part, secondary veins 5 or 6 each

Distribution of ***Dierama tysonii***.

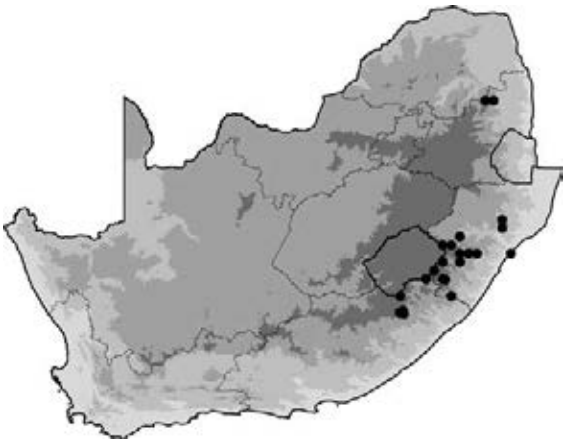
Distribution of ***Dierama nixonianum***.

side of main vein. *Flowers* funnel-shaped with tepals widely flaring, pale to bright magenta-pink; perianth tube 5–6 mm long; tepals 14–18 × 4.5–7.0 mm. *Anthers* 6.5–8.5 mm long. *Stigmas* held 5–9 mm below top of perianth. *Flowering time*: September to October.

Distribution and ecology: a narrow endemic of southern KwaZulu-Natal, South Africa, between Swartberg and Ngeli, possibly extending into Eastern Cape; in open grassland, from 1 370–1 650 m elevation.

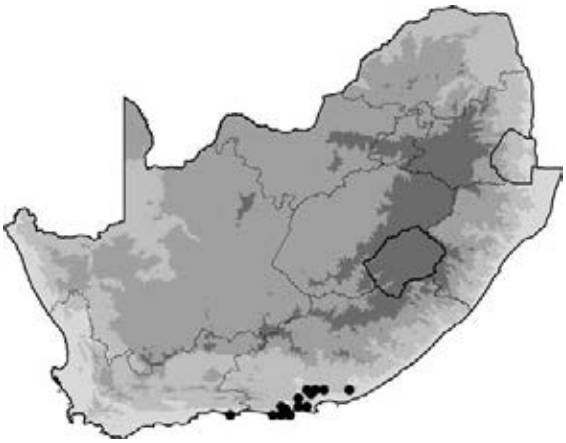
Diagnosis: a clump-forming species with erect spikes of pale to deep pink flowers with perianth 19–23 mm long, and translucent, lightly flecked bracts. *Dierama galpinii* from southern Mpumalanga and northern KwaZulu-Natal has similar spikes but longer stems 1.0–1.5 m tall in smaller tufts, and more flowers on the lateral spikes, mostly 6 to 13.

3. **Dierama nixonianum** *Hilliard* in Hilliard & Burtt, Dierama: 143 (1991). Type: South Africa, [KwaZulu-Natal], near Pietermaritzburg on Wartburg road, Bloemendal, *Nixon s.n.* (E, holo.).



Plants 100–750 mm high, solitary or up to 15 stems tufted together. *Corm* 10–17 mm diam. *Stem* with lowermost internode (when present) 25–100 mm long. *Foliage leaves* 3 or 4, borne on a separate shoot and often not fully developed at flowering, ± 150–330 × 0.75–2.50 mm; sheathing cauline leaves 3 or 4. *Spikes* ± pendulous or suberect, terminal 1- to 8-flowered, laterals lacking or up to 5, pendulous, each 1- to 5-flowered; bracts obovate to lanceolate, acute, 8–15 × 4–6 mm, up to ± 2 internodes long or shorter, lightly flecked orange-red at base and along midline or all over, midline often ± solidly brown, secondary veins 3 or 4 each side of main vein. *Flowers* bell-shaped with tepals suberect and flaring distally, pale mauve; perianth tube 6–8 mm long; tepals 11–13 × 4.0–5.5 mm. *Anthers* 4.5–6.0 mm long. *Stigmas* held 5–8 mm below top of perianth. *Flowering time*: late August to September.

Distribution and ecology: confined to northern and south-central KwaZulu-Natal, South Africa, from Utrecht to Wartburg; in grassland over sandstone, at ± 760–1 500 m elevation.



Diagnosis: a small, early-flowering species with foliage leaves produced on a separate shoot alongside the flowering stem and often not fully formed at flowering, rather closed flowers with tepals only twice as long as the perianth tube, and short bracts, 8–15 mm long. *Dierama trichorhizum* has a similar habit, with the current season's foliage leaves on a shoot alongside the flowering stem, but with a characteristic long internode between the corm and the lowest cauline leaf on the flowering stem, cormlets in the lowest leaf axil, and widely funnel-shaped flowers with spreading tepals three times as long as the perianth tube.

4. **Dierama trichorhizum** *(Baker) N.E.Br.* in Journal of the Royal Horticultural Society 54: 202 (1929). *Morphixia trichorhiza* Baker: 237 (1876). *Ixia trichorhiza* (Baker) Baker: 165 (1892). Type: South Africa, [KwaZulu-Natal], near Port Natal, *Sutherland s.n.* (K, holo.; TCD, iso.).

Plants 100–600 mm high, solitary or up to ± 3 tufted together. *Corm* ± 15 mm diam. *Stem* with basal internode 5–20 mm long, developing 1 or 2 cormlets in axil of lowest cauline leaf; lowermost peduncle (when present) 20–160 mm long. *Foliage leaves* up to 4, borne on a separate shoot and often not developed at flowering, ± 150–400 × 2.0–3.5 mm; sheathing cauline leaves 4 or 5. *Spikes* with terminal erect, 1- to 5-flowered, laterals lacking or up to 4, pendulous, each 1- to 3(5)-flowered; bracts ovate, 3-toothed with median tooth largest, 6–14 × 5–8 mm, ½ to 1½ internodes long, lightly to heavily flecked reddish brown, lateral veins 4 or 5 each side of main vein, delicate. *Flowers* funnel-shaped with tepals flaring widely, pale mauve or pink to light purple; perianth tube 4.5–5.0(–7.0) mm long; tepals 12–19 × 4–7 mm. *Anthers* 5–8 mm long. *Stigmas* held 7–12 mm below top of perianth. *Flowering time*: August to September.

Distribution of ***Dierama trichorhizum***.

Distribution of ***Dierama pendulum***.

Distribution and ecology: scattered along the eastern seaboard and interior of South Africa, from Mt Sheba in Mpumalanga through eastern Lesotho and the Drakensberg and Midlands of KwaZulu-Natal south to Umzimkhulu; often on moist or marshy grassy slopes but sometimes in drier stony areas.

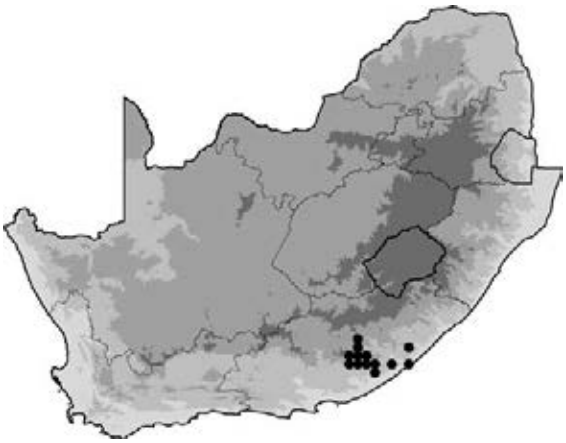
Diagnosis: a small, early-flowering species with foliage leaves produced on a separate shoot alongside the flowering stem and often not fully formed at flowering, and flowers with spreading tepals three times as long as the perianth tube. The small, 3-toothed bracts, 6–14 mm long, are also diagnostic. *Dierama trichorhizum* is unique in the genus in the well-developed basal internode between the corm and the lowest cauline leaf on the flowering stem, and in producing cormlets in the lowest leaf axil. *Dierama nixonianum* has a similar habit, producing the foliage leaves on a shoot alongside the flowering stem, but lacks the pronounced basal internode and axillary cormlets, and has rather more closed flowers with tepals only twice as long as the perianth tube.

5. **Dierama pendulum** *(L.f.) Baker* in Journal of the Linnean Society, Botany 16: 99 (1877). *Ixia pendula* L.f.: 91 (1782). *Watsonia palustris* Pers.: 43 (1805), illegitimate superfluous name for *I. pendula* L.f. *Sparaxis pendula* (L.f.) Ker Gawl.: t. 1482 (1812). Type: South Africa, [Eastern Cape], Humansdorp, Kromme River, *Thunberg s.n.* (LINN58.5, holo.).

   Gladiolus pendulus Mund ex Eckl.: 16 (1827). Type: South Africa, [Eastern Cape], George [District], ex hort. Cape Town, ?*Ecklon s.n.* [S, lecto., designated by Nordenstam: 292 (1972)].

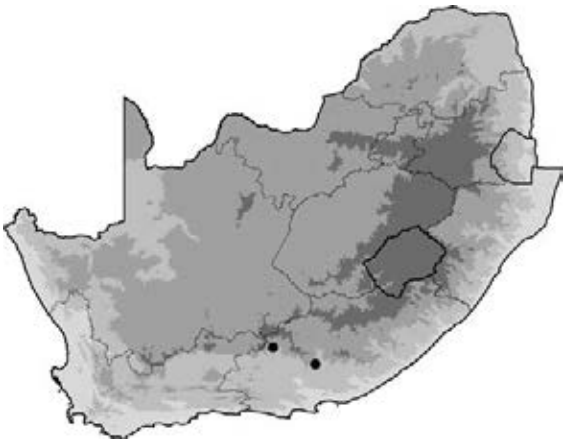
   Dierama ensifolium K.Koch & C.D.Bouché in Koch: 10 (1855). Type: South Africa, without precise locality or collector, ex hort. Berlin (type unknown, possibly B†).

Plants ± 1–2 m high, solitary or a few stems tufted in small clumps. *Corm* 25–45 mm diam. *Stem* with lowermost peduncle 40–120 mm long. *Foliage leaves* several to many, 600–900 × 6.0–8.5 mm; reduced sheathing leaves ± 5. *Spikes* pendulous, terminal densely 5- to 9-flowered, laterals 3 to 7, each 2- to 7-flowered; bracts oblanceolate to elliptic, acute to shortly acuminate, 18–30 × 8–13 mm, rarely up to 2 internodes long, flecked brownish all over but more lightly toward margins, appearing brown to eye, lateral veins 5(6) each side of main vein. *Flowers* funnel-shaped, purplish pink; perianth tube (8–)9–13 mm long; tepals (20–)22–32 × 8–12(–16) mm. *Anthers* 8–9(–10) mm long. *Stigmas* held mostly 10–20 mm below top of perianth. *Flowering time*: June to November.



Distribution and ecology: restricted to the southern coast from Knysna in Western Cape to the Zuurberg and Grahamstown in Eastern Cape, South Africa; in stony or marshy grassland and grassy fynbos.

Diagnosis: restricted to the southern coastal and near inland areas, and occurring as solitary stems or small clumps with stems ± 1–2 m tall, leaves 6.0–8.5 mm wide, and pendulous spikes held well above the leaves, bearing moderate-sized to large, purplish pink flowers with funnel-shaped perianth 28–48(–50) mm long. *Dierama igneum* from Grahamstown eastward has narrower bracts mostly 5–8 mm wide and a mostly shorter perianth, 16–34 mm long with the tube 5–8 mm long, and spikes nodding down to reach the tips of the leaves.



6. **Dierama pulcherrimum** *(Hook.f.) Baker* in Journal of the Linnean Society, Botany 16: 99 (1877). *Sparaxis pulcherrima* Hook.f.: t. 5555 (1866). Type: South Africa, [Eastern Cape], between the Keiskamma and Buffalo Rivers, ex hort. Backhouse, England, *Backhouse s.n.* (K, holo.).

   Dierama longiflorum G.J.Lewis: t. 541 (1934a). Type: South Africa, [Eastern Cape], Katberg, *Dyer s.n.* (BOL, holo.; PRE, iso. [fragment]).

Plants 0.9–1.8 m high, solitary or a few stems together in small tufts. *Corm* ± 30–40 mm diam. *Stem* with lowermost peduncle 45–135 mm long. *Foliage leaves* several

Distribution of ***Dierama pulcherrimum***.

Distribution of ***Dierama grandiflorum***.

to many, 500–900 × 4–9(–11) mm; reduced sheathing leaves 4 or 5. *Spikes* pendulous, terminal 4- to 8-flowered, laterals 4 to 7, each 2- to 5(6)-flowered; bracts elliptic-lanceolate to elliptic-obovate, acute, 23–34 × 10–12 mm, up to 2 internodes long, flecked brownish all over but more lightly toward margins, appearing brown, lateral veins ± 5 each side of main vein. *Flowers* ovoid, magenta-pink or deep purple-red; perianth tube mostly 10.0–14.0(–15.5) mm long; tepals 23–35(–39) × 10–19, suberect and cohering to weakly flared, not or scarcely spreading at the tips. *Anthers* (8–)10–11 mm long. *Stigmas* held 12–21 mm below top of perianth. *Flowering time*: mainly December to February.

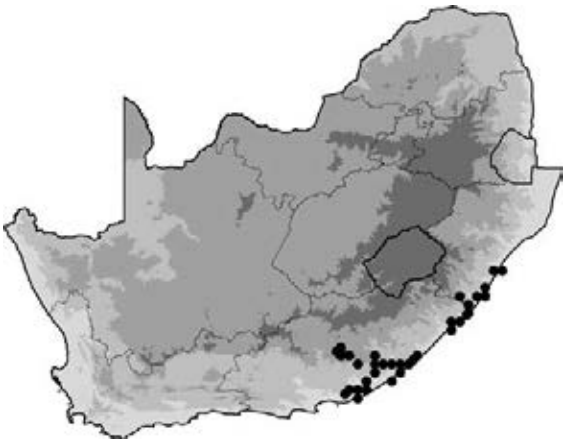
Distribution and ecology: endemic to the Eastern Cape, South Africa, from Baziya Mt near Engcobo to the Amatole Mtns; in open grassland, from ± 900–1 700 m elevation.

Diagnosis: occurring as solitary stems or small clumps with stems 900–1 800 mm tall, leaves 4–11 mm wide, and pendulous inflorescences of moderately large, magenta to purple flowers with a rather closed perianth 35–54 mm long. The species is easily recognised in the living state by the characteristic flowers, with suberect tepals from a conical base. *Dierama pendulum*, with widely spreading tepals from a rounded base, has a more southern distribution.

Forms with dark red flowers occur in areas of sympatry with dark-flowered *Dierama atrum* (Dohne, Stutterheim, Pirie and King William's Town) and *D. reynoldsii* (Baziya-Engcobo), suggesting possible hybridisation. Hybridisation with *D. igneum* in the Hogsback area is also a possibility.

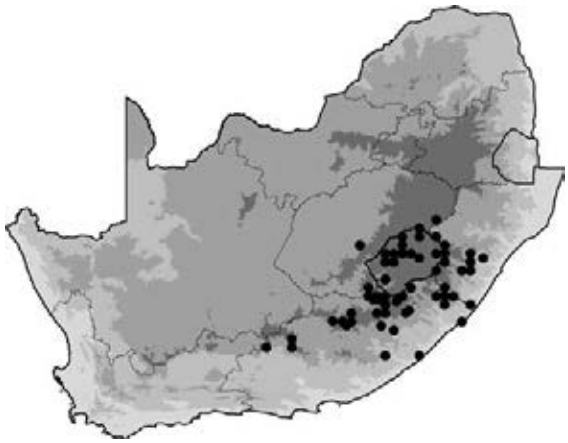
7. **Dierama grandiflorum** *G.J.Lewis* in Flowering Plants of South Africa 14: t. 542 (1934b). Type: South Africa, Eastern Cape, Somerset East, ex hort. Kirstenbosch, *Harries s.n.* Nat. Bot. Gard. 1881/29 (BOL, lecto., designated by Hilliard & Burtt: 80 (1991); PRE, isolecto.).

Plants ± 1 500 mm high, solitary or a few stems tufted together. *Corm* ± 25 mm diam. *Stem* with lowermost peduncle 55–110 mm long. *Foliage leaves* several, 600–900 × 4–8 mm; reduced sheathing leaves 3 or 4. *Spikes* pendulous, terminal 6- to 8-flowered, laterals (4)7 to 10, each 3- to 6-flowered; bracts elliptic, acute, 17–30 × 8–10 mm, less than two internodes long, flecked brownish all over but more lightly toward margins or sometimes whitish, lateral veins 5 each side of main vein. *Flowers* funnel-shaped, dark pink with purplish tube; perianth tube (8.5–)15.0–24.0 mm long; tepals (20–)33–46 × (8–)10–16 mm, ± conduplicate apically with tips recurved and twisted. *Anthers* 8.5–11.0 mm long. *Stigmas* held 11–24 mm below top of perianth. *Flowering time*: October to December.



Distribution and ecology: a narrow endemic extending from the Ouberg northwest of Graaff-Reinet and the Boschberg north of Somerset East, South Africa; on grassy slopes among rocks and in scrub, from 1 200–1 300 m elevation.

Diagnosis: restricted to the mountains near Graaff-Reinet and Somerset East and occurring as solitary stems or small clumps with stems ± 1 500 mm tall, leaves 4–8 mm wide, and pendulous inflorescences of large, dark pink flowers with funnel-shaped perianth (30–)50–70 mm long, the tips of the tepals characteristically folded together, recurved and twisted.



8. **Dierama igneum** *Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 388 (1882). Type: South Africa, [Eastern Cape], mtns between Kat and Klipplaat Rivers, *Drège 3491* (B†, holo.).

   Dierama pansum N.E.Br.: 201 (1929). Type: South Africa, without precise locality or collector, *Herbert s.n.* (CGE, holo.).

Plants 450–1 350 mm high, solitary or several stems together forming small tufts. *Corm* ± 15–30 mm diam. *Stem* with lowermost peduncle 45–180 mm long.

Distribution of ***Dierama igneum***.

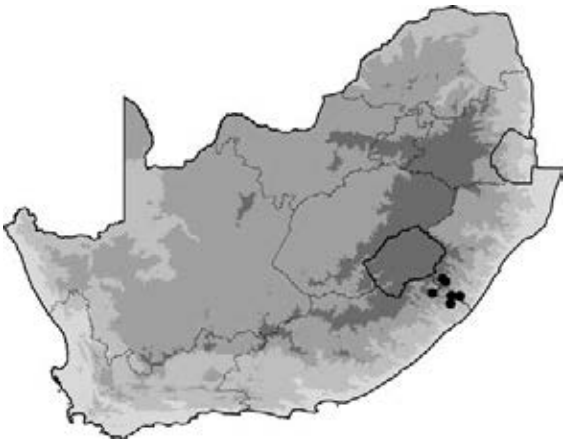
Distribution of ***Dierama robustum***.

Foliage leaves several to many, 300–900 × 2.5–6.0(–9.0) mm; reduced sheathing leaves 3 or 4. *Spikes* pendulous, terminal 4- to 11-flowered, laterals (1)4 to 8, each 2- to 10-flowered; bracts lanceolate to oblong-obovate, acute to acuminate, 10–25 × 5–8 mm, rarely up to 2 internodes long, usually lightly to heavily flecked all over or with white margins and shoulders, secondary veins 4 to 6 each side of main vein. *Flowers* funnel-shaped, pale to dark pink or rarely almost white; perianth tube 5–8(–9) mm long; tepals (10–)13–20(–25) × 5–11 mm. *Anthers* (5.0–)5.5–8.0 mm long. *Stigmas* held 2.5–15.0 mm below top of perianth. *Flowering time*: (June) September to December (April).

Distribution and ecology: extending through coastal KwaZulu-Natal from Durban south to East London and inland to the Katberg in Eastern Cape, South Africa; in open grassland, from near sea-level to 1 500 m elevation.

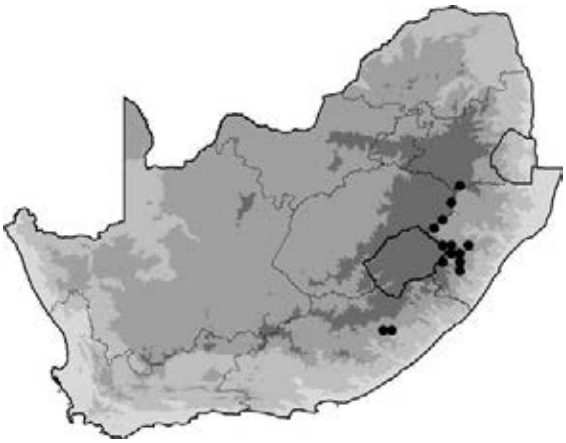
Diagnosis: a solitary or tufted species with stems 450–1 350 mm tall and pendulous spikes of moderately-sized pink flowers with perianth 16–31(–34) mm long and tube 5–8(–9) mm long. *Dierama pendulum* has broader bracts, 8–13 mm wide and generally larger flowers with perianth tube 9–13 mm long and longer anthers 8–9 mm long. The two species co-occur at Grahamstown. *Dierama igneum* is also sympatric with *D. pulcherrimum*, which is distinguished by its mostly larger, bell-shaped perianth 35–54 mm long, and the two species appear to hybridise in the Amatole Mtns.

9. **Dierama robustum** *N.E.Br.* in Journal of the Royal Horticultural Society 54: 201 (1929). Type: South Africa, without precise locality (as Drakensberg), *Cooper 3177* (K, holo.).



Plants (0.7–)1.0–2.0 m high, solitary or a few stems tufted together. *Corm* 25–40 mm diam. *Stem* with lowermost peduncle 45–150 mm long. *Foliage leaves* several, 400–1 200 × (3–)4–8(–10) mm; reduced sheathing leaves 4 or 5. *Spikes* pendulous, terminal (6)8- to 12-flowered, laterals 3 to 7, each (3)5- to 12-flowered; bracts obovate, acute to acuminate, (18–)20–35 × 8–14 mm, ± 2 internodes long, usually lightly to heavily flecked brownish or rarely white, lateral veins 5 each side of main vein. *Flowers* funnel-shaped, creamy white to pale pink or pale mauve; perianth tube (7–)8–12(–13) mm long; tepals (16–)18–26 × 7–10(–13) mm. *Anthers* (7–)8–10(–12) mm long. *Stigmas* held 3–12 mm below top of perianth. *Flowering time*: (October) December to January (March).

Distribution and ecology: South Africa, extending through the eastern interior, from Harrismith in the Free State along the Drakensberg through Lesotho, KwaZulu-Natal and Eastern Cape to the Stormberg, Zuurberg, Lootsberg and Koueveldberge near Murraysburg, possibly also the Camdeboo Mtns; in rocky grassland, from 1 600–2 900 m elevation.



Diagnosis: a solitary-stemmed or tufted species with pendulous spikes of moderately sized, creamy white to pale pink flowers, the perianth (24–)26–35 mm long with a tube (7–)8–12(–13) mm long. *Dierama latifolium* from lower elevations forms large clumps and usually has silvery white bracts. *Dierama cooperi* is distinguished by its closely veined bracts and mostly smaller, often bright pink flowers but probably hybridises with *D. robustum* in northern Lesotho and eastern Free State.

10. **Dierama ambiguum** *Hilliard* in Hilliard & Burtt in Notes from the Royal Botanic Garden, Edinburgh 45: 79 (1988). Type: South Africa, [KwaZulu-Natal], Zuurberg near Weza, ± 5 000 ft [1 670 m], *Hilliard & Burtt 8071* (E, holo.; K, NU, PRE, S, iso.).

Plants 900–1 200 mm high, of several stems forming a small clump. *Corm* ± 10–15 mm diam. *Stem* with lowermost peduncle 40–80 mm long. *Foliage leaves* few, 300–450 × 4.0–6.5 mm; reduced sheathing leaves 3 or 4. *Spikes* pendulous, terminal 7- to 11-flowered, laterals 2 to 6, each 5- to 9-flowered; bracts lanceolate to obovate, acute to acuminate, 15–22 × 6–8 mm, ± 2 internodes long, lightly to moderately flecked along midline and

Distribution of ***Dierama ambiguum***.

Distribution of ***Dierama dissimile***.

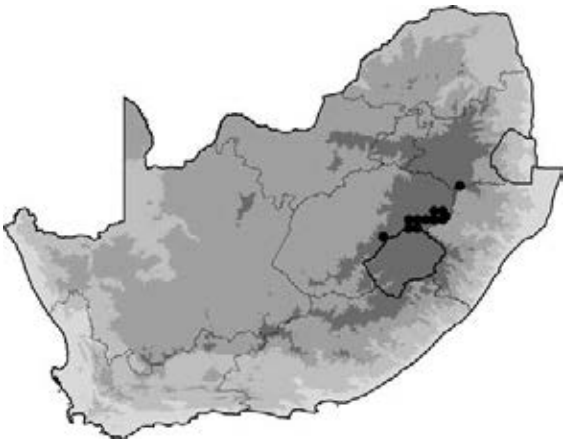
toward base with broad white shoulders and margins, lateral veins 6 to 9 each side of main vein with tertiary veins strongly developed, all veins coalescing to form an almost solid base. *Flowers* funnel-shaped, magenta-pink; perianth tube 6–10 mm long; tepals 11–16 × 4–6 mm. *Anthers* 4.5–6.0 mm long. *Stigmas* held 5–8 mm below top of perianth. *Flowering time*: mainly November to February.

Distribution and ecology: restricted to southern KwaZulu-Natal and adjacent Eastern Cape, South Africa, between Weza and Mt Ayliff; in open montane grassland, from 1 000–1 800 m elevation.

Diagnosis: a clump-forming species with pendulous spikes of magenta-pink flowers, characteristic bracts with 6 to 9 lateral veins each side of the main vein and with the intermediate veins strongly developed, the veins all coalescing toward the base into solid tissue. The primary spike has 7 to 11 flowers. *Dierama dracomontanum* has the veins well-spaced with thinner tissue between them, and mostly fewer flowers in the main spike, 4 to 7, with a shorter perianth tube 5–7 mm vs. 6–10 mm long. Occasional hybrids between the two species are known from the Zuurberg and Ngeli Mtns where they co-occur.

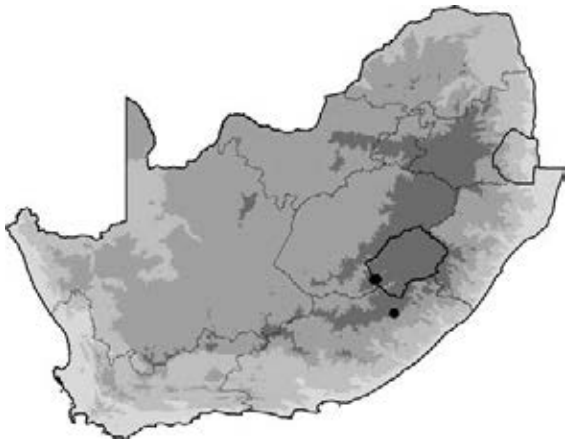
11. **Dierama dissimile** *Hilliard* in Hilliard & Burtt in Notes from the Royal Botanic Garden, Edinburgh 45: 79 (1988). Type: South Africa, [KwaZulu-Natal], Underberg, Cobham Forest Reserve, 5 700 ft [1 740 m], *Hilliard & Burtt 13388* (E, holo.; NU, iso.).

Plants 500–700 mm high, solitary or a few stems tufted together. *Corm* ± 15–20 mm diam. *Stem* with lowermost peduncle 50–100(–140) mm long. *Foliage leaves* few, 300–600 × (1.5–)2.0–3.5(–4.0) mm; reduced sheathing leaves 3 or 4. *Spikes* pendulous, terminal 5- to 8(9)-flowered, laterals 2 to 4(6), each 3- to 5(7)-flowered; bracts obovate-elliptic, acute-apiculate, 13–20 × 6–9 mm, up to ± 2 internodes long, lightly to moderately flecked throughout or with white margins, lateral veins 5 each side of main vein. *Flowers* bell-shaped, pale to dark pink or magenta-pink; perianth tube 5–7(–8) mm long; tepals (11–)13–15(–16) × (4–)5–6 mm. *Anthers* (5.0–)5.5–6.0(–7.0) mm long. *Stigmas* held 4–8 mm below top of perianth. *Flowering time*: mainly October to November.



Distribution and ecology: extending through the Drakensberg foothills from Majuba Mt in KwaZulu-Natal to the mountains between Tabankulu and Engcobo in Eastern Cape, South Africa; in grassland, from 1 500–2 200 m elevation.

Diagnosis: a solitary-stemmed or tufted species with pendulous spikes of relatively small, pale to deep pink flowers, the perianth 18–22 mm long with a tube 5–7(–8) mm long. *Dierama dracomontanum*, with which it is sympatric, has a clumped habit and slightly larger flowers with perianth 19–29 mm long, and flowers slightly later, mainly November to February.



12. **Dierama cooperi** *N.E.Br.* in Journal of the Royal Horticultural Society 54: 199 (1929). Type: South Africa, [Free State], top of the Witteberge, *Cooper 876* (K, holo.; BOL, E, iso.).

Plants 0.6–1.4(–2.0) m high, solitary or 2 or 3 stems tufted together. *Corm* ± 20 mm diam. *Stem* with lowermost peduncle 45–100 mm long. *Foliage leaves* several, 300–700 × 3–5 mm; reduced sheathing leaves 3 or 4. *Spikes* pendulous, terminal 8- to 13-flowered, laterals 3 to 7, each 5- to 10-flowered; bracts lanceolate to oblong-elliptic, acute to acuminate, 15–30 × 6–8 mm, usually ± 2 internodes long, lightly flecked throughout or with white margins, lateral veins ± 6 each side of main vein, with intermediate veins well developed, all veins very close together and parallel. *Flowers* funnel-shaped, pink; perianth tube 5.0–7.5 mm long; tepals 10.5–15.0 × 4.5–6.5 mm. *Anthers* 4.5–6.0(–7.0) mm long. *Stigmas* held 5–8 mm below top of perianth. *Flowering time*: October to February.

Distribution and ecology: centred in northeastern Free State extending into adjacent KwaZulu-Natal, South Africa, and around Leribe in Lesotho; in grassland.

Distribution of ***Dierama cooperi***.

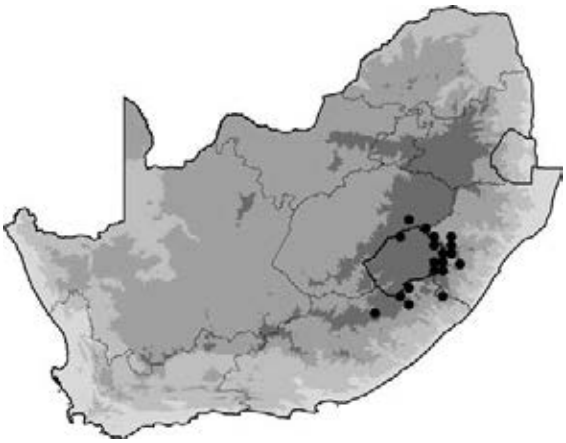
Distribution of ***Dierama jucundum***.

Diagnosis: a solitary-stemmed or tufted species with pendulous spikes of relatively small, often bright pink flowers, the perianth 16–23 mm long with a tube 5.0–7.5 mm long and characteristic bracts with ± 6 secondary veins each side of the main vein and well-developed intermediate veins, the veins all parallel and so close together that the base of the bract appears almost solid. The primary spike has 8 to 13 flowers. *Dierama robustum* has the bract veins further apart and mostly paler, slightly larger flowers, the tepals 17–26 × 7–12 mm and the tube 7–12 mm long. The two species probably hybridise in northern Lesotho and neighbouring Free State.

13. **Dierama jucundum** *Hilliard* in Hilliard & Burtt in Notes from the Royal Botanic Garden, Edinburgh 45: 81 (1988). Type: South Africa, [Eastern Cape], Barkly East, Fetcani Pass, ex hort. RBG Edinburgh, *Hilliard & Burtt 13140* (E, holo.; NU, iso.).

Plants 800–950 mm high, forming clumps. *Corm* ± 30 mm diam. *Stem* with lowermost peduncle 70–85 mm long. *Foliage leaves* several, 450–650 × 4.5–7.0 mm; reduced sheathing leaves ± 4. *Spikes* pendulous, terminal 6- to 10-flowered, laterals 3 to 5, each 4- to 6-flowered; bracts obovate, acute, 15–19 × 8–11 mm, < 2 internodes long, lightly to heavily flecked along midline with broad white shoulders, lateral veins 5 to 7 each side of main vein. *Flowers* widely funnel-shaped, pale mauve with nectar guides visible; perianth tube 6–9 mm long; tepals 18–23 × 8–12 mm. *Anthers* 6.0–8.5 mm long. *Stigmas* held 8–13 mm below top of perianth. *Flowering time*: October.

Distribution and ecology: a local endemic from Fetcani Pass near Barkly East in Eastern Cape, South Africa, and the Mohale's Hoek–Mafeteng area of southern Lesotho; on rocky slopes.



Diagnosis: a clump-forming species with pendulous spikes of moderately large, widely funnel-shaped, pale lilac flowers with perianth 25–28 mm long and broad tepals 8–12 mm wide. *Dierama dracomontanum* has slightly smaller, pink to almost red flowers with perianth 19–25 mm long and tepals 5–8 mm wide.

14. **Dierama dracomontanum** *Hilliard* in Hilliard & Burtt in Notes from the Royal Botanic Garden, Edinburgh 45: 79 (1988). Type: South Africa, [KwaZulu-Natal], Mpendhle, Highmoor Forest Reserve, ridge SE of Giant's Castle, 7 800 ft [2 380 m], 6 Jan. 1983, *Hilliard & Burtt 16269* (E, holo.; NU, iso.).

Plants 300–1 050 mm high, forming clumps. *Corm* 10–20 mm diam. *Stem* with lowermost peduncle 30–65(–100) mm long. *Foliage leaves* several, 300–650 × 3.5–6.5 mm; reduced sheathing leaves 3 or 4. *Spikes* pendulous (rarely suberect), terminal 4- to 7-flowered, laterals 2 to 5, each (1)2- to 6-flowered; bracts obovate, obtuse to acute, mostly 13–20 × 6–12 mm, up to 2 internodes long, lightly to heavily flecked along midline and toward base with broad white shoulders, lateral veins ± 5 each side of main vein. *Flowers* widely funnel-shaped, mostly pale to dark rose-pink or coral-pink to red, rarely mauve; perianth tube 5–7 mm long; tepals 13–20 × 5–8 mm. *Anthers* 5.0–6.5 mm long. *Stigmas* held 7–12 mm below top of perianth. *Flowering time*: November to February.

Distribution and ecology: confined to the Drakensberg from northeastern Free State through Lesotho and KwaZulu-Natal to Saalboom Neck near Clifford in Eastern Cape, South Africa; on grassy slopes, from 1 525–2 800 m elevation, sometimes dominating entire mountainsides.

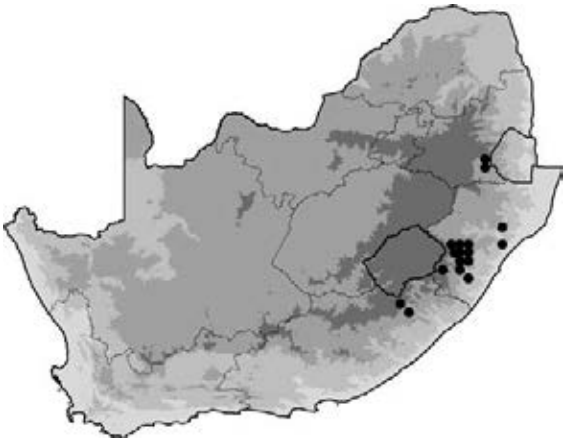
Diagnosis: a clump-forming species with pendulous (or rarely suberect) spikes of moderate-sized, mostly rose–coral-pink flowers with perianth 19–25(–29) mm long, the primary spike with 4 to 7 flowers. *Dierama dissimile* has the stems solitary or a few in small tufts, narrower leaves mostly 2.0–3.5 mm wide and smaller flowers with perianth 18–22 mm long, and flowers mainly August to October. *Dierama floriferum* has the clumped habit of

Distribution of ***Dierama dracomontanum***.

D. dracomontanum but mostly smaller flowers with perianth 15.5–20.5 mm long, and 4 to 9 lateral spikes per stem with 4 to 9 flowers each.

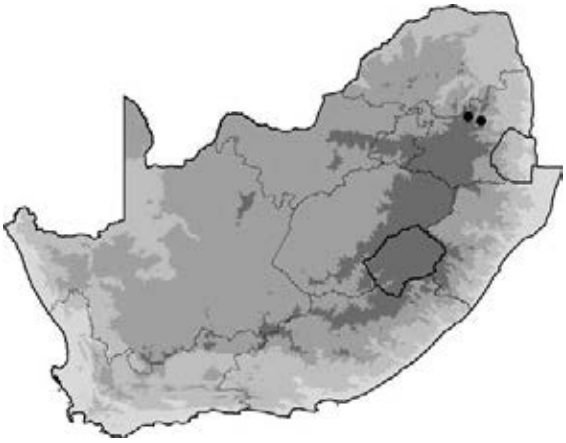
15. **Dierama floriferum** *Hilliard* in Hilliard & Burtt in Notes from the Royal Botanic Garden, Edinburgh 45: 80 (1988). Type: South Africa, [KwaZulu-Natal], Lions River, Curry's Post to Nottingham Road, 18 Nov. 1980, *Hilliard & Burtt 13482* (E, holo.; NU, iso.).

Plants 400–750 mm high, forming clumps. *Corm* 10–20 mm diam. *Stem* with lowermost peduncle 33–80(–120) mm long. *Foliage leaves* several, 380–700 × 2.5–5.0 mm; reduced sheathing leaves usually 4. *Spikes* pendulous, terminal 5- to 9-flowered, laterals (3)4 to 9, each (2)4- to 8-flowered; bracts obovate-lanceolate, acute to acuminate, 10–17 × 5–8 mm, ± 2 internodes long, usually flecked in lower ½ and along midline leaving broad white shoulders, sometimes flecked all over or without flecks, lateral veins mostly 4 to 6 each side of main vein. *Flowers* funnel-shaped, pale pink to purplish pink; perianth tube (4.0)5.0–6.5 mm long; tepals 10.0–14.5 × 4–6 mm. *Anthers* 4.5–6.0 mm long. *Stigmas* held 3.5–7.5 mm below top of perianth. *Flowering time*: August to November.



Distribution and ecology: extending from Piet Retief and Amsterdam in southern Mpumalanga through the KwaZulu-Natal Midlands to Ixopo and reaching to Ugie in Eastern Cape, South Africa; often in massed colonies in moist grassland, from 800–1 675 m elevation.

Diagnosis: a short, strongly clump-forming species with stems 400–750 mm high barely exceeding the leavers and spikes of relatively small, pale pink to purplish flowers with perianth 15.5–20.0 mm long. Flower colour varies within a single colony and there is also significant variation in the flecking of the bracts among populations, some with lightly flecked to almost pure white bracts. *Dierama dracomontanum* from mostly higher altitudes has larger flowers 19–29 mm long and generally fewer lateral spikes with fewer flowers in each, mostly 2 to 5.



16. **Dierama formosum** *Hilliard* in Hilliard & Burtt Notes from the Royal Botanic Garden, Edinburgh 45: 80 (1988). Type: Zimbabwe, summit, Inyangani Mt., ± 8 500 ft [2 590 m], *Plowes 2268* (K, holo.; PRE, iso.).

Plants 0.75–1.65 m high, forming large clumps. *Corm* 30–35 mm diam. *Stem* with lowermost peduncle 75–165 mm long. *Foliage leaves* several, 300–750 × (4–)6–10 mm; reduced sheathing leaves 5. *Spikes* pendulous, terminal 6- to 10-flowered, laterals 3 to 5 or more by compounding, each 3- to 9-flowered; bracts lanceolate to obovate, acute to acuminate, 20–25 × 6–10 mm, ± 2 internodes long, heavily or almost solidly reddish brown, rarely more lightly flecked, lateral veins 5 each side of main vein. *Flowers* funnel-shaped, pale lilac-pink to bright cerise-pink; perianth tube (6.5–)8.0–12.0 mm long; tepals (17–)19–26 × 6–11 mm. *Anthers* 7–9 mm long. *Stigmas* held 2.5–14.0 mm below top of perianth. *Flowering time*: November to January.

Distribution and ecology: extending through the eastern highlands, from near Dullstroom in Mpumalanga,

Distribution of ***Dierama floriferum***.

Distribution of ***Dierama formosum***.

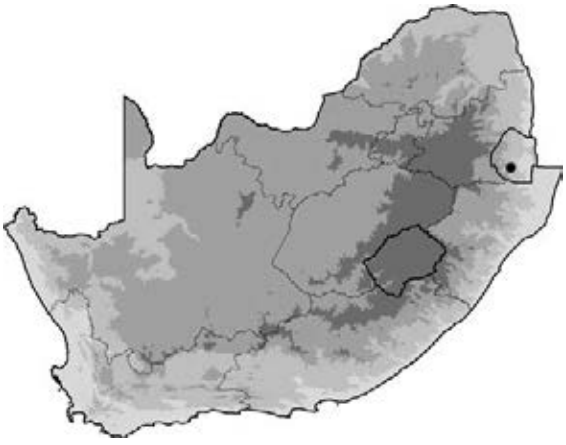
South Africa, and farther north on Gorongosa Mt in Mozambique, eastern Zimbabwe, and Mulanje and Zomba Mt. in Malawi; in high altitude grassland, from 1 900–2 000 m elevation.

Diagnosis: a clump-forming species with stems 750–1 650 mm tall, leaves mostly 6–10 mm wide, and large flowers with the perianth 26–37 mm long. The bracts are 20–25 mm long and usually heavily flecked reddish brown, with the veins often very closely set in the lower part. Other species from the Mpumalanga Escarpment are mostly solitary-stemmed or form small tufts, with shorter bracts and smaller flowers. *Dierama tyrium*, usually with darker purple flowers, typically has more flowers in the terminal spike and more numerous coflorescences, 8 to 11, narrower bracts 5–8 mm wide, and a shorter perianth tube 6–8 mm long.

17. **Dierama elatum** *N.E.Br.* in Journal of the Royal Horticultural Society 54: 199 (1929). Type: Swaziland [Eswatini], Hlatikulu, *Stewart 10* (K, holo.; SAM, iso.).

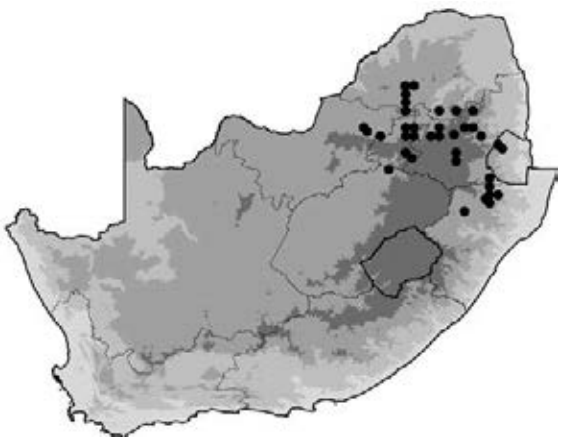
Plants ± 1.5 m high, probably solitary or in small tufts. *Corm* unknown. *Stem* with lowermost peduncle 70–110 mm long. *Foliage leaves* not seen, probably few; reduced sheathing leaves ± 5 mm wide. *Spikes* pendulous, terminal 6- to 9-flowered, laterals possibly 4, each 6- to 8-flowered; bracts elliptic-lanceolate, acute to acuminate, 18–20 × 9 mm, ± 2 internodes long, heavily or almost solidly dark brown in lower part and up midline with paler shoulders and margins, lateral veins 5 each side of main vein. *Flowers* bell-shaped with tepals suberect and flaring slightly apically, white; perianth tube 5.5–7.5 mm long; tepals 17–19 × 8–12 mm. *Anthers* 7–9 mm long. *Stigmas* held ± 8 mm below top of perianth. *Flowering time*: unknown.

Distribution and ecology: only known from the Hlatikulu area of Eswatini.



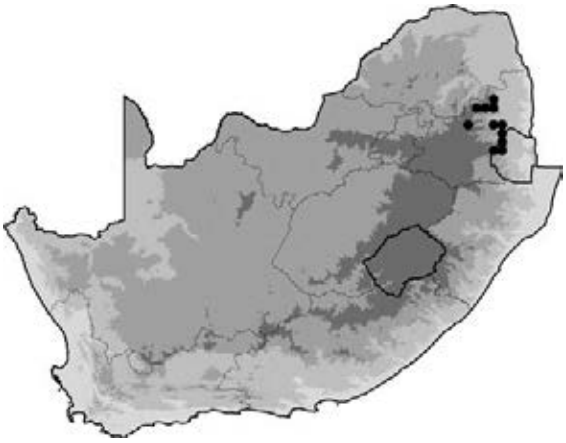
Diagnosis: an incompletely known species recognised on the basis of its moderate-sized, white flowers with perianth tube 5.5–7.5 mm long and tepals 17–19 mm long. Possibly allied to *Dierama formosum*.

18. **Dierama mossii** *(N.E.Br.) Hilliard* in Hilliard & Burtt, Notes from the Royal Botanic Garden, Edinburgh 45: 82 (1988). *D. medium* var. *mossii* N.E.Br.: 202 (1929). Type: South Africa, [Gauteng], Premier Mine, 13 Oct. 1917, *Moss 4313* (J, K, syn.).

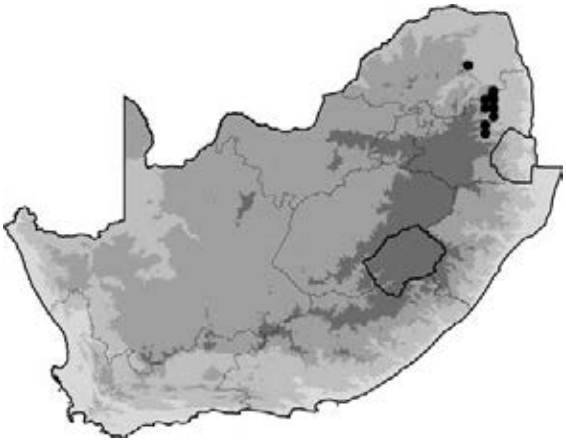


Plants 0.5–1.0 m high, with few to several stems in tufts. *Corm* ± 15–20 mm diam. *Stem* with lowermost peduncle 35–95(–160) mm long. *Foliage leaves* few, 300–650 × 1.5–3.5(–4.5) mm; reduced sheathing leaves 3 to 5. *Spikes* pendulous, terminal 3- to 6(9)-flowered, laterals 1 to 4(8), each 1- to 5(7)-flowered; bracts very delicate, oblong to lanceolate, acute to acuminate, 10–18 × 4–8 mm, < 2 internodes long, usually lightly or more heavily flecked along midline but sometimes pure white, lateral veins ± 5 each side of main vein, fading out in lower ½. *Flowers* funnel-shaped, mauve to magenta-pink; perianth tube 5–7 mm long; tepals 13–18(–20) × 4–6 mm. *Anthers* (5–)6–7(–8) mm long. *Stigmas* held 5–7(–12) mm below top of perianth. *Flowering time*: September to December.

Distribution and ecology: extending in an arc from the Waterberg in Northwest south to Heidelberg in Gauteng thence eastward to Ermelo in southern Mpumalanga, South Africa, Forbes Reef in adjacent Eswatini and to Paulpietersburg, Dannhauser and Dundee in northern KwaZulu-Natal, South Africa; forming large colonies in marshes and along streams.



Diagnosis: a tufted species with stems up to 1 000 mm tall and leaves 1.5–4.5 mm wide, and relatively lax spikes of mauve to magenta-pink flowers with perianth 18–25 mm long. The bracts are very delicate and usually speckled but sometimes pure white. *Dierama medium*, which is sympatric with *D. mossii* in southeastern Mpumalanga and Eswatini, has more crowded spikes of mostly smaller flowers, the perianth mostly 13–18 mm long with anthers 4.5–6.0 mm long.



Distribution of ***Dierama elatum***.

Distribution of ***Dierama mossii***.

Distribution of ***Dierama medium***.

Distribution of ***Dierama adelphicum***.

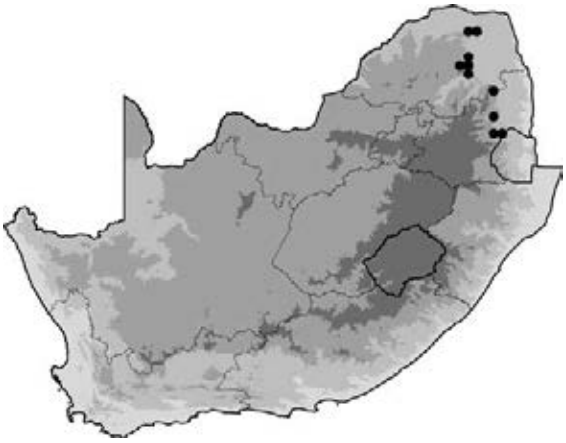
19. **Dierama medium** *N.E.Br.* in Journal of the Royal Horticultural Society 54: 201 (1929). Type: South Africa, [Mpumalanga], grassy slopes, without precise locality, *Mudd s.n.* (K, holo.).

Plants 300–750 mm high, solitary or a few stems in tufts. *Corm* ± 15–20 mm diam. *Stem* with lowermost peduncle 35–140 mm long. *Foliage leaves* few, 250–600 × 1.5–3.0(–4.0) mm; reduced sheathing leaves 3 to 5. *Spikes* pendulous, terminal densely (4)6- to 10-flowered, laterals 2 or 3(4), each 2- to 6(9)-flowered; bracts elliptic to lanceolate, acute to acuminate, (10–)14–16 × 4–6(–7) mm, 2 internodes long or longer, lightly to heavily flecked, then almost uniformly brown below with unmarked whitish margins, lateral veins ± 5 each side of main vein. *Flowers* funnel-shaped, pale mauve to magenta-pink; perianth tube 4.5–6.0 mm long; tepals (8–)10–15 × 4–6 mm. *Anthers* 4.5–6.0 mm long. *Stigmas* held 2.0–6.5 mm below top of perianth. *Flowering time*: mainly September to October.

Distribution and ecology: confined to the northeastern escarpment in Mpumalanga, South Africa, and adjacent Eswatini, from Graskop to Mbabane, but possibly extending into northern KwaZulu-Natal, South Africa, near Louwsberg; in seasonally wet or marshy grassland, from 1 350–1 980 m elevation.

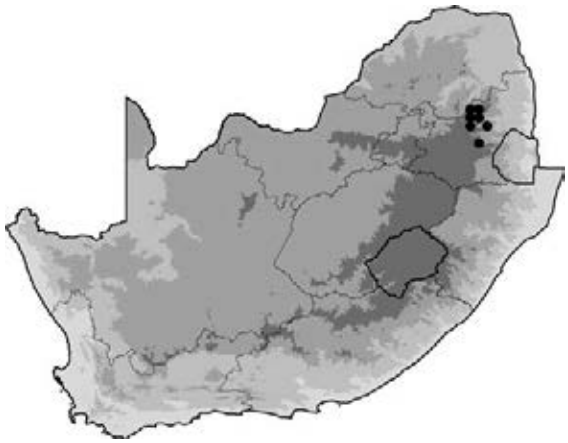
Diagnosis: a dainty species 300–750 mm tall with leaves 1–4 mm wide and short, dense spikes of small, mauve to magenta flowers, the perianth 13–18(–20) mm long. The short bracts, (10–)14–16 mm long, are lightly to densely flecked but always with whitish margins. *Dierama floriferum* differs in its clumped habit and more numerous coflorescences (mostly 4 to 9 vs. 2 or 3).

20. **Dierama adelphicum** *Hilliard* in Hilliard & Burtt in Notes from the Royal Botanic Garden, Edinburgh 45: 78 (1988). Type: South Africa, [Mpumalanga], MacMac Forest Station, 23 Oct. 1985, *Hilliard & Burtt 18440* (E, holo.; NU, iso.).



Plants 0.6–1.2 mm high, solitary or in small tufts. *Corm* ± 20–30 mm diam. *Stem* with lowermost peduncle 50–135(–175) mm long. *Foliage leaves* few, 350–600 × (2.5–)3.0–5.0 mm; reduced sheathing leaves 3 to 5. *Spikes* pendulous, terminal 8- to 11-flowered, laterals 5 to 7, each 5- to 9-flowered; bracts elliptic to lanceolate, acute, 10–18 × 4–6 mm, up to 2 internodes long, lightly flecked or more densely along midline and base, lateral veins ± 5 each side of main vein, fading out in lower part. *Flowers* funnel-shaped, pale mauve to magenta-pink; perianth tube (4–)5–6 mm long; tepals 11–16 × 4.5–6.5 mm. *Anthers* 5.0–6.5 mm long. *Stigmas* held 2–6 mm below top of perianth. *Flowering time*: September to early November.

Distribution and ecology: restricted to northeastern southern Africa, from Magoebaskloof in Limpopo to Ermelo in southern Mpumalanga and adjacent Eswatini; on open grassy slopes and flats.



Diagnosis: a solitary-stemmed or tufted species with stems up to 1.2 m high, leaves mostly 3–5 mm wide, and 8- to 10-flowered terminal spikes with 5 to 7 lateral spikes, and mauve to magenta flowers with perianth 15–21 mm long. *Dierama gracile* is a clump-forming species with generally shorter stems, 300–750 mm tall, with fewer lateral spikes, 1 to 5 per stem, and delicately veined bracts with just 3 or 4 lateral veins each side of the main vein.

21. **Dierama gracile** *N.E.Br.* in Journal of the Royal Horticultural Society 54: 202 (1929). Type: South Africa, [Limpopo], Woodbush Mtns, grassveld, *Moss 15438* (K, holo.; BOL, J, PRE, iso.).

Plants 300–750 mm high, clump-forming. *Corm* ± 20 mm diam. *Stem* with lowermost peduncle 35–95 mm long. *Foliage leaves* several, 250–600 × 2.5–5.0 mm; reduced sheathing leaves 3. *Spikes* pendulous, terminal 5- to 10-flowered, laterals 1 to 6, each 3- to 8-flowered; bracts broadly elliptic to lanceolate-elliptic, acute, 10–15 × 4–6 mm, ± 2 internodes long, lightly to heavily flecked all over or margins pale, delicately

Distribution of ***Dierama gracile***.

Distribution of ***Dierama nebrownii***.

veined with 3 or 4 lateral veins each side of main vein, extending < halfway up bract. *Flowers* funnel-shaped, pale to deep mauve or magenta-pink; perianth tube 4–6(–8) mm long; tepals 7–14 × 4–6(–8) mm. *Anthers* 4–6(–8) mm long. *Stigmas* held 3–6 mm below top of perianth. *Flowering time*: August to November.

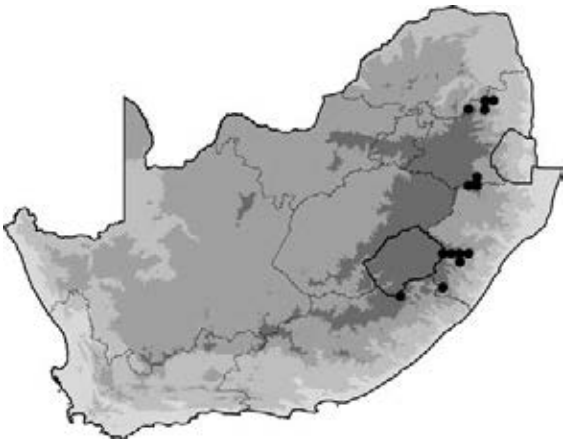
Distribution and ecology: endemic to the northeastern escarpment, from the Soutpansberg in Limpopo to Nelshoogte southwest of Barberton in Mpumalanga, South Africa; in open grassland, from 1 200 to 1 600 m elevation.

Diagnosis: a clump-forming species with relatively short stems 300–750 mm tall and short, delicately veined bracts with just 3 or 4 lateral veins each side of the main vein.

22. **Dierama nebrownii** *Hilliard* in Hilliard & Burtt in Notes from the Royal Botanic Garden, Edinburgh 45: 82 (1988). Type: South Africa, [Mpumalanga], 6 miles [10 km] NE of Dullstroom, 6 800 ft [1 790 m], 2 Nov. 1949, *Codd 5640* (PRE, holo.; K, iso.).

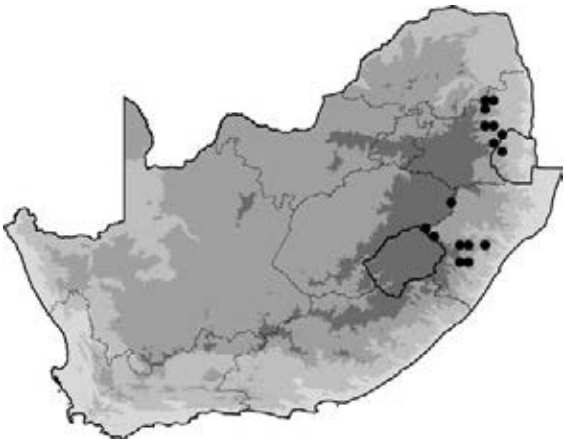
Plants 0.8–1.0 m high, solitary or a few stems tufted together. *Corm* 20–25 mm diam. *Stem* with lowermost peduncle 55–130 mm long. *Foliage leaves* few, 450–550 × 2.5–4.0 mm; reduced sheathing leaves 4 or 5. *Spikes* pendulous, terminal 6- to 11-flowered, laterals 2 to 5(7), each 4- to 9-flowered; bracts obovate, obtuse or cuspidate, 12–18 × 5–9 mm, mostly 2 internodes long, solidly to heavily flecked or paler on shoulders, lateral veins 6 to 8 each side of main vein. *Flowers* funnel-shaped, pale to deep mauve-pink; perianth tube 5.5–7.5 mm long; tepals 14–23 × 5.0–7.5 mm. *Anthers* 5.5–7.0(–8.0) mm long. *Stigmas* held (7–)8–12 mm below top of perianth. *Flowering time*: October to November.

Distribution and ecology: locally endemic to the high-lying parts of Mpumalanga, South Africa, recorded mainly between Belfast and Lydenburg, and also near Kaapsche Hoop; in stony grassland, from 1 750–2 000 m elevations.



Diagnosis: a solitary-stemmed or tufted species, 800–1 000 mm tall, with diagnostic obovate bracts, 12–18 × 5–9 mm, solidly to heavily flecked brown and with 6 to 8 lateral veins each side of the main vein. *Dierama pictum*, which flowers from November to February, has similar bracts with more sharply contrasting white shoulders, and slightly smaller flowers with a perianth 15–23 mm long (vs. 20–29 mm long).

23. **Dierama pauciflorum** *N.E.Br.* in Journal of the Royal Horticultural Society 54: 200 (1929). Type South Africa, [Free State], near Harrismith, 7 000 ft [2 134 m], Nov. 1944, *Sankey 290* (K, holo.).



Plants 300–600 mm high, usually forming dense clumps but sometimes solitary. *Corm* ± 15 mm diam. *Stem* with lowermost peduncle 25–45(–75) mm long. *Foliage leaves* several, 100–400 × 1–4 mm; reduced sheathing leaves ± 3. *Spikes* pendulous, terminal 1- to 4(5)-flowered, laterals up to 5, each 1- to 3(4)-flowered; bracts broadly obovate-elliptic to lanceolate-elliptic, 12–18 × 7–10 mm, usually 1.5 internodes long, bright rusty brown and flecked as well, lateral veins 6 to 8 each side of main vein. *Flowers* funnel-shaped with tepals flaring, bright pink or reddish; perianth tube 5–7 mm long; tepals 14–22 × 4.5–8.5 mm. *Anthers* 5–7 mm long. *Stigmas* held (6–)9–15 mm below top of perianth. *Flowering time*: mainly November to December.

Distribution and ecology: widespread along the eastern escarpment, from Naude's Nek in Eastern Cape, South Africa, along the KwaZulu-Natal Drakensberg and foothills to Harrismith and north to Mt Sheba in Mpumalanga, also in Inyanga in Zimbabwe; forming dense tussocks in marshes, from 1 500–2 400 m elevation.

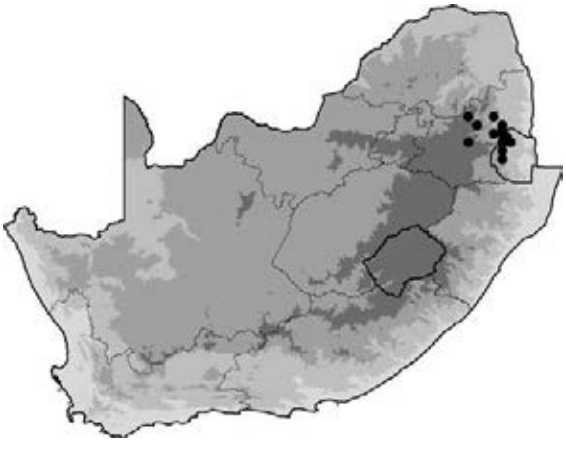
Diagnosis: a small, clump-forming species 300–600 mm tall, with narrow leaves 1–4 mm wide and delicate, few-flowered spikes of funnel-shaped, pink to reddish flowers with characteristic small, rusty red bracts 12–18 mm long, with 6 to 8 veins each side of the main vein. The perianth is 20–28 mm long, with narrow

Distribution of ***Dierama pauciflorum***.

Distribution of ***Dierama pictum***.

tepals 4.5–8.5 mm wide. *Dierama nebrownii*, also with brown bracts with 6 to 8 veins each side of the main vein, is a taller species with mostly solitary stems 800–1 000 mm tall.

24. **Dierama pictum** *N.E.Br.* in Journal of the Royal Horticultural Society 54: 198 (1929). Type: South Africa, [Mpumalanga], Pilgrims Rest, *Reynolds 14936* (K, holo.; PRE, iso.).



Plants 0.60–1.05 m high, solitary or up to 15 in small tufts. *Corm* ± 25 mm diam. *Stem* with lowermost peduncle 60–110(–125) mm long. *Foliage leaves* few, 550–750 × (3.0–)3.5–5.5(–7.0) mm; reduced sheathing leaves 4 or 5. *Spikes* pendulous, terminal (7)9- to 12(17)-flowered, laterals (1)3 to 6, each 5- to 11-flowered; bracts obovate or sometimes lanceolate, acute to acuminate, 14–23 × (5–)7–11 mm, usually > 2 internodes, heavily or almost solidly dark brown in lower part with broad white or lightly flecked shoulders, lateral veins 6 to 8 each side of main vein. *Flowers* bell-shaped with tepals suberect and flaring slightly apically, pale to deep mauve-pink, magenta or deep wine-red; perianth tube 5–8 mm long; tepals (9–)10–15 × (4–)5–7(–8) mm. *Anthers* 5.0–6.0(–7.5) mm long. *Stigmas* held 2.5–6.0 mm below top of perianth. *Flowering time*: November to January.

Distribution and ecology: relatively widespread along the eastern escarpment, from Pilgrim's Rest in Mpumalanga, South Africa, through western Eswatini and eastern Free State to Greytown in northern KwaZulu-Natal, South Africa; in rocky grassland, from ± 1 350–2 200 m elevation.

Diagnosis: occurring either as solitary plants or small tufts, the stems rarely more than 1 000 m tall, with relatively small, pale to magenta-pink or deep wine-red flowers, the perianth 15–23 mm long, with characteristic bracts, with dark brown base and sharply contrasting white shoulders, rather closely veined with 6 to 8 lateral veins each side of the main vein. The species may hybridise with *Dierama mobile* in Eswatini.

25. **Dierama mobile** *Hilliard* in Hilliard & Burtt in Notes from the Royal Botanic Garden, Edinburgh 45: 81 (1988). Type: South Africa, [Mpumalanga], Barberton, Fairview Mine, Russell's Beacon, *Mauve & Scheepers 1* (PRE, holo.; K, iso.).

Plants 0.75–1.5 m high, solitary or a few in small tufts. *Corm* ± 20 mm diam. *Stem* with lowermost peduncle (70–)90–230 mm long. *Foliage leaves* few, 450–750 × 2.5–3.5 mm; reduced sheathing leaves 4 or 5. *Spikes* pendulous, terminal 8- to 14-flowered, laterals 3 to 5, each 5- to 14-flowered; bracts obovate to elliptic-lanceolate, acute to acuminate, 14–19 × 6–10 mm, ± 2 internodes long, heavily flecked reddish brown toward base, thinning toward shoulders and paler or whitish, lateral veins 4 or 5 each side of main vein. *Flowers* bell-shaped with tepals suberect and flaring slightly apically, magenta-pink to deep wine-red; perianth tube 5–8 mm long; tepals 8–12(–14) × 4–5 mm. *Anthers* 5–6(–7) mm long. *Stigmas* held 2–7 mm below top of perianth. *Flowering time*: mainly August to November, to January in Eswatini.

Distribution of ***Dierama mobile***.

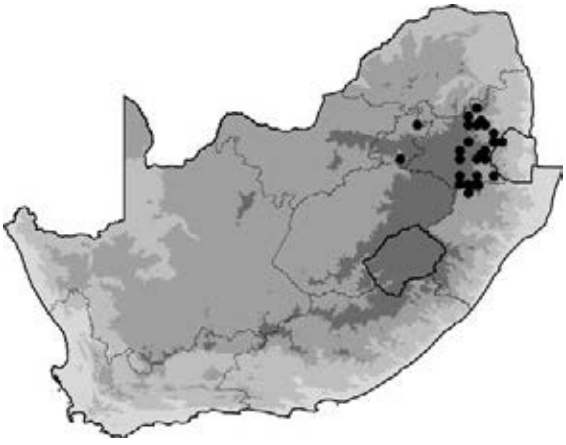
Distribution and ecology: restricted to the eastern escarpment, from Mt Sheba, Dullstroom and Carolina in Mpumalanga, South Africa, to Forbes Reef and Mbabane in Eswatini; in rocky grassland.

Diagnosis: endemic to Mpumalanga and Eswatini, occurring as solitary plants or small tufts up to 1 500 mm tall, with relatively small, magenta-pink to deep wine-red flowers, the perianth 16–20 mm long, and lateral spikes borne on strikingly long peduncles, usually 90–230 mm long. The bracts have 4 or 5 veins each side of the main vein. *Dierama pictum* has similar flowers but the plants are mostly shorter, usually barely up to 1 000 mm tall, with shorter peduncles 60–125 mm long, and dark brown bracts with sharply contrasting white shoulders and 6 to 8 veins each side of the main vein. The two species may hybridise in Eswatini (Hilliard & Burtt, 1991).

26. **Dierama insigne** *N.E.Br.* in Journal of the Royal Horticultural Society 54: 198 (1929). Type: South Africa, [Mpumalanga], Rayton, Jan. 1914, *Rogers 12931* (K, holo.; PRE, SRGH, iso.).

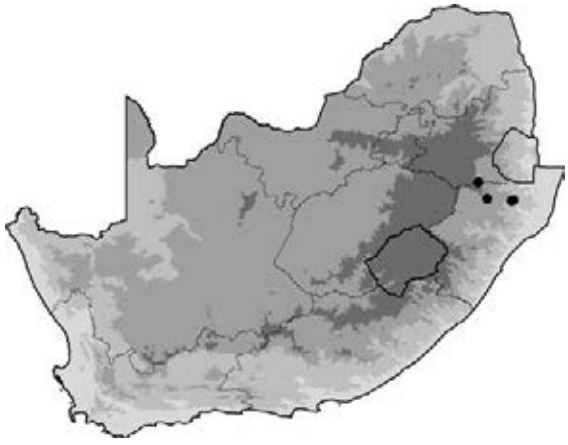
Dierama davyi N.E.Br.: 198 (1929). Type: South Africa, [Mpumalanga], Oshoek, *Burtt Davy 2719* (K, PRE, syn.).

Dierama rupestre N.E.Br.: 198 (1929). Type: South Africa, [Mpumalanga], Berlin, Godwan River, *Hofmeyer & Davison 82* (K, PRE, syn.).



Plants 0.65–1.5 m high, either solitary or in small tufts. *Corm* 20–30 mm diam. *Stem* with lowermost peduncle 35–120(–170) mm long. *Foliage leaves* several, 350–700 × 2.0–4.5(–6.0) mm; reduced sheathing leaves 3 or 4. *Spikes* pendulous, terminal densely (4)6- to 12-flowered, laterals 2 to 4(5), each 3- to 12-flowered; bracts elliptic-lanceolate, acuminate, (16–)20–30 × 6.5–10.0 mm, 2 or more internodes long, basal ⅓–⅔ herbaceous and green drying buff-coloured to brown, rest of bract scarious and almost pure white to sparsely to heavily flecked or almost entirely brown, veins many, coalescing below in solid patch. *Flowers* funnel–bell-shaped, pale pink to magenta-pink; perianth tube 7–16 mm long; tepals (12–)15–20 × (4.5–)6.0–11.0 mm. *Anthers* 5.5–7.5(–9.0) mm long. *Stigmas* held 1.0–8.5 mm below top of perianth. *Flowering time*: mainly October to November (February).

Distribution and ecology: restricted to the eastern escarpment, from Lydenburg in Mpumalanga westward to Pretoria and Johannesburg in Gauteng, South Africa, and southward through western Eswatini to Majuba and Groenvlei south of Wakkerstroom in northern KwaZulu-Natal, South Africa; in montane grassland, often among rocks.



Diagnosis: growing as solitary plants or in small tufts with stems mostly less than 1.5 m tall, leaves 2–6 mm wide, and pendulous spikes with partly or mostly solid bracts. The flowers are bell-shaped and pale to magenta-pink. *Dierama erectum* from Ngome, also with partly solid bracts, is a clump-forming species with taller stems 1.50–1.65 m tall, leaves 6–12 mm wide, and erect inflorescences with more numerous coflorescences, and subrotate flowers with conspicuous red and yellow markings at the base of the tepals.

27. **Dierama erectum** *Hilliard* in Hilliard & Burtt in Notes from the Royal Botanic Garden, Edinburgh 45: 80 (1988). Type: South Africa, [KwaZulu-Natal], Ngome, ± 3 500 ft [1 067 m], *Hilliard & Burtt 9901* (E, holo.; NU, iso.).

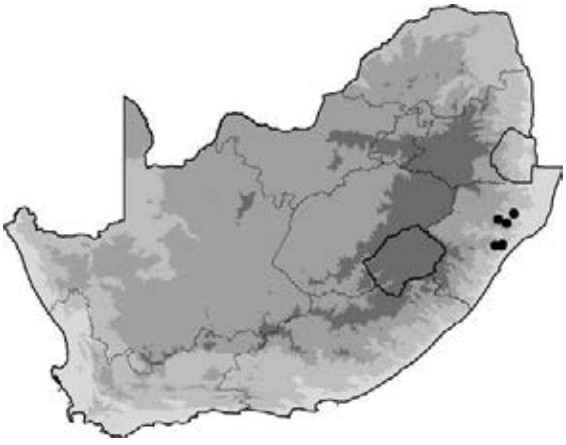
Plants 1.50–1.65 m high, forming clumps. *Corm* ± 30 mm diam. *Stem* with lowermost peduncle 45–90 mm long. *Foliage leaves* several, 800–900 × 6–12 mm; reduced sheathing leaves ± 5. *Spikes* erect, terminal densely 11- to 13-flowered, laterals ± 10, each 5- to 10-flowered; bracts lanceolate to elliptic, acuminate, 14–20 × 8 mm, 2 or more internodes long, basal ⅓–½ green drying brown, often flecked brownish, rest of bract membranous and whitish very sparsely flecked reddish brown or ochre-coloured with midline reddish brown to ochre-coloured, veins many, coalescing below in solid patch. *Flowers* subrotate, pale magenta-pink with conspicuous red and yellow diamonds at base of tepals; perianth tube (5–)7–8 mm long; tepals 18–19 × 7.0–8.5 mm.

Distribution of ***Dierama insigne***.

Distribution of ***Dierama erectum***.

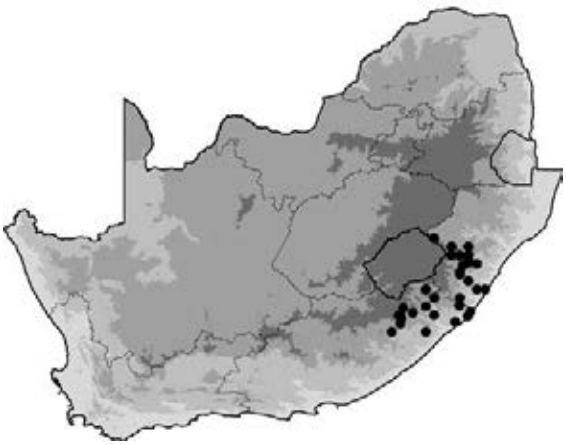
Anthers 6–7 mm long. *Stigmas* held 7–9 mm below top of perianth. *Flowering time*: January to April.

Distribution and ecology: restricted to northern KwaZulu-Natal, known only from Ngome east of Vryheid, South Africa; forming clumps in montane grassland, sometimes along streams.



Diagnosis: a clump-forming species with stems more than 1.5 m tall, leaves 6–12 mm wide, and erect spikes with partly solid bracts. The flowers are subrotate with a well-marked red and yellow eye at the base of each tepal. *Dierama insigne*, also with partly solid bracts, has the stems solitary or a few in small tufts, narrower leaves 2–6 mm wide, and pendulous spikes with fewer laterals, mostly 2 to 4.

28. **Dierama dubium** *N.E.Br.* in Journal of the Royal Horticultural Society 54: 202 (1929). Type: South Africa, [KwaZulu-Natal], without precise locality, *Buchanan s.n.* (K, holo.).



Plants 0.75–1.5 m high, solitary. *Corm* ± 15–30 mm diam. *Stem* with lowermost peduncle ± 80–180 mm long. *Foliage leaves* several, 400–850 × 3–5 mm; reduced sheathing leaves 4. *Spike* pendulous, densely 8- to 14-flowered, coflorescences 3 to 7(9), each 6- to 11-flowered; bracts obovate to lanceolate, acuminate, (13–)16–24 × 5–8 mm, longer than two internodes, white or lightly flecked all over, main veins 4 or 5 each side of midvein. *Flowers* bell-shaped with tepals suberect or flaring apically, dark purple-red; perianth tube (5.5–)6.0–7.0 mm long; tepals 8.0–11.5 × 3–5 mm. *Anthers* 5–6 mm long. *Stigmas* held at top of perianth or up to 4 mm below. *Flowering time*: August to January.

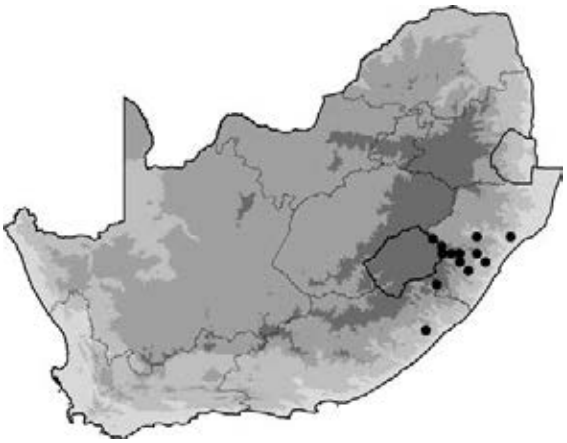
Distribution and ecology: a local endemic of the eastern midlands of northern KwaZulu-Natal, South Africa, from near Ulundi to Stanger, in grassland, from 1 200–1 500 m elevations.

Diagnosis: occurring as solitary stems with white or lightly flecked bracts, and remarkable for its very small, dark purple-red flowers often shorter than the bracts, the perianth 14–18 mm long.

Distribution of ***Dierama dubium***.

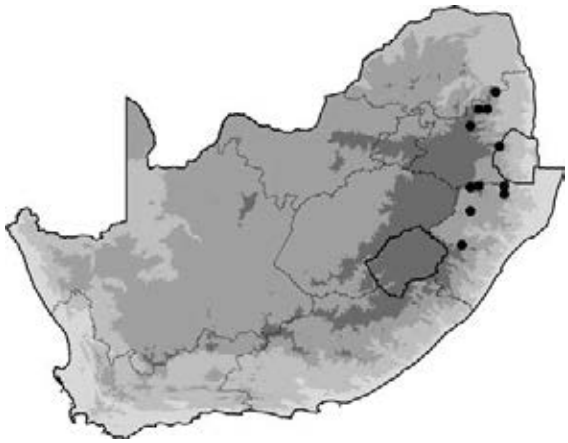
Distribution of ***Dierama reynoldsii***.

29. **Dierama reynoldsii** *I.Verd.* in Flowering Plants of South Africa 21: t. 836 (1941). Type: South Africa, [Eastern Cape], 5 miles [8 km] N of Engcobo, ex hort. Johannesburg, *Reynolds 3153* (PRE, holo.; BOL, SAM, iso.).



Plants 1–2 m high, solitary or 2 or 3 in small tufts. *Corm* ± 30 mm diam. *Stem* with lowermost peduncle 55–160 mm long. *Foliage leaves* few, 450–900 × (3–)4–6 mm; reduced sheathing leaves ± 5. *Spikes* pendulous, terminal 6- to 12-flowered, laterals 3 to 8, each 3- to 11-flowered; bracts obovate-elliptic to elliptic-lanceolate, acute to acuminate, 18–32 × 7–10 mm, ± 2 internodes long, white or very lightly flecked all over but appearing white, lateral veins ± 6 each side of main vein. *Flowers* funnel–bell-shaped, dark wine-red; perianth tube 6–12 mm long; tepals (10–)13–20 × (5–)6–9 mm. *Anthers* 7.0–10.5 mm long. *Stigmas* held at top of perianth or up to 5 mm below. *Flowering time*: mainly November to February.

Distribution and ecology: relatively widespread, from Muden in central KwaZulu-Natal south to Maclear in Eastern Cape, South Africa; in stony grassland, from ± 600–1 550 m elevation.



Diagnosis: occurring as solitary stems or up to three in small tufts, with pure white or lightly flecked bracts appearing silvery white, and dark wine-red flowers with perianth 17–30 mm long. *Dierama dubium* has much smaller flowers usually shorter than the bracts, the perianth 14–18 mm long. Purple-flowered forms of *D. latifolium* are distinguished by the markedly clumped habit and often broader leaves, 5–15 mm.

30. **Dierama latifolium** *N.E.Br.* in Journal of the Royal Horticultural Society 54: 199 (1929). Type: South Africa, [KwaZulu-Natal], Inanda, *Wood 1005* (K, holo.; NU, iso.).

?*Dierama palustre* N.E.Br.: 199 (1929). Type: Zimbabwe, Mashonaland, without precise locality, *Appleton 38* (K, holo.). [Locality probably incorrect and real source uncertain].

Distribution of ***Dierama latifolium***.

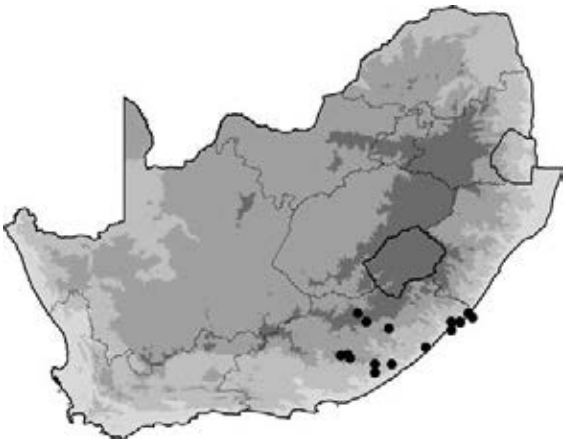
Distribution of ***Dierama tyrium***.

Plants 1.1–2.7 m high, forming large clumps. *Corm* 35–40 mm diam. *Stem* with lowermost peduncle 45–100(–140) mm long. *Foliage leaves* many, 550–1 500 × 5–15 mm; reduced sheathing leaves ± 5. *Spikes* pendulous or sometimes suberect, terminal 7- to 16-flowered, laterals 6 to 11 or more by compounding, each 5- to 16-flowered; bracts elliptic to elliptic-lanceolate, acute to acuminate, (13–)18–27 × 7–10 mm, ± 2 internodes long, white or very lightly flecked but appearing white, lateral veins 4 or 5 each side of main vein. *Flowers* funnel–bell-shaped, pale to deep pink or rarely dark wine-red; perianth tube (5–)8–10 mm long; tepals (12–)14–23 × (5–)6–10 mm. *Anthers* (7–)8–10 mm long. *Stigmas* held 2–10 mm below top of perianth. *Flowering time*: October to May.

Distribution and ecology: extending from central KwaZulu-Natal to Umtata in Eastern Cape, South Africa; in open grassland, from ± 600–2 100 m elevation.

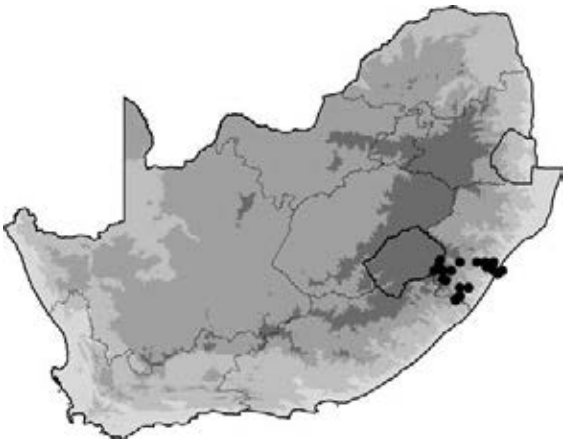
Diagnosis: characterised by the conspicuously clumped habit, typically broad leaves, 5–15 mm wide, and pink or rarely dark wine-red flowers with white or faintly speckled bracts. Dark-flowered plants are sympatric with *Dierama reynoldsii* but that species grows as solitary stems or in small tufts of up to three stems, with narrower leaves 3–6 mm wide.

31. **Dierama tyrium** *Hilliard* in Hilliard & Burtt in Notes from the Royal Botanic Garden, Edinburgh 45: 82 (1988). Type: South Africa, [KwaZulu-Natal], Louwsberg, Itala Nature Reserve, ± 1 300 m, *Hilliard & Burtt 17723* (E, holo.; NU, iso.).



Plants 1.2–2.1 m high, solitary or up to 20 in small tufts. *Corm* ± 30 mm diam. *Stem* with lowermost peduncle 45–120 mm long. *Foliage leaves* few, 450–1 350 × (4–)5–10 mm; reduced sheathing leaves 4 or 5. *Spikes* pendulous, terminal 8- to 18-flowered, laterals 5 to 11 or more by compounding, each (4)6- to 13-flowered; bracts elliptic-lanceolate, acuminate, 18–25(–40) × 5–8 mm, ± 2 internodes long, almost solidly coloured to lightly flecked red-brown at base and along midline, paler and more lightly flecked on shoulders, lateral veins 5 or 6 each side of main vein. *Flowers* funnel- or bell-shaped, rich magenta-pink to dark reddish magenta or deep purple; perianth tube 6–11 mm long; tepals 15–23 × 5–10 mm. *Anthers* 6.5–9.0 mm long. *Stigmas* held 2–9 mm below top of perianth. *Flowering time*: mainly December to March.

Distribution and ecology: South Africa, from Mariepskop in Mpumalanga to Estcourt in northern KwaZulu-Natal; in open, rocky grassland, often wedged in crevices, from ± 1 200–2 100 m elevation.



Diagnosis: occurring as solitary stems or small tufts, 1 200–2 100 mm tall, with moderately sized, dark magenta to purple flowers, perianth 22–31 mm long, and bracts partly or ± entirely flecked with reddish brown. *Dierama mobile* and *D. pictum*, also from Mpumalanga and KwaZulu-Natal have similar coloured but smaller flowers, with perianth 15–23 mm long. *Dierama atrum* from Eastern Cape is a shorter plant, 750–1 250 mm tall, with fewer, darker maroon flowers in the terminal spike, mostly 4 to 8, and slightly broader bracts, 8–11 mm wide.

32. **Dierama atrum** *N.E.Br.* in Journal of the Royal Horticultural Society 54: 198 (1929). Type: South Africa, [Eastern Cape], Lusikisiki, 10 Jan. 1928, *Blenkiron sub Moss 16033* (PRE, holo.; BOL, J, K, iso.).

Plants 0.75–1.25 m high, solitary or a few in small tufts. *Corm* ± 25–30 mm diam. *Stem* with lowermost peduncle (55–)90–130 mm long. *Foliage leaves* few, 300–750 × 3.0–6.5 mm; reduced sheathing leaves 4 or 5. *Spikes* pendulous, terminal 4- to 8(13)-flowered, laterals 1 to 5(6), each 2- to 7(10)-flowered; bracts elliptic-lanceolate, acute to acuminate, 17–26 × 8–11 mm, < or up to 2 internodes long, lightly to heavily flecked all over but more lightly on shoulders, appearing pale brown, lateral veins 5 or 6 each side of main vein. *Flowers* bell-shaped with tepals suberect and flaring slightly apically,

Distribution of ***Dierama atrum***.

Distribution of ***Dierama argyreum***.

dark maroon to purple-black, rarely paler; perianth tube 8–12 mm long; tepals 15–22 × 5–9 mm. *Anthers* 6–9 mm long. *Stigmas* held 1–5 mm below top of perianth. *Flowering time*: November to February.

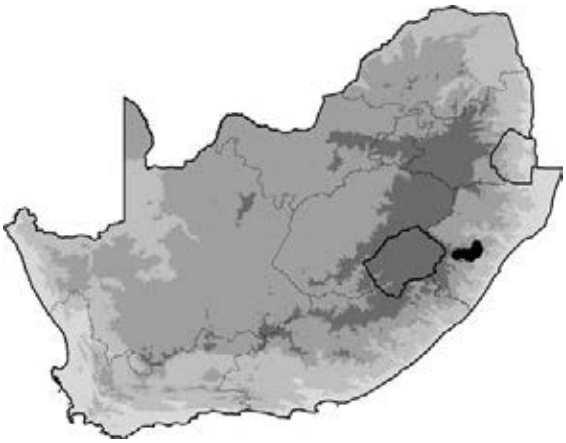
Distribution and ecology: restricted to Eastern Cape, South Africa, from the Great Winterberg and Stormberg to Lusikisiki; in open grassland, from ± 600–1 800 m elevation.

Diagnosis: endemic to Eastern Cape, occurring as solitary stems or small tufts, 750–1 250 mm tall, with moderately sized, dark maroon to purple-black (rarely light purple) flowers, the perianth 21–32 mm long, and bracts flecked all over and appearing pale brown to the eye.

33. **Dierama argyreum** *L.Bolus* in Annals of the Bolus Herbarium 4: 42 (1926). Type: South Africa, [KwaZulu-Natal], without precise locality, ex hort. Kirstenbosch, *Williams s.n.* (BOL, holo.).

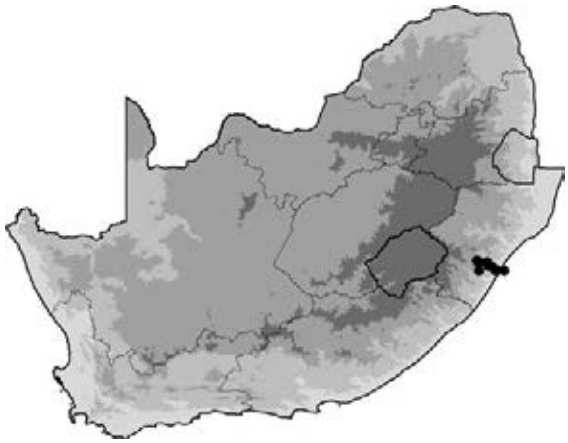
Dierama argyreum var. *majus* N.E.Br.: 202 (1929). Type: South Africa, [KwaZulu-Natal], Kranzkloof, *Rogers 24627* (K, holo.).

Plants (0.40–)0.65–1.35 m high, solitary or up to ± 5 in small tufts. *Corm* 25–30 mm diam. *Stem* with lowermost peduncle 45–110(–135) mm long. *Foliage leaves* few, (300–)500–750(–1 000) × (2.5–)3.5–6.5 mm; reduced sheathing leaves mostly 4 or 5. *Spikes* pendulous, terminal (4)6- to 11-flowered, laterals (2)3 to 7, each (3)4- to 9-flowered; bracts elliptic to oblong, acute to obtuse, 14–24 × 7–10 mm, < or up to 2 internodes long, membranous, pure white or rarely with a few flecks, lateral veins usually 6 or 7 each side of main vein. *Flowers* funnel- or bell-shaped, white or ivory-coloured, sometimes tinged pink at base or rarely wholly mauve-pink; perianth tube (4–)6–12 mm long; tepals (14–)16–20(–25) × (5.0–)6.5–10.0(–14.0) mm. *Anthers* 6–10 mm long. *Stigmas* held level with top of perianth or up to 10 mm below. *Flowering time*: mainly October to December.



Distribution and ecology: confined to southern KwaZulu-Natal and adjacent Eastern Cape, South Africa, from Umlaas Road south of Pietermaritzburg and Krantzkloof to Weza in the south; in grassland, from 400–1 700 m elevation.

Diagnosis: occurring as solitary stems or small tufts with rather blunt, pure white bracts, rarely with a few flecks, and bell-shaped, mostly white or ivory-coloured (rarely mauve-pink) flowers with a perianth 18–30(–35) mm long. Populations from lower elevations up to ± 900 m have smaller flowers, the perianth mostly 18–25 mm long with tube 4–6(–7) mm long, and those at higher elevations larger flowers, the perianth mostly 25–35 mm long with a longer tube ± 7–12 mm long. *Dierama pallidum* from between Pietermaritzburg and Durban, also with creamy white to pale yellow flowers sometimes tinged pinkish, has acuminate bracts and smaller, more closed flowers, 15–18 mm long.



34. **Dierama luteoalbidum** *I.Verd.* in Flowering Plants of South Africa 22: t. 845 (1942). Type: South Africa, [KwaZulu-Natal], Nottingham Road, 15 Nov. 1940, *Reynolds 3723* (PRE, holo.; BOL, NBG, iso.).

Plants 0.65–1.1 m high, solitary or 2 or 3 in small tufts. *Corm* 15–20 mm diam. *Stem* with lowermost peduncle 65–95 mm long. *Foliage leaves* few, 350–650 × 3–4 mm; reduced sheathing leaves 4 or 5. *Spikes* pendulous, terminal 3- to 6-flowered, laterals 1 to 3, each 1- to 5-flowered; bracts elliptic to obovate, acute, 24–32 × 12–16 mm, < or up to 2 internodes long, membranous, pure white or lightly flecked all over, veins 10 to 12 each side of main vein due to strongly developed intermediate veins. *Flowers* bell-shaped with tepals suberect or scarcely flaring apically, white to pale creamy yellow; perianth tube 10–13 mm long; tepals 20–35 × 9–18 mm. *Anthers* 8–11 mm long. *Stigmas* held (6–)12–19 mm below top of perianth. *Flowering time*: October to December.

Distribution and ecology: a local endemic of central KwaZulu-Natal, South Africa, around Nottingham Road

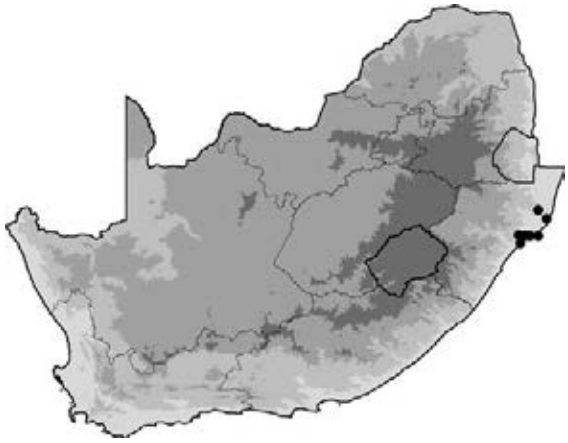
Distribution of ***Dierama luteoalbidum***.

Distribution of ***Dierama pallidum***.

and Dargle and in the Karkloof; in open grassland, from ± 1 100–1 700 m elevation.

Diagnosis: occurring as solitary stems or small tufts with large, translucent bracts, 24–32 mm long, and 3- to 6-flowered spikes of large, rather closed, white to creamy yellow flowers, the perianth 30–50 mm long with the anthers and style deeply included. *Dierama argyreum* has mostly 6- to 9-flowered spikes of smaller, widely flared flowers with perianth 18–30(–35) mm long.

35. **Dierama pallidum** *Hilliard* in Hilliard & Burtt, Dierama: 143 (1991). Type: South Africa, [KwaZulu-Natal], Inchanga Hill, ± 600 m, 5 Mar. 1971, *Hilliard & Burtt 6777* (E, holo.; NU, iso.).



Plants 0.50–1.05 m high, solitary or few in small tufts. *Corm* ± 20 mm diam. *Stem* with lowermost peduncle (70–)100–230 mm long. *Foliage leaves* few, 350–650 × 3.0–4.5 mm; reduced sheathing leaves ± 4. *Spikes* pendulous, terminal 7- to 12-flowered, laterals 2 to 5, each 4- to 9-flowered; bracts elliptic-lanceolate, acuminate, 15–25 × 6–9 mm, ± 2 internodes long, membranous, pure white or with a few flecks along main vein, lateral veins ± 5 each side of main vein. *Flowers* bell-shaped with tepals suberect or scarcely flaring apically, creamy white to pale yellow, rarely tinged pink or lilac; perianth tube (4.5–)5.0–6.0(–)7.0 mm long; tepals 9–12 × 4–5 mm. *Anthers* 5–6 mm long. *Stigmas* held 3–6 mm below top of perianth. *Flowering time*: October to March.

Distribution and ecology: a local endemic of south-central KwaZulu-Natal, South Africa, between Pietermaritzburg and Mt. Vernon near Durban; in stony and sandy grassland, from 300–900 m elevations.

Diagnosis: occurring as solitary stems or small tufts with acuminate, pure white bracts, and small, rather closed, creamy white to pale yellow (rarely tinged pink or mauve) flowers, the perianth 14–18 mm long. *Dierama sertum* from northern coastal KwaZulu-Natal has similar flowers but bracts well flecked in the lower part and along the midline. *Dierama argyreum*, also with white bracts, has larger, bell-shaped white or ivory-coloured flowers, and the perianth 18–35 mm long with flaring tepals.

36. **Dierama sertum** *Hilliard* in Hilliard & Burtt, Dierama: 143 (1991). Type: South Africa, [KwaZulu-Natal], Mtunzini, Farm Twinstreams, 16 Jan. 1956, *Hilliard & Burtt 19070* (E, holo.; NU, iso.).

Plants 0.70–1.25 m high, solitary or few in small tufts. *Corm* ± 15 mm diam. *Stem* with lowermost peduncle 45–110 mm long. *Foliage leaves* few, 550–850 × 3–5(–9) mm; reduced sheathing leaves ± 4. *Spikes* pendulous, terminal 6- to 12-flowered, laterals 2 to 5, sometimes compounded, each 4- to 10-flowered; bracts elliptic-lanceolate, acuminate, 15–18(–23) × 5–8 mm, < or up to 2 internodes long, membranous, pale reddish brown and well flecked in lower part and along midline, margins and shoulders white, lateral veins ± 5 each side of main vein. *Flowers* bell-shaped with tepals suberect or scarcely flaring apically, creamy white to pale yellow, rarely pale pink; perianth tube 6–8 mm long; tepals 9–12 ×

Distribution of ***Dierama sertum***.

4–6(–7) mm. *Anthers* 5–7 mm long. *Stigmas* held 3–4(–9) mm below top of perianth. *Flowering time*: probably mainly May to January.

Distribution and ecology: restricted to coastal and near-interior northern KwaZulu-Natal, South Africa, from Umhlatuzi to Stanger inland to the Noodsberg and Ngoye; in grassland between forest patches.

Diagnosis: occurring as solitary stems or small tufts with brown-flecked bracts, and small to moderately sized, rather closed, creamy white to pale yellow (rarely pale pink) flowers, the perianth 16–19(–25) mm long. *Dierama pallidum* from south-central KwaZulu-Natal between Pietermaritzburg and Durban has similar flowers but pure white bracts. *Dierama argyreum*, also with white bracts, has larger, bell-shaped white or ivory-coloured flowers, the perianth 18–35 mm long with flaring tepals.

37. **Dierama pumilum** *(Baker) N.E.Br.* in Journal of the Royal Horticultural Society 54: 199 (1929). *D. pendulum* var. *pumilum* Baker: 160 (1892). Type: South Africa, [KwaZulu-Natal], without precise locality, *Buchanan s.n.* (K, holo.).

Plants 0.65–1.35 m high, solitary. *Corm* ± 10 mm diam. *Stem* with lowermost peduncle 100–220 mm long. *Foliage leaves* 2 or 3, 300–750 × 1.0–2.5 mm; reduced sheathing leaves 2 or 3. *Spikes* pendulous, terminal densely 5- to 13-flowered, laterals 1 to 5, each 4- to 11-flowered; bracts obovate-elliptic, acute, 13–24 × 8–9 mm, 2 internodes long or longer, solidly coloured or heavily flecked dark reddish brown, paler toward margins, lateral veins ± 7 each side of main vein. *Flowers* bell-shaped with tepals suberect or scarcely flaring apically, pale creamy yellow; perianth tube 6.5–8.0 mm long; tepals 9–11 × 4–6 mm. *Anthers* 5–6 mm long. *Stigmas* held 4.0–6.5 mm below top of perianth. *Flowering time*: December to February.

Distribution of ***Dierama pumilum***.

Distribution and ecology: a local endemic of northern KwaZulu-Natal, South Africa, known with certainty from the Noodsberg and the Mlabathini–Melmoth–Nkandla areas; in rocky grassland.

Diagnosis: occurring as solitary stems, with very narrow, almost needle-like leaves, 1.0–2.5 mm wide, solid brown or heavily flecked bracts, and small, pale creamy yellow, rather closed flowers, the perianth 13–19 mm long.

Revisionary accounts: De Vos: 105–163 (1982); De Vos: 347–422 (1983); De Vos: 89–127 (1999).

From the Latin, *triton,* a weathervane, for the variable orientation of the stamens in some species.

Deciduous geophytes, with pale membranous cataphylls. *Corm* globose to obconic, axial in origin, tunics of finely to coarsely netted fibres. *Stem* mostly well developed, sometimes contracted, ± subterranean in 1 species. *Leaves* several, mostly basal, forming a 2-ranked fan, blade usually plane, linear to falcate with a definite main vein, rarely round to elliptic in section, occasionally margins undulate to crisped, inrolled, or winged, blades thus H-shaped in section, cauline leaves few and reduced; margin usually without vascular bundle and epidermal cells columnar and thickened, rarely with marginal bundle and epidermal cells unspecialised. *Inflorescence* a spike, rarely flowers solitary and terminal on axes, often secund; bracts relatively small, green and firm, or membranous to dry, outer usually 3-toothed, inner smaller than outer and 2-toothed or notched apically. *Flowers* usually zygomorphic, rarely radially symmetric, long-lived, bilabiate to salver-shaped or rotate, often orange to yellow, or red, pink, cream-coloured or white, often with darker veins, lower tepals often bearing bright yellow median tooth (callus) or raised ridge, occasionally sweetly scented, with nectar from septal nectaries; perianth tube funnel-shaped or cylindric, short or long; tepals subequal or unequal with dorsal largest and lower 3 forming a lip. *Stamens* unilateral, arcuate or diverging, rarely symmetrically disposed and erect; filaments included or exserted. *Ovary* globose; style filiform, unilateral or central, 3-branched distally, branches slender, curved, rarely shorter and expanded apically. *Capsules* cartilaginous, globose to ellipsoid. *Seeds* globose, flattened at chalazal end, smooth or rarely rugose, shiny, surface cells obscured by thick cuticle, ovular vascular trace excluded. *Pollen* monosulcate-operculate, operculum 2-banded, exine perforate-scabrate. *Basic chromosome number x* = 11.

Species 30, mainly southern Africa, also tropical Africa, centred in the winter-rainfall zone, with just 2 species occurring north of South Africa: *Tritonia moggii* Oberm. so far known from southern Mozambique is included in this account for completeness; *T. laxifolia* has an unusual disjunct distribution in southeastern South Africa and Malawi, Tanzania and Zimbabwe.

Originally limited to a small group of species with relatively large, short-tubed flowers with radially symmetric perianth, *Tritonia* now also includes species with short- to long-tubed, zygomorphic flowers. It forms part of a small clade of genera including *Dierama*, *Duthiastrum, Ixia* and *Sparaxis* defined by netted corm tunics, mostly radially symmetric flowers, more-or-less dry and papery or membranous bracts, and specialised, subglobose seeds with a smooth, glossy testa and a raphal vascular bundle excluded from the seed body during ripening (Goldblatt et al. 2006). *Tritonia* is immediately related to *Dierama* and *Ixia*, the latter also often with 3-toothed bracts. *Tritonia* is separated from these two genera by its more sturdy and firm (not wiry) stem, leaves usually with specialised margins lacking a vascular bundle and having instead columnar epidermal cells with thickened walls, and possibly ancestrally zygomorphic flowers, often with the main vein on some or all lower tepals thickened or raised in a fleshy or bony callus or tooth. Similar teeth are developed elsewhere only in some species of *Lapeirousia* and *Afrosolen* (tribe Watsonieae). In several species the perianth is thin-textured with prominent, dark veins. Most species have a basic chromosome number of *x* = 11 (exceptionally *x* = 10).

Four species are anomalous in the genus in their leaf anatomy, possessing a marginal vascular trace with associated sclerenchyma cap and lacking the specialised, thickened epidermal cells that are characteristic of the other species of *Tritonia* (see De Vos, 1982). These are the two Richtersveld endemics, *T. delpierrei* and *T. marlothii*, with narrow, leathery or subsucculent leaves, and two that have narrow, essentially centric leaves, *T. bakeri*, with stiffly linear, compressed elliptical or subterete leaves; and *T. kamisbergensis* with wiry, terete and fibrous leaves.

Pollination in the genus has been little studied, but the diversity of flower types in *Tritonia* signals a

corresponding range of pollination systems. The ancestral system, as found in the species with colourful, funnel-shaped flowers, appears to be pollination by long-tongued anthophorine bees, which visit flowers to forage for nectar. This system occurs almost throughout the range of the genus but is overshadowed by two derived pollination systems in the southern African winter-rainfall zone. Here, species with pale, long-tubed flowers are adapted for pollination by long-proboscid horseflies (Tabanidae) and tangle-winged flies (Nemestrinidae), and species with a short-tubed, radially symmetric perianth, mostly with transparent patches or large dark markings, are adapted for pollination by hopliine scarab beetles.

Relationships among the species have not been tested using molecular sequences. We assume that the genus is ancestrally zygomorphic by analogy with other genera of Crocoideae, containing species with both actinomorphic and zygomorphic flowers. In light of its close relationship with *Dierama* and *Ixia*, both of which have ancestrally radially symmetrical flowers, this assumption remains to be confirmed.

De Vos (1982, 1983) initially grouped the species into five sections, referring the majority to sect. *Montbretia*, defined by zygomorphic flowers with one or all of the lower tepals bearing a well-developed, tooth- or axe-like crest or callus on the midline near the base. Previously segregated at generic rank, this section is widely distributed from southern to south tropical Africa, and comprises three distinct groups of species identified by De Vos as possible subsections. The largest included nine species with orange to yellow or pink to red, strongly bilabiate flowers with large, axe-like calluses on the lower tepals. A second group included two species from the Richtersveld with subsucculent leaves without thickened marginal epidermis and pale, salver-shaped flowers, *T. delpierrei* and *T. marlothii*. The remaining two species, *T. florentiae* and *T. karooica* from the western central karroid zones of South Africa, were considered taxonomically distantly related by De Vos, but both share similar long, crest-like calluses on the lower tepals and unusually large capsules.

Sect. *Tritonia* included four species with short-tubed, bowl-shaped, orange or pink flowers with a radially symmetrical perianth lacking well-developed calluses on the lower tepals, and with central or loosely unilateral stamens. One of the species included here, *T. dubia*, is almost certainly misplaced, differing from the other species in its ± rotate flowers with erect, symmetrically disposed stamens inserted near the top of the perianth tube, and larger, ellipsoid capsules. Similar capsules are found in *T. laxifolia* and *T. moggii* (sect. *Montbretia*), suggesting an alliance with those species. All members of sect. *Tritonia* are local endemics of southwestern South Africa.

The remaining species in the genus have zygomorphic flowers, usually without tepal calluses. The monotypic sect. *Teretifoliae* included just *Tritonia kamisbergensis* from Namaqualand, distinguished by its fibrous, subterete leaves, small, subherbaceous bracts and red flowers. Sect. *Pectinatae* included four species with a dense, almost horizontal spike of pale pink to cream-coloured or white flowers with an elongate perianth tube. Three are fynbos endemics with uniquely modified leaves that develop longitudinal, flange-like outgrowths from the adaxial surface and margins. The fourth, *T. tugwelliae* from the western Great Karoo, has conventional plane leaves and small, uniformly pale bracts without dark upper margins and is thus evidently misplaced here. The residue of the species were accommodated in sect. *Subcallosae*, which was poorly and essentially negatively diagnosed as lacking the distinctive features of the other sections. The distinction between sect. *Subcallosae* and sect. *Montbretia* is, however, blurred by *T. pallida*, which sometimes has large, axe-like calluses on the lower tepals, and the two sections were combined by De Vos (1999). The species in sect. *Subcallosae* fall into two distinct groups based on flower shape: one with pale, long-tubed flowers restricted to the winter-rainfall region of South Africa, and a second with yellow or orange to red, funnel-shaped flowers, mainly from the eastern seaboard and near-interior. The long-tubed *T. bakeri* is anomalous in the section in its centric, terete or compressed leaves without true margins and its association with the other long-tubed species in the group may be mistaken.

Morphological evidence suggests that at least some of the species are currently misplaced in the existing sections but additional phylogenetic data are required to resolve relationships in the genus. Provisionally, we have rearranged some of the existing sections by removing anomalous taxa and have split others into smaller, morphologically homogeneous sections. This arrangement serves to isolate the species clusters that we have been able to identify.

Key to species

1a Perianth actinomorphic, ± rotate with spreading tepals longer than tube; stamens either erect and central or weakly unilateral and diverging:
2a Flowering spike erect; flowers perfectly actinomorphic with stamens erect and inserted near top of tube; perianth tube only slightly shorter than tepals; capsules elliptic, longer than bracts. . . . . 14. *T. dubia*
2b Flowering spike inclined; flowers slightly zygomorphic with the stamens arcuate and slightly spreading, inserted in lower half of tube; perianth tube half as long as tepals or less; capsules subglobose, shorter than bracts [sect. *Tritonia*]:
3a Tepal claws without wide hyaline margins; tepals unmarked or outer tepals with dark blotch at base of limb; perianth tube yellow with prominent star-shaped yellow patch outlined with red in throat . . . . . 15. *T. deusta*

3b Tepal claws with wide hyaline margins; tepals unmarked; perianth tube with hardly any yellow colouring in throat:
4a Perianth bright orange-red to vermilion . . . . . 16. *T. crocata*
4b Perianth pale to bright mauve-pink. . . . . 17. *T. squalida*
1b Perianth more-or-less zygomorphic, usually with posterior tepal larger, rarely subactinomorphic but then tepals much shorter than tube; stamens arcuate and unilateral with anthers ± contiguous:
5a Spike strongly deflexed and almost horizontal, ± pectinate-secund, closely flowered; flowers long-tubed, white to pink with red streaks on lower tepals; leaves with margins crisped-undulate or inrolled or winged:
6a Leaves distichous, falcate, margins crisped or undulate; bracts 3–8 mm long, pale without conspicuous dark upper margins; tepals 7–9 × 2–4 mm long [sect. *Pseudopectinatae*]: . . . . . 23. T. *tugwelliae*
6b Leaves not clearly distichous, more-or-less narrowed below and pseudopetiolate, margins inrolled and straight or undulate crisped; bracts 5–15 mm long, with conspicuous dark reddish brown, crisped upper margins; tepals 12–25 × 3–13 mm [sect. *Pectinatae*]:
7a Flowers almost salver-shaped, lower tepals with two short red lines near base; perianth tube straight, (17–)20–25 mm long; leaves often narrowed between base and sheath into slender petiolar portion, blade linear-lanceolate with margins in rolled; plants from Piketberg . . . . . 25. *T. lancea*
7b Flowers bilabiate, lower tepals with lozenge-shaped red markings; perianth tube slightly curved, (20–)40–60(–85) mm long; leaves otherwise; plants not from Piketberg:
8a Leaf blade weakly involute with crisped or undulate margins. . . . . 26. *T. undulata*
8b Leaf blade X- or H-shaped with straight margins . . . . . 24. *T. cooperi*
5b Spike suberect and not as above; leaves plane or subterete but margins not variously elaborated:
9a Leaves wiry, centric and terete or compressed-cylindric in section, striate with several translucent veins, 1–3 mm diam.:
10a Flowers obliquely funnel-shaped, ruby-red; stamens inserted in lower half of tube; bracts ± green and leathery with membranous margins; plants from Namaqualand [sect. *Teretifoliae*]. . . . . 30. *T. kamisbergensis*
10b Flowers salver-shaped with long, slender tube; stamens inserted near mouth of tube; bracts papery or membranous throughout; plants from Little Karoo [sect. *Subteretifoliae*]. . . . . 27. *T. bakeri*
9b Leaves plane and linear to lanceolate or falcate, with evident midrib:
11a Flowers ± salver-shaped with subcylindric perianth tube widening slightly in upper ½ to ± 2 mm diam. at mouth; bracts green and leathery in lower half; lower tepals puberulous on upper surface; leaves slightly succulent with one or two veins evident but not raised; plants from Richtersveld and Bushmanland [sect. *Deserticola*]:
12a Flowers pale creamy yellow; perianth tube 12–22 mm long. . . . . 28. *T. delpierrei*
12b Flowers pale mauve to purple; perianth tube 28–42 mm long . . . . . 29. *T. marlothii*
11b Flowers with funnel-shaped or cylindric perianth tube widening conspicuously above to ± 5–10 mm diam. at mouth; bracts membranous or papery throughout; lower tepals not puberulous on upper surface; leaves not subsucculent, always with midrib evident and raised; plant not from Richtersveld:
13a Stems contracted or plants acaulescent; leaves falcate, leathery; calluses long and crest-like, crisped or undulate and much longer than high [sect. *Montbretiopsis*]:
14a Plants shortly caulescent; inflorescence a spike of one or more flowers; flowers pale or dull orange with dark veins; perianth tube sharply curved, about twice as long as tepals; plants flowering in spring, in August and September . . . . . 18. *T. karooica*
14b Plants acaulescent; inflorescence of one or more 1-flowered units; flowers bright yellow; perianth tube almost straight, about as long as tepals; plants flowering in winter in May and June . . . . . 19. *T. florentiae*
13b Stems well developed; leaves suberect or spreading; calluses reduced to low ridges or axe-like but never crisped or undulate:
15a Flowers white to pink; perianth tube longer than tepals, narrow and cylindric, widening only near mouth; leaves never with prominent submarginal vein [sect. *Pallidae*]:
16a Leaves linear, 1–3 mm wide, as long as flowering stem or longer; plants flowering in December. . . . . 21. *T. linearifolia*
16b Leaves lanceolate, 4–15 mm wide, shorter than flowering stem; plants flowering September to November:
17a Leaves stiffly erect, attenuate, mostly 4–10 mm wide; bracts attenuate-aristate, with outer mostly 15–40 mm long, much exceeding inner in lower part of spike; plants from southern coastal mountain ranges. . . . . 22. *T. flabellifolia*
17b Leaves softer and suberect or spreading, acute to acuminate, mostly 10–15 mm wide; bracts ± 3-toothed, acute or acuminate, outer mostly 7–10(–15) mm long, always only slightly longer than inner; plants from Little Karroo and S slopes of the western Langeberg. . . . . 20. *T. pallida*
15b Flowers creamy yellow, orange or red; perianth tube shorter or longer than tepals, usually funnel-shaped and widening in upper half; leaves with or without prominent submarginal vein:
18a Calluses on lower tepals reduced to low, thickened median ridge or rarely triangular and about as high as long; leaves always with prominent submarginal vein: [sect. *Subcallosae*]
19a Leaves linear, 1.5–4.0 mm wide; flowers with prominent, triangular calluses on lower tepals. . . . . 3. *T. drakensbergensis*
19b Leaves narrowly lanceolate, 5–20 mm wide; flowers without calluses on lower tepals:
20a Flowers cream, straw-coloured or pale yellow, sometimes with apricot or pale orange tints toward tip of perianth or on reverse, usually with dark veining; flowering August to November (rarely December) . . . . . 1. *T. gladiolaris*
20b Flowers red, orange-red or pink, rarely with dark veining; flowering (December) January to April 2. *T. disticha*
18b Calluses on lower tepals axe-like, higher than long, rarely lacking, but then leaves without prominent submarginal vein [sect. *Montbretia*]:

TRITONIA. T. watermeyeri: A, flowering plant; B, half-flower. ***T. karrooica***: C, dehisced capsule; D, seed. ***T. deusta*** subsp. ***miniata***: E, outer bract (right) and inner bract (left); F, flower front view; G, half-flower. ***T. pallida***: H, flower front view (left) and side view (right). ***T. bakeri***: I, flower side view (left) and front view (right).

21a Leaves linear, flaccid, mostly 1.5–2.0 mm wide; flowers without calluses on lower tepals; filaments short, 4–5 mm long, included in perianth tube; plants from Cederberg in Western Cape . . . . 7. *T. cedarmontana*
21b Leaves various, usually wider; flowers always with calluses on median or all lower tepals; filaments 6–18 mm long, shortly or well exserted from perianth tube; plants not from Cederberg:
22a Perianth tube (18–)20–40 mm long and about twice as long as the dorsal tepal:
23a Plants not stoloniferous; leaves without prominent submarginal vein; flowers pale to bright yellow, sometimes flushed with apricot; all 3 lower tepals with well-developed calluses; plants of Western and Eastern Cape . . . . . 13. *T. chrysantha*
23b Plants stoloniferous; leaves with prominent submarginal vein; flowers orange-pink or salmon-pink; lower median tepal with well-developed callus; plants of southern Mozambique . . . . . 12. *T. moggii*
22b Flowers orange to red, rarely yellowish; perianth tube (6–)10–15(–20) mm long, about as long as the dorsal tepal or rarely up to one and a half times as long:
24a Leaves linear, (1–)2–6 mm wide, stiffly erect, closely several-veined and striate when dry; plants mostly 300–600 mm tall:
25a Flowers dark red drying blackish purple; leaves with main and submarginal veins prominent; plants from Eastern Cape near Butterworth. . . . . 9. *T. atrorubens*
25b Flowers orange, not darkening when dry; leaves with all veins equally prominent; plants from northern provinces of South Africa and Botswana. . . . . 10. *T. nelsonii*
24b Leaves various but not as above, always with a prominent main and sometimes submarginal vein but other veins inconspicuous; plants mostly less than 300 mm tall; from southeastern South Africa (also subtropical Africa):
26a Plants flowering in late summer and autumn, (January) March to May; corms often with stolons bearing a small cormlet; capsules ellipsoid, (12–)15–22 mm long, erect and pressed against the rachis . . . . . 11. *T. laxifolia*
26b Plants flowering in winter and spring, August to November (December); corms without stolons; capsules ovoid to ellipsoid, 6–10 mm long, not pressed against the rachis:
27a Leaves with thickened submarginal vein more prominent than midrib . . . . . 8. *T. strictifolia*
27b Leaves with submarginal vein unthickened or less prominent than main vein:
28a Leaves ± spirally twisted and margins usually undulate or crisped; plants from Montagu and Barrydale to Anysberg in Western Cape. . . . . 5. *T. watermeyeri*
28b Leaves not spirally twisted or crisped-undulate; plants from east of Anysberg in Western and Eastern Cape:
29a Leaves linear, mostly, 1–2(–3) mm wide, sometimes as long as stem . . . . . 6. *T. parvula*
29b Leaves lanceolate, (4–)6–10(–12) mm wide, ± ½ as long as stem . . . . . 4. *T. securigera*

Sect. 1. **Subcallosae** *M.P.de Vos* in Journal of South African Botany 49: 351 (1983). Type: *Tritonia lineata* (Salisb.) Ker Gawl. = *T. gladiolaris* (Lam.) Goldblatt & J.C.Manning

Leaves shorter than inflorescence, narrowly lanceolate, firm-textured, plane with thickened midrib and a prominent submarginal vein along edge. *Spike* erect or weakly inclined, moderately dense; bracts papery and translucent speckled and flecked brown distally. *Flowers* zygomorphic, pale yellow to red or pink; perianth tube obliquely funnel-shaped, ± as long as tepals or very slightly longer; lower tepals either without calluses or with triangular calluses. *Stamens* arcuate, unilateral, inserted near middle of tube; anthers apiculate. *Capsules* subglobose or obovoid, 8–10 mm long.

Species 3: summer-rainfall southern Africa.

A group of three closely allied species from the summer-rainfall grasslands of the eastern seaboard and near interior of South Africa and Lesotho, distinguished by their firm-textured leaves with a prominent submarginal vein just inside the edge, and suberect spikes of similar, obliquely funnel-shaped, pale yellow to orange, red or pink flowers, either without calluses or (*Tritonia drakensbergensis*) with a triangular callus at the base of the lower tepals. The separation from sect. *Montbretia* is possibly arbitrary, and the shared development of a well-developed submarginal vein in the leaves in both sections points to a close relationship.

1. **Tritonia gladiolaris** *(Lam.) Goldblatt & J.C.Manning* in Bothalia 36: 57 (2006). *Ixia gladiolaris* Lam.: 341 (1789). Type: South Africa, Cape of Good Hope, cultivated in Paris, flowering March and April, collector unknown (P–Herb. Lamarck, holo.).

Ixia striata Vahl: 65 (1805). Type: South Africa, without precise locality or collector (C–Herb. Vahl, holo.).

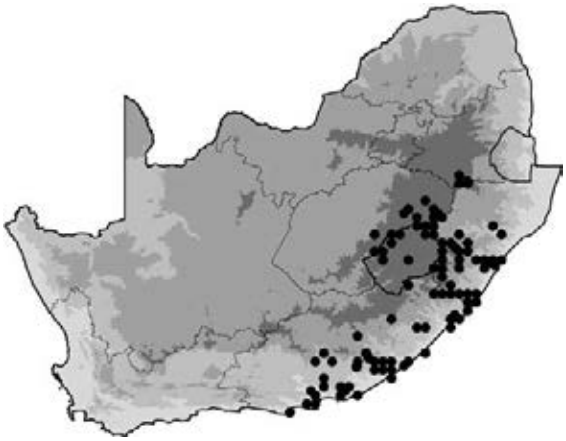
Ixia squalida var. *stricta* Aiton: 61 (1789). *Gladiolus lineatus* Salisb.: 40 (1796). *Tritonia lineata* (Salisb.) Ker Gawl.: 228 (1804b). *T. catenularis* Salisb.: 319 (1812), illegitimate superfluous name for *G. lineatus* Salisb. *Montbretia lineata* (Salisb.) Voigt: 610 (1845). *Tritonixia lineata* (Salisb.) Klatt: 357 (1882). Type: South Africa, without precise locality, *Masson s.n.* ex hort. Kew in 1781 [BM, lecto., designated by De Vos: 371 (1983)].

Gladiolus venosus Willd.: 58 (1809). *Ixia venosa* (Willd.) Link: 51 (1821). Type: South Africa, without

precise locality or collector (B–Herb. Willdenow 929, holo.).

Ixia reticulata Thunb.: 60 (1823). Type: South Africa, without precise locality, *Thunberg s.n.* (UPS–THUNB 989, holo.).

Tritonia tristis Dehnh.: 24 (1832). Type: unnumbered plate '*Tritonia tristis* Dehnh.' at Botanical Garden of Naples, neo., designated by Del Guacchio et al.: 1413 (2016).



Tritonia kraussii Baker: 194 (1892). Type: South Africa, [KwaZulu-Natal], summit Table Mt., *Krauss 200* [K, lecto., designated by De Vos: 368 (1983)].

Tritonia flavida Schltr.: 91 (1907). Type: South Africa, [KwaZulu-Natal], Alexandra County, Jolivet, near Fairfield, *Rudatis 91* (B, holo.).

Tritonia lineata var. *parvifolia* M.P.de Vos: 374 (1983). Type: South Africa, [Eastern Cape], Jeffrey's Bay, *Fourcade 3345* (NBG, holo.; K, MO, PRE, iso.).

Plants (150–)200–500(–800) mm high. *Corm* subglobose to depressed-globose, 10–20 mm diam.; tunics of fine-textured fibres, sometimes extended into a fibrous or papery collar. *Stem* erect or flexed outward above upper leaf and inclined, simple or with 1(2) suberect branches from upper ½. *Leaves* 5 to 8, suberect, firm-textured, narrowly lanceolate or rarely falcate, (40–)150–300(–500) × (5–)7–10(–18) mm, acute or acuminate, with raised main vein and strong submarginal vein ± 1 mm from margin, usually not reaching base of spike, cauline leaves ± overlapping in lower ½ of stem, uppermost dry and clasping, bract-like. *Spike* suberect or inclined, nearly 2-ranked, moderately dense or lax, 4- to 12(–15)-flowered; bracts dry, papery, brown or pale-translucent below, densely speckled and flecked with dark brown in upper ½, outer 7–10(–12) mm long, ± 3- to 5-toothed with middle tooth reduced or irregularly toothed, inner slightly shorter, bifid. *Flowers* slightly zygomorphic, cream-coloured to pale yellow, straw or flushed with pale apricot near tips or on reverse, usually with dark veins, unscented; perianth tube obliquely funnel-shaped, 10–15 mm long with basal 2–4 mm narrow, curved outward, widening up to 8–10 mm diam.; tepals subequal in length, oblong to obovate, (15–)18–20(–23) mm long, obtuse, spreading, dorsal slightly wider, 8–10(–14) mm wide, others 5–8(–10) mm wide, lower median tepal sometimes with low thickened basal ridge. *Filaments* unilateral, arcuate, 7–12 mm long, included; anthers 5–9 mm long, curved, apiculate, pink or yellow. *Style* dividing near apex of anthers or beyond, branches 3–5 mm long. *Capsules* subglobose or obovoid, ± 8 mm long. *Flowering time*: August to November (December).

Distribution and ecology: extending through south-eastern and eastern South Africa from Humansdorp in Eastern Cape through KwaZulu-Natal, eastern Free State and Lesotho to Wakkerstroom in Mpumalanga; in stony grassland; from near sea level to the high Drakensberg, typically on dolerite or sandstone soils.

Distribution of ***Tritonia gladiolaris***.

Diagnosis: recognised by its lanceolate leaves (5–)7–10(–18) mm wide, with a prominent submarginal vein, and funnel-shaped, cream- or straw-coloured to pale yellow or pale apricot-flushed flowers usually with dark veins and lacking well-developed calluses. Flowering is from spring to early summer, mainly August to November, rarely into December. *Tritonia gladiolaris* is closely allied to and largely sympatric with *T. disticha*, which flowers in mid- to late summer, mainly December to February or March, rarely earlier in November, and has red, orange-red or pink flowers, the lower tepals, especially the median, marked at the base with a small yellow blotch outlined with red.

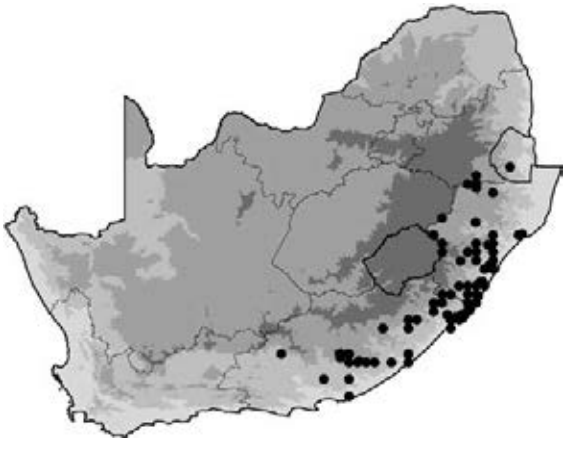
2. **Tritonia disticha** *(Klatt) Baker*, Handbook of the Irideae: 193 (1892). *Tritonixia disticha* Klatt: 356 (1882). Type: South Africa, [Eastern Cape], heights above Umsamvubo [Mzimvubu] River, *Drège 4549* (B– Herb. Lubeck, holo.; P, S, iso.).

Tritonia coccinea L.Bolus: 27 (1925), illegitimate homonym, not *T. coccinea* Eckl. (1827). Type: South Africa, [Eastern Cape], Pondoland, Port St Johns, *MacNair s.n. NBG89/23* (BOL, holo.).

Tritonia rubrolucens R.C.Foster: 46 (1936), as a replacement name for *T. rosea* Klatt: 760 (1863), illegitimate homonym, not *T. rosea* (Jacq.) Aiton (1810). *Montbretia rosea* Baker: 169 (1877), as replacement name for *T. rosea* Klatt, illegitimate homonym. *T. disticha* subsp. *rubrolucens* (R.C. Foster) M.P.de Vos: 378 (1983), new synonym. Type: South Africa, [Eastern Cape], Katberg, *Ecklon & Zeyher Irid. 98* (S, lecto., designated by De Vos: 378 (1983); G, SAM, isolecto.).

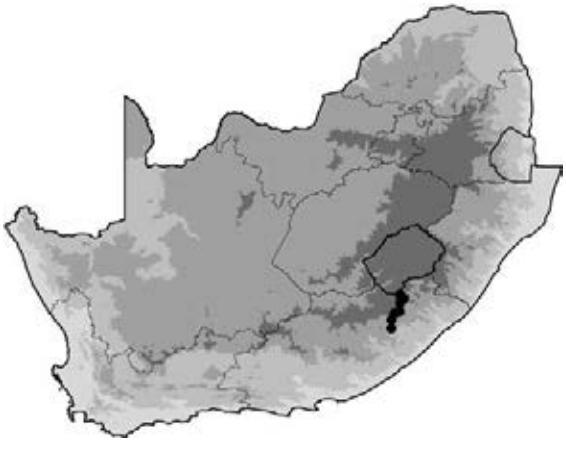
Plants (200–)300–500(–800) mm high. *Corm* subglobose to depressed-globose, 10–30 mm diam.; tunics of fine fibres, sometimes extending in a fibrous or papery collar. *Stem* erect or flexed outward above upper leaf and slightly inclined, simple or with up to 2(3) suberect branches from upper ½. *Leaves* 5 to 8, suberect, firm-textured, narrowly lanceolate, (100–)150–300(–500) ×

(5–)8–12(–20) mm, acute or acuminate, with raised main vein and strong submarginal vein ± 1 mm from margin, often reaching base of spike, usually forming a pseudostem at base, cauline leaves ± overlapping in lower ½ of stem, uppermost dry and clasping, bract-like. *Spike* suberect or inclined, ± 2-ranked, moderately dense or lax, 4- to 12(–15)-flowered; bracts dry and papery, pale translucent or straw-coloured below, densely speckled and flecked with dark brown above or at tips, often striate with brown veins, (8–)10–15(–18) mm long, acute to acuminate, obtuse, or minutely ± 3-toothed with middle tooth reduced, inner slightly shorter, bifid. *Flowers* slightly zygomorphic, bright red, orange red or pink, lower tepals with a small yellow blotch sometimes outlined with red, sometimes smaller on laterals, tepals sometimes prominently dark-veined, unscented; perianth tube obliquely funnel-shaped, (8–)12–16 mm long with basal 2–3 mm narrow, curved outward, widening up to 8–10 mm diam.; tepals oblong to obovate, (10–)15–18(–20) mm long, obtuse, spreading, dorsal slightly wider, 8–10 mm wide, others 5–8 mm wide, lower median sometimes with a low thickened basal ridge. *Filaments* unilateral, arcuate, 7–12 mm long, included or exserted up to 3 mm; anthers 5–7 mm long, curved, apiculate, pink or yellow. *Style* dividing between middle and apex of anthers or sometimes beyond, branches 2–4 mm long. *Capsules* subglobose or obovoid, ± 10 mm long. *Flowering time*: (November) December to February (March).



Distribution and ecology: extending along the eastern seaboard and interior of South Africa, from Port Elizabeth in Eastern Cape through KwaZulu-Natal and north-eastern Free State to Wakkerstroom in Mpumalanga, also in southern Eswatini; in stony grassland, from near sea level inland to the foothills of the Drakensberg, typically on dolerite or sandstone soils.

Diagnosis: *Tritonia disticha* is recognised by its lanceolate leaves (5–)8–12(–20) mm wide with a prominent submarginal vein and funnel-shaped, red, orange-red or pink flowers, sometimes darkly veined, lacking well-developed calluses. The lower tepals, especially the median, are marked at the base with a small yellow blotch outlined with red. It is closely allied to and largely sympatric with *T. gladiolaris*, which blooms earlier, mainly August to November (rarely into December), and has cream- to straw-coloured or pale yellow flowers, sometimes flushed pale apricot-coloured, usually with prominent dark veins.



Plants with ± 3-toothed or irregularly toothed bracts, the lower bracts sometimes acute, were separated as subsp. *rubrolucens* from typical *T. disticha* with obtuse to acuminate or sometimes 3-toothed bracts, recorded mainly from the coastal Eastern Cape and KwaZulu-Natal. The distinction between the two variants is not at all clear and we do not admit subsp. *rubrolucens*.

3. **Tritonia drakensbergensis** *M.P.de Vos* in Journal of South African Botany 49: 397 (1983). Type: South Africa, [Eastern Cape], Transkei, Little Bush, Cala, *Pegler 1699* (BOL, holo.).

Plants 180–300 mm high. *Corm* subglobose, 10 mm diam.; tunics of fine-textured fibres. *Stem* erect, simple. *Leaves* 5 to 8, suberect, firm-textured, linear, (50–)70–180(–200) × 1.5–3.0(–4.0) mm, acute or acuminate, with raised main vein and strong submarginal vein ± 0.5 mm from each edge, not reaching base of spike, cauline leaves ± overlapping in lower ½ of stem, uppermost dry, clasping, bract-like. *Spike* inclined, ± 2-ranked, moderately dense, 2- to 7(8)-flowered; bracts dry and papery, pale translucent below, densely speckled and flecked with dark brown in above or at tips, often striate with brown veins, 7–11 mm long, obtuse or minutely ± 3-toothed to irregularly toothed, inner slightly shorter, bifid. *Flowers* slightly zygomorphic, bright red or pinkish red, lower tepals with small, spade-shaped yellow blotch outlined with red, smaller on laterals, and 3 small yellow spots on lower inside of tube, tepals not notably dark-veined, unscented; perianth tube widely funnel-shaped, 8–10 mm long, basal 2–3 mm narrow, curved outward, widening up to 8–10 mm diam. above; tepals subequal in length, oblong to obovate, (13–)15–20 mm long, obtuse,

Distribution of ***Tritonia disticha***.

Distribution of ***Tritonia drakensbergensis***.

spreading, dorsal slightly wider, 8–10 mm wide, others 6–8 mm wide, lower each with a small triangular yellow callus at base 1.5 mm high. *Filaments* unilateral, arcuate, 9–12 mm long, shortly exserted; anthers 5–6 mm long, curved, apiculate, pink or yellow. *Style* dividing opposite or shortly beyond anther tips, branches ± 2.5 mm long. *Flowering time*: January to early March.

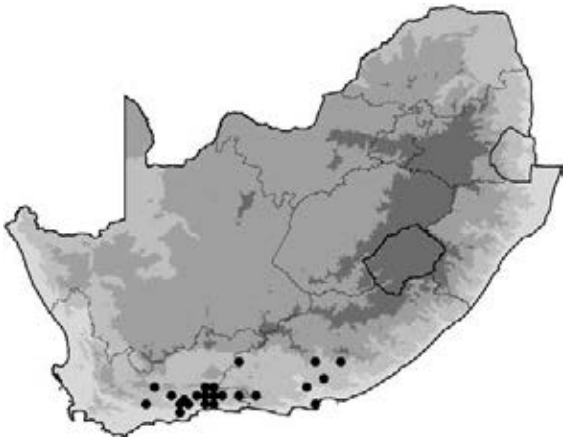
Distribution and ecology: a montane species of the southern Drakensberg in Eastern Cape, South Africa, recorded from Cala and Barkly Pass to Maclear; in high altitude grassland on steep, seasonally moist or wet slopes on basalt, between 1 000 and 2 300 m elevation.

Diagnosis: a slender species distinguished by its narrow, linear leaves, 1.5–3.0(–4.0) mm wide with a prominent submarginal vein, and widely funnel-shaped, red to deep pink flowers with a yellow blotch at the base of the lower tepals, these surrounding small, triangular calluses 1.0–1.5 mm high. *Tritonia drakensbergensis* can be confused in the dried state with narrow-leaved forms of *T. disticha*, which has similarly shaped and coloured flowers, also with a yellow spot at the base of the lower tepals, but that species lacks calluses (represented at most by a low, ridge-like thickening) and the leaves are narrowly lanceolate and (5–)8–12(–20) mm wide. *Tritonia disticha* typically occurs at lower altitudes in drier grassland on dolerite or sandstone.

Sect. 2. **Montbretia** *(DC.) Pax* in Engler & Prantl, Die natürlichen Pflanzenfamilien, edn. 2, 5: 155 (1888). *Montbretia* DC.: 151 (1803). *Tritonia* subg. *Montbretia* (DC.) Baker: 190 (1892). Type species: *M. securigera* (Aiton) DC. = *T. securigera* (Ait.) Ker Gawl.

Leaves shorter than or as long as inflorescence, linear to lanceolate, usually plane with thickened midrib and sometimes a prominent submarginal vein along edge, or all veins ± equally thickened and leaves striate, rarely margins undulate or crisped. *Spike* erect or weakly inclined, moderately dense or dense; bracts papery and translucent speckled and flecked brown distally. *Flowers* zygomorphic, pale yellow, orange or red to dark red; perianth tube obliquely funnel-shaped, ± as long as tepals or up to twice as long; lower tepals usually with prominent quadrangular or axe-shaped calluses, rarely without calluses. *Stamens* arcuate, unilateral, inserted near middle or top tube; anthers apiculate. *Capsules* subglobose to ovoid, 8–22 mm long.

Species 11: subtropical and South Africa.



A group of florally similar species from the winter- and summer-rainfall parts of South Africa and subtropical Africa, distinguished by their obliquely funnel-shaped, pale yellow to orange or red flowers, usually with a quadrate callus on the lower tepals. We provisionally include *Tritonia cedarmontana* here although it lacks calluses on the lower tepals. Flowers lacking calluses are characteristic of sect. *Subcallosae*, but the soft-textured leaves lacking a prominent submarginal vein of *T. cedarmontana* are anomalous there. The separation of sect. *Montbretia* from sect. *Subcallosae* is possibly arbitrary, and the shared development of a well-developed submarginal vein in the leaves in both sections points to a likely close relationship.

4. **Tritonia securigera** *(Aiton) Ker Gawl.* in König & Sims, Annals of Botany 1: 228 (1804b). *Gladiolus securiger* [Soland. in] Aiton: 65 (1789). *Montbretia securigera* (Aiton) DC. in Redouté: t. 53 (1804a). Type: South Africa, without precise locality or date, ex hort. Chelsea in 1778, *F. Masson s.n.* [BM, lecto., designated by De Vos: 384 (1983)].

