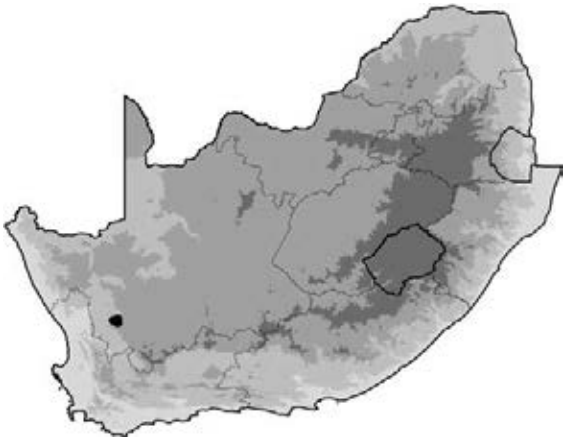
Plants 50–80(–120) mm high, often clump-forming. *Corm* globose, rounded, 8–10 mm diam., oblique, tunics woody, splitting into curved teeth below, with fibrous neck 20–50 mm long. *Stem* subterranean. *Leaves* ± 5, all basal, suberect and ± straight, up to twice as long as flowering stems, terete or compressed, narrowly 4-grooved, 1.5–2.0 mm diam., median ribs softly villous on margins with hairs up to 1 mm long. *Peduncles* up to 5, well exserted, terete; outer bracts green with narrow, colourless membranous margins, 18–25 mm long, closely ribbed (8 to 10 veins/mm), inner bracts with broad colourless membranous margins. *Flowers* salver-shaped, white with yellowish throat outlined with purple, tepals flushed mauve and feathered purple on reverse, tube longitudinally banded with purple and yellow; perianth tube cylindric, 20–33 mm long; tepals narrowly elliptic, spreading, 12–20 × 2.5–4.0 mm long. *Filaments* inserted at mouth of tube, ± 4 mm long, glabrous, white; anthers 6–7 mm long, dark purple; pollen reddish brown. *Style* dividing near anther apices, branches ± 2 mm long, divided ± halfway. *Flowering time*: September, October.

Distribution of ***Romulea syringodeoflora***.

Distribution of ***Romulea albiflora***.

Distribution and ecology: a narrow endemic of the Roggeveld Escarpment west of Middelpos in Northern Cape, South Africa; on seasonally moist clay flats in renosterveld shrubland.

Diagnosis: occurring north of *Romulea syringodeoflora* and distinguished from it by the longer, suberect and softly villous leaves with hairs up to 1 mm long and white, salver-shaped flowers with perianth tube 30–33 mm long.



Ser. **Tubiformes** *J.C.Manning & Goldblatt*, new series. Type: *Romulea hantamensis* (Diels) Goldblatt

[*Romulea* ser. *Tubiformes* in Manning & Goldblatt: 97 (2001), invalid name without author.]

Corms pointed downward, tunics with straight basal teeth. *Flowers* salver-shaped, tube 35–70 mm long. *Chromosome number* 2*n* = 30.

84. **Romulea hantamensis** *(Diels) Goldblatt* in Flowering Plants of Africa 41: t. 1613 (1970); De Vos: 289 (1972). *Lapeirousia hantamensis* Diels: 116 (1909). Type: South Africa, [Northern Cape], Calvinia, Hantamsberg, *Diels 732* (B, holo.).

Plants 70–150 mm high. *Corm* ovoid and pointed at base, 8–15 mm diam., oblique, tunics woody with straight or slightly curved teeth converging to basal point. *Stem* subterranean. *Leaves* ± 6 to 10, arcuate or spreading, all basal, terete, narrowly 4-grooved, 1.0–1.5 mm diam. *Peduncles* up to 5, not or very shortly exserted from leaf bases, remaining erect in fruit; outer bracts green flushed purple at base with narrow colourless membranous margins, 28–35 mm long, sheathing lower part of perianth tube, closely ribbed (8 to 10 veins/mm), inner bracts with wider, colourless or brown-speckled membranous margins. *Flowers* salver-shaped, dull pink or magenta to purple (rarely white) with dark blotch in distal third and dark veins and white throat, outer tepals greenish with purple veins on reverse; perianth tube cylindric, 35–70 mm long; tepals elliptic, spreading, 10–14 × 3–5 mm. *Filaments* inserted near top of tube, exserted, 3 mm long, glabrous, white; anthers 3–5 mm long, purple-striped with whitish pollen. *Style* dividing just below to just beyond anther apices. *Capsules* oblong, 12–15 mm long, borne above ground. *Flowering time*: August, September.

Distribution of ***Romulea hantamensis***.

Distribution and ecology: a narrow endemic restricted to the summit plateau of the Hantamsberg near Calvinia in Northern Cape, South Africa; on seasonally wet dolerite flats and rock sheets in renosterveld. The distinctive flowers are adapted to pollination by the long-proboscid fly *Prosoeca* sp. (Nemestrinidae).

Diagnosis: one of the most distinctive species in the genus, *Romulea hantamensis* has salver-shaped, pink to purple flowers with the tepals strikingly marked and veined with purple with white streaks, and a cylindric perianth tube 30–70 mm long, partially concealed by long bracts 28–35 mm long. The diploid chromosome number 2*n* = 30 is unique in sect. *Roseae* although recorded for several species in sections *Romulea* and *Aggregatae*.

UNCERTAIN SPECIES

Ixia bulbocodioides D.Delaroche, Descriptiones plantarum aliquot novarum: 19 (1766). *Romulea bulbocodioides* (D.Delaroche) Eckl.: 18 (1827). Type: Unknown and identity uncertain but applied by Ecklon: 18 (1827) and Baker: 88 (1877) and later authors to *R. flava*.

Ixia fugax Hornem., Hortus regius botanicus Hafniensis 1: 50 (1813), illegitimate homonym, not *I. fugax* Salisb. (1796). Type: South Africa, without precise locality, *Masson s.n.* (possibly cultivated), (C, holo.). Identity uncertain.

Romulea barbata Baker in Journal of Botany, British and foreign 14: 236 (1876). Type: coloured drawing in Lindley Library of the Royal Horticultural Society, London, named '*Trichonema barbatum* W. Herb. (ined).' It shows a plant with elongated stem and lilac flowers with narrow tepals and style overtopping the stamens. Possibly a horticultural form.

Romulea dielsii Bég. in Malpighia 23: 96 (1909). Type: *Diels 146* (B), not found and probably destroyed. Identity unknown.

Romulea tubata Klatt in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 401 (1882). Type: *Drège 2636* (Lübeck), not seen and probably destroyed. The species is described as having an elongated stem and yellow flowers with a perianth tube twice as long as the tepals. Identity unknown.

[*Romulea zeyheri* Eckl.: 19 (1827), invalid name without description. *Trichonema zeyheri* Eckl. ex Steud.: 702 (1841), invalid name without description. Evidently based on a *Geissorhiza* species, its identity is uncertain.]

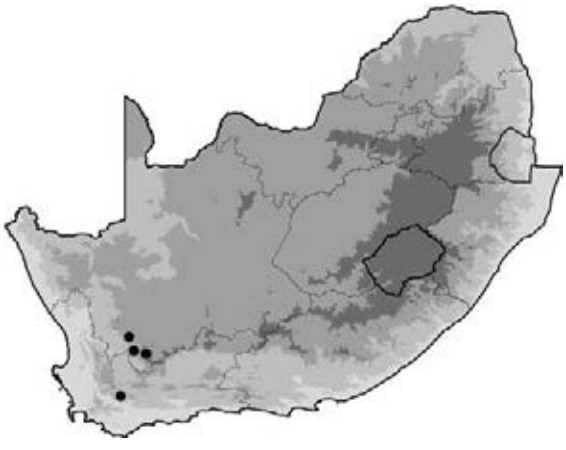
31. Afrocrocus

Afrocrocus *J.C.Manning & Goldblatt* in Goldblatt & Manning, The Iris Family: 160 (2008). Type: *A. unifolius* (Goldblatt) Goldblatt & J.C.Manning

Syringodea subg. *Rhipidopsis* M.P.de Vos: 249 (1974). Type: *S. unifolia* Goldblatt = *Afrocrocus unifolius* (Goldblatt) Goldblatt & J.C.Manning

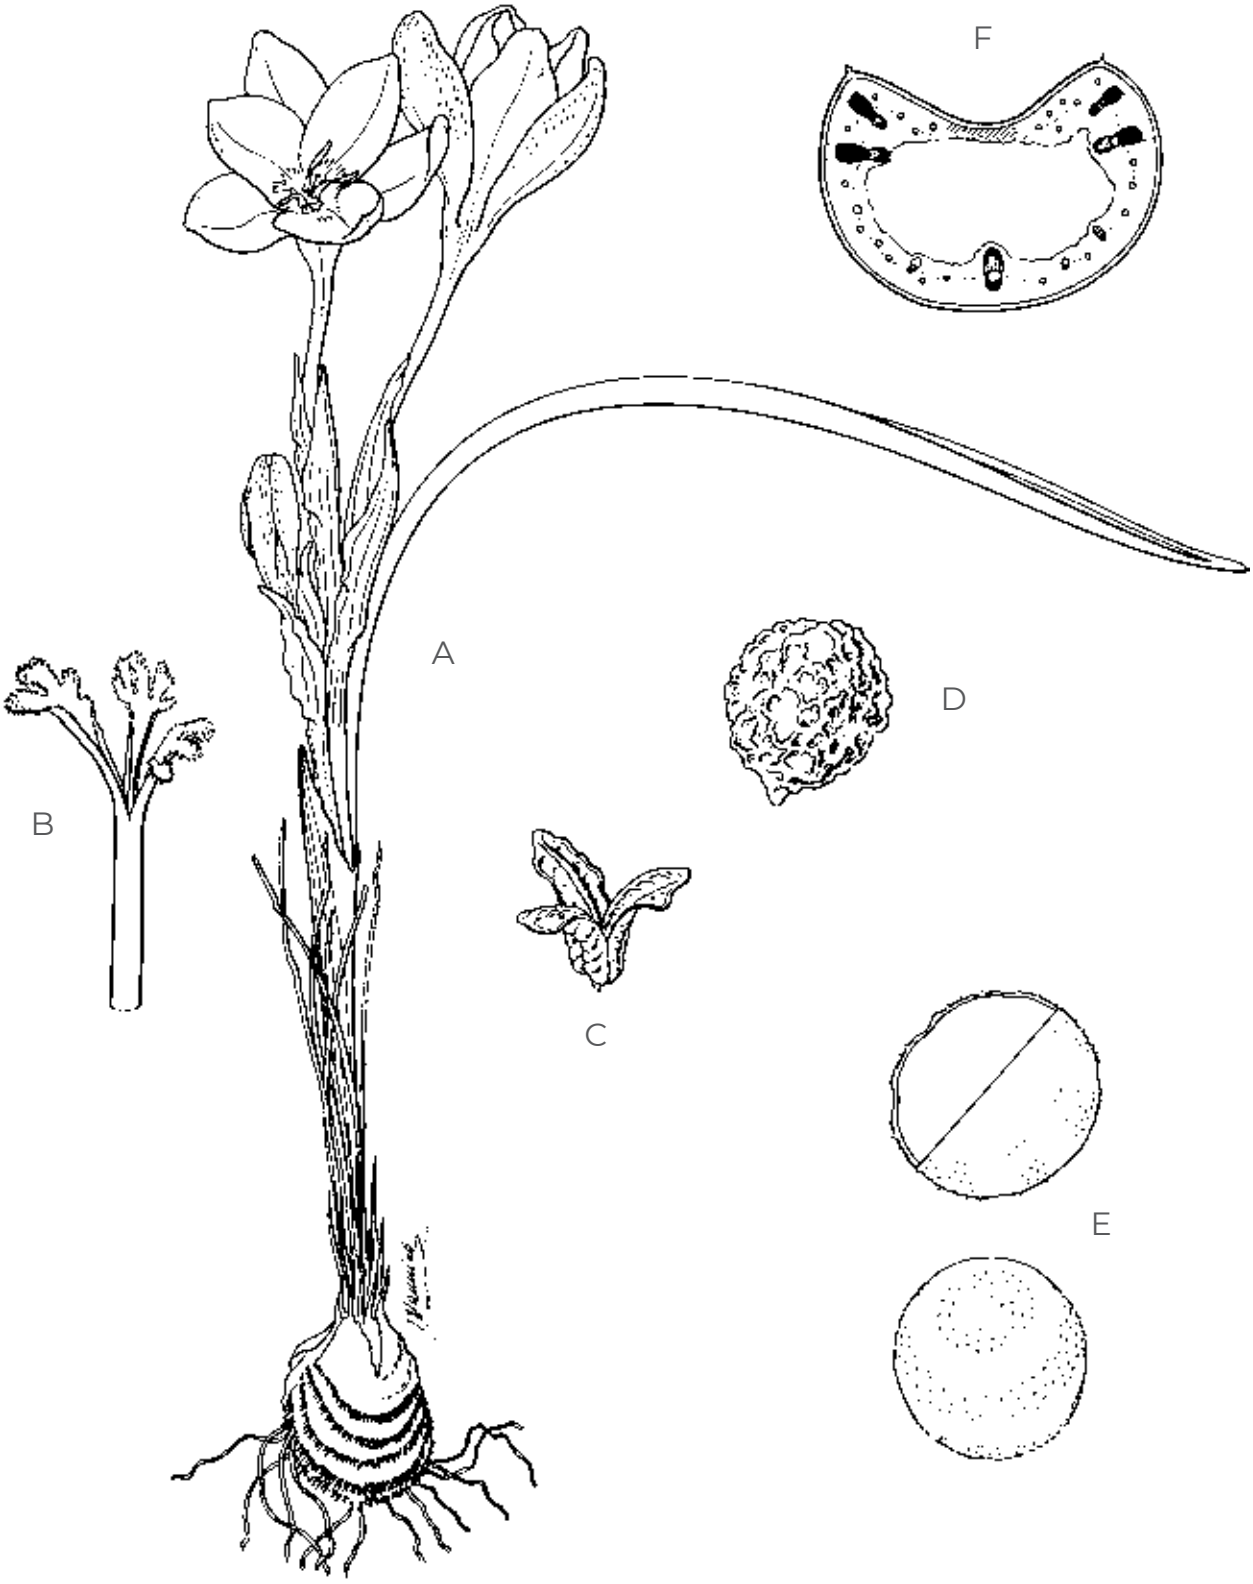
Named for its resemblance to the Northern Hemisphere genus *Crocus* and its occurrence in Africa.

Acaulescent, deciduous geophytes. *Corm* asymmetric, laterally compressed and lens-shaped with wide, fan-shaped basal ridge, axial in origin; tunics woody, splitting into fine parallel fibrils on basal ridge and into a fibrous neck at apex. *Cataphylls* 2, membranous. *Stem* short and subterranean, hidden by leaf bases. *Leaves* one or rarely two, largely bifacial, falcate with dorsal groove but shortly unifacial distally and subterete at apex, smooth or margins ciliolate. *Inflorescence* of solitary, sessile flowers terminal on axes; bracts largely membranous, outer subhyaline and minutely brown-flecked but greenish distally in midline, tubular below, acute, inner similar but two-veined and apically notched, greenish distally along veins. *Flowers* actinomorphic, long-lived, salver-shaped, blue to mauve or white, with greenish yellow or orange markings at base of tepals, unscented, opening in warm weather, nectar from septal nectaries; perianth tube elongate, narrowly trumpet-shaped; tepals subequal, spreading, obovate, concave, subacute. *Stamens* suberect, inserted near top of tube, exserted; anthers diverging, yellow. *Ovary* subterranean, ellipsoid; style filiform, 3-branched distally, branches oblanceolate, longitudinally folded, apex lacerate or shortly multifid. *Capsules* borne at ground level, ellipsoid, cartilaginous. *Seeds* subglobose, testa rugulose, glossy dark brown. *Pollen grains* globose, trizonasulculate, exine punctuate-scabrate. *Basic chromosome number x* = 11.



Species 1, only *Afrocrocus unifolius*; South Africa, semi-arid, winter-rainfall western Karoo in Northern Cape and interior Western Cape.

Afrocrocus is closely allied to the genus *Syringodea* and placed as sister to it in molecular analyses. It was initially included in *Syringodea* as the monotypic subg. *Rhipidopsis* but numerous morphological and anatomical differences between *S. unifolia* and the remaining *Syringodea* species prompted Goldblatt & Manning (2008) to treat it as the separate genus *Afrocrocus*. It is distinguished from *Syringodea* by several derived character states, notably the laterally compressed corm with subdermal sclerenchyma layers differentiated into an outermost layer of anticlinally oriented, plate-like platysclereids and a multiseriate inner layer of periclinally oriented, fusiform sclereids; the presence of a dorsal strand of subdermal collenchyma in the leaf, forming a longitudinal window in the adaxial groove; and by its trizonasulculate pollen. The loculicidal capsule, in contrast, represents the ancestral condition compared with the hygroscopic, septicidal capsules in *Syringodea*.



1. **Afrocrocus unifolius** *(Goldblatt) Goldblatt & J.C.Manning* in Goldblatt & Manning, The Iris Family: 160 (2008) [basionym cited as 1972 in error]. *Syringodea unifolia* Goldblatt: t. 1638 (1971). Type: South Africa, [Western Cape], Matroosberg, 3 miles [4.5 km] north of Matroosberg hut, *Stayner s.n.* (NBG 87602, holo.; BOL, iso.).

Plants 50–120 mm high. *Corm* laterally compressed and lens-shaped, 10–25 mm wide with wide, fan-shaped basal ridge. *Leaves* 1(2), falcate, mostly channelled with pale adaxial groove but terete distally, 50–150 mm long and 1.5–3.0 mm diam., smooth or ciliolate on margins. *Flowers* salver-shaped, pale to deep violet or white, sometimes darker at base of tepals, with greenish yellow or orange oval-shaped marking at base of tepals; perianth tube narrowly trumpet-shaped, widening in distal 5 mm, 30–40 mm long; tepals obovate, 15–30 × 7–14 mm, obtuse. *Stamens* suberect; filaments 6–9 mm long, white, ciliate or shortly bearded basally; anthers 5–10 mm long, slightly diverging, yellow or orange. *Style* 45–65 mm long, erect or curved outward distally, dividing near tips of anthers, branches ± 5 mm long, lacerate-multifid. *Capsules* ellipsoid, up to 20 mm long. *Seeds* subglobose, ± 2 mm diam., dark brown, testa rugulose. *Chromosome number* 2*n* = 22. *Flowering time*: April to June.

Distribution and ecology: restricted to the western edge of the central plateau in Northern Cape, South Africa, occurring on the Hantamsberg, Roggeveld, and on the Matroosberg and the summit of the Hex River Pass in Western Cape; on stony clay flats in open renosterveld shrubland.

Distribution of ***Afrocrocus unifolius***.

Afrocrocus unifolius: A, flowering plant; B, detail of style branches; C, dehisced capsule; D, seed; E, pollen grains; F, tissue plan of leaf transection.

Plate 72. ***Afrocrocus unifolius***, Sutherland, NC.

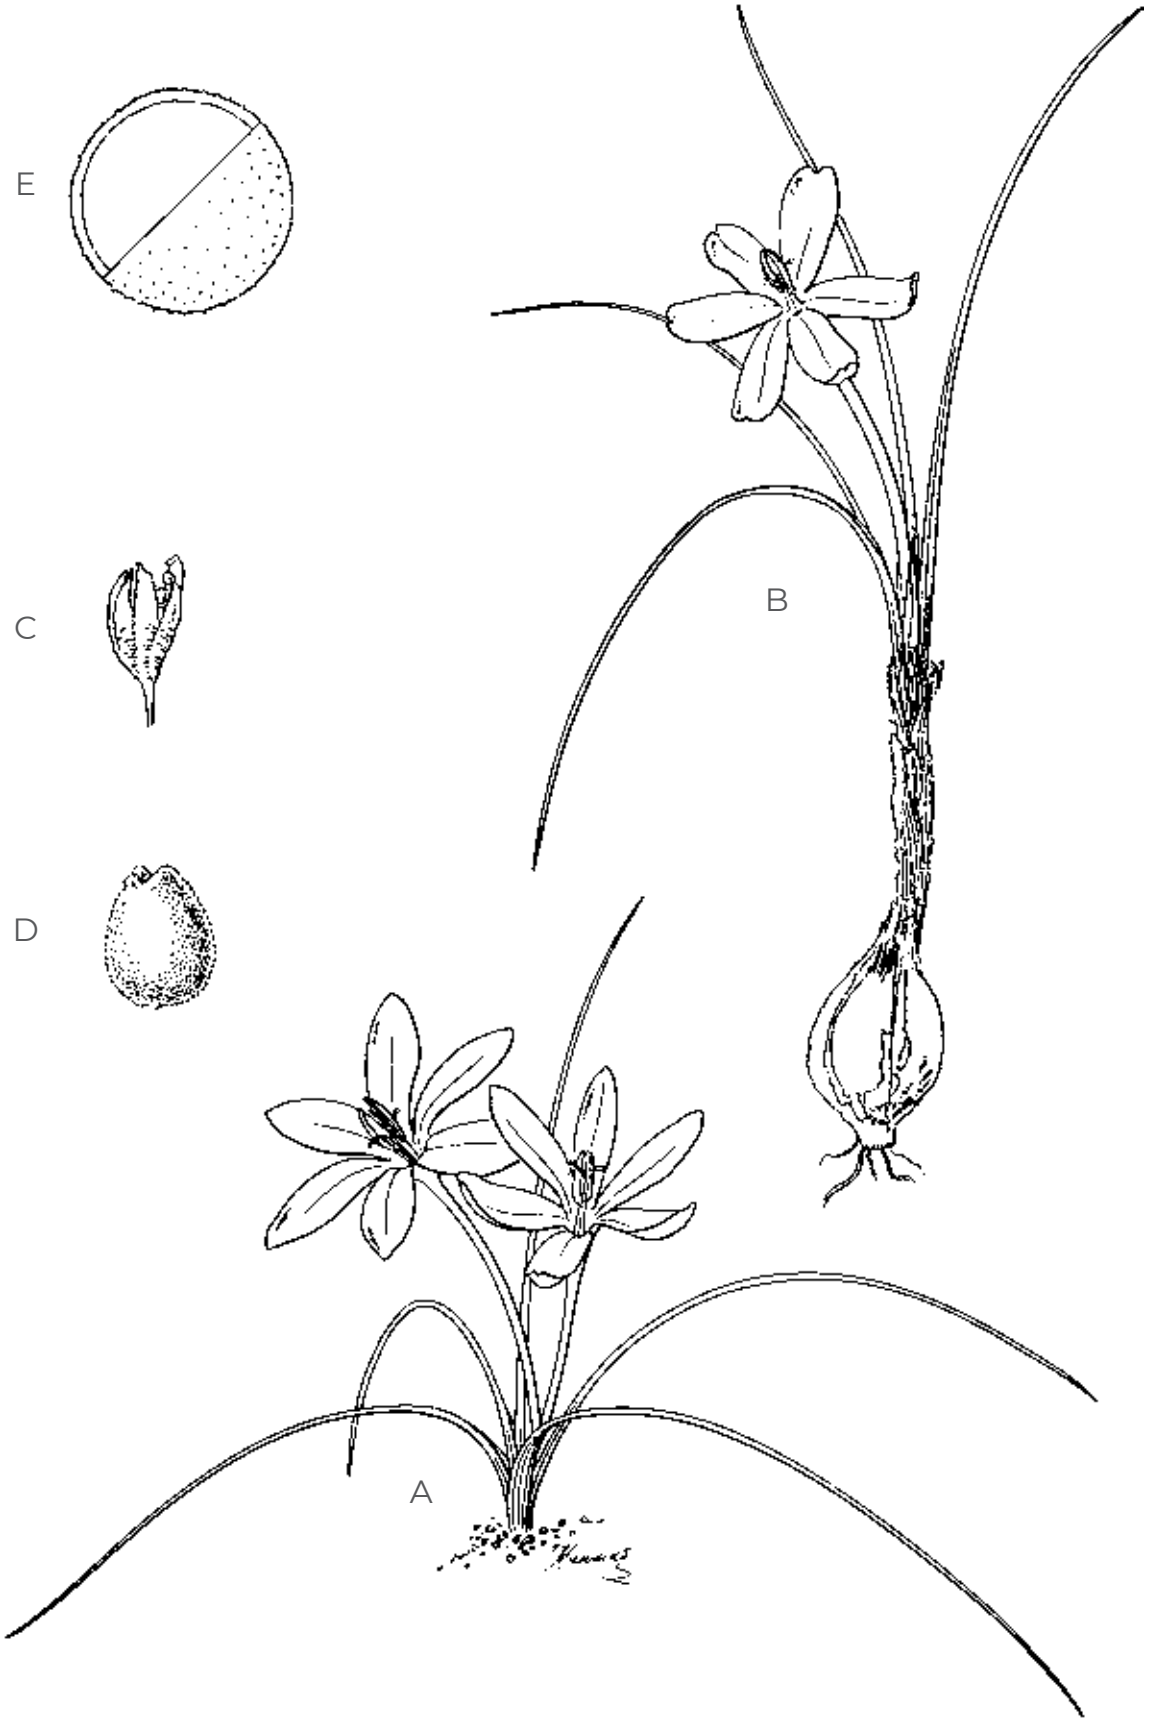
32. **Syringodea**

Syringodea *J.D.Hook* Curtis's Botanical Magazine 99: t. 6072 (1873), conserved name. Type: *S. pulchella* J.D.Hook.

Revisionary account: De Vos: 201–254 (1974).

From the Greek *syrinx*, a pipe, alluding to the long perianth tube.

Small, acaulescent, deciduous geophytes. *Corm* asymmetric, turbinate or obovoid with a short, oblique, crescent-shaped basal ridge, axial in origin; tunics papery or woody, splitting into fine parallel fibrils on the basal ridge and into a fibrous neck at the top. *Cataphylls* usually 2, membranous. *Stem* short and subterranean, hidden by the leaf bases. *Leaves* one to several, basal, suberect to prostrate, largely bifacial and linear to lanceolate and conduplicate or filiform with a dorsal groove, shortly unifacial distally and then subterete, glabrous or margins ciliolate. *Inflorescence* of solitary, sessile flowers terminal on axes; bracts largely membranous or papery, subhyaline and minutely brown-flecked but greenish distally in midline, tubular below, acute, inner similar but apically notched and greenish distally along two veins. *Flowers* actinomorphic, salver-shaped, blue to mauve or pink or white, sometimes with yellow throat, unscented, thermonastic, nectar from septal nectaries; perianth tube elongate, narrowly trumpet-shaped or cylindric; tepals subequal, spreading, obovate to elliptic, concave, acute to emarginate. *Stamens* erect, inserted near top of tube, exserted; anthers suberect or apically incurved. *Ovary* subterranean, ellipsoid; *style* filiform, 3-branched distally, branches linear or oblanceolate, conduplicate, rarely lacerate apically. *Capsules* geocarpic, clavate or turbinate with sterile pseudopedicellate base, loculicidal and septicidal, hydrochastic and splitting into six, recurved valves above when wet, shrinking longitudinally and finely transversely wrinkled when dry. *Seeds* subglobose or weakly angled, testa reticulate to foveate or colliculate, brown or black. *Pollen grains* globose, inaperturate, exine perforate-scabrate. *Basic chromosome number x* = 6.



Species 7; South Africa, mainly semi-arid areas, mostly in the winter-rainfall region including the Little and Upper Karoo and interior margins of the winter-rainfall region but extending north to southern Gauteng and east to Dordrecht in Eastern Cape.

A small genus distinguished by its acaulescent habit, woody corm tunics and largely bifacial foliage, blue to mauve, long-tubed salver-shaped flowers with a subterranean ovary, and uniquely hygrochastic capsules that open when wet rather than when dry as in other Iridaceae. The inaperturate pollen is also diagnostic. Molecular analyses confirm a close relationship with *Afrocrocus* and *Romulea*, and these three genera together with the Eurasian genus *Crocus* comprise subtribe *Crocinae.*

The genus is subdivided into the two sections *Syringodea* and *Saxatiles* based on corm shape and leaf number.

Key to species

1a Corms turbinate with very small ridge on pointed base; leaves several; foliage overtopping flowers; plants from Northern Cape near Carnarvon through Eastern Cape and Free State (sect. *Syringodea*)
  2a Perianth tube cylindric throughout, tepals bifid, pink or lilac . . . . . 4. *S. pulchella*
  2b Perianth tube slightly expended apically, tepals ± acute, blue to purple:
    3a Throat of perianth tube white . . . . . 1. *S. concolor*
    3b Throat of perianth tube yellow or orange:
      4a Diameter of open flower < 20 mm diam., tepals 5–8 × ± 2 mm . . . . . 3. *S. flanaganii*
      4b Diameter of open flower 25–55 mm diam., tepals > 10 × 4 mm . . . . . 2. *S. bifucata*
1a Corms obovoid with basal ridge 4–7 mm wide; leaves 1 to several; flowers usually overtopping foliage; plants from Western and western parts of Northern Cape (Namaqualand and Roggeveld) (sect. *Saxatiles*)
  5a Foliage leaf solitary, falcate, unifacial and terete distally or apically . . . . . 7. *S. saxatilis*
  5b Foliage leaves several, mostly or entirely bifacial:
    6a Leaves mostly 6 to 8, linear-filiform, 0.5–1.5(–2.0) mm wide, often flexuous or twisted; perianth tube 20–33 mm long and tepals 10–15 mm long . . . . . 5. *S. longituba*
    6b Leaves 3 to 5, oblong-lanceolate, 3–6 mm wide, spreading; perianth tube 25–35 mm long and tepals 15–20 mm long . . . . . 6. *S. derustensis*

SYRINGODEA. S. concolor: A, flowering plant. ***S. pulchella***: B, flowering plant. ***S. longituba***: C, dehiscing capsule; D, seed; E. pollen grain.

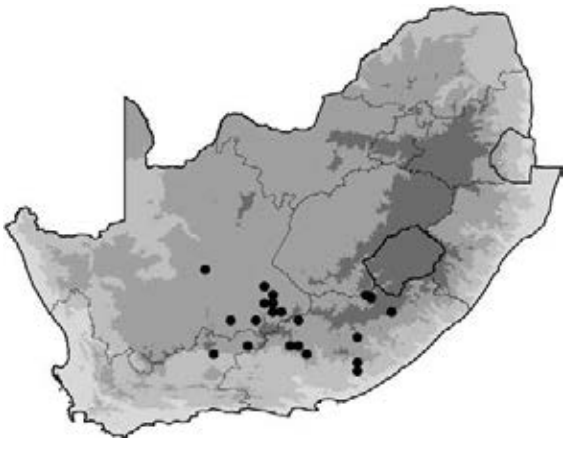
Sect. 1. **Syringodea**

Corm turbinate with very small ridge on pointed base; tunics smooth, subdermal sclerenchyma layers uniform, all sclereids periclinal, idioblasts scattered throughout layers. *Leaves* several, linear, longer than flowers.

1. **Syringodea concolor** *(Baker) M.P.de Vos* in Journal of South African Botany 40: 233 (1974). *S. bicolor* var. *concolor* Baker: 96 (1892). Type: South Africa, [Eastern Cape], Murraysburg, Farm Coetzierskraal, *Tyson 346* (K, holo.; BOL, SAM, iso.).

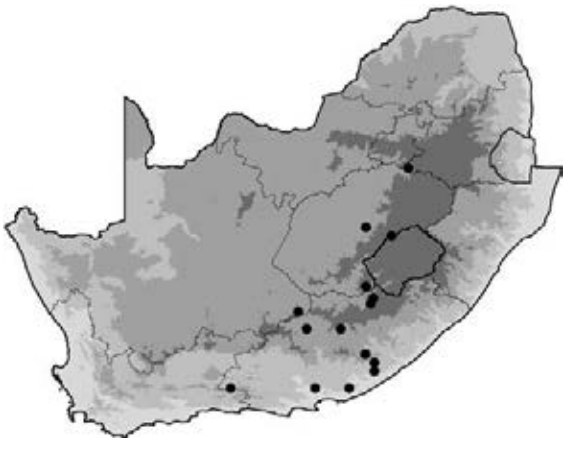
Plants (30–)100–250 mm high. *Corm* turbinate with small ridge on pointed base, 10–18 mm diam. *Leaves* 4 to 8, linear-canaliculate with pale adaxial groove, (30–)100–250 × 0.5–1.5 mm, smooth or ciliolate on margins. *Flowers* hypocrateriform, pale to deep violet, sometimes darker at base of tepals, with white throat; perianth tube narrowly trumpet-shaped, widening in distal 5 mm, (30–)50–80 mm long; tepals oblanceolate or elliptic, 12–20 × 5–9 mm, ± acute. *Stamens* erect; filaments 5–8 mm long, white; anthers 5–8 mm long, yellow. *Style* 50–85 mm long, dividing between middle and beyond anthers, branches 4–5 mm long, spathulate-lacerate. *Capsules* clavate, 12–20 mm long. *Seeds* angled, ± 1.5 mm diam., black, testa reticulate-foveate. *Chromosome number* 2*n* = 12. *Flowering time*: March, April (May).