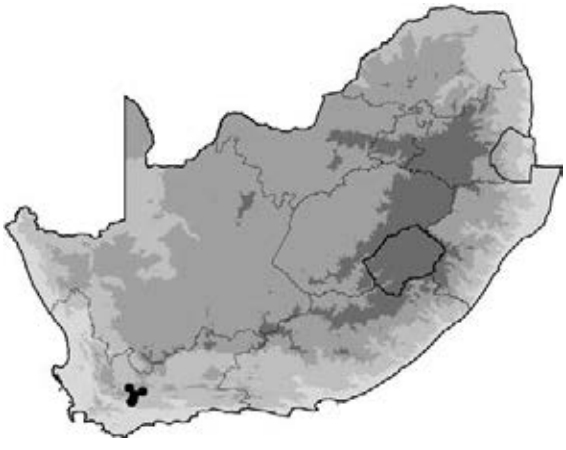
Ixia thunbergii Roem. & Schult.: 391 (1817), as a replacement name for *I. squalida* Thunb. (1803), illegitimate homonym, not *I. squalida* Aiton (1789). Type: South Africa, Cape of Good Hope, without precise locality, *Thunberg s.n.* (UPS–THUNB 996, holo.).

Ixia flabellularis Vahl: 67 (1805). Type: South Africa, without precise locality or collector (C–ex Herb Royen, holo.).

Plants (100–)150–250(–350) mm high. *Corm* subglobose, 10–20 mm diam.; tunics of fine-textured or wiry fibres, sometimes thickened into flattened claws at base. *Stem* suberect or flexed outward above uppermost sheath, usually unbranched, rarely with 1 branch from near base. *Leaves* 4 to 8, linear-lanceolate to lanceolate, suberect or spreading in a 2-ranked fan, usually ± ½ as long as stem, (40–)80–200(–250) × (4–)6–10(–12) mm wide, acute to acuminate, main vein moderately thickened, margins slightly thickened, uppermost cauline leaf membranous, bract-like, sheathing, sometimes concealed by uppermost foliage leaf. *Spike* suberect, moderately lax, subsecund, 2- to 15-flowered; bracts dry-membranous, translucent flushed brown and speckled in upper half, 7–10(–12) mm long, minutely 3- or irregularly toothed, inner ± as long, shortly bifid. *Flowers* zygomorphic, orange or apricot-coloured with yellow throat and yellow spot on lower tepals surrounding callus; perianth tube obliquely funnel-shaped, (10–)12–15(–20) mm long, lower cylindric portion 3–6(–15) mm long, widening up to 6–8 mm diam.; tepals unequal, obovate, dorsal larger, slightly hooded over anthers, often paler inside, upper laterals spreading, lower tepals deflexed, upper tepals 10–15(–20) × 7–15 mm, lower (10–)12–15 × 5–8 mm, each with a quadrate yellow callus 2–4 mm high near base. *Filaments* unilateral, arcuate, 9–12(–15) mm long, exserted up to 6 mm; anthers (4–)5–6 mm long, often curved, violet. *Style* dividing opposite or beyond anthers, branches 4–6 mm long. *Capsules* ellipsoid, 7–10 mm long. *Flowering time*: late August to October or November.

Distribution of ***Tritonia securigera***.

Distribution and ecology: extending through southern Western Cape near Ladysmith and Mossel Bay eastward through the Little Karoo and southern Cape to Adelaide and Somerset East in Eastern Cape, South Africa; on stony flats in renosterveld and karroid shrubland.



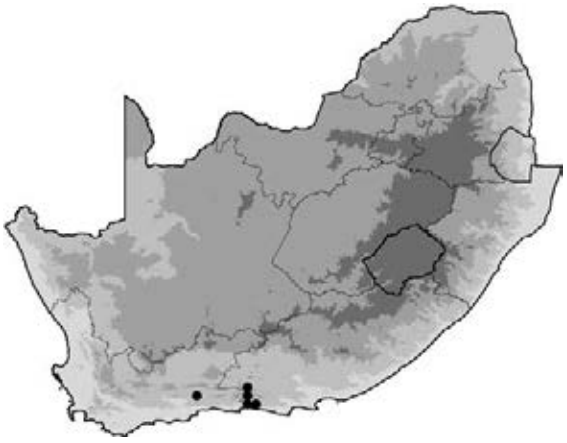
Diagnosis: the central species in a taxonomically difficult group that is characterised by similar two-lipped, orange flowers with an obliquely funnel-shaped tube conspicuously yellow in the throat and about as long as the tepals (sometimes slightly longer), the lower tepals each with a yellow blotch near the base bearing a quadrate or axe-like callus 1–4 mm high. Within this group, *Tritonia securigera* is applied to plants with plane, lanceolate or linear-lanceolate leaves, usually forming an erect fan up to half as long as the stem, the main vein raised and the margins thickened and without a prominent submarginal vein. The perianth tube is usually 10–15 mm long, with the narrow basal portion 3–6 mm long. Plants from Kommadagga are variable in tube length, the tube in some individuals up to ± 20 mm long with the narrow basal portion 15 mm long. Introgression with *T. chrysantha* may be indicated here.

Tritonia nelsonii from Gauteng, Limpopo and Northwest is usually taller with narrow, stiffly erect leaves with numerous prominent veins; *T. strictifolia* from interior Eastern Cape around Grahamstown, is distinguished by the prominent submarginally veined leaves; and *T. laxifolia* from Eastern Cape and subtropical Africa, flowers in late summer and autumn and has larger capsules 12–15 mm long closely appressed to the stem. Two other taxa are less clearly separated: *T. parvula* from the central and eastern Little Karoo, is a mostly smaller plant with linear leaves, mostly 1–2(–3) mm wide; and *T. watermeyeri* from the western Little Karroo, has more-or-less spirally twisted leaves with the margins often undulate or crisped.

5. **Tritonia watermeyeri** *L.Bolus* in Annals of the Bolus Herbarium 4: 44 (1926). *Montbretia watermeyeri* (L.Bolus) Sealy: t. 428 (1963). *T. securigera* subsp. *watermeyeri* (L.Bolus) Goldblatt & J.C. Manning: 60 (2006). Type: South Africa, [Western Cape], allegedly from Vanrhynsdorp, Kareebergen, flowered at Kirstenbosch Gardens, Sept. 1907, *Watermeyer s.n. BOL18050* (BOL, holo.).

Plants (50–)60–150(–200) mm high. *Corm* conical-globose, 7–15 mm diam.; tunics of moderately fine-textured or wiry fibres forming flattened claws at base, extending in a papery or fibrous neck. *Stem* ± strongly deflexed above uppermost sheath, usually unbranched, rarely with 1 branch from near base. *Leaves* 4 to 8, linear-lanceolate, suberect or trailing, usually ± as long as stem, blade 50–100 × 1.5–4.0(–5.0) mm wide, acute to acuminate, loosely or tightly spirally twisted, margins plane or closely undulate or crisped, main vein moderately thickened, margins slightly thickened, cauline leaf membranous, bract-like, sheathing, concealed by uppermost foliage leaf. *Spike* inclined, moderately lax, 2- to 6-flowered; bracts dry-membranous, translucent flushed brown and speckled in upper ½, outer 6–9 mm long, minutely 3-toothed or irregularly toothed, inner ± as long, shortly bifid. *Flowers* zygomorphic, orange to reddish orange with yellow throat and yellow spot on lower tepals surrounding callus; perianth tube obliquely funnel-shaped, 10–16 mm long, lower cylindric portion 3–7 mm long, widening up to ± 8 mm diam.; tepals obovate, dorsal larger and slightly hooded over anthers, often paler inside, upper laterals spreading and lower tepals deflexed, upper tepals 15–10(–22) × (7–)8–12(–15) mm, lower tepals 11–14 × 5–9 mm, each with a quadrate or truncate yellow callus 3–4 mm high near base. *Filaments* unilateral, arcuate, 12–18 mm long, exserted up to 6 mm; anthers 4–5 mm long, often curved, exserted, violet. *Style* dividing opposite base to middle of anthers, branches 3–4 mm long. *Capsules* obovoid, ± 10 mm long. *Flowering time*: August to October.

Distribution and ecology: a local endemic of the western Little Karoo in Western Cape, South Africa, from Montagu and Barrydale to Anysberg; on stony clay flats and banks in renosterveld and karroid shrubland.



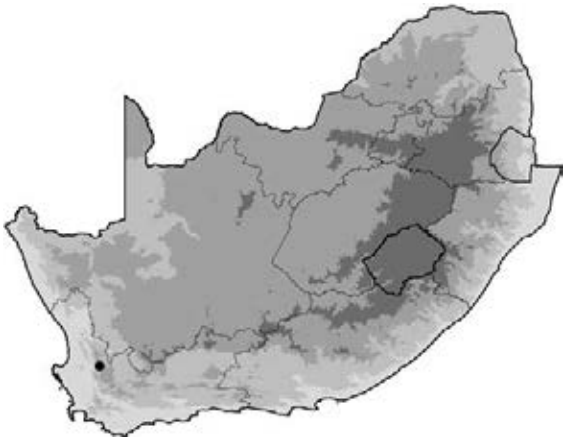
Distribution of ***Tritonia watermeyeri***.

Diagnosis: a small plant with relatively large flowers, *Tritonia watermeyeri* is distinguished from *T. securigera* by the narrow, more-or-less spirally twisted leaves, 1.5–4.0(–5.0) mm wide, with the margins often tightly undulate or crisped. The corm tunics are always wiry with the fibres thickened at the base into flattened claws. *Tritonia watermeyeri* occurs west and northwest of the range of *T. securigera*. Populations between Montagu and Barrydale are readily recognised by their tightly twisted and crisped leaves but populations from the Anysberg are less distinctive, with plane, only loosely twisted leaves. These plants can scarcely be separated from narrow-leaved forms of *T. securigera* and the taxon was treated as a subspecies by us (Goldblatt & Manning, 2006). It is, however, no less distinct from typical *T. securigera* than is *T. parvula*. The status of these taxa in relation to *T. securigera* remains unclear but we treat them here as separate species.

6. **Tritonia parvula** *N.E.Br.* in Bulletin of Miscellaneous Information, Kew 1931: 452 (1931). Type: South Africa, [Western Cape], near Oudtshoorn, *Muir 4724* (K, holo.).

Plants (50–)80–150(–200) mm high. *Corm* conical-globose, 5–10 mm diam.; tunics of fine-textured fibres, extending in a papery or fibrous neck. *Stem* suberect or deflexed above uppermost sheath, usually unbranched, rarely with 1 branch from near base. *Leaves* 4 to 8, linear, flaccid, suberect or spreading to trailing, usually ± as long as stem or longer, 50–150(–200) × (0.5)1.0–2.0(–3.0) mm wide, acute to acuminate, main vein moderately thickened, margins slightly thickened, cauline leaf membranous, bract-like, sheathing, concealed by uppermost foliage leaf. *Spike* inclined, moderately lax, 2- to 6-flowered; bracts dry-membranous, translucent flushed brown and speckled in upper ½, 5–9 mm long, minutely 3-toothed, inner shortly bifid. *Flowers* zygomorphic, reddish orange to salmon-orange with yellow throat and yellow spot on lower tepals surrounding callus; perianth tube obliquely funnel-shaped, 6–10(–13) mm long, lower cylindric portion 3–6 mm long, widening above to 6–8 mm diam.; tepals obovate, dorsal larger and slightly hooded over anthers, often paler inside, upper laterals spreading, lower tepals deflexed, upper tepals 11–15 × 6–10(–12) mm, lower tepals 8–10 × 4–6 mm, each with a quadrate yellow callus 1–2 mm diam. near base, calluses on laterals sometimes smaller than median. *Filaments* unilateral, arcuate or sometimes slightly divergent, 6–10 mm long, exserted up to 4 mm; anthers 4–5 mm long, often curved, violet to red-purple. *Style* dividing opposite middle to tips of anthers, branches 2–3 mm long. *Capsules* shortly ellipsoid, ± 6 mm long. *Flowering time*: late September to October (December).

Distribution and ecology: endemic to the Little Karoo between Ladismith in Western Cape and the Long Kloof from Uniondale to Joubertina in Eastern Cape, South Africa; on stony clay or loamy flats and banks in renosterveld and karroid shrubland, also crevices in sandstone cliffs.



Distribution of ***Tritonia parvula***.

Diagnosis: a relatively small plant, *Tritonia parvula* is distinguished from *T. securigera* by the narrower, linear leaves mostly 1–2(–3) mm wide, sometimes as long as the flowering stem. Some individuals are difficult to place, notably those growing in crevices in sandstone cliffs and with trailing leaves. *Tritonia parvula* most closely resembles *T. cedarmontana* from the Cederberg in habit but that species lacks calluses on the lower tepals and has shorter filaments 4–5 mm long with the anthers half-included in the perianth tube.

7. **Tritonia cedarmontana** *Goldblatt & J.C.Manning* in Bothalia 41: 171 (2011). Type: South Africa, [Western Cape], southern Cederberg, Krom River Kloof, 4 000 ft [1 220 m], 13 Dec. 1950, *Esterhuysen 18009* (BOL, holo.; NBG, PRE, iso.).

Plants (50–)150–300 mm high. *Corm* conical-globose, 7–10 mm diam.; tunics of fine-textured fibres, extending in a papery or fibrous neck. *Stem* ± erect, usually unbranched, rarely with 1 short branch. *Leaves* 4 to 6, linear, flaccid, usually ± as long as stem or longer, mostly 100–200 × 1.5–2.0 mm, acute to acuminate, main vein moderately thickened, margins slightly thickened and hyaline, cauline leaf membranous, bract-like, sheathing, concealed by uppermost foliage leaf. *Spike* inclined, moderately lax, 2- to 5-flowered; bracts dry-membranous, translucent with sparse brown speckling apically on teeth, 4–6 mm long, shallowly 3-toothed, inner ± as long, shortly bifid. *Flowers* zygomorphic, salmon-orange; perianth tube obliquely funnel-shaped, 9–10 mm long, lower cylindric portion 4–5 mm long, widening up to 6–8 mm diam.; tepals slightly unequal, dorsal ovate, 13–14 × 7.0–7.5 mm, other tepals elliptic, ± 13 × 5.5–6.5 mm, lower lacking calluses. *Filaments* unilateral, arcuate, 4–5 mm long, included; anthers 3.5–4.0 mm long, partially included in upper part of tube, yellow. *Style* dividing opposite anther tips, branches ± 3 mm long. *Immature capsules* subglobose or obovoid, ± 4.5 mm diam. *Flowering time*: December.

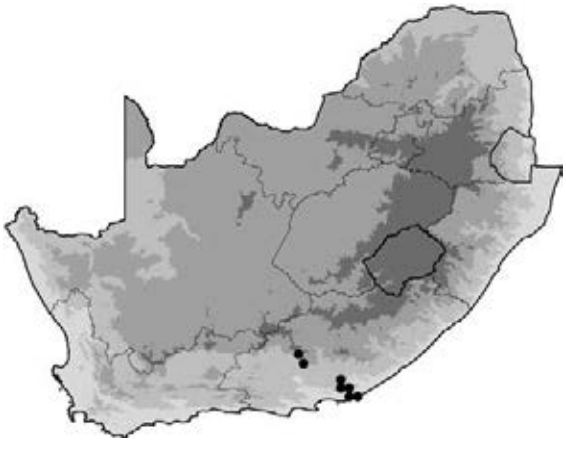
Distribution and ecology: known only from the type collection from Krom River Kloof in the southern

Distribution of ***Tritonia cedarmontana***.

Cederberg in Western Cape, South Africa; on ledges and steep sandstone slopes along streams.

Diagnosis: a diminutive species with rather flaccid, linear leaves mostly 1.5–2.0 mm wide and a moderately lax spike of two to five, small, salmon-orange flowers without evident calluses on the lower tepals. The filaments are short, 4–5 mm long, with the anthers half-included in the funnel-shaped tube 9–10 mm long. The species most closely resembles *T. parvula* from the Little Karoo but that species has the lower tepals flexed downward, with prominent, ± oblong calluses at the bases, and slightly longer filaments, 6–10 mm long with the anthers shortly exserted from the perianth tube.

The relationships of *Tritonia cedarmontana* remain puzzling. The funnel-shaped flowers without calluses suggest a relationship with sect. *Subcallosae* from the summer-rainfall grasslands, but the relatively soft-textured leaves without a prominent submarginal vein are inconsistent with this. We provisionally include the species in sect. *Montbretia* on the basis of its general resemblance to *T. parvula*.



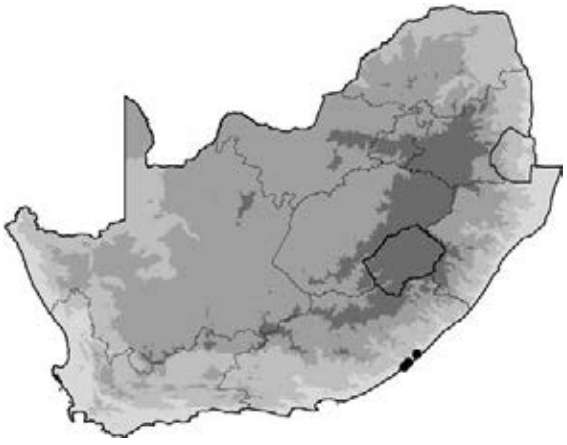
8. **Tritonia strictifolia** (*Klatt*) *Benth. & Hook.f. ex B.D.Jacks.* in Index Kewensis 2: 1129 (1895). *Montbretia strictifolia* Klatt: 753 (1863). *T. laxifolia* var. *strictifolia* (Klatt) Baker: 195 (1892). Type: South Africa, [Eastern Cape], Uitenhage, Kalkhoogte between the Swartkops and Sundays Rivers, *Ecklon & Zeyher 100* (B, lecto., designated by De Vos: 118 (1999); G, S, SAM, Z, isolecto.).

Tritonia parviflora Baker: 865 (1901). Type: South Africa, [Eastern Cape], without precise locality, *Ecklon & Zeyher 100* (Z, holo.; B, G, S, SAM, iso.).

Plants mostly 150–250 mm high. *Corm* subglobose, 10–20(–30) mm diam.; tunics of fine-textured fibres. *Stem* suberect or flexed outward above uppermost sheath, usually unbranched, rarely with 1 branch from near base. *Leaves* 4 to 8, linear-lanceolate, suberect or spreading in a fan, usually ± ½ as long as stem, (30–)50–150(–200) × (2–)3–6 mm, acute to acuminate, main vein moderately thickened, with prominently thickened submarginal vein just inside margins, uppermost cauline leaf membranous and sheathing, bract-like, exserted or concealed by uppermost foliage leaf. *Spike* suberect, moderately lax, subsecund, 3- to 8(10)-flowered; bracts dry-membranous, translucent flushed brown and speckled above, outer 7–10 mm long, minutely 3-toothed or irregularly toothed, inner ± as long, shortly bifid. *Flowers* zygomorphic, reddish orange or apricot-coloured with yellow throat and yellow spot on lower tepals surrounding callus; perianth tube obliquely funnel-shaped, 10–15 mm long, lower cylindric portion 3–6 mm long, widening above up to 6–8 mm diam.; tepals unequal, obovate, dorsal larger, slightly hooded over anthers, often paler inside, upper laterals spreading and lower tepals deflexed, upper tepals 13–18 × 5–10(–15) mm, lower 10–15 × 5–8 mm, each with quadrate yellow callus 2–4 mm high near base. *Filaments* unilateral, arcuate, 7–12 mm long, exserted up to 6 mm; anthers 4–5 mm long, often curved, violet. *Style* dividing opposite upper ½ of anthers, branches 3–5 mm long. *Flowering time*: September to November (December).

Distribution and ecology: originally thought to be restricted to the immediate vicinity of Grahamstown but now known to range somewhat more widely, from Pearston to Bathurst, South Africa; in stony or rocky grassland.

Diagnosis: distinguished from *Tritonia securigera* and its allies with similar short-tubed, orange flowers by the presence of a conspicuously thickened submarginal vein within 0.5 mm of the leaf margins. These are typically more prominent than the lightly thickened midrib. Similar leaves are characteristic of sect. *Subcallosae* but these species lack the quadrate calluses and conspicuous yellow mouth to the perianth tube characteristic of *T. securigera* and its allies.



Distribution of ***Tritonia strictifolia***.

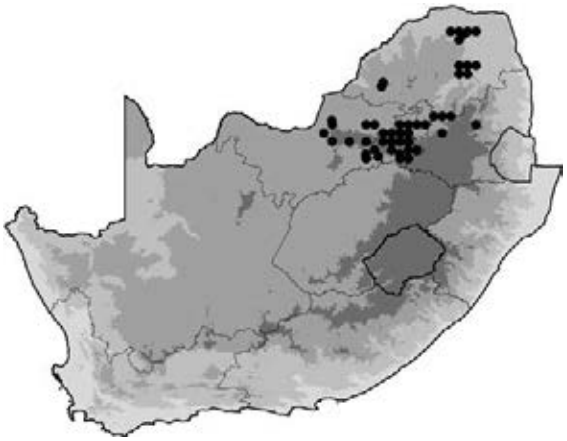
9. **Tritonia atrorubens** *(N.E.Br.) L.Bolus* in Journal of Botany, British and foreign 67: 133 (1927). *Gladiolus atrorubens* N.E.Br.: 135 (1914). Type: South Africa, [Eastern Cape], Transkei, Kentani, near Manubi, *Saxton 13* (K, holo.).

Tritonia flanaganii L.Bolus: 161 (1918). Type: South Africa, [Eastern Cape], Transkei, near Impetu, between Komgha and Kei Mouth, *Flanagan 55* [BOL, lecto., designated by De Vos: 400 (1983)].

Plants 300–600 mm high. *Corm* subglobose, 10–15 mm diam.; tunics of fine-textured fibres, sometimes with a papery neck. *Stem* inclined outward above uppermost sheath, usually unbranched or rarely with 1 branch from near middle. *Leaves* 4 to 8, linear, suberect in basal fan, ± ½ as long to as long as stem, 80–200 × (1–)2–5 mm wide, acuminate, striate with main vein and submarginal vein thickened, intervening secondary vein slightly thickened, cauline leaves smaller and sheathing, uppermost often concealed by upper foliage leaf. *Spike* inclined, moderately dense or dense, secund, 2- to 10-flowered; bracts dry-membranous, translucent or straw, flushed dark reddish brown, speckled in upper half, outer 8 to 10, acute or 3-toothed, inner ± as long or shorter, bifid. *Flowers* zygomorphic, dark red drying to blackish purple; perianth tube obliquely funnel-shaped, 15–17 mm long, lower cylindric portion 3–6 mm long, widening above to 6–8 mm diam.; tepals obovate, dorsal larger, slightly hooded over anthers, often paler inside, upper laterals spreading, lower deflexed, upper tepals 10–14 × 5–10 mm, lower tepals 8–14 × 4–8 mm, each with quadrate callus near base, with median 2–4 mm high and yellow, laterals smaller. *Filaments* unilateral, arcuate, 10–12 mm long, shortly exserted; anthers 5–7 mm long, often curved, dark. *Style* dividing opposite anthers, branches 3–4 mm long. *Flowering time*: December to January.

Distribution and ecology: a local endemic from east of Butterworth in Eastern Cape, South Africa, known from a few records between Kentani and Willowvale; in grassland.

Distribution of ***Tritonia atrorubens***.



Diagnosis: readily recognised by its stiff, linear leaves (1–)2–5 mm wide with the main vein, submarginal and intervening veins moderately thickened, the blades thus striate, and the dark red flowers drying blackish purple. The lower median tepals bear a yellow, axe-shaped callus and evidently smaller, dark calluses on the lower lateral tepals. It has a superficial resemblance to *Tritonia disticha* but this species has broader leaves, (5–)8–12(–20) mm wide, and orange to red flowers without evident calluses on the lower tepals. It is more likely to be confused with *T. drakensbergensis*, which has similarly narrow (but not striate) leaves and red flowers with yellow calluses on the lower tepals, but this is a high altitude species from basalt soils and the calluses are lower and triangular in shape.

10. **Tritonia nelsonii** *Baker*, Handbook of the Ideae: 195 (1892). Type: South Africa, [Limpopo], Houtbosberg, summit, *Nelson 440* (K, holo.; PRE, iso.).

Tritonia petrophila Baker: 1004 (1904). Type: South Africa, [Gauteng], granite rocks at Modderfontein, *Conrath 585* (Z, holo.; K, iso.).

Plants (200–)300–600(–800) mm high. *Corm* subglobose, 15–30 mm diam., sometimes deep-seated; tunics of fine-textured fibres, sometimes with a papery neck. *Stem* erect or inclined outward above, usually unbranched or 1- or 2-branched from near middle. *Leaves* 4 to 8, linear, suberect in a loose fan, weakly twisted toward tips, as long as stem or slightly longer, (50–)100–300(–450) × (1–)2–4(–6) mm, acute to acuminate, striate with main vein moderately thickened and with 3 or 4 other vein pairs also slightly thickened, without prominently thickened submarginal vein, cauline leaves smaller and sheathing, uppermost sometimes concealed by upper foliage leaf. *Spike* suberect, moderately lax, subsecund, 5- to 12-flowered; bracts dry-membranous, translucent or purplish, flushed dark reddish brown, speckled in upper ⅓ or at tips, outer (6–)8–12(–15) mm long, acute or 3-toothed, inner ± as long or shorter, bifid. *Flowers* zygomorphic, reddish orange to bright red with pale yellowish throat and yellow spot on lower tepals surrounding callus; perianth tube obliquely funnel-shaped, 10–15 mm long, lower cylindric part 3–6 mm long, widening up to 6–8 mm diam.; tepals unequal, obovate, dorsal larger and slightly hooded over anthers, often paler inside, upper laterals spreading and lower tepals deflexed, upper tepals 13–18 × 5–10(–15) mm, lower tepals 10–15 × 5–8 mm, each with a quadrate yellow callus 2–4 mm high near base. *Filaments* unilateral, arcuate, 12–14 mm long, shortly exserted up to 6 mm; anthers 5–6 mm long, often curved, cream-coloured to violet. *Style* dividing opposite upper ½ of anthers, branches 2–3 mm long. *Capsules* subglobose to shortly ellipsoid, 7–10 mm long. *Flowering time*: (December) February to March (June).

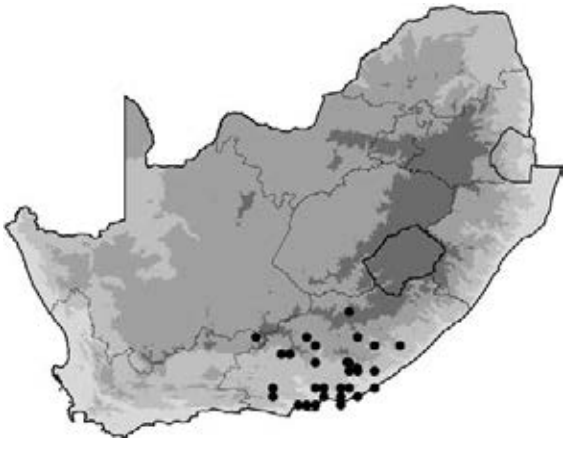
Distribution and ecology: restricted to northern South Africa, from Heidelberg in Gauteng north to Soutpansberg in Limpopo and west to Zeerust in Northwest, and as far east as Waterval Boven in Mpumalanga, possibly

Distribution of ***Tritonia nelsonii***.

also Botswana; in rocky grassland and savanna, often in quartzite, with the corms wedged in rock crevices.

Diagnosis: distinguished from *Tritonia securigera* and its allies including *T. laxifolia* with similar short-tubed, orange flowers by its taller, more upright habit, the plants mostly 300–600 mm tall, and the stiffly erect, linear-striate leaves, (1–)2–4(–6) wide, with the main vein and 3 or 4 secondary vein pairs ± equally prominent. Other members of the group have the midrib and sometimes submarginal vein thickened and prominent but not the intervening secondary veins, the blades thus not conspicuously striate.

11. **Tritonia laxifolia** *(Klatt) Baker*, Handbook of the Irideae: 195 (1892). *Montbretia laxifolia* Klatt: 754 (1863). Type: South Africa, [Eastern Cape], without precise locality, *Drège 3489a* (K, lecto., designated by De Vos: 392 (1983); G, L, MO, S, SAM, iso.).



Tritonia bakeri Klatt: 203 (1894), illegitimate homonym, not *T. bakeri* Klatt (1882), replacement name for *Montbretia laxifolia* Baker: 155 (1875), illegitimate homonym, not *M. laxifolia* Klatt (1863). Type: Tanzania [as German East Africa], *Speke & Grant s.n.* (K, holo.).

Tritonia clusiana Worsley: 269 (1905). *T. bracteata* Worsley: 2 (1906), illegitimate superfluous name for *T. clusiana* Worsley, based on the same type. Type: South Africa, [KwaZulu-Natal], Greytown District, *Worsley s.n.* (K, holo.).

Plants (100–)200–450(–600) mm high. *Corm* subglobose, 10–15 mm diam., with short or long stolons with terminal cormlet; tunics of fine-textured fibres. *Stem* suberect, unbranched or 1- or 2-branched from near base or middle. *Leaves* 4 to 8, lanceolate or narrowly lanceolate, suberect or sometimes spreading in a fan, ± ½ as long to as long as stem, (40–)80–150(–200) × 5–10(–12) mm, acute to acuminate, main vein moderately thickened, sometimes with slightly thickened submarginal vein ± 1 mm from edge, uppermost cauline leaf sheathing, leaf-like or membranous and bract-like, exserted or concealed by upper foliage leaf. *Spike* stiffly erect, moderately lax, subsecund, 6- to 15-flowered; bracts dry-membranous, translucent flushed brown and speckled in upper ½, outer 6–12(–18) mm long, 3-toothed or rarely 5-toothed or acute, inner ± as long as or slightly shorter, bifid. *Flowers* zygomorphic, salmon-pink, reddish orange or apricot-coloured with yellow throat and yellow spot on lower tepals surrounding callus; perianth tube obliquely funnel-shaped, 12–16 mm long, lower cylindric part 3–6 mm long, widening up to 6–8 mm diam.; tepals obovate, dorsal larger, slightly hooded over anthers, often paler inside, upper laterals spreading, lower tepals deflexed, upper tepals 10–15 × 8–12 mm, lower tepals 10–15 × 5–8 mm, each with a quadrate yellow callus 2–4 mm high near base. *Filaments* unilateral, arcuate, 12–15 mm long, exserted up to 6 mm; anthers 4–6 mm long, often curved, exserted, mauve. *Style* dividing opposite or beyond anthers, branches 2–4 mm long. *Capsules* ellipsoid, (12–)15–22 mm long, erect and appressed to axis. *Flowering time*: (January) March to May (to July in tropical Africa).

Distribution and ecology: with an unusual disjunct distribution in South and tropical East Africa, recorded from Port Elizabeth to Queenstown and Keiskamma in Eastern Cape, and also in Mozambique, Malawi, Tanzania and Zambia; in woodland and grassland.

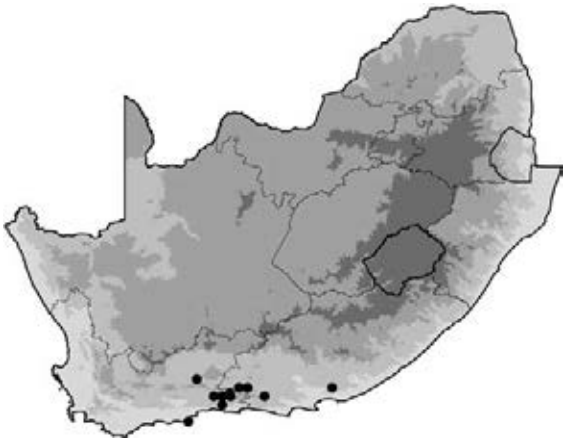
Diagnosis: *Tritonia laxifolia* is distinguished from spring-flowering *T. securigera* and its allies with similar short-tubed, orange flowers by its later flowering, from late (rarely mid-) summer to early winter, and by its characteristic capsules, ellipsoid and much larger than in other species of the genus, (12–)15–22 mm long and appressed to the axis. The stiffly erect, often elongate spike is distinctive, and the species often (?always) produces short or long stolons terminating in a solitary cormlet. In other species the cormlets are subsessile. *Tritonia laxifolia* is replaced in the northern provinces of South Africa by *T. nelsonii*, a generally taller and more slender plant with narrower, linear-striate leaves (1–)2–4(–6) wide, and shorter, subglobose capsules 7–10 mm long. Both species bloom from midsummer to early winter.

Distribution of ***Tritonia laxifolia***.

12. **Tritonia moggii** *Oberm.* in Kirkia 3: 24 (1963). Type: Mozambique, Inhaca Island, SW of Saco Bay, *Mogg 27315* (PRE, holo.; J, SRGH, iso.).

Plants 200–450 mm high. *Corm* subglobose, 10–15 mm diam., with short or long stolons with solitary cormlet; tunics of fine-textured fibres. *Stem* suberect, unbranched or up to 3-branched from near base or in lower ½. *Leaves* 4 to 8, lanceolate or narrowly lanceolate, suberect or sometimes spreading in a fan, ± ½ as long as to as long as stem, (50–)70–150(–200) × 4–8(–12) mm, acute to acuminate, main vein moderately thickened and submarginal vein evident ± 0.5 mm from edge, soft-textured, uppermost cauline leaf sheathing leaf-like or membranous and bract-like, shortly exserted or concealed by upper foliage leaf. *Spike* stiffly erect, moderately lax, subsecund, 6- to 15-flowered; bracts dry-membranous, translucent flushed brown and speckled in upper ½, 6–12(–15) mm long, acute or 3-toothed, inner ± as long or slightly shorter, shortly bifid. *Flowers* zygomorphic, orange-red or salmon-pink, yellow throat and yellow spot on lower tepals; perianth tube subcylindric widening distally and funnel-shaped, (18–)25–35(–40) mm long, lower cylindric part 20–25 mm long, widening above to 6–8 mm diam.; tepals unequal, oblanceolate to elliptic, dorsal larger and slightly hooded over anthers, upper laterals spreading and lower deflexed, (12–)15–22 × 6–9 mm, lower median tepal with a quadrate yellow callus 2–4 mm high near base and lower laterals with or without smaller calluses. *Filaments* unilateral, arcuate, 12–16 mm long, exserted up to 6 mm; anthers 6–7 mm long, often curved, mauve. *Style* dividing below or opposite middle of anthers, branches ± 4 mm long. *Capsules* ellipsoid, (8–)10–15 mm long, erect and appressed against axis. *Flowering time*: April to July (October).

Distribution and ecology: endemic to coastal Mozambique as far south as Maputo and Inhaca; on dunes and in open woodland at or near the coast. The species thrives in cultivated lands, where the cormlets are dispersed by tilling. The long-tubed, orange-red flowers bear a remarkable resemblance to those of *Freesia grandiflora* and *F. laxa* and are probably adapted to pollination by butterflies.



Diagnosis: recognised by the relatively soft-textured leaves with evident submarginal vein, and long-tubed, orange flowers with perianth tube (18–)25–35(–40) mm long and ± twice as long as the dorsal tepal. Although all three lower tepals have a yellow blotch near the base, typically only the median has a well-developed callus, the laterals either without calluses or with reduced calluses. The stiffly erect stems, relatively large capsules appressed to the rachis, and the development of stolons from the base of the corm all indicate a close relationship with *Tritonia laxifolia*.

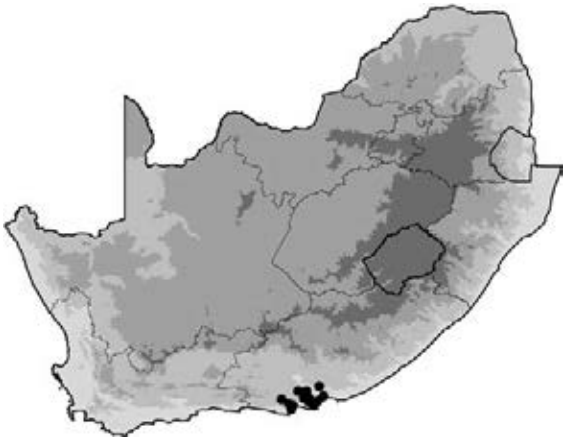
13. **Tritonia chrysantha** *Fourc.* in Transactions of the Royal Society of South Africa 21: 77 (1932). Type: South Africa, [Eastern Cape], hills south of Georgida, *Fourcade 4394* (BOL, lecto. [as holo.], effectively designated by De Vos: 387 (1983); K, NBG, isolecto.).

Plants 150–300(–350) mm high. *Corm* subglobose, 10–20 mm diam.; tunics of fine-textured or wiry fibres forming flattened claws at base. *Stem* flexed outward above uppermost sheath then suberect, unbranched or 1- or 2-branched from near base. *Leaves* 4 to 8, lanceolate, suberect or spreading in a wide fan, usually < ½ as long as stem, 40–100(–150) × (2–)5–10 mm, acute, main vein moderately thickened, sometimes with slightly prominent submarginal vein, margins slightly thickened and hyaline, uppermost cauline leaf membranous and sheathing, bract-like, exserted or concealed by uppermost foliage leaf. *Spike* suberect or inclined, moderately lax, subsecund, 2- to 8-flowered; bracts dry-membranous, translucent flushed brown and speckled in upper ½, outer 6–12 mm long, obtuse and 3-toothed or irregularly toothed, inner ± as long, shortly bifid. *Flowers* zygomorphic, bright or paler yellow, sometimes tinged apricot, unscented; perianth tube slender and subcylindric widening distally and funnel-shaped, (18–)20–28 mm long, lower cylindric part 12–25 mm long, widening above to 6–8 mm diam.; tepals obovate, dorsal larger, slightly hooded over anthers, often paler inside, upper laterals spreading and lower deflexed, upper tepals 10–15(–20) × 7–15 mm, lower tepals (10–)12–15 × 5–8 mm, each with a quadrate yellow callus 2–4 mm high near base. *Filaments* unilateral and arcuate, 7–10 mm long, not or shortly exserted; anthers 4–6 mm long, often curved, brown or yellow. *Style* dividing opposite anthers, branches 3–5 mm long. *Capsules* subglobose, ± 6 mm long. *Flowering time*: late August to October.

Distribution and ecology: from Oudtshoorn in Western Cape eastward to Grahamstown in Eastern Cape, South Africa, with an outlying record from the mouth of the Gouritz River; mostly on drier clay soils in renosterveld and karroid scrub.

Diagnosis: distinguished from *Tritonia securigera* by the pale to bright yellow flowers, sometimes flushed apricot, with proportionally longer perianth tube, (18–)20–28 mm long and about twice as long as the dorsal tepal, and vegetatively by the more wiry tunics thickened into claws at the base. The tunics in *T. securigera* are always

Distribution of ***Tritonia chrysantha***.



fine-textured and the mostly orange flowers have a shorter perianth tube more-or-less as long as the dorsal tepal or rarely slightly longer but never twice as long.

14. **Tritonia dubia** *Eckl. ex Klatt* in Linnaea 32: 761 (1864). *Montbretia dubia* (Eckl. ex Klatt) Baker: 169 (1877). *Tritonixia dubia* (Eckl. ex Klatt) Klatt: 356 (1882). Type: South Africa, [Eastern Cape], Uitenhage, *Ecklon & Zeyher Irid 102* (SAM, lecto., designated by De Vos: 140 (1982); G, S, iso.).

Tritonia bolusii Baker: 337 (1876). *Tritonixia bolusii* (Baker) Klatt: 356 (1882). Type: South Africa, [Eastern Cape], Uitenhage, *H. Bolus 1883* (K, lecto., designated by De Vos: 140 (1982); BOL, S, iso.).

[*Tritonia dubia* Eckl.: 30 (1827), invalid name without description.]

Plants 120–200(–300) mm high. *Corm* subglobose, 8–20 mm diam., with cormlets at base and in lower leaf axils; tunics of fine fibres. *Stem* erect, simple or up to 3-branched from near base. *Leaves* 5 to 8, suberect to falcate, lanceolate-ensiform, 40–150 × 3–7 mm, acute, with evident main vein, cauline leaves bract-like and often dry. *Spike* erect, subsecund, (3)5- to 10-flowered; bracts dry and papery, whitish or flushed pink but brown and densely speckled with rusty brown distally and on upper margins, outer 5–10 mm long, obtuse or 3-toothed to irregularly-toothed, inner subequal or slightly shorter, bifid. *Flowers* actinomorphic, rotate, pale orange or salmon-pink to red, with dark veins and yellow tube; perianth tube funnel-shaped, 6–10 mm long, ± filiform below widening in upper 2–3 mm to ± 3 mm diam.; tepals subequal spreading, elliptic, obtuse, 10–15(–20) × 4–6(–8) mm, without calluses. *Filaments* central and erect, 3–5 mm long, reaching < halfway up perianth; anthers 3.0–4.5 mm long, pale yellow; pollen yellow. *Style* 7–8 mm long, dividing below or opposite base of anthers, branches 3–5 mm long. *Capsules* elongate-ellipsoid, trigonous, 15–20(–25) × 5–6 mm, exserted beyond bracts. *Flowering time*: (July) August to September.

Distribution of ***Tritonia dubia***.

Distribution and ecology: a local endemic in southern Eastern Cape, South Africa, between Hankey and Paterson; in grassy fynbos and grassy clearings in thicket.

Diagnosis: unique in the genus, *Tritonia dubia* has perfectly radially symmetric flowers with erect, centrally placed stamens surrounding the style. The stamens are inserted near the top of the perianth tube which thus widens only in the upper 2–3 mm. In other species with a regular perianth the stamens are inserted in the lower half of the tube and the flowers thus have a prominent gullet. Plants appear to set seed readily and completely, and are thus evidently autogamous, an observation consistent with the branching of the style below the anthers where the stigmas will become dusted with self pollen. The capsules are unusually large and elongate for the genus, ellipsoid and 15–25 mm long, quite unlike the short capsules included in the bracts of other species in sect. *Tritonia*. The floral symmetry and structure and capsule size and shape suggest our placing of *T. dubia* in sect. *Montbretia* near *T. laxifolia*, which has similar capsules, rather than the earlier assignment by De Vos (1982) to sect. *Tritonia*.

Sect. 3. **Tritonia**

Tritonia subg. *Tritonixia* Klatt ex Baker: 190 (1892). Type species: *Tritonia squalida* (Aiton) Ker Gawl., lecto., designated by De Vos: 127 (1982), invalid name typified by the type of the genus.

Leaves distichous, lanceolate-ensiform; anatomically thickened marginal epidermal cells. *Spike* inclined or moderately deflexed; bracts dry and papery, densely speckled with rusty brown distally and along upper margins. *Flowers* subactinomorphic, perianth bowl-shaped, pink to reddish orange; perianth tube funnel-shaped, much shorter than tepals, with very short filiform lower portion expanded abruptly above into a wide cup or gullet; tepals ± obovate-spathulate, calluses lacking or reduced to thickened ridges. *Stamens* unilateral, laxly diverging. *Capsules* shortly ellipsoid to obovoid, 7–8 mm long.

Species 3: southwestern and southern Western Cape, South Africa.

A group of three closely allied species restricted to the lowlands and coastal plain in the southwestern and southern Western Cape, diagnosed by the relatively large, bowl-shaped flowers with symmetric perianth but arcuate, laxly diverging stamens. The perianth tube is less than half as long as the tepals and funnel-shaped with a very short, filiform basal portion widening abruptly into a broad gullet, the stamens inserted at the junction between the two portions, thus in the lower

half of the tube and scarcely exserted from it. The colourful flowers are adapted to pollination by hopliine beetles and adaptations include the development of hyaline zones along the tepal claws in two species and the presence of large, dark markings in the third.

A fourth species with short-tubed, actinomorphic flowers, *Tritonia dubia*, was included in the section by De Vos (1982) but differs from the other species in having perfectly actinomorphic flowers, with a proportionally longer tube only slightly shorter than the tepals and expanded near the top, thus without a gullet, and stamens inserted near the mouth of the tube and erect around the style. The floral similarities with the other members of the section are thus entirely superficial. In addition, the capsules in *T. dubia* are unlike those elsewhere in the section, much larger and ellipsoid in shape. Similar capsules are found in *T. laxifolia* and its allies in sect. *Montbretia* to which we have accordingly transferred it.

15. **Tritonia deusta** *(Aiton) Ker Gawl.* in Curtis's Botanical Magazine 17: t. 622 (1803a). *Ixia deusta* [Soland. in] Aiton: 60 (1789). *Waitzia deusta* (Aiton) Kreysig: 52 (1829). *Montbretia deusta* (Aiton) Endl.: 166 (1842). *Crocosmia deusta* (Aiton) Planch.: 161 (1851). *Tritonixia deusta* (Aiton) Klatt: 356 (1882). Type: South Africa, [Western Cape], without precise locality, *Masson s.n.* [BM, lecto. (as holo.), designated by De Vos: 136 (1982)].

Ixia gibba Salisb.: 38 (1796), illegitimate superfluous name for *I. deusta* Aiton. Type: unknown, probably as for *I. deusta*.

Plants (50)100–300(–400) mm high. *Corm* subglobose, 15–30 mm diam., with cormlets at base; tunics of fine-textured fibres. *Stem* erect, simple or with up to 2 branches. *Leaves* 5 to 8, suberect to falcate, lanceolate-ensiform, (20–)40–100(–200) × (2–)3–10(–15) mm, acute or subobtuse, with evident midrib, cauline leaves bract-like and often dry. *Spike* moderately deflexed, subsecund, (2)5- to 15-flowered; bracts dry and papery, whitish or flushed pink but brown and densely speckled with rusty brown distally and on upper margins, 5–13 mm long, outer obtuse or 3-toothed with median tooth smaller, inner bifid. *Flowers* subactinomorphic, widely cup-shaped, long, bright orange to orange-red or salmon, outer tepals sometimes with a dark reddish black blotch or transverse band at base of limb or lower tepals with small yellow or dark blotch or line, tube yellow with star-shaped yellow mouth outlined with red, unscented; perianth tube abruptly funnel-shaped, 8–12 mm long, subfiliform and arcuate in lower 2–4 mm widening abruptly to 6–8 mm diam.; tepals subequal or inner slightly broader, spreading, elliptic or obovate to obovate-spathulate, obtuse or minutely emarginate, (13–)15–25 × 5–12 mm, lower median or all 3 outer tepals with low ridge-like callus along midline. *Filaments* unilateral but diverging, 7–9 mm long, reaching < halfway up perianth, often orange distally; anthers 5–8 mm long, pale or purple; pollen yellow. *Style* 15–20 mm long, dividing opposite middle of anthers, branches 3–5 mm long. *Capsules* shortly ellipsoid or obovoid, 7–8 × 6 mm. *Flowering time*: late September to mid- or late October.

Distribution and ecology: historically relatively widespread through the lowlands in southwestern and southern Western Cape, South Africa, from Cape Town to Riversdale and Albertinia, but now probably extinct in the extreme west; on stony clay or granite soils mainly in renosterveld scrub, rarely on limestone in fynbos, now largely restricted to road verges or stony sites.

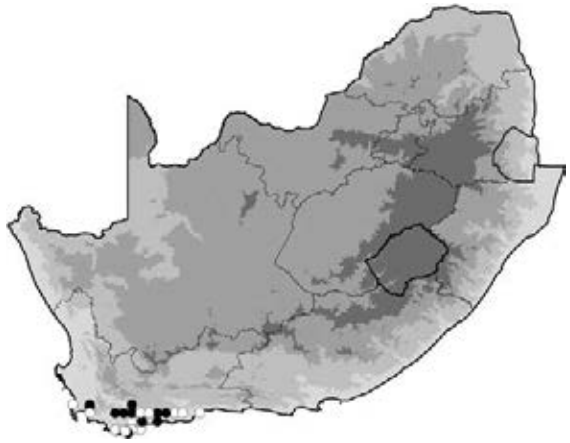
Diagnosis: recognised by the bright orange, bowl-shaped flowers with a star-shaped yellow marking in the throat, often outlined with red. The prominent yellow throat or gullet and the lack of hyaline zones along the margins of the tepal claws separates *Tritonia deusta* from both orange-flowered *T. crocata* and pink-flowered *T. squalida*. It is often also smaller in stature and flower size than either of these species. Hybrids are recorded with both *T. crocata* and *T. squalida*.

Tritonia deusta varies in the number, size and shape of the dark markings on the tepals: populations west of Swellendam typically lack dark markings on the outer tepals, although unmarked plants are also found further east, whereas plants east of Swellendam mostly have a prominent dark reddish black blotch at the base of the outer tepal limbs. The prominently marked forms conform to the type of the species, whereas unmarked plants were described as *Ixia miniata* Jacq. The two forms were reduced to subspecies by De Vos (1982).

Key to subspecies

1a Flowers with prominent reddish black blotch on outer tepals, rarely also on inner tepals . . . . . 15a. subsp. *deusta*

1b Flowers without prominent dark blotches on tepals, sometimes with yellow blotches on lower tepals or a small yellow or dark blotch on lower median tepal only . . . . . 15b. subsp. *miniata*



15a. subsp. **deusta**

Ixia crocata var. *nigromaculata* Andrews: t. 134 (1799). *I. miniata* var. *nigromaculata* (Andrews) DC. in Redouté: t. 89 (1804b). Type: South Africa, [Western Cape], without precise locality or collector, illustration in Andrews: t. 134 (1799).

Tritonia coccinea Eckl.: 29 (1827). *T. crocata* var. *coccinea* (Eckl.) Baker: 163 (1877). Type: unknown.

Tritonia maculata Denh.: 178 (1839). Type: illustration '*Ixia Miniata* nigro maculata' in Redouté: t. 89 (1804b), neo., designated by Del Guacchio *et al.*: 1413 (2016).

Outer tepals with a reddish black blotch or band at base of blade sometimes extending onto claw, each blotch usually with a dark, median ridge or callus; smaller blotches sometimes present on one or more lower tepals.

Distribution of ***Tritonia deusta*** subsp. ***deusta***, ●; subsp. ***miniata***, ○.

Distribution and ecology: the less widespread form of the species, ranging from Robertson and Bonnievale to Swellendam and eastward to Riversdale and Albertinia.

Diagnosis: distinguished by the presence of a large reddish black blotch or transverse band on the outer tepals at the base of the limb.

15b. subsp. **miniata** *(Jacq.) M.P.de Vos* in Journal of South African Botany 48: 139 (1982). *Ixia miniata* Jacq.: 10 (1797). *Tritonia miniata* (Jacq.) Ker Gawl.: t.609 (1803b). *Waitzia miniata* (Jacq.) Kreysig: 52 (1829). *Montbretia miniata* (Jacq.) Voigt: 611 (1845). *Crocosmia miniata* (Jacq.) Planch.: 161 (1851). *Tritonixia miniata* (Jacq.) Klatt: 356 (1882). *Tritonia crocata* var. *miniata* (Jacq.) Baker: 190 (1892). Type: South Africa, [Western Cape], without precise locality or collector, illustration in Jacq.: t. 24 (1797).

Tritonia aurantiaca Eckl.: 29 (1827). *Ixia aurantiaca* (Eckl.) Czerw.: 4 (1867), illegitimate homonym, not *I. aurantiaca* Klatt (1882). *T. crocata* var. *aurantiaca* (Eckl.) Baker: 163 (1877). Type: unknown [details of description suggest this determination].

Tritonia tardiflora Dehnh.: 179 (1939). Type: unnumbered plate '*Tritonia tardiflora* Dehnh.' in Botanical Garden of Naples, neo., designated by Del Guacchio et al.: 1413 (2016).

Outer tepals without dark blotches or markings; lower tepals sometimes with yellow, often red-margined blotch or small dark spot or median line in throat.

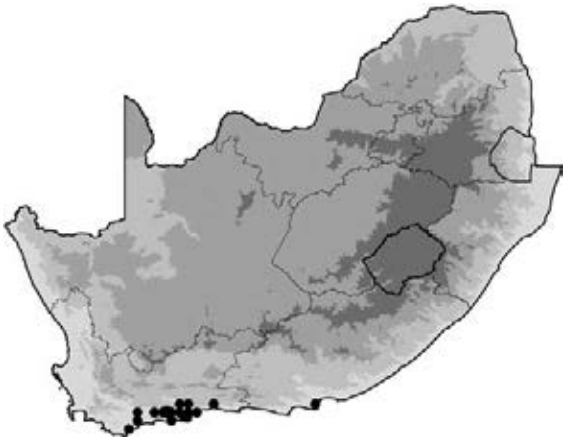
Distribution and ecology: occurring throughout the range of the species and historically recorded as far west as the Cape Peninsula but now possibly extinct there and encountered mainly between Caledon and Bredasdorp and Struisbaai, but also occurring in populations further east near Swellendam, Riversdale and Albertinia.

Diagnosis: distinguished by the lack of prominent, dark blotches on the outer tepals, although a small yellow or dark spot may be present on the lower median tepal.

16. **Tritonia crocata** *(L.) Ker Gawl.* in Curtis's Botanical Magazine 16: t. 581 (1802a). *Ixia crocata* L.: 52 (1762). *I. hyalina* Salisb.: 38 (1796), illegitimate superfluous name for *I. crocata* L. (1762). *Gladiolus crocatus* (L.) Pers.: 44 (1805). *Waitzia crocata* (L.) Hoffm.: 14 (1824). *Montbretia crocata* (L.) Endl.: 166 (1842). *Crocosmia crocata* (L.) Planch.: 161 (1851). *Tritonixia crocata* (L.) Klatt: 356 (1882). Type: South Africa, [Western Cape], without precise locality or collector [LINN 58.24, lecto. (as holo.), designated by De Vos: 132 (1982)].

Ixia iridifolia D.Delaroche: 24 (1766). Type: South Africa, [Western Cape], without precise locality or collector (L: Herb. van Royen, holo.).

Ixia hyalina L.f.: 91 (1782). *Tritonia hyalina* (L.f.) Baker: 163 (1877). *Tritonixia hyalina* (L.f.) Klatt: 356 (1882). Type: None cited.



Ixia fenestrata Jacq.: 289 (1791). *Belamcanda fenestrata* (Jacq.) Moench: 529 (1794). *Tritonia fenestrata* (Jacq.) Ker Gawl.: t. 704 (1804a). *Waitzia fenestrata* (Jacq.) Kreysig: 52 (1829). *Montbretia fenestrata* (Jacq.) Endl.: 166 (1842). *Crocosmia fenestrata* (Jacq.) Planch.: 161 (1851). Type: South Africa, [Western Cape], without precise locality or collector, illustration in Jacq.: 289 (1792 [1788–1795]).

Ixia purpurea Lam.: 341 (1789). *Tritonia purpurea* (Lam.) Ker Gawl.: sub t. 1275 (1810a). *Montbretia purpurea* (Lam.) Heynh.: 418 (1847). *Tritonia crocata* var. *purpurea* (Lam.) Baker: 163 (1877). *Tritonixia purpurea* (Lam.) Klatt: 356 (1882). Type: South Africa, [Western Cape], without precise locality, *Thunberg s.n.* (UPS–THUNB '*Ixia crocata* var. c' or P: Herb. Lamarck?, holo.].

Tritonia sanguinea Eckl.: 29 (1827). *T. crocata* var. *sanguinea* (Eckl.) Baker: 163 (1877). *Montbretia sanguinea* (Eckl.) Heynh.: 418 (1847). Type: South Africa, [Western Cape], without precise locality or collector (S, holo.).

[*Ixia planifolia* Mill. ex Roem. & Schult.: 400 (1817), invalid name only in synonymy of *I. crocata* L.]

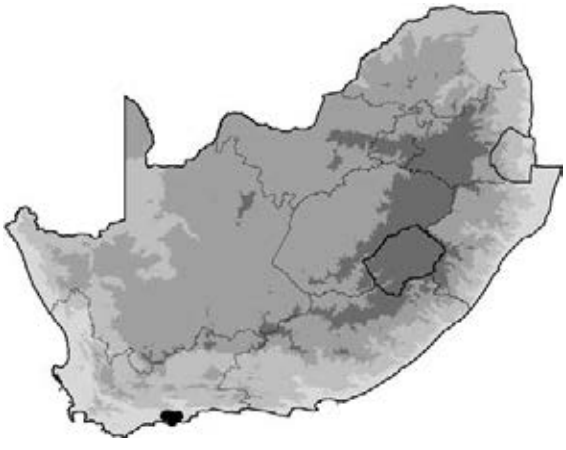
Plants 150–300(–500) mm high. *Corm* subglobose, 15–30 mm diam., with cormlets at base; tunics of fine-textured fibres. *Stem* erect, simple or up to 2-branched. *Leaves* 6 to 10, suberect to falcate, lanceolate-ensiform, (40–)50–200 × 4–10(–15) mm, acute or subobtuse, with evident main vein, cauline leaves bract-like, often dry. *Spike* moderately deflexed, subsecund, (2)5- to 15-flowered; bracts dry and papery, whitish or flushed pink but brown and densely speckled with rusty brown distally and on upper margins, (5–)10–16 mm long, outer obtuse or 3-toothed with median tooth smaller, inner

Distribution of ***Tritonia crocata***.

bifid. *Flowers* subactinomorphic, widely cup-shaped, bright fiery orange to orange-red or pinkish orange, lower median or all 3 tepals with a narrow yellow stripe in throat and sometimes a yellow patch at base, unscented; perianth tube abruptly funnel-shaped, (8–)12–15 mm long, subfiliform and arcuate in lower 2–4 mm widening abruptly to 7–10 mm diam.; tepals subequal or inner slightly broader, spreading, obovate-spathulate, obtuse or minutely emarginate, (16–)20–28 × 10–20 mm, claws with wide hyaline marginal zones, lower median or all three tepals sometimes with low ridge-like callus along midline. *Filaments* unilateral but diverging, 7–9 mm long, reaching < halfway up perianth, often orange distally; anthers 5–8 mm long, pale or purple with yellow pollen. *Style* 15–20 mm long, dividing opposite upper half or slightly beyond anthers, branches 5–6 mm long. *Capsules* shortly ellipsoid or obovoid, 7–8 × 6 mm. *Flowering time*: late September to mid- or late October.

Distribution and ecology: restricted to the southern coast of Western Cape from Swellendam to George and east to Humansdorp in Eastern Cape, South Africa; mainly in shale soils in renosterveld, rarely in loamy sands, now largely restricted to roadsides and isolated rocky sites that have escaped the plough.

Diagnosis: distinguished from the two other species with large, bowl-shaped flowers with spathulate tepals and diverging filaments by the broad, orange to red tepals with hyaline margins on the claws, the lower 3 tepals with a narrow median yellow stripe in the throat, sometimes raised as a low ridge. Orange-flowered *Tritonia deusta* lacks the hyaline margins to the tepals and has a distinct, large yellow star-like marking in the throat of the tube and often a large dark blotch on the outer tepals, and *T. squalida* has pink to mauve, often narrower tepals, also with hyaline margins on the claws. Hybrids between *T. crocata* and *T. deusta* have been recorded between Riversdale and Albertinia where the ranges of the two species overlap.



17. **Tritonia squalida** *(Aiton) Ker Gawl.* in Curtis's Botanical Magazine 16: t. 581 (1802a). *Ixia squalida* [Soland. in] Aiton: 61 (1789). *Waitzia squalida* (Aiton) Kreysig: 52 (1829). *Montbretia squalida* (Aiton) Voigt: 611 (1845). *Tritonixia squalida* (Aiton) Klatt: 356 (1882). Type: South Africa, [Western Cape], without precise locality, *Masson s.n.* (BM, holo.).

Ixia squalida var. *patula* [Soland. in] Aiton: 61 (1789). *I. similis* Salisb.: 38 (1796), as a new name for *I. squalida* var. α [*patula*] and superfluous name for *I. hyalina* L.f. (1782) (= *Tritonia crocata* (L.) Ker Gawl.). Type: South Africa, [Western Cape], without precise locality, *Masson s.n.* (BM, holo.).

Ixia hyalina DC. in Redouté: t. 87 (1804b), illegitimate homonym, not *I. hyalina* L.f. (1782). Type: South Africa, without precise locality or collector, illustration in Redouté: t. 87 (1804b).

Tritonia pulchella Dehnh.: 24 (1839). Type: unnumbered plate '*Tritonia pulchella* Dehnh.' in Botanical Garden of Naples, neo., designated by Del Guacchio et al.: 1414 (2016).

Plants 150–300(–500) mm high. *Corm* subglobose, 10–20(–30) mm diam., with cormlets at base; tunics of fine-textured fibres. *Stem* erect, simple or up to 2-branched. *Leaves* 6 to 10, suberect to falcate, lanceolate or sword-shaped, (50–)70–200 × 4–10(–15) mm, acute or subobtuse, with evident main vein, cauline leaves bract-like and often dry. *Spike* moderately deflexed, subsecund, (2)6- to 10(15)-flowered; bracts dry and papery, whitish or flushed pink but brown and densely speckled with rusty brown in distal ½ and on upper margins, outer (8–)10–16 mm long, outer obtuse or 3-toothed with median tooth smaller, inner subequal or slightly shorter, bifid. *Flowers* subactinomorphic, widely cup-shaped, deep mauve-pink to pale pink or almost white, with dark veins, often dark pink or yellowish at base and lower 3 tepals sometimes with pale pink or yellow line in throat, unscented; perianth tube abruptly funnel-shaped, (8–)12–15 mm long,

Distribution of ***Tritonia squalida***.

subfiliform and arcuate in lower 2–4 mm widening abruptly to 7–10 mm diam.; tepals subequal or inner slightly broader, spreading, rhomboid-spathulate to obovate-spathulate, obtuse or minutely emarginate, (16–)20–28 × 8–18 mm, claws with wide hyaline marginal zones, lower 3 sometimes with low ridges along midline. *Filaments* unilateral but diverging, 8–12 mm long, reaching < halfway up perianth, often pink distally; anthers 5–8 mm long, pale or purple with yellow or mauve pollen. *Style* 15–20 mm long, dividing opposite middle of anthers, branches 5–6 mm long. *Capsules* shortly ellipsoid or obovoid-trigonous, 7–8 × 6 mm. *Flowering time*: late September to mid- or late October.

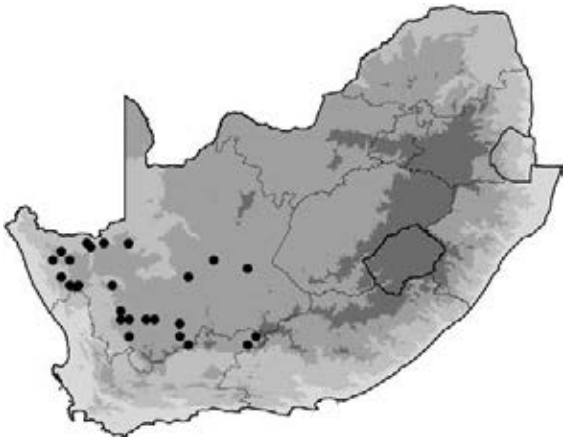
Distribution and ecology: a local endemic of the south coast of Western Cape, South Africa, between Riversdale, Albertinia and Still Bay; on stony laterite and calcareous soils, often in crevices in rock pavement or outcrops.

Diagnosis: one of three closely allied species with almost symmetric, bowl-shaped flowers with more-or-less spathulate tepals and weakly diverging filaments, *Tritonia squalida* is distinguished by its pale to deep or dusty pink to mauve tepals, the claws with broad hyaline margins. It is separated from orange-flowered *T. crocata* from shale soils in the same region primarily by flower colour, but it seems that the style also branches slightly lower down and the tepals are never as broad as seen in some plants of *T. crocata*. The two species have different soil preferences and no intermediates between them have been found in the wild. Putative hybrids between *T. squalida* and *T. deusta* have been recorded near Albertinia.

Sect. 4. **Montbretiopsis** *(L.Bolus) J.C.Manning & Goldblatt*, new rank. *Montbretiopsis* L.Bolus in South African Gardening and Country Life 19: 215 (1929). Type species: *Tritonia florentiae* (Marloth) Goldblatt

Leaves ± falcate, leathery, with translucent midvein. *Stem* very short or subterranean. *Spike* short or modified into several 1-flowered units; bracts membranous or papery and translucent or pale straw-coloured. *Flowers* zygomorphic, funnel-shaped, cream-coloured to orange or bright yellow; perianth tube funnel-shaped, as long as or longer than tepals; lower tepals with long, crest-like calluses on lower half. *Stamens* arcuate, unilateral. *Capsules* large, sometimes inflated, ovoid to ellipsoid, 12–20 mm long.

Species 2: western interior South Africa.



The section includes two short-stemmed or acaulescent species from the arid western interior of South Africa, characterised by their tight fan of falcate or recurved, leathery leaves and large, fragrant, cream-coloured to yellow or orange flowers with conspicuous, long, crest-like calluses on the lower tepals. The bracts are relatively large and translucent or pale straw-coloured finely stippled or speckled with brown. The capsules are large, 12–20 mm long, and in *Tritonia florentiae* are markedly inflated. This species is unique in the genus in having an inflorescence of several 1-flowered units, interpreted as a branched spike with each branch bearing a solitary terminal flower. This led to its segregation in the new genus *Montbretiopsis* L.Bolus (1929) but a similar specialised inflorescence is found in short-stemmed species in several other genera, and it was later transferred to *Tritonia* (Goldblatt, 1974).

18. **Tritonia karooica** *M.P.de Vos* in Journal of South African Botany 49: 407 (1983). Type: South Africa, [Eastern Cape], Murraysburg, *Tyson 311* (BOL, holo.; BM, K, NH, SAM, iso.).

Plants (60–)80–150 mm high. *Corm* moderately deep-seated, obovoid-conic, 15–30 mm diam.; tunics of moderately coarse-textured fibres sometimes thickened into claws at base, extending upward in a fibrous and papery collar. *Stem* suberect, shortly exserted up to 50 mm above leaves, usually simple, rarely with up to 3 suberect branches from base. *Leaves* 6 to 10, in close fan, falcate or rarely suberect, slightly succulent, 30–80(–100) × 3–7 mm, obtuse or acute, with translucent main vein only, cauline leaves all subbasal or rarely shortly exserted above basal fan, leaf-like. *Spike* inclined, moderately dense, 2-ranked, 2- to 6-flowered; bracts dry and papery, pale or pinkish translucent, minutely speckled brown above, outer (12–)15–20 mm long, acute or 3-toothed with middle tooth largest, inner subequal or slightly longer. *Flowers* zygomorphic, dull yellow or brownish yellow or sometimes cream, orange or salmon-coloured, conspicuously dark-veined; perianth tube funnel-shaped, sharply bent, 25–32 mm long, widening in upper ½ to ± 8–10 mm diam.; tepals unequal, upper 3 slightly wider, spreading or recurved, elliptic to obovate, 12–18 mm long, upper 7–12 mm wide, lower 6–7 mm wide, each with long, crisped or undulate, crest-like callus on lower ½ extending shortly into throat, 0.5–0.8 mm high and 6–10 mm long. *Filaments* unilateral, arcuate, 15–22 mm long, not or scarcely exserted; anthers 6–7 mm long; pollen creamy white. *Style* 28–35 mm long, dividing near middle of anthers, branches 4–5 mm long. *Capsules* shortly ellipsoid-trigonous or obovoid-trigonous, 8–12 mm long. *Flowering time*: August, September or sometimes early October.

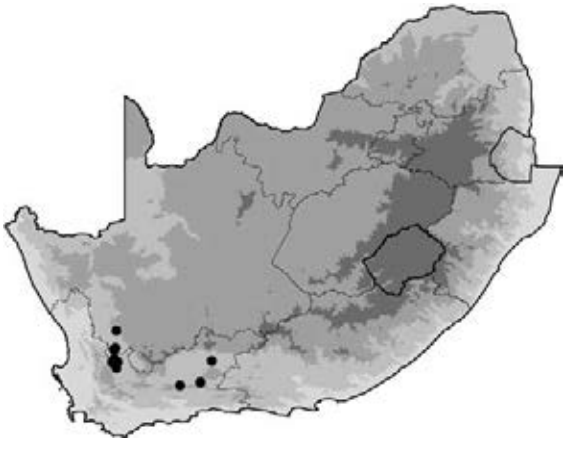
Distribution and ecology: extending through the arid southwestern interior of South Africa, from northeast of Springbok through Bushmanland eastward to Kakamas and south through Calvinia and the Roggeveld to Leeu Gamka and inland across the Upper Karoo to Hanover and Carnarvon; on dry, stony or gravel flats.

Diagnosis: recognised by its short stature, tight fan of usually falcate or strongly curved, leathery leaves with the cauline leaves seldom visible above the basal fan,

Distribution of ***Tritonia karooica***.

and short, inclined spike of large, funnel-shaped flowers with a sharply bent perianth tube 25–32 mm long and about twice as long as the tepals. The stem is shortly exserted above the leaves and the fragrant flowers are pale creamy to dull orange, with conspicuous dark veins, and long, bright yellow ridge or crest-like calluses less than 1 mm high on the lower tepals extending into the throat.

The congested fan of recurved, leathery leaves, short stem, and large, funnel-shaped flowers with long, crest-like calluses, and large capsules all suggest a relationship with *Tritonia florentiae* from the Tanqua and western Great Karoo. Flowering in the winter in May and June, acaulescent *T. florentiae* has bright yellow flowers without conspicuous veins and a perianth tube about as long as the tepals.



19. **Tritonia florentiae** *(Marloth) Goldblatt* in Bothalia 11: 281 (1974). *Gladiolus florentiae* Marloth: 241 (1912). *Montbretiopsis florentiae* (Marloth) L.Bolus: 215 (1929). Type: South Africa, [Western Cape], near Groot Tygerberg, Prince Albert, *Marloth 4452* (PRE, holo.; BOL, iso.).

Plants 50–70 mm high. *Corm* moderately deep-seated, ovoid-conical, 10–20 mm diam.; tunics of fine-textured fibres, extending upward in a fibrous and papery neck. *Stem* subterranean, with up to 4 branches ± 10 mm long. *Leaves* 5 to 8, in a close fan, falcate, slightly succulent, 30–70 × 3–6 mm, acute, with translucent main vein, cauline leaves not exserted above basal fan, dry and bract-like. *Inflorescence* of up to 4, 1-flowered spikes hidden among leaf bases; bracts membranous or dry and papery, soon crumpled, translucent or pale straw-coloured translucent and finely stippled or speckled brown, 12–18 mm long, outer acute, soon lacerated, inner 2-toothed. *Flowers* zygomorphic, bright yellow, reddish in throat, lower tepals with red arrow-shaped mark and bright yellow median calluses; perianth tube funnel-shaped, (15–)18–25(–30) mm long, filiform in lower 8–10(–15) mm widening strongly in upper ½ to ± 8–10 mm diam.; tepals recurved distally, (15–)20–25 mm long, dorsal largest, obovate, 13–15(–18) mm wide, upper laterals oblanceolate, 8–10 mm wide, lower tepals oblanceolate, 5–7(–9) mm wide, each with long, crisped or undulate, crest-like callus on lower ½, 0.5–1.0 mm high, 8–10 mm long. *Filaments* unilateral, arcuate, 10–13 mm long, shortly exserted up to 5 mm; anthers 5–6 mm long, pale to mauve; pollen pale yellow. *Style* 25–33 mm long, dividing shortly beyond anthers, branches 3–4 mm long. *Capsules* inflated, ovoid-trigonous to ellipsoid-trigonous, 12–20 mm long. *Flowering time*: May to June.

Distribution and ecology: a local endemic of dry inland basins in Western Cape, South Africa, recorded from the northern half of the Tanqua Karoo and further east in the western Great Karoo between Prince Albert and Beaufort West; on gravel flats in washes and drainage lines, flowering in winter and responding rapidly to early winter rains that fall erratically.

Diagnosis: a dwarf species, *Tritonia florentiae*, the only acaulescent member of the genus, has a tight fan of recurved, leathery leaves and large, fragrant, bright yellow flowers with long, crest-like calluses on the lower tepals. The species exhibits some highly unusual features, presumably associated with its ecology and habit. The inflorescence is reduced to several short, one-flowered branches, a development that has evolved several times in acaulescent members of several different genera of Crocoideae, including *Crocus*, *Duthiastrum* and *Syringodea*. The large, inflated capsules are unique in the genus.

Tritonia florentiae resembles spring-flowering *T. karooica* in general habit, notably the tight fan of recurved, leathery leaves, and large flowers with long, crest-like calluses on the lower tepals, but the latter has an aerial stem, cream-coloured to dull orange flowers with conspicuous dark veins and a relatively longer, sharply bent perianth, about twice as long as the tepals.

Distribution of ***Tritonia florentiae***.

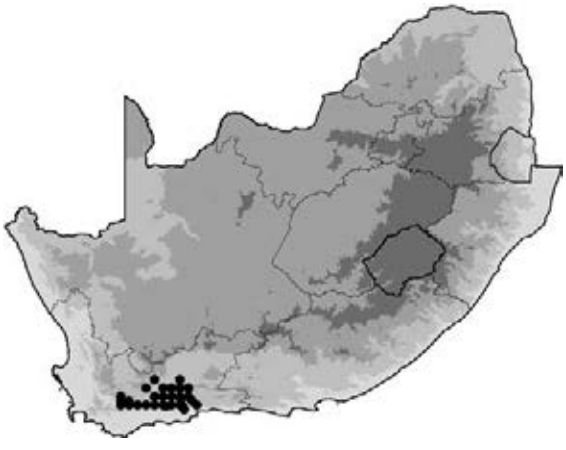
Sect. 5. **Pallidae** *J.C.Manning & Goldblatt*, new section. Type species: *Tritonia pallida* Ker Gawl.

Corm moderately deeply seated. *Leaves* shorter or longer than spike, linear to lanceolate, plane with thickened midrib. *Spike* erect, moderately dense; bracts papery and translucent speckled and flecked brown distally. *Flowers* zygomorphic, white to pink; perianth tube long and cylindric, widening and funnel-shaped distally, two to four times as long as tepals; lower tepals often with thickened median ridges or rarely with obliquely quadrate callus on median tepal and smaller peg-like calluses on lower laterals. *Stamens* arcuate, unilateral, inserted near top of tube; anthers apiculate, purple. *Capsules* ellipsoid, 12–20 mm long.

Species 3: southern Western Cape, South Africa.

A group of three, parapatric species from the Little Karoo and southern coast of Western Cape, with pale, long-tubed flowers usually lacking calluses and adapted to pollination by long-proboscid flies in the families Tabanidae and Nemestrinidae. The species often have a thickened, ridge-like callus on the lower tepals, sometimes high and axe-like in *Tritonia pallida*, suggesting an alliance with sect. *Montbretia*. De Vos (1982, 1999) included the florally similar *T. bakeri* here but this species stands apart in its distinctive, more-or-less terete leaves lacking a distinct main vein and its salver-shaped, inverted flowers.

20. **Tritonia pallida** *Ker Gawl.* in Curtis's Botanical Magazine 31: sub t. 1275 (1810), as a replacement name for *Gladiolus longiflorus* Jacq.: 6 (1795 [1788–1795]) [not *T. longiflora* (P.J.Bergius) Ker Gawl.]. *Waitzia pallida* (Ker Gawl.) Heynh.: 855 (1841). *Montbretia pallida* (Ker Gawl.) Baker: 168 (1877). Type: South Africa, without precise locality, illustration in Jacq.: t. 262 (1794 [1788–1795]).



Tritonia tayloriae [as *taylorae*] L.Bolus: 44 (1926). *T. pallida* subsp. *tayloriae* (L.Bolus) M.P.de Vos: 362 (1983), new synonym. Type: South Africa, [Western Cape], near Oudtshoorn, Bankhoogte, dry hills, *Taylor 251* (BOL, holo.).

Tritonia ventricosa Dehnh.: 162 (1839). Type: unnumbered plate '*Tritonia* [...] *ventricosa* Dehnh.' in Botanical Garden of Naples, lecto., designated by Del Guacchio et al.: 1413 (2016).

Plants 150–300(–450) mm high. *Corm* subglobose, 10–20 mm diam., sometimes deep-seated; tunics of fine-textured fibres, sometimes extending into a fibrous or papery neck. *Stem* usually flexed outward above upper leaf and slightly inclined, simple or with up to 2(3) suberect branches from lower ½. *Leaves* 5 to 8, often drying at flowering, suberect or arcuate, narrowly lanceolate, 30–150(–200) × (3–)5–10(–15) mm, acute or acuminate, thin-textured with raised main vein, ± ½ as long as flowering stem, cauline leaves dry, clasping, bract-like. *Spike* inclined, ± 2-ranked, rather lax, 4- to 10-flowered; bracts dry and papery, pale and translucent below, densely speckled and flecked reddish to dark brown above or at tips, outer (7–)10–15(–18) mm long, minutely ± 3-toothed, often recurved at tips, inner slightly shorter, bifid. *Flowers* zygomorphic, suberect, white or cream-coloured to pale lilac with dark veins, especially on tube, lower 3 tepals often with greenish yellow median streak or callus, rarely outlined with red or with red lines at base, unscented; perianth tube ± cylindric, (30–)45–65(–70) mm long, straight below, curved outward and widening in upper 7–10 mm to 5–8 mm diam.; tepals obtuse, dorsal largest, suberect or curved outward, upper (10–)15–20 mm long, dorsal obovate to suborbicular, 8–13 mm wide, upper laterals oblong-elliptic, 5–8 mm wide, lower oblong, 8–15 × 4–6 mm, without calluses or with low, thickened basal ridge, usually best developed on lower median and sometimes oblong and ± 1 mm high, rarely lower median tepal with a forward-directed, obliquely quadrate callus up to 2 mm high and lower laterals with smaller peg-like calluses. *Filaments* unilateral and arcuate, (7–)10–14 mm long, shortly exserted; anthers 4–8 mm long, apiculate, purple; pollen violet. *Style* dividing shortly below or above anther tips, branches 2–4 mm long. *Capsules* ellipsoid, 12–20 mm long. *Flowering time*: late September to early November.

Distribution and ecology: centred in the western Little Karoo in Western Cape, South Africa, extending from Robertson to Calitzdorp and the Gamkaberg, also along the northern foothills of the Witteberg and Swartberg; typically on stony shale slopes and banks in succulent karroid shrubland with the corms wedged in crevices in rocks.

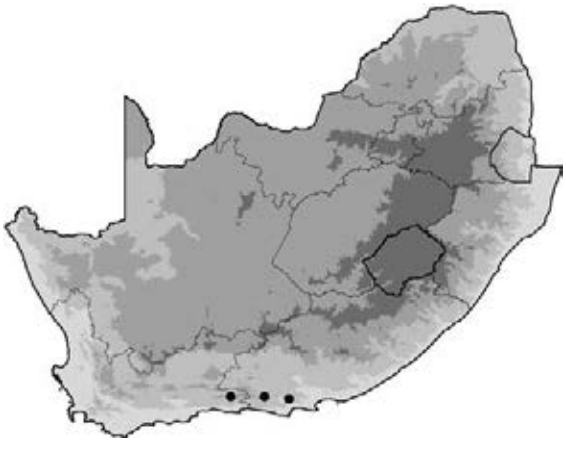
Diagnosis: distinguished from other species with white, long-tubed flowers by its narrowly lanceolate, often spreading, soft-textured leaves, typically about half as long as the flowering stem and mostly 10–15 mm wide with a prominent main vein and the ± 3-toothed outer bracts mostly 7–10(–15) mm long. The lower three or

Distribution of ***Tritonia pallida***.

only the median tepal often has a yellow ridge-like or low, oblong callus near the base. Rarely, especially in the plants on the Rooiberg and Gamkaberg, the calluses are enlarged into obliquely square teeth up to 2 mm high, as found in sect. *Montbretia*. Populations near Robertson are distinctive in having longitudinal red streaks near the bases of the lower tepals.

Plants with a shorter perianth tube, 30–35(–45) mm long vs. 45–65(–70) mm long, were segregated as subsp. *tayloriae* by De Vos (1983). Shorter-tubed populations are recorded from the western and eastern periphery of the range of the species, between Robertson and Montagu, and north and south of Calitzdorp. They do not differ in any other way from typical plants, and short- and long-tubed populations display a similar variation in the development of a callus on the median lower tepal. In the absence of any clear geographical pattern we regard the short-tubed populations as local variants.

Tritonia pallida can be confused with the parapatric *T. flabellifolia*, which ranges from the Riviersonderend Mtns eastward along the foot of the coastal ranges as far as Riversdale, but that species has distinctive attenuate-aristate bracts mostly 15–40 mm long and stiffly erect, linear to linear-lanceolate, attenuate leaves mostly 4–10 mm wide.



21. **Tritonia linearifolia** *Goldblatt & J.C.Manning* in Bothalia 41: 173 (2011). Type: South Africa, Eastern Cape, Joubertina, Kouga Mtns, valley of Dwarsrivier west of Kransfontein Farm, 12 Dec. 2009, *Manning 3244* (NBG, holo.; MO, iso.).

Plants mostly 150–500 mm high. *Corm* subglobose or depressed-globose, 10–20 mm diam., tunics somewhat papery, of fine-textured fibres, extending in a papery or fibrous neck, with clusters of cormlets at base on short, fasciated stolons. *Stem* ± erect below, simple or with up to 2 branches. *Leaves* 7 to 12, dry at flowering, linear, suberect or trailing, slightly twisted, ± as long as or slightly longer than stem, (10–)20–60 × 1–2 mm, soft-textured, main vein moderately thickened. *Spike* inclined, ± 2-ranked, (2–)4- to 8-flowered; bracts soft-textured, papery of membranous, translucent or straw-coloured lightly flushed or speckled brownish distally, outer 8–12 mm long, acute or minutely 3-toothed, inner bracts slightly shorter, bifid. *Flowers* zygomorphic, white with purple veins on reverse, lower 3 tepals with narrow, median, yellowish green longitudinal mark at base, unscented; perianth tube cylindric, 35–45 mm long, straight but curved outward and widening in upper 5–7 mm to 5–8 mm diam.; tepals unequal, uppermost largest, dorsal and lower median tepals suberect, other tepals spreading in distal half, dorsal tepal ovate-elliptic, 18–20 × 10–12 mm, remaining tepals oblong, 18–20 × 5–7 mm, lower 3 tepals with low, median, ridge-like callus. *Filaments* arcuate and unilateral, 13–16 mm long; anthers 5–6 mm long, apiculate, purple; pollen purple. *Style* dividing opposite middle to apex of anthers, branches ± 2 mm long. *Flowering time*: early to mid-December.

Distribution and ecology: centred in the Kouga and Baviaanskloof Mtns in Eastern Cape but also recorded from the northern foothills of the Fouriesberg at the western end of the Outeniqua Mtns in Western Cape, South Africa; on cooler south-facing sandstone lower slopes in arid and grassy fynbos, with the corms wedged among rocks.

Diagnosis: recognised by the linear, grass-like leaves as long as the flowering stem or longer, 1–2 mm wide and dry at flowering, and inclined spikes of white, long-tubed, zygomorphic flowers with low, greenish yellow, ridge-like calluses on the lower tepals. The corms bear short, fasciated stolons and many small cormlets. The species flowers in summer, in December, at which time the leaves are dry and withered. The flowers are almost indistinguishable from those of *Tritonia pallida* and the two may comprise a vicariant species pair. That species, centred in the western and central Little Karoo, has lanceolate leaves mostly 8–15 mm wide and about half as long as the flowering stem, and occurs on shale slopes, primarily in renosterveld or transitional vegetation types, flowering from mid-September to late October.

The long, linear leaves of *Tritonia linearifolia* may lead to confusion with the partially sympatric *T. bakeri*, a long-tubed species widespread through the Little Karoo from Ladismith to the Long Kloof, but the leaves of *T. bakeri* are highly characteristic, fleshy and semi-terete in section when fresh, without thickened main vein or margins. Flowering is also somewhat earlier, mainly October to November, at which time the foliage is still green. The two species are florally very different, although this is best seen when alive. *Tritonia linearifolia* has zygomorphic flowers with arcuate stamens whereas the perianth in *T. bakeri* is almost actinomorphic and salver-shaped, with the flowers inverted, curved or slightly twisted at the base, so that the dorsal tepal is lowermost and the stamens almost central with the anthers facing upwards.

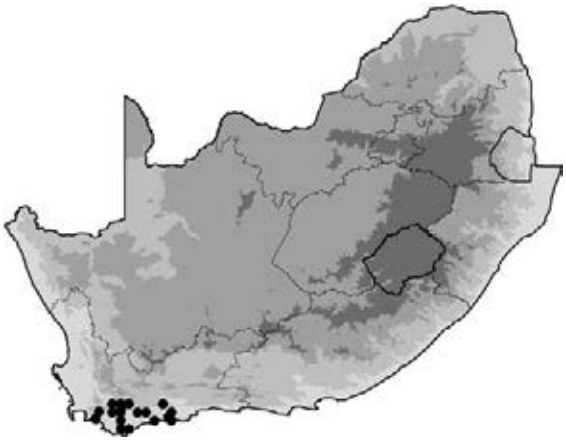
Distribution of ***Tritonia linearifolia***.

22. **Tritonia flabellifolia** *(D.Delaroche) G.J.Lewis* in Journal of South African Botany 7: 30 (1941). *Ixia flabellifolia* D.Delaroche: 24 (1766). *Acidanthera flabellifolia* (D.Delaroche) N.E.Br.: 135 (1929). Type: South Africa, without precise locality or collector [L-Herb. Van Royen, neo., designated by Goldblatt & Barnard (1970)].

Gladiolus flavus [Soland. in] Aiton: 65 (1789). *Tritonia flava* (Aiton) Ker Gawl.: 228 (1804b). *Freesea flava* (Aiton) Eckl.: 30 (1827), illegitimate name [genus not validly published]. *Waitzia flava* (Aiton) Kreysig: 52 (1829). *Montbretia flava* (Aiton) Heynh.: 417 (1847). Type: South Africa, without precise locality, cultivated in Great Britain, *Paterson s.n.* (BM, holo.).

Gladiolus roseus Jacq.: 5 (1795 [1788–1795]). *Watsonia amoena* Ehrh. ex Pers.: 43 (1805), as a replacement name for *G. roseus* Jacq. [not *Watsonia rosea* Ker Gawl. (1804b)]. *Tritonia rosea* (Jacq.) Aiton: 91 (1810). *Waitzia rosea* (Jacq.) Heynh.: 855 (1841). *Montbretia rosea* (Jacq.) Voigt: 610 (1845). *Tritonixia rosea* (Jacq.) Klatt: 356 (1882). Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 261 (1795 [1788–1795]).

Tritonia capensis var. *major* Ker Gawl.: sub t. 1531 (1813), new synonym. *T. flabellifolia* var. *major* (Ker Gawl.) M.P.de Vos: 367 (1983): Type: South Africa, without precise locality or collector, illustration in Ker Gawl: t. 618 (1802b).



Tritonia flabellifolia var. *thomasiae* M.P.de Vos: 368 (1983), new synonym. Type: South Africa, [Western Cape], between Bot River and Hawston, *Thomas s.n.* (NBG, holo.; NBG, iso.).

[*Gladiolus amoenus* Ehrh. ex Roem. & Schult.: 435 (1817), invalid name only in synonymy, identity uncertain.]

[*Freesea secunda* Eckl.: 30 (1827), invalid name without description.]

[*Tritonia secunda* Eckl. ex Steud.: 719 (1841), invalid name without description.]

Plants 150–300(–450) mm high. *Corm* subglobose or depressed-globose, 10–20(–30) mm diam., tunics of fine-textured fibres, extending in a papery or fibrous neck. *Stem* ± erect below, inclined above, uppermost cauline leaf, simple or up to 3-branched. *Leaves* 6 to 10, drying and brown at flowering, stiffly suberect or arcuate, ± reaching to base of spike, linear to linear-lanceolate, 50–150(–200) × (2–)4–6(–10) mm, acuminate to attenuate, firm, with main vein moderately thickened, secondary veins prominent and lightly thickened, cauline leaves smaller, entirely sheathing. *Spike* inclined, subsecund, 3- to 7-flowered; bracts dry and papery, translucent below, pale brownish densely speckled with dark reddish brown above, outer (10–)15–30(–50) mm long, acuminate or attenuate-aristate, rarely with 3 acuminate tips held close together, keeled with strong median vein, inner slightly to much shorter than outer, bifid-aristate. *Flowers* zygomorphic, white or cream-coloured to pale pink with darker veins, lower 3 tepals with median red streak or narrow yellow mark outlined with red, unscented; perianth tube cylindric or narrowly funnel-shaped, (30–)35–60(–65) mm long, slender and straight but curved outward and widening in upper 10–20 mm to 8–10 mm diam.; tepals obtuse, uppermost largest, often suberect, others spreading distally, dorsal obovate, 17–25 × 10–15 mm, remaining tepals oblanceolate, 13–20 × 5–8 mm, without calluses. *Filaments* unilateral, arcuate, (13–)15–18 mm long; anthers 5–7(–9) mm long, apiculate, purple; pollen purple. *Style* dividing shortly below or beyond anther apices, branches 4–7 mm long. *Capsules* obovoid, 7–10 mm long. *Flowering time*: early to mid-December.

Distribution of ***Tritonia flabellifolia***.

Distribution and ecology: endemic to the southern coastal districts of Western Cape, South Africa, from Botrivier and the lower northern and southern slopes of the Riviersonderend Mtns to Bredasdorp and across the coastal plain south of the Langeberg as far east as Riversdale; on stony clay slopes and shale outcrops in renosterveld or transitional fynbos vegetation.

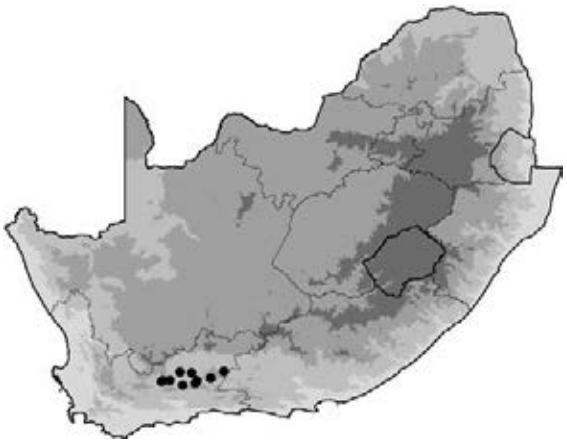
The flowers are pollinated by long-proboscid flies, including *Philoliche rostrata* (Tabanidae).

Diagnosis: distinguished from the florally similar *Tritonia pallida* from the Little Karoo by always lacking calluses on the lower tepals, which are marked with a red or yellow and red streak, and by its stiffly erect, narrowly lanceolate-attenuate leaves, mostly 4–10 mm wide, and distinctive attenuate-aristate bracts mostly 15–40 mm long.

Long-tubed plants with the perianth tube (45–)50–65 mm long were distinguished by De Vos as var. *major* but these forms grade imperceptibly into typical var. *flabellifolia* with perianth tube 30–40 mm long. Both forms have the tube two or three times as long as the tepals. A population between Hawston and Botrivier at the extreme western edge of the range with pink

flowers and relatively larger tepals was recognised as var. *thomasiae* by De Vos (1983). This taxon, still known only from the type collection and now probably extinct, was distinguished by its perianth tube, 30–45 mm long and ±1.5 times as long as the tepals but we have measured the flowers on the type and find them to have the perianth tube twice as long as the tepals, thus no different from the typical variety.

Sect. 6. **Pseudopectinatae** *J.C.Manning & Goldblatt*, new section. Type species: *Tritonia tugwelliae* L.Bolus



Leaves distichous, falcate, with ± crisped or undulate margins. *Spike* strongly deflexed and horizontal, secund and densely-flowered thus ± pectinate; bracts small, uniformly pale to pale reddish brown. *Flowers* zygomorphic, suberect, white with small red or purple spot on lower median or all lower tepals; perianth tube slender and subcylindric, much longer than tepals; lower tepals narrower than upper, without calluses. *Stamens* arcuate, unilateral; anthers violet or purple. *Capsules* unknown.

Species 1: western Great Karoo of Western Cape, South Africa.

A monotypic section from the western Great Karoo, Western Cape, with a fan of falcate leaves with crisped or undulate margins, and a horizontal spike of small, white, long-tubed flowers arranged in a dense, comb-like spray, with small, pale pinkish or brownish bracts without darker tips. The sole species was included by De Vos (1982) in sect. *Pectinatae* but is anomalous there in its unspecialised, plane leaves and small, uniformly pale bracts without dark upper margins.

23. **Tritonia tugwelliae** *L.Bolus* in Annals of the Bolus Herbarium 4: 45 (1926). Type: South Africa, [Western Cape], near Prince Albert, *Tugwell s.n. BOL13487* (BOL, holo.).

Plants 100–150(–200) mm high. *Corm* conical, 10–25 mm diam.; tunics of fine to coarse fibres. *Stem* suberect, simple or up to 3-branched. *Leaves* 6 to 8, lanceolate-falcate, 50–100 × (3–)5–10(–12) mm, acute or acuminate, margins undulate or crisped, cauline leaves smaller and often dry and bract-like. *Spike* sharply deflexed, horizontal, secund, densely 5- to 15-flowered; bracts small, dry and membranous, translucent or pale brown, lightly speckled in upper ½, outer 3–8 mm long, obtuse, acute or obscurely 3-toothed, inner slightly shorter, bifid. *Flowers* zygomorphic, suberect, white with red streaks in throat and small red or purple dot on lower 3 or only lower median tepal, unscented; perianth tube ± cylindric, curved outward above, (20–)25–30 mm long, widening gradually in upper 5 mm to ± 3 mm diam. and laterally compressed; tepals unequal, upper 3 largest, dorsal spreading and upper laterals reflexed, oblong-spathulate, 7–9 × 3–4 mm, lower 3 spreading, oblong, 6–8 × 2–3 mm, without calluses. *Filaments* unilateral and arcuate, 5–7 mm long, enclosed by upper part of gullet, scarcely exserted; anthers ± 3 mm long, lilac; pollen purple. *Style* dividing at or shortly beyond anther apices, branches 1.5–2.0 mm long. *Flowering time*: September.

Distribution of ***Tritonia tugwelliae***.

Distribution and ecology: local in the western Great Karoo in Western Cape, South Africa, between Laingsburg and Prince Albert; on dry stony flats, often in seasonal washes and drainage lines.

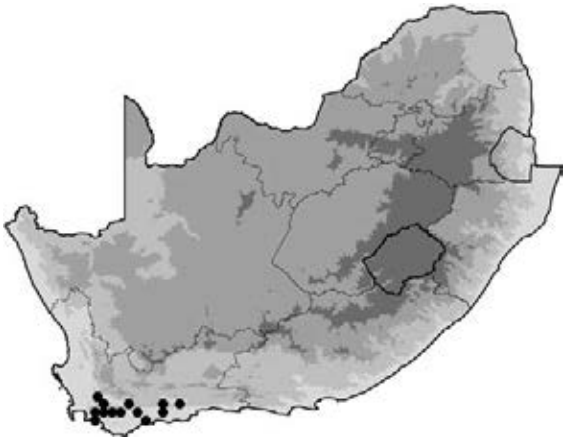
Diagnosis: a distinctive species with a remarkable superficial resemblance to *Freesia verrucosa*, and recognised by the fan of falcate, acuminate leaves with crisped or undulate margins and the dense, horizontal spike of long-tubed, white flowers with cylindric perianth tube 10–30 mm long, compressed in the gullet, with the upper lateral tepals sharply reflexed behind the spreading dorsal tepal.

Sect. 7. **Pectinatae** *M.P.de Vos* in Journal of South African Botany 48: 143 (1982). Type species: *Tritonia crispa* (L.f.) Ker Gawl. = *T. undulata* (Burm.f.) Baker

Leaves morphologically specialised through the development of one or more longitudinal flanges from the face or adaxial margin of the blade, the edges more-or-less revolute, either plane or crispulate-undulate, sometimes ciliolate or ciliate. *Spike* inclined to horizontal, secund and densely-flowered thus ± pectinate; bracts with dark, red-brown, crisped upper margins. *Flowers* zygomorphic, suberect, white or cream-coloured

to pink with red markings on lower tepals; perianth tube slender and subcylindric, much longer than tepals; lower tepals narrower than upper, without calluses but lowermost sometimes with slight median thickening in throat. *Stamens* arcuate, unilateral; anthers violet or purple. *Capsules* shortly ellipsoid, 5–7 mm long.

Species 3: mountians of Western Cape, South Africa.



A group of three closely allied, allopatric species from fynbos habitats in the western mountains of Western Cape, all with pale, long-tubed flowers adapted to pollination by long-proboscid flies in the families Nemestrinidae and Tabanidae. The section is characterised by its distinctive leaf structure, the blade developing one or two longitudinal flanges from the lower margin and the upper face, these secondary elaborations assuming the appearance of the true margins. These 'false margins' are more-or-less inrolled and the leaf blade is thus variously involute on one or both faces. The bracts have dark reddish brown upper margins and the spikes are inclined or horizontal with the flowers closely arranged, thus comb-like in appearance. A fourth species from the western Great Karoo, *Tritonia tugwelliae*, with similar inflorescence and flowers was included here by De Vos (1982), but it has anatomically unspecialised plane leaves and smaller, unmarked bracts and is removed here to a separate section, *Pseudopectinatae*.

24. **Tritonia cooperi** *(Baker) Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 358 (1882). *Morphixia cooperi* Baker: 237 (1876). *Ixia cooperi* (Baker) Baker: 166 (1892). Type: South Africa, [Western Cape], Worcester District, *Cooper 1683* [K, lecto., designated by De Vos: 156 (1982)].

Gladiolus longiflorus L.f.: 96 (1782). *Hyalis longiflora* (L.f.) Salisb.: 318 (1812). *Freesea longiflora* (L.f.) Eckl.: 30 (1827), illegitimate name, genus invalid. *Waitzia longiflora* (L.f.) Kreysig: 52 (1829). *Babiana longiflora* (L.f.) Steud.: 686 (1840). *Montbretia longiflora* (L.f.) Voigt: 610 (1845). *Crocosmia longiflora* (L.f.) Klatt in W.C.H.Peters: 516 (1864). *Tritonia longiflora* (L.f.) N.E.Br.: 25 (1928), illegitimate homonym, not *T. longiflora* (P.J.Berg.) Ker Gawl. (1804a). *Tritonia longituba* R.C.Foster: 45 (1936), as a new name for *T. longiflora* (L.f.) N.E.Br. Type: South Africa, without precise locality, *Thunberg s.n.* [UPS-THUNB 1041, lecto., designated by De Vos: 156 (1982)].

Tritonia cooperi subsp. *quadrialata* M.P.de Vos: 157 (1982), new synonym. Type: South Africa, [Western Cape], Potberg, Bredasdorp, 16 Nov. 1965, *Tropper s.n.* (NBG [as STE], holo.).

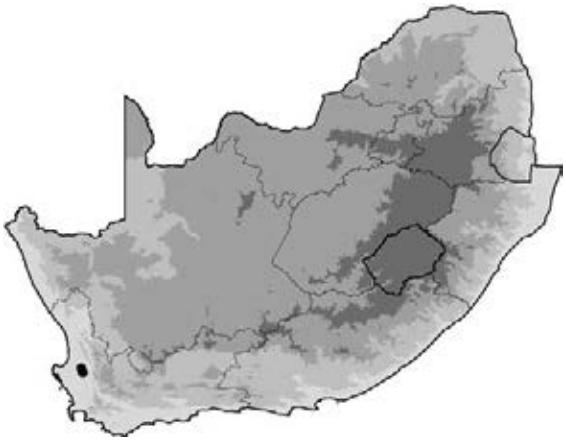
Plants mostly 250–350 mm high. *Corm* conic, 15–30 mm diam.; tunics of fine fibres, often extending upward in a fibrous or papery collar. *Stem* suberect or flexed outward, simple or 1- or 2-branched. *Leaves* 5 to 8, suberect, linear and grooved or almost quadrangular to lanceolate with four longitudinal flanges, thus H-shaped in section, with long clasping base, (50–)100–200 × (0.5–)2.0–10.0(–20.0) mm, acute or acuminate, with prominent main vein, margins sometimes ciliolate, cauline leaves smaller, entirely sheathing. *Spike* suberect or deflexed, secund-pectinate, densely 5- to 10-flowered; bracts dry and membranous, sometimes greenish below, upper margins dark reddish brown, outer 5–10(–13) mm long, irregularly 3-toothed with median tooth smaller or slightly lacerate, upper margins crisped, inner subequal or slightly shorter, bifid. *Flowers* zygomorphic, sometimes inverted, cream- to pale apricot-coloured or pale to bright pink, lower tepals with a lozenge-shaped red or purple median marking sometimes with a yellow central stripe, unscented; perianth tube cylindric, widening gradually above, slightly curved, (30–)40–55 mm long, widening up to 5–8 mm diam.; tepals unequal, dorsal largest, suberect, obovate-spathulate, 12–18(–24) × 7–15(–20) mm, upper laterals spreading, 5–15 mm wide, lower 3 oblanceolate-spathulate, 4–9 mm wide, without calluses. *Filaments* unilateral and arcuate, 8–12(–16) mm long, inserted 2–3 mm from mouth of tube, exserted; anthers 4–6(–8) mm long, purple. *Style* dividing shortly below or above anther tips, branches 3–5(–7) mm long. *Capsules* shortly ellipsoid, ± 7 mm long. *Flowering time*: late mid-November to December.

Distribution of ***Tritonia cooperi***.

Distribution and ecology: restricted to the coastal plain and mountains of Western Cape, South Africa, from Du Toit's Kloof to Kogelberg and east across the Riviersonderend Mtns and Langeberg to Riversdale and the Potberg; on sandstone slopes in fynbos, flowering well after fire.

Diagnosis: distinguished from other species in sect. *Pectinatae* by the linear to lanceolate leaves that develop broad wings on the edges typically rendering them H-shaped in section. The wing edges are smooth or ciliolate. The flanges or wings are flattened when pressed, making it difficult to establish the form of the leaves in herbarium specimens. The species resembles *Tritonia undulata* closely in its flowers but lacks the inrolled and crisped or undulate leaf edges characteristic of that species. Plants from the Riviersonderend Mtns have

broader leaves with poorly or incompletely developed wings and look vegetatively remarkably like *T. lancea* but the flowers are clearly bilabiate with longer tubes, 30–55 mm long.



Plants with broader leaves 6–10 mm wide from the coastal plain and lower mountain slopes between Betty's Bay and Cape Infanta were segregated by De Vos (1982) as subsp. *quadrialata*. Exceptionally broad-leaved plants have been collected from the Riviersonderend and Potberg ranges but these represent the extreme in a more-or-less continuous range of variation.

25. **Tritonia lancea** *(Thunb.) N.E.Br.* in Journal of the Linnean Society of London, Botany 48: 48 (1928). *Ixia lancea* Thunb.: 18 (1783). *Montbretia lancea* (Thunb.) Endl. ex Heynh.: 417 (1847). Type: South Africa, [Western Cape], below Piketberg, *Thunberg s.n.* (UPS-THUNB 963, holo.).

Ixia pectinata Vahl: 62 (1805). *Waitzia pectinata* (Vahl) Heynh.: 855 (1841). *Montbretia pectinata* (Vahl) Heynh.: 418 (1847). *M. lacerata* var. *pectinata* (Vahl) Baker: 168 (1877). *Tritonia crispa* var. *pectinata* (Vahl) Baker: 192 (1892). Type: South Africa, [Western Cape], without precise locality or collector (C-Herb. Vahl, holo.).

Plants mostly 150–250 mm high. *Corm* conic, 10–20 mm diam.; tunics of fine-textured fibres, often extending upward in a fibrous or papery collar. *Stem* flexed outward, then suberect, often flexuose, simple. *Leaves* 5 to 7, suberect, linear-lanceolate to lanceolate, with long clasping base, often contracted above sheath into filiform, petiole-like portion up to 100 mm long, 30–120 × 2–7(–10) mm, acute or acuminate, slightly concave with margins curved inward, often ciliate, with prominent main vein raised on concave surface, cauline leaves smaller, entirely sheathing. *Spike* suberect or deflexed, secund-pectinate, densely 2- to 7-flowered; bracts dry-membranous, sometimes greenish and leathery below, upper margins dark reddish brown, outer 7–10(–12) mm long, irregularly 3-toothed with median tooth smaller or slightly lacerate, crisped upper margins crisped, inner subequal or slightly shorter, bifid. *Flowers* zygomorphic, almost salver-shaped, sometimes inverted, white flushed red on reverse of tepals, lower tepals with 2 short red lines near base, unscented; perianth tube cylindric, (17–)20–25 mm long, widening up to 5 mm diam.; tepals subequal but upper 3 broader, oblanceolate or oblong, 12–18 × 7–10 mm, lower 5–7 mm wide, without calluses. *Filaments* unilateral, arcuate, 6–7 mm long, inserted 2–3 mm from mouth, shortly exserted; anthers ± 5 mm long, purple. *Style* 22–30 mm long, dividing opposite upper ½ of anthers, branches 3–4 mm long. *Capsules* shortly ellipsoid, 5–7 mm long. *Flowering time*: late August to September.

Distribution and ecology: a local endemic of upper elevations of the Piketberg in Western Cape, South Africa; on sandstone slopes in fynbos, flowering mainly after fire.

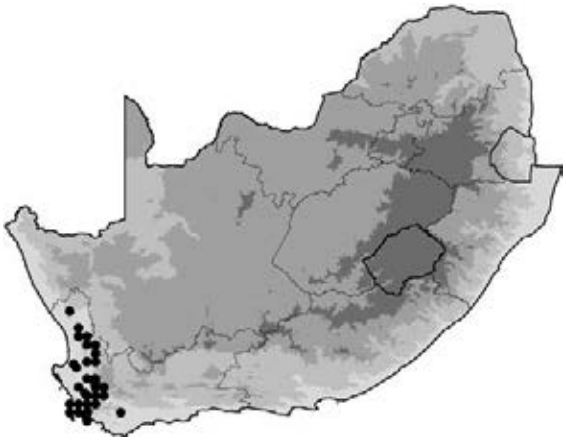
Distribution of ***Tritonia lancea***.

Diagnosis: distinguished from the other members of sect. *Pectinatae* by its linear-lanceolate leaves with slightly concave blade with margins inrolled but never crisped, and by its salver-shaped flowers with relatively short tube up to 25 mm long, spreading, subequal tepals, the lower three slightly smaller and marked with two short red lines near the bases, and short filaments 6–7 mm long. Both *Tritonia undulata*, with crisped leaf margins, and *T. cooperi* with winged leaf margins, have more markedly bilabiate flowers with longer tubes, usually more than 30 mm long, and filaments 8–12 mm long.

26. **Tritonia undulata** *(Burm.f.) Baker* in Journal of the Linnean Society, Botany 16: 163 (1877). *Ixia undulata* Burm.f.: 1 (1768). *Tritonixia undulata* (Burm.f.) Klatt: 357 (1882). Type: South Africa [Western Cape], without precise locality, collector unknown (G-BU, holo.).

Gladiolus crispus L.f.: 94 (1782). *Tritonia crispa* (L.f.) Ker Gawl.: t. 678 (1803c). *Freesea crispa* (L.f.) Eckl.: 30 (1827), illegitimate name, genus invalid. *Waitzia crispa* (L.f.) Kreysig: 52 (1829). *Montbretia crispa* (L.f.) Voigt: 610 (1845). *Acidanthera crispa* (L.f.) Pax: 155 (1887). Type: South Africa, [Western Cape], without precise locality, *A. Sparrman s.n.* (LINN 59.18, holo.).

Tritonia crispa var. *parviflora* Baker: 192 (1892). Type: South Africa [Western Cape], Winterhoek, Tulbagh, *C.L. Pappe s.n.* (K, holo.).



Tritonia crispa var. *grandiflora* Baker: 192 (1892). Type: South Africa [Western Cape], foot of Table Mt. below Kasteelpoort, Oct. 1883, *MacOwan 2389* (K, lecto., designated here).

Plants mostly 250–350 mm high. *Corm* conical, 10–20(–30) mm diam.; tunics of fine-textured fibres, often extending upward in a fibrous or papery neck. *Stem* suberect or flexed outward, simple or with up to 3 branches. *Leaves* 5 to 8, suberect, lanceolate to sword-shaped, with long clasping base, (50–)100–200 × (5–)10–15(–25) mm, acute or acuminate, plane with prominent main vein,

margins crisped to undulate and often ciliate, cauline leaves smaller and entirely sheathing. *Spike* suberect or inclined, secund-pectinate, densely 4- to 12-flowered; bracts dry and membranous, sometimes greenish below, upper margins dark reddish brown, outer (5–)7–12(–15) mm long, irregularly 3-toothed with median tooth smaller or slightly lacerate, upper margins crisped, inner ± equal or slightly shorter, bifid. *Flowers* zygomorphic, sometimes inverted, cream-coloured to pale yellow or shell-pink to bright or salmon-pink, lower tepals with a lozenge-shaped red or purple median marking sometimes with a yellow central stripe, unscented; perianth tube cylindric, (20–)40–60(–85) mm long, slightly curved, widening up to ± 7 mm diam.; tepals unequal, upper 3 largest, spreading, obovate-spathulate, (12–)15–20(–25) × 5–13 mm, lower 3 spreading, oblanceolate, 3–10 mm wide, without calluses. *Filaments* unilateral, arcuate, 8–12 mm long; anthers 3–6 mm long, purple. *Style* (32–)40–70(–85) mm long, dividing shortly below or above anther tips, branches 3–6 mm long. *Capsules* shortly ellipsoid, ± 7 mm long. *Flowering time*: late September to November.

Distribution and ecology: widespread along the lower slopes of the western mountains of Western Cape, South Africa, from Gifberg to Gordon's Bay; on stony sandstone slopes in fynbos, flowering stimulated by fire.

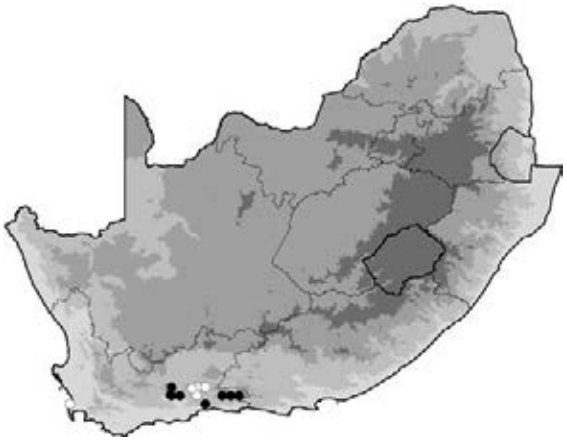
Diagnosis: distinguished in sect. *Pectinatae* by the plane, lanceolate to sword-shaped leaves with closely crisped and undulate, often ciliate margins. The only other species with crisped leaves and long-tubed flowers, *Tritonia tugwelliae* from the western Great Karoo, has plane, falcate leaves and uniformly pale bracts, thus evidently not immediately related to the species of sect. *Pectinatae* in which it was once included.

Distribution of ***Tritonia undulata***.

The length of the perianth tube in *Tritonia undulata* varies widely across its range, with a trend for longer tubes, 60–85 mm long, in populations in the north and west, from the Olifants River Valley along the coast to the Cape Peninsula, and shorter tubes, 22–50 mm, inland and to the south, from Tulbagh to Gordon's Bay. This pattern presumably reflects variation in proboscis length of the local pollinators, species of long-proboscid, nemestrinid or tabanid flies.

Sect. 8. **Subteretifoliae** *J.C.Manning & Goldblatt*, new section. Type species: *Tritonia bakeri* Klatt

Leaves compressed-cylindric or subterete, firm-textured, with several strands of sclerenchyma, appearing striate when dry; anatomically with marginal vein and associated sclerenchyma bundle present, lacking thickened marginal epidermal cells. *Spike* erect, moderately dense; bracts dry and papery, brown in upper ½. *Flowers* weakly zygomorphic, white to pink, somewhat salver-shaped; perianth tube subcylindric, ± twice as long as tepals, lower tepals without calluses. *Stamens* unilateral but suberect and almost central, inserted near top of tube; anthers violet. *Capsules* obovoid, 10–12 mm long.



Species 1: southern Western Cape, South Africa.

A monospecific section erected here for *Tritonia bakeri*, which was previously associated by De Vos (1982, 1983) with other species with pale, long-tubed flowers segregated here as sect. *Pallidae*. It differs markedly from them in its centric, subterete or compressed-terete leaves without an evident main vein and anatomically lacking a true margin, and in its subactinomorphic, salver-shaped flowers with almost central stamens lying above the dorsal tepal.

27. **Tritonia bakeri** *Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 358 (1882), as a new name for *Montbretia striata* Sol. ex Baker: 337 (1876), illegitimate homonym, not *M. striata* (Jacq.) Heynh. (1847). *T. striata* Klatt: 208 (1894), illegitimate homonym, not *T. striata* (Jacq.) Ker Gawl. Type: South Africa, 'Promont. b. Spei.', *Masson & Oldenburg s.n.* (BM, holo.).

[*Gladiolus striatus* Sol. ex Baker: 337 (1876), invalid name only in synonymy.]

Plants mostly 300–500 mm high. *Corm* subglobose, 15–30 mm diam., sometimes deep-seated; tunics of fine-textured fibres, extending into a thick, fibrous collar. *Stem* simple or with up to 2 suberect or weakly spreading branches. *Leaves* 5 to 8, ± erect, firm, compressed-cylindric or ± terete, (150–)200–300(–600) × 1–2(–3) mm, acute, striate with translucent veins when dry but without evident thickened main vein, sometimes as long as stem, cauline leaves dry and clasping, bract-like. *Spike* erect or arching, rather lax, (3–)6- to 10-flowered; bracts dry and

Distribution of ***Tritonia bakeri*** subsp. ***bakeri***, ●; subsp. ***lilacina***, ○.

papery, pale and translucent below and brown speckled dark brown at tips, outer (6–)10–15(–18) mm long, obtuse or ± 3-toothed with median tooth sometimes reduced, inner subequal, bifid. *Flowers* weakly zygomorphic, nodding, inverted, white to cream-coloured or pink to pale pink to rose-pink, darkly veined, unscented; perianth tube cylindric, curving outward, (20–)30–45(–55) mm long, slender, widening in upper 6–8 mm to 5–7 mm diam.; tepals subequal or outer, especially dorsal, wider, spreading, oblong to oblanceolate, (15–)20–25(–30) × (5–)7–10 mm but dorsal 8–14 mm wide, without calluses. *Filaments* unilateral, ± horizontal, (8–)15–20(–25) long, exserted; anthers 5–10 mm long, facing upward through inversion of flower, purple or cream; pollen violet or cream-white. *Style* dividing opposite upper ½ of anthers, branches 3–5 mm long. *Capsules* obovoid, 10–12 mm long. *Flowering time*: October to early December.

Distribution and ecology: restricted to the central and eastern Little Karoo, from Ladismith in Western Cape to the upper Long Kloof east of Avontuur in Eastern Cape, South Africa; on stony lower slopes, mainly on clay.

Diagnosis: readily recognised among the pale-flowered, long-tubed species of *Tritonia* by its slender, straight leaves, terete to elliptic in section without an evident main vein, and almost symmetrical, salver-shaped perianth with a slender, curved tube, the flowers tilted backward so that the anthers face upwards. The long-tubed species of sect. *Pectinatae* have plane leaves with a thickened main vein and zygomorphic, bilabiate flowers facing outward, with arcuate stamens held under the arching to horizontal dorsal tepal.

Populations from the southern foothills of the Swartberg between Calitzdorp and De Rust typically have pale to rose-pink but sometimes white flowers with a slightly shorter perianth tube and sometimes smaller tepals than the typical form. Treated as subsp. *lilacina*, they may represent a local pollination ecotype.

Key to subspecies

1a Flowers white to cream; perianth tube (30–)40–50(–65) mm long; tepals 18–25(–30) × 7–12 mm . . . . . 27a. subsp. *bakeri*

1b Flowers pale to rose-pink, rarely white; perianth tube 20–30(–35) mm long; tepals 15–22(–25) × 5–8(–10) mm . . . . . 27b. subsp. *lilacina*

27a. subsp. **bakeri**

Flowers white to cream; perianth tube (30–)40–50(–65) mm long; tepals 18–25(–30) × 7–12 mm.

Distribution and ecology: extending from the central Little Karoo near Ladismith across the Rooiberg to the northern slopes of the Outeniqua Mtns and in the upper Long Kloof between Avontuur and Haarlem.

Diagnosis: recognised by its white to cream-coloured flowers with a longer perianth tube, mostly more than 30 mm long and up to 65 mm long.

27b. subsp. **lilacina** *(L.Bolus) M.P.de Vos* in Journal of South African Botany 49: 358 (1983). *Tritonia lilacina* L.Bolus: 161 (1918). Type: South Africa, [Western Cape], exhibited at the Cape Town Wild Flower Show among plants sent from Riversdale, without precise locality or collector, *BOL13755* (BOL, holo.).

Flowers pale to rose-pink, usually with dark veins, rarely white; perianth tube 20–30(–35) mm long; tepals 15–22(–25) × 5–8(–10) mm.

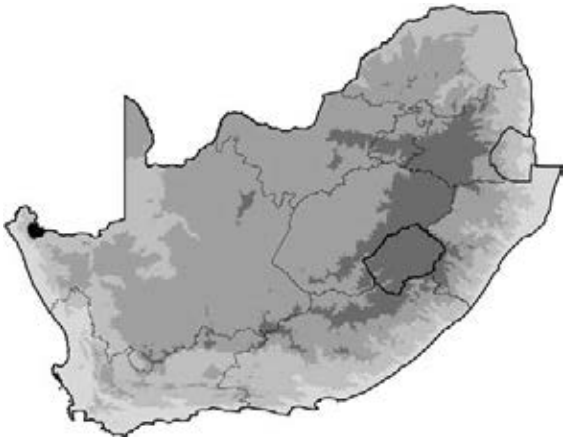
Distribution and ecology: restricted to the southern foothills of the Swartberg between Calitzdorp and De Rust.

Diagnosis: distinguished by its pale to rose-pink (rarely white) flowers with shorter perianth tube, mostly 20–30 mm long. Flowering is somewhat earlier than in subsp. *bakeri*.

Sect. 9. **Deserticolae** *J.C.Manning & Goldblatt*, new section. Type species: *Tritonia marlothii* M.P. de Vos

Leaves linear to falcate, slightly succulent, with main vein and sometimes an additional secondary vein translucent, margins also translucent; anatomically with marginal vein and associated sclerenchyma bundle, lacking thickened marginal epidermal cells. *Spike* erect, lax or dense; bracts ± green, leathery. *Flowers* weakly zygomorphic, ± salver-shaped, pale yellow or mauve; perianth tube subcylindric, much longer than tepals; lower tepals puberulous in lower ½, with small obliquely peg-like callus toward base. *Stamens* arcuate,

unilateral; anthers pale. *Capsules* subglobose, 5–10 mm long. *Basic chromosome number x* = 10.



Species 2: winter-rainfall northwestern Northern Cape, South Africa.

A section of two closely allied species from the Richtersveld and northern Bushmanland, distinguished by their subsucculent leaves with only the midvein and sometimes one additional vein evident and with translucent margins representing a marginal bundle and associated sclerenchyma strand, thus lacking the thickened marginal epidermis typical of the genus. The bracts are ± entirely green and leathery, later becoming dry from the tips, and the long-tubed, bilabiate or almost salver-shaped flowers are unique in the genus in having the lower tepals finely puberulous on the upper surface. The lower 3 tepals each bear a small, wedge-shaped or obliquely peg-like callus less than 1 mm high.

The two species were included in sect. *Subcallosae* by De Vos (1982) but are distinctive in several features, notably the subsucculent leaves without thickened marginal epidermis, green bracts, puberulous lower tepals, and derived chromosome number.

28. **Tritonia delpierrei** *M.P.de Vos* in Journal of South African Botany 49: 403 (1983). *T. marlothii* subsp. *delpierrei* (M.P.de Vos) M.P.de Vos: 121 (1999). Type: South Africa, [Northern Cape], Richtersveld, top of Helskloof, *De Vos 2462* (NBG [as STE], holo.).

Plants 200–350 mm high. *Corm* moderately deep-seated, subglobose, 15–30 mm diam.; tunics of fine–moderately coarse-textured fibres, extending into a fibrous and papery collar. *Stem* flexed outward near base then suberect, simple or with up to 3 suberect branches. *Leaves* 5 to 7, linear to narrowly lanceolate or falcate, slightly succulent, 50–120 × (1.5–)2.0–4.0 mm, acuminate, with translucent main vein and sometimes 1 additional vein, margins translucent, cauline leaves bract-like and often dry. *Spike* erect, almost 2-ranked, rather lax, 5- to 9-flowered; bracts green and leathery becoming dry and membranous above or dry entirely, margins membranous, brown, speckled dark brown at tips, outer 5–10 mm long, 2- or 3-toothed or subacute, inner ± equal or slightly shorter, bifid. *Flowers* weakly zygomorphic, ± salver-shaped, sometimes inverted, cream-coloured or creamy yellow, lower tepals paler, lightly sweet-scented; perianth tube subcylindric to narrowly funnel-shaped, 12–22 mm long, widening gradually from near middle to 2 mm diam.; tepals subequal, elliptic, spreading but dorsal initially suberect, 8–12 × 3–5 mm, lower tepals puberulous, each with small, obliquely peg-like callus 0.5 mm high. *Filaments* unilateral, arcuate, 5–7 mm long, shortly exserted; anthers 3–5 mm long, pale yellow; pollen cream. *Style* 18–25 mm long, dividing between middle and tips of anthers, branches 1.5–2.0 mm long. *Capsules* subglobose, 5–10 mm long. *Flowering time*: late July to early October, depending on the rains.

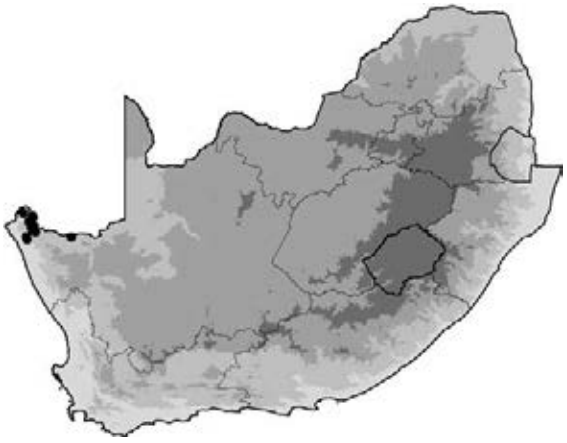
Distribution of ***Tritonia delpierrei***.

Distribution and ecology: endemic to the Richtersveld in Northern Cape, South Africa, from Helskloof to Eksteenfontein; in light clay, loam or gravelly soils, sometimes among quartzite pebbles.

The sweetly scented flowers are probably adapted to pollination by long-tongued bees.

Diagnosis: closely allied to the largely sympatric *Tritonia marlothii*, with which it shares similar narrow, leathery leaves without evident secondary veins and spikes of long-tubed flowers with short, often largely herbaceous bracts and unusual lower tepals minutely puberulous on the upper surface. They are distinguished by details of the flowers, *T. delpierrei* having fragrant, pale creamy yellow flowers with a perianth tube 12–22 mm long and *T. marlothii* with odourless, pale to deep purple flowers with a longer tube 28–42 mm long.

29. **Tritonia marlothii** *M.P.de Vos* in Journal of South African Botany 49: 406 (1983). Type: South Africa, [Northern Cape], Richtersveld, *Marloth 12296* (BOL, holo.; PRE, iso.).



Plants 200–350 mm high. *Corm* not seen. *Stem* flexed outward near base then suberect, simple or with up to 3 suberect branches. *Leaves* 5 to 7, linear to narrowly lanceolate or falcate, slightly succulent, 50–120 × 1.5–4.0 mm, acuminate, with translucent main vein and sometimes 1 additional vein, margins translucent, cauline leaves bract-like and often dry. *Spike* erect, nearly 2-ranked, rather lax to dense, 5- to 12-flowered; bracts green and leathery becoming dry and membranous above or entirely, brown and speckled dark brown at tips, outer 7–12 mm long, margins membranous, 2- or 3-toothed or subacute, inner subequal or slightly shorter, bifid. *Flowers* weakly zygomorphic, almost salver-shaped, mauve to violet, lower tepals pale creamy yellow in lower ½ with median purple blotch, unscented; perianth tube subcylindric, 28–42 mm long, widening gradually to 2 mm diam.; tepals subequal, spreading, elliptic to obovate, 8–12 × 3–5(–6) mm, lower tepals puberulous and each with small, obliquely peg-like

callus 0.5–0.8 mm high. *Filaments* unilateral, arcuate, 6–8 mm long, exserted 3–5 mm; anthers 3–5 mm long, pale; pollen cream. *Style* 32–45 mm long, dividing between base and middle of anthers (or shortly below them), branches 1.5–2.0 mm long. *Capsules* subglobose, 6–10 mm long. *Flowering time*: late August to November, depending on the rains.

Distribution and ecology: centred in the Richtersveld in Northern Cape, South Africa, mainly north of Eksteenfontein, with an outlying population on the Abbasasberg in northern Bushmanland; on rocky slopes and outcrops with the corms often wedged in cracks and fissures.

The long-tubed flowers are adapted to pollination by the long-proboscid nemestrinid fly *Prosoeca peringueyi* (Manning & Goldblatt, 1996).

Diagnosis: *Tritonia marlothii* is closely allied to *T. delpierrei,* also from the Richtersveld, and shares with it similar narrow, leathery leaves without evident secondary veins and spikes of long-tubed flowers with short, often largely green bracts and unusual lower tepals minutely puberulous on the upper surface, especially toward the base. The two species are distinguished by the flowers, *T. marlothii* having odourless, pale to deep purple flowers with a perianth tube 28–42 mm long and style branching between the base and middle of the anthers, and *T. delpierrei* having fragrant, pale creamy yellow flowers with a perianth tube 12–22 mm long and style dividing between the middle and apex of the anthers. Plants of the disjunct population in Bushmanland differ in their smaller size, softer-textured leaves and flowers with slightly broader, obovate tepals, the style branching shortly below the anthers.

Distribution of ***Tritonia marlothii***.

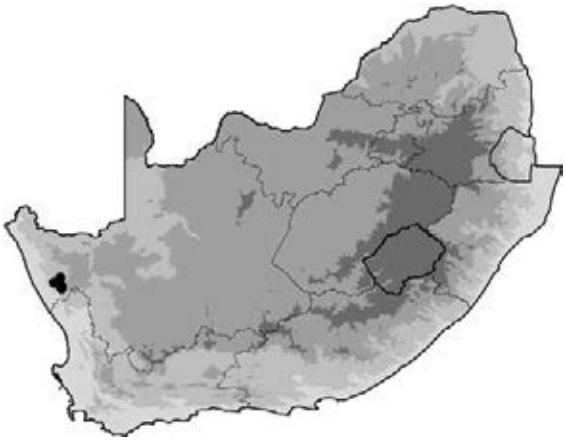
Sect. 10. **Teretifoliae** *M.P.de Vos* in Journal of South African Botany 48: 159 (1982). Type species: *Tritonia kamisbergensis* Eckl. ex Klatt

Corm deeply seated with matted tunics accumulating in a long, fibrous collar. *Leaves* longer than inflorescence, terete or subterete, wiry, striate with several strands of sclerenchyma, appearing closely ribbed when dry; anatomically with marginal vein and associated sclerenchyma bundle present, lacking thickened marginal epidermal cells. *Spike* erect, lax; bracts small, green and leathery in lower ½. *Flowers* zygomorphic; perianth tube obliquely funnel-shaped, twice as long as tepals; lower tepals without calluses. *Stamens* arcuate, unilateral. *Capsules* subglobose, 5–10 mm long.

Species 1: Namaqualand in Northern Cape, South Africa.

A monotypic section including only *Tritonia kamisbergensis* from the Kamiesberg in central Namaqualand, Northern Cape, without evident affinities and characterised by the long, striate, wiry leaves, and the partially leathery bracts. The leaves are centric and lack the specialised, thickened marginal epidermal cells typical of the genus. In this respect they resemble those of *T. bakeri*, *T. delpierrei* and *T. marlothii*, but in these species the leaves are subsucculent and in *T. bakeri* markedly sclerified or fibrous. The corms of *T. kamisbergensis* are exceptionally deep-seated, with the old tunics accumulating as a dense, matted covering. The dark ruby-red or purple flowers are remarkably *Freesia*-like in appearance.

30. **Tritonia kamisbergensis** *Eckl. ex Klatt* in Linnaea 32: 760 (1864). *Montbretia kamisbergensis* (Eckl. ex Klatt) Baker: 169 (1877). *Tritonixia kamisbergensis* (Eckl. ex Klatt) Klatt: 356 (1882). Type: South Africa, [Northern Cape], 'Kamiesbergen' [Kamiesberg], *Ecklon & Zeyher Irid 109* (B, holo.; G, MO, S, SAM, iso.).



[*Freesea kamisbergensis* Eckl., unpublished name. in herb. S]

Plants 300–700 mm high, forming dense tufts. *Corm* deep-seated, obliquely subglobose, 20–30 mm diam.; tunics of moderately coarse fibres forming thickly matted layers, extending in a thick, fibrous collar. *Stem* simple or with up to 2 suberect branches. *Leaves* 6 to 8, wiry, terete to elliptic in section, 600–700 × 1–3 mm, acuminate, striate with translucent veins and margins, often longer than stem, cauline leaves bract-like, often dry. *Spike* erect, 2-ranked, rather lax, 4- to 12-flowered; bracts green, leathery becoming membranous and dry above, margins membranous, brown and speckled dark brown at tips, 5–8 mm long, outer acuminate or ± 3-toothed with median tooth largest, inner bifid. *Flowers* zygomorphic, bilabiate, sometimes inverted, bright ruby-red or purple, lower tepals with white median patch, unscented; perianth tube obliquely funnel-shaped, 16–20 mm long with basal tubular portion ± 5 mm long, widening obliquely to ± 8 mm diam.; tepals unequal, dorsal largest, suberect,

hooded, subrotund, 9–12 × 8–10 mm, others oblong to obovate, obtuse, 7–9 × 6–9 mm, inner wider than outer, lower 3 recurved, without calluses. *Filaments* unilateral, arcuate, 12–15 mm long, shortly exserted; anthers 4–6 mm long, violet; pollen cream. *Style* (18–)20–25 mm long, dividing opposite middle of anthers, branches 1.5–2.0 mm long. *Capsules* subglobose, 5–10 mm long. *Flowering time*: November to early December.

Distribution and ecology: a local endemic restricted to middle and upper elevations of the Kamiesberg in Northern Cape, South Africa; in renosterveld scrub with the corms deeply wedged in fissures in granite outcrops.

Diagnosis: a very distinct species with long, striate, firm-textured, terete or subterete leaves often taller than the inflorescence and with a dense fibrous collar around the base. The lax spikes bear zygomorphic, ruby-red or purple, somewhat *Freesia*-like flowers with a funnel-shaped perianth tube 16–20 mm long. The small, leathery bracts are dry and papery only near the tips.

Distribution of ***Tritonia kamisbergensis***.

28. **Ixia**

Ixia *L.*, Species plantarum, edn. 2, 1: 51 (1762), conserved name. Type (conserved): *I. polystachya* L.

Houttuynia Houtt.: 448 (1780), rejected name, not *Houttuynia* Thunb. (1784). Type: *H. capensis* Houtt. = *Ixia paniculata* D.Delaroche

Morphixia Ker Gawl.:105 (1827). Type: *M. latifolia* (D. Delaroche) Ker Gawler = *Ixia latifolia* D.Delaroche

[*Dichone* Lawson ex Salisb.: 320 (1812), invalid name without description.]

[*Hyalis* Salisb.: 317 (1812), invalid name without description.]

Revisionary accounts: Lewis (1962); Goldblatt & Manning (2011: 83–134; 2012a: 87–110; 2016: 175–198).

From the Greek, *ixias*, the 'chameleon plant', originally the parasite *Loranthus*, possibly because of the sticky seeds, like a chameleon's tongue, but evidently applied arbitrarily by Linnaeus to an African genus of Iridaceae, at the time including species now referred to other genera.

Deciduous perennials. *Rootstock* a globose corm, rooting from below and axial in origin; tunics of fine to moderately coarse, netted fibres, sometimes with collar of fibres around base. *Stem* aerial, rarely subterranean, usually slender and wiry, terete, often branched. *Leaves* unifacial, with a definite main vein, usually plane, sword-shaped, falcate or linear, sometimes margins thickened, occasionally crisped or rarely winged, thus blade H-shaped in transverse section; marginal anatomy with undifferentiated epidermal cells and a subepidermal strand of sclerenchyma. *Inflorescence* a spike, flowers spirally arranged or in 2 ranks, often flexuose; bracts membranous, occasionally dry, usually translucent, short, outer usually 3-veined (or 1- or 5-veined), usually 3-toothed, inner smaller, 2-veined, 2-toothed or forked at apex. *Flowers* usually actinomorphic, rarely zygomorphic, variously coloured, pink, mauve or yellow, sometimes darker in the centre, occasionally fragrant, with nectar from septal nectaries or without nectar; perianth tube funnel-shaped or cylindric, short or elongate; tepals subequal, usually spreading. *Stamens* symmetrically disposed, rarely unilateral; filaments slender or somewhat flattened, sometimes included in tube, free or partly to entirely united; anthers linear to oblong, splitting longitudinally or sometimes incompletely from base, occasionally sharply bent above base. *Ovary* globose, sessile; style filiform, dividing into short to long, undivided, slender branches, either channelled and slightly broadened above, or tubular and stigmatic apically. *Capsules* globose, cartilaginous, smooth or slightly warty. *Seeds* globose or slightly angled, smooth or wrinkled, hard and shiny, with raphal vascular trace excluded. *Pollen grains* monosulcate-operculate with 1-banded operculum, exine perforate-scabrate. *Basic chromosome number x* = 10.

Species 100, South Africa, mainly in the winter-rainfall zone in the southwest but extending north into Namaqualand and east to Grahamstown.

Almost restricted to the southern African winter-rainfall region, *Ixia* is distinguished by the translucent, membranous floral bracts, the outer usually darkly 3-veined and 3-toothed, radially symmetric flowers except in a few instances and mostly narrow leaves and slender stems. The style branches are undivided, typical of Ixieae, but the pollen grains are exceptional in the tribe in having a 1-banded operculum (2-banded in all but a few species in related genera) and a basic chromosome number of $x = 10$, shared with the closely related genera *Dierama* and *Sparaxis*. Molecular studies show that these genera plus *Tritonia* are most closely related to *Ixia*. Within the genus important variation includes leaf number, consistent for species, perianth tube length and inclusion or not of the filaments or stamens within the perianth tube. Species are divided among four sections.

Sect. *Ixia* is distinguished by the narrow perianth tube, the walls clasping the style, and filaments inserted at the top of the tube and occluding the mouth. Most species of the section have contrasting, usually dark markings, at the bases of the tepals. Pollination is predominantly by hopliine beetle species. Sect. *Dichone* has the perianth tube like that of sect. *Ixia* but is separated by the tubular style branches with margins involute and stigmatic surfaces confined to tips. Several species of the section have short, ovoid anthers sometimes dehiscing incompletely from the base. So-called buzz-pollination has been recorded for *I. scillaris*.

Species of the remaining sections, *Hyalis* and *Morphixia* have a conventional hollow tube containing nectar at the base. Sect. *Hyalis* is distinguished by the presence of several leaves, the uppermost not entirely sheathing. Among its species, several have elongate perianth tubes, notably *Ixia paniculata*, and are pollinated by long-proboscid flies. Most members of sect. *Morphixia* have two basal leaves with expanded blades and a third one almost, or entirely sheathing the stem. Species of the *I. rapunculoides* group are distinguished in sect. *Morphixia* by the short stamens, the filaments and often the anthers included in the perianth tube. Most species are pollinated by large anthophorine bees or honey bees.

Key to sections

Notes: care must be taken in measuring floral parts of preserved specimens: depending on method of drying, the perianth can shrink as much as 30%. Presence of stolons is difficult to establish as they often become detached during collection unless corms are removed from the ground with particular care.

Measure filaments from point of insertion on perianth tube to base of anther, not to point of insertion above the anther base. For bracts measure those in the middle portion of the main spike (those at the base and near the apex of the spike are often longer or shorter than normal).

1a Style branches tubular with margins involute and stigmatic surfaces confined to tips of style branches; perianth tube filiform throughout and blocked by the style; anthers ovoid and short, sometimes dehiscing incompletely from base; flowers pink to mauve, pale violet (or white). . . . . 4. sect. *Dichone*
1b Style branches channelled with margins conduplicate below and stigmatic surfaces extending along distal half of style branches; perianth tube either filiform throughout and blocked by the style or funnel-shaped to cylindric and hollow above or throughout; anthers ± linear, dehiscing completely; flowers variously coloured:
2a Perianth tube filiform throughout with filaments inserted at mouth of tube; filament bases often expanded (tepals sometimes connate basally for a short distance); perianth brightly coloured, usually with dark centre. . . . . 2. sect. *Ixia*
2b Perianth tube funnel-shaped to cylindric and hollow throughout or filiform in lower part with filaments inserted within tube and decurrent; filament bases not expanded; perianth usually shades of pink or pale blue to white, occasionally brilliantly coloured and rarely with a dark centre:
3a Leaves 4 to 6(–10), with upper leaves partly sheathing stem and not sharply differentiated from lower leaves; plants sometimes acaulescent; perianth tube sometimes blocked by style in lower part . . . . . 1. sect. *Hyalis*
3b Leaves mostly 3 (sometimes 4 or 5, rarely only 2), with upper 1 (or 2) leaves almost or entirely sheathing and usually clearly differentiated from lower leaves; plants never acaulescent; perianth tube always hollow to base . . . . . 3. sect. *Morphixia*

Sect. 1. *Hyalis*

1a Plants acaulescent with flowers borne at ground level; leaves falcate or prostrate, without evident midrib:
2a Flowers uniformly yellow; perianth tube hollow, 15–20 mm long; style dividing opposite bases of free filaments . . . . . 7. *I. acaulis*
2b Flowers yellow with red-brown centre; perianth tube filiform, 35–45 mm long with apex blocked by bases of united filaments; style dividing opposite middle of anthers. . . . . 8. *I. macrocarpa*
1b Plants with an aerial stem; leaves falcate to upright, usually with evident midrib; flowers usually shades of white or pink to orange, rarely red or yellow but then not as above:
3a Floral bracts with 3(–5) subequal major veins and ± equally 3-lobed to 3-dentate:
4a Anthers and style branches included in lower half of perianth tube; style dividing below or opposite filament bases. . . . . 13. *I. recondita*
4b Anthers and style branches exserted or partly included, tips of anthers usually emerging from tube or at least reaching beyond upper ⅓ of tube; style dividing above filament bases:
5a Corm tunics extending upward in a short collar of fibres around base; leaves ± linear and firm-textured; bracts 4–5 mm long; filaments exserted ± 6 mm from the tube. . . . . 10. *I. cochlearis*
5b Corm tunics not extending upward in a short collar of fibres around base; leaves sublinear to sword-shaped and relatively soft-textured; bracts 5–8 mm long; filaments exserted up to 5 mm or included:
6a Filaments exserted 2–5 mm from tube; style branches 2.0–2.5 mm long; flowers white to pink with red on reverse and red marks in throat . . . . . 11. *I. fucata*
6b Filaments included or exserted up to 1 mm; style branches 1.0–2.3 mm long; flowers pink. . . . . 12. *I. stohriae*
3b Floral bracts with one major vein (or no dark veins evident) and either with one prominent lobe or tooth, or 3-toothed with central tooth smaller than lateral teeth, or ± truncate with apex minutely serrated:
7a Perianth tube ± cylindric, usually elongate, 12–70 mm long:
8a Anthers fully exserted from tube:
9a Perianth tube 12–33(–35) mm long; flowers pink (rarely white spots present in pink-flowered populations); filaments 4–9 mm long, exserted up to 5 mm from tube . . . . . 3. *I. longituba*
9b Perianth tube 35–40 mm long; flowers beige, flushed pink outside; filaments ± 15 mm long, exserted 10–11 mm from tube. . . . . 4. *I. bellendenii*
8b Anthers fully to partly included in tube:
10a Anthers dark purple-black (rarely pale yellow); perianth tube 35–70 mm long; style dividing between lower ⅓ and apex of anthers, rarely shortly beyond anther tips. . . . . 9. *I. paniculata*
10b Anthers yellow to white; perianth tube 18–30 mm long; style dividing below or opposite lower ⅓ of anthers:
11a Perianth pink to brick-red; perianth tube 27–30 mm long; tepals 15–18 mm long; anthers 5–6 mm long . . . . . 5. *I. splendida*
11b Perianth white or flushed pale pink; perianth tube 18–20 mm long; tepals ± 10 mm long; anthers ± 4 mm long. . . . . 6. *I. linderi*
7b Perianth tube widely to narrowly funnel-shaped, narrow and cylindric below, obviously widening at ± middle or upper ⅓ into a flared upper part:

12a Filaments and bases of anthers included in perianth tube; flowers white with large purple blotch on lower part of each tepal; bracts large, 7–10 mm long, pellucid flushed pink or brownish . . . . . 2. *I. leipoldtii*
12b Filament apices exserted from tube; flowers and bracts not as above:
13a Perianth tube (12–)15–19 mm long; flowers light purple or yellow to orange or brick-red with dark centre:
14a Flowers yellow to orange or brick-red, with a dark centre; bracts dark rusty brown in distal half. . . .18. *I. tenuifolia*
14b Flowers light purple; bracts pale-translucent . . . . . 19. *I. purpureorosea*
13b Perianth tube 4–12 mm long; flowers white, pink to brick-red or yellow, without a dark central mark:
15a Plants 100–250 mm high; flowers brick-red, facing ± to side; bracts opaque, brownish, 7–9 mm long 1. *I. pumilio*
15b Plants 100–650 mm high; flowers yellow to orange or white to pink, suberect; bracts pellucid, 5–7 mm long:
16a Flowers white or pink to mauve; filaments 5–6 mm long; stem usually 1- to 4-branched . . . . . .14. *I. orientalis*
16b Flowers yellow to orange, rarely white but then filaments < 3.5 mm long; stem usually unbranched:
17a Plants 100–150(–350) mm high; perianth tube 4.5–6.0 mm long; style dividing between base and middle of anthers . . . . . 16. *I. esterhuyseniae*
17b Plants 180–550 mm high; perianth tube 7–15 mm long; style dividing below base of anthers:
18a Tepals yellow or white, 9–11 × ± 5 mm; leaves often linear, barely, if at all twisted distally, 2–10 mm wide; filaments relatively short, up to 3 mm long . . . . . 15. *I. odorata*
18b Tepals orange, 16–23 × 7–9 mm; leaves ± lanceolate and loosely twisted distally, (8–)10–16 mm wide; filaments longer, 5–6 mm long. . . . . 17. *I. aurea*

Sect. 2. *Ixia*

Note: Measure perianth tube from the top of the ovary to the point of separation of the tepals (usually up to 1 mm above the filiform part of the tube. In species where the tepals are connate above the tube in horizontal orientation this is not considered part of the tube (e.g. 32. *Ixia superba*).

1a Flowers shades of yellow to orange either with dark red to brown or almost black centre or ± uniformly pale yellow (but see 34. *I. abbreviata* below):
2a Flowers uniformly pale yellow; anthers elliptic with lateral thecae and connective visible abaxially . . . . . 40. *I. angelae*
2b Flowers with dark central mark; anthers linear with thecae parallel and closely set:
3a Bracts pale-translucent, uniformly pale or often flushed pink; filaments free, rarely basally connate:
4a Plants usually unbranched, when present, branches ascending; style usually yellow and dividing opposite middle of filaments to lower ⅓ of anthers; corm with moderately coarse fibrous tunics and not producing stolons. . . . . 33. *I. dubia*
4b Plants with one or more short branches diverging widely from main axis; style usually dark green or brown, dividing opposite base to middle of filaments; corm with finely fibrous or papery tunics and usually bearing slender stolons . . . . . .39. *I. sarmentosa*
3b Bracts opaque, pallid or rust-brown distally or entirely; filaments usually partly to entirely united (rarely ± free):
5a Bracts at most speckled with brown spots in upper half, but with cusps thickened, twisted and dark brown; perianth tube 10–15 mm long, exserted from bracts; corm always without stolons . . . . . .47. *I. curta*
5b Bracts rust-brown distally or entirely; perianth tube 5–8(–10) mm long, ± as long as bracts; corm always with stolons (sometimes lacking in herbarium material):
6a Tepals forming concave cup in central dark zone and spreading horizontally; central eye of perianth 6–12 mm diam., dark brown or ± black, often with star-shaped mark within; filaments yellow:
7a Flowers yellow with back centre; stolons unbranched, up to 100 mm long, bearing a single terminal cormlet, mostly > 5 mm diam.; anthers dark. . . . . 45. *I. fuscocitrina*
7b Flowers usually orange, occasionally yellow with dark brown centre, often with radiating pale lines; stolons branches, short, up to 20 mm long, bearing multiple cormlets, each up to 3 mm diam.; anthers yellow to orange . . . . . .44. *I. maculata*
6b Tepals without concave in dark zone, when fully open forming shallow cup and curved uniformly from base to apex; central eye of perianth (6–)8–20 mm diam., glossy brown or red with pale reddish halo or dull, translucent red; filaments dark red-brown (violet when dry). . . . . 46. *I. calendulacea*
1b Flowers not shades of yellow or orange (then white, beige, pink, mauve, blue, green, red or purple, usually with contrasting dark, or sometimes paler centre)
8a Filaments united at least for half their length; cusps of floral bracts thickened, blackish and twisted . . . 48. *I. monadelpha*
8b Filaments free (rarely basally connate); cusps of floral bracts not as above:
9a Tepals shorter than to as long as perianth tube; foliage leaves two or three . . . . . .25. *I. helmei*
9a Tepals at least 1.5 times and up to 3 times as long as perianth tube; foliage leaves three or more:
10a Outer bracts with three long setaceous cusps 3–4 mm long; corm bearing short, flattened, shortly branched stolons with several small cormlets. . . . . 26. *I. stolonifera*
10b Outer bracts 3- or 1-toothed but apices not drawn into long cusps; cormlets if present, only at base of parent corm or borne on unbranched stolons:
11a Bracts 4–6 mm long and as wide or wider than long; style dividing opposite base to apex of anthers:
12a Flowers white or bright red, without prominent contrasting central mark; style reaching to middle or apex of anthers . . . . . 28. *I. campanulata*
12b Flowers pale pink, mauve or light purple with small dark mark around throat; style reaching to base or middle of anthers . . . . . .29. *I. metelerkampiae*
11b Bracts (5)6–10 mm long and as long or longer than wide; style usually dividing opposite base of filaments to base (occasionally to middle) of anthers:

IXIA. ***Ixia latifolia***: A, flowering plant; B, half-flower. ***I. pavonia***: C, flowering plant; D, outer bract (left) and inner bract (right); E, half-flower.

13a Flower without conspicuous solid dark centre; style always dividing opposite middle of filaments or higher:
14a Leaves ± linear, 1.5–2.0 mm wide; flowers pale pink with white centre; anthers elliptic with connective visible on abaxial surface . . . . . 24. *I. roseoalba*
14b Leaves lanceolate to almost linear, mostly 6–12 mm wide (rarely 1.5–2.0 mm); flowers white, red or pink, sometimes white to pale yellow at tepal bases; anthers linear or oblong with thecae parallel and closely set:
15a Tepals red to deep pink, ± 20 × 10 mm. . . . . 21. *I. patens*
15b Tepals uniformly white or white to pale pink except sometimes with darker longitudinal streaks in lower half:
16a Filaments often thickened in lower half; tepals white to pink with dark longitudinal lines in lower half; flowers strongly scented . . . . . .20. *I. flexuosa*
16b Filaments uniformly filiform; tepals uniformly white or pink without markings; flowers unscented or faintly scented:
17a Flowers white, pale yellow in throat . . . . . 22. *I. leucantha*
17b Flowers pink, white in throat . . . . . .23. *I. alticola*
13b Flower with conspicuous solid darker centre:
18a Style dividing opposite upper ⅓ of filaments or base to apex of anthers (rarely exceeding anthers):
19a Tepals connate basally into a shallow cup ± 3 mm deep, spreading distally . . . . . 32. *I. superba*
19b Tepals ± free from base without basal cup:
20a Leaf margins undulate to crisped; flowers red with dark centre. . . . . .27. *I. vanzijliae*
20b Leaf margins straight; flowers white to pink or purple with dark centre:
21a Plants with prominent collar of fibres around base; leaves narrowly sword-shaped, 3–9 mm wide, with veins not especially thickened . . . . . 30. *I. mostertii*
21b Plants without collar of fibres around base; leaves linear to narrowly sword-shaped:
22a Leaves linear, 1.2–2.0(2.5) mm wide, with prominently thickened veins . . . . . 31. *I. longistylis*
22b Leaves narrowly lanceolate or sometimes linear, mostly 3–8 mm wide and usually without prominently thickened veins or margins . . . . . 38. *I. polystachya*
18b Style dividing opposite base to lower ⅓ (rarely to middle) of filaments:
23a Lowermost leaves exceeding spike; plants with fibrous collar around base. . . . . 43. *I. vinacea*
23b Leaves reaching to between middle of stem and ± base of spike; plants with or without fibrous collar around base:
24a Bracts dry-papery and usually rust-brown distally . . . . . .34. *I. abbreviata*
24b Bracts ± membranous, pale, sometimes speckled brown distally:
25a Perianth dark red with blackish centre . . . . . 35. *I. gloriosa*
25b Perianth blue, green, pink or white with dark centre:
26a Leaf margins thickened, cartilaginous, ± arching over leaf surface at edge, thickenings crenulate or crisped; stamens with anthers erect, occasionally connivent at tips . . . . . 42. *I. versicolor*
26b Leaves plane with margins straight, thickened or not but thickenings not arching over leaf surface:
27a Anthers with connective visible between thecae on abaxial (outer) surface; tepals (usually weakly) narrowed ± into claws in lower part, thus gapped between bases:
28a Anthers ± arrow-shaped with thecae dehiscing laterally; corms without stolons . . . . . 36. *I. atrandra*
28b Anthers ± linear with thecae dehiscing outward; branches often present and diverging ± at right angles to main stem and ascending distally; corms with stolons . . . . . .37. *I. rouxii*
27b Anthers narrow, ± linear with sides parallel and connective not exposed on abaxial surface; tepals ovate, not claw-like below, thus contiguous or slightly overlapping below:
29a Open flowers laxly arranged in an elongate spike (not crowded apically):
30a Flowers green, blue-green or pale blue . . . . . 41. *I. viridiflora*
30b White or pink, occasionally pale blue but never green. . . . . 38. *I. polystachya*
29b Open flowers crowded at spike apex (bracts usually about as long as spike internode):
31a Anthers suberect; plants of marshy ground; corm bearing long stolons with single terminal cormlet . . . . . .39. *I. sarmentosa*
31b Anthers ± horizontal when flowers fully open; plants of dry habitats; corms not bearing stolons. . . . . 38. *I. polystachya*

Sect. 3. *Morphixia*

1a Leaf blades linear-filiform and up to 2 mm (and usually less than 1.5 mm) wide when alive:
2a Leaves ovate-elliptic in cross section; perianth tube ± 5 mm long. . . . . 59. *I. teretifolia*
2b Leaves not as above, either with a slightly to prominently thickened main vein ± in centre of blade or margins raised into narrow fleshy wings and main vein obscure or with main vein not evident when alive unless held to the light, lying closer to abaxial margin, when dry, main vein and margins become evident and appear thickened due to collapse of mesophyll between them; perianth tube 4–22 mm long:
3a Leaf margins raised into narrow fleshy wings and main vein obscure; perianth tube ± 5 mm long . . . . 60. *I. linearifolia*
3b Leaves with margins not raised and with main vein either slightly to prominently thickened or main vein not raised when alive:
4a Leaf with main vein slightly to prominently thickened; flowers with perianth tube cylindric throughout, (12–)15–20 mm long and uniformly ± 2 mm diam. . . . . .69. *I. stenophylla*
4b Leaf with main vein not evident when alive unless held to light and lying closer to abaxial margin (when dry, main vein and margins become evident and appear thickened due to collapse of tissue between them); perianth tube funnel-shaped to cylindric, 4–22 mm long:

5a Perianth tube 4–10 mm long; filaments included or exserted up to 2 mm from tube; anthers symmetrically arranged in a column enclosing style:
6a Perianth tube 4–8 mm long; tepals 11–15 mm long, thus ± twice as long as tube; filaments exserted 1–2 mm and anthers fully exserted; anthers (3–)4–5 mm long . . . . . 79. *I. capillaris*
6b Perianth tube 8–10 mm long; tepals 8–10 mm long, thus ± as long or slightly longer than the tube; filaments included and bases of anthers held within tube; anthers 3.5–4.0 mm long . . . . . 80. *I. exiliflora*
5b Perianth tube 12–22 mm long; filaments included or well exserted from tube; anthers either symmetrically arranged or unilateral and facing upward and style then lying below anthers:
7a Stamens symmetrically arranged; filaments included, 3–6 mm long; anthers 2.5–3.5 mm long, bases usually included in tube. . . . . 81. *I. dieramoides*
7b Stamens usually (?always) unilateral and horizontal to declinate; filaments 12–15 mm long, exserted 2–10 mm from tube; anthers 4–5 mm long, fully exserted from tube:
8a Filaments exserted 2–6 mm from tube; stem simple or with 1 or 2(3) lateral branches, branches subtended by attenuate bracts and prophylls; cataphylls chestnut-brown above ground . . . . . 82. *I. pauciflora*
8b Filaments exserted 8–10 mm from tube; stem with 1 to 3 lateral branches, branches subtended by truncate bracts and prophylls; cataphylls green with ± membranous margins . . . . . 83. *I. reclinata*

1b Foliage leaves 1 to 4, blades linear to lanceolate or falcate, rarely linear-filiform but then with a moderately to prominently thickened central vein, usually > 2 mm wide in mature plants; main vein evident when alive, ± central or slightly displaced toward abaxial margin:
9a Foliage leaves with margins broadly winged, thus H-shaped in cross section; ovary and capsules warty:
10a Flowers pale pink with white to pale yellow throat; perianth tube 5–6 mm long; anthers ± 5 mm long . . . . . 62. *I. alata*
10b Flowers pale blue-mauve, white in throat; perianth tube 8–10 mm long; anthers ± 6 mm long . . . . . 63. *I. thomasiae*
9b Foliage leaves plane, sometimes with margins heavily thickened but never winged; ovary and capsules smooth, rarely surface obscurely roughened:
11a Perianth tube cylindric or subcylindric; tepals shorter than tube:
12a Perianth tube 12–18 mm long; flowers pale lilac to white flushed lilac. . . . . 65. *I. dolichosiphon*
12b Perianth tube 20–34 mm long; flowers pale beige, white or pale cherry-red:
13a Corm tunics of coarse, woody fibres; flowers pale beige, usually purple outside; tepals oblong, 11–15 × 3.0–4.5 mm . . . . . 64. *I. paucifolia*
13b Corm tunics of fine, pale fibres; tepals ovate, 10–16 × 5–6 mm:
14a Flowers white, sometimes flushed mauve to pink outside, and sweetly scented; lower two leaves subequal, both 2–4(5) mm wide . . . . . 66. *I. cedarmontana*
14b Flowers pale cherry-red, unscented; lower two leaves unequal with lowermost 6–8 mm wide . . . . . 67. *I. seracina*
11b Perianth tube broadly or narrowly funnel-shaped; tepals usually as long as or longer than tube:
15a Filaments reaching mouth of perianth tube or exserted (sometimes for only 1 mm); anthers always completely exserted:
16a Foliage leaf solitary, linear; stem usually unbranched. . . . . 50. *I. saundersiana*
16b Foliage leaves 2 to 4, linear to lanceolate; stem simple or branched:
17a Perianth tube (2.5–)3.0–5.0 mm long; lateral branches usually several and always short, bearing 1 to 3(4) flowers:
18a Filaments pale blue to white, 5–7 mm long; lateral branches mostly 2- or 3-flowered . . . . . 58. *I. marginifolia*
18b Filaments purple-black, ± 4 mm long; lateral branches mostly 1-flowered . . . . . 59. *I. pavonia*
17b Perianth tube 6–18 mm long; lateral branches various:
19a Lateral branches mostly 3 to 6, short and thread-like, each bearing 1 or 2(3) flowers; perianth deep maroon-purple, magenta-pink, blue-mauve or white with yellow cup . . . . . 54. *I. ramulosa*
19b Lateral branches mostly 1 to 3, or plants unbranched, branches typically well developed, straight or twisted, bearing 1 to 6 or more flowers:
20a Branches straight and bearing 2–several flowers in distal half or plants unbranched:
21a Leaves soft textured, linear, up to 3 mm wide; margins not raised and thickened . . . . . 55. *I. nutans*
21b Leaves firm and leathery, usually falcate, > 5 mm wide; margins somewhat to strongly thickened:
22a Leaves (5–)10–18 mm wide, with moderately to heavily thickened margins; perianth tube 14–23 mm long; tepals 15–18 mm long; bracts 8–10 mm long; perianth usually deep pink to cherry-red . . . . . 51. *I. latifolia*
22b Leaves mostly narrowly sword-shaped to falcate, usually < 5 mm wide, with slightly thickened margins; perianth tube 8–11 mm long; tepals 11–14 mm long; bracts 5–7 mm long; perianth white, pale pink or purple:
23a Branches 0 to 2, short, wiry and suberect; corm with papery, onion-skin-like, pale brown tunics not persisting; perianth tube ± 10 mm long; tepals 12–17 mm long . . . . . 52. *I. monticola*
23b Branches nearly always present, diverging; corm with fibrous, medium to coarse fibres; perianth tube 8–11 mm long; tepals 11–14 mm long:
24a Branches mostly held at more than 45° from main axis, sometimes nearly horizontally; perianth tube 8–11 mm long; filaments exserted (1–)2 mm or included in tube; anthers 4.0–5.5 mm long . . . . . 49. *I. divaricata*
24b Branches ascending; perianth tube 12–14 mm long; filaments exserted ± 4 mm from tube; anthers ± 6 mm long . . . . . 68. *I. arenosa*
20b Branches and main spike always 1-flowered or branches twisted and flexuose, with flowers not obviously crowded in distal half:
25a Perianth tube 11–23 mm long; tepals 13–23 mm long; bracts pale, ± translucent with dark veins evident. . . . . 51. *I. latifolia*

25b Perianth tube (5–)6–11 mm long; tepals 10–15 mm long; bracts with veins ± obscured:
26a Bracts pale; stem with (1)2 or 3 short, wiry twisted branches 5–8 mm long, each bearing a solitary flower . . . . . 56. *I. ecklonii*
26b Bracts purple to glossy brown and veins obscured; stem branching not as above:
27a Plants mostly < 10 mm high; bracts 5–6 mm long, flushed purple; cormlets when present borne at base of corm . . . . . 53. *I. parva*
27b Plants mostly 250–450 mm high; bracts 7–10 mm long, glossy dark brown; cormlets borne on long, slender stolons . . . . . 57. *I. brunneobracteata*
15b Filaments not reaching mouth of perianth tube; anthers partly to entirely included in tube:
28a Main spike long, straight and erect, lateral spikes ascending to spreading, with upright flowers crowded in distal half . . . . . 49. *I. divaricata*
28b Inflorescence not as above:
29a Plants up to 150 mm high; flowers upright, purple with pale yellow cup; main spike and branchlets twisted and flexuose, inclined to nearly horizontal . . . . . 78. *I. contorta*
29b Plants usually taller; flowers not as above:
30a Perianth tube (12–)13–20 mm long; anthers partially or fully included in perianth tube:
31a Anthers half exserted from perianth tube; cormlets borne at base of main corm . . . . . 75. *I. namaquana*
31b Anthers fully included in the perianth tube; cormlets borne at ends of flattened stolons . . . . 76. *I. oxalidiflora*
30b Perianth tube 5–12(–14) mm long; anthers partially included in perianth tube:
32a Leaf blades of lower two or three leaves 8–15 mm wide (rarely 3–7 mm); filaments 2–4 mm long:
33a Bracts and prophylls subtending branches attenuate, up to 5 mm long, often deflexed distally; leaves (1)2 with well-developed blades; perianth tube (10–)12–14 mm long; outer bracts with (4)5 major veins, 5-toothed . . . . . 73. *I. lacerata*
33b Bracts and prophylls subtending branches short, obtuse to truncate, < 2 mm long; leaves 2 or 3(4) with well-developed blades; perianth tube 5.5–8.0(–10.2) mm long; outer bracts with 3 major veins, 3-toothed or 3-lobed:
34a Foliage leaves 2(3), blades usually falcate; base of stem rarely with fibrous collar; anthers 2.3–3.5 mm long. . . . . 70. *I. rapunculoides*
34b Foliage leaves 3(4); blades usually sword-shaped; base of stem covered by a collar of fibres; anthers 3.5–4.0 mm long . . . . . 71. *I. robusta*
32b Leaf blades mostly 2.0–3.5 mm wide; filaments 3–4 mm long:
35a Plants of streambanks and marshes, often growing in water; perianth tube 8–9 mm long; flowers white with yellow throat . . . . . 72. *I. rivulicola*
35b Plants of hillsides and flats; perianth tube 5–10 mm long; flowers white (rarely flushed pale blue), or pale pink, slate-blue with white or yellow throat, horizontal to nodding:
36a Corm tunics of firm, fine to medium-textured, netted fibres accumulating with age; corms bearing sessile cormlets at base (and rarely a slender stolon); perianth whitish or flushed palest blue with white throat; style dividing opposite middle of anthers, style branches extending between them. . . . . 74. *I. mollis*
36b Corm tunics of soft, ± papery (not fibrous) layers, not accumulating significantly; corms bearing flattened, ribbon-like stolons; perianth pink, blue-grey, slate-blue or white; style dividing opposite anther tips, rarely beyond them, style branches extending beyond anthers . . . . . 77. *I. sobolifera*

Sect. 4. *Dichone*

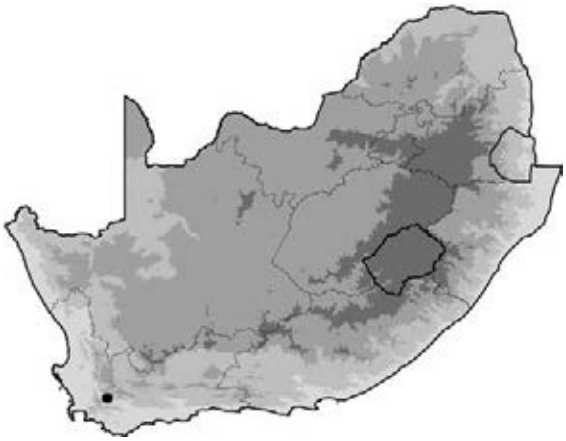
1a Plants 0.9–1.2 m high; perianth tube funnel-shaped with flared upper portion ± 2 mm long and ± as long as filiform lower half; style dividing opposite middle of filaments . . . . . 84. *I. altissima*
1b Plants 0.2–0.6 m high; perianth tube cylindric almost throughout, flared only in upper 0.5–1.0 mm if at all; style dividing opposite or just above bases of filaments:
2a Flowers radially symmetric, upright to half nodding; stamens erect with anthers parallel or diverging:
3a Perianth tube very short, 2.0–2.5 mm long; stem with short, stiffly erect lateral branches held close to main axis, each with up to 8 flowers . . . . . 85. *I. rigida*
3b Perianth tube 2.5–6.0 mm long; stem simple or with 1(–several) suberect to spreading branches:
4a Leaves ± terete or filiform, rarely more than 1 mm wide; corm tunics of fine fibres extending upward in a collar around the stem base:
5a Style branches straight and extending outward below anthers, 3–5 mm long; filaments filiform; outer floral bracts with 3 main veins and several secondary veins, acutely 3-toothed . . . . . 92. *I. micrandra*
5b Style branches falcate, recurved at tips, up to 2 mm long; filaments flattened and wider in middle; outer floral bracts with 3 main veins but lacking secondary veins, usually shallowly 3-toothed or 3-lobed . . . . 93. *I. minor*
4b Basal and sometimes other leaves linear to sword-shaped or lanceolate, usually at least 1.5 mm wide, blades plane with main vein and sometimes multiple veins ± equally prominent; corm tunics fine to coarse-textured, with or without fibrous collar around the stem base:
6a Anthers 4–5 mm long, oblong and > twice as long as wide; spike nodding in bud, becoming erect as flowers open:
7a Anthers yellow; perianth pink, tepals darker at base and yellow in throat; foliage leaves (2.5–)5.0–12.0 mm wide; style branches 4–5 mm long . . . . . 86. *I. trifolia*
7b Anthers purple; perianth light purple with small dark centre; foliage leaves 1.5–2.0 mm wide; style branches up to 2 mm long . . . . . 87. *I. brevituba*
6b Anthers 1.5–3.0 mm long, suborbicular to broadly oblong and < twice as long as wide; spike erect in bud:

8a Leaves 2, basal leaf with expanded, ± lanceolate blade, upper leaf entirely sheathing:
9a Basal leaf with 3 ± equally prominent, thickened veins; style branches falcate to recurved (white drying ± white); tepals 12–15 × 6–8 mm when fully open; spike mostly 7- to 12-flowered . . . . . 89. *I. trinervata*
9b Basal leaf with 1 prominent vein (translucent when alive, appearing raised when dry); style branches ascending, ± straight (pink, often drying purple); tepals remaining slightly cupped, 12–14 × 5–7 mm; spike mostly 4- to 7-flowered . . . . . .90. *I. bifolia*
8b Leaves 2 to 4, with no visible veins or only main vein prominent:
10a Leaves (3)4 or 5, often drying at anthesis; foliage leaf blades lanceolate, mostly 4–9 mm wide . . . . . .94. *I. stricta*
10b Leaves (2)3 or 4; foliage leaf blades linear, mostly 1.5–4.0 mm wide . . . . . 91. *I. confusa*
2b Flowers usually half to fully nodding, facing to side; stamens unilateral with anthers held horizontally or pendent:
11a Anthers dehiscing completely by longitudinal slits . . . . . 88. *I. curvata*
11b Anthers dehiscing by short slits from base to middle, not reaching apex:
12a Foliage leaf usually single, sometimes 2 (uppermost leaf ± entirely sheathing), blade ± linear, 1.0–4.5 mm wide; flowers usually 4 to 8 per spike; perianth tube ± 4.5 mm long . . . . . 99. *I. simulans*
12b Foliage leaves 3 to 7, blades lanceolate to falcate, mostly 4–20 mm wide, or closely undulate and then only 2–4 mm wide; flowers mostly 6 to 20 per spike; perianth tube 2.5–4.0 mm long:
13a Leaves 2–4(5) mm wide; corm tunics of fine, soft fibres; perianth tube 2–3 mm long:
14a Leaf margins strongly undulate and crisped; anthers ± 1.5 mm long . . . . . 95. *I. erubescens*
14b Leaf margins plane; anthers 2–3 mm long:
15a Corms producing slender stolons from base, terminating in a single, large cormlet; anthers ± 3 mm long . . . . . 98. *I. flagellaris*
15b Corms not producing stolons; anthers 2.0–2.5 mm long . . . . . .97. *I. tenuis*
13b Leaves 4–25 mm wide and margins plane or sometimes undulate(–crisped); corm tunics of firm, medium-textured to coarse fibres; perianth tube 2.5–5.0 mm long:
16a Plants rarely more than 600 mm high, simple or branched, with branches ascending to suberect; filaments ± uniformly filiform, < ½ as wide as anthers; style branches not noticeably flared at tips . . . . . 96. *I. scillaris*
16a Plants up to 900 mm high, often branched, with branches held at right angles to main axis, becoming suberect distally; filaments expanded toward apex and becoming as wide as anthers; style branches widely flared at tips . . . . . 100. *I. collina*

Sect. 1. **Hyalis** *(Baker) Diels* in Engler & Prantl, Die natürlichen Pflanzenfamilien, edn. 2, 15a: 486 (1930). Goldblatt & Manning: 92 (2011). *Ixia* subg. *Hyalis* Salisb. ex Baker: 161 (1892); Goldblatt & Manning: 63 (1999). Type: *I. paniculata* D.Delaroche, lecto., effectively designated by Lewis: 149 (1962).

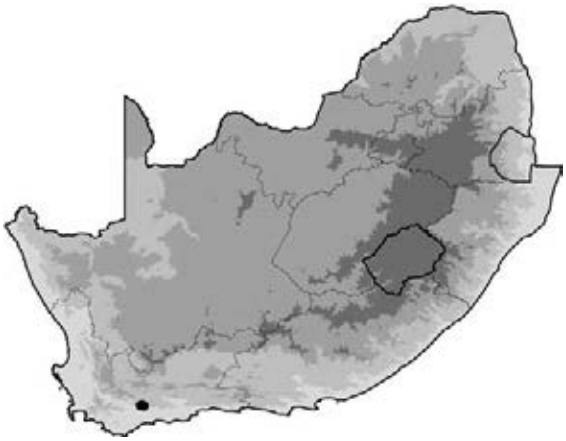
Leaves usually at least 4, sometimes up to 10, in a loose fan with uppermost leaves not sharply distinct from lower and usually not entirely sheathing but distal portion with a produced blade. *Spike* with outer bracts usually dry-membranous and opaque, outer with 1(or 3) prominent veins and with 1 or sometimes 3 teeth, the central usually longest. *Flowers* variously coloured, rarely pale blue-mauve, usually erect or ascending; perianth tube hollow to base or walls of tube clasping style in proximal half, funnel-shaped to cylindric; tepals subequal, spreading. *Stamens* symmetrically arranged in a ring around central style and contiguous, rarely unilateral, then horizontal or declinate; filaments inserted at base of upper part of tube, decurrent, not expanded below, included to well exserted; anthers splitting longitudinally, exserted, partly included or rarely fully included. *Ovary* and *capsules* smooth, rarely papillate (*Ixia pumilio*); style slender, central and straight, or when stamens unilateral then displaced to lie beneath filaments.

Species 19: mainly Western Cape, South Africa.



The section is recognised by an indeterminate leaf number, usually at least four, the upper leaves weakly differentiated from the lower and usually with free blades. The cylindrical or funnel-shaped perianth tube ranges from hollow throughout to filiform in the lower ⅔ and expanded above, always with decurrent filaments inserted within the tube. Nectar is normally produced and the flowers are often scented, although those pollinated by long-proboscid flies are unscented. A feature of most species is the outer bracts with usually only one prominent central vein. The section is divided into three series.

Ser. **Hyalis** *(Baker) Goldblatt & J.C.Manning,* name at new rank. *Ixia* subg. *Hyalis* Salisb. ex Baker: 161 (1892). *I.* sect. *Hyalis* (Baker) Diels in Engler & Prantl: 486 (1930). Type: *I. paniculata* D.Delaroche, lecto., effectively designated by Lewis: 149 (1962).



Plants sometimes acaulescent. *Flowers* red, pink, white or yellow, rarely with dark centre; perianth tube elongate or short and funnel-shaped. *Filaments* sometimes barely exserted.

1. **Ixia pumilio** *Goldblatt & Snijman* in South African Journal of Botany 51: 68 (1985); Goldblatt & Manning: 93 (2011). Type: South Africa, [Western Cape], banks of Breede River south of Worcester, Farm Reiersrus, 30 Aug. 1983, *Snijman 737* (NBG, holo.; K, MO, PRE, iso.).

Plants mostly 120–160 mm high. *Corm* 7–12 mm diam.; tunics of fine netted fibres. *Stem* simple or with 1,

Distribution of ***Ixia pumilio***.

Distribution of ***Ixia leipoldtii***.

rarely 2 or 3 short branches subtended by dry, attenuate, translucent bracts and prophylls ± 3 mm long. *Leaves* 3 or 4, upper 1 or 2 partly sheathing stem, blades narrowly sword-shaped to sublinear, reaching to base or middle of spike, 2–5 mm wide, main vein slightly thickened. *Spike* elongate, mostly 6- to 10-flowered, branches with fewer flowers; bracts dry-membranous, pale brown, mostly 8–9 mm long, outer with prominent central vein, acute or obscurely 3-toothed, inner 2-veined and forked apically, usually slightly exceeding outer. *Flowers* ± erect, old rose-coloured to brick-red, with conspicuously darker veins, unscented; perianth tube funnel-shaped, widening in upper half, 8–10 mm long; tepals subequal, ovate-oblong, 11–13(–16) × 5.5–6.0 mm, spreading horizontally. *Filaments* 5–6 mm long, exserted ± 3 mm from tube; anthers 4.0–5.5 mm long, yellow. *Style* dark purple, dividing opposite middle of anthers, branches ± 1.5 mm long, ovary surface minutely warty. *Flowering time*: mid-August to mid-September.

Distribution and ecology: an extremely local endemic, known only from near Moordkuil and the foot of the Sandberg south of Worcester in Western Cape, South Africa; in alluvial sand close to the Breede River.

Diagnosis: *Ixia pumilio* is distinguished by its low stature, the plants seldom exceeding 150 mm, and unusually coloured dull reddish flowers with pale brown, opaque bracts. The filaments are exserted ± 4 mm from the perianth tube and the dark purple style divides opposite the middle of the anthers. The ovary and capsules are unusual in the genus in their minutely warty surface. The relationships of *I. pumilio* are uncertain.

2. **Ixia leipoldtii** *G.J.Lewis* in Annals of the South African Museum 40: 121 (1954); Goldblatt & Manning: 93 (2011). Type: South Africa, [Western Cape], Eikekraal, east of Prince Albert (but locality probably wrong), 27 Sept. 1935, *Leipoldt s.n.* (BOL 21808, holo.; SAM, iso.).

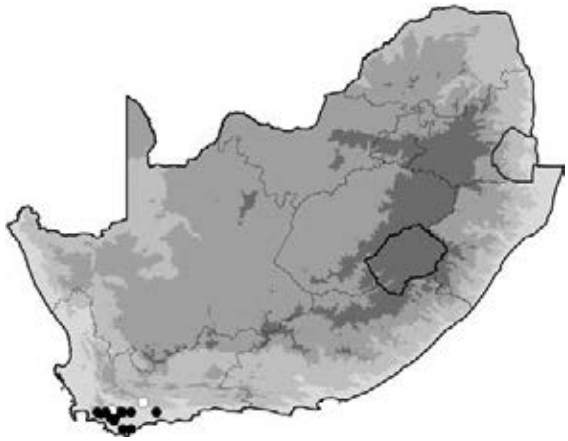
Plants mostly 150–200 mm high. *Corm* 1.0–1.4 mm diam., with tunics of medium-textured fibres. *Stem* simple or with 1 or 2 short branches subtended by dry, translucent brown, attenuate bracts and prophylls 3–5 mm long. *Leaves* usually 3 or 4, lower 2 (or 3) with expanded blades, lanceolate to falcate, ± half as long as stem, upper leaf sheathing stem in lower ⅔, free in upper ⅓. *Spike* erect, 2- to 4(–6)-flowered; bracts dry-membranous, translucent brown with dark veins, 8–9 mm long, outer 3-veined, with 3 subacute teeth, central tooth longest, inner 2-veined and forked at apex, slightly shorter than outer. *Flowers* salver-shaped, white with large dark red-purple centre and plale greenish tube, unscented; perianth tube funnel-shaped, ± 11 mm long; tepals ascending below, spreading above, ovate, (17–)20–22 × 11–13 mm. *Filaments* 3–4 mm long, included in tube; anthers 4–5 mm long, yellow, bases included in tube. *Style* dividing opposite lower third of anthers, branches ± 2 mm long. *Flowering time*: September.

Distribution and ecology: known with certainty only from the heights at the top of Op-de-Tradouw Pass, west of Barrydale in Western Cape, South Africa; on stony clay loam.

Diagnosis: a striking plant in full bloom, *Ixia leipoldtii* has large, predominantly white flowers with tepals up to 22 mm long, and a dark purple central blotch with pale greenish throat. Apart from the unusual flower colouring, *I. leipoldtii* is readily distinguished by the translucent brown bracts, broadly ovate to almost orbicular tepals, and filaments included in the perianth tube. The relatively short perianth tube, a weak distinction between lower and upper leaves, and outer floral bracts with a single or prominent central cusp conform to its placing in sect. *Hyalis*.

3. **Ixia longituba** *N.E.Br.* in Journal of the Linnean Society, Botany 48: 44 (1928); Goldblatt & Manning: 94 (2011). Type: South Africa, without precise locality, illustration in Ker Gawl.: t. 589 (1802a).

Plants (180–)250–450 mm high. *Corm* depressed-globose; tunics of pale, fine fibres. *Stem* simple or more



often 1- or 2-, rarely 3-branched, branches subtended by pale, membranous, attenuate bracts and prophylls 3–5 mm long. *Leaves* mostly 4 to 8, ± sword-shaped to lanceolate, usually reaching to ± base of spike, 5–15 mm wide, firm-textured; margins moderately to heavily thickened, sometimes crisped. *Spike* densely 7- to 12-flowered, branches, when present, with fewer flowers; bracts pale and ± translucent, often flushed pink distally, outer with a single prominent vein and 1- or obscurely 3-toothed, inner forked at tips, 2-toothed, ± as long or slightly longer than outer. *Flowers* salver-shaped, ± suberect to almost horizontal, pale to deep pink (except for rare white sports), darker pink at tepal bases, pale green to yellow in mouth of tube, unscented; perianth tube slender, widening slightly near mouth, (10–)12–33(–35) mm long, 3–4 mm wide at mouth; tepals subequal, spreading horizontally, 16–22 × 7–11 mm, inner narrower than outer. *Filaments* 5–10 mm long, inserted 2–3 mm below mouth of perianth tube, thus exserted 3–7 mm; anthers 4–6 mm long, yellow. *Style* mostly dividing opposite top of filaments or lower to middle third of anthers, rarely shortly beyond anther tips, branches 3–5 mm long. *Flowering time*: mid-September to late October.

Distribution and ecology: endemic to the Caledon and Bredasdorp Districts of Western Cape, South Africa, extending from Bot River in the west to Swellendam and Bredasdorp in the east and south; usually at low elevations on heavy clay soils, also on dry, stony, sandstone slopes.

Diagnosis: *Ixia longituba* is distinguished among the longer-tubed species of sect. *Hyalis* by the pink flowers with filaments exserted 5–7 mm, anthers 4–6 mm long, and well-developed style branches 3–5 mm long. Perianth tube length is remarkably variable, mostly 12–33 mm long, but as short as 10 mm and occasionally as long as 35 mm. Two subspecies are recognised, subsp. *longituba* for plants with a perianth tube (10–)12–23 mm and subsp. *macrosiphon* for those with a tube 25–35 mm long. Subsp. *macrosiphon* comprises the northern populations of the species, all close to the foot of the Riviersonderend Mtns. However, plants from the south of its range, near Bredasdorp may have a perianth tube 22–23 mm long. There appears to be pattern of tube length across the range from south to north. Historically, *Ixia longituba* was confused with *I. bellendenii* but this species has white flowers, a longer perianth tube 35–40 mm long and filaments exserted up to 11 mm. Observations on the pollination biology of a long-tubed population of *Ixia longituba* show the species is pollinated by the long-proboscid horsefly, *Philoliche gulosa*.

Key to subspecies

1a Perianth tube (10–)12–23 mm long; filaments 5–9 mm long and exserted 3–6 mm from tube; anthers 4–5 mm long. . . . . 3a. subsp. *longituba*
1b Perianth tube 25–33(–35) mm long; filaments 8–10 mm long and exserted 6–7 mm from tube; anthers 5–6 mm long. . . . . 3b. subsp. *macrosiphon*

Distribution of ***Ixia longtituba*** subsp. ***longituba***, ●; subsp. ***macrosiphon***, ○.

3a. subsp. **longituba**

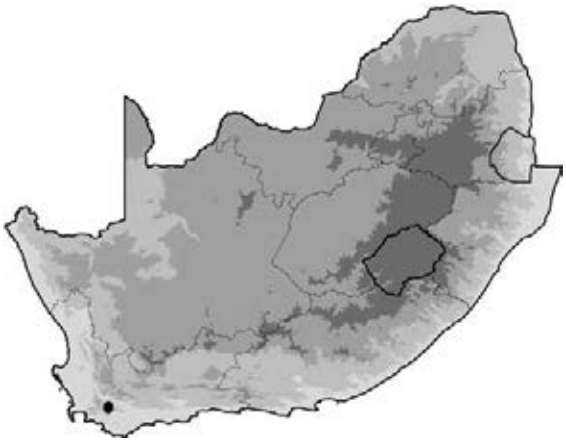
Flowers with perianth tube (10–)12–23 mm long; tepals 14–18 × 6–9 mm. *Filaments* 5–9 mm long, exserted 3–6 mm from mouth of tube; anthers 4–5 mm long. *Style* dividing opposite middle third to apex of anthers, rarely at apex of filaments.

Distribution and ecology: subsp. *longituba* extends from Bot River in the west to Swellendam in the east and as far south as Bredasdorp, thus in the central and southern part of the range of *Ixia longituba*.

3b. subsp. **macrosiphon** *Goldblatt & J.C.Manning* in Bothalia 41: 95 (2011). Type: [Western Cape], hills 6 km SW of Greyton, 8 Oct. 1995, *Goldblatt & Manning 10341* (NBG, holo.; MO, iso.).

Flowers with perianth tube 25–33(–35) mm long, tepals 16–22 × 8–11 mm. *Filaments* 8–10 mm long, exserted 6–7 mm from mouth of tube; anthers 5–6 mm long. *Style* usually dividing between base and middle of anthers.

Distribution and ecology: subsp. *macrosiphon* is known from a few populations in heavy clay ground at the foot of the Riviersonderend Mtns and near Barrydale, in the northern parts of the range of *Ixia longituba*.



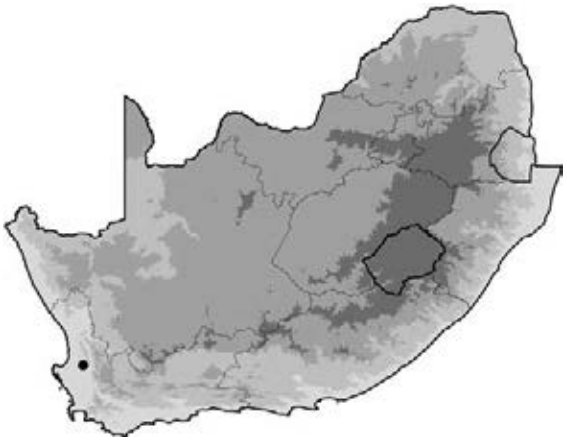
4. **Ixia bellendenii** *R.C.Foster* in Contributions from the Gray Herbarium of Harvard University 114: 47 (1936), as replacement name for *Tritonia rochensis* Ker Gawl.: t. 1503 (1812a); Lewis: 155 (1962, in part); Goldblatt & Manning: 95 (2011). *T. rocheana* Sweet: 398 (1826), orthographic variant for '*rochensis*' Ker Gawl. *Waitzia rochensis* (Ker Gawl.) Heynh. : 855 (1841). *Montbretia rocheana* (Ker Gawl.) Heynh.: 418 (1847), orthographic variant for '*rochensis*'. *Crocosmia rochensis* (Ker Gawl.) Klatt in Peters: 516 (1864). *Morphixia*

paniculata var. *rochensis* (Ker Gawl.) Baker: 97 (1877). *Ixia paniculata* var. *rochensis* (Ker Gawl.) Baker: 166 (1892). *I. rochensis* (Ker Gawl.) L.Bolus: 133 (1929a), illegitimate homonym, not *I. rochensis* Ker Gawl. (1803c) (= *Geissorhiza radians* (Thunb.) Goldblatt). *I. longituba* var. *bellendenii* (R.C.Foster) M.P.de Vos: 63 (1999). Type: South Africa, without precise locality, illustration in Ker Gawler: t. 1503 (1812a).

Plants 400–550 mm high. *Corm* globose 18–22 mm diam.; tunics of fibrous layers. *Stem* simple or with 1 to 3 short branches subtended by pale translucent, deltoid-apiculate bracts 5–6 mm long and long-awned prophylls 7–8 mm long. *Leaves* mostly 4 or 5, lower 3 or 4 with fully developed blades, firm-textured, ± sword-shaped to lanceolate, reaching to ± middle of stem, (2–)5–10 mm wide, dry at flowering, margins moderately to heavily thickened, sometimes crisped. *Spike* mostly 6- to 12-flowered; bracts ± opaque-whitish, tinged pink distally, 6–9 mm long, veins slightly darkener distally, outer with a single prominent vein, subacute or with a short apical tooth, inner 2-toothed, 1–2 mm longer than outer. *Flowers* salver-shaped, spreading horizontally, ± white with pink to purple veins outside, more pronounced with age, yellow in tube and greenish yellow at tepal bases, unscented; perianth tube slender, widening slightly toward mouth, 35–40 mm long, ± 2.5 mm wide at mouth; tepals subequal, spreading at right angles to tube, 18–22 × 6–10 mm. *Filaments* ± 15 mm long, exserted ± 11 mm; anthers 5–6 mm long. *Style* dividing opposite upper half of anthers, sometimes up to 6 mm beyond anthers, branches 1.5–2.0 mm long. *Flowering time*: mid-November to early December.

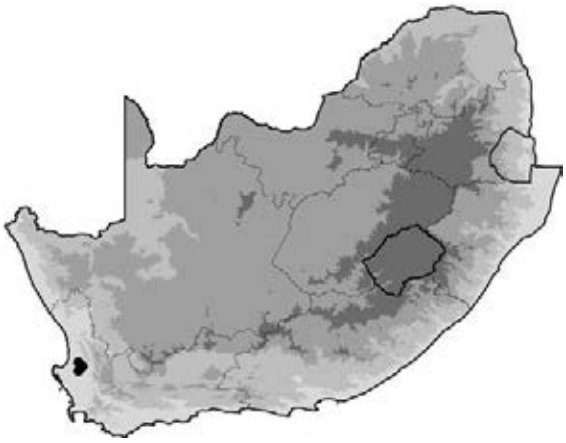
Distribution and ecology: restricted to the northern slopes of the Riviersonderend Mtns in Western Cape, South Africa; in loamy sand among sandstone rocks on lower middle slopes, flowering late in the season.

Diagnosis: *Ixia bellendenii* is readily recognised by the almost white flowers suffused pale pink outside, an elongate perianth tube 35–40 mm long, filaments ± 15 mm long and exserted ± 11 mm, and prominent anthers 5–6 mm long. Blooming late in the season, the leaves are usually withered and dry when flowering commences. Shorter-tubed, pink-flowered *I. longituba,* has shorter filaments exserted 5–7 mm.



Distribution of ***Ixia bellendenii***.

5. **Ixia splendida** *G.J.Lewis* in Journal of South African Botany 4: 9 (1938); Lewis: 153 (1962); Goldblatt & Manning: 97 (2011). Type: South Africa, [Western Cape], Piketberg, Zebra Kop, near stream, 10 Nov. 1934, *Pillans 7183* (BOL, lecto. [as holo.], designated by De Vos: 65 (1999); BOL, PRE, SAM, isolecto.).



Plants 300–600 mm high. *Stem* simple or with a single short branch subtended by acute, translucent bracts and prophylls ± 1 mm long. *Corm* 14–18 mm diam., with tunics of fine, netted fibres. *Leaves* 5 to 7, all with expanded blades, narrowly sword-shaped to sublinear, 2–5 mm wide, reaching to ± middle of stem, upper 2 leaves sheathing stem for ½–⅔ their length. *Spike* densely 5- to 7-flowered; bracts membranous and translucent, evidently dry and turning brown near tips, 6–7 mm long, outer weakly 3-veined, truncate or obscurely 3 lobed, inner 2-veined and forked apically, ± as long as outer. *Flowers* salver-shaped, pale brick-red or pink, evidently unscented; perianth tube subcylindric, slightly expanding from base to apex, 27–30 mm long; tepals subequal, oblong, obtuse to emarginate, 15–18 × 6–8 mm, spreading. *Filaments* 4–5 mm long, included in tube; anthers 5–6 mm long, included or tips exserted. *Style* dividing opposite lower third of anthers, branches ± 1.5 mm long. *Flowering time*: mid-October and November.

Distribution and ecology: a poorly known and rare Western Cape endemic, evidently restricted the upper slopes of Zebra Kop, highest peak of the Piketberg, South Africa; along streams and presumably on stony sandstone soil.

Diagnosis: *Ixia splendida* is distinguished by the slender perianth tube 27–30 mm long, expanding gradually and uniformly from base to apex, dull reddish or deep pink perianth, and fully included stamens. The floral bracts are unusual: the outer of the pair is truncate and obscurely 3-veined, whereas the inner is fairly typical in having 2 veins and is shallowly forked at the tip. It has been assumed to be closely related to the more widespread *I. paniculata*, which also has a long perianth tube and included stamens. Flowers of *I. paniculata* are pale yellow to beige, sometimes almost white, and also have partly to fully included stamens, but the anthers are usually dark and the perianth tube is cylindric and usually longer, up to 75 mm but only 35–50 mm at the southern end of its range, compared to the gradually flared tube 27–30 mm long and yellow anthers of *I. splendida*. In addition, the outer floral bracts of the two differ substantially. Those of *I. paniculata* are elongate and attenuate, with a single prominent vein, whereas

Distribution of ***Ixia splendida***.

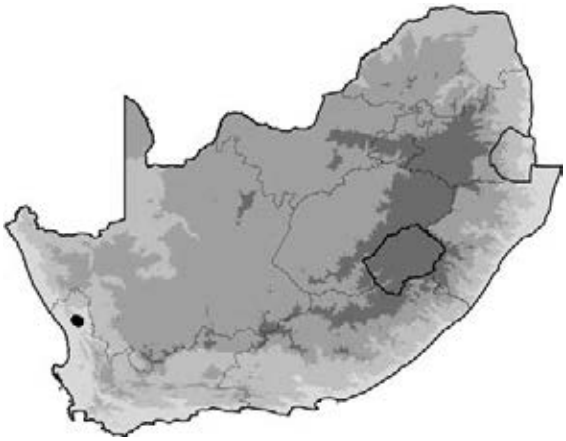
Distribution of ***Ixia linderi***.

those of *I. splendida* have 3 veins and are truncate or obscurely 3-lobed apically. The bract differences suggest that the two species may not be immediately related.

The long-tubed flowers of *I. splendida* resemble those of other species of *Ixia* adapted for pollination by long-proboscid flies and they are inferred to have the same pollination system.

6. **Ixia linderi** *Goldblatt & J.C.Manning* in Bothalia 41: 97 (2011). Type: South Africa, [Western Cape], Piketberg, Zebra Kop, east-facing ledges near water, ± 1 100 m, 7 Nov. 1973, *Linder 103* (BOL, holo.).

Plants 300–450 mm high, base enclosed by a poorly developed fibrous collar. *Corm* 8–10 mm diam.; tunics of fine fibres. *Stem* unbranched. *Leaves* 3 or 4, ± linear, 1.5–3.0 mm wide, main vein prominent, margins slightly thickened. *Spike* 2- to 6-flowered; bracts membranous, evidently dry near tips, ± 5 mm long, outer without dark veins, truncate, inner 2-veined, veins pale, forked apically, slightly longer than outer. *Flowers* suberect, white or faintly pink, tepals flushed pale pink outside, presence of scent unknown; perianth tube subcylindric, gradually expanding from base to apex, 18–20 mm long; tepals subequal, oblong, obtuse, ± 10 × 4 mm, spreading horizontally. *Filaments* ± 1.5 mm long, inserted ± 6 mm below mouth of tube; anthers ± 4 mm long, apices just reaching mouth of tube. *Style* dividing shortly below anther bases, branches ± 1 mm long, reaching lower third of anthers. *Flowering time*: November.



Distribution and ecology: known from just two collections from Zebra Kop, highest peak of the Piketberg in Western Cape, South Africa; on moist sandstone slopes and rock ledges near water.

Diagnosis: the white flowers with a relatively long, narrow perianth tube, 18–20 mm long, with the stamens and style included in the tube immediately set *Ixia linderi* apart in sect. *Hyalis*. The filaments, only 1.5 mm long, are inserted ± 6 mm below the mouth of the tube and the anthers, ± 4 mm long, just reach the mouth. The style divides just below the anther bases and the short style branches ± 1 mm long are retained within the tube. The species most closely resembles a second Piketberg endemic, *I. splendida*, but this species is a more robust plant with leaves up to 5 mm wide and larger, brick-red to pink flowers with a perianth tube 27–30 mm long. Like *I. linderi*, the flowers of *I. splendida* have the stamens and style included in the tube. Both species have distinctive, translucent, ± truncate outer floral bracts with minute terminal teeth.

7. **Ixia acaulis** *Goldblatt & J.C.Manning* in Novon 3: 152 (1993); Goldblatt & Manning: 98 (2011). Type: South Africa, [Western Cape], Vanrhynsdorp, Knersvlakte, farm Rooiberg, low limestone ridge, 19 May 1992, *Snijman & Manning 1249* (NBG, holo.; MO, PRE, iso.).

Plants acaulescent, leaves and flowers reaching 20–30 mm above ground, often in small clumps, occasionally branched. *Corm* narrowly cone-shaped, ± 3–4 mm wide near base, tapering above, ± 15 mm long; tunics moderately to finely fibrous, accumulating with age in a dense mass. *Stem* unbranched. *Leaves* 3 to 5, linear to narrowly lanceolate, 1.5–2.0 mm wide, prostrate or inclined, leathery, without thickened margins or main vein. *Spike* 1- or 2-flowered; bracts membranous, ± 10 mm long, reaching up to 5 mm above ground, outer with upper margin slightly fringed, inner 2-veined and shallowly forked apically. *Flowers* yellow, whitish in tube, usually faintly sweet-scented; perianth tube 15–20 mm long, arising below ground level, extending ± 10 mm above ground, cylindric; tepals subequal, obtuse to emarginate, 6–7 × ± 3 mm, spreading. *Filaments* arising at top of tube, ± 1.5 mm long, decurrent; anthers ± 2 mm long. *Style* dividing at or just beyond mouth of tube, branches short, ± 1 mm long, apices emerging between filaments. *Flowering time*: (April)May–June.

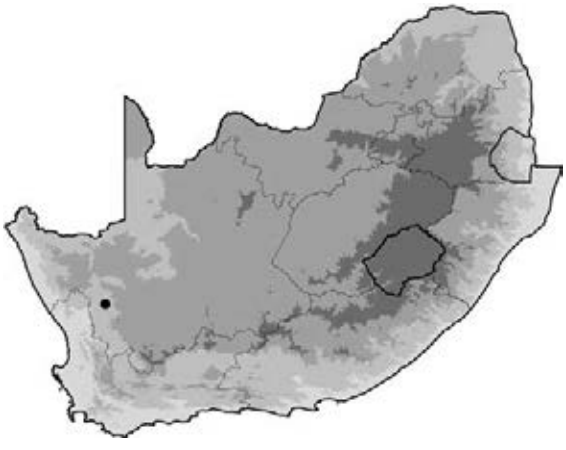
Distribution and ecology: restricted to the arid Knersvlakte of southern Namaqualand in Western Cape,

Distribution of ***Ixia acaulis***.

South Africa, known from four populations; on limestone ridges and outcrops.

Diagnosis: recognised by its acaulenscent habit, short leaves without thickened midrib or margins, and long-tubed yellow flowers with subterranean ovary. Corms are wedged in rock crevices and are very difficult to extract undamaged. The capsules are typical of the genus but are borne at ground level. *Ixia macrocarpa*, a second acaulescent species, is thought to be closely allied to *I. acaulis* as it has similar leaf morphology but the yellow flowers have brown markings at the base of the tepals, filaments inserted at the mouth of the tube, a longer style dividing opposite the middle of the anthers, and unusual, large capsules, ± 20 mm long and sterile in the upper third, unique for the genus.

The immediate relationships of *I. acaulis* within *Ixia* are uncertain but it has provisionally been assigned to sect. *Hyalis* because of the decurrent filaments and membranous bracts without prominent veins. Similar fringed outer bracts are found in *I. linderi* and *I. splendida*, both of which also have an elongate perianth tube but have well-developed aerial stems and anthers included in the perianth tube.



8. **Ixia macrocarpa** *Goldblatt & J.C.Manning* in South African Journal of Botany 98: 112 (2015). Type: South Africa, Northern Cape, clay flats near Loeriesfontein airstrip, 17 Aug. 2014, *Helme 8117* (NBG, holo.).

Plants acaulescent, leaves and flowers reaching 30–50 mm above ground, often in small clumps. *Corm* broadly conic, 6–8 mm diam.; tunics of pale brown, fine, netted fibres. *Stem* underground, sheathed by membranous cataphylls reaching ground level. *Leaves* 6 or 7, falcate-flabellate, basal, 5–15 × (3–)4–6 mm, obtuse, leathery, glaucous, without evident main vein, margins cartilaginous. *Spike* contracted, few-flowered, hidden in leaf bases; bracts membranous, translucent, flushed green distally, outer linear-oblong, ± 30 mm long, median vein visible only near apex, acute, inner slightly shorter with 2 veins visible distally, acute. *Flowers* salver-shaped, pale yellow with red-brown blotch at bases of tepals, presence of scent unknown; perianth tube filiform, 35–45 mm long, cylindric, occluded by walls closely clasping style; tepals spreading, subequal, elliptic, slightly spooned, 12–15 × 4–5 mm. *Filaments* inserted at mouth of tube, united in a column ± 4 mm long; anthers diverging, curving inward distally, ± 4 mm long, yellow. *Ovary* subterranean, flask-shaped, 6 mm long. *Style* dividing just below apex of filament column, ± 2.5 mm long, extending between anthers. *Capsules* largely subterranean, concealed in leaf sheaths, oblong-ellipsoid, 20 × 5 mm, sterile in upper third, splitting at ground level to release seeds. *Seeds* globose, smooth, ± 3 mm diam., reddish brown, raphal vascular trace excluded. *Flowering time*: early to mid-August, probably from mid-July.

Distribution and ecology: known from a single, small population near Loeriesfontein, Northern Cape, South Africa, mostly within the Loeriesfontein Airfield grounds; on stony, shale flats in fine-grained clay ground, in Hantam Karoo vegetation.

Diagnosis: *Ixia macrocarpa,* the second acaulescent species known in *Ixia*, has long-tubed, pale yellow flowers with dark markings at the base of the tepals. Despite the shared acaulescent habit, it may not be closely allied to *I. acaulis,* the other acaulescent species of the genus, restricted to rocky outcrops of limestone and marble in the Knersvlakte southwest of Loeriesfontein. *Ixia macrocarpa* differs in having broader, falcate leaves arranged in a tight fan, filaments united in a column enclosing the style, and diverging anthers. The pale yellow flowers have the tepals marked dark red-brown at the bases. *Ixia acaulis* has narrow, spreading to prostrate leaves, and uniformly yellow flowers with the style dividing opposite the bases of free filaments, and parallel anthers. Seeds of *I. macrocarpa* are smooth and unusually large, ± 3 mm diam.

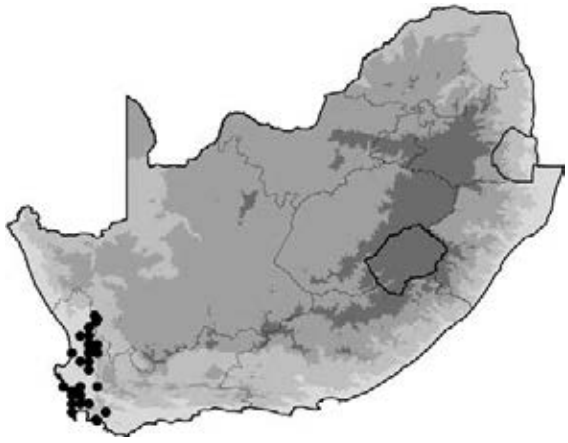
Ixia macrocarpa is provisionally included in sect. *Hyalis* because of the membranous bracts without prominent veins and broad resemblance to *I. acaulis* but the

Distribution of ***Ixia macrocarpa***.

occluded perianth tube is anomalous in the section. Similar occluded perianth tubes define sect. *Ixia* and sect. *Dichone* and its presence in *I. macrocarpa* thus appears to be a parallel development, in this case related to the acaulescent habit, where the tube functions as a false pedicel, raising the flower above the ground. The capsules are unique in *Ixia* in being flask-shaped, ± 20 mm long and sterile in the upper third. United filaments are unusual in *Ixia* but are known in species of the *I. maculata* group of the genus and *I. monadelpha*, all sect. *Ixia*. These species all have aerial stems and seem unlikely to be closely related to *I. macrocarpa*.

9. **Ixia paniculata** *D.Delaroche*, Descriptiones plantarum aliquot novarum: 26, t. 1 (1766); Lewis: 99: (1962); Goldblatt & Manning: 99 (2011). *Morphixia paniculata* (D.Delaroche) Baker: 97 (1877). *Tritonia paniculata* (D.Delaroche) Klatt: 358 (1882). Type: South Africa, without precise locality or collector, Herb. Burman (G-DEL, holo.).

Ixia longiflora P.J.Bergius: 7, 360 (1767), illegitimate superfluous name for *I. paniculata* D.Delaroche. *Tritonia longiflora* Ker Gawl.: 228 (1804a). *Gladiolus longiflorus* Jacq. (1795), illegitimate homonym, not L.f. (1782). *Hyalis longiflora* Salisb.: 318 (1812). *Babiana longiflora* Steud.: 683 (1821). Type: South Africa, without precise locality, cultivated in Holland, *Kallstrom s.n.* (HBT, holo.).



Houttuynia capensis Houtt.: 448 (1780). *Tritonia capensis* (Houtt.) Ker Gawl.: t. 618 (1803b). *Montbretia capensis* (Houtt.) Voigt: 611 (1845). *Acidanthera capensis* (Houtt.) Benth. ex Baker: 187 (1892). Type: South Africa, without precise locality, cultivated in Holland, illustration in Houttuyn: t. 85, f. 3 (1780).

Ixia longiflora Lam.: 342 (1789), illegitimate homonym, not *I. longiflora* P.J.Bergius (1767). Type: Uncertain, P (Herb. Lamarck or Herb. Jussieu).

Ixia tenuiflora Vahl: 66 (1805). *Tritonia tenuiflora* (Vahl) Ker Gawl.: sub t. 1275 (1810a). *Morphixia paniculata* var. *tenuiflora* (Vahl) Baker: 97 (1877). *Waitzia tenuiflora* (Ker Gawl.) Heynh.: 855 (1841). *Montbretia tenuiflora* (Ker Gawl.) Voigt: 611 (1845). *Crocosmia tenuiflora* (Ker Gawl.) Klatt in Peters: 516 (1864). *Morphixia paniculata* var. *tenuiflora* (Vahl) Baker: 97 (1877). *I. paniculata* var. *tenuiflora* (Vahl) Baker: 166 (1892). Type: evidently unknown, possibly Herb. Vahl: C.

Gladiolus ixioides Thunb.: 208 (1811). Type: South Africa, without precise locality, *Thunberg s.n.* (UPS-THUNB 1035, holo.).

Tritonia concolor Sweet: 398 (1826). *Waitzia concolor* (Sweet) Heynh.: 854 (1841). *Montbretia concolor* (Sweet) Voigt: 611 (1845). Type: South Africa, without precise locality or collector, illustration in Ker Gawler: t. 1502, var. γ, *corolla ochroleuca concolor* (1812b).

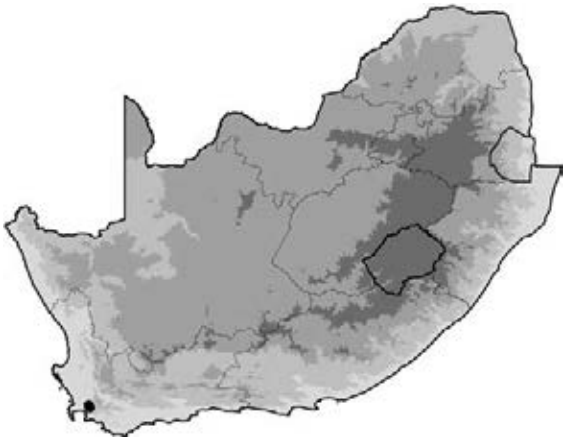
Distribution of ***Ixia paniculata***.

Plants 500–650 mm high. *Corm* 15–20 mm diam., often bearing cormlets on short, thick stolons from base; tunics of fine netted fibres. *Stem* simple or often with 1 or 2 ascending to horizontal branches, subtended by dry, cuspidate, brown-flecked bracts and prophylls 1.5–3.0 mm long. *Leaves* 5 or 6 in a loose fan, lower leaves becoming dry and brown at flowering, lanceolate, often slightly twisted in upper half, mostly 4–7 mm wide, reaching to middle or to near top of stem; margins and main vein slightly thickened. *Spike* crowded, 8- to 16-flowered, branches mostly 3- to 8-flowered; bracts membranous, translucent below but sparsely to closely flecked with rust-brown distally, (7–)9–15 mm long, outer with 1 prominent vein, acute or obscurely 3-lobed with a prominent central tooth, inner 2-veined, ± as long as outer or slightly longer or shorter, 2-veined, forked apically. *Flowers* pale yellow to creamy beige, lower fifth of tepals sometimes darker, unscented; perianth tube cylindric, 35–65(–75) mm long, widened in upper 3–5 mm; tepals oblong-elliptic, 16–25 mm long, outer ± 6 mm, inner ± 4 mm wide. *Filaments* 5–6 mm long, included (rarely partly exserted), inserted 8–10 mm below mouth of tube; anthers 4.5–7.0 mm long, dark purple (rarely pale), half to fully included with tips ± 1 mm below mouth of tube, rarely fully exserted. *Style* dividing opposite lower to upper third of anthers, rarely opposite anther tips or up to 3 mm beyond them, branches ± 2 mm long. *Flowering time*: mid-November to early December.

Distribution and ecology: extending from the Bokkeveld Mtns north of Nieuwoudtville in Northern Cape through the western half of Western Cape, South Africa to the coast near Kleinmond; in both montane and lowland habitats, usually on sandy or stony sandstone ground in seasonally wet situations, in marshes, seeps, drainage lines or along streams.

Diagnosis: *Ixia paniculata* is distinctive in its fairly tall stature and remarkably long-tubed flowers, the tube usually 40–65 mm long, with the darkly coloured anthers included in the tube (sometimes partly or rarely fully exserted). The perianth is pale yellow to pale beige

with the undersides of the tepals often flushed with pink or red. Plants from inland in the north of its range, from Piketberg to the Bokkeveld Mtns, have tubes 45–65 mm long, those from the coast north of Cape Town are consistently long-tubed, 65–75 mm long, but those from the Cape Peninsula and the False Bay Coast have shorter tubes 35–55 mm long. Collections from the Cape Flats stand out in their pale anthers and style dividing ± 2 mm beyond the anther tips. In other populations the style divides between the lower and upper third of the anthers, exceptionally opposite the anther tips. The anthers, usually dark brown or almost black, are typically 5.0–6.5 mm long and half exserted but sometimes fully included. The Cape Flats plants are particularly unusual, not only in the short perianth tube and long style but the pale anthers are only 4.5 mm long. Flowers of *I. paniculata* are adapted for pollination by long-proboscid flies and along the Western Cape Atlantic Coast are pollinated by *Moegistorhynchus longirostris*. At least in the Bokkeveld Mtns plants set seed in the absence of its pollinator and are thus facultatively autogamous.



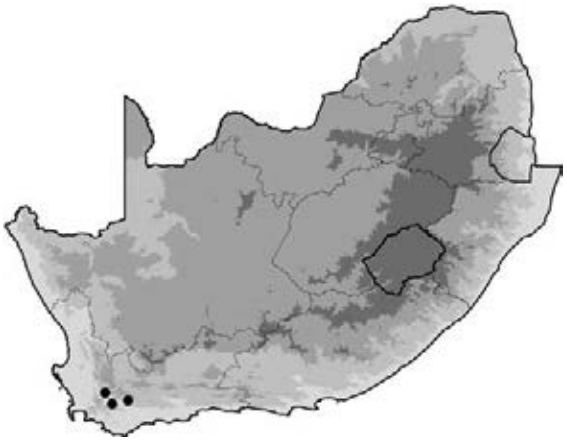
A surprising hybrid from near Kleinmond represents a cross between *Ixia paniculata* and *I. sarmentosa* (sect. *Ixia*). Extensive hybrid swarms between *Ixia paniculata* and *I. monadelpha* (also sect. *Ixia*) occur on Rondenbosch Common on the Cape Peninsula where the two species come into contact. Hybrids in *Ixia* are otherwise rare in the wild and there are no other records of intersectional hybrids in the genus.

Ser. **Fucatae** *Goldblatt & J.C.Manning*, new series. Type: *Ixia fucata* Ker Gawl.

Plants with well-developed stem. *Flowers* pink to white. *Filaments* partly exserted or included, or anthers also included.

10. **Ixia cochlearis** *G.J.Lewis* in Flowering Plants of Africa 25: t. 969 (1945); Goldblatt & Manning: 101 (2011). Type: South Africa, [Western Cape], Jonkershoek, Nov. 1943, *Wicht s.n.* (PRE 27196, holo.; BOL 39125, iso.).

Plants mostly 200–300 mm high, sheathed at base by collar of fibres. *Corm* 14–20 mm diam. with tunics of fine netted fibres. *Stem* unbranched. *Leaves* 4 to 7, upper 1 to 3 partly sheathing; blades narrowly sword-shaped to sublinear, reaching at least to base, or sometimes exceeding spike, 1.5–3.0 mm wide, main vein slightly thickened. *Spike* elongate, mostly 6- to 12-flowered; bracts membranous with dark veins, 4–6 mm long, outer 3-veined and 3-toothed, inner 2-veined and forked apically, slightly exceeding outer. *Flowers* deep pink, presence of scent unknown; perianth tube narrowly funnel-shaped, expanded in upper ⅓, (10–)12–18 mm long, ± 3 mm wide at mouth; tepals subequal, oblong, 14–17 × 6–8 mm, spreading horizontally but remaining concave. *Filaments* ± 10 mm long, usually exserted ± 6 mm; anthers ± 4 mm long, yellow. *Style* dividing opposite anther tips, branches ± 1.5 mm long. *Flowering time*: November, sometimes lasting into early December.



Distribution of ***Ixia cochlearis***.

Distribution and ecology: restricted to the mountains immediately east of Stellenbosch in Western Cape, South Africa; on rocky slopes at elevations of 305–550 m, at least sometimes on granite substrate, flowering well only after fire.

Diagnosis: *Ixia cochlearis* is distinctive in sect. *Hyalis* in the deep pink flowers with a narrowly funnel-shaped perianth tube mostly 12–18 mm long, at least four, and up to seven, narrow, fairly firm leaves, and in the presence of a fibrous collar around the stem base. The relatively long and narrow perianth tube is reminiscent of *I. fucata* and *I. stohriae*, also montane species, but occurring to the north and east, in the Hex River Mtns and Langeberg. These two species have broader, soft-textured leaves and shorter stamens, the filaments exserted only 2–5 mm in *I. fucata* and up to 1 mm in *I. stohriae*, compared with the longer filaments of *I. cochlearis*, which are exserted up to 6 mm.

11. **Ixia fucata** *Ker Gawl.* in Curtis's Botanical Magazine 34: t. 1379 (1811a); Goldblatt & Manning: 101 (2011). Type: South Africa, without precise locality, illustration in Ker Gawl.: t. 1379 (1811a). Epitype: South Africa, [Western Cape], Worcester District, Hex River Mtns, Milner Ridge Peak, west slopes, 5 000–6 000 ft [1 525–1 830 m], 11 Nov. 1943, *Esterhuysen 9326* (BOL, epi.).

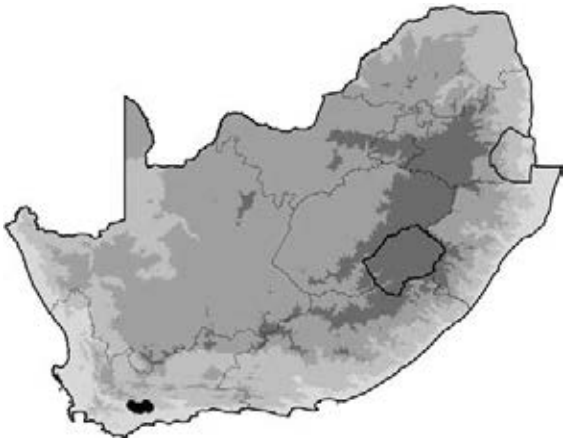
Plants (150–)250–400 mm high, usually with weakly developed fibrous collar around base. *Corm* globose, 7–9 mm diam., with tunics of fine, soft, netted fibres. *Stem* usually unbranched, or with a single short, erect branch subtended by translucent, membranous, attenuate bracts and prophylls 2–3 mm long, these present even when branch not produced. *Leaves* (3)4 or 5, narrowly sword-shaped to sublinear, 1.5–3.0 mm wide, main vein and margins usually slightly thickened, uppermost (1)2 leaves largely or entirely sheathing. *Spike* flexuose, (2–)4- to 7(–14)-flowered; bracts 5–8 mm long, outer 5-veined and acutely 3-toothed, inner bracts as long or slightly longer than outer, 2-veined and forked

Distribution of ***Ixia fucata***.

apically. *Flowers* salver-shaped, suberect, sometimes with unilateral stamens, white to pale or deep pink with darker lines or streaks at mouth of tube and uniformly pink or red outside; perianth tube 10–15 mm long, straight, slightly flared, ± 2 mm diam.; tepals subequal, 12–14 × ± 6 mm, spreading at right angles to tube. *Filaments* 3–6 mm long, exserted ± 2–5 mm from tube; anthers 3.5–4.0 mm long, shortly tailed, often purple; pollen yellow (brown). *Style* dividing opposite lower third to middle of anthers, branches 2.0–2.5 mm long, recurved. *Flowering time*: mainly late September to early November, occasionally in early September.

Distribution and ecology: restricted to higher elevations of the Hex River Mtns, Keeromsberg and the western Langeberg as far east as Montagu in Western Cape, South Africa; on sandstone slopes and outcrops in restioid fynbos, evidently flowering well only in the years immediately following a wildfire unless in exposed situations.

Diagnosis: based on a plant of unknown provenance grown in Great Britain, the type of *Ixia fucata* is an illustration of a species of *Ixia* with a white flower, pink on the outside and with small red streaks at the base of the tepals. The yellowish tube is narrow but well developed, and there are five narrowly sword-shaped (± sublinear) leaves, the uppermost of which sheaths the stem for about ⅔ its length. The name is now associated with plants from the Hex River Mtns. *Ixia fucata* is somewhat variable: plants from the Langeberg have pink flowers, with the bases of the tepals red, the outside of the tube and tepals are dark pink, and unusual for *Ixia*, the stamens are unilateral and declinate. The parallel anthers thus lie in one plane and face upward toward the top of the spike. In contrast, plants from the Hex River Mountains have symmetrically disposed stamens.



12. **Ixia stohriae** *L.Bolus* in South African Gardening and Country Life 21: 281 (1931a); Goldblatt & Manning: 102 (2011). Type: South Africa. [Western Cape], Swellendam, Tradouw Pass, 14 Sept. 1931, *Smith s.n.* (BOL 19879, lecto., designated by Lewis: 97 (1962); K, isolecto.).

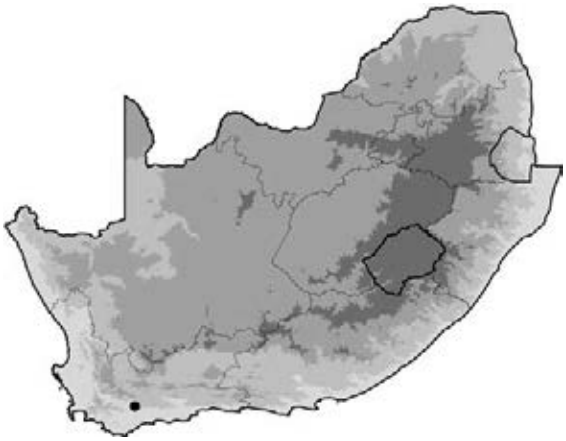
Tritonixia conferta Klatt: 356 (1882) [not *Ixia conferta* R.C.Foster]. Type: South Africa, [Western Cape], Voormansbosch, Oct. ± 1830, *Zeyher 4014* (SAM, lecto., designated by De Vos: 29 (1999); K, PRE, Z, isolecto.).

Plants 180–400 mm high. *Corm* globose, 9–12 mm diam. bearing small cormlets at base; tunics of fine, netted fibres. *Stem* usually 1- to 3-branched, or simple, branches subtended by pale, membranous, darkly keeled bracts and prophylls 2–4 mm long. *Leaves* (4)5 or 6(–8), lower with well-developed blades grading partly to almost entirely sheathing above, blades narrowly sword-shaped to sublinear, usually reaching to ± base of spike, (2–)3–5(–6) mm wide, relatively firm-textured, main vein slightly raised, when dry a pair of secondary veins evident. *Spike* 5- to 10-flowered; bracts membranous, pale and translucent, ± 5 mm long, outer 3-veined and shortly 3-toothed, inner 2-veined and 2-toothed, slightly shorter than outer. *Flowers* pale pink, dark pink on reverse of tepals, tube dark red-purple outside, unscented; perianth tube widening very gradually from base to apex, (12–)14–22 mm long; tepals subequal, ovate, 12–14 mm long, spreading at right angles to tube. *Filaments* 1.5–3.0 mm long, inserted 2–4 mm below mouth of tube, included or exserted up to 1 mm; anthers 2–3 mm long, exserted or partly to entirely included in tube, yellow; pollen yellow. *Style* dividing 0.5–1.0 mm below anther bases, branches 1.0–2.3 mm long, tips reaching at least to anther bases, rarely shortly exceeding anther tips. *Flowering time*: late August to mid-September.

Distribution and ecology: endemic to the central Langeberg of Western Cape, South Africa, occurring in Protea Valley above Swellendam and Voormansbosch nearby, as well as in Tradouw Pass and Grootvadersbos to the east; on rocky sandstone slopes, flowering only in the years immediately after fire.

Diagnosis: *Ixia stohriae* is recognised by the pink flowers with a relatively long, nearly cylindric perianth tube mostly 14–22 mm long and by the partly included

Distribution of ***Ixia stohriae***.



(rarely just exserted) anthers. Well-grown plants may reach as much as 400 mm high. *Ixia stohriae* appears to be most closely allied to *I. fucata* of the western Langeberg and Hex River Mtns to the west and they are virtually identical vegetatively. *Ixia fucata* has either white or pink flowers, the filaments are exserted 2–5 mm from the tube, and the style branches are consistently longer than in most collections of *I. stohriae*, 2.0–2.5 mm long.

13. **Ixia recondita** *Goldblatt & J.C.Manning* in Bothalia 41: 103 (2011). Type: South Africa, [Western Cape], Montagu, kloof at base of Leeuriviersberg [Grootberg], on sparsely vegetated sloping ledges, pale pink, 1 Sept. 1958, *Esterhuysen 27870* (BOL, holo.; K, MO, iso.).

Plants 250–750 mm high. *Corm* globose, 10–12 mm diam., bearing small cormlets at base; tunics of fine, netted fibres. *Stem* erect or inclined, rarely with 1 branch subtended by membranous, darkly keeled attenuate bracts and prophylls 2–4 mm long. *Leaves* (3)4, lower 2 or 3 with well-developed blades, uppermost partly to almost entirely sheathing, blades narrowly sword-shaped to sublinear, usually exceeding stem but trailing above, (2–)3–4(–6) mm wide, soft-textured, main vein slightly raised, when dry a pair of secondary veins evident, margins not thickened. *Spike* subsecund, crowded, suberect or inclined, 4- to 8-flowered, branches with fewer flowers; bracts membranous, pale translucent with dark veins, flushed pink distally, 5–6 mm long, outer 3-veined and 3-toothed, inner 2-veined and 2-toothed, ± as long to slightly longer or shorter than outer. *Flowers* salver-shaped, pale pink, with a small, dark purple mark at tube apex between tepal bases, flushed red outside, unscented; perianth tube 10–12 mm long, subcylindric, widening gradually from base to apex, ± 1.5 mm diam. at mouth; tepals subequal, oblong-elliptic, 10–13 × 4–5 mm, spreading at right angles to tube. *Filaments* included in tube, 2–3 mm long, inserted ± 3 mm above tube base, shortly decurrent; anthers 2.0–2.5 mm long, tips reaching 3.5–5.0 mm below tube mouth, white; pollen yellow. *Style* 1–2 mm long, dividing shortly below or opposite filament bases, branches 1.5–2.0 mm long, reaching to base or middle of filaments. *Flowering time*: late August to mid-October.

Distribution and ecology: a narrow endemic of southern Western Cape, South Africa, restricted to the Leeuriviersberg, now Grootberg, section of the Langeberg west of Swellendam, collected only twice; on stony, south-facing slopes and rocky ledges, possibly flowering well only after fire.

Diagnosis: *Ixia recondita* is distinctive in having not only the filaments but also the anthers, style and style branches included within the narrow perianth tube, and in its soft-textured leaves. It broadly resembles *I. stohriae*, which also has short filaments, either included in the perianth tube or shortly exserted up to 1 mm and the bases of the anthers sometimes partly included in the tube, but is otherwise a more robust plant and most collections consist of plants with sturdy, erect

Distribution of ***Ixia recondita***.

stems with at least one branch (rarely up to 5 branches). The style in *I. stohriae* reaches at least to the middle of the anthers and sometimes exceeds them, thus always reaching the mouth of the perianth tube. This contrasts with the condition in *I. recondita*, in which the style, just 2–3 mm long, divides opposite the filament bases in the lower half of the perianth tube and the style branches barely reach the middle of the filaments.

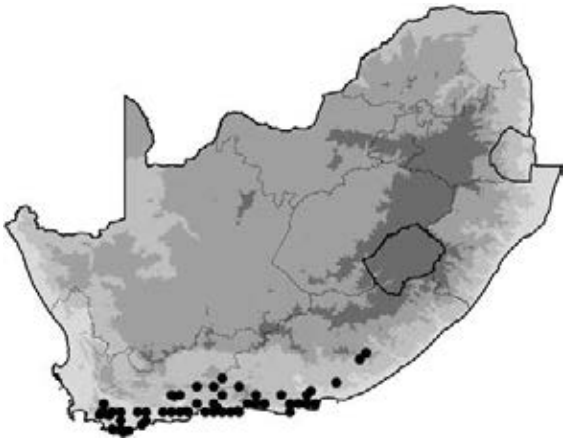
Like *Ixia stohriae* and closely related *I. fucata*, *I. recondita* usually has four leaves, sometimes three or five, the lower two or three with well-developed blades and the upper one or two partly to almost entirely sheathing. In the length of the perianth tube, ± 12 mm long, *I. recondita* is intermediate between its two relatives: the tube of *I. stohriae* is (12–)14–22 mm long, and that of *I. fucata* 10–15 mm long. Both *I. fucata* and *I. stohriae* are Langeberg endemics, the latter recorded from the mountains between Grootvadersbos and Swellendam, while *I. fucata* occurs further west from Montagu to Keeromsberg, as well as in the Hex River Mtns. The range of *I. recondita* thus lies between that of its two relatives.

Ser. **Angustisiphon** *Goldblatt & J.C.Manning*, new series. Type: *Ixia orientalis* L.Bolus

Plants with well-developed stem. *Flowers* mostly pale pink, white or yellow, also orange; perianth tube narrowly funnel-shaped, almost filiform below, only slightly wider above. *Filaments* sometimes barely exserted. *Style* usually dividing below or opposite bases of anthers.

14. **Ixia orientalis** *L.Bolus* in South African Gardening and Country Life 19: 27 (1929b); Goldblatt & Manning: 104 (2011). Type: South Africa. [Eastern Cape], Albany, between Seven Fountains and Sidbury, Nov. 1928, *Dyer 1684* (BOL, holo.; GRA, K, PRE, iso.).

Ixia alba Eckl.: 27 (1827), illegitimate homonym, not *I. alba* L. (= *Sparaxis bulbifera* (L.) Ker Gawl.). Type: South Africa, [Western Cape], *Ecklon & Zeyher 70.10* (PRE, S, syn.).



Ixia scariosa var. *longifolia* Baker: 165 (1892). Type: South Africa, [Western Cape], mountains at Avontuur, Nov. 1870, *H. Bolus 2487* (K, lecto., designated by De Vos: 33 (1999); BOL, isolecto.).

Plants usually 400–600(–800) mm high. *Corm* globose, with sessile cormlets at base; tunics of fine to medium-textured fibres. *Stem* 1- to 3(4)-branched, rarely unbranched; branches suberect, closet to main axis, subtended by membranous, attenuate bracts and prophylls mostly 3–5 mm long. *Leaves* (3)4 to 6, narrowly sword-shaped to sublinear, 1.5–6.5(–8.0) mm wide, upper 1 or 2 leaves partly sheathing. *Main spike* erect, flexuose, (2–)7- to 12(–16)-flowered, lateral spikes 2- to 8-flowered; bracts membranous, 5–8 mm long, usually ± 1 internode long, occasionally longer, outer with 1 prominent vein and prominent central cusp, sometimes with a shorter tooth either side of central cusp, inner bract 2-veined and forked apically, slightly shorter to slightly longer than outer. *Flowers* salver-shaped, pink or white, not scented; perianth tube narrowly funnel-shaped, 8–12 mm long, lower half filiform; tepals ovate, 10–14(–16) × 5–8 mm, spreading horizontally. *Filaments* 5–6 mm long, exserted 2–4 mm; anthers 4–5 mm long. *Style* dividing below base to lower third of anthers, rarely opposite upper third of anthers, branches mostly 4–5 mm long, ascending, emerging between anthers. *Flowering time*: mainly mid-September to late October, as late as December at high elevations.

Distribution and ecology: the most widespread species of the genus, extending from Bot River and Villiersdorp in Western Cape to Bathurst and the Amatole Mtns in Eastern Cape, South Africa; in a remarkably varied range of habitats, including seasonally marshy sites, stony coastal grassland, clay hills, and well-drained sandstone slopes and flats.

Diagnosis: one of only two species of the genus that extend outside the Greater Cape flora region (the other being *Ixia marginifolia*), *I. orientalis* is a relatively unspecialised species lacking any outstanding features, thus difficult to diagnose. It can be identified by the combination of branched stems, spikes often with seven or more flowers, four to six leaves (rarely only three), none completely sheathing the stem, and small, pink or white flowers. The perianth tube, 8–12 mm long, is narrowly funnel-shaped with the proximal half to two thirds always extremely narrow. Well-grown specimens have stems with 2 to 4 branches and the main spike usually bears 7 to 12, rarely up to 16 flowers, although in plants from the mountains of the southern Cape the stems may be unbranched and the spikes have fewer flowers. Typical plants from Eastern Cape have the largest flowers, with the tube 12 mm and tepals ± 14 mm long, but to the west, particularly around Caledon, flowers are smaller, sometimes with a tube only 8 mm long and tepals ± 10 mm long, but there seem to be no other differences and the pattern of variation lacks clear discontinuities so that it is impossible to recognise infraspecific taxa.

Late flowering, *I. orientalis* is seldom seen before the middle of September, although there are records as early as August. It may be most closely related to the largely montane Western Cape species, *I. odorata*, which typically has slightly smaller flowers, usually yellow, rarely white, with a strong sweet scent and distinctive, relatively short filaments up to 3 mm long (measured to the base of the anthers), and the style dividing between the base and apex of the filaments. This contrasts with longer filaments, up to 6 mm long, and a style usually dividing between the base and upper third of the anthers (rarely shortly below the filaments) in *I. orientalis*. It is also difficult to distinguish from *I. flexuosa* (sect. *Ixia*) without careful dissection. Both may have a perianth tube of similar length, with a relatively short, wider distal portion, a style often dividing opposite the bases of the anthers, and many-flowered spikes. The filaments, inserted at the base of the wider part of the tube are uniformly narrow and shortly decurrent in *I. orientalis* and although similarly positioned in *I. flexuosa*, the filaments are flattened and broader toward the bases, the feature that places it in sect. *Ixia* rather than sect. *Hyalis*.

Distribution of ***Ixia orientalis***.

Observations on pollination indicate that *I. orientalis* is a generalist: insect visitors include large butterflies, hopliine beetles and large anthophorine bees.

15. **Ixia odorata** *Ker Gawl.* in The botanist's register 7: Notes [3] (1821a); Ker Gawler: 101 (1827); Goldblatt & Manning: 106 (2011). *Morphixia odorata* (Ker Gawl.) Baker: 97 (1877). *I. erecta* var. *lutea-odorata* Ker Gawl.: t. 1173 (1809). Type: South Africa, without precise locality or collector, cultivated in Britain, illustration in Ker Gawl.: t. 1173 (1809).

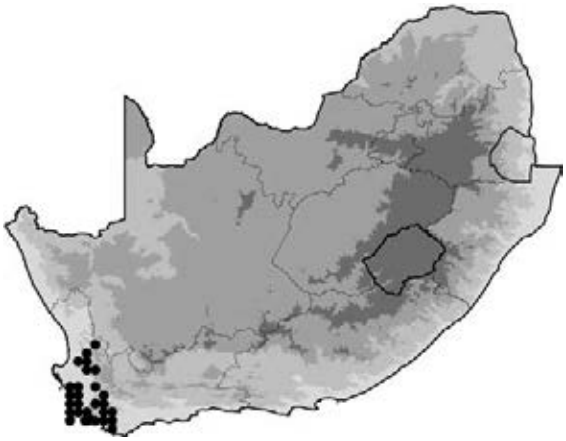
Ixia erecta Thunb.: 16 (1783), illegitimate homonym, not *I. erecta* P.J.Bergius (1767). *I. avellana* R.C.Foster: 47 (1936), as replacement name for *I. erecta* Thunb. Type: South Africa, without precise locality, *Thunberg* s.n. (S, UPS-THUNB, syn.).

Ixia flavescens Eckl. ex Baker: 161 (1892). *Ixia polystachya* var. *flavescens* (Eckl. ex Baker) Baker: 78 (1896). Type: none cited in protologue but *Zeyher s.n.* from Worcerster cited by Baker (1896) and

Zeyher s.n. (TUB 006804) is a potential syntype that authenticates the name).

Ixia odorata var. *hesperanthoides* G.J.Lewis: 96 (1962). Type: South Africa, [Western Cape], Piketberg, top of ridge south of Zebra Kop, 9 Nov. 1934, *Pillans 7184* (BOL, (two sheets), PRE, SAM, syn.).

[*Ixia flavescens* Eckl.: 26 (1827), invalid name without description.]



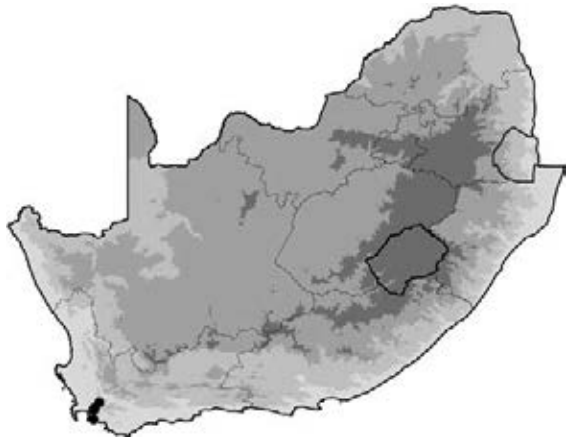
[*Agretta pallidiflavens* Eckl.: 24 (1827), genus invalid.]

Plants (200–)400–550 mm high. *Corm* 6–8 mm diam.; tunics of fine netted fibres. *Stem* slender, simple, rarely 1-branched; branches subtended by short, acute bracts and prophylls ± 1 mm long. *Leaves* (3)4 to 6(–10), lower 2 to 4 with expanded blades, reaching to ± middle of stem, narrowly sword-shaped to lanceolate, often slightly twisted distally, 2–10 mm wide, upper 1 or 2 partly sheathing. *Spike* erect, crowded, mostly 10- to 16-flowered; bracts membranous, translucent, rarely flushed pink, 6–7 mm long, usually 1.5–2.0 internodes long, sometimes longer, outer usually with a single prominent vein and 1 central cusp, or obscurely 3-lobed with central cusp prominent, inner ± as long as outer, 2-veined and shallowly forked at apex. *Flowers* clear yellow (often whitish when dry), rarely white, outer tepals sometimes flushed red to brown outside, sweetly scented; perianth tube filiform below, flared in upper third, (7–)8–12 mm long, 3–5 mm wide at mouth; tepals subequal, 9–11 × ± 5 mm, spreading horizontally. *Filaments* 2.5–3.0 mm long, exserted 1.5–2.0 mm; anthers 5–6 mm long, yellow. *Style* dividing between base and apex of filaments, thus within tube up to ± 2 mm above mouth of tube, branches (3–)4–6 mm long, arching outward below or between bases of anthers. *Flowering time*: mid-September to early November.

Distribution and ecology: extending in Western Cape, South Africa, from the Piketberg and Olifants River Mtns near Citrusdal south to the Cape Peninsula and eastward to Hermanus and Elim; largely montane and usually on sandstone slopes but also on granite-derived soils in the vicinity of Darling.

Diagnosis: *Ixia odorata* is well named for its particularly sweetly scented flowers crowded at the top of the short spike. Typical *I. odorata* has the following characteristics: bracts 6–7 mm long; perianth tube 7–12 mm long; tepals 9–11 × ± 5 mm; filaments 2.5–3.0 mm long, exserted 1–2 mm; anthers 5–6 mm long.

Populations of short, few-flowered plants from middle and upper elevations in the Hottentots Holland–Jonkershoek Mt complex are now treated as a separate species, *I. esterhuyseniae*, this very different in stature from the taller, fairly small-flowered *I. odorata*, but they share outer floral bracts with a single main vein and usually a single tooth, in contrast to the more common 3-veined and 3-dentate outer bracts of the genus. Apart from its low stature, *I. esterhuyseniae* has style branches dividing above the bases of the anthers, usually opposite



Distribution of ***Ixia odorata***.

the middle third of the anthers, thus unlike *I. odorata* in which the style divides below the anthers, sometimes within the tube and opposite the bases of the filaments.

Plants treated as *I. odorata* var. *hesperanthoides* Lewis (1962) remain puzzling. The type collection has white flowers with a perianth tube only ± 5 mm long, tepals ± 8 mm long, and anthers 3.5–4.5 mm long, all smaller than in typical *I. odorata*. Other features accord with typical *I. odorata*, although the length of the style branches is also shorter than the normal 4–5 mm of the species. The type collection was said to have flowers opening in the late afternoon, unlike ± 11:00 for typical, yellow-flowered *I. odorata*, indicating that some white-flowered populations, as the type of var. *hesperanthoides*, represent a separate race, possibly even a separate species. Additional research is needed to assess their status. *Ixia odorata* is sometimes mistaken for the southern Western Cape and Eastern Cape *I. orientalis* and the two can be confused when flower colour is not known, although the latter is almost always branched, whereas *I. odorata* is rarely so. White- or pink-flowered *I. orientalis* has a perianth tube of similar dimensions, and with a filiform lower portion but the style typically divides opposite the base of the anthers (rarely just below them), and it has longer filaments 5–6 mm long (vs. 2.5–3.0 mm) exserted 2–4 mm (vs. 1–2 mm), and unscented or only weakly scented flowers.

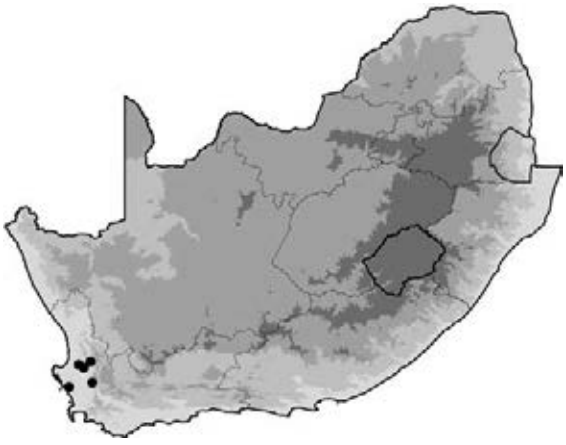
16. **Ixia esterhuyseniae** *M.P.de Vos* in South African Journal of Botany 54: 600 (1988); Goldblatt & Manning: 107 (2011). Type: South Africa, [Western Cape], Somerset West, peaty slope along Panorama trail, after fire, 3 000 ft [915 m], 9 Jan. 1973, *Esterhuysen 33089* (BOL, holo.; MO, iso.).

Plants mostly 100–150(–200) mm high. *Stem* simple or rarely with 1 short, suberect branch subtended by attenuate, brown-tipped bracts and prophylls, bracts 4–8 mm long and prophylls 2–3 times longer, up to 18 mm long. *Corm* depressed-globose, 8–10 mm diam.; tunics of fine fibres. *Leaves* 5 or 6, all with expanded

Distribution of ***Ixia esterhuyseniae***.

blades or uppermost largely sheathing, sword-shaped, reaching to between middle and top of stem, 4–6 mm wide, main vein slightly raised. *Spike* crowded, closely 2- to 4(–6)-flowered; bracts membranous, ± 4.5 mm long, outer with a prominent central vein, inner 2-veined and bidentate. *Flowers* rotate, upright, yellow, tepals flushed red to purple outside, lily-scented; perianth tube funnel-shaped, flared in upper half, 4.5–6.0 mm long, ± 4.5 mm wide at mouth; tepals subequal, 10–11 × 5–6 mm, spreading horizontally. *Filaments* ± 3.5 mm long, exserted ± 1.5 mm; anthers 3.5–4.0 mm long, yellow. *Style* dividing opposite lower to middle ⅓ of anthers, branches 2.0–2.5 mm long, extending between upper ⅓ of anthers. *Flowering time*: December and January.

Distribution and ecology: restricted to the Jonkershoek–Hollentots Holland Mt complex of Western Cape, South Africa; at relatively high elevations, usually over 1 000 m, in seeps and along drainage lines and flowering in midsummer, usually only in the years following a fire.



Diagnosis: *Ixia esterhuyseniae* can be confused with *I. odorata*, normally a taller plant with multi-flowered spikes, but *I. esterhuyseniae* has a shorter and sometimes wider perianth tube, 4–5 mm long and ± 4.5 mm wide at the mouth (vs. (7–)8–12 mm long and 3–5 mm wide at the mouth in *I. odorata*), the tepals thus about twice as long as the tube. The style divides opposite the middle of the anthers into branches ± 2.5 mm long, whereas in *I. odorata* the style divides below the anther bases (sometimes opposite the bases of the filaments), and the style branches are up to 5 mm long. Preliminary observations of the pollination of *I. esterhuyseniae* indicate that the only insect visitors are the short-proboscid horsefly, *Philoliche atricornis*, the likely pollinator.

17. **Ixia aurea** *J.C.Manning & Goldblatt* in Bothalia 29: 61 (1999); Goldblatt & Manning: 107 (2011). Type: South Africa, [Western Cape], Farm Wolwefontein west of Darling, rocky slope among granite boulders, 22 Sept. 1998, *Goldblatt & Manning 11029* (NBG, holo.; K, MO, PRE, S, WAG, iso.).

Plants 200–400 mm high. *Corm* globose, ± 10 mm diam., often with a few small cormlets at base; tunics of fairly fine netted fibres. *Leaves* 5 or 6, all basal, narrowly lanceolate, usually reaching to ± middle of stem, (8–)10–16 mm wide, lightly twisted in upper half, uppermost leaf usually entirely sheathing, margins and main vein not or hardly thickened. *Stem* usually unbranched. *Spike* flexuose, crowded, (6–)12- to 20-flowered; bracts dry, translucent, outer ± 7 mm long, with prominent dark central vein, obscurely 3-toothed, central tooth cusp-like and much exceeding lateral teeth, inner ± as longer as outer, 2-keeled, each with a prominent dark vein, 2-toothed. *Flowers* salver-shaped, actinomorphic, uniformly deep yellow or light orange, scentless; perianth tube narrowly funnel-shaped, 8–11 mm long, filiform in lower ½–⅔, widening gradually above, basal part tightly clasping style, with nectar in upper third; tepals obovate-elliptic, subequal, spreading, margins slightly upcurved, 16–23 × 7–9 mm. *Filaments* inserted ± 1 mm below apex of tube, decurrent for ± 1 mm, 5–6 mm long, straight, slightly diverging; anthers 5–6 mm long (before anthesis), diverging, yellow; pollen yellow. *Ovary* ovoid, ± 3 mm long; style straight, erect, dividing opposite lower ⅓ of anthers, branches arching outward, 4.5–6.5 mm long, reaching to shortly above base of anthers. *Flowering time*: September, occasionally in early October.

Distribution and ecology: a rare endemic of the Western Cape lowlands, South Africa, extending from the lower slopes of the Olifants River Mtns south of Citrusdal to the Piketberg and Darling; on granitic, sandy gravel or sandstone derived soils.

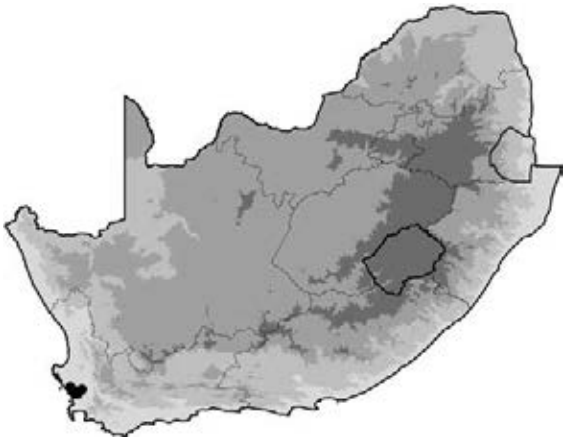
Diagnosis: *Ixia aurea* has bright yellow-orange flowers in crowded spikes and has been confused with *I. dubia* (sect. *Ixia*), because of the general resemblance to that species, despite the lack of a dark central mark to the flowers. The flowers of *I. aurea* have a narrowly funnel-shaped tube, tightly enclosing the style in the cylindric lower half but containing nectar in the upper third unlike *I. dubia*, in which the perianth tube is cylindric and closely clasping the style almost to the apex and the filaments are basally coherent or connate, thus

Distribution of ***Ixia aurea***.

occluding the mouth of the tube. In *I. aurea* the filaments diverge from the base and do not block the tube. The relationships of *I. aurea* lie with the short-tubed species, possibly *I. odorata*, flowers of which are sweetly scented, smaller, pale yellow or white and have tepals up to 15 mm long (vs. 16–23 mm in *I. aurea*). The flowers of *I. aurea* are pollinated by a range of insects, mainly hopliine beetles but the horsefly *Mesomyia edentula* has also been reported as a visitor.

18. **Ixia tenuifolia** *Vahl*, Enumeratio plantarum 2: 62 (1805); Goldblatt & Manning: 108 (2011). Type: South Africa, without locality or collector, (C: Herb. Vahl, holo.).

Ixia pulcherrima Eckl.: 25 (1827). Type: none known but *Zeyher s.n.*, from near Klipfontein (PRE), annotated '*Ixia* sp. (*I. pulcherrima* Eckl.)', possibly by P. MacOwan, appears to authenticate the identity of the species; *Ecklon & Zeyher Irid 81* (MO, SAM) '*Ixia pulcherrima*' Groenekloof, and '*Ixia pulcherrima* Eckl.' from Klipfontein, Zwartland likewise authenticate the name.



Ixia framesii L.Bolus: 368 (1931b); Lewis 91 (1962). Type: South Africa, [Western Cape], near Darling, September 1928, flowered in Cape Town, Sept.–Oct. 1931, *Ross-Frames s.n.* (BOL 19896, holo.; K, iso.).

[*Freesea mineatolateritia* Eckl.: 30 (1827), genus invalid.]

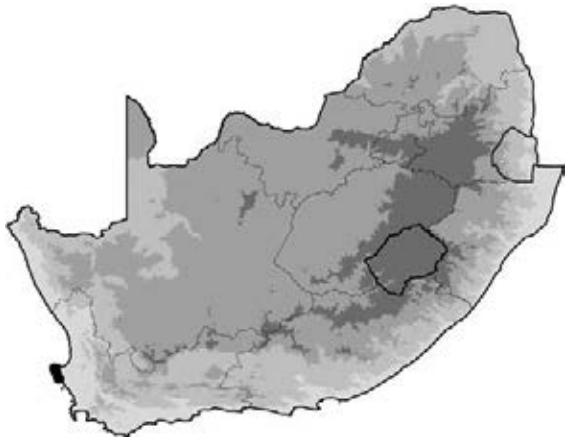
Plants 120–240 mm high. *Corm* 10–18 mm diam.; tunics of fine, soft netted fibres. *Stem* unbranched, wiry. *Leaves* mostly 3(4), reaching or shortly exceeding spike, firm-textured, linear, 1.3–2.0 mm wide, main vein ± central or displaced abaxially, uppermost leaf sheathing in lower half. *Spike* densely 3 to 8(–14)-flowered; bracts dry-membranous, 6–8 mm long, opaque, pale below, rust-brown distally, outer with 1 prominent vein, acute, inner 2-veined and 2-toothed, ± as long as outer. *Flowers* salver-shaped, salmon-pink or yellow to orange, dark red-brown in centre, unscented; perianth tube filiform below, narrowly funnel-shaped in upper third, 3–5 mm wide at mouth, (12–)15–19 mm long; tepals subequal, 15–19 × 8–10 mm, spreading horizontally. *Filaments* 4–5 mm long, exserted 1.0–1.5 mm; anthers ± 5 mm long, yellow. *Style* dividing just below or shortly above anther bases, branches 2.5–3.0 mm long. *Flowering time*: mainly mid-September to mid-October.

Distribution and ecology: endemic to the rolling plains between Cape Town and Malmesbury in Western Cape, South Africa, and common until the 1950s; on seasonally moist, loamy flats. Intense agricultural development since the 1960s has eliminated it from almost its entire range and the only known viable population occurs in the Nature Reserve at Riverlands, near Mamre Road Station.

Diagnosis: *Ixia tenuifolia* is readily identified not only by the relatively long perianth tube, (12–)15–19 mm, particularly narrow in the lower half, and short floral bracts, 6–8 mm long, but by the unbranched stem and firm, leathery, straight leaves. The floral bracts are distinctive in being ± opaque, pale in the lower half and rust-brown above. The flowers, either deep salmon-pink, orange-red or yellow to orange, usually have a dark brown or reddish centre.

Distribution of ***Ixia tenuifolia***.

Pollination studies show that *I. tenuifolia* has a bimodal pollination system, the flowers visited by the hopliine beetle, *Lepithrix ornatella* and by the horsefly *Philoliche atricornis* (Tabanidae), which presumably feeds on nectar retained in the perianth tube.



19. **Ixia purpureorosea** *G.J.Lewis* in Journal of South African Botany 28: 126 (1962); Goldblatt & Manning: 109 (2011). Type: South Africa, [Western Cape], Saldanha Bay, Postberg, 8 Sept. 1957, *Lewis 5243* (NBG, holo.).

Plants mostly 400 to 600 mm high. *Corm* up to 20 mm diam., with broad, fasciated stolons up to 60 mm long, branching distally and each branch with a small terminal cormlet; tunics of brown, membranous layers later becoming fibrous. *Stem* simple or with 1 short branch subtended by acute bracts and prophylls. *Leaves* 4 or 5, sword-shaped, often slightly twisted distally, main vein thickened, margins not raised, upper 2 leaves sheathing stem, uppermost often entirely sheathing. *Spike* fairly crowded, mostly 15- to 20-flowered; bracts translucent white turning pale straw-coloured above with age, mostly ± 8 mm long, ± reaching node above, outer obscurely 3-veined, central vein more prominent, 3-lobed, central lobe longest, acute, outer lobes ± obtuse, inner 2-veined and 2-cusped. *Flowers* salver-shaped, pink-purple, dark purple in throat, bases of tepals white sometimes edged with pale pink, tube dark red-purple to brown outside, unscented; perianth tube 13–15 mm long, ± filiform below, flaring in upper 3 mm, with nectar held in upper part; tepals ovate, 20–22 × 10 mm long spreading but remaining ± spooned. *Filaments* erect, contiguous, white, ± 4 mm long, exserted ± 2.5 mm from tube; anthers diverging, 6–8 mm long, yellow. *Style* dividing opposite or shortly above base of anthers, branches arching

outward, between anthers, white, ± 5.5 mm long. *Flowering time*: September to early October.

Distribution and ecology: an edaphic endemic, restricted to the environs of Saldanha Bay in Western Cape, South Africa; in pockets of peaty sand in crevices in rocky, limestone pavement.

Diagnosis: *Ixia purpureorosea* is recognised by the purple-pink flowers with the tepals white at the base, sometimes edged with pale pink, and a perianth tube dark red-purple to brown outside. A particularly striking feature of *I. purpureorosea* is the presence of one or more broad stolons produced from the corm base. Unique in the genus, the stolons are thick and fasciated, up to 60 mm long, branching distally with each branch bearing a small terminal cormlet.

Distribution of ***Ixia purpureorosea***.

Sect. 2. **Ixia**

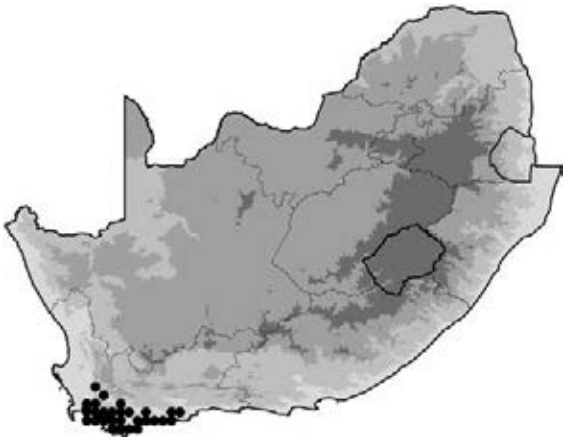
Ixia [unranked] *Eurydice* Pers.: 48 (1805). *I.* subg. *Eurydice* (Pers.) Baker: 92 (1877). Type: *I. monadelpha* D.Delaroche.

Flowers with a filiform perianth tube, usually well developed and sometimes elongate; anthers linear, dehiscent along their entire length; style branches narrowly channelled, and stigmatic along the margins, sometimes only toward the tips. The stamens are always symmetrically arranged with the filaments inserted at the base of the tepals and not decurrent. Leaf number is indeterminate, but usually at least four and up to 10. The upper leaves decrease in size progressively above, becoming partly to largely sheathing, but lack a sharp distinction between basal foliage and upper sheathing leaves. Flowers are usually unscented and often brightly coloured and frequently have a dark central mark, either restricted to the tepal bases or including the filaments and sometimes the anthers and style branches.

Species 29: southwestern Western Cape, South Africa.

Ser. **Longistylae** *Goldblatt & J.C.Manning* in South African Journal of Botany 104: 180 (2016a). Type: *Ixia patens* Aiton

Flowers usually with dark markings in centre or pale in centre or uniformly coloured. *Stamens* free but filaments sometimes contiguous. *Style* dividing opposite upper half of filaments or opposite anthers (rarely above anther apices).



20. **Ixia flexuosa** *L.*, Species plantarum, edn. 2, 1: 51 (1762); Lewis: 110 (1962); Goldblatt & Manning: 180 (2016a). *I. flexuosa* Mill.: 3 (1768), illegitimate superfluous name based on the same type. Type: South Africa, without precise locality or collector, illustration in Miller: t. 156, f. 2 (1760).

[*Ixia pallidorosea* Eckl.: 24 (1827), invalid name without description.]

Plants 300–600 mm high. *Corm* ± globose, 8–13 mm diam.; tunics of fine, ± netted fibres. *Stem* usually with 1 to 3 short, suberect branches. *Leaves* usually 4 or 5, lower 3 or 4 linear to narrowly sword-shaped, ± as long as stem, 2–5 mm wide, firm, often slightly twisted, uppermost leaf sheathing stem with short free apex. *Main spike* crowded, mostly 6- to 12-flowered; bracts 5–7 mm long, translucent, usually flushed pink, outer with 3 prominent veins, 3-toothed, central tooth sometimes much exceeding laterals, inner 2-veined, 2-toothed. *Flowers* rotate, pale pink, mauve or ± white, usually with darker veins radiating from tepal bases, usually strongly scented; perianth tube filiform, 4–6 mm long; tepals united basally for ± 1 mm, ± elliptic, obtuse, 10–16 mm long, spreading. *Filaments* inserted at top of tube, 3.5–4.5 mm long, broader at base; anthers ± linear, 3.0–4.5 mm long, white to creamy yellow. *Style* dividing opposite upper ⅓ of filaments to middle of anthers, branches 2–4 mm long. *Flowering time*: mainly August and September.

Distribution and ecology: extending in Western Cape, South Africa, from the Cape Peninsula eastward to Swellendam, Riversdale and Still Bay; favouring clay, shale and sometimes limestone slopes. Once common, its range has been much reduced by agriculture and urban development.

Diagnosis: recognised by its small flowers, among the smallest in sect. *Ixia*, *I. flexuosa* has a perianth tube typically 5–6 mm long and tepals, mostly 10–14 mm long, thus about twice as long as the tube (occasionally perianth tube only ± 4 mm long and tepals ± 8 mm long). Coloured white to pink or light purple with fine, dark longitudinal veining on the lower half of the tepals, the flowers have a penetrating, honeysuckle-like scent. The style is relatively long, usually dividing between the base and middle of the anthers, rarely just below the anther

Distribution of ***Ixia flexuosa***.

bases. The stem may have up to four short, erect branches seldom bearing more than six flowers, whereas the main spike has up to 15 flowers. The leaves are linear to narrowly sword-shaped, mostly 2–5 mm wide and often less than a third as long as the wiry stems. Somewhat unusual in the section, the outer floral bracts usually have three prominent veins terminating in three short, sometimes acute teeth. Smaller-flowered morphs of *I. polystachya* are easily confused with *I. flexuosa* but have outer floral bracts with a single prominent central tooth and flowers almost always with a solid, darker centre.

Lacking dark pigment in the centre of the flower, *Ixia flexuosa* fits uncomfortably in sect. *Ixia*, especially as the perianth tube is slightly flared near the apex for ± 1.5 mm and the flowers are conspicuously scented. Despite its predominantly filiform perianth tube, typical of sect. *Ixia*, *I. flexuosa*, most closely resembles *I. orientalis* (sect. *Hyalis*), which has a narrowly funnel-shaped perianth tube, almost filiform in the lower half. Only close examination of the outer floral bracts and filaments makes it possible to separate the two. In *I. flexuosa* the filaments are broadened basally, whereas *I. orientalis* has uniformly slender filaments decurrent on the tube and the outer floral bracts have a single central tooth, sometimes with a shorter lobe or tooth on either side of the central cusp. The style of *I. flexuosa*, usually reaching to between the base to middle of the anthers (rarely slightly below the anther bases), also often differs from that in *I. orientalis*, where the style typically divides close to the filament apices or opposite the anther bases. *Ixia flexuosa* is the only member of sect. *Ixia* known to produce nectar. It is probably most closely related to *I. patens*, which also has slender, wiry stems, and flowers lacking a dark central stain, but this species has larger, deep pink (to dull red) flowers that lack the dark longitudinal streaking in flowers of *I. flexuosa*. Floral scent in the two species appears identical, although of weaker intensity in *I. patens*. The flowers of *I. patens* lack nectar.

21. **Ixia patens** *Aiton*, Hortus Kewensis 1: 59 (1789); Lewis: 116 (1962); Goldblatt & Manning: 180 (2016a). *I. flaccida* Salisb.: 35 (1796), illegitimate superfluous name for *I. patens* Aiton. [*I. pallens* Steud.: 453 (1821), orthographic variant?] Type: South Africa, without precise locality or collector, ex. hort. Kew (BM, holo., digital image).

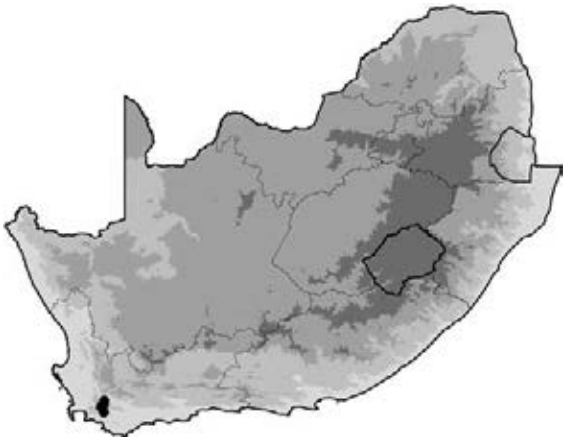
Gladiolus pyramidalis Burm.f.: 2 (1768) [not *Ixia pyramidalis* Lam. 1789]. Type: South Africa, without precise locality or original collector (G: Herb. Burman, holo., not seen).

Ixia filiformis Vent.: t. 48 (1801). Type: South Africa, without precise locality or collector, illustration in Vent.: t. 48 (1801).

Ixia punicea Eckl.: 24 (1827), illegitimate homonym, not *I. punicea* Jacq. (1795). Type: South Africa, without precise locality, *Ecklon s.n.* [S, lecto., designated by Nordenstam: 283 (1972)].

Ixia patens var. *kermesina* Regel: t. 356 (1862). Type: South Africa, without precise locality or collector, illustration in Regel: t. 356 (1862).

Ixia densiflora Klatt: 397 (1882). Type: South Africa, [Western Cape], without precise locality, *Zeyher 309* (B: Herb. Lubeck, holo., probably not extant).



Ixia dispar N.E.Br.: 134 (1929a). Type: South Africa, [Western Cape], near Worcester, *Cooper 3611* (K, holo.).

Ixia angusta L.Bolus: 367 (1931b), illegitimate homonym, not *I. angusta* Jacq. (1795). Type: South Africa, ex Hort. Univ. Stellenbosch 661, said to be from Nieuwoudtville but cultivated there, *Buhr s.n.* (BOL, holo.).

Ixia patens var. *linearifolia* G.J.Lewis: 119 (1962). Type: South Africa, without precise locality, *Thom s.n.* (K, holo.).

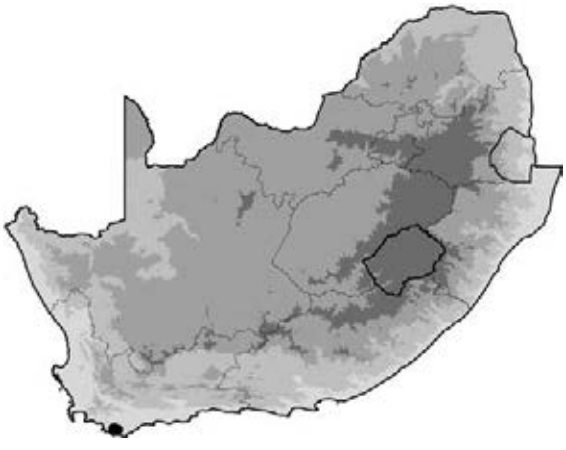
Plants 200–400 mm high. *Corm* ± globose, 12–18 mm diam.; tunics of fine, netted fibres. *Stem* simple or with 1 or 2 short, suberect branches. *Leaves* usually 4 to 6, all ± basal, linear to narrowly sword-shaped, ± as long as stem, (1.5–)4.0–10.0 mm wide, firm, often slightly twisted, uppermost leaf sheathing stem with short free apex. *Main spike* crowded, mostly 5- to 12-flowered, flexuose; bracts 6–8 mm long, dry, opaque, usually flushed pink, outer with 3 prominent veins, 3-toothed, central tooth sometimes much exceeding laterals, inner 2-veined, 2-toothed. *Flowers* rotate, red to deep pink (white), usually small, greenish white centre, faintly scented; perianth tube filiform, 3–6 mm long; tepals united basally for ± 1(2) mm, ± elliptic, obtuse, 16–24 × 5–12 mm, spreading. *Filaments* inserted at top of tube, 4–6 mm long, white; anthers ± linear, 6–8 mm long, white to creamy yellow. *Style* dividing opposite base to lower ⅓ of anthers, pale yellow, branches 3–4 mm long. *Flowering time*: late August to mid-September.

Distribution and ecology: a rare and endangered species of Western Cape, South Africa, known only from the hills in the vicinity of Villiersdorp and extending some 25 km north into the Doorn River Valley; on clay slopes in renosterveld.

Distribution of ***Ixia patens***.

Diagnosis: *Ixia patens* comprises two morphs, one with narrow, almost linear leaves, a slender stem, and pink or red-purple flowers; the other has broader, lanceolate leaves with somewhat thickened margins and dull red flowers. Both have terminally crowded flowers, outspread tepals, erect filaments, yellow anthers and a style dividing opposite the bases of the anthers. Diagnostic features are the long, yellow anthers 6–8 mm long, pale yellow style dividing opposite the base or lower third of the anthers, a stem occasionally with one or two short branches, a perianth tube 3–5 mm long and tepals connate basally for up to 2 mm. The outer floral bracts are variable, sometimes prominently 3-cusped and flushed with pink in the upper third or 1-cusped and uniformly pale and opaque. Plants with narrow leaves up to 2 mm wide called var. *linearifolia* from Villiersdorp have pink flowers and a slightly shorter perianth tube ± 3 mm long (elsewhere 4–5 mm long). The variety is not currently recognised.

White-flowered, late blooming plants in flower in October and November referred to *I. patens* by De Vos (1999) from near Elim are *I. leucantha* Jacq. Typical *I. patens* flowers from late August to mid-September.



22. **Ixia leucantha** *Jacq.*, Icones plantarum rariorum 2: 7 (1795 [1788–1795]); Goldblatt & Manning: 182 (2016a). *I. patens* var. *leucantha* (Jacq.) Ker Gawl.: 98 (1827). Types: South Africa, without precise locality or collector, illustration in Jacq.: t. 278 (1795 [1788–1795]); South Africa, Western Cape, east of and near Baardskeerdersbos, 10 Nov. 1985, *De Vos 2637* (NBG, epi.).

    [*Ixia candida* Delile in Redouté: t. 426 (1814), invalid name [not accepted author], based on illustration in Redouté: t. 426 (1814), without locality or collector.]

Plants 150–650 mm high, sometimes with 1 short, suberect branch subtended by scale-like, translucent, acute bracts and prophylls 2–4 mm long. *Corm* ± globose, (10–)15–20 mm diam., bearing several cormlets at base; tunics of relatively fine, netted fibres. *Leaves* usually 5, all with expanded blades, ± ⅔ as long as stem, narrowly sword-shaped to almost linear, mostly 2–5 mm wide; margins and main vein moderately thickened, pale, hyaline and slightly raised when dry. *Spike* (3–)6- or 7-flowered, branches when present fewer-flowered; bracts membranous, translucent or flushed pink, 5–6 mm long, outer with single prominent central vein and prominent acute tooth, inner 2-veined, 2-keeled and acutely 2-toothed. *Flowers* upright, rotate, white with pale yellow throat, faintly rose-scented; perianth tube ± 5 mm long, filiform; tepals barely connate basally, obovate, 20–22 × 9–10 mm, spreading ± horizontally. *Filaments* erect, ± 4 mm long, white; anthers ± 6 mm long, suberect, yellow; pollen yellow. *Style* dividing opposite lower ⅓ of anthers, branches ± 2.3–3.0 mm long, white. *Flowering time*: late October to mid-November.

Distribution and ecology: a local endemic of the central portion of the Agulhas Plain in Western Cape, South Africa, recorded from near Elim and Baardskeerdersbos; in shale and loamy clay in renosterveld and Elim fynbos vegetation, flowering well after fire.

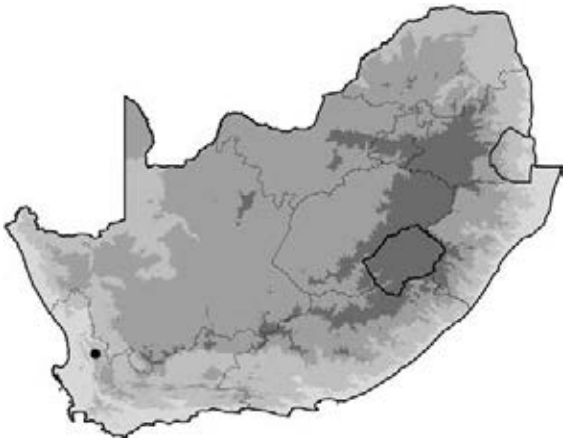
Diagnosis: typical of sect. *Ixia*, *I. leucantha* has the filiform perianth tube and filaments inserted at the tube mouth diagnostic for the section, but the flowers lack the dark centre of most species of the alliance. The species was included by De Vos (1999) with *I. patens*, which has larger, deep pink (rarely red) flowers usually somewhat darker in the centre and relatively narrow tepals, whereas *I. leucantha* has white flowers. It differs additionally from *I. patens* by the longer style dividing opposite the lower third of the anthers and short style branches 2.3–3.0 mm long. In *I. patens* the style typically divides opposite the anther bases and the style branches are unusually slender, ± 4 mm long. Significantly, *I. patens* flowers from late August to mid-September, whereas *I. leucantha* flowers from late October to November and possibly even into early December.

Distribution of ***Ixia leucantha***.

23. **Ixia alticola** *Goldblatt & J.C.Manning* in South African Journal of Botany 104: 182 (2016a). Type: South Africa, Western Cape, Cederberg, Farm Kalkoenfontein, Dwarsrivier, 969 m, 27 Nov. 2013, *Lane & Wheeler s.n.* (NBG, holo.; K, MO, iso.).

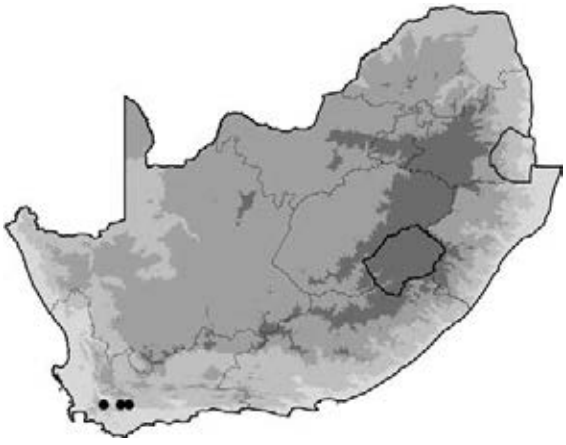
Plants 350–800(–1 000) mm high. *Corm* ± globose, 10–15 mm diam. bearing flat, ribbon-like stolons from base; tunics of soft to medium-textured fibres. *Stem* simple or 1(2)-branched. *Leaves* 4 or 5(6), all with expanded blades, ½–⅔ as long as stem, narrowly sword-shaped, mostly 4–8(–11) mm wide; margins, main vein and a pair of secondary veins slightly thickened, raised, pale when dry. *Spike* with up to 25 flowers, branches when present fewer-flowered; bracts pale and translucent or finely brown-speckled distally, outer 4–6 mm long, with single main vein and a few secondary veins, apex of lower bracts tricuspidate, inner 2-veined and acutely 2-toothed. *Flowers* upright, rotate, mauve-pink with small dark blue mark near base of tepals; perianth tube 6–8 mm long, filiform; tepals connate basally for ± 1 mm, ± elliptic, 10–12 × 4–5 mm, spreading ± horizontally. *Filaments* erect, 3.5–4.0 mm long, flushed purple; anthers ± 3 mm long, suberect, linear; pollen yellow. *Style* dividing opposite lower ⅓ to middle of anthers, branches ± 3.5 mm long, flushed purple. *Flowering time*: November to December.

Distribution and ecology: known only from higher elevations above 900 m in the Cederberg in Western Cape on Sneeuberg and Middelberg, South Africa; in seeps and marshy ground along streams.



Diagnosis: with a filiform perianth tube and filaments inserted at the mouth of the narrow part of the perianth tube, *Ixia alticola* conforms closely to sect. *Ixia*. The pale mauve-pink flowers have a relatively long style, dividing opposite the lower third to middle of the anthers, indicating placement of *I. alticola* in series *Longistylae*. It stands out in the rather short, pale translucent bracts 4–6 mm long, tall stature (occasionally to 1 m tall) and spikes of up to 25 flowers.

24. **Ixia roseoalba** *Goldblatt & J.C.Manning* in South African Journal of Botany 104: 183 (2016a). Type: South Africa, Western Cape, entrance to Cogmans Kloof, just south of Montagu, 1 Sept. 2007, *Goldblatt & Manning 12941* (NBG, holo.; MO, iso.).



Plants 500–650 mm high. *Corm* ± globose, ± 12 mm diam. with tunics of medium-textured, mostly vertical fibres. *Stem* simple or with 1 short, filiform branch subtended by scale-like, translucent, acute bract and prophylls 2–3 mm long. *Leaves* 3 or 4, all with expanded blades, ± ⅔ as long as stem, linear, 1.5–5.0 mm wide; margins and main vein moderately thickened, pale, hyaline, raised when dry. *Spike* 8- to 11-flowered, branches when present fewer-flowered; bracts membranous, translucent, 5.5–7.0 mm long, outer several veined, with only central vein or 3 veins prominent, 1- or 3-toothed with central tooth largest, inner 2-veined, 2-keeled and acutely 2-toothed. *Flowers* upright, rotate, pink, tepals white in lower ⅓, unscented; perianth tube ± 5 mm long, filiform; tepals united basally for ± 1 mm, obovate, 14–16 × 7 mm, spreading ± horizontally. *Filaments* erect, ± 3.5 mm long, white, ± 4 mm long; anthers suberect, ovoid, connective expanded, visible on abaxial surface; pollen yellow. *Style* dividing opposite lower ⅓ to middle of anthers, branches ± 3.5 mm long, yellow. *Flowering time*: mid-August to mid-September.

Distribution and ecology: a narrow endemic of Western Cape, South Africa, known only from the western Langeberg at Dassieshoek and Macgregor near Robertson and east to Cogmans Kloof, Montagu; in stony clay ground among grass at the edge of bush.

Diagnosis: with a filiform perianth tube and filaments inserted at the tube mouth, *Ixia roseoalba* is distinguished in sect. *Ixia* by the relatively small, pale pink flowers, the tube ± 5 mm long and tepals ± 16 × 7 mm. Unusual for the section, the flowers have a white centre. The filaments and anthers are pale yellow and the style divides opposite the lower third to middle of the

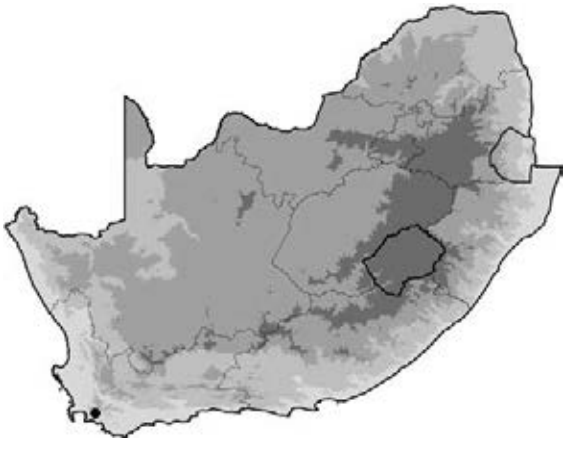
Distribution of ***Ixia alticola***.