Distribution and ecology: widely distributed through the eastern half of the Upper Karoo from Prieska, Carnarvon, Victoria West and Colesberg in Northern Cape to Grahamstown in Eastern Cape, South Africa; in washes or seasonal drainage lines on clay flats in karroid scrub and open grassland.



Diagnosis: recognised among the other summer-rainfall species in sect. *Syringodea* with a narrowly funnel-shaped perianth tube by its relatively large, pale to deep violet flowers with a white throat.

Treated by Baker (1892) as merely a variety of *Syringodea bifucata* with a pale rather than yellow throat, *S. concolor* was recognised by De Vos (1974) as a distinct species on the basis of the flower colour difference combined with darker, more finely sculptured seeds.



2. **Syringodea bifucata** *M.P.de Vos* in Flora of southern Africa 7(2, 2): 4 (1983), as a replacement name for *S. bicolor* Baker: 67 (1876), illegitimate superfluous name for *Trichonema longitubum* Klatt (1866). Type: South Africa, [Free State], Fat River [Vet Rivier], *Burke 447* [K, lecto., designated by De Vos: 235 (1974)].

Plants 60–250 mm high. *Corm* turbinate with small ridge on pointed base, (7–)10–15 mm diam. *Leaves* 4 to 8, linear-canaliculate with pale adaxial groove, 60–250 × 0.5–1.5 mm, smooth or ciliolate on margins. *Flowers* hypocrateriform, pale to deep violet or sometimes white, paler at base ± and strongly marked with yellow or orange in throat; perianth tube narrowly trumpet-shaped, widening in distal 5 mm, 45–70 mm long; tepals oblanceolate or elliptic, (12–)18–28 × 7–10 mm, ± acute or obtuse. *Stamens* erect; filaments 5–8 mm long, white or yellow; anthers 5–8 mm long, yellow. *Style* 50–75 mm long, dividing between middle and beyond anthers, branches 4–5 mm long, spathulate-lacerate. *Capsules* clavate, 15–20 mm long. *Seeds* angled, ± 1.5 mm diam., brown, testa coarsely reticulate-foveate. *Chromosome number* 2*n* = 12. *Flowering time*: (February) March, April (May).

Distribution and ecology: scattered through the eastern Great and Upper Karoo, South Africa, from Willowmore in Eastern Cape and Colesberg in Western Cape through the central parts of Eastern Cape and the central Free State to Heidelberg in Gauteng; in washes or seasonal drainage lines on clay flats in karroid scrub and open grassland.

Distribution of ***Syringodea concolor***.

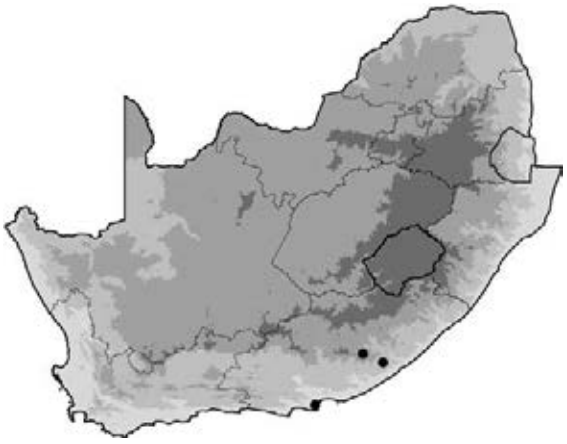
Distribution of ***Syringodea bifucata***.

Diagnosis: parapatric with *Syringodea concolor* and distinguished from it (De Vos 1974) by the yellow or orange throat and brown seeds with coarsely sculptured testa with 5 or 6 interstitial cavities per mm. The larger flowers, mostly more than 16 mm diam., distinguish it from *S. flanaganii*.

3. **Syringodea flanaganii** *Baker* in Bulletin of Miscellaneous Information, Kew 1893: 158 (1893). Type: South Africa, [Eastern Cape], top of Gonubie Hill, near Draaibos and Komgha, *Flanagan 720* (K, holo.; B, BOL, PRE, SAM, iso.).

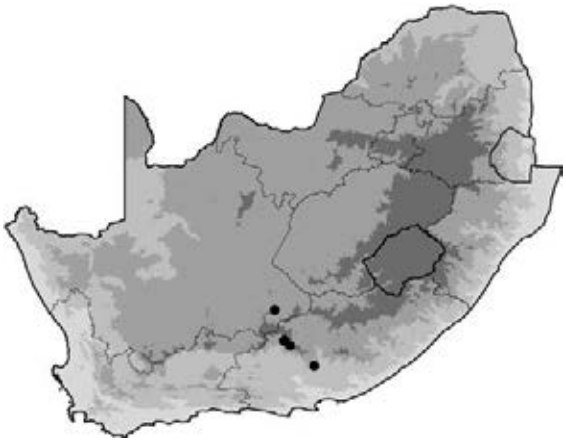
Plants 30–120 mm high. *Corm* turbinate with small ridge on pointed base, 4–10 mm diam. *Leaves* 5 to 9, linear-canaliculate with pale adaxial groove, 30–100 × 0.5–1.0 mm, smooth or ciliolate on margins. *Flowers* hypocrateriform, pale to deep violet, paler at base ± and marked with yellow or orange in throat; perianth tube narrowly trumpet-shaped, widening in distal 3–5 mm, 25–50 mm long; tepals narrowly elliptic, 5–10 × ± 2 mm, ± acute or obtuse. *Stamens* erect; filaments 2–5 mm long, white or yellow; anthers 3–5 mm long, yellow. *Style* 30–55 mm long, dividing ± at middle of anthers, branches 1–2 mm long, spathulate. *Capsules* clavate, 7–8 mm long. *Seeds* unknown. *Flowering time*: March, April.

Distribution and ecology: restricted to Eastern Cape, South Africa, from Port Elizabeth to Dordrecht; on rock sheets and stony flats in open grassland.



Diagnosis: retained as distinct from *Syringodea bifucata*, with which it shares a perianth tube marked with yellow or orange in the throat, on the basis of its much smaller flowers less than 16 mm diam., with tepals 5–10 × ± 2 mm and style branches 1–2 mm long.

4. **Syringodea pulchella** *Hook.f.* in Curtis's Botanical Magazine 99: t. 6072 (1873). Type: South Africa, [Eastern Cape], Sneeuberg Mtns, *H. Bolus 1852* (K, holo.; BOL, iso.).



Plants 120–200 mm high. *Corm* turbinate with small ridge on pointed base, 8–15 mm diam. *Leaves* 3 to 7, linear-canaliculate with pale adaxial groove, 100–250 × 0.5–1.5 mm, smooth or ciliolate on margins. *Flowers* hypocrateriform, pale pink to lilac, sometimes flushed darker at base of tepals; perianth tube cylindric throughout, 60–100 mm long; tepals oblanceolate or oblong, 12–22 × 5–7 mm, bifid or bilobed with apices slightly incurved. *Stamens* erect; filaments 3–4 mm long, white; anthers 5–9 mm long, yellow. *Style* 65–120 mm long, dividing between middle and beyond anthers, branches 4–5 mm long, spathulate. *Capsules* clavate, 20–30 mm long. *Seeds* angled, ± 1.5 mm diam., black, testa reticulate-foveate. *Chromosome number* $2n = 12$. *Flowering time*: March, April.

Distribution and ecology: endemic to the Sneeuberg and adjacent Boschberg in Eastern Cape, South Africa; on stony clay flats in karroid scrub.

Diagnosis: a distinctive species, with pale lilac flowers with notched or bifid tepals and a uniquely cylindric perianth tube 60–100 mm long and not widening at the throat.

Distribution of ***Syringodea flanaganii***.

Distribution of ***Syringodea pulchella***.

Sect. 2. **Saxatiles** *M.P.de Vos* in Journal of South African Botany 40: 238 (1974). Type species: *Syringodea saxatilis* M.P.de Vos

Corm obovoid with basal ridge 4–7 mm wide; tunics smooth or rough, subdermal sclerenchyma layers differentiated, with outermost layer of sclereids anticlinal and inner layers periclinal, idioblasts concentrated in outermost layer immediately beneath epidermis. *Leaves* 1–several, terete or linear to oblong-lanceolate, usually shorter than flowers.

5. **Syringodea longituba** *(Klatt) Kuntze* in Revisio generum plantarum 3(2): 309 (1898). *Trichonema longitubum* Klatt: 665 (1866). Type: South Africa, without precise locality, *Mund & Maire 1101* (B, holo.).

Plants mostly 40–100 mm high, solitary or clumped. *Corm* obovoid, 5–20 mm diam. with basal ridge 4–6 mm wide. *Leaves* (4)6 to 8, subterete or with median adaxial groove, sometimes only partially emergent at flowering, 15–60 × 0.5–1.5(–2.0) mm, mostly loosely coiled or helically twisted, ciliolate or ciliate on margins. *Flowers* hypocrateriform, pale to deep violet, and white or orange in throat; perianth tube trumpet-shaped, widening in distal 5 mm, (15–)20–25 mm long; tepals obovate, (8–)10–15 × (3–)4–8 mm, subacute. *Stamens* erect; filaments 3–5(–8) mm long, white, yellow or lilac; anthers suberect, 3–6 mm long, yellow. *Style* (20–)25–40 mm long, dividing near middle of anthers or beyond, branches 2–4(–5) mm long, linear-spathulate. *Capsules* clavate or turbinate, 8–25 mm long. *Seeds* angled, ± 1 mm diam., brown, testa colliculate or partly foveolate. *Chromosome number* 2*n* = 12. *Flowering time*: April to June.

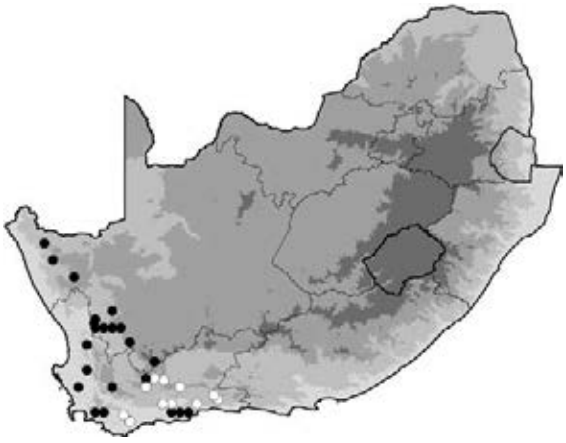
Distribution and ecology: widespread through southwestern South Africa, from northern Namaqualand, the Kamiesberg and Bokkeveld Plateau in Northern Cape to Riversdale in Western Cape; on stony flats and rock sheets in karroid or other open scrub.

Diagnosis: distinctive in sect. *Saxatiles* in its several to numerous, often loosely coiled or helically twisted leaves mostly less than 2 mm diam., and relatively small flowers with perianth tube 15–25 mm long and tepals 8–15 × 3–8 mm.

Key to subspecies

1a Throat of perianth and filaments bright yellow or orange ..... 5a. subsp. *longituba*
1b Throat of perianth and filaments white or lilac .. .. .5b. subsp. *violacea*

5a. subsp. **longituba**



Syringodea filifolia Baker: 67 (1876). Type: South Africa, without precise locality, *Bowie s.n.* (BM, holo.).

Syringodea montana Klatt: 403 (1882). Type: South Africa, [Northern Cape], Hantam Mtns, *Meyer s.n.* (B, holo.).

Syringodea leipoldtii L.Bolus: 12 (1931). Type: South Africa, [Western Cape], near Malmesbury, *Leipoldt s.n.* (BOL 191924, holo.; K, iso.).

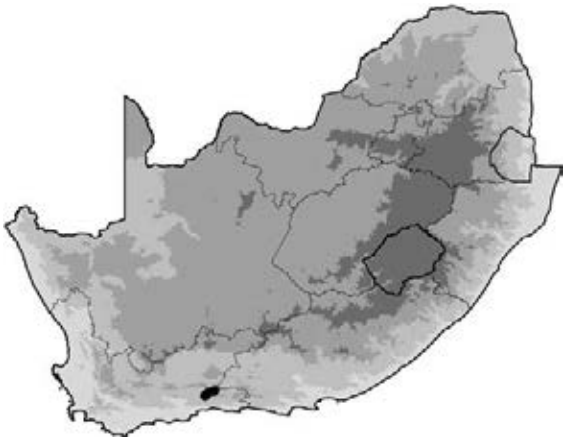
Perianth with deep yellow or orange throat. *Filaments* yellow.

Distribution and ecology: mainly in the north and west of the range of the species, from the highlands of northern and central Namaqualand and the Bokkeveld and Roggeveld Escarpments in Northern Cape to Caledon in Western Cape, with isolated populations near Riversdale.

Distribution of ***Syringodea longituba*** subsp. ***longituba***, ●; subsp. ***violacea***, ○.

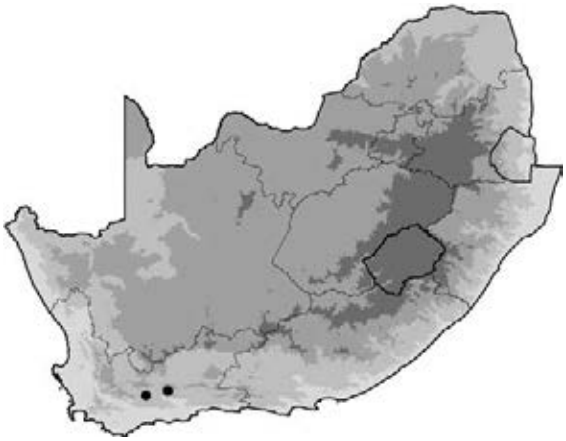
5b. subsp. **violacea** *(M.P.de Vos) Goldblatt & J.C.Manning* in Manning & Goldblatt in Strelitzia 29: 807 (2012). *Syringodea longituba* var. *violacea* M.P.de Vos: 243 (1974). Type: South Africa, [Western Cape], 12 miles [19 km] north of Muiskraal to Van Wyksdorp, *M.P. de Vos 2270* (NBG, holo.).

Perianth with white or lilac throat. *Filaments* white or lilac.



Distribution and ecology: in the south and east of the range of the species in Western Cape, from Matjiesfontein and Laingsburg through the Little Karoo to Bredasdorp and Riversdale.

6. **Syringodea derustensis** *M.P.de Vos* in Journal of South African Botany 40: 245 (1974). Type: South Africa, [Western Cape], Drinkrivier near De Rust, stony hill, *M.P. de Vos 2269* (NBG, holo.).



Plants 50–80 mm high. *Corm* ellipsoid, 10–15 × 7–12 mm with basal ridge 4–6 mm wide. *Leaves* 3 to 5, spreading, linear to lanceolate, plane or weakly conduplicate, 30–60 × 3–6 mm, ciliolate on margins, apices slightly thickened and boat-shaped. *Flowers* hypocrateriform, pale to deep violet or rarely white; perianth tube trumpet-shaped, widening in distal 5 mm, 25–35 mm long; tepals obovate, 15–20 × 8–10 mm, subacute. *Stamens* erect; filaments 5–6 mm long, white; anthers suberect, 5–7 mm long, yellow. *Style* 33–38 mm long, dividing near middle of anthers, branches 4–5 mm long, spathulate or lacerate. *Capsules* clavate or turbinate, 5–10 mm long. *Seeds* angled, ± 1.5 mm diam., brown, testa colliculate or partly foveolate. *Chromosome number* 2*n* = 12. *Flowering time*: May to June.

Plate 73. A, ***Syringodea concolor***, Hanover, NC; B, ***S. derustensis***, De Rust, WC; C, ***S. longituba*** subsp. ***violacea***, Calitzdorp, WC; D, ***S. longituba*** subsp. ***longituba***, Porterville, WC; E, ***S. pulchella***, Graaff-Reinett, EC; F, ***S. saxatilis***, Ladismith, WC.

Distribution of ***Syringodea derustensis***.

Distribution of ***Syringodea saxatilis***.

Distribution and ecology: endemic to the eastern Little Karoo, Western Cape, South Africa, between Oudtshoorn and De Rust; in stony washes on quartzite slopes.

Diagnosis: distinctive in its 3 to 5, linear to lanceolate leaves 3–6 mm wide and showy flowers with perianth tube 25–35 mm long and obovate tepals 15–20 × 8–10 mm.

7. **Syringodea saxatilis** *M.P.de Vos* in Journal of South African Botany 40: 246 (1974). Type: South Africa, [Western Cape], Ladismith, 300 m from wine cellars, among succulents, *M.P. de Vos 2264* (NBG, holo.).

Plants 40–80 mm high. *Corm* ellipsoid, 7–12 mm diam. with basal ridge 5–7 mm wide. *Leaf* solitary, falcate, unifacial and subcylindric distally or apically, bifacial and conduplicate basally with ciliolate margins, 50–120 × 1.5–2.5 mm. *Flowers* hypocrateriform, pale to deep violet; perianth tube trumpet-shaped, widening in distal 5 mm, 15–20 mm long; tepals obovate, 10–20 × 5–8 mm, subacute. *Stamens* erect; filaments 5–7 mm long, white; anthers suberect, 3–5 mm long, yellow. *Style* 20–25 mm long, dividing near middle of anthers, branches 4–5 mm long, spathulate. *Capsules* clavate or turbinate, 6–10 mm long. *Seeds* subglobose or angled, ± 1 mm diam., brown, testa colliculate or partly foveolate. *Chromosome number* 2*n* = 12. *Flowering time*: May to June.

Distribution and ecology: endemic to the western Little Karoo, Western Cape, South Africa, around Ladismith and along the southern foothills of the Anysberg; in stony washes on low quartzite or sandstone outcrops.

Diagnosis: unique in the genus in its solitary, falcate leaf with short, unifacial and subcylindric blade. The leaf in juvenile plants is entirely unifacial and terete. The close association of daughter corms with the parent may result in adult plants appearing to produce more than one leaf per corm.

EXCLUDED SPECIES

Syringodea minuta (L.f.) Klatt: 403 (1882). This is a synonym of *Pauridia minuta* (L.f.) Th.Durand & H.Schinz (Hypoxidaceae).

4. Subfamily **IRIDOIDEAE**

IRIDOIDEAE *Eaton*, A botanical dictionary, edn. 4: 28 (1836). Type: *Iris* L.

Deciduous or evergreen perennials, rarely annuals, with rhizomes, bulbs or apically rooting corms. *Leaves* unifacial or bifacial, rarely terete. *Inflorescence* units rhipidia tightly enclosed in a pair of opposed leafy bracts (rhipidial spathes) with flowers exserted serially. *Flowers* fugaceous or long lasting, actinomorphic, often with perigonal nectaries at base of tepals, often only outer whorl, or on surface of all tepals; tepals free or united below, variously coloured. *Stamens* free or filaments partly to entirely united, alternating with style branches or opposite and appressed to style branch; anthers loculicidal and extrorse or rarely porose; endothecial thickenings U-shaped, annular or helical. *Ovary* inferior; style slender or more often short, divided into 3 variously developed branches, either thread-like and stigmatic apically, or flattened and sometimes petaloid and with a pair of subapical crests above transverse stigma. *Capsules* submembranous to woody. *Seeds* angled to globose or discoid, sometimes arillate. *Pollen grains* usually monosulcate, rarely disulcate or zonosulcate, exine reticulate, retipilate, rugulate or verrucate. *Basic chromosome number x* = ?10 (many other numbers).

Genera ± 30, 4 in southern Africa; species ± 920; in 5 tribes, only Irideae in southern Africa.

Tribe **Irideae**

Irideae *M.B.Kittel* in A.Richard, Nouveaux élémens de botanique, edn. 3: 736 (German translation) (1840). Type: *Iris* L.

Subtribe *Ferrariineae* Goldblatt: 438 (1971). Type: *Ferraria* Burm. ex Miller

Subtribe *Homeriineae* Goldblatt: 438 (1971). Type: *Homeria* Vent. = *Moraea* Miller

Deciduous or evergreen perennials with rhizomes or apically rooting corms; stem well developed or subterranean. *Leaves* unifacial or bifacial, rarely terete. *Flowers* fugaceous or long lasting, tepals free or united below. *Filaments* free or united below or entirely, alternate with style branches and/or appressed or joined to opposed style branch; anthers loculicidal, extrorse or latrorse. *Style* slender, short, divided into 3 variously developed branches, either thread-like and stigmatic apically, or flattened and sometimes petaloid with paired crests above transverse stigma; seeds globose to angular or discoid. *Basic chromosome number x* = 10 (9, 8, 6, 5).

Key to genera

1a Rootstock a creeping or erect rhizome or indistinct; plants evergreen or deciduous; leaves unifacial (oriented edgewise to stem) or centric (oval or round in section):
  2a Style (to the naked eye) usually dividing into 3 slender branches, or branches flattened distally, extending between or above the anthers; tepals not clawed and usually subequal, occ. those of the outer or inner whorl smaller . . . . . 34. *Bobartia*
  2b Style usually dividing into 3 thickened or radially or tangentially compressed more-or-less petaloid branches remaining opposite appressed to the stamens; tepals subequal or those of the inner whorl smaller . . . . . 33. *Dietes*
1b Rootstock a corm; plants nearly always deciduous; leaves bifacial and channelled or unifacial or centric (oval or round in section)
  3a Foliage leaves unifacial, oriented edgewise to stem; old corms persisting for some years, with tunics membranous and soon decaying; tepals with crisped edges; style branches bearing a fringe of fine hair-like processes, collectively forming a feathery tuft . . . . . 35. *Ferraria*
  3b Foliage leaves bifacial and channelled to flat, oriented with the adaxial surface facing the stem, or terete; old corm usually resorbed annually, with persistent fibrous to woody tunics; tepals with plane or wavy edges; style branches rarely with marginal processes but other characters not as above . . . . . 36. *Moraea*

33. **Dietes**

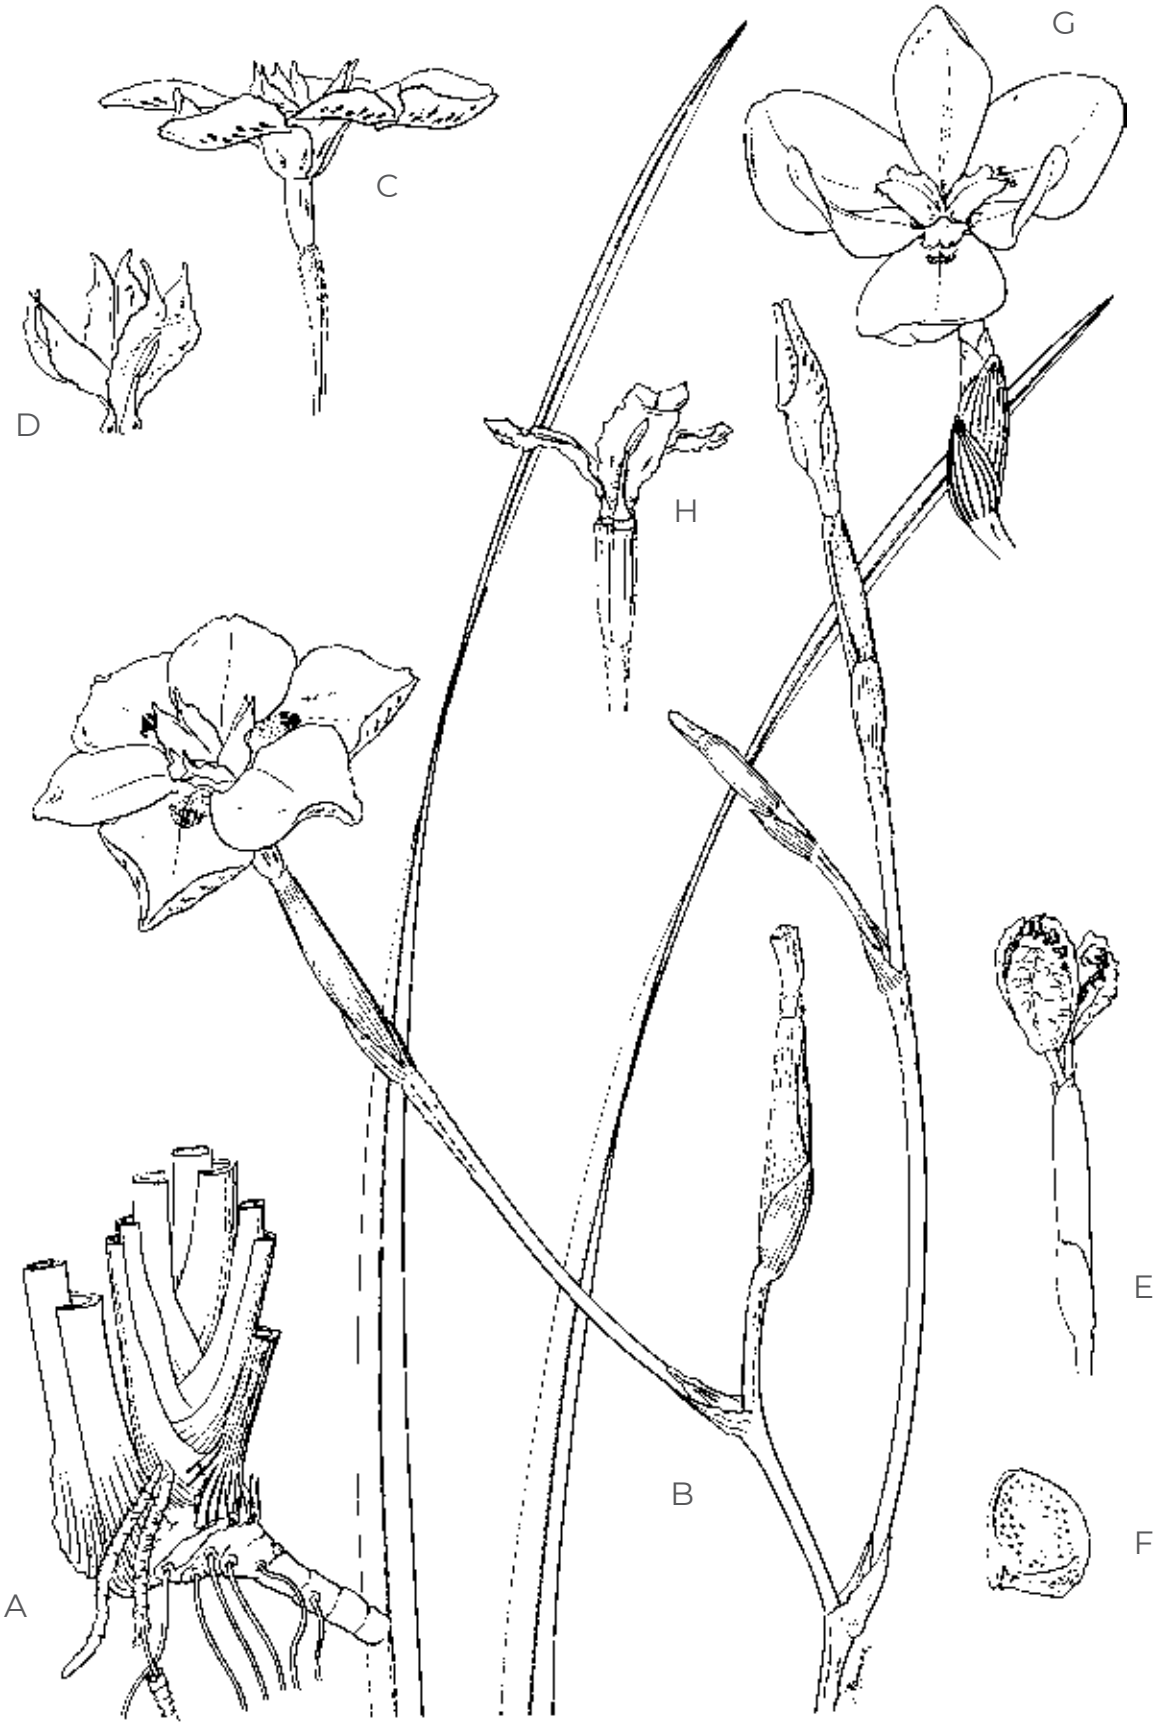
Dietes *Salisb. ex Klatt* in Linnaea 34: 583 (1866), name conserved. Type: *D. compressa* (Thunb.) Klatt = *D. iridioides* (L.) Sweet ex Klatt

Naron Medik. 6: 419 (1790). Type: *N. orientale* Medik. = *Dietes iridioides* (L.) Sweet ex Klatt

Revisionary account: Goldblatt: 132–153 (1981).

From the Greek, *di-*, two or dual, *etes*, affinities, for the mixed features of *Iris* and *Moraea* exhibited by the genus.

Plants perennial, evergreen herbs. *Rootstock* a thick, fibrotic creeping rhizome, persisting for several years. *Stem* usually erect, sometimes inclined to trailing, with foliage leaves at lower nodes and entirely sheathing bract-like leaves at upper nodes; branching irregularly in the upper half or dichotomously several-branched. *Foliage leaves* several, in 2-ranks, terminal on rhizome, tough, leathery, unifacial, linear to sword-shaped or lanceolate; margins with submarginal sclerenchyma without marginal vein. *Inflorescences* several-flowered rhipidia, flowers borne on rigid pedicels, pubescent near apices, enclosed in paired, opposed, sheathing, bract-like spathes, inner larger than outer, margins free to base. *Flowers* radially symmetric, large, pale coloured with nectar guides at bases of limbs of outer tepals, claws of outer tepals velvety to papillate in midline; tepals free, outer whorl larger, both whorls of tepals with an ascending claw and spreading limb. *Stamens* usually free; filaments with slightly expanded base or broad based and contiguous or united in lower half; anthers linear, appressed to style branches. *Ovary* green, ± cylindric, included or exserted from spathes; styles short, dividing to form 3 broad, flattened, petal-like branches terminating in paired crests, bearing transverse stigma lobes on abaxial face at base of crests. *Fruit* a many-seeded capsule, either indehiscent, or splitting partly to entirely along locule sutures. *Seeds* large, ± angular. *Pollen grains* monosulcate or zonosulcate, exine reticulate. *Basic chromosome number x* = 10.



Species 6; southern Africa to East Africa, 1 on Lord Howe Island.

All evergreen, the species of *Dietes* closely resemble in appearance and flowers various species of the northern hemisphere genus *Iris*. The broad, petaloid style branches bearing paired crests and with an anther appressed to each branch, are exactly like those of an *Iris*, as are the larger outer tepals that bear markings. *Dietes* species also have a rhizomatous rootstock as do most species of *Iris*. The differences are subtle, but include tepals free to the base whereas almost all species of *Iris* have the tepals united basally in a tube or cup. The filaments are free to the base and broadened in the lower half or in some populations of *D. iridioides* partly united and in *Iris* are joined to the tubular part of the perianth and are slender throughout. Five of the six species of *Dietes* are African, but only the white-flowered *D. iridioides* is widespread, extending from southern Western Cape into tropical Africa as far north as Kenya. The remainder are relatively narrow endemics. Only *D. robinsoniana* occurs outside Africa, and is restricted to Lord Howe Island between Australia and New Zealand, an extraordinary geographic disjunction not only for Iridaceae but for plants in general. Molecular phylogenetic studies have shown beyond doubt that *D. robinsoniana* is correctly placed to genus and is most closely related to the Eastern Cape *D. bicolor*.

Pollination of *Dietes* has not been studied but the flowers, attractive though they are, do not produce nectar and the reward to pollinating agents is uncertain. Several species are used in horticulture, especially in urban landscapes, as they are easy to propagate and drought resistant, tolerating light frost, full sun or partial shade.

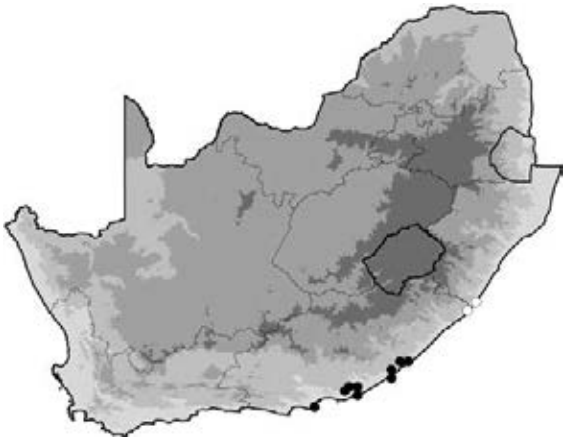
Key to species

1a Leaves 30–50 mm or more at widest point; stem irregularly branched. . . . . 3. *D. butcheriana*
1b Leaves < 25 mm at widest point; stem irregularly or dichotomously branched:
2a Tepal limbs ± round and inner overlapping outer for some distance; branching dichotomous; cauline sheathing leafy bracts 9–20 mm long, subtending branches, obviously paired . . . . . 1. *D. bicolor*
2b Tepal limbs ± obovate to lanceolate and inner not or hardly overlapping outer; branching irregular; cauline sheathing leafy bracts 25–50 mm long, some not subtending branches, not obviously paired and inner much smaller, or evidently lacking:
3a Outer tepals 45–60 mm long; style branches excluding crests 12–20 mm long; inner tepals with brown markings on claws; flowers lasting 3 days. . . . . 5. *D. grandiflora*
3b Outer tepals 24–40 mm long; style branches excluding crests 7–9 mm long; inner tepals not marked; flowers lasting a single day, rarely 2 days:
4a Flowers pale yellow with orange-brown nectar guides and yellow (occasionally blue-flushed) style branches; capsules nodding to pendent, smooth and without beak; filaments always free. . . . . 4. *D. flavida*
4b Flowers white with yellow nectar guides and blue-mauve to blue-flushed or white style branches; capsules erect, rough-walled, usually furrowed and with short beak; filaments sometimes united in lower half . . . 2. *D. iridioides*

DIETES. D. bicolor subsp. ***bicolor***: A, rhizome; B, leaves and flowering stem; C, flower side view; D, detail of stamens and style; E, dehiscing capsule; F, seed. ***D. robinsoniana***: G, flower, detail of stamens and style.