Distribution of ***Ixia roseoalba***.

anthers. More important, the anthers are unusual in having the connective expanded and visible as a narrow line between the thecae on the outer (abaxial) surface, rendering the thecae almost latrorse. The bracts, typical of sect. *Ixia*, are translucent and the outer, with several veins, the central one most prominent and reaching the margin, is 3-toothed with the central tooth largest or all three teeth subequal. The long style dividing opposite the lower third to middle of the anthers recalls *I. patens* but this species, often more slender but with larger, pink or red flowers usually sometimes more darkly pigmented in the centre, has tepals ± 20 × 10 mm and conventional linear anthers without visible connective.

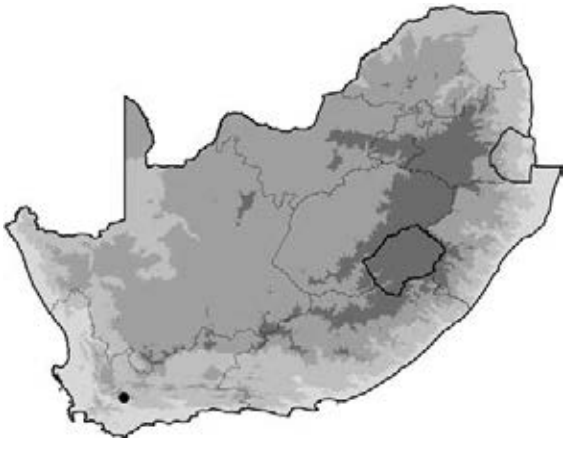
25. **Ixia helmei** *Goldblatt & J.C.Manning* in South African Journal of Botany 104: 183 (2016a). Type: South Africa, Western Cape, Farm Welgemoed, 12 km N of Bot River, 2 km W of Aasvoëlkop, 280 m, 26 Oct. 2000, *Helme 3429* (NBG, holo.).

Plants 150–200 mm high. *Corm* ovoid, ± 8 mm diam.; tunics of fine netted fibres. *Stem* usually with 1 or 2 short branches. *Leaves* 2 or 3, lower 1 or 2 basal, narrowly sword-shaped, ± as long as stem, 3–7 mm wide, main vein and margins slightly thickened, pale when dry, upper leaf sheathing lower ⅓–½ of stem, with a short free blade. *Main spike* 3- to 6-flowered, lateral branches 1- to 3-flowered; bracts membranous, translucent, 3.5–5.0 mm long, outer with 3 prominent light brown veins, 3-toothed, teeth attenuate, inner 2-veined and 2-toothed. *Flowers* salver-shaped, pale to bright pink with yellow throat; perianth tube filiform, 12–15 mm long, flaring in upper 1–2 mm; tepals narrowly ovate, 11–12 × 4.0–4.5 mm, inner three slightly smaller than outer. *Filaments* inserted at mouth of tube, 3–5 mm long; anthers 4–5 mm long, yellow; pollen yellow. *Style* dividing between middle of filaments and base of anthers, branches ± 4 mm long. *Flowering time*: October and early November.



Distribution and ecology: currently known from two records in the hills north of Bot River in Western Cape, South Africa; on south trending shale slopes in renosterveld.

Diagnosis: somewhat unusual in sect. *Ixia*, *I. helmei* has a relatively long perianth tube 12–15 mm long and slightly longer than the tepals, and is readily recognised by this feature alone. The presence of two or three leaves, the uppermost almost entirely sheathing, the relatively long perianth tube, and the late flowering time in mid- to late October, combine to confirm its taxonomic isolation. The relatively long style, dividing just below or opposite the bases of the anthers, places it in ser. *Longistylae* but its immediate relationships are uncertain. The flowers are adapted for pollination by the long-proboscid fly *Philoliche gulosa* (Tabanidae).



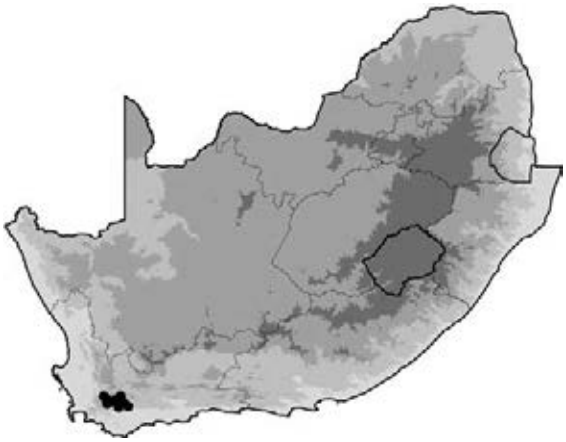
26. **Ixia stolonifera** *G.J.Lewis* in Annals of the South African Museum 40: 14 (1952); Lewis: 113 (1962). Type: South Africa, Western Cape, Montagu, Keisiesberg, 3 000 ft [915 m], Sept. 1946, *Lewis 1605* (SAM, holo.; BOL, NBG, iso.).

Plants 200–500 mm high. *Corm* globose, 5–8 mm diam., bearing short, branched stolons from base, each with small terminal cormlet; tunics of fine, almost membranous, fine netted fibres. *Stem* simple or with 1 short branch from upper third. *Leaves* 3, all basal, lanceolate, somewhat shorter than stem, 3–10 mm wide, loosely spirally twisted distally, uppermost sheathing stem in lower half. *Spike* closely 6- to 12-flowered; bracts 7–8 mm long, outer 3-veined, with 3 long dry cusps 3–4 mm long, inner 2-veined, with 2 long dry cusps. *Flowers* rotate, mauve-pink with small dark purple central mark, very faintly scented; perianth tube cylindric, 2–4 mm long; tepals cupped, ovate, 9–12 × 6–7 mm. *Filaments* ± 2 mm long, erect, purple; anthers suberect, 5–6 mm long, yellow with reddish line of dehiscence. *Style* dividing opposite base of anthers, branches ± 3 mm long, purple fading pink distally. *Flowering time*: September.

Distribution and ecology: a narrow endemic known only from the lower slopes of Keisiesberg and Burger's Pass, west of Montagu in Western Cape, South Africa; on steep, south-facing slopes in moist gulleys at an elevation of ± 900 m, in gravelly scree in renosterveld, flowering after fire.

Distribution of ***Ixia helmei*** .

Distribution of ***Ixia stolonifera***.



Diagnosis: *Ixia stolonifera* is recognised by the unusual floral bracts with setaceous cusps, the outer bracts with three to five veins and three ± equal cusps, and by the distinctive stolons produced from the corm bases. The stolons are broadened distally and shortly branched, each branch terminating in a tiny cormlet, at most 2 mm diam. The flowers are relatively small and cupped, with a pale mauve-pink perianth with a small, dark purple stain in the centre, a perianth tube 2–4 mm long, and tepals mostly 10–12 mm long. The style divides close to the bases of the anthers. Like almost all species of sect. *Ixia* the open flowers are crowded together, close to the spike apex.

27. **Ixia vanzijliae** *L.Bolus* in Annals of the Bolus Herbarium 4: 114 (1927); Lewis: 134 (1962). Type: South Africa, [Western Cape], without precise locality, *Van Zijl s.n.* (BOL18537, holo.).

Plants 200–400 mm high. *Corm* ± globose, 8–15 mm diam.; tunics of fine, netted fibres. *Stem* simple or with 1 short, upright branch. *Leaves* usually 5, lower 3(4) basal, < half as long as stem, lanceolate, 4–12 mm wide, spirally twisted, margins undulate to crisped, upper 1(2) leaves cauline, longer than basal, mostly sheathing with short free blades. *Spike* closely 2- to 7-flowered; bracts 9–13 mm long, outer acute or 3-toothed, inner slightly shorter, 2-toothed. *Flowers* salver-shaped, brick-red to pink to mauve-pink with small dark central mark; perianth tube filiform, 8–10 mm long; tepals spreading, united basally for 1–2 mm, obovate to elliptic, 13–20 × 8–11 mm. *Filaments* ± 3 mm long; anthers 6–7 mm long, yellow. *Style* dividing opposite middle of anthers, branches ± 2.5 mm long. *Flowering time*: mainly September.

Distribution and ecology: a rare species of the dry karroid hills between Worcester and Bonnievale in Western Cape, South Africa; on clay ground among low succulent vegetation or in renosterveld.

Diagnosis: distinctive in the twisted blades of the three or four basal leaves with tightly undulate to crisped margins, *Ixia vanzijliae* has attractive brick-red to salmon-pink flowers with a small, dark central eye. Plants

Distribution of ***Ixia vanzijliae***.

are usually relatively short, up to 200 mm high but may reach up to 400 mm under favourable conditions. The filiform perianth tube is 8–12 mm long and the dark purple style divides opposite the lower to middle third of the anthers. The floral bracts are pale except for a brown flush toward the tips.

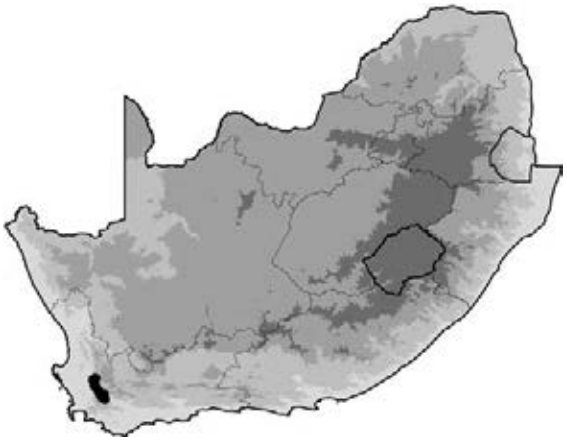
28. **Ixia campanulata** *Houtt*., Natuurlijke historie 12: 42, t. 78 f. 4 (1780); Lewis: 127 (1962). Type: South Africa, without precise locality or collector [G: Herb. Burman, lecto. (as holo.), designated by Brown: 133 (1929)].

Ixia aristata Thunb.: 14 (1783) [misapplied to *I. patens* by Schneev.: (1793) and to *I. latifolia* by Ker Gawl.: t. 589 (1802c) and later authors]. *I. leucantha* var. *aristata* (Thunb.) Baker: 162 (1892). Type: South Africa, without precise locality, *Thunberg s.n.* (UPS–THUNB '*Ixia aristata* a, b, c', syn.).

Ixia concolor Salisb.: 36 (1796). Type: unknown, identified from description.

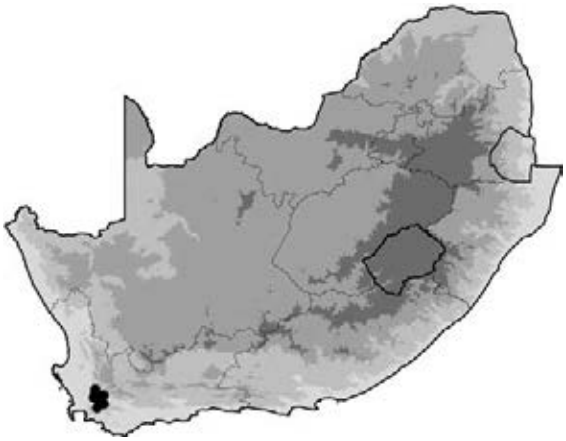
Ixia speciosa Andrews: t. 186 (1801a). Type: South Africa, without precise locality or collector, illustration in Andrews: t. 186 (1801a).

Ixia crateroides Ker Gawl.: t. 594 (1802d, superfluous name for *I. speciosa* Andrews (1801a). Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 594 (1802d.



Ixia coccinea Thunb.: 241 (1811). *Gladiolus coccineus* (Thunb.) Schrank: 197 (1822). Type: South Africa, without precise locality, *Thunberg s.n.* (UPS–THUNB '*Ixia coccinea* α', holo.).

Ixia coccinea Eckl.: 24 (1827), illegitimate homonym, not *I. coccinea* Thunb. (1811). Type: unknown, identified from description.



Plants 100–350 mm high. *Corm* ± globose, 10–18 mm diam.; tunics of fine, netted fibres extending upward in a collar around base. *Stem* simple or with 1 branch from near base. *Leaves* 5 to 10, ½–⅔ as long as stem, 2–5 mm wide, ± linear, ± straight, main vein and margins slightly thickened. *Spike* closely (1)2- to 9-flowered; bracts ± orbicular, 4–6 × 5–7 mm long, white or pink, outer usually 3-toothed, inner slightly shorter, 2-toothed. *Flowers* ± rotate or bell-shaped, uniformly bright red or white then often flushed red outside; perianth tube filiform, 2–3 mm long; tepals slightly ascending, united in basal 1–2 mm, obovate to elliptic, 12–25 × 8–12 mm. *Filaments* 3–5 mm long; anthers 6–8 mm long, yellow. *Style* dividing opposite middle to apex of anthers or beyond them, branches 3–4 mm long. *Flowering time*: October and November.

Distribution and ecology: restricted to the Tulbagh District and mid-Breede River Valley west of Worcester in Western Cape, South Africa; on lower mountain slopes in sandy sites.

Diagnosis: very narrow, sword-shaped to almost linear leaves, an unusually sturdy stem, relatively few flowers crowded at the spike apex and usually with uniformly brilliant red, glossy tepals are diagnostic for *I. campanulata*.

Distribution of ***Ixia campanulata***.

Distribution of ***Ixia metelerkampiae***.

The perianth tube is unusually short, 2–3 mm long, even for sect. *Ixia*. Another aid to identification is the style, which divides opposite the middle to upper third of the anthers, sometimes even exceeding them. A white-flowered form is known, evidently occurring in uniform stands. The short floral bracts, up to 3 mm long, are half as long to almost as long as the spike internodes and the outer has three short, subequal teeth. Spikes typically have 2 to 4 flowers but there are examples of white-flowered plants with up to 8-flowered spikes. Lewis (1962) regarded *I. campanulata* as most closely related to *I. metelerkampiae*, which also has a short perianth tube, 3–4 mm long, narrow leaves and obovate tepals, these however, pale pink, lilac or blue-mauve but with a dark red to purple throat and markings, and is a taller plant, reaching up to 700 mm, and colourless bracts with inconspicuous cusps. In *I. campanulata* the bracts are white or deep pink and have prominent, dark veins and usually prominent cusps. Both species usually have a well-developed collar of fibres around the base.

29. **Ixia metelerkampiae** *L.Bolus* in South African Gardening and Country Life 19: 27 (1929b); Lewis: 130 (1962). Type: South Africa, [Western Cape], Bain's Kloof, cultivated at Kirstenbosch Gardens, *Metelerkamp s.n. as Nat. Bot. Gard. 1710/26* (BOL, K, syn.).

Plants 350–750 mm high. *Corm* ± globose, 10–20 mm diam.; tunics of fine, netted fibres extending upward in a collar around base. *Stem* simple or subdivaricately 1- or 2-branched. *Leaves* 5 to 9, ± half as long as stem, 1–6 mm wide, ± linear to narrowly lanceolate, ± straight, main vein and margins slightly thickened. *Spike* closely 5- to 14-flowered; bracts ± orbicular, truncate or obtuse, pellucid, 4–5 × 5–7 mm long, outer 1- or 3-toothed, inner slightly shorter, 2-toothed. *Flowers* ± rotate or bell-shaped, pale pink to mauve or purple, tepals marked red to purple near base and in midline; perianth tube filiform, 3–4 mm long; tepals slightly ascending, united in basal 1–2 mm, obovate to elliptic, 14–22 × 6–12 mm. *Filaments* 4–5 mm long; anthers 5–6 mm long, yellow. *Style* dividing opposite apex of filaments to lower ⅓ of anthers, branches 3–4 mm long. *Flowering time*: November to early December.

Distribution and ecology: a montane species of south-western Western Cape, South Africa, recorded from Elandskloof, west of Wolseley, south to Bain's Kloof and the mountains east of Paarl; on well drained sandstone slopes, flowering well only after fire.

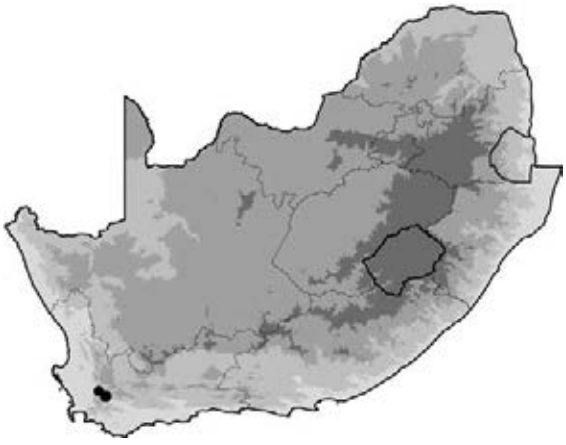
Diagnosis: *Ixia metelerkampiae* is recognised by the pale pink, lilac or pale to deep mauve flowers, the tepals with an irregularly shaped, small, dark red or purple mark or ring at the base surrounded by a white zone and a dark spot in the lower midline. The obovate tepals remain slightly cupped even when the flowers are fully open, showing pale, nearly white stamens with erect filaments enclosing the style, and divergent anthers. The style divides opposite the base or lower third of the anthers. Added to the flowers, which are unusual for sect. *Ixia*, the leaves are linear to narrowly lanceolate, up to 6 mm wide, and the plants may have a well-developed collar of fibres around the base (sometimes not collected when plants are not extracted with care from the ground). Plants produce one or more relatively large cormlets at the base of the main corm and/or thick, rhizome-like stolons that terminate in a large corm. *Ixia metelerkampiae* is closely allied to *I. campanulata* but differs in its taller stature, reaching up to 700 mm, and flowers differently coloured and marked (flowers usually ± uniformly red, less often white, in *I. campanulata*) and short, colourless bracts, 4–5 mm long, with inconspicuous cusps. Both also have an unusually short perianth tube for sect. *Ixia*, 2–4 mm long.

Ixia metelerkampiae is adapted for pollination by hopline beetles, with different species of beetles recorded at different sites.

30. **Ixia mostertii** *M.P.de Vos* in South African Journal of Botany 54: 598 (1988); Goldblatt & Manning: 187 (2016a). Type: South Africa, [Western Cape], Romans River, Wolseley, 5 Sept. 1986, *Mostert sub De Vos 2654* (NBG, holo.).

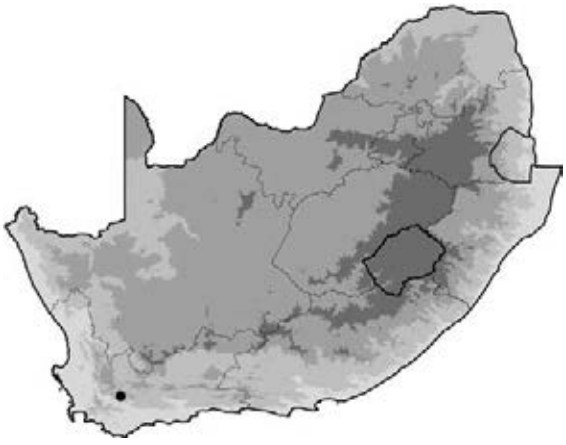
Plants 350–750 mm high. *Corm* ± globose, 10–20 mm diam.; tunics of fine, netted fibres extending upward in a collar around base. *Stem* simple or subdivaricately 1- or 2-branched. *Leaves* 5 to 9, ± half as long as stem, 1–6 mm wide, ± linear to narrowly lanceolate, ± straight, main vein and margins slightly thickened. *Spike* closely 5- to 14-flowered; bracts ± orbicular, truncate or obtuse, pellucid, 4–5 × 5–7 mm long, outer 1- or 3-toothed, inner slightly shorter, 2-toothed. *Flowers* ± rotate or bell-shaped, pale pink to mauve or purple, tepals marked red to purple near base and in midline; perianth tube filiform, 3–4 mm long; tepals slightly ascending, united in basal 1–2 mm, obovate to elliptic, 14–22 × 6–12 mm. *Filaments* 4–5 mm long; anthers 5–6 mm long, yellow. *Style* dividing opposite apex of filaments to lower third of anthers, branches 3–4 mm long. *Flowering time*: September to October.

Distribution and ecology: restricted to the mid-Breede River Valley in Western Cape, South Africa, recorded from near Romans River, south of Wolseley, and in the foothills of the Hex River Mtns northwest of Worcester; on relatively dry, stony clay slopes and flats in mixed renosterveld and fynbos. Much of its known range is now lost to urban development or vineyards.



Diagnosis: recognised by the hard, coarse corm tunics, the fibres extending upward as a collar around the base of the plant, *Ixia mostertii* also has relatively large flowers, somewhat crowded apically and with a prominent dark central eye. The flowers are either pink, mauve-pink or white with the central mark dark blue or iridescent green. Notably, the style is long, dividing opposite or above the bases of the anthers. It has been suggested to be allied to *I. vinacea* on account of the coarse collar of fibres around the base and flowers with a dark centre, but *I. vinacea* has linear leaves up to 3 mm wide and exceeding the spike, very different from the shorter, broader leaves of *I. mostertii*. It also differs in the relatively few-flowered spike and short style dividing opposite or slightly above the base of the filaments. The prominent anthers, up to 9 mm long (before anthesis), remain straight and suberect as the flower ages, another important feature of *I. mostertii* and useful in distinguishing plants collected without corms from *I. polystachya*, the anthers of which spread widely, often becoming somewhat twisted and almost horizontal after anthesis.

31. **Ixia longistylis** *(M.P.de Vos) Goldblatt & J.C.Manning* in South African Journal of Botany 104: 187 (2016a). *I. polystachya* var. *longistylis* M.P.de Vos: 39 (1999). Type: South Africa, [Western Cape], Worcester–Rawsonville, Farm Pokkraal, vlakte, 11 Nov. 1986, *De Vos 2681* (NBG, holo.).



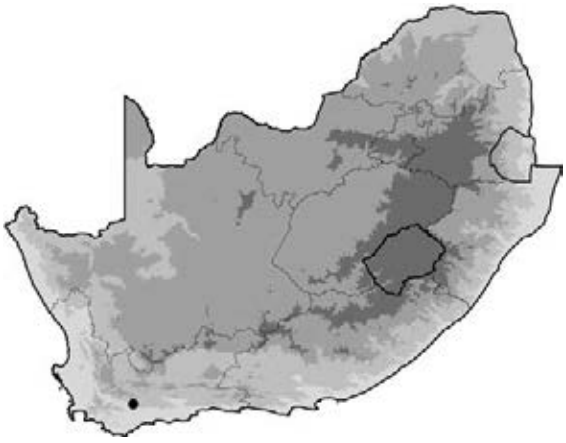
Plants 300–400 mm high, sometimes with a single, slender branch. *Corm* 12–17 mm diam.; tunics of fine, soft, netted fibres. *Leaves* linear, fibrotic, 1.2–2.0 mm wide (possibly up to 2.5 mm when alive), when dry veins prominent and main vein hyaline and strongly raised. *Spike* mostly 8- to 12-flowered, slightly flexuose; bracts translucent-opaque, outer 5.5–7.0 mm long, with a single prominent median vein, apex acute, inner slightly shorter, forked apically, apices acute, light brown. *Flowers* ± rotate, deep mauve-pink or white, dark blue-purple in centre; perianth tube 5–8 mm long; tepals ovate, 16–18 × 8–15 mm, inner smaller than outer. *Filaments* 4–6 mm long; anthers (6–)7–8 mm long, dark purple; pollen evidently yellow. *Style* dark purple, dividing 5–7 mm opposite lower to middle ⅓ of anthers. *Flowering time*: mid-August to mid-September.

Distribution and ecology: restricted to the mid-Breede River Valley in Western Cape, South Africa, known only from the area between Rawsonville and Worcester; on stony, alluvial flats.

Diagnosis: *Ixia longistylis* is distinguished from *I. polystachya* first by the long style, dividing opposite the lower third of the anthers, and the particularly long, erect anthers, (6–)7–8 mm long. Another important character is the particularly narrow leaves up to 1.5 mm wide, when dry with unusually prominent veins. *Ixia polystachya* is very different and may not even be closely

Distribution of ***Ixia mostertii***.

Distribution of ***Ixia longistylis***.



allied to *I. longistylis*. It has broader leaves, sometimes up to 8 mm wide, the stems are often branched and the flowers typically have shorter anthers, mostly 4–6 mm long, usually spreading ± horizontally when flowers are fully open and the style typically divides opposite the base or sometimes the middle of the filaments. Flowers of *I. longistylis* are deep mauve-pink (or sometimes white) with a dark purple centre, a colour rare but not unknown in *I. polystachya*. *Ixia longistylis* may be most closely allied to broad-leaved *I. mostertii*, which has similar, relatively large flowers with long, ascending anthers up to 9 mm long and a style dividing opposite or above the bases of the anthers.

32. **Ixia superba** *J.C.Manning & Goldblatt* in Novon 14: 289 (2004); Goldblatt & Manning: 188 (2016a). Type: South Africa, Western Cape, Montagu District, Klipheuwel, foot of the Langeberg, 9 Sept. 1993, *Goldblatt, Manning & Porter 12180* (NBG, holo.; K, MO, PRE, S, iso.).

Plants 200–600 mm high. *Corm* globose, 15–20 mm diam.; tunics of medium to coarsely textured fibres. *Stem* simple or with 1 to 3 straight, widely divergent branches. *Leaves* 3, all basal, lower 2 narrowly to broadly lanceolate, (3–)5–10 mm wide, usually ± half as long as stem, main vein and margins moderately thickened, uppermost leaf entirely sheathing, reaching to middle or upper third of stem, almost straight. *Spike* usually 3- to 6-flowered, lateral spikes 1- to 4-flowered; bracts membranous, translucent, outer 8–10 mm long, with 3 purple veins, shallowly 3-toothed, inner as long to slightly longer than outer, 2-veined, forked at apex. *Flowers* salver-shaped, pale to deep pink, tepals purple to blackish toward base, lightly sweet-scented; perianth tube slightly curved and cylindric for 2–3 mm, widening abruptly into a cup ± 3 mm deep; tepals obovate, spreading at ± right angles to tube, subequal, (14–)18–22 × (6–)10–12 mm, inner slightly wider than outer. *Filaments* inserted at mouth of narrow part of tube, connivent, 5–6 mm long, ± black; anthers divergent, 6–7 mm long (before anthesis), black; pollen yellow. *Style* dividing opposite anther bases, black, branches 2–3 mm long. *Flowering time*: late August to mid-September.

Distribution and ecology: a narrow endemic of the Montagu District of Western Cape, South Africa, recorded from just three farms, between 10 to 30 km east of Montagu; on loamy sandy clay along the northern foot of the Langeberg at the interface of the Table Mountain and Bokkeveld Systems.

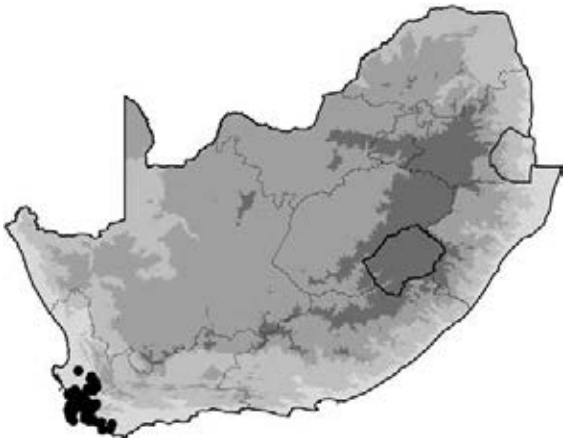
Diagnosis: *Ixia superba* is recognised by the relatively crowded spike of large flowers and the pink perianth with a large, glossy black centre. Unusual for sect. *Ixia* the black bases of the tepals are united in a wide cup ±3 mm deep. The stamens and style branches are also darkly pigmented with the erect filaments clasping the style and the anthers diverging. Significantly, the style divides above the bases of the anthers. The lower two leaves are lanceolate and comparatively broad, up to 10 mm wide and the third leaf sheathes the stem for its entire length. It has been confused with *I. gloriosa* and was at first included in that species, perhaps due to the flower colour, although *I. gloriosa* has deep magenta flowers with a blackish centre when seen alive. Differences between the two, apart from perianth colour, include leaf width (leaves of *I. gloriosa* are linear and only up to 3 mm wide), shape of the flowers and the short, erect branches of *I. gloriosa* in contrast to the spreading branches of *I. superba*. The style of *I. gloriosa* divides opposite the bases of the filaments unlike that in *I. superba*. Both species have the outer floral bracts 3-toothed, sometimes with the central tooth somewhat more prominent.

Distribution of ***Ixia superba***.

33. **Ixia dubia** *Vent.*, Choix de plantes dont la plupart sont cultivées dans le jardin de Cels no. 10 & t. 10 (1803); Lewis: 134 (1962); Goldblatt & Manning: 188 (2016a). Type: South Africa, without precise locality or collector, illustration in Vent.: t. 10 (1803).

Gladiolus umbellatus Schrank: 202 (1822). Type: South Africa, without precise locality, probably *Brehm s.n.* (M, holo., according to Lewis (1962) but not seen by us).

Ixia frederickii M.P.de Vos: 596 (1988). Type: South Africa, [Western Cape], near Mamre, north of Bokbaai, 16 Oct. 1987, *Duckitt sub De Vos 2694* (holo., NBG as STE).



Plants 200–300(–600) mm high. *Corm* globose, 12–17 mm diam.; tunics of medium to coarsely textured, netted fibres. *Stem* simple or with 1 or 2 short branches. *Leaves* 5 to 7, narrowly to broadly lanceolate, reaching to ± middle of stem, 1.5–8.0 mm wide, main vein and margins moderately thickened, sometimes slightly twisted. *Spike* crowded, usually 3- to 15-flowered; bracts membranous, translucent pink, outer 5–9 mm long, with 1 or 3 prominent veins, 1- or 3-toothed, inner 2-veined, 2-toothed. *Flowers* salver-shaped, yellow to orange, rarely red, with small dark brown to black central eye, unscented; perianth tube cylindric, 6–12 mm long; tepals obovate to elliptic, spreading, subequal, 15–22 × 6–12 mm. *Filaments* occasionally united at base, connivent, 3–5 mm long,

brown to black; anthers divergent, 6–8 mm long, yellow; pollen yellow. *Style* dividing opposite middle to apex of filaments, branches 3–5 mm long. *Flowering time*: late September to November, rarely December.

Distribution and ecology: restricted to southwestern Western Cape, South Africa, extending from Piketberg and the Tulbagh Valley to the Cape Peninsula and east to Hermanus; on sandy and gravelly granitic slopes and flats, occasionally on clay, at elevations up to 760 m, as well as coastal lowlands.

Diagnosis: *Ixia dubia* is recognised among the species of sect. *Ixia* with yellow or orange (occasionally red as in the synonym *I. frederickii*) flowers by the pale but semi-translucent floral bracts often flushed and veined pink and a moderate-sized flower with tepals mostly 12–15 mm long. The flowers have a comparatively small, brown to purple stain in the centre about one quarter the length of the tepal. The filaments are comparatively long, 5–6 mm long, darkly coloured and the style divides at or close to the anther bases so that the yellow style branches arch outward between the lower half of the divergent anthers. The outer floral bracts either have a single prominent median tooth or three small teeth, the central one more prominent than the laterals. Filaments of *I. dubia* are typically free (or rarely basally united) and the perianth tube is usually 6–9 mm long, but ± 12 mm long in plants from the Tulbagh Valley. Plants are usually of moderate height, rarely exceeding 300 mm, are seldom branched and although the narrowly lanceolate leaves reach to about the middle of the stem, plants growing in dense undergrowth have longer and narrower, sometimes almost linear leaves. Flowers are pollinated by hopliine beetles, different species of which have been captured at different sites.

Historically *Ixia dubia* has often been confused with orange-flowered *I. maculata*, but that species has very different, large floral bracts, rust-brown in the upper half or entirely, partly to entirely united filaments and the corms bear stolons. Yellow-flowered plants with corm tunics of particularly fine fibres or papery layers and bearing stolons sometimes included in the past in *I. dubia* and also treated as *I. polystachya* var. *lutea* are *I. sarmentosa*, a species of wet habitats in Western Cape. Although superficially similar to *I. dubia*, *I. sarmentosa* typically has a larger central stain (up to one third the length of the tepals), and a short, dark style dividing at the mouth of the perianth tube so that the style branches extend between the base to middle of the filaments. The filaments diverge slightly and are relatively short, up to 2.5 mm long (3–5 mm long in *I. dubia*).

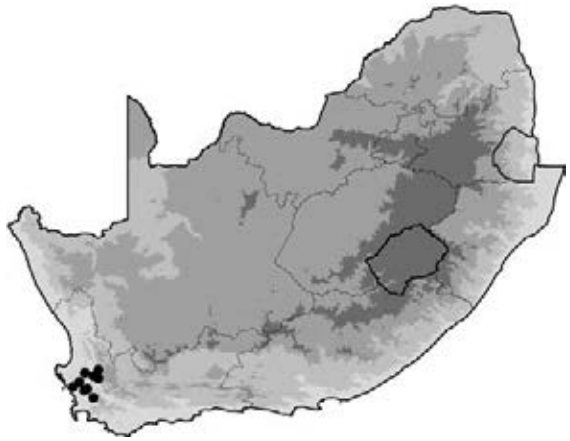
Distribution of ***Ixia dubia***.

Ser. **Ixia**

Flowers usually with dark markings in centre. *Stamens* free, filaments usually diverging. *Style* dividing between base and about middle of filaments, branches short, falcate.

34. **Ixia abbreviata** *Houtt.*, Natuurlijke historie 12: 41 (1780); G.J.Lewis: 120 (1962, as *I. conferta*); Goldblatt & Manning: 188 (2016a). Type: South Africa, without precise locality or collector, illustration in Houttuyn: t. 78 f. 3 (1780).

Ixia capitata var. *ovata* Andrews: t. 23 (1798a). *I. conferta* R.C.Foster: 47 (1936), new name for *I. ovata* (Andrews) Sweet: 399 (1826), illegitimate homonym, not *I. ovata* Burm.f. (1768). *I. lutea* var. *ovata* (Andrews) B.Nord.: 284 (1972). *I. abbreviata* var. *ovata* (Andrews) Goldblatt & J.C.Manning: 64 (2010). Type: South Africa, without precise locality or collector, illustration in Andrews: t. 23 (1798a).



Ixia maculata var. *ochroleuca* Ker Gawl.: t. 1285 (1810b). *I. ochroleuca* (Ker Gawl.) Sweet: 502 (1830), illegitimate homonym, not Vahl (1805). *I. conferta* var. *ochroleuca* (Ker Gawl.) G.J.Lewis: 121 (1962). Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 1285 (1810b).

Ixia lutea Eckl.: 24 (1827); De Vos: 51 (1999). Type: South Africa, without precise locality, cultivated in Cape Town, *Ecklon s.n.* (S, holo.).

?*Ixia alboflavens* Eckl.: 27 (1827). Type: unknown.

Ixia nigroalbida Klatt: 396 (1882). *I. maculata* var. *nigroalbida* (Klatt) Baker: 163 (1892). Type: South Africa, without precise locality or collector, illustration in Andrews: t. 159 (1802e).

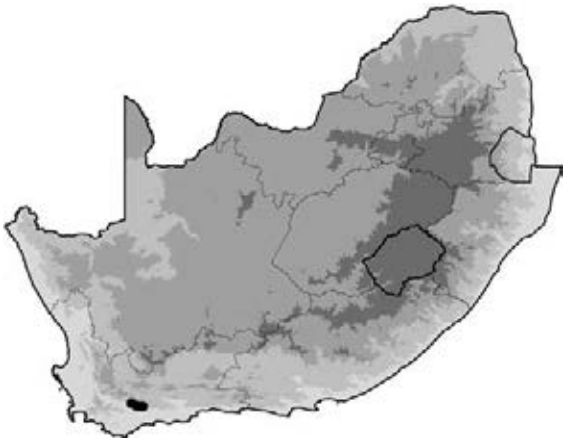
Plants 200–300(600) mm high. *Corm* globose, 10–15 mm diam.; tunics of coarse, almost woody fibres. *Stem* usually simple. *Leaves* 4 to 6, narrowly to broadly lanceolate, mostly ± ⅔ as long as stem, 3–15 mm wide, main vein and margins moderately thickened, sometimes slightly twisted. *Spike* crowded, closely 2- to 10-flowered; bracts membranous, opaque to translucent, usually flushed rust-brown in upper half, outer 7–12 mm long, with 1 or 3 prominent veins, 1- or 3-toothed, inner 2-veined, 2-toothed. *Flowers* salver-shaped, white to cream(–pale yellow) or deep pink to purple with small dark brown to purple central eye, unscented; perianth tube

Distribution of ***Ixia abbreviata***.

cylindric, 6–12 mm long; tepals ovate to elliptic, spreading, subequal, 15–26 × 8–20 mm. *Filaments* connivent, 3.5–5.0 mm long, brown or purple; anthers, divergent, 7–9 mm long, purple or brown; pollen yellow. *Style* dividing opposite base of filaments, branches falcate, 3–5 mm long. *Flowering time*: late August to October.

Distribution and ecology: extending in Western Cape, South Africa, from the Piketberg south to Darling and Paarl and inland to the Tulbagh Valley; mostly on clay or granitic flats and slopes in renosterveld.

Diagnosis: typical *Ixia abbreviata* is recognised by the relatively large flowers crowded near the top of the spike, either white to creamy yellow or deep pink to red-purple, with a dark brown to green or purple centre. The style divides at the mouth of the tube into short, curved branches, usually pale violet in colour. The floral bracts are typically brown distally, the outer with a prominent central cusp and the inner are forked to about the middle. The bracts are often relatively long, 10–12 mm, but plants from Elandsberg Nature Reserve have bracts only 7–8 mm long. Unusual for the species, a population from Darling Nature Reserve has uniformly pale bracts but with brown veins.



Over much of its range *Ixia abbreviata* has white to creamy yellow flowers (also described as pale yellow) with a brown central eye, but plants from Porterville and the Tulbagh Valley have deep pink to purple flowers with a dark purple centre. Although treated as separate varieties in the past, the two colour morphs are merely colour variants differing in no other features and are not recognised taxonomically. Similar shifts in flower colour are known for several species of different genera from the Tulbagh Valley and nearby.

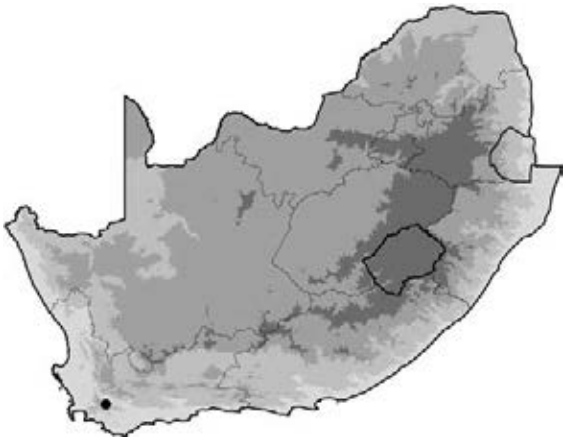
35. **Ixia gloriosa** *G.J.Lewis* in Journal of South African Botany 28: 132 (1962); Goldblatt & Manning: 189 (2016a). Type: South Africa, [Western Cape], foot of the Langeberg near Grootberg [Leeurivierberg], *Esterhuysen 24556* (BOL, holo.; MO, iso.).

Plants 350–650 mm high. *Corm* globose, 10–13 mm diam.; tunics of fine, pale, netted fibres. *Stem* usually with 2 or 3 slender, ± erect branches held close to main stem. *Leaves* 3 or 4, linear, ½ to ± ⅔ as long as stem, 1–3 mm wide, main vein and margins moderately thickened, uppermost leaf partly sheathing stem. *Spike* laxly 4- to 6-flowered; bracts membranous, translucent, pale, outer 8–10 mm long, usually with 3 prominent veins, 3-toothed, inner 2-veined, 2-toothed. *Flowers* ± rotate, brilliant magenta with small, purple-black central mark, unscented; perianth tube cylindric, 3–6 mm long; tepals elliptic, spreading, subequal, 16–20 × 7–12 mm. *Filaments* connivent, 4–5 mm long, purple-black; anthers 5–7 mm long, dark purple-black; pollen purple-black. *Style* dividing opposite base of filaments, branches falcate, up to 5 mm long. *Flowering time*: late August to September.

Distribution and ecology: a narrow endemic of the western Little Karoo in Western Cape, South Africa, restricted to a small portion of the northern foothills of the Langeberg between the Op-de-Tradouw heights near Barrydale and Grootberg [Leeuriviersberg] east of Montagu; on clay ground in renosterveld.

Diagnosis: a striking species in bloom, *Ixia gloriosa* has a bright magenta perianth with a small, glossy, almost black centre, and purple-black stamens and style branches. The leaves are particularly narrow, typically 2–3 mm wide and the corm tunics are composed of fine fibres. The species is also distinctive in having up to three short branches held close to the main axis, each usually bearing fewer blooms than the 4 to 6 on the main spike. Plants give the illusion of having a particularly long, lax spike with flowers scattered along its entire length but some of the open flowers are borne on the branches. The pale floral bracts, ± 6 mm long, have prominent purple veins, the outer with three short, acute teeth. When described by Lewis (1962), *I. gloriosa* included *I. superba* and the original description is an amalgam of the two species. The anthers, 5–7 mm long and slightly more than twice as long as the filaments, were originally described as connivent at the tips, but

Distribution of ***Ixia gloriosa***.



there is no evidence of this in available preserved material. The style divides at or just above the bases of the filaments and style branches are unusually long, reaching up to 5 mm and exceeding the shorter filaments. Among other differences, *I. superba* has a longer style, dividing above the bases of the anthers, but shorter style branches 2–3 mm long.

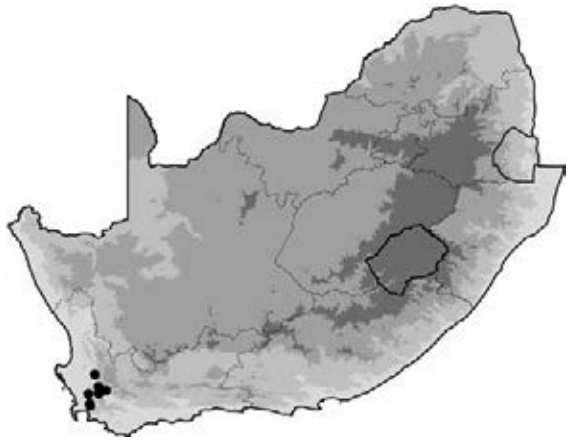
36. **Ixia atrandra** *Goldblatt & J.C.Manning* in Bothalia 31: 191 (2001); Goldblatt & Manning: 189 (2016a). Type: South Africa, [Western Cape], Villiersdorp, 5 km along Doornrivier road, Farm Die Hoek, 3 Oct. 2000, *Goldblatt 11604* (NBG, holo.; K, MO, PRE, iso.).

Plants 250–500 mm high. *Corm* globose, 15–20 mm diam.; tunics of medium-textured, wiry, netted fibres. *Stem* usually unbranched or with 1 short, ascending branch. *Leaves* usually (3)4, all basal, lanceolate, usually reaching to ± middle of stem, 6–10 mm wide, plane or lightly twisted in upper half, uppermost leaf usually entirely sheathing, main vein and margins hyaline, lightly thickened. *Spike* crowded, (3)4- to 10-flowered; bracts dry, translucent, veins ± pink above, outer 5–6 mm long, obscurely 3-toothed, inner usually slightly shorter, 2-toothed. *Flowers* salver-shaped, pink or rarely creamy white, lower third of tepals dull pink or yellowish to ochre-coloured with an outer band of deep lilac, unscented; perianth tube filiform, 6–9 mm long, widened in upper 1 mm; tepals obovate, somewhat narrowed below into a short claw, spreading with distal margins curving upward, 11–14 × 6–8 mm. *Filaments* 2.5–3.0 mm long, weakly diverging, free or united at base, blue to brownish; anthers 5–6 × 1.5–2.0 mm, with broad connective, thecae restricted to margins, dehiscing laterally, initially erect, diverging and becoming slightly twisted, black; pollen yellow. *Style* dividing opposite or shortly above base of filaments, blue, branches 3–4 mm long, ultimately reaching bases of anthers. *Flowering time*: late September to mid-October.

Distribution and ecology: a narrow endemic of the Bossiesveld region in the Hoeksrivier Valley in the south western corner of the Worcester Karoo, South Africa; on clay soils derived from shales of the Bokkeveld series in renosterveld.

Diagnosis: *Ixia atrandra* is distinctive in the terminally crowded flowers with pink or creamy white tepals with a large dark centre, tepals narrowed near the base ± into short claws and arrow-shaped, black anthers, broadest at the base, and with the connective visible on the abaxial surface. The connective bears small, rounded, blue deposits, evidently an epidermal secretion. *Ixia rouxii*, which also has an exposed anther connective, likewise has these surface deposits and also has tepals somewhat narrowed below and on these grounds they have been considered immediately allied. Both species have the style dividing at or just above the bases of the filaments and 3-toothed outer floral bracts, the teeth very short in *I. atrandra*.

Distribution of ***Ixia atrandra***.



The flowers of *Ixia atrandra* display the typical adaptations for pollination by hopliine beetles: a congested, subcapitate inflorescence, brightly coloured bowl-shaped flowers with central dark marking, lack of nectar or fragrance and dark anthers.

37. **Ixia rouxii** *G.J.Lewis* in South African Gardening and Country Life 21: 368 (1931); Lewis: 125 (1962); Goldblatt & Manning: 190 (2016a). Type: South Africa, [Western Cape], near Porterville, ex hort. Kirstenbosch, *Roux s.n.* as *Natl. Bot. Gard. 209/27* (BOL 36476, lecto. (as holo.), designated by De Vos: 41 (1999); BOL, K, isolecto.).

Plants 350–550 mm high. *Corm* globose, 12–15 mm diam.; tunics of coarse, netted fibres. *Stem* usually 1 to 3 slender, short, strongly divergent branches. *Leaves* 4 to 6, linear to narrowly lanceolate, ½ to ± ⅔ as long as stem, 2–6 mm wide, main vein and margins moderately thickened, uppermost leaf partly sheathing stem. *Spike* closely 5- to 9-flowered; bracts membranous, translucent, flushed dark brown, outer 5–6 mm long, usually with 3 prominent purple veins, either 3-toothed or with one prominent tooth, inner 2-veined, 2-toothed. *Flowers* ± salver-shaped, pink to purple or blue-mauve with large, purple-black or turquoise central mark, unscented; perianth tube cylindric, 5–7 mm long; tepals obovate to elliptic, spreading, subequal, 15–20 × 7–12 mm. *Filaments* ± 5 mm long, purple-black; anthers 5–7 mm long, dark purple-black; pollen yellow. *Style* dividing opposite base of filaments, branches falcate, 4–5 mm long. *Flowering time*: October to mid-November.

Distribution and ecology: rare today and restricted to the lowlands of Western Cape, South Africa, extending from near Porterville to the Paardeberg and Stellenbosch Flats and inland in the upper Tulbagh Valley; on well-drained sandy ground, most sites under cultivation today.

Diagnosis: with narrow, sublinear leaves 2–6 mm wide, flowers crowded terminally, *Ixia rouxii* is distinguished

Distribution of ***Ixia rouxii***.

primarily by the flowers with large, dark central stain, almost black stamens and distinctive, short lateral branches extended outward almost horizontally and curving upward at the tips. The tepals range in colour from purple to deep pink or blue-mauve (rarely white), always with a dark brown to purple-black central stain covering ± one third their length. Spikes bear relatively few flowers, often only 4 to 6 on the main spike (sometimes more), and fewer on the branches and the bracts are ± papery and pale below, becoming brown distally and the outer may have one tooth or three ± equal teeth, this varying even in the same population. Somewhat unusual for sect. *Ixia*, the corms bear short, relatively slender stolons, the remains of which can be seen on most herbarium specimens. *Ixia rouxii* has been regarded as allied to *I. polystachya*, which typically has two or more ascending to upright branches, many more flowers per spike, floral bracts usually pale throughout and the corms do not produce stolons. The style in *I. rouxii* divides at or shortly above the filament bases, occasionally opposite the middle of the filaments. The central stain of dark pigment is often less pronounced in *I. polystachya*, which also usually has the style dividing opposite the filament bases. Both Lewis (1962) and De Vos (1999) remarked that the tepals are unusually narrowed below into short claws (tepals unguiculate or subunguiculate according to Lewis), but there seems little merit in this distinction.

Notable features of *Ixia rouxii* are the black anthers, the thecae of which are separated from one another to expose a narrow strip of connective on the abaxial (outer) surface. Anthers in the type from Porterville, and in a collection said to be from 'near Hopefield' have particularly prominent connectives, ovate in shape. This recalls the condition in *I. atrandra*, suggesting a possible relationship between them. The use of this feature in circumscribing *I. rouxii* is limited because anthers from the southern end of the range at Stellenbosch and nearby have nearly parallel thecae with the connective not, or barely exposed. The pollen, a bright yellow colour, contrasts with the black anther tissue in dehisced thecae.

38. **Ixia polystachya** *L.*, Species plantarum, edn. 2, 1: 51 (1762); Lewis: 102 (1962, including *I. linearifolia* and *I. sarmentosa*); Goldblatt & Manning: 190 (2016a). *I. serotina* Salisb.: 34 (1796), illegitimate superfluous name for *I. polystachya* L. (1762), *I. erecta* P.J.Berg. (1767) and *I. thyrsiflora* D.Delaroche (1766). Type: South Africa, without precise locality or collector, illustration in Mill.: t. 155 f. 2 (1760).

Ixia erecta P.J.Bergius: 5 (1767) [name misapplied to *I. odorata* by Thunb.: 16 (1783); misapplied by Jacq.: t. 18 (1797) to *I. polystachya* var. *lutea*]. Type: unknown, identity according to G.J.Lewis (1962).

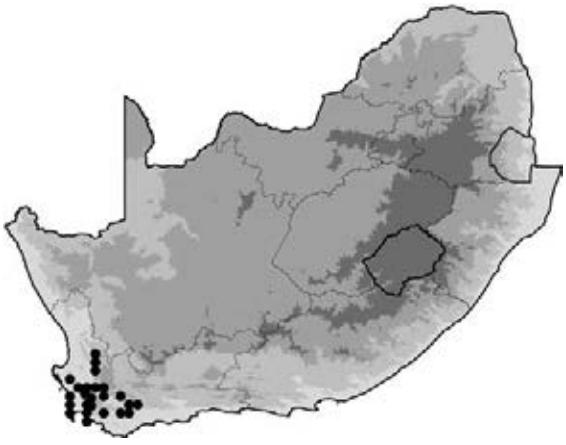
Ixia polystacia Mill.: 3 (1768), illegitimate homonym and superfluous name for *I. polystachya* L. Type: South Africa, without precise locality or collector, illustration in Mill.: t. 155 f. 2 (1760).

Ixia maculata var. *caesia* Ker Gawl.: t. 530 (1821b). *I. viridiflora* var. *caesia* (Ker Gawl.) Baker: 92 (1877). Type: South Africa, without precise locality or collector, illustration in Ker. Gawl.: t. 530 (1821b).

Wuerthia [as *Würthia*] *elegans* Regel: 595 (1851). *Ixia aristata* var. *elegans* (Regel) Baker: 162 (1892). *I. elegans* (Regel) N.E.Br.: 43 (1928). Type: South Africa, without precise locality or collector, illustration in Regel: 98, t. 46, f. 2 (1853).

Watsonia campanulata Klatt: 354 (1882): Type: South Africa, without precise locality or collector, illustration in Andrews: t. 196 '*I. maculata*' (1801b).

Ixia polystachya var. *crassifolia* G.J.Lewis: 108 (1962). Type: South Africa, [Western Cape], 1 mile [1.5 km] north of Malmesbury, Sept., *Schelpe 4225* (SAM, holo.; BOL, iso.).



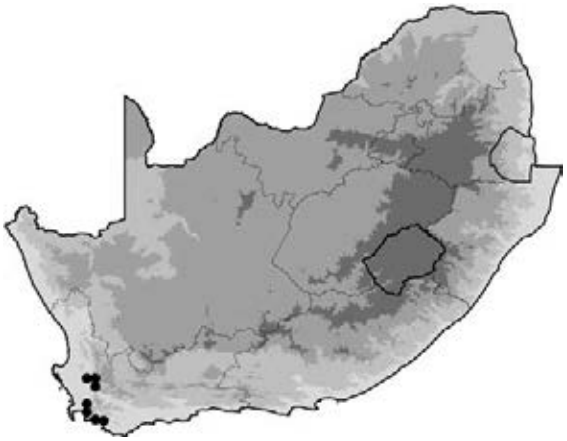
Plants mostly 300–500 mm high. *Corm* 9–20 mm diam.; tunics of fine, netted fibres. *Stem* usually 2- or 3-branched, sometimes simple. *Leaves* 5 to 8, reaching to ± middle of stem or base of spike, narrowly sword-shaped to linear, mostly 3–8 mm wide, upper leaves partly sheathing, free distally. *Spike* mostly 8- to 12-flowered, slightly flexuose; bracts pale, ± translucent, flushed pink to brown near tips, outer 4–7(–9) mm long, with a single prominent median vein, apex subacute, 1-toothed or unequally 3-lobed with longer central tooth, inner 2-veined, 2-toothed. *Flowers* rotate to ± salver-shaped, suberect, pink, blue-mauve, blue-grey or purple with small dark blue, purple, black or grey centre, often faintly scented; perianth tube 6.5–11.0 mm long; tepals ± elliptic, subequal, 9–18 × 4–8 mm. *Filaments* 2–4 mm long; blue-mauve to purple; anthers 4–7 mm long, spreading or suberect, pale mauve to ± white; pollen white or pale yellow. *Style* pale mauve, purple or white, usually dividing opposite base of filaments or opposite middle to apex of filaments, branches 3–4 mm long. *Flowering time*: late October to early December.

Distribution and ecology: restricted to the western half of Western Cape, South Africa, extending from the Olifants

River Mtns near Warm Baths to the Cape Peninsula and Cape Hangklip; on mid- to lower slopes and flats, often in cooler sites as at the edge of bush but also in renosterveld in the Swartland, on clay loam or sandy ground.

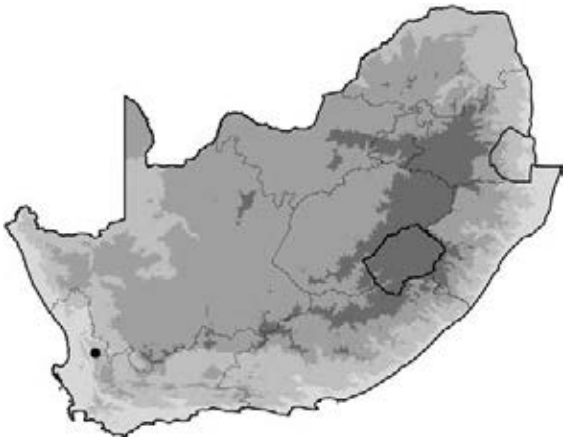
Diagnosis: *Ixia polystachya* is recognised by moderate-sized flowers crowded together at the top of the spike, and a stem typically with two or three short, ascending branches. Flowers range from white to pink or blue-mauve with a relatively small darker blue, purple or grey centre and have tepals 9–18 mm and a perianth tube 6.5–11.0 mm long and half as long as the tepals. Added to this, the floral bracts are usually pale translucent and the outer has a prominent central vein and an acute central cusp, sometimes with a pair of small lateral lobes. The style typically divides at the mouth of the perianth tube with the style branches extending between the bases of the filaments. Plants also usually have dark anthers and as the flower ages the anthers spread outward to become almost horizontal and slightly twisted. The specific epithet, *polystachya* (many-branched), is misleading for although stems sometimes have one, two or even three branches (as in the type illustration), this character is not consistent and plants are sometimes unbranched.

Curiously, plants sometimes have an unusually long style dividing shortly below to shortly above the base of the anthers. Such plants are most common on the Cape Peninsula but also occur in populations from the Olifants River Mtns. The short-styled plants are most frequent at lower elevations between Cape Town and Tulbagh. Style length may even vary within some populations. Plants referred in the past to var. *lutea* are now regarded as a separate species, *Ixia sarmentosa*, which has pale yellow to white flowers with a large central stain and corms usually bearing stolons (not present in *I. polystachya*). A second variety, var. *crassifolia*, said to have leathery leaves, slightly smaller flowers and leaf margins somewhat thickened, is not currently recognised. *Ixia polystachya* var. *longistylis* (De Vos 1999) from the mid-Breede River Valley near Rawsonville, distinguished by particularly narrow, prominently veined and fibrous leaves 2.0–2.5 mm wide and a style dividing opposite the middle of the anthers, is treated as the separate species *I. longistylis*, probably not closely related to *I. polystachya*.



Distribution of ***Ixia polystachya***.

39. **Ixia sarmentosa** *Goldblatt & J.C.Manning* in South African Journal of Botany 104: 191 (2016a). Type: South Africa, Western Cape, Bo-Hermon, Elandsberg Reserve, marshy ground south-east of Bosplaas homestead, 11 Nov. 2011, *Goldblatt & Manning 13747* (NBG, holo.; K, MO, PRE, S, iso.).



Plants mostly 250–500 mm high. *Corm* ± globose, mostly 8–10 mm diam., often with stolons from base or cormlets virtually sessile; tunics of fine, soft fibres or ± membranous to papery layers. *Stem* usually with 1 or 2(3) short, rigid, spreading branches. *Leaves* mostly 4 to 6, all with expanded blades, ± ⅔ to nearly as long as stem, linear to narrowly sword-shaped, mostly 2–5 mm wide, main vein and margins hyaline when alive (appearing thickened when dry). *Spike* closely 3- to 6(–8)-flowered, branches mostly 2- or 3-flowered; bracts membranous, translucent, sometimes dark at tips, 5.5–7.0 mm long, outer with only central vein prominent, 1-toothed or with a small tooth lateral to central tooth, inner 2-veined, acutely 2-toothed. *Flowers* upright, rotate, sulphur-yellow to white, rarely pale pink, with green to brown central zone up to ± ⅓ length of tepals, flushed red outside, unscented; perianth tube 5–9 mm long, filiform; tepals united basally for up to 1 mm, obovate, (12–)16–22 × (5–)7–10 mm, spreading ± horizontally when fully open. *Filaments* ± 2 mm long, ± coherent, usually dark green to brownish purple, rarely yellow; anthers 5–8 mm long, remaining erect or suberect, linear, yellow; pollen yellow. *Style* dividing opposite base to middle of filaments, green or yellow, branches 3.0–3.5 mm long, emerging between filaments. *Flowering time*: mostly October to late November; opening ± 10:00 and closing 13:30–14:00.

Distribution and ecology: restricted to the southwestern corner of Western Cape, South Africa, extending from Porterville in the north to Kleinmond and Hermanus in the south; in seasonally wet habitats at the foot of mountains, usually in loamy, sandy ground.

Diagnosis: *Ixia sarmentosa* is distinguished by the narrow leaves, small corms with particularly soft tunics, either membranous or composed of fine, soft fibres and usually bearing slender stolons with a single terminal cormlet. The relatively short, stiff branches spread at a wide angle from the main stem and bear few flowers. Branches, usually produced in *I. polystachya*, in which collections of *I. sarmentosa* were often included (sometimes as var. *lutea*), are more-or-less upright and bear numerous flowers. The flowers of *I. sarmentosa* also consistently have short filaments, ± 2 mm long, and the style, pale green to pale yellow, divides opposite the base to middle of the short filaments, the style branches then extending outward between the filaments. *Ixia polystachya* has larger corms with well-developed fibrous tunics and does not produce stolons.

Distribution of ***Ixia sarmentosa***.

Distribution of ***Ixia angelae***.

Flowers of *Ixia sarmentosa* are relatively large, especially in northern populations, the tepals mostly 17–22 × 8–10 mm, but in populations from the mountains around Stellenbosch and Somerset West the tepals are 12–16 × 5–7 mm. Other than the smaller flowers there appears to be no difference between these and the larger flowered plants.

Surprisingly, given their very different flowers and different pollinators, hybrids are known between long-tubed *Ixia paniculata* (sect. *Hyalis*), pollinated by long-proboscid flies, and *I. sarmentosa* (originally reported as *I. paniculata* × *I. dubia*) (Goldblatt & Manning 2011) where the two co-occur near Kleinmond. Like most members of sect. *Ixia*, *I. sarmentosa* is evidently adapted for pollination by hopliine beetles, two species of which have been captured on the flowers.

40. **Ixia angelae** *Goldblatt & J.C.Manning* in South African Journal of Botany 104: 192 (2016a). Type: South Africa, Western Cape, Cederberg, wet cliffs along road above Algeria Forest Station, 13 Nov. 2012, *Manning & Parker 3459* (NBG, holo.; K, MO, PRE, iso.).

Plants 120–250(–400) mm high. *Corm* conical, 8–10 mm diam., sometimes producing short stolons; tunics of fine to medium-textured fibres. *Stem* usually unbranched but with up to 3 widely spreading branches curved upwards distally. *Leaves* 3 to 6, narrowly lanceolate, 3–6 mm wide. *Spike* (2)4- to 7(12)-flowered; bracts pale-translucent, ± dry in upper half, outer ± 5 mm long, without dark veins when alive, when dry with a prominent, dark, median vein reaching upper margin and several more shorter veins, 3-toothed, inner as long or slightly shorter than outer, 2-veined, forked apically. *Flowers* clear pale yellow, sometimes slightly paler in centre, often red to brown on reverse; perianth tube filiform, 6–7 mm long; tepals subequal, elliptic, spreading, 12–18 × 5–7 mm. *Stamens* with filaments ± 3.5 mm long, erect, diverging slightly distally, ± white; anthers suberect, 4.5–7.0 mm long, elliptic and with elliptic connective visible on abaxial surface, latrorse, yellow; pollen yellow. *Style* yellow, dividing opposite base of filaments but branches held together below, only diverging opposite middle to upper half of filaments, branches arching outward to reach bases of anthers, 3–5 mm long. *Flowering time*: early October to mid-November.

Distribution and ecology: currently known only from Uitkyk Pass in the central Cederberg above Algeria Forest Station in Western Cape, South Africa; on mossy seeps on relatively steep cliffs or wet banks.

Diagnosis: *Ixia angelae* is distinguished by the pale yellow flowers with nearly white, erect filaments held closely together for part of their length so that the style branches emerge between them halfway up their length, then arching outward, reaching to about the base of the anthers. Not clearly visible in dried specimens, the anthers are unusual, being elliptic with the connective visible between the thecae on the abaxial surface. The dehiscence is latrorse, unusual for *Ixia* although known in a few other species, none apparently closely related to *I. angelae.* The flowers have a relatively short perianth tube, 6–7 mm and tepals ±12 mm long, about twice as long as the tube. The corms have tunics of fine, soft fibres and produce cormlets on stolons at the base. *Ixia angelae* stands out in sect. *Ixia*, especially among the short-styled species of the section in the uniformly coloured tepals without any hint of a dark centre. *Ixia polystachya*, in which De Vos (1999) included specimens available to her, has pink to mauve or white flowers, never yellow, and always with a darker central stain, divergent spreading anthers with parallel thecae, and style branches arching outward between the bases of the filaments, thus unlike *I. angelae.* The habitat, in wet moss on cliffs and muddy banks is unusual for the genus.

41. **Ixia viridiflora** *Lam.*, Encyclopédie méthodique. Botanique 3: 340 (1789); Lewis: 114 (1962); Goldblatt & Manning: 194 (2016a). Type: South Africa, without precise locality or collector (P: Herb. Lamarck, holo.).

Ixia spectabilis Salisb.: 35 (1796). Type: unknown.

Ixia spicata var. *viridi-nigra* Andrews: t. 29 (1798b). Type: South Africa, without precise locality or collector, illustration in Andrews: t. 29 (1798b).

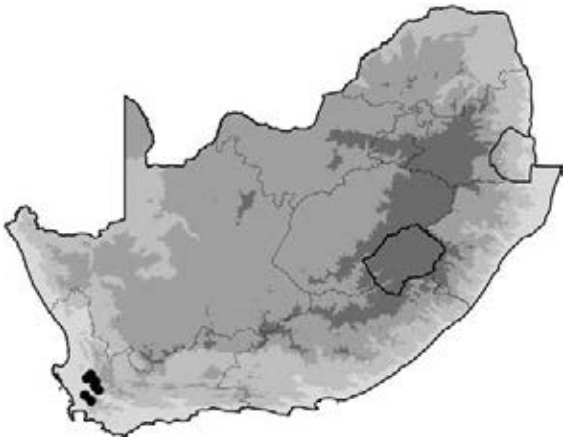
Ixia maculata var. *amethystina* Ker Gawl.: t. 789 (1804b). Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 789 (1804b).

Ixia viridis Thunb.: 242 (1811). Type: South Africa, [Western Cape], 'Roode Sand', *Thunberg s.n.* (S, UPS–THUNB, syn.).

Ixia maculata var. *viridis* Ker Gawl.: t. 549 (1802e). *I. pulchra* Salisb.: 320 (1812), replacement names for *I. maculata* var. *viridis* Ker Gawl. [not *I. viridis* Thunb.]. Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 549 (1802e).

Ixia cana Eckl.: 26 (1827). *I. viridiflora* var. *cana* (Eckl.) Baker: 164 (1892). Type: South Africa, without precise locality, cultivated in Cape Town, *Ecklon s.n.* [S, lecto., designated by Nordenstam: 285 (1972)].

Ixia viridifolia var. *minor* M.P.de Vos: 45 (1999). Type: South Africa, Western Cape, Wolseley, Mostertshoek, *Mostert sub De Vos 2722* (NBG [as STE], holo.).



[*Ixia maculata viridis* Jacq.: t. 23 (1797), invalid name.]

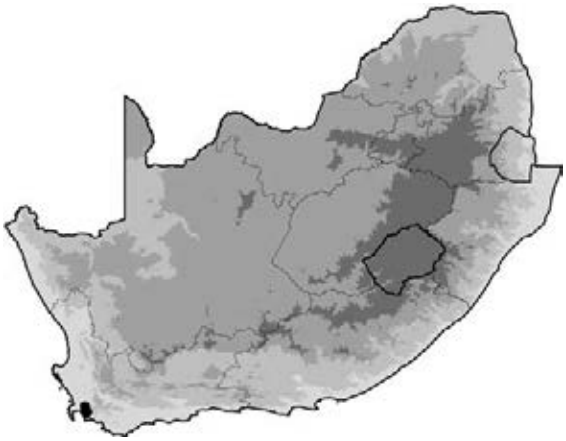
[*Ixia prasina* Sol. ex Baker: 92 (1877), invalid name only cited in synonymy.]

Plants 500–950 mm high. *Corm* ± globose, 10–18 mm diam.; tunics of fine, pale, netted dark fibres. *Stem* usually with 1 or 2 short, erect branches held close to main stem. *Leaves* 5 to 7, ± linear, leathery, reaching to between middle of stem and nearly to base of spike, 2–7 mm wide, firm, with 3 or 4 prominent veins. *Spike* laxly 10- to many-flowered; bracts ± dry, straw-coloured, outer 8–10 mm long, with 1 prominent vein, mostly 1-toothed, inner slightly shorter than outer, 2-veined, 2-toothed. *Flowers* half nodding, salver-shaped, green, blue-green or grey-blue, usually with prominent, dark purple or reddish to ± black centre (rarely whitish in centre); perianth tube filiform, 6–9 mm long; tepals subequal, ± elliptic, spreading, connate in lower ± 1 mm, (10–)16–25 × (4–)7–11 mm. *Filaments* (2–)3–4 mm long, parallel, purple (rarely whitish); anthers suberect, (5–)9–13 mm long; pollen yellow. *Style* dividing opposite base (rarely middle) of filaments, purple (rarely whitish), branches falcate, ± 3 mm long. *Flowering time*: late September and October.

Distribution and ecology: a rare, relatively narrow endemic of Western Cape, South Africa, extending from near Porterville and the upper Tulbagh Valley south to the southern end of the Paardeberg; on loamy clay and gravel.

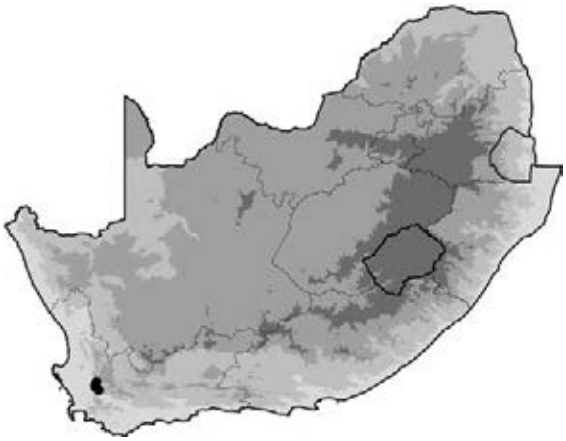
Diagnosis: this lovely plant, with its extraordinary green to turquoise, or sometimes grey-blue flowers usually with maroon to almost black centre, is unmistakeable. Added to the unique flower colour is an elongate spike with large blooms open at the same time and spaced well apart from one another. The particularly long anthers are mostly 9–13 mm long (occasionally only 5–7 mm long) and always suberect and the style divides at or shortly above the bases of the free filaments. The elongate spike is unique in the genus.

Distribution of ***Ixia viridiflora***.



Ixia viridiflora var. *minor* was named for two collections from Romans River Farm near Wolseley that vary slightly from typical plants in a number of characters, most importantly the leaves mostly 4–7 mm wide, bracts with several veins, perianth tube 4–7 mm long, short anthers 5–7 mm long, and the style said to divide near the middle of the filaments. Typical *I. viridiflora* has leaves 2–5 mm wide, usually 1-veined bracts, perianth tube 6–9 mm long, anthers 9–13 mm long, and the style always dividing opposite the filament bases. The species is still known from very few plants, many of them derived from the same populations. Even at the time, some of the characters separating var. *minor* were problematic — the holotype of var. *minor* actually has the style branching at the top of the tube but other collections, which have a pale green perianth lacking a dark centre, are mixed for this character. More recent collections of *I. viridiflora* from additional populations have rendered the distinction between the two varieties untenable, in particular plants with flowers typical of var. *viridiflora* but with the broader leaves of var. *minor.*

Small-flowered populations with a pale centre, including the anthers, are recorded from Romans River Farm and from Weltevrede Farm near Botha, along with typical large-flowered, dark-centred populations. These anomalous populations may represent pollination ecotypes.



Like several other species of sect. *Ixia*, *I. viridiflora* is pollinated by hopliine beetles.

42. **Ixia versicolor** *G.J.Lewis* in Journal of South African Botany 28: 123 (1962). Type: South Africa, [Western Cape], between Gordon's Bay and Strand, *Lewis s.n.* [BOL 21758, lecto. (as holo.), designated by De Vos: 51 (1999)].

Plants 150–300 mm high. *Corm* ± globose, 10–15 mm diam.; tunics ± coarse, dark fibres, netted above. *Stem*

Distribution of ***Ixia versicolor***.

Distribution of ***Ixia vinacea***.

unbranched. *Leaves* 5 or 6, narrowly lanceolate, spirally twisted, reaching to ± the middle or upper third of stem, 3–5 mm wide, firm with prominent main vein, margins ridged, cartilaginous, ± crenate. *Spike* closely 3- to 7-flowered; bracts ± opaque, dry, 3–7 mm long, outer with prominent central cusp and short lateral teeth, inner 2-veined, 2-toothed. *Flowers* salver-shaped, white or blue-purple with dark central eye; perianth tube 8–12 mm long; tepals subequal, obovate to elliptic, spreading, 12–17 × 6–9 mm. *Filaments* ± 2.5 mm long, parallel, ± white; anthers suberect, ± 4.5 mm long, yellow; pollen yellow. *Style* yellow, dividing opposite base of filaments, branches 3–4 mm long. *Flowering time*: late September and October.

Distribution and ecology: a narrow Western Cape endemic, once common between Simondium, south of Paarl, and the flats between Gordon's Bay and Strand, South Africa, now rare as a result of urban development; on sandy gravel flats and lower mountain slopes.

Diagnosis: a relatively short plant, seldom exceeding 300 mm, *Ixia versicolor* is distinguished primarily by the narrowly lanceolate leaves, the blades somewhat twisted and with thickened and raised, partly crenulate margins. The terminally crowded flowers are purple or white with a prominent dark centre, the colour variation present even in a single population. The dark stamens are free and the anthers are erect or curving inward distally. The anthers are important in distinguishing *I. versicolor* from *I. polystachya*, which sometimes has flowers almost identically coloured, but anthers usually widely diverging and almost horizontal. Both species have outer floral bracts with only a prominent central cusp and the style dividing at the mouth of the perianth tube, the branches thus extending between the bases of the filaments (the latter feature is variable in *I. polystachya*, the style occasionally reaching the bases or lower third of the anthers).

43. **Ixia vinacea** *G.J.Lewis* in Journal of South African Botany 28: 131 (1962); Goldblatt & Manning: 194 (2016a). Type: South Africa, [Western Cape], Tulbagh, 9 Sep 1960, *Lewis 5742* (NBG, holo.; K, iso.).

Plants 350–450 mm high. *Corm* ± globose, 17–20 mm diam.; tunics of hard, coarse, mostly vertical fibres extending upward in a collar around base. *Stem* usually simple or 1-branched, branch held close to main stem. *Leaves* 3, lower 3 basal, exceeding spike, linear, leathery, firm-textured, 2–3 mm wide, uppermost leaf partly sheathing with short free blade. *Spike* closely 3- to 9-flowered; bracts ± dry, pale or flushed pink, 5–8 mm long, outer with several prominent veins, either 1-toothed or shortly 3-toothed, inner 2-veined, 2-toothed. *Flowers* rotate, ± erect, dark red with dark blue to purple centre; perianth tube filiform, 4–7 mm long; tepals subequal, ± elliptic, spreading, connate in lower ± 1 mm, 17–20 × 7–10 mm. *Filaments* erect, ± 3.5 mm long, parallel, purple-blue; anthers suberect, ± 7 mm long; pollen dark purple. *Style* dividing opposite base of filaments, purple, branches falcate, ± 4 mm long. *Flowering time*: late August and September.

Distribution and ecology: a narrow endemic of the Tulbagh Valley in Western Cape, South Africa, recorded only in the immediate vicinity of Tulbagh; on stony clay flats and slopes in renosterveld.

Diagnosis: particularly distinctive in sect. *Ixia*, *I. vinacea* has linear, firm, somewhat fibrous leaves up to 3 mm wide, the lowermost one or two of which are unusual in exceeding the spike. The corm tunics consist of coarse fibres that extend upward, forming a prominent collar around the stem base. Not only are the leaves and corm tunics unusual but the few, terminally crowded flowers are deep red with a dark purple to navy blue centre. The style divides opposite the base to middle of the filaments. On the basis of the coarse corm tunics, fibrous basal collar and dark centre of the flower *I. vinacea* has been considered closely related to *I. mostertii*, but that species differs significantly in having relatively broad leaves, differently coloured flowers and a longer style dividing opposite the lower third to middle of the anthers.

Ser. **Maculatae** *Goldblatt & J.C.Manning* in South African Journal of Botany 104: 195 (2016a). Type: *Ixia maculata* L.

Flowers yellow to orange (pink to purple or white in *I. monadelpha*), always with dark markings in centre; floral bracts often rust-coloured or dark distally. *Stamens* united near base or entirely. *Style* dividing opposite middle of anthers, branches ascending.

44. **Ixia maculata** *L.*, Species plantarum, edn. 2, 2: 1664 (1763); Lewis: 137 (1962, including *I. calendulacea* and *I. fuscocitrina*); Goldblatt & Manning: 195 (2016a). Type: South Africa, without precise locality or collector (LINN 58.21, holo., image seen).

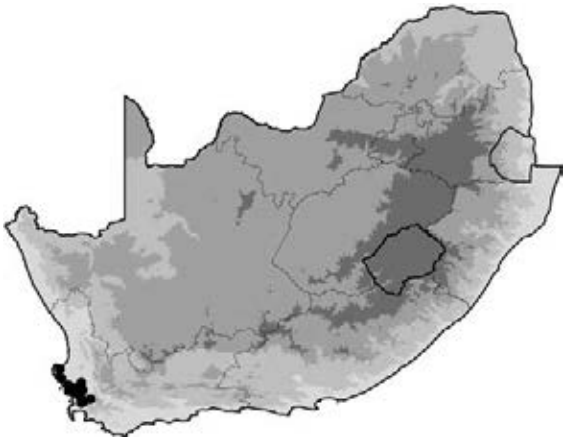
Ixia milleri P.J.Bergius: 8 (1767). Type: South Africa, without precise locality or collector, illustration in Miller: t. 156, f. 1 (as f. 2) (1760).

?*Ixia amoena* Salisb.: 35 (1796). Type: unknown, identified by use of name by contemporaries.

Ixia conica Salisb.: 36 (1796). Type: unknown, identified from description.

Ixia capitata Andrews: t. 50 (1799). Type: South Africa, without precise locality or collector, illustration in Andrews: t. 50 (1799).

Ixia flava Hornem.: 5 (1819), illegitimate homonym, not *I. flava* Lam. (1791). Type: unknown.



?*Ixia pallideflavens* Eckl.: 25 (1827). Type: unknown [identity uncertain].

?*Ixia vitellina* Eckl.: 25 (1827). Type: unknown [identity uncertain].

Ixia duckittiae L.Bolus: 281 (1931a). Type: South Africa, [Western Cape], Darling, *Duckitt s.n.* as Natl. Bot. Gard. *3202/15* (BOL, holo.).

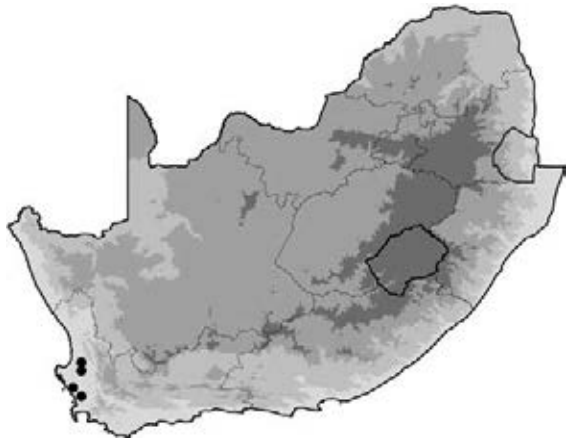
Plants 300–500 mm high. *Corm* ± globose, 10–15 mm diam., bearing short, branched stolons to 20 mm long, each branch with a small cormlet up to 3 mm diam.; tunics of membranous, ± papery layers. *Stem* usually unbranched. *Leaves* mostly 4, ± linear to narrowly lanceolate, ± ⅔ as long as stem, 2–7 mm wide, uppermost sheathing lower ½ of stem, free distally. *Spike* congested, 4- to 8-flowered; bracts dry, papery, rust-brown entirely or only distally then pallid below, 8–15 mm long, outer obscurely 3-toothed or lacerate, without prominent veins, inner 2-veined and shortly forked at apex, as long or slightly shorter than outer. *Flowers* salver-shaped, deep orange (rarely yellow) with dark brown to black, star-shaped (or circular) centre 6–12 mm diam., unscented; perianth tube cylindric, 5–8 mm long; tepals elliptic, subequal, 15–22 × 8–12 mm. *Filaments* 2.5–5.5 mm long, united in lower ⅓ (rarely only at base), yellow; anthers ascending, 8–11 mm long, yellow; pollen yellow. *Style* yellow, dividing opposite base of anthers, branches 3.5–4.0 mm long. *Flowering time*: mid-September to early October.

Distribution and ecology: restricted to the Atlantic Coast of Western Cape, South Africa, extending from near Hopefield and Langebaan south to Melkbosstrand, a short distance north of Cape Town; in granite outcrops or granite-derived gravel.

Distribution of ***Ixia maculata***.

Diagnosis: *Ixia maculata* is recognised by orange or sometimes yellow flowers with a small dark brown, star-shaped or round centre. The central dark part of the flower is slightly cupped with only the distal ⅔ of the tepals outspread. The yellow filaments are united in the lower half or completely, with the style dividing above the bases of the anthers. Particularly unusual are the short, branched stolons produced from the corm base, each branch bearing a small cormlet. Similar branched stolons are also found in *I. stolonifera* of sect. *Ixia* and in *I. purpureorosea* (sect. *Hyalis*). The stem is usually unbranched and the linear to narrowly lanceolate leaves are mostly 2–7 mm wide. *Ixia maculata* is one of few species of sect. *Ixia* with large dry floral bracts rust-brown in the upper half or entirely. *Ixia maculata* was initially broadly circumscribed, thus including several species with flowers of various colours but with a dark centre.

Lewis (1962) recognised two varieties of *Ixia maculata*, one of them, var. *intermedia*, now *I. calendulacea*, differs in its larger flower, tepals not concave below, brown filaments (drying purple), broader leaves, typically 12–20 mm wide, and long, slender stolons bearing solitary terminal cormlets. Lewis's second variety, var. *fuscocitrina*, now *I. fuscocitrina*, has yellow flowers with a large, solid dark brown to almost black centre, the dark portion concave, and relatively broad, soft-textured leaves. It shares with *I. calendulacea* the production of long, flattened stolons bearing large solitary cormlets at the tips.



Reports in older literature of *I. maculata* on the Cape Peninsula, e.g. Lewis (1950), are for *I. dubia*, with which *I. maculata* has often been confused. The species has been documented as pollinated by several species of hopliine beetles.

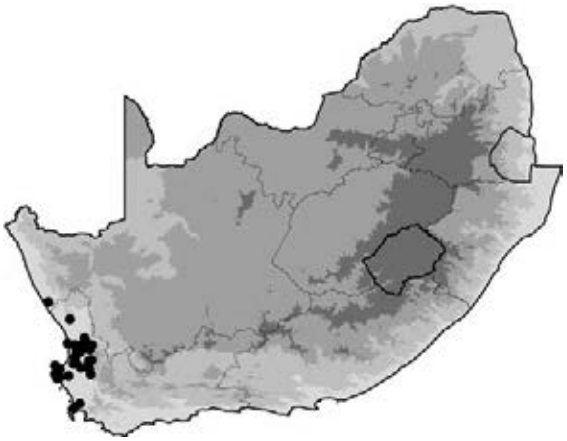
45. **Ixia fuscocitrina** *Desf. ex DC.* in Redouté: t. 86 (1804); Goldblatt & Manning: 195 (2016a). *I. maculata* var. *fuscocitrina* (DC.) G.J.Lewis: 144 (1962). Type: South Africa, without precise locality or collector, illustration in Redouté: t. 86 (1804).

Plants 300–500 mm high. *Corm* globose, 12–16 mm diam. bearing long horizontal stolons ± 1.5 mm diam., up to 100 mm long, each bearing a large terminal cormlet ± 6 mm diam.; tunics fibrous, mostly oriented vertically, sometimes accumulating. *Stem* usually unbranched, robust plants sometimes with a node in upper ⅓ bearing a dry, attenuate scale, sheathing only at base, often recurved. *Leaves* mostly 4, lanceolate, somewhat fleshy and soft-textured, ± ½ as long as stem, 8–15 mm wide, uppermost sheathing lower ½ of stem, free distally, fleshy and soft-textured. *Spike* congested, 3- to 7-flowered; bracts brown above, green or becoming white to pale grey below, outer 9–12 mm long, with short acute central tooth and rounded lateral lobes, only central vein developed, inner 2-veined, shortly forked at apex, as long or slightly shorter than outer. *Flowers* salver-shaped, pale yellow with dark brown to black, shallowly concave centre, unscented; perianth tube 10–13 mm long; tepals ovate, subequal or inner slightly smaller, 21–30 × 8–15 mm. *Filaments* 3.5–5.0 mm long, united in lower ⅓ (rarely only at base), ± brown below, pale blue or yellow in upper ½; anthers ascending, 8–11 mm long, yellow; pollen yellow. *Style* dividing opposite base of anthers, branches 2.5–4.5 mm long. *Flowering time*: September to mid-October.

Distribution and ecology: restricted to the Western Cape coastal forelands from Darling to the Piketberg, South Africa; in alluvial sand in seasonally wet sites.

Diagnosis: *Ixia fuscocitrina* is recognised by the pale yellow perianth with a large, solid dark brown to black centre, the dark portion concave, partly united filaments and relatively broad, soft-textured leaves 8–15 mm wide. It shares with orange-flowered *I. calendulacea* corms that produce long, ribbon-like stolons, each bearing a single large cormlet. Closely related *I. maculata* and *I. calendulacea* also have filaments partly united and similar dry floral bracts rust-brown in the upper half. The differences between these three species are subtle and poorly preserved specimens lacking corms and their stolons can be difficult to distinguish. When seen alive they are unmistakeable as their flowers differ in colour and shape, as well as in leaf shape and texture. The stolons in *I. maculata* are short, branched and bear several small cormlets.

Distribution of ***Ixia fuscocitrina***.



46. **Ixia calendulacea** *Goldblatt & J.C.Manning* in Bothalia 40: 61 (2010); Goldblatt & Manning: 196 (2016a). Type: South Africa, Western Cape, granite-topped hill east of Langebaan, in deep sand, 19 Sept. 2008, *Goldblatt & Porter 13152* (NBG, holo.; K, MO, PRE, iso.).

Ixia maculata var. intermedia G.J.Lewis: 142 (1962). Type: South Africa, [Western Cape], Redelinghuys, Sept., *Barker 2591* (NBG, holo.).

Plants 200–500 mm high. *Corm* depressed-globose, 12–16 mm diam., bearing horizontal stolons up to 120 mm long, ± 1.5 mm diam., each bearing a terminal cormlet 8–9 mm diam.; outer tunics fibrous with fibres mostly oriented vertically, sometimes accumulating. *Stem* usually unbranched, robust plants often with a node in upper ⅓ bearing a short branch or dry, attenuate scale sheathing only at base and often curved back against stem. *Leaves* (3)4 to 6, lanceolate, lowermost largest, ⅔–¾ as long as stem, mostly (8–)12–20 mm wide, often twisted in one or two rotations, upper leaves decreasing in size above, uppermost ± entirely sheathing. *Spike* flexuose, mostly 5- to 8-flowered; bracts (6–)8–12 mm long, dry, white-translucent below, brown in upper half or third, outer ± truncate or bilobed with a short central tooth, becoming ± lacerate, inner 2-veined, forked into attenuate cusps ± 2 mm long. *Flowers* shallowly cupped when fully open, orange with brown or dull red central marking usually with translucent reddish halo; perianth tube cylindric, 5–8(–10) mm long; tepals subequal, ascending, overlapping slightly when fully open, (18–)22–30 × 11–15 mm, outer ± 2 mm wider than inner. *Filaments* 3–4 mm long, united in lower ½ or entirely (rarely ± free), dark red-brown (often drying violet but ultimately losing colour); anthers ascending, 9–11 mm long, yellow. *Style* dividing between base and lower ⅓ anthers, branches (3–)4 mm long. *Flowering time*: mid-September to mid-October.

Distribution and ecology: the most widespread species of sect. *Ixia*, extending along the southern African Atlantic Coast and near interior in Northern and Western Cape from near Groen River mouth to the Cape Peninsula, South Africa; mostly on deep sands or limestone flats and slopes in sandveld and strandveld, but also in dry fynbos as in the Olifants River Valley.

Diagnosis: *Ixia calendulacea* is recognised by the large orange flowers with tepals slightly cupped even when fully expanded and a solid, red to brown centre, partly to entirely united filaments, also dark in colour, and dry floral bracts rust-brown in the upper half. The relatively broad leaves are usually twisted distally and the corms have softly fibrous tunics and bear long white stolons from the base, each terminating in a single, relatively large cormlet. The species was first recognised as *I. maculata* var. *intermedia* but was later was found to be

Distribution of ***Ixia calendulacea***.

a separate species with different floral and vegetative morphology and habitat preferences. *Ixia maculata* has flowers with narrower tepals and a small dark central eye, the corms produce short, branched stolons bearing small cormlets and the filaments and anthers are yellow. *Ixia calendulacea* bears a striking resemblance to *I. curta*, which has a slightly longer perianth tube, bracts usually paler but with dark brown tips and conical corms without stolons. Hopliine beetles have been recorded as pollinators.

47. **Ixia curta** *Andrews*, The Botanist's Repository 9: t. 564 (1809); Lewis: 145 (1962). *Morphixia curta* (Andrews) Klatt: 384 (1882). *I. monadelpha* var. *curta* (Andrews) Ker Gawl.: t. 1378 (1811b), invalid combination (sometimes listed as valid). Type: South Africa, without precise locality or collector, illustration in Andrews: t. 564 (1809).

Plants 150–400 mm high. *Corm* ± globose, 10–15 mm diam.; tunics of fine, netted fibres. *Stem* simple or with 1 short, spreading branch. *Leaves* 4 to 6, lanceolate, straight or somewhat twisted, ⅔ to ± as long as stem, mostly 3–6 mm wide, decreasing in size above, uppermost largely sheathing. *Spike* closely 3- to 8-flowered; bracts 7–10 mm long, dry, pallid speckled with brown distally, outer 3-toothed with longer central tooth, inner 2-veined, 2-toothed. *Flowers* salver-shaped, orange with brown or greenish or red central marking, unscented; perianth tube cylindric, 10–15 mm long; tepals ± elliptic, subequal, spreading, 20–25 × 10–15 mm. *Filaments* 3–4 mm long, usually united entirely, brown; anthers ± erect, 9–10 mm long, yellow; pollen yellow. *Style* dividing between base and middle of anthers, branches 2–3 mm long. *Flowering time*: late September to October.

Distribution and ecology: local in the extreme southwest of Western Cape, South Africa, extending from near Hopefield to Malmesbury and Darling; in sandy habitats, often waterlogged in winter and spring (much of its range is now lost to agriculture or overrun by alien vegetation).

Diagnosis: *Ixia curta* is distinguished by the orange flowers with a brown centre often edged in green, united filaments, erect, contiguous anthers and an elongate, filiform perianth tube, 10–15 mm long, substantially exceeding the bracts, 7–12 mm long. Unlike the superficially similar *I. maculata*, which has orange or yellow flowers but a perianth tube mostly 5–8 mm long, about as long as the bracts, the corms of *I. curta* do not produce stolons and the bracts are pellucid, sometimes speckled with brown distally, rather than partly to entirely rust-brown.

48. **Ixia monadelpha** *D.Delaroche*, Descriptiones plantarum aliquot novarum: 22 (1766) [*I. monadelphia* Burm.f.: 1 (1768), orthographic variant]; Lewis: 146 (1962). *Morphixia monadelpha* (D.Delaroche) Klatt: 384 (1882). Type: South Africa, without precise locality or collector (syntypes, G: Herb. Burman; L: Herb. A. van Royen).

Ixia cartilaginea Lam.: 340 (1789). Type: South Africa, without precise locality or collector (holotype, P: Herb. Lamarck).

Ixia columnaris Salisb.: 36 (1796). Type: unknown.

Ixia columnaris var. *grandiflora* Andrews: t. 250 (1802b). *I. grandiflora* (Andrews) Pers.: 48 (1805), illegitimate homonym, not *I. grandiflora* D.Delaroche (1766). *Morphixia grandiflora* (Andrews) Klatt: 383 (1882). Type: South Africa, without precise locality or collector, illustration in Andrews: t. 250 (1802b).

Ixia columnaris var. *latifolia* Andrews: t. 213 (1802c). *Morphixia latifolia* (Andrews) Klatt: 385 (1882). Type: South Africa, without precise locality or collector, illustration in Andrews: t. 213 (1802c).

Morphixia purpurea Klatt: 383 (1882). *Ixia purpurea* (Klatt) Klatt: 186 (1894), illegitimate homonym, not *I. purpurea* Lam. (1789). Type: South Africa, without precise locality or collector, illustration in Andrews: t. 203 (1802a).

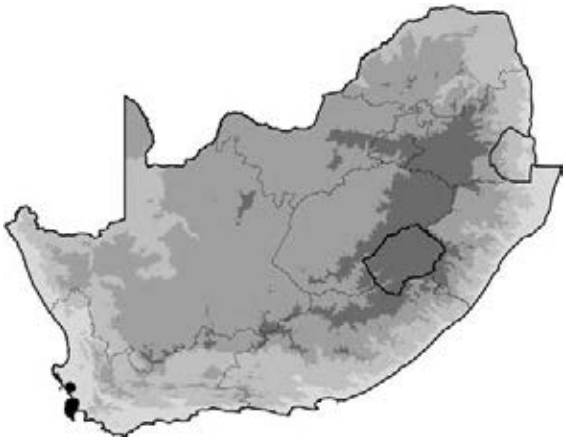
Ixia columnaris var. *versicolor* Andrews: t. 211 (1802d). *Morphixia versicolor* (Andrews) Klatt: 385 (1882). Type: South Africa, without precise locality or collector, illustration in Andrews: t. 211 (1802).

Galaxia ixiiflora DC. in Redouté: t. 41 (1803). *Ixia galaxioides* Klatt: 184 (1894), illegitimate superfluous name for *G. ixiiflora* DC. Type: South Africa, without precise locality or collector, illustration in Redouté: t. 41 (1803).

Ixia columellaris Ker Gawl.: t. 630 (1803d). *Morphixia columellaris* (Ker Gawl.) Klatt: 384 (1882). Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 630 (1803d).

Ixia columnaris var. *angustifolia* Andrews: t. 392 (1804). *Morphixia angustifolia* (Andrews) Klatt:

384 (1882). *I. angustifolia* (Andrews) Klatt: 182 (1894). *I. columellaris* var. *rhodolarynx* Baker: 91 (1877), superfluous name for *I. columnaris var. angustifolia* Andrews (1804). Type: South Africa, without precise locality or collector, illustration in Andrews: t. 392 (1804).



[*Ixia variegata* Banks ex Ker Gawl.: t. 630 (1803d), invalid name only in synonymy.]

[*Galaxia ramosa* DC. in Redouté: t. 41 (1803), invalid name only in synonymy.]

Plants 200–400 mm high. *Corm* ± globose, 12–20 mm diam.; tunics of soft, ± papery layers. *Stem* simple or with 1 or 2 short, spreading branches. *Leaves* 4 to 7, lanceolate, ± ½ as long as stem, mostly 3–12 mm wide, often loosely twisted, decreasing in size above, margins slightly thickened, hyaline when dry. *Spike* closely 4- to 12-flowered, flexuose; bracts 5–10 mm long, dry, pale below, spotted brown distally, in upper ½, outer ± truncate or with conspicuous dark brown, twisted central tooth and 2 smaller lateral lobes, inner with 2 dark brown, twisted cusps. *Flowers* salver-shaped, grey-blue, purple, violet, or pink (white or grey-yellow), with large, dark green, reddish, brown or purple central mark, unscented; perianth tube cylindric, 10–18 mm long; tepals ± elliptic, subequal, spreading, connate for up to 1.5 mm, 13–20 × 6–11 mm. *Filaments* 3–6 mm long, united in lower ½ or entirely, purple anthers erect, 7–8 mm long; pollen pale grey-blue. *Style* dividing between base and middle of anthers, branches 2–3 mm long. *Flowering time*: mainly September and October, occasionally later.

Distribution and ecology: restricted to a narrow stretch of the Western Cape Atlantic Coast between Darling and Hout Bay on the Cape Peninsula, South Africa, a distance of some 85 km; on seasonally wet, sandy gravel flats and lower mountain slopes, now eliminated from much of its range by urban development and farming activity.

Diagnosis: a striking species, *Ixia monadelpha* has grey-blue to light purple or even pink flowers (rarely white to grey-yellow), dark purple, iridescent green to almost black in the centre edged with a light brown to green halo. The stamens are also darkly coloured and even the pollen is blue to grey. The species was named for the united filaments, sometimes for only half their length, unusual in the genus, and even the anthers are erect and contiguous. The pale floral bracts are minutely speckled brown or red distally but are distinctive in the somewhat thickened, twisted, almost black cusps, the outer with the central cusp more prominent than the laterals. Added to these unusual features are a perianth tube 10–18 mm long and a stem usually bearing two or more branches held at right angles to the main axis and curving upward distally.

Distribution of ***Ixia monadelpha***.

Ixia monadelpha has often been associated with orange-flowered *I. curta*, which also has united filaments, contiguous anthers and an unusually long perianth tube, and the two have at times been treated as a single species. The two may well be closely related but can be separated not only by flower colour, but *I. curta* has corm tunics of fine, soft fibres, a markedly thicker perianth tube and the stem is rarely branched. The united filaments and contiguous anthers led to the recognition of subg. *Eurydice* for *I. monadelpha* by Persoon (1805). As in most species of sect. *Ixia*, *I. monadelpha* is pollinated by hopliine beetles. The species hybridises with *I. paniculata* where they co-occur on Rondebosch Common on the Cape Peninsula.

Sect. 3. **Morphixia** *(Ker Gawl.) Pax*, Die natürlichen Pflanzenfamilien 2, 5: 154 (1888); Goldblatt & Manning: 109 (2011). *Ixia* subg. *Morphixia* (Ker Gawl.) Goldblatt & J.C.Manning: 63 (1999). Type: *M. aulica* (Aiton) Ker Gawl., designated by Goldblatt & Manning: 109 (2011) = *Ixia latifolia* D.Delaroche

Leaves usually 3, sometimes up to 5, but always dimorphic, lower foliage leaves with well-developed blades and uppermost 1 (rarely 2 when basal foliage leaves more than 2) entirely sheathing. *Spike* with bracts usually membranous and translucent, rarely flushed with purple and opaque, outer with 3(5) prominent veins and 3-lobed to 3-toothed (or 5-toothed when 5-veined). *Flowers* usually actinomorphic, rarely bilateral, mostly pale blue-mauve, sometimes pink or white, occasionally deep purple, white to yellow in throat, erect, ascending or nodding, often scented; perianth tube funnel-shaped to cylindric; tepals subequal, spreading. *Filaments* contiguous around central style, rarely unilateral and then horizontal or declinate, inserted at base of upper part of tube, decurrent, not expanded below, included to well exserted; anthers dehiscing longitudinally, exserted, partly included or rarely fully included. *Ovary* and capsules usually smooth, rarely warty (*Ixia alata*

and *I. thomasiae*); style slender, central and straight, or when stamens unilateral then displaced to lie beneath filaments.

Species 35: winter-ranfall parts of Northern and Western Cape, South Africa.

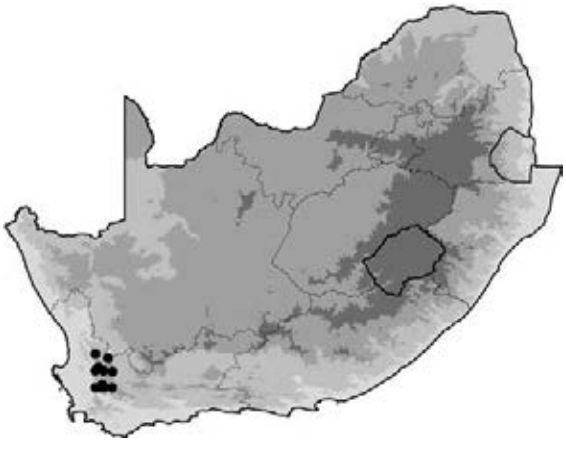
Ser. **Morphixia** *Goldblatt & J.C.Manning*, new series. Type: *Ixia latifolia* D.Delaroche

Leaf blades plane, sometimes with thickened margins. Flowers mostly pale to deep pink or white; perianth tube moderately long, funnel-shaped. *Filaments* shortly to well exserted.

49. **Ixia divaricata** *Goldblatt & J.C.Manning* in Bothalia 38: 18 (2008a) as new name for *I. latifolia* var. *angustifolia* G.J.Lewis: 86 (1962); Goldblatt & Manning: 110 (2011). Type: South Africa, [Western Cape], Witzenberg, middle east face opposite Farm Rosendal, 26 Nov. 1941, *Pillans 9790* (BOL, holo.).

Ixia rapunculoides var. *rigida* G.J.Lewis: 77 (1962). Type: South Africa, [Western Cape], Hex River Valley, 1 Oct. 1893, *P. MacOwan in Herbario Normale Austro-Africana 1653* (BOL [as Hex River Pass, *Bolus s.n.* in *Guthrie 3077*], G, K [as near Hex River East, 1 500 ft (± 460 m)], MO [as Hex River Valley, De Doorns, Oct. 1893, *H. Bolus s.n.*], SAM, Z, syn.).

Ixia rapunculoides var. *subpendula* G.J.Lewis: 77 (1962). Type: South Africa, [Western Cape], between Groot River and Elandskloof, Oct. 1939, *Leipoldt 3026* (BOL, holo.).



?*Ixia capitata* var. *stellata* Andrews: t. 232 (1802f). *I. stellata* (Andrews) Klatt: 396 (1882). *I. ovata* var. *stellata* (Andrews) Baker: 164 (1892). Type: South Africa, without precise locality or collector, illustration in Andrews: t. 232 (1802f).

Plants 300–500 mm high. *Corm* subglobose, tunics of medium-textured, netted fibres, bearing 1–few sessile cormlets at base. *Leaves* 3 to 5, lower 2 to 4 narrowly sword-shaped to linear, (1.5–)3.0–5.0 mm wide, margins moderately thickened, hyaline when dry, straight, usually ± ⅓–½ as long as stem, uppermost 1 or 2 leaves sheathing stem. *Stem* with (1–)3 straight lateral branches mostly held at 30–45(–50)° to main axis, filiform, bearing flowers in upper half. *Main spike* 4- to 7-flowered, lateral spikes (1–)3- to 5-flowered; bracts translucent, outer with 3 dark veins, mostly 6–7 mm long, inner with 2 dark veins and forked apically. *Flowers* upright, whitish or pale to deep pink or light purple with pale yellow cup, unscented or with faint sweet scent; perianth tube funnel-shaped, 8–11 mm long; tepals subequal, 11–14 × 5.5–7.0 mm, proximal 3–4 mm forming part of floral cup, subpatent. *Filaments* erect, 4–5 mm long, distal 1–2 mm exserted from tube, rarely reaching only to top of tube, inserted ± 5 mm above tube base; anthers 4.0–5.5 mm long, fully exserted from tube, tips exserted from floral cup. *Style* dividing opposite middle of anthers, branches 1–2 mm long, extending between anthers. *Flowering time*: from late August at low elevations to October, November and December at higher elevations.

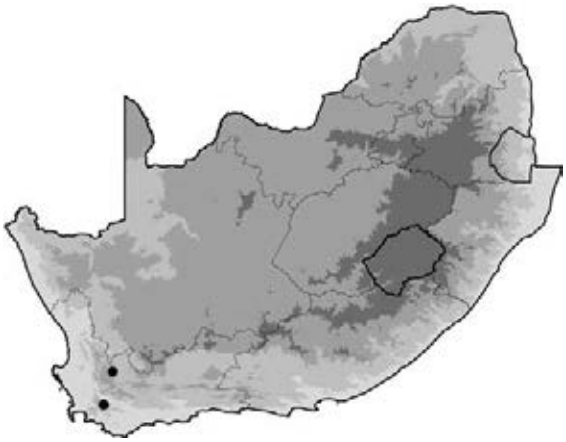
Distribution and ecology: scattered through the mountains of Western Cape, South Africa, extending from Elandskloof, east of Citrusdal, through the Cold Bokkeveld to Tulbagh and the Hex River Valley; in seasonally wet, stony sandstone flats and rocky sites.

Diagnosis: *Ixia divaricata* is unmistakable in its unusual branching pattern; the stiff, straight lateral branches are held at angles of 30–50° to the main axis and bear mostly 3 to 5 flowers crowded in the distal half. The white or pale pink (rarely deep pink or purple) flowers are held erect, with the tepals spreading but not fully patent. It was treated as var. *subpendula* of *I. rapunculoides* despite its distinctive branching pattern and upright flowers, not inclined or nodding. The anthers, 4.0–5.5 mm long, are usually fully exserted from the tube or rarely with the bases included. Specimens with anthers exserted 1–2 mm were sometimes included in *I. latifolia*, but typical *I. latifolia* has larger, deep pink flowers with a perianth tube 14–17 mm long, filaments ± 10 mm long, and broad basal leaves, mostly 10–18 mm wide. Plants from upper Moraine Kloof in the Hex River Mtns, flowering in January, are provisionally included here. They have a similar branching pattern but somewhat smaller, purple flowers with a tube ± 5 mm long, tepals ± 10 mm long, and anthers ± 3.2 mm long. The style divides at the top of the anthers and has branches ± 1.3 mm long that extend above the anther tips, whereas in typical *I. divaricata* the style divides opposite the middle of the anthers. The specimens lack corms and leaves without which a decision about the status of this late-flowering population cannot be made.

The immediate relationships of *Ixia divaricata* are most likely with *I. latifolia*, with which it was associated historically. Confusion with that species is due in part to some collections with a longer tube, 12–14 mm and also with relatively short, broad leaves, up to 18 mm wide

Distribution of ***Ixia divaricata***.

(also found in *I. latifolia*) but fairly slender branches (characteristic of *I. divaricata*). These are almost certainly hybrids between the two species, which sometimes grow within sight of one another, although on different soils, *I. latifolia* favouring heavy clay or loam.



Flowers are pollinated by a range of medium-sized and large bees including *Lasioglossum* sp. (Halictidae) and *Anthophora diversipes* and *Amegilla spilostoma* (Apidae) (Goldblatt & Manning 2008a).

50. **Ixia saundersiana** *Goldblatt & J.C.Manning* in Bothalia 41: 111 (2011) Type: South Africa, Western Cape, Worcester, Milner Peak, rock cracks in humus with restios, 7 Dec. 2008, *Saunders & Saunders sub Manning 3237* (NBG, holo.).

Plants 150–200 mm high. *Corm* ovoid-conic, ± 8 mm diam.; tunics of fine netted fibres. *Stem* usually simple, rarely with up to three short, ascending branches. *Leaves* 2, lower basal, linear, 1.0–2.5 mm wide, sometimes shortly exceeding stem, central vein strongly and margins slightly thickened, pale when dry, upper sheathing the lower ½–⅔ of stem, with a short free blade. *Spike* 2- or 3(–5)-flowered; bracts membranous, translucent, outer with 3 main veins and 2 smaller lateral veins, shortly 3-toothed, inner 2-veined and 2-toothed. *Flowers* blue-mauve, yellow in throat; perianth tube funnel-shaped, ± 5 mm long; tepals ovate, ± 11 × 5.5 mm. *Filaments* erect, ± 3 mm long, reaching mouth of tube; anthers ± 4 mm long, yellow; pollen yellow. *Style* dividing opposite base to lower ⅓ of anthers, branches ± 1.5 mm long. *Flowering time*: late October to December.

Distribution and ecology: known from a few collections from the Hex River Mtns and Swartruggens some distance to the northeast in Western Cape, South Africa; in rock cracks in damp humus among restios.

Diagnosis: the high altitude *Ixia saundersiana* is immediately recognised by the single linear foliage leaf and a second, largely sheathing leaf, together with a mostly unbranched stem and spike of 2 or 3(–5) small, blue-mauve flowers yellow in the throat. Well-grown plants may have up to three, short, straight, ascending branches with up to four flowers per branch. The flowers are unremarkable and have a funnel-shaped perianth tube ± 5 mm long, spreading tepals, and relatively short filaments only 3 mm long, that reach only to the mouth of the perianth tube. We suspect that the species is most closely allied to *I. divaricata* but that species has a longer perianth tube, 8–11 mm long, filaments 4.0–5.5 mm long, usually exserted 1–2 mm from the tube and the stem is typically branched, with the long, straight branches diverging strongly from the main axis.

Distribution of ***Ixia saundersiana***.

51. **Ixia latifolia** *D.Delaroche*, Descriptiones plantarum aliquot novarum: 22 (1766); Goldblatt & Manning: 112 (2011). *Geissorhiza latifolia* (D.Delaroche) Baker: 94 (1877). *Tritonia latifolia* (D.Delaroche) N.E.Brown: 135 (1929). Type: South Africa, without precise locality or collector (G-DEL, holo.).

Ixia aulica [Soland in] Aiton: 57 (1789). *I. capillaris* var. *aulica* (Aiton) Ker Gawl.: t. 1013 (1807). *Morphixia aulica* (Aiton) Ker Gawl.: 107 (1827). Type: South Africa, 'Cape of Good Hope', cultivated in Britain, without precise locality, illustration in Ker Gawl.: t. 1013 (1807).

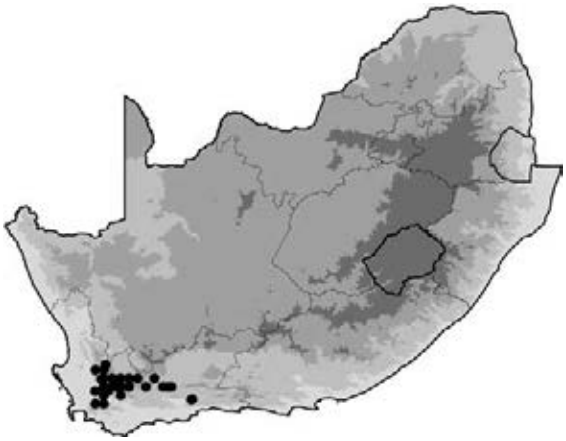
Ixia incarnata Jacq.: 7 (1795 [1788–1795]). *I. capillaris* var. *incarnata* (Jacq.) Ker Gawl.: t. 617 (1803a). *Morphixia incarnata* (Jacq.) Ker Gawl.: 107 (1827). *Morphixia capillaris* var. *incarnata* (Jacq.) Baker: 97 (1877). Types: South Africa, without precise locality or collector, illustration in Jacq.: t. 282 (1795 [1788–1795]); South Africa, [Western Cape], Ceres, Theronsberg Pass, 20 Oct. 1983, *Snijman 779* (NBG, epi.; PRE, iso.).

Ixia scariosa Thunb.: 243 (1811). Type: South Africa, [Western Cape], probably in the Cold Bokkeveld, Sept. 1773, but not stated, *Thunberg s.n.* [UPS-THUNB 990, lecto., designated by Goldblatt & Manning: 112 (2011)].

Ixia phlogiflora Delile in Redouté: t. 432 (1814). Type: South Africa, [Western Cape], without precise locality or collector, illustration in Redouté: t. 432 (1814).

Ixia latifolia var. *curviramosa* G.J.Lewis: 86 (1962). Type: South Africa, [Western Cape], Laingsburg Division, Tweedside, on flats, 27 Sept. 1951, *Barker 7469* (NBG, holo.; NBG, PRE, iso.).

[*Hyalis latifolia* (D.Delaroche) Salisb.: 317 (1812), genus invalid.]



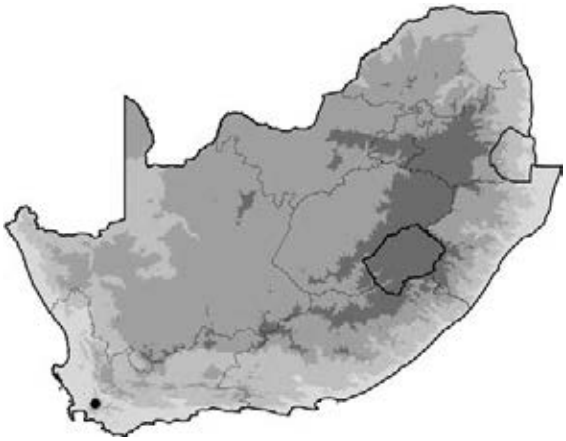
[*Hyalis aulica* (Aiton) Salisb.: 318 (1812), genus invalid.]

Plants mostly 150–350 mm high. *Corm* subglobose, mostly 15–25 mm diam.; tunics of firm, often coarsely wiry, netted fibres, bearing small cormlets at base. *Stem* usually 1- to 3-branched, rarely simple; branches either ascending, fairly long and straight or shorter and

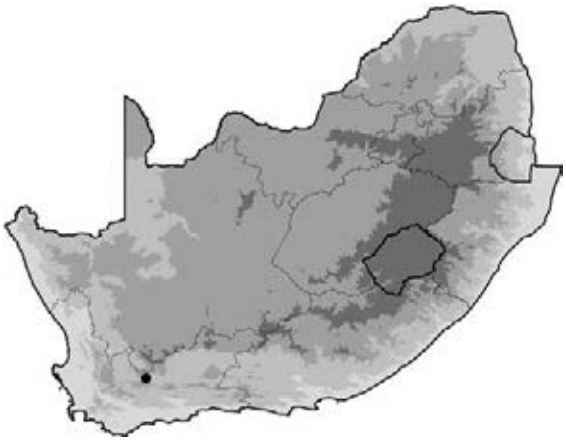
± twisted, subtended by obscure, obtuse bracts and prophylls ± 1 mm long. *Leaves* usually 3, lower 2 lanceolate to sword-shaped, oblong or falcate, (5–)10–18 mm wide, ± ⅓ as long as stem, margins moderately to strongly thickened, sometimes slightly crisped, uppermost leaf sheathing lower ½–⅔ of stem. *Main spike* mostly 3- to 7-flowered, lateral spikes (1–)3- to 6-flowered, either ± straight or twisted; bracts translucent sometimes tinged brown, especially in fruit, outer with 3 dark veins, mostly 7–11 mm long, acutely 3-toothed, inner ± as long or slightly longer, with 2 dark veins, 2-toothed at apex. *Flowers* nodding, deep pink, pale mauve or blue-mauve, white or yellow in throat, sometimes edged darker pink or purple, unscented or with a faint rose or sour odour; perianth tube (7–)10–18(–23) mm long, narrowly funnel-shaped, flaring in upper ⅓, slightly curved near base; tepals subequal, ovate, 13–20(–23) × (6–)7–10 mm, spreading. *Filaments* 8–12 mm long, exserted 6–8 mm; anthers 3–5 mm long before splitting. *Style* dividing between base and middle of anthers, branches 1.8–3.0 mm long, extending between anthers. *Flowering time*: mainly mid-September to mid-October.

Distribution and ecology: extending in Western Cape, South Africa, from the Cold Bokkeveld and Worcester eastward to Karoo Poort at the edge of the Tanqua Karoo and southeast through the Witteberg Karoo and northern foothills of the Klein Swartberg, with isolated populations in the Little Karoo as far east as the Gamkaberg; on clay, clay loam and sandy soils in renosterveld, or occasionally dry fynbos, fairly common at higher elevations in the interior southwestern part of Western Cape.

Diagnosis: *Ixia latifolia* is recognised by the relatively large, deep pink, purple, mauve-pink or blue-mauve flowers usually with a relatively well-developed perianth tube, (7–)10–18(–23) mm long that gradually widens toward the mouth, and spreading tepals 13–20(–23) long. The long stamens have filaments exserted 6–8 mm from the tube and anthers 3–5 mm long. The floral bracts are mostly 8–10 mm long and distinctive in having narrowly acute teeth. The two basal leaves are usually fairly broad, 10–18 mm, but occasionally only 5 mm wide. The third leaf sheaths the stem for its entire length. Plants with short, somewhat twisted, rather than straight, lateral branches and slightly smaller flowers, described by G.J. Lewis (1962) as var. *curviramosa*, are now included in *I. latifolia*. The degree of twisting and length of the branches is not consistently correlated with any other character, and is often difficult to determine because plants with shorter, ± straight branches, conform to neither taxon. Flower size is unusually variable. Both the northernmost populations of *I. latifolia* in the arid Tanqua Basin and the easternmost near Oudtshoorn are exceptional: the Tanqua populations, growing in perhaps the most arid habitat for the species, have the largest flowers with a tube 20–23 mm long and tepals up to 21 × 10.5 mm. In contrast, the Gamkaberg populations have flowers with a tube 7–8 mm long and tepals 13–15 × ± 7 mm, among the smallest in the species. But plants from several other localities have flowers almost as small. The plants from the Tanqua Karoo reverse the usual trend for smaller stature and flower size in the driest habitats and merit further study.



Distribution of ***Ixia latifolia***.



Ixia latifolia is probably most closely related to *I. divaricata*, a plant of wet, sandstone habitats in the Cold Bokkeveld and surrounding mountains, which has long, slender, straight lateral branches with flowers crowded in the upper half and a smaller perianth with a tube 8–11 mm long, tepals 11–14 mm long, and filaments 4–5 mm long reaching 1–2 mm beyond the mouth of the perianth tube or sometimes only to the mouth of the tube. *Ixia divaricata* typically has pale pink or white flowers and narrow leaves, thus very different from the larger, deep pink-mauve or purple flowers with well-exserted filaments, and broad, fairly short leaves of *I. latifolia*. Plants with broader leaves may be the result of crossing with *I. latifolia*, and plants of that species with particularly long branches may be the result of occasional crosses with *I. divaricata* at sites where the habitats of the two are close together.

52. **Ixia monticola** *Goldblatt & J.C.Manning* in Bothalia 41: 115 (2011). Type: South Africa, [Western Cape], Du Toit's Peak, rocky upper slopes and ledges, west aspect, ± 6 000 ft [1 820 m], 21 Dec. 1975, *Esterhuysen 34162* (BOL, holo.; MO, iso.).

Plants mostly 80–250 mm high, sheathed at base by pale brown cataphylls. *Corm* ± 6 mm diam.: tunics rust-brown, submembranous, not accumulating. *Stem* usually simple or 1(2)-branched, branches thread-like, suberect, often slightly twisted, 10–15 mm long, subtended by obscure, membranous bracts and prophylls ± 1 mm long. *Leaves* 2 or 3(4), lower 1 or 2(3) narrowly sword-shaped to linear, ½ as long to ± as long as stem, mostly 2.5–4.5 mm wide, uppermost leaf mostly sheathing but with a free unifacial tip. *Main spike* erect, slightly flexuose, 2- or 3-flowered, lateral spikes 1- or 2-flowered; bracts 5–6 mm long, membranous or becoming dry, flushed red-purple, outer bract shortly 3-cusped, inner forked apically. *Flowers* pink, yellow in throat, presence of scent unknown; perianth tube narrowly

Distribution of ***Ixia monticola***.

Distribution of ***Ixia parva***.

funnel-shaped, ± 10 mm long; tepals subequal, 12–17 × 6–7 mm. *Filaments* ± 6 mm long, exserted 2–3 mm from tube; anthers 3.5–4.0 mm long, yellow. *Style* dividing between base and middle of anthers, branches ± 1 mm long. *Flowering time*: December to mid-January.

Distribution and ecology: a local endemic of the mountains of Western Cape, South Africa, between Victoria Peak and Wemmershoek Peak; on sandstone rocks and cliffs, above 1 200 m elevation, evidently flowering well only after fire.

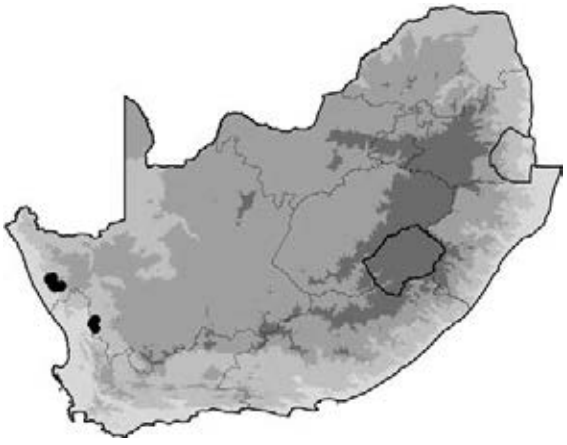
Diagnosis: *Ixia monticola* is recognised primarily by the small corm, ± 6 mm in diameter, with rust-brown, submembranous, non-accumulating, onion-skin-like tunics, often a fairly low stature and usually a simple, rarely 1(2)-branched stem. The moderate-sized pink flowers are unremarkable and have a funnel-shaped perianth tube ± 10 mm long, tepals 12–17 mm long, and short filaments exserted 2–3 mm from the mouth of the tube. The leaves are ± straight, 2.5–4.5 mm wide, and the cataphylls are typically rust-brown. *Ixia monticola* is most easily confused with the relatively small-flowered *I. divaricata*, the higher elevation populations of which often have few-branched or unbranched stems, and similar narrow, erect leaves. *Ixia divaricata* more often has white or very pale pink flowers, and while the floral proportions are similar to those of *I. monticola*, *I. divaricata* always has well-developed fibrous corm tunics.

53. **Ixia parva** *Goldblatt & J.C.Manning* in Bothalia 41: 116 (2011) as a new name for *I. latifolia* var. *parviflora* G.J.Lewis: 86 (1962) [not *I. parviflora* Salisb. (1796)]. Type: South Africa, [Western Cape], Laingsburg Division, Karoo Garden, Whitehill, 9 Sept. 1935, *Compton 5592* (NBG, holo.).

Plants mostly 70–120 mm high. *Corm* 12–16 mm diam.; tunics of medium-textured, netted fibres, bearing medium-sized cormlets at base. *Stem* usually 1- or 2-branched, branches short, twisted, subtended by membranous, attenuate bracts and prophylls 2–3 mm long. *Leaves* 3, lower 2 sword-shaped to falcate, 3–9 mm wide, margins and midrib slightly thickened, uppermost leaf sheathing lower ½–⅔ of stem. *Main spike* mostly 3- to 6-flowered, markedly flexuose, branches (1–)3- to 5-flowered; bracts 5–7 mm long, membranous or papery, opaque-purple or rust-coloured and veins hardly evident, with short acute teeth, inner ± as long or slightly longer than outer. *Flowers* nodding, bright purple-pink, yellow in throat with base of tepals edged with red, strongly scented of sweet pea; perianth tube funnel-shaped, 6–8 mm long; tepals subequal, oblong, 10–12 × ± 4 mm, spreading at right angles to tube. *Filaments* 6–7 mm long, ± 5 mm; anthers ± 4 mm long. *Style* dividing below or opposite bases of anthers, branches ± 3 mm long, spreading below anthers. *Flowering time*: mid-August to late September.

Distribution and ecology: local in the western Karoo between Laingsburg and Matjiesfontein in Western Cape, South Africa; in decomposed shale on south-trending slopes.

Diagnosis: *Ixia parva* is readily distinguished from related *I. latifolia* by its small, red-purple flowers and low stature, up to 120 mm tall. Plants also have distinctive dark purple bracts and unusually long style branches, ± 3 mm long, unexpected in a small flower with tepals 10–12 mm long. The style divides at or slightly below the apices of the filaments and the style branches extend outward beneath the anthers where they are conspicuous. The flowers are strongly scented of sweet pea, a feature unique among the species of the *I. latifolia* group where scent is lacking or weakly developed.



54. **Ixia ramulosa** *(G.J.Lewis) Goldblatt & J.C.Manning* in Bothalia 41: 117 (2011). *I. latifolia* var. *ramulosa* G.J.Lewis: 86 (1962). Type: South Africa, [Northern Cape], Grootvlei, Kamieskroon, Sept. 1945, *Lewis 1372* (SAM, holo.; SAM [2 sheets], iso.).

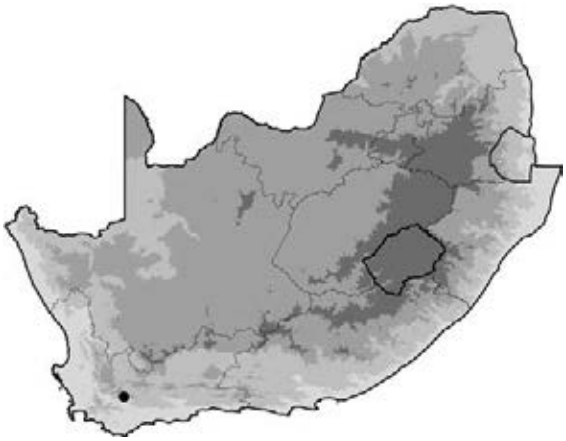
Plants mostly 150–400(–650) mm high. *Corm* with tunics of coarse, netted fibres. *Stem* with 3 to 6(–8) short,

slightly twisted branches subtended by minute, scale-like, ± truncate to obtuse bracts and prophylls 1(–2) mm long. *Leaves* 3, lower 2 sword-shaped to falcate, 4–10 mm wide, margins and main vein moderately to barely thickened, uppermost leaf sheathing lower ½–⅔ of stem. *Main spike* mostly 2- or 3-flowered, branchlets mostly 1- or 2(3)-flowered; bracts mostly 7–8 mm long, often rust-brown in distal half, with short acute teeth, inner bract ± as long or slightly longer than outer. *Flowers* deep purple, white in throat or mauve, sometimes pink, blue-mauve or white with yellow throat, presence of scent unknown; perianth tube widely funnel-shaped, 7–9(–10) mm long; tepals subequal, ovate, 10–15 × 5–7 mm, spreading at right angles to tube. *Filaments* 4–6(–8) mm long, exserted 2–4(–6) mm from tube; anthers 4–5 mm long, slightly shorter to slightly longer than filaments. *Style* dividing between lower and middle ⅓ of anthers, branches ± 1.0–1.8 mm long, apices emerging between anthers. *Flowering time*: mainly late August to early October, or early November at higher elevations.

Distribution and ecology: extending from the Kamiesberg in central Namaqualand to the Bokkeveld Escarpment in Northern Cape and adjacent Koebee Mtns in Western Cape, South Africa; in granitic sand or light clay loam.

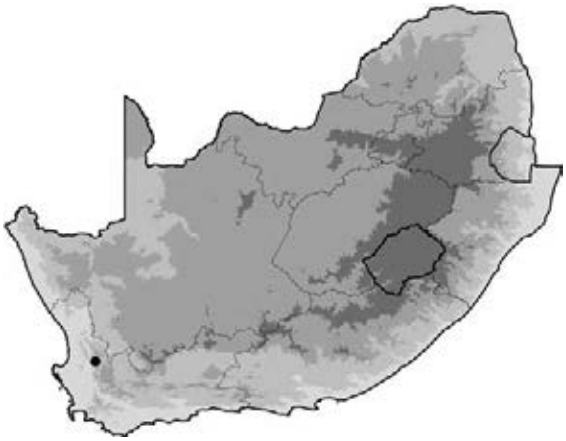
Diagnosis: *Ixia ramulosa* has the narrowly funnel-shaped perianth tube and moderately to well-exserted anthers of its allies but is distinguished by the perianth tube 7–9(–10) mm long and several, short, wiry, lateral branchlets each bearing 1 or 2 or occasionally 3 flowers. The species normally has just three leaves, the two lowermost with well-developed blades, and the upper one largely to entirely sheathing the stem. *Ixia ramulosa* is best known from central Namaqualand in the vicinity of Kamieskroon and nearby Grootvlei and Skilpad farms where plants have brilliant, dark purple (also described as magenta) flowers with a white throat. Plants from higher elevations in the Kamiesberg east of Kamieskroon have pink or blue-mauve flowers with a yellow throat and also differ in perianth tube length, 7–8 mm long vs. 8–9(–10) mm for purple-flowered plants from lower elevations. Their later flowering, in October to early November, may be explained by the higher elevation. Among these Kamiesberg populations some consist of particularly tall, slender plants up to 650 mm high with long narrow leaves 5–6 mm wide, very different from the short-leaved populations and possibly explained by their marshy habitat. Alternatively these plants may represent a separate taxon.

Distribution of ***Ixia ramulosa***.



Provisionally, plants from the Bokkeveld Mtns to the south are included in *Ixia ramulosa*. Like typical *I. ramulosa*, these plants have stems with several short, filiform, few-flowered lateral branches and bracts sometimes flushed rust-brown distally, but a perianth tube 8–9 mm long and filaments ± 8 mm long (longer than in typical *I. ramulosa*), exserted ± 5 mm from the tube. These southern populations have branchlets with one to three flowers and white or pale blue-mauve flowers with a yellow cup and may be exceptionally robust, up to 750 mm high.

55. **Ixia nutans** *Goldblatt & J.C.Manning* in South African Journal of Botany 106: 194 (2016b). Type: South Africa, Western Cape, valley west of Montagu, south of Farm Pietersfontein, on stony, sandstone outcrop, 24 Aug. 2015, *Goldblatt & Porter 14109* (NBG, holo.; K, MO, PRE, iso.).



Plants 200–300 mm high. *Corm* 10–13 mm diam.; tunics of fine to medium-textured fibres. *Stem* usually with 2 or 3, short, drooping, filiform branches, subtended by scale-like, acuminate-truncate bracts and prophylls ± 1 mm long. *Leaves* 3, lower 2 basal, linear, slightly twisted (juvenile leaves loosely coiled distally), ± ⅓ as long as stem, ± 3 mm wide; main vein slightly raised, margins not thickened, uppermost leaf ± entirely sheathing with short free tip, enclosing most of stem. *Main spike* 2- or 3-flowered, lateral spikes mostly 1-flowered; bracts membranous, translucent with light brown veins, 6–7 mm long, outer 3-veined and acutely 3-toothed, inner 2-veined and 2-toothed, ± as long as outer. *Flowers* nodding to half pendent, pale mauve, faintly rose-scented; perianth tube funnel-shaped, 6–7 mm long, narrow lower part ± 3 mm long; tepals ascending below, spreading distally, obovoid-ellipsoid, 12–14 × 6–7 mm. *Filaments* ± 7 mm long, exserted ± 1.5 mm from mouth of tube; anthers ± 3 mm long, ± parallel, later weakly diverging, yellow. *Style* dividing opposite middle to upper ⅓ of anthers, 1.5(–2.5) mm long. *Flowering time*: August, probably also late July.

Distribution and ecology: known only from a single population near Farm Pietersfontein west of Montagu in Western Cape, South Africa; restricted to sandstone outcrops.

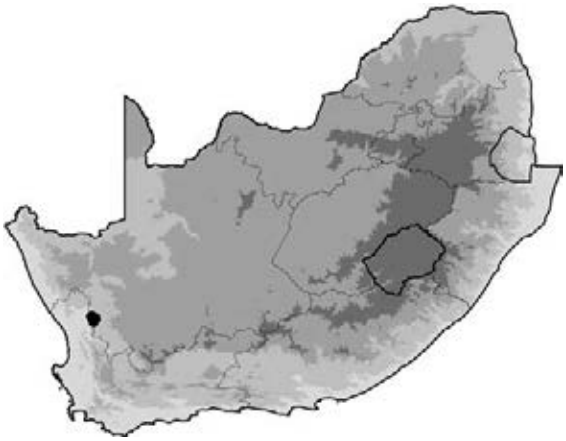
Diagnosis: *Ixia nutans* is immediately recognised by the two linear, soft-textured basal foliage leaves without thickened margins, ± 3 mm wide and slightly twisted

Distribution of ***Ixia nutans***.

Distribution of ***Ixia ecklonii***.

distally, together with short-tubed, nodding to slightly pendent flowers. The flowers conform most closely to those of the *I. latifolia* group in their perianth tube of moderate length, at least 6 mm long, and partly exserted filaments. The unusual leaf morphology does not indicate any particular close relationship to other members of the series.

56. **Ixia ecklonii** *Goldblatt & J.C.Manning* in Bothalia 41: 118 (2011). Type: South Africa, [Western Cape], Olifants River Valley, without date, *Ecklon & Zeyher Irid. 271* (MO, holo.; B–Herb. Treviranus, iso.).



Plants 300–500 mm high. *Corm* 7–12 mm diam.; tunics of matted, ± fibrous layers. *Stem* with (1)2 or 3 short, wiry twisted branches 5–8 mm long, subtended by short, subacute bracts and prophylls ± 1 mm long. *Leaves* 3, lower 2 lanceolate, reaching to ± middle of stem, 4–8 mm wide, uppermost leaf sheathing stem almost to base of spike. *Spike* half nodding, 1-flowered, branches also 1-flowered; bracts membranous, dark translucent brown, 7–9 mm long, outer 3-veined and 3-toothed, inner 2-veined and 2-toothed, ± as long as outer. *Flowers* nodding, colour and presence of scent unknown; perianth tube narrow, flared uniformly from base, curving outward, 10–11 mm long, ± 4 mm wide at mouth; tepals ± 10 × ± 4 mm. *Filaments* exserted ± 1.5 mm from tube; anthers 3–4 mm long. *Style* dividing opposite lower ⅓ of anthers, branches ± 2 mm long. *Flowering time*: not recorded.

Distribution and ecology: evidently extremely rare, currently known from just one early 19th century collection from the Olifants River Valley in Western Cape, South Africa; habitat unknown.

Diagnosis: *Ixia ecklonii* is immediately recognised by the slender stem bearing up to three short, filiform branchlets, these as well as the main axis each bearing a single flower. The flowers have a slightly curved, narrow perianth tube 10–11 mm long, flaring uniformly from base to apex and they obviously face to the side but colour and other aspects of the perianth are not known. The filaments are exserted ± 1.5 mm from the tube and the comparatively large anthers 3–4 mm long and well-developed style branches place *I. ecklonii* among a poorly defined cluster of species allied to *I. rapunculoides*. The general appearance of the plants recalls *I. mollis* and *I. namaquana*, but both have a funnel-shaped perianth tube and the filaments and bases of the anthers included in the tube. The translucent, brown floral bracts recall the Bokkeveld Mtn species, *I. brunneobracteata*, but that species has a shorter, funnel-shaped perianth tube 5–7 mm long, the main axis bears 3 to 5 flowers, and the branches are not particularly short and usually bear 2 to 4 flowers.

57. **Ixia brunneobracteata** *G.J.Lewis* in Journal of South African Botany 28: 80 (1962); Goldblatt & Manning: 118 (2011). Type: South Africa, [Northern Cape], 5 miles [8 km] from Nieuwoudtville on Grasberg road, 16 Sept. 1961, *Barker 9555* (NBG, holo.; BOL, NBG, PRE, iso.).

Plants 200–500 mm high. *Corm* 7–10 mm diam.; tunics of medium-textured fibres, bearing short to long stolons up to 12 mm long, each with terminal cormlet. *Stem* simple or 1- or 2(3)-branched, branches subtended by ± dry, translucent brown, acute to attenuate bracts and prophylls 1.5–4.0 mm long. *Leaves* 3, lower 2 ascending to falcate, up to 4 mm wide, uppermost leaf mostly entirely sheathing stem. *Main spike* 3- to 5-flowered, lateral spikes 2- or 3(–5)-flowered; bracts membranous, dark translucent brown, 6–11 mm long, outer 3-veined and 3-toothed, inner 2-veined and 2-toothed, ± as long as outer. *Flowers* pale pink or white, pale yellow in tube, tepals sometimes flushed pink or light purple outside, scented faintly of fresh coriander; perianth tube funnel-shaped, 5–7 mm long; tepals ascending below, spreading above, ovate, 10–15 × 5–8 mm *Filaments* 6–8 mm long, exserted ± 3.5 mm from mouth of tube; anthers 4–5 mm long. *Style* dividing opposite middle ⅓ of anthers, branches 1.5–2.0 mm long. *Flowering time*: mid-September to mid-October.

Distribution of ***Ixia brunneobracteata***.