1. **Dietes bicolor** *(Steud.) Sweet ex Klatt* in Linnaea 34: 584 (1866) [*D. bicolor* Sweet (1830), invalid name]; Goldblatt: 143 (1981). *Iris bicolor* Lindl.: t. 1404 (1831), illegitimate homonym, not *I. bicolor* Miller (1758). *Moraea bicolor* Steud.: 159 (1841). Type: South Africa, without precise locality or collector, illustration in Lindl.: t. 1404 (1831).

[*Dietes bicolor* Spae: t. 70 (1846), invalid name.]



Plants 800–1 200 mm high. *Stem* erect, ± dichotomously branched. *Foliage leaves* mostly 500–800 mm long, linear, with distinct, usually double main vein, 6–12 mm wide, mostly basal, cauline leaves at lower nodes shorter; upper nodes bearing short, paired, opposite, entirely sheathing bract-like leaves, these green or becoming dry and brown, 9–20 mm long, acute, margins free to base. *Rhipidial spathes* obtuse to emarginate; inner 30–45 mm long, outer ± half as long. *Flowers* yellow to ± white, outer tepal limbs usually with solid, dark brown or orange nectar guides at bases or guides speckled, outer tepal claws densely hairy, often speckled orange to brown; outer tepals 32–35 × 20–23 mm, claws ± 12 mm long, limbs round to oblanceolate, spreading; inner tepals 25–35 × ± 18 mm, limbs spreading. *Stamens* free; filaments ± 6 mm long, broad and contiguous in lower half, filiform above; anthers 4–8 mm long. *Ovary* 9–10 mm long; style ± 2 mm long, branches 8–15 × 7–9 mm, crests 5–9 mm long. *Capsules* 18–25 × 15–20 mm, globose-truncate, dehiscing in upper half. *Seeds* angular, dark brown. *Chromosome number* 2*n* = 40. *Flowering time*: mainly spring and summer, August to February; lasting a single day.

Distribution and ecology: restricted to coastal and near interior Eastern Cape and southern KwaZulu-Natal, South Africa, extending from Port Edward to Grahamstown; along streams, riverbanks and marshy places. A record from Town Bush Valley, Pietermaritzburg, probably does not represent a native population.

Dietes bicolor is a valuable ornamental, now widely cultivated and often used as a street planting. Plants may be very free flowering, and although each flower lasts only one day, plants usually produce one or more flowers almost daily for several months.

Diagnosis: taxonomically isolated, *Dietes bicolor* is distinguished by the dichotomously branched flowering stem and pale yellow to white flowers, the outer tepal limbs usually bearing dark brown nectar guides at the bases. The tepal limbs are rounded, with the inner tepals overlapping the outer. *Dietes bicolor* is the only polyploid species of the genus and is more closely related to the Lord Howe Island species, *D. robinsoniana*, than to any of the other African species. Both share a similar dichotomous branching pattern.

Northern populations from southern KwaZulu-Natal and adjacent Eastern Cape with white to creamy white flowers and orange nectar guides are recognised as subsp. *armeniaca*, and those to the south, from Kei Mouth to Grahamstown, with yellow flowers and brown nectar guides represent subsp. *bicolor*.

Distribution of ***Dietes bicolor*** subsp. ***bicolor***, ●; subsp. ***armeniaca***, ○.

Key to subspecies

1a Inner rhipidial spathe 34–45 mm long; flowers pale yellow with solid (rarely speckled) brown nectar guides at bases of outer tepal limbs; outer tepal claws 10–12 mm long; anthers 6–9 mm long; style crests ± 5 mm long . . . . . 1a. subsp. *bicolor*

1b Inner rhipidial spathe 33–40 mm long; flowers white to creamy white, with orange nectar guides at bases of outer tepal limbs, sometimes with minute pale or dark spot in centre of guides; outer tepal claws 9–10 mm long; anthers 4.5–6.0 mm long; style crests 5–9 mm long . . . 1b. subsp. *armeniaca*

1a. subsp. **bicolor**

Inner rhipidial spathe 34–45 mm long. *Flowers* pale yellow with solid (rarely speckled) brown nectar guides at bases of outer tepal limbs; outer tepals 30–35 × 20–31 mm, claws 10–12 mm long; inner tepals 25–35 × ± 18 mm. *Anthers* 6–9 mm long. *Ovary* ± 10 mm long; style branches 8–10 × 9–12 mm, crests ± 5 mm long. *Capsules* 18–25 mm long.

Distribution and ecology: restricted to Eastern Cape, extending from near the mouth of the Kei River south to Grahamstown; at the edges of bush, usually along streams.

Diagnosis: flowers of subsp. *bicolor* are pale yellow, the outer tepal limbs with solid, dark brown nectar guides (rarely brown-speckled) and brown-spotted claws.

1b. subsp. **armeniaca** *Goldblatt & J.C.Manning* in Bothalia 45: 41 (2015). Type: South Africa, KwaZulu-Natal, Leopard Beach, riverbed, Nov. 2011, *Abbott 9381* (NBG, holo.; MO, iso.).

Inner rhipidial spathe 33–40 mm long. *Flowers* white to creamy white, with orange nectar guides at bases of outer tepal limbs, sometimes with minute pale or dark spot in centre of guides; outer tepals 23–33 × 21–29, claws

9–10 mm long; inner tepals 23–33 × 17–22. *Anthers* 4.5–6.0 mm long. *Ovary* 9–10 mm long; style branches 8–15 × 9–12 mm, crests 5–9 mm long. *Capsules* 18–20 mm long.

Distribution and ecology: extending from southern KwaZulu-Natal to the Mkhambathi Gorge in northern coastal Eastern Cape; rocky places in and along streams.

Diagnosis: distinguished by the white to palest yellow flowers with orange nectar guides and orange-spotted outer tepal claws, somewhat smaller rhipidial spathes 33–40 mm long (34–45 mm in subsp. *bicolor*), and generally slightly smaller outer tepals, 23–33 × 21–29 mm vs. 30–35 × 20–31 mm, and anthers, 4.5–6.0 mm vs. 6–9 mm long. The ovary and capsules in subsp. *armeniaca* are also slightly shorter than in subsp. *bicolor.*

2. **Dietes iridioides** *(L.) Sweet ex Klatt* in Th. Durand & H. Schinz, Conspectus florae africae 5: 186 (1894) [*D. iridioides* (L.) Sweet: 497 (1830) invalid name]; Goldblatt: 145 (1981). *Moraea iridioides* L.: 28 (1767). [*M. irioides* Gaertn.: 40 (1788), orth. var.]. *Naron orientale* Medik.: 419 (1790), superfluous name for *M. iridioides* L. *Naron iridioides* (L.) Moench: 627 (1794). *Ferraria blanda* Salisb.: 42 (1796), superfluous name for *M. iridioides* L. *Iris moraeoides* Ker Gawl.: sub t. 1407 (1811), superfluous name for *M. iridioides* L. Type: South Africa, without precise locality or collector, illustration in Miller; t. 238, f. 1 (1758).

Iris compressa L.f.: 98 (1782). *Dietes compressa* (L.f.) Klatt: 584 (1866). Type: South Africa, [Western Cape], near Seekoe River, *Thunberg. s.n.* [UPS–THUNB 1117, lecto., designated by Goldblatt: 145 (1981)].

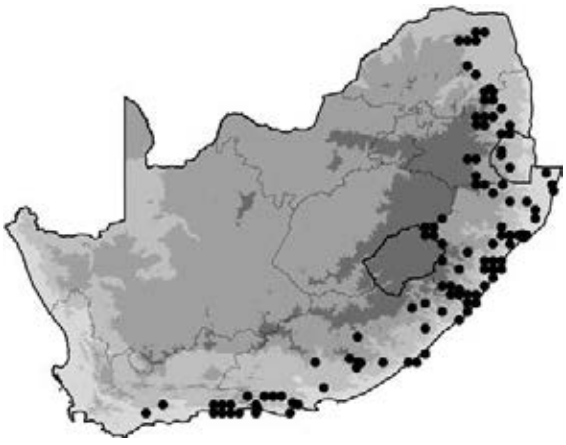
Moraea catenulata Lindl.: t. 1074 (1827). *Dietes catenulata* (Lindl.) Sweet ex Klatt: 585 (1866). *Iris catenulata* (Lindl.) Baker: 147 (1877). *M. iridioides* var. *catenulata* (Lindl.) Baker: 60 (1892). Type: Mauritius, *R. Barclay*, illustration in Lindl.: t. 1074 (1827).

Moraea iridioides var. *prolongata* Baker: 26 (1896). [*M. prolongata* Baker: 60 (1892), invalid name only in synonymy.] *Dietes prolongata* (Baker) N.E.Br.: 37 (1928). Type: South Africa, without precise locality, ex hort. Leichtlin (K, likely holo.).

Dietes prolongata var. *galpinii* N.E.Br.: 37 (1928). Type: South Africa, Transvaal [Mpumalanga], near Barberton, *Galpin 1206* [K, lecto., designated by Goldblatt: 150 (1981)].

[*Dietes iridifolia* Salisb.: 307 (1812), invalid name.]

[*Iris crassifolia* G.Lodd.: t. 1861 (1832), invalid name without description (but accepted by some authorities). *Dietes crassifolia* G.Lodd. ex G.Don in Sweet: 661 (1839), invalid name without dsecription.]



[*Dietes macleayi* Baker: 60 (1892), invalid name only in synonymy.]

subsp. **iridioides**

Plants (150–)300–600 mm high. *Stem* suberect or inclined, irregularly branched, bearing entirely sheathing bract-like leaves from cauline nodes 25–30 mm long, grey-green, often becoming dry and brownish distally; old stem often arching toward ground and producing terminal clusters of leaves, these later taking root. *Foliage leaves* shorter or longer than stems, 250–400(–600) mm long, linear to sword-shaped, (6–)10–15(–25) mm wide. *Rhipidial spathes* obtuse to emarginate; inner 35–50(–55) mm long, outer ± half to nearly $^{2}/_{3}$ as long. *Flowers* white with speckled yellow nectar guides at bases of outer tepal limbs, claws of outer and sometimes inner tepals dotted orange or brown either side of midline with raised central ridge of velvety hairs; style branches blue-violet or white, then often flushed with blue; outer tepals 24–35 × 12–20 mm, claws ± 16 mm long, velvety in midline, limbs spreading to recurved distally; inner tepals (16–)24–30 × 9–13 mm, limbs ± spreading. *Filaments* 5–9 mm long, united below or broader and contiguous in lower ± 3 mm or free and not contiguous; anthers 3–6 mm long; pollen creamy white or pale mauve. *Ovary* 8–15 mm long, lightly ridged; style 2–3 mm long, branches 7–9 × 4–6 mm, crests ± 5 mm long. *Capsules* ± ellipsoid to ± cylindric, usually beaked, 20–30 × 14 mm. *Seeds* angular, dark brown. *Chromosome number* 2*n* = 20. *Flowering time*: sporadic during spring and summer, blooming earliest in areas of winter rainfall; lasting a single day, rarely two days.

Distribution and ecology: the most widespread and common species of the genus, extending from southern Western Cape, South Africa, near Riviersonderend, through eastern southern Africa to Kenya, also local in Angola where subsp. *angolensis* occurs; usually in shade in evergreen forest, often near streams, occasionally in thorn thicket.

Diagnosis: distinguished by its relatively small white flowers usually with pale blue-mauve to violet style branches, usually uniformly white inner tepals, and elongate capsule with a short beak. The capsules are roughly fissured longitudinally and usually tardily dehiscent, sometimes appearing indehiscent. Plants often produce

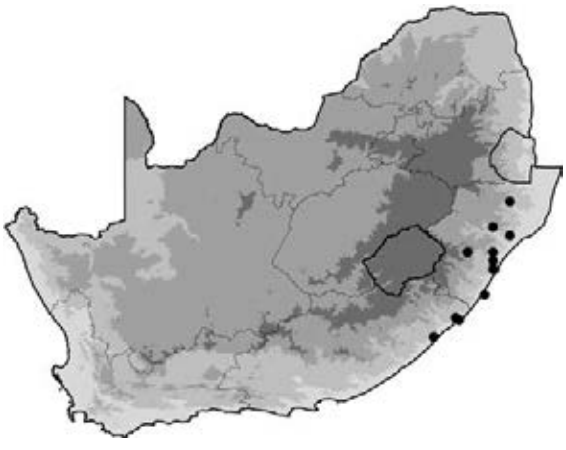
Distribution of ***Dietes iridioides*** subsp. ***iridioides***.

new clusters of leaves at the tips of old flowering stems, these arching to the ground where they take root.

Plants in the southern part of its range, in southern Western Cape between the Riviersonderend Mtns and Humansdorp have filaments united in the lower half and form a bulbous column towards the base. Further north in Eastern Cape, plants have filaments with similar broad bases but these are free although contiguous. Elsewhere filaments are narrower, with only slightly expanded bases and usually not contiguous.

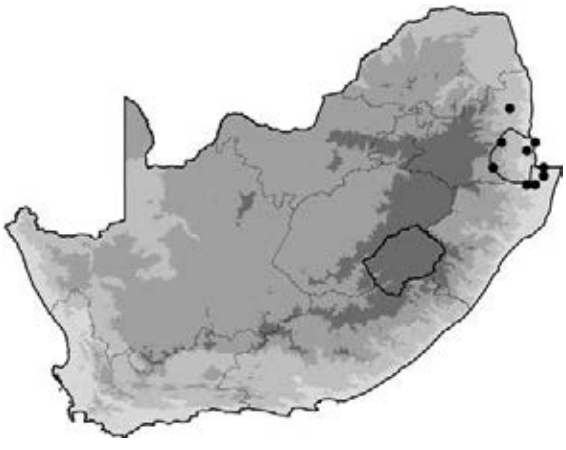
3. **Dietes butcheriana** *Gerstner* in Journal of South African Botany 9: 149 (1943); Goldblatt: 150 (1981). Type: South Africa, [KwaZulu-Natal], Nkandla Forest, *Gerstner 601* [NH, lecto., designated by Goldblatt: 150 (1981)].

Plants mostly 500–900 mm high. *Stem* inclined, often somewhat flexuose, bearing sheathing leaves at upper nodes 30–60 mm long; irregularly few-branched, branches relatively short. *Foliage leaves* usually exceeding stem, up to 1 000 mm long, sword-shaped, 30–48 mm wide. *Rhipidia* ± obtuse or emarginate, dark green; inner 45–60 mm long, outer ± half as long. *Flowers* white with speckled yellow nectar guides at bases of outer tepals, claws of both whorls speckled orange, style branches white; outer tepals 30–35 × 13–20 mm, claws ± 12 mm long, densely hairy, limbs ± spreading; inner tepals 25–35 × ± 12 mm, limbs spreading. *Stamens* free; filaments ± 6 mm long, ± filiform throughout; anthers ± 4.5 mm long. *Ovary* ± 10 mm long; style ± 3 mm long, branches 7–9 × 6–8 mm, crests 5–10 mm long. *Capsules* subglobose, 25–35 × 20 mm, smooth, nodding, indehiscent, decaying to release seeds. *Seeds* angular, dark brown. *Chromosome number* 2*n* = 20. *Flowering time*: sporadic, mainly spring and summer; lasting a single afternoon.



Distribution and ecology: South Africa, occurring in coastal KwaZulu-Natal and northern Eastern Cape as far south as Port St Johns; in shade in coastal and mistbelt forest.

Diagnosis: recognised by its very broad leaves, mostly 30–50 mm wide, *Dietes butcheriana* has white flowers closely resembling those of *D. iridioides* but with white rather than blue-purple flushed style branches. The large capsules, up to 35 × 20 mm, are pendent and have a smooth surface and rounded apex quite different from the beaked and wrinkled capsules of *D. iridioides* and are indehiscent, the walls slowly decaying to release the seeds.

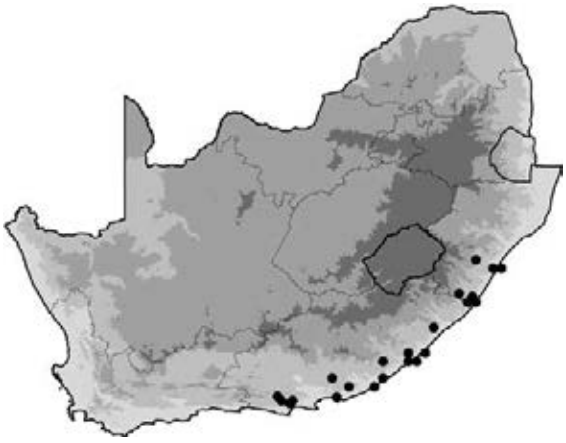


4. **Dietes flavida** *Oberm.* in Flowering Plants of Africa 38: t. 1488 (1967); Goldblatt: 148 (1981). Type: South Africa, [KwaZulu-Natal], Jozini Dam, *Admiraal 5293* (PRE, holo.).

Plants 500–700 mm high. *Stem* ± erect, inclined or trailing, bearing entirely sheathing, bract-like leaves 30–50 mm long at upper nodes, branching irregularly. *Foliage leaves* 300–500 mm long, narrowly sword-shaped, 15–22 mm wide; bract-like leaves at upper nodes entirely sheathing. *Rhipidial spathes* obtuse to emarginate; inner 40–50 mm long, outer ± half as long. *Flowers* pale yellow to creamy white, with speckled, orange-brown nectar guides at bases of outer tepal limbs and spotted on claws, inner tepal claws sometimes spotted brown in 2 lines; outer tepals 30–40 × 15–17 mm long, claws ± 15 mm long, limbs spreading; inner tepals smaller, 27–38 mm long, limbs spreading. *Stamens* free; filaments 4–6 mm long, broad and contiguous in lower half, filiform above; anthers 5–6 mm. *Ovary* 10–14 mm long; style 2–3 mm long, branches ± 8 × 3–4 mm, crests 5–10 mm. *Capsules* ovoid, nodding to pendent, smooth, 30–35 × ± 12 mm, dehiscing irregularly, not along suture lines. *Chromosome number* 2*n* = 20. *Flowering time*: sporadically during the summer months.

Distribution and ecology: occurring in the southern Lebombo Mtns of Eswatini, northern KwaZulu-Natal, South Africa, and adjacent southern Mozambique (possibly in southern Mpumalanga); along forest margins, cliffs and lightly shaded areas, sometimes along streams.

Distribution of ***Dietes butcheriana***.



Distribution of ***Dietes flavida***.

Diagnosis: closely related to the widespread *Dietes iridioides* and easily confused with it, *D. flavida* has pale yellow flowers of much the same size and proportions and the outer tepals with brown-spotted nectar guides. The style branches are usually also creamy yellow or rarely very lightly flushed with purple, and the leaves have a greyish waxy covering. The capsules of *D. flavida* are ± ovoid, nodding to pendent, with a completely smooth surface and dehisce irregularly instead of along the carpel sutures. The ± cylindric capsules of *D. iridioides* are usually distinctly beaked, with an irregular, fissured surface, and eventually dehisce from the apex downwards for some distance, sometimes seemingly indehiscent.

5. **Dietes grandiflora** *N.E.Br.* in Journal of the Linnean Society, Botany 48: 35 (1928); Goldblatt: 150 (1981). Type: South Africa, [Eastern Cape], Kentani, *A. Pegler 484* (K, lecto., designated by Goldblatt: 150 (1981); BOL, isolecto.).

Plants mostly 1.1–1.5 m high. *Stem* erect, irregularly branched, bearing short, entirely sheathing bract-like leaves at upper nodes 25–50 mm long, apices obtuse apiculate. *Foliage leaves* 750–1 000 mm long, ± linear, 10–15(–20) mm wide. *Rhipidial spathes* obtuse to emarginate; inner 50–80 mm long, outer ± half as long. *Flowers* white, outer tepal limbs with velvety, yellow nectar guides at bases and dotted on claws, inner tepals streaked dark brown either side of white midline, style branches pale blue-mauve; outer tepals mostly 45–60 × 25–35 mm, claws 20–26 mm long, with a dense yellow beard along midline, limbs spreading or curving down distally; inner tepals (36–)40–45 × 22–25 mm, limbs spreading. *Stamens* free; filaments 10–13 mm long, broad and contiguous at bases tapering to slender upper half; anthers 7–10 mm long. *Ovary* 13–16 mm long; style ± 5 mm long, branches 12–20 × 6–8 mm, crests 12–15 mm long. *Capsules* ± ellipsoid, 28–45(–50) mm long, ridged and furrowed vertically. *Seeds* angular, dark brown. *Chromosome number* 2*n* = 20. *Flowering time*: sporadic, during spring and summer; usually lasting 3 days.

Distribution of ***Dietes grandiflora***.

Distribution and ecology: South Africa, extending from Inanda near Durban in southern KwaZulu-Natal in the north, to Grahamstown in Eastern Cape in the south; along the margins of bush and forest, sometimes along streams.

Diagnosis: the largest-flowered species of the genus, *Dietes grandiflora* is easily recognised not only by the larger flowers, which last three days in contrast to those of other members of the genus, but also by the floral markings. The white outer tepals are conspicuously marked with a velvety, yellow nectar guide at the base of the limbs, and a yellow velvety band in the centre of the claws while the inner tepals have dark brown lines either side of the pale midline. The flowers in well-grown plants may be up to 100 mm in diam.

The species is widely cultivated in areas of warm temperate and subtropical climates, and it will withstand light frost. Once established, the plants are extremely persistent even when neglected.

34. **Bobartia**

Bobartia *L.*, Species plantarum: 54 (1753). Type: *B. indica* L.

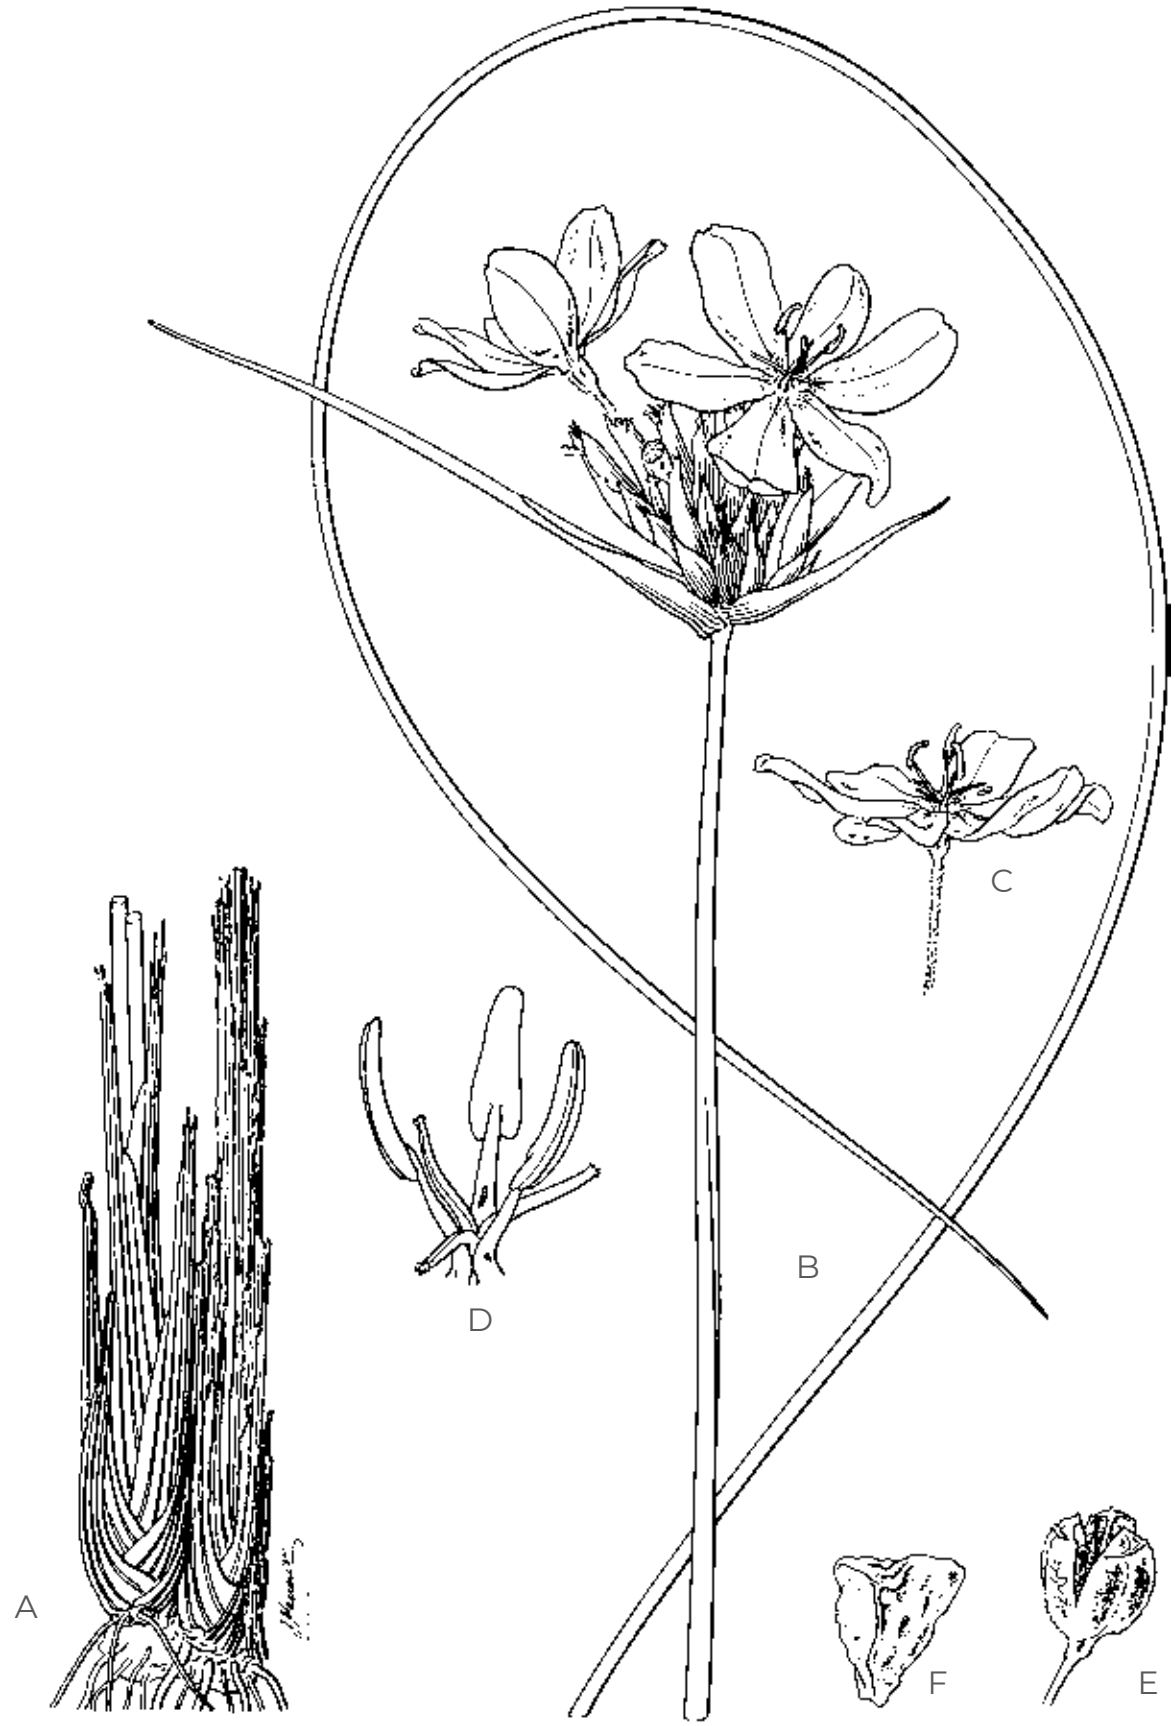
[*Hecaste* Sol. ex Schumach.: 10 (1793), invalid name only in synonymy.]

Revisionary account: Strid: 1–45 (1974).

Named for Jakob Bobart (1641–1719), German botanist and first curator of the botanic garden at Oxford, England.

Evergreen, mostly tufted perennials with creeping or erect rhizomes, often compact and corm-like. *Flowering stem* aerial, terete or flattened, usually with basal internode greatly elongated, laxly paniculately branched with sticky internodes in two species, smooth or minutely striate-furrowed. *Leaves* several, mostly basal, linear in 2 ranks or terete and usually resembling flowering stem, smooth or minutely striate-grooved, sometimes long and trailing, uppermost cauline leaf (spathe) subtending inflorescence, either green and leaf-like or dry and fibrous; margins when leaves plane with submarginal sclerenchyma without marginal vein. *Individual inflorescences* few- to several-flowered rhipidia, each solitary or usually few to many crowded in a tight cluster subtended by a prominent bract, usually with several additional overlapping bracts; rhipidial spathes green and leathery; pedicels ± hairy distally. *Flowers* actinomorphic, fugaceous, stellate or rotate, usually yellow, rarely deep blue (blue-mauve), unscented; with traces of nectar from septal nectaries; tepals free or rarely united in a short tube, subequal, spreading, without obvious claws. *Stamens* free, suberect; filaments slender; anthers yellow. *Ovary* excluded or included in rhipidial spathes, obovoid to top-shaped, smooth or tuberculate; style short, dividing into 3 filiform branches extending between filaments, stigmatic apically. *Capsules* ovoid-truncate, woody, with septa separating from central axis. *Seeds* numerous, angular. *Pollen grains* monosulcate, exine reticulate. *Basic chromosome number x* = 10.

Species 17, South Africa, in Western Cape and Eastern Cape, mainly on sandstone slopes or sandy flats in fynbos.



The genus comprises evergreen, often tufted, rhizomatous perennials with tough, fibrous leaves, these either plane and isobilateral or terete in section. The rhizomes are short and contracted, with each season's growth resulting in a rounded, corm-like increment. In most species the flowering stem consists of the basal, much elongated internode, and in many species both stems and leaves bear fine, longitudinal intercostal furrows containing the stomata surrounded by papillae or short hairs. The pedicels are ± hairy in the upper part just beneath the ovary and the flowers are rotate with six, subequal, spreading tepals, free suberect stamens, and a short style dividing into three slender branches stigmatic only at the tips. The individual inflorescences are few-flowered rhipidia. In most species these are crowded into a more-or-less dense head (a synflorescence), but *Bobartia paniculata* and *B. lilacina* have a laxly branched stem, the branches with sticky nodes and each bearing a single rhipidium. Similar branched stems with sticky nodes are characteristic of the early branching lineages in both *Ferraria* and *Moraea* and thus may represent the ancestral condition. The flowers are similar throughout the genus and yellow, except in *B. lilacina*, which has dark blue (blue-mauve) flowers. *Bobartia anceps* and *B. macrospatha* are exceptional in having the ovary included in the spathes, with the perianth usually exserted on a short tube.

There is an evident transition series from the laxly branched stem with two or three well-developed internodes in *Bobartia lilacina*, through *B. paniculata*, in which the stem is formed largely from the basal internodes but the flowering stem is laxly branched, to the remaining species in which the unbranched stem is formed entirely from the basal internode with several to many rhipidia crowded in a somewhat head-like synflorescence.

Molecular DNA sequence data associate *Bobartia* with the other genera of African Iridoideae *Dietes, Ferraria* and *Moraea*, where it appears most closely allied to *Dietes*, with which it shares hairy pedicels and the presence of fibres in the phloem tissue of the leaves. The morphologically simple flowers are evidently a reversal from the more complex *Iris*-type characterised by dimorphic tepal whorls and petaloid style branches.

The two species with laxly branches stems, *Bobartia lilacina* and *B. paniculata*, were segregated from the remaining species as sect. *Ramosae* by Lewis (1945) but the detailed anatomical investigations by Strid (1974) suggest that the relationships among the species are more complex. On the basis of stem anatomy Strid (1974) recognised three groups of species: 1. Stem without sclerenchyma strands; stomatal furrows and hairs lacking; cuticle thin; vascular bundles without sclerenchyma caps (*B. lilacina*); 2. Stem with sclerenchyma strands; stomatal furrows and hairs lacking; cuticle thick; vascular bundles with sclerenchyma caps (*B. filiformis, B. gladiata, B. paniculata*); 3. Stem with sclerenchyma strands; stomatal furrows and hairs present; cuticle thick; vascular bundles with sclerenchyma caps (all other species). Combining these anatomical observations with inflorescence structure suggests to us that a more natural classification recognises the four sections *Ramosae*, *Paniculatae*, *Gladiatae* and *Bobartia*.