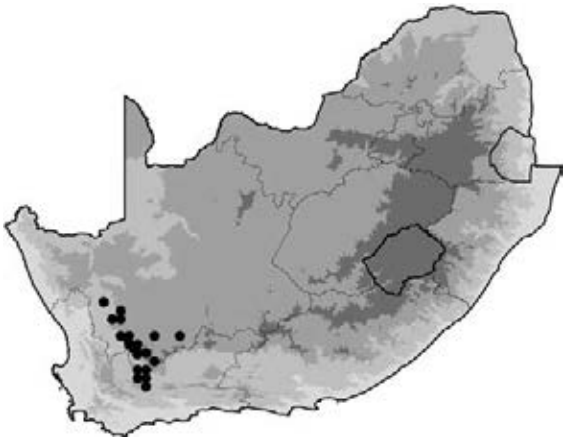
Distribution and ecology: a narrow endemic of the Bokkeveld Mtns of Northern Cape, South Africa, extending from the top of Vanrhyns Pass to the northern edge of the range; in seasonally wet or marshy sites in sandy ground.

Diagnosis: as its name suggests, *Ixia brunneobracteata* is immediately recognised by its unusually dark floral bracts, which although membranous and semi-translucent, are a glossy dark chestnut-brown. The pale pink or white flowers have a funnel-shaped perianth tube 5–7 mm long and spreading tepals 10–15 mm long. An unusual feature of the species is the production of stolons from the base of the corm, each bearing a small cormlet. The production of cormlets on stolons is relatively rare in *Ixia*; the only other species of sect. *Morphixia* that have stolons, *I. oxalidiflora* and *I. sobolifera*, both allied to *I. rapunculoides*, appear to have evolved this capacity independently and both favour heavier soils of clay or clay loam.

Ser. **Brevitubae** *Goldblatt & J.C.Manning*, new series. Type: *Ixia marginifolia* Salisb. ex G.J.Lewis

Plants with leaves plane or with margins often thickened or narrowly to broadly winged (H-shaped in section) or terete. *Flowers* nodding, pink, mauve, purple or white, dark in centre in *I. pavonia*; perianth tube short, 2–5 mm long, widely funnel-shaped. *Filaments* partly exserted.

58. **Ixia marginifolia** *Salisb. ex G.J.Lewis* in Journal of South African Botany 28: 66 (1962) [but as a combination based on *Hyalis marginifolia* Salisb.: 318 (1812), genus invalid]; Goldblatt & Manning: 119 (2011). *Ixia lancea* Jacq.: 7 (1795 [1788–1795]), illegitimate homonym, not *Ixia lancea* Thunb. (1783). *Ixia capillaris* var. *lancea* Ker Gawl.: sub t. 570 (1802b) as a new name at varietal rank for *I. lancea* Jacq. *Morphixia capillaris* var. *lancea* (Ker Gawl.) Baker: 97 (1877). *Morphixia lancea* (Ker Gawler) Klatt: 383 (1882). Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 281 (1795 [1788–1795]).



Ixia capillaris var. *stricta* Ker Gawl.: t. 617 (1803a). Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 617 of *Ixia capillaris* var. *stricta* (1803a).

[*Hyalis marginifolia* Salisb.: 318 (1812), genus invalid.]

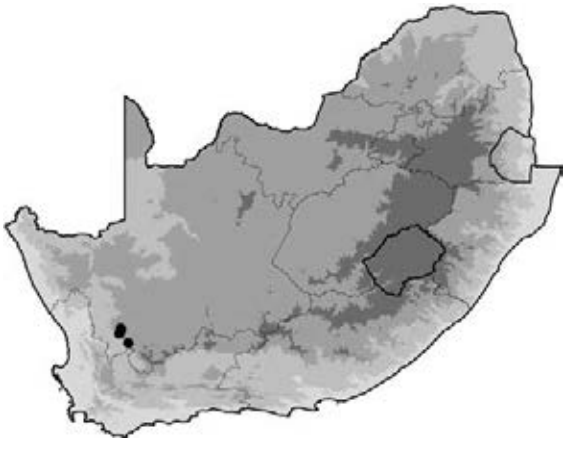
Plants 200–500 mm high, often with a collar of fibres around base. *Corm* 15–20 mm diam.; tunics of medium-textured to coarse fibres. *Stem* usually with 4–several (up to 10), short, filiform, straight or twisted branches, subtended by scale-like truncate bracts and prophylls ± 1 mm long. *Leaves* (3–)5, lower (2–)4 broadly lanceolate to falcate, ¼–⅓ as long as stem, 8–15 mm wide; margins moderately to heavily thickened, pale, hyaline when dry, uppermost 1 or 2 leaves entirely sheathing. *Main spike* 1- to 3(–5)-flowered, lateral spikes (1)2- to 4-flowered; bracts membranous, translucent with dark veins, often dry and brown distally, 6–7 mm long, subequal, outer 3-veined and obscurely 3-lobed, inner 2-veined and forked apically. *Flowers* nodding, blue-mauve, pink, or white, faintly freesia- or rose-scented, sometimes with an acrid odour or unscented; perianth tube funnel-shaped, 2.5–4.0 mm long; tepals spreading distally, ovate, (7–)10–13 × 5.5–8.0 mm. *Filaments* 5–7 mm long, exserted (1.5–)3.5–5.0 mm from mouth of tube; anthers 3.0–4.5 mm long, usually diverging at ± 30°, pale yellow. *Style* dividing opposite lower to middle ⅓ of anthers, branches 1.5(–2.5) mm long. *Flowering time*: mostly mid-August to late September, but October at higher elevations.

Distribution and ecology: a widespread and often relatively common species in the western Karoo, South Africa, extending from Kubiskou Mtn west of Loeriesfontein to Calvinia and then across the Bokkeveld Plateau south through the Roggeveld as far as Verlatekloof in Northern Cape, east to Fraserburg and the Nuweveld Mtns near Beaufort West in Western Cape, and south to interior Western Cape near Matjiesfontein; mostly in renosterveld or karroid scrub on clay and loamy ground, usually the fine-grained, pale soils derived from Ecca or Beaufort shales and sandstones or occasionally loam in Witteberg Sandstone or even on the heavy red clays derived from dolerite.

Diagnosis: distinctive in its short perianth tube, 2.5–4.0 mm long, and stem bearing several short, few-flowered, wiry branches, *Ixia marginifolia* also has unusually broad, short, leathery leaves with strongly thickened margins. It is sometimes confused in herbaria with *I. rapunculoides*, which is similar in general aspect, including flower colour and leaves with thickened margins, but the latter has short filaments included in the perianth tube, whereas *I. marginifolia* has the filaments exserted (1.5–)3.5–4.0 mm so that the anthers are prominently displayed.

Distribution of ***Ixia marginifolia***.

Ixia marginifolia displays an unusual pattern of variation in flower colour. Populations in the northeast of its range have a pink perianth, but to the southeast in the Calvinia area flowers are pale blue-mauve, the same shade as equally common *I. rapunculoides* with which it is easily confused from a distance. On the northern and central Roggeveld Escarpment plants have either blue-mauve or white flowers, occasionally both colours occurring together, but at the southern end of the escarpment populations are uniformly white-flowered, as is also reported for the Nuweveld population. Plants from the southern end of the range have violet flowers. White flowers remain open long after nightfall, whereas those of other colours close shortly after sunset.



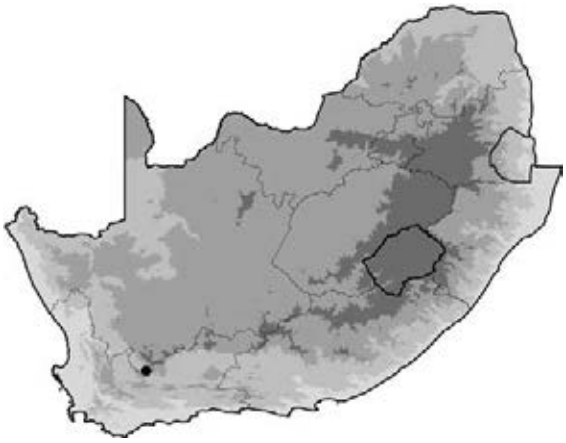
Variation in the number of flowers per branch is notable: while 2 or 3 flowers is most common, plants with predominantly or only single-flowered branches occur throughout the range of the species, perhaps a reflection of poor growing conditions rather than genetically based. A few collections, e.g. from the base of the Voetpadsberg near Pietermeintjies Siding in Western Cape, consist of plants with smaller flowers than are considered typical for *I. marginifolia*, with tepals ± 7 × 5.5 mm (vs. 10–12 × 6–8 mm), short filaments exserted ± 1.5 mm from the tube (vs. 3.5–5.0 mm). These plants also have 1-flowered branches; both this and the smaller than normal floral features may again result from of poor growing conditions that particular season. Plants from near Matjiesfontein a short distance to the east of the Pietermeintjies site and collected in another year have flowers typical in size for the species.

59. **Ixia pavonia** *Goldblatt & J.C.Manning* in Bothalia 41: 120 (2011). Type: South Africa, Northern Cape, Calvinia, Roggeveld Escarpment, opposite entrance to farm Vondelingsfontein on Vaalfontein–Nooiensrivier road, renosterveld, 15 Sept. 2009, *Goldblatt, Manning & Porter 13355* (NBG, holo.; K, MO, PRE, S, iso.).

Plants 150–500 mm high. *Corm* 15–18 mm diam.; tunics of coarse, netted fibres. *Stem* usually with 2 to 5(–12) short, filiform, branches 2–6 mm long, subtended by scale-like truncate bracts and prophylls ± 1 mm long. *Leaves* usually 4 (or 3), lower 2 with expanded blades, broadly lanceolate to falcate, ± ¼–½ as long as stem, 8–15 mm wide; margins thickened, pale, hyaline when dry; upper two leaves partly to entirely sheathing, uppermost reaching to between upper ⅓ of stem and base of spike. *Main and lateral spikes* 1- to 3-flowered; bracts membranous, translucent, becoming brown and dry distally, 8–12 mm long, outer 3-veined and shortly 3-toothed, inner 2-veined and forked at tip. *Flowers* mostly half nodding, blue-mauve, tepals dark red at base, black in wide part of tube, filaments and style dark purple, faintly acrid scented; perianth tube ± 3 mm long, funnel-shaped; tepals obovate, 12–15 × 6–8 mm, ascending to form a wide cup. *Filaments* purple, 5–7 mm long, exserted ± 3–5 mm; anthers 4–5 mm long, parallel, contiguous, yellow; pollen yellow. *Style* purple, dividing opposite middle of anthers, branches ± 2 mm long, purple below, becoming pale blue distally. *Flowering time*: September.

Distribution and ecology: a narrow endemic of Northern Cape, South Africa, restricted to a small area at the edge of the Roggeveld Escarpment south of Calvinia; on clay ground in renosterveld.

Diagnosis: based on morphological similarity, *Ixia pavonia* must be regarded as most closely allied to the widespread western Karoo species *I. marginifolia* and like that species, it has three leathery basal leaves with thickened margins and main vein, a stem bearing three or more, short lateral branches, and a flower with a short perianth tube ± 3.5 mm long. Unlike the uniformly blue-mauve, white or pink flowers of *I. marginifolia*, *I. pavonia* has a blue-mauve perianth with a black centre surrounded by a broad red zone. Accompanying the colour difference in the perianth are purple-black filaments and style. Although the perianth tube and tepals are about the same dimensions as in *I. marginifolia*, the filaments in that species are 5–7 mm long and typically exserted 3.5–5.0 mm from the tube. The short filaments of *I. pavonia*, only 4 mm long and exserted ± 1.5 mm stand in sharp contrast.



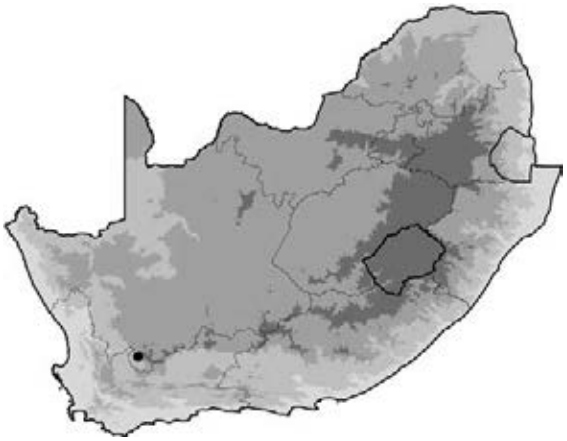
Distribution of ***Ixia pavonia***.

60. **Ixia linearifolia** *Goldblatt & J.C.Manning* in Bothalia 41: 121 (2011). Type: South Africa, Northern Cape, Sutherland, Klein Roggeveld, Farm De Hoop, Smoushoogte heights, in stony clay ground, 30 Aug. 2007, *Goldblatt & Porter 12921* (NBG, holo.; K, MO, PRE, iso.).

Plants mostly 450–900 mm high, sheathed below by prominent, pale, dry-membranous, often irregularly torn cataphylls. *Corm* 12–18 mm diam.; tunics of medium-textured fibres. *Stem* usually with 2 to 5 short branches up to 5 mm long, branches subtended by pale, dry, attenuate scale-like bracts and prophylls 2–4 mm long. *Leaves* 3, lower 2 linear ± ½ as long as stem, mostly 1.5–2.0 mm wide (when alive), leathery succulent, main vein slightly raised; margins thickened and fleshy; uppermost leaf entirely sheathing. *Main spike* 2- or 3-flowered, lateral spikes 1- or 2(3)-flowered; bracts silvery membranous, translucent with darker veins, 9–11 mm long, outer 3-veined and 3-lobed to 3 toothed, inner 2-veined, shallowly forked at apex. *Flowers* nodding, white with a pale bluish cast, with pale green marks at tepal bases, faintly rose-scented; perianth tube broadly funnel-shaped, ± 5 mm long; tepals spreading distally, ovate, 15–16 × 6.5–7.5 mm, outer tepals wider than inner. *Filaments* ± 5 mm long, exserted ± 2 mm from tube; anthers 4.5–5.0 mm long, parallel or slightly diverging when flower fully open. *Style* dividing opposite lower ⅓ of anthers, branches ± 2 mm long. *Flowering time*: mostly mid-August to mid-September.

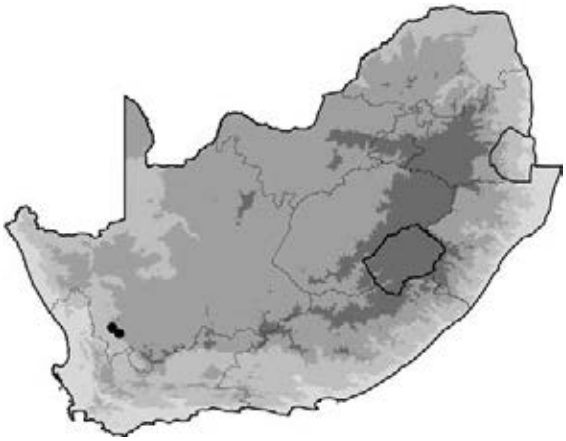
Distribution and ecology: rare and highly localised, known only from the upper, south-facing slopes of the Smoushoogte in the Klein Roggeveld in Northern Cape, South Africa; in fairly dense mountain renosterveld, often among tufts of grasses, in light clay among rocks.

Diagnosis: the short perianth tube, ± 5 mm long, flowers with outspread tepals and exserted filaments with prominently displayed anthers, and the several short lateral branchlets closely resemble *Ixia marginifolia*, but the leaves of *I. linearifolia* are quite unlike the short, broad, falcate leaves of that species. Instead the leaves are linear and about half as long as the stems, the latter mostly 45–90 mm high. The pale white flowers have a faint blue cast and the tepals have pale green marks at their bases. Unlike *I. marginifolia* the leaf margins are not prominently thickened and hyaline but instead are raised forming slightly fleshy, ridge-like wings without hyaline edges. The flowers of *I. linearifolia* are slightly larger than those of *I. marginifolia* with tepals 15–16 × 6.5–7.5 mm compared with (7–)10–13 × 5.5–8.0 mm.



Distribution of ***Ixia linearifolia***.

61. **Ixia teretifolia** *Goldblatt & J.C.Manning* in Bothalia: 42: 140 (2012b). Type: South Africa, Northern Cape, Sutherland, Roggeveld Escarpment, Farm Blesfontein, in dense tall grass tufts below sandstone cliffs at escarpment edge, 25 Sept 2011, *Goldblatt & Manning 13671* (NBG, holo.; K, MO, PRE, iso.).



Plants mostly 1.2–1.5 m high, sheathed below by prominent, pale, dry-membranous, often irregularly torn cataphylls with age accumulating in a dense mass. *Corm* 12–18 mm diam., with tunics of relatively fine fibres. *Stem* usually with 3 to 5 short branches up to 4 mm long, branches subtended by pale, dry, attenuate scale-like bracts and prophylls 2–4 mm long. *Leaves* 3, lower 2 terete, ± ½ as long as stem, mostly 1.5–2.0 mm diam., firm-textured without evident veins when alive; uppermost leaf entirely sheathing or almost so, reaching to spike base or to lowermost branches. *Main spike* (1)2(3)-flowered, lateral spikes 1- or 2(3)-flowered; bracts silvery membranous, translucent with narrow, dark purple veins, ± 7 mm long, outer 3-veined and 3-toothed or 3-lobed; inner 2-veined, shallowly forked. *Flowers* upright to half nodding, pale blue, pale green in throat, faintly rose-scented, with bright yellow anthers prominently displayed; perianth tube broadly funnel-shaped, ± 5 mm long, narrow part ± 2 mm long; tepals spreading, patent distally, ovate, ± 12 × 6.0–6.5 mm, outer slightly wider than inner. *Filaments* ± 6 mm long, exserted ± 4 mm from tube; anthers 4–5 mm long, ± parallel, yellow; pollen yellow. *Style* dividing opposite lower ⅓ of anthers, branches ± 3 mm long, slender, extending between anthers. *Flowering time*: mostly mid-September to mid-October, possibly later.

Distribution and ecology: restricted to edge of the Roggeveld Escarpment west of Sutherland in Northern Cape, South Africa, known only from the Farm Blesfontein; at the base of sandstone cliffs among rocks, nested in dense tufts of grass.

Diagnosis: the short, widely funnel-shaped perianth tube, ± 5 mm long, flowers with outspread tepals and partly exserted filaments with prominently displayed anthers, and the several short lateral branchlets place *Ixia teretifolia* close to *I. marginifolia*. The tall stature and habitat are shared in sect. *Morphixia* with *I. alata* but the several very short branches, each with 1 or 2(3) flowers differ from that species, and recall particularly *I. linearifolia*. The centric leaves lacking visible veins are unique in sect. *Morphixia* and unusual in the genus, almost all

Distribution of ***Ixia teretifolia***.

Distribution of ***Ixia alata***.

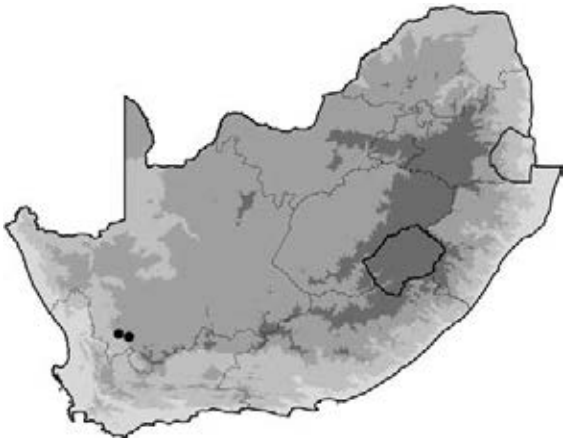
species of which have plane, isobilateral leaves. Except for their slightly smaller size, the flowers of *I. teretifolia* differ very little from those of *I. marginifolia* and its immediate allies, which have a short, funnel-shaped perianth tube, tepals spreading distally and fully exserted anthers.

62. **Ixia alata** *Goldblatt & J.C.Manning* in Bothalia 41: 121 (2011). Type: South Africa, Northern Cape, southeastern foothills of Driefontein se Berg, SE of Calvinia, rocky, northeast-facing dolerite slope, 15 Sept. 2009, *Goldblatt, Manning & Porter 13380* (NBG, holo.; K, MO, PRE, iso.).

Plants mostly 0.7–1.1 m high, sheathed below by prominent, dry remains of cataphylls and leaf bases. *Corm* 20–25 mm diam.; tunics of medium-textured fibres accumulating in a fairly dense mass. *Stem* usually with 2 to 4 short branches up to 8 mm long; branches subtended by pale, dry, attenuate scale-like bracts and prophylls 5–7 mm long, bracts sheathing in lower part. *Leaves* 3, lower 2 linear, ± ⅓–½ as long as stem, mostly 3–4 mm wide (when alive), leathery, main vein strongly thickened, margins raised into wings held ± at right angles to blade, wings tilted to same side with one surface more exposed, uppermost leaf entirely sheathing. *Main spike* 4- to 6-flowered, lateral spikes mostly 3- to 5-flowered; bracts translucent with light brown veins drying purple, 6–8 mm long, outer 3-veined and shallowly 3-lobed, often secondary veins not reaching bract apices, inner 2-veined, shallowly 2-lobed. *Flowers* half(–fully) nodding, pale pink, white at base of tepals and in tube, with short purple lines at tepal bases and throat, unscented; perianth tube widely funnel-shaped, 5–6 mm long, narrow lower part ± 2.5 mm long; tepals laxly spreading distally but remaining slightly cupped, ovate, 13–16 × 5–8 mm, outer slightly wider than inner, indented abaxially along midline above filament insertion to a rounded median adaxial crest. *Filaments* ± 5 mm long, exserted ± 2 mm from wide part of tube, adaxial base with a flange decurrent on tepal midline; anthers 4–5 mm long, white, parallel or slightly diverging when flower fully open; pollen yellow. *Ovary* minutely warty; style dividing opposite middle to upper third of anthers, branches ± 2 mm long, suberect and extending above anther tips. *Flowering time*: mostly mid-August to mid-September.

Distribution and ecology: restricted to the northern edge of the Roggeveld Escarpment in Northern Cape, South Africa, only on a few farms south of Calvinia; locally common on heavy, red clay soils in dolerite outcrops or in light sandy ground with ferricrete and dolerite fragments.

Diagnosis: *Ixia alata* is very much like *I. thomasiae* in its tall stature, stem with half nodding branches, half to fully nodding flowers and, in particular, the long narrow leaves with broadly winged margins. The two differ, however, in flower size: the perianth tube of *I. alata* is just 5–6 mm long and the tepals 13–16 × 5–8 mm compared with a tube 8–10 mm long and tepals 14–20(–25) × 5.0–6.5(–8.0) mm. The perianth tube in particular is significantly shorter, and the tepals only slightly shorter but about as wide as those of *I. thomasiae*. Added to these differences are a main spike of 4 to 6 flowers and floral bracts 6–8(–10) mm long in *I. alata* compared with spikes of 7 to 10 flowers and floral bracts 9–12 mm in *I. thomasiae*. While *I. alata* blooms from mid-September to early October, *I. thomasiae* growing a short distance away, does not come into flower until the end of September and sometimes not until the second week of October. Both species have slightly warty capsules, not known in other species of *Ixia*.



63. **Ixia thomasiae** *Goldblatt* in Journal of South African Botany 45: 87 (1979); Goldblatt & Manning: 123 (2011). Type: South Africa, [Northern Cape], Roggeveld Escarpment, Blomfontein Farm, between Middelpos and Calvinia, 30 Sept. 1976, *Goldblatt 4268* (MO, holo.; K, NBG, PRE, S, iso.).

Plants mostly 0.6–1.5 m high, with remains of old cataphylls and leaf bases persisting as a fibrous collar

around stem base. *Corm* 15–20 mm diam., with tunics of coarse netted fibres. *Stem* usually with 1 to 3 short, twisted branches subtended by acute bracts and prophylls 4–10 mm long. *Leaves* 3, lower 2 linear, reaching upper ⅓ of stem, 3–5 mm wide, main vein thickened and narrowly winged, margins forming broad wings held at right angles to blade, upper leaf sheathing stem. *Main spike* half nodding, 7- to 10-flowered, branches mostly 3- to 5-flowered; bracts membranous, translucent, becoming light brown distally, 9–12 mm long, outer 3-veined above with prominent central vein, lateral veins paired in lower part and sometimes not reaching bract apex, obtuse to obscurely 3-lobed, inner 2-veined, forked apically, slightly shorter than outer. *Flowers* half to ± fully nodding, pale blue-mauve, white in throat, presence of scent unknown; perianth tube funnel-shaped, widening in upper ½, 8–10 mm long; tepals subequal, ovate-oblong, 14–20(–25) × 5.0–6.5(–8.0) mm, spreading ± at right angles to tube, indented abaxially along midline above filament insertion to form a rounded median adaxial crest. *Filaments* ± 6 mm long, included or exserted up to 2 mm from tube; anthers ± 6 mm long, yellow. *Ovary* slightly warty; style usually dividing opposite upper ⅓ of anthers, or just above anther tips, branches ± 2.0 mm long. *Flowering time*: October, rarely late September.

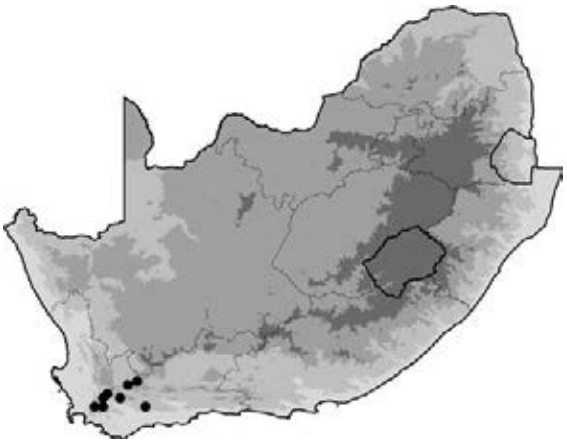
Distribution and ecology: restricted to the central Roggeveld Escarpment west of Middelpos in Northern Cape, South Africa; in clay ground, flowering relatively late in the season, mainly in October.

Diagnosis: the distinctive leaves with raised and winged margins, thus ± H-shaped in cross section, combined with a perianth tube 8–10 mm long and the unusual, warty ovary and capsules make *Ixia thomasiae* unmistakable. The leaf shape and warty ovary and capsules are not known elsewhere in *Ixia* except in related *I. alata*. Flowers of *I. thomasiae* are pale blue-mauve and slightly larger than those of *I. alata* which has pale pink flowers. The two species are evidently most likely allied to the *I. marginifolia* group with which they share a funnel-shaped perianth tube and partly exserted filaments and fully sheathing uppermost leaf. The particularly large anthers of *I. thomasiae*, ± 6 mm long, and style branches, up to 2 mm long, are consistent with other species of the group.

Distribution of ***Ixia thomasiae***.

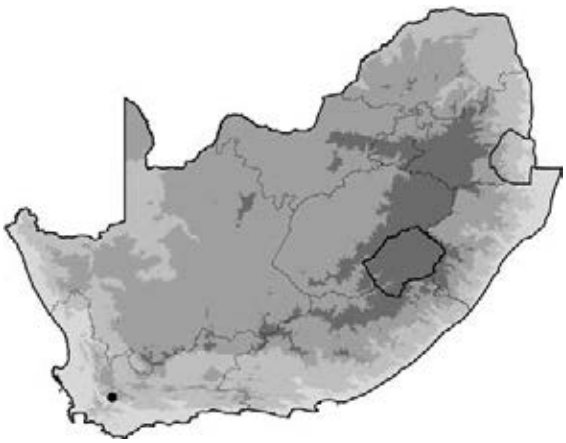
Ser. **Paucifolieae** *Goldblatt & J.C.Manning*, new series. Type: *Ixia paucifolia* G.J.Lewis

Plants with leaves plane, lanceolate to linear. *Flowers* white, cream-coloured or pink to red; perianth tube elongate, cylindric. *Filaments* shortly exserted or included.



64. **Ixia paucifolia** *G.J.Lewis* in South African Gardening and Country Life 23: 213 (1933); Goldblatt & Manning: 125 (2011). Type: South Africa, [Western Cape], Vanwyksdorp, 23 Oct. 1932, [*Compton &*] *Archer 534* [BOL, lecto., designated by De Vos: 65 (1999)].

Ixia bolusii G.J.Lewis: 10 (1938). Type: South Africa, [Western Cape], Hex River Valley near De Doorns, Oct. 1907, *Bolus s.n.* (BOL 13197, holo.; PRE, iso.).



Plants 120–300 mm high. *Corm* 12–15 mm diam.; tunics of hard, coarse, netted fibres. *Stem* simple or with 1(2) ± straight branches subtended by pale, membranous, subacute to attenuate bracts and prophylls 2–5 mm long. *Leaves* 3, lower 2 basal, falcate, mostly 3–5 mm wide, margins moderately thickened, lowermost leaf usually wider and longer than next, uppermost leaf sheathing lower ½ of stem. *Main spike* mostly 4- to 10-flowered, lateral spikes 2- to 4-flowered; bracts pale and membranous, (6–)8–9 mm long, outer 3-veined and 3-dentate, inner ± 1 mm longer than outer, 2-veined, 2-toothed. *Flowers* beige to creamy white, often flushed purple outside, unscented; perianth tube 24–34 mm long, slender and cylindric, divided inside into 3 compartments by decurrent filaments; tepals oblong, 11–15 × 3.0–4.5 mm, spreading at right angles to tube. *Filaments* ± 3 mm long, exserted ± 2 mm from tube; anthers ± 4 mm long. *Style* dividing shortly below or opposite anther tips, branches ± 1 mm long, arching above anther tips, minutely forked. *Flowering time*: late September and October.

Distribution and ecology: a Western Cape, South Africa, endemic extending from Hex River Pass and De Doorns eastward to the Bonteberg, Vanwyksdorp near Ladismith and south to Koo; on exposed, fairly dry shale slopes and flowering particularly well after fire, then conspicuous among regenerating shrubby vegetation.

Diagnosis: *Ixia paucifolia* is recognised by the pale beige to creamy white flowers (sometimes described as pale yellow), a cylindric perianth tube (22–)25–35 mm long, and narrow tepals 11–15 × 3.0–4.5 mm, spooned at the tips. The filaments are ± 3 mm long and exserted ± 2 mm from the tube, and the style divides close to or opposite the anther tips so that the style branches arch over the anthers. The species is readily distinguished from *I. dolichosiphon* in herbaria by the

Distribution of ***Ixia paucifolia***.

Distribution of ***Ixia dolichosiphon***.

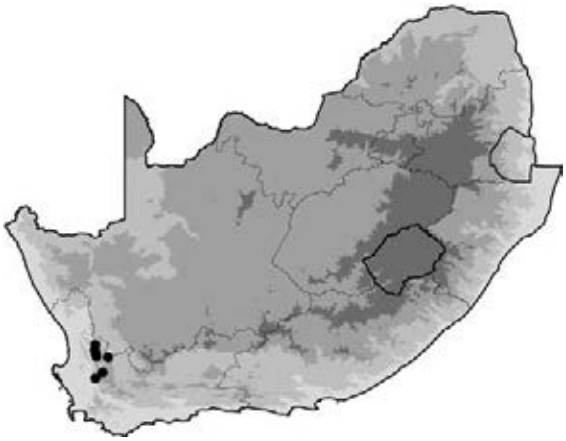
very coarse-textured corm tunics, longer floral bracts, (6–)8–9 mm long, longer perianth tube (15–18 mm in *I. dolichosiphon*, which has bracts 5–6 mm long, white flowers flushed pale lilac, and veined purple outside). The shorter style divides opposite the middle of the anthers with the style branches extending between them. The two species also differ in flowering time and habitat: *I. dolichosiphon* blooms in August and early September and favours south-facing sandstone slopes, whereas *I. paucifolia* grows on clay and shale slopes and blooms in late September and October. White- or pink-flowered plants from sandstone slopes in the Cold Bokkeveld and Cederberg, included by Lewis in *I. paucifolia*, are now two separate species, *I. cedarmontana* and *I. seracina*, distinguished by their finely fibrous corm tunics, as well as flower colour and leaf differences.

65. **Ixia dolichosiphon** *Goldblatt & J.C.Manning* in Bothalia 41: 126 (2011). Type: South Africa, Western Cape, Hex River Kloof, SW-facing sandy mountain slopes of Keeromsberg above De Wet, Farm Rheboksfontein, 9 Sept. 1993, *Goldblatt & Manning 9690* (NBG, holo.; K, MO, PRE, S, WAG, iso.).

Plants 120–200 mm high. *Corm* 10–16 mm diam., with tunics of medium-textured netted fibres. *Stem* (1–)3- or 4-branched, lower branches rarely also branched; branches twisted, diverging at 90° from main axis, subtended by pale, membranous, attenuate bracts and prophylls (1–)3–8 mm long. *Leaves* 3, lower 2 lanceolate to falcate, (5–)7–12 mm wide, usually reaching to ± base of or sometimes shortly exceeding spike; margins and main vein slightly thickened; uppermost leaf entirely sheathing, reaching at least to middle of stem or to base of spike. *Spike* flexuose, 4- to 10-flowered, lateral spikes somewhat contorted, 2- to 8-flowered, horizontal below first flower, then erect; bracts membranous and transparent, outer 5–6 mm long, 3-veined, slightly 3-dentate, inner slightly shorter to ± as long as outer, 2-veined and 2-toothed. *Flowers* white or flushed pale lilac, tepals sometimes each with a purple basal mark, tepals and tube veined purple outside, scentless; perianth tube ± cylindric, tapering uniformly from ± 1 mm diam. at base to 2 mm diam. at apex, 15–18 mm long, internally divided into 3 compartments by decurrent filaments extending downward nearly to base; tepals obovate, spreading at right angles to tube, subequal, 9–13 × 6–7 mm. *Filaments* ± 2 mm long, inserted ± 1 mm below tube apex, decurrent nearly to base, mostly exserted ± 1 mm; anthers ± 3 mm long before anthesis, yellow. *Style* dividing between middle and upper ⅓ of anthers, branches extending between anthers, ± 2 mm long. *Flowering time*: late August to mid-September.

Distribution and ecology: a narrow endemic of the western end of the Langberg near De Wet (east of Worcester) in Western Cape, South Africa; on lower slopes in stony sandstone, south and southwest-trending slopes, flowering only after fire.

Diagnosis: *Ixia dolichosiphon* is distinguished by its relatively long perianth tube, 15–18 mm long, white or pale lilac-flushed perianth and short filaments ± 2 mm long, included or exserted up to 1.5 mm from the tube. It is closely allied to, and most easily confused with beige-flowered *I. paucifolia*, a species of shale slopes in the dry interior valleys of the southwestern Cape. That species has flowers with a perianth tube (22–)25–34 mm long, slightly constricted at the apex, spreading tepals 12–15 × 5 mm, filaments ± 3 mm long, exserted 2–3 mm from the perianth tube and anthers ± 4 mm long. Although confined to cooler, south-facing slopes, *I. dolichosiphon* flowers from late August to mid-September, earlier than any population of *I. paucifolia*. It differs from *I. paucifolia* not only in its white or pale lilac-flushed flowers, veined purple on the outside, and shorter perianth tube, but in the tepals, stamens and style. The tepals are 9–13 mm long, the anthers are ± 3 mm long and the style divides opposite the middle of the anthers with the style branches emerging between them in contrast to the longer style of *I. paucifolia* that divides close to the anther tips with the style branches arching above the anthers. As in *I. paucifolia*, the filaments of *I. dolichosiphon* are decurrent almost to the base of the tube, dividing the interior of the tube into three compartments.



Like *I. paucifolia*, flowers of *I. dolichosiphon* are adapted for pollination by long-proboscid flies.

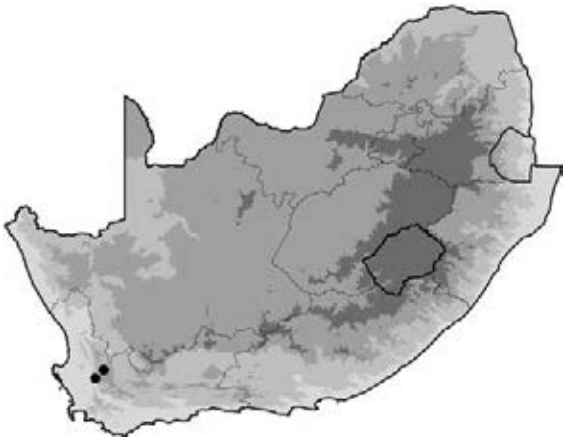
66. **Ixia cedarmontana** *Goldblatt & J.C.Manning* in Bothalia 41: 126 (2011 incl. *I. seracina*). Type: South Africa, [Western Cape], Wuppertal, Heuningvlei, Groot Koupoort, 3 200 ft [975 m], seasonally moist, 11 Oct. 1975, *Kruger 1668* (PRE, holo.; NBG, iso.).

Plants 150–300(–500) mm high. *Corm* globose, 7–12 mm diam., bearing cormlets at base; tunics of fine netted fibres. *Stem* slender, rarely with 1 or 2 straight branches diverging at 40–80° from axis, subtended by obscure, membranous acute bracts and prophylls 1–2 mm long. *Leaves* 2 or 3(4), lower 1 or 2 (rarely 3) with expanded blades, ± basal, narrowly sword-shaped to ± linear, mostly 2–4(–5) mm wide, with moderately thickened main vein and margins, uppermost leaf sheathing lower part of stem. *Main spike* (1–)3- to 5(–7)-flowered, lateral spikes 1- to 5-flowered; bracts translucent, often flushed pink or purple distally, 6–9 mm long, outer 3-veined and 3-toothed to 3-lobed, inner ± as long or 1 mm longer than outer, 2-veined and 2-toothed. *Flowers* usually half to fully nodding, white to pale pink, sometimes flushed light purple to pink outside, yellow in throat, tube finely lined with purple, not closing at night, usually sweetly scented, especially evenings; perianth tube ± cylindric, 20–24 mm long; tepals subequal, ovate, 10–16 × 5–8 mm, outer slightly wider than inner. *Filaments* 6–10 mm long, reaching mouth of tube or exserted up to 4 mm; anthers ± 4(–5) mm long, pale yellow. *Style* dividing opposite middle to apex of anthers, branches 1–2 mm long. *Flowering time*: October, rarely in late September.

Distribution and ecology: a fairly rare species of Western Cape, South Africa, restricted to the northern and central Cederberg; in peaty sandstone-derived soils, usually in moist habitats such as wet, poorly drained flats, seeps and seasonal marshes.

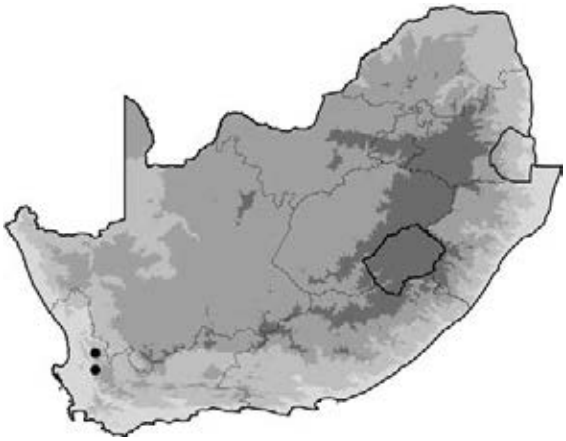
Diagnosis: *Ixia cedarmontana* is recognised by a combination of a relatively long perianth tube, 20–25 mm long, and small to moderate-sized corms with finely fibrous corm tunics. Most populations have white flowers, pale yellow in the throat, but those with pale pink tepals have been recorded. Flowers are sweetly scented and remain open at night. Some white-flowered plants were included by Lewis (1962) in *I. paucifolia* but that species is distinguished by falcate leaves, coarsely fibrous corm tunics and typically beige flowers with a perianth tube mostly 25–35 mm long. Flowers of *I. cedarmontana* have ovate tepals 10–16 × 5–8 mm, thus about twice as long as wide, and filaments reaching the apex or exserted up to 4 mm from the perianth tube. The flowers of *I. paucifolia* are always unscented, have narrower tepals, 12–15 × 3.0–4.5 mm, thus about three to four times as long as wide, and the filaments are consistently exserted 2–3 mm. Because the flowers are scented and remain open at night, moth pollination is inferred for *I. cedarmontana.* In contrast, flowers of *I. paucifolia,* a plant of relatively dry, well-drained open clay and shale slopes, are unscented, close at night and are pollinated by long-proboscid flies.

Distribution of ***Ixia cedarmontana***.



Relatively tall plants from the Great Winterhoek Mtns and Bokkeveld Tafelberg, up to 500 mm high, and with deep pink to pale cherry-red flowers and leaves 4–8 mm wide included in the past in *Ixia cedarmontana* are now regarded as a separate species, *I. seracina.*

67. **Ixia seracina** *Goldblatt & J.C.Manning* in South African Journal of Botany 98: 110 (2015). Type: South Africa, Western Cape, slopes of Bokkeveld Tafelberg, 1550 m, 26 Nov. 2010, *Helme 6635* (NBG, holo.).



Plants 250–320 mm high. *Corm* globose, 12–15 mm diam.; tunics of fine pale fibres. *Stem* simple or with 1 short branch subtended by obscure, membranous acute bracts and prophylls 1–2 mm long. *Leaves* (2)3, lower 2 basal, upper entirely sheathing, lowermost longest, half to as long as stem, mostly 6–8 mm wide, margins and main vein slightly thickened and hyaline when dry, second leaf smaller, 3–4 mm wide. *Spike* 4- to 8-flowered; bracts mostly 6–8 mm long, reaching to or slightly beyond node above, outer prominently 3-veined and 3-toothed, inner 2-veined and 2-toothed. *Flowers* salver-shaped, deep pink to pale cherry-red with exserted yellow-orange anthers; perianth tube cylindric, 23–25 mm long; tepals spreading, ovoid-obovate, ± 10 × 5 mm. *Filaments* ± 5 mm long, reaching mouth of tube; anthers ± 4 mm long, bright yellow; pollen yellow. *Style* dividing opposite upper ⅓ of anthers, branches ± 1 mm long. *Flowering time*: mid-November to mid-December.

Distribution and ecology: a rare Western Cape endemic, restricted to high elevations in the Cold Bokkeveld and Groot Winterhoek Mtns, South Africa; evidently favouring the shale band of the Cape Sandstone System, flowering well after fire.

Diagnosis: *Ixia seracina* is distinguished by the deep pink to cherry-red, odourless flowers with a perianth tube 23–25 mm long, relatively short tepals ± 10 mm long,

Distribution of ***Ixia seracina***.

Distribution of ***Ixia arenosa***.

and bright yellow anthers borne on short filaments that reach only to the mouth of the perianth tube. Another distinctive feature is the relatively broad, lowermost foliage leaf, 6–8 mm wide, and much narrower second basal leaf. *Ixia cedarmontana* is broadly similar in habit but has either uniformly white or sometimes pale pink flowers that, as far as is known, remain open at night and are sweetly scented. The two foliage leaves of *I. cedarmontana* are more-or-less equal in length and linear, mostly 2–4 mm wide (exceptionally to 5 mm) and its flowers have a perianth tube 20–24 mm long and tepals 12–16 mm long. *Ixia seracina* has been collected on shale bands in bloom from mid-November to mid-December, whereas *I. cedarmontana* occurs on peaty sand in somewhat marshy sites and blooms mainly in October and early November.

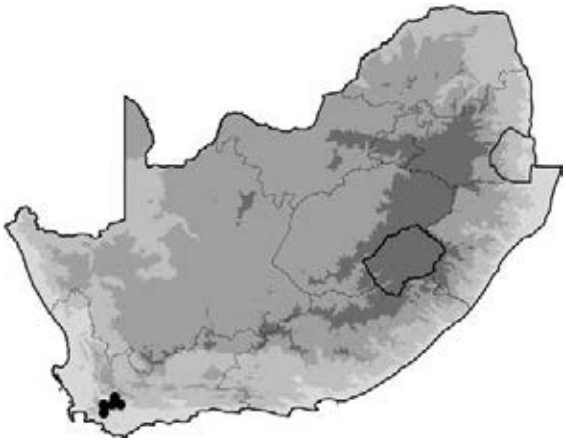
68. **Ixia arenosa** *Goldblatt & J.C.Manning* in South African Journal of Botany 98: 111 (2015). Type: South Africa, Western Cape, Cederberg, sandy flats near Sneeuberg Hut, in grassland with Restionaceae, 1 300 m, 25 Oct. 1989, *Le Maitre 620* (NBG, holo.; PRE, iso.).

Plants 150–250 mm high, slender. *Corm* ovoid, 7–12 mm diam., sometimes with small cormlets at base; tunics of fine, netted fibres. *Stem* simple or with 1, rarely 2 short, straight branches diverging from axis, subtended by obscure, membranous, acute bracts and prophylls ± 1 mm long. *Leaves* (2)3(4), lower 1 to 3 ± basal, linear, 1.5–2.0 mm wide, with moderately thickened main vein and margins, uppermost leaf sheathing lower part of stem. *Main spike* 2- to 4-flowered, lateral spikes 1- or 2-flowered; bracts translucent, often flushed pink or purple distally, 7–9 mm long, outer 3-veined and 3-toothed or 3-lobed, inner ± as long or 1 mm longer than outer, 2-veined and 2-toothed. *Flowers* upright, bright pink to rose or white, yellow in throat, flushed light purple to pink outside, closing at night, scented; perianth tube funnel-shaped, 12–18 mm long; tepals subequal, ovate-elliptic, outer slightly wider than inner, 12–15 × 5–8 mm. *Filaments* ± 6 mm long, exserted 1.5–3.5 mm; anthers 4–5 mm long, often with wide abaxial connective. *Style* dividing opposite middle to apex of anthers, branches 1–2 mm long. *Flowering time*: October, possibly in early November.

Distribution and ecology: at middle to upper elevations in the Cederberg and Cold Bokkeveld Mtns of Western Cape, South Africa; on stony sandstone ground.

Diagnosis: *Ixia arenosa* is recognised by the pink to rose-coloured (rarely white) flowers with a funnel-shaped perianth tube 12–18 mm long and linear foliage leaves, the blades 1.5–2.0 mm wide, with moderately thickened main vein and margins. Plants typically have three leaves, the uppermost entirely sheathing, but plants with only two or even four leaves are known. Early collections of the species were included in *I. cedarmontana*, but that species is now restricted to plants of moist habitats with usually white, occasionally pale pink, scented flowers with a cylindric perianth tube 20–24 mm long. The affinities of *I. arenosa* remain uncertain but it is provisionally included in the *Paucifolieae* group, in which the presence of four leaves in some specimens is exceptional.

69. **Ixia stenophylla** *Goldblatt & J.C.Manning* in Bothalia 41: 129 (2011) as new name and rank for *I. fucata* var. *filifolia* G.J.Lewis: 99 (1962) [not *I. filifolia* Redouté (1809)]. Type: South Africa, [Western Cape], Riviersonderend Mtns, northern slopes (as Boschjesveld Mtns, Worcester side), 1 Oct. 1955, *Stokoe s.n.* (SAM 68608 & 68609 (2 sheets), syn. [SAM 69608 was said by De Vos (1999) to be the holotype in error]).



Plants 200–400 mm high. *Corm* globose, 7–15 mm diam.; tunics of fine to medium-textured netted fibres, sometimes thickened and claw-like below. *Stem* flexed at base of spike, simple or rarely with a single branch subtended by silvery, attenuate bracts and prophylls up to 4 mm long. *Leaves* 3, lower 2 linear-filiform, 0.8–1.2 mm wide, main vein heavily thickened and raised, thickened secondary veins sometimes present, margins not thickened, uppermost leaf usually entirely sheathing. *Spike* slightly flexuose, 1- or 2(3)-flowered; bracts

6–8 mm long, outer 3-veined and 3-toothed, inner ± as long as outer, 2-veined, forked apically. *Flowers* nodding, salver-shaped, with unilateral stamens, white or flushed pale mauve, with a ring of dark streaks at tube mouth, pale mauve outside, with dark lines on tube; perianth tube cylindric, (12–)15–20 mm long, ± 2 mm diam., straight; tepals ± elliptic, subequal, 12–15 × 6–8 mm, spreading at right angles to tube. *Filaments* unilateral, horizontal, 5–6 mm long, exserted ± 3 mm; anthers 3–4 mm long, facing lower tepals. *Style* dividing opposite middle to upper ⅓ of anthers, branches ± 1.5 mm long, weakly recurved. *Flowering time*: late September and October, rarely in late August.

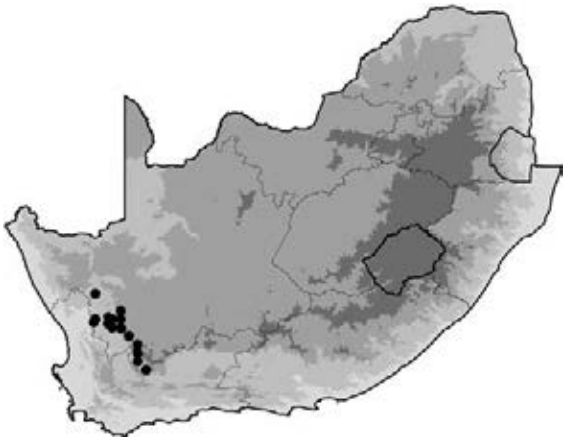
Distribution and ecology: a narrow Western Cape endemic, restricted to Brandwag Peak in the Hex River Mtns and the western end of the Riviersonderend Mtns extending from Boesmanskloof Pass above Greyton to near Villiersdorp, South Africa; in rocky sites, usually in low vegetation of upper northern slopes on sandy ground, sandstone outcrops or on shale slopes.

Diagnosis: *Ixia stenophylla* somewhat resembles *I. fucata* but is distinguished by its three leaves, the basal two with filiform blades up to 1.2 mm wide, and the absence of a collar of fibres around the stem base. It also differs in having a spike with only 1 or 2, rarely 3 flowers, and the stem is almost invariably unbranched. The white flowers are flushed mauve outside and have dark veining on the relatively wide perianth tube (12–)15–20 mm long. The stamens are also unilateral (properly visible only in living plants) and extended horizontally with the parallel anthers facing the lower tepals, an orientation unique in *Ixia*.

The immediate relationships of *Ixia stenophylla* are uncertain. The two linear and very narrow foliage leaves suggest it belongs to the *I. capillaris* complex, all species of which also have narrow leaves. The leaf blades, however, differ significantly in having a strongly thickened and raised central vein and a thickened secondary vein, whereas the leaves of all species of the *I. capillaris* complex lack thickened veins.

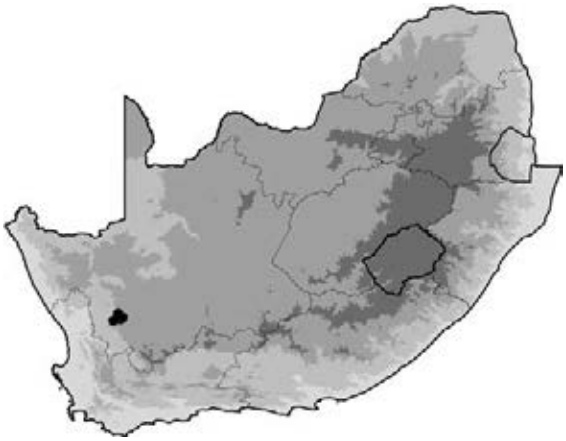
Distribution of ***Ixia stenophylla***.

Ser. **Rapunculoides** *Goldblatt & J.C.Manning*, new series. Type: *Ixia rapunculoides* Delile



Plants with leaves plane, mostly lanceolate, sometimes broadly so, or falcate. *Flowers* mostly blue-mauve, or pink or creamy white; perianth tube relatively short, funnel-shaped. *Filaments* included and anthers partly to fully included.

70. **Ixia rapunculoides** *Delile* in Redouté, Les Liliacées 8: t. 431 (1814); Goldblatt & Manning: 7 (2008a). Type: South Africa, without precise locality, collector unknown, illustration in Redouté: t. 431 (1814). Epitype: South Africa, [Northern Cape], Nieuwoudtville, Klipkoppies, red clay, 9 Aug. 1961, *Lewis 5853* (NBG, epi., designated by Goldblatt & Manning: 7 (2008a); K, PRE, iso.).



Plants mostly 150–400 mm high. *Corm* subglobose, mostly 14–18 mm diam.; tunics of firm, wiry fibres accumulating in dense mass, with small cormlets at base. *Stem* erect, nodding above, with several to many (up to 10) short, thread-like, ascending to horizontal branchlets subtended by obtuse bracts and prophylls ± 1(–2) mm long. *Leaves* (2)3(4), lower 2 lanceolate to falcate, mostly (3–)7–12 mm wide, ± ¼–½ as long as stem, margins thickened, sometimes lightly crisped, uppermost leaf sheathing stem, rarely unifacial in upper 10–30 mm. *Main spike* mostly 3- to 5-flowered, lateral spikes (1)2- to 5 flowered; bracts translucent sometimes tinged brown especially in fruit, outer with 3 dark veins, mostly 5–6 mm long, 3-toothed or bluntly 3-lobed, inner ± as long, with 2 dark veins, forked apically. *Flowers* ± half to fully nodding, pale blue (mauve or blue-grey) with pale yellow cup, or pink with white cup, faintly rose-scented or evidently unscented; perianth tube 5.5–8.0(–10.0) mm long, widely funnel-shaped, flaring in upper 3–5 mm; tepals subequal, ovate, 11–16 × 4.5–6.0 mm, proximal ± 3 mm forming part of floral cup, spreading distally. *Filaments* 2–3 mm long, inserted 2–4 mm above base of tube; anthers 2.3–3.5 mm long, half exserted from tube but included in floral cup, pale yellow. *Style* dividing shortly below anther tips, branches 0.7–1.2 mm long, not reaching anther tips. *Flowering time*: August to mid-September, sometimes July.

Distribution and ecology: widespread across the Western Karoo, South Africa, from the Langberg west of Loeriesfontein and the Hantamsberg in the north across the Bokkeveld Plateau and Roggeveld Escarpment as far south as Sutherland; mostly on stony clay soils.

Diagnosis: *Ixia rapunculoides* is recognised by the half to fully nodding, mostly blue flowers with a yellow cup (locally pale pink with a white cup), short perianth tube mostly 5.5–8.0 mm long, short filaments 2–3 mm long and anthers 2.3–3.5 mm long and half included in the perianth tube. In the vicinity of the Hantamsberg the species co-occurs with *I. robusta*, which was distinguished at the varietal level by Lewis (1962) by the

Distribution of ***Ixia rapunculoides***.

Distribution of ***Ixia robusta***.

presence of a short collar of fibres sheathing the base of the stem, and three or sometimes four, rather than the usual two leaves with expanded blades. A significant variant of *I. rapunculoides* from the Keiskie Mtns south of Calvinia has long narrow tepals ± 18 × 4 mm, a perianth tube 8.5 mm long and filaments inserted ± 4 mm above the tube base and ± 4 mm long. Elsewhere flowers of *I. rapunculoides* have broader tepals 11–15 × 4.5–6.0 mm, a perianth tube rarely more than 8 mm long, filaments inserted 2–4 mm above the tube base and 2–3 mm long. The anthers of the Keiskie population are also longer, ± 4 mm, compared with 2.3–3.5 mm for *I. rapunculoides*. These plants merit further investigation.

Ixia rapunculoides have been shown to be pollinated by large-bodied anthophorine bees but small empidid flies (Empididae) are frequently found visiting the flowers and likely play a role in pollination. The reward for visiting insects is nectar, small amounts of which are present in the base of the perianth tube.

71. **Ixia robusta** *(G.J.Lewis) Goldblatt & J.C.Manning* in Bothalia 38: 9 (2008a). *I. rapunculoides* var. *robusta* G.J.Lewis: 74 (1962). Type: South Africa. [Northern Cape], Moordenaarspoort, 26 miles [± 40 km] NE of Calvinia, 26 September 1952, *Lewis 2503* (SAM, holo.; BOL, PRE, iso.).

Plants mostly 0.5–1.0 mm high. *Corm* subglobose, mostly 14–18 mm diam., tunics of firm, wiry fibres accumulating in dense mass, with small cormlets at base. *Leaves* usually 4 (5 or 6), lower 3 or 4 lanceolate to subfalcate, mostly 8–14 mm wide, ± ¼–⅓ as long as stem, margins thickened, usually plane, uppermost 1 or 2 leaves sheathing stem below spike. *Stem* erect, sheathed below ground by collar of fibres, with up to 10 short, slender, ascending branchlets subtended by truncate-apiculate bracts and prophylls 0.5–1.0(–2.0) mm long. *Main spike* suberect, mostly 4- to 6-flowered, lateral spikes ascending, mostly 2- to 6-flowered; bracts translucent becoming tinged brown at tips, outer with 3 dark veins, (6–)8–10 mm long, 3-toothed or bluntly 3-lobed, subequal or inner slightly longer, with 2 dark veins and forked apically. *Flowers* ± nodding, pale pink with white cup, faintly acrid-metallic-scented or apparently unscented; perianth tube 7.5–10.2 mm long, widely funnel-shaped, flaring in upper 4–5 mm; tepals subequal, narrowly ovate to subspathulate, (15–)17–20 × 7–9 mm, proximal ± 3 mm forming part of floral cup, spreading distally. *Filaments* ± 4 mm long, inserted ± 3.5 mm above base of tube; anthers 3.5–4.0 mm long, half exserted from tube but included in floral cup, yellow. *Style* dividing opposite middle ⅓ of anthers, branches 1.5–2.0 mm long, extending between anthers. *Flowering time*: late August to late September.

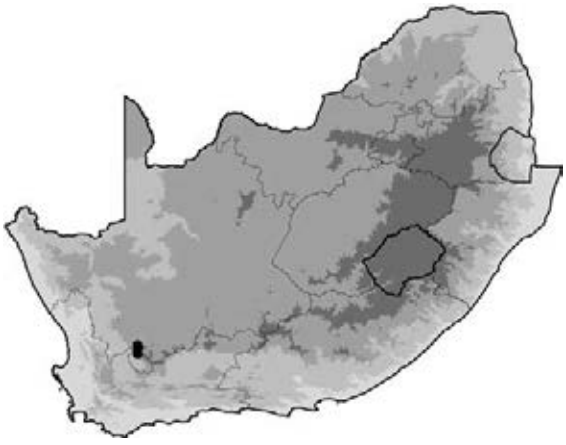
Distribution and ecology: local in Northern Cape in the western Karoo on the plateau and eastern and northern slopes of the Hantamsberg, South Africa; in heavy dolerite-derived clay among dolerite boulders.

Diagnosis: *Ixia robusta* is recognised by its tall stature, up to 1 m high, pink flowers with a white cup, and at least three (and often four) lanceolate basal leaves, the blades thick and leathery to almost succulent. The corms, which are difficult to remove from the rocky ground, are large, and covered with wiry tunics, and the underground part of the stem is enclosed by a collar of coarse fibres, a feature often not preserved in herbarium collections. Closely related *I. rapunculoides* often grows parapatrically with *I. robusta*, sometimes even together, never with any sign of intergradation. Associated with its larger flower, *I. robusta* has anthers ± 4 mm long, the perianth tube is 7.5–10.2 mm long and the style branches are 1.5–2.0 mm long, contrasting with anthers mostly 2.3–3.5 mm long and style branches 0.7–1.0 mm long in *I. rapunculoides*.

72. **Ixia rivulicola** *Goldblatt & J.C.Manning* in Bothalia 38: 9 (2008a). Type: South Africa, Northern Cape, Roggeveld Escarpment, drift across Bo-Vis River at Noudrif Farm, in muddy ground, 11 Oct. 2004, *Goldblatt & Porter 12666* (NBG, holo.; K, MO, PRE, iso.).

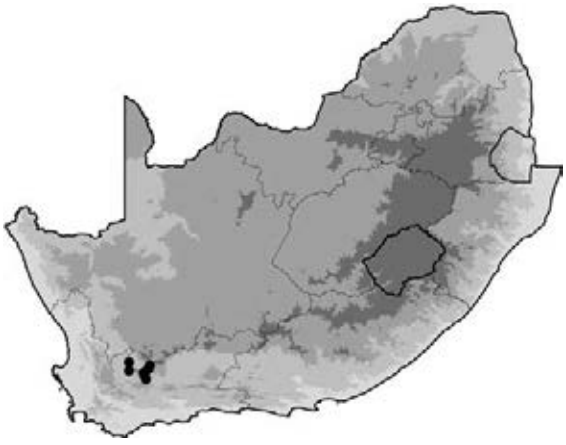
Plants 450–800 mm high. *Corm* subglobose, with 1–few cormlets at base; tunics of submembranous fibres soon disintegrating. *Leaves* 3(4 or 5), lower 2 to 4 narrowly sword-shaped to linear, 3–7 mm wide, margins moderately thickened, straight, usually ± ⅓–½ as long as stem, uppermost leaf sheathing stem, penultimate leaf often sheathing in lower half. *Stem* with 3 to 5 straight, filiform lateral branchlets mostly held at ± 30° to main axis. *Main spike* mostly 2- or 3-flowered; lateral spikes 1- or 2-flowered; bracts translucent, mostly ± 8 mm long, outer with 2 dark veins, inner with 2 dark veins, forked apically. *Flowers* ascending to nearly horizontal, white with pale yellow cup, with strong fruity scent; perianth tube funnel-shaped, 8–9 mm long; tepals subequal, 17–18 × 5.0–7.5 mm, proximal 3–4 mm forming part of floral cup, spreading at right angles to tube distally. *Filaments* 3–4 mm long, included; anthers 4.5–5.5 mm long, lower ½ included in tube. *Style* dividing opposite upper ⅓ of anthers, branches ± 0.8 mm long, extending between anthers. *Flowering time*: mainly October.

Distribution and ecology: restricted to the upper reaches of the Bo-Vis River and its tributaries on the Roggeveld Escarpment in Northern Cape, South Africa; around ponds and in shallow water, a habitat unique in *Ixia*.



Diagnosis: *Ixia rivulicola* is recognised first by the habitat, in streams, pools and marshy ground, but also by the consistently white tepals 17–18 mm long, a tube 8–9 mm long and anthers 4.5–5.5 mm long. The long, narrow leaves are fairly soft-textured and up to half as long as the stem. It is closely related to *I. rapunculoides* which usually has a shorter tube, 5.5–8.0(–10.0) mm long, tepals 11–16 mm long, and anthers 2.3–3.5 mm long. The ascending to horizontally oriented flowers have a pale yellow cup and are particularly sweetly scented. Typical blue-flowered *I. rapunculoides* grows on the slopes above the Bo-Vis River and blooms in August and early September, and is in fruit by the time *I. rivulicola* comes into flower at the end of September or in October. Like other members of the *I. rapunculoides* complex, the flowers are pollinated by a range of large bees.

73. **Ixia lacerata** *Goldblatt & J.C.Manning* in Bothalia 38: 10 (2008a). Type: South Africa, Western Cape, Klein Roggeveld, ±24 km north of N1 on road to Sutherland, dolerite slope, 26 Aug. 2006, *Goldblatt & Porter 12702* (NBG, holo.; K, MO, PRE, iso.).



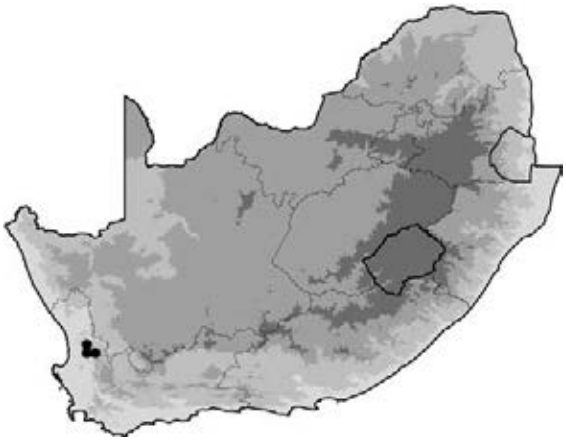
Plants 150–350 mm high. *Corm* subglobose, 14–20 mm diam.; tunics of firm, coarse fibres, with small cormlets at base. *Stem* wiry, sometimes somewhat twisted below spike, simple or with 1 to 3 short, thread-like, twisted branchlets subtended by filiform, forked or lacerate, silvery bracts and prophylls up to 5 mm long, distally spreading to reflexed. *Leaves* 3, lower 2 lanceolate to falcate, 5–10 mm wide, plane, sometimes slightly twisted distally, ± ¼–⅓ as long as stem, margins slightly to moderately thickened, uppermost leaf sheathing stem in lower ½–⅔. *Main spike* (2)3- to 6-flowered, suberect, lateral spikes (1–)3- or 4-flowered; bracts translucent below, becoming rust-coloured in upper ⅓, 6–7 mm long, outer mostly with 5 main veins and 5 attenuate teeth, sometimes slightly lacerate, inner with 2 main and 2 smaller veins, with 2 to 4 attenuate teeth. *Flowers* ± nodding, pale blue-mauve, tepals often whitish at base, with pale yellow cup, weakly rose-scented; perianth tube 10–12(–14) mm long; tepals subequal, (10–)12–14 × 5–6 mm. *Filaments* ± 3 mm long, included; anthers ± 3 mm long, yellow. *Style* dividing opposite middle of anthers, branches ± 1 mm long. *Flowering time*: mainly August to early September.

Distribution and ecology: restricted to the Klein Roggeveld and the Koedoes Mtns in Northern Cape, South Africa; on slopes and flats on shales or mudstones of the Ecca System, or occasionally on rocky, dolerite slopes, remarkably common in years of ample rainfall.

Diagnosis: *Ixia lacerata* is recognised by the nodding pale blue-mauve flowers with a pale yellow cup, a perianth tube 10–14 mm long and unusual outer bracts usually with five major veins and often two smaller veins, terminating in attenuate teeth. The bracts are diagnostic,

Distribution of ***Ixia rivulicola***.

Distribution of ***Ixia lacerata***.



contrasting with related *I. rapunculoides* and most other species of sect. *Morphixia*, which have 1- or 3-veined outer bracts and 2-veined inner bracts, the veins terminating in short, acute or blunt teeth. In addition to the floral differences, the flowering stem has only 1 to 3 branchlets, each bearing 1 to 3(4) flowers, and the branchlets are subtended by forked, thread-like bracts and prophylls that are spreading or directed downward distally, unlike the short, truncate and inconspicuous bracts in most other members of the *I. rapunculoides* complex. Pollination studies have shown that the most common insect visitor is an unnamed long-proboscid fly, *Prosoeca* sp. (Nemestrinidae), also the main pollinator of other moderately long-tubed Iridaceae in the Roggeveld and Klein Roggeveld.

74. **Ixia mollis** *Goldblatt & J.C.Manning* in Bothalia 41: 130 (2011), as new name for *I. flaccida* (G.J.Lewis) Goldblatt & J.C.Manning: 17 (2008a), illegitimate homonym, not *I. flaccida* Salisb. (1796). *I. rapunculoides* var. *flaccida* G.J.Lewis: 74 (1962). Type: South Africa, [Western Cape], Boschkloof, 7 Aug. 1896, *Schlechter 8432* (BOL, holo.; BM, G, K, L, MO, PRE [2 sheets], S, Z, iso.).

Plants 200–350 mm high. *Corm* subglobose, bearing 1–few sessile basal cormlets and rarely a short, filiform stolon; tunics of medium-textured, netted fibres. *Stem* slender-filiform, with 4 to 6 loosely twisted, filiform branchlets up to 35 mm long, spreading at right angles to main axis, subtended by minute, acute bracts and prophylls ± 1 mm long. *Leaves* 3(4), lower 2(3) sword-shaped to linear, 4–9 mm wide, margins hardly thickened, usually ± ½ as long as stem, uppermost leaf sheathing stem. *Main spike* 2- to 4-flowered, lateral spikes 1- to 3-flowered; bracts translucent light brown, outer with 3 dark veins, mostly 5–6 mm long, inner as long or slightly longer than outer, with 2 dark veins, forked at apex. *Flowers* nodding, white or pale blue with white to greenish cup, evidently unscented; perianth tube funnel-shaped or with upper part somewhat urn-shaped, 7–9 mm long; tepals subequal, ± 14 × 3.5–4.5 mm, proximal 3–4 mm forming part of floral cup, spreading distally. *Filaments* 2.5–3.0 mm long, included, inserted 3–4 mm above base of tube; anthers ± 2.5 mm long, half included in tube. *Style* dividing opposite middle of anthers, branches ± 1 mm long, extending between anthers. *Flowering time*: late July to early September.

Distribution and ecology: restricted to the Olifants River Valley and nearby in Western Cape, South Africa; on seasonally moist, south-facing sandy, or sometimes light, loamy clay slopes, among rocks usually in the shade of shrubs and small trees.

Diagnosis: distinguished by the nodding, relatively small, white or pale blue flowers, *Ixia mollis* has tepals ± 14 × 3.4–4.5 mm, a perianth tube 7–9 mm long and anthers ± 2.5 mm long, half included in the tube. The corms bear small cormlets at the base and occasionally a slender stolon and the tunics consist of medium-textured to fine fibres. The nearly linear to narrowly sword-shaped leaves are soft-textured and these, as well as the white or pale blue flowers readily distinguish the species from the closely allied *I. rapunculoides*, which has blue to blue-mauve or sometimes pink flowers with a yellow cup. *Ixia mollis* was confused in the past with what is now *I. sobolifera,* which included pink-flowered plants from the Bokkeveld Plateau and white-flowered plants from the Little Karoo. These plants have soft-textured, short-lived tunics and produce long, ribbon-like stolons and also differ in the longer bracts, 6–10 mm long (vs. 5–6 mm long in *I. mollis*) and, in *I. sobolifera* subsp. *carnea*, a longer perianth tube 9–10 mm long and longer anthers 3–4 mm long.

Distribution of ***Ixia mollis***.

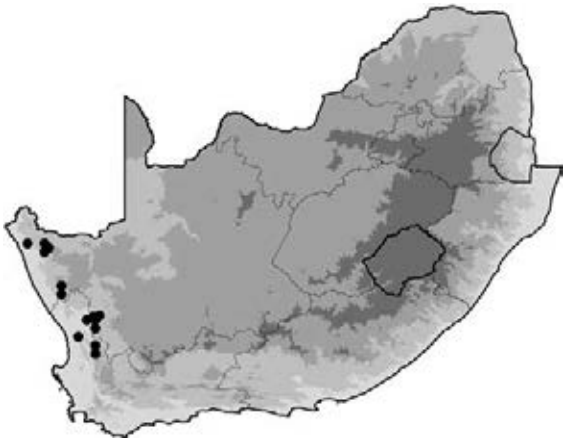
75. **Ixia namaquana** *L.Bolus* in South African Gardening and Country Life 21: 368 (1931b); Goldblatt & Manning: 14 (2008a). *I. rapunculoides* var. *namaquana* (L.Bolus) G.J.Lewis: 76 (1962). Type: South Africa, [Northern Cape], Klipfontein, Sept. 1883, *H. Bolus* as *Herbario Normale Austro-Africana 698* (BOL, lecto., designated by De Vos: 15 (1999); B, G, K, PRE, SAM, Z, iso.).

Plants mostly 300–500 mm high. *Corm* 12–15 mm diam.; tunics of medium-textured to coarse fibres. *Stem* with several short, filiform, twisted lateral branchlets subtended by short bracts and prophylls ± 2 mm long. *Leaves* 3, lower 2 sword-shaped to falcate, mostly 8–18 mm wide, margins thickened and hyaline, sometimes minutely crisped, usually ± ⅓ as long as stem but sometimes shorter, uppermost leaf sheathing stem. *Main spike* 2- or 3-flowered, lateral spikes 1- or 2-flowered; bracts translucent, outer with 3 dark veins, ± 10 mm long, with 3 short, subequal teeth, inner with 2 dark veins, forked at apex. *Flowers* ± nodding, whitish to light mauve, lilac, pale blue or pink with yellow cup edged with a band of short vertical lines, often flushed lilac to mauve outside, violet-scented or unscented; perianth tube 12–16(–18) mm long, narrowly funnel-shaped; tepals subequal, ovate, inner (12–)14–17

× 5–7 mm, outer 6–8 mm, proximal 4–6 mm forming part of floral cup, spreading at right angles to tube in distal 10–12 mm. *Filaments* 4–5 mm long, included; anthers 3.5–4.5 mm long, half exserted from tube but included in floral cup. *Style* mostly dividing opposite upper ⅓ of anthers, branches ± 1 mm long, extending between anthers (in type, dividing at anther tips with branches arching above anthers and 1.5 mm long). *Flowering time*: mainly August to mid-September, rarely October.

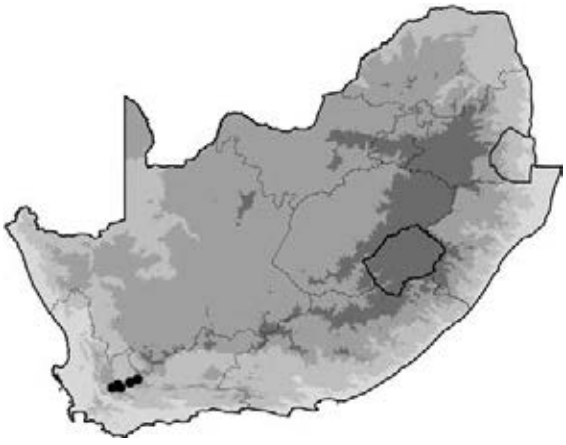
Distribution and ecology: scattered across western Northern and Western Cape, South Africa, occurring in the Richtersveld and northern Namaqualand, the southern Kamiesberg in central Namaqualand, and the Bokkeveld Mtns and northern Cederberg to the south; in sands and gravels derived from granite or sandstone.

Diagnosis: *Ixia namaquana* is readily distinguished in the *I. rapunculoides* complex by the longer perianth tube, mostly 13–16 mm long, short branchlets bearing 1 or 2 flowers each, and corm with tunics of coarse, netted fibres. The flowers are relatively large with tepals mostly 14–16 mm long and anthers 3.5–4.5 mm long. The proximal halves of the tepals form a floral cup that fully encloses the stamens. The flowers are usually sweetly scented but are appear unscented in the Bokkeveld Mtns. Pink-flowered plants with a perianth tube 16–20 mm long from Hex River Pass and nearby identified in the past as *I. namaquana* are a different species, *I. oxalidiflora*, distinguished by the longer perianth tube, suberect rather than horizontally oriented flowers, fully included anthers, and most significantly by the corms with papery to finely fibrous tunics and bearing ribbon-like stolons.



The type of *Ixia namaquana* from Klipfontein near Steinkopf in northern Namaqualand has particularly large flowers, with the tube up to 18 mm long, and the style divides opposite the anther tips with the branches extending above them. The northern populations need additional study.

76. **Ixia oxalidiflora** *Goldblatt & J.C.Manning* in Bothalia 38: 17 (2008a). Type: South Africa, [Western Cape], Hex River Pass, south-facing clay slopes, 2 Sept. 1992, *Goldblatt & Manning 9397* (NBG, holo.; MO, iso.).



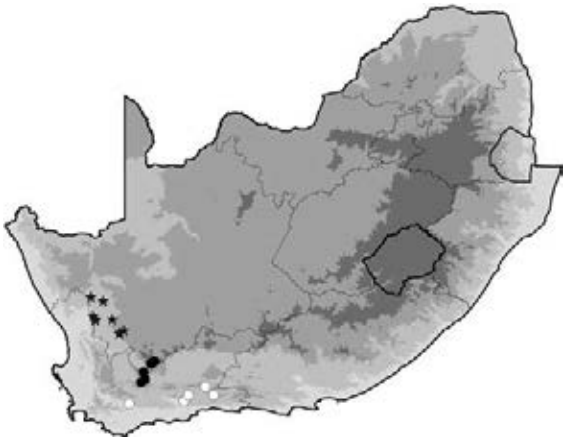
Plants 200–450 mm high. *Corm* 6–8(–10) mm diam., bearing broad, flattened stolons; tunics of fine netted fibres, soon decaying. *Leaves* 3, lower 2 narrowly sword-shaped to linear, fairly soft-textured, 6–12(–15) mm wide, margins straight and not thickened, uppermost leaf sheathing stem. *Stem* usually with 1 or 2 filiform, twisted lateral branches up to 12 mm long. *Main spike* 2- to 4-flowered, lateral spikes 1- or 2-flowered; bracts translucent, outer with 3 dark veins, 10–12 mm long, with 3 subequal acuminate tips, inner 2-veined, forked at apex. *Flowers* ascending to ± upright, purple-pink with white cup, unscented; perianth tube 16–22 mm long, funnel-shaped; tepals subequal, ovate, 14–18 × 6–7 mm, spreading in distal 10–12 mm. *Filaments* ± 4 mm long, included; anthers ± 3.5 mm long, reaching up to 0.5–2.0 mm below mouth of tube. *Style* dividing opposite middle of anthers, branches ± 1 mm long, extending between anthers. *Flowering time*: mid-August to mid-September.

Distribution and ecology: a fairly rare species of interior Western Cape, South Africa, known from the top of Hex River Pass, near Tweedside Station, and at Memorial Hill near Matjiesfontein; mainly on south-trending slopes in clay or loamy soils, the corms typically wedged in crevices of shale rock.

Diagnosis: *Ixia oxalidiflora* stands out in having the stamens fully included in the perianth tube, with the anther tips reaching 0.2–0.5 mm below the tube apex, and the perianth tube itself 16–22 mm long. In related *I. namaquana* only the bases of the anthers are included in the shorter tube, mostly 13–16 mm long. The corms, which have soft-textured tunics bear long stolons, likewise differ from those of *I. namaquana*, which have coarsely fibrous tunics and lack stolons. The

Distribution of ***Ixia namaquana***.

Distribution of ***Ixia oxalidiflora***.



flowers are held upright, a feature only apparent when plants are seen alive, thus unlike the nodding flowers of *I. namaquana*. The purple-pink flowers with a white cup (also described as pale yellow) closely resemble in shape and colouring those of co-occurring *Oxalis heterophylla* DC. (Oxalidaceae) which blooms at the same time.

77. **Ixia sobolifera** *Goldblatt & J.C.Manning* in Bothalia 38: 11 (2008a). Type: South Africa, Northern Cape, north of Matjiesfontein on road to Sutherland, 9 Sept. 2006, *Goldblatt & Porter 12809* (NBG, holo.; MO, PRE, iso.).

Plants (150–)250–750 mm high. *Corm* subglobose, 8–12 mm diam., producing flattened stolons from base; tunics soft, ± papery. *Stem* with 1 to 5 twisted, filiform branchlets subtended by forked, attenuate bracts and prophylls 2–5 mm long. *Leaves* 3, lower 2 linear, often trailing above, (1.5–)2.0–5.0(–8.0) mm wide, ± ½ as long as stem, margins plane, barely thickened, edges flat or concave, uppermost leaf sheathing stem below spike. *Main spike* nodding, 2- to 5(–7)-flowered, lateral spikes nodding, (1)2- to 4(5)-flowered; bracts translucent, or dry and brown distally with age, 6–10 mm long, outer 3-veined, inner 2-veined, forked apically. *Flowers* half to fully nodding, pink or slate-blue with white cup, or white with pale yellow cup, faintly rose- to strongly carnation-scented; perianth tube 5–10 mm long, funnel-shaped, flaring in upper ± 5 mm; tepals subequal, ovate or narrowly ovate, 10–17 × 4.5–7.0 mm, proximal ± 3 mm forming part of floral cup, spreading distally. *Filaments* 2–3 mm long, included; anthers 3.0–4.5 mm long, included or half exserted from tube but included in floral cup, uniformly pale yellow or marked with dark, longitudinal streaks. *Style* dividing opposite or slightly beyond anther tips, branches 1.0–1.5 mm long, usually exceeding anthers when mature. *Flowering time*: August to mid-September.

Distribution and ecology: relatively widespread, extending from the Langberg and Kubiskou ranges northwest of Loeriesfontein in Northern Cape through the Western Karoo and interior Western Cape to the Little Karoo, South Africa (detailed distribution and habitat information is provided under the subspecies).

Diagnosis: recognised by the combination of corms with soft papery (rather than fibrous) tunics and producing prominent, ribbon-like stolons, *Ixia sobolifera* has a main spike bearing 2 to 5(–7), half nodding to half pendent flowers. The tepals are either pink, slate-blue or white and the floral cup white or yellow and the perianth tube is 6–10 mm long. Stems are usually several-branched and the branches are subtended by filiform bracts and prophylls. Three geographic subspecies are recognised, distinguished by relatively small morphological differences. Subsp. *carnea* from the Bokkeveld Plateau and its extensions, the Kubiskou and Langberg, has a pink perianth with white cup, bracts somewhat dry and dark brown at the tips with age and anthers marked with dark longitudinal lines. Subsp. *sobolifera*, from the Klein Roggeveld and nearby, has slate-blue

Distribution of ***Ixia sobolifera*** subsp. ***sobolifera***, ●; subsp. ***albiflora***, ○; subsp. ***carnea***, ★.

flowers and particularly slender stems. Lastly subsp. *albiflora* from the Little Karoo has white, intensely fragrant flowers. Closely related *I. mollis* from the Olifants River Valley has horizontally oriented, white or pale blue flowers, a stem with longer branchlets, and short floral bracts 5–7 mm long (vs. 5–10 mm in *I. sobolifera*). The corm bears subsessile cormlets at the base and has tunics of medium-textured, netted fibres rather different from the soft, papery corm tunics of *I. sobolifera* and long, ribbon-like stolons.

Key to subspecies

1a Perianth pink with yellow throat; perianth tube 9–10 mm long; anthers 3–4 mm long, yellow with dark longitudinal lines on anther lobes . . . . . 77b. subsp. *carnea*

1b Perianth white with pale yellow throat or slate-blue with white throat; perianth tube 5–7 mm long; anthers 2–3 mm long, uniformly yellow:

2a Perianth white with yellow throat; perianth tube 6–7 mm long . . . . . 77c. subsp. *albiflora*

2b Perianth slate-blue with white or pale yellow throat; perianth tube 5–6 mm long . . . . . 77a. subsp. *sobolifera*

77a. subsp. **sobolifera**

Plants with stems slender and drooping above, branchlets mostly 1- or 2-flowered. *Spike* with bracts 7–9 mm long, translucent with dark veins, not turning rust-coloured above with age. *Flowers* slate- or grey-blue with white cup, faintly scented; perianth tube 5–6 mm long, tepals 10–12 × 4.5–5.5 mm. *Filaments* 2–3 mm long; anthers 4.0–4.5 mm long, uniformly yellow; style reaching or exceeding anther tips, branches 1.0–1.5 mm long.

Distribution and ecology: restricted to the Klein Roggeveld and adjacent hills in Northern Cape and the Witteberg and nearby in Western Cape; on stony slopes in sparse vegetation.

Diagnosis: subsp. *sobolifera* is distinguished by its nodding to nearly pendent, slate-blue flowers borne on very slender, arching stems. Unlike pink-flowered subsp. *carnea*, the bracts do not turn dark brown above with age, and the spike and branchlets have one or two, rarely three flowers, fewer than either subsp. *carnea* or the white-flowered subsp. *albiflora*. A distinctive feature of the southern populations of the subspecies is the longer style, which overtops the anthers, and not known elsewhere in the species.

77b. subsp. **carnea** *Goldblatt & J.C.Manning* in Bothalia 38: 13 (2008a). Type: South Africa, Northern Cape, Nieuwoudtville, Glenlyon Farm, dolerite koppies, in bush, 2 Sept. 2001, *P. Goldblatt & L.J. Porter 11810* (NBG, holo.; MO, PRE, iso.).

Plants (150–)250–750 mm high. *Leaves* 3, blades linear, often trailing above, 1.5–3.5 mm wide. *Stem* with 1 to 3 twisted, filiform branchlets. *Main spike* mostly 2- to 4-flowered, lateral spikes 1- to 3(4)-flowered; bracts translucent, becoming brown with age in upper half, outer 8–10 mm long. *Flowers* pale to deep pink with white cup, faintly rose-scented; perianth tube 9–10 mm long, tepals 12–16 × 4.5–6.0 mm. *Filaments* ± 3 mm long, inserted ± 4 mm above base of tube; anthers 3–4 mm long, pale yellow with dark longitudinal lines on thecae; style reaching anther tips.

Distribution and ecology: restricted to the northern end of the range of the species, extending in the Northern Cape from the Langberg in the west to the Bokkeveld Plateau and the Hantamsberg in the east; most often on dolerite-derived clay or on shale slopes but also on sandy tillite soils among sandstone rocks.

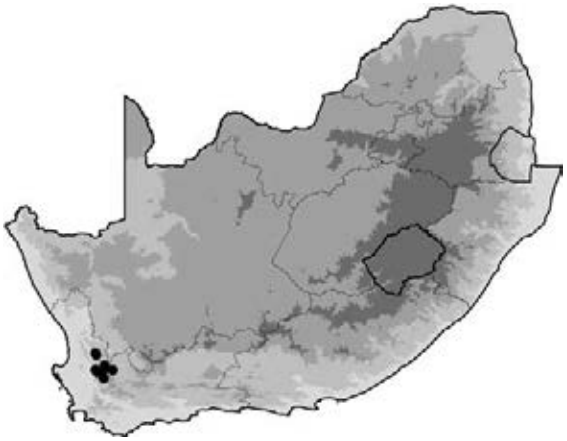
Diagnosis: apart from the pink perianth, for which it is named, anthers of subsp. *carnea* have dark longitudinal lines that contrast with the otherwise yellow colour. Plants are sympatric and bloom at the same time as the longer-tubed *I. namaquana* northwest of Nieuwoudtville and with *I. rapunculoides* in the dolerite hills east of Nieuwoudtville and on the Hantamsberg.

77c. subsp. **albiflora** *Goldblatt & J.C.Manning* in Bothalia 38: 14 (2008a). Type: South Africa, Western Cape, Farm Buffelskloof, 35 km from Dysseldorp on Laudina road, S-facing shale hillside, 12 Sept. 2003, *P. Goldblatt & L.J. Porter 12291* (NBG, holo.; K, MO, PRE, iso.).

Plants 400–650 mm high. *Leaves* linear to narrowly sword-shaped, 4–8 mm wide. *Stem* erect, with 2 or 3(–5) suberect to spreading, filiform branchlets subtended by silvery-translucent bracts mostly 3–4 mm long. *Main spike* 4- or 5(–7)-flowered, lateral spikes (1)2- or 3(–5)-flowered; bracts membranous and translucent, mostly 6–8 mm long. *Flowers* creamy white with pale yellow cup, sometimes flushed grey-mauve outside, nodding, intensely carnation-scented; perianth tube 6–7 mm long, tepals 12–17 × 5.0–7.5 mm. *Filaments* ± 3 mm long; anthers ± 3 mm long, uniformly pale yellow; style reaching anther tips. *Flowering time*: August to mid-September.

Distribution and ecology: restricted to the central Little Karoo in Western Cape, and known from just a handful of sites, mostly south and east of Oudtshoorn, with one record from the northern foothills of the Swartberg, east of Prince Albert; on stony, clay loam slopes.

Diagnosis: subsp. *albiflora* is distinguished from its sister subspecies mainly by the strongly carnation-scented flowers with white tepals and a yellow cup, and also by the 4- or 5(–7)-flowered main spike, perianth tube 6–7 mm long (perianth tube 9–10 mm long in subsp. *carnea* and 5–6 mm in subsp. *sobolifera*), and often broader leaves, 4–8 mm wide. Early collections of subsp. *albiflora* were included in what is now *I. mollis,* which occurs in the Olifants River Valley, well to the west.



78. **Ixia contorta** *Goldblatt & J.C.Manning* in Bothalia 38: 21 (2008a). Type: South Africa, Western Cape, Cold Bokkeveld, low hill east of Farm Waboomsrivier, well-drained sandy ground, 17 Sept. 2006, *P. Goldblatt & L.J. Porter 12854* (NBG, holo.; MO, PRE, iso.).

[*Ixia rapunculoides* var. *rigida* sensu G.J.Lewis: 77 (1962), but excluding the type.]

Plants (70–)100–300 mm high. *Corm* subglobose, 10–14 mm diam., bearing 1–few sessile cormlets at base; tunics of medium-textured to fine, dark, wiry, netted fibres. *Leaves* 3, lower 2 linear to narrowly sword-shaped or falcate, (2–)3–5 mm wide, ± ⅓ as long as stem, margins and main vein moderately thickened, uppermost leaf sheathing lower ½ of stem. *Stem* suberect, usually with 1 to 3 short, twisted branchlets mostly held at 60–90° to main axis. *Main spike* conspicuously flexuose, bent at base and inclined to ± horizontal, 2- to 6-flowered, lateral spikes 1- to 6-flowered; bracts mostly 7–9 mm long, translucent, often flushed brown or purple, outer 3-veined, bluntly 3-lobed apically, inner 2-veined, forked apically. *Flowers* upright, purple (or said to be blue) with a yellow cup sometimes edged with a band of dark purple, unscented; perianth tube funnel-shaped, 9–13(–14) mm long; tepals subequal, 9–12 × (4.5–)6.0–8.0 mm. *Filaments* ± 3 mm long, included; anthers 3–4 mm long, lower ⅓–½ included in tube. *Style* dividing opposite middle of anthers, branches ± 1 mm long, extending between anthers. *Flowering time*: mid-September to October.

Distribution and ecology: centred in the Cold Bokkeveld, extending north to the Cederberg and east to Touws River in Western Cape, South Africa; in well-drained, sandy ground.

Diagnosis: *Ixia contorta* is distinguished among species of sect. *Morphixia* with included filaments by the markedly flexuose spikes and by the main axis strongly flexed below the first flower, thus inclined to nearly horizontal. The purple flowers (also sometimes described as blue or

Distribution of ***Ixia contorta***.

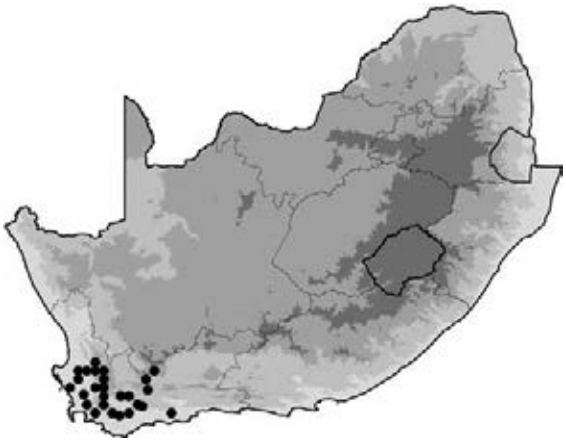
lilac) have a yellow cup sometimes edged in dark purple, and are held upright on the spikes. The perianth tube is 9–13(–14) mm long and the tepals are 9–12 mm long. The very different appearance of the flowers suggests that these plants are not immediately allied to *I. rapunculoides* with which they were first associated and its relationship to the *I. rapunculoides* complex seems questionable. Plants from the north of the range near Alberta Farm, and in the Cederberg stand out in having a longer and sometimes wider perianth tube, 12–14 mm long.

Plants are usually fairly short, seldom exceeding 150 mm, but collections from Gydo Pass (e.g. *Leipoldt 3023*) are taller, some reaching 300 mm. Typical *Ixia contorta* has also been collected on Gydo Pass and it seems likely that the taller plants with narrow leaves are not simply a local variant of the species but hybrids, the result of crossing with *I. divaricata*, which also grows there. The longer, narrower leaves, paler flower colour and slightly larger perianth in these plants may also reflect the influence of genes of *I. divaricata*.

Ser. **Capillares** *Goldblatt & J.C.Manning*, new series. Type: *Ixia capillaris* L.f.

Plants with leaves plane, linear, with main vein not raised when fresh. *Flowers* blue-mauve, pink or white; perianth tube short and funnel-shaped or elongate and cylindric. *Filaments* sometimes unilateral, shortly exserted or included.

79. **Ixia capillaris** *L.f.*, Supplementum plantarum: 92 (1782); Goldblatt & Manning: 117 (2008b). *Morphixia capillaris* (L.f.) Ker Gawl.: 106 (1827). *I. gracilis* Salisb.: 37 (1796), illegitimate superfluous name for *I. capillaris* L.f. *Hyalis gracilis* Salisb.: 317 (1812) illegitimate name. Type: South Africa, [Western Cape], without precise locality, collected c. 1773, *Thunberg s.n.* (UPS-THUNB 935 & 936, syn.).



Ixia capillaris var. *gracillima* Ker Gawl.: t. 570 (1802b). Type: South Africa, without precise locality, illustration in Ker Gawl.: t. 570 (1802b).

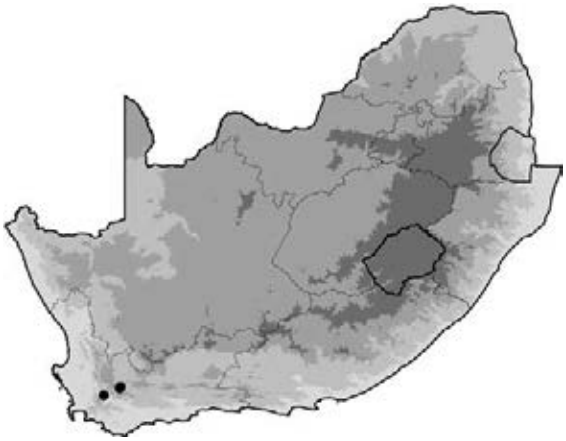
Ixia tenella Klatt: 396 (1882). Type: South Africa, without precise locality or date, *Zeyher 557* (B: Herb. Lubeck, believed destroyed, drawing at S, not seen).

Plants 200–350(–500) mm high, sheathed at base by chestnut-brown (green) cataphylls. *Corm* globose, 8–12(–15) mm diam.; tunics of fine to medium-textured, netted fibres. *Stem* slender, usually with thin collar of fibres around base; usually with 1 to 3 lateral branches, rarely unbranched, then with 1 or more scale-like bracts on stem; branchlets mostly 8–15 mm long, filiform, curving outward, subtended by translucent, irregularly lobed, attenuate bracts and prophylls 2–3 mm long. *Leaves* 3, lower 2 linear, 1.2–2.0 mm wide, ⅓–⅔ as long as stem, main vein not raised when fresh, margins occasionally slightly raised, uppermost leaf sheathing stem, sometimes to base of spike. *Spike* drooping above, (1)2- or 3-flowered, lateral branchlets 1- or 2(3)-flowered; bracts translucent with dark veins, 7–10 mm long, outer 3-toothed, inner notched apically. *Flowers* ± nodding, pale blue to pale mauve, white or creamy yellow, evidently unscented; perianth tube funnel-shaped, (4–)5–7(–8) mm long; tepals subequal, 11–15 × 4–7 mm, spreading. *Filaments* ± 5 mm long, usually exserted 1–2 mm from tube, rarely reaching only to mouth of tube; anthers (3–)4–5 mm long. *Style* usually dividing between middle and upper third of anthers, branches 1–2 mm long. *Flowering time*: mainly late July to late September.

Distribution and ecology: extending in Western Cape, South Africa, from the Piketberg and Cold Bokkeveld in the north to Bot River in the south and through the southern Cape to Riversdale; on clay slopes, usually in wetter sites, thus often on south-facing slopes.

Diagnosis: *Ixia capillaris* is distinguished by the narrow, linear leaves up to 2 mm wide, corm tunics of fine, netted fibres and a main spike with 1 to 3 flowers. Branchlets when present are very short and 1- or 2-flowered. The pale blue or occasionally creamy yellow flowers have a perianth tube ± 5 mm long, enclosed by

Distribution of ***Ixia capillaris***.

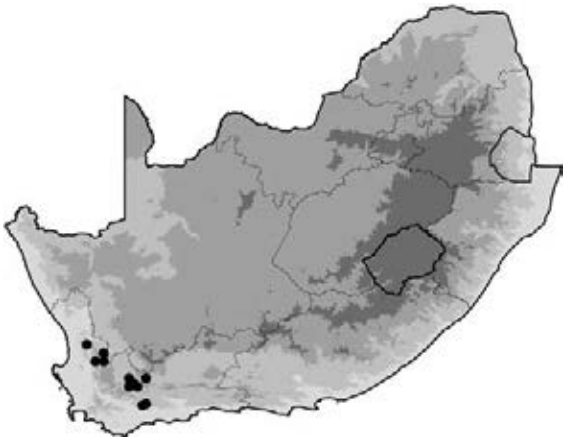


the translucent floral bracts, 6–8 mm long, the flowers, excluding the ovary, are ± 20 mm long. The plants typically have a prominent dark brown cataphyll, a feature more prominent in the northern populations of the species and the upper leaf sheathes the stem for ± half its length. The type material is readily matched by plants from the Western Cape mountains, long known by the name, that have filaments exserted 1–2 mm and anthers held in a column 4.0–4.5 mm long and a style dividing opposite the upper third of the anthers into short branches 1–2 mm long. *Ixia capillaris* is most likely to be confused with *I. exiliflora*, specimens of which were often included in the past as that species. Whereas *I. capillaris* has flowers with a perianth tube 4–7, rarely 8 mm long, and tepals about twice as long as the tube, *I. exiliflora* has a perianth tube 8–10 mm long, and tepals about as long as the tube. The bases of the anthers of *I. exiliflora* are included in the tube but those of *I. capillaris* have anthers that are normally exserted 1–2 mm, or rarely barely exserted on included filaments.

80. **Ixia exiliflora** *Goldblatt & J.C.Manning* in Bothalia 38: 119 (2008b). Type: South Africa, Western Cape, ± 0.8 km S of turnoff to Montagu from N1, flat plateau, 3 200 ft [± 1 050 m], 25 Aug. 2006, *Goldblatt & Porter 12688* (NBG, holo.; K, MO, PRE, iso.).

Plants 250–700 mm high, with green cataphylls becoming dry distally. *Corm* subglobose, 8–12 mm diam., with small cormlets at base; tunics of fine fibres. *Stem* usually with 2 or 3 branchlets subtended by bracts and prophylls 3–4 mm long, acute to attenuate, translucent white. *Leaves* 3, lower 2 linear, reaching lower ⅓ to middle of stem, 1.0–1.7 mm wide, loosely twisted in upper ½, main vein not evident when alive, slightly raised when dry. *Spike* with main axis (2)3- or 4-flowered, lateral spikes (1)2- or 3-flowered; bracts 6–8 mm long, translucent, outer 3-veined and 3-toothed, inner 2-veined, 2-toothed. *Flowers* nodding, grey-blue to dingy white with creamy yellow cup, with faint rose scent; perianth tube narrowly funnel-shaped, 8–10 mm long; tepals ovate, 8–10 × 4–5 mm. *Filaments* 3–4 mm long, included; anthers 3.5–4.0 mm long, half included in tube and entirely within floral cup, yellow. *Style* dividing close to anther tips, branches ± 1.3 mm long, when fully expanded often shortly exceeding anthers. *Flowering time*: July to mid-September.

Distribution and ecology: restricted to the Laingsburg, Montagu and Worcester Districts of Western Cape, South Africa, extending from the hills north of Worcester and the heights east of Hex River Pass to near Matjiesfontein; on loamy clay soils in stony ground, sometimes with sandstone bedrock.



Diagnosis: at first appearing to be a slightly smaller-flowered variant of the widespread, short-tubed *Ixia capillaris*, *I. exiliflora* is distinguished by the longer perianth tube 8–10 mm [vs. (4–)5–7(–8) mm in *I. capillaris*] and anthers partly included in the tube, whereas the filaments are usually exserted ± 2 mm in *I. capillaris*. The partly included anthers recall the *I. rapunculoides* complex of species but the very different, narrow leaves and small corms with finely fibrous tunics, as well as the smaller flowers, make it clear that the included filaments are convergent. Plants from near Simonskloof, west of Koo, stand out in having white flowers with a yellow cup, but otherwise closely resemble blue-flowered *I. exiliflora* and have the characteristic short stamens and partly included anthers of the species.

Distribution of ***Ixia exiliflora***.

81. **Ixia dieramoides** *Goldblatt & J.C.Manning* in Bothalia 38: 120 (2008b). Type: South Africa, Western Cape, north of N1 between Matjiesfontein and Touws River, sandstone outcrop, 27 Aug. 2006, *Goldblatt & Porter 12713* (NBG, holo.; K, MO, PRE, BOL, iso.).

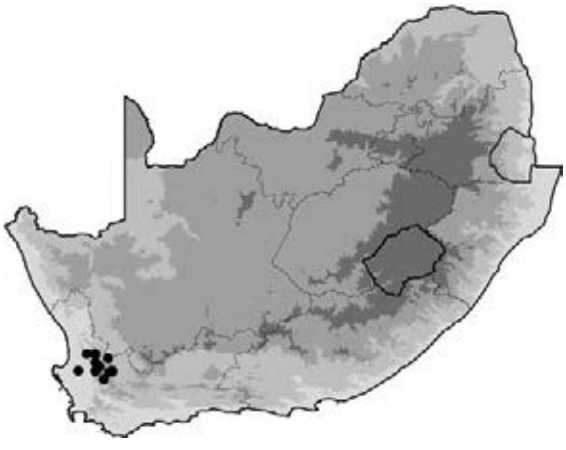
Plants 350–700 mm high, with a sparse collar of fibres around stem base and green or brown cataphylls often dry distally. *Corm* subglobose, 9–14 mm diam., bearing small cormlets at base; tunics of fine fibres. *Stem* sometimes inclined, often nodding above, with 1 to 3 short lateral branchlets up to 10 mm long, occasionally unbranched, bracts and prophylls subtending branchlets lanceolate to attenuate 3–8 mm long, silvery-translucent. *Leaves* 3, lower 2 linear, leathery, reaching between middle and upper ⅓ of stem, ± 1.2–2.0 mm wide, loosely twisted in upper ½, main vein not evident when alive, slightly raised when dry and lying closer to abaxial margin. *Spike* with main axis (1)2- or 3(4)-flowered, lateral branchlets 1- or 2-flowered; bracts translucent, (8–)9–11 mm long, outer 3-veined and 3-toothed, inner sometimes slightly longer than outer, 2-veined and 2-toothed. *Flowers* half nodding, pale mauve-blue to watery lilac or ± violet with pale yellow cup, often sweetly scented; perianth tube 13–18(–22) mm long, widening ± uniformly from base, 5–6 mm diam. at mouth; tepals ovate, outer 13–18 × 7–9 mm, inner 11–14 × 5–8 mm, ascending below. *Filaments* 3–6 mm long, included or rarely barely exserted ± 1 mm from tube, included in floral cup; anthers 2.5–3.5 mm long, yellow, exserted or bases included. *Style* dividing opposite lower to middle ⅓ of anthers, branches 1–2 mm long, when fully extended not reaching anther tips. *Flowering time*: early August to early October.

Distribution of ***Ixia dieramoides***.

Distribution and ecology: fairly common on south-facing slopes of the Bonteberg and Voetpadsberg north and west of Touws River in Western Cape, South Africa, also recorded locally in the southern Cederberg and Little Karoo; on stony sandstone slopes.

Diagnosis: with corms with fine, netted tunics and narrow, leathery leaves of the *Ixia capillaris* type, *I. dieramoides* is recognised mainly by the larger flowers with a tube 13–18(–22) mm long and with filaments and often the bases of the anthers included in the tube. The smaller flowers of *I. capillaris* have a tube (4–)5–7(–8) mm long, tepals spreading from the base and filaments typically exserted 1–2 mm. Unlike *I. capillaris*, the flowers are often faintly scented. Well-grown plants usually reach 600 mm high, thus extending substantially above the surrounding vegetation, which may be only 350 mm high. In dry, stony ground in poor soils, plants may be just 250 mm high, have one or two flowers and may be unbranched. Seen from a distance, the flowering spikes nodding in the breeze resemble species of *Dierama*.

Ixia dieramoides from the Cederberg has short, included filaments 2.5–5.0 mm long, as well as shorter anthers and style branches.



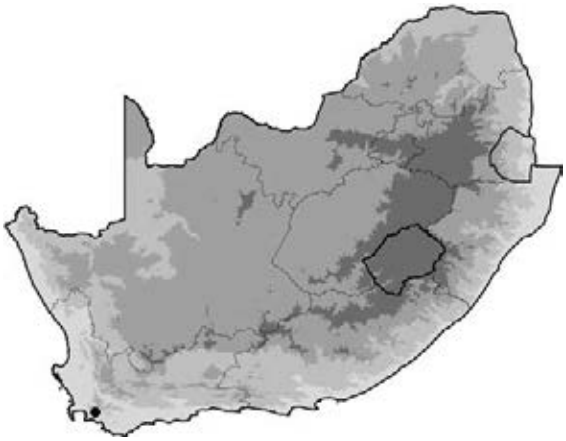
82. **Ixia pauciflora** *G.J.Lewis* in Journal of South African Botany 28: 88 (1962); Goldblatt & Manning: 121 (2008b). Type: South Africa, [Western Cape], Cold Bokkeveld, north of Waboomsrivier, 2 Sept. 1956, *Barker 8635* (NBG, holo.).

Plants 150–300(–400) mm high, with chestnut-brown cataphylls and collar of fibres around base. *Corm* 9–14 mm diam.; tunics of fine, dark fibres. *Stem* usually unbranched, then often with a node bearing a short membranous scale, or with 1 or 2(–4) short branchlets up to 10 mm long, subtended by thread-like, attenuate bracts and prophylls 4–8 mm long. *Leaves* 3, lower 2 linear, leathery, ± 1.8 mm wide; uppermost leaf sheathing stem often to base of spike. *Main spike* 1- or 2(3)-flowered, branchlets 1(2)-flowered; bracts 9–14 mm long, outer 3-veined and 3-toothed, inner 2-veined and 2-toothed. *Flowers* nodding, zygomorphic (?or sometimes radially symmetric) with unilateral stamens, pale blue to blue-mauve, whitish or palest yellow, pale yellow in throat, tepals spreading distally, proximal 3 mm directed forward and forming part of floral cup, odourless or faintly scented; perianth tube expanding uniformly from base to apex, 15–18 mm long; tepals subequal, 16–18 × 8–10 mm, ascending in lower ⅓, spreading above. *Filaments* unilateral, 12–13 mm long, exserted 2–6 mm; anthers (4–)5–6 mm long, horizontal, facing dorsal tepal. *Style* dividing opposite lower ⅓ of anthers, branches 3.0–4.5 mm long, extending between anthers. *Flowering time*: mid-August to mid-September.

Distribution and ecology: restricted to the interior mountains of Western Cape, South Africa, extending from the Cederberg near Algeria south through the Cold Bokkeveld to Gydo Pass; in seasonally moist sites on rocky sandstone slopes or sometimes on loamy clay.

Diagnosis: *Ixia pauciflora* typically has just one or two flowers on slender, often unbranched stems, or with one or two (rarely to four) short branchlets. The flowers are relatively large, having tepals 16–18 mm long, ± as long as the flared perianth tube, long filaments exserted 2–6 mm from the tube, and anthers 4–6 mm long. The stamens on fully open flowers are unilateral and are held horizontally with the anthers facing the dorsal tepal, a feature impossible to determine from pressed specimens. Vegetatively, the species is virtually identical to the more common *I. capillaris* in its two linear leaves, small corms with finely fibrous tunics, a collar of fine fibres around the underground part of the stem, and dry, chestnut-brown cataphylls. Blooms of *I. capillaris* are radially symmetric and have a perianth tube 4–8 mm long, ± half as long as the tepals, and filaments ± 5 mm long, usually exserted 1–2 mm from the tube.

Ixia pauciflora also closely resembles the local Villiersdorp endemic, *I. reclinata*, in its flower, including the unilateral stamens, extended horizontally with declinate anthers, but the latter has longer filaments, exserted 8–10 mm (vs. 2–6 mm in *I. pauciflora*). *Ixia reclinata*



Distribution of ***Ixia pauciflora***.

also lacks the collar fibres around the stem base present in *I. pauciflora*, the stems typically have one or two branchlets, and the cataphylls are green or partly membranous when alive and not dry and brown. *Ixia reclinata* also differs in having the bracts and prophylls subtending the branchlets short and obtuse to subacute, quite different to the fine, thread-like bracts and prophylls of the remaining species of the *I. capillaris* group.

83. **Ixia reclinata** *Goldblatt & J.C.Manning* in Bothalia 38: 123 (2008b). Type: South Africa, Western Cape, Caledon, hills south of Theewaterskloof Dam, Farm Cranesfield, north of Draaiberg road, stony shale outcrops, 24 Aug. 2006, *Goldblatt, Manning & Porter 12686* (NBG, holo.; K, MO, PRE, S, iso.).

Plants 300–450 mm high. *Corm* 10–12 mm diam.; tunics of fine to medium-textured fibres. *Stem* with 1 or 2(3) short branchlets subtended by broad, obtuse to subacute bracts often with dark central vein, 2–3 mm long, exceeding prophylls. *Leaves* 3, lower 2 linear, leathery, ± 1.5 mm wide, main vein not evident when alive, when dry visible and close to abaxial margin, margins hyaline when dry; uppermost leaf entirely sheathing, reaching to shortly below first branch or with a free tip reaching middle of spike. *Spike* (1)2- or 3-flowered; branchlets 1- to 3-flowered; bracts translucent brown, 8–13 mm long, outer shortly 3-toothed, inner forked at apex. *Flowers* nodding, zygomorphic with declinate stamens, white suffused with blue-mauve, pale yellow in throat, with age veins becoming dark, faintly sweet-scented; perianth tube funnel-shaped, 13–15 mm long; tepals 16–21 × 8.5–11.0 mm, spreading, inner slightly wider than outer. *Filaments* 11–12 mm long, unilateral, exserted 8–10 mm from tube; anthers 4–5 mm long, horizontal, facing dorsal tepal. *Style* dividing just below to opposite lower ⅓ of anthers, branches 4.5–5.0 mm long. *Flowering time*: mid-August to early September.

Distribution and ecology: restricted to the low hills south of Theewaterskloof Dam near Villiersdorp in Western Cape, South Africa; one of the most threatened species in the genus with populations reduced to narrow strips of native renosterveld in rough and rocky clay ground among ploughed land and pasture.

Distribution of ***Ixia reclinata***.

Diagnosis: *Ixia reclinata* has linear leaves typical of the *I. capillaris* group but considerably larger flowers with a perianth tube up to 15 mm long and spreading tepals forming a flower ± 40 mm in diameter. The style divides just below to opposite the bases of the anthers and has branches ± 5 mm long, unusual for the complex. This contrasts with blue-mauve (or pale yellow) flowers with a tube up to 8 mm long, flower diameter of ± 20 mm, style dividing opposite the upper third of the anthers and with branches < 1.5 mm long in *I. capillaris*. The flowers of *I. reclinata* are white, suffused with blue-mauve and zygomorphic, having unilateral stamens with parallel filaments extended horizontally with the anthers held closely together and facing upward. Unilateral stamens are rare in *Ixia* but are known in *I. pauciflora* of the *I. capillaris* group, to which *I. reclinata* appears to be most closely related. In *I. pauciflora* the stems are usually unbranched, the pink flowers have filaments exserted only 2–5 mm and the style usually divides opposite the lower third of the anthers. Stems of *I. pauciflora* are typically sheathed below by a collar of fibres, a feature uncommon in *Ixia*, but also present in the *I. capillaris* group in *I. dieramoides*.

Sect. 4. **Dichone** *(Salisb. ex Baker) Goldblatt & J.C.Manning* in Bothalia 29: 63 (1999). *Tritonia* sect. *Dichone* Salisb. ex Baker: 163 (1877). *Tritonia* subg. *Dichone* (Salisb. ex Baker) Baker: 190 (1892). *Tritonixia* sect. *Dichone* (Salisb. ex Baker) Klatt: 357 (1882). *Ixia* subg. *Dichone* (Salisb. ex Baker) G.J.Lewis: 150 (1962). Type: *Ixia scillaris* L., lectotype designated by Goldblatt & Manning: 89 (2012a) [Lewis: 159 (1962) and Goldblatt & Manning: 63 (1999) listed *I. crispa* L. (or its synonym *I. erubescens* Goldblatt) as the type but only *Tritonia undulata* (with its presumed synonym *I. crispa*) and *I. scillaris* were included by Baker in the section when it was first validly described].

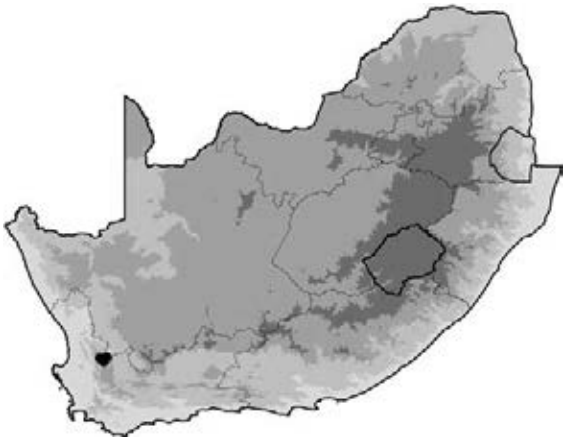
[*Dichone* Lawson ex Salisb.: 320 (1812), invalid name without description.]

[*Agretta* Eckl.: 23 (1827), invalid name without description.]

Corm as in *Ixia*; stolons with a terminal cormlet produced in *I. flagellaris*. *Leaves* as in *Ixia* but sometimes only two and then lower with expanded blade and upper largely to entirely sheathing. *Spike*: outer bracts with (1)3 main veins, acutely 3-toothed, 3-lobed, or

1-toothed. *Flowers* pink to magenta or mauve (rarely white), tepal bases white or yellow edged darker pink (with dark centre in *I. brevituba*); perianth tube usually relatively short, filiform below and clasping style, sometimes funnel-shaped with upper part flared. *Stamens* symmetrically disposed or unilateral and reclinate, filaments inserted at apex of narrow part of tube, filiform or flattened; anthers straight and linear to oblong or short and suborbicular with vestigial connective, thecae fully or incompletely dehiscent, then splitting from base. *Style* dividing at mouth of tube opposite or just above base of filaments, branches filiform-tubular and involute, stigmatic only at tips, straight or falcate-recurved.

Species 17: southwestern South Africa.



Ser. **Euanthera** *Goldblatt & J.C.Manning* in Bothalia 42: 90 (2012a). Type: *Ixia micrandra* Baker.

Plants with leaves plane, lanceolate to linear. *Flowers* sometimes nodding, blue-mauve, pink or white; perianth tube short and funnel-shaped or elongate and cylindric. *Filaments* symmetrically arranged, partly exserted; anthers longitudinally dehiscent. *Style* with branches straight or falcate.

84. **Ixia altissima** *Goldblatt & J.C.Manning* in Bothalia 42: 90 (2012a). Type: South Africa, Western Cape, Wuppertal, Gonnafontein, seep in sandstone ground among *Kniphofia*, 900 m, 5 Dec. 2005, *Pond 303* (NBG, holo.).

Plants 0.9–1.2 m high. *Corm* 15–18 mm diam.; mature tunics not known. *Stem* simple or with 1 or 2 branches subtended by translucent, attenuate bracts and prophylls up to 8 mm long. *Leaves* 4, lower 3 ± basal, reaching to ± middle of stem, blades linear to linear-sword-shaped, (3–)4–10 mm wide, firm-textured, margins and main vein and often a pair of secondary veins thickened and hyaline (at least when dry), uppermost leaf largely sheathing. *Main spike* slender, weakly flexuose, 14- to 20-flowered, lateral spikes 6- to 14-flowered; bracts dry, membranous, translucent, flecked with brown in upper half, ± 7 mm long, outer usually with 3 prominent veins and 3-toothed, inner bracts sometimes slightly shorter than outer, 2-veined and 2-toothed. *Flowers* rotate, mauve-pink; perianth tube narrowly funnel-shaped, ± 4 mm long, filiform and clasping style below, flared in distal ± 2 mm; tepals spreading, oblong-ovate, 12–13 × ± 4 mm. *Filaments* inserted at base of wide part of tube, ± 4 mm long, ± white; anthers oblong, ± 3 mm long, dehiscing fully, yellow. *Style* dividing opposite middle ⅓ of anthers, branches ± 2 mm long, falcate, tubular, arching outward between or shortly overtopping anthers. *Flowering time*: November to mid-December.

Distribution and ecology: known from two sites in the central and southern Cederberg in Western Cape, South Africa, the Matjies River Nature Reserve and Gonnafontein to the south; along streambanks or in marshy seeps on sandstone derived soil.

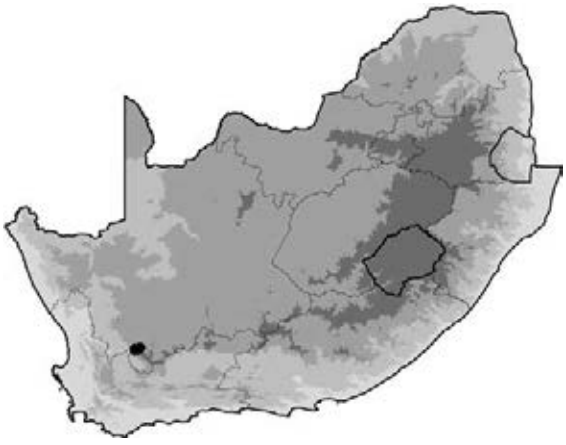
Distribution of ***Ixia altissima***.

Diagnosis: a tall plant, sometimes standing over 1 metre high and flowering late in the season, well into December, *Ixia altissima* has anthers with the vestigial connective and involute style branches, stigmatic only at the tips, characteristic of sect. *Dichone* but the funnel-shaped perianth tube with the filaments inserted in the middle of the upper part of the tube are unusual for the section, in which other species have the tube virtually filiform throughout. The perianth tube, only ± 4 mm long, and the pale floral bracts are reminiscent of two Roggeveld species of the section, *I. rigida* and *I. trifolia*, the former also flowering relatively late in the season, often in November. Both share with *I. altissima* relatively unspecialised, longitudinally dehiscent anthers. *Ixia altissima* seems most like *I. rigida*, also a tall plant, up to 600 mm high, which has flowers with a similarly funnel-shaped perianth tube 2–3 mm long and silvery-translucent floral bracts. This contrasts with the slightly longer perianth tube, ± 4 mm long, and shorter anthers just 3 mm long in *I. altissima*, which is also unusual in the section in having the style dividing opposite the middle of the anthers.

85. **Ixia rigida** *Goldblatt & J.C.Manning* in Bothalia 42: 91 (2012a). Type: South Africa, Northern Cape, ± 38 km north of Sutherland to Middelpos, Farm Geelhoek, rocky dolerite slope with red clay soil, 3 108 ft [950 m], 7 Sept. 2006, *Goldblatt & Porter 12796* (MO, holo.; NBG, iso.).

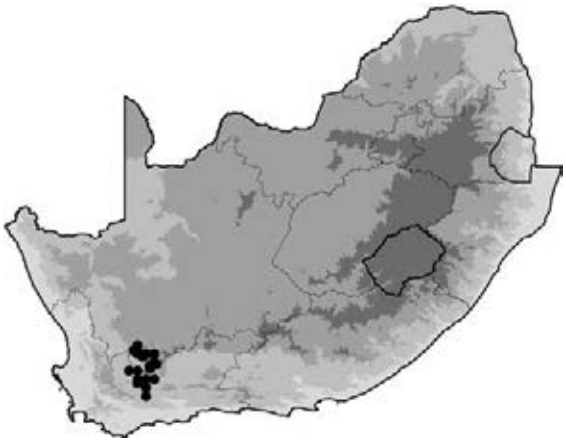
Plants (150–)300–600 mm high. *Corm* 12–18 mm diam.; tunics of firm, relatively hard fibres. *Stem* usually with 2 or 3 ± erect branches held close to axis, sheathed at base by firm, chestnut-brown cataphylls, combining with old corm tunics and leaf bases to form collar around base. *Leaves* (3–)5 to 7, lower (2)3 to 6 with expanded blades, sword-shaped to ± linear, (3–)5–8 mm wide, main vein, margins, and often secondary vein pairs moderately thickened, hyaline when dry, upper 1 or 2 leaves sheathing lower ⅓ to middle of stem. *Main spike* weakly flexuose, nodding in bud, mostly 8- to 15-flowered, lateral spikes with fewer flowers; bracts

membranous, silver-translucent, ± 5.5–7.0 mm long, outer with prominent brown or purple central vein and few secondary veins not reaching upper margin, acute or with 2 obscure lateral lobes, inner 2-veined and acutely 2-toothed. *Flowers* rotate, pale pink, darker at tepal bases and ± white in throat, sweetly rose-scented; perianth tube funnel-shaped, ± 2.5–3.0 mm long, filiform and clasping style in basal 1.5 mm or less, widely flared distally for up to 1 mm; tepals spreading, ovate-oblong, ± 12(–15) × 5(–7) mm, obtuse. *Filaments* ± 1.5(2.5) mm long, ± white; anthers oblong to linear, 3–4(5) mm long, slightly recurved basally, thecae subacute at base, dehiscing fully, yellow. *Style* dividing at base of filaments, branches ± straight, 2.0–3.0(3.5) mm long, ± filiform-tubular. *Flowering time*: September to mid-November.



Distribution and ecology: restricted to the Roggeveld Escarpment in Northern Cape, South Africa, the Farms Fransplaas, Quaggasfontein, Uitkyk, Houdenbek and a short distance inland northwest of Sutherland on the Farm Geelhoek; on dolerite outcrops in rocky ground in the heavy red clay.

Diagnosis: *Ixia rigida* is easily recognised by the moderately tall stem up to 600 mm high with 2 or 3 upright branches held close to the axis and the silvery-translucent floral bracts subtending very short-tubed flowers, the tube up to 2.5 mm long with the narrow portion up to ± 1.5 mm long. Plants have up to seven leathery leaves with prominently thickened margins, main and secondary veins. *Ixia rigida* was until 2012 associated with *I. brevifolia*, but this is now understood to be a separate species. Although fairly uniform across its range populations inland and flowering three to four weeks earlier than those along the edge of the escarpment, thus in September, have slightly larger flowers and less fibrous leaves. The escarpment populations mostly have 6 or 7 leaves, typically 5–7 mm wide, tepals ± 12 × 5 mm, anthers ± 3 mm long, and style branches ± 2 mm long. The inland populations have 4 or 5 leaves, mostly 7–8 mm wide, tepals ± 14–16 × 6–8 mm, slightly longer filaments, anthers 4(5) mm long, and style branches ± 3.5 mm long. The bracts of the inland plants also stand out in their darker purple veins. Too little is known about *I. rigida* to assess the significance of this variation.



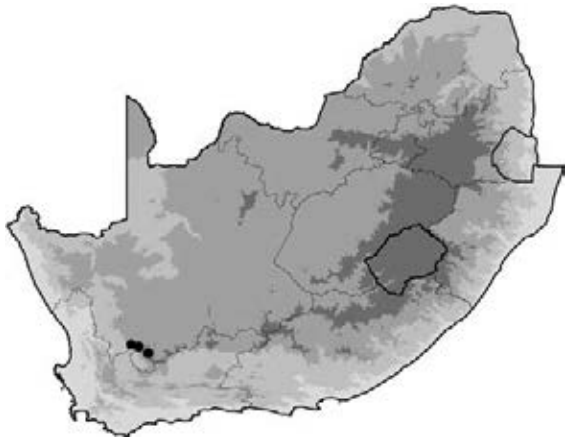
86. **Ixia trifolia** *G.J.Lewis* in Flowering Plants of South Africa 14: t. 543 (1934); Lewis: 171 (1962); Goldblatt & Manning: 92 (2012a). Type: South Africa, [Western Cape], Tweedside, cultivated in Cape Town, Sept. 1932, *Lewis s.n.* (Nat. Bot. Gard. 2706/32 in BOL, lecto., designated by Goldblatt & Manning: 91 (2012a); BOL, K, PRE, SAM, isolecto.).

Plants mostly 150–300 mm high. *Corm* mostly 10–18 mm diam.; tunics of coarse fibres, vertical members often forming claw-like ridges. *Stem* usually with 1 or 2(3) short branches, or simple. *Leaves* 3 or 4(5), lower 2 or 3 with expanded blades, lanceolate to falcate, ½–⅔ as long as stem, (2.5–)5.0–8.0(–12.0) mm wide, main vein and margins moderately thickened, upper 1(2) leaves sheathing lower ⅓–⅔ of stem, without expanded blade. *Spike* drooping in bud, weakly flexuose, mostly 3- to 7-flowered; bracts membranous, translucent, outer 5–6 mm long, with prominent central vein, sometimes with 2 prominent secondary veins, acute or trilobed, inner slightly shorter than outer, 2-veined and 2-toothed. *Flowers* rotate, pale to deep pink (rarely mauve), yellow or white edged with darker pink at base of tepals, unscented; perianth tube funnel-shaped, 3.5–4.0 mm long, filiform in basal 2.5–3.0 mm and clasping style, flared in distal 1 mm, tepals spreading, ovate-elliptic, obtuse to retuse, 12–15 × 5.0–6.5 mm. *Filaments* erect, inserted at base of wide part of tube, 3–4 mm long, free or united basally for up to 0.7 mm, filiform, ± white; anthers oblong-linear, 3–4 mm long, yellow, thecae obtuse at base, dehiscing fully. *Style* dividing between base and lower ⅓ of filaments, branches 4–5 mm long, weakly arched outward, filiform-involute, pale pink. *Flowering time*: mid-August to late September.

Distribution and ecology: extending along the Roggeveld Escarpment from the Farm Uitkyk southward through the Klein Roggeveld to the Laingsburg Karoo as far west as Tweedside, thus in southwestern Northern Cape

Distribution of ***Ixia rigida***.

Distribution of ***Ixia trifolia***.



and interior Western Cape, South Africa; on stony clay ground in low, karroid scrub or mountain renosterveld.

Diagnosis: *Ixia trifolia* is recognised by the combination of two or three, relatively broad foliage leaves plus one (or two) more sheathing the stem and bright pink, rarely mauve flowers, white to yellow in the throat edged with a narrow dark pink line, always held upright on inclined spikes. Like other western Karoo species of sect. *Dichone* the style branches are slender and nearly straight and the anthers dehisce completely. A unique feature for the section, the filaments may be united basally for up to one quarter of their length and the style is exserted up to 1.5 mm from the filiform part of the perianth tube. *Ixia trifolia* is perhaps most closely allied to *I. brevituba*, which has similarly oriented, upright flowers on an inclined spike but with narrower leaves, up to 1.5 mm wide, and mauve flowers darker in the centre. Both species stand out in the section in having the spikes drooping in bud.

87. **Ixia brevituba** *G.J.Lewis* in Journal of South African Botany 28: 170 (1962, including *I. rigida*); Goldblatt & Manning: 93 (2012a). Type: South Africa, [Northern Cape], 'Quagas [sic] Pass [probably Ganagga Pass], road between Middelpos and Ceres', Sept. 1929, *Grant & Theiler 4931* (BOL, holo.).

Ixia amethystina J.C.Manning & Goldblatt: 139 (2006). Type: South Africa, Northern Cape, west of Farm Agterkop, near top of Gannaga Pass, 16 Sept. 1997, *Goldblatt & Manning 10745A* (NBG, holo.; MO, iso.).

Plants 150–300 mm high. *Corm* 12–20 mm diam., tunics of medium-textured, wiry, reticulate fibres, extending up in papery collar 30–70 mm long. *Stem* either unbranched and then with scale-like leaves at aerial nodes, or with up to 2 short branches, erect below, inclined above, sheathed at base by ± membranous, red-brown cataphylls. *Leaves* 3 or 4, basal, uppermost completely sheathing lower ⅔ of stem, blades suberect or lowermost slightly falcate, 1.5–2.0 mm wide, reaching to near top of stem, firm-textured, margins and main vein hyaline, lightly thickened. *Spike* inclined, nodding in bud, crowded, 5- to 7-flowered, branches fewer-flowered; bracts dry-membranous, translucent or flushed purple above, outer 5–7 mm long, acute or obscurely 3-dentate, inner ± as long as outer or slightly shorter, 2-veined and 2-toothed, margins united in lower 1.5 mm. *Flowers* rotate, light purple with small dark purple stain in centre, lightly scented; perianth tube ± funnel-shaped, ± 2.3 mm long, filiform below and clasping style, flaring in distal 1 mm; tepals spreading and lightly spooned distally, obovate, ± narrowed below into a short claw, 12–13 × 7–8 mm. *Filaments* inserted at apex of tube, diverging above, 2.5 mm long, blackish purple; anthers ± oblong, 4.5–5.0 mm long, blackish purple, dehiscing laterally along entire length. *Style* dividing at or slightly above bases of filaments, ± 2 mm long, branches filiform, involute, purple, falcate, 2.0–2.5 mm long. *Flowering time*: late September to early October; opening ± 08:00, even in cool, overcast conditions, closing in late afternoon.

Distribution of ***Ixia brevituba***.

Distribution and ecology: known from a small area on the edge of the Roggeveld Escarpment near Gannagga Pass southwest of Middelpos in Northern Cape, South Africa; in stony, light clay in renosterveld.

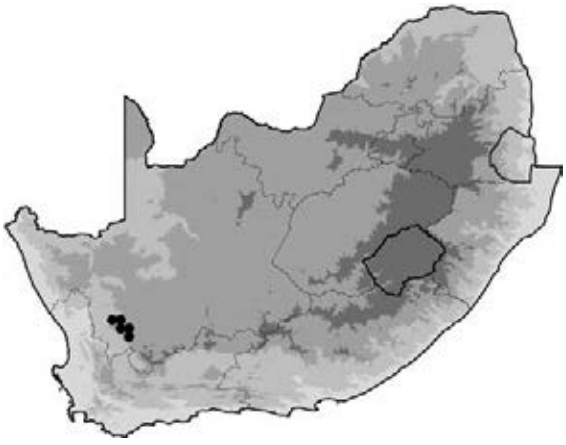
Diagnosis: *Ixia brevituba* is distinguished by its pale mauve flowers with small, dark eye, and relatively broad, blackish anthers that dehisce laterally, the light-coloured pollen then contrasting with the dark anther tissue. The style is ± as long as the filaments and the short branches 2.0–2.5 mm long scarcely project between them. The flowers are borne on inclined spikes and they face directly upward. *Ixia brevituba* falls among a small group of species that are endemic or near-endemic to the Roggeveld Escarpment and Klein Roggeveld, including *I. curvata*, *I. rigida* and *I. trifolia*, all of which share conventional longitudinally dehiscent anthers. *Ixia brevituba* appears to be most closely allied to *I. trifolia* on the basis of their distinctive, inclined spikes that are decurved and nodding when young. Other related species have spikes erect from bud to fruit. The two species also share a perianth tube 2–3 mm long but the pink (or mauve) flowers of *I. trifolia* have a pale central eye and yellow anthers. The leaves of *I. trifolia* are broader than in *I. brevituba*, (2.5–)5.0–12.0 mm wide, and the tunics are more coarsely fibrous, with the lower fibres developed into woody claws but not drawn into a collar above. In addition, the style branches of *I. trifolia* are longer than the filaments, 4–5 mm long, and project conspicuously between them.

Ixia brevituba has flowers that conform to the hopliine beetle pollination syndrome and the beetle *Kabousia axillaris* has been captured visiting the flowers.

88. **Ixia curvata** *G.J.Lewis* in Journal of South African Botany 28: 171 (1962); Goldblatt & Manning: 95 (2012a). Type: South Africa, [Northern Cape], Agterhantamsberg, Moordenaarspoort, 26 miles [± 39 km] NE of Calvinia, 25 Sept. 1952, *Lewis 3532* (SAM, holo.; BOL [as SAM 61919], PRE, iso.).

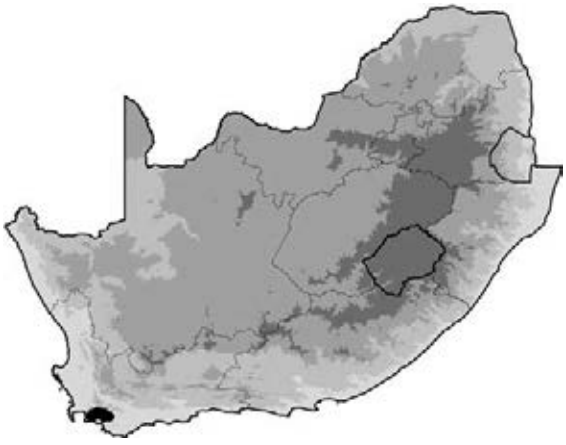
Plants 120–350 mm high, with long, chestnut-brown cataphylls and a collar of fibres at base. *Corm* 12–20 mm diam., tunics of medium-textured fibres. *Stem* simple or with 1 or 2 upright branches. *Leaves* usually 4 or 5, lower 3 or 4 with sword-shaped to falcate blades, ± ½ as long as stem and (2–)3–5 mm wide, uppermost leaf entirely sheathing, main vein and margins slightly to moderately thickened. *Spike* flexuose, 2-ranked, mostly 6- to 12-flowered; bracts membranous, translucent, outer 4–5 mm long, outer with prominent central vein or secondary veins equally prominent, 3-lobed with central lobe largest or ± equally 3-lobed, inner slightly shorter than outer, 2-veined and 2-toothed. *Flowers* nodding with tepals held vertically, deep pink (sometimes called purple), white (sometimes edged with dark pink) at base of tepals, unscented; perianth tube filiform but expanded near mouth, 3–5 mm long; tepals oblong, (8–)10–14 × 4–8 mm. *Filaments* symmetrical in bud, becoming unilateral in open flower, held horizontally at right angles to tepals, inserted at mouth of tube, filiform, 2–3(–4) mm long, white; anthers oblong-linear, 2.5–4.0 mm long, yellow, dehiscing completely. *Style* dividing between base and lower ⅓ of filaments, branches ± 2 mm long, tubular, strongly falcate. *Flowering time*: mid-August to late September.

Distribution and ecology: a fairly narrow endemic of the western Karoo in Northern Cape, South Africa, extending from the eastern end of the Hantamsberg at Moordenaars Poort northeast of Calvinia south to Middelpos on the Roggeveld Plateau; on red clay soils derived from dolerite but also found in pale clay ground.



Diagnosis: relatively low growing, *Ixia curvata* is a small plant, seldom exceeding 200 mm (although taller plants are known) and has nodding, pink flowers with vertically oriented tepals with horizontal stamens. Like other members of ser. *Euanthera*, the anthers split completely. The four or five leaves are typically falcate and leathery rather than fibrous. Other species of the series have upright flowers with tepals spreading horizontally. The plants are notable for the thick collar of fibres around the base and chestnut-brown cataphylls.

89. **Ixia trinervata** *(Baker) G.J.Lewis* in Journal of South African Botany 28: 169 (1962); Goldblatt & Manning: 96 (2012a). *Tritonia trinervata* Baker: 191 (1892); Baker: 212 (1896). Type: South Africa, [Western Cape], Appelskraal, Riviersonderend, *Ecklon & Zeyher Irid. 242* (K, holo.; G, Z, iso.).