Microscopic examination is necessary to determine whether or not the stomata are confined to intercostal furrows, especially in dried specimens where shrinkage

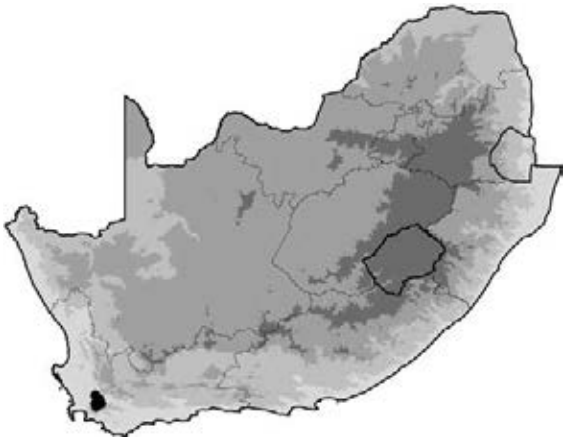
BOBARTIA. ***B. indica***: A, rhizome; B, flowering stem and leaf; C, flower; D, detail of stamens and style. ***B. fasciculata***: E, dehiscing capsule; F, seed.

causes superficial intercostal striations to form between the subdermal sclerenchyma ridges in those species in which they are present. The stems of *Bobartia lilacina* are unique in lacking sclerenchyma strands and are thus always smooth whereas those of *B. filiformis, B. gladiata* and *B. paniculata* are smooth when fresh but develop minute, shallow intercostal grooves when dry. The remaining species have stems that are finely and closely striate, with the papillae or hairs that occlude the stomatiferous intercostal furrows evident under high magnification.

The taxonomy of the genus remains problematic, despite the careful work by Strid (1974), and the circumscriptions of some species remain to be fully resolved.

Flowers in *Bobartia* last less than a day each, but preliminary observations reveal differences in the timing of anthesis among species, viz. flowers of *Bobartia indica* open mid-morning and fade mid-afternoon whereas those of *B. gladiata* open only in the late afternoon. Detailed observations are lacking for other species.

Key to sections and species



1a Rhipidia solitary and terminal on branches; stems sticky below nodes; leaves plane:
2a Stem with lower 2 internodes both well-developed; flowers deep blue (blue-mauve) [sect. 1. *Ramosae*] . . . . . 1. *B. lilacina*
2b Stem with lowermost internode greatly elongated and succeeding ones reduced; flowers yellow [sect. 2. *Paniculatae*]. . . . . 2. *B. paniculata*
1b Rhipidia several and congested, usually ± capitate in crowded synflorescence; stem not sticky below nodes:
3a Stem without stomatal furrows (smooth when fresh but shallowly grooved when dry), often linear and flattened; spathes always leaf-like; rhipidia only 1 to 6 per stem [sect. 3. *Gladiatae*]:
4a Stem 2.5–8.0 mm wide; synflorescence strongly flattened; inner rhipidial spathes 25–65 mm long . . . . . 5. *B. gladiata*
4b Stem up to 2 mm wide; synflorescence of 1 or more rhipidia but not flattened; inner rhipidial spathes 25–45 mm long:
5b Stem linear, ± 2 mm wide; synflorescence of 3 to 6 rhipidia; plants from Outeniqua Mtns . . . . . 3. *B. vlokii*
5b Stem linear or terete and up to 1.5 mm diam.; synflorescence of a solitary (rarely 2 or 3) rhipidium; plants from west of the Langeberg . . . . . .4. *B. filiformis*
3b Stem with numerous, fine stomatal furrows (apparently smooth at low magnification but with numerous, fine furrows lined with papillae or hairs visible at higher magnification), usually terete; subtending bract either leaf-like or dry and fibrous; rhipidia few to many crowded together [sect. 4. *Bobartia*]:
6a Ovary not exserted from rhipidial spathes and capsules remaining enclosed; pedicels 2–6 mm long; perianth tube absent or up to 7 mm long:
7a Stem and leaves terete or subterete; subtending bract ± brown and fibrous, dilated and partly sheathing synflorescence; rhipidia up to 15 in an obovoid head, suberect, inner spathe mostly 15–20 mm long; capsules 8–10 mm long . . . . . 16. *B. macrospatha*
7b Stem and leaves flat, rarely subterete; subtending bract green and leaf-like, narrow, not much expanded at base or sheathing synflorescence; rhipidia 15 to 40 in a globose head, spreading, inner spathe 12–15 mm long; capsules subglobose to broadly oblong, 5–8(–10) mm long. . . . . 17. *B. anceps*
6b Ovary and capsule exserted from rhipidial spathes; pedicels at least 8 mm long; perianth tube always lacking:
8a Subtending bract fibrous, grey or brown, dilated or expanded and ± sheathing young synflorescence:
9a Plants 150–400 mm high, slender; synflorescence narrow, of 3 to 7 rhipidia, ± completely enclosed by dark reddish or chestnut-brown subtending bract; capsules smooth; plants from Langeberg . . . . . .15. *B. parva*
9b Plants > 500 mm high; synflorescence of > 12 rhipidia; capsules smooth or tuberculate:
10a Stem 3–6 mm diam.; subtending bract usually green in upper part; tepals 20–32 mm long, inner > half as wide as outer; capsules conspicuously rugose to muricate; plants from southern coastal regions . . . . 14. *B. robusta*
10b Stem 1–4 mm diam.; subtending bracts usually entirely dry; tepals 16–23 mm long, inner half as wide as outer; capsules smooth to tubercled, plants from west coast mountains:
11a Synflorescence globose with rhipidia in distinct fascicles of 2 to 6; outer rhipidial spathe greyish brown and much shorter than inner spathes . . . . . 12. *B. fasciculata*
11b Synflorescence obconic, flat-topped, with rhipidia not or indistinctly grouped in fascicles; outer rhipidial spathe dark reddish brown, acuminate and not much shorter than inner spathe . . . . . 13. *B. rufa*
8b Subtending bract narrow, leaf-like, green or with a well-developed foliar tip, not or scarcely sheathing young synflorescence:
12a Leaves flexible, much longer than stem; subtending bract suberect or horizontally spreading; pedicel densely villous distally . . . . . 8. *B. indica*
12b Leaves about as long as stem; subtending bract usually suberect or erect; pedicels puberulous to villous:
13a Synflorescence of 10–80(–120) rhipidia; inner rhipidial spathes 10–18 mm long; capsules 4–6 mm long . . . . . 9. *B. orientalis*
13b Synflorescence of up to 10(–20) rhipidia; inner rhipidial spathes 18 mm or more long:
14a Ovary and capsules papillate or tubercled; subtending bract often greatly prolonged appearing as an extension of stem, synflorescence thus apparently lateral . . . . . 11. *B. aphylla*
14b Ovary and capsule smooth:
15a Capsules subglobose, strongly trilobed, 5–8 mm long. . . . . 10. *B. gracilis*
15b Capsules obovoid to top-shaped, 10–19 mm long:
16a Synflorescence shortly pedunculate; plants from Humansdorp to Grahamstown . . . . . 7. *B. macrocarpa*
16b Synflorescence usually sessile; plants from west of the Breede River . . . . . .6. *B. longicyma*

Sect. 1. **Ramosae** *G.J.Lewis* in Journal of South African Botany 11: 108 (1945). Type: *Bobartia lilacina* G.J.Lewis, lecto., designated here.

Flowering stem with lower 2 internodes subequally developed, laxly branched in upper half, sticky below nodes, without stomatal furrows or hairs and smooth when fresh and dry; anatomically without sclerenchyma strands, vascular bundles without sclerenchyma caps, cuticle thin. *Leaves* plane, linear. *Rhipidia* solitary at branch tips, spathes green, without associated bracts. *Flowers* blue to mauve.

1. **Bobartia lilacina** *G.J.Lewis* in Journal of South African Botany 11: 108 (1945). Type: South Africa, [Western Cape], Franschhoek Pass, Villiersdorp side, lower rocky slopes of Gem Peak, *E. Esterhuysen 11441* (SAM, holo.; BOL, iso.).

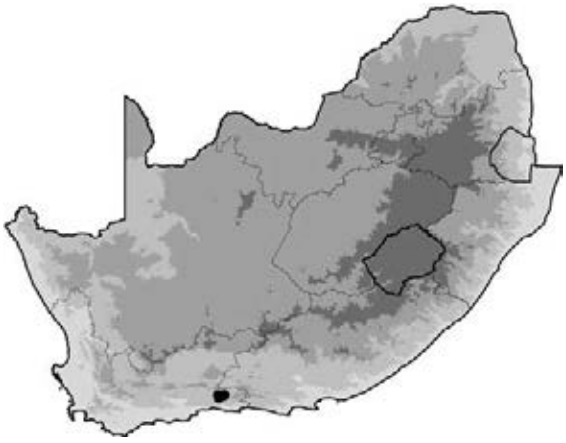
Plants 300–700 mm high. *Rhizome* short, erect, 5–15 mm diam. *Stem* 2 or 3 internodes long, terete or subterete, elliptic in section toward base, smooth, 2.5–4.0 mm diam. near base, laxly branched in upper $^1/_2$, viscid for some distance below nodes. *Foliage leaves* 6 to 11 in a basal fan, $^1/_3$ to $^1/_2$ as long as stem, linear, 4–11 mm wide, striate, uppermost leaf with plane blade, 30–100 mm long, well separated from first branch. *Rhipidia* solitary on slender branches; pedicels puberulous; spathes sometimes flushed purple, with translucent or brown-speckled membranous margins and apices; outer ± $^1/_3$ to $^1/_4$ as long as inner, 5–7 mm long, inner 15–22 mm long. *Flowers* deep blue (blue-mauve); tepals free, elliptic, outer 14–18 × 6–8 mm, inner slightly smaller. *Filaments* 4–6 mm long, pale blue-mauve; anthers ± 5 mm long, yellow. *Ovary* exserted, smooth; style 1–2 mm long, branches 5–7 mm long. *Capsules* obovoid to subglobose, smooth, 4–7 mm long. *Chromosome number* 2*n* = 20. *Flowering time*: January to March.

Distribution of ***Bobartia lilacina***.

Distribution and ecology: a narrow endemic of the mountains from Bain's Kloof to Franschhoek Pass in Western Cape, South Africa; restricted to cooler, S-facing sandstone slopes, from 600–1 500 m elevation, flowering mainly after fire.

Diagnosis: unique in the genus in the laxly branched stem and blue to blue-mauve flowers. The terete or subterete flowering stem, with conspicuously viscid or sticky patches below the nodes, is well differentiated from the plane leaves. The lowermost cauline leaf or spathe is inserted in the lower $^1/_3$ of the flowering stem and is leaf-like, with a short unifacial blade. The only other species with a similar laxly branched stem with sticky internodes, *Bobartia paniculata*, has yellow flowers and a bract-like spathe inserted in the upper $^1/_3$ of the stem at the top of a conspicuously elongated internode.

Sect. 2. **Paniculatae** *J.C.Manning & Goldblatt*, new section. Type: *Bobartia paniculata* G.J.Lewis



Flowering stem with basal internode greatly elongated, several-branched above, without stomatal furrows and hairs, smooth when fresh but shallowly grooved when dry; anatomically with sclerenchyma strands, vascular bundles with sclerenchyma caps, cuticle thick. *Leaves* plane, linear, unifacial. *Rhipidia* solitary on short branches, internodes sticky; subtending bract reduced and leaf-like. *Flowers* yellow.

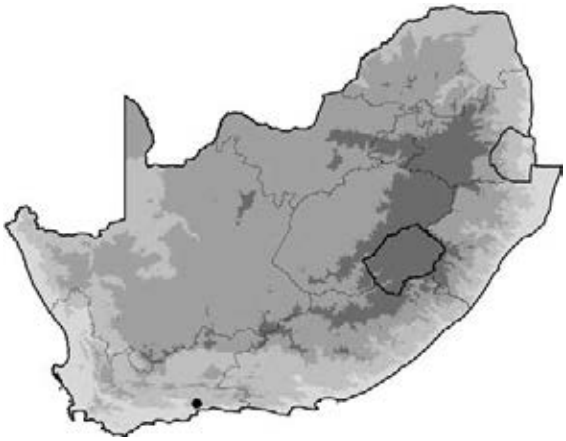
2. **Bobartia paniculata** *G.J.Lewis* in Journal of South African Botany 7: 50 (1941). Type: South Africa, [Western Cape], Kamanassie Mts., lower slopes, *Zinn s.n.* (SAM 54287, holo.; BOL, iso.).

Plants 300–1 000 mm high, forming large, loose tufts. *Rhizome* compact and corm-like, ± 20 mm diam. *Stem* consisting of 1 long basal internode, slightly flattened, elliptic in section, 2–4 mm diam. near base, striate when dry but without stomatiferous furrows, branching in upper $^1/_3$, forming a hemispherical, ± laxly panicle. *Foliage leaves* 4 to 8 in a basal fan, ± $^2/_3$ as long as flowering stem, linear, 3–7 mm wide, striate. *Rhipidia* several, solitary at branch tips, together forming a lax panicle, on branches 10–30 mm long subtended by leaf-like bract with unifacial blade, 20–50 mm long, immediately associated with next bract, internodes viscid; pedicels subglabrous; spathes with translucent membranous margins and brownish apices; outer ± $^1/_3$ as long as inner, 4–7 mm long, inner 14–20 mm long. *Flowers* yellow; tepals free, elliptic, outer 10–16 × 4–6 mm, inner slightly smaller. *Filaments* 2–3 mm long; anthers ± 3 mm long. *Ovary* exserted, smooth; style 1–2 mm long, branches 3–4 mm long. *Capsules* broadly obovoid to subglobose, smooth, 6–10 mm long. *Flowering time*: December to February.

Distribution and ecology: endemic to the Kamanassie Mtns east of Oudtshoorn in Western Cape, South Africa; relatively common on the upper southern slopes of Mannetjiesberg, from 1 200–1 800 m elevation, flowering mainly after fire.

Diagnosis: distinguished by the hemispherical, paniculate inflorescence with sticky internodes and relatively small, yellow flowers. The basal internode of the stem is conspicuously elongated, with the inflorescence thus clearly borne at the tip. This is intermediate between the inflorescence type in *Bobartia lilacina*, in which the two or three lower internodes are subequally developed, and the remaining species in the genus, which have only the lowermost internode elongated and a congested inflorescence. The stem lacks stomatiferous furrows and is thus smooth when fresh but the presence of peripheral longitudinal sclerenchyma strands causes it to become slightly striate when dry.

Distribution of ***Bobartia paniculata***.



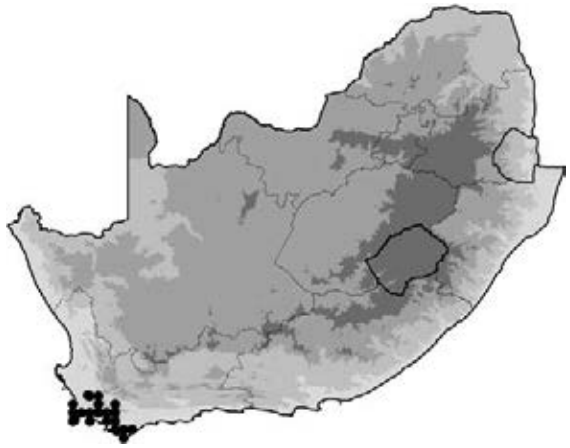
Sect. 3. **Gladiatae** *J.C.Manning & Goldblatt*, new section. Type: *Bobartia gladiata* (L.f.) Ker Gawl.

Flowering stem with basal internode elongated, without stomatal furrows and hairs, smooth when fresh but shallowly grooved when dry; anatomically with sclerenchyma strands, vascular bundles with sclerenchyma caps, cuticle thick. *Leaves* plane and linear or terete. *Rhipidia* sessile, single or several crowded in a compact, flattened synflorescence. *Flowers* yellow.

3. **Bobartia vlokii** *Goldblatt & J.C.Manning*, new species. Type: South Africa, Western Cape, Outeniqua Mtns, Jonkersberg, upper southern slopes of Skurweberg, in wet, peaty soil, 24 Oct. 1998, *J.H.J. Vlok 1654* (NBG, holo.; MO, iso.).

Plants 300–550 mm high, usually solitary or forming small tufts. *Rhizome* compact and corm-like, ± 10 mm diam. *Stem* formed by basal internode only, subterete to slightly flattened and elliptic in section or linear, often twisted, ± 2 mm diam., striate when dry but without stomatiferous furrows. *Foliage leaves* 2 to 6 in a basal tuft, shorter than flowering stem, linear or subterete, often twisted, ± 1 mm wide, striate. *Rhipidia* 3 to 6, sessile crowded together, subtended by erect, leaf-like, rigid bract, 50–70 mm long; spathes grey-green, outer 10–15 mm long, inner 25–30 mm long; pedicels puberulous. *Flowers* yellow, sometimes flushed reddish on reverse; tepals free or connate at base, elliptic, outer 22–25 × 6–10 mm, inner slightly smaller. *Filaments* 3–4 mm long; anthers ± 6 mm long. *Ovary* shortly exserted, smooth; style ± 3 mm long, branches ± 4 mm long. *Capsules* obovoid, smooth, 8–10 mm long. *Flowering time*: October to November.

Distribution and ecology: restricted to the upper southern slopes of the Outeniqua Mtns near Mossel Bay, Western Cape, South Africa, recorded from Ruitersberg and Jonkersberg; in wet peaty soil on steep south-facing slopes from 800 to 1 200 m elevation.



Distribution of ***Bobartia vlokii***.

Diagnosis: closely resembling *Bobartia filiformis* in stature and appearance, and anatomically in lacking stomatiferous furrows on the stem and leaves, but distinguished from it by the more numerous rhipidia, 3 to 6 per stem vs 1 (rarely 2 or 3) in *B. filiformis*.

Additional specimens

South Africa, Western Cape, 3322 (Oudtshoorn): Outeniqua Mtns, middle slopes of Ruitersberg, deep, wet, peaty soils on steep south-facing slope, (–CC), 24 Oct. 1986, *J.H.J. Vlok 1660* (MO, NBG); 7 Dec. 1986 [fruiting], *J.H.J. Vlok 1756* (MO, NBG).

4. **Bobartia filiformis** *(L.f.) Ker Gawl.*, Iridearum genera: 30 (1827). *Moraea filiformis* L.f.: 100 (1782). *Sisyrinchium filiforme* (L.f.) Spreng.: 166 (1824). *Marica filiformis* Ker Gawl.: t. 229 (1817). Type: South Africa, [Western Cape], without precise locality, *Thunberg s.n.* [UPS-THUNB 1215, lecto., designated by Strid: 22 (1974)].

Distribution of ***Bobartia filiformis***.

Plants 150–550 mm high, usually solitary or forming small tufts. *Rhizome* compact and corm-like, 5–10 mm diam. *Stem* consisting of basal internode only, subterete to linear and elliptic in section, 0.5–1.5 mm diam., striate when dry but without stomatiferous furrows. *Foliage leaves* 2 to 6 in a basal tuft, shorter than flowering stem, linear or subterete, often twisted, 0.5–2.0 mm wide, striate. *Rhipidia* 1 (rarely 2 or 3), subtended by erect, leaf-like bract, usually shorter than rhipidia, 15–65 mm long; spathes grey-green, outer 7–16 mm long, inner 25–45 mm long; pedicels subglabrous or sparsely pubescent. *Flowers* yellow, sometimes speckled near base, often flushed reddish on reverse; tepals free or connate at base, elliptic, outer 17–26 × 8–13 mm, inner slightly smaller. *Filaments* 3.5–6.0 mm long; anthers ± 6 mm long. *Ovary* shortly exserted, smooth; style 1.5–3.0 mm long, branches 4–6 mm long. *Capsules* broadly obovoid, smooth, 8–12 mm long. *Chromosome number* $2n = 20$. *Flowering time*: September to December.

Distribution and ecology: restricted to the mountains in extreme southwestern Western Cape, from Michell's Pass near Ceres to the Cape Peninsula and Hottentots Holland Mtns to Bredasdorp, South Africa; mainly on S-facing sandstone slopes or moist flats, flowering best after fire.

Diagnosis: a small, slender species up to 550 mm high but often less, typically with a solitary rhipidium (rarely two or three) on a slender, plane, linear or subterete stem up to 1.5 mm diam. The stems and leaves are faintly striate but lack fine, stomatiferous furrows. Larger plants with two or three rhipidia are difficult to separate from *Bobartia gladiata*, and the two species may hybridise.

5. **Bobartia gladiata** *(L.f.) Ker Gawl.*, Iridearum genera: 30 (1827). *Ixia gladiata* L.f.: 93 (1782). *Moraea gladiata* (L.f.) Thunb.: 8 (1787). *Marica gladiata* (L.f.) Ker Gawl.: t. 229 (1817). *Sisyrinchium gladiatum* (L.f.) Spreng.: 166 (1824). Type: South Africa, without precise locality, *Sparrman s.n.* (LINN, probable holo.).

Plants 200–800 mm high, usually solitary or forming small tufts. *Rhizome* compact and corm-like, 10–25 mm diam. *Stem* formed by basal internode only, usually flattened and 2.5–8.0 mm wide, rarely subterete and 2–3 mm diam., striate when dry but without stomatiferous furrows. *Foliage leaves* 2 to 6 in a basal fan, usually ± as a long as and resembling stem. *Rhipidia* 3 to 12 alternating in laterally flattened cluster subtended by erect, leaf-like, rigid bract, 20–120 mm long; pedicels sparsely to densely pubescent distally; spathes with outer greyish green or purplish, ± keeled, 7–16 mm long, inner green, 25–65 mm long. *Flowers* yellow, tepals sometimes speckled near base, sometimes flushed reddish on reverse; tepals free or connate at base, elliptic, outer 22–34 × 10–17 mm, inner slightly smaller. *Filaments* 3.0–4.5 mm long; anthers ± 9 mm long. *Ovary* shortly exserted, smooth; style 2–3 mm long, branches 4.5–7.0 mm long. *Capsules* obovoid, smooth, 9–16 mm long. *Chromosome number* $2n = 20$. *Flowering time*: September to December.

Distribution and ecology: restricted to the mountains in southwestern Western Cape, South Africa, from Bain's Kloof to Hermanus; on sandstone slopes in sandy places, mainly between 300–950 m elevation, flowering best after fire.

Diagnosis: usually readily recognised by the linear, flattened stems and leaves and the compressed inflorescence, but some forms have subterete or rarely terete leaves and stems. The stems and leaves are striate but lacking fine, stomatiferous furrows. Although microscopic, this character is reliable for separating terete-stemmed forms of the species from other, superficially similar species. Smaller, more delicate forms with only 3 rhipidia are difficult to distinguish from *Bobartia filiformis*.

Highly variable in size, three subspecies are recognised in *Bobartia gladiata*. The typical subspecies is characterised by flattened leaves and stem mostly up to 5 mm wide, and an inflorescence of 3 to 7 rhipidia. Plants from the southern Cape Peninsula with broader leaves 5–8 mm wide and an inflorescence of 6 to 12 rhipidia are segregated as subsp. *major*, and those with subterete or terete leaves and stems are treated as subsp. *teres*.

Key to subspecies

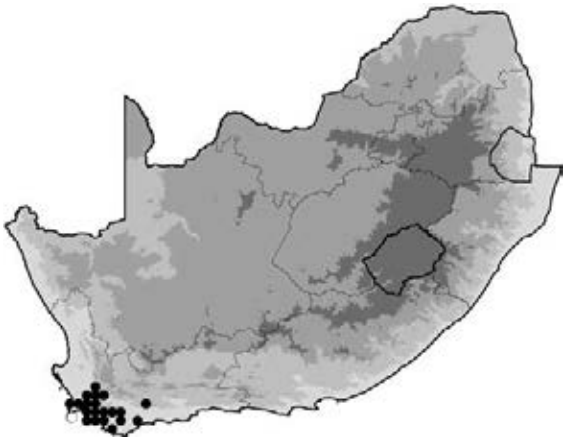
1a Leaves terete or subterete, 1.5–3.0 mm diam. . . . . 5c. subsp. *teres*
1b Leaves flat:
  2a Leaves 2.5–5.0 mm wide; rhipidia 3 to 7 per inflorescence . . . . . 5a. subsp. *gladiata*
  2b Leaves 5.0–8.0 mm wide; rhipidia 6 to 12 per inflorescence . . . . . 5b. subsp. *major*

5a. subsp. **gladiata**

Stem and leaves flat or rarely stem subterete, 2.5–5.0 mm wide. *Rhipidia* 3 to 7 per stem.

Distribution and ecology: throughout the range of the species but replaced by subsp. *major* in the southern Cape Peninsula; on seasonally moist sandy flats.

5b. subsp. **major** *(G.J.Lewis) Strid* in Opera Botanica 37: 24 (1974). *Bobartia gladiata* var. *major* G.J.Lewis: 50 (1941). Type: South Africa, [Western Cape], Cape Peninsula, Patrys Vlei, *T.M. Salter s.n.* (SAM, holo.).



Stem and leaves flat, 5–8 mm wide. *Rhipidia* 6 to 12 per stem.

Distribution and ecology: restricted to the extreme southern Cape Peninsula, between Smitswinkel and Olifantsbosch, near seasonally marshy flats.

5c. subsp. **teres** *Strid* in Opera Botanica 37: 25 (1974). Type: South Africa, [Western Cape], Stellenbosch Division, western slopes of Helderberg, *Gillett 3749* (BOL, holo.; BM, BOL, K, SAM, iso.).

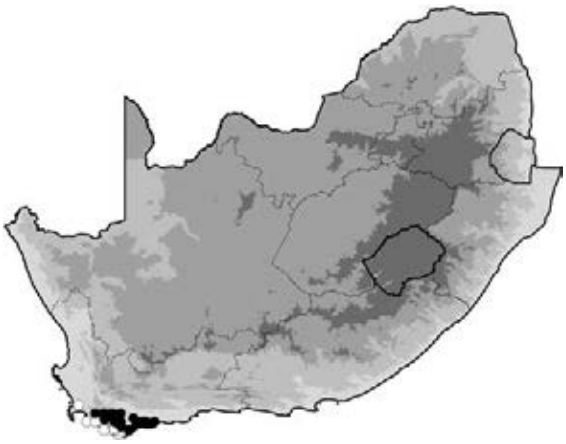
Stem and leaves subterete or rarely terete, 1.5–3.0 mm diam. *Rhipidia* 3 to 7 per stem.

Distribution and ecology: scattered through most of the range of the species, from Bain's Kloof to Hangklip.

Distribution of ***Bobartia gladiata*** subsp. ***gladiata*** and subsp. ***teres***, ●; subsp. ***major***, ○.

The status of this taxon is unclear. Some plants are evidently merely extreme variants of subsp. *gladiata*, but Strid (1974) also speculated that it may represent a stabilised hybrid swarm between *Bobartia gladiata* and *B. longicyma*.

Sect. 4. **Bobartia**



Flowering stem with basal internode greatly elongated, striate with numerous, fine stomatal furrows lined with papillae or short hairs; anatomically with sclerenchyma strands, vascular bundles with sclerenchyma caps, cuticle thick. *Leaves* usually terete, rarely flattened. *Rhipidia* sessile, several to many, congested but not flattened, with associated inflorescence bracts. *Flowers* yellow, rarely with well-developed perianth tube.

6. **Bobartia longicyma** *Gillett* in Journal of Botany, British and foreign 68: 104 (1930). Type: South Africa, [Western Cape], Caledon, Swartberg, 1300 ft [430 m], Oct. 1899, *H. Bolus 9158* (BOL, holo.).

Plants 0.5–1.8 m high, sometimes forming large tussocks. *Rhizome* compact and corm-like, 10–20 mm diam. *Stem* formed by basal internode only, terete, 1.5–4.0 mm diam., with fine stomatiferous furrows. *Foliage leaves* 2 to 8 in a basal tuft, ± as long as flowering stem, resembling stem but slightly thinner. *Rhipidia* 2 to 20, straight or curved, in a triangular or hemispherical head, subtended by erect, green, terete bract, sometimes extended in a long pungent tip; pedicels densely puberulous distally; outer rhipidial spathe and associated bracts firm textured, usually greenish or purplish, 8–20 mm long, ovate, often with dry papery tips, inner spathe 20–40 mm long, dull green. *Flowers* yellow, usually with reddish spots and reddish midline on reverse; tepals free, elliptic or oblong, outer 16–39 × 6–20 mm, inner slightly smaller. *Filaments* 2.5–4.0 mm long; anthers 6–9 mm long. *Ovary* scarcely or shortly exserted, smooth; style 2–3 mm long, branches 4.5–6.6 mm long. *Capsules* exserted, ovoid to narrowly ovoid, truncate or with shortly conical apex, smooth, 10–19 mm long, greyish to brown. *Flowering time*: mainly August to November, rarely to January.

Distribution and ecology: relatively common in southern Western Cape, South Africa, from Betty's Bay to the Breede River Mouth, with one record from the Cape Flats; mainly on sandy flats at low altitudes, flowering best after fire.

Diagnosis: a relatively poorly defined species recognised by its erect, leaf-like bract subtending the synflorescence

Distribution of ***Bobartia longicyma*** subsp. ***longicyma***, ●; subsp. ***magna***, ○.

and mostly relatively long rhipidia, the bracts often dry and papery at the tips, and the inner rhipidial spathe 20–40 mm long.

Strid (1974) recognised three subspecies but subsp. *microflora* from Potberg grades imperceptibly into subsp. *longicyma* and appears to represent merely the smaller extreme of that taxon.

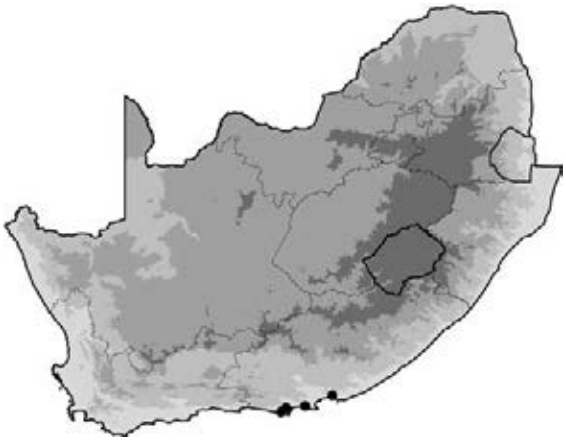
Key to subspecies

1a Rhipidia 2 to 5, suberect, in narrowly obtriangular synflorescence; occurring east of Caledon . . . . . 6a. subsp. *longicyma*

1b Rhipidia 5 to 25, suberect or spreading, in hemispherical synflorescence; occurring west of Caledon . . . . . 6b. subsp. *magna*

6a. subsp. **longicyma**

Bobartia longicyma subsp. *microflora* Strid in Opera Botanica 37: 27 (1974), new synonym. Type: South Africa, [Western Cape], Bredasdorp Division, Potberg above Potberg Farm, ± 260 m, *Dahlgren & Strid 3637* (NBG, holo.; K, LD, iso.).



Distribution and ecology: from Caledon and Riviersonderend eastward to Potberg and the Breede River Mouth.

6b. subsp. **magna** *Gillett ex Strid* in Opera Botanica 37: 26 (1974). Type: South Africa, [Western Cape], Caledon Division, sandy flats ± 7 miles east of Stanford, ± 160 m, *Dahlgren & Strid 3699* (NBG, holo.; K, LD, iso).

Distribution and ecology: from the Cape Flats and Betty's Bay along the coast to Elim.

7. **Bobartia macrocarpa** *Strid* in Opera Botanica 37: 33 (1974). Type: South Africa, [Eastern Cape], grassy hillside, Port Elizabeth to East London, ± 150 ft [45 m], *Batten s.n.* (NBG, holo.).

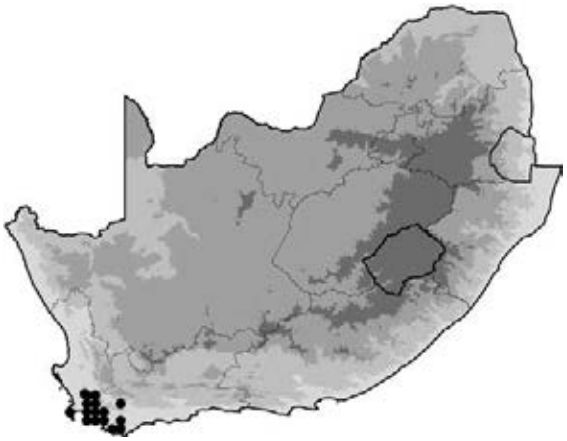
Plants up to ± 1 m high, sometimes forming tussocks. *Rhizome* compact and corm-like, 10–20 mm diam. *Stem* formed by basal internode only, terete, ± 3 mm diam., with fine stomatiferous furrows. *Foliage leaves* 2 to 6 in a basal tuft, terete, ± as long as flowering stem, resembling stem but slightly thinner. *Rhipidia* 2 to 6, sessile, crowded in a triangular head on a short peduncle subtended by erect, green, terete bract, sometimes extended in a long pungent tip appearing as a continuation of stem; pedicels densely puberulous distally; bracts and outer rhipidial spathe firm textured, usually greenish or purplish, spathe 12–25 mm long, ovate, often with dry papery tips, inner spathe 30–45 mm long, dull green. *Flowers* yellow; tepals free, elliptic or oblong, outer 18–24 × 6–10 mm, inner slightly smaller. *Filaments* 3.0–4.5 mm long; anthers ± 6 mm long. *Ovary* shortly exserted, smooth; style ± 2.5 mm long, branches ± 5 mm long. *Capsules* exserted, obovoid to barrel-shaped, truncate, smooth, 10–16 mm long, dull green to brown. *Flowering time*: mainly August to February.

Distribution of ***Bobartia macrocarpa***.

Distribution and ecology: a local endemic of coastal Eastern Cape, South Africa, from Humansdorp to East London and Grahamstown; in grassy fynbos.

Diagnosis: a poorly understood species superficially resembling *Bobartia longicyma* subsp. *longicyma* but distinguished from it by the rhipidia borne on a short common peduncle above the spathe.

8. **Bobartia indica** *L.* in Species plantarum: 54 (1753). *B. juncea* Salisb.: 313 (1812), illegitimate superfluous name for *B. indica* L. Type: South Africa, [Western Cape], without precise locality [BM; herb. Hermann, lecto., designated by Strid: 27 (1974)].



Moraea spathacea L.f.: 99 (1782). *Sisyrinchium spathaceum* (L.f.) Pers.: 50 (1805). *Marica spathacea* (L.f.) Ker Gawl.: sub. t. 229 (1817). *Aristea spathacea* (L.f.) Spreng.: 158 (1824). *Bobartia spathacea* (L.f.) Ker Gawl.: 30 (1827). *Hecaste spathacea* (L.f.) Kuntze: 309 (1898) genus invalid. Type: South Africa, without precise locality, *Thunberg s.n.* [UPS-THUNB 1228, lecto., designated by Strid: 27 (1974)].

Xyris altissima G.Lodd.: t. 1900 (1833). Type, South Africa, without precise locality or collector, illustration in G.Lodd.: t. 1900 (1833).

Bobartia purcellii Gillett: 105 (1930). Type: South Africa, Caledon, Zwartberg near the hot springs, April 1916, *Purcell 322* (SAM, holo.).

Bobartia indica var. *minor* G.J.Lewis in Journal of South African Botany 7: 51 (1941), new synonym. Type: South Africa, [Western Cape], Cape Peninsula, between Fish Hoek and Kommetjie, *T.M. Salter s.n. SAM53192* (SAM, holo.).

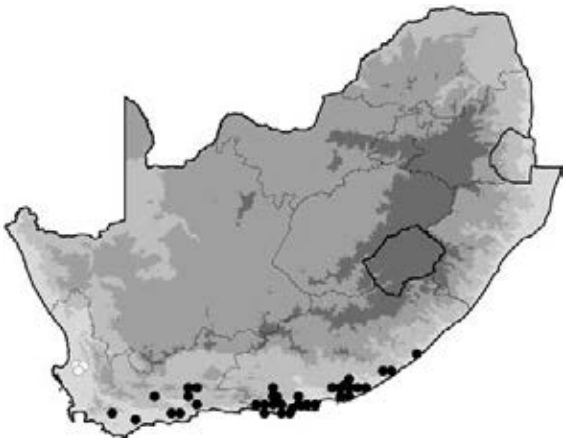
[*Hecaste juncea* Sol. ex Schumach.: 11 (1793), invalid name only in synonymy.]

Distribution of ***Bobartia indica***.

Plants 250–800 mm high, sometimes forming large clumps. *Rhizome* compact and corm-like, 5–15 mm diam. *Stem* formed by basal internode only, terete, 1.2–3.0 mm diam., with fine stomatiferous furrows. *Foliage leaves* 2 to 6 in a basal tuft, terete, much longer than flowering stem, flexible and trailing, resembling stem but slightly thinner. *Rhipidia* 6 to 40 in a dense, ± globose head subtended by horizontally spreading, rigid, terete, leaf-like bract, 30–80(–200) mm long, expanded at base and partially sheathing, succeeding bract similar but smaller; pedicels villous distally; rhipidial bracts and spathes firm textured, grey-green, outer 8–18 mm long, ovate, inner 18–30 mm long. *Flowers* yellow; tepals free, elliptic, outer 19–28 × 6–14 mm, inner slightly smaller. *Filaments* 4–6 mm long; anthers ± 6 mm long. *Ovary* exserted, smooth; style 1.5–3.0 mm long, branches 5–8 mm long. *Capsules* exserted, broadly ovoid, trilobed, smooth, 5–11 mm long, grey to blackish. *Chromosome number* 2*n* = 20. *Flowering time*: mainly October to March.

Distribution and ecology: endemic to the southwestern corner of Western Cape, South Africa, extending from Mamre and Goudini to Caledon, common on the Cape Peninsula; on sandy flats or slopes, mainly below 500 m elevation, flowering mainly after fire.

Diagnosis: distinguished from similar species with a narrow, leaf-like spathe subtending the synflorescence by the characteristically long, trailing leaves, much longer than the flowering stem. The dense, globose synflorescence of several to many, narrow rhipidia is subtended by two horizontally spreading, narrow, rigid, leaf-like bracts or spathes, the lowermost longest and the other much shorter and almost awl-like. The pedicels are characteristically densely villous distally. *Bobartia indica* is probably most closely allied to *B. orientalis*, which has leaves ± as long as the flowering stem, diagnostic short rhipidia with inner spathes 10–18 mm long and small, subglobose capsules mostly 4–6 mm long.



Although Strid (1974) considered var. *minor* G.J.Lewis (1941) to represent one extreme in a range of variation he neglected to formally relegate the name to synonymy.

9. **Bobartia orientalis** *Gillett* in Journal of Botany, British and foreign 68: 104 (1930). Type: South Africa, [Eastern Cape], Albany Division, Howison's Poort, *Gillett 2444* (BOL, holo.).

Plants 400–1 300 mm high, sometimes forming large tussocks. *Rhizome* compact and corm-like, ± 10 mm diam. *Stem* formed by basal internode only, terete, 1.2–2.5 mm diam., with fine stomatiferous furrows. *Foliage leaves* 2 to 8 in a basal tuft, ± as long as flowering stem, flexible, resembling stem but slightly thinner. *Rhipidia* 10–80(–120) sessile in a dense, ± globose head subtended by suberect or erect (rarely spreading) bract, usually green but rarely grey and fibrous, sometimes extended in a long flexible tip, not partially sheathing; pedicels slightly or more densely puberulous distally; rhipidial bracts and outer spathe firm textured, usually greenish but sometimes brown, usually short and obtuse or sometimes acute, 5–9 mm long, ovate, inner spathe narrow and often curved, 10–18 mm long, dull green. *Flowers* yellow; tepals free, elliptic or oblong, outer 11–22 × 3.5–9.0 mm, inner slightly smaller or only half as wide. *Filaments* 2.5–4.5 mm long; anthers 3.5–6.0 mm long. *Ovary* exserted, smooth or minutely tubercled; style 1.2–2.5 mm long, branches 3.5–6.0 mm long. *Capsules* exserted, subglobose, trilobed with rounded valves, smooth or minutely tubercled, 4–6 mm long, grey-green to brown. *Chromosome number* 2*n* = 20. *Flowering time*: mainly September to November.

Distribution and ecology: widespread and extending from Riviersonderend in Western Cape to the Kei River in Eastern Cape, South Africa, with outlying populations on the Swartberg and the Piketberg, mainly at lower altitudes along the coastal plain, where it may be locally common or even dominant, especially around Humansdorp and Grahamstown; on a wide variety of substrates, in fynbos, especially grassy fynbos, and in renosterveld; growth and flowering is strongly stimulated by fire.

Diagnosis: usually readily recognised by the dense inflorescence of up to 120 small, narrow rhipidia, the inner spathes 10–18 mm long and the outer ± one third as

Distribution of ***Bobartia orientalis*** subsp. ***orientalis***, ●; subsp. ***occidentalis***, ○.

long and often obtuse or truncate, and characteristic, small, subglobose capsules 4–6 mm long with strongly rounded valves. Forms with fewer or larger rhipidia are less easily recognised, and can be confused with several other species with narrow, green rhipidial spathes.

The isolated population from the Piketberg was distinguished as subsp. *occidentalis* Strid (1974). The status of this population deserves further investigation.

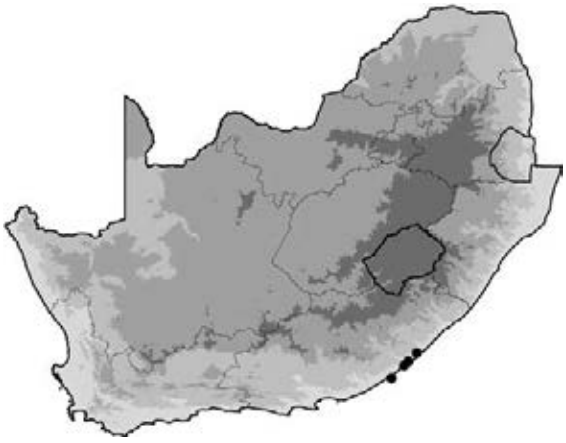
Key to subspecies

1a Bract subtending synflorescence usually green and leaf-like, rarely grey and fibrous, erect or spreading; lower rhipidial bracts usually green, rarely chestnut-brown, mostly obtuse or truncate but sometimes acute; capsules smooth or tubercled; occurring from Riviersonderend eastwards . . . . . 9a. subsp. *orientalis*

1b Bract subtending synflorescence grey, fibrous, spreading; lower rhipidial bracts chestnut-brown, acute; capsules tubercled; restricted to the Piketberg. . . . . 9b. subsp. *occidentalis*

9a. subsp. **orientalis**

Distribution and ecology: ranging from Riviersonderend east to the Kei River with outlying populations in the Little Karoo on the Swartberg and Gamkaberg.



9b. subsp. **occidentalis** *Strid* in Opera Botanica 37: 33 (1974). Type: South Africa, [Western Cape], Piketberg, upper east slopes of Kapteinskloof, 2950 ft [900 m], 21 Oct. 1935, *Pillans 7797* (BOL, holo.).

Distribution and ecology: restricted to the Piketberg, where it has been collected from several localities on the range.

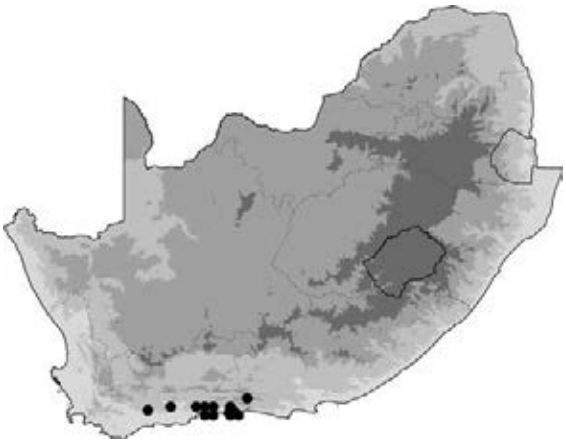
The characters used to discriminate this variant all occur in the typical subspecies and were it not for its highly disjunct distribution it is unlikely to have been recognised taxonomically. Its status requires further investigation.

10. **Bobartia gracilis** *Baker* in Bulletin of Miscellaneous Information Kew 1901: 134 (1901). Type: South Africa, [Eastern Cape], East London, West Bank, near Cove Rock, 21 Aug. 1898, *Galpin 3254* (K, lecto., designated by Strid: 31 (1974); PRE, isolecto.).

Plants 250–500 mm high, sometimes forming clumps. *Rhizome* compact and corm-like, ± 10 mm diam. *Stem* formed by basal internode only, subterete, 1–2 mm diam., with fine stomatiferous furrows. *Foliage leaves* 1 to 4 in a basal tuft, ± as long as flowering stem, resembling stem. *Rhipidia* erect, 2 to 6 in a narrow, shortly pedunculate head, often appearing lateral on stem, subtended by erect, terete, leaf-like bract, often greatly extended, stiff or flexible, appearing as a continuation of stem, green; pedicels puberulent distally; rhipidial bracts and spathes firm-textured, bracts and outer spathe lanceolate, 10–16 mm long, dull green or flushed purplish,

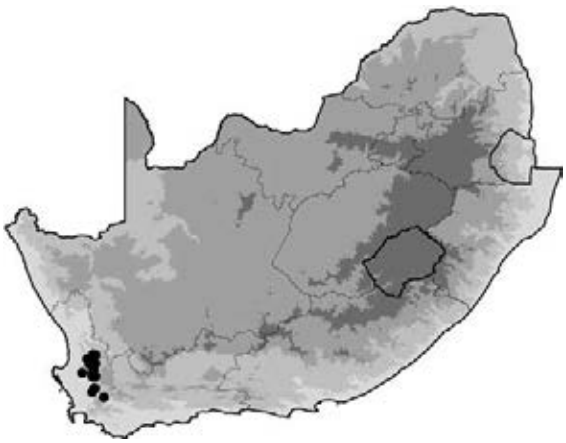
Distribution of ***Bobartia gracilis***.

inner 18–30 mm long, green. *Flowers* yellow; tepals free, elliptic, outer 16–23 × 6–9 mm, inner slightly smaller. *Filaments* 3–4 mm long; anthers ± 6 mm long. *Ovary* shortly exserted, smooth; style 2–3 mm long, branches 4–5 mm long. *Capsules* exserted, obovoid to subglobose, trilobed, smooth, 5–8 mm long, brown. *Flowering time*: throughout the year.



Distribution and ecology: restricted to the Eastern Cape coast, South Africa, from near East London to Kei River Mouth; on grassy slopes.

Diagnosis: superficially similar to *Bobartia aphylla* and distinguished by its small, smooth, subglobose capsules, 5–8 mm long. A poorly understood species that can also be difficult to separate from forms of *B. orientalis* but typically with fewer, longer rhipidia.



11. **Bobartia aphylla** *(L.f.) Ker Gawl.*, Iridearum genera: 30 (1827). *Moraea aphylla* L.f.: 99 (1782). *Marica aphylla* (L.f.) Ker Gawl.: t. 229 (1817). *Sisyrinchium aphyllum* (L.f.) Spreng.: 166 (1824). Type: South Africa, without precise locality, *Thunberg s.n.* [UPS-THUNB 1205 (left hand specimen), lecto., designated by Strid: 29 (1974)].

Bobartia keetii E.Phillips: 335 (1920). Type: South Africa, [Western Cape], Knysna Division, Gouna Plateau, *Keet 26* (PRE, holo.; K, iso.).

Plants 300–700 mm high, sometimes forming clumps. *Rhizome* compact and corm-like, 8–15 mm diam. *Stem* formed by basal internode only, subterete, 1–3 mm diam., with fine stomatiferous furrows. *Foliage leaves* 2 to 6 in a basal tuft, terete, usually shorter than flowering stem, resembling stem. *Rhipidia* erect, 3 to 10 in a narrow, shortly pedunculate head, often appearing lateral on stem, subtended by erect, terete, leaf-like bract, often greatly extended (up to ± 400 mm), stiff or flexible, appearing as a continuation of stem; pedicels puberulent distally; rhipidial bracts and spathes firm-textured, green, outer spathe lanceolate, inner 20–35 mm long. *Flowers* yellow; tepals free, elliptic, outer 18–26 × 8–12 mm, inner

Distribution of ***Bobartia aphylla***.

Distribution of ***Bobartia fasciculata***.

slightly smaller. *Filaments* 2–4 mm long; anthers ± 6 mm long. *Ovary* shortly or scarcely exserted, weakly to densely papillate; style ± 2 mm long, branches 4–6 mm long. *Capsules* exserted, obovoid, tuberculate, 8–13 mm long, dark reddish brown. *Chromosome number* 2*n* = 20 (Strid, 1974). *Flowering time*: mainly November to March.

Distribution and ecology: extending along the southern coast and near inland, from Mossel Bay in Western Cape to Plettenberg Bay in Eastern Cape, South Africa, extending up to 600 m elevation on the Outeniqua and Tsitsikamma Mtns and on the Langeberg; on sandy soils in grassy fynbos.

Diagnosis: a relatively slender species mostly less than 700 mm tall, with a narrow, shortly pedunculate synflorescence of 3 to 10 rhipidia subtended by a narrow, leaf-like spathe with terete blade often greatly prolonged and appearing as an extension of the stem, the synflorescence thus apparently lateral. The ± papillate ovaries develop into tuberculate capsules 8–13 mm long. The Langeberg populations are anomalous in their smooth ovaries and capsules.

The species is superficially similar to *Bobartia gracilis*, which is distinguished by its smaller, smooth, subglobose capsules 5–8 mm long.

12. **Bobartia fasciculata** *Gillett ex Strid* in Opera Botanica 37: 34 (1974). Type: South Africa, [Western Cape], near top of Gray's Pass, 20 Sept. 1965, *Dahlgren & Strid 3227* (NBG, holo.; K, LD, iso.).

Plants 0.8–1.5 m high, sometimes forming large clumps. *Rhizome* compact and corm-like, 10–20 mm diam. *Stem* formed by basal internode only, terete, 1.5–4.0 mm diam., with fine stomatiferous furrows. *Foliage leaves* 2 to 6 in a basal tuft, shorter than stem, terete, resembling stem but slightly thinner. *Rhipidia* 16 to 60 grouped in fascicles of 2 to 6 in a crowded, ± globose head, subtended by spreading, rigid, fibrous bract, usually grey and ± inconspicuous but sometimes with prominent green foliar tip, not much sheathing; pedicels pubescent distally; rhipidial bracts and outer spathe greyish brown, 10–16 mm long, ovate, inner spathe 18–24 mm long, straw-coloured. *Flowers* yellow; tepals free, elliptic, outer 16–23 × 8–11 mm, inner ± $^1/_2$ as wide. *Filaments* 3.5–4.5 mm long; anthers ± 5 mm long. *Ovary* shortly exserted, smooth or rugulose; style ± 2.5 mm long, branches 4.5–6.0 mm long. *Capsules* exserted, obovoid to ovoid, slightly to conspicuously rugulose, tubercled or smooth, 7–12 mm long, greyish. *Chromosome number* 2*n* = 20. *Flowering time*: August to November.

Distribution and ecology: endemic to the Olifants River and Elandskloof Mtns in Western Cape, South Africa, extending from south of Citrusdal to Hermon; on stony sandstone slopes in fynbos or transitional renosterveld, from 350 to 750 m elevation.

Diagnosis: distinguished by the fibrous spathe-like bract subtending the synflorescence, usually greyish and inconspicuous but sometimes with a long foliar tip, and the dense, globose inflorescence of 16 to 60 rhipidia characteristically grouped in fascicles of 2 to 6. The rhipidial bracts are grey or brown and much shorter than the straw-coloured inner spathe. The capsules are typically prominently rugose or tubercled but are smooth in populations from the Elandskloof Mtns in the south.

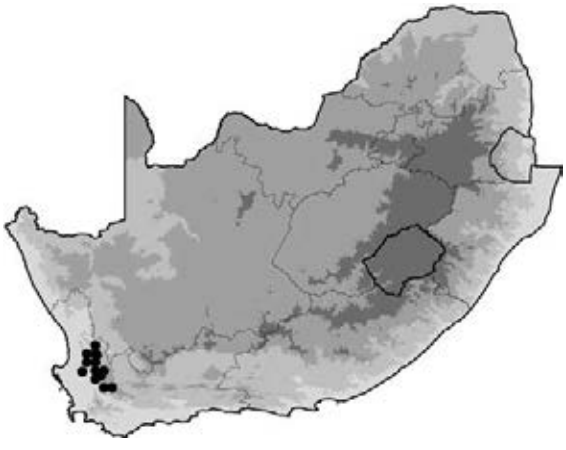
Bobartia fasciculata is closely allied to *Bobartia rufa*, sharing with it a similar fibrous bract subtending the synflorescence and ± tubercled (or smooth) capsules, and remarkably narrow inner tepals, ± half as wide as the outer. The two species are sympatric on the Olifants River Mtns and are readily confused there. *B. rufa* is distinguished by its ± flat-topped, obconical synflorescence with attenuate, dark red outer rhipidial bracts closely overlapping and concealing the inner rhipidial spathe.

13. **Bobartia rufa** *Strid* in Opera Botanica 37: 37 (1974). Type: South Africa, [Western Cape], Piketberg, upper southern part of Versfeld Pass, 27 Oct. 1965, *Dahlgren & Strid 3860* (NBG, holo.; LD, iso.).

Plants 500–900 mm high, sometimes forming clumps. *Rhizome* compact and corm-like, 10–16 mm diam. *Stem* formed by basal internode only, terete, 1–3 mm diam., with fine stomatiferous furrows. *Foliage leaves* 2 to 6 in a basal tuft, shorter than flowering stem, terete, resembling stem but slightly thinner. *Rhipidia* suberect, up to ± 50, grouped indistinctly in fascicles in a crowded, obconical, ± flat-topped head, subtended by suberect, fibrous, grey, expanded bract, following bract similar, together partially sheathing synflorescence; pedicels subglabrous; rhipidial bracts and outer spathe usually dark reddish brown, acuminate, 10–35 mm long, ± concealing inner spathe, this not or scarcely longer than the outer and straw-coloured. *Flowers* yellow; tepals free, elliptic, outer 15–19 × 7–9 mm, inner ± ½ as wide. *Filaments* 3.0–4.5 mm long; anthers ± 4.5 mm long. *Ovary* shortly exserted, smooth or rugulose; style ± 2.5 mm long, branches 4.0–5.5 mm long. *Capsules* exserted, obovoid, smooth or tubercled, 5–8 mm long, dark to reddish brown. *Flowering time*: September to November.

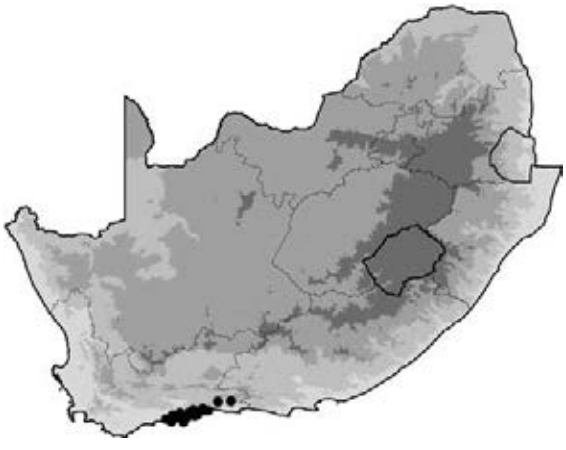
Distribution and ecology: endemic to the coastal and near interior mountains of the Atlantic Coast of Western Cape, South Africa, from Pakhuis Pass in the Cederberg through the Cold Bokkeveld and Olifants River Mtns to the Piketberg and Hex River Mtns; on sandstone slopes in fynbos from 900 to 1 400 m elevation.

Diagnosis: recognised by the obconical, ± flat-topped synflorescence partially sheathed by a pair of grey, fibrous spathe-like bracts, the rhipidia with conspicuous, acuminate, dark reddish brown bracts and lower rhipidial spathe not much shorter than the straw-coloured inner spathe and concealing it. The capsules are either smooth or tubercled.



Bobartia rufa is clearly closely allied to *B. fasciculata*, sharing with it a similar fibrous spathe and ± tubercled capsules, and remarkably narrow inner tepals, ± half as wide as the outer. The two species are sympatric on the Olifants River Mtns and may be confused there. *Bobartia fasciculata* is distinguished by its globose inflorescence with more clearly fasciculate rhipidia with greyish or brown outer rhipidial spathes much shorter than the inner rhipidial spathes.

14. **Bobartia robusta** *Baker*, Handbook of the Irideae: 120 (1892). Type: South Africa, [Western Cape], without precise locality, *W. Burchell 6124* (K, holo.).



Plants 0.7–2.1 m high, sometimes forming large clumps. *Rhizome* compact and corm-like, 20–30 mm diam. *Stem* formed by basal internode only, terete, 3–6 mm diam., with fine stomatiferous furrows. *Foliage leaves* 2 to 7 in a basal tuft, sessile, ± as long as and resembling stem. *Rhipidia* suberect, 8 to 40 crowded in a dense obovoid head subtended by suberect bract, usually green in upper part but dry and ± papery or fibrous below, expanded and partially sheathing young synflorescence; pedicels sparsely pubescent distally; rhipidial bracts and spathes firm-textured, bracts and outer spathe broadly lanceolate, papery or fibrous, reddish brown, inner spathe 15–25 mm long, usually ± green. *Flowers* yellow, sometimes tinged red on reverse; tepals free, elliptic, outer 20–32 × 10–18 mm, inner slightly smaller. *Filaments* 3–5 mm long; anthers ± 8 mm long. *Ovary* scarcely exserted or not, weakly to densely papillate; style 2–3 mm long, branches 5–7 mm long. *Capsules* exserted, obovoid to broadly cylindric, conspicuously rugose or verrucose to muricate, 7–18 mm long, dark reddish brown. *Chromosome number* 2*n* = 20. *Flowering time*: mainly August to October.

Distribution and ecology: locally abundant on the coastal plain from south of Swellendam to George in Western Cape, South Africa; in coastal fynbos and renosterveld, usually in sand.

Diagnosis: a large, often clump-forming species with robust stems 3–6 mm diam. and a dense, obovoid synflorescence of 8 to 40 suberect rhipidia and ± papillate ovary scarcely exserted from the rhipidial spathes. The large flowers have tepals, 20–32 mm long and the large capsules, 7–18 mm long, are conspicuously rugose or verrucose to muricate. *Bobartia aphylla*, also with

Distribution of ***Bobartia rufa***.

Distribution of ***Bobartia robusta***.

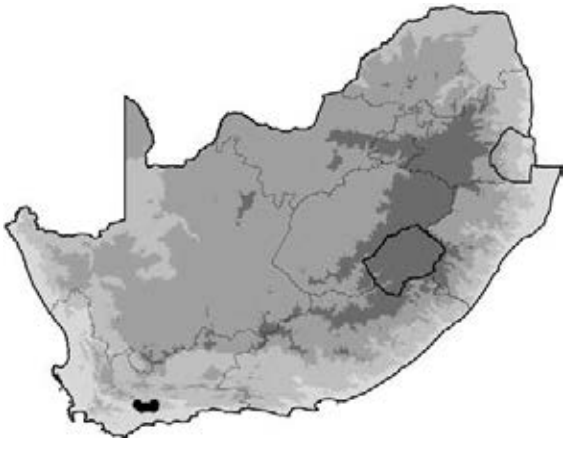
usually verrucose capsules, is a smaller, more slender species mostly less than 700 mm tall, with a narrow, green, leaf-like spathe subtending a narrow, ellipsoid synflorescence of up to ten rhipidia. Old individuals form large, rush-like tussocks.

15. **Bobartia parva** *Gillett* in Journal of Botany, British and foreign 68: 104 (1930). Type: South Africa, [Western Cape], Swellendam, Lemonshoek Peak, 4 000 ft [1 220 m], *Thorne s.n.* (SAM, holo.).

Plants slender, 150–500 mm high, usually forming small tufts. *Rhizome* compact and corm-like, 5–10 mm diam. *Stem* formed by basal internode only, terete, 1–2 mm diam., with fine stomatiferous furrows. *Foliage leaves* 2 to 6 in a basal tuft, shorter to as long as stem, terete, resembling stem but slightly thinner. *Rhipidia* suberect, 2 to 7 crowded in a ± cylindric head subtended by broad, fibrous, dark reddish or chestnut-brown bract, usually without foliar tip, almost completely sheathing young synflorescence, next inflorescence bract similar in texture and size; pedicels subglabrous; rhipidial bracts and spathes firm-textured, bracts and outer spathe lanceolate, 6–10 mm long, brown, inner spathe ± 22 mm long, greenish. *Flowers* yellow; tepals free, elliptic, outer 14–18 × 5–8 mm, inner slightly smaller. *Filaments* 2–3 mm long; anthers ± 4 mm long. *Ovary* exserted, smooth; style 2–3 mm long, branches 3–4 mm long. *Capsules* exserted, obovoid, smooth, 8–10 mm long. *Flowering time*: November to February.

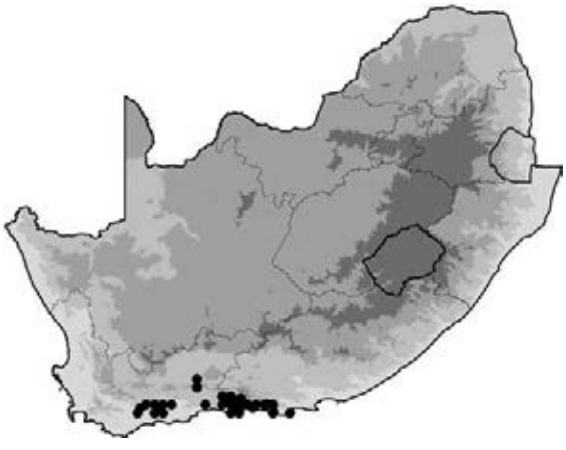
Distribution and ecology: a narrow endemic of the Langeberg above Swellendam in Western Cape, South Africa; on south-facing sandstone slopes at high altitude.

Diagnosis: a small, slender species, 150–500 mm tall, with 2 to 7 rhipidia in a narrow, cylindric synflorescence ± completely enclosed by an erect, broad, fibrous, dark reddish or chestnut-brown subtending bract. The species resembles small forms of *Bobartia macrospatha* but is distinguished by the exserted ovary and capsules.



16. **Bobartia macrospatha** *Baker*, Handbook of the Irideae: 119 (1892). Type: South Africa, [Western Cape], Swellendam, *W. Burchell 6987* (K, holo.).

Bobartia burchellii Baker: 120 (1892). Type: South Africa, [Western Cape], Swellendam, *W. Burchell 7145* (K, holo.).