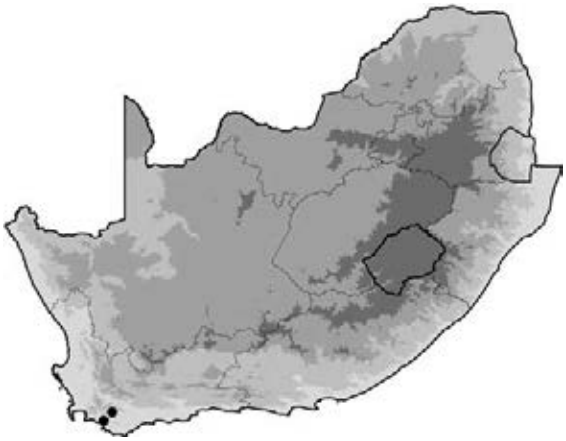
Plants 250–450 mm high. *Corm* 9–18 mm diam., tunics of firm, medium-textured, netted fibres. *Stem* usually unbranched or with a single short branch. *Leaves* 2, lower 1 ± basal, lanceolate, (4–)6–10 mm wide, conspicuously 3-veined, main vein moderately thickened, secondary veins slightly less so, margins not or barely thickened, upper leaf sheathing stem in lower ½. *Spike* flexuose, 5- to 12-flowered; bracts membranous, translucent, sometimes turning rusty brown in upper ⅓, outer 5–6 mm long, with prominent main vein and up to 6 secondary veins, 1-toothed or ± fringed, inner ± as long as outer, 2-veined and 2-toothed. *Flowers* rotate, deep rose-pink, unscented; perianth tube filiform, 4–5 mm long, clasping style; tepals spreading, ovate-elliptic, obtuse to retuse, 12–15 × 6–8 mm. *Filaments* inserted at mouth of tube, filiform, 2–4 mm long, ± white; anthers erect, suborbicular, ± 2 mm long, yellow, thecae acute, recurved at base, dehiscing almost to apex. *Style* dividing at base of filaments, branches falcate, 2.5–3.0 mm long, tubular-filiform, pale pink. *Flowering time*: September.

Distribution and ecology: a narrow endemic of the Caledon District of Western Cape, South Africa, extending from Elgin Station and the Farm Arieskraal in the west to Riviersonderend in the east; on clay soils in renosterveld, often in stony ground, flowering well after fire.

Diagnosis: *Ixia trinervata* is readily recognised by the presence of just one foliage leaf, the blade narrowly sword-shaped, mostly 6–10 mm wide, with three ± equally conspicuous veins and unthickened margins. A second leaf is largely to entirely sheathing, although relatively broad. The flowers are an intense, rose-pink also described as red-magenta. Related *I. bifolia* recalls

Distribution of ***Ixia curvata***.

Distribution of ***Ixia trinervata***.



I. trinervata in its single foliage leaf, but the leaf blade is much narrower, usually only 3–5 mm wide, with a single main vein embedded in the leathery, almost succulent leaf tissue. When dry the leaf margins appear moderately thickened, unlike those of *I. trinervata*. The flowers of *I. bifolia* are slightly smaller than those of *I. trinervata* and have unusual, almost straight, deep pink style branches in marked contrast to the pale pink, falcate style branches of *I. trinervata*.

90. **Ixia bifolia** *Goldblatt & J.C.Manning* in Bothalia 42: 97 (2012a). Type: South Africa, Western Cape, Caledon, northern slopes below Shaw's Pass, Farm Treintjiesrivier, 13 Sept. 2009, *Goldblatt & Manning 13444* (NBG, holo.; MO, PRE, iso.).

Plants mostly 160–300 mm high, with dry, brown cataphylls and collar of fibres at base. *Corm* 10–12 mm diam., bearing cormlets at base; tunics of fine, soft to firm fibres. *Stem* unbranched, with short scale ± 1 mm long, inserted 12–30 mm below base of spike. *Leaves* 2, lower 1 with long sheath, blade ± lanceolate, 60–80 × 3–5(–8) mm, reaching middle of stem, leathery-succulent, main vein not raised when alive (visible as a pale line when held against light, slightly raised when dry), margins thickened, hyaline, transparent when alive, when dry appearing raised and hyaline, upper leaf largely sheathing, sometimes with short free blade similar to basal but 2–3 mm wide. *Spike* mostly 4- to 7-flowered, ± straight; bracts translucent pink with purple veins, 5–6 mm long, outer with 3 main veins terminating in acute teeth and 1 or 2 secondary veins along margins, inner 2-veined and acutely 2-toothed. *Flowers* rotate, upright, deep pink, darker toward tepal bases, rose-scented; perianth tube filiform, 5–6 mm long; tepals obovate, 12–14 × 6–7 mm. *Filaments* erect, filiform, inserted at mouth of narrow part of tube, ± 1.5 mm long, deep pink (drying purple); anthers suborbicular, 2.0–2.5 mm long, yellow, thecae obtuse basally, dehiscing completely or almost so. *Style* dividing at base of filaments, branches 3.8–4.0 mm long, deep pink (drying purple), ± straight, extending outward below anthers, bilobed at tips. *Flowering time*: mostly late August to September.

Distribution and ecology: restricted to the Caledon District of Western Cape, South Africa, recorded on the northern slopes of Shaw's Mt south of Caledon and from the lower slopes of the Swartberg east of Caledon; in hard, stony clay.

Diagnosis: *Ixia bifolia* stands out in the very short, leathery-succulent foliage leaf blade, up to 80 mm long and 5–7 mm wide. The leaf has a single vein and moderately thickened margins. The flowers seem most like those of *I. confusa* but the short, deep pink filaments ± 1.5 mm long and deep pink, straight style branches ± 4 mm long (both drying purple) are quite different from those of *I. confusa*, which has white filaments 1.3–2.5 mm long and white, strongly falcate style branches 1–2 mm long. *Ixia bifolia* is evidently closely allied to *I. trinervata*, which has larger flowers on longer spikes but also a single foliage leaf, this relatively broad and always with three prominent veins and unthickened margins. *Ixia bifolia* shares with other members of the *I. micrandra* complex the finely fibrous corm tunics that extend upward around the stem base. Stems are almost always unbranched and have an odd feature, a small, nearly microscopic, translucent scale and prophyll, ± 1 mm long, inserted 12–30 mm below the base of the spike. Stems of *I. confusa* may be branched and are normally taller than in *I. bifolia* but also have a translucent stem scale in populations from the Swartberg and sometimes elsewhere across its range. *Ixia confusa* has 3 or 4 linear leaves, usually ± 2 mm, but occasionally up to 4 mm wide.

Distribution of ***Ixia bifolia***.

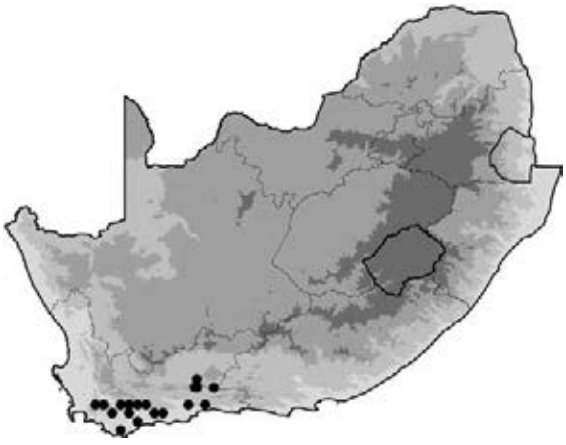
91. **Ixia confusa** *(G.J.Lewis) Goldblatt & J.C.Manning* in Bothalia 42: 97 (2012a). *I. micrandra* var. *confusa* G.J.Lewis: 162 (1962). Type: South Africa, [Western Cape], Montagu, Donkerkloof, 26 Sept. 1946, *Compton 18481* (NBG, holo.; BOL, iso.).

Plants (150–)250–500 mm high. *Corm* 8–10 mm diam.; tunics of fine, soft fibres sometimes extending upward in weakly developed collar. *Stem* simple or 1-branched, often with short scale ± 1 mm long, inserted 25–40 mm below base of spike. *Leaves* (2)3(4), lower (1)2 or 3 with linear to narrowly sword-shaped blades, ± ⅓ as long to reaching top of stem, 1.5–4.0 mm wide, upper leaf largely sheathing, with short free blade. *Spike* slightly flexuose, (2–)5- to 9(–12)-flowered; bracts membranous, becoming dry from tips, 4–5 mm long, outer 1- or 3-veined, irregularly 2- or 3(–5)-lobed or shortly toothed, inner often slightly longer than outer, 2-veined and 2-toothed. *Flowers* rotate, upright, pink to light red-purple, rose-scented; perianth tube filiform, 3–4 mm long; tepals spreading, ± ovate, mostly 12–15 × 6–7 mm. *Filaments* inserted at mouth of tube, filiform, 1.0–2.8 mm long; anthers oblong, 2.0–2.3 mm long, yellow, thecae acute, recurved at base, usually dehiscing almost to apex. *Style* dividing opposite base to middle of filaments, branches 1.5–2.0 mm long, falcate, tubular with expanded ciliate,

stigmatic tips, sometimes shortly forked apically. *Flowering time*: mostly July to early December.

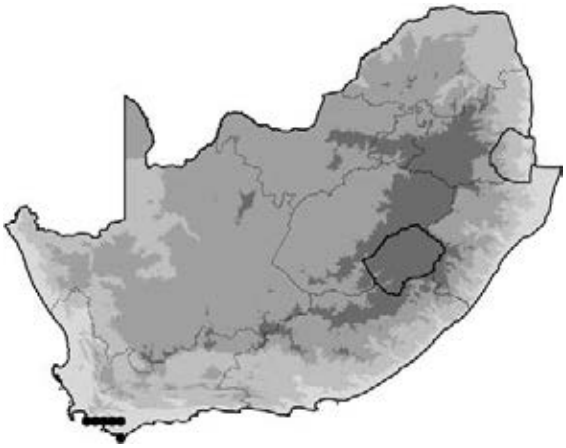
Distribution and ecology: widespread in Western Cape, South Africa, extending from near Elim and the Riviersonderend Mtns in the west through the Langeberg to the Outeniqua Mtns and inland in the Great Swartberg from Swartberg Pass east to Blesberg; mostly on moist S-facing slopes in loamy clay or sandy ground in renosterveld–thicket transition vegetation or fynbos, flowering well after fire and also in unburned veld.

Diagnosis: *Ixia confusa* is recognised by the spikes mostly with 5 to 9 small pink flowers with a perianth tube 3–4 mm long and tepals 12–15 mm long and narrow, plane leaves up to 4 mm wide. Both *I. micrandra* and closely related *I. minor* have terete to subterete or linear leaves mostly 1.0–1.5 mm at widest, and spikes of 2 to 4, rarely up to 6 flowers. *Ixia micrandra* has anthers 3–4 mm long, and slender, ± straight, ascending style branches 3–4 mm long, thus quite different from the shorter anthers, ± 1.0–2.5 mm long, and falcate style branches 1.5–2.5 mm long of *I. confusa*. The falcate style branches of *I. confusa* match those of *I. minor* but the terete or subterete leaf blades, flattened filaments and consistently few-flowered spikes of the latter immediately separate them. Leaf number is variable in *I. confusa*, usually three but sometimes two or four, whereas *I. micrandra* and *I. minor* always have two leaves.



Ixia confusa may also be confused with *I. bifolia* but this species has a single, relatively broad, leathery-succulent foliage leaf and flowers with shorter filaments ± 1 mm long, and longer, straight style branches ± 4 mm long. Both the filaments and style branches of *I. bifolia* are dark pink and dry dark purple, unlike the pale filaments and style branches of *I. confusa*, which dry to a pale, almost colourless state.

Populations of *Ixia confusa* in the Swartberg stand out in having slightly shorter filaments, 1–2 mm long, than typical *I. confusa* (up to 2.8 mm long), the style sometimes dividing above the mouth of the perianth tube, often opposite the middle of the filaments, and anther dehiscence sometimes not reaching the middle of the thecae. The plants have a small, translucent scale and prophyll on the upper part of the stem, a feature occasionally present in southern populations. Additional study may show that the later-flowering Swartberg populations merit separate taxonomic status.



92. **Ixia micrandra** *Baker* in Journal of Botany, British and foreign 5: 237 (1876); Baker: 78 (1896); Lewis: 159 (1962, including *I. confusa* and *I. minor*); Goldblatt & Manning: 99 (2012a). Type: South Africa, [Western Cape], Houw Hoek Mtns, July 1830, *Zeyher 4011* (K, lecto., designated by Lewis: 161 (1962); PRE, SAM, S, Z, isolecto.).

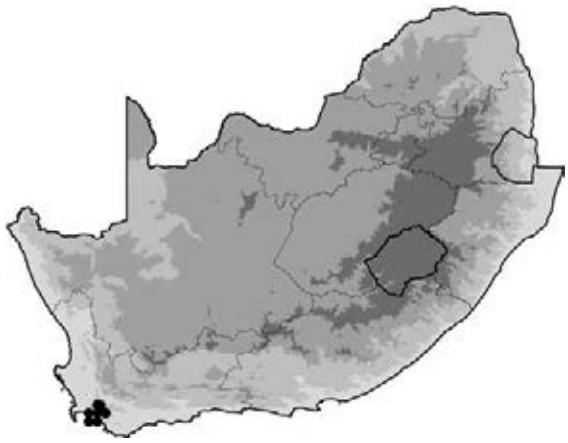
Plants 250–350 mm high. *Corm* 9–18 mm diam., tunics of fine fibres extending upward as a collar. *Stem* slender, unbranched. *Leaves* 2, lower 1 ± basal, linear, (0.5–)1.0–1.5(–2.0) mm wide, margins and main vein slightly thickened, hyaline when dry, upper leaf sheathing stem in lower ½–⅔, apex free for up to 100 mm. *Spike* ± straight, (1)2- to 4(–6)-flowered; bracts membranous, translucent, sometimes suffused with purple distally, outer 5–7 mm long, prominently 3-veined, usually with secondary veins evident, acutely 3-toothed, sometimes central tooth smaller, inner ± as long or slightly longer, 2-veined and 2-toothed. *Flowers* rotate, pale pink to mauve-pink; perianth tube filiform, 3–4 mm long, clasping style; tepals spreading, ovate-elliptic, 12–15 × 4–6 mm. *Filaments* inserted at mouth of tube, linear, straight, 0.6–1.8(–2.5) mm long, ± pale pink; anthers oblong, 2.0–2.6 mm long, erect, yellow, thecae slightly recurved basally, dehiscing completely. *Style* dividing at or shortly above base of filaments, branches ± straight, diverging or slightly arched, 2.0–5.0 mm long, usually longer than stamens, filiform-involute, sometimes forked at apex, pale pink. *Flowering time*: mostly late July to early September, occasionally later.

Distribution and ecology: restricted to southern Western Cape, South Africa, from Houw Hoek to Bredasdorp and

Distribution of ***Ixia confusa***.

Distribution of ***Ixia micrandra***.

De Hoop; mainly montane and typically on sandstone slopes and flowering well only in seasons immediately after veld fires, also in sandy ground over limestone.



Diagnosis: *Ixia micrandra* is immediately recognised by its solitary long, narrow foliage leaf, mostly 1.0–2.0 mm long, almost linear filaments, and unusually long style branches 2.0–3.5 mm long either straight or slightly arched, extending between the bases of the anthers. *Ixia confusa* has similarly slender but somewhat shorter filaments, slightly shorter anthers, and shorter, strongly arched style branches, 1.5–2.0 mm long. The leaves of *I. confusa* have plane, usually wider blades up to 4 mm wide (vs. 0.5–1.5(–2.0) mm) and without the prominently thickened main vein of *I. micrandra*. The style branches are similarly strongly arched in *I. minor* but that species has unusual flattened, lanceolate filaments, narrowed and kinked at the tips. The ranges of *I. micrandra* and *I. minor* are almost complementary, that of *I. micrandra* extending east of *I. minor*, but the two have been collected in flower on the same day in the Houw Hoek Mtns, where their distributions overlap.

93. **Ixia minor** *(G.J.Lewis) Goldblatt & J.C.Manning* in Bothalia 42: 100 (2012a). *I. micrandra* var. *minor* G.J.Lewis: 162 (1962). Type: South Africa, [Western Cape], Hottentots Holland Mtns, 10 Sept. 1928, *J. Hutchinson 481* (BOL, holo.; K, PRE, iso.).

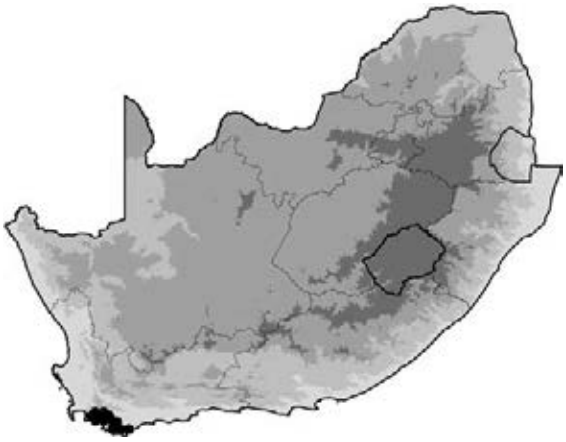
Plants 200–300 mm high, with membranous to dry, brown cataphylls at base. *Corm* 8–10 mm diam., tunics of fine fibres extending upward as a collar, often in a thick mass. *Stem* unbranched. *Leaves* 2, lower 1 ± basal, largest, terete or oval in section, up to 1 mm diam., main vein evident only when dry, upper leaf sheathing stem in lower ½–⅔, with short free blade. *Spike* straight, mostly 2- to 4-flowered, bracts membranous, translucent, usually flushed purple, outer 5–7 mm long, usually prominently 3-veined, shallowly 3-lobed to acutely 3-toothed, inner ± as long as or slightly longer than outer, 2-veined and 2-lobed or 2-toothed. *Flowers* rotate, bright pink to mauve-pink; perianth tube filiform, 3–5 mm long, clasping style; tepals spreading, ovate-elliptic, 12–14 × 5–6 mm. *Filaments* inserted at mouth of tube, flattened, ± oblanceolate but narrowed and kinked at tips, ± white, 1.0(–1.5) mm long; anthers ovoid, ± 1.0 mm long, yellow, abruptly incurved near base, dehiscing fully, often more widely at base, yellow. *Style* dividing opposite base to middle of filaments, branches 2–3 mm long, involute, tubular-falcate, ± compressed, narrowed at tips. *Flowering time*: late July to mid-September, rarely later.

Distribution and ecology: a narrow endemic of the southwestern corner of Western Cape, South Africa, extending from Franschhoek Pass and the Wemmershoek Mtns south through the Hottentots Holland to Houw Hoek and Kogelberg; on stony sandstone slopes.

Diagnosis: like *Ixia micrandra, I. minor* has a slender, usually unbranched stem, small corms with fine, netted tunics that extend upward in a collar around the base, and a dry, often brown, upper cataphyll. The critical

Distribution of ***Ixia minor***.

differences between the two species lie in their flowers. *Ixia minor* has flattened, ± wedge-shaped to oblanceolate filaments abruptly narrowed and kinked at the tips, and shorter and broader anthers, often not dehiscing to the apex. The style branches are also shorter, 2–3 mm long, wider, and strongly arched whereas those of *I. micrandra* are more-or-less straight and (2)3–5 mm long. To these microscopic details can be added a brighter pink perianth. Flowers of *I. micrandra* have pale pink to purple-pink tepals, straight, filiform filaments and longer, oblong anthers dehiscing to the apex. The leaves of the two species also differ somewhat: those of *I. minor* are subterete to oval in section, thus when alive without margins or evident central vein, whereas *I. micrandra* has plane, linear leaf blades with slightly thickened margins and, when dry, a visibly raised main vein. Evidence for their separation is provided by collections of both species made in the Houw Hoek Mtns flowering on the same date and visibly different in appearance.



Ser. **Dichone** *Goldblatt & J.C.Manning*, new series. Type: *Ixia scillaris*.

Flowers upright or nodding, radially symmetric (*I. stricta*) or zygomorphic. *Filaments* symmetrically arranged (*I. stricta*) or unilateral and horizontal to pendent; anthers oblong, recurved and acute at base, dehiscing incompletely from base. *Style* with branches always falcate.

94. **Ixia stricta** *(Eckl. ex Klatt) G.J.Lewis* in Journal of South African Botany 28: 167 (1962); Goldblatt & Manning: 101 (2012a). *Tritonixia stricta* Eckl. ex Klatt: 357 (1882). *Tritonia scillaris* var. *stricta* (Eckl. ex Klatt) Baker: 191 (1892). Type: Western Cape, Caledon, Swartberg and vicinity of the Baths, December 1830, *Zeyher 4008* (SAM, lecto., designated by Lewis: 162 (1962); K, PRE, isolecto.).

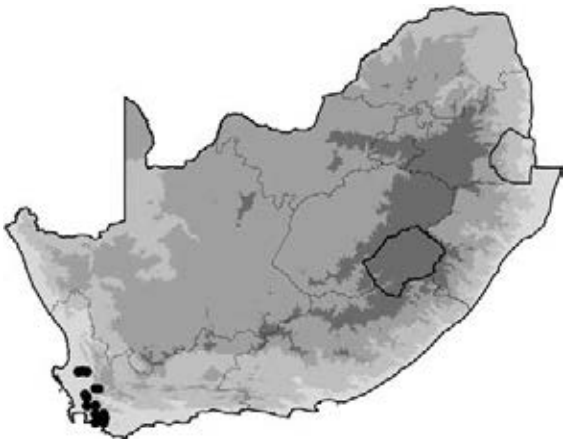
[*Agretta stricta* Eckl.: 23 (1827), invalid name without description.]

Plants to 200–450 mm high. *Corm* mostly ± 10–15 mm diam.; tunics of medium-textured, shaggy fibres. *Stem*

Distribution of ***Ixia stricta***.

simple or with 1 or 2 ± erect branches subtended by acute, translucent bracts and prophylls. *Leaves* (3)4 or 5, often ± dry at flowering, all basal, lower 2 or 3 ± sword-shaped, plane, 2–5 mm wide, upper 1 or 2 sheathing stem in lower ½–⅔, free distally for short distance, margins and main vein thickened (hyaline when dry). *Spike* flexuose, 6- to 12(–18)-flowered, bracts membranous, translucent, outer 5–6 mm long, usually with 1 prominent vein, and 1-toothed, inner ± as long or slightly shorter or longer, 2-veined and 2-toothed. *Flowers* rotate, pink to purple, pale yellow edged with darker pink at tepal bases, sweetly scented; perianth tube filiform, 4–5 mm long, clasping style; tepals spreading, obovate, ± obtuse, ± 10 × 4–5 mm. *Filaments* 1.0–1.5 mm long, white; anthers oblong, ± 2 mm long, erect, yellow, thecae acute and slightly recurved at base, dehiscing near base. *Style* dividing opposite base of filaments, branches arching outward, ± 1.5 mm long, falcate, tubular, pale pink. *Flowering time*: November to mid-December.

Distribution and ecology: restricted to the Caledon–Bredasdorp area of Western Cape, South Africa, extending from the Houw Hoek Mtns east to Bredasdorp; mostly in montane habitats, usually at fairly low elevations, in sandstone and loamy clay soils.



Diagnosis: typically flowering late in the year, in November and December, the foliage of *Ixia stricta* is often more-or-less dry at flowering. Not particularly distinctive, the pink flowers are radially symmetric and have short, erect stamens. It is identified in ser. *Dichone* by a combination of the rotate flowers and a basal fan of (3)4 or 5 sword-shaped leaves with a prominent main vein and thickened margins. The sweetly scented flowers have a filiform tube about half as long as the tepals and particularly short style branches ± 1.5 mm long.

95. **Ixia erubescens** *Goldblatt* in Journal of South African Botany 37: 233 (1971), as a new name for *I. crispa* L.f.: 91 (1782), illegitimate superfluous name for *I. undulata* Burm.f. (1768). *Agretta crispa* Eckl.: 24 (1827), illegitimate name. *Tritonia thunbergii* N.E.Br.: 137 (1929), new name for *I. crispa* in *Tritonia* [not *T. crispa* (L.f.) Ker Gawl.; not *I. thunbergii* Roem. & Schult.]. Type: South Africa without precise locality, *Thunberg s.n.* [LINN 58.25, lecto., designated by Lewis: 173 (1962)].

Plants 120–300 mm high, usually forming clumps. *Corm* mostly 5–8 mm diam.; tunics of fine fibres, usually with large cormlets at base. *Stem* simple, rarely 1-branched. *Leaves* 4 to 6, ± lanceolate, all basal, ± ¼–⅓ as long as stem, 2–4(–6) mm wide, main vein well developed, margins or half blades crisped and deeply undulate. *Spike* lax, secund, weakly flexuose, mostly 6- to 10-flowered; bracts mostly green, ± translucent at tips, turning purple along distal margins, 3–4 mm long, outer with 3 acute-attenuate cusps, obscurely 3-veined, inner 2-veined and acutely 2-toothed. *Flowers* zygomorphic with stamens unilateral, nodding with tepals held ± vertically, pink, yellow-green in throat edged with dark purple at tepal bases, unscented; perianth tube filiform, 2–3 mm long, tightly clasping style; tepals ovate, spreading ± at right angles to tube, 8–11 × 4–6 mm, outer tepals slightly narrower than inner. *Filaments* unilateral, ± 2 mm long, greenish white (drying yellow); anthers oblong, 2.0–2.5 mm long, yellow, parallel and horizontal, becoming slightly pendent, thecae acute, recurved at base, dehiscing incompletely by a narrow slit at base, yellow. *Style* dividing at base of filaments, branches 1.5–2.0 mm long, greenish white, falcate, recurved in distal third, tubular. *Flowering time*: mainly mid-August to mid-September.

Distribution and ecology: restricted to southwestern Western Cape, South Africa, extending from Piketberg and Tulbagh south to Stellenbosch and the Caledon District as far east as Franskraal but absent from the Cape Peninsula; mostly on heavy clay or granitic alluvium in seasonally damp places, flowering especially well after fire.

Diagnosis: a relatively small plant, *Ixia erubescens* is immediately recognised by the fine corm tunic fibres,

Distribution of ***Ixia erubescens***.

4 to 6 narrow leaves with deeply undulate and crisped margins, usually unbranched stem, nodding, pink flowers with vertically oriented tepals and the stamens unilateral and slightly pendent when fully open. *Ixia erubescens* is evidently closely allied to *I. scillaris*, which typically has medium to coarse corm tunic fibres, broader leaves, usually with plane margins, and somewhat to substantially larger flowers, also with unilateral stamens, but with a perianth tube up to 4.5 mm long and tepals up to 14 mm long (vs. tube 2–3 mm long and tepals 11–12 mm long). Occasional populations of *I. scillaris* with undulate or crisped leaves are readily distinguished from *I. erubescens* by their broader leaves, larger flowers, and coarser corm tunic fibres.

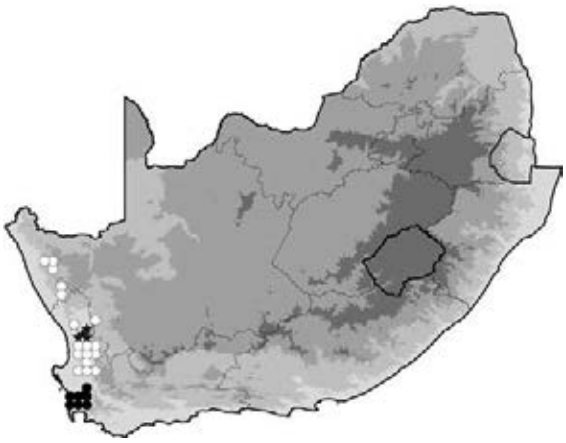
96. **Ixia scillaris** *L.*, Species plantarum, edn. 2, 1: 52 (1762); Lewis: 173 (1962); Goldblatt & Manning: 102 (2012a). *Tritonia scillaris* (L.) Baker: 163 (1877). *Tritonixia scillaris* (L.) Klatt: 357 (1882). Type: South Africa, without precise locality of collector [LINN 58.25, lecto., designated by Lewis: 174 (1962)].

Plants mostly 250–500 mm high. *Corm* 10–15 mm diam., with cormlets at base, especially numerous in subsp. *toximontana*; tunics of medium-textured to coarse fibres. *Stem* often with 1 or 2, rarely up to 6, branches, occasionally simple. *Leaves* 3 to 7, mostly in basal fan, ⅓–½ as long as stem, lanceolate or falcate, (3–)6–20 mm wide, main and sometimes additional veins raised but not thickened, margins markedly thickened in subsp. *toximontana*, occasionally undulate(–crisped) in subsp. *scillaris*. *Spike* erect, fairly lax, flexuose to ± straight, secund in 2 ranks, mostly 10- to 20-flowered; bracts membranous, translucent, sometimes turning purple distally, 3–5 mm long, outer prominently 3-veined and 3-toothed, inner 2-veined and 2-toothed. *Flowers* ± nodding with tepals held vertically with lowermost slightly reflexed, zygomorphic with stamens unilateral, bright to pale pink, occasionally white, tepal bases yellow or white edged in darker pink, lightly rose-scented or unscented; perianth tube filiform, 2.5–4.0 mm long, tightly clasping style; tepals ovate-elliptic, (8–)10–15 × 5–9 mm, inner 3 slightly larger than outer, lowermost tepal held apart. *Filaments* unilateral, inserted at mouth of tube, 1.6–3.5 mm long, arching upward near tips, white to pale yellow; anthers oblong-linear, 2.3–4.0 mm long, parallel, horizontal or slightly pendent, thecae recurved, acute at base, dehiscing incompletely from base, yellow. *Style* dividing ± opposite base of filaments, branches ± 1.5 mm long, pale yellow, falcate, tubular. *Flowering time*: mainly mid-August to mid-October, occasionally later.

Distribution and ecology: relatively widespread along the Atlantic Coast and near interior of Western Cape, South Africa, extending from the Cape Peninsula north to the Gifberg and Koebee Mtns, along the coastal plain and mountains as far inland as the Cederberg and the Pakhuis–Nardouw Mtns, with isolated populations in the Spektakel Mtns in Northern Cape; on a variety of soils but most commonly on heavier clays derived from shale or granite.

Diagnosis: the most common and widespread species of sect. *Dichone*, *Ixia scillaris* is recognised primarily by the nodding flowers with vertically oriented tepals and unilateral, slightly pendent and often relatively long anthers, combined with a fan of 3 to 7 basal leaves, (3–)6–20 mm wide. Related *I. erubescens* has narrow, ± falcate leaves, 2–4(–6) mm wide, with closely crisped margins, and is a smaller plant with smaller flowers, the tepals 8–11 × 4–6 mm and anthers 2.0–2.5 mm long vs. tepals mostly 10–15 × 5–9 mm and anthers 3–4 mm long in *I. scillaris*. Apparently closely allied *I. simulans*, with half to fully nodding flowers and unilateral stamens with pendent anthers, has a single basal, ± linear foliage leaf and a second leaf sheathing the stem for most of its length.

Three subspecies are recognised: subsp. *scillaris* from Darling and Tulbagh to the Cape Peninsula has (4)5 to 7 relatively narrow leaves, mostly 5–8 mm wide, with 3 to 5 secondary veins conspicuous only when dry, mostly branched stems (rarely with up to 7 branches), and moderately dense spikes with flowers spaced 8–12 mm apart. The flowers are relatively small, with tepals 8–10 × 4–5 mm and ± symmetrically arranged, although the lowermost tepal is held slightly apart and recurved, and anthers 2.0–2.8 mm long. In contrast, subsp. *lata* (a new name for the homonym subsp. *latifolia*) from the Olifants River Valley and low elevations in the Cederberg, Bokkeveld and Spektakel Mtns are always taller, with 2 to 4, broader leaves mostly 15–20 mm wide, usually with at least two conspicuous secondary veins in addition to the main vein, stems simple or with 1(2) branches, and lax spikes with flowers distantly spaced, 15–25 mm apart. The flowers are larger, with tepals 14–16 × 5–9 mm, the upper tepals overlapping and separated from the three lower tepals, and anthers 3.2–4.0 mm long. A third subspecies, subsp. *toximontana* occurs on the Gifberg–Matsikamma Mt complex and comprises small plants, seldom exceeding 20 mm in height, with small flowers (tepals ± 8 × ± 4 mm, anthers ± 2 mm long), thus like subsp. *scillaris* but with just three leaves (rarely two in depauperate individuals).



Key to subspecies

1a Leaves (4)5 to 7, lower two up to 10 mm wide, usually lanceolate and lacking submarginal veins (margins rarely undulate); tepals 8–10 × 4–5 mm; anthers 2.0–3.5 mm long . . . . . 96a. subsp. *scillaris*

1b Leaves 2 to 4, lower two 3–25 mm wide, usually ± falcate, sometimes with pair of prominent secondary veins, these often submarginal (margins sometimes undulate to crisped, then without prominent secondary veins); tepals 8–15 × 4–9 mm; anthers 2–4 mm long:

2a Leaves (9–)12–25 mm wide; tepals 10–15 × 5–9 mm; anthers mostly 3–4 mm long . . . . . 96b. subsp. *lata*

2b Leaves 3–8 mm wide; tepals ± 8 × 4 mm; anthers 1.6–2.5 mm long. . . . . 96c. subsp. *toximontana*

Distribution of ***Ixia scillaris*** subsp. ***scillaris***, ●; subsp. ***lata***, ○; subsp. ***toximontana***, ★.

96a. subsp. **scillaris**

Gladiolus ramosus L.: 37 (1753) [not *Ixia ramosa* Ker Gawl. (1802) = *Geissorhiza scillaris* A. Dietr.]. *Melasphaerula ramosa* (L.) Klatt: 203 (1894). Type: South Africa, without precise locality or collector, ex hort. Leiden, *A. van Royen s.n.* (L: Herb. Royen, holo. – digital image).

Ixia pentandra L.f.: 92 (1782). *Agretta pentandra* (L.f.) Eckl.: 23 (1827). Type: South Africa, [Western Cape], near Groene Kloof, without date, *Thunberg s.n.* (UPS-THUNB, holo.).

Plants mostly 15–35 mm high, stem usually branched, sometimes with up to 6 branches. *Corm* mostly 12–14 mm diam. *Leaves* 5 to 7, lanceolate to sword-shaped or subfalcate, margins sometimes undulate, 5–8 mm wide, upper leaves progressively smaller than lower. *Spike* mostly 10- to 15-flowered, flowers mostly 6–12 mm apart; bracts 3.5–4.8 mm long. *Flowers* pale to deep pink, darker at base of tepals, not pale in throat; perianth tube 2.5–4.0 mm long; tepals subequal, upper 5 tepals overlapping and evenly disposed with lower laterals extended horizontally, lowermost held apart, directed forward above base and then downward, 8–10 × 4–5 mm, inner narrower than outer. *Filaments* 1.5–2.0 mm long; anthers mostly 2–3 mm long. *Flowering time*: mainly mid-September to late October (rarely in late August).

Distribution and ecology: restricted to the southwestern corner of Western Cape, recorded from Tulbagh and Darling to the Cape Peninsula and Somerset West; mainly on granite-derived sandy gravels.

Diagnosis: subsp. *scillaris* can be distinguished by the several, (4)5 to 7, leaves mostly 5–8 mm wide, in which only the main vein is prominent when fresh. The flowers are slightly smaller than in subsp. *lata*, with tepals 8–10 × 4–5 mm, the lowermost slightly recurved and held separate from the upper five. The anthers are also slightly smaller than in subsp. *lata*, 2–3 mm vs. mostly 3–4 mm long.

96b. subsp. **lata** *Goldblatt & J.C.Manning*, new name for subsp. *latifolia* Goldblatt & J.C.Manning in Bothalia 42: 105 (2012a), illegitimate homonym, not *I. scillaris* var. *latifolia* Ker Gawl. (1801). Type: South Africa, Western Cape, Cederberg, Nieuwoudt Pass, burned slopes, *Goldblatt & Porter 13475* (NBG, holo.; K, MO, PRE, iso.).

Ixia reflexa Andrews: t. 14 (1797). *I. rotata* [Ker Gawl.] in Andrews: 3 (1801c), illegitimate superfluous name for *I. reflexa* Andrews. Type: South Africa, without precise locality, cultivated in Great Britain by Messrs. Lee & Kennedy and sent to them by J. Pringle but possibly collected by F. Masson or W. Paterson, illustration in Andrews: t. 14 (1797).

Ixia polystachya var. *incarnata* Andrews: t. 128 (1800). Type: South Africa, without precise locality, cultivated in Great Britain by Messrs. Lee & Kennedy and sent to them by J. Pringle but possibly collected by Francis Masson or William Paterson, illustration in Andrews: t. 128 (1800).

Ixia scillaris var. *angustifolia* Ker Gawl. in Sims: sub t. 542 (1801), illegitimate superfluous name including type of *I. polystachya* var. *incarnata* Andrews. Type: not designated, two illustrations cited.

Ixia scillaris var. *latifolia* Ker Gawl. in Sims: t. 542 (1801). Type: South Africa, without precise locality, cultivated in Great Britain, *Masson s.n.*, illustration in Sims: t. 542 (1801).

Ixia scillaris var. *subundulata* G.J.Lewis: 177 (1962). Type: South Africa, Western Cape, Klipfonteinrand, 13 Sept. 1947, *Barker 4727* (NBG, holo.; BOL, iso.).

Plants mostly 300–500 mm high, stem simple or with 1 or 2(3) branches. *Corm* mostly 14–20 mm diam. *Leaves* 3 or 4, sometimes an additional leaf present at base of a branch, lower 2 or 3 broadly falcate, (9–)12–25 mm wide, usually with pair of conspicuous secondary veins and often well-developed submarginal vein, upper leaf/leaves smaller, margins plane or undulate, then without well-developed secondary veins. *Spike* mostly 15- to 20-flowered, flowers mostly 14–20 mm apart; bracts 4–5 mm long. *Flowers* pale to deep pink or white, then flushed pale pink near tepal bases; perianth tube 3.5–4.0 mm long; tepals subequal, upper 3 held close together, lowermost held slightly apart arched backward, 10–15 × 5–9 mm. *Filaments* 2.0–3.5 mm long, broader at base; anthers 3–4 mm long. *Style branches* ± 2.5 mm long, almost reaching anther bases. *Flowering time*: mainly mid-August to mid-September, rarely to early October at higher elevations).

Distribution and ecology: centred in the Olifants River Valley in Western Cape extending to lower elevations on the surrounding Cederberg, Pakhuis–Biedouw Mtns,

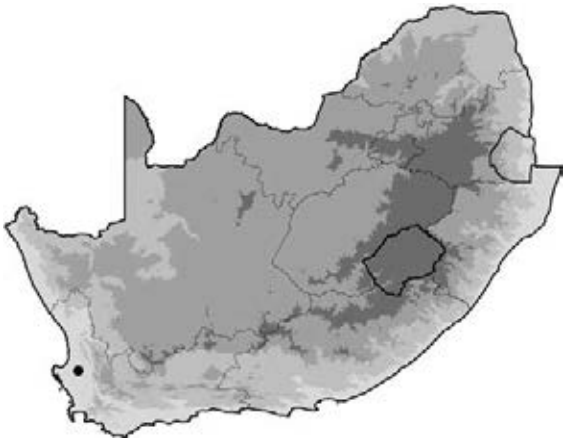
also local in the Bokkeveld Mtns and with isolated populations on the Spektakel Mtns of Northern Cape; mainly in rocky habitats in sandy ground, flowering well after fire or clearing of vegetation.

Diagnosis: subsp. *lata* is distinguished by the presence of three or four leaves and by the relatively larger flowers, the tepals 10–15 × 5–9 mm and anthers 3–4 mm long (vs. tepals 8–10 × 4–5 mm and anthers 2–3 m long in other subspecies). The upper three tepals are held more closely together than the lower three and the lowermost is conspicuously recurved. Variation in leaf morphology in subsp. *lata* is notable. Plants from Clanwilliam and nearby have a conspicuous submarginal vein, but those from elsewhere have a prominent secondary vein pair distant from the margins, and plants from the Spektakel Mtns of Namaqualand show no prominent secondary veins and appear thinner in texture. No other feature seems to set the Spektakel population apart. Populations east of the Pakhuis–Nardouw Mtns have leaf margins slightly to markedly undulate and without conspicuous veins apart from the main vein.

96c. subsp. **toximontana** *Goldblatt & J.C.Manning* in Bothalia 42: 106 (2012a). Type: South Africa, Western Cape, Gifberg, summit plateau in sandy ground over rocky pavement, common after fire, 1 Nov. 2011, *Goldblatt & Porter 13703* (NBG, holo.; K, MO, PRE, iso.).

Plants 120–250 mm high. *Corms* globose-conic, mostly 15–18 mm at widest diam., bearing conspicuous cormlets at base; tunics of hard, coarse fibres. *Stem* simple or with 1 or 2, rarely 3 branches. *Leaves* (2)3(4), all ± basal, mostly 3–8 mm wide, with main vein and secondary pair of veins hyaline when alive, raised when dry, margins appearing thickened when dry. *Spike* mostly 10- to 15-flowered, flowers mostly 8–12 mm apart; bracts 3–4 mm long. *Flowers* opening pale pink turning deep pink next day, tepal bases yellow edged dark pink, throat pale yellow; perianth tube ± 3 mm long; tepals subequal, ± 8 × 4 mm lowermost held slightly apart and arched backward. *Filaments* 1.0–1.6 mm long; anthers 1.6–2.5 mm long. *Style branches* ± 1.5 mm long, almost reaching anther bases. *Flowering time*: late September to mid-November.

Distribution and ecology: restricted to the Gifberg and Matsikamma Mtn complex of northern Western Cape; in shallow, sandy ground overlying sandstone pavement.



Diagnosis: subsp. *toximontana* is distinguished in *Ixia scillaris* by its low stature, seldom exceeding 150 mm, combined with relatively small flowers and only 2 or 3 leaves, these short and relatively narrow, 3–8 mm wide. The flowers have tepals ± 8 × 4 mm and anthers ± 2.3 mm long, smaller than in subsp. *lata* or subsp. *scillaris*. In their small size they recall subsp. *scillaris* rather than subsp. *lata*, in whose range it is nested.

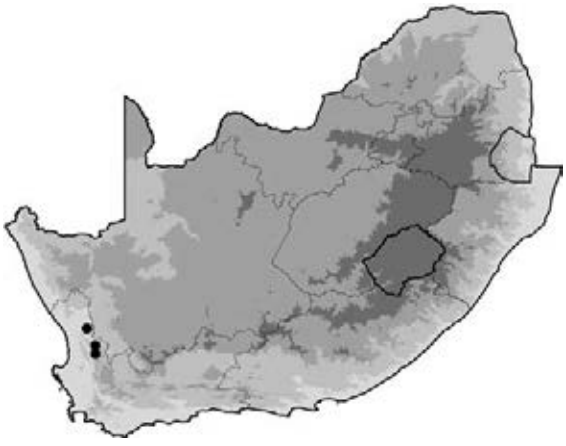
97. **Ixia tenuis** *Goldblatt & J.C.Manning* in Bothalia 42: 106 (2012a). Type: South Africa, Western Cape, Piketberg, Farm Noupoort, in wet mossy seeps on sandstone rocks, 2 Nov. 2011, *Goldblatt & Porter 13710* (NBG, holo.; K, MO, PRE, iso.).

Plants slender, 180–350 mm high. *Corms* globose, 7–10 mm diam.; tunics of fine fibres. *Stem* simple or rarely 1-branched. *Leaves* mostly (2)3, occasionally 4 but then uppermost very small, ± linear to narrowly sword-shaped, ¼–½ as long as stem, mostly 1.5–3.0 mm wide, relatively soft-textured, pale grey-green, when alive main vein slightly raised (appearing thickened when dry), margins not raised (rarely undulate, then blade up to 5 mm wide). *Spike* mostly 4- to 10-flowered, flowers mostly 10–15 mm apart; bracts 2–3 mm long. *Flowers* nodding, deep magenta with tepal bases yellow edged with darker magenta (or pale pink or white, throat pale yellow); perianth tube 3.0–3.5 mm long, expanded in upper 1 mm; tepals 8–9 × 4–5 mm, oriented vertically with lowermost tepals recurved. *Filaments* unilateral, ± 2 mm long; anthers 2.0–2.5 mm long, parallel. *Style* with branches ± 1 mm long, reaching to ± middle of filaments. *Flowering time*: mid-October to mid-November.

Distribution and ecology: restricted to the Piketberg Mtns in Western Cape, South Africa, mostly at elevations of 650–800 m; on rocky sandstone slopes, often in wet moss pads.

Diagnosis: *Ixia tenuis* is distinguished from the widespread *I. scillaris* by its very slender habit, the stems rarely branched, usually three, narrow leaves, mostly 1.5–3.0 mm wide, and relatively small flowers with tepals 8–9 × 4–5 mm and anthers 2.0–2.5 mm long. The corms are also relatively small, mostly less than 10 mm in diameter and with relatively fine tunic fibres. Corms of *I. scillaris* are larger, typically 12–18 (rarely only 10) mm in diameter, with relatively coarse tunic fibres, and the species has broader leaves, mostly 8–25 mm wide. Provisionally collections from De Hoek

Distribution of ***Ixia tenuis***.



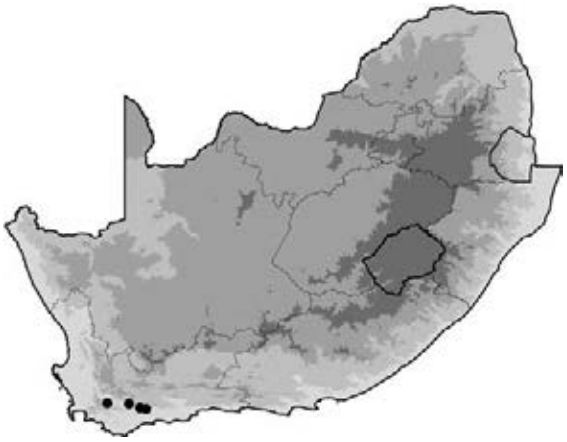
at the southern end of the Piketberg and flowering in September are included here. These plants have slightly broader but shorter leaves than typical *I. tenuis* and have undulate margins.

98. **Ixia flagellaris** *Goldblatt & J.C.Manning* in Bothalia 42: 107 (2012a). Type: South Africa, [Western Cape], Wuppertal, Heuningvlei, Groot Koupoort, common on wet sandy flats burnt last summer, 3 150 ft [± 960 m], 11 Oct. 1975, *Kruger 1687* (NBG, holo.; PRE, iso.).

Plants 150–330 mm high. *Corm* small, up to 10 mm diam., bearing stolons from base up to 50 mm long, with a large terminal cormlet up to 5 mm diam.; tunics finely fibrous to moderately coarse. *Stem* simple, rarely with 1 branch. *Leaves* 4, uppermost sheathing for most of its length, foliage leaves narrowly sword-shaped to falcate, ± ⅓ as long as stem, mostly 2–4 mm wide, main vein prominent, margins slightly thickened. *Spike* mostly 5- to 9-flowered; bracts translucent with purple veins, 3–4 mm long, outer 3-veined, acutely 3-toothed, inner slightly shorter than outer, 2-veined and 2-toothed. *Flowers* evidently zygomorphic, nodding with tepals vertical, pink, throat and tepal bases yellow edged with deep pink; perianth tube filiform, ± 3 mm long; tepals ovate, ± 9 × 4.5 mm. *Filaments* evidently unilateral, slightly flattened, ± 2 mm long; anthers oblong-orbicular, ± 3 mm long, yellow, thecae recurved, acute at base, splitting incompletely from base. *Style* dividing at base of filaments, branches ± 1.8 mm long, falcate, slender. *Flowering time*: October and November.

Distribution and ecology: restricted to middle and upper elevations in the Cederberg in Western Cape, South Africa, known from Heuning Vlei in the north and from Sneeuberg in the south; on damp flats, most likely on peaty sandstone ground, flowering well after fire.

Diagnosis: the outstanding feature of *Ixia flagellaris* is the corm, which is remarkable in the *I. scillaris* complex in the finely fibrous corm tunics and in the production of slender stolons up to 50 mm long each terminating in a relatively large cormlet. No other member of sect. *Dichone* produces stolons although they are known in a few species of other sections. *Ixia flagellaris* otherwise accords closely with *I. scillaris* subsp. *toximontana*, notably in its relatively low stature, 150–330 mm high, and small flowers with tepals ± 9 × 4.5 mm, but differs in lacking prominent, thickened leaf margins. The late flowering and moist habitat, seeps and marshy sites, are unusual for the complex, although known in the Piketberg species, *I. tenuis*. Plants from Koebee Pass may belong here as they have fine corm tunics and unthickened leaf margins but they evidently do not produce stolons. Their exact status remains uncertain.



Distribution of ***Ixia flagellaris***.

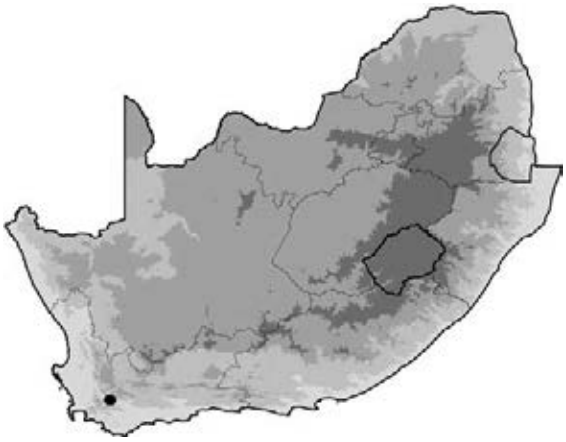
99. **Ixia simulans** *Goldblatt & J.C.Manning* in Bothalia 42: 107 (2012a). Type: South Africa, Western Cape, Langeberg Mtns, gorge near Montagu hot springs above Keisie River, on steep rocky sandstone slopes, 1 Sept. 2007, *Goldblatt & Porter 12946* (NBG, holo.; K, MO, PRE, iso.).

Plants 400–700 mm high. *Corm* ± 10 mm diam., tunics of fine, netted fibres. *Stem* usually simple, rarely with a single branch. *Leaves* 2(3), lower 1(2) with narrowly sword-shaped to linear blade with single prominent vein, ± ½ as long as stem, 1.5–6.5 mm wide, margins thickened and slightly raised, hyaline when dry; upper leaf sheathing lower ½ of stem, with short, unifacial tip. *Spike* fairly lax, weakly flexuose or straight, 4- to 8-flowered; bracts membranous, translucent, purple at tips, ± 4 mm long, outer usually 3-veined and 3-toothed, inner 2-veined and forked at apex. *Flowers* ± nodding with tepals inclined in nearly vertical plane, zygomorphic with stamens unilateral, bright (rarely pale) pink, tepal bases white, unscented; perianth tube filiform, ± 4.5 mm long, tightly clasping style; tepals spreading, ovate-elliptic, (10–)12–14 × 5–6 mm, inner whorl slightly larger than outer. *Filaments* unilateral, inserted at mouth of tube, ± 2.5 mm long, white; anthers oblong, 2.0–2.5 mm long, yellow, horizontal or slightly pendent, thecae acute and slightly recurved at base, dehiscing incompletely from base. *Style* dividing opposite lower ⅓ of filaments, branches ± 1.3 mm long, white, tubular, falcate. *Flowering time*: mid-August to mid-October.

Distribution and ecology: restricted to the western Langeberg in Western Cape, South Africa, from Dassieshoek near Robertson to Swellendam and Suurbraak, and in Lemoenpoort in the northern foothills of the Riviersonderend Mtns; on rocky sandstone slopes.

Diagnosis: *Ixia simulans* closely resembles *I. scillaris* in general appearance and in the pink flowers, which have unilateral, horizontal to slightly pendent anthers that dehisce incompletely by narrow slits near the base. It differs most conspicuously in its single, or rarely two, long, foliage leaves with ± linear blades 1.0–4.5 mm wide, spikes of only 4 to 8 flowers, relatively short floral bracts ± 4 mm long and the spreading, subequal tepals, those of the inner whorl being slightly shorter than the outer. The tepals are inclined and all held in the same

Distribution of ***Ixia simulans***.



plane whereas those of *I. scillaris* are always held vertically and the lowermost tepal is weakly to strongly recurved and held apart from the other five tepals.

100. **Ixia collina** *Goldblatt & Snijman* in South African Journal of Botany 51: 68 (1985); Manning & Goldblatt: 108 (2012a). Type: South Africa, [Western Cape], Aan de Doorns, SW of Worcester, Farm Alfalfa, 30 Aug. 1983, *Snijman 721* (NBG, holo.; MO, PRE, S, iso.).

Plants 500–900 mm high. *Corm* globose, 7–12 mm diam., often with cormlets at base; tunics of medium-textured fibres. *Stem* usually 2- or 3-branched, branches held at right angles to main axis, distally suberect, subtended by short, acute bracts and prophylls. *Leaves* 3 or 4, lower 2 or 3 ± linear to narrowly sword-shaped, ± ½ as long as stem, 4–8 mm wide, main vein moderately thickened, uppermost leaf sheathing lower ½ of stem. *Main spike* flexuose, 7- to 16-flowered, lateral spikes with fewer flowers; bracts membranous, translucent, 4.5–7.0 mm long, outer with 3 prominent, purple veins, 3- or 5-toothed, inner 2-veined and 2-toothed. *Flowers* zygomorphic, half to fully nodding, pink, tepal bases white to yellow edged deep pink, sweetly scented; perianth tube filiform, ± 5 mm long, expanded in upper 0.5 mm; tepals subequal, ovate, ± obtuse, 9–12 × ± 5 mm. *Filaments* unilateral, ± horizontal, inserted at mouth of filiform part of tube, ± 3 mm long, curved at right angles in upper 1 mm and becoming flattened and as wide as anthers; anthers ± 3 mm long, oblong, yellow, thecae acute and recurved near base, dehiscing incompletely from base. *Style* dividing at base of filaments, branches ± 2.5 mm long, tubular, falcate, apex bifid. *Flowering time*: late August to mid-September.

Distribution and ecology: a narrow endemic of the mid-Breede River Valley in Western Cape, South Africa, near Aan de Doorns south of Worcester and on the Rooiberg south of Robertson; on south-trending slopes of low clay hills above the Breede River flood plain.

Diagnosis: *Ixia collina* is easily distinguished from other members of ser. *Dichone* by the unusual branching pattern: the relatively short branches extend outward horizontally and curve upward distally, as well as by an unusual floral feature. The filaments are unique in the section in being filiform below, curved at right angles in the distal 1 mm and broadened so that they are as wide as the anthers. As in *I. scillaris,* the flowers are zygomorphic and have unilateral stamens.

Distribution of ***Ixia collina***.

UNCERTAIN SPECIES

Ixia aurantiaca Klatt. See synonymy of *I. erecta* var. *lutea* Ker Gawl. below.

Ixia bicolorata Klatt: 396 (1882). *I. polystachya* var. *bicolorata* (Klatt) Baker: 78 (1896). Type: South Africa, [Western Cape], near Cape Town, *Spilhaus s.n.* (B: Herb. Lubeck, holo. not extant). The identity of the type, no longer extant, is uncertain. If correctly from near Cape Town (by inference on the Cape Peninsula) (Klatt 1882) this pale yellow-flowered plant is most likely *I. dubia* but the low stature, 6–12 inches [150–300 mm] high, no mention of the characteristic dark central mark in the flower and bracts violet at the tips argues against this determination. Lewis (1962) suggested the species might equally be *I. polystachya*, but this is also usually taller and likewise has a flower with a darker central mark. De Vos (1999) suggested that *I. bicolorata* might not be an *Ixia.*

Ixia erecta var. *lutea* Ker Gawl. in Curtis's Botanical Magazine 22: t. 846 (1805). *I. aurantiaca* Klatt: 397 (1882), new name for *I. lutea* (Ker Gawl.) Baker: 91 (1877), illegitimate homonym, not *I. lutea* Eckl. (1827). *I. polystachya* var. *lutea* (Ker Gawl.) G.J.Lewis: 107 (1962). Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 846 (1805). No plant matching this illustration is known.

Ixia hybrida Ker Gawl.: 227 (1804a). Type: South Africa, without precise locality or collector, illustration in Curtis's Bot. Mag. 7: t. 127 (as 128) '*Ixia flexuosa*' (1790). The illustration shows a plant with flowers white with tepals red at base edged with a broader pink halo, erect, white filaments, diverging anthers and style dividing opposite the base of the anthers and said to be scented. The illustration matches no known member of sect. *Ixia* and may well be an interspecific hybrid.

Ixia retusa Salisb., Prodromus stirpium in horto ad Chapel Allerton vigentium: 35 (1796). *Watsonia retusa* (Salisb.) Klatt: 354 (1882). Type: unknown. The identity of this species has remained a mystery as the description is inadequate to identify the plant and no type is known. Ker Gawler (in Sims 1801) associated the name with what he called *Ixia polystachya* (actually *I. scillaris*, thus not the same as Linnaeus's species), and Lewis (1962) queried whether *I. retusa* might be *I. stricta*. Although *I. retusa* may be a member of sect. *Dichone*, it is impossible to tell which species and the name has been rejected.

EXCLUDED SPECIES

Ixia minuta L.f.: 92 (1782). This is the basionym of *Pauridia minuta* (L.f.) Th.Durand & H.Schinz (Hypoxidaceae).

Ixia nervosa Vent.: t. 10 (1803), invalid name. The name was proposed by Ventenat for *I. dubia* and *I. maculata* should they be considered conspecific.

Subtribe 6. **Radinosiphoninae**

Radinosiphoninae *Goldblatt & J.C.Manning*, new subtribe. Type: *Radinosiphon* N.E.Br.

Corm tunics papery becoming fibrous; stem well developed, angled. *Leaf* margins with subepidermal sclerenchyma strand. *Inflorescence* a spike. *Flowers* zygomorphic with stamens arcuate; style branches simple or notched apically; seed epidermal cell outlines prominent; ovular vasculature intact; $x = 15$.

Genera 1, only *Radinosiphon* (2 spp.): southern Africa to east tropical Africa.

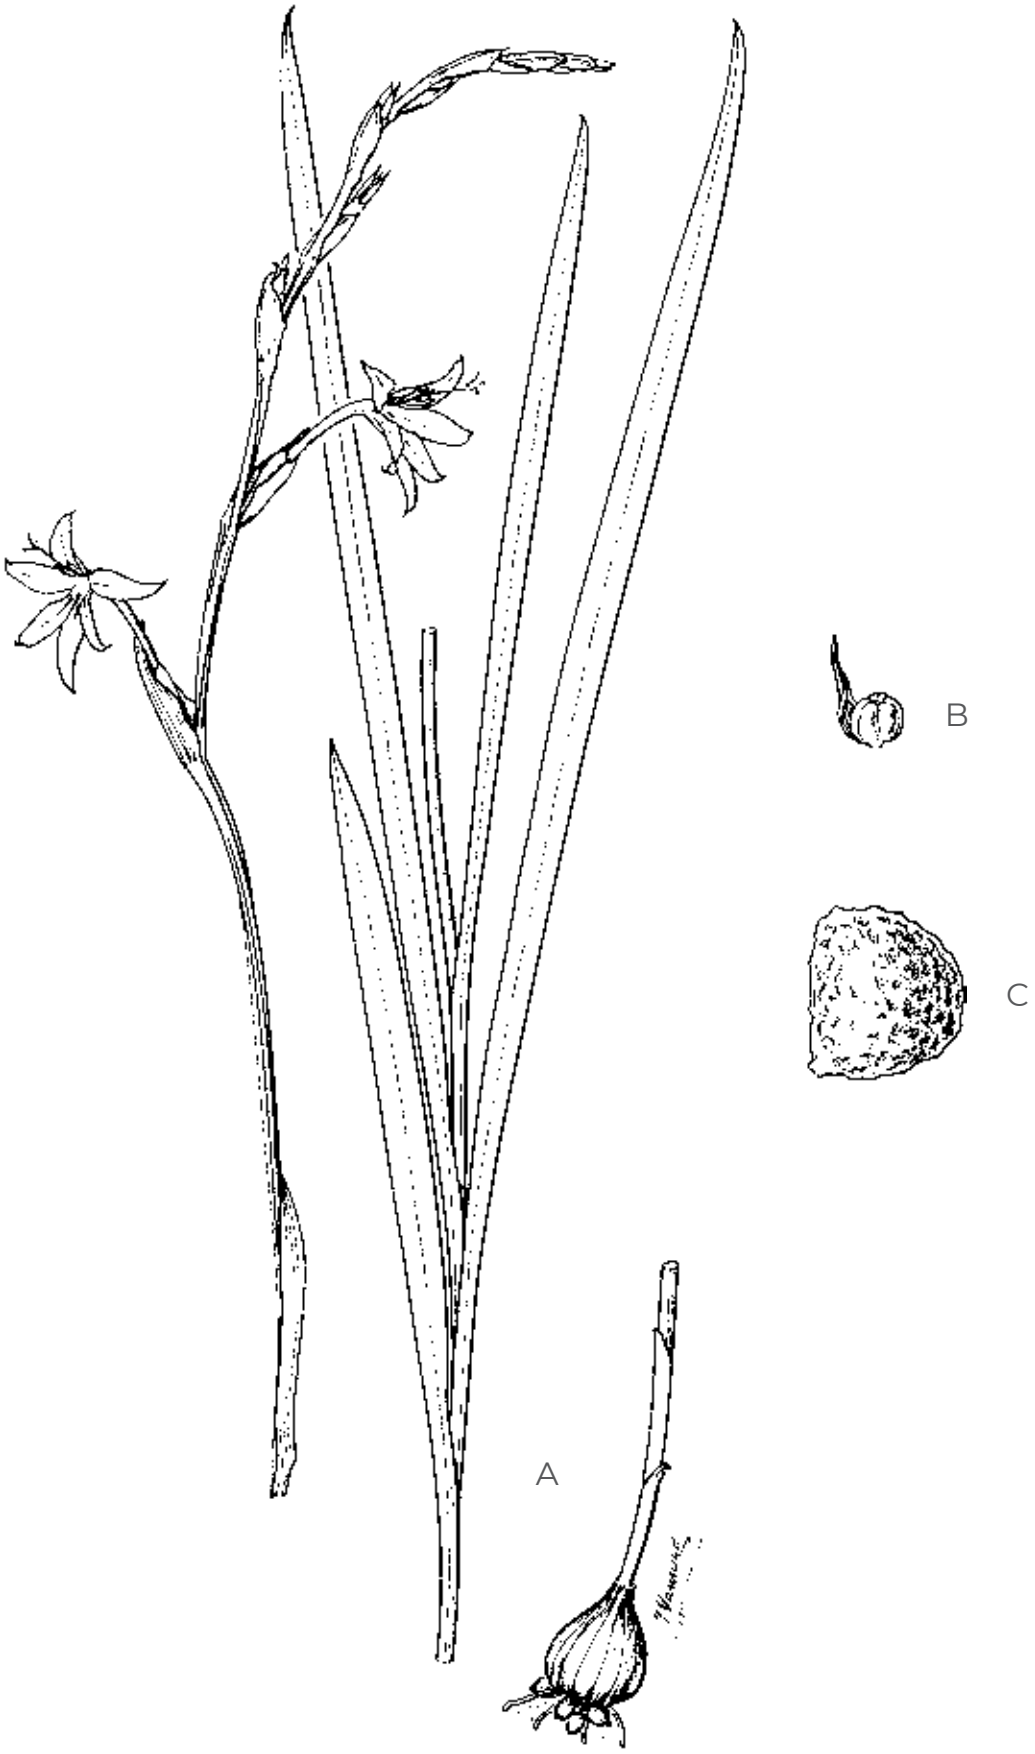
29. **Radinosiphon**

Radinosiphon *N.E.Br.* in Transactions of the Royal Society of South Africa 20: 262 (1932). Lectotype: *R. leptostachya* (Baker) N.E.Br., designated by Goldblatt & Manning: 155 (2008).

Revisionary accounts: Brown: 261–280 (1932); Carter: t. 1384 (1962).

From the Greek, *radinosus*, slender, *siphon*, tube, for the tubular flowers.

Deciduous geophytes, often stoloniferous or rhizomatous. *Corm* globose, axial in origin, tunics papery, becoming finely fibrous. *Cataphylls* 2 or 3, dry and papery or uppermost green. *Stem* aerial, simple or few-branched, compressed and angled or weakly winged. *Leaves* several, unifacial, sword-shaped, mostly basal and forming a lax 2-ranked fan, blade plane with definite main vein, ± soft textured; marginal bundle with fibre cap, epidermis unspecialised. *Inflorescence* a spike, secund; bracts green or flushed purple and soft-textured or submembranous, becoming dry apically, inner similar to outer thus multi-veined without two main veins but shorter and notched apically. *Flowers* zygomorphic, long-lived, salver-shaped, pink to light purple, lower tepals with darker median streaks, unscented, with nectar from septal nectaries; perianth tube elongate, suberect and curved outward distally, cylindric widening slightly distally; tepals subequal and weakly spreading, narrowly lanceolate, dorsal slightly larger and arching over anthers, weakly hooded, lower 3 forming a lip. *Stamens* unilateral and arcuate; filaments inserted shortly below top of perianth tube; anthers mauve. *Ovary* subglobose; style filiform, 3-branched distally, branches narrowly oblanceolate, longitudinally folded or channelled, diverging. *Capsules* subglobose, cartilaginous. *Seeds* few to several per locule, globose, flattened at chalazal end, lightly wrinkled, matte, testa cells domed. *Pollen grains* monosulcate-operculate, operculum 2-banded, exine perforate-scabrate. *Basic chromosome number* $x = 15$.



Species 2, northeastern South Africa and Eswatini through eastern Zimbabwe, Zambia and Malawi to southern Tanzania, mainly montane in rocky habitats, or low grassland and light bush.

A taxonomically isolated genus, *Radinosiphon* is unusual in Crocoideae in the angled or lightly winged stems and in having the inner bracts resembling the outer in both texture and venation – in most other Crocoideae the inner bracts are strongly 2-veined and often more completely membranous than the outer. Molecular data place the genus as sister to the clade including *Romulea* and related acaulescent genera, but there is no evident morphological support for this relationship. Although Brown recognised five species when he described the genus, later opinion (Carter 1962) favoured their reduction to a single, variable species *R. leptostachya*. We are able, however, to recognise two species among the southern African material, although the distinction between them is not always clear. Large-flowered plants that we have seen on the Mauchsberg and adjacent peaks east of Lydenburg represent a distinctive race, which we treat under the name *R. lomatensis*. These populations differ from typical *R. leptostachya* not only in their larger flowers but evidently also in their outbreeding system and mode of vegetative reproduction.

Key to species

1a Perianth tube (25–)30–45 mm long; tepals 12–15 mm long, uppermost 3–7 mm wide; seeds up to 8 per locule; plants outbreeding . . . . . 1. *R. lomatensis*

1b Perianth tube 15–30 mm long; tepals 8–12(–15) mm long, uppermost 2–3 mm wide; seeds mostly 1 or 2(–5) per locule; plants autogamous . . . . . 2. *R. leptostachya*

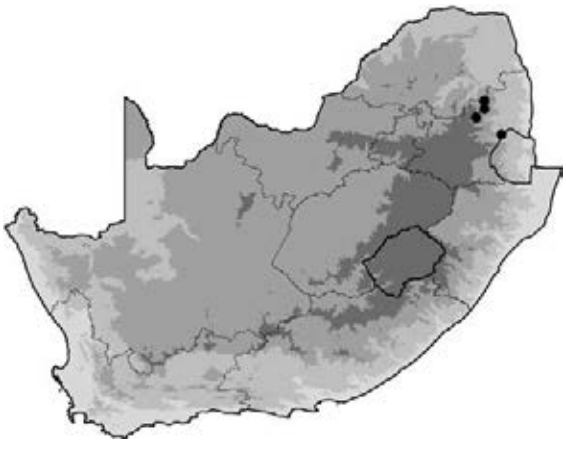
Radinosiphon leptostachya: A, flowering plant; B, capsule; C, seed.

1. **Radinosiphon lomatensis** *(N.E.Br.) N.E.Br.* in Transactions of the Royal Society of South Africa 20: 263 (1932). *Acidanthera lomatensis* N.E.Br.: 298 (1921). Type: South Africa, Transvaal [Mpumalanga], Lomati Valley, near Barberton, among rocks, 1 200 m, *G. Thorncroft 1065* (K, holo.).

Plants 300–750 mm high. *Corm* 8–15 mm diam., producing naked stolons from base; tunics papery, becoming finely fibrous. *Stem* simple or branched. *Leaves* 6 to 9, mostly basal and reaching base of spike, narrowly lanceolate, 150–300 × 4–15 mm, cauline leaves ± 3, progressively smaller and entirely sheathing. *Spike* inclined, 2- to 10-flowered; bracts 10–18 mm long. *Flowers* pale to deep pink, all or only lower 3 tepals with dark pink median streak; tube (25–)30–45 mm long; tepals ± spreading, linear to lanceolate, 12–15 × 2–3, uppermost lanceolate, 3–7 mm wide. *Filaments* 6–7 mm long, exserted ± 4 mm from tube; anthers 5–6 mm long, purple. *Style* dividing opposite or beyond anther tips, branches 2–3 mm long. *Capsules* subglobose, ± 10 mm long. *Seeds* up to 8 per locule, 2–3 mm diam. *Flowering time*: January, February.

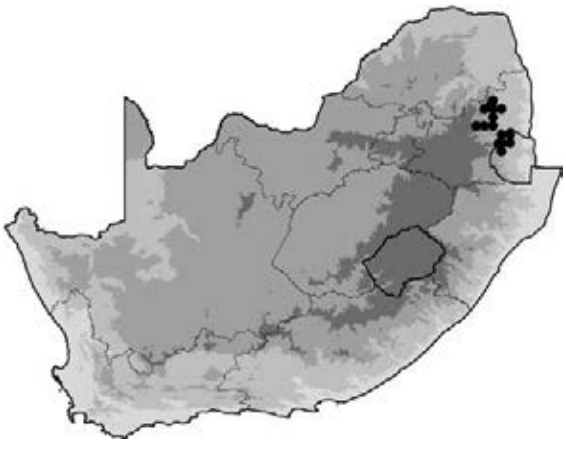
Distribution and ecology: a local endemic restricted to the highlands above 2 000 m elevation, between Pigg's Peak in northern Eswatini and the mountains west of Lydenburg, South Africa; in quartzite outcrops in montane grassland. It has been confirmed to be pollinated by long-proboscid nemestrinid flies.

Diagnosis: distinguished from *Radinosiphon leptostachya* by its larger flowers, with longer perianth tube, (25–)30–45 mm long, broader tepals, the uppermost 12–15 × 3–7 mm, slightly longer filaments 6–7 mm long, and anthers 5–6 mm long. Plants of *R. lomatensis* reproduce vegetatively by slender, naked stolons quite different from the thick, scaly rhizomes developed in *R. leptostachya*. The species is evidently outcrossing, producing larger capsules with up to 8 seeds per locule, unlike autogamous *R. leptostachya*, which produces small capsules, 4–6 mm long, containing just 1 or 2 seeds (rarely up to 5 in tropical Africa) per locule.



2. **Radinosiphon leptostachya** *(Baker) N.E.Br.* in Transactions of the Royal Society of South Africa 20: 263 (1932). *Lapeirousia leptostachya* Baker: 170 (1892). *Acidanthera leptostachya* (Baker) N.E.Br.: 297 (1921). Type: South Africa, Transvaal [Mpumalanga], Lydenburg District, Macmac [Mac Mac], *Mudd s.n.* (K, holo.).

Lapeirousia holostachya Baker: 391 (1894). *Acidanthera holostachya* (Baker) N.E.Br.: 297 (1921). *Radinosiphon holostachya* (Baker) N.E.Br.: 263 (1932). Type: [Zambia], Fwambo, Lake Tanganyika, Feb. 1893, *A. Carson 14* (K, holo.)



Tritonia acroloba Harms in Engler: 278 (1901). Type: [Tanzania], Ubena, eastern Livingstone Mtns, Mar. 1899, *Goetze 814* (B, holo.).

Radinosiphon cameronii N.E.Br.: 263 (1932). Type: Nyasaland, [Malawi], summit of Chiradzulu, 1905, *Cameron 179* (K, holo.).

Plants (80–)150–500(–750) mm high. *Corm* 8–15 mm diam., developing scaly rhizomes from base, sometimes producing cormlets; tunics papery, becoming finely fibrous. *Stem* usually branched, rarely with small cormlet in axils of upper leaves when unbranched. *Leaves* 6 to 9, mostly basal and reaching base of spike, narrowly lanceolate, 150–300 × 3–10(–15) mm, cauline leaves ± 3, progressively smaller and entirely sheathing. *Spike* inclined, (2–)4- to 12-flowered; bracts 8–18(–25) mm long. *Flowers* pale to deep pink, all or only lower 3 tepals with dark pink median streak; perianth tube 15–30 mm long; tepals ± spreading, linear to lanceolate, 8–12(–15) × 1–2(–3), uppermost lanceolate, 2–3 mm wide. *Filaments* 4–6 mm long, exserted ± 3 mm from tube; anthers 2.5–5.0 mm long, purple. *Style* dividing opposite or beyond anthers tips, branches 1.5–2.0 mm long. *Capsules* globose, 4–6 mm long. *Seeds* 1 or 2 (rarely up to 5 in tropical Africa) per locule, 2–3 mm diam., lightly wrinkled. *Flowering time*: January to March.

Distribution of ***Radinosiphon lomatensis***.

Distribution of ***Radinosiphon leptostachya***.

Distribution and ecology: ranging along the north eastern escarpment, from Eswatini to Pilgrim's Rest in Mpumalanga in southern Africa, and northward though Mozambique and eastern Zimbabwe to Malawi, Tanzania and Zambia; in quartzite outcrops and crevices in montane grassland, 1 000–2 000 m elevation.

Diagnosis: as far as we can determine this is an autogamous species which is prone to the development of local forms varying in flower size, especially perianth tube length and tepal dimensions, several of which were described as distinct species. Among the southern African material we are able distinguish two more-or-less distinct entities, smaller flowered plants corresponding to *Radinosiphon leptostachya* and larger-flowered, outbreeding plants which we treat as *R. lomatensis*. Typically, *R. leptostachya* has flowers with the perianth tube 15–30 mm long, and narrow, almost linear lower tepals 8–12 × 1–2 mm, with the upper tepals at most 3 mm wide. The small capsules, 4–6 mm long, contain just one or two seeds per locule (up to five in tropical African material). The species appears to have a very distinctive means of vegetative reproduction through the development of thick, scaly rhizomes. These do not always elongate, resulting in the formation of clusters of corms that are well illustrated in Carter (1962).

Subtribe 7. **Crocinae**

Crocinae [as subtribe Croceae] *Bentham & Hooker*, Genera Plantarum 3: 683 (1883). Type: *Crocus* L.

Corm often asymmetric, tunics woody or fibrous; stem often contracted and subterranean. *Leaves* often filiform or bifacial, margins either with a subepidermal sclerenchyma strand or with columnar epidermis. *Inflorescence* with solitary flowers, sometimes angled. *Flowers* actinomorphic; style branches simple or deeply divided (*Romulea*); seed epidermal cell outlines smooth; ovular vasculature intact; x = ?14 (12, 10, 7, 6, many other numbers in *Crocus*).

Genera 4, 3 in southern Africa; species ± 180, 92 in southern Africa: *Romulea* 84; *Afrocrocus* 1; *Syringodea* 7.

30. **Romulea**

Romulea *Maratti*, Plantarum Romuleae et Saturniae: 13 (1772), name conserved against *Ilmu* Adans. [Vienna Congress 1905]. Type: *Romulea bulbocodium* (L.) Sebast. & Maur. (conserved type).

Bulbocodium Gronov.: 38 (1755), illegitimate homonym, not *Bulbocodium* L. (1737). Type: *B. crocifolium* Gronov. = *Romulea bulbocodium* (L.) Sebast. & Mauri

Ilmu Adans.: 497 (1763). Type: Unknown.

Trichonema Ker Gawl.: t. 575 (1802). *Romulea* subg. *Trichonema* (Ker Gawl.) Klatt: 400 (1882). Type: *T. cruciatum* (Jacq.) Ker Gawl. = *R. cruciata* (Jacq.) Bég.

Spatalanthus Sweet: t. 300 (1829). Type: *S. speciosus* Sweet = *Romulea monadelpha* (Sweet) Baker

Bulbocodium Ludw. ex Kuntze: 700 (1891), illegitimate homonym, not *Bulbocodium* L. (1737). Type: not designated.

Revisionary accounts: De Vos: 1–307 (1972); De Vos: 10–76 (1983); Manning & Goldblatt: 59–108 (2001).

Named for Romulus, one of the legendary founders of Rome, where the type species is native.

Deciduous geophytes. *Corm* asymmetric with a pointed or crescent-shaped basal ridge, or bell-shaped with a circular basal rim, axial in origin, the tunics of hard, woody or rarely fibrous layers. *Cataphylls* 1 to 3, dry and papery or membranous. *Leaves* solitary to several, lower (1)2 or evidently all basal, blade usually bifacial and ± terete, filiform or cylindric, straight or twisted, main vein and margins ± thickened or winged and blade longitudinally 4(8)-grooved or H-shaped, rarely bifacial and channelled, glabrous or ribs ciliate; margin with fibrous vascular bundle and unspecialised epidermis. *Stem* short and subterranean or longer and aerial, angles occasionally pubescent, usually branched, sometimes only below the ground, sometimes coiled in fruit. *Inflorescence* composed of solitary flowers terminal on branches; outer bracts green with narrow or broader, colourless or brown-flecked, membranous margins, usually glabrous, smooth or prominently veined, inner bracts with broad membranous margins or ± entirely membranous, 2-veined and acute or bifid apically. *Flowers* actinomorphic, long-lived, closing tightly at night, mostly cup-shaped with shallow or deep cup, or salver-shaped, variously coloured, often pink or yellow, usually paler in centre, sometimes with darker markings around cup, sometimes with prominently coloured veining on outside, usually unscented, with nectar from septal nectarines (often only traces or lacking); perianth tube usually short and funnel-shaped, sometimes elongate and cylindric; tepals equal or subequal, usually ascending below and spreading above. *Stamens* central and symmetrically arranged; filaments inserted shortly below top of tube, ± contiguous, rarely united (in *R. monadelpha*), often slightly swollen and hairy below; anthers linear, diverging or contiguous, yellow to black. *Ovary* subglobose; style filiform, branching opposite or beyond anthers, 3-branched distally, branches usually divided for half their length or ± multifid. *Capsules* cartilaginous, oblong to subglobose. *Seeds* subglobose or lightly angled, flattened at chalazal end, smooth, matte, surface cells usually colliculate. *Pollen grains* monosulcate-operculate, operculum (1)2-banded, exine perforate-scabrate. *Basic chromosome number* x = 14 or 13, other base numbers 12, 11, 10, 9.

Species ± 94, widespread across Africa, southern Europe and the Middle East, but centred in the winter-rainfall zone of South Africa, with a secondary centre in the western Mediterranean and Canary Islands; 84 spp. in southern Africa, another 2 spp. in tropical Africa, and a further ± 8 spp. in Europe.

Romulea is recognised by the mostly stemless or short-stemmed habit, narrow and needle-like (sometimes winged) leaves with four (rarely three or eight) longitudinal grooves, and radially symmetric, funnel-shaped or more rarely salver-shaped flowers borne singly at the

branch tips. The style branches are deeply divided, even multifid in some species. The corms are usually asymmetric (rarely bell-shaped) with a rounded or pointed base, often with a crescent-shaped basal ridge, and the tunics are ± woody. The shape of the corm and the way in which the tunics fragment are diagnostic for the sections and these features are critical for correct identification of the species. Bell-shaped corms with a circular basal rim have evolved at least twice (in sections *Aggregatae* and *Romulea*). The anatomy of the leaves is taxonomically valuable, notably the degree of development of the bundle caps (touching the epidermis as vascular girders or not), the absence of secondary bundles, and the presence of fibre strands or additional vascular bundles in the rib margins (Table 1).

Molecular data place the genus in a clade with *Crocus, Syringodea* and *Afrocrocus*, all of which are distinguished by their ± bifacial leaves and variously derived pollen. Outgroup comparison suggests that oblique corms with a crescent-shaped basal ridge and woody tunics splitting into fine parallel fibres, as found in sect. *Romulea*, is ancestral for *Romulea*.

The presence or absence of yellow pigmentation in the distal part of the tepals (i.e. not the cup, which is often yellow) is often correlated with characters of the leaf anatomy or chromosome number or both. Tepal colour was therefore considered to be taxonomically critical by De Vos (1972), who treated plants with yellow to orange or salmon-pink flowers as specifically distinct from morphologically similar plants with magenta or lilac flowers. Currently *Romulea dichotoma* is the only species that includes yellow as well as pink-flowered plants. Differentiating between yellow and blue shades of pink can be difficult (and impossible in dried material without adequate colour notes).

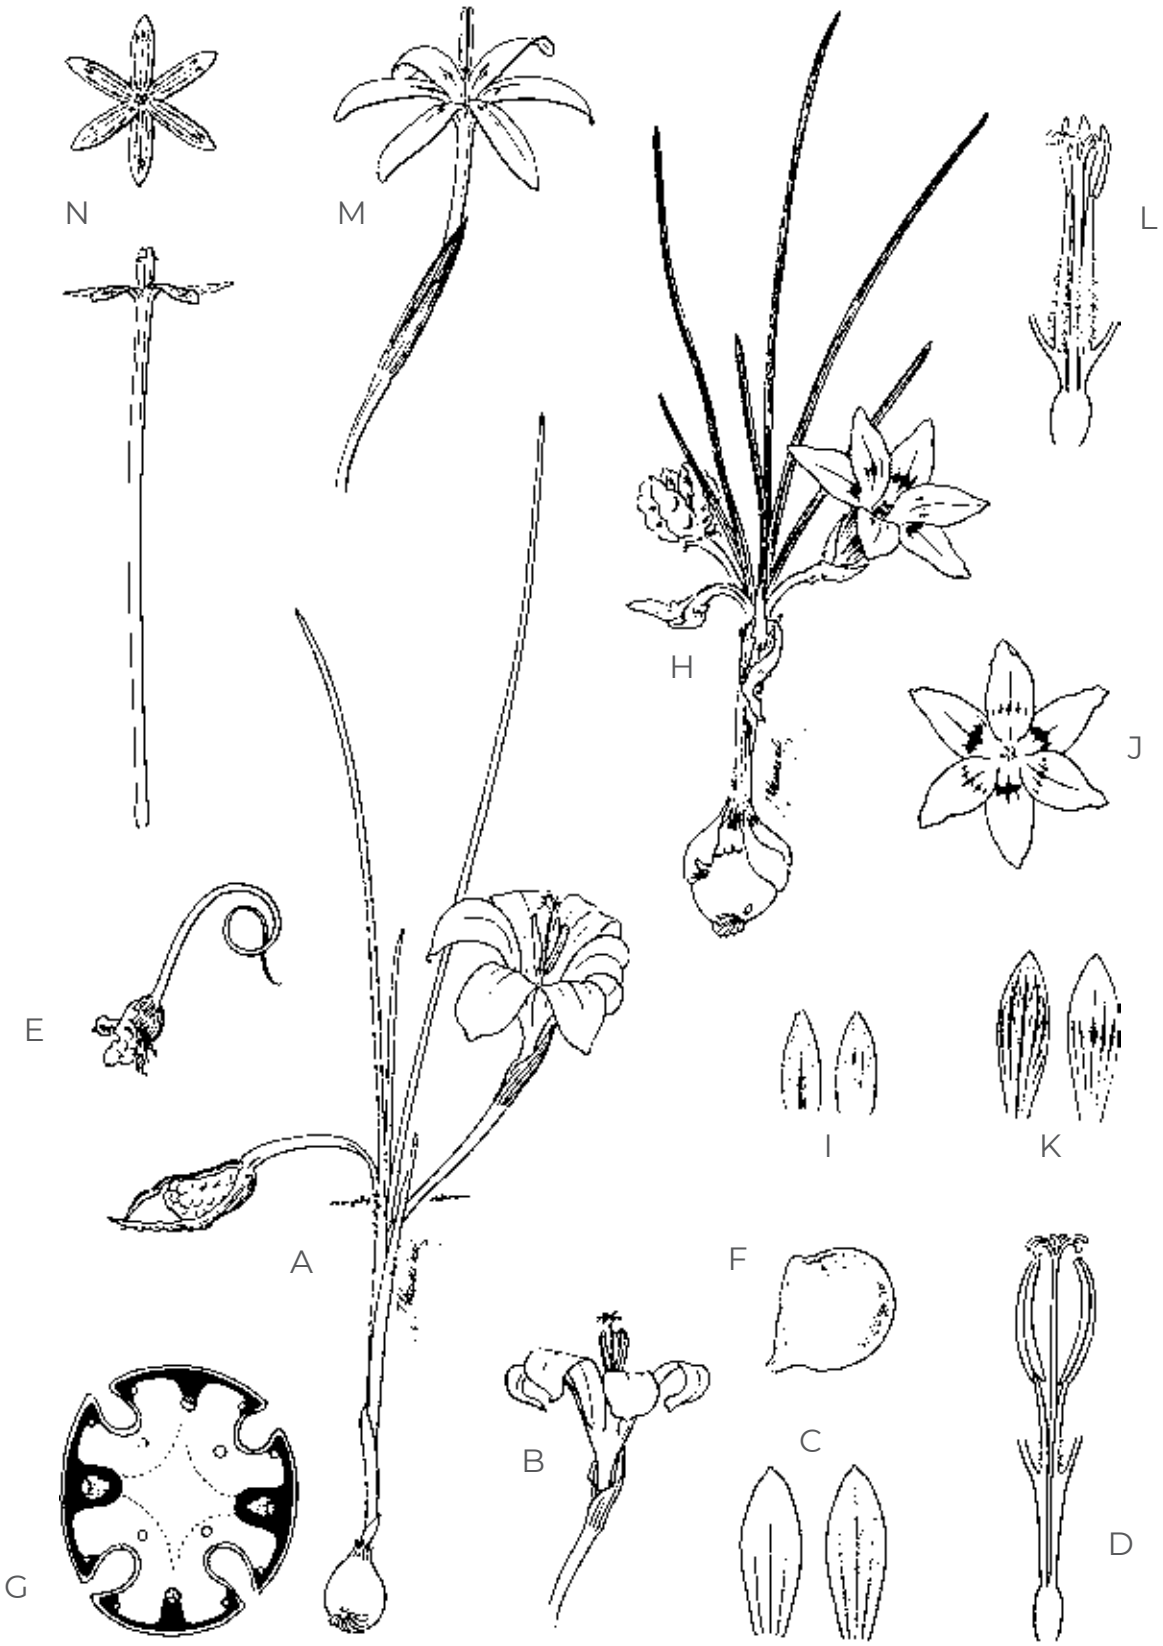
Pollination systems in the genus are less diverse than in other large genera of Iridaceae, evidently a consequence of the conservative floral architecture and flowering phenology, and significant diversity is restricted to the winter-rainfall region species. Species with unmarked or weakly marked, cup-shaped flowers, comprising the majority, are pollinated by pollen-collecting bees, sometimes in combination with hopliine beetles (Scarabaeidae: Hopliini); those with larger, red or dark pink flowers conspicuously marked with dark blotches are specialised for pollination by hopliine beetles; and species with long floral tubes are adapted for pollination by long-proboscid flies (Goldblatt et al. 2002).

Key to sections

1a Corms rounded or pointed at base, tunics splitting into coarse, bent or straight teeth without fibrous tips; stem short and subterranean . . . . . sect. 4 *Roseae*
1a Corms either obliquely or vertically flattened toward base with crescent- or fan-shaped basal ridge, or bell-shaped with circular basal ridge, tunics fringed or splitting into fibrils or slender teeth on basal ridge or rim; stems short or well-developed:
2a Basal fibres aggregated into small, rounded clusters, the fibrils in each cluster converging and pointed, a root emerging from each cluster . . . . . sect. 3 *Aggregatae*
2b Basal fibres or teeth not aggregated into clusters of converging fibrils, sometimes the basal ridge more deeply incised between groups of parallel fibres but roots not emerging only from fibril clusters, fibrils ± blunt:
3a Corms with moderate-sized to small oblique basal ridge up to half as wide as corm; tunics splitting into slender, pointed or flexed teeth. . . . . sect. 2 *Autumnales*
3b Corms with prominent basal ridge, more than ½ as wide as corm; tunics splitting into fine, truncated fibrils . . . . . sect. 1 *Romulea*

Key to species

1. Sect. *Romulea*



1a Corms symmetrical and bell-shaped with circular basal rim (ser. *Hirsutae*):
2a Flowers apricot-coloured or pink to magenta with yellow cup:
3a Tepals 3–5 mm wide, pale pink without dark blotches in throat . . . . . 22. *R. gracillima*
3b Tepals 6–12 mm wide, pink to apricot-coloured, with or without dark blotches in throat . . . . . 23. *R. hirsuta*
2b Flowers yellow or white with yellow cup:
4a Corm strongly depressed, disc-shaped; flowers yellow with black blotches in throat . . . . . 26. *R. discifera*
4b Corm bell-shaped; flowers white or yellow without dark blotches in throat:
5a Flowers yellow (rarely white), outer tepals greenish or cream-coloured on reverse; basal rim of the corm narrow; fruiting peduncles suberect or slightly spreading . . . . . 24. *R. triflora*
5b Flowers white, outer tepals purplish or green on reverse; basal rim of corm wide and scalloped; fruiting peduncles abruptly spreading . . . . . 25. *R. sladenii*
1b Corms obliquely flattened with crescent-shaped basal ridge or compressed with fan-shaped basal ridge:
6a Flowers salver-shaped with cylindric perianth tube ≥ 10 mm long, white to purple or magenta; filaments usually glabrous:
7a Flowers yellow; outer bracts with broad membranous margins or entirely submembranous . . . . . 33. *R. tubulosa*

ROMULEA. R. eburnea: A, flowering plant; B, flower; C, detached inner tepal (left) and outer tepal showing lower surface; D, detail of stamens and style; E, dehisced capsule; F, seed; G, tissue plan of leaf transection. ***R. collina***: H, flowering plant; I, outer bract (left) and inner bract (right); J, flower front view; K, detached outer tepal (left) and inner tepal (right) showing lower surface; L, detail of stamens and style. ***R. albiflora***: M, flower. ***R. hantamensis***: N, flower front view (top) and side view (bottom).

7b Flowers white or blue to purple; outer bracts with narrow membranous margins:
8a Leaf 1(2); filaments inserted near top of tube, thus ± entirely exserted; perianth tube 11–17 mm long (ser. *Stellanthe*) . . . . . 21. *R. stellata*
8b Leaves 3 to 6; filaments inserted near middle of tube, thus mostly or entirely included:
9a Perianth tube 17–25 mm long; filaments inserted in upper half of tube, 4–5 mm long, glabrous 19. *R. kamisensis*
9b Perianth tube 10–13 mm long; filaments inserted in lower half of tube, 8–9 mm long, pilose basally . . . . . 17. *R. singularis*
6b Flowers funnel-shaped with perianth tube < 10 mm long; filaments often hairy:
10a Basal foliage leaves 4-winged, H-shaped in section and usually conspicuously ciliate; peduncles hairy (ser. *Tetragonae*) . . . . . 36. *R. tetragona*
10b Basal foliage leaves ± terete and narrowly grooved, rarely T-shaped in section but never winged and H-shaped in section; peduncles glabrous:
11a Leaf blades 5- to 8-grooved; plants aquatic with corms submerged (ser. *Aquaticae*):
12a Basal foliage leaves 2; style 12–15 mm long, dividing near anther apices; fruiting peduncles widely spreading, 50–90 mm long . . . . . 27. *R. multisulcata*
12b Basal foliage leaf 1; style 4–8 mm long, dividing near anther bases; fruiting peduncles erect, 10–50 mm long . . . . . 28. *R. aquatica*
11b Leaf blades 4-grooved, sometimes channelled above; plants not aquatic but sometimes growing in marshy ground:
13a Outer bracts with conspicuous brown-streaked membranous apices and/or margins (ser. *Namaquana*):
14a Flowers carmine-red. . . . . 30. *R. speciosa*
14b Flowers white to mauve or yellow:
15a Stem well-exserted with long internode above basal leaf . . . . . 29. *R. rupestris*
15b Stem subterranean or shortly exserted:
16a Upper cataphyll pale green; flowers yellow . . . . . 32. *R. pearsonii*
16b Upper cataphyll purple speckled white; flowers white . . . . . 31. *R. maculata*
13b Outer bracts with narrow or scarcely visible membranous apices and margins:
17a Inner bracts wholly scarious or submembranous, differing markedly from outer bracts; basal foliage leaf 1 when stem elongated; outer tepals without dark feathering on reverse:
18a Flowers white with large black blotches bordered with yellow in throat; leaves widely 2-grooved and T-shaped in section . . . . . 8. *R. barkerae*
18b Flowers without dark blotches; leaves 4-grooved:
19a Flowers pale or sulphur-yellow, white or blue; inner bracts usually scarious . . . . . 9. *R. flava*
19b Flowers golden- or orange-yellow (rarely cream-coloured with golden-yellow cup); inner bracts often greenish in upper half, central part sometimes spotted with brown . . . . . 7. *R. saldanhensis*
17b Inner bracts usually with green median zone and wide membranous margins, rarely both outer and inner bracts membranous; basal leaves usually 2 when stem elongated; outer tepals with or without dark feathering on reverse:
20a Flowers uniformly yellow:
21a Outer bracts membranous throughout or in lower half, rarely green; leaves often channelled for most of length (ser. *Tortuosae*):
22a Perianth tube 13–35(–65) mm long, lower part elongate and cylindric, widening distally; bracts 20–60 mm long . . . . . 40. *R. macowanii*
22b Perianth tube 3–10 mm long, cylindric basal part very short; bracts 10–25 mm long:
23a Foliage leaf 1(2), with adhering sand particles . . . . . 39. *R. sphaerocarpa*
23b Foliage leaves 2 to 8, without adhering sand particles:
24a Basal ridge oblique to vertical, sometimes fan-shaped and much wider than corm; leaves 4 to 8, often flexuous or twisted, bifacial almost to tip, sometimes conspicuously ciliate; outer bracts largely membranous or submembranous . . . . . 38. *R. tortuosa*
24b Basal ridge oblique, not or scarcely wider than corm; leaves 2 to 4(6), suberect or spreading, bifacial only in lower half, never ciliate; outer bracts green or submembranous in lower half . . . . . 37. *R. austinii*
21b Outer bracts mostly green with or without narrow membranous margins:
25a Filaments at least twice as long as anthers:
26a Leaves 3 to 5, filiform, acute; bracts ovate-lanceolate, inner with broad membranous margins > 1 mm wide; perianth tube 4–5 mm long; tepals acute, with dark marks at base . . . . . 12. *R. sulphurea*
26b Leaves 2 or 3, terete to subclavate, obtuse; bracts suborbicular, inner with narrow membranous margins < 1 mm wide; perianth tube 7–8 mm long; tepals obtuse, without dark marks at base . . . . . 13. *R. quartzicola*
25b Filaments less than twice as long as anthers, mostly ± as long as anthers:
27a Inner bracts with relatively narrow colourless margins widened only at base; reverse of outer tepals green with brown flecks along margins . . . . . 10. *R. elliptica*
27b Inner bracts with wide, brownish or brown-flecked margins; reverse of outer tepals green or irregularly streaked but without distinct brown flecks along margins:
28a Basal foliage leaf 1; flowers unmarked. . . . . 11. *R. lutea*
28b Basal foliage leaves 2; flowers with or without dark marks in throat:
29a Corm with narrow basal ridge and fibrils uniformly arranged; fruiting peduncles at first curved, later suberect. . . . . 14. *R. citrina*
29b Corm with wide basal ridge, often wider than the corm, fibrils irregularly clustered; fruiting peduncles widely spreading . . . . . 15. *R. montana*

20b Flowers not entirely yellow although usually with a yellow cup:
30a Filaments inserted in middle of tube or above, usually red or reddish black; flowers with little or no yellow in cup. . . . . 18. *R. namaquensis*
30b Filaments inserted in lower half of tube, yellow to orange:
31a Corm higher than wide with high, chisel-shaped basal ridge; stem subterranean; flowers up to 20 mm long; inner bracts usually with conspicuously brown-spotted membranous margins (ser. *Minutiflorae*):
32a Flowers 7–15 mm long, often with mauve throat, tepals 4–9 mm long and < 3 mm wide; inner bract margins conspicuously brown-spotted . . . . . 34. *R. minutiflora*
32b Flowers 15–20 mm long, white, tepals 10–12 × 3–4 mm; inner bract margins inconspicuously spotted . . . . . 35. *R. sinispinosensis*
31b Corm ± as wide as high or wider; stem usually aerial; flowers up to 35 mm long; inner bracts with unspotted or spotted membranous margins:
33a Flowers rose-coloured or pink with large violet or purple blotches in yellow throat . . . . . 20. *R. biflora*
33b Flowers without blotches in throat or rarely pale lilac with small blotches:
34a Anthers sagittate, connectives attenuate and produced 2.5–6.0 mm above thecae . . . . . 4. *R. flexuosa*
34b Anthers oblong, connectives not produced:
35a Corm obliquely flattened with wide, fan-like basal ridge. . . . . 16. *R. toximontana*
35b Corm not flattened, with narrow, crescent-shaped basal ridge:
36a Tepals usually bicoloured above cup, lower third or half yellow and upper part white to blue or lilac; fruiting peduncles at first recurved, later suberect; inner bract margins flecked with brown:
37a Basal leaves 2; bracteole green and leathery with broad membranous margins; upper part of tepals cream-coloured or white, 5–8 mm wide; outer tepals not blotched on reverse . . . . 6. *R. leipoldtii*
37b Basal leaf usually 1; bracteole green or submembranous with central part flushed purplish; upper part of tepals bluish or white, usually up to 5 mm wide; outer tepals often irregularly blotched on reverse . . . . . 5. *R. tabularis*
36b Tepals unicoloured above cup; fruiting peduncles not recurved; inner bract margins translucent or speckled:
38a Outer tepals shiny and wine-red on reverse, inner tepals pale; tepals mostly obtuse. . . . . 3. *R. vinacea*
38b Outer tepals not shiny and wine-red; tepals acute to subobtuse:
39a Stem rigid; flowers pale lilac to mauve, pink or cream-coloured; stamens 8–19 mm long . . . . . 1. *R. schlechteri*
39b Stem slender and wiry; flowers magenta, rarely pale pink; stamens 6–8 mm long . . . . 2. *R. saxatilis*

2. Sect. *Autumnales*

1a Corm with inconspicuous, pointed basal ridge much less than half as wide as corm; flowers often pink or purple with yellow cup:
2a Corm tunics papery, splitting into slender teeth curved over basal ridge, becoming almost fibrous with age; leaves 3 or 4; stem exserted (ser. *Alticolae*). . . . . 41. *R. alticola*
2b Corm tunics woody, splitting into small teeth converging on basal point; leaves up to 6; stem subterranean (ser. *Autumnales*):
3a Stamens and style not reaching halfway up perianth, included in cup; tepals mostly 20–30 mm long; bracts sparsely striate and soft-textured basally . . . . . 42. *R. autumnalis*
3b Stamens and style reaching more than halfway up perianth, exserted from cup; tepals mostly 12–20 mm long; bracts closely ribbed, rarely softer basally . . . . . 43. *R. camerooniana*
1a Corm with prominent basal ridge at least half as wide as corm, tunics splitting into teeth bent over and fragmenting across basal ridge; stem subterranean or aerial; flowers white or pale pink to blue with greenish yellow cup (ser. *Pratenses*):
4a Corm tunics with basal fibrils parallel and not clustered; bract green throughout; flowers usually white . . . . 44. *R. gigantea*
4b Corm tunics with basal fibrils aggregated into regular clusters converging at tips, each cluster separated by a deeper cleft; bract submembranous in lower half; flowers usually pale pink. . . . . 45. *R. pratensis*

3. Sect. *Aggregatae*

1a Flowers carmine-red with or without whitish or yellow cup; anthers longer than filaments (ser. *Amoenae*):
2a Corm bell-shaped with circular basal rim; flowers with paler cup and dark blotches in throat; filaments whitish, puberulous below. . . . . 46. *R. pudica*
2a Corm oblique with incompletely circular basal rim; flowers uniformly carmine-red; filaments reddish, glabrous . . . . . 47. *R. sanguinalis*
1b Flowers magenta, pink, apricot-coloured, orange, yellow or white with yellow cup; anthers shorter than or as long as filaments (ser. *Aggregatae*):
3a Stem usually short; leaves filiform, glabrous; inner bracts with membranous margins unmarked:
4a Flowers white to pink, outer tepals flushed dark on reverse . . . . . 54. *R. albomarginata*
4b Flowers yellow to apricot-coloured . . . . . 53. *R. setifolia*
3b Stem usually well-developed; leaves filiform to H-shaped and winged, glabrous or median ribs pilose; inner bracts with membranous margins usually brown-flecked or edged, at least in upper part:
5a Leaves falcate, 4–6 mm wide, H-shaped in section with median ribs winged and pilose, lateral ribs not raised; bracts pilose . . . . . 52. *R. pilosa*

5b Leaves filiform to linear, 1–2 mm wide, X-shaped or I-shaped with median ribs thickened and glabrous or pilose and lateral ribs thickened and raised; bracts glabrous:
6a Corm tunics split from base into long strips fringed with converging fibrils along edges and clustered at tips, fibrous above and forming conspicuous neck; flowers pink to magenta with violet blotches in throat . . . .48. *R. fibrosa*
6b Corm tunics not split into long strips from base, with clusters of fibrils only at tips, with or without fibrous neck; flowers variously coloured:
7a Basal foliage leaves 2, median ribs glabrous or ciliate on margins; flowers pale greenish, cream-coloured, yellow or apricot-coloured, often with dark apricot-coloured veins; plants from near Port Elizabeth eastwards . . . . . 49. *R. longipes*
7b Basal foliage leaf 1 (rarely 2 but then lower leaf shorter), median ribs often villous or pilose on margins; flowers pink or yellow to orange; plants from west of Humansdorp:
8a Leaves X-shaped in cross section, lateral and median ribs subequal and angled, with secondary vein on either side of median vein (visible under microscope only); flowers orange; plants form Little Karoo mountains . . . . . .50. *R. jugicola*
8b Leaves ± I-shaped in section, lateral ribs reduced and rounded, partially concealed by arching, winged median ribs, without secondary veins; flowers pink to orange or yellow; plants from coastal mountains . . . . . 51. *R. dichotoma*

4. Sect. *Roseae*

1a Flowers salver-shaped with cylindric perianth tube 15–70 mm long; filaments inserted near top of tube, glabrous:
2a Corm pointed with straight basal teeth; peduncles not or scarcely exserted at flowering; perianth tube 35–70 mm long (ser. *Tubiformes*). . . . . 84. *R. hantamensis*
2b Corm rounded with curved or bent basal teeth; peduncles ± exserted at flowering; perianth tube 15–30 mm long (ser. *Lomurea*):
3a Flowers white; leaves conspicuously hairy, ± straight and at least twice as long as inflorescence . . . . . 83. *R. albiflora*
3b Flowers pink to purple; leaves sparsely hairy, curved outward below flowers . . . . . 82. *R. syringodeoflora*
1b Flowers cup- or funnel-shaped with perianth tube up to 6 mm long; filaments inserted near base of tube, usually pilose below:
4a Basal leaves 4-winged and H-shaped in section, with two wide lateral grooves and a strong vein up the middle of each groove, glabrous to villous; flowers pale yellow (ser. *Hirtae*) . . . . . 76. *R. hirta*
4b Basal leaves narrowly 4-grooved, without evident vein up middle of grooves:
5a Inner and often also outer bracts submembranous or at most subherbaceous in upper half:
6a Corm pointed, with straight basal teeth; flowers without dark blotches . . . . . .75. *R. membranacea*
6b Corm rounded, with curved or bent basal teeth; flowers with or without dark blotches:
7a Leaves 7 to 9; flowers with dark blotches in throat; filaments ± twice as long as anthers . . . . . .74. *R. collina*
7b Leaves 1 to 4; flowers without dark blotches in throat; filaments ± as long as anthers or only slightly longer:
8a Inner bracts without brown spotting; fruiting peduncles unknown; plants from Cederberg and Swartruggens:
9a Leaf emergent at flowering; peduncles short, flowers borne at ground level; outer bract entirely membranous or submembranous . . . . . 72. *R. fuscomontana*
9b Leaf fully developed at flowering; peduncles well-developed, flowers well exserted; outer bract ± herbaceous . . . . . .71. *R. monophylla*
8b Inner bracts with brown-speckled membranous margins; fruiting peduncles coiled; plants from Klein Roggeveld and Koo:
10a Perianth tube 10–13 mm long; tepals 23–25 mm long; anthers ± 8 mm long; style exserted beyond stamens . . . . . 70. *R. eburnea*
10b Perianth tube 5–9 mm long; tepals 8–20 mm long; anthers 3–4 mm long; style shorter than stamens . . . . . 73. *R. malaniae*
5b Inner and outer bracts ± herbaceous with membranous margins:
11a Outer bracts with well-developed membranous tips; fruiting peduncles usually coiled (ser. *Atrandrae*):
12a Flowers yellow:
13a Leaves 6 to 9; tepals unequal, inner 2–3 mm wider than outer, uniformly golden-yellow; bracteoles with colourless or pale brownish membranous margins; style exserted beyond anthers . . . . . .69. *R. diversiformis*
13b Leaves 2 to 6; tepals subequal; bracteoles usually with brown-flecked membranous margins; style not exserted beyond anthers:
14a Corm tunics woody; perianth tube cup- or funnel-shaped, less than half as long as tepals; tepals 16–35 mm long; filaments inserted near base of tube, ± as long as anthers; anthers 4–9 mm long; plants from Northern and Western Cape . . . . . .67. *R. luteoflora*
14b Corm tunics papery; perianth tube narrowly funnel-shaped, more than half as long as tepals; tepals 10–12 mm long; filaments inserted at or above middle of tube, longer than anthers; anthers 2–3 mm long; plants from Lesotho/KwaZulu-Natal Drakensberg. . . . . 68. *R. sanisensis*
12b Flowers white or lilac to magenta with yellow or white cup:
15a Corm pointed, with straight basal teeth . . . . . .63. *R. vlokii*
15b Corm rounded, with curved or bent basal teeth:
16a Style branches much-divided, stigmas usually more than 12; leaves 2 or 3 . . . . . 66. *R. multifida*
16b Style branches bifid, stigmas usually 6:
17a Perianth cup brown at base, not longitudinally striped; membranous margins of inner bract as wide as green median part throughout; anthers usually coiled; pollen usually orange or rust-red, rarely yellow . . . . . 65. *R. komsbergensis*

17b Perianth cup yellow at base, often longitudinally striped; membranous margins of inner bract narrower than green median portion at least below; anthers erect; pollen yellow to orange:
18a Outer bracts with ovate or oblong green median zone; flowers white or lilac to magenta. . . . . 62. *R. atrandra*
18b Outer bracts with triangular green median zone; flowers pale lilac-blue. . . . . 64. *R. hallii*
11b Outer bracts with inconspicuous membranous tip; fruiting peduncles never coiled:
19a Corm pointed with straight basal teeth; capsules pointed and obscurely beaked:
20a Flowers (35–)40–60 mm long, old-rose to terracotta-coloured with dark blotches in throat and with pale yellow or greenish yellow cup; filaments (6–)9–12 mm long. . . . . 59. *R. eximia*
20b Flowers 25–35 (40) mm long, magenta to lilac with dark blotches in throat and with golden-yellow or orange-yellow cup; filaments 3–6 mm long. . . . . 58. *R. cruciata*
19b Corm rounded with curved or bent basal teeth; capsule obtuse to truncate:
21a Inner bracts 2-keeled with 2 stronger veins, especially in upper half; outer bract often distinctly keeled in upper half; perianth tube cup-shaped (ser. *Bicarinatae*):
22a Flowers yellow. . . . . 81. *R. viridibracteata*
22b Flowers red, orange or pink:
23a Leaves ± 1 mm diam., filiform with 4 narrow grooves; outer bracts with membranous margins sometimes ± entirely black:
24a Filaments oblong, black, fused in a stout column or free but closely adpressed; peduncle angled. . . . 80. *R. monadelpha*
24b Filaments tapering, pale or dark, free; peduncle terete . . . . . 79. *R. sabulosa*
23b Leaves 2–5 mm wide, ± swollen with 4 wide grooves, sometimes H-shaped; outer bracts with membranous margins colourless or lightly brown-flecked:
25a Leaves 4 to 9; flowers pinkish red . . . . . 77. *R. subfistulosa*
25b Leaf 1 (rarely 2 or 3 but then additional leaves much smaller); flowers orange-red . . . . . 78. *R. unifolia*
21b Inner bracts not 2-keeled and without 2 stronger veins; outer bract not keeled; perianth tube funnel-shaped:
26a Flowers bright yellow with darker veins in throat; membranous margins of bracteoles ± as wide as central green portion; fruiting peduncles suberect or curved; from Bokkeveld and Matsikamma-Giffberg . . . . . 61. *R. monticola*
26b Flowers lilac to pink, apricot-coloured or white, rarely yellow but then membranous margins of bracteoles distinctly narrower than central green portion and fruiting peduncles widely spreading; from Cederberg southwards:
27a Leaves 3 to 12, terete, 0.5–1.5 mm diam.; flowers 2 or more; anthers ± as long as or longer than filaments:
28a Flowers apricot-, terracotta-, deep old-rose-coloured or yellow; fruiting peduncles widely spreading from base. . . . . 60. *R. obscura*
28b Flowers magenta, lilac-pink or rosy pink to white; fruiting peduncles straightening and suberect . . . . . 57. *R. rosea*
27b Leaves 1 or 2, rarely 3, filiform, ± 0.5–1.0 mm diam.; flowers 1, rarely 2; anthers half as long as filaments or less:
29a Leaves usually 2, not sticky; inner bracts with purple central portion; flowers with distinct yellow cup, tepals 7–16 mm long; stamens yellow, filaments 5–6 mm long . . . . . 55. *R. cedarbergensis*
29b Leaf 1, sticky; inner bracts ± entirely membranous; flowers yellow at base of tepals but without distinct yellow cup, tepals 16–20 mm long; stamens lilac, filaments 9–10 mm long. . . . . 56. *R. lilacina*

Sect. 1. **Romulea**

[Ser. *Romulea* is entirely European and is distinguished from ser. *Ciliatae* by the presence of fibre strands in the leaf rib margins and by a somatic chromosome number $2n = 34, 36$.]

Ser. **Ciliatae** *(M.P.de Vos) J.C.Manning & Goldblatt*, name at new rank and new synonym. *Romulea* subsect. *Ciliatae* M.P.de Vos in Journal of South African Botany, Suppl. 9: 60 (1972). *R.* sect. *Ciliatae* (M.P.de Vos) J.C.Manning & Goldblatt: 76 (2001). Type: *R. flava* (Lam.) M.P.de Vos

Corm subglobose, obliquely flattened toward base or almost bilaterally compressed; basal rim finely fringed. *Stem* subterranean or aerial. *Leaves* usually with secondary bundles and vascular girders, without rib marginal fibre strands or rib marginal bundles. *Chromosome number* $2n = 24, 26, 28$.

1. **Romulea schlechteri** *Bég.* in Botanische Jahrbücher für Systematik 38: 335 (1907). Type: South Africa, [Western Cape], Pakhuis Mtns, *Schlechter 8648* (B, lecto., designated by De Vos: 64 (1972); BOL, BM, G, K, Z, isolecto.).

Romulea elegans var. *parviflora* Baker: 42 (1896). Type: South Africa, [Western Cape], Swartberg, Caledon, *Zeyher 4043* (K, holo.; K, P, iso.).

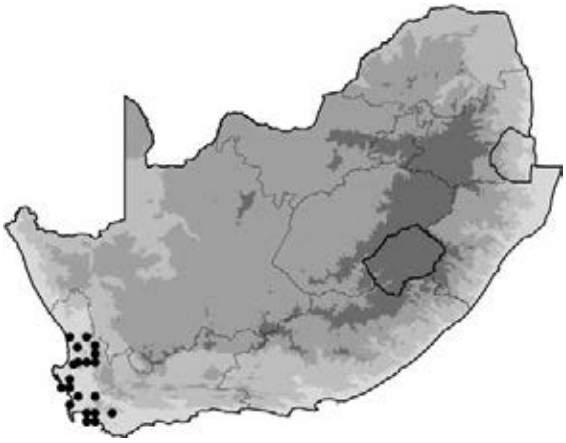
Romulea ×*hybrida* Bég.: 339 (1907). Type: South Africa, [Western Cape], Swartberg near Caledon, *Zeyher 4043* (G, holo.; K, P, iso.).

Plants (20–)40–200 mm high. *Corm* globose, obliquely flattened toward base with crescent-shaped basal ridge ± as wide as corm, 7–15 mm diam., tunics splitting into fine parallel fibrils along ridge, sometimes forming fibrous neck above. *Stem* subterranean or aerial, exserted

up to 200 mm. *Leaves* 3 to 5 (rarely more), lowermost 2 basal, terete or compressed-cylindric and narrowly 4-grooved, 0.5–1.5 mm diam., sometimes ciliolate along rib margins. *Peduncles* mostly up to 4, rarely up to 12, semiterete, sometimes ciliolate on sharp angles, suberect or spreading in fruit; outer bracts green with narrow membranous margins, 10–25 mm long, widely striate (3 or 4 veins/mm), inner bracts with broad, colourless membranous margins. *Flowers* pale violet, lilac-pink, white or cream-coloured, sometimes with dark lines in throat, cup pale to golden-yellow or orange, outer tepals green or irregularly blotched or streaked on reverse, sweetly scented; perianth tube funnel-shaped, 3–7 mm long; tepals elliptic, 12–40 × 4–12 mm. *Filaments* 4–10 mm long, pilose at base, yellow; anthers 4–9 mm long, pale or golden-yellow. *Style* dividing below or above anther tips, branches 2–4 mm long, divided halfway. *Capsules* ellipsoid, 8–10 mm long. *Flowering time*: July to September (October)

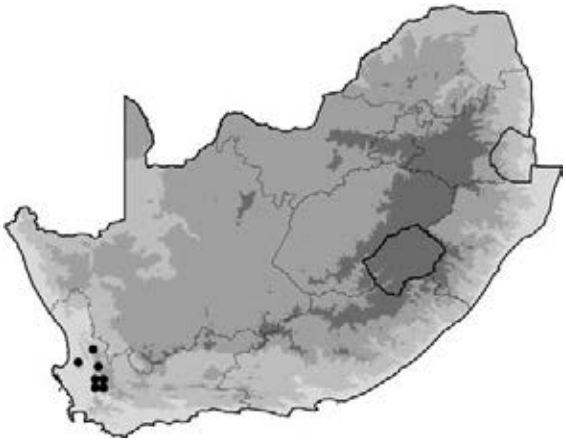
Distribution and ecology: scattered through the extreme southwestern parts of Western Cape, South Africa, from Vredendal along the coast to Mamre and inland from the Cederberg to the Kleinrivier Mtns above Hermanus; in sandy soils in fynbos.

An especially attractive race with large, cream-coloured flowers with orange cups occurs in coastal sandveld vegetation between Mamre and Yzerfontein.



Diagnosis: a poorly defined species without any distinctive features and including those members of ser. *Ciliatae* with two basal leaves (glabrous or ciliolate on the rib margins), bracteoles with unmarked membranous margins, and lilac-pink, pale violet or white to cream-coloured flowers with a pale or golden-yellow cup. The outer tepals are greenish or irregularly blotched with purple. See *Romulea saxatilis* and *R. vinacea* for characteristics of those species. Confusion is also possible with forms of *R. tabularis* in which the basal yellow pigmentation on the tepals is reduced but this species, which favours waterlogged or marshy sandy flats, has a solitary basal leaf and the bracteole margins are flecked with brown on the edges.

2. **Romulea saxatilis** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 71 (1972). Type: South Africa, [Western Cape], Ceres, *Guthrie 18558* (BOL, holo.).



Plants (40–)70–200 mm high. *Corm* globose, obliquely flattened toward base with crescent-shaped basal ridge ± as wide as corm, 7–15 mm diam., tunics splitting into fine parallel fibrils along ridge, sometimes forming fibrous neck above. *Stem* usually aerial, exserted up to 200 mm, very slender, almost wiry. *Leaves* 3 to 4, lowermost 2 basal, filiform and narrowly 4-grooved, 0.5–1.0 mm diam. *Peduncles* up to 3, semiterete, suberect or spreading in fruit; outer bracts green with narrow membranous margins, 8–15 mm long, finely striate (5 or 6 veins/mm), inner bracts with broad, membranous margins colourless or brown-flecked along edge. *Flowers* deep (rarely pale) pink, with short dark lines or small blotches in throat, cup golden-yellow, outer tepals streaked on reverse, rose-scented; perianth tube funnel-shaped, 4–6 mm long; tepals elliptic, 9–22 × 4–6 mm. *Filaments* 3–5 mm long, pilose at base or throughout, golden-yellow; anthers 3–4 mm long, pale yellow. *Style* dividing just below or just beyond anthers apices, branches ± 2 mm long, divided halfway. *Capsules* subglobose to ellipsoid, 5–8 mm long. *Flowering time*: September, October (November).

Distribution and ecology: a montane species endemic to the western mountains in Western Cape, South Africa, from the Cederberg through the Cold Bokkeveld and Olifants River Mtns to Tulbagh and on the Piketberg; in rocky sand in fynbos.

Diagnosis: distinguished from *Romulea schlechteri* by the very slender, almost wiry stems, mostly smaller, usually deep pink flowers with golden-yellow cup, and shorter stamens 6–8 mm long. The two species differ also in chromosome number (De Vos 1972). *Romulea saxatilis* may also be confused with *R. vinacea*, which has the outer tepals dark plum-coloured or wine-red on the reverse, and distinctly ciliate leaves and peduncles.

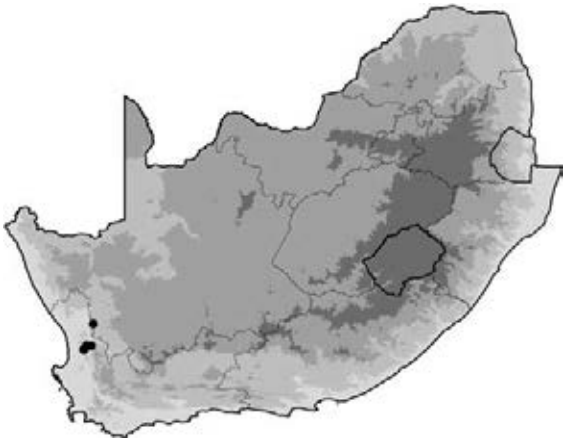
Distribution of ***Romulea schlechteri***.

Distribution of ***Romulea saxatilis***.

3. **Romulea vinacea** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 69 (1972). Type: South Africa, [Western Cape], Pakhuis Pass, *Lewis 2120* (SAM, holo.; PRE, iso.).

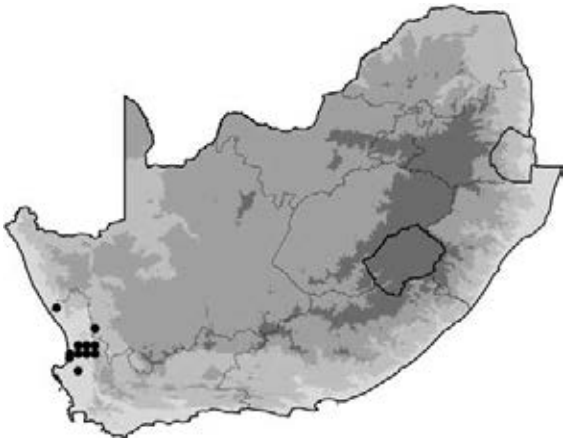
Plants 40–150(–200) mm high. *Corm* globose, obliquely flattened toward base with crescent-shaped basal ridge ± as wide as corm, 5–15 mm diam., tunics splitting into fine parallel fibrils along ridge, sometimes forming fibrous neck above. *Stem* subterranean or aerial, exserted up to 100 mm. *Leaves* 3 to 5, lowermost 2 basal when stem exserted, terete or filiform and narrowly 4-grooved, 1.0–1.5 mm diam., ciliate along rib margins. *Peduncles* up to 3, up to 50 mm long, semiterete, ciliolate along angles, suberect in fruit; outer bracts green with narrow membranous margins, 12–25 mm long, finely striate (5 or 6 veins/mm), inner bracts with broad, membranous margins brown-flecked along edge. *Flowers* pale lavender or lilac with darker veins or small blotch at base around cream-coloured cup marked with yellow at base, outer tepals glossy plum-coloured or wine-red on reverse, inner tepals pale lilac; perianth tube funnel-shaped, 4–6(–8) mm long; tepals elliptic, 14–28 × 6–10 mm, usually obtuse. *Filaments* 6–9 mm long, pilose throughout or only basally, cream-coloured; anthers 4–6 mm long, cream-coloured. *Style* dividing ± at anther apices, branches ± 3 mm long, divided halfway. *Capsules* subglobose to ellipsoid, 5–15 mm long. *Flowering time*: (July) August, September.

Distribution and ecology: endemic to the western mountains of Western Cape, South Africa, and originally thought to be restricted to the Pakhuis Mtns near the top of Pakhuis Pass but now including populations from the Olifants River Mountains near Graafwater and also Oorlogskloof on the Bokkeveld Mountains; in rocky sand in fynbos.



Diagnosis: distinguished from similar pink or lilac-flowered species such as *Romulea schlechteri* and *R. saxatilis* by the strongly discolorous outer segments glossy dark plum-coloured or wine-red on the reverse, contrasting strongly with the pale inner tepals. Additional features of the species are leaves with ciliate rib margins, peduncles with ciliolate angles, and inner bracts with the margins brown-flecked along the edge.

4. **Romulea flexuosa** *Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 400 (1882). Type: South Africa, without precise locality, *Drège 4038* (1 and 4) (S, holo.).



Romulea attenuata M.P.de Vos: 101 (1955). Type: South Africa, [Western Cape], Clanwilliam, Elandsfontein, *Leipoldt 4247* (BOL, holo.; STE, iso.).

Plants 50–150(–200) mm high. *Corm* globose, obliquely flattened toward base with crescent-shaped basal ridge ± as wide as corm, 8–20 mm diam., tunics splitting into fine parallel fibrils along ridge. *Stem* usually aerial, exserted up to 200 mm. *Leaves* 3 to 5, lowermost 2 basal when stem exserted, terete or filiform and narrowly 4-grooved, 0.5–1.0 mm diam. *Peduncles* up to 3, up to 60 mm long, semiterete, arcuate in fruit; outer bracts green with narrow membranous margins, 15–30 mm long, lightly striate (5 or 6 veins/mm), inner bracts with broad, colourless membranous margins. *Flowers* white or rarely pale lilac with darker veins and buff- or cream-coloured cup, outer tepals irregularly streaked with purple or green on reverse, lightly scented; perianth tube funnel-shaped, 5–8 mm long; tepals elliptic or narrowly oblanceolate-acuminate, (20–)25–35 × 7–11 mm. *Filaments* 6–7 mm long, pilose basally, white; anthers 12–15 mm long, widely sagittate below, connective attenuate and produced 2.5–6.0 mm beyond thecae, white. *Style* dividing near middle of anthers, branches 2–3 mm long, divided halfway. *Capsules* ellipsoid, up to 10 mm long. *Flowering time*: April to July.

Distribution and ecology: an early-flowering, mainly montane species ranging along the West Coast, South Africa, recorded from west of Bitterfontein in Namaqualand, and from the Bokkeveld Escarpment in Northern Cape along the Cederberg and Olifants River Mtns to the Piketberg in Western Cape, with a single

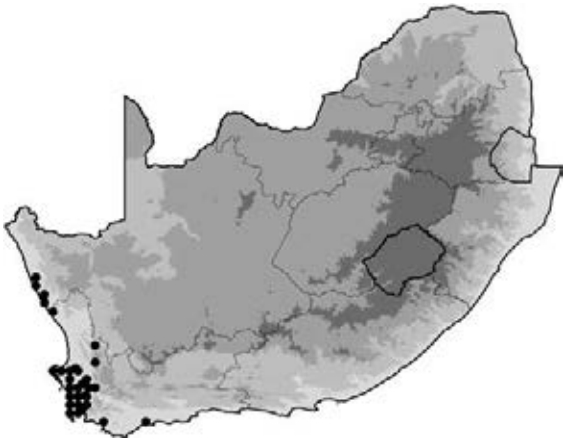
Distribution of ***Romulea vinacea***.

Distribution of ***Romulea flexuosa***.

unlocalised and unsubstantiated collection from the Hottentots Holland Mtns; on granite or sandstone slopes among rocks.

Diagnosis: instantly recognised by the unique anthers, sagittate at the base with the connective produced apically well beyond the thecae as an attenuate membranous appendage. The white to pale lilac flowers are relatively large, with ± acuminate tepals.

5. **Romulea tabularis** *Eckl. ex Bég.* in Botanische Jahrbücher für Systematik 38: 337 (1907). Type: South Africa, [Western Cape], Cape of Good Hope, *Ecklon & Zeyher 595 Irid. 199* (B, holo.).



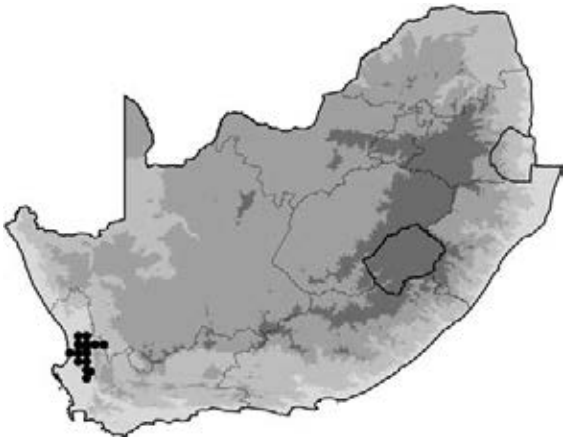
Romulea rosea var. *parviflora* Baker: 104 (1892). Type: South Africa, without precise locality, *Drège s.n. 'Trichonema recurvum* b' (K, holo. [in part]).

Romulea versicolor Bég.: 116 (1909). Type: South Africa, [Western Cape], Darling, *Schlechter 5340* (BOL, lecto., designated by De Vos: 94 (1972); GRA, K, Z, iso.).

Romulea duthieae L.Bolus: 342 (1928). Type: South Africa, [Western Cape], Stellenbosch flats, *Duthie s.n.* (BOL, holo.; NBG, iso.).

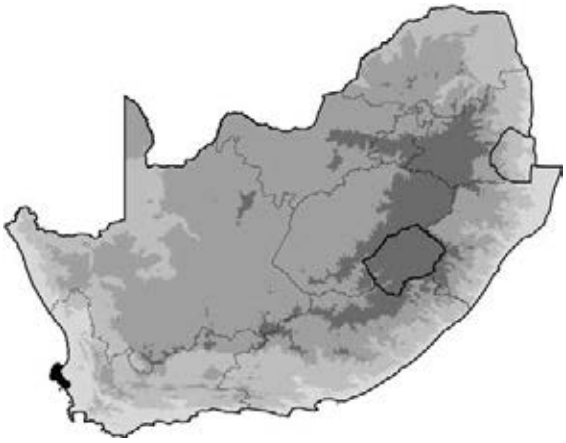
Plants 50–150(–200) mm high. *Corm* globose, obliquely flattened toward base with crescent-shaped basal ridge ± as wide as corm, 5–10 mm diam., tunics splitting into fine parallel fibrils along ridge. *Stem* usually aerial, exserted up to 150 mm. *Leaves* 2 to 5, lowermost 1(2) basal when stem exserted, terete or compressed-cylindric and narrowly 4-grooved, 1–2 mm diam., cauline leaves clustered at stem apex. *Peduncles* up to 10, up to 80 mm long, semiterete, strongly curved initially in fruit but later suberect; outer bracts green with narrow membranous margins, 8–16(–20) mm long, lightly striate (4 or 5 veins/mm), inner bracts either green or submembranous with central part flushed purplish, with broad membranous margins speckled with brown along margins and sometimes in central area. *Flowers* usually pale or darker lavender-blue or white to cream-coloured in distal half, cup and lower half of segments orange or golden-yellow, often with pale transverse band in throat, outer tepals irregularly streaked or entirely purple or green on reverse, sometimes lightly scented; perianth tube funnel-shaped, 3–5 mm long; tepals elliptic, 10–28 × 3–7 mm. *Filaments* 3–6 mm long, pilose basally, yellow; anthers 3–6 mm long. *Style* dividing slightly below to beyond anther tips, branches 1–2 mm long, divided halfway. *Capsules* ellipsoid or cylindric, ± 10 mm long. *Flowering time*: July to October.

Distribution and ecology: largely coastal, from Hondeklip Bay in Northern Cape along the West Coast to Bredasdorp in Western Cape, South Africa; on seasonally waterlogged or marshy, sandy or loamy flats, often in dense colonies.



Distribution of ***Romulea tabularis***.

Diagnosis: varying in the length of the stem, number of basal leaves, flower colour, and length of the style but generally recognised by the lavender-blue (rarely white) flowers with orange or golden-yellow cup extending onto the basal half of the tepals, mostly solitary basal leaf, and often somewhat submembranous inner bracts with brown-flecked membranous margins. The species is closely allied to *Romulea leipoldtii*, which is distinguished by its invariably two basal leaves, generally larger, white or cream-coloured flowers with tepals 18–35 × 5–8 mm, the outer tepals not marked on the reverse, and inner bracts that are green and leathery in the centre.



Specimens with two basal leaves may also be confused with *Romulea schlechteri* from drier situations, which has the yellow pigment restricted to the cup itself and not extending onto the lower half of the tepals, and inner bracts without brown flecks on the membranous margins.

6. **Romulea leipoldtii** *Marais* in Curtis's Botanical Magazine 175: t. 460 (1964). Type: South Africa, [Western Cape], Citrusdal, Warm Baths, *Leipoldt s.n.* (K, holo.).

Plants 60–300 mm high. *Corm* globose, obliquely flattened toward base with crescent-shaped basal ridge ± as wide as corm, 7–15 mm diam., tunics splitting into fine parallel fibrils along ridge. *Stem* usually aerial, exserted up to 200 mm. *Leaves* 3 to 5, lowermost 1 or 2 basal when stem exserted, filiform or terete and narrowly 4-grooved, 1.0–1.5 mm diam., cauline leaves clustered at stem apex. *Peduncles* up to 8, up to 70 mm long, semiterete, arcuate initially in fruit but later suberect; outer bracts green with narrow membranous margins, 12–18(–20) mm long, lightly striate (4 or 5 veins/mm), inner bracts green with broad membranous margins speckled or spotted with brown along margins and sometimes in central area. *Flowers* white to cream-coloured in distal half, cup and lower half of segments orange or golden-yellow, outer tepals sometimes fawn or greenish on reverse, sweetly scented; perianth tube funnel-shaped,

Distribution of ***Romulea leipoldtii***.

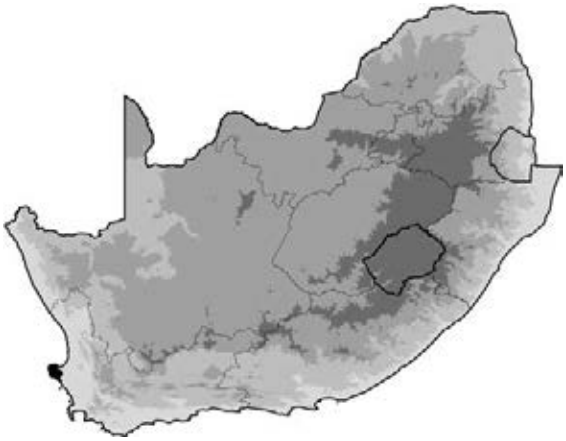
Distribution of ***Romulea saldanhensis***.

4–8 mm long; tepals elliptic, 18–35 × 5–8 mm. *Filaments* 5–8 mm long, pilose basally, yellow; anthers 5–8 mm long. *Style* dividing at or beyond anther tips, branches 2 mm long, divided halfway. *Capsules* ellipsoid or cylindric, ± 10 mm long. *Flowering time*: September, October.

Distribution and ecology: endemic to Western Cape, South Africa, from Nardousberg through Cederberg and the Olifants River Valley to Graafwater and Porterville; on seasonally waterlogged sandy flats.

Diagnosis: closely allied to *Romulea tabularis* and sharing with it the yellow pigmentation extending onto the lower half of the tepals but occurring mostly inland of that species [both species are recorded around Piketberg] and separated from it by the mostly two basal leaves, generally larger, white to cream-coloured flowers with tepals mostly more than 5 mm wide, and the firm-textured inner bracts. It can be confused with white-flowered forms of *R. schlechteri* but that species has inner bracts with unmarked membranous margins.

7. **Romulea saldanhensis** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 108 (1972). Type: South Africa, [Western Cape], Saldanha Bay, *De Vos 1772* (NBG [as STE], holo., iso.).



Plants 50–200 mm high. *Corm* globose, obliquely flattened toward base with crescent-shaped basal ridge, 8–15 mm diam., tunics splitting into fine parallel fibrils along ridge. *Stem* usually aerial, exserted up to 200 mm, elongating in fruit. *Leaves* 3 or 4, lowermost 1 basal, terete or compressed-cylindrical and narrowly 4-grooved, 1–2 mm diam., cauline leaves clustered at stem apex. *Peduncles* up to 8, up to 60 mm long, semiterete, sharply arcuate initially in fruit but later suberect; outer bracts green with narrow membranous margins, 12–20 mm long, striate or lightly ribbed (5 or 6 veins/mm), inner bracts submembranous in lower half and green or flushed maroon above, central portion sometimes conspicuously brown-spotted, with broad membranous margins usually streaked or speckled with brown. *Flowers* cadmium- or golden-yellow with slender dark lines in cup, rarely cream-coloured with golden-yellow cup, outer tepals frequently irregularly marked brown on reverse; perianth tube funnel-shaped, 3–5 mm long; tepals oblanceolate to obovate, 18–30 × 6–14 mm. *Filaments* 5–7 mm long, pilose basally, yellow; anthers 5–7 mm long, at first joined apically. *Style* dividing at or beyond anther tips, branches 2 mm long, divided halfway. *Capsules* ellipsoid or shortly cylindric, ± 10 mm long. *Flowering time*: August, September.

Distribution and ecology: a rare and local endemic around Saldanha Bay, Western Cape, South Africa, most common on the Vredenburg Peninsula but extending south toward Yzerfontein; on seasonally waterlogged sandy and loam flats on granite.

Diagnosis: allied to *Romulea flava* in the solitary, often rather thick basal leaf and submembranous inner bracts, and distinguished by the large, cadmium to golden-yellow (rarely cream-coloured) flowers with broad tepals, and the slightly firmer-textured inner bracts. The central portion of the inner bracts is sometimes spotted with brown, and plants with cream-coloured tepals and a golden-yellow cup may be confused with *R. leipoldtii* but that species has two basal leaves and narrower tepals.

8. **Romulea barkerae** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 106 (1972). Type: South Africa, [Western Cape], Vredenburg, Cape Columbine, *Barker s.n.* (NBG, holo.).