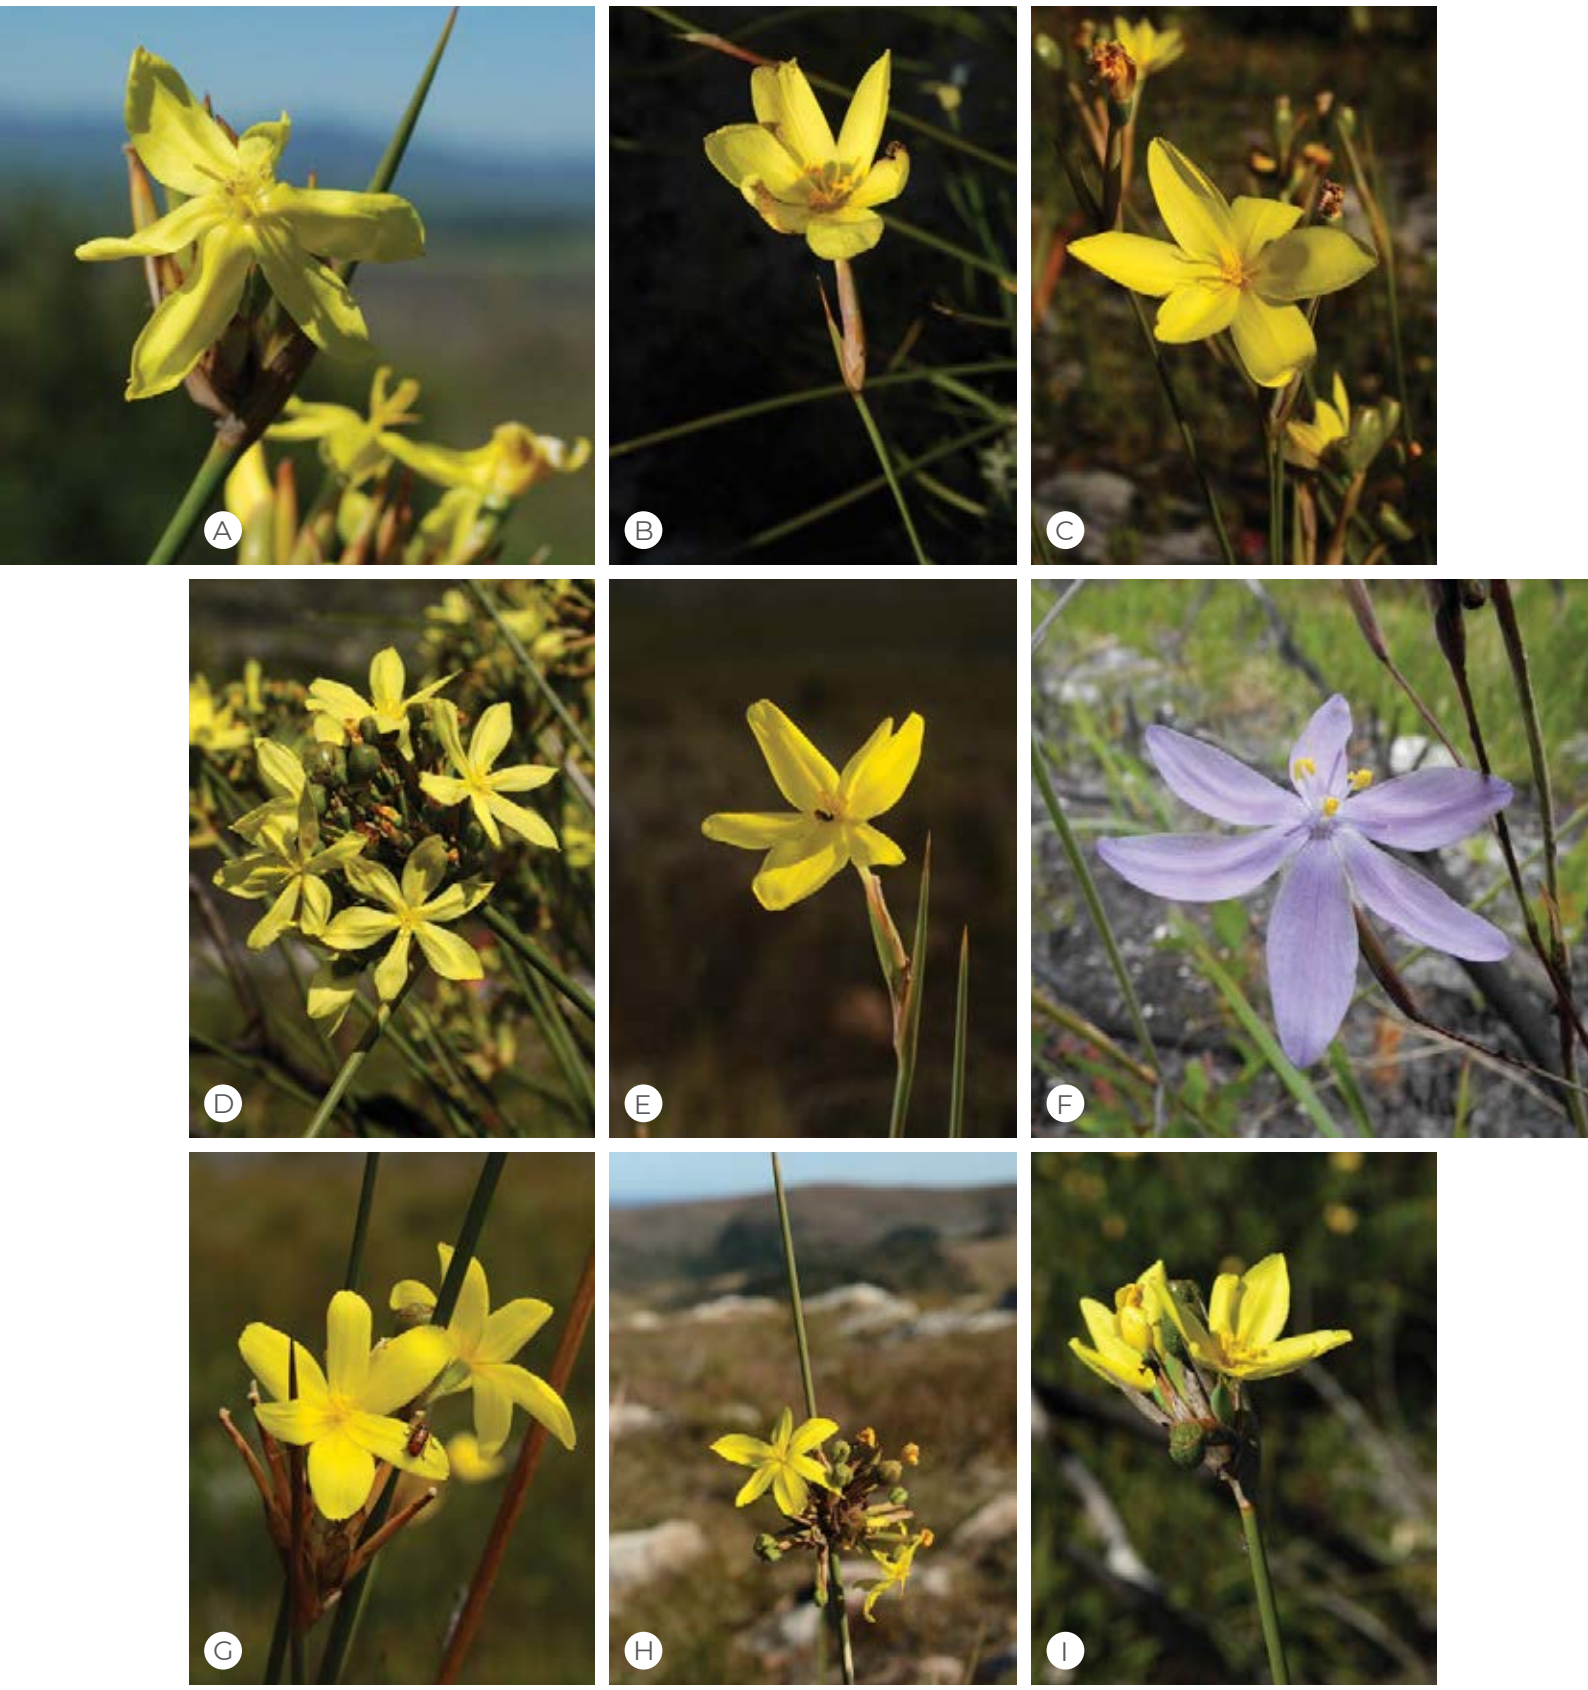
Bobartia tubata Gillett: 105 (1930). Type: South Africa, [Western Cape], Knysna, Goukamma uplands, *Gillett 1578* [BOL, lecto., designated by Strid: 35 (1974)].

Plants (0.25–)0.50–1.10(–1.50) m high, usually forming tufts. *Rhizome* compact and corm-like, ± 10 mm diam. *Stem* formed by basal internode only, terete or subterete, 1–3 mm diam., with fine stomatiferous furrows. *Foliage leaves* 2 to 6 in a basal tuft, sessile, usually slightly shorter than but resembling stem. *Rhipidia* suberect, (3–)8 to 15 crowded in a dense obovoid head, subtended by suberect, dry, ± fibrous bract, expanded and partly sheathing young synflorescence; pedicels 2–6(–10) mm long, subglabrous; rhipidial bracts and spathes firm-textured, bracts and outer spathe broadly lanceolate, 6–11 mm long, dark reddish brown, inner 15–24 mm long, often silvery-papillose. *Flowers* yellow; tepals free or connate in a tube 4–7 mm long, elliptic, outer 18–32 × 9–15 mm, inner slightly smaller. *Filaments* 1.5–3.5 mm long; anthers ± 5 mm long. *Ovary* included, smooth; style 4–10 mm long, branches 5–6 mm long. *Capsules* included, ovoid, smooth, (8–)10–15 mm long. *Chromosome number* $2n = 20$. *Flowering time*: mainly September to November.

Distribution and ecology: occurring along the southern foothills of the Langeberg and Outeniqua Mtns from Swellendam in Western Cape to Humansdorp in Eastern Cape, South Africa, but evidently absent between Riversdale and George although also occurring in the Long Kloof with outlying populations in the Great Swartberg; on lower sandstone slopes from 150–350 m elevation, in fynbos or transitional fynbos.

Distribution of ***Bobartia parva***.

Distribution of ***Bobartia macrospatha***.



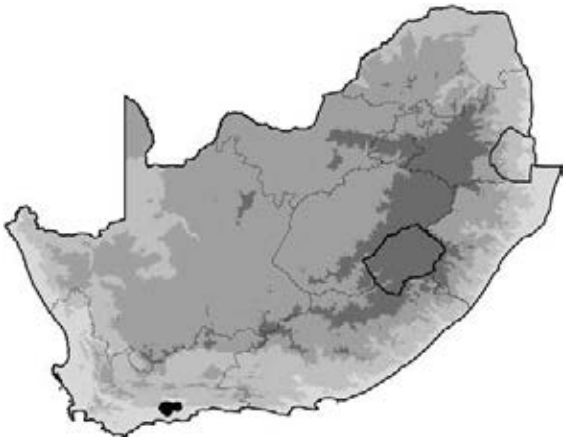


Plate 75. A, ***Bobartia fasciculata***, Hermon, WC; B, ***B. filiformis***, Cape Peninsula, WC; C, ***B. gladiata*** subsp. ***gladiata***, Cape Peninsula, WC; D, ***B. indica***, Cape Peninsula, WC; E, ***B. longicyma*** subsp. ***longicyma***, Napier, WC; F, ***B. lilacina***, Bain's Kloof, WC (photograph: R. Saunders); G, ***B. longicyma*** subsp. ***magna***, Betty's Bay, WC; H, ***B. orientalis***, Grahamstown, EC; I, ***B. robusta***, Still Bay, WC.

Diagnosis: one of two species in the genus with the ovary included in the rhipidial spathes, and the capsules remaining concealed by the bracts, *Bobartia macrospatha* is distinguished from *B. anceps* by its terete or subterete leaves and stem, the mostly dry and fibrous bract subtending a relatively small synflorescence of up to 15 suberect rhipidia. The bract is ± expanded at the base and sheaths the relatively small inflorescence. The inner spathes of the suberect rhipidia are (13–)15–20 mm long. The capsules are ovoid and 8–10 mm long.

Both *Bobartia macrospatha* and *B. anceps* occur in Garcia's Pass and intermediates may represent hybrids between them. The presence of these intermediates convinced Strid (1974) to treat the two as subspecies of a single variable species but nearly all specimens can be assigned to one or other of the taxa, and the several differences between them suggest that separation at species rank is more appropriate.

17. **Bobartia anceps** *Baker*, Handbook of the Irideae: 121 (1892). *B. macrospatha* subsp. *anceps* (Baker) Strid: 36 (1974). Type: South Africa, [Western Cape], Swellendam, *W. Burchell 6913* (K, holo.).

Plants (0.25–)0.50–1.10(–1.50) m high, usually forming tufts. *Rhizome* compact and corm-like, ± 10 mm diam. *Stem* formed by basal internode only, flattened or rarely subterete and elliptic in section, 3–6 mm wide, with fine stomatiferous furrows. *Foliage leaves* 2 to 6 in a basal fan, usually slightly shorter than flowering stem, resembling stem. *Rhipidia* 15 to 40, spreading, crowded in a dense rounded head, subtended by usually spreading, green, leaf-like bracts with narrow blade; pedicels 2–6(–10) mm long, subglabrous; rhipidial bracts and spathes firm-textured, bracts and lower spathe broadly lanceolate, 6–11 mm long, dark reddish brown, inner 13–15 mm long. *Flowers* yellow; tepals free or connate in a tube 4–7 mm long, elliptic, outer 18–32 × 9–15 mm, inner slightly smaller. *Filaments* 1.5–3.5 mm long; anthers ± 5 mm long. *Ovary* included, smooth; style 4–10 mm long, branches 5–6 mm long. *Capsules* included, subglobose to broadly oblong, smooth, 4–8(–10) mm long. *Flowering time*: mainly September to November.

Distribution of ***Bobartia anceps***.

Distribution and ecology: a local endemic of the Langeberg foothills near Riversdale in Western Cape, South Africa, and best known from Garcia's Pass; on stony clay or loamy soils.

Diagnosis: distinguished from *Bobartia macrospatha,* the only other species in the genus with the ovary not exserted from the rhipidial spathes, by its flattened or subterete leaves and stem, 3–6 mm wide, mostly spreading, leaf-like spathe not expanded or enclosing the synflorescence, and the more numerous, spreading rhipidia densely clustered in a rounded head. The individual rhipidia are relatively small, with the inner spathe 13–15 mm long, and the capsules are also small, subglobose to broadly oblong, 4–8(–10) mm long.

35. **Ferraria**

Ferraria *Burm. ex Miller*, Figures of plants, vol. 2: 187 t. 280 (1759a) and The Gardener's Dictionary, edn. 7 (1759b). Type species: *Ferraria foliis lanceolatis* etc. ... = *F. crispa* Burm.

Revisionary account: Goldblatt & Manning: 1–140 (2011).

Named for the 15th century artist, Giovanni Ferrari, whose illustrated works were much celebrated by contemporaries; his *Flora seu de florum cultura* (Flora of cultivated plants) included the first illustration of *Ferraria*, *F. crispa* drawn from plants grown in Italy (Ferrari 1633).

Small to medium-sized seasonal perennials. *Corm* depressed-globose, consisting of several internodes, producing roots from terminal bud, lacking tunics when mature. *Stem* aerial or largely to entirely underground, usually branched, branches often short and crowded distally. *Leaves* several, lower 3 or 4 lacking blades, thus cataphylls, foliage leaves with isobilateral, sword-shaped to linear, unifacial blades, sometimes not produced on flowering stem, basal 1 or more, largest, progressively smaller above, becoming entirely sheathing and bract-like at distal nodes; margins with subepidermal sclerenchyma without marginal vein. *Inflorescences* 2- to several- flowered rhipidia; spathes green, often leafy, enclosing flower buds, inner always longer than outer, margins free to base. *Flowers* actinomorphic, fugaceous or lasting 2(3) days, often dull coloured, usually creamy white to buff-coloured or brownish, sometimes yellow, rarely blue-violet, spotted and blotched dark brown, green or purple, without scent or scented with sweet, spicy or rotting odours; tepals free, clawed, outer slightly to significantly larger than inner, claws forming a wide or narrow cup or shallow basin, limbs spreading to slightly reflexed, margins crisped, tips attenuate and twisted; producing nectar from nectaries at base or middle of claws. *Stamens* symmetrically arranged; filaments united in lower ± $^{2}/_{3}$ in smooth column, free and diverging in upper $^{1}/_{4}$–$^{1}/_{3}$; anthers appressed to style branches, lobes joined to connective but not to each other, parallel and ± contiguous or diverging from tips. *Ovary* included or exserted, sometimes with sterile beak; style enclosed by filament column, dividing at column apex into short branches, each forked into flattened, diverging, conduplicate arms, usually prominently fringed on adaxial margins, stigmatic surfaces terminal on style branches or on grooved lobe below tip of abaxial margin. *Capsules* globose-truncate, ovoid or ellipsoid, then often beaked. *Seeds* usually angular, mostly 5- or 6-sided, facets separated by winged angles, ± smooth or wrinkled, in one species ± globose and reticulate. *Pollen grains* monosulcate, exine reticulate. *Basic chromosome number x* = 10.

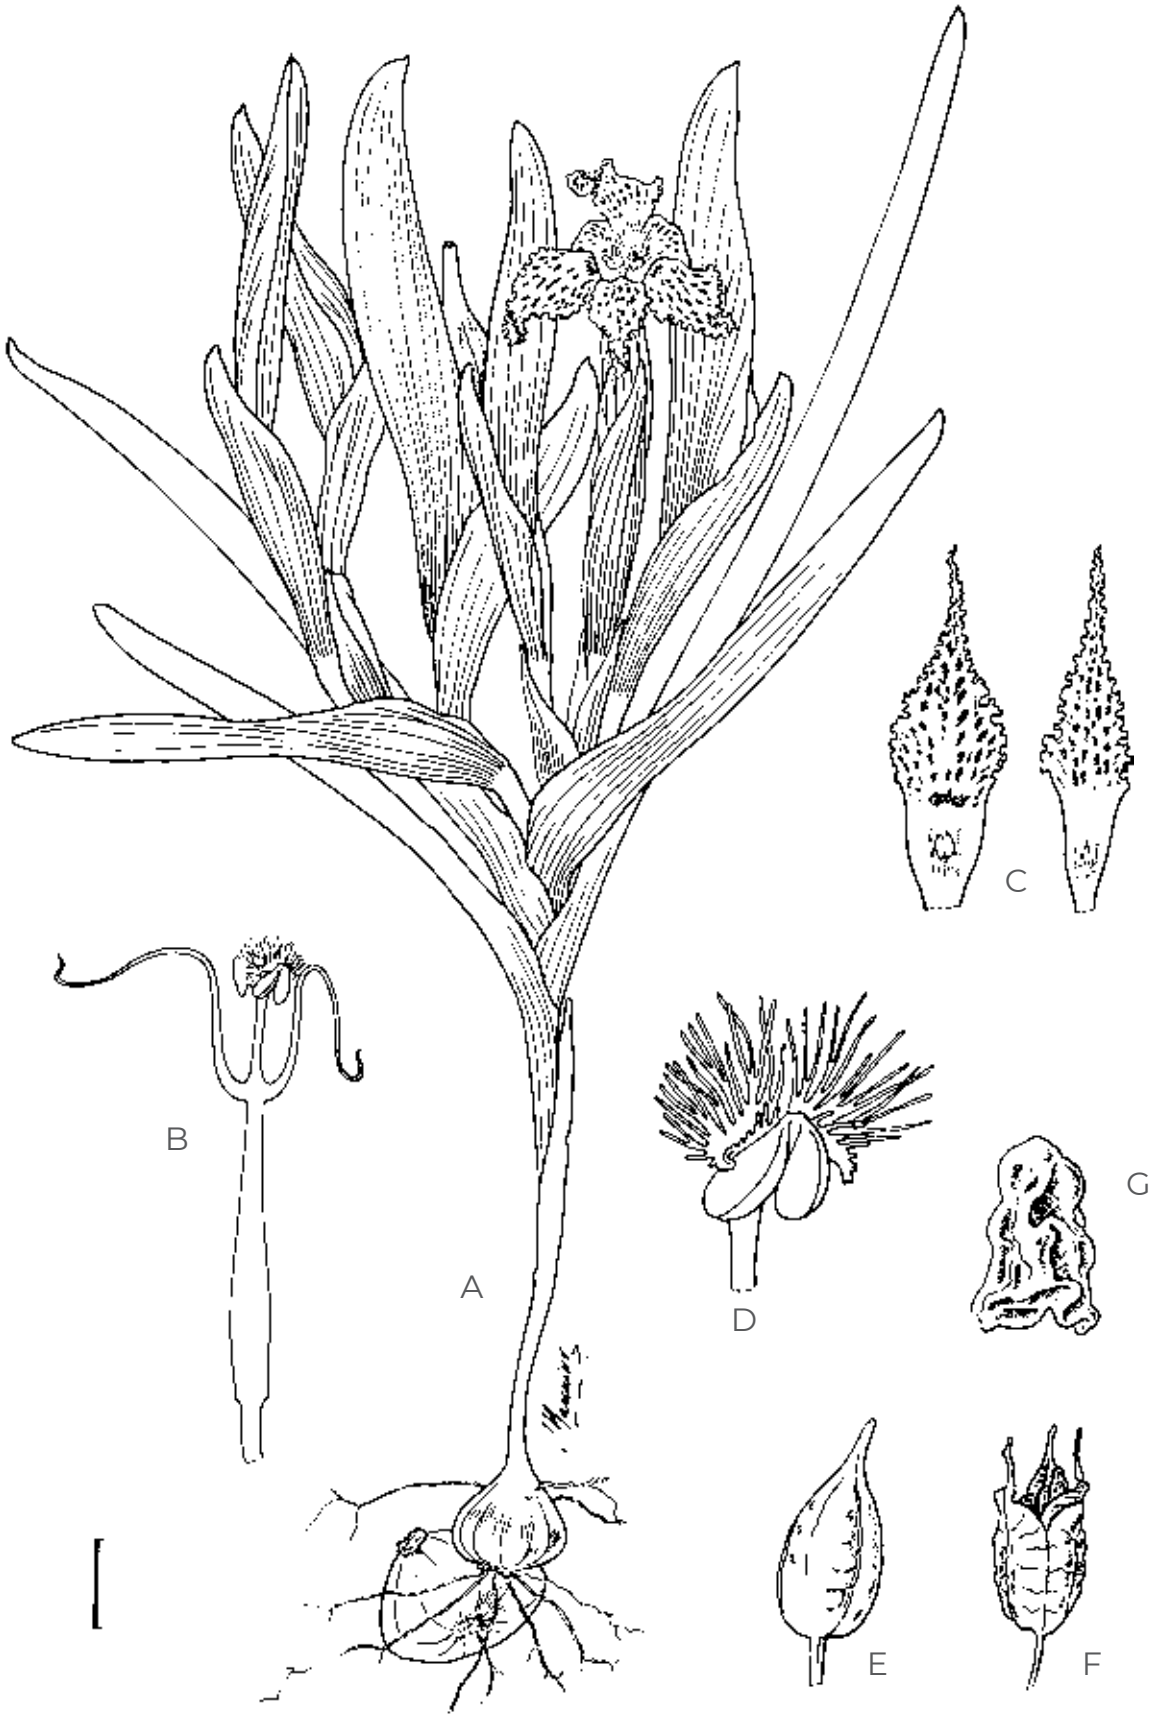
Species 18; dry parts of central and southwestern Africa, with a centre along the southern African west coast and near interior, 15 in southern Africa; generally favouring sandy soils.

The small African genus *Ferraria* stands out in its unusual flowers with the style branches somewhat flattened and terminating in a feathery tuft of fine segments. The tepals are more-or-less equal in size and distinctly clawed, the claws together forming a wide to shallow cup and bearing nectaries of various shapes and sometimes colours. The flowers are scented, sometimes pleasantly but more often not, with odours reminiscent of bitter cocoa or burned sugar in combinations difficult to describe and the tepals are usually dull-coloured and darkly spotted. The flowers of some species are specialised for fly pollination and others for wasps.

The four species of summer-rainfall southern and tropical Africa have an open-branched stem and sticky, viscid nodes, both probably ancestral features whereas the species of the winter-rainfall west coast and interior of southern Africa have smooth stems with short branches hidden by leafy bracts. Some of the latter are almost acaulescent, with the flowers produced almost at ground level. *Ferraria* is sister genus to the larger genus *Moraea* and the two differ not only in the flowers, those of *Moraea* most often *Iris*-like, but in the corms and leaves. In *Ferraria* the corm is persistent, consists of multiple internodes and has soft, evanescent tunics, and the foliage leaves are isobilateral as in most Iridaceae. In *Moraea* the corm is annual, replaced at the end of the growing season, consists of a single internode and has fibrous, persistent tunics and the leaves are dorsiventral and usually channelled. Despite these several and fundamental differences the two genera have been shown by molecular studies to be immediately related.

Key to species

1a Anthers with filament insertion in lower $^{1}/_{3}$ and lobes parallel and usually contiguous above filament insertion when fully dehisced; capsules globose- to ovoid-truncate or acute or beaked in one species; perianth with the tepal claws usually forming a shallow cup and bearing prominent nectaries $^{1}/_{3}$–$^{1}/_{2}$ as long as claw; stigmas minute, terminal on apices of style branch arms:



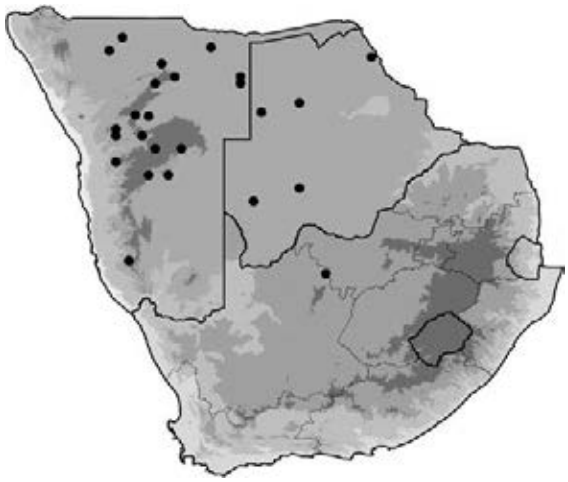
2a Upper internodes below flower clusters with sticky exudate; ovary ovoid- to globose-truncate, short, < 10 mm long; capsules ovoid to globose and truncate (subg. *Glutinosae*). . . . . 1. *F. glutinosa*

2b Plants ± acaulescent or stem aerial, then upper internodes below flower clusters not sticky; ovary ± fusiform, > 10 mm long; capsules usually ovoid, rounded at apex or with short sterile beak (sect. *Ferraria*):
3a Stem aerial, slender with internodes partly exposed; basal leaves linear to falcate, with blades usually < 5 mm wide:
4a Plants ± acaulescent; tepal claws narrow in lower 1/3, thus forming a windowed cup; nectaries concave, at apex of narrow part of claw and with raised and lobed to fringed distal edge . . . . . 7. *F. ornata*
4b Plants with aerial stems: tepal claws broad and not abruptly narrowed in lower part, cup not windowed; nectaries relatively large, in centre of tepal claws and without raised distal edges:
5a Cauline leaves lanceolate-attenuate; flowers grey or blue-green with minute brown, maroon or violet speckling; nectaries yellowish green . . . . . 6. *F. densepunctulata*
5b Cauline leaves ovate-cucullate; flowers yellow with brown margins and a few conspicuous spots; nectaries cream-coloured streaked maroon . . . . . 5. *F. ovata*
3b Stem stout, mostly covered by leaf bases; leaves sword-shaped to falcate, with blades > 5 mm wide:
6a Ovary with short tapering beak, ± 8 mm long; tepals 22–25(–30) mm long, pale yellow with dark brown margins and blotches, often coalescing in outer quarter; flowers sweetly scented . . . . . 4. *F. schaeferi*
6b Ovary fusiform, without tapering beak; tepals 25–35 mm long, flowers variously coloured, usually dark maroon or purple with paler margins or cream-coloured to pale yellow and variously striped and blotched; flowers with an unpleasant, burnt-sugar or putrid scent:
7a Blades of basal leaves with a slightly thickened zone in middle and prominent central vein; leaves 2-ranked . . . . . 2. *F. crispa*
7b Blades of basal leaves much thickened in middle but with weakly developed central vein; leaves spirally 2-ranked . . . . . 3. *F. foliosa*
1b Anthers with filament insertion in upper 1/3 and lobes held together only at tips, usually widely divergent when fully dehisced, rarely subparallel but not contiguous (not always so in freshly opened flowers); capsules always prominently beaked; perianth with tepal claws forming deep, narrow or wide cup; stigmas consisting of groove below tips of style branch arms (sect. *Macroscyphae*):
8a Floral cup widening substantially toward apex, rim ± as wide or wider than depth of cup:
9a Flowers small, sweetly, slightly clove-scented; floral cup ± 8 mm deep, ± 7 mm wide at rim; outer tepals 18–22 mm long; filament column ± 6 mm long . . . . . 9. *F. parva*
9b Flower relatively large, unscented or faintly unpleasantly scented; floral cup 12–15 mm deep, 13–20 mm wide at rim; outer tepals 30–45 mm long; filament column 8–13 mm long:
10a Plants usually subacaulescent and stem mostly covered by sheathing parts of leaves; flowers lasting 2 days; seeds (4)5(6)-sided, facets separated by raised angles, surface smooth . . . . . 11. *F. variabilis*
10b Plants with aerial stem and branching only distally; flowers lasting a single day; seeds ± globose, surface matte . . . . . 10. *F. divaricata*
8b Flowers with narrow cup, sides ± erect (rim of cup 1/2–2/3 as wide as depth of cup):
11a Stem produced well above ground; basal leaves sharply distinct from cauline leaves and with internodes partly exposed; flowers with floral cup 17–20 mm deep; outer tepals 30–40 mm long . . . . . 8. *F. ferrariola*
11b Stem not or only shortly extended above ground (unless growing in shade); basal leaves often hardly distinct from cauline leaves (or from spathes enclosing flower clusters); floral cup 10–12 mm deep; outer tepals 25–35 mm long:
12a Basal leaves broad, leathery-succulent, 8–20 mm wide, cauline leaves and spathes different from basal leaves; flowers lasting a single day, deep yellow; anthers and pollen yellow . . . . . 12. *F. flava*
12b Basal leaves hardly distinct from cauline leaves, rarely exceeding 12 mm wide, flowers lasting two days, watery yellow, blue or shades of beige to cream-coloured dotted with blue spots; anthers and pollen usually orange to ± red:
13a Flowers usually predominantly blue to violet with dull yellow-green to khaki-coloured margins, occasionally tepal limbs pale bluish or cream-coloured, then speckled dark blue; margins of at least lowermost leaves conspicuously thickened, hyaline and partly crisped and undulate; marginal thickenings smooth . . . 13. *F. uncinata*
13b Flower pale watery yellow with darker yellow to buff- or khaki-coloured margins; leaf margins either thickened then lower leaves with margins plane or serrulate to crenate, or sometimes slightly crisped or unthickened and margins plane; marginal thickenings when present often shortly velvety:
14a Basal leaves with extended, lanceolate to linear blades longer than sheaths . . . . . 14. *F. macrochlamys*
14b Leaves with short, oblique, ovate blades < 1/2 as long as sheaths . . . . . 15. *F. brevifolia*

Subg. 1. **Glutinosae**

Subg. **Glutinosae** *(M.P.de Vos) Goldblatt & J.C.Manning* in Bothalia 41: 11 (2011). *Ferraria* sect. *Glutinosae* M.P.de Vos: 329 (1979). Type: *F. glutinosa* (Baker) Rendle

Plants with open, aerial branching system and stem sticky below the nodes. *Rhipidia* with > 2 and up to 6 flowers each. *Flowers* with tepals claws forming a wide cup, bearing prominent nectaries with dry nectar. *Filaments* inserted in lower 1/3 of anthers; anther lobes parallel, contiguous above filament insertion when fully dehisced. *Ovary* exserted, ovoid; stigmas minute, terminal on apices of style branch arms. *Capsules* globose- to ovoid-truncate.



Ferraria parva: A, flowering plant; B, half-flower; C, detached outer tepal (left) and inner tepal (right); D, detail of anther and one stigmatic branch; E, undehisced capsule; F, dehisced capsule; G, seed.

1. **Ferraria glutinosa** *(Baker) Rendle*, Catalogue of the African plants collected by Dr. Friedrich in 1853–61, vol. 1: 27 (1899); Goldblatt & Manning: 11 (2011). *Moraea glutinosa* Baker: 271 (1878). Type: Angola, Huila, near Lopollo, Ferrão da Sola, Feb. and Apr. 1860, *Welwitsch 1543* (BM, holo.; K, LISU, P, iso.).

Ferraria bechuanica Baker: 344 (1898). Type: Botswana, Ngamiland, Kalahari Desert near Manumwe, 'flowers chocolate with yellow fringe', 26 Feb. 1897, *Lugard 237* (K, holo.).

Moraea randii Rendle in Rand: 144 (1898). *Ferraria randii* (Rendle) Rendle: 54 (1905). Type: Zimbabwe, Bulawayo, January 1898, *Rand 223* (BM, lecto., designated by Goldblatt & Manning: 11 (2011); BR, isolecto.).

Ferraria viscaria Schinz: 77 (1900). Type: Namibia, Omupanda, *Wulfhorst 45* (Z, holo.).

Distribution of ***Ferraria glutinosa***.

Plants mostly 400–600 mm high. *Stem* exposed above sheaths of lower leaves, branched from upper nodes, branches rarely also branched; distal 5–6 mm of upper internodes sticky, often with sand adhering. *Leaves* at base solitary or up to 4, sometimes basal leaf poorly developed; blades linear, straight, 4–6(–10) mm wide, with visible central vein, cauline leaves moderately well-developed, often longer than basal, progressively reduced above, becoming largely sheathing. *Rhipidia* 4- to 6-flowered; inner spathe 30–42 mm long, outer entirely sheathing, usually ± $^1/_3$–$^1/_2$ as long. *Flowers* on pedicels as long or longer than spathes; usually dark brown to dull purple or maroon; tepal limbs with pale yellow to gold-coloured margins, sometimes limbs marked or sparsely spotted yellow near base or with large irregular brown blotches on pale background; claws brown or yellow streaked with purple or brown, odourless; tepals diverging, claws forming wide cup ± 10 mm deep, 15–18 mm wide at rim, limbs spreading to ± reflexed; margins crisped; nectaries dark brown, 1.5 × 2.0 mm, 3–4 mm above claw bases; outer tepals 23–33 × ± 10 mm; inner tepals slightly smaller, claws tapering to narrow base. *Filaments* united in minutely papillate column, 8–11 mm long, free in upper 1.5–2.0 mm; anthers parallel, 5–6 mm long, shorter after anthesis, dark brown; pollen orange. *Ovary* narrowly ovoid, usually exserted, 5–7 mm long; style branches 2 mm long, dividing into diverging, fringed arms 2–3 mm long, fringes smooth or minutely papillate, 4–5 mm long; stigmas terminal on style arms. *Capsules* ovoid- to globose-truncate, mostly 12–18 mm long. *Seeds* glossy, brown, 4–5 mm long, ± 5-sided, facets separated by raised ridges, wrinkled. *Chromosome number* 2*n* = 40. *Flowering time*: mostly January to March, occasionally later; lasting a single day.

Distribution and ecology: occurring across a wide belt of summer-rainfall southern and central Africa, and relatively common across Botswana and northern Namibia, also in Northern Cape and North West Provinces of South Africa (and in Angola, Zimbabwe and Malawi); usually in sandy ground with corms deeply buried, also in rocky places.

Diagnosis: differing from all other southern African species of the genus in the sticky stems, open branching habit, and rhipidia with several (usually 4 to 6) flowers. The capsules are subglobose and flat-topped, unlike capsules of the remaining southern African species. Flowers are variously coloured, ranging from almost uniformly brown to dark purple or maroon with pale yellow to light brown crisped margins to partly marked with yellow streaks or bands. The corms are edible and eaten raw or roasted.

Subg. 2. **Ferraria**

Plants acaulescent or with aerial stems with relatively short branches enclosed by leaf sheaths. *Stems* not sticky below nodes. *Rhipidia* 2-flowered. *Flowers* with tepal claws widely diverging, forming a shallow cup, with large nectaries with non fluid nectar, or forming a deep, wide to narrow cup with small nectaries and with fluid nectar. *Filaments* inserted in lower $^1/_3$ or near apex of anthers; anther lobes parallel and usually contiguous above filament insertion or lobes not contiguous and becoming widely divergent when fully dehisced. *Ovary* included, with or without sterile beak; stigmas minute, terminal on apices of style branch arms, or larger, on lobes below style arms tips. *Capsules* ovoid-oblong and obtuse or with prominent beak.

Sect. 1. **Ferraria**

Ferraria [unranked] *Brachyscyphae* Baker: 106 (1877). Type: *F. undulata* L. = *F. crispa* Burman, lecto., designated here.

Flowers with tepal claws widely diverging, forming a shallow cup, with large nectaries with non fluid nectar; filaments inserted in lower $^1/_3$ of anthers; anther lobes parallel and contiguous above filament insertion; ovary ellipsoid, sometimes with sterile beak; stigmas minute, terminal on apices of style branch arms; capsules ovoid-oblong and obtuse or with prominent beak.

2. **Ferraria crispa** *Burman* in Nova acta physico-medico Academiae Caesareae Leopoldino-Carolinae germanicae naturae curiosorum 2: 199 (1761); Goldblatt & Manning: 17 (2011). Type: South Africa, without precise locality, illustration in Burman: 199, t. 3, f. 1 (1761).

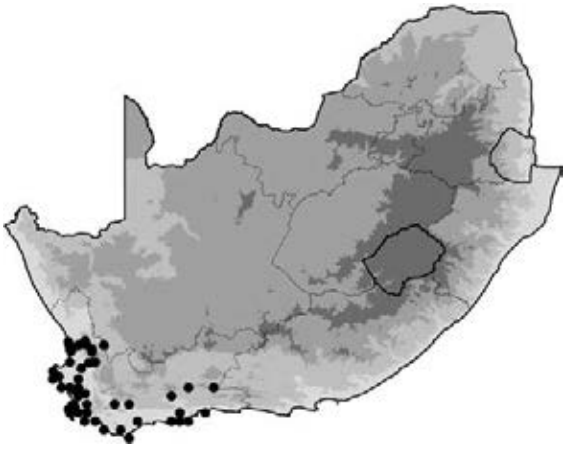
Ferraria undulata L.: 1353 (1763), illegitimate superfluous name for *F. crispa* Burman. *Moraea undulata* (L.) Thunb.: no. 14 (1787). Type: South Africa, without locality or collector, illustration in Miller: 187, t. 280 (1759a), lecto., designated by Goldblatt & Manning: 17 (2011).

Ferraria ensiformis Mill. (1768), illegitimate superfluous name for *F. crispa* Burman. Type: not designated, probably as for *F. crispa*.

Ferraria obtusifolia Sweet: t. 148 (1826a). Type: illustration in Sweet: t. 148 (1826a).

Ferraria atrata G.Lodd., The Botanical Cabinet 14: t. 1356 (1828), new synonym. Type: illustration in G.Lodd.: t. 1356 (1828).

Ferraria vandermerwei L.Bolus: 276, fig. D (1932). Type: South Africa, [Western Cape], near Swellendam, cultivated in Cape Town, Sept.–Oct. 1932, *Van der Merwe s.n.* (BOL, holo.).



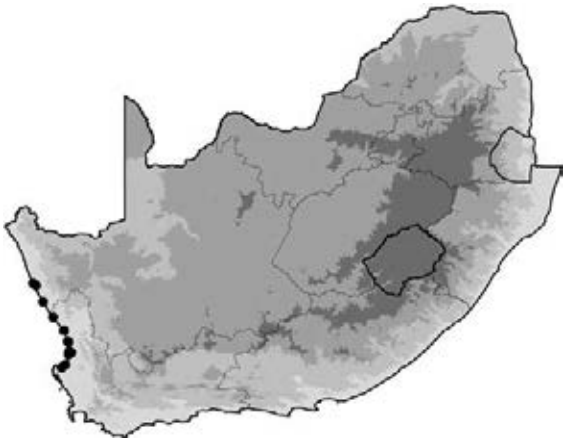
Ferraria crispa subsp. *nortieri* M.P.de Vos: 338 (1979). Type: South Africa, [Western Cape], heights north of Verlorenvlei, 28 Aug. 1976, *De Vos 2366* (NBG, holo.).

[*Ferraria major* Eckl.: 18 (1827), invalid name without description.]

Plants usually robust, (300–)450–1 500 mm high. *Stem* much branched in upper half, sheathed by leaf bases below; cataphylls and bases of leaf sheaths often speckled pale on red background. *Leaves* several, linear to sword-shaped, (4–)6–12 mm wide, basal longest, with visible main vein. *Rhipidia* 2-flowered; spathes green with membranous margins, inner 45–65 mm long, outer ± half as long, usually entirely sheathing. *Flowers* on pedicels 40–60 mm long, variously pale yellow to beige with brown to dull purple mottling and brown margins to mostly brown with pale yellow margins, strongly scented, odour ± of caramel or molasses, tepals widely diverging, claws forming shallow bowl 6–8 mm deep, 13–18 mm wide at mouth, nectary covering ± half length of claw, limbs spreading; outer tepals 28–35 mm long, claws 8–12 mm long, limbs up to 25 mm long, inner tepals slightly shorter and narrower. *Filaments* united in smooth column ± 6 mm long, free in upper 3 mm; anthers ± 3 mm long, thecae parallel, shortly apiculate; pollen orange. *Ovary* ellipsoid, without beak, included in spathes, 12–20 mm long; style branches ± 4 mm long, forked in upper half, divided into diverging arms; 4–5 mm long, prominently fringed; stigmas terminal on style arms. *Capsules* ovoid to oblong, 15–25 mm long, obtuse or pointed at apex. *Seeds* angular, mostly 5-sided, ± 4 mm long, facets slightly wrinkled. *Chromosome number* $2n$ = 40, 60. *Flowering time*: August to October; lasting a single day.

Distribution and ecology: best known from the Atlantic Coast of Western Cape, South Africa, extending from Pakhuis Pass through the Witteberg and Swartberg Mtns to Georgida in the Baviaanskloof of Eastern Cape and along the coast as far as Herold's Bay near George; most common along the coast but showing a striking ecological shift, also in montane habitats, sometimes along streams in deep, coarse sand, or on seasonally moist south-facing slopes; coastal populations flower annually but the montane populations flower well only after fire the previous summer.

Diagnosis: recognised by the growth habit, with stems produced well above the ground and bearing numerous branches crowded in the upper half, *Ferraria crispa* has a flower with a wide, shallow cup and an ovoid to ellipsoid capsule rounded or acute at the apex and lacking a beak. The sword-shaped lower leaves and shorter cauline leaves have a definite main vein and form two opposed ranks. The strongly scented flowers have tepals speckled or blotched dark brown to dull purple on a cream-coloured to pale yellowish background, or occasionally predominantly dark brown, always with pale crisped margins, these sometimes almost golden



Distribution of ***Ferraria crispa***.

yellow when the tepals are otherwise brown. The tepal claws each bear a large, glistening nectary, often covering almost half the surface. The nectaries produce minute droplets of concentrated nectar scattered over the entire surface.

Northern populations of *Ferraria crispa* have been treated as subsp. *nortieri* because of their pale green rather than slightly glaucous leaves, and slightly smaller flowers with the floral cup mostly ± 8 mm deep and ± 10 mm wide at the rim, and the ovary < 20 mm long. The distinction is less clear than at first believed and these northern populations are not recognised here. The northern populations are tetraploid, $2n$ = 40, whereas those in the south and east are hexaploid, $2n$ = 60. The ecological range of *F. crispa* is remarkable but there appear to be no vegetative or floral differences between coastal populations that favour rocky outcrops and those from sandy mountain slopes, except the latter may be taller, sometimes reaching up to 1.5 m.

3. **Ferraria foliosa** *G.J.Lewis* in Annals of the South African Museum 40: 117 (1954); Goldblatt & Manning: 18 (2011). Type: South Africa, [Western Cape], near Elandsbaai [Elands Bay], 12 Sept. 1955, *Lewis 2301* (SAM [*SAM60809*], holo.; NBG, SAM [2 sheets], PRE, iso.).

Plants 300–800 mm high. *Stem* leafy and much-branched, branches rotated in clockwise fashion. *Leaves*: basal (and juvenile) linear, diamond-shaped in cross section, thickened in midline, ± 8–10 mm wide, main vein hardly evident below thickened midline; cauline leaves falcate, channelled below, distally horizontal, main vein often not evident, arranged in a two-ranked spiral. *Rhipidia* 2-flowered; inner spathe 48–50 mm long, often inflated, outer 28–30 mm long, sheathing below, diverging in upper half, hooked at tips. *Flowers* on pedicels 17–20 mm long, dull maroon to purple or dark brown, usually with darker purple-maroon blotches, margins pale brown, claws usually maroon-speckled with white, putrid- or molasses-smelling, tepal claws broad, forming a wide cup, 7.5–8.0 mm deep, 13–18 mm wide at rim, nectaries pale green, heart-shaped, prominent, covering $^1/_3$–$^1/_2$ of claw, limbs ± spreading; outer tepals 33–40 mm long, inner tepals 28–35 mm long, claws 9–10 mm long. *Filaments* united in a column 8–11 mm long, upper 1.5–2.5 mm free; anthers ± 3.5 mm long before anthesis, thecae parallel; pollen orange. *Ovary* ellipsoid, not beaked, included, 15–20 mm long; style branches ± 4.5 mm long, diverging, with prominently fringed arms; stigmas terminal on style arms. *Capsules* ellipsoid, 28–35 mm long, round at apex. *Seeds* angular, ± 5-sided, ± 3 mm long, facets slightly wrinkled, light brown, shiny. *Chromosome number* $2n$ = 20. *Flowering time*: late August to October; lasting a single day.

Distribution of ***Ferraria foliosa***.

Distribution and ecology: extending along the Atlantic Coast of Northern and Western Cape, South Africa, from near Hondeklipbaai in the north to Velddrif in the south; on dunes and sandy beaches in deep sand.

Diagnosis: vegetatively, *Ferraria foliosa* can be distinguished by the long, linear basal leaves much thickened in the midline, thus ± diamond-shaped in cross section, and sometimes dry by flowering time. The basal leaves differ markedly from the shorter, broader cauline leaves, the blades also thickened in the middle and arching outward, ultimately spreading horizontally. Successive leaves are opposed but collectively the leaves have a spirally two-ranked arrangement. This is also reflected in the short lateral branches, which are crowded in the upper half of the stem, the successive ones rotated slightly in a clockwise direction. The flowers differ little from those of closely related *F. crispa* in their darkly mottled pigmentation, broad tepal claws with large nectaries, and wide, shallow floral cup. Whereas the flowers of *F. crispa* are usually shades of dull yellow, buff-coloured and brown, those of *F. foliosa* are mottled dull purplish, or brownish maroon on a paler grey-purple background.

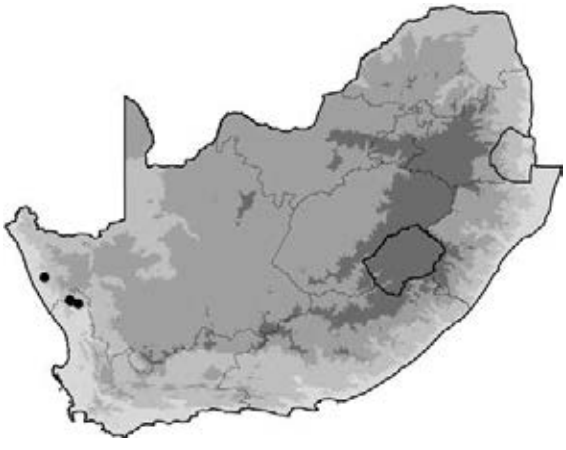
4. **Ferraria schaeferi** *Dinter* in Repertorium Novae Species Regni Vegetabilium 16: 339 (1920). Goldblatt & Manning: 19 (2011). Type: Namibia, Klinghardt Mtns, Dreikugelberg, 14 Aug. 1913, *Schäfer 562* [B, neo., designated by De Vos: 344 (1979)].

Plants 200–500 mm high. *Stem* sheathed by leaf bases, branching repeatedly in upper axils, branches rotated in clockwise spiral; corm bearing long runners from base, each terminating in a small corm. *Leaves* with overlapping sheaths; blades thick and leathery, thickened in midline and main vein usually evident, arranged in a two-ranked spiral, spreading horizontally above, 12–20 mm wide. *Rhipidia* 2-flowered; spathes firm, leafy in texture, with translucent membranous upper margins, inner 50–60 mm long, outer somewhat shorter, sheathing only near base, arching outward in upper half. *Flowers* on pedicels 40–50 mm long; creamy yellow with small to large brown spots, margins dark brown, usually sweetly scented (of violets), tepal claws broad, forming a wide cup, ± 8 mm deep, 12–15 mm wide at rim, with brownish purple, heart-shaped nectaries in lower half, ± half as long as claw; outer tepals ±

Distribution of ***Ferraria schaeferi***.

25 mm long, inner tepals 22–24 mm long, claws of both whorls ± 8 mm long. *Stamens* with filament united in a column ± 7.5 mm long, free in upper 2 mm; anther thecae parallel, ± 5 mm long at anthesis, later shrinking; pollen dull brown to orange. *Ovary* ellipsoid, 20–25 mm long, tapering to a slender beak, ± 8 mm long, included; style branches ± 2 mm long, diverging into prominently fringed arms ± 2 mm long; stigmas terminal on style arms. *Capsules* ± ellipsoid, 20–25 mm long, excluding beak. *Seeds* light brown, glossy, 5- or 6-angled, ± smooth. *Chromosome number* 2*n* = 40, 60. *Flowering time*: mid-July to September; lasting a single day.

Distribution and ecology: extending from near Lüderitz Bay in southwestern Namibia in the north to Grootmis in Northern Cape, South Africa, in the south; in deep sands and dunes, mainly along the coast, or a short distance inland.



Diagnosis: unlike the flowers of the related species, *Ferraria crispa* and *F. foliosa*, those of *F. schaeferi* sometimes have, at least to the human nose, a pleasant, sweet scent reminiscent of violets, but with a slightly sour undertone. The flowers otherwise resemble those *F. crispa* and *F. foliosa*, having widely spreading tepals, the broad claws forming a shallow cup, ± 8 mm deep and some 12 mm wide at the rim. The tepal claws bear large heart-shaped nectaries, while the limbs have a creamy pale yellow ground colour speckled with small dark brown spots, the same colour as the crisped margins. In vegetative form, *F. schaeferi* most closely resembles *F. foliosa*, which also has the leaves and branches arranged in a two-ranked spiral, and the leaf blades are similarly thick and leathery with a weakly defined central vein. In addition to the differently coloured perianth, the ovary and capsule have a pronounced beak up to 8 mm long. This readily separates *F. schaeferi* from *F. foliosa*. In its sandy habitat, plants spread vegetatively by long runners produced from the base of the stem that can extend below the ground a metre or more from the parent plant, each terminating in a corm.

5. **Ferraria ovata** *(Thunb.) Goldblatt & J.C.Manning* in Novon 12: 461 (2002); Goldblatt & Manning: 20 (2011). *Moraea ovata* Thunb.: 186 (1800). Type: South Africa, [Northern Cape], Namaqualand, near Kooksfontein [as Koksfontein, also Cocksfonteyn], (now Soebatsfontein), probably in 1793, *Masson s.n.* (UPS–THUNB 1225, holo.).

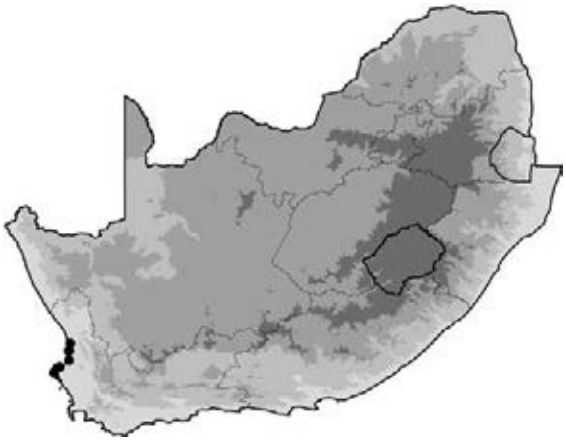
Plants often small, (40–)100–200 mm high. *Stem* erect, unbranched, lower half partly exposed. *Leaves*: basal and juvenile with short, linear blades, up to 45 × 2 mm; cauline entirely bifacial, broadly ovate to rotund, amplexicaul, 15–18 mm long, spreading, concave; margins membranous, often reddish. *Rhipidia* 2-flowered; spathes leafy, green, often brown at tips, inner 18–20 mm long, outer 12–20 mm long, sheathing in lower half, arching outward above. *Flowers* on pedicels 7–12 mm long, pale yellow with brown spots in midline and base of limbs, margins closely crisped, dark brown, acrid-smelling; tepal claws broad, 7–8 mm long, forming a cup ± 7 mm deep, ± 8 mm wide at rim, nectaries ± 2 mm long, above base of claws, ± 2 × 2 mm, paired or bilobed, greenish, tepal limbs spreading; outer tepals 17–20 mm long, limbs 8–12 mm long, inner slightly smaller than outer. *Filaments* united in a column 7–8 mm long, free in upper 1 mm; anther thecae parallel, ± 2 mm long; pollen orange. *Ovary* ellipsoid, ± 6 mm long, without beak, included; style branches ± 2 mm long, diverging into prominently fringed arms; stigmas terminal on style arms. *Capsules* ovoid (mature capsules and seeds unknown). *Flowering time*: June to July; lasting a single day.

Distribution and ecology: restricted to central Namaqualand in Northern Cape, where it is recorded from a few isolated sites from Soebatsfontein in the north to the low hills of the southern Kamiesberg between Bitterfontein and Kliprand; usually in gritty granitic gravel among rocks that provide protection from predation.

Diagnosis: the parallel anthers, wide and shallow tepal cup, spindle-shaped ovary without a beak, and stigmas

Distribution of ***Ferraria ovata***.

terminal on the style arms, place *Ferraria ovata* in sect. *Ferraria* where it is unusual in the few-branched or simple stem and strongly dimorphic leaves, the basal linear and the cauline bifacial, short and spoon-shaped. The relatively small flowers are strikingly coloured yellow and glossy dark brown. The nectaries are bilobed or paired well above the bases of the tepal claws.



Ferraria ovata is one of three winter-flowering species in the genus, the others being the coastal species *F. densepunctulata* and *F. ornata*.

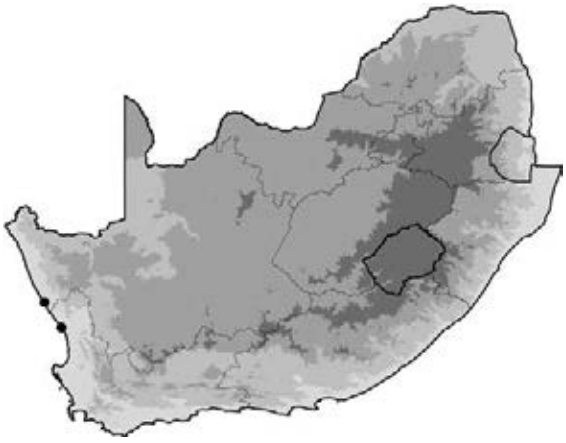
6. **Ferraria densepunctulata** *M.P.de Vos* in Journal of South African Botany 45: 346 (1979); Goldblatt & Manning: 22 (2011). Type: South Africa, [Western Cape], Elandsbaai, 14 Jun. 1974, *Loubser sub De Vos 2317* (NBG, holo.; PRE, iso.).

Plants slender, mostly 120–250 mm high. *Stem* few-branched in upper half, lower half of stem partly visible; leaf sheaths and cataphylls often flushed red with pale spotting. *Leaves*: basal with long compressed-cylindric blades, loosely 2-ranked, 3–5 mm wide, margins hyaline to reddish; cauline shorter, spreading outward, tips often hooked; juvenile leaves up to 6 in 2-ranked cluster, terete, hollow, dark green. *Rhipidia* 2-flowered; spathes green with narrow membranous margins pale or flushed red; inner 40–50 mm long, outer ± 25 mm long, sheathing below, diverging and hooked distally. *Flowers* on pedicels slightly shorter to ± as long as spathes; pale greenish to grey-blue, outer tepals densely speckled with small maroon to purple or dark blue spots, inner tepal limbs maroon to purple or dark blue blotch in lower half, faintly spice-scented, tepal claws forming a shallow cup, ± 9 mm deep, 15–20 mm wide at rim; nectaries bilobed, above base of outer tepal claws, in midline of inner tepal claws, tepal limbs spreading horizontally, undulate or only slightly crisped; outer tepals 25–30 × 11–13 mm, inner tepals 20–23 × ± 10 mm, claws of both whorls ± 10 mm long, inner narrower than outer. *Filaments* united in a column 8–10 mm long, free in upper ± 2 mm; anther thecae parallel, ± 4 mm long before anthesis; pollen orange or dull yellow. *Ovary* ellipsoid, without beak but sterile in upper 3–4 mm, sometimes exserted, 12–15 mm long; style ± 10 mm long, style branches ± 3 mm long, divided in upper $^1/_3$ into diverging, fringed arms; stigmas terminal on style arms. *Capsules* ovoid, 15–25 mm long, apex subacute. *Seeds* pale, glossy brown, ± 3 mm diam., 5-sided, lightly wrinkled. *Chromosome number* 2*n* = 20. *Flowering time*: May to July; lasting two days.

Distribution and ecology: restricted to the Atlantic Coast of Western Cape, South Africa, from Lambert's Bay in the north to Langebaan in the south; on granite or limestone outcrops or calcareous sands.

Diagnosis: early flowering and relatively rare, *Ferraria densepunctulata* is distinctive in the narrow basal leaves, oval in cross section, and rather different from the shorter, broader cauline leaves, and in the unusually coloured flowers, minutely dark blue to purple spotted on a pale greenish to grey-blue background, but with the limbs of the inner tepals so densely speckled as to appear solidly coloured, either maroon or dark slate blue. The flowers are also unusual in having the tepal limb margins undulate instead of closely crisped. Small bilobed nectaries are located at the base of the outer tepals but in the midline of the inner tepal claws, the lower halves of which are linear and ± 1 mm wide. Like other members of sect. *Ferraria*, the stigmas are terminal on the arms of the style branches and the ovary is not beaked. The flowers are unique in the section in lasting two days instead of a single day. The leaves of non-flowering plants are so strikingly different from those of mature, flowering individuals that they appear to represent a different species. Four to six in number, they are held in a close, 2-ranked fan and the blades are dark green, terete and hollow.

Distribution of ***Ferraria densepunctulata***.



The early flowering habit of *Ferraria densepunctulata* is matched in the genus by *F. ornata* and *F. ovata*, both of which also have the narrow basal leaves differentiated from the shorter and broader cauline leaves.

7. **Ferraria ornata** *Goldblatt & J.C.Manning* in Bothalia 41: 24 (2011). Type: South Africa, Northern Cape, central Namaqualand, sandy slopes 10 km inland of Groen River Mouth, Farm Van Zylsrus, 500 m along dirt track N of main road, strandveld in deep sand, 2 June 2008, *Manning 3174* (NBG, holo.; MO, iso.).

Plants acaulescent, 50–80 mm high. *Stem* closely 2- to 4-branched; replacement corms not present at flowering, developing later; cataphylls (usually only uppermost) turning red above ground. *Leaves* 4 or 5, clasping stem, lanceolate-concave, up to 40 × 15 mm, glaucous with purple tips; margins membranous, reddish, finely crisped, basal leaf with blades 5–10 mm long, subterete to cylindric, obtuse-apiculate, 3–4 mm diam.; non-flowering plants with 1 to 3(–5) leaves; blades suberect or falcate, subterete or cylindric, ± 4-sided to

round in section, 60–80 × 2–4 mm, obtuse-apiculate, glaucous with purple apex and sheath, sheath margins and veins minutely hairy abaxially. *Rhipidia* 2-flowered; spathes leathery, glaucous, with translucent, membranous margins, inner 40–50 mm long, outer about half as long, sheathing in lower half, arching outward. *Flowers* on pedicels 30–40 mm long; white with base of tepal limbs yellow, limbs finely brown-spotted basally and with fewer, larger brown spots distally, margins finely crisped, yellow and brown, claws streaked with brown, unscented, with bilobed, concave nectaries in middle of claws, distal nectary margin prominently crested, pale lilac with purple streaks, tepal claws narrowed below, forming a windowed cup 7–8 mm deep and ± 10 mm wide at rim, limbs spreading or slightly reflexed; outer tepals ± 19 × 10 mm with claws ascending, ± 8 mm long, narrowed below and ± 2 mm wide, inner ± 13 × 6 mm with claws ± 6 mm long, narrow proximal part ± 1.5 mm wide. *Filaments* united in column 8–9 mm long, upper ± 2 mm free; anthers diverging, thecae parallel, ± 3 mm long, brown; pollen orange. *Ovary* ellipsoid, 10–12 mm long, included; style branches diverging, deeply divided into diverging, fringed arms; stigmas terminal on style arms. *Capsules* broadly ovoid, 14–18 mm long, tapering to acute tip. *Seeds* irregularly 5(6)-sided, ± 3 × 2 mm, facets separated by pale straw-coloured, wavy ridges, usually ± plane, dark brown. *Flowering time*: May to early June; lasting a single day.

Distribution and ecology: known from two extended populations on the Atlantic Coast of South Africa, one on slopes above the lower Groen River in central Namaqualand, Northern Cape, and the other west of Koekenaap in Western Cape, some 120 km to the south; in deep sandy soils in sandveld.

Distribution of ***Ferraria ornata***.

Diagnosis: stemless and with the tepal claws unusually narrow in the lower part, thus forming a windowed cup, *Ferraria ornata* is easily recognised by these features, as well as its small size, flowering individuals standing only 50–80 mm high. The apparently scentless flowers are unique in the fleshy crests bordering the distal margins of the nectaries, which are situated in the middle of the tepal claws and secrete miniscule quantities of sticky, sweet nectar. The short, concave cauline leaves of flowering plants contrast with the long, cylindric leaves of juvenile and non-flowering individuals. Both the early flowering and unusual, concave cauline leaves of flowering plants suggest it is most closely allied to *F. ovata*, which has a similar growth strategy of early flowering and small, concave cauline leaves on a taller flowering stem. Replacement corms of flowering individuals are absent at flowering and develop later as the capsules ripen.

Sect. 2. **Macroscyphae** *(Baker) M.P.de Vos* in Journal of South African Botany 45: 349 (1979). *Ferraria* [unranked] *Macroscyphae* Baker: 106 (1877); Goldblatt & Manning: 25 (2011) [as 'sect. *Macroscyphae* Baker']. Type: *Ferraria divaricata* Sweet, lecto., designated by De Vos: 350 (1979).

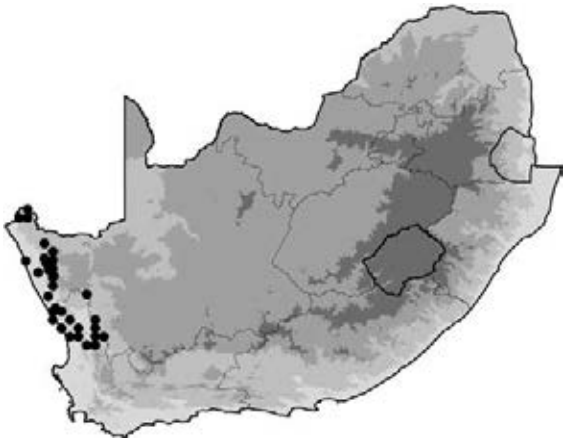
Flowers with tepal claws forming a deep, wide or narrow cup containing fluid nectar; filaments inserted near apex of anthers; anther lobes when fully dehisced usually widely divergent, rarely parallel but never contiguous; ovary always with sterile beak; stigmas on lobes below apices of style branch arms; capsules with prominent beak.

Ser. **Subdivaricatae** *Goldblatt & J.C.Manning*, new series. Type: *Ferraria ferrariola* (Jacq.) Willd.

Tepal claws forming a narrow cup 7–12 mm diam. at rim. *Anther* thecae ± parallel at dehiscence, later divergent.

8. **Ferrari**a **ferrariola** *(Jacq.) Willd.*, Species plantarum, edn. 4, 3: 581 (1800); Goldblatt & Manning: 25 (2011). *Moraea ferrariola* Jacq.: 141 (1791). Type: South Africa, without precise locality or collector, illustration in Jacq.: 24, t. 450 (1804).

Ferraria viridiflora Andrews: 285 (1803) [*F. viridis* Ker Gawl. (1804), orth. var.]. Type: South Africa, collected by W. Synnot, without precise locality, illustration in The Botanist's Repository 4: t. 285 (1803); no preserved material known.



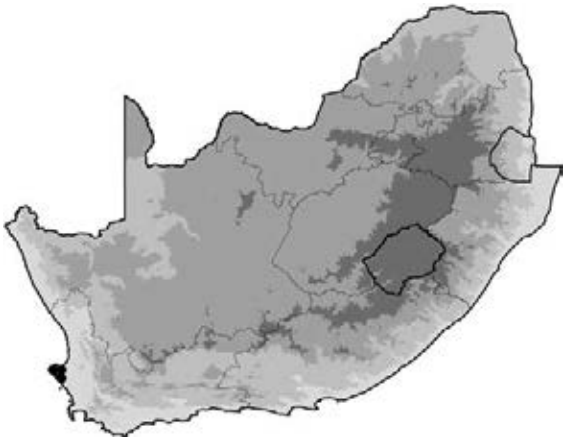
Ferraria longa Barnes: 313 (1930). Type: South Africa, [Northern Cape], Nieuwoudtville, cultivated at Kirstenbosch, Jul. 1930, *P. Ross-Frames s.n. BOL19720* (BOL, holo.).

Plants slender, mostly 150–250 mm high. *Stem* sheathed below by mottled cataphylls and leaf sheaths; lower internodes usually partly exposed, usually branched in upper half. *Leaves*: basal linear, unifacial, usually slightly longer than stem, mostly 2–3 mm wide, main

vein usually well delineated; cauline leaves markedly shorter and broader than basal leaves and resembling spathes. *Rhipidia* 2-flowered; spathes glaucous or pale green, with broad transparent margins, hooked at tips, inner 45–60(–70) long, often inflated, outer ± $^{1}/_{2}$–$^{2}/_{3}$ as long, sheathing below, diverging in upper half. *Flowers* on pedicels 20–30 mm long; greenish blue, grey-blue, or pale watery yellow to pale green, usually with darker spots and streaks on outer tepal limbs, faintly sweet- or spice-scented, sometimes odourless, tepal claws forming a narrow, closed cup, 17–20 mm deep, ± 12 mm wide at mouth; nectaries small, at base of tepals; outer tepals (30–)35–40 mm long, claws fairly narrow, 17–20 mm long, inner slightly shorter and narrower, limbs of outer ± spreading, inner usually reflexed. *Filaments* united in a column 14–19 mm long, upper 1–2 mm free; anther thecae initially parallel, ± 4 mm long at anthesis, later diverging and shrinking to almost 2 mm. *Ovary* ellipsoid, 20–25 mm long, with sterile beak, (5–)8–12 mm long; included; style branches ± 2.5 mm long, with diverging, fringed arms, ± 2.5 mm long; stigmas irregularly shaped lobes in middle of style arms, arching over anthers. *Capsules* ovoid-oblong, 14–20(–25) mm long, beak (5–)8–12 mm long. *Seeds* mostly 5-sided, 3.0–3.5 × 2.5–3.0 mm, smooth, shiny, brown, facets separated by prominent, pale wavy ridges, facets light yellow-brown, smooth or slightly wrinkled. *Chromosome number* 2*n* = 20. *Flowering time*: June to August; lasting two days.

Distribution and ecology: relatively common along the Atlantic Coast of South Africa, extending from the Richtersveld in northern Namaqualand to the Bokkeveld Mtns in Northern Cape and through the Olifants River Valley as far south as Clanwilliam in Western Cape; on granite and sandstone slopes, or in sandy ground usually not far from rock outcrops .

Diagnosis: *Ferraria ferrariola* is readily recognised by the linear basal leaves, quite different from the shorter cauline leaves, the stem usually partly exposed, and with red-flushed and white-speckled cataphylls and lowermost leaf sheath. The large flowers have a deep and relatively narrow floral cup, 17–20 mm deep and ± 12 mm wide at the mouth. The flowers are usually shades of turquoise-grey to pale slate-blue with a pale yellow nectar guide lightly speckled with darker colour on the limbs of the outer tepals. The flowers have a faint sweet odour, often with spicy overtones of almond, cinnamon or vanilla, unique in the genus. *Ferraria ferrariola* has been confused with *F. parva*, which has flowers of similar shape with a narrow floral cup but much smaller, with a floral cup ± 6 mm deep and outer tepals 18–22 mm long compared to (30–)35–40 mm in *F. ferrariola*. The sheaths and cataphylls of *F. parva* also lack the red flush and white speckling characteristic of *F. ferrariola*.