Plants 30–200 mm high. *Corm* globose, obliquely flattened toward base with crescent-shaped basal ridge, 8–15 mm diam., tunics splitting into fine parallel fibrils along ridge. *Stem* subterranean or aerial, exserted up to 200 mm, elongating in fruit. *Leaves* 3 or 4, lowermost 1 basal when stem exserted, ± 3-angled or narrowly3-winged, almost T-shaped in section with 2 wide grooves separating a narrow and a wider rib, 1.5–2.5 mm diam., rib margin ciliolate, cauline leaves clustered at stem apex. *Peduncles* up to 7, up to 70 mm

Distribution of ***Romulea barkerae***.

long, semiterete, often ciliolate along edges, sharply recurved in fruit; outer bracts green with narrow membranous margins, 15–18 mm long, lightly striate (5 or 6 veins/mm), inner bracts entirely membranous or scarious, central portion conspicuously brown-spotted, with broad margins streaked or speckled with brown. *Flowers* white with broad black blotch edged with yellow in throat and extending to base of cup, outer tepals green on reverse; perianth tube funnel-shaped, 5–6 mm long; tepals oblanceolate to obovate, 15–28 × 5–10 mm. *Filaments* 5–6 mm long, pilose basally, pale yellow; anthers 5–6 mm long, yellow. *Style* dividing below or beyond anther tips, branches 2 mm long, divided halfway. *Capsules* ellipsoid or shortly cylindric, ± 10 mm long. *Flowering time*: (late June) July, August.

Distribution and ecology: a rare and local endemic of the Vredenburg Peninsula, Western Cape, South Africa, from Paternoster to Saldanha; on limestone outcrops in coastal thicket.

Diagnosis: unmistakable in its unique, T-section leaves with two broad grooves separating a narrower and a broader rib and white flowers with large black blotches outlined with yellow in the throat. The solitary basal leaf and entirely membranous inner bracts ally it to *Romulea flava*.

9. **Romulea flava** *(Lam.) M.P.de Vos* in Goldblatt & Barnard in Journal of South African Botany 36: 306 (1970). *Ixia flava* Lam.: 109 (1791). *Bulbocodium flavum* (Lam.) Kuntze: 700 (1891). Type: South Africa, without precise locality or collector [P: Herb. Lamarck, lecto., designated by De Vos: 99 (1972)].

Ixia recurva F.Delaroche in P.J.Redouté: t. 251 (1809), illegitimate homonym, not *I. recurva* Vahl (1805). *Ixia recurvifolia* Poir. in Lam.: 201 (1813), as a replacement name for *I. recurva* F.Delaroche. *Trichonema recurvifolium* (Poir.) Ker Gawl.: 83 (1827). *Geissorhiza recurvifolia* (Poir.) Klatt: 655 (1866). *Trichonema recurvum* Spreng.: 149 (1824), as a replacement name for *Ixia recurva* F.Delaroche. *Romulea recurva* Eckl.: 20 (1827), as a replacement name for *Ixia recurva* F.Delaroche. Type: South Africa, without precise locality, illustration in P.J.Redouté: t. 251, lower figure (1809).

Trichonema caulescens Ker Gawl.: t. 1392 (1811). *Trichonema hypoxidiflorum* Salisb.: 316 (1812), illegitimate superfluous name for *T. caulescens* Ker Gawl. *Romulea caulescens* (Ker Gawl.) Klatt: 399 (1882). Type: South Africa, without precise locality, illustration in Ker Gawl.: t. 1392 (1811).

Ixia reflexa Thunb.: 220 (1811), illegitimate homonym, not *I. reflexa* Andrews (1797). *Romulea reflexa* Eckl.: 18 (1827), as a replacement name for *I. reflexa* Thunb. *Trichonema reflexum* (Eckl.) Steud.: 702 (1841). *Romulea rosea* var. *reflexa* (Eckl.) Bég.: 158 (1908). [misapplied to *R. rosea*, also by De Vos: 63 (1983)]. Type: South Africa, without precise locality, *Thunberg s.n.* [UPS–THUNB 984, lecto., designated by De Vos: 27 (1983)].

Romulea similis Eckl.: 19 (1827). *Trichonema simile* (Eckl.) Steud.: 702 (1841). *Bulbocodium simile* (Eckl.) Kuntze: 700 (1891). Type: South Africa, without precise locality, *Ecklon s.n.* (BM, OXF, ?S, syn.).

?*Trichonema candidum* Ten. 12: 4 (1842). *Romulea candida* (Ten.) Ten.: 95 (1845). Type: Unknown.

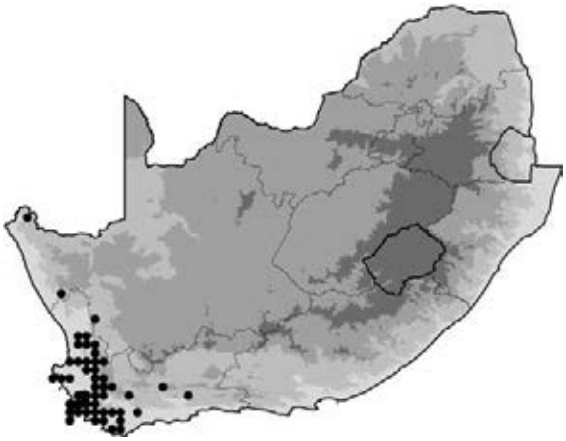
[*Romulea vulgaris* Eckl.: 18 (1827), invalid name without description.]



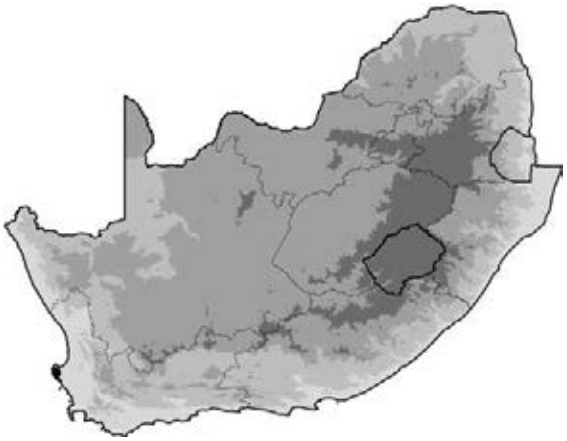
[*Romulea arenaria* Eckl.: 18 (1827), invalid name without description. *Trichonema arenarium* Eckl. ex Steud.: 702 (1841), invalid name without description. *Bulbocodium arenarium* Eckl. ex Kuntze: 700 (1891), invalid name without description.]

Plants 50–300 mm high. *Corm* globose, obliquely flattened toward base with crescent-shaped basal ridge, 6–15 mm diam., tunics splitting into fine parallel fibrils along ridge. *Stem* subterranean or aerial, exserted up to 200 mm, elongating in fruit. *Leaves* 3 or 4, lowermost 1 basal, terete or compressed-cylindrical, narrowly or widely 4-grooved, 1–3 mm diam., glabrous or ciliolate along rib margins, cauline leaves clustered at stem apex, sheaths often wide. *Peduncles* up to 8, up to 70 mm long, semiterete, glabrous or ciliolate along angles, sharply arcuate in fruit or ultimately suberect; outer bracts green with narrow membranous margins, 8–20(–28) mm long, striate or lightly ribbed (4 to 6 veins/mm), inner bracts entirely membranous or sometimes submembranous in centre, central portion sometimes conspicuously brown-spotted, with broad membranous margins streaked or speckled with brown. *Flowers* pale or sulphur-yellow, white, pale blue or rarely pink, with yellow or greenish cup, outer tepals frequently green or greenish brown on reverse, white forms sometimes scented; perianth tube funnel-shaped, 3–7 mm long; tepals elliptic or oblanceolate, 10–30 × 2–12 mm. *Filaments* 4–7 mm long, pilose basally, yellow; anthers 3–7 mm long. *Style* dividing shortly below or beyond anther tips, branches 2 mm long, divided halfway. *Capsules* ellipsoid or shortly cylindric, ± 10 mm long. *Flowering time*: June.

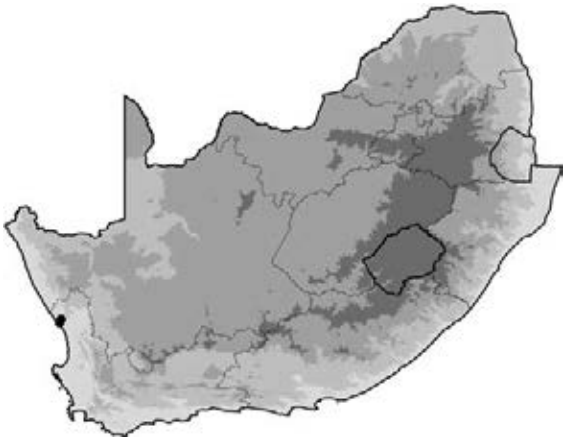
Distribution and ecology: widespread through the coastal and near-inland parts of Northern and Western Cape, South Africa, from the Richtersveld to Swellendam, with isolated records from Riversdale, Albertinia and Humansdorp; in seasonally damp or moist places.

Diagnosis: recognised by the solitary, often rather swollen basal leaf, the cauline leaves typically with wide sheathing bases, the entirely membranous or submembranous inner bracts, and the canary-yellow or white to pale blue flowers.

A common, widely distributed and polymorphic species varying greatly in size, growth form, leaf thickness and ciliation, and flower colour. Flower colour is genetically determined but growth form is at least partly influenced by growing conditions.



Distribution of ***Romulea flava***.



Many of the variants were described as separate species and De Vos (1972) maintained some of them at varietal level as follows: var. *flava* for plants with glabrous leaves 1–3 mm diam. and yellow, white or blue flowers; var. *minor* (Bég.) M.P.de Vos for similar forms with smaller, invariably yellow flowers less than 25 mm long; var. *hirsuta* (Bég.) M.P.de Vos for plants with mostly ciliolate leaves 2–3 mm diam., short stems, and white to blue flowers; and var. *viridiflora* (Bég.) M.P.de Vos for similar plants with frequently elongated stems and leaves less than 1 mm diam. At least one population of the latter was polyploid, $2n = 48$. We are unable, however, to retain the varieties in view of the existence of numerous intermediates among them, their widespread occurrence throughout the range of the species, and the existence of other combinations of characters, notably plants with ciliolate leaves and yellow flowers.

10. **Romulea elliptica** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 83 (1972). Type: South Africa, [Western Cape], Vredenburg to Saldanha, *De Vos 2226* (PRE [as STE], holo.; PRE, iso.).

Plants 50–200(–300) mm high. *Corm* globose, obliquely flattened with crescent-shaped basal ridge as wide as or slightly wider than corm, 5–10 mm diam., tunics splitting into fine, parallel fibrils along ridge. *Stem* short or exserted up to 200 mm. *Leaves* 3 or 4, lower 2 basal, filiform to terete, narrowly 4-grooved, 0.5–1.5 mm diam. *Peduncles* up to 4, semiterete, up to 40 mm long, suberect in fruit; outer bracts green with narrow membranous margins, 13–30 mm long, lightly striate (5 or 6 veins/mm), conduplicate, inner bracts with narrow, unmarked membranous margins widening toward base. *Flowers* buttercup-yellow, sometimes with few short dark veins in cup, outer tepals lime-green on reverse with reddish brown flecks along margins; perianth tube funnel-shaped, 4–5 mm long; tepals ± obtuse, outer

Distribution of ***Romulea elliptica***.

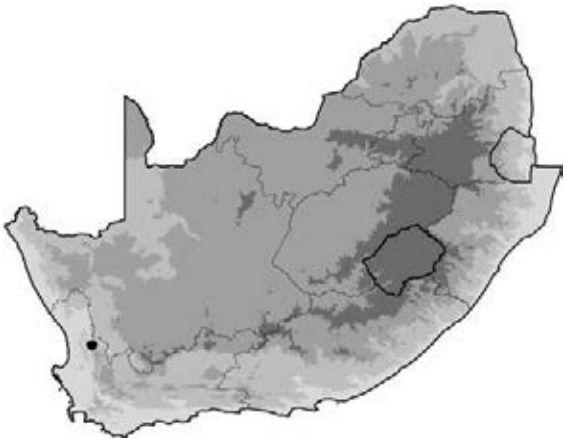
Distribution of ***Romulea lutea***.

elliptic, inner slightly wider and oblanceolate, 18–27 × 4–9 mm. *Filaments* 6–7 mm long, pilose toward base, yellow; anthers 4–6 mm long, yellow. *Style* dividing near anther apices, branches ± 2 mm long, divided halfway. *Capsules* shortly cylindric, 10–18 mm long. *Flowering time*: August.

Distribution and ecology: a rare and narrow endemic from west of Vredenburg, Western Cape, South Africa; in deep sands in coastal thicket.

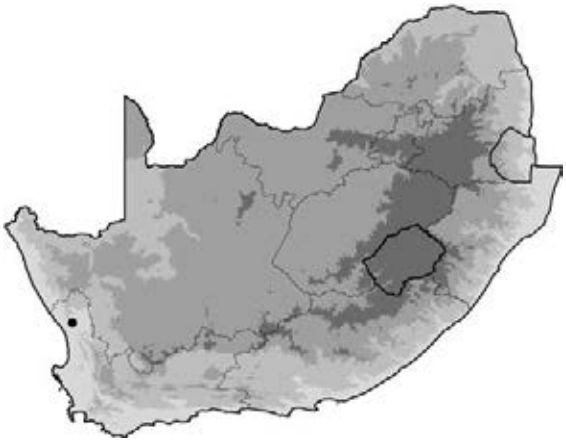
Diagnosis: distinguished by the plain yellow flowers, the outer tepals narrower than the inner and lime-green on the reverse with distinctive brownish flecks along the margins, and the green inner bracts with narrow, colourless membranous margins widened only at the base. Superficially similar yellow-flowered species of *Romulea* with two basal leaves have inner bracts with broad, brownish or brown-flecked membranous margins and inner tepals coloured differently on the reverse.

11. **Romulea lutea** *J.C.Manning & Goldblatt* in Bothalia 38: 78 (2008). Type: South Africa, Western Cape, coastal sandveld west of Koekenaap at Farm Skaapkraal, local in drainage line, 24 Aug. 2007, *P. Goldblatt & J.C. Manning 12868* (NBG, holo.; MO, PRE, iso.).



Plants 50–100 mm high. *Corm* globose, obliquely flattened toward base with crescent-shaped basal ridge ± as wide as corm, 8–15 mm diam., tunics splitting into fine parallel fibrils along ridge. *Stem* usually subterranean, or shortly exserted up to 30 mm. *Leaves* 3 or 4, lowermost 1 basal when stem exserted, terete, narrowly 4-grooved, 0.5–1.0 mm diam. *Peduncles* up to 4, up to 80 mm long, semiterete, strongly curved initially in fruit; outer bracts green with narrow membranous margins, 8–10 mm long, lightly striate (3 or 4 veins/mm), inner bracts thin-textured or submembranous with central part flushed green or purplish, with broad membranous margins speckled with brown along margins and sometimes in central area. *Flowers* golden-yellow with darker cup, outer tepals pale green on reverse, lightly scented; perianth tube funnel-shaped, 3–4 mm long; tepals elliptic, 11–13 × 4–5 mm. *Filaments* 4 mm long, pilose basally, yellow; anthers 4 mm long. *Style* dividing below anther tips, branches 1 mm long, divided halfway. *Capsules* ellipsoid, ± 8 mm long. *Flowering time*: August, September.

Distribution and ecology: a local endemic from west of Koekenaap in southern Namaqualand in Western Cape, South Africa; in loamy soil in seasonally moist drainage lines and depressions.



Diagnosis: resembling *Romulea tabularis* in the solitary basal leaf (when stem exserted) but differing in the golden-yellow flowers with relatively short bracts, 8–10 mm long. The solitary basal leaf and distribution separate *R. lutea* from similar yellow-flowered species.

12. **Romulea sulphurea** *Bég.* in Botanische Jahrbücher für Systematik 38: 331 (1907). Type: South Africa, [Western Cape], Pakhuis Pass, *Schlechter 10818* (Z, lecto., designated by De Vos: 87 (1972); B, BM, BOL, GRA, K, PRE, S, US, isolecto.).

Plants 50–150 mm high. *Corm* subglobose, 5–10 mm diam., obliquely flattened toward base with crescent-shaped basal ridge, tunics splitting into fine parallel fibrils along basal ridge. *Stem* subterranean or exserted up to 150 mm. *Leaves* 3 to 5, lower 2 basal, filiform, narrowly 4-grooved, 0.5–1.0 mm diam. *Peduncles* up to 4, semiterete, ciliolate along angles; outer bracts green with narrow membranous margins, widely striate (3 or 4 veins/mm), 8–15 mm long, inner bracts with wide membranous margins brown-speckled along edges. *Flowers* golden-yellow dark marks at base of tube, outer tepals copper-coloured on reverse with dark feathering; perianth tube funnel-shaped, 4–5 mm long; tepals elliptic, 12–25 × 3.5–7.0 mm. *Filaments* 6–9 mm long, pilose, yellow; anthers 3–4.0 mm long, yellow. *Style* dividing below anther apices, branches 2 mm long, divided halfway. *Capsules* and *seeds* unknown. *Flowering time*: mid-July, August.

Distribution of ***Romulea sulphurea***.

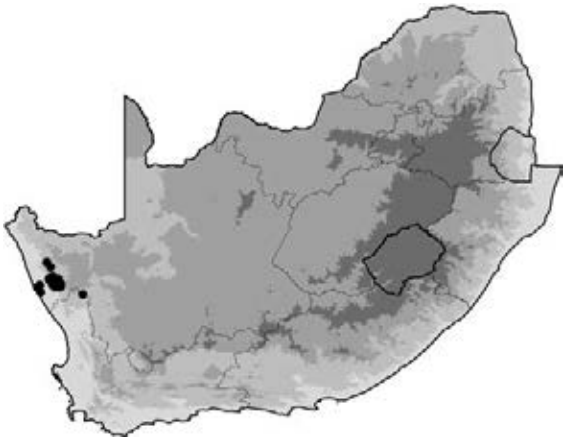
Distribution of ***Romulea quartzicola***.

Distribution and ecology: a rarely collected local endemic from the Pakhuis Pass in the Cederberg, Western Cape, South Africa; on seasonally wet sandstone pavement.

Diagnosis: distinctive among the yellow-flowered species in sect. *Romulea* in its relatively long filaments, ± twice as long as the anthers. Similar stamens are also characteristic of *R. quartzicola* from the Knersvlakte but that species has diagnostic broadly ovate or suborbicular outer and inner bracts, the inner with unusually narrow membranous margins < 1 mm wide.

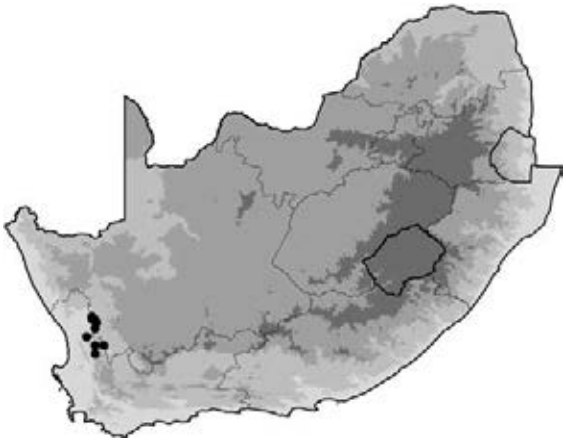
13. **Romulea quartzicola** *J.C.Manning & Goldblatt* in Bothalia 41: 274 (2011). Type: South Africa, Western Cape, Knersvlakte, Farm Moedverloor, ± 15 km NE of Lutzville, *A.D. Harrower & J.C.Manning 4395* (NBG, holo.; MO, iso.).

Plants 50–80 mm high. *Corm* subglobose, ± 10 mm diam., obliquely flattened toward base with crescent-shaped basal ridge, tunics splitting into fine parallel fibrils along basal ridge. *Stem* shortly exserted up to 35 mm. *Leaves* 2 or 3, lower 2 basal, mostly ± as long as flowering stem, terete, obtuse or subclavate, narrowly 4-grooved, 1.5–2.5 mm diam. *Peduncles* 1 or 2; outer bracts broadly elliptic-suborbicular, concave, obtuse, green with narrow, often purplish membranous margins, widely striate (3 veins/mm), 8–13 mm long, inner bracts similar with narrow membranous margins minutely brown-speckled along edges. *Flowers* bright chrome-yellow or rarely peach-coloured with 3 to 5 inconspicuous dark veins at base of cup, outer tepals rarely flushed copper or pale green on reverse, weakly clove-scented; perianth tube funnel-shaped, 7–8 mm long; tepals oblanceolate, 20–22 × 6–10 mm. *Filaments* 7–9 mm long, pilose, base, yellow; anthers 4–5 mm long, thecae well separated by broad connective, yellow. *Style* dividing opposite upper half of anthers, branches ± 3 mm long, divided to base into six filiform branchlets. *Capsules* and *seeds* unknown. *Flowering time*: mid-June to July.



Distribution and ecology: a rare and local endemic of the Moedverloor drainage basin near Lutzville, Western Cape, South Africa; on cooler quartzite slopes and outcrops.

Diagnosis: an unusual, early-flowering species with short, rather blunt leaves and broad, almost suborbicular outer and inner bracts, the inner similar to the outer with unusually narrow membranous margins only slightly wider than on the outer bracts, relatively long filaments ± twice as long as the anthers, and style branches divided to the base. Similarly long filaments are also characteristic of *R. sulphurea* from the Cederberg but that species has inner bracts with typically broad membranous margins.



14. **Romulea citrina** *Baker* in Handbook of the Irideae: 100 (1892). Type: South Africa, [Northern Cape], Namaqualand, near Modderfontein, *H. Bolus 6619* (K, holo.; BOL, GRA, iso.).

Plants 50–200 mm high. *Corm* globose, obliquely flattened toward base with crescent-shaped basal ridge, 8–15 mm diam., tunics splitting into fine parallel fibrils along ridge. *Stem* subterranean or exserted up to 150 mm. *Leaves* 3 to 5, lower 2 basal when stem exserted, filiform or terete to compressed-terete, narrowly 4-grooved, 0.5–1.5 mm diam. *Peduncles* up to 4, up to 80 mm long, semiterete, strongly curved initially in fruit but later erect; outer bracts green with narrow membranous margins, 8–10 mm long, lightly ribbed (5 or 6 veins/mm), inner bracts with broad, brown-streaked or -edged membranous margins and sometimes speckled in central area below. *Flowers* lemon- or canary-yellow, sometimes paler or darker in cup and veins sometimes darker, outer tepals often greenish or brownish on reverse; perianth tube funnel-shaped, 4–7 mm long; tepals elliptic, 15–32 × 4–10 mm. *Filaments* 5–8 mm long, pilose basally, yellow; anthers 4–7 mm long, yellow. *Style* dividing shortly below to shortly above anther tips, branches 2–3 mm long, divided halfway. *Capsules* shortly cylindric, 10–15 mm long. *Flowering time*: August, September.

Distribution and ecology: endemic to the higher-lying parts of central Namaqualand, Northern Cape, South

Distribution of ***Romulea citrina***.

Distribution of ***Romulea montana***.

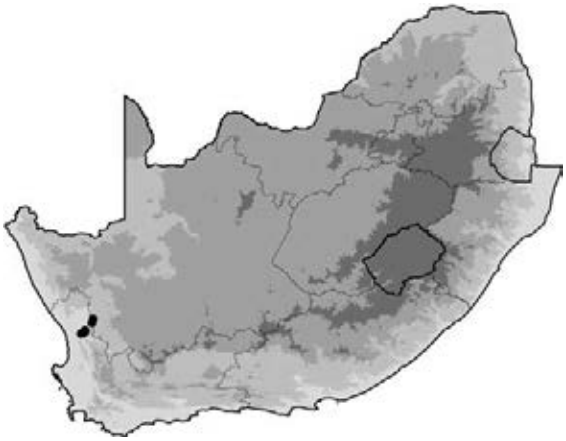
Africa, between Springbok and Bitterfontein in Western Cape; in seasonal washes on granite.

Diagnosis: the common, yellow-flowered *Romulea* species of central Namaqualand, *Romulea citrina*, is relatively undistinguished among the yellow-flowered members of sect. *Romulea*, and is diagnosed by the crescent-shaped basal ridge, two basal leaves when the stem is exserted, and lemon- or canary-yellow flowers lacking dark blotches or streaks in the throat. The leaves are distinctive in the development of marginal fibre strands in the ribs, a feature also of the Namaqualand species in ser. *Namaquana*.

15. **Romulea montana** *Schltr. ex Bég.* in Botanische Jahrbücher für Systematik 38: 332 (1907). Type: South Africa, [Northern Cape], Bokkeveld Mtns, Oorlogskloof, *Schlechter 10949* (G, holo.; B, BOL, GRA, K, PRE, S, iso.).

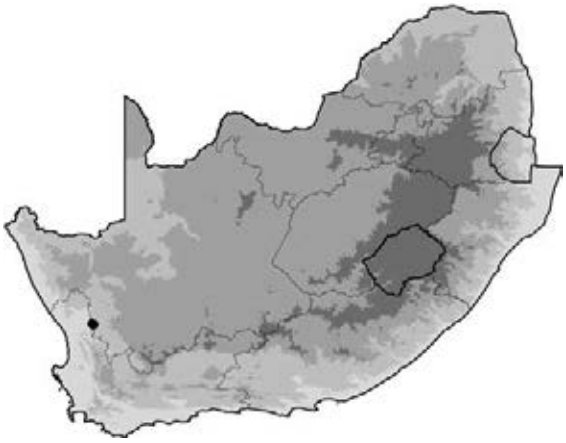
Romulea hirsuta var. *aurantiaca* Schltr.: 90 (1899). *Romulea ambigua* var. *aurantiaca* (Schltr.) Bég.: 80 (1909). Type: South Africa, [Western Cape], Clanwilliam, Matjiesrivier, *Schlechter 8847* (B, holo.; BM, BOL, GRA, K, PRE (in part), S, US, Z, iso.).

Romulea rosea var. *flavescens* Bég.: 63 (1909). Type: South Africa, *Mund & Maire 580* (B, holo.).



Plants 50–200 mm high. *Corm* globose, obliquely flattened with wide, fan- or crescent-shaped basal ridge as wide as or wider than corm and sometimes almost circular, 8–15 mm diam., tunics splitting into fine, parallel fibrils clustered into scalloped fascicles along ridge. *Stem* subterranean or exserted up to 150 mm. *Leaves* 4 to 6, lower 2 basal when stem developed, filiform to terete or compressed-terete, 4-grooved, 0.5–1.5 mm diam. *Peduncles* up to 5, semiterete, up to 60 mm long, spreading in fruit, each pair diverging at ± 90°; outer bracts green with narrow membranous margins, 10–22 mm long, striate (5 or 6 veins/mm), inner bracts with broad, brownish or brown-edged membranous margins. *Flowers* buttercup-yellow with yellow cup usually edged with dark brown blotches sometimes reduced to dark veins or rarely absent, outer tepals brown or reddish or faintly feathered on reverse; perianth tube funnel-shaped, 4–6 mm long; tepals elliptic, 15–35 × 5–10 mm. *Filaments* 5–6 mm long, pilose toward base, yellow; anthers 4–8 mm long, yellow. *Style* dividing near anther apices, branches ± 2 mm long, divided halfway. *Capsules* ellipsoid, 8–10 mm long. *Flowering time*: July to September.

Distribution and ecology: common on the Bokkeveld Escarpment in Northern Cape, South Africa, extending onto the Pakhuis Mtns to the northern Cederberg but absent from the Matsikamma–Gifberg; on seasonally moist or waterlogged sandy soils or seepages and sandstone pavement.



Diagnosis: resembling white-flowered *Romulea toximontana* in the wide, scalloped basal ridge on the corm but distinguished by its bright yellow flowers, usually with dark blotches or streaks in the throat. The species is essentially identical in flower to the Bokkeveld endemic *R. discifera*, but that species has a conspicuously depressed corm with a complete, circular, similarly scalloped basal rim. Another common, yellow-flowered species, *R. monticola* (sect. *Roseae*), has flowers without dark markings, bracts with narrow, brown-speckled markings, and corms with coarse, bent teeth.

16. **Romulea toximontana** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 89 (1972). Type: South Africa, [Western Cape], Gifberg, *De Vos 2020* (NBG [as STE], holo.; PRE, iso.).

Plants 30–200 mm high. *Corm* globose, obliquely flattened with wide, fan- or crescent-shaped basal ridge wider than corm, 10–15 mm diam., tunics splitting into fine, parallel fibrils clustered into scalloped fascicles along ridge. *Stem* subterranean or exserted up to 150 mm. *Leaves* 3 to 6, lower 2 basal when stem developed, filiform, 4-grooved, 0.5–1.0 mm diam., sometimes sparsely ciliolate on rib margins. *Peduncles* up to 5, clustered at stem apex, semiterete, up to 30 mm long, spreading in fruit, each pair diverging at ± 90°; outer

Distribution of ***Romulea toximontana***.

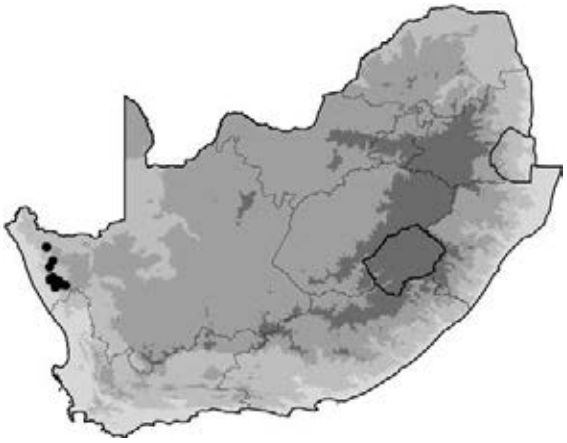
Distribution of ***Romulea singularis***.

bracts green with narrow membranous margins, 10–20 mm long, striate (3 or 4 veins/mm), inner bracts with broad, brown-edged membranous margins. *Flowers* white to cream-coloured with yellow cup, outer tepals green or purple or irregularly blotched on reverse; perianth tube funnel-shaped, 4–5 mm long; tepals elliptic, 13–22 × 4–9 mm. *Filaments* 3–5 mm long, pilose toward base, yellow; anthers 4–6 mm long, pale yellow. *Style* dividing near anther apices, branches ± 2 mm long, divided halfway. *Capsules* ellipsoid, 5–8 mm long. *Flowering time*: August, September.

Distribution and ecology: a local endemic restricted to the Matsikamma–Gifberg massif in Western Cape, South Africa; on seasonally waterlogged sandstone pavement.

Diagnosis: one of two species in ser. *Ciliatae* with a wide, fan-shaped basal ridge on the corm and green bracts, *Romulea toximontana* is distinguished from yellow-flowered *R. montana*, which occurs on the Bokkeveld Mtns and Cederberg but is absent from the Gifberg, by its white or cream-coloured flowers with pale yellow anthers and a chromosome number $2n = \pm 28$. It is readily confused in flower with another Gifberg endemic, *R. sladenii*, which has a bell-shaped corm with circular basal ridge and more widely spreading peduncles diverging at ± 180°.

17. **Romulea singularis** *J.C.Manning & Goldblatt* in Bothalia 36: 142 (2006). Type: South Africa, Northern Cape, Oorlogskloof Nature Reserve, farm Uitkomst, 4 km east of Arrie-se-Punt, overlooking Saaikloof, seasonally moist sandstone pavement in Bokkeveld Sandstone fynbos, 830 m, 18 Sept. 2005, *N.A. Helme 3564* (NBG, holo.).



Plants 20–40 mm high. *Corm* globose, obliquely flattened with wide, crescent-shaped basal ridge wider than corm, 10–12 mm diam., tunics splitting into fine, parallel fibrils clustered into scalloped fascicles along ridge. *Stem* subterranean or shortly exserted up to 5 mm. *Leaves* 4 to 6, lower 2 basal when stem developed, short and spreading, compressed, 4-grooved, 0.5–1.5 mm diam. *Peduncles* up to 4, semiterete, short, up to 15 mm long; outer bracts green with narrow membranous margins, 7–15 mm long, striate (3 or 4 veins/mm), inner bracts green in centre with broad membranous margins flecked or flushed light brown. *Flowers* narrowly funnel-shaped, mauve to lilac or pink with yellow throat streaked with purple, tube reddish ochre-coloured on outside; perianth tube narrowly funnel-shaped, 10–13 mm long; tepals lanceolate, ± 13 × 3 mm. *Filaments* inserted in lower half of tube 3–4 mm from base, 8–9 mm long, exserted ± 2 mm, pilose at base; anthers ± 3 mm long, pale yellow. *Style* dividing between base and middle of anthers, branches ± 2 mm long, divided halfway. *Capsule* unknown. *Flowering time*: August, September.

Distribution and ecology: endemic to the Bokkeveld Mtns in Northern Cape, South Africa, along the edges of the Oorlogskloof and Koebee River gorges; on seasonally wet sandstone pavement.

Diagnosis: a distinctive species with narrowly funnel-shaped, mauve to lilac or pink flowers with yellow tube 10–13 mm long, and uniquely long filaments, 8–9 mm long inserted in the lower half of the tube and exserted ± 2 mm. In other species with a long perianth tube the elongation is of the lower portion of the tube below the filaments, which remain short and are inserted near the top of the tube. The wide, scalloped basal ridge on the corm suggests a possible relationship with *Romulea toximontana*.

18. **Romulea namaquensis** *M.P.de Vos* in Journal of South African Botany 21: 103 (1955). Type: South Africa, [Northern Cape], Kamiesberg, Witsand to Leliefontein, *Pearson sub Sladen Expedition 6656* (BOL, holo.; K, iso.).

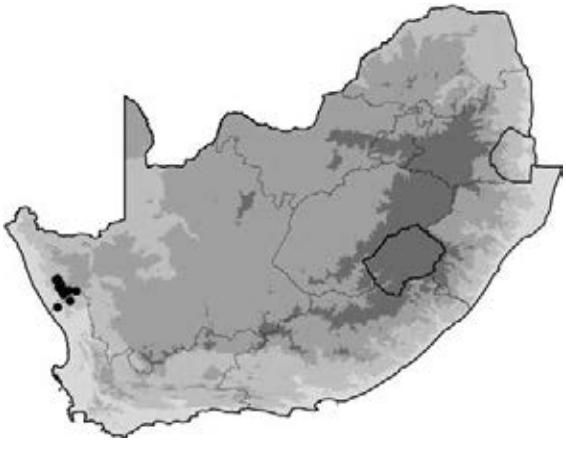
    Romulea namaquensis subsp. *bolusii* M.P.de Vos: 79 (1972). Type: South Africa, [Northern Cape], near Okiep, *H.Bolus 6620* (NBG, holo.; BOL, K, iso.).

Distribution of ***Romulea namaquensis***.

Plants 40–200 mm high. *Corm* globose, obliquely flattened toward base with crescent-shaped basal ridge ± as wide as corm, 6–10 mm diam., tunics splitting into fine parallel fibrils along ridge. *Stem* subterranean or aerial, exserted up to 150 mm. *Leaves* 3 to 5, lowermost 2 basal when stem exserted, filiform and narrowly 4-grooved, 0.5–1.0 mm diam. *Peduncles* up to 3, up to 60 mm long, semiterete, suberect in fruit; outer bracts green with narrow membranous margins, 12–30 mm long, sometimes keeled above, closely ribbed (3 or 4 veins/mm), inner bracts with broad, brown-flecked or -edged membranous margins. *Flowers* glossy rose-coloured to coppery salmon-pink, brick-red or pale pink to white, with small dark blotches or lines in throat, sometimes pale yellow at base of tube, outer tepals irregularly blotched pink and yellow on reverse; perianth tube narrowly funnel-shaped, 4–12 mm long; tepals elliptic or oblanceolate, 16–40 × 5–10 mm. *Filaments* inserted in middle of tube or slightly above, 4–10 mm long, pilose basally, yellow or maroon; anthers 5–10 mm long, golden-yellow. *Style* dividing shortly below to shortly beyond anther apices, branches 2–3 mm long, divided halfway. *Capsules* ellipsoid, up to 12 mm long. *Flowering time*: July to September.

Distribution and ecology: restricted to the higher-lying parts of Namaqualand, Northern Cape, South Africa, from Steinkopf to Garies but most commonly seen on the Kamiesberg; in seasonally moist places on granite.

Diagnosis: variable in colour and distinguished by the narrowly funnel-shaped perianth tube with the filaments inserted at or above the middle, often black or reddish, with very little yellow in the cup. The leathery bracts are closely ribbed and often keeled in the upper part. Forms with glossy rose-coloured to coppery salmon-pink or brick-red flowers are especially attractive.



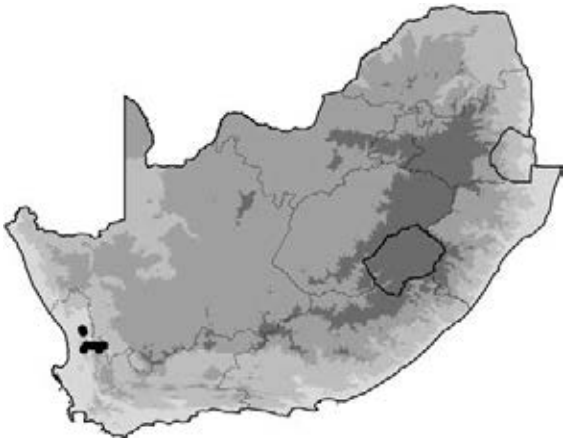
19. **Romulea kamisensis** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 81 (1972). Type: South Africa, [Northern Cape], Kamiesberg, Studer's Pass, *Stayner s.n.* (NBG, holo.).

Plants 40–150 mm high. *Corm* globose, obliquely flattened with narrow, crescent-shaped basal ridge as wide as corm, 7–15 mm diam., tunics splitting into fine, parallel fibrils along ridge. *Stem* subterranean or exserted up to 50 mm. *Leaves* 3 to 7, lower 2 basal when stem developed, suberect, terete, narrowly 4-grooved, 0.5–1.0 mm diam. *Peduncles* up to 3, semiterete, suberect; outer bracts green with narrow membranous margins, 13–25 mm long, leathery, ± keeled above, closely ribbed (3 or 4 veins/mm), inner bracts similar but with wider, translucent membranous margins, rarely with a few brown flecks. *Flowers* narrowly funnel–salver-shaped, magenta-purple with violet veins and blotch at mouth, throat white with purple lines; perianth tube narrowly funnel-shaped, 17–25 mm long; tepals lanceolate or elliptic, 11–16 × 3.5–5.0 mm. *Filaments* inserted in upper ½ of tube; 4–5 mm long, included, glabrous; anthers 4–5 mm long, golden-yellow. *Style* dividing opposite upper ½ of anthers, branches ± 2.5 mm long, divided halfway. *Capsule* ellipsoid, 10–12 mm long. *Flowering time*: August, September.

Distribution and ecology: endemic to the higher-lying parts of central Namaqualand in Northern Cape, South Africa, centred on the Kamiesberg but extending south to Bitterfontein in Western Cape and east to Loeriesfontein; restricted to moist cracks and seepages in granite outcrops.

Diagnosis: a distinctive species recognised by the narrowly funnel- or salver-shaped, magenta-purple flowers with perianth tube 17–25 mm long with relatively short, glabrous filaments 4–5 mm long inserted in the upper half of the tube and included within it. The inner and outer bracts are unusually similar in texture for the genus, both green and leathery with the inner differing only by their relatively broader, colourless membranous margins.

A relationship with *Romulea namaquensis* was proposed by De Vos (1972), and both species have leaves lacking secondary veins, filaments inserted above the middle of the perianth tube, and a chromosome number $2n = 26$.



Distribution of ***Romulea kamisensis***.

20. **Romulea biflora** *(Bég.) M.P.de Vos* in Journal of South African Botany, Suppl. 9: 75 (1972). *Romulea ambigua* var. *biflora* Bég.: 80 (1909). Type: South Africa, [Western Cape], Biedouw Mtns, *Schlechter 8694* (G, holo.; B, BM, GRA, K, PRE, S, iso.).

Plants 40–150(–200) mm high. *Corm* globose, obliquely flattened toward base with crescent- or horseshoe-shaped basal ridge ± as wide as corm, 10–15 mm diam., tunics splitting into fine parallel fibrils along ridge. *Stem* subterranean or aerial, exserted up to 150 mm. *Leaves* 3 to 5, lowermost 2 basal when stem exserted, terete or filiform and narrowly 4-grooved, 1.0–1.5 mm diam. *Peduncles* up to 4, up to 50 mm long, semiterete, suberect or bent in fruit; outer bracts green with narrow membranous margins, 12–25 mm long, widely striate (3 or 4 veins/mm), inner bracts with broad, brown-flecked membranous margins. *Flowers* bright pink to old rose-coloured with large, violet to purple blotches around small, golden-yellow cup with dark veins in cup, outer tepals mottled or striped red and greenish on reverse; perianth tube funnel-shaped, 4–6 mm long; tepals elliptic, 18–35 × 6–10 mm. *Filaments* 5–7 mm long, pilose basally, orange-yellow; anthers 5–8 mm long, yellow or rarely violet. *Style* dividing below or beyond anther apices, branches ± 2 mm long, deeply divided. *Capsules* subglobose to ellipsoid, up to 12 mm long. *Flowering time*: August (September).

Distribution and ecology: locally endemic in Western Cape, South Africa, at the foot of the Gifberg–Matsikamma near Vanrhynsdorp and around the Biedouw Valley; in seasonally moist clay or loamy soils in renosterveld shrublands.

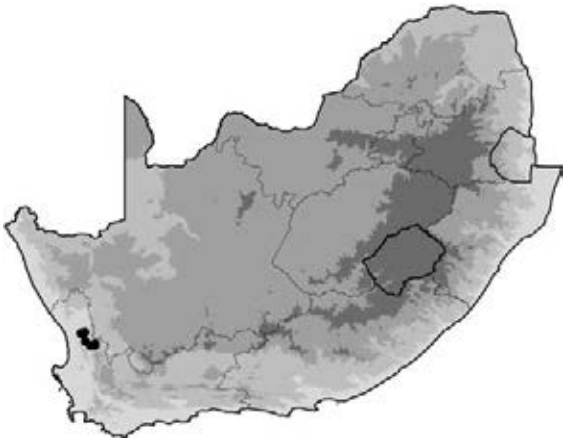
Diagnosis: distinguished from other species in the section with an oblique corm by the pink flowers with conspicuous violet or purple blotches in the throat of a yellow cup. Similarly coloured and marked flowers are characteristic of *Romulea hirsuta* and may indicate a relationship between them (De Vos 1972) but the corm in *R. hirsuta* is bell-shaped with a circular basal rim. Plants from the foot of the Gifberg have smaller yellow cups than those from the Biedouw Valley.

Distribution of ***Romulea biflora***.

Ser. **Stellanthe** *(M.P.de Vos) J.C.Manning & Goldblatt*, new rank. *Romulea* sect. *Stellanthe* M.P.de Vos in Journal of South African Botany, Suppl. 9: 291 (1972). Type: *R. stellata* M.P.de Vos

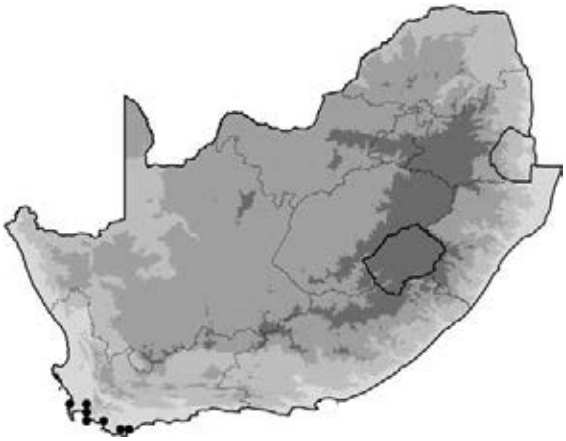
[*Romulea* ser. *Stellatae* (as *Stellata*) in Manning & Goldblatt: 87 (2001), name only.]

Corm subglobose, obliquely flattened toward base; basal rim finely fringed. *Stem* subterranean. *Leaves* without secondary bundles, vascular girders, rib marginal fibre strands or rib marginal bundles. *Flowers* salver-shaped, violet. *Stamens* inserted near mouth of tube; filaments glabrous. *Chromosome number* unknown.



21. **Romulea stellata** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 291 (1972). Type: South Africa, [Western Cape], Pakhuis Pass, *De Vos 2171* (NBG [as STE], holo.).

Plants 15–50 mm high but leaf up to 150 mm long. *Corm* subglobose, obliquely flattened toward base with crescent-shaped basal ridge ± as wide as corm, 5–10 mm diam., tunics splitting into fine parallel fibrils along ridge. *Stem* subterranean. *Leaf* 1(2), basal, filiform and conduplicate for most of its length, distal portion narrowly 4-grooved, 0.5–0.8 mm diam. *Peduncles* 1 or 3, semiterete, 5–20 mm long, suberect in fruit; outer and inner bracts entirely membranous and colourless or flushed reddish brown or greenish in upper half. *Flowers* salver-shaped, lilac to purple with darker ring around throat and yellow or orange in upper part of tube, outer tepals mottled purple on reverse; perianth tube narrowly tubular widening slightly above, 11–17 mm long; tepals spreading, elliptic, 7–11 × 2–4 mm. *Filaments* inserted almost at top of tube, 2.0–3.5 mm long, glabrous; anthers 2–3 mm long, violet with paler pollen. *Style* dividing near top of anthers, branches ± 1 mm long, divided for half their length. *Capsules* ellipsoid, 5–8 mm long. *Flowering time*: May to July.



Distribution and ecology: a local endemic of the western mountains of the Western Cape, South Africa, from the Matsikamma–Gifberg south along the Nardousberg to the northern Cederberg; on seasonally waterlogged sandstone pavement in shallow soils.

Diagnosis: a distinctive species recognised by its one or two filiform conduplicate leaves and small, violet to purple, salver-shaped flowers with stamens inserted at the mouth of the tube, and entirely membranous bracts outer and inner bracts.

Its relationships are obscured by the highly derived flowers but the absence of secondary veins in the leaves is an unusual character found in relatively few species in the genus, typically in members of sect. *Tortuosae* which also have a tendency for conduplicate leaves but which are uniformly yellow-flowered, and have the

Distribution of ***Romulea stellata***.

Distribution of ***Romulea gracillima***.

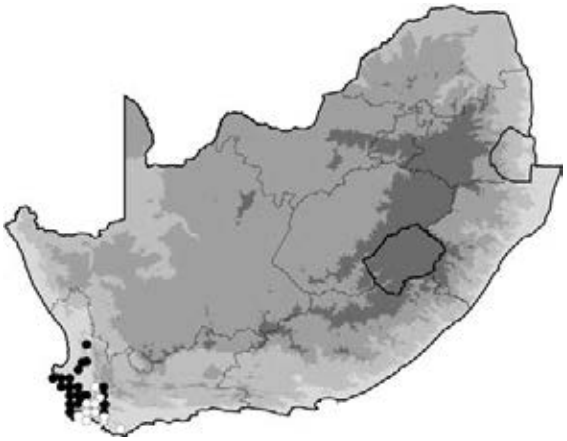
derived chromosome number $2n$ = 30 or 32. A more likely alliance is with species such as *R. vinacea*, with similar leaf anatomy and lilac flowers.

Ser. **Hirsutae** *(Bég.) J.C.Manning & Goldblatt*, new rank. *Romulea* "Stirps" *Hirsutae* Bég. in Annuaire du Conservatoire du Jardin Botaniques de Genève: 159 (1908). *Romulea* subsect. *Hirsutae* (Bég.) M.P.de Vos: 120 (1972). *Romulea* sect. *Hirsutae* (Bég.) J.C.Manning & Goldblatt: 89 (2001). Type: *Romulea hirsuta* (Steud. ex Klatt) Baker

Corm bell-shaped with circular basal rim; basal rim finely fringed, sometimes scalloped. *Stem* subterranean or aerial. *Leaves* usually without secondary bundles, without vascular girders, rib marginal fibre strands or rib marginal bundles. *Chromosome number* $2n$ = 24 (?22).

22. **Romulea gracillima** *Baker*, Handbook of the Irideae: 103 (1892); De Vos: 133 (1972). Type: South Africa, [Western Cape], Drakenstein Mtns, *Drège s.n.* (K, holo.; BM, G, OXF, P, iso.).

Plants 50–100 mm high. *Corm* bell-shaped with flat base and pronounced circular basal rim, 5–10 mm diam., tunics woody, basal rim irregularly fringed. *Stem* short, subterranean or exserted up to 40 mm. *Leaves* 3 to 6, lower 2 basal, narrowly 4-grooved, 0.5–1.0 mm diam. *Peduncles* up to 4, hemiterete, erect fruit; outer bracts green with narrow, colourless membranous margins, 7–15 mm long, finely striate (4 or 5 veins/mm), inner bracts with narrow, colourless membranous margins. *Flowers* pale pink or salmon-pink, sometimes with red lines in throat, with yellow cup, outer tepals darker on reverse; perianth tube funnel-shaped, ± 3 mm long; tepals elliptic, 12–18 × 3–5 mm. *Filaments* 3–5 mm long, pilose in lower part; anthers 2–4 mm long, yellow. *Style* dividing at anther apices, branches divided. *Capsules* oblong, 6–8 mm long. *Flowering time*: August, September.



Distribution and ecology: endemic to the mountains in the southwestern Western Cape, from Table Mt to Bredasdorp; on sandstone in fynbos.

Diagnosis: distinguished from *Romulea hirsuta* essentially by its more slender habit and smaller, pale pink to salmon-coloured flowers with tepals 12–18 × 3–5 mm. It may represent merely a small variant of that species (De Vos 1972).

23. **Romulea hirsuta** *(Steud. ex Klatt) Baker* in Journal of the Linnean Society, Botany 16: 89 (1877); De Vos: 125 (1972). *Trichonema hirsutum* Steud. ex Klatt: 665 (1866). Type: South Africa, [Western Cape], Cape Peninsula, Devil's Peak, *Ecklon 703* [S, neo., designated by M.P.de Vos: 127 (1972); B, G, K, M, PRE, Z, iso.].

Plants 50–200 mm high. *Corm* bell-shaped with flat base and pronounced circular basal rim, 5–10 mm diam., tunics woody, basal rim irregularly fringed, sometimes scalloped. *Stem* short and subterranean or aerial and exserted up to 150 mm, sometimes extensively branched. *Leaves* 3 to 9, lower 2 basal, straight or weakly to strongly sinuous, terete and narrowly 4-grooved or compressed and broadly 4-grooved, 0.5–4.0 mm diam., glabrous or ciliate on rib margins. *Peduncles* up to 9, hemiterete, glabrous or ciliolate along angles, suberect or spreading in fruit; outer bracts green with narrow, colourless or brown-flecked membranous margins, 10–25 mm long, finely striate (4 or 5 veins/mm), inner bracts with narrow or wider, colourless or brown-flecked membranous margins. *Flowers* magenta to salmon-pink, apricot-coloured or coppery orange, with or without reddish or violet blotches in the throat, with pale or golden-yellow cup, outer tepals mostly darker on reverse, sometimes with paler median stripe; perianth tube funnel-shaped, 3–6 mm long; tepals oblanceolate to elliptic, 15–35 × 6–12 mm. *Filaments* 4–8 mm long, pilose in lower part, yellow; anthers 3–7 mm long, yellow or with dark streaks. *Style* dividing shortly below to shortly above anther apices, branches 2–3 mm long, divided, rarely multifid. *Capsules* oblong, ± 10 mm long. *Flowering time*: August, September.

Distribution and ecology: relatively common along the West Coast and adjacent mountains of Western Cape,

Distribution of ***Romulea hirsuta*** subsp. ***hirsuta***, ●; subsp. ***cuprea***, ○.

South Africa, from the northern Cederberg to the Cape Peninsula in the south and east to Elim; on damp sandy flats.

Diagnosis: distinguished by the bell-shaped corm and moderate-sized to large flowers with the distal part of the tepals ranging in colour from magenta through salmon-pink to coppery orange or pale apricot-coloured, with or without dark markings around the cup. The presence of some pink anthocyanin pigment in the tepals is essentially what separates *Romulea hirsuta* from yellow-flowered *R. triflora* [see further under subsp. *cuprea*].

Romulea hirsuta is relatively common in the lowlands and coastal mountains of the Western Cape, and is highly variable in habit, width and vestiture of the leaves, and in the size, colour and markings of the flowers. Apart from orange-flowered plants, which were treated as var. *cuprea*, De Vos (1972) segregated two additional variants as varieties but there seems to be little to be gained by this as the extremes of the last two varieties are connected to the typical variety by intermediates, even within populations. Even with their segregation, typical *R. hirsuta* remains a variable species with numerous local forms. We have accordingly reduced the following two varieties to synonymy: var. *framesii* (L.Bolus) M.P.de Vos, recorded from between Darling and Yzerfontein, was distinguished by its relatively broad tepals, 12–20 mm wide, marked with a narrow median dark blotch flanked by cream-coloured patches; and var. *zeyheri* (Baker) M.P.de Vos, which is scattered along the West Coast, especially around Saldanha Bay, was distinguished by its mostly broader leaves, 1.5–4.0 mm wide but grades imperceptibly into the typical variety, and plants corresponding to both frequently co-occur. We continue to recognise orange plants as a separate taxon on account of their distinctively coloured flowers and possible uncertainty about their specific affinity [see below for further discussion]. We treat them at subspecific level as subsp. *cuprea* (Bég.) J.C.Manning & Goldblatt on account of their largely separate distribution, to the east and the south of the typical, pink-flowered form.

Another taxon recognised by De Vos (1972), *Romulea tortilis* Baker (= *R. torta* Baker), was separated from *R. hirsuta* solely by its tightly sinuous leaves. Although all collections of the typical variant of the species are consistent in this feature, the type of *R. torta* var. *dissecta* includes plants with both straight and sinuous leaves. In addition, some plants of *R. hirsuta* have moderately sinuous leaves, making the distinction between the two species tenuous. Other members of the genus, e.g. *R. tortuosa* (Licht. ex Roem. & Schult.) Baker, vary greatly in the degree of flexing of the leaves, and retaining the two taxa on the basis of the degree of leaf flexing alone is unjustified in our opinion.

23a. subsp. **hirsuta**

?*Ixia campanulata* Lam.: 109 (1791), illegitimate homonym, not *I. campanulata* Houtt. (1782). *Bulbocodium campanulatum* Kuntze: 700 (1891), as a replacement name for *I. campanulata* Lam., illegitimate homonym. Type: Unknown, not cited by the author. Apparently a new name for *Ixia bulbocodium* [Thunb.?] var. δ.

Romulea uncinata Klatt: 401 (1882). Type: South Africa, without precise locality, *Pappé s.n.* (S, holo.).

Romulea rosea var. *zeyheri* Baker: 103 (1892), new synonym. *Romulea zeyheri* (Baker) Eckl. ex Bég.: 338 (1907). *R. hirsuta* var. *zeyheri* (Baker) M.P.de Vos: 129 (1972). Type: South Africa, [Western Cape], without precise locality, *Zeyher s.n.* (K, holo.).

Romulea tortilis Baker: 1003 (1904), new synonym. Type: South Africa, [Western Cape], near Porterville, *Schlechter 4890* (Z, holo.; B, G, GRA, K, PRE, SAM, iso.).

Romulea torta Baker: 24 (1906), new synonym. Type: South Africa, [Western Cape], Clanwilliam, Olifants River, *Penther 687* (K, lecto., designated by De Vos: 55 (1983); BM, BOL, M, isolecto.).

Romulea rubrolutea Baker: 25 (1906). Type: South Africa, [Western Cape], Clanwilliam, Olifants River, *Penther 678* [K, lecto., designated by De Vos: 3 (1983)].

Romulea klattii Bég.: 333 (1907), new synonym. Type: South Africa, [Western Cape], Hopefield, *Bachmann 1579* (B, Z, syn.); Darling, *Bachmann 513* (B, syn.).

Romulea bulbocodioides var. *ambigua* Bég.: 163 (1908), new synonym. Type: South Africa, [Western Cape], without locality, as *Drege Irid 208*, probably in error for *Ecklon & Zeyher Irid. 208* [G, holo.—cited as lecto. by De Vos: 31 (1983)].

Romulea framesii L.Bolus: 13 (1931), new synonym. *R. hirsuta* var. *framesii* (L.Bolus) M.P.de Vos: 132 (1972). Type: South Africa, [Western Cape], near Darling, *Ross Frames s.n.* (BOL, holo.).

Romulea torta var. *dissecta* M.P.de Vos: 133 (1972), new synonym. Type: South Africa, [Western Cape], Clanwilliam District, near The Rest, *Bolus 21265* (BOL, holo.).

[*Romulea hirsuta* Eckl.: 19 (1827), invalid name without description.]

[*Romulea ramosa* Eckl.: 19 (1827), invalid name without description.]

[*Trichonema ramosum* Eckl. ex Steud.: 702 (1841), invalid name without description.]

Flowers magenta, rosy-pink or dark apricot-pink with golden or yellow cup or sometimes very little yellow, usually with dark brownish or violet blotches in the throat but sometimes unmarked.

Distribution and ecology: as for the species.

23b. subsp. **cuprea** *(Baker) J.C.Manning & Goldblatt*, name at new rank. *Romulea cuprea* Baker in Journal of Botany, British and foreign 14: 236 (1876). *Bulbocodium cupreum* (Baker) Kuntze: 700 (1891). *Romulea rosea* var. *cuprea* (Baker) Bég.: 63 (1909). *Trichonema cupreum* Herb. ex Baker: 89 (1877), listed in synonymy. *Romulea hirsuta* var. *cuprea* (Baker) M.P.de Vos: 131 (1972). Type: South Africa, [Western Cape], without precise locality or collector, painting in Lindley Library, Royal Horticultural Society, London.

Flowers apricot-coloured or coppery orange with yellow cup, without dark blotches around cup.

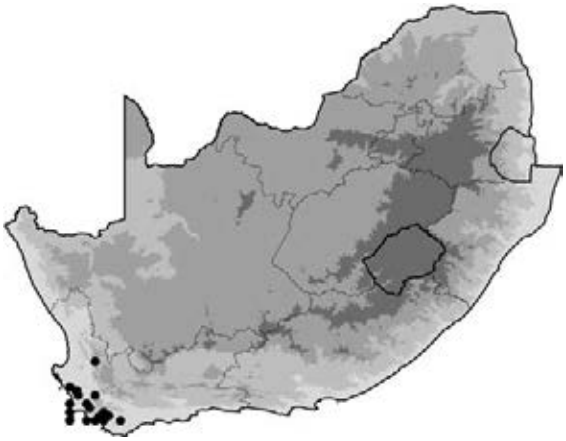
Distribution and ecology: distributed mainly in the east and the south of the range of the species, and especially common from Ceres into the Worcester Valley and along the Hottentots Holland Mtns to Hermanus; on damp sandy flats.

Plants with unmarked tepals coloured apricot or coppery orange in the upper half are currently segregated as subsp. *cuprea* of *Romulea hirsuta*, but the recorded occurrence of individuals with both pure yellow as well as orange and yellow flowers in a population from near Wolseley [*De Vos 1882* (NBG)] may indicate a closer relationship with *R. triflora*. Experimental crosses between subsp. *cuprea* and *R. triflora* were unsuccessful (De Vos 1972) and this, plus the occasional occurrence of marked and unmarked plants in the same population, prompted De Vos (1972) to retain the taxon in *R. hirsuta*. We follow her taxonomy in the absence of additional insights.

24. **Romulea triflora** *(Burm.f.) N.E.Br.* in Bulletin of Miscellaneous Information, Kew 1929: 131 (1929); De Vos: 122 (1972). *Crocus triflorus* Burm.f.: 2 (1768). Type: South Africa, without locality or collector (G – Herb. Burman, holo.).

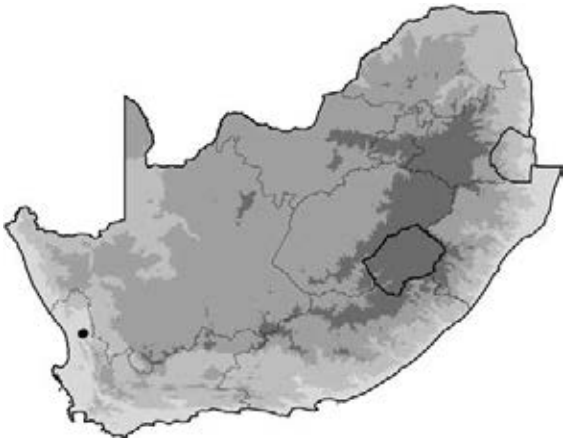
Ixia sublutea Lam.: 335 (1789). *Geissorhiza sublutea* (Lam.) Ker Gawl.: 224 (1804). *Romulea sublutea* (Lam.) Baker: 88 (1877). *Bulbocodium subluteum* (Lam.) Kuntze: 700 (1891). Type: Unknown.

Ixia filifolia F.Delaroche in Redouté: t. 251 (1809). *Romulea filifolia* (F.Delaroche) Eckl.: 20 (1827). *Trichonema filifolium* (F.Delaroche) Ker Gawl.: 82 (1827). *Bulbocodium filifolium* (F.Delaroche) Kuntze: 700 (1891). Type: South Africa, [Western Cape], without precise locality, illustration in Redouté: t. 251 fig. 2 (1809).



Ixia crocea Thunb.: 218 (1811). Type: South Africa, without precise locality, *Thunberg s.n.* (UPS–THUNB 946, holo.).

Romulea schlechteriana Schinz: 395 (1895). Type: South Africa, [Western Cape], Cape Town, Rondebosch, *Schlechter 852* (Z, holo.).



Plants 50–200 mm high. *Corm* bell-shaped with flat base and pronounced circular basal rim, 5–10 mm diam., tunics woody, basal rim irregularly fringed, sometimes scalloped. *Stem* aerial and exserted up to 150 mm or rarely short and subterranean, sometimes extensively branched. *Leaves* 3 to 7, lower 2 basal, terete and narrowly 4-grooved, 0.5–1.0 mm diam., glabrous. *Peduncles* up to 7, hemiterete, spreading in fruit; outer bracts green with narrow, colourless or rarely brown-flecked membranous margins, 10–20 mm long, finely striate (4 or 5 veins/mm), inner bracts with narrow or wider, colourless or rarely brown-flecked membranous margins. *Flowers* golden-yellow or rarely white, sometimes with a dark median line or diffuse brown zone in throat, outer tepals sometimes greenish or brown on reverse; perianth tube funnel-shaped, 4–6 mm long; tepals oblanceolate to elliptic, 15–30 × 7–12 mm, often obtuse. *Filaments* 4–7 mm long, pilose in lower part, yellow; anthers 3–7 mm long, yellow. *Style* dividing shortly below to shortly above anther apices, branches divided. *Capsules* oblong, ± 10 mm long. *Flowering time*: August to October.

Distribution and ecology: largely restricted to the West Coast lowlands of Western Cape, South Africa, from Citrusdal southward along the coastal plain to the Cape Peninsula, where it is most commonly collected, and east to Caledon; on seasonally wet, sandy or loamy flats.

Diagnosis: readily distinguished by its exserted stem, ± unmarked golden-yellow flowers (rarely white with a yellow cup), and bell-shaped corm. White morphs are

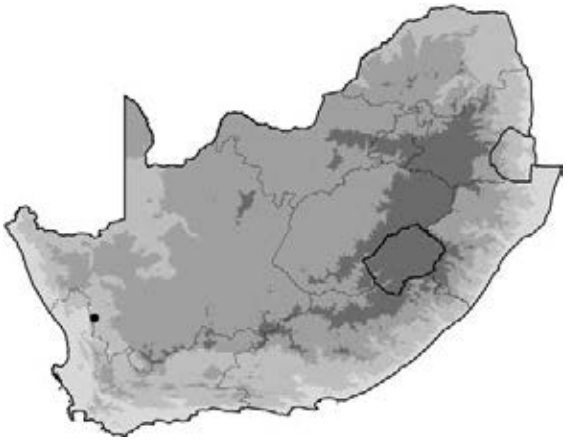
Distribution of ***Romulea triflora***.

Distribution of ***Romulea sladenii***.

known only from near Stanford, and the populations in the Overberg near Caledon are unusual in having the outer tepals flushed dark brown on the reverse – all other populations have the tepals yellow on both sides. Plants with ± bicoloured tepals in which the outer half is tinged salmon-coloured or orange are referred to *Romulea hirsuta* subsp. *cuprea* [see that taxon for further discussion].

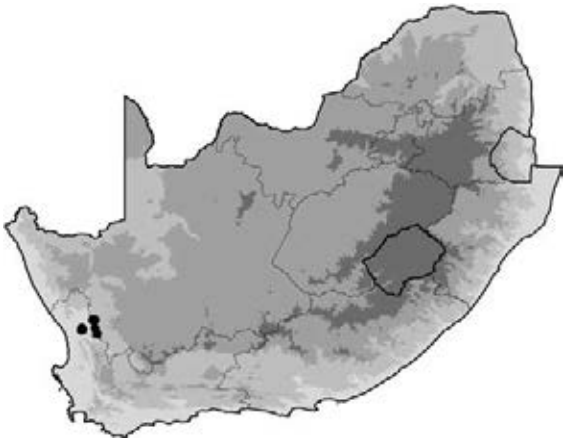
25. **Romulea sladenii** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 135 (1972). Type: South Africa, [Western Cape], Matsikamma Mtns, *De Vos 2018* (NBG [as STE], holo.).

Plants 30–150(–200) mm high. *Corm* bell-shaped, 5–10 mm diam., tunics woody, basal rim irregularly fringed and scalloped. *Stem* aerial and exserted up to 150 mm. *Leaves* 3 to 5, lower 2 basal, subterete and 4-grooved, 0.5–1.0 mm diam., glabrous. *Peduncles* up to 5, subterete, spreading in fruit; outer bracts green, with narrow, colourless or brown-edged membranous margins, 10–18 mm long, finely striate (4 veins/mm), inner bracts with narrow, colourless or brown-edged membranous margins. *Flowers* white with orange-yellow cup, outer tepals greenish or pink to purple on reverse; perianth tube funnel-shaped, 4–5 mm long; tepals oblanceolate, 15–25 × 4–8 mm. *Filaments* inserted near base of tube, 5–7 mm long, puberulous below, orange-yellow; anthers 4–6 mm long, yellow. *Style* dividing at tips of anthers, branches forked. *Capsules* oblong, 8–10 mm long. *Flowering time*: August, September.



Distribution and ecology: a local endemic of the Matsikamma–Gifberg massif in Western Cape, South Africa; on seasonally wet sandstone rock sheets and flushes in fynbos.

Diagnosis: recognised by the white flowers with orange-yellow cup, the outer tepals flushed green or pink on the reverse, and the bell-shaped corm. The presence of secondary veins in the leaf ribs appears to be unique in the section. In the field the species is easily confused with another Gifberg endemic, *Romulea toximontana*, unless excavated, when the latter is readily identified by its laterally compressed, oblique corm with wide basal ridge. The two species differ slightly in their flowers, with the bright yellow anthers in *R. sladenii* partially exserted from the cup on filaments 5–7 mm long and the cream-coloured anthers of *R. toximontana* included in the cup on shorter filaments 3–5 mm long.



26. **Romulea discifera** *J.C.Manning & Goldblatt* in Adansonia, ser. 3, 23: 91 (2001). Type: South Africa, Northern Cape, Bokkeveld Plateau, north of Nieuwoudtville, west of road to waterfall, 27 July 1999, *Goldblatt & Manning 11075* (NBG, holo.; K, MO, PRE, iso.).

Plants 100–150(–200) mm high. *Corm* flattened bell-shaped, 15–20 mm diam., tunics woody, basal rim irregularly fringed and scalloped. *Stem* subterranean or aerial and exserted up to 80 mm. *Leaves* 3 to 5, lower 2 basal, subterete and 4-grooved, 1.2–2.0 mm diam., glabrous or ciliolate on rib margins. *Peduncles* up to 3, subterete, suberect in fruit; outer bracts green, often flushed purple, with narrow, colourless membranous margins, 15–28 mm long, finely striate (4 veins/mm), inner bracts with narrow, colourless membranous margins. *Flowers* bright yellow with a darker yellow cup, inner tepals with narrow dark median line and sometimes diffuse dark zone in throat, outer tepals with dark median blotch in throat, streaked with reddish longitudinal bands on reverse; perianth tube funnel-shaped, ± 5 mm long; tepals oblanceolate, 25–35 × 6–10 mm. *Filaments* inserted near base of tube, 5–6 mm long, densely pilose below; anthers 6–7 mm long, yellow. *Style* dividing opposite middle of anthers, branches 2–3 mm long, divided for half their length. *Capsules* oblong-ovoid, ± 8 mm long. *Flowering time*: July (August).

Distribution and ecology: a local endemic of the Bokkeveld Mountains north of Nieuwoudtville in Northern Cape, South Africa; on seasonally damp clay flats in renosterveld shrubland.

Distribution of ***Romulea discifera***.

Distribution of ***Romulea multisulcata***.

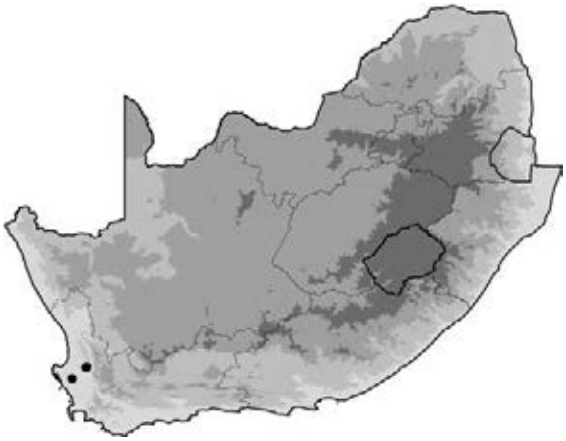
Diagnosis: a distinctive species with large, yellow flowers with dark brown blotches on the inner tepals and unique, flattened bell-shaped corm much wider than high.

Ser. **Aquaticae** *(M.P.de Vos) J.C.Manning & Goldblatt*, new rank. *Romulea* subsect. *Aquaticae* M.P.de Vos in Journal of South African Botany, Suppl. 9: 139 (1972). Type: *R. aquatica* G.J.Lewis

[*Romulea* ser. *Aquaticae* in Manning & Goldblatt: 62 (2001), name only]

Plants aquatic. *Corm* subglobose, obliquely flattened toward base; basal rim finely fringed. *Stem* aerial. *Leaves* 5- to 8-grooved, with secondary bundles, with or without vascular girders, with rib marginal fibre strands but without rib marginal bundles. *Chromosome number* 2*n* = 24.

27. **Romulea multisulcata** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 139 (1972). Type: South Africa, [Northern Cape], between top of Vanrhyn's Pass and Nieuwoudtville, *De Vos 2183* (NBG [as STE], holo.).



Plants 100–450 mm high. *Corm* subglobose, obliquely flattened toward base with crescent-shaped basal ridge ± as wide as corm, 6–15 mm diam., tunics splitting into fine parallel fibrils along ridge. *Stem* aerial, exserted (20–)60–150 mm, sometimes branching above. *Leaves* 3 or 4, lower 2 basal, the second usually sheathing the stem, terete and narrowly 6- to 8-grooved, 1–2 mm diam. *Peduncles* semiterete, 30–70 mm long, deflexed and widely spreading in fruit and 50–90 mm long; outer bracts green and thin-textured with narrow or well-developed, finely brown-speckled membranous margins and sometimes submembranous tips, 18–25(–30) mm long, inner bracts with very broad, brown-flecked or -speckled membranous margins and narrow green centre. *Flowers* white with golden-yellow cup or entirely golden-yellow, sometimes paler toward tips, outer tepals greenish or brown-striped on reverse, sweetly scented; perianth tube funnel-shaped, 3–5 mm long; tepals 15–25 long, outer oblanceolate, ± 7 mm wide, inner obovate-spathulate, ± 9 mm wide. *Filaments* 4–6 mm long, pilose basally; anthers 6–8 mm long, pale yellow. *Style* dividing at or just beyond anther apices, branches 1–2 mm long, divided for half their length. *Capsules* subglobose, 5–8 mm long. *Flowering time*: August, September.

Distribution and ecology: an aquatic species locally endemic to a few vernal pools on the Bokkeveld Escarpment in Northern Cape and the adjacent flats around Vanrhynsdorp in Western Cape, South Africa; flowering in the water with the corm and stem submerged.

Diagnosis: one of two truly aquatic species with more than four longitudinal grooves in the leaves, *Romulea multisulcata* is characterised by two basal leaves, the upper usually sheathing the stem, funnel-shaped perianth tube with filaments 4–6 mm long and anthers 6–8 mm long, style dividing near the top of the anthers, and widely spreading fruiting peduncles elongating slightly in fruit and ultimately 50–90 mm long. The type and other collections from around Nieuwoudtville on the northern Bokkeveld Escarpment have yellow flowers but populations from the southern Bokkeveld and from the flats below Vanrhyn's Pass around Vanrhynsdorp have white flowers with a yellow cup.

28. **Romulea aquatica** *G.J.Lewis* in Journal of South African Botany 4: 8 (1938). Type: South Africa, [Western Cape], Elandsvlei north of Piketberg, *Barker 190* (NBG, holo.).

Plants 100–250 mm high. *Corm* subglobose, obliquely flattened toward base with crescent-shaped basal ridge ± as wide as corm, 10–20 mm diam., tunics splitting into fine parallel fibrils along ridge. *Stem* aerial, exserted (20–)50–150 mm, peduncles congested at apex. *Leaves* 2 or 3(4), lower 1 basal, terete and narrowly 5- to 8-grooved, 0.8–1.5 mm diam. *Peduncles* semiterete, 10–30 mm long, suberect and up to 50 mm long in fruit; outer bracts green with narrow colourless or finely brown-speckled membranous margins, 7–16 mm long, finely veined (5 or 6 veins/mm), inner bracts with very

Distribution of ***Romulea aquatica***.

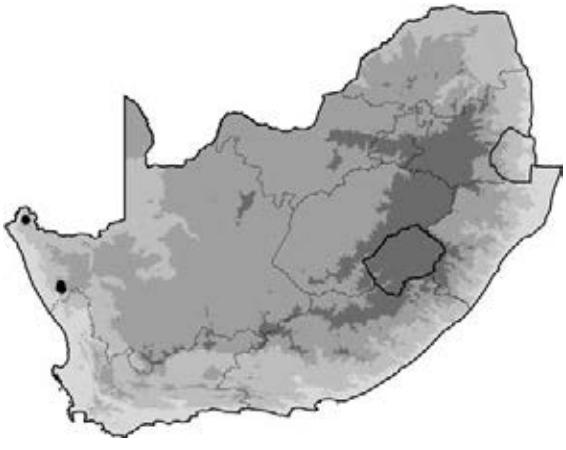
broad, brown-speckled membranous margins. *Flowers* white with golden-yellow cup with three slender dark lines in lower half, sweetly scented; perianth tube cup-shaped, 4 mm long; tepals 16–20 long, outer obovate, 6–9 mm wide, inner spathulate, 9–13 mm wide. *Filaments* 2–3 mm long, pilose at base; anthers 3–5 mm long, erect or slightly spreading, pale yellow. *Style* dividing near base or lower half of anthers, branches ± 2 mm long, divided for half their length. *Capsules* subglobose, 8–10 mm long. *Flowering time*: August, September.

Distribution and ecology: a locally endemic aquatic species known from two vernal pools in the Swartland in Western Cape, South Africa, one at Pools near Piketberg and the other at Koperfontein near Hopefield; flowering in the water with the corm and stem submerged. Both known localities are surrounded by agricultural lands and the species is highly endangered.

Diagnosis: one of a pair of allied aquatic species with more than four longitudinal grooves in the leaves, *Romulea aquatica* is recognised by its solitary basal leaf, cup-shaped perianth tube with short filaments, 2–3 mm long, short anthers 3–5 mm long, and short, suberect fruiting peduncles, 10–30(–50) mm long.

Ser. **Namaquanae** *J.C.Manning & Goldblatt*, new series. Type: *R. rupestris* J.C.Manning & Goldblatt

Plants from Namaqualand hardeveld. *Corm* subglobose, obliquely flattened toward base; basal rim finely fringed. *Stem* aerial. *Leaves* 4-grooved, with secondary bundles, vascular girders and rib marginal fibre strands. Outer bracts with well-developed membranous margins and tips. *Chromosome number* unknown.



29. **Romulea rupestris** *J.C.Manning & Goldblatt* in Adansonia, 3, 23: 80 (2001). Type: South Africa, [Northern Cape], Rooiberg, granite hills at Welkom, 9 June 1980, *Goldblatt 5567* (NBG, holo.; MO, iso.).

Plants 150–300 mm high. *Corm* globose, obliquely flattened toward base with crescent-shaped basal ridge ± as wide as corm, 10–15 mm diam., tunics splitting into fine parallel fibrils along ridge and forming fibrous neck above. *Stem* aerial, exserted 100–250 mm, cauline leaves clustered at apex. *Leaves* 2 or 3, lowermost 1 basal, oval in section and narrowly 4-grooved, 1.0–1.5 mm diam. *Peduncles* 1 to 3, rather short, up to 35 mm long, semiterete; outer bracts green with well-developed colourless or brown-speckled membranous margins and brown-flecked tips, 18–25(–30) mm long, finely striate (5 or 6 veins/mm), inner bracts with broad, brown-flecked membranous margins and narrow green centre. *Flowers* white to pale mauve with pale yellow cup with dark veins in cup, outer tepals streaked with maroon or dark green on reverse; perianth tube funnel-shaped, 5–6 mm long; tepals elliptic, 25–30 × 5–8 mm. *Filaments* inserted near base or middle of tube, 5–6 mm long, pilose basally; anthers 8–10 mm long, pale yellow. *Style* dividing opposite upper third of anthers, branches ± 2 mm long, divided for half their length. *Flowering time*: May to August.

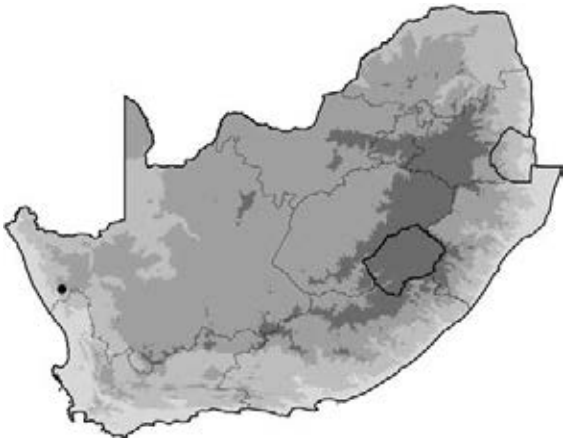
Distribution and ecology: a poorly collected endemic of the higher-lying parts of northern and central Namaqualand in Northern Cape, South Africa, recorded from Vandersterrberg in the Richtersveld and from Rooiberg in the Kamiesberg; on rocky slopes in fynbos.

Diagnosis: readily distinguished by the solitary basal leaf, well-exserted stem with cauline leaves clustered at the apex, outer bracts with brown-flecked membranous margins and inner bracts with very wide, brown-flecked membranous margins, and white to pale mauve flowers with pale yellow cup.

Superficially resembling *Romulea tabularis*, a coastal species extending north to Hondeklip Bay with similar aerial stem, solitary basal leaf, and pale blueish but generally much smaller flowers, the tepals 10–28 mm long, and shorter bracts 8–16 mm long with scarcely visible membranous margins.

Distribution of ***Romulea rupestris***.

30. **Romulea speciosa** *(Ker Gawl.) Baker* in Journal of the Linnean Society, Botany 16: 89 (1877). *Trichonema speciosum* Ker Gawl.: 223 (1804). *Bulbocodium speciosum* (Ker Gawl.) Kuntze: 700 (1891). *Romulea rosea* var. *speciosa* (Ker Gawl.) Baker: 103 (1892). *Ixia neglecta* Schult.: 279 (1822), as a replacement name for *Trichonema speciosum* Ker Gawl. [not *Ixia speciosa* Andrews (1801a)]. Type: South Africa, without precise locality or collector, illustration in Andrews: t. 170 '*Ixia bulbocodium* var. *flore speciosissimo*' (1801b).



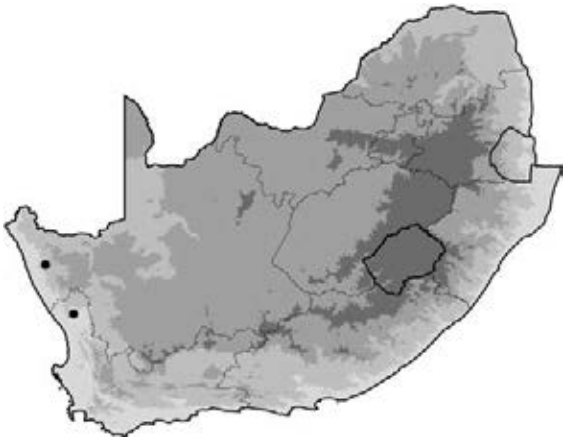
Romulea oliveri M.P.de Vos: 116 (1972). Type: South Africa, [Northern Cape], Kamiesberg, Farm Welkom, *Oliver 3169* (NBG [as STE], holo.; PRE, iso.).

Romulea neglecta M.P.de Vos: 29 (1983), illegitimate homonym, not *R. neglecta* Jord. & Fourr. (1868). Type: South Africa, without precise locality, possibly collected by J. Niven, illustration in Ker Gawl.: t. 1476 '*Ixia speciosa*' (1812).

Plants 50–150(–200) mm high. *Corm* subglobose, obliquely flattened toward base with crescent-shaped basal ridge, ± 15 mm diam.; tunics woody, split into fine parallel fibrils on basal ridge and forming fibrous neck. *Stem* subterranean or exserted up to 100(–120) mm. *Leaves* 2 or 3, lowermost 1 basal or evidently all basal when stemless, ± 1 mm diam., narrowly 4-grooved. *Peduncles* 1 to 3, hemiterete; outer bracts green with distinct, brownish or brown-flecked membranous margins, 15–30 mm long, closely ribbed (10–12 veins/mm), sometimes with stronger median vein, inner bracts with broad, dark brown-flecked membranous margins, central portion green with ± 20 closely spaced raised veins. *Flowers* carmine-red with pale yellow cup with black veins in cup, outer tepals feathered with yellow and purple on reverse; perianth tube funnel-shaped, 4–5 mm long, tepals oblanceolate, (20–)25–35 × (5–)7–10 mm. *Filaments* inserted near base of tube, 4.0–4.5 mm long, pilose at base, yellow to orange or darker toward base; anthers 8–10 mm long, pale yellow. *Style* dividing between middle and below anther apices, branches ± 2 mm long, divided for half their length. *Flowering time*: September.

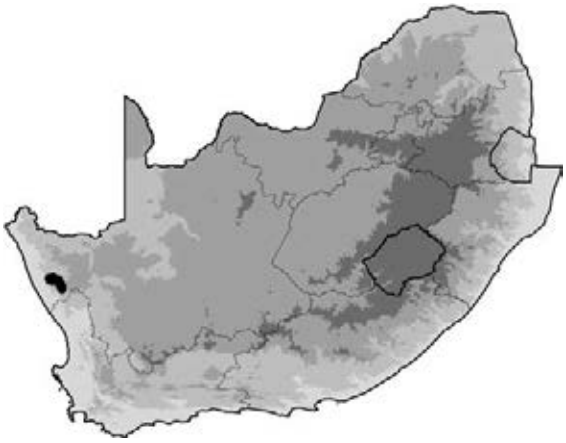
Distribution and ecology: a poorly collected species known with certainty only from the Farm Welkom on the Kamiesberg in Northern Cape, South Africa; on cooler, southeast-facing gravelly slopes in renosterveld shrubland.

Diagnosis: distinguished by the well-developed brownish or brown-flecked membranous margins to the outer bracts and the large, carmine-red flowers with anthers longer than the filaments. The membranous bract margins and the leaf anatomy (sclerenchyma strands present along the groove margins and sclerenchyma girders developed on the main vascular bundles) associate it with a small group of Namaqualand species including white-flowered *Romulea maculata* and *R. rupestris*, and yellow-flowered *R. pearsonii*.



Distribution of ***Romulea speciosa*** .

The confused nomenclatural history of the species was clarified by Manning et al. (2011).



31. **Romulea maculata** *J.C.Manning & Goldblatt* in Adansonia, 3, 23: 81 (2001). Type: South Africa, [Western Cape], northern Knersvlakte, Flaminkberg (also Rooiberg), north-facing upper slope in rocky loam on quartzite, *IPC-NGS Expedition 7* (NBG, holo.).

Plants 50–100 mm high. *Corm* subglobose, obliquely flattened toward base with crescent-shaped basal ridge, 10–15 mm diam.; tunics woody, split into fine parallel fibrils on basal ridge and forming short fibrous neck. *Cataphylls* purple, upper speckled with white above ground. *Stem* subterranean or shortly exserted. *Leaves* 3 or 4, lowermost basal or evidently all basal when stemless, 1.0–1.5 mm diam., oval in section, narrowly 4-grooved. *Peduncles* 1 to 3, hemiterete; outer bracts green with narrow or broader, brown-flecked membranous margins widening to prominent, brown-flecked membranous tip, 21–23 mm long, ribbed (5 or 6 veins/mm), sometimes with stronger median vein, inner bracts with broad, dark brown-flecked membranous margins, central portion green with ± 12 well-spaced raised veins. *Flowers* white with pale yellow cup, outer tepals feathered with dark purple on reverse; perianth tube funnel-shaped, 7–8 mm long, tepals oblanceolate, 27–30 × 10–13 mm. *Filaments* ± 6 mm long, puberulous basally; anthers ± 11 mm long, yellow. *Style* dividing opposite upper third of anthers, branches ± 1 mm long, divided for half their length. *Flowering time*: August, September.

Distribution and ecology: a poorly collected species known from south of Springbok in Northern Cape and near Nuwerus in Western Cape, South Africa; on south-facing or seasonally moist, rocky slopes in succulent karoo shrubland.

Distribution of ***Romulea maculata***.

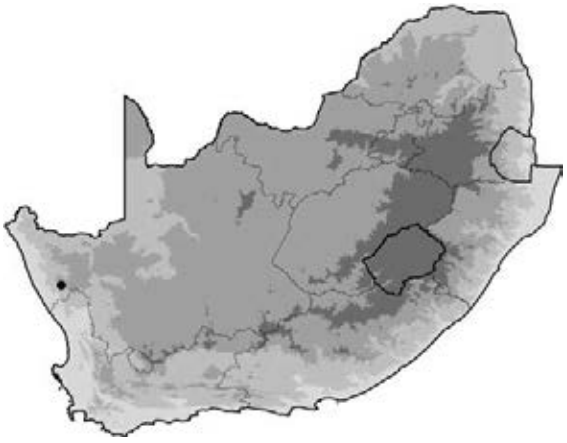
Distribution of ***Romulea pearsonii***.

Diagnosis: one of a small group of Namaqualand species with prominent, brown-flecked membranous apices to the outer bracts, distinguished by the stemless or short-stemmed habit, large white flowers with outer tepals feathered purple on the reverse, and the purple upper cataphyll conspicuously and finely speckled with white above ground.

32. **Romulea pearsonii** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 113 (1972). Type: South Africa, [Northern Cape], Kamiesberg, Khomsoap Ravine, *Pearson sub Sladen Expedition 6550* (BOL, holo.; K, iso.).

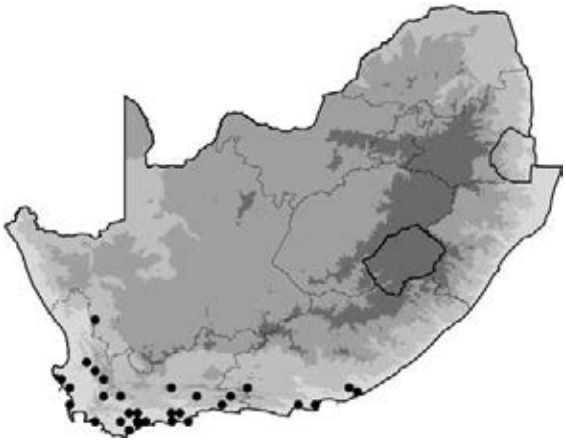
Plants 50–100 mm high. *Corm* subglobose, obliquely flattened toward base with crescent-shaped basal ridge, 8–10 mm diam., tunics woody, split into fine parallel fibrils on basal ridge. *Stem* subterranean. *Leaves* (2)3 to 5, all evidently basal, narrowly 4-grooved, 0.5–1.0 mm diam. *Peduncles* up to 4, hemiterete, suberect or slightly arching in fruit; outer bract green, with narrow, brown-flecked membranous margins widening above into prominent, brown-flecked membranous apex, 15–25 mm long, ribbed (± 6 veins/mm), inner bracts with broad, brown-flecked membranous margins, central portion green with 16 to 18 raised veins. *Flowers* pale to buttercup yellow, sometimes with orange throat, outer tepals greenish streaked brown on reverse; perianth tube ± cup-shaped, 4–5 mm long; tepals oblanceolate to elliptic, 25–40 × 8–14 mm. *Filaments* 6–8 mm long, pilose near base; anthers 7–10 mm long, yellow. *Style* dividing near anther apices, branches divided. *Capsules* shortly cylindric, 10–15 mm long. *Flowering time*: August, September.

Distribution and ecology: endemic to central Namaqualand in Northern Cape, South Africa, between Garies and Kamieskroon, especially on the Kamiesberg.



Diagnosis: one of a small group of Namaqualand species with prominent, brown-flecked membranous apices to the outer bracts, distinguished by the stemless habit and yellow, funnel-shaped flowers. This group shares similar leaf anatomy, notably the development of sclerenchyma vascular girders and rib marginal fibre strands, and absence of phloem caps on the secondary bundles.

33. **Romulea tubulosa** *J.C.Manning & Goldblatt* in Bothalia 38: 80 (2008). Type: South Africa, Northern Cape, Kamiesberg, ± 2 km SE of Leliefontein near Naras Farm, local in renosterveld, *R. & R. Saunders sub J.C. Manning 3117* (NBG, holo.).



Plants 30–40 mm high. *Corm* subglobose, obliquely flattened toward base with crescent-shaped basal ridge, 5–10 mm diam., tunics woody, split into fine parallel fibrils on basal ridge. *Stem* subterranean. *Leaves* 3 to 6, all evidently basal, narrowly 4-grooved, ± 0.5 mm diam., ciliate on rib margins. *Peduncles* up to 4, hemiterete; outer bract submembranous or green with broad, colourless membranous margins widening above into prominent, brown-flecked membranous apex, 10–15 mm long, ribbed above (5 or 6 veins/mm), inner bracts submembranous or with broad, brown-flecked membranous margins. *Flowers* ± salver-shaped, pale canary-yellow with orange throat, tepals with median brown streak near base, outer tepals streaked reddish brown on reverse; perianth tube subcylindric, widening slightly from base to apex, 13–14 mm long; tepals elliptic, 9–10 × 2.0–2.5 mm. *Filaments* inserted near top of tube ± 1 mm below mouth, shortly decurrent, glabrous, 1.5–3.0 mm long; anthers 3–4 mm long, yellow. *Style* dividing opposite middle of anthers, branches ± 1 mm long, divided for ± halfway. *Flowering time*: August to early September.

Distribution and ecology: a rare endemic of the higher parts of the Kamiesberg in Northern Cape, South Africa, on Rooiberg and Sneeuberg; occurring in small communities in renosterveld shrubland and on gravel pans on granite rock sheets in fynbos.

Diagnosis: the only species in the genus with yellow, salver-shaped flowers, the perianth tube 13–14 mm long with the stamens inserted near the top of the tube. Other species in sect. *Ciliatae* with this perianth type

Distribution of ***Romulea tubulosa***.

Distribution of ***Romulea minutiflora***.

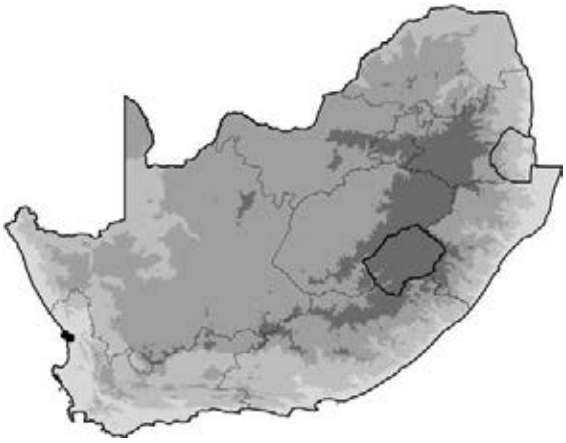
have purple to mauve flowers. The glabrous filaments are typical of species with salver-shaped flowers. The broad, membranous outer bract margins place it in a small group of Namaqualand species with similar bracts and leaf anatomy, viz. the development of vascular girders and rib marginal fibre strands but no phloem caps on the secondary bundles. The stemless habit and yellow perianth suggest a close relationship with *Romulea pearsonii*, also from the Kamiesberg.

Ser. **Minutiflorae** *(M.P.de Vos) J.C.Manning & Goldblatt*, name at new rank. *Romulea* subsect. *Minutiflorae* M.P.de Vos in Journal of South African Botany, Suppl. 9: 143 (1972). Type: *R. minutiflora* Klatt

Corm somewhat elongated, higher than wide, obliquely flattened toward base with high, somewhat flattened basal ridge; basal ridge finely fringed. *Stem* subterranean. *Leaves* with secondary bundles, with or without vascular girders, with rib marginal fibre strands, without rib marginal bundles. *Chromosome number* 2*n* = 26, c. 50.

34. **Romulea minutiflora** *Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 399 (1882). Type: South Africa, [Western Cape], Worcester, Hex River Mtns, *Drège 538* [S, lecto., designated by De Vos: 146 (1972)].

Plants 30–150 mm high. *Corm* obovoid to oblong, obliquely flattened toward base with high, crescent-shaped or ± flattened or wavy basal ridge, 10–15 × 5–10 mm, tunics splitting into fine parallel fibrils along ridge. *Stem* subterranean. *Leaves* 4 to 12, apparently all basal, often 2-ranked, lowermost arcuate or spreading, terete to oval in section and narrowly 4-grooved, 1.0–1.5 mm diam. *Peduncles* 1 to 4, rather short, up to 50 mm long, semiterete, initially arcuate in fruit but later erect; outer bracts submembranous or greenish in upper half, finely rust- or brown-speckled, finely and widely striate (3 to 5 veins/mm), with colourless or brown-spotted membranous margins, 6–10 mm long, inner bracts membranous or somewhat herbaceous in centre near tip with wide, prominently brown-spotted or -blotched membranous margins. *Flowers* pale mauve to lilac or rarely white, with greenish yellow cup, usually with violet circle in throat, outer tepals greenish or mottled on reverse; perianth tube funnel-shaped, 1.5–3.5 mm long; tepals elliptic, 4–9 × 1.5–2.5 mm. *Filaments* 2–4 mm long, glabrescent; anthers 1.5–2.0 mm long, pale yellow. *Style* dividing near tops of anthers, branches ± 1 mm long, divided. *Capsules* ellipsoid, 9–15 mm long. *Flowering time*: (July) August, September.



Distribution and ecology: widely scattered through the Cape Floristic Region , South Africa, from the Bokkeveld Escarpment in Northern Cape through the southern parts of Western Cape into Eastern Cape to Port Elizabeth and also Grahamstown (introduced to Australia); mostly in sandy soils, usually in ruderal situations such as roadsides and grassy swards.

The propensity of the species for disturbed places and road verges makes it difficult to assess its natural distribution. Early records indicate a native range in the southwestern Cape, but the records from Grahamstown are from lawns and may be introductions.

Diagnosis: recognised by its stemless habit and small, mostly pale mauve flowers, the tepals 4–9 mm long, submembranous outer bracts finely speckled with rusty brown throughout and inner bracts with prominently brown-spotted margins, and corm with a high, almost spathulate basal ridge. *Romulea sinispinosensis* from coastal sands north of Lamberts Bay on the West Coast has larger, white flowers, the tepals 10–12 mm long, pale bracts, and bracteoles with weakly spotted margins.

35. **Romulea sinispinosensis** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 147 (1972). Type: South Africa, [Western Cape], Vredendal, Doringbaai, *De Vos 2106* (NBG [as STE], holo.).

Plants 30–100 mm high. *Corm* obovoid to oblong, obliquely flattened toward base with high, crescent-shaped

Distribution of ***Romulea sinispinosensis***.

or ± flattened or wavy basal ridge, 12–15 × 8–12 mm, tunics splitting into fine parallel fibrils along ridge. *Stem* subterranean. *Leaves* 5 to 12, apparently all basal, mostly arcuate or spreading, terete to oval in section and narrowly 4-grooved, 1.0–1.5 mm diam. *Peduncles* up to 5, rather short, up to 50 mm long, semiterete, initially arcuate in fruit but later erect; outer bracts thin-textured or submembranous, reddish green in upper half, finely and widely striate (3 to 5 veins/mm), with narrow, ± colourless membranous margins, 8–10 mm long, inner bracts largely membranous or somewhat herbaceous in centre near tip with wide, membranous margins weakly or sparsely brown-spotted near tip. *Flowers* white with greenish yellow cup, outer tepals greenish on reverse; perianth tube funnel-shaped, 2.5–3.5 mm long; tepals elliptic, 10–12 × 3–4 mm. *Filaments* 3–4 mm long, minutely puberulous; anthers 3.5–4.0 mm long, pale yellow. *Style* dividing near tops of anthers, branches ± 1 mm long, divided. *Capsules* ellipsoid, 10–15 mm long. *Flowering time*: August.

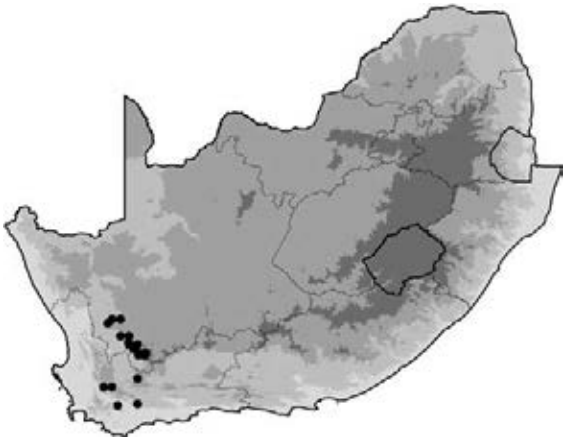
Distribution and ecology: a local endemic known only from the West Coast between Doringbaai and Lamberts Bay, South Africa, with a possible sight record further south near Velddrif; in sandy, often hard-packed soil, typically in open places along paths or in yards.

Diagnosis: a polyploid species closely allied to *Romulea minutiflora* from more southerly and inland locations, which has smaller, mostly pale lilac or mauve flowers with tepals 4–9 × 1.5–2.5 mm, often with a dark ring in the throat, finely rust-coloured speckled outer bracts, and inner bracts with membranous margins only inconspicuously brown-spotted or -speckled near the tips.

Ser. **Tetragonae** *J.C.Manning & Goldblatt*, new series. Type: *R. tetragona* M.P.de Vos

Corm subglobose, obliquely flattened toward base; basal rim finely fringed. *Stem* subterranean. *Leaves* 4-winged with lateral ribs reduced and median ribs winged, glabrous or ciliate on wing margins; peduncles and bracts ± pubescent. *Chromosome number* 2*n* = 26.

36. **Romulea tetragona** *M.P.de Vos* in Flowering Plants of Africa 29: t. 1136 (1952c). Type: South Africa, [Western Cape], Ceres, Theronsberg Pass, *De Vos 1569* (NBG [as STE], holo.).



Romulea tetragona var. *flavandra* M.P.de Vos: 273 (1972), new synonym. Type: South Africa, [Western Cape], Tweedside, *De Vos 1800B* (NBG [as STE], holo.).

Plants 20–100(–150) mm high. *Corm* subglobose, oblique with crescent-shaped basal ridge, 8–10 mm diam., tunics splitting into fine parallel fibrils along ridge; stem subterranean. *Leaves* (2)3 to 10(–15), lower mostly falcate, H-shaped in section, lower leaves 2–5(–7) mm wide but narrowed toward base, uppermost leaves generally narrower and as little as 1 mm wide, lateral ribs reduced and median (apparently marginal) ribs produced into flange-like wings, variously and sparsely or densely ciliolate, ciliate or ciliolate-ciliate along margins of wings or subglabrous. *Peduncles* up to 5, subterete, hirsute or villous, spreading but ultimately suberect in fruit; outer bracts green with brownish, brown-streaked or colourless margins widening upward to prominent membranous tip, 10–18 mm long, finely striate (± 5 veins/mm), hirsute or villous in lower half or throughout, inner bracts green with broad brown-speckled or colourless margins, hirsute along veins or rarely glabrous. *Flowers* pale lilac to magenta, sometimes with blue tips, rarely white, with small yellow or violet cup with darker violet blotch or band in throat, outer tepals greenish with purple feathering on reverse; perianth tube cup-shaped, 3–6 mm long; tepals obovate to elliptical, 12–28 × 5–8 mm. *Filaments* 3–4 mm long, minutely pilose basally, whitish; anthers 2–6 mm long, suberect to apically incurved, purple with reddish or orange pollen or rarely yellow with yellow pollen. *Style* dividing between base and apices of anthers, branches 2–5 mm long, deeply forked, whitish. *Capsules* oblong, 8–10 mm long. *Flowering time*: August to mid-September.

Distribution and ecology: distributed from the summit of the Hantamsberg along the Roggeveld Escarpment to the Komsberg and down to Tweedside in Northern Cape, with outlying stations to the south on the Theronsberg near Ceres and Kwadousberg near Worcester in Western Cape, South Africa; in seasonally waterlogged clay soils or seeps in renosterveld shrubland.

Diagnosis: a very distinct species without evident close allies, readily recognised by its distinctive H-shaped leaves, usually variously pubescent on the wing-margins, the pubescent peduncles and outer bracts, which have relatively broad membranous margins and apices, and the relatively small, lilac to magenta (rarely white) flowers with yellowish or violet cup. The leaves are often relatively short, not longer than the flowering stems.

Both yellow-flowered *Romulea hirta* (sect. *Roseae*) and orange-flowered *R. pilosa* (sect. *Aggregatae*) have developed remarkably similar 4-winged leaves.

Distribution of ***Romulea tetragona***.

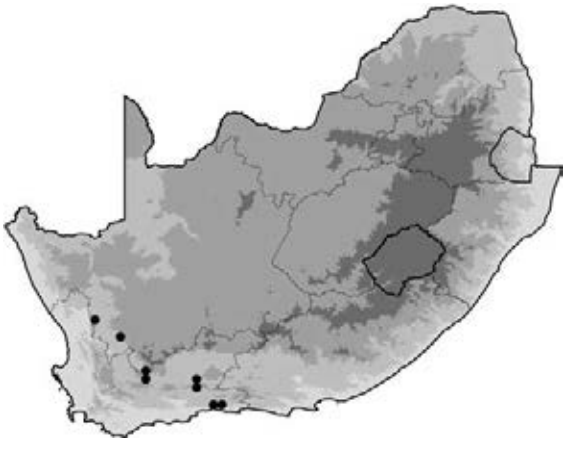
The development of sclerenchyma strands in the wing (= lateral rib) margins of the leaves of *Romulea tetragona* is relatively uncommon in sect. *Romulea* and this, plus a shared chromosome number $2n = 26$, may indicate an alliance with *R. minutiflora*, which also has relatively broad, brown-streaked outer bract margins.

The species is variable in the colouring of the floral cup, anthers and pollen, and in the length of the style. Two populations from near Sutherland and one from Tweedside with yellow anthers and pollen were segregated by De Vos (1972) as var. *flavandra* but we prefer not to recognise these populations formally as they differ in no other way from typical plants with dark anthers.

Ser. **Tortuosae** *(Bég.) J.C.Manning & Goldblatt*, name at new rank. *Romulea* "Stirps" *Tortuosae* Bég. in Annuaire du Conservatoire du Jardin Botaniques de Genève: 160 (1908). *Romulea* sect. *Tortuosae* (Bég.) M.P.de Vos: 151 (1972). Type: *Romulea tortuosa* Baker

Romulea subsect. *Longitubae* M.P.de Vos: 163 (1972), new synonym. Type: *R. macowanii* Baker

[*Romulea* sect. *Macowania* M.P.de Vos: 283 (1970), invalid name without description.]



Corm hemispherical, obliquely flattened with wide or fan-shaped basal rim. *Stem* subterranean. *Leaves* largely or entirely bifacial, without secondary bundles, vascular girders or rib marginal fibre strands or rib marginal bundles. *Outer* and *inner bracts* submembranous in basal half or entirely membranous. *Flowers* golden-yellow, often orange in cup. *Chromosome number* $2n = 30, 32$.

37. **Romulea austinii** *E.Phillips* in Flowering Plants of South Africa 3: t. 90 (1923). Type: South Africa, [Western Cape], Laingsburg, Matjesfontein, *Austin 2572* (PRE, holo.; BOL, K, iso.).

Plants 30–100 mm high. *Corm* hemispherical, 5–15 mm diam., obliquely flattened on one side and convex on the other, with wide, crescent-shaped basal ridge as wide as corm, tunics woody, split into parallel fibrils along ridge. *Stem* subterranean. *Leaves* 2 to 4(6), all basal, subterete, bifacial in lower ± half with adaxial groove open, narrowly 4-grooved distally, 0.5–1.0 mm diam., sometimes sparsely ciliolate along rib margins. *Peduncles* 1 to 3, up to 50 mm long, subterete, curved or slightly flexuose in fruit; outer bracts submembranous or greenish in lower half, green and subherbaceous distally, with narrow membranous margins, 10–22 mm long, widely striate (3 or 4 veins/mm), inner bracts submembranous in lower half and subherbaceous distally, with wide, brown-stippled membranous margins. *Flowers* canary-yellow with golden-yellow cup, usually with spade-shaped brownish markings in throat, outer tepals dark veined or feathered on reverse; perianth tube funnel-shaped, 4–5 mm long; tepals oblanceolate to elliptic, 14–25 × 5–9 mm. *Filaments* 5–7 mm long, pilose basally, yellow; anthers 3–6 mm long, yellow. *Style* dividing shortly below or beyond anther apices, branches 2 mm long, divided halfway. *Capsules* ellipsoid, 6–10 mm long. *Flowering time*: May to July.

Distribution and ecology: distributed through the drier interior southwestern parts of Western Cape, South Africa, from the Tanqua Karoo and western Great Karoo into the Little Karoo as far as the Long Kloof; on seasonally damp, stony clay flats in renosterveld.

Diagnosis: diagnosed by the hemispherical corm with broadly crescent-shaped basal ridge not wider than the corm itself, subterranean stem, leaves that are unifacial in the lower half, canary-yellow flowers with golden-yellow cup, usually with brown markings around the throat, and inner and outer bracts that are submembranous in the basal half but green and subherbaceous above. *Romulea austinii* is difficult to separate from forms of *R. tortuosa* lacking strongly compressed corms with a wide, fan-shaped basal ridge but that species typically has entirely papery or membranous bracts and more numerous leaves, bifacial almost to the tips and usually flexuous or twisted and sometimes conspicuously ciliate. Although De Vos (1972) cited the relatively

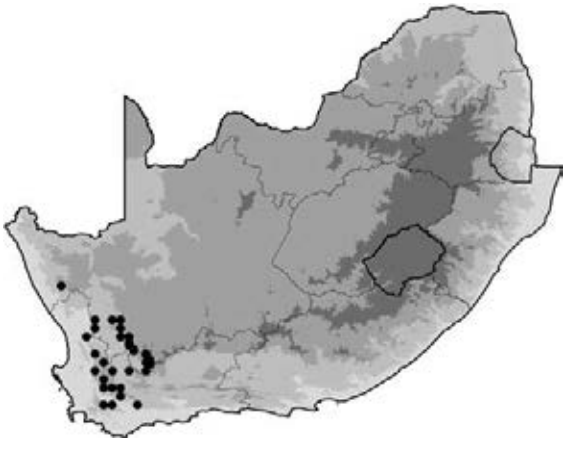
Distribution of ***Romulea austinii***.

shorter anthers in *R. austinii* as another character separating it from *R. tortuosa*, this is not infallible as some populations of *R. tortuosa* have similarly short anthers. The two species are largely parapatric, with *R. tortuosa* ranging to the north and west, from Namaqualand onto the Bokkeveld, Cold Bokkeveld and Roggeveld as far south as Worcester, thus overlapping with *R. austinii* on the Bokkeveld Plateau between Nieuwoudtville and Calvinia, and below the escarpment in the western Great Karoo between Matjiesfontein and Laingsburg.

38. **Romulea tortuosa** *(Licht. ex Roem. & Schult.) Baker* in Journal of the Linnean Society, Botany 16: 88 (1877). *Ixia tortuosa* Licht. ex Roem. & Schult.: 375 (1817). *Trichonema tortuosum* (Licht. ex Roem. & Schult.) Ker Gawl.: 83 (1827). *Bulbocodium tortuosum* (Licht. ex Roem. & Schult.) Kuntze: 701 (1891). Type: South Africa, without precise locality, *Lichtenstein s.n.* (B, holo.).

Romulea tridentifera Klatt: 398 (1882). Type: South Africa, [Northern Cape], Hantam Mtns, *Meyer s.n.* in 1869 (B†, holo.; S, iso.).

Romulea aurea Klatt: 399 (1882), new synonym. *R. tortuosa* subsp. *aurea* (Klatt) M.P.de Vos: 157 (1972). Type: South Africa, [Northern Cape], Hantam Mtns, *Meyer s.n.* in 1869 (B†, holo.; S, iso.).



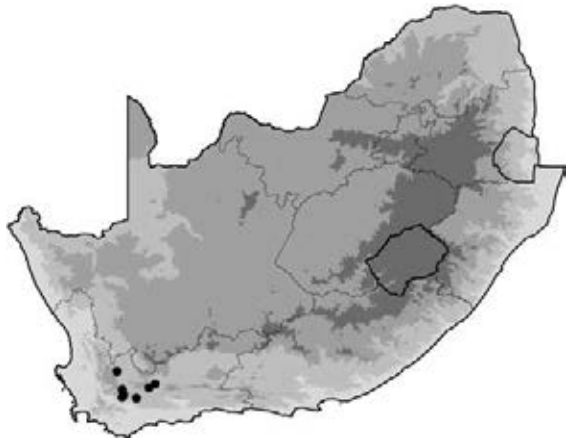
Romulea tortuosa subsp. *depauperata* M.P.de Vos: 159 (1972), new synonym. Type: South Africa, [Western Cape], summit Gydo Pass, *De Vos 1273* (NBG [as STE], holo.).

Plants 30–100 mm high. *Corm* hemispherical, 7–20 mm diam., obliquely flattened on one side and convex on the other, with wide, crescent- or fan-shaped, sometimes almost vertical basal ridge as wide as corm or wider, tunics woody, split into parallel fibrils irregularly grouped along ridge. *Stem* subterranean. *Leaves* 4 to 8, all basal, sometimes flexuous or twisted, conduplicate and bifacial almost to tip with adaxial groove open, narrowly 4-grooved beneath, 0.5–1.0 mm diam., glabrous or ciliolate to ciliate or pilose along rib margins. *Peduncles* 1 to 4, up to 80 mm long, subterete, curved or reflexed to spirally twisted in fruit; outer and inner bracts largely membranous or submembranous, greenish apically or with green or reddish veins, white or brownish to brown-stippled, 10–25 mm long, widely striate (3 or 4 veins/mm). *Flowers* pale to golden-yellow with darker cup sometimes extending onto base of tepals, unmarked or with tridentate or spade-shaped black blotch in throat, sometimes reduced to black veins, outer tepals sometimes greenish brown on reverse, sweetly scented; perianth tube funnel-shaped, 3–10 mm long; tepals oblanceolate to elliptic, 10–40 × 2–12 mm. *Filaments* 3–10 mm long, pilose basally, yellow; anthers 3–10 mm long, yellow. *Style* dividing shortly below or beyond anther apices, branches 2–6 mm long, divided halfway. *Capsules* subglobose to ellipsoid, 6–10 mm long. *Flowering time*: June to September.

Distribution and ecology: distributed through the near interior of the Northern and Western Cape, South Africa, on the Kamiesberg and the Bokkeveld Escarpment south through the Cold Bokkeveld and Swartruggens to Worcester and inland across the Hantam Plateau to Williston and along the Roggeveld to Laingsburg; on seasonally wet, loamy or clay flats and seepages, mainly in renosterveld shrublands, often forming dense colonies.

Diagnosis: usually readily recognised by the several, often flexuous leaves bifacial to the tips and sometimes conspicuously ciliate or pilose, the yellow flowers subtended by ± entirely membranous inner and outer bracts, and the often strongly vertically flattened corm with broad, fan-like basal rim. Some forms of *Romulea tortuosa* have been confused with *R. austinii*, but that species has fewer leaves, 2 to 4(6) that are unifacial in the upper half and never more than sparsely ciliolate, and only partially membranous inner and outer bracts that are green and herbaceous or subherbaceous in the upper half.

Romulea tortuosa varies greatly in the size and markings of the flowers, which range from less than 25 mm long and pale yellow with conspicuous dark black or brown blotches to over 40 mm long and golden-yellow without markings. Three subspecies were recognised by De Vos (1972) to accommodate this variation: subsp. *tortuosa* for plants with golden-yellow flowers mostly more than 25 mm long, usually with dark markings in the throat and occurring throughout the range of the species; subsp. *aurea* for similar large-flowered forms without markings, from the Bokkeveld and Roggeveld; and subsp. *depauperata* for plants with smaller, paler yellow flowers mostly less than 25 mm long with or without dark markings, from the Cold Bokkeveld to Worcester. The morphological and geographical distinctions between these three variants is, however, inconsistent, and that between subsp. *aurea* and subsp. *tortuosa* is especially untenable given the intra-population variation evident on the Bokkeveld and Roggeveld.



Distribution of ***Romulea tortuosa***.

39. **Romulea sphaerocarpa** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 161 (1972). Type: South Africa, [Western Cape], Sandvlei, 23 km from Matroosberg Station to Koo, *De Vos 2102* (NBG [as STE], holo.).

Plants 30–100 mm high. *Corm* hemispherical, 8–18 mm diam., obliquely flattened on one side and convex on the other, with wide crescent-shaped basal ridge as wide as corm, tunics woody, split into parallel fibrils along ridge. *Stem* short, subterranean, elongating to 40 mm after flowering. *Leaf* 1, basal, subterete, bifacial in lower ± third with adaxial groove open, narrowly 4-grooved distally, ± 1 mm diam., with adhering sand grains. *Peduncles* 1 or 2, up to 50 mm long, subterete, reddish and with adhering sand grains, arcuate and elongating slightly in fruit; outer bracts submembranous flushed purple in lower half, green and subherbaceous distally, with narrow, colourless, membranous margins, 15–18 mm long, widely striate (3 or 4 veins/mm), with adhering sand grains, inner bracts submembranous flushed purple in lower half and subherbaceous distally, with wide, brown-stippled membranous margins. *Flowers* golden-yellow with 3 or 5 brownish veins in throat, outer tepals brownish, yellowish or veined or feathered on reverse; perianth tube funnel-shaped, 5–7 mm long; tepals oblanceolate to elliptic, 15–30 × 5–12 mm. *Filaments* 5–7 mm long, pilose basally, yellow; anthers 6–8 mm long, yellow. *Style* dividing shortly below or beyond anther apices, branches 2 mm long, divided halfway. *Capsules* globose, 6–10 mm long. *Flowering time*: June, July.

Distribution and ecology: endemic to the interior mountains of Western Cape, South Africa, from the Swartruggens and Waboomsberg to Anysberg; locally common in sandy pockets in arid fynbos.

Diagnosis: a distinctive species recognised by the obliquely hemispherical corm, solitary leaf up to 200 mm long with adhering sand grains, and one or two golden-yellow flowers with both outer and inner bracts submembranous and flushed purple in the lower half and also with adhering sand grains. The corm, partially bifacial leaf, submembranous outer and inner bracts, yellow flower, and chromosome number $2n$ = ± 30, 32 all indicate a relationship with *Romulea tortuosa* and its allies but the solitary leaf with mucilage secretions is diagnostic.

Distribution of ***Romulea sphaerocarpa***.

40. **Romulea macowanii** *Baker* in Journal of Botany, British and foreign 14: 236 (1876). *Bulbocodium macowanii* (Baker) Kuntze: 700 (1891). Type: South Africa, [Eastern Cape], Somerset East, Boschberg, *MacOwan 1547* (K, lecto., designated by De Vos: 166 (1972); BM, BOL, G, GRA, PRE, isolecto.).

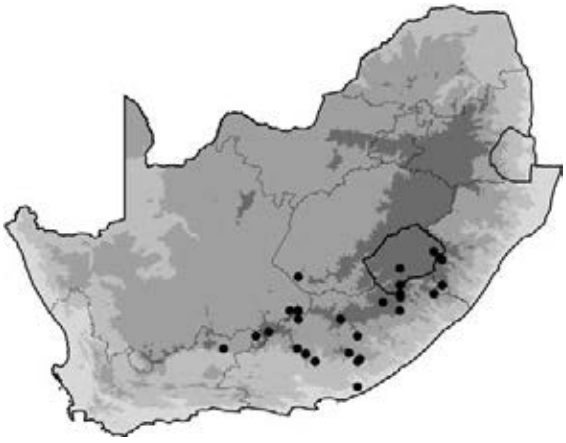
Syringodea luteonigra Baker: 281 (1897). Type: South Africa, [Eastern Cape], Queenstown, summit of Andriesberg and Hangklip, *Galpin 1516* (K, holo.; BOL, PRE, iso.).

Romulea longituba L.Bolus: 342 (1928). Type: South Africa, [KwaZulu-Natal], Mt Ingele. *Tyson 1267* (syntypes, GRA, SAM).

Romulea longituba G.J.Lewis: 43 (1941), illegitimate homonym, not *R. longituba* L.Bolus (1928) and an illegitimate superfluous name for *R. longituba* L.Bolus. Type: South Africa, [KwaZulu-Natal], Mt Ingele, *Tyson 1267* (SAM, holo.).

Romulea longituba var. *alticola* B.L.Burtt, new synonym: t. 515 (1967). *Romulea macowanii* var. *alticola* (B.L.Burtt) M.P.de Vos: 168 (1972). Syntypes: Lesotho, without precise locality, *Milford s.n.* (possibly not preserved) and illustrated in Burtt: t. 515 (1967).

Romulea macowanii var. *oreophila* M.P.de Vos: 169 (1972), new synonym. Type: South Africa, [Eastern Cape], Naude's Nek, summit of road, *De Vos 2186* (NBG [as STE], holo.).



Plants 20–100 mm high. *Corm* hemispherical, 8–15 mm diam., obliquely flattened on one side and convex on the other, with crescent-shaped basal ridge as wide as corm, tunics woody, split into parallel fibrils irregularly grouped along ridge. *Stem* subterranean. *Leaves* 3 to 6, all basal, narrowly 4-grooved, 0.5–1.0 mm diam. *Peduncles* 1 to 3, subterranean or shortly exserted, subterete, recurved in fruit; outer bracts submembranous below, green and subherbaceous in distal half, 20–60 mm long, widely striate (3 or 4 veins/mm), inner bracts largely membranous or subherbaceous above, sometimes with wide, colourless membranous margins. *Flowers* golden-yellow with orange cup often extending onto lower half of tepals, outer tepals often brownish or purplish or striped or feathered on reverse; perianth tube narrowly funnel-shaped, (13–)20–60 mm long, tubular below widening distally; tepals oblanceolate to elliptic, (10–)15–45 × 5–15 mm. *Filaments* 5–10 mm long, pilose basally or glabrescent, yellow; anthers 5–12 mm long, yellow. *Style* dividing shortly below or beyond anther apices, branches ± 2 mm long, divided

halfway. *Capsules* ellipsoid, 10–12 mm long. *Flowering time*: mainly January to May.

Distribution and ecology: a high-altitude species from the southeastern central plateau and adjacent mountains, ranging from Lesotho and Ngele in southern KwaZulu-Natal through the southern Free State westward as far as the Sneeuberge in Eastern Cape and Murraysburg in Western Cape, South Africa, and south to Grahamstown, with an isolated record near Fraserburg; in moist, open grassland and on rock sheets.

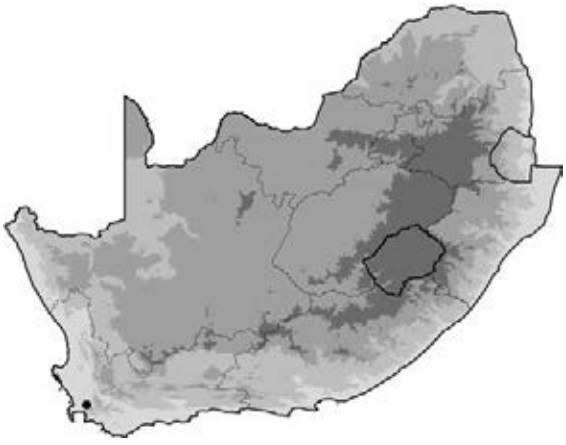
Diagnosis: readily distinguished by the very shortly pedunculate, yellow flowers with relatively long, funnel-shaped perianth tube, (13–)20–65 mm long, and correspondingly long, submembranous bracts, 20–60 mm long.

Three varieties were recognised by De Vos (1972): var. *macowanii* for plants with large flowers mostly more than 55 mm long and tepals 8–15 mm wide; var. *oreophila* for plants with smaller flowers mostly less than 55 mm long and narrower tepals 4–7 mm long; and var. *alticola* for plants with longer perianth tubes, 35–65 mm long. These differences are trivial in light of the variation evident in the species, and in some instances at least merely reflect growing conditions, with multiple collections from the same locality blurring these distinctions.

Distribution of ***Romulea macowanii***.

Sect. 2. **Autumnales** *(M.P.de Vos) J.C.Manning & Goldblatt*, name at new rank. *Romulea* subsect. *Autumnales* M.P.de Vos in Journal of South African Botany, Suppl. 9: 202 (1972). Type: *R. autumnalis* L.Bolus

Corms with oblique, crescent-shaped basal ridge usually less than half as wide as corm; tunics splitting into slender teeth. *Leaves* with secondary bundles, usually with vascular girders and rib marginal fibre strands but without rib marginal bundles.



Ser. **Alticolae** *J.C.Manning & Goldblatt*, new series. Type: *R. alticola* J.C.Manning & Goldblatt

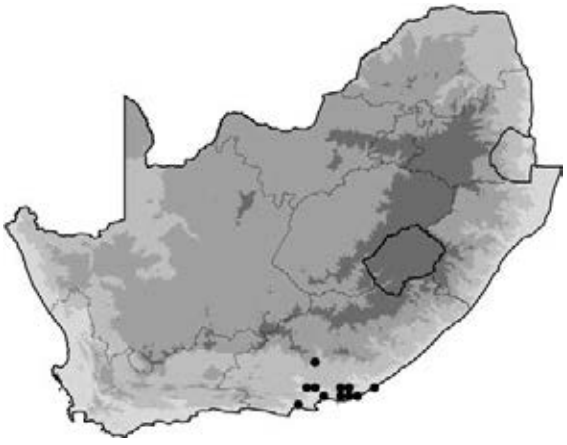
Corm with inconspicuous basal ridge much less than half as wide as corm, tunics papery with long, slender teeth curving over basal ridge. *Stem* exserted. *Leaves* with secondary bundles and vascular girders, without rib marginal strands.

41. **Romulea alticola** *J.C.Manning & Goldblatt* in South African Journal of Botany 95: 132 (2014). Type: South Africa, Western Cape, Jonkershoek, lower slopes, *Kerfoot 6010* (NBG, holo.; PRE, iso.).

Plants 50–100(–200) mm high. *Corm* ovoid, 5–7 mm diam., obliquely pointed with small basal ridge, tunics papery, split into slender teeth bent over ridge, ± fibrous and extending upward in a softly fibrous neck. *Stem* usually exserted up to 50 mm. *Leaves* (2)3 or 4, lower (1)2 basal, terete-filiform, narrowly 4-grooved, 0.5–1.0 mm diam. *Peduncles* up to 3, subterete-angled; outer bracts green with narrow, colourless membranous margins, 10–16 mm long, laxly ribbed (± 5 veins/mm) with papillate grooves between ribs, inner bracts with wide, brown-speckled membranous margins. *Flowers* purple with orange-yellow cup, outer tepals pale green with purple feathering on reverse; perianth tube funnel-shaped, ± 4 mm long; tepals oblanceolate to elliptic, 14–20 × 4–6 mm. *Filaments* shortly exserted from cup, ± 5 mm long, puberulous or pilose basally; anthers ± 4 mm long, yellow. *Style* dividing just below anther apices, branches ± 1.5 mm long, shortly divided. *Flowering time*: September, October.

Distribution and ecology: known from two collections from the Jonkershoek Mtns above Stellenbosch in Western Cape, South Africa.

Distribution of ***Romulea alticola***.



Diagnosis: distinctive in its softly papery corm tunics splitting at the base into slender teeth curved over a small basal ridge, the tunics becoming almost fibrous with age and forming a softly fibrous neck above, and in the exserted stem. The purple flowers with an orange-yellow cup are subtended by unusual bracts with prominently ridged veins separated by wide, distinctly papillate stomatiferous grooves. The tunics splitting into narrow teeth are consistent with sect. *Autumnales* but the papery tunics with teeth curved over a small basal ridge, exserted stem, and leaves without rib marginal strands are anomalous in the section.

Ser. **Autumnales** *(M.P.de Vos) J.C.Manning & Goldblatt*, name at new rank. *Romulea* subsect. *Autumnales* M.P.de Vos in Journal of South African Botany, Suppl. 9: 202 (1972). Type: *R. autumnalis* L.Bolus

Corm with inconspicuous basal ridge much less than half as wide as corm, tunics with small teeth converging on basal point. *Leaves* with secondary bundles, vascular girders and rib marginal strands.

42. **Romulea autumnalis** *L.Bolus* in Journal of Botany, British and foreign 69: 12 (1931); De Vos: 203 (1972). Type: South Africa, [Eastern Cape], Grahamstown, *Dyer 2414* [BOL, lecto., designated by De Vos: 205 (1972)].

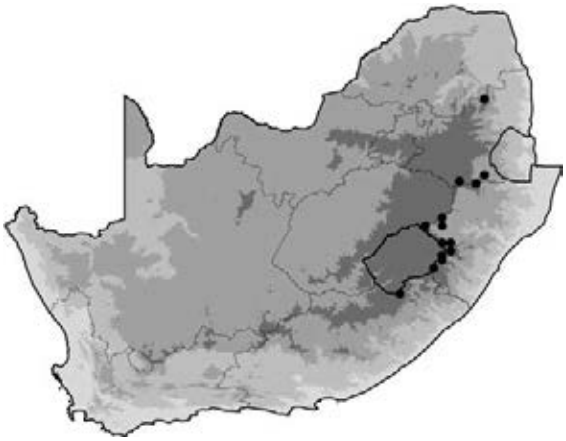
Plants 50–150(–200) mm high. *Corm* ovoid, 10–20 mm diam., obliquely pointed with small basal ridge, tunics woody or papery, split into fine teeth below. *Stem* short, subterranean. *Leaves* 3 to 8, all basal, subterete, narrowly 4-grooved, 1–2 mm diam. *Peduncles* up to 4, subterete, erect in fruit; outer bracts green or greenish with narrow, colourless membranous margins, 17–25 mm long, finely striate (5 or 6 veins/mm), inner bracts with wide, colourless membranous margins. *Flowers* pink to white with yellow cup, outer tepals pale green with purple feathering on reverse; perianth tube funnel-shaped, 5–7 mm long; tepals oblanceolate to elliptic, 18–30 × 6–12 mm. *Filaments* ± included in cup, 4–10 mm long, pilose basally, orange-yellow; anthers (5–)6–8 mm long, yellow. *Style* dividing below anther apices, branches 2–3 mm long, shortly divided. *Capsules* oblong, 8–10 mm long. *Flowering time*: April to July.

Distribution of ***Romulea autumnalis***.

Distribution and ecology: endemic to Eastern Cape, South Africa, from the Zuurberg through Grahamstown and Port Alfred to Hogsback and the Boschberg near Somerset East; in grassland or grassy fynbos up to 1 000 m elevation.

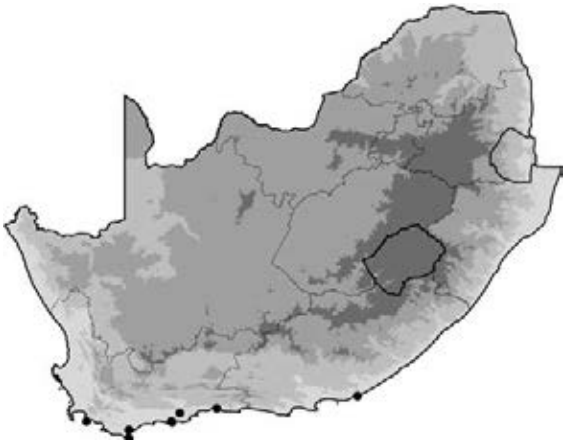
Diagnosis: allied to the widespread African *Romulea camerooniana* and sharing with it a corm with a small, narrowly toothed basal ridge but distinguished by the often larger flowers with finely veined bracts and short stamens and style, not reaching the middle of the perianth and thus included in the floral cup.

43. **Romulea camerooniana** *Baker* in Journal of Botany, British and Foreign 14: 236 (1876); Goldblatt: 63 (1993), 36 (1996). *Bulbocodium cameroonianum* (Baker) Kuntze: 700 (1891). *Romulea campanuloides* var. *camerooniana* (Baker) Cufod.: 1585 (1972). Type: Cameroon, Mt. Cameroon, *Mann 2135* (K, holo.).



Romulea campanuloides Harms: 28 (1894); De Vos: 207 (1972). Type: Tanzania, Mt Kilimanjaro, above Mambam, *Volkens 782* (B, holo.; K, iso.).

Romulea alpina Rendle: 401 (1895). Type: Tanzania, Mt Kilimanjaro, above Morang, 1888, *Taylor s.n.* (BM, holo.).



Romulea thodei Schltr.: 318 (1898). Type: South Africa, [Free State], Mont-aux-Sources, *Thode s.n.* (B, BOL, NBG, syn.).

Romulea thodei subsp. *gigantea* M.P.de Vos: 106 (1955). *Romulea campanuloides* var. *gigantea* (M.P.de Vos) M.P.de Vos: 209 (1972). Type: South Africa, [Free State], Van Reenen's Pass, *Thode s.n.* (NBG, holo.).

Plants 50–100(–200) mm high. *Corm* ovoid, 8–20 mm diam., obliquely pointed with small basal ridge, tunics woody or cartilaginous, split into fine teeth below, often extending upward in a fibrous neck. *Stem* short, subterranean. *Leaves* (1)2 to 4(6), all basal, subterete, narrowly 4-grooved, 1–2 mm diam. *Peduncles* up to 4, subterete, erect in fruit; outer bracts green or greenish with narrow, colourless membranous margins, 10–20 mm long, closely ribbed (± 8 veins/mm) or rarely softer basally, inner bracts similar or with wider colourless margins basally. *Flowers* magenta to white with yellow or greenish cup, outer tepals pink or green with or without purple feathering on reverse; perianth tube funnel-shaped, 4–8 mm long; tepals oblanceolate to elliptic, (9–)12–20(–35) × 4–8 mm. *Filaments* inserted in lower half of tube, shortly exserted from cup, 4–10 mm long, puberulous or pilose basally; anthers 3–7 mm long, yellow or with purplish lines. *Style* dividing below or up to 4 mm beyond anther apices, branches 1–2 mm long, shortly

Distribution of ***Romulea camerooniana***.

Distribution of ***Romulea gigantea***.

divided. *Capsules* ovoid-oblong, 7–10 mm long. *Flowering time*: October to February.

Distribution and ecology: widely distributed along the eastern Escarpment in southern and tropical Africa, in the Drakensberg from Naude's Nek in Eastern Cape through eastern Free State, KwaZulu-Natal and Lesotho to southern Mpumalanga and Eswatini, and thence from the Eastern Highlands of Zimbabwe to southern Sudan; in montane grasslands and on stony plateaus, from ± 1 500–3 000 m elevation.

Diagnosis: allied to *Romulea autumnalis* from lower altitudes in the Eastern Cape and sharing with it a corm with a small, narrowly toothed basal ridge but distinguished by the mostly smaller flowers with closely ribbed bracts and longer stamens and style, typically more than half as long as the perianth and thus exserted from the floral cup.

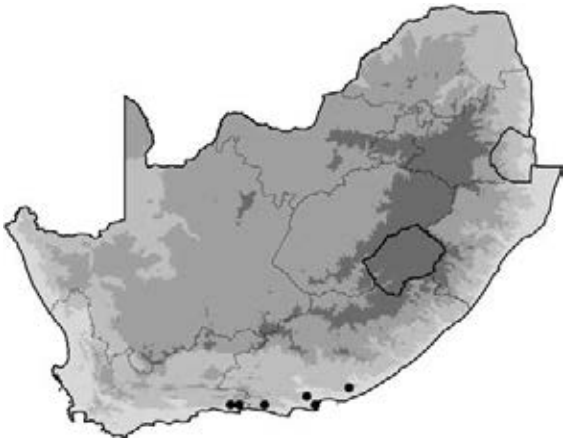
Ser. **Pratenses** *(M.P.de Vos) J.C.Manning & Goldblatt*, name at new rank. *Romulea* sect. *Pratenses* M.P.de Vos in Journal of South African Botany, Suppl. 9: 196 (1972). Type: *R. pratensis* M.P.de Vos

Corm with basal ridge at least half as wide as corm, tunic teeth bent over and fracturing on basal ridge.

44. **Romulea gigantea** *Bég.* in Botanische Jahrbücher für Systematik 38: 333 (1907); De Vos: 117 (1972). Type: South Africa, [Western Cape], Riversdale, *Rust 622* (B, holo.).

Plants (50–)100–200 mm high. *Corm* ovoid, 7–15 mm diam., oblique with crescent-shaped basal ridge, tunics woody or cartilaginous, split into fine, parallel fibril-like teeth sharply bent over ridge, ultimately breaking into slender, hooked teeth 2–3 mm long. *Stem* short, subterranean or exserted up to 20 mm. *Leaves* 5 to 7, lower 2 basal, compressed-cylindric, narrowly 4-grooved, 1–3 mm diam. *Peduncles* mostly 3 to 5, angled, erect in fruit; outer bracts green with narrow, colourless membranous margins, 10–20 mm long, closely ribbed (± 8 veins/mm), inner bracts with wide brown-flecked membranous margins. *Flowers* white to pale pink or blue with or without darker median line, with greenish yellow cup, outer tepals green and ± irregularly marked on reverse; perianth tube funnel-shaped, 2–3 mm long; tepals elliptic, 10–15 × 3–4 mm. *Filaments* 3–7 mm long, puberulous or pilose basally, pale yellow; anthers 3–4 mm long, yellow. *Style* dividing shortly below anther apices. *Capsules* oblong, 8–10 mm long. *Flowering time*: September, October.

Distribution and ecology: distributed along the coast from Kleinmond in Western Cape eastward to Port Alfred in Eastern Cape, South Africa; on damp grassy flats or along salt marshes.



Diagnosis: a polyploid species like *Romulea pratensis* and distinguished from it by the corm tunics splitting on the crescent-shaped basal ridge into slender, hooked teeth not aggregated into clusters, and by the uniformly green bracts. Plants of *R. gigantea* with smaller basal ridges on the corms may be confused with *R. autumnalis*, but that species has almost pointed corms with straight teeth converging on the very narrow basal ridge, and the inner bracts have colourless, not brown-flecked membranous margins.

45. **Romulea pratensis** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 198 (1972). Type: South Africa, [Eastern Cape], Grahamstown, *Dyer 1619* (GRA, holo.; PRE, iso.).

Plants 50–100 mm high. *Corm* ovoid, 7–10 mm diam., oblique with crescent-shaped basal ridge, tunics woody, split into strips comprising clusters of fibril-like teeth converging at the tips and sharply bent over ridge. *Stem* short, subterranean. *Leaves* 5 to 8, mostly spreading, terete to compressed-cylindric, narrowly 4-grooved, 1–2 mm diam. *Peduncles* mostly 3 to 5, angled, erect in fruit; outer bracts green, often paler and submembranous in lower half, with narrow, colourless or brown-speckled membranous margins, 10–20 mm

long, closely ribbed above but striate below (± 7 veins/mm), inner bracts submembranous in lower half with wide brown-speckled membranous margins. *Flowers* pale pink to almost white, often with 1 or 3 darker lines in throat, with greenish yellow cup, outer tepals purple or green with purple stripes on reverse; perianth tube funnel-shaped, 2.0–3.5 mm long; tepals elliptic, 8–15 × 3–5 mm. *Filaments* 3–4 mm long, puberulous or pilose basally; anthers 3–4 mm long, yellow. *Style* dividing shortly below or at anther apices. *Capsules* oblong, 10–13 mm long. *Flowering time*: July to September.

Distribution and ecology: endemic to Eastern Cape, South Africa, from the Tsitsikamma Mtns to Grahamstown, where it may become weedy in lawns; in damp grassland and grassy fynbos. The species has weedy tendencies in the east of its range.

Distribution of ***Romulea pratensis***.

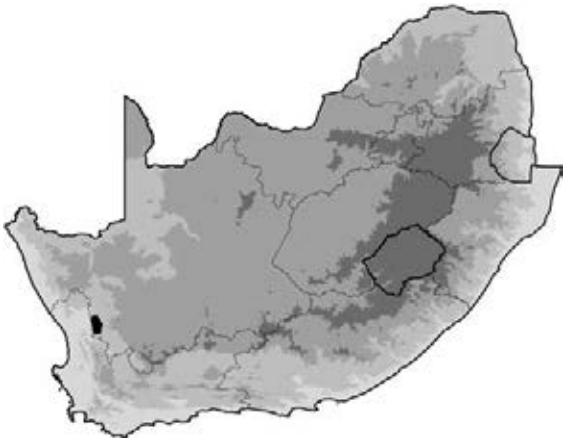
Diagnosis: distinguished by the characteristic corms, splitting at the basal ridge into longitudinal strips that are finely split at the tips into clusters of converging fibril-like teeth, and by the inner and outer bracts paler and submembranous in the lower half. The membranous margins of the inner bracts are spotted with brown rather than flecked, as in *R. gigantea*, which also differs in its corm tunics splitting into slender parallel teeth.

Sect. 3. **Aggregatae** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 170 (1972). Type: *Romulea setifolia* N.E.Br.

Corm usually ovoid with oblique, crescent-shaped basal ridge or rarely bell-shaped with complete or incomplete basal rim; basal ridge fringed small clusters of converging fibrils with roots emerging from each cluster. *Leaves* usually with secondary bundles but without vascular girders, and rib marginal fibre strands or bundles.

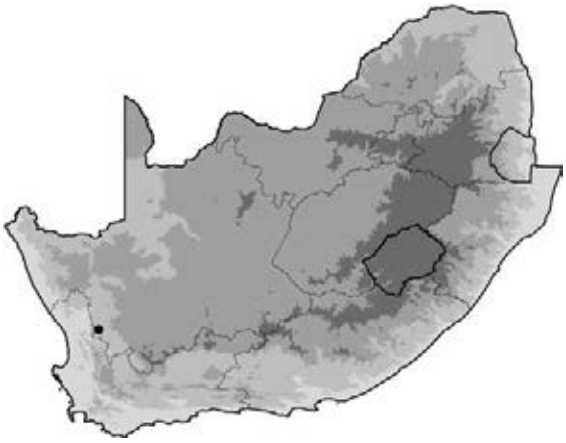
Ser. **Amoenae** *(M.P.de Vos) J.C.Manning & Goldblatt*, name at new rank. *Romulea* subsect. *Amoenae* M.P.de Vos in Journal of South African Botany, Suppl. 9: 191 (1972). Type: *R. amoena* Bég. = *R. pudica* (Ker Gawl.) Baker

Corm ± bell-shaped with circular or horseshoe-shaped basal rim. *Leaves* ± without vascular girders. *Flowers* deep carmine-red. *Filaments* shorter than anthers. *Chromosome number* 2*n* = 24.



46. **Romulea pudica** *(Sol. ex Ker Gawl.) Baker* in Journal of the Linnean Society, Botany 16: 89 (1877). *Trichonema pudicum* Soland. ex Ker Gawl.: t. 1244 (1810). *Ixia pudica* (Soland. ex Ker Gawl.) Roem. & Schult.: 377 (1817). *Geissorhiza pudica* (Soland. ex Ker Gawl.) Klatt: 655 (1866). *Bulbocodium pudicum* (Soland. ex Ker Gawl.) Kuntze: 700 (1891). *Romulea rosea* var. *pudica* (Soland. ex Ker Gawl.) Baker: 42 (1896). Lectotype: South Africa, without precise locality, illustration in Ker Gawl.: t. 1244 (1810), designated by Manning et al.: 274 (2011).

Romulea amoena Schltr. ex Bég.: 334 (1907); De Vos: 194 (1972). Type: South Africa, [Northern Cape], Bokkeveld Mtns, Papkuilsfontein, *Schlechter 10896* (G, holo.; BM, BOL, GRA, K, MO, PRE, S, Z, iso.).



[*Trichonema pudicum* Ker Gawl.: 223 (1804) and Ker Gawl: sub t. 1225 (1809), invalid name without description.]

Plants 50–200 mm high. *Corm* bell-shaped with circular basal rim, 5–10 mm diam., tunics woody, basal rim with clusters of converging fibrils. *Stem* subterranean or shortly aerial and exserted up to 20 mm. *Leaves* 3 to 5, all or lower 2 basal, subterete and narrowly 4-grooved, 0.5–1.5 mm diam., glabrous. *Peduncles* up to 3, subterete, green or reddish brown; outer bracts green, with narrow, colourless margins,17–30 mm long, finely ribbed (5 or 6 veins/mm), inner bracts with wide, brown-flecked membranous margins. *Flowers* carmine-red to deep rosy-pink with yellow or white cup finely streaked with black and with V-shaped marks at base, with black blotches in throat, outer tepals irregularly marked with red and yellow; perianth tube funnel-shaped, 5–7 mm long; tepals oblanceolate, 18–35(–50) × 9–15 mm. *Filaments* inserted in lower half of tube, 3–5 mm long, puberulous below, whitish; anthers 8–10 mm long, yellow. *Style* dividing between middle and apex of anthers, branches forked. *Flowering time*: August.

Distribution and ecology: a narrow endemic of the Bokkeveld Mtns south of Nieuwoudtville in Northern Cape, South Africa, from Oorlogskloof to Lokenburg; locally common on seasonally wet or waterlogged sandy flats over sandstone pavement in fynbos.

Distribution of ***Romulea pudica***.

Distribution of ***Romulea sanguinalis***.

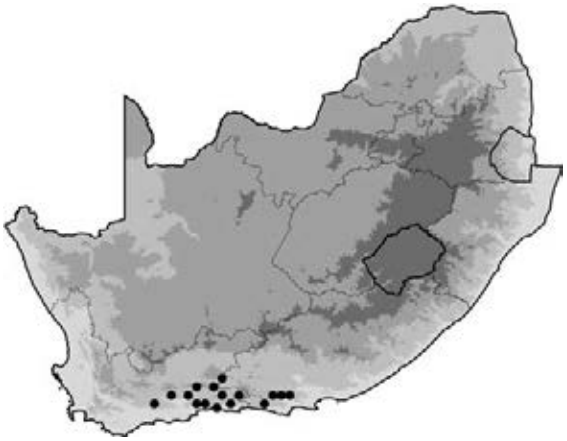
Diagnosis: distinctive in its large, carmine- or deep rosy-red flowers with a white or rarely yellow cup finely lined with black and with black blotches in the throat, and bell-shaped corm with small fibril clusters on the basal rim. The species was known until recently under the name *R. amoena* Schltr. ex Bég., when the identity of the earlier name *R. pudica* (Soland. ex Ker Gawl.) Baker was established (Manning et al. 2011).

47. **Romulea sanguinalis** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 191 (1972). Type: South Africa, [Northern Cape], Bokkeveld Mtns, Menzies Kraal, *Burger s.n.* (NBG, holo.).

Plants 100–200 mm high. *Corm* obliquely flattened at base with horseshoe-shaped basal rim, 8–10 mm diam., tunics woody, basal rim with clusters of converging fibrils. *Stem* subterranean or aerial and exserted up to 80 mm. *Leaves* ± 3, lower 2 basal, subterete and narrowly 4-grooved, ± 1 mm diam., glabrous. *Peduncles* up to 2, subterete, reddish brown; outer bracts green, with narrow, colourless margins,18–28 mm long, finely ribbed (5 or 6 veins/mm), inner bracts with wide, colourless or brown-flecked membranous margins. *Flowers* carmine-red, outer tepals irregularly marked with red and yellow; perianth tube funnel-shaped, 5–6 mm long; tepals oblanceolate, 22–35 × 8–12 mm. *Filaments* inserted in middle of tube, ± 5 mm long, glabrous, reddish; anthers 8–10 mm long, golden-yellow. *Style* dividing at or shortly above apex of anthers, branches forked. *Flowering time*: Aug.

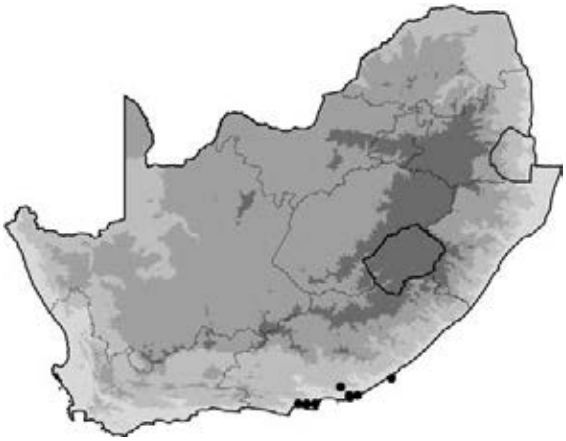
Distribution and ecology: known only from the type collection made on the farm Menzieskraal on the Bokkeveld Mtns south of Nieuwoudtville in Northern Cape, South Africa.

Diagnosis: an enigmatic species unique in the genus in its entirely red flowers without a paler cup. It might be considered a colour form of *R. amoena* but also differs from that species in the incomplete basal rim on the corm and in its glabrous, reddish filaments. The type comprises two plants that flowered in cultivation in 1952 and the species has not been seen again.



Ser. **Aggregatae** *(M.P.de Vos) J.C.Manning & Goldblatt*, name at new rank. *Romulea* sect. *Aggregatae* M.P.de Vos in Journal of South African Botany, Suppl. 9: 170 (1972). Type: *Romulea setifolia* N.E.Br.

[*Romulea* subsect. *Aggregatae* in M.P.de Vos: 171 (1972), invalid name without author.]



Corm oblique with crescent-shaped basal ridge. *Leaves* usually with well-developed vascular girders. *Flowers* variously coloured, never carmine-red. *Filaments* longer than anthers. *Chromosome number* 2*n* = 30, 32.

48. **Romulea fibrosa** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 183 (1972), as a replacement name for *Romulea alpina* L.Bolus: 342 (1928), illegitimate homonym, not *R. alpina* Rendle (1895). Type: South Africa, [Western Cape], Uniondale, Bloubosberg, *Fourcade 2831* (BOL, lecto., designated by De Vos: 184 (1972); K, isolecto.).

Plants 60–250(–500) mm high. *Corm* ovoid, 10–20 mm diam., oblique with crescent-shaped basal ridge, tunics cartilaginous or papery, with clusters of converging fibrils on ridge, each cluster splitting longitudinally into narrow strips fringed on margins, decaying above into a softly fibrous neck 20–80 mm long. *Stem* aerial, filiform, exserted up to 300 mm, branching near apex. *Leaves* 3 or 4, lower 1 or 2 basal, terete-filiform, narrowly 4-grooved, 0.5–1.0 mm diam., glabrous or ciliolate on rib margins, cauline leaves much shorter and clustered near top of stem. *Peduncles* up to 4, terete, suberect in fruit; outer bracts green or submembranous with narrow colourless or reddish membranous margins and tips, 10–25 mm long, lightly striate (5 to 7 veins/mm), inner bracts with wide membranous margins, usually

Distribution of ***Romulea fibrosa***.

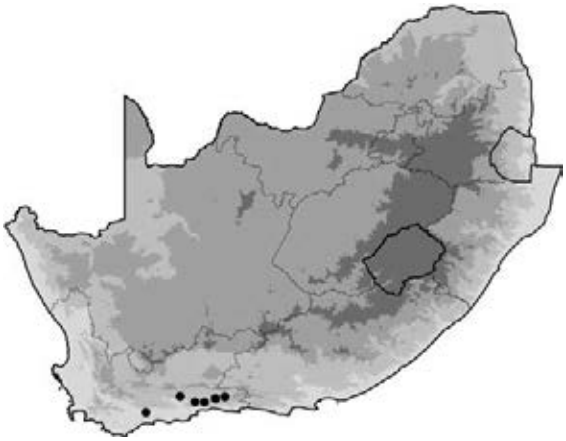
Distribution of ***Romulea longipes***.

rusty-red in upper half or colourless. *Flowers* pink to purple with yellow or orange cup and with diffuse purple blotches in throat, outer tepals reddish purple or veined and feathered on reverse; perianth tube funnel-shaped, 4–7 mm long; tepals oblanceolate or obovate, 16–25 × 7–10 mm. *Filaments* 5–8 mm long, sparsely puberulous basally or glabrous, yellow; anthers 4–6 mm long, yellow to mauve. *Style* dividing shortly below anther apices. *Capsules* oblong, ± 8 mm long. *Flowering time*: October to December.

Distribution and ecology: a high altitude species from the southern coastal and inland mountains of the Western and Eastern Cape, South Africa, ranging from the Langeberg and Swartberg to the Great Winterhoek Mtns in the east; on damp sandstone slopes and along drainage lines from 1 000–1 800 m elevation.

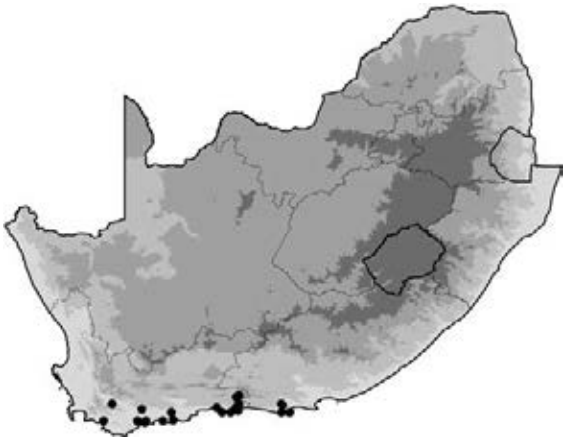
Diagnosis: a montane species distinguished by the corm tunics splitting longitudinally into narrow, fringed strips with a well-developed fibrous neck above, and the pink to purple flowers. The species may have 1 or 2 basal leaves, and colourless or ± densely brown-flecked membranous margins to the outer and inner bracts.

49. **Romulea longipes** *Schltr.* in Journal of Botany 36: 377 (1898); De Vos: 181 (1972). Type: South Africa, [Eastern Cape], Bathurst, Port Alfred, *Galpin 3023* (B, holo.; PRE, iso.).



Plants 100–200(–500) mm high. *Corm* ovoid, 6–15 mm diam., oblique with crescent-shaped basal ridge, tunics woody, with spreading clusters of converging fibrils on ridge. *Stem* aerial, exserted up to 500 mm, branching near apex. *Leaves* 2 to 5, lower (1)2 basal, terete-filiform, narrowly 4-grooved, 0.5–1.0 mm diam., glabrous or ciliate on margins of median ribs, cauline leaves clustered near top of stem. *Peduncles* up to 8, terete, glabrous or ciliolate on angles, suberect or slightly spreading in fruit; outer bracts green or submembranous toward base with narrow colourless membranous margins, 12–20 mm long, lightly striate (5 to 7 veins/mm), inner bracts with wide brown-edged membranous margins. *Flowers* white or pale yellow to pale apricot-coloured, often with darker veins, cup yellow with brown marks, outer tepals greenish or darkly feathered on reverse; perianth tube funnel-shaped, 3–5 mm long; tepals oblanceolate, 15–30 × 6–8 mm. *Filaments* included in cup, 3–8 mm long, pilose basally, yellow; anthers 5–7 mm long, apically connate when young, yellow or rarely purple. *Style* dividing near anther apices. *Capsules* oblong, ± 10 mm long. *Flowering time*: July to –December.

Distribution and ecology: a coastal and lowland species of Eastern Cape, South Africa, extending from west of Port Elizabeth to East London and inland to Grahamstown; on sandy flats in grasslands.



Diagnosis: distinguished from other species in the section with aerial stems by its mostly two basal leaves with narrow grooves, white or pale yellow to pale apricot-coloured flowers, and more easterly distribution.

50. **Romulea jugicola** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 185 (1972). Type: South Africa, [Western Cape], Little Karoo, 31 km SE of Dysseldorp, *Acocks 20592* (PRE, holo.; K, M, iso.).

Plants (50–)100–200(–300) mm high. *Corm* ovoid, 6–15 mm diam., oblique with crescent-shaped basal ridge, tunics woody, with clusters of converging fibrils on ridge. *Stem* aerial, exserted up to 200 mm, branching near apex, glabrous or ciliate on angles in upper part. *Leaves* 2 or 3, lower 1 basal, terete, narrowly 4-grooved, 0.5–1.5 mm diam., pubescent or villous on margins of median ribs, cauline leaves clustered near top of stem. *Peduncles* up to 3, terete, glabrous or ciliolate on angles, suberect or slightly spreading in fruit; outer bracts green with narrow colourless membranous margins, 12–20 mm long, striate (5 to 7 veins/mm), inner bracts with wide brown-flecked membranous margins. *Flowers* orange with small yellow cup, outer tepals greenish or reddish on reverse; perianth tube funnel-shaped,

Distribution of ***Romulea jugicola***.

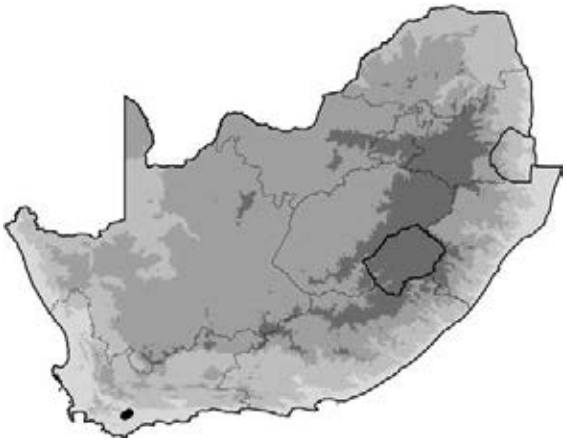
Distribution of ***Romulea dichotoma***.

4–6 mm long; tepals oblanceolate, 15–30 × 6–12 mm. *Filaments* included in cup, 6–7 mm long, pilose basally, yellow; anthers 4–6 mm long, apically connate when young, yellow. *Style* dividing near anther apices. *Capsules* oblong, 10–15 mm long. *Flowering time*: August, September.

Distribution and ecology: restricted to the interior mountains of the Little Karoo from Ladismith to Uniondale in Western Cape, South Africa, on the Kammanassie Mtns, Witberg, Rooiberg and Gamkaberg; on clay soils in renosterbos shrubland from 800–1 000 m elevation.

Diagnosis: recognised by the solitary, narrowly grooved basal leaf with pilose median ribs, and orange flowers.

51. **Romulea dichotoma** *(Thunb.) Baker* in Journal of the Linnean Society, Botany 16: 89 (1877); De Vos: 187 (1972). *Gladiolus dichotomus* Thunb.: 10 (1784). *Trichonema dichotomum* (Thunb.) Klatt: 666 (1866). *Bulbocodium dichotomum* (Thumb.) Kuntze: 700 (1891). *Romulea rosea* var. *dichotoma* (Thumb.) Baker: 104 (1892). Type: South Africa, without precise locality, *Thunberg s.n.* (UPS–THUNB 1019, holo.).



Romulea caplandica Bég.: 332 (1907). Type: South Africa, [Western Cape], Riversdale, *Rust 556B* [as *s.n.* 1891–93] (B, holo.).

Plants (50–)100–200(–400) mm high. *Corm* ovoid, 6–15 mm diam., oblique with crescent-shaped basal ridge, tunics woody, with clusters of converging fibrils on ridge. *Stem* aerial, exserted up to 300 mm, branching near apex, glabrous or ciliate on angles in upper part. *Leaves* 2 to 5, lower 1 basal, linear and ± I-shaped in section, ± broadly 4-grooved, 1–2 mm diam., marginal ribs reduced and rounded, without secondary veins, median ribs flange-like or narrowly winged, curving over partially obscuring lateral ribs, often pubescent or villous on margins, cauline leaves clustered near top of stem. *Peduncles* up to 3, terete, glabrous or ciliolate on angles, spreading in fruit; outer bracts green with narrow colourless membranous margins, 12–20 mm long, striate (5 to 7 veins/mm), inner bracts with wide, reddish or brown-flecked membranous margins. *Flowers* yellow, orange or pink to purple, with small yellow cup with V-shaped marks in base, outer tepals greenish or reddish or darkly veined or feathered on reverse; perianth tube funnel-shaped, 3–5 mm long; tepals oblanceolate, 15–32 × 6–10 mm. *Filaments* ± included in cup, 4–8 mm long, minutely pilose basally, yellow; anthers 4–7 mm long, apically connate when young, yellow. *Style* dividing near anther apices. *Capsules* oblong, ± 10 mm long. *Flowering time*: (late July) August to October.

Distribution and ecology: a species of the forelands and coastal mountain ranges, South Africa, from the Riviersonderend Mtns in Western Cape eastward to Humansdorp in Eastern Cape; on sandy or gravelly flats and slopes in fynbos or transitional fynbos.

Diagnosis: the only species in the genus that includes plants with yellow as well as pink flowers, *Romulea dichotoma* is recognised by its characteristic basal leaf, the median ribs reduced and much smaller than the marginal ones and the blade thus almost I-shaped in section. The median ribs are flange-shaped or winged and curve over and partially conceal the marginal veins, which are rounded in section and lacking secondary veins (visible only under the microscope). Plants with pale orange flowers can be confused with *R. jugicola* from the inland mountains ranges unless the leaves are examined carefully. That species has terete leaves with all four ribs subequal in size and form. Similarly, plants at the east of the range with pale flowers may be confused with *R. longipes*, but that species has two basal leaves.

52. **Romulea pilosa** *J.C.Manning & Goldblatt* in Bothalia 41: 271 (2011). Type: South Africa, Western Cape, Farm Fonteinkloof, between Riviersonderend and Protem, hill W of homestead, *Manning 3220* (NBG, holo.; MO, iso.).

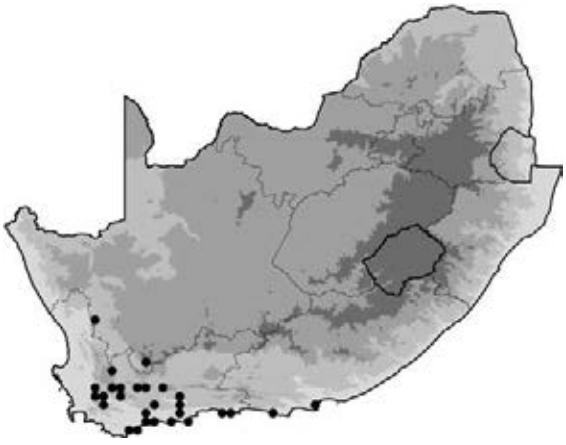
Distribution of ***Romulea pilosa***.

Plants ± 60 mm high. *Corm* subglobose, oblique with crescent-shaped basal ridge, tunics woody, split into clusters of convergent fibrils on basal ridge; stem subterranean or shortly aerial. *Leaves* 2, lowermost basal, falcate, H-shaped in section, 4–6 mm wide, lateral ribs reduced and median (apparently marginal) ribs produced into flange-like wings, densely villous along margins of wings with hairs in two diverging rows. *Peduncles* 1 or 2, villous along angles in distal part, spreading in fruit; outer bracts green with narrow colourless margins, subobtuse, 13–15 mm long, strongly keeled and villous along median and submarginal veins, inner bracts green with broad colourless white margins, keels densely villous. *Flowers* salmon-pink to dull orange with golden-yellow cup extending onto lower third of tepal limbs, outer tepals flushed coppery on reverse; perianth tube funnel-shaped, 5 mm long; tepals oblanceolate, 20–30 × 7–10 mm. *Filaments* 5–6 mm long, pilose in lower half, yellow; anthers 4 mm long, apically connate when young, yellow. *Style* dividing opposite lower ½ of anthers, branches ± 1.5 mm long, forked. *Capsules* oblong-ellipsoid, 7– 9 mm long. *Flowering time*: August.

Distribution and ecology: a highly local endemic from the southern foothills of the Riviersonderend Mtns in Western Cape, South Africa; in stony soils in renosterveld shrublands.

Diagnosis: unmistakable in its falcate, H-shaped leaves 4–6 mm wide with villous, winged margins, villous bracts, and orange flowers with conspicuous yellow cup extending onto the lower third of the tepal limbs. Similar leaves are otherwise known only in yellow-flowered *Romulea hirsuta* (sect. *Stellanthe*) and pink-flowered *R. tetragona* (sect. *Roseae*). The species is highly threatened by agriculture.

53. **Romulea setifolia** *N.E.Br.* in The Gardeners' Chronicle, ser. 3, 92: 467 (1932); De Vos: 171 (1972). Type: South Africa, [Western Cape], Mossel Bay, Gourits River, *Muir 4847* (K, holo.; PRE, iso.).



Romulea setifolia var. *aggregata* M.P.de Vos: 175 (1972), new synonym. Type: South Africa, [Western Cape], Worcester, near Breede River bridge NE of Bain's Kloof, *De Vos 1276* (NBG [as STE], holo.).

Romulea setifolia var. *belviderica* M.P.de Vos: 173 (1972), new synonym. Type: South Africa, [Western Cape], Knysna, Belvedere Estate, *Duthie 1246* (NBG, holo.).

Romulea setifolia var. *ceresiana* M.P.de Vos: 175 (1972), new synonym. Type: South Africa, [Western Cape], Ceres, flats west of Theronsberg Pass, *De Vos 1676* (NBG [as STE], holo.).

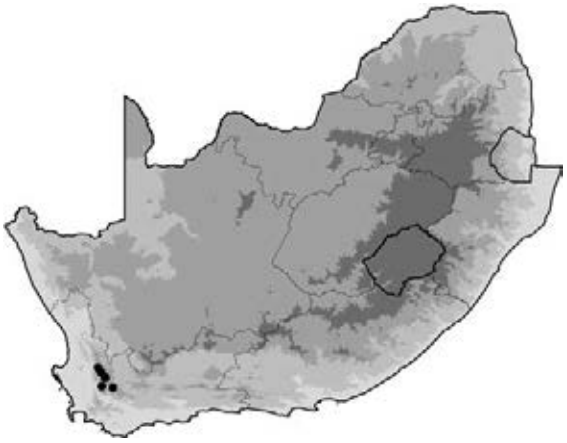
Plants 50–200 mm high. *Corm* ovoid, 5–10 mm diam., oblique with crescent-shaped basal ridge, tunics woody, usually minutely pitted, with clusters of converging fibrils on basal ridge. *Stem* subterranean or rarely aerial and exserted up to 100 mm. *Leaves* 3 to 6, lower 2 basal or all seemingly so in short-stemmed forms, terete-filiform, narrowly 4-grooved, 0.5–1.5 mm diam. *Peduncles* up to 5, semi-terete, erect or suberect in fruit; outer bracts green with narrow colourless membranous margins, 8–25 mm long, striate (5or 6 veins/mm), inner bracts with wide, usually colourless or rarely brown-flecked membranous margins. *Flowers* yellow or pale apricot-coloured with orange-yellow cup and sometimes arrow-shaped dark markings in throat extending to base of cup as dark lines or reduced to median dark line; perianth tube funnel-shaped, 3–7 mm long; tepals oblanceolate, 8–35 × 3–10 mm. *Filaments* 4–7 mm long, pilose basally, yellow; anthers 2–8 mm long, yellow. *Style* dividing near anther apices. *Capsules* oblong, ± 10 mm long. *Flowering time*: July to September (to November at high altitudes).

Distribution and ecology: ranging from the Bokkeveld Mtns in Northern Cape, with outlying populations from the Klein Roggeveld to Touws Rivier, through the Cold Bokkeveld and Breede River Valley to Heidelberg and Bredasdorp in Western Cape thence along the coast to Port Elizabeth in Eastern Cape, South Africa; mostly on sandy flats.

Distribution of ***Romulea setifolia***.

Diagnosis: a mostly acaulescent, rarely short-stemmed species with filiform leaves, usually colourless (rarely brown-flecked) membranous margins to the inner bracts, and yellow to apricot-coloured flowers with a yellow cup, sometimes with dark blotches in the throat.

Romulea setifolia is highly variable in the dimensions and markings of the flowers and in the relative lengths of anthers and filaments. These differences led De Vos (1972) to recognise four varieties in the species. Populations from the Cold Bokkeveld, summit of the Hex River Pass, and the Bonteberg with a larger or smaller, dark median blotch near the base of each tepal, extending as a median line to the base of the cup (sometimes reduced in extent to these median streaks), were segregated as var. *ceresiana*. They differ from other populations of the species in no other respect, and both marked and unmarked plants were collected in a single population at Aan de Doorns in the Hex River Valley [*Walters 126* (NBG)]. Many species in the genus with marked flowers display a similar variation without taxonomic recognition at varietal level. Populations from the Swartruggens are unusual in having just a solitary basal leaf but otherwise accord with other collections previously segregated as var. *ceresiana* and we provisionally include them in *R. setifolia*.



A second variety, var. *aggregata*, was recognised for populations from the northwest of the range, from the Bokkeveld Mtns to Worcester, with unmarked flowers, 25–45 mm long with the anthers as long as the filaments or longer. Populations with mostly smaller flowers, 12–25 mm long with the anthers shorter than the filaments, from near Touws Rivier and then along the southern coast from Caledon to Port Elizabeth, were treated as var. *setifolia*, with the exception of plants from Belvidere near Knysna, which were segregated as a fourth variety, var. *belviderica* on the basis of their seeds that were sticky or glutinous when dry and their inability to produce viable seeds in crosses with the typical variety. The latter characteristic was, however, documented by De Vos (1972) in infraspecific crosses in other species without any taxonomic implications. In view of similar levels of variation in flower size and markings in other species of the genus without accommodating taxonomic recognition we see little to recommend the continued recognition of these varieties.

54. **Romulea albomarginata** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 177 (1972). Type: South Africa, [Western Cape], 37 km N of Gydo Pass, *De Vos 1999* (NBG [as STE], holo.).

Plants 50–100 mm high. *Corm* ovoid, 5–10 mm diam., oblique with crescent-shaped basal ridge, tunics woody, usually minutely pitted, with clusters of converging, soft-textured fibrils on basal ridge separated by apically grooved teeth. *Stem* subterranean or rarely shortly aerial. *Leaves* 3 to 6, lower 2 basal or all seemingly so in short-stemmed forms, terete-filiform, narrowly 4-grooved, 0.5–1.0 mm diam. *Peduncles* up to 4, semi-terete, erect or suberect in fruit; outer bracts green with narrow colourless membranous margins, 12–25 mm long, striate (5 or 6 veins/mm), inner bracts with wide, colourless membranous margins. *Flowers* white or pink to magenta with orange-yellow cup and dark lines in throat, outer tepals maroon or darkly feathered on reverse; perianth tube funnel-shaped, 4–6 mm long; tepals oblanceolate, 15–25 × 5–9 mm. *Filaments* 4–5 mm long, pilose basally, yellow; anthers 4–7 mm long, yellow. *Style* dividing just below or beyond anther apices. *Capsules* oblong, ± 10 mm long. *Flowering time*: August to October.

Distribution and ecology: a local endemic of Western Cape, South Africa, recorded from the Cold Bokkeveld and around Ceres, from 500–1 800 m elevation; on sandy or loamy flats in fynbos.

Diagnosis: distinguished from yellow–orange-flowered *Romulea setifolia* by its white or pink to magenta flowers and distinctive corm tunics, the converging clusters of basal fibrils rather soft in texture and separated by small woody teeth that are grooved apically over the basal ridge. In *R. setifolia*, as in all other members of sect. *Aggregatae*, the converging fibrils are woody and not different in texture from the rest of the tunic. The species was originally known only from one or two pink-flowered populations from the Cold Bokkeveld but we include in it additional populations from Ceres and the northern slopes of the Hex River Mtns with white flowers but the same distinctive corms with soft fibril clusters.

Distribution of ***Romulea albomarginata***.

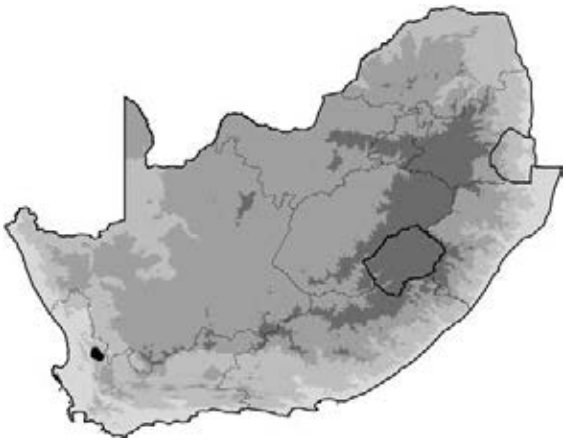
Sect. 4. **Roseae** *(Bég.) M.P.de Vos* in Journal of South African Botany, Suppl. 9: 202 (1972). *Romulea* 'Stirps' *Roseae* Bég.: 60 (1909). Type: *R. rosea* (L.) Eckl.

Ser. **Roseae** *(Bég.) J.C.Manning & Goldblatt*, name at new rank. *Romulea* 'Stirps' *Roseae* Bég. in Malpighia: 60 (1909). *R.* sect. *Roseae* (Bég.) M.P.de Vos: 202 (1972). Type: *R. rosea* (L.) Eckl.

Romulea subsect. *Cruciatae* M.P.de Vos: 259 (1972), new synonym. *Romulea* sect. *Cruciatae* (M.P.de Vos) J.C.Manning & Goldblatt: 96 (2001). Type: *Romulea cruciata* (Jacq.) Baker

Romulea subsect. *Campestres* M.P.de Vos: 231 (1972), new synonym. Type: *R. obscura* Klatt

[*Romulea* subsect. *Roseae* in M.P.de Vos: 246 (1972), invalid name without author.]



Corms rounded and tunics with curved basal teeth, or corms pointed and tunics with straight basal teeth. *Leaves* ± terete and narrowly 4-grooved. *Flowers* funnel-shaped; outer bracts with narrow membranous margins and tip.

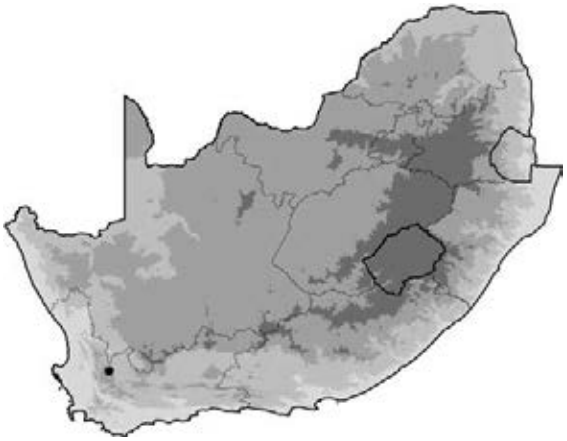
55. **Romulea cedarbergensis** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 245 (1972). Type: South Africa, [Western Cape], Cederberg, Wolfsberg, *Uys sub De Vos 2030* (NBG [as STE], holo.).

Plants 15–30 mm high. *Corm* globose or obovoid, 3–6 mm diam., rounded or crested below, tunics woody, split into curved or bent, grooved teeth below. *Stem* subterranean. *Leaves* (1)2, basal, filiform, narrowly 4-grooved, 0.3–0.5 diam., upper usually smaller. *Peduncle* 1, semi-terete, reddish brown, suberect in fruit; outer bract submembranous and greenish or purplish, with narrow, colourless membranous margins, 6–15 mm long, faintly veined (5 or 6 veins/mm), inner bracts with wide, membranous margins brown-speckled near tip. *Flowers* white or pale pink with golden-yellow cup, outer tepals striped purple on reverse; perianth tube funnel-shaped, 3–5 mm long; tepals oblanceolate to elliptic, 7–16 × 2.5–6.0 mm. *Filaments* 4–6 mm long, pilose basally, golden-yellow; anthers 2.0–3.5 mm long, pale yellow. *Style* dividing near anther apices. *Capsules* oblong, ± 8 mm long. *Flowering time*: August, September.

Distribution and ecology: endemic to the Cederberg in Western Cape, South Africa, at ± 1 500 m elevation; in seasonally damp, sandy hollows in fynbos.

Diagnosis: a diminutive species separated from *Romulea rosea* by its one or two filiform leaves up to 0.5 mm diam., and solitary, white to pale pink flowers with golden-yellow cup and anthers ± half as long as the filaments. An allied, winter-flowering species from the Cold Bokkeveld, *Romulea lilacina*, has a solitary, sticky leaf and larger, lilac flowers without a yellow cup, the tepals 16–20 mm long and filaments 8–9 mm long,

Distribution of ***Romulea cedarbergensis***.



produced in May and June. Anatomically, the leaves lack secondary veins and have highly reduced fibre strands in the rib margins.

56. **Romulea lilacina** *J.C.Manning & Goldblatt* in Adansonia, ser. 3, 23: 98 (2001). Type: South Africa, Western Cape, Cold Bokkeveld, Zeekoegat, west bank of Riet River at foot of Katbakkies Pass, deep sand in open restio veld, 5 June 2000, *Manning 2252* (NBG, holo.; PRE, iso.).

Plants 20–50(–100) mm high. *Corm* globose or obovoid, 5–7 mm diam., rounded or crested below, tunics woody, split into curved or bent, grooved teeth below. *Stem* subterranean. *Leaves* 1(2), basal, filiform, narrowly 4-grooved, sticky with adhering sand grains, purplish, 0.5–1.0 mm diam. *Peduncles* 1 to 3, semi-terete; outer bract submembranous below, purplish, with narrow, colourless membranous margins, 10–15 mm long, faintly veined (5 or 6 veins/mm), sticky with adhering sand grains, inner bracts ± entirely membranous with purple veins, brown-speckled near tip. *Flowers* pale to dark lilac with darker veining, especially in the concolorous cup, outer tepals striped purple on reverse; perianth tube funnel-shaped, 5–6 mm long; tepals oblanceolate to elliptic, 16–20 × 5–7 mm. *Filaments* 8–9 mm long, pilose, lilac; anthers 3.5–4.0 mm long, lilac. *Style* dividing opposite upper half of anthers. *Flowering time*: May to June.

Distribution and ecology: a local endemic of the Cold Bokkeveld in Western Cape, South Africa, known from a single extended population at the foot of Katbakkies Pass; in open washes in deep sand between Restionaceae.

Diagnosis: an early flowering species instantly recognised by its solitary (rarely two), sticky leaf with adhering sand grains, sticky bracts, and lilac flowers without

Distribution of ***Romulea lilacina***.

a yellow cup and with concolorous stamens. A similar, later flowering species from the Cederberg, *Romulea cedarbergensis*, is even smaller, with mostly two leaves without adhering sand grains and smaller, white to pale pink flowers with golden-yellow cup and stamens, the tepals only 7–16 mm long and filaments 4–6 mm long.

57. **Romulea rosea** *(L.) Eckl.* in Topographisches Verzeichniss der Pflanzensammlung von C.F. Ecklon: 19 (1827); De Vos: 246 (1972). *Ixia rosea* L.: 75 (1767). *Trichonema roseum* (L.) Ker Gawl.: t. 1225 (1809). *Syringodea rosea* (L.) Klatt: 403 (1882). *Bulbocodium roseum* (L.) Kuntze: 700 (1891). Type: South Africa, without precise locality or collector, illustration in Miller: t. 240 (1760).

Plants 30–200 mm high. *Corm* globose or obovoid, 5–15 mm diam., rounded or crested below, tunics woody, split into curved or bent, grooved teeth below. *Stem* subterranean. *Leaves* 2 to 12, all evidently basal, terete-filiform or compressed-cylindric, narrowly 4-grooved, 0.5–2.5 mm diam. *Peduncles* up to 5, semi-terete, recurved but straightening and suberect in fruit; outer bracts greenish or purplish, with narrow, brown-speckled, membranous margins, 12–25 mm long, closely veined (± 8 veins/mm), inner bracts with wide, brown or brown-streaked membranous margins. *Flowers* magenta, lilac-pink or pink to white with pale yellow to golden-yellow cup, often with violet-blue zone in throat, outer tepals feathered or irregularly marked on reverse; perianth tube funnel-shaped, 2–8 mm long; tepals oblanceolate to elliptic, 10–38 × 3–10 mm. *Filaments* 3–8 mm long, pilose basally; anthers 3–10 mm long, yellow. *Style* dividing opposite or above anthers. *Capsules* oblong or shortly cylindric, 10–15 mm long. *Flowering time*: July to October.

Distribution and ecology: widespread in the Cape Floral Region, South Africa, from the Bokkeveld Mtns in Northern Cape through the coastal and near interior Western Cape to Port Elizabeth in Eastern Cape but absent from the drier parts, including the Little Karoo; mostly in seasonally moist sandy soils in fynbos. Naturalised in Australia, New Zealand, California, Channel Islands, Tristan da Cunha and St Helena.

Diagnosis: the most common species in the genus, diagnosed by the rounded corms and magenta to lilac-pink or white flowers with greenish or golden-yellow cup, often with a violet zone in the throat but without distinct blotches, herbaceous outer bracts with narrow membranous margins and apices, and peduncles curving after flowering but straightening and ± erect as the capsules dry out. It is distinguished from *Romulea obscura* by the lack of yellow pigmentation in the tepals (apart from the cup), the flowers thus either white or pink with a bluish cast, fruiting peduncles straightening in fruit, and a somatic chromosome number $2n = 18$.

Romulea rosea is a polymorphic species with a number of variants and forms, often connected by intermediates (De Vos 1972). The typical variety is based on white- or pink-flowered plants with the style overtopping the anthers but the longer styles are not consistent within populations, which invariably also include short-styled variants, treated by De Vos (1972) under the name var. *reflexa* (Eckl.) Bég., actually a synonym of *R. flava* (Lam.) M.P.de Vos, the correct name for the taxon at varietal level being *R. rosea* var. *muirii* N.E.Br. (Manning et al. 2011). Vegetatively similar plants with white flowers with a golden-yellow cup were segregated as var. *elegans*. We include both of these variants in the typical variety as part of the natural variation in the taxon.

Two additional varieties were recognised for plants with broader, ± compressed-cylindric leaves mostly more than 1 mm diam. and up to 2.5 mm diam., with var. *australis* for plants with smaller flowers mostly less than 23 mm long, and var. *communis* for those with larger flowers mostly more than 23 mm long. Flower size in the two variants is genetically fixed but they hybridise readily in cultivation with intermediates known in the wild, and var. *communis* may be essentially a larger-flowered form of var. *australis* (De Vos 1972). Under normal circumstances we would have little hesitation in including them as part of the general variation in the species but the smaller-flowered var. *australis* is a common autogamous ruderal of roadsides and farmyards in the Western Cape coastal districts, and has become naturalised in Australia and New Zealand as a troublesome weed under the name onion grass or Guildford grass, and in California, the Channel Islands, Tristan da Cunha and St. Helena. In view of its obvious economic importance we continue to recognise it at varietal level but include in it the vegetatively similar but larger-flowered var. *communis*.

Key to varieties

1a Widest leaves 1 mm diam., terete; flowers 22–48 mm long. . . . . 57a. var. *rosea*

1b Widest leaves 1.0–2.5 mm diam., compressed-cylindric; flowers 15–25(–35) mm long. . . . . 57b. var. *australis*

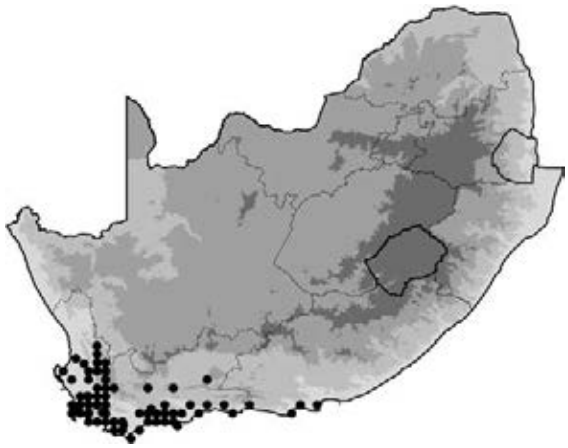
Romulea elegans Klatt: 400 (1882), new synonym. *Romulea rosea* var. *elegans* (Klatt) Bég.: 63 (1909). Type: South Africa, [Western Cape], Doornhoogte, *Zeyher 1602* (S, holo.; B, G, GRA, K [in part], PRE, SAM, Z, iso.).

Romulea muirii N.E.Br.: 467 (1932), new synonym. *Romulea rosea* var. *muirii* (N.E.Br.) J.C.Manning & Goldblatt: 277 (2011). Type: South Africa, [Western Cape], Riversdale, *Muir 4848* (K, holo.).

[*Romulea rosea* var. *reflexa* sensu Bég. (1908) and De Vos (1972), not of (Eckl.) Bég. (1908) (= *R. flava* (Lam.) M.P.de Vos)].

Distribution and ecology: widespread through the natural range of the species, from the Cederberg to Riversdale.

Diagnosis: characterised by narrow leaves, mostly 0.5–1.0 m wide, and relatively large flowers, 22–48 mm long.



57b. var. **australis** *(Ewart) M.P.de Vos* in Journal of South African Botany, Suppl. 9: 254 (1972). *Romulea cruciata* var. *australis* Ewart: 43, t. XII (1907). Type: Australia, Victoria, near Melbourne, *Tovey s.n.* (MEL, lecto., designated by De Vos: 252 (1972); BOL, MEL, isolecto.).

Trichonema longifolium Salisb.: 316 (1812). *Romulea longifolia* (Salisb.) Baker: 89 (1877). *Bulbocodium longifolium* (Salisb.) Kuntze: 700 (1891). Type: South Africa, without precise locality or collector, illustration in Ker Gawler: t. 575 (1802).

Romulea parviflora Eckl.: 19 (1827). *Trichonema parviflorum* (Eckl.) Steud.: 702 (1841). Type: South Africa, [Western Cape], Cape Peninsula, Green Point, Sept. 19–24, *Ecklon s.n.* (S, holo.).

Romulea rosea var. *communis* M.P.de Vos: 257 (1972), new synonym. Type: South Africa, [Western Cape], Stellenbosch, near Papegaaiberg, *De Vos 1099* (NBG [as STE], holo.).

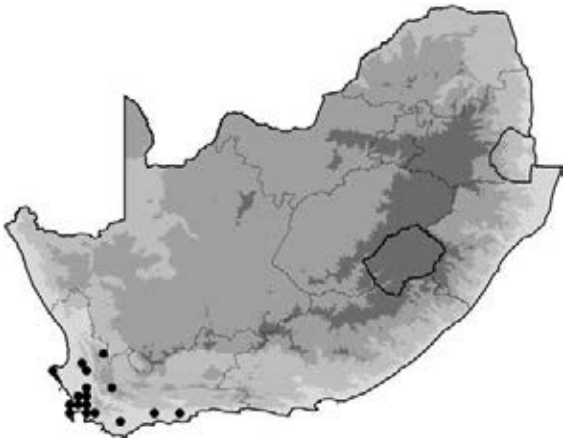
Distribution and ecology: throughout the range of the species, from the Bokkeveld Mtns to Port Elizabeth, mostly as a weed of roadsides and unkempt lawns and pastures. Naturalised in Australia, New Zealand, California, the Channel Island, Tristan da Cunha and St Helena.

Distribution of ***Romulea rosea***.

Diagnosis: distinguished from the typical variety by the broader, compressed-cylindric leaves 1.0–2.5 mm wide, and often smaller flowers, mostly 15–22 mm long but up to 35 mm long.

58. **Romulea cruciata** *(Jacq.) Bég.* in Botanische Jahrbücher für Systematik 38: 335 (1907). *Ixia cruciata* Jacq.: 8 (1795 [1788–1795]). *Trichonema cruciatum* (Jacq.) Ker Gawl.: sub. t. 575 (1802). *Bulbocodium cruciatum* (Jacq.) Kuntze: 700 (1891). *Romulea bulbocodium* var. *cruciata* (Jacq.) Ewart: 298 (1931). Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 290 (1794 [1788–1795]).

Romulea cruciata var. *neglecta* Bég.: 337 (1907). Type: Several collections cited, no type designated.



Romulea cruciata var. *parviflora* Bég.: 337 (1907). Type: Several collections cited, no type designated.

Romulea cruciata var. *vulgaris* Bég.: 336 (1907). Type: Several collections cited, no type designated.

Romulea ×*intermedia* Bég.: 339 (1907), new synonym. *Romulea cruciata* var. *intermedia* (Bég.) M.P.de Vos: 263 (1972). Type: South Africa, without precise locality, *Zeyher 4044* (G, holo.; GRA, K, P, S, Z, iso.).

Romulea ambigua Bég.: 338 (1907). Type: South Africa, [Western Cape], 'in collibus prope Brakfontein,' *Schlechter 10784* (B, lecto., designated by De Vos: 66 (1983); G, K, PRE, S, isolecto.).

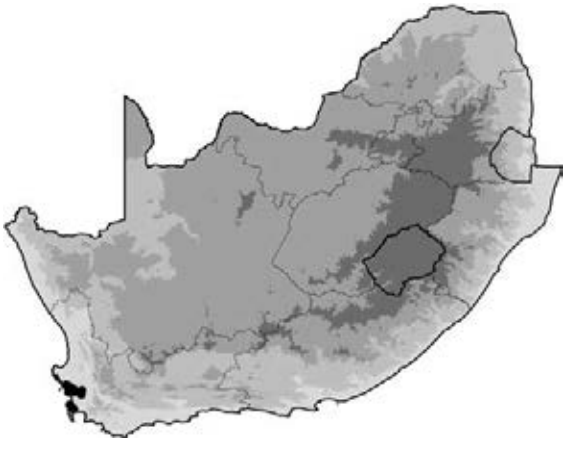
Plants 30–200 mm high, sometimes clumped. *Corm* obovoid, 8–15 mm diam., pointed, tunics woody, split into straight or slightly recurved teeth converging toward basal point. *Stem* subterranean. *Leaves* 2 to 8(–12), all evidently basal, terete-filiform and narrowly 4-grooved to compressed-cylindric or H-shaped and widely grooved or channelled, sometimes with raised

Distribution of ***Romulea cruciata***.

secondary veins in channels, 0.5–5.0 mm diam. *Peduncles* up to 7, semi-terete, recurved but straightening and suberect in fruit; outer bracts greenish or purplish, with narrow, colourless membranous margins, 10–28 mm long, closely veined (± 8 veins/mm), inner bracts with wide, brown or brown-streaked (rarely colourless) membranous margins. *Flowers* magenta to lilac-pink with golden-yellow or orange-yellow cup, with purple or bluish transverse blotches in throat with median line extending into cup, outer tepals irregularly streaked or feathered on reverse; perianth tube funnel-shaped, 3–5 mm long; tepals oblanceolate to elliptic, 15–30(–35) × 5–10 mm. *Filaments* 3–6 mm long, pilose basally; anthers 4–8 mm long, yellow or with dark lines. *Style* usually dividing opposite upper half of anthers. *Capsules* oblong or ellipsoid, acute and shortly beaked, 6–14 mm long. *Flowering time*: July to September.

Distribution and ecology: distributed in South Africa from the Bokkeveld Mtns in Northern Cape along the West Coast to Elim and Albertinia in Western Cape but most common between Porterville and the Cape Peninsula; on seasonally moist sandy and granite flats in fynbos.

The species is replaced by *Romulea eximia* between Malmesbury and Atlantis.



Diagnosis: distinguished by the pointed corm with straight or slightly recurved teeth converging on the basal point, and small to moderate-sized, 22–35 mm long, magenta to lilac-pink flowers with golden- or orange-yellow cup with dark blue or purplish ± transverse blotches in the throat, and unusual, acute and almost beaked capsules. The leaves vary from terete and narrowly 4-grooved to H-shaped with wide grooves or channels. The pointed corms, flowers with prominent dark blotches around the cup, and the acute capsules separate the species from *Romulea rosea*, with which it shares a somatic chromosome number $2n = 18$.

Populations with larger, (35–)40–50 mm long, old-rose-pink (i.e. with some yellow admixture to the pink) flowers with a pale or greenish yellow cup from the small triangle Malmesbury–Yzerfontein–Atlantis are treated as the distinct species *Romulea eximia*, evidently differing from *R. cruciata* also in leaf anatomy in having smaller, lignified epidermal cells (De Vos 1972). A second purported difference between the two, viz. a subdermal layer of sclerenchyma extending across the ribs in *R. eximia*, is also developed in narrow-leaved forms of *R. cruciata* and is thus not consistent. Crosses between the two taxa are usually unsuccessful but occasionally yield fertile seeds.

Plants matching the type illustration in having wider leaves, 1–4 mm wide, cylindric or H-shaped with relatively wide longitudinal grooves or channels, sometimes with raised veins in the channels, and treated by De Vos (1972) as var. *cruciata* were separated from plants with narrower, terete leaves 0.5–1.0 mm diam., treated as var. *intermedia*. Plants with exceptionally wide leaves, 5 mm wide, have been collected around Porterville but elsewhere the distinction between the two leaf forms is less compelling, with intermediates between them in many populations. A similar variation in leaf shape is known in *R. hirsuta* and we do not uphold the formal taxonomic distinction between them.

59. **Romulea eximia** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 267 (1972). Type: South Africa, [Western Cape], near Darling, *De Vos 1687* (NBG [as STE], holo.).

Plants 30–200 mm high. *Corm* obovoid, 8–15 mm diam., pointed, tunics woody, split into straight or slightly recurved teeth converging toward basal point. *Stem* subterranean. *Leaves* 2 to 8, all evidently basal, terete-filiform and narrowly 4-grooved, 0.5–1.5 mm diam. *Peduncles* up to 5, semi-terete, recurved but straightening and suberect in fruit; outer bracts greenish or purplish, with narrow, colourless membranous margins, 20–30 mm long, closely veined (± 8 veins/mm), inner bracts with wide, brown or brown-streaked membranous margins. *Flowers* old-rose-pink to terracotta-coloured with pale or greenish yellow cup, with purple-reddish blotches in throat with median line extending into cup, outer

Distribution of ***Romulea eximia***.

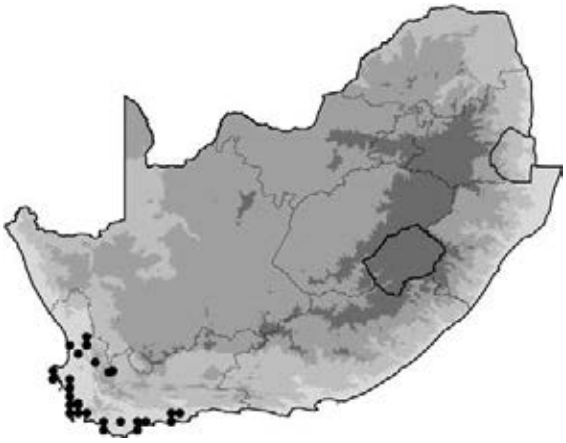
tepals irregularly streaked on reverse; perianth tube funnel-shaped, 5–8 mm long; tepals oblanceolate, (25–)30–40(–50) × 7–14 mm. *Filaments* (6–)9–12 mm long, pilose basally; anthers 7–12 mm long, yellow or with dark lines. *Style* usually dividing opposite upper half of anthers. *Capsules* oblong or ellipsoid, acute and shortly beaked, ± 10 mm long. *Flowering time*: August, September.

Distribution and ecology: a narrow endemic of Western Cape, South Africa, restricted to the triangle Malmesbury–Yzerfontein–Atlantis; on seasonally wet granite or loamy flats in fynbos or renosterveld shrubland.

Diagnosis: sharing a pointed corm and acute, ± beaked capsules with *Romulea cruciata* and distinguished from it by the larger, (35–)40–50 mm long [vs. 22–35 mm long], old-rose to terracotta-coloured flowers (i.e. with a yellow admixture to the pink) with a pale or greenish yellow cup [vs. magenta to rose-pink with golden- or orange-yellow cup]. Anatomically it is also distinguished by the smaller, thickened leaf epidermal cells. The two species share the somatic chromosome number $2n$ = 18 but hybrids between them are only partially fertile (De Vos 1972). True *R. cruciata* is absent from range of *R. eximia* and the two taxa are thus parapatric.

The species is florally very similar to the often sympatric *Romulea hirsuta* with bell-shaped corm and often exserted stem but has a pale or greenish yellow vs. golden- or orange-yellow cup.

60. **Romulea obscura** *Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 399 (1882); De Vos: 231 (1972). Type: South Africa, [Western Cape], *Drège 4041* (S, lecto., designated by De Vos: 233 (1972); BM, isolecto.).



Romulea papyracea Wolley-Dod: 170 (1900), new synonym. Type: South Africa, [Western Cape], Table Mountain, in the plantation on the Lower Plateau, *Wolley-Dod 3075* (BOL, holo.; BM, K, iso.).

Romulea obscura var. *blanda* M.P.de Vos: 239 (1972), new synonym. Type: South Africa, [Western Cape], between Mamre and Ysterfontein, *Bolus 20725* (BOL, holo.; K, iso.).

Romulea obscura var. *campestris* M.P.de Vos: 237 (1972), new synonym. Type: South Africa, [Western Cape], between Clanwilliam and Graafwater, *De Vos 1897* (NBG [as STE], holo.).

Romulea obscura var. *subtestacea* M.P.de Vos: 238 (1972), new synonym. Type: South Africa, [Western Cape], Malmesbury, Soutpan NW of Ysterfontein, *De Vos 2037* (NBG [as STE], holo.).

Plants 30–150 mm high. *Corm* globose or obovoid, 5–15 mm diam., rounded or crested below, tunics woody, split into curved or bent, grooved teeth below. *Stem* subterranean. *Leaves* 2 to 12, all evidently basal, terete-filiform, narrowly 4-grooved, 0.5–1.0 mm diam. *Peduncles* up to 5, semi-terete, recurved and widely spreading in fruit; outer bracts greenish or brownish, with narrow,

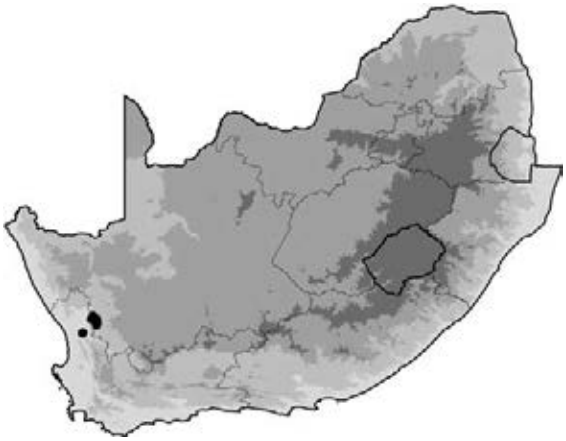
Distribution of ***Romulea obscura***.

brown-speckled, membranous margins, 8–22 mm long, closely veined (± 8 veins/mm), inner bracts with wide, colourless or brown-speckled membranous margins. *Flowers* yellow, apricot-, terracotta-coloured, dark old-rose or rosy pink, with or without dark blotches or streaks in throat, with greenish yellow or orange-yellow cup, outer tepals irregularly marked or striped on reverse; perianth tube funnel-shaped, 2–5 mm long; tepals oblanceolate to elliptic, 10–40 × 3–12 mm. *Filaments* 3–8 mm long, pilose basally or glabrescent; anthers 3–9 mm long, yellow. *Style* dividing opposite lower half of anthers. *Capsules* oblong, 10–15 mm long. *Flowering time*: August to October.

Distribution and ecology: a species of the Western Cape lowlands, extending from Clanwilliam and Graafwater along the West Coast to the Cape Peninsula and eastward to Stilbaai; in seasonally moist, sandy soils in fynbos.

Diagnosis: distinguished from *Romulea rosea* by the somatic chromosome number $2n$ = 22 ($2n$ = 18 in *R. rosea*), the presence of some degree of yellow pigmentation in the tepals (distal to the cup), the flowers ranging from yellow through apricot-, terracotta-coloured and salmon-pink to rosy-pink, with a greenish yellow to orange-yellow cup, and the fruiting peduncles remaining widely spreading on drying. Flowering plants without careful colour notes are impossible to assign between the two species with any accuracy. Yellow-flowered forms resemble *R. monticola* from the Bokkeveld and Matsikamma-Gifberg Mtns, but the flowers are duller in hue with proportionally longer outer bracts more than half as long as the flowers, inner bracts with membranous margins distinctly narrower than the central green portion, and peduncles widely spreading in fruit.

Romulea obscura is best known historically from the West Coast between Saldanha and the Cape Peninsula but is now less often encountered as a result of increasing urbanisation. The species is polymorphic for flower size, colour and markings, with four varieties recognised by De Vos (1972), all interfertile to some degree and with intermediates between them. The typical variety



is associated with plants with relatively small, yellow or apricot-coloured flowers 15–25(–35) mm long, recorded along the coast from Hopefield to Stilbaai. Similarly small-flowered plants but with a rose-pink to terracotta-coloured perianth, often with dark blotches in the throat, and recorded between Hopefield and the Cape Peninsula, were treated as var. *subtestacea*, with intermediates between the two varieties recorded near Kraaifontein. Larger flowered plants with flowers 25–50 mm long were similarly segregated by perianth colour into var. *campestris*, with yellow, apricot-coloured or pale rosy pink flowers, usually without blotches in the throat, and var. *blanda*, with rosy pink flowers always with dark blotches in the throat. The former variety is most common in the Olifants River Valley but extends south to Hopefield, with the latter recorded from Vredenburg to the Cape Peninsula. Intermediates between var. *campestris* and var. *obscura* are recorded from Bredasdorp.

Similar variations in flower size, perianth colour or tepal markings are encountered in other species of *Romulea*, including *R. rosea*, evidently part of a complex pattern of small-scale variation within species. In view of the numerous intermediates between them we see little point in retaining formal recognition of the extremes at varietal level.

Romulea papyracea Wolley-Dod (1900) was treated as a synonym of *R. schlechteri* by Manning & Goldblatt (2001) but we have re-examined the type collection and conclude that it is conspecific with *R. obscura*. The rounded corm, with traces of teeth on the remaining inner tunics, subterranean stem with several basal leaves, and 'flesh' flowers (noted on the holotype) with closely veined outer bracts, and inner bracts with broad, colourless membranous margin are all consistent with this identification.

61. **Romulea monticola** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 241 (1972). Type: South Africa, [Northern Cape], top of Vanrhyn's Pass, *De Vos 1924* (NBG [as STE], holo.).

Plants 50–100 mm high. *Corm* globose or obovoid, 5–15 mm diam., rounded or crested below, tunics woody, split into curved or bent, grooved teeth below. *Stem* subterranean. *Leaves* 3 to 12, all evidently basal, terete-filiform, narrowly 4-grooved, 0.5–1.0 mm diam., sometimes minutely ciliolate on rib margins. *Peduncles* up to 5, semi-terete, reddish brown, suberect or recurved in fruit; outer bracts greenish or brownish and submembranous in lower half, with brown-speckled, membranous margins, 10–30 mm long, closely ribbed above (± 8 veins/mm), inner bracts with wide, brown-speckled membranous margins. *Flowers* golden-yellow, often with darker cup, with 1 or more dark veins in throat, outer tepals reddish brown or streaked with brown on reverse; perianth tube funnel-shaped, 3–4 mm long; tepals oblanceolate to elliptic, 18–27 × 5–7 mm. *Filaments* 4–5 mm long, pilose basally, yellow; anthers 3–4 mm long, initially joined at tips, yellow. *Style* dividing opposite anthers. *Capsules* subglobose or oblong, 8–10 mm long. *Flowering time*: (July) August, September.

Distribution of ***Romulea monticola***.

Distribution and ecology: endemic to the Bokkeveld Mtns in Northern Cape and adjacent Matsikamma-Gifberg massif in Western Cape, South Africa; on seasonally moist sandy or loamy flats in renosterveld shrubland and transitional fynbos.

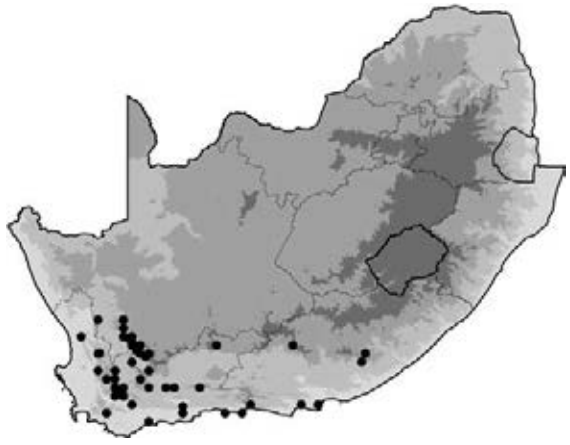
Diagnosis: distinguished from other members of sect. *Roseae* with rounded corms by the golden-yellow flowers, usually with dark veins in the cup, dark reddish brown, subterete peduncles not spreading or coiling in fruit, and subherbaceous outer bracts with relatively narrow, finely brown-speckled margins. Closely resembling yellow-flowered forms of *Romulea obscura* from the Olifants River Valley but distinguished by its brighter yellow flowers with proportionally shorter bracts less than half as long as the perianth, inner bracts with broader membranous margins ± as wide as the central green portion, and the peduncles remaining suberect or curved in fruit. The flowers in *R. obscura* are mostly dull yellow (to salmon-pink) with the bracts more than half as long as the flowers, the membranous margins of the inner bracts distinctly narrower than the central green portion, and peduncles widely spreading in fruit.

Romulea monticola may also be confused with *R. luteoflora*, which typically has more strongly herbaceous bracts with whitish margins and apices marked with larger, dark flecks, and peduncles that ultimately coil up in fruit. Neither *R. obscura* nor *R. luteoflora* have been recorded from the Bokkeveld and Matsikamma-Gifberg. It is also superficially similar to *R. montana* (sect. *Romulea*), which usually has dark markings on the tepals, bracts without visible membranous margins, and corms with a crescent-shaped basal ridge.

Ser. **Atrandrae** *(M.P.de Vos) J.C.Manning & Goldblatt*, name at new rank. *Romulea* subsect. *Atrandrae* M.P.de Vos in Journal of South African Botany, Suppl. 9: 209 (1972). Type: *R. atrandra* G.J.Lewis

Corms rounded and tunics with curved basal teeth. *Leaves* ± terete, 4-grooved. *Flowers* funnel-shaped; *outer*

bracts with well-developed membranous tip. *Peduncles* often coiling in fruit.



62. **Romulea atrandra** *G.J.Lewis* in Flowering Plants of South Africa 14: t. 544 (1934); De Vos: 212 (1972). Type: South Africa, [Western Cape], Laingsburg, Tweedside, cultivated Hort. Kirstenbosch *Lewis s.n.* (BOL, holo.; PRE, iso.).

Romulea atrandra var. *esterhuyseniae* M.P.de Vos: 215 (1972), new synonym. Type: South Africa, [Western Cape], Ladismith, Swartberge, Towerkop, *Esterhuysen 13924* (BOL, holo.; K, NBG, PRE, SAM, iso.).

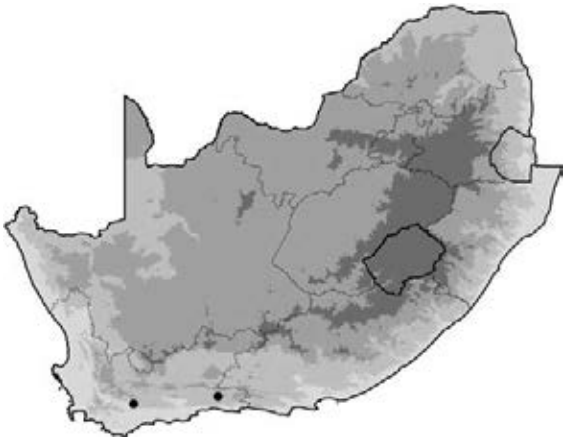
Romulea atrandra var. *lewisiae* M.P.de Vos: 217 (1972), new synonym. Type: South Africa, [Eastern Cape], Port Elizabeth, Victoria Park, *Lond 617* (PRE, holo.; GRA, K, iso.).

Plants 50–200 mm high. *Corm* globose or obovoid, 10–25 mm diam., rounded or crested below, tunics woody, split into curved or bent, grooved teeth below. *Stem* subterranean. *Leaves* 3 to 10, all evidently basal, terete or compressed-cylindric, narrowly or more widely 4-grooved, 1–4 mm diam. *Peduncles* up to 5, semi-terete, recurved and coiling in fruit; outer bracts green with narrow, brown-flecked, membranous margins expanding to prominent membranous tip, 10–30 mm long, closely ribbed (± 8 veins/mm), inner bracts with wide, brown-flecked membranous margins. *Flowers* white, pale blue or lilac to magenta with whitish to golden-yellow cup sometimes veined with black, with or without purple blotches around cup, outer tepals blotches or feathered with purple on reverse; perianth tube funnel-shaped, 4–8 mm long; tepals oblanceolate to obovate, 15–35 × 3–15 mm. *Filaments* 4–8 mm long, pilose basally, yellow or blackish; anthers (2.5–)5.0–10.0 mm long, yellow, purple or black; pollen yellow. *Style* dividing opposite anthers. *Capsules* cylindric, 10–14 mm long. *Flowering time*: July to October.

Distribution and ecology: widely distributed through the near-interior, winter-rainfall parts of Northern and Western Cape, from the Gifberg through the Cederberg and Cold Bokkeveld to Worcester and eastward to Port Elizabeth and onto the Hogsback in Eastern Cape, and from Calvinia and Williston along the Roggeveld to the Swartberg in the Little Karoo and onto the mountains around Graaff-Reinet; typically on seasonally damp shale or clay flats in renosterveld shrubland but also other open vegetation.

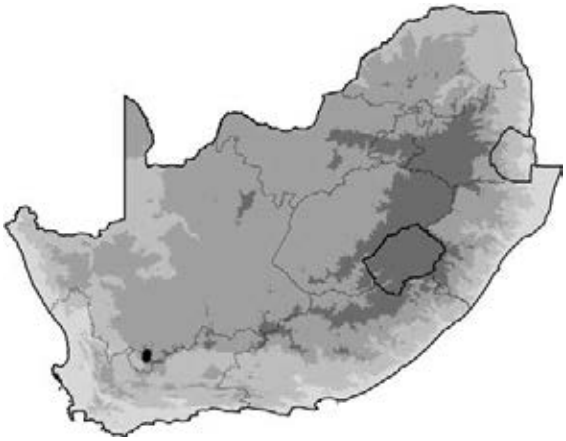
Distribution of ***Romulea atrandra***.

Diagnosis: the central species in ser. *Atrandrae*, *Romulea atrandra* is highly variable in size, flower colour and markings. It is diagnosed by the rounded corm, firm-textured and closely ribbed outer bracts with conspicuous brown-flecked membranous tips, and white, pale blue or lilac to magenta flowers with white to golden-yellow cup, with or without dark blotches around the cup or dark lines in the cup.



Plants with narrow leaves were distinguished as var. *esterhuyseniae* and those with small flowers 25 mm long or less as var. *lewisiae* (De Vos 1972). These represent two extremes of a much more complex pattern of variation. There is little doubt that they are not natural as currently interpreted and we elect not to recognise them.

The most striking form, occurring over much of the Roggeveld, has large, bright magenta flowers with a pale yellow or whitish cup boldly striped with black on the veins, and banded with black in the throat. Other populations have white or pale blue to pink or magenta flowers with unstriped cups, either pale or golden-yellow and with or without dark markings in the throat. Populations along the south coast have small, unmarked, white to pale blue flowers and may be confused with forms of *R. rosea*, from which they differ in the closely ribbed bracts with conspicuous brown-flecked tips, and anatomically in lacking veins in the rib margins.



63. **Romulea vlokii** *M.P.de Vos* in Flora of southern Africa 7(2,2): 55 (1983). Type: South Africa, [Western Cape], Kammanassie Mtns, Buffelsberg, near Diepkloof, *Vlok 384* (NBG, holo.).

Plants 50–150 mm high. *Corm* ovoid, 5–12 mm diam., pointed below, tunics woody, split into ± straight teeth converging on basal point. *Stem* subterranean. *Leaves* 2 to 4, all evidently basal, terete, narrowly 4-grooved, ± 1 mm diam., upper leaves much smaller than lower. *Peduncles* up to 4, semi-terete, recurved and coiling in fruit; outer bracts green with narrow, brown-flecked, membranous margins expanding to prominent membranous tip, 15–25 mm long, closely ribbed (± 8 veins/mm), inner bracts with wide, brown-flecked membranous margins. *Flowers* magenta with golden-yellow cup, with or without purple blotches around cup, outer tepals blotches or feathered with purple on reverse; perianth tube funnel-shaped, 5–7 mm long; tepals obovate, 22–25 × 8–12 mm. *Filaments* 4–6 mm long, pilose basally, orange-yellow; anthers ± 7 mm long, yellow. *Style* dividing opposite anthers. *Flowering time*: June–July.

Distribution and ecology: a rarely collected species endemic to the Little Karoo in Western Cape, South Africa,

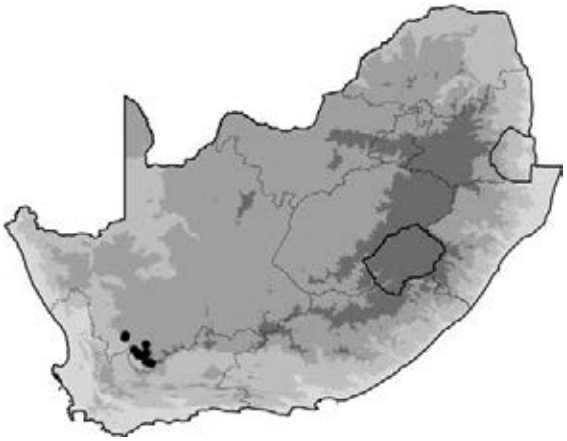
Distribution of ***Romulea vlokii***.

Distribution of ***Romulea hallii***.

where it has been recorded from the Kammanassie Mtns and east of Montagu; on moist stony slopes in renosterveld shrubland.

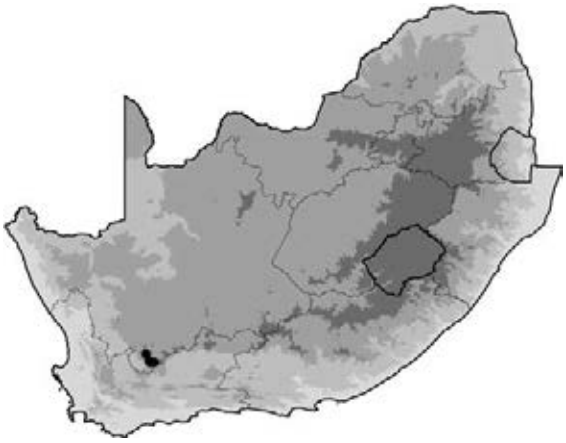
Diagnosis: distinguished by the basally pointed corm, conspicuous membranous tips to the outer bracts, and magenta flowers with yellow cup. Similar corms occur in several species in sect. *Roseae* but the immediate relationships of the species appear to lie with *Romulea atrandra* and other species with strongly veined outer bracts with prominent membranous tips, rather than with other pink-flowered species with pointed corms and lightly veined outer bracts lacking prominent membranous tips, such as *R. cruciata*. The species may be confused with *R. atrandra* in the Little Karoo and examination of the corms is necessary to separate *R. vlokii*, with straight basal teeth converging to a basal point, from *R. atrandra*, with a rounded corm with basal teeth curved or bent over a basal ridge.

64. **Romulea hallii** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 217 (1972). Type: South Africa, [Northern Cape], Sutherland, top of Verlatekloof, *Hall 3176* (NBG, holo.).



Plants 30–50(–80) mm high. *Corm* globose, 10–25 mm diam., obliquely rounded below, tunics woody, split into bent, grooved teeth below. *Stem* subterranean. *Leaves* 3 to 8, all evidently basal, compressed-terete, 4-grooved, 2–3 mm diam. *Peduncles* up to 4, semi-terete, recurved or flexuous in fruit; outer bracts green and herbaceous in lower half, with wide, brown-flecked, membranous margins and tip, 15–18 mm long, herbaceous portion triangular and closely ribbed (8 veins/mm), inner bracts with wide, brown-flecked membranous margins. *Flowers* pale lilac or wisteria-blue with orange-yellow cup and purple and black blotches extending as a median line into cup, outer tepals feathered with purple on reverse; perianth tube funnel-shaped, 5–6 mm long; tepals obovate, 15–22 × 8–10 mm. *Filaments* 5–6 mm long, pilose basally, orange-yellow; anthers 4–5 mm long, yellow. *Style* dividing just below anther apices. *Capsules* oblong, ± 10 mm long. *Flowering time*: May to July.

Distribution and ecology: a narrow endemic known only from the Roggeveld Escarpment south of Sutherland in Northern Cape, South Africa, where it is known from the top of the Verlatekloof Pass; on clay flats in renosterveld shrubland.



Diagnosis: an early-flowering species allied to *Romulea atrandra* and resembling thick-leaved forms of that species but separated by its winter-flowering and pale lilac or wisteria-blue flowers with orange-yellow cup, and outer bracts with acute, triangular herbaceous basal portion.

65. **Romulea komsbergensis** *M.P.de Vos* in Annale van die Universiteit van Stellenbosch, Reeks A, Wis-Natuurkunde 28(3): 69 (1952a): De Vos: 219 (1972). Type: South Africa, [Northern Cape], Sutherland, north of Komsberg Pass, *De Vos 1582* (NBG [as STE], holo.).

Plants 30–100(–150) mm high. *Corm* globose, 7–15 mm diam., obliquely rounded below, tunics woody, split into bent, grooved or channelled teeth below. *Stem* subterranean. *Leaves* 5 to 12, all evidently basal, filiform, narrowly 4-grooved, 1.0–1.5 mm diam. *Peduncles* up to 5, semi-terete, recurved and coiling in fruit; outer bracts softly herbaceous and submembranous or herbaceous in upper half, striate (± 6 veins/mm), with broad, mostly fawn and brown-speckled membranous margins and tip, 14–24 mm long, inner bracts with wide, brown-flecked membranous margins. *Flowers* magenta, often fading blue at tips, with yellow cup edged with narrow blue band and stained brown at base, outer tepals irregularly marked or feathered with purple on reverse; perianth tube funnel-shaped, 3–4 mm long; tepals obovate, 15–28 × 8–15 mm. *Filaments* ± included, ± 4 mm long, pubescent basally, brownish; anthers 3–5 mm long, circinnate, purple ageing yellow; pollen rust-coloured. *Style* usually dividing between base and middle of anthers, rarely exserted up to 4 mm beyond anthers, branches forked. *Capsules* oblong, 8–10 mm long. *Flowering time*: August, September.

Distribution of ***Romulea komsbergensis***.

Distribution of ***Romulea multifida***.

Distribution and ecology: originally thought to be endemic to the Komsberg in Northern Cape but now known to extend along the higher-lying parts of the Roggeveld Escarpment as far north as Middelpos, South Africa; forming large colonies in seepages or the margins of seasonal streams and pools in renosterveld shrubland.

Diagnosis: distinguished from allied species in ser. *Atrandrae* with magenta flowers by the conspicuous brown stain covering the base of the floral cup and filaments, and cytologically in a having $2n = 20$ rather than 22. The orange-yellow cup is rimmed with a purple or blue transverse band and the tepals often fade bluish at the tips. The species typically has a short style dividing near the base of the anthers but populations around Middelpos in the north of the range have the style well exserted, up to 4 mm beyond the anthers.

66. **Romulea multifida** *M.P.de Vos* in Annale van die Universiteit van Stellenbosch, Reeks A, Wis-Natuurkunde 28(3): 71 (1952a); De Vos: 221 (1972). Type: South Africa, [Northern Cape], plateau west of Sutherland, *Joubert s.n.* (NBG [as STE], holo.).

Plants 20–50 mm high. *Corm* globose, 6–15 mm diam., obliquely rounded below, tunics woody, split into bent, grooved or channelled teeth below. *Stem* subterranean. *Leaves* 2 or 3, all evidently basal, terete-filiform, narrowly 4-grooved, 0.5–1.0 mm diam. *Peduncles* 1 or 2, semi-terete, recurved and coiling in fruit; outer bracts softly herbaceous, striate (± 6 veins/mm), with narrow colourless membranous margins and conspicuous brown-flecked membranous tip, 14–18 mm long, inner bracts with wide, brown-flecked membranous margins. *Flowers* magenta with yellow cup and chestnut-brown blotches edged above by a narrow purple or lilac band, outer tepals feathered with purple on reverse; perianth tube funnel-shaped, 5–7 mm long; tepals obovate, 14–20 × 6–9 mm. *Filaments* ± included, 5–6 mm long, pilose basally, yellow; anthers 2.5–4.0 mm long, circinnate, purple or yellowish. *Style* dividing well below anthers, purple, branches 3–4 mm long, multifid with 12 or more lobes. *Capsules* oblong, ± 8 mm long. *Flowering time*: August.

Distribution and ecology: a narrow endemic of the Komsberg south of Sutherland in Northern Cape; restricted to sandy flats in renosterveld.

Diagnosis: a rare species with 2 or 3 filiform leaves and magenta flowers with yellow cup, and diagnostic style dividing well below the anthers into purple or blackish, antler-like branches that are further once or twice divided, thus with 12 or more stigmas. The species co-occurs with *R. komsbergensis* and may be overlooked but the latter has more numerous leaves and flowers with a characteristic brown stain at the bottom of the cup and once-forked style branches, and is ecologically separated by its preference for seepages and marshy situations.

67. **Romulea luteoflora** *(M.P.de Vos) M.P.de Vos* in Journal of South African Botany, Suppl. 9: 210 (1972). *Romulea atrandra* var. *luteoflora* M.P.de Vos: t. 1135 (1952b). Type: South Africa, [Western Cape], Ceres, top of Theronsberg Pass, *De Vos 1570* (NBG [as STE], holo.).

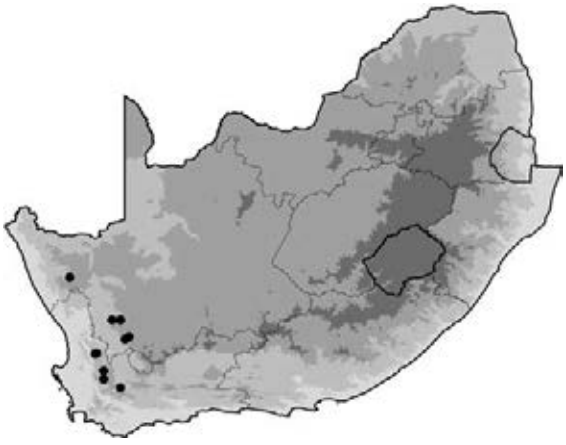
Plants 50–100(–150) mm high. *Corm* globose, 5–20 mm diam., obliquely rounded below, tunics woody, split into bent, grooved teeth below. *Stem* subterranean. *Leaves* 2 to 6, all evidently basal, terete-filiform, narrowly 4-grooved, 1–2 mm diam. *Peduncles* up to 6, semi-terete, 30–140 mm long, recurved and later coiling in fruit; outer bracts green with narrow, translucent or brown-blotched membranous margins expanding to a well-developed, brown-blotched, membranous tip, 12–25 mm long, closely ribbed (± 8 veins/mm), inner bracts with wide, brown-flecked or rarely colourless membranous margins. *Flowers* pale or buttercup-yellow with darker yellow cup, unmarked or with brown blotches around cup, sometimes reduced to lines, outer tepals feathered or blotched with brown on reverse; perianth tube cup- or funnel-shaped, 4–6 mm long; tepals oblanceolate, (16–)18–35 × (4–)5– 15 mm. *Filaments* 4–7 mm long, pilose basally, yellow; anthers (4–)6–9 mm long, yellow. *Style* dividing between middle

and top of anthers. *Capsules* oblong, ± 10 mm long. *Flowering time*: July to September.

Distribution and ecology: with a rather scattered distribution along the western escarpment, on the Kamiesberg, Hantam and Roggeveld Mtns in Northern Cape, and from the Cold Bokkeveld to Worcester in Western Cape, South Africa; on seasonally moist stony clay flats, mostly in renosterveld shrubland. The species is absent from the Bokkeveld Mtns.

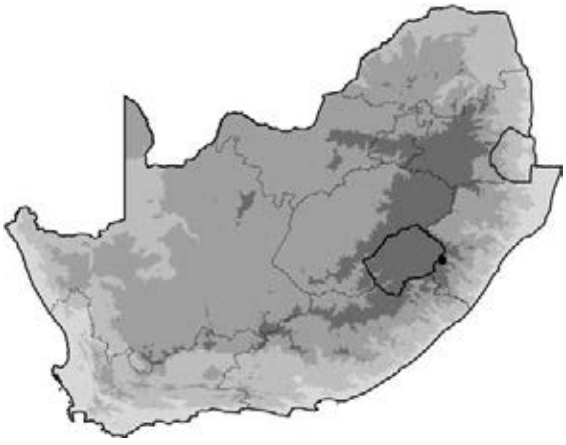
Diagnosis: distinguished from allied species in the series with herbaceous outer bracts with prominent membranous margins by its yellow flowers, sometimes streaked or blotched with brown, and style not exserted above the anthers. Plants from the Roggeveld have thicker, shorter leaves. The fruiting peduncles coil up when ripe.

Romulea luteoflora was originally treated as a variety of pink-flowered *R. atrandra* but differing from it in chromosome number as well as flower colour. Experimental hybrids between the two species are only slightly fertile (De Vos 1972).



Romulea luteoflora may be confused with *R. diversiformis* but the latter is readily identified by the longer style well exserted beyond the anthers, more numerous (6 to 12) leaves, and preference for marshy soils in seepages and around seasonal pools. It has also been confused with *R. monticola* from the Bokkeveld Mtns and *R. obscura* from the Cold Bokkeveld, both of which have the outer bracts less firmly herbaceous below and the inner bracts with finely brown-speckled membranous margins. The fruiting peduncles in *Romulea monticola* are slender and reddish brown, and remain suberect or are curved in fruit, whereas they are typically thicker in *R. obscura* and spread widely in fruit. Both species differ from *R. luteoflora* anatomically in lacking rib marginal veins in the leaves.

Outlying collections from around Albertinia assigned to the species by De Vos (1972) are anomalous in their smaller flowers, softer outer bracts, and finely reddish-speckled membranous margins to the inner bract. The plants, which have not yet set fruit and thus do not show the diagnostic characters of the fruiting peduncles, are unusually delicate for the species, with relatively unsubstantial membranous tips to the bracts. They closely resemble collections of *R. obscura* from the Agulhas Plain and we include them in that species.



Plants from the summit of the Sani Pass on the Lesotho/KwaZulu-Natal border with softer corm tunics and small flowers with proportionally longer, narrowly funnel-shaped tubes and smaller anthers were treated as *Romulea luteoflora* var. *sanisensis* M.P.de Vos (1983) but the morphological differences between them and typical plants from the Western and Northern Cape, in conjunction with the extraordinary geographical disjunction, suggest that that they represent a distinct species, which we recognise as *R. sanisensis*.

68. **Romulea sanisensis** *(M.P.de Vos) J.C.Manning & Goldblatt*, name at new rank. *Romulea luteoflora* var. *sanisensis* M.P.de Vos in Flora of southern Africa 7(2,2): 56 (1983). Type: Lesotho, Sani Pass, west of Border Post in grassland, *Hilliard & Burtt 7153* (PRE [as 'STE'], holo.; NU, iso.).

Plants 20–50 mm high. *Corm* globose, 6–10 mm diam., obliquely rounded below, tunics firm-papery, split into bent, grooved teeth below. *Stem* subterranean. *Leaves* 4 to 8, all evidently basal, terete, narrowly 4-grooved, ± 1 mm diam. *Peduncles* 1 to 4, semi-terete, 25–45 mm long; outer bracts green with narrow, translucent or brown-blotched membranous margins expanding to a well-developed, brown-blotched, membranous tip, 11–14 mm long, closely ribbed (± 8 veins/mm), inner bracts with wide membranous margins flecked with brown distally. *Flowers* yellow to pale apricot-coloured, unmarked, outer tepals feathered with brown on reverse; perianth tube narrowly funnel-shaped, 6 mm long; tepals elliptic, 10–12 × 3–5 mm. *Filaments* inserted at or above middle of tube, 4–5 mm long, puberulous basally, yellow; anthers 2–3 mm long, yellow. *Style* dividing opposite middle of anthers, branches 1–2 mm long, divided halfway. *Capsules* oblong, ± 7 mm long. *Flowering time*: October to early November.

Distribution of ***Romulea luteoflora***.

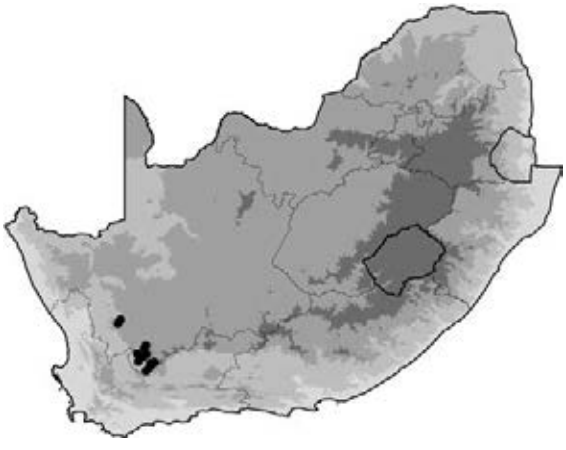
Distribution of ***Romulea sanisensis***.

Distribution and ecology: an early-flowering species still known only from the type locality in marshy turf at the top of Sani Pass just inside Lesotho, where it forms colonies in company with other dwarf geophytes.

Diagnosis: distinguished from *Romulea luteoflora* by the smaller flowers with proportionally longer, narrowly funnel-shaped tube, tepals 10–12 mm long and thus not more than twice as long as the tube, filaments inserted at or above the middle of the tube and 4–5 mm long, thus longer than the anthers, 2–3 mm long.

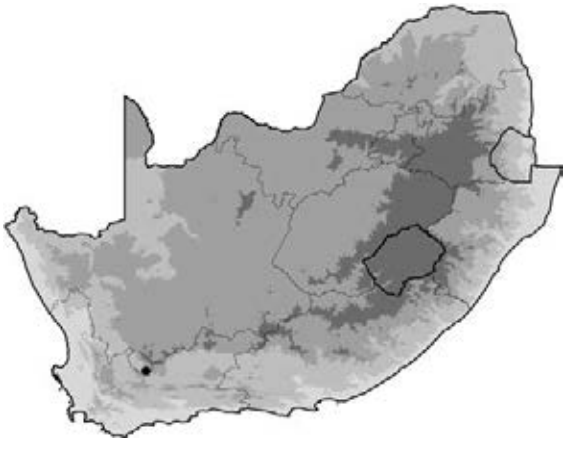
69. **Romulea diversiformis** *M.P.de Vos* in Annale van die Universiteit van Stellenbosch, Reeks A, Wis-Natuurkunde 28(3): 63 (1952a); De Vos: 225 (1972). Type: South Africa, [Northern Cape], Sutherland, Damslaagte, *De Vos 1581* (NBG [as STE], holo.).

Plants 50–100(–150) mm high. *Corm* globose, 8–15 mm diam., obliquely rounded below, tunics woody, split into bent, grooved teeth below. *Stem* subterranean. *Leaves* 6 to 12, all evidently basal, terete-filiform, narrowly 4-grooved, 0.5–1.5 mm diam. *Peduncles* up to 6, semi-terete, recurved and later coiling in fruit; outer bracts green with narrow membranous margins expanding to well-developed, colourless or whitish membranous tip, 12–20 mm long, closely ribbed (± 8 veins/mm), inner bracts with wide, colourless or whitish membranous margins. *Flowers* buttercup- or chrome-yellow, outer tepals brownish or feathered with brown on reverse; perianth tube cup- or funnel-shaped, 4–6 mm long; tepals obovate, ± unequal, 18–28 mm long, outer 7–12 mm wide, inner 10–16 mm wide. *Filaments* 4–6 mm long, pilose basally, yellow; anthers 5–8 mm long, yellow. *Style* exserted and dividing 3–6 mm beyond anthers, branches forked. *Capsules* oblong, 7–10 mm long. *Flowering time*: August, September.



Distribution and ecology: described from the Klein Roggeveld in Northern Cape, South Africa, but now recorded further north along Roggeveld Escarpment west of Sutherland and from the summit of the Hantamsberg near Calvinia; in seepages and around seasonal pools on shale soils.

Diagnosis: readily recognised by its bright yellow, unmarked flowers with relatively broad, obovate tepals, the inner notably broader than the outer, and the long style, exserted 3–6 mm beyond the anthers. The numerous leaves and the whitish or colourless membranous margins to the inner and outer bracts are also distinctive. The species has been confused with *Romulea luteoflora*, but that species has fewer leaves (2 to 6), brown-flecked membranous margins to the inner and outer bracts, and a shorter style not exserted beyond the stamens.



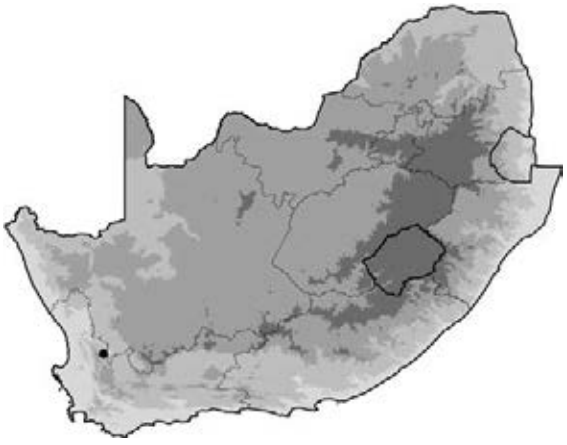
70. **Romulea eburnea** *J.C.Manning & Goldblatt* in Bothalia 34: 19 (2004). Type: South Africa, [Northern Cape], 28 km along Komsberg Pass road from southern end, foot of Smoushoogte, alluvial wash along Meintjiesplaasrivier, 28 August 2003, *J. Manning 2886* (NBG, holo.; MO, iso.).

Plants 50–100 mm high. *Corm* globose, 5–10 mm diam., obliquely rounded below, tunics woody, split into bent, grooved teeth below. *Stem* subterranean. *Leaves* 2 to 4, terete, narrowly 4-grooved, ± 1 mm diam. *Peduncles* 1 or 2, semiterete, recurved and later coiling in fruit; outer bracts submembranous, with broad, brown-flecked membranous margins and tip, 18–22 mm long, inner bracts submembranous with broad, brown-flecked membranous margins. *Flowers* golden-yellow or pale creamy apricot-coloured with lower ⅔ of tepals and cup deep yellow, outer tepals flushed dull olive-coloured on reverse; perianth tube deeply funnel-shaped, 10–13 mm long, tepals oblanceolate, 23–27 × 7–9 mm. *Filaments* pilose below, 6–7 mm long, yellow; anthers ± 8 mm long, yellow. *Style* dividing at or just beyond anthers, branches 3 mm long, deeply divided. *Capsules* oblong, 10–11 mm long. *Flowering time*: August, September.

Distribution and ecology: evidently endemic to the Klein Roggeveld in Northern Cape, where it has been recorded twice on the Komsberg; on sandy flats on Beaufort sandstone in renosterveld shrubland.

Distribution of ***Romulea diversiformis***.

Distribution of ***Romulea eburnea***.



Diagnosis: distinguished by the relatively few (2 to 4), filiform leaves, submembranous bracts, and yellow or pale apricot-coloured flowers with narrowly funnel-shaped tube 10–13 mm long. Possibly most closely allied to *Romulea malaniae*, another species with few leaves and pedicels coiling in fruit but with smaller flowers with shorter perianth tube. Anatomically, the leaves are unusual in lacking secondary veins on either side of the main veins and in having a subdermal sclerenchyma layer joining the main and marginal bundles.

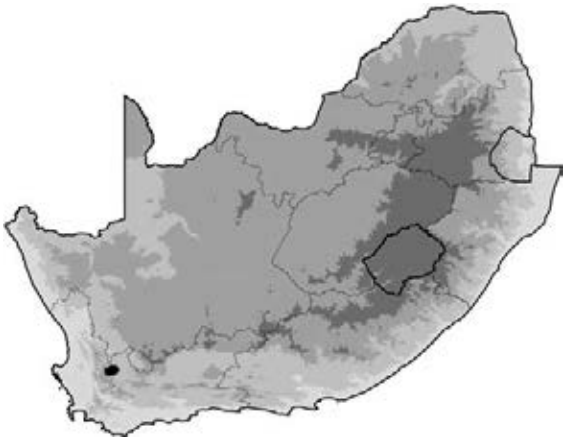
71. **Romulea monophylla** *J.C.Manning & Goldblatt* in South African Journal of Botany 95: 133 (2014). Type: South Africa, Western Cape, Cederberg, 4 km before Farm Sederberg, fynbos on sand, 12 Aug. 1986, *C.M. van Wyk 2539* (PRE, holo.).

Plants 100–150 mm high. *Corm* globose, ± 10 mm diam., rounded or crested below, tunics woody, split into bent, grooved teeth below. *Stem* subterranean. *Leaf* solitary, basal, terete, narrowly 4-grooved, ± 1 mm diam. *Peduncle* 1, semi-terete, reddish brown; outer bracts green or flushed brown, with scarcely visible, colourless membranous margins, 15–22 mm long, ribbed above (± 6 veins/mm), inner bract ± entirely membranous or distal half with narrow herbaceous central portion, with purple or green veins in centre and wide, colourless margins. *Flowers* orange, ?with dark lines in throat, outer tepals finely feathered and marbled with brown on reverse; perianth tube funnel-shaped, 6–7 mm long; tepals oblanceolate to elliptic, 20–22 × 6–8 mm. *Filaments* ± 8 mm long, pilose in lower half, yellow; anthers ± 8 mm long, yellow. *Style* dividing opposite middle of anthers, branches 2 mm long, divided halfway. *Flowering time*: August.

Distribution and ecology: a rare species known from the type collection from the Farm Sederberg in the Cederberg, Western Cape; in sandy soil in fynbos.

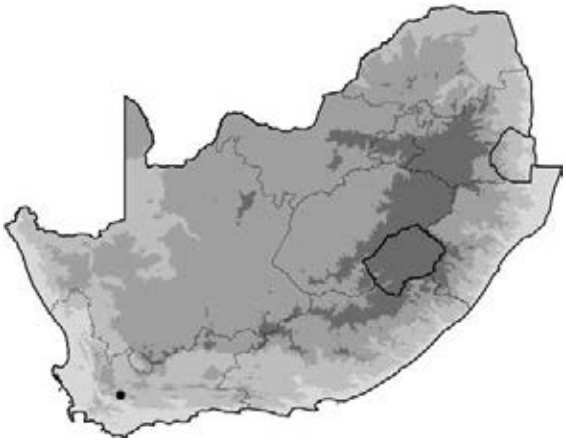
Diagnosis and relationships: distinctive in the solitary leaf and orange flowers with herbaceous outer bracts with narrow, scarcely visible membranous margins but ± entirely membranous inner bracts with unmarked margins. *Romulea monophylla* is distinguished from other yellow-flowered species with membranous inner bracts by the strictly solitary leaf, herbaceous outer bract with narrow membranous margins, and the unspotted inner bracts.

Distribution of ***Romulea monophylla***.



72. **Romulea fuscomontana** *J.C.Manning & Goldblatt*, sp. nov. Type: South Africa, Western Cape, Swartruggens, Knolfontein, arid mountain fynbos in sand, 28 May 2019, *I. Jardine* (NBG, holo.).

Plants 30–50 mm high at flowering. *Corm* globose, ± 10–15 mm diam., rounded or crested below, tunics woody, split into bent, grooved teeth below. *Stem* subterranean. *Leaf* solitary, basal, emergent at flowering, terete, stiffly erect, narrowly 4-grooved, mostly condupliacte with just the apex unifacial, ultimately 50–60 mm long, ± 1 mm diam. *Peduncle* 1, short and stout, scarcely exserted abve ground level, semi-terete, pale flushed reddish brown; outer bracts ± entirely membranous or submembranous, with broad colourless membranous margins and membranous tip flushed pale brown, 12–15 mm long, mauve-ribbed above (± 6 veins/mm), inner bract ± entirely membranous with mauve flushed veins in centre and wide, colourless margins flushed golden brownish apically. *Flowers* golden yellow with dark lines in throat, outer tepals finely feathered with brown on reverse; perianth tube funnel-shaped, 4–5 mm long; tepals oblanceolate to elliptic, 20–22 × 5–7 mm. *Filaments* ± 7 mm long, pilose basally, yellow; anthers ± 7 mm long, yellow. *Style* dividing opposite upper third of anthers, branches 2 mm long, divided halfway. *Flowering time*: May.



Distribution and ecology: a rare species known from the type collection from the farm Knolfontein in the Swartruggens, Western Cape; on sandy loamy flats in arid fynbos, along wash lines among pebbles.

Diagnosis and relationships: an early winter-flowering species, *Romulea fuscomontana* is distinctive in the genus in the solitary, short, stiff leaf that is emergent or only partly developed at flowering, and solitary, golden yellow flower borne at ground level, with ± entirely membranous or submembranous outer bracts with broad, colourless margins and tip flushed pale brown, and entirely membranous inner bracts with unmarked margins. Anatomically, the leaves are unusual in lacking rib marginal veins as well as secondary veins on either side of the main veins, and in having a subdermal sclerenchyma layer joining the main veins to the marginal fibre strands. This subdermal sclerenchyma layer, which gives the leaves their characteristic rigidity, is also found in *R. eburnea* from the Klein Roggeveld, but that species has a marginal vein associated with the marginal strands. *Romulea eburnea*, also with submembranous outer and inner bracts as in *R. fuscomontana*, has two or more leaves, and flowers with a much deeper perianth tube, 10–13 mm long.

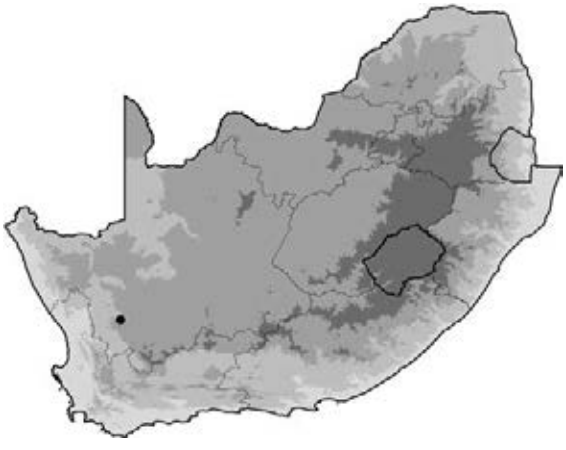
Romulea fuscomontana may be confused with spring-flowering *Romulea malaniae*, which resembles it in

Distribution of ***Romulea fuscomontana***.

Distribution of ***Romulea malaniae***.

having the flowers borne at ground level on a very short peduncle with a characteristic knee-bend just below the flower, and in the submembranous outer bracts but that species has much smaller flowers, with tepals 8–20 mm long and anthers only 3–4 mm long, and the margins of the inner bracts and the tip of the outer bracts are distinctly flecked with brown. It also differs anatomically from *R. fuscomontana* in having secondary and marginal vascular bundles in the leaves, without a joining subdermal sclerenchyma layer. *Romulea monophylla* from the Cederberg, with a solitary leaf and large orange flowers resembling those of *R. fuscomontana*, is a spring-flowering species with the leaf fully developed at flowering, and the flowers are borne well above ground level on long peduncles, with herbaceous outer bracts.

73. **Romulea malaniae** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 223 (1972). Type: South Africa, [Western Cape], Sandvlei, 23 km S of Matroosberg Station, *Malan s.n.* (NBG [as STE], holo.).



Plants 30–50 mm high. *Corm* globose, 5–10 mm diam., obliquely rounded below, tunics woody, split into bent, grooved teeth below. *Stem* subterranean. *Leaves* 1 to 3, all evidently basal, terete, narrowly 4-grooved, ± 1 mm diam. *Peduncles* up to 3, semi-terete, short and stout, recurving and later coiling in fruit; outer bracts pale and membranous or subherbaceous in upper half, with broad membranous margins and apex brown-speckled at tips only, 12–18 mm long, inner bracts pale and membranous, with broad, brown-flecked membranous margins. *Flowers* pale canary-yellow with outer tepals brownish on reverse; perianth tube funnel-shaped, 5–9 mm long; tepals oblanceolate, 8–20 × 4–5 mm. *Filaments* 4–5 mm long, pilose basally, yellow; anthers 3–4 mm long, yellow. *Style* dividing below anther apices, branches divided. *Capsules* subglobose to oblong, 5–8 mm long. *Flowering time*: August.

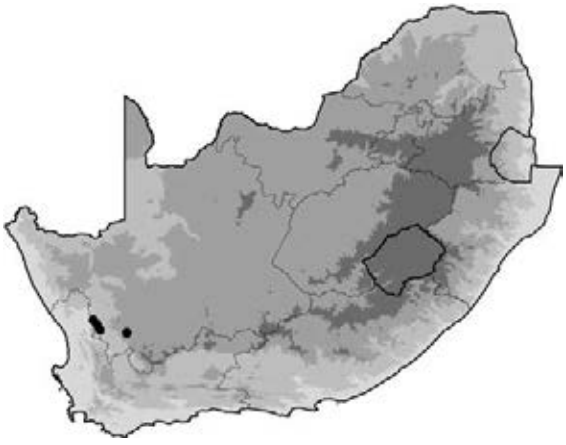
Distribution and ecology: known only from the type locality near the summit of Rooihoogte Pass on the Waboomsberg in Western Cape; in sandy patches on a sandstone ridge in open fynbos.

Diagnosis: a small and inconspicuous member of ser. *Atrandrae* distinguished by the 1 to 3 leaves, ± membranous inner and outer bracts, and unmarked, pale yellow flowers with tepals 8–20 mm long and short anthers 3–4 mm long. The short, stout peduncles have a characteristic knee-bend just below the flower.

74. **Romulea collina** *J.C.Manning & Goldblatt* in Bothalia 34: 17 (2004). Type: South Africa, Northern Cape, summit of Hantamsberg at base of radio mast, August 2002, flowered in cult. July 2003, *IBSA 5* (NBG, holo.).

Plants 50–100 mm high, growing in clumps. *Corm* globose, 10–15 mm diam., obliquely rounded below, tunics woody, split into bent, grooved teeth below, with fibrous neck 20–40 mm long. *Stem* subterranean. *Leaves* 7 to 9, all evidently basal, terete, narrowly 4-grooved, 1.0–1.5 mm diam. *Peduncles* up to 4, semi-terete, short and stout, suberect in fruit; outer bracts pale and membranous or subherbaceous in centre, with broad, brown-flecked membranous margins and apex, 10–12 mm long, inner bracts pale and membranous, with broad, brown-flecked membranous margins. *Flowers* pale canary-yellow with

Distribution of ***Romulea collina***.



golden-yellow cup, outer tepals with dark median blotch or transverse zone in throat and feathered with maroon on reverse, inner tepals with narrow brownish maroon median line and diffuse transverse zone in throat; perianth tube funnel-shaped, ± 4 mm long; tepals oblanceolate, ± 20 × 7 mm. *Filaments* ± 6 mm long, pilose basally, yellow; anthers 2.5–3.0 mm long, yellow. *Style* dividing below anther apices, branches 1.5–2.0 mm long, deeply divided. *Capsules* subglobose, ± 8 mm long. *Flowering time*: late June to July.

Distribution and ecology: known from a single collection from the summit of the Hantamsberg near Calvinia in Northern Cape, South Africa; on seasonally moist clay flats in renosterveld shrubland.

Diagnosis: one of a small group of species in sect. *Roseae* with ± membranous or papery outer and inner bracts, and yellow flowers, among which it is distinguished by the rounded corm, numerous (7 to 9) leaves, and flowers with a golden-yellow cup marked with dark blotches and streaks around the throat.

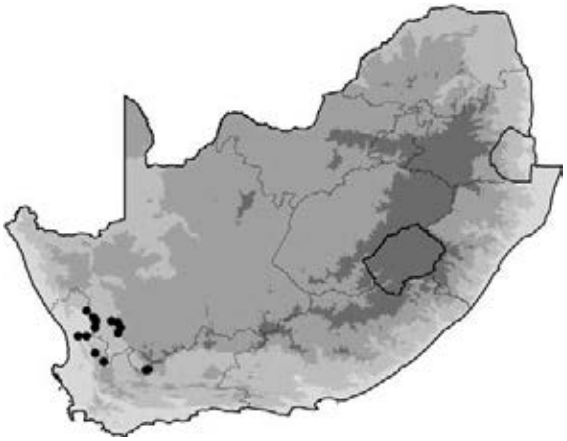
75. **Romulea membranacea** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 227 (1972). Type: South Africa, [Northern Cape], Elandsfontein, 29 km NW of Middelpos, *Salter 3488* (BOL, holo.; BM, K, iso.).

Plants 30–100 mm high. *Corm* ovoid, 5–12 mm diam., pointed below, tunics woody, split into ± straight teeth converging on basal point. *Stem* subterranean. *Leaves* 6 to 10, all evidently basal, filiform, narrowly 4-grooved, ± 0.5 mm diam. *Peduncles* up to 4, semi-terete, recurving in fruit; outer bracts pale and membranous or subherbaceous in upper half, with broad, brown-flecked membranous margins and apex, 10–14 mm long, inner bracts pale and membranous, with broad, brown-flecked membranous margins. *Flowers* golden-yellow with 1 to 3 dark veins in throat, outer tepals blotched or striped brownish on reverse; perianth tube funnel-shaped, 3–5 mm long; tepals oblanceolate, 15–22 × 4–7 mm. *Filaments* 5–6 mm long, pilose basally, yellow; anthers 3–4 mm long, yellow. *Style* dividing below or at anther apices, branches divided. *Capsules* subglobose, ± 5 mm long. *Flowering time*: July, August.

Distribution of ***Romulea membranacea***.

Distribution and ecology: described from the Roggeveld west of Middelpos in Northern Cape, South Africa, but now also recorded from the southern Bokkeveld Escarpment; in washes on sandy or calcareous soils in renosterveld or succulent karoo shrublands.

Diagnosis: one of a handful of species with basally pointed corms, distinguished by the soft inner bract, subherbaceous only in the upper half, and with wide membranous margins and tips, and the golden-yellow flowers with darker veins in the throat.



Ser. **Hirtae** *(Bég.) J.C.Manning & Goldblatt*, name at new rank. *Romulea* 'Stirps' *Hirtae* Bég. in Annuaire du Conservatoire du Jardin Botaniques de Genève: 159 (1908). *Romulea* sect. *Hirtae* (Bég.) M.P.de Vos: 269 (1972). Type: *R. hirta* Schltr.

Corms rounded and tunics with curved basal teeth. *Leaves* 4-winged with lateral ribs reduced and median ribs winged, glabrous or ciliate on wing margins; peduncles glabrous or pilose along angles. *Flowers* funnel-shaped; *outer* bracts with membranous margins and often prominent membranous tip.

76. **Romulea hirta** *Schltr.* in Botanische Jahrbücher für Systematik 27: 91 (1899); De Vos: 269 (1972). Type: South Africa, [Western Cape], Koudeberg, Wuppertal, *Schlechter 8766* (B, holo.; BM, K, P, S, Z, iso.).

Plants 50–150 mm high. *Corm* globose or obovoid, 8–15 mm diam., rounded or crested below, tunics woody, split into bent teeth below. *Stem* subterranean. *Leaves* 3 to 9, all evidently basal, 4-winged, lateral ribs reduced, median ribs marginally winged and glabrous or ciliate and sometimes also sparsely villous on margins, sometimes crisped, 2–5 mm wide. *Peduncles* up to 5, angled, glabrous or pilose on angles, recurved or suberect in fruit; outer bracts green or submembranous below, with narrow, usually brown-flecked, membranous margins, 10–18 mm long, closely ribbed (± 8 veins/mm), inner bracts with wide, brown-flecked membranous margins. *Flowers* pale yellow (rarely white), sometimes with golden-yellow cup, often with diffuse brownish or greenish transverse band in throat, rarely with brown blotches in throat, outer tepals greenish yellow on reverse; perianth tube funnel-shaped, 4–5 mm long; tepals oblanceolate or elliptic, 12–25 × 4–8 mm. *Filaments* 5–6 mm long, pilose basally or subglabrous, yellow; anthers 3–5, yellow. *Style* dividing opposite anthers. *Capsules* subglobose to oblong, up to 10 mm long. *Flowering time*: July to September.

Distribution and ecology: with a scattered distribution on the Bokkeveld Mountains around Nieuwoudtville, the Hantam Plateau around Calvinia (where white-flowered plants have been recorded as well as the usual yellow) and the Klein Roggeveld in Northern Cape, and the northern Cederberg in Western Cape, South Africa; in seasonally moist loam in renosterveld shrubland.

Distribution of ***Romulea hirta***.

Diagnosis: one of three species in the genus with similar, 4-winged leaves, often hairy on the wing margins, but the only one with this leaf type in sect. *Roseae* and also the only one with pale yellow flowers. The flowers often have an indistinct dark band in the throat but are only rarely (a single collection from the Nieuwoudtville Wildflower Reserve) marked with distinct black blotches.

The exact relationships of the species are not clear. There is a tendency for the bracts to develop prominent membranous apices as in ser. *Atrandrae*, and specimens with dark markings have been confused with *Romulea luteoflora* but the somatic chromosome number, $2n = 26$, is anomalous there and consistent with ser. *Bicarinatae*.

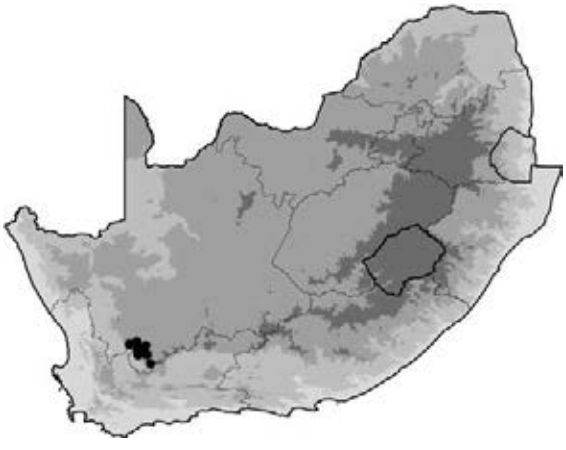
Ser. **Bicarinatae** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 274 (1972). Type: *R. sabulosa* Bég.

Spatalanthus Sweet: t. 300 (1829). *Romulea* subg. *Spatalanthus* [as *Spathalanthus*] (Sweet) Baker: 37 (1896). Type: *S. speciosus* Sweet = *Romulea monadelpha* (Sweet) Baker

[*Romulea* sect. *Spatalanthus* in Manning & Goldblatt: 98 (2001), invalid name without author.]

[*Romulea* ser. *Spatalanthus* in Manning & Goldblatt: 104 (2001), invalid name without author.]

Corms rounded, tunics with bent or curved basal teeth. *Leaves* terete or compressed-cylindric, 4-grooved, sometimes subfistulose. *Flowers* cup-shaped; *outer* bracts keeled in upper half, inner bracts strongly 2-keeled.



77. **Romulea subfistulosa** *M.P.de Vos* in Annale van die Universiteit van Stellenbosch, Reeks A, Wis-Natuurkunde 28(3): 66 (1952a); De Vos: 275 (1972). Type: South Africa, [Northern Cape], near Sutherland, *Joubert & De Vos 1585* (NBG [as STE], holo.).

Romulea vanzyliae M.P.de Vos: 284 (1972) [as ×*vanzyliae*]. Type: South African, Northern Cape, without precise locality, cultivated in Cape Town, *Van Zyl s.n.* (BOL, holo.; PRE, iso.).

Plants 50–150 mm high. *Corm* globose, rounded, 10–20 mm diam., oblique, tunics woody, splitting into curved teeth below. *Stem* subterranean. *Leaves* 4 to 9, basal, compressed-terete, arcuate or suberect, X-shaped and broadly 4-grooved to H-shaped with median ribs winged, 2–5 mm diam. *Peduncles* up to 3, angled, recurving but suberect in fruit; outer bracts green with narrow, colourless or brown-speckled membranous margins, 160–25 mm long, closely and heavily ribbed (8 to 10 veins/mm), usually with stouter midvein in upper half, inner bracts 2-keeled with stouter veins on keels, with colourless or brown-flecked membranous margins. *Flowers* cup-shaped, shiny carmine-pink with yellow cup and reddish black blotches in throat, extended as median line into cup, outer tepals with yellow longitudinal stripes and dark feathering on reverse; perianth tube cup-shaped, 3.0–5.5 mm long; tepals obovate, 25–50 × 10–17 mm long. *Filaments* inserted at base of tube, 4–6 mm long, pilose at base, yellow or purple to black; anthers 8–11 mm long, apically joined at first, yellow. *Style* dividing opposite middle of anthers, branches forked. *Capsules* oblong to subglobose, 8–10 mm long. *Flowering time*: (August) September (October).

Distribution and ecology: largely restricted to the Roggeveld in Northern Cape, South Africa, between Middelpos and Sutherland but also recorded from the Hantam Plateau east of Calvinia; on seasonally damp stony dolerite flats in open shrubland.

Diagnosis: the only member of ser. *Bicarinatae* with pink flowers with a yellow cup, *Romulea subfistulosa* is also readily distinguished by the several, subfistulose leaves 2–5 mm wide, either X-shaped and widely 4-grooved or more usually ± H-shaped with the median ribs winged. Plants from Calvinia were originally regarded as a hybrid with *R. sabulosa* (although *R. subfistulosa* was still then known only from the Roggeveld) but do not differ in any significant way from typical

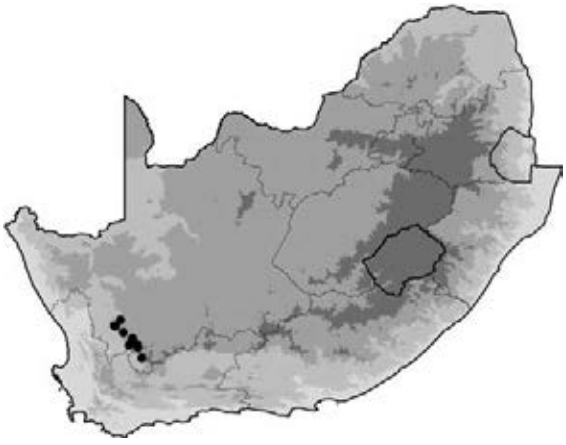
Distribution of ***Romulea subfistulosa***.

R. subfistulosa and were assigned to this species by Manning & Goldblatt (2001).

78. **Romulea unifolia** *M.P.de Vos* in South African Journal of Botany 53: 247 (1987). Type: South Africa, [Northern Cape], Roggeveld Escarpment, Farm Fransplaas, *Oliver 8933* (NBG [as STE], holo.; K, MO, NBG, PRE, iso.).

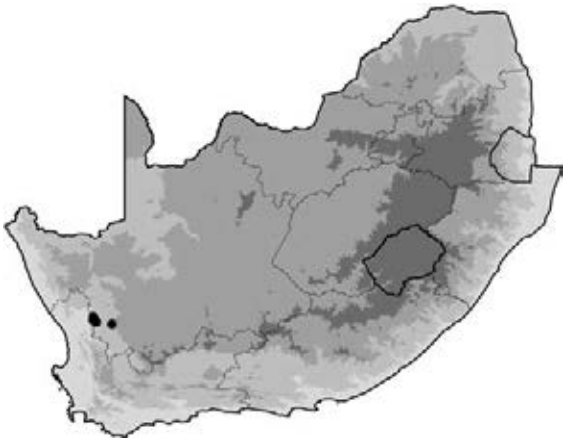
Plants (50–)80–150 mm high. *Corm* globose, rounded, 10–20 mm diam., oblique, tunics woody, splitting into curved teeth below. *Stem* subterranean. *Leafs* 1, rarely up to 3 but then additional leaves much reduced, basal, compressed-terete, arcuate or spreading, subfistulose, broadly 4-grooved, 2–5 mm diam. *Peduncles* up to 3, angled; outer bracts green with narrow, colourless or brown-speckled membranous margins, 20–30 mm long, closely and heavily ribbed (8 to 10 veins/mm), usually with stouter midvein in upper half, inner bracts 2-keeled with stouter veins on keels, with colourless or brown-flecked membranous margins. *Flowers* cup-shaped, shiny orange to reddish orange with black blotch above yellow in throat, outer tepals with dark feathering on reverse; perianth tube cup-shaped, 3–5 mm long; tepals obovate-cuneate, (28–)30–45(–50) × 10–20 mm long. *Filaments* inserted at base of tube, 5–6 mm long, minutely pilose, blackish; anthers 9–12 mm long, apically joined at first, yellow. *Style* dividing opposite middle of anthers, branches forked. *Flowering time*: August, September.

Distribution and ecology: a local endemic of the Northern Cape, South Africa, originally and still best known from the Roggeveld to the west and south of Middelpos but also recorded on the Bokkeveld Plateau between Calvinia and Nieuwoudtville; restricted to dolerite flats in open shrubland.



Diagnosis: distinctive in the genus in its mostly solitary leaf (rarely with an additional one or two much reduced leaves) and large, orange to reddish orange flowers with black and yellow markings in the cup. The basal leaf is thick and subfistulose, 2–4 mm wide and broadly 4-grooved.

79. **Romulea sabulosa** *Schltr. ex Bég.* in Botanische Jahrbücher für Systematik 38: 334 (1907); De Vos: 279 (1972). Type: South Africa, [Northern Cape], Bokkeveld Mtns, Oorlogskloof, *Schlechter 10964* (G, lecto., designated by De Vos: 281 (1972); B, BM, BOL, GRA, K, PRE, S, Z, isolecto.).



Plants 80–150(–200) mm high. *Corm* globose, rounded, 8–15 mm diam., oblique, tunics woody, splitting into curved teeth below. *Stem* subterranean. *Leaves* 3 to 5, all basal, terete, narrowly 4-grooved, ± 1 mm diam. *Peduncles* up to 4, terete, suberect in fruit; outer bracts green with narrow, usually black-blotched or ± entirely black membranous margins, 20–35 mm long, closely and heavily ribbed (8–10 veins/mm) with stouter midvein, inner bracts 2-keeled with stouter veins on keels, with colourless or brown-flecked membranous margins. *Flowers* cup-shaped, shiny scarlet or currant-red with elongated black markings in throat on greyish green or lilac background above a yellow V-shaped blotch, outer tepals with yellow lines and black feathering on reverse; perianth tube cup-shaped, 2–4 mm long; tepals obovate-cuneate, 25–40(–55) × 12–20(–25) mm long. *Filaments* inserted at base of tube, 3–5 mm long, triangular, glabrous or sparsely pilose, whitish to dark; anthers 8–12 mm long, apically joined at first, yellow or purplish with yellow pollen. *Style* dividing opposite middle of anthers, branches forked, whitish. *Capsules* oblong, ± 15 mm long. *Flowering time*: (July) August (September).

Distribution and ecology: a narrow endemic of the Bokkeveld Mtns around Nieuwoudtville in Northern Cape, South Africa; on seasonally moist loamy tillite flats in renosterveld shrubland.

Diagnosis: one of three species in ser. *Bicarinatae* with large, glossy red to orange, cup-shaped flowers, *Romulea sabulosa* is distinguished from *R. unifolia* by the several, narrow leaves ± 1 mm diam. and scarlet to currant-red flowers, and from *R. monadelpha* by the free

Distribution of ***Romulea unifolia***.

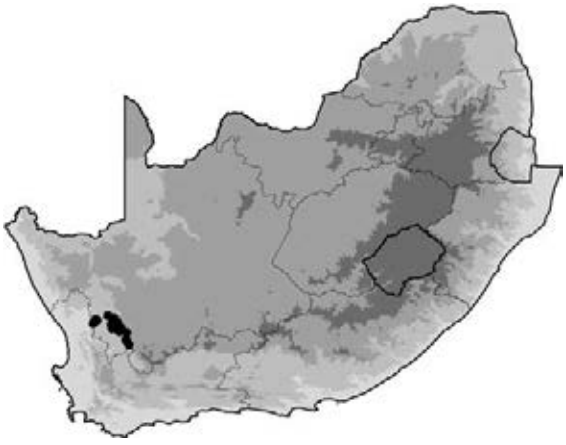
Distribution of ***Romulea sabulosa***.

stamens, widened toward the base and tapering above. It is ecologically separated from these two species, both restricted to heavy clay soils derived from dolerite, by its preference for loamy tillite.

80. **Romulea monadelpha** *(Sweet ex Steud.) Baker*, Handbook of the Irideae: 104 (1892); De Vos: 283 (1972) [not *R. speciosa* (Andrews) Baker (1877)]. *Spatalanthus speciosus* Sweet: t. 300 (1829). *Trichonema monadelphum* Sweet ex Steud.: 702 (1841) [as a new name for *Spatalanthus speciosus* Sweet, not *Trichonema speciosum* Ker Gawl (1804)]. Type: South Africa, without precise locality or collector, illustration in Sweet: t. 300 (1829).

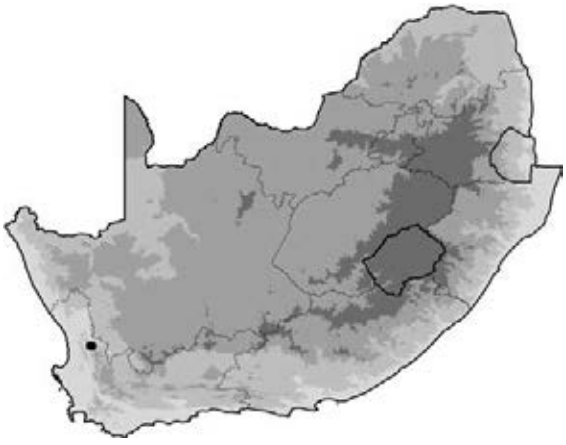
Plants (50–)80–150 mm high. *Corm* globose, rounded, 10–20 mm diam., oblique, tunics woody, splitting into curved teeth below. *Stem* subterranean. *Leaves* 3 to 8, basal, terete, narrowly 4-grooved, 1–2 mm diam. *Peduncles* up to 4, angled, curved in fruit; outer bracts green with narrow, colourless or ± entirely black membranous margins, 20–30 mm long, closely and heavily ribbed (8 to 10 veins/mm), usually with stouter midvein in upper half, inner bracts 2-keeled with stouter veins on keels, with colourless or brown-flecked membranous margins. *Flowers* cup-shaped, shiny strawberry or claret-red with black blotch on pale greyish or purple background above yellow mark (sometimes with black median line) in throat, outer tepals with dark feathering on reverse; perianth tube bowl-shaped, 2–3 mm long; tepals obovate-cuneate, 25–40(–45) × 12–25 mm long. *Filaments* inserted at base of tube, 3–6 mm long, either oblong and longitudinally appressed or connate in stout cylindric collar, glabrous or pilose basally, blackish; anthers 10–15 mm long, apically joined at first, yellow or purplish with yellow pollen. *Style* dividing opposite base to middle of anthers, branches forked. *Capsules* oblong, 10–15 mm long. *Flowering time*: August, September.

Distribution and ecology: endemic to Northern Cape, South Africa, on the Bokkeveld Plateau from Nieuwoudtville to Calvinia and southward along the Roggeveld to Middelpos; restricted to seasonally moist dolerite flats in open shrubland.



Diagnosis: the type and all subsequent collections from the Bokkeveld Plateau are diagnosed by the filaments fused into a stout, smooth, cylindric column, but collections from the Roggeveld have oblong, closely appressed but free filaments bearded basally. These populations may be confused with *R. sabulosa*, but that species has the filaments triangular in section and distinctly tapered above, and ± terete peduncles.

81. **Romulea viridibracteata** *M.P.de Vos* in Journal of South African Botany, Suppl. 9: 277 (1972). Type: South Africa, [Western Cape], Pakhuis Pass, *Salter 3652* (BOL, holo.; BM, K, iso.).



Plants 80–100 mm high. *Corm* globose, rounded, 7–15 mm diam., oblique, tunics woody, splitting into curved teeth below. *Stem* subterranean. *Leaves* 3 to 5, all basal, terete, narrowly 4-grooved, 0.8–2.0 mm diam. *Peduncles* up to 4, terete, suberect in fruit; outer bracts green with narrow, black-blotched membranous margins and brown-flecked membranous apices, 17–30 mm long, closely and heavily ribbed (8 to 10 veins/mm), often with stouter mid-vein in upper half, inner bracts 2-keeled with stouter veins on keels, with colourless or brown-flecked membranous margins. *Flowers* cup-shaped, bright yellow with black, 3-toothed markings in throat and black flecks at base, outer tepals blackish on reverse; perianth tube cup-shaped, 2–4 mm long; tepals obovate, 20–35 × 6–10 mm long. *Filaments* inserted at base of tube, 4–5 mm long, pilose; anthers 6–9 mm long, apically joined at first. *Style* dividing opposite upper half of anthers, branches forked. *Capsules* oblong, 15 mm long. *Flowering time*: August, September.

Distribution and ecology: a local endemic of Western Cape, South Africa, known only from the top of Pakhuis Pass; in renosterveld shrubland.

Diagnosis: the only member of ser. *Bicarinatae* with yellow flowers, distinguished from other species in

Distribution of ***Romulea monadelpha***.

Distribution of ***Romulea viridibracteata***.

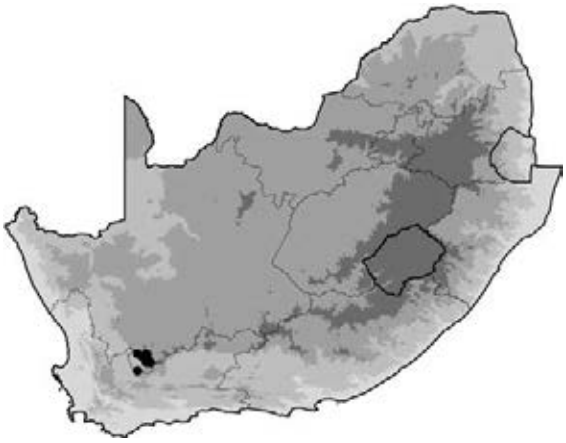
the genus with yellow flowers blotched with brown in the throat by the large size of the flowers and by the strongly ribbed inner and outer bracts, the inner bracts 2-keeled with the keel veins stouter than the others. The black-chequered bract margins are characteristic.

Ser. **Lomurea** *(M.P.de Vos) J.C.Manning & Goldblatt*, name at new rank. *Romulea* subg. *Lomurea* M.P.de Vos in Journal of South African Botany, Suppl. 9: 285 (1972). Type: *Romulea syringodeoflora* M.P.de Vos

[*Romulea* sect. *Lomurea* in M.P.de Vos: 287 (1972), invalid name without author.]

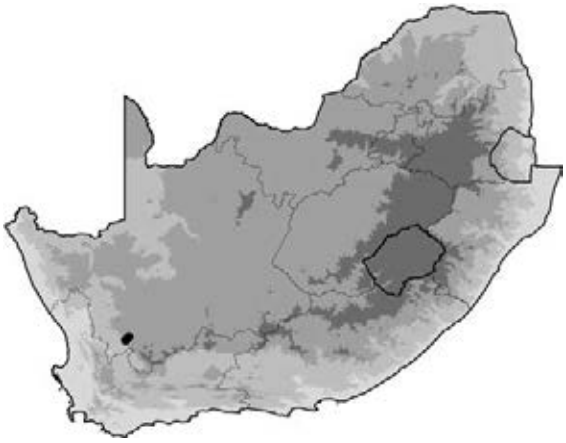
Corms rounded and tunics with curved basal teeth. *Flowers* salver-shaped, tube 15–30 mm long. *Chromosome number* 2*n* = 20.

82. **Romulea syringodeoflora** *M.P.de Vos* in Annale van die Universiteit van Stellenbosch, Reeks A, Wis-Natuurkunde 28(3): 74 (1952a); De Vos: 287 (1972). Type: South Africa, [Northern Cape], near Sutherland, *De Vos 1587* (NBG [as STE], holo.).



Plants 20–50 mm high. *Corm* globose, rounded, 10–15 mm diam., oblique, tunics woody, splitting into curved teeth below, with fibrous neck 20–50 mm long. *Stem* subterranean. *Leaves* 5 to 7, all basal, arcuate or spreading, terete, narrowly 4-grooved, 1.5–2.5 mm diam., median ribs glabrous or ciliate on margins with hairs up to 0.5 mm long. *Peduncles* up to 5, usually shortly exserted, terete; outer bracts green with narrow, colourless membranous margins, 15–20 mm long, closely ribbed (8 to 10 veins/mm), inner bracts with broad colourless membranous margins. *Flowers* salver-shaped, magenta to dark pink with yellowish throat outlined with red or purple, tepals feathered purple on reverse, tube longitudinally banded with purple and yellow; perianth tube cylindric, 15–22 mm long; tepals narrowly elliptic, spreading, 10–17 × 3–5 mm long. *Filaments* inserted at mouth of tube, 4–5 mm long, glabrous, white; anthers 4–6 mm long, dark purple; pollen reddish brown. *Style* dividing near anther apices, branches ± 2 mm long, divided ± halfway. *Flowering time*: September, October.

Distribution and ecology: endemic to the Roggeveld Escarpment in Northern Cape, South Africa, from west of Sutherland to the Komsberg; on seasonally wet clay flats in renosterveld shrubland.



Diagnosis: recognised by the rounded corm, arched or abruptly spreading, smooth or shortly ciliate leaves and pink to magenta, salver-shaped flowers with perianth tube 15–22 mm long.

83. **Romulea albiflora** *J.C.Manning & Goldblatt* in Adansonia, ser. 3, 23: 106 (2001). Type: South Africa, [Northern Cape], Roggeveld Escarpment, Farm Blomfontein, west of Middelpos, *Goldblatt & Manning 10367* (NBG, holo.; K, MO, PRE, S, WAG, iso.).