Distribution of ***Ferraria ferrariola***.

9. **Ferraria parva** *Goldblatt & J.C.Manning* in Bothalia 41: 26 (2011). Type: South Africa, Western Cape, sandveld west of Vredenburg, north side of Saldanha highway, opposite cemetery, under shrubs and restios, 19 Sept. 2007, *Goldblatt & Manning 13000* (NBG, holo.; MO, iso.).

Plants mostly 80–150 mm high, excluding basal leaves. *Stem* branched near base and in upper part, lower half often partly exposed; cataphylls and sheath of lowermost leaf pale. *Leaves* unifacial, basal 2 or 3 ± linear, usually exceeding spathes, 3–5 mm wide, upper leaves subtending branches lanceolate, spreading, shorter and wider than basal, mostly 4–6 mm wide, margins and main vein not evident when alive; non-flowering plants with 2 or 3 linear leaves, oval in cross section. *Rhipidia* 2-flowered; spathes pale green, apices slightly hooked, inner 45–65 mm long, often inflated with age, margins transparent, outer spathe ± half as long as inner, often diverging in upper $^{1}/_{3}$. *Flowers* on pedicels 18–20 mm long; spotted with dark brown in a dull yellow, light red-brown or pale greenish blue background, margins crisped, buff- to khaki-coloured, sweetly scented of jasmine and coconut, tepal claws forming a narrow cup ± 8 mm deep, ± 7 mm wide at rim; outer tepals 18–22 × 8–10 mm, claws 7–8 mm long with a pouch-like bilobed nectary in lower midline; inner tepal slightly shorter and ± half as wide, limbs slightly reflexed, inner more so than outer. *Filaments* united in a column ± 6 mm long, free in upper ± 1.5 mm; anther thecae initially parallel, later divaricate, ± 3 mm long at anthesis, later ± $^{2}/_{3}$ as long. *Ovary* spindle-shaped, 12–15 mm long, with a sterile beak up to 7 mm long; style branches ± 2 mm long, forked in upper half, prominently fringed; stigmas narrow, at lateral ends of style branches, arching forward. *Capsules* ovoid-oblong, 15–20 mm long, with beak up to 2–7 mm long. *Seeds* angular, smooth, shiny, golden-brown, mostly 5-sided, facets smooth or slightly wrinkled. *Flowering time*: late August to mid-September; lasting two days.

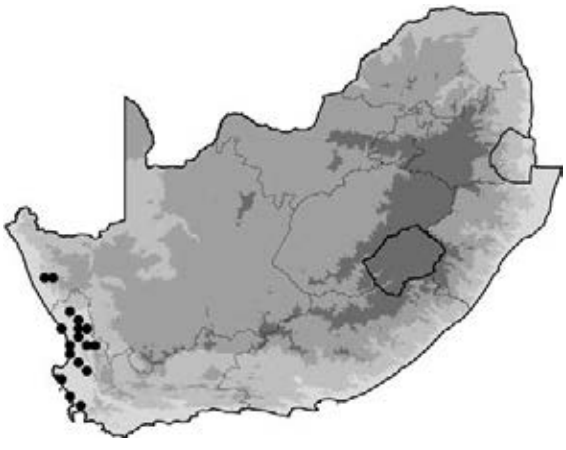
Distribution and ecology: a narrow endemic of the Atlantic Coast and near interior of Western Cape, South Africa, from the lower Berg River Valley near Hopefield to Vredenburg (and possibly further south); in sandveld and limestone fynbos in deep sandy ground, sometimes over limestone, or in cracks in limestone or calcrete pavement.

Distribution of ***Ferraria parva***.

Diagnosis: a small plant reaching up to 150 mm and with the stem usually covered by leaf sheaths, *Ferraria parva* has flowers with a narrow floral cup ± 8 mm deep and tepals 18–22 mm long with slightly reflexed limbs. It has been confused with the larger-flowered *F. ferrariola,* which has a floral cup 17–20 mm deep and tepals (30–)35–40 mm long. The cataphylls and basal leaf sheath of *F. parva* are uniformly pale coloured, whereas those of *F. ferrariola* are speckled and usually flushed red.

Ser. **Macroscyphae** *(Baker) Goldblatt & J.C.Manning*, new rank. *Ferraria* [unranked] *Macroscyphae* Baker in Journal of the Linnean Society, Botany 16: 106 (1877). Type: *F. divaricata* Sweet

Flowers relatively large, floral cup widening substantially upwards, rim ± as wide as or wider than depth of cup, 13–20 mm diam. at rim. *Anther* thecae divergent.



10. **Ferraria divaricata** *Sweet* in British Flower Garden: t. 192 (1827); Goldblatt & Manning: 27 (2011). Type: South Africa, without precise locality, collected by W. Synnot, illustration in Sweet: t. 192 (1827) (no preserved material known).

    Ferraria divaricata subsp. *arenosa* M.P.de Vos: 358 (1979). Type: South Africa, [Western Cape], Clanwilliam, Nardouw Pass, Farm de Lille, Oct. 1973, *Van Breda sub De Vos 2295* (NBG holo.; PRE, iso.).

Plants (250–)350–500 mm high. *Stem* well developed, much-branched distally. *Leaves* sword-shaped to linear, 6–15 mm wide, often with a slightly raised main vein, glaucous, margins sometimes slightly raised, basal leaves longest, cauline leaves progressively shorter above and becoming bract-like. *Rhipidia* 2-flowered; spathes glaucous, with broad membranous margins, inner 70–85 mm long, outer ± half as long, sheathing entirely or in lower $^{2}/_{3}$, then often slightly S-shaped. *Flowers* on pedicels 6–15 mm long; variously dark chocolate to golden-brown, crisped part of margins similarly coloured or paler, claws pale, streaked with fine longitudinal lines or with a broad median darker centre, forming a cup, 14–18 mm deep, 15–18 mm wide at rim, outer tepals (30–)35–44 × 14–16 mm, inner tepals (28–)36–38 × 8–10 mm, claws of both whorls (13–)16–19 mm long, nectaries at base of claws, ± black or pale yellow-green, 1.3–4.0 mm long. *Filaments* united in a column 11–13 mm long, free and arching outward in upper ± 3 mm; anther thecae usually widely diverging, initially ± 4 mm long, shrinking after dehiscence; pollen orange. *Ovary* ellipsoid, 33–42 mm long, including beak 15–20 mm long; style branches ± 2 mm long, dividing into diverging, prominently fringed arms ± 4 mm long; stigmas on small lobes below tips of style arms, arching over anthers. *Capsules* 15–22 mm long (excluding beak 15–20 mm long). *Seeds* globose, ± 3 mm diam., pale matte brown, surface lightly wrinkled, epidermal cells concave. *Chromosome number* $2n = 20$. *Flowering time*: mainly late September to early November; lasting a single day.

Distribution and ecology: extending along the west coast and adjacent mountains of Northern Cape and Western Cape, South Africa, from near Komaggas in northern Namaqualand southward to the Cape Flats; in deep sandy soils, in sandveld or marginal fynbos habitats.

Diagnosis: one of the taller species of *Ferraria, F. divaricata* has a branched stem up to 500 mm high and flowers with divaricate anthers, a beaked ovary, and beaked capsules. As in most *Ferraria* species, floral colour and patterns are variable: the tepal limbs may be uniform in colour except for the margins, and range from light to chocolate-brown with paler margins or dull yellow-brown, then with little or no colour difference at the margins. The tepal claws are creamy white to palest yellow with fine, dark, longitudinal streaks and usually a dark median stripe. A second species, *F. variabilis*, has been confused with *F. divaricata* but is typically a low-growing, usually ± tufted plant, mostly 100–200 mm tall. It has similar flowers but more varied in colour. The vegetative differences are correlated with differences in the seeds. Those of *F. divaricata* are globose with a wrinkled surface and concave epidermal

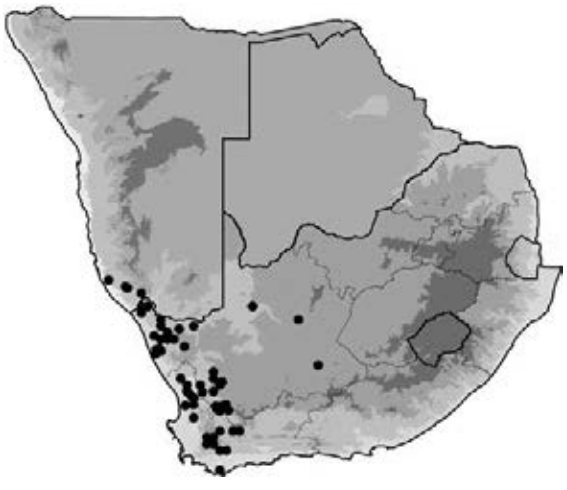
Distribution of ***Ferraria divaricata***.

cells, whereas other *Ferraria* species, including *F. variabilis*, have angular seeds with 5 or 6 flattened facets separated by thickened ridges. Flowers of *F. divaricata* last a single day whereas those of *F. variabilis* last two or sometimes three days.

11. **Ferraria variabilis** *Goldblatt & J.C.Manning* in Bothalia 35: 73 (2005) & 29 (2011). Type: South Africa, [Northern Cape], Nieuwoudtville, Klipkoppies, lower slopes, 15 Sept. 1961, *Barker 9537* (NBG, holo.; MO, iso.).

Ferraria antherosa Ker Gawl.: t. 751 (1804), illegitimate superfluous name for *F. viridiflora* [as *F. viridis*] Andrews [= *F. ferrariola* (Jacq.) Willd.]. Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 751 (1804).

Ferraria divaricata subsp. *australis* M.P.de Vos: 359 (1979). Type: South Africa, [Western Cape], Karoo Garden, Whitehill, 17 Sept. 1945, *Compton 17412* (NBG, holo.).



Plants 60–200(–300) mm high. *Stem* often branched just above base, branches crowded and ± equal in length, often forming small tufts. *Leaves* sword-shaped to linear, usually ± as long as stem, sometimes up to twice as long, (2–)3–15(–22) mm wide, mostly subbasal, without visible midrib, often slightly striate, margins often slightly thickened, rarely obscurely crisped, sheaths usually overlapping and concealing stem. *Rhipidia* 2-flowered; spathes glaucous-green, inner mostly 60–75 mm long, outer slightly shorter to ± as half as long, entirely sheathing or arching outward in distal $^1/_3$. *Flowers* on pedicels 10–15 mm long; predominantly pale to dull yellowish to pale or mid-brown, or dull grey-blue, limbs with solid dark brown to blackish purple at base, or with scattered dark spots, margins darker or paler in colour, claws uniformly pale or with dark longitudinal streaks or with a broad darker median streak, forming a floral cup 12–15 mm deep, 13–15 mm wide at rim, usually slightly putrid smelling, nectaries usually basal, rarely in pouches in centre of claws, pale or dark coloured; outer tepals 30–40(–45) × 10–15 mm, claws 10–15 mm long; inner tepals 25–40(–45) × 8–10 mm. *Filaments* united in a column 8–13 mm long, free and arching outward in the upper 2–4 mm; anthers 3.5–5.0 mm long, shorter after dehiscence, thecae joined only at apices, usually widely diverging (rarely almost parallel). *Ovary* ellipsoid, 15–20 mm long, with sterile beak 5–8 mm long; style branches 2–3 mm long, dividing into diverging, prominently fringed arms, ± 4 mm long; stigmas on small lobes below tips of style arms and arching over anthers. *Capsules* ellipsoid, 30–50 mm long. *Seeds* rounded, usually angled by pressure, dull-coloured and lightly wrinkled. *Chromosome number* $2n$ = 20, 40. *Flowering time*: August to November; lasting two (three) days.

Distribution and ecology: widespread in the western parts of southern Africa, from the Klinghardt Mtns of southwestern Namibia though Northern and Western Cape, South Africa, to Oudtshoorn, including Bushmanland and the Upper Karoo and as far east as Upington and Britstown; in a variety of habitats including shale flats, granite outcrops, and deep sands.

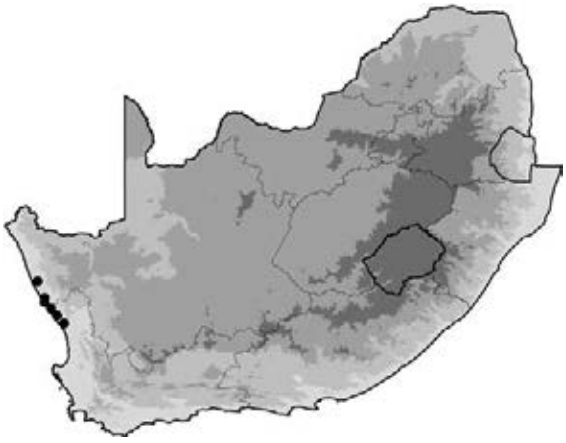
Diagnosis: *Ferraria variabilis* is distinguished by its fairly low, tufted habit, rarely exceeding 200 mm in height, with the relatively few branches crowded near the base, combined with fairly large flowers with broad tepal claws forming a deep, relatively wide bowl in which nectar accumulates in a pool. The spreading tepal limbs vary considerably in colour and marking. In the north of its range, in Namaqualand and southern Namibia, flowers have light brown tepal limbs with a dark purple longitudinal band toward the base and light brown margins, while the claws are pale greenish cream-coloured with a narrow darker band running down the midline. The nectaries in the northern populations are fairly large and green or less often purple-black. In the western and southern Karoo and the southern Cape, populations have greenish yellow or pale to middle brown tepal limbs, usually darker in the midline, and with small or medium-sized spots in the lower $^1/_3$ or when brown then often with spots irregularly scattered across the limb and the margins sometimes slightly darker coloured. The claws are pale, usually with a darker streak in the midline and have a small dark nectary at the base or on the inner tepals, shortly above the base. Perianth colour can vary as much within a population as across the entire southern Cape and western Karoo.

Ferraria variabilis is heteroploid, the northern populations are diploid, $2n$ = 20, whereas the southern are tetraploid, $2n$ = 40, this based on several counts across its range.

A notable variant from the Olifants River Valley and adjacent mountains has leaves broader and more succulent than found elsewhere, up to 20–22 mm wide (versus typically 4–12 mm for most other populations), and the rest of the plant is also larger, thus the outer spathes are 50–70 mm long and the inner may reach

Distribution of ***Ferraria variabilis***.

85 mm. Plants form circular mats in stony ground, which suggests spreading by vegetative means.



Populations from the Tanqua Basin and nearby hills stand out in having the nectaries located in prominent pouches in the middle of the tepal claws, rather than at the bases of the claw. The anthers in these populations and some others from nearby have the anther thecae held ± parallel, although joined together only at the tips, as they are in plants from other parts of the range, which have widely diverging anther thecae.

12. **Ferraria flava** *Goldblatt & J.C.Manning* in Bothalia 41: 31 (2011). Type: South Africa, Western Cape, sandveld west of Koekenaap, Farm Kommandokraal, 10 Sept. 2008, *Goldblatt & Porter 13105* (NBG, holo., K, MO, PRE, iso.).

Ferraria divaricata subsp. *aurea* M.P.de Vos: 359 (1979). Type: South Africa, [Western Cape], ± 9 miles [± 13.5 km] north of Lambert's Bay, Farm Langdam, 28 Sept. 1973, *Van Breda sub M.P. de Vos 2297* (NBG, holo.; PRE, iso.).

Plants ± acaulescent, up to 120 mm high, excluding leaves. *Stem* with (2)4 or 5 primary branches produced from below or shortly above ground level, each with several secondary branches, crowded basally and congested, together bearing up to 50 rhipidia. *Leaves* suberect, 5 to 7, sword-shaped, up to 300 mm long, lower 3 to 5 much exceeding spathes and flowers, mostly 12–20 mm wide, glaucous, ± succulent, without visible main vein. *Rhipidia* 2-flowered, numerous, crowded on short, ± horizontal or ascending branches; spathes green, margins transparent, inner mostly 40–55 mm long, outer ± $^{2}/_{3}$ as long, usually entirely sheathing or diverging above, apex curving inward. *Flowers* on pedicels up to 10 mm long; clear yellow, tepal limbs with minute blue-green spots in lower $^{1}/_{3}$, margins slightly paler in colour, claws translucent white inside, forming a floral cup 14–15 mm deep, 8–9 mm wide at rim, tepals limbs spreading, crisped, usually sweet vanilla-scented, nectaries at tepal bases pale green; outer tepals ± 30 × 10 mm, inner tepal limbs ± 12 × 5 mm, claws of both whorls ± 15 mm long. *Filaments* united in a column 11–12 mm long, free and diverging in upper ± 1 mm; anthers pale yellow with dark purple-brown on lines of dehiscence, ± 3.5 mm long, shorter after dehiscence, thecae joined at apices, widely diverging; pollen pale yellow. *Ovary* ellipsoid, 20–25 mm long, with sterile beak ± 10 mm long, style branches ± 3 mm long, with diverging, prominently fringed arms, ± 5 mm long; stigmas on small lobes below tips of style arms and arching over anthers. *Capsules* and *seeds* unknown. *Chromosome number* 2*n* = 20. *Flowering time*: September to late October; lasting a single day.

Distribution and ecology: restricted to the sandveld of coastal Western and Northern Cape, South Africa, from the flat sandy country north of Lambert's Bay and Klawer to the Groen River and Komaggas in Namaqualand; in deep sand among sandveld species such as *Willdenowia* (Restionaceae) and the willowy *Wiborgia obcordata* (Fabaceae), often on the slopes of low, stabilised and vegetated dunes.

Distribution of ***Ferraria flava***.

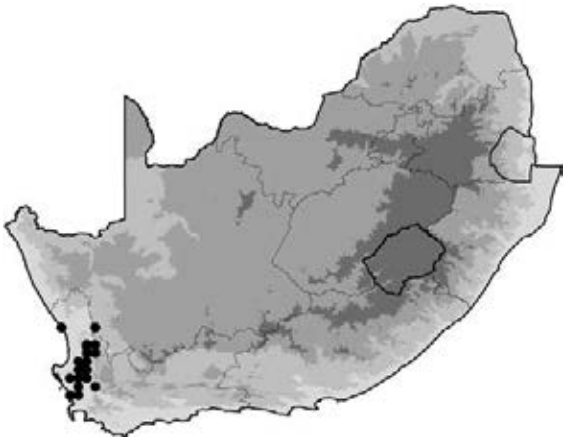
Diagnosis: *Ferraria flava* is immediately recognised by the bright yellow, sweetly scented flowers and typically stemless habit, with well-grown plants bearing 3 or 4 main branches arising below the ground and with numerous rhipidia set closely together. The several broad, firm to rigid leathery leaves, up to 300 × 20 mm, recall those of *F. divaricata*, which has aerial stems and larger, usually predominantly brown flowers (but sometimes dull yellow) with a wider floral cup. The flowers of *F. flava* resemble those of *F. macrochlamys* and its immediate allies in having a relatively narrow floral cup but are larger, with tepals ± 30 × 10 mm and claws ± 15 mm long, and last a single day, unlike those of the *F. macrochlamys* group, which have smaller tepals with claws 10–14 mm long, and last two days.

Ferraria divaricata var. *aurea* is provisionally included here as a synonym. The type, from near Lambert's Bay, has short, aerial stems but flower colour and shape are consistent with *F. flava*. Plants should be examined at the type locality to confirm their identity.

Ser. **Uncinatae** *Goldblatt & J.C.Manning*, new series. Type: *Ferraria uncinata* Sweet

Flowers small to moderately sized with narrow cup, sides ± erect and rim of cup $^{1}/_{2}$–$^{2}/_{3}$ as wide as depth of cup, 5–7 mm diam. at rim. *Anther* thecae divergent.

13. **Ferraria uncinata** *Sweet* in British Flower Garden: t. 161 (1826b); Goldblatt & Manning: 33 (2011). Type: South Africa, without precise locality, illustration in Sweet: t. 161 (1826b), originally collected by *W. Synnot* (no preserved specimen known).



Ferraria framesii L.Bolus: 123 (1931). Type: South Africa, [Western Cape], ± 6 miles [± 9 km] south of Clanwilliam, 22 Oct. 1931, *Ross Frames s.n. BOL19928* (BOL, holo.; SAM, iso.).

Plants 90–200(–300) mm high. *Stem* either ± subterranean and few-branched at base, or stem produced above ground and branched from upper nodes. *Leaves* lanceolate, mostly 8–12 mm wide, sheaths usually concealing stem, usually prominently multi-veined without visible main vein, flat or lightly twisted, apex often hooked, margins thickened, hyaline, smooth, usually crisped and undulate at least proximally. *Rhipidia* 2-flowered; spathes green, usually with hooked tips, inner mostly 40–60 mm long, outer ± $^{1}/_{2}$–$^{2}/_{3}$ as long as inner, usually entirely sheathing. *Flowers* on pedicels 12–20 mm long; usually pale to dark blue-violet, or light brown with blue speckling, margins crisped, dull yellow-green to khaki-coloured, with a narrow cup, 8–12 mm deep, ± 7 mm wide at rim, often unscented, lightly foetid-smelling, or scented of lemon and cinnamon, nectaries minute, at base of tepals; outer tepals 28–35 × 7–10 mm, limb at least 1.5 times as long as claw, and up to three times as long, often long-attenuate and coiled, claws 8–12 mm long; inner tepals 28–30 mm long, limbs reflexed, claws slender, 7–12 mm long. *Filaments* united in a column 7–11 mm long, free in upper ± 1.5 mm; anthers ± 3 mm long, ± half their length after dehiscence, thecae divergent. *Ovary* ellipsoid, 15–28 mm long, with beak 8–12 mm long; style branches ± 1.5 mm long, with diverging, prominently fringed arms, ± 1.5 mm long; stigmas on small lobes below tips of style arms and arching over anthers. *Capsules* 12–16 mm long, excluding beak. *Seeds* 3–4 mm long, dark brown, angular, 5- or 6-sided, surfaces slightly wrinkled. *Chromosome number* 2*n* = 20. *Flowering time*: late August to October; lasting two days.

Distribution and ecology: endemic to the Western Cape, South Africa, from the slopes of the Gifberg near Klawer southward through the Olifants River Valley and the Piketberg to Malmesbury and Mamre, some 65 km north of Cape Town; mostly in sandstone outcrops in relatively dry sites, but sometimes in open ground in coarse, granite-derived gravel or on sandstone slopes in deep sand.

Diagnosis: typically with a tufted habit, *Ferraria uncinata* has flowers with a narrow floral cup 8–12 mm deep, the tepals either deep blue to violet edged with dull yellow-green or in the north of its range buff-coloured to dull yellow with violet speckles and yellow-brown margins. The leaf margins are thickened with at least the edges of the lower leaves crisped and undulate. The margin surface itself is smooth. The hooked tips of the leaves and spathes, the character for which the species was named (*uncinatus* = Latin for hooked), is frequent, though not constant, not only in *F. uncinata* but in several other species of the genus.

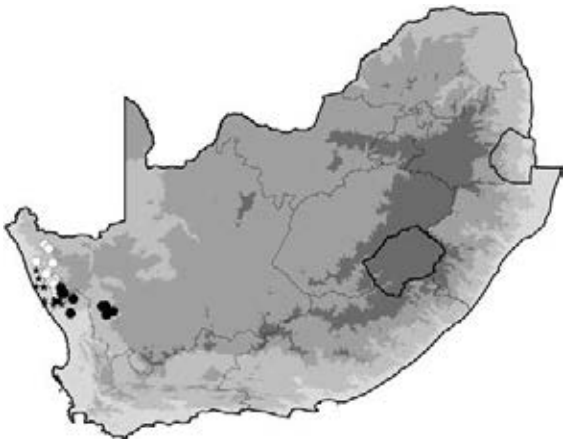
The yellow-flowered central Namaqualand species, *Ferraria macrochlamys* has at times been included in *F. uncinata*, but is now understood to be a separate species differing not only in the pale yellow flower colour but in the fine structure of the thickened leaf margins, which resemble those of *F. uncinata* only superficially. In *F. macrochlamys* subsp. *macrochlamys* the marginal thickenings are usually densely ciliate and irregularly

Distribution of ***Ferraria uncinata***.

serrulate or crenulate, as well as sometimes being slightly crisped. The tepal limbs of *F. uncinata* are at least 1.5 times as long as the claws and up to three times as long in the northern populations, and the tepal apices are unusually extended. In *F. macrochlamys* the tepal limbs are slightly shorter to ± 1.5 times as long as the claws and are less prominently attenuate.

14. **Ferraria macrochlamys** *(Baker) Goldblatt & J.C.Manning* in Novon 14: 293 (2004); Goldblatt & Manning: 34 (2011). *Lapeirousia macrochlamys* Baker: 338 (1876). *F. uncinata* subsp. *macrochlamys* (Baker) M.P.de Vos: 369 (1979). Type: South Africa, without precise locality or date, as Herb. Forsyth (K, holo.).

Plants mostly 70–100 mm high, forming low tufts. *Stem* few- to several-branched (rarely simple), branches crowded close to base, branches and spathes all ± same length. *Leaves* narrowly sword-shaped to linear, mostly (2.0–)4.5–7.0 mm wide, ± straight, or all curving to same side, or serpentine (loosely wavy in concertina fashion), tips oblique or hooked, sometimes densely papillate-ciliate; margins heavily thickened then sometimes velvety, often irregularly serrulate or crenate, sometimes slightly crisped. *Rhipidia* 2-flowered; inner spathes 37–62 mm long, abaxial margins sometimes crisped, outer 24–50 mm long, usually entirely sheathing, or free distally, often hooked at apex. *Flowers* on pedicels 10–23 mm long; pale watery yellow with slightly darker yellow to light brown margins, outer tepal limbs often minutely speckled grey-blue at base, with a narrow cup, 9–13 mm deep, 5–7 mm wide at rim, with a faint, green apple or slightly sour odour; outer tepals 26–32 mm long, limbs spreading to slightly reflexed, inner tepals 26–28 mm long, limbs often ultimately ± reflexed, claws of both whorls 10–14 mm long. *Filaments* united in a column 10–12 mm long, free and diverging in upper ± 1 mm; anthers 2.2–3.0 mm long, thecae divergent; pollen orange. *Ovary* ellipsoid, 15–20 mm long with beak 7–15 mm long; style branches 1.0–1.5 mm long, with diverging, prominently fringed arms, 1.0–1.5 mm long; stigmas on small lobes below tips of style arms and arching over



anthers. *Capsules* 15–20 mm long excluding beak. *Seeds* angular, mostly 5- or 6-sided, ± 2.7–3.0 mm diam., dark brown, facets slightly wrinkled. *Chromosome number* 2*n* = 20. *Flowering time*: late August to the end of September, rarely to mid-October; lasting two days.

Distribution and ecology: restricted to Namaqualand in western Northern Cape, South Africa, from Steinkopf in the north to the southern foothills of the Kamiesberg near Bitterfontein in the south and west toward the coast, with isolated populations inland in the western Karoo near Loeriesfontein; on a variety of soils, subsp. *macrochlamys* and subsp. *kamiesbergensis* in gritty to loamy granite-derived soils, sometimes in granite outcrops, in vegetation dominated by succulent-leaved shrubs, and subsp. *serpentina* mostly in quartzitic sand, usually among rocks.

Diagnosis: recognised by the tufted habit and small, pale yellow flowers with a narrow floral cup and divaricate anther thecae, *Ferraria macrochlamys* is exceptionally variable in leaf morphology. Three subspecies are currently accepted, based mainly on leaf morphology and minor size differences in the flowers. Typical subsp. *macrochlamys* has leaves with heavily thickened margins irregularly serrate to crenate, or sometimes crisped, and sometimes densely velvety; subsp. *kamiesbergensis* has leaves with smooth, straight margins, not or very little thickened and the blades curving in the same direction; and subsp. *serpentina*, also with unthickened leaf margins, has the blades serpentine, thus loosely wavy in concertina fashion.

Key to subspecies

1a Leaf margins thickened, hyaline, and sometimes shortly velvety, at least lower leaves with serrulate to crenulate margins; leaf blades ± straight or laxly undulate; outer spathes sheathing for most of their length and not > $^{2}/_{3}$ as long as inner . . . . . 14a. subsp. *macrochlamys*

Distribution of ***Ferraria macrochlamys*** subsp. ***macrochlamys***, ●; subsp. ***kamiesbergensis***, ○; subsp. ***serpentina***, ★.

1b Leaf margins hardly, if at all, thickened, and smooth:
2a Leaf blades in upper half inclined to curving to the same side; outer spathes not sheathing in distal half and ± as long as inner; outer tepals 30–35 mm long; filament column ± 12.5 mm long . . . . . 14b. subsp. *kamiesbergensis*
2b Leaf blades in upper half serpentine, thus loosely folded back on themselves in concertina fashion; outer spathes sheathing for most of their length and ± $^{2}/_{3}$ as long as inner; outer tepals 25–28 mm long; filament column 10–11 mm long . . . . . 14c. subsp. *serpentina*

14a. subsp. **macrochlamys**

Ferraria crispulata L.Bolus: 260 (1931). Type: South Africa, [Northern Cape], near Bowesdorp, 27 Aug. 1929, *L. Bolus s.n.* (BOL[*19162*], holo.; BM, K, iso.).

Plants with leaves often densely papillate-ciliate; margins heavily thickened, thickenings smooth or densely ciliate, often irregularly serrulate or crenate, sometimes lightly crisped. *Rhipidial spathes*: inner 45–62 mm long, abaxial margins sometimes crisped, outer 30–50 mm long, usually entirely sheathing, or tips free. *Flowers* with narrow cup 11–13 mm deep, ± 7 mm wide at rim, with faint, green-apple or slightly sour odour; outer tepals 28–32 mm long, limbs spreading to slightly reflexed, inner tepals 26–28 mm long, claws of both whorls (11–)12–14 mm long. *Filaments* united in column ± 12 mm long, free and diverging in upper ± 1 mm; anther thecae ± 3 mm long before dehiscence. *Ovary* 23–28 mm long with beak 15–18 mm long. *Flowering time*: late August to late September.

Distribution and ecology: restricted to central Namaqualand, subsp. *macrochlamys* extends from Steinkopf in the north to Garies in the south and inland to the northern Kamiesberg; in gritty to loamy granite-derived soils.

Diagnosis: subsp. *macrochlamys* stands out in its spreading leaves with thickened margins, either crenate or crisped and sometimes velvety. The flowers often serve to distinguish it from subsp. *serpentina* in their slightly larger size, but that difference is not consistent. Subsp. *macrochlamys* is always acaulescent, whereas subsp. *serpentina*, in years of ample rainfall, develops an aerial stem rendering it very different in general appearance.

14b. subsp. **kamiesbergensis** *(M.P.de Vos) Goldblatt & J.C.Manning* in Bothalia 41: 36 (2011). *Ferraria kamiesbergensis* M.P.de Vos: 362 (1979). Type: South Africa, [Northern Cape], Kamiesberg, Rondefontein, 1 Sept. 1976, *Oliver 5970* [NBG, lecto., designated by Goldblatt & Manning: 292 (2004)].

Plants forming low tufts, usually few-branched. *Leaves* firm, suberect to falcate, mostly 70–100 × 3–6 mm, all weakly to strongly curving in the same direction; margins plane, slightly or not at all thickened. *Rhipidial spathes*: inner 50–65 mm long, outer 50–57 mm long, sheathing in lower half, arching outward distally.

Flowers with tepal claws forming narrow cup mostly 12–14 mm deep, ± 7 mm wide at rim, limbs laxly spreading; outer tepals 25–35 mm long, 8–10 mm at widest, limbs 13–20 mm long, slightly exceeding claws, inner tepals 25–30 mm long, claws of both whorls 12–14 mm long. *Filaments* united in a column 10.5–12.5 mm long, free upper 1 mm; anther thecae ± 3 mm long, shorter after anthesis. *Ovary* 18–22 mm long with tubular beak ± 12 mm long; style branches ± 1 mm long, dividing into diverging, prominently fringed arms, ± 2 mm long. *Flowering time*: September to early October; lasting 2 days.

Distribution and ecology: centred in central Namaqualand, Northern Cape, extending from Rooiberg in the Kamiesberg south to near Bitterfontein in Western Cape, with isolated populations to the southeast near Loeriesfontein and the hills northwest of Calvinia; usually in coarse, gritty decomposed granite or in cracks in granite pavement.

Diagnosis: subsp. *kamiesbergensis* is distinctive only in its vegetative morphology, having firm and leathery to almost succulent leaves, usually dark green and in the upper half all curve to the same side and the margins are plane, smooth and not at all, or only barely, thickened. Otherwise plants have the tufted habit of subsp. *macrochlamys* and flowers virtually identical to that subspecies. Their ranges do not overlap, with subsp. *macrochlamys* mostly from the highlands west and north of the Kamiesberg but also from Leliefontein and nearby in the Kamiesberg, which is north of the range of subsp. *kamiesbergensis*.

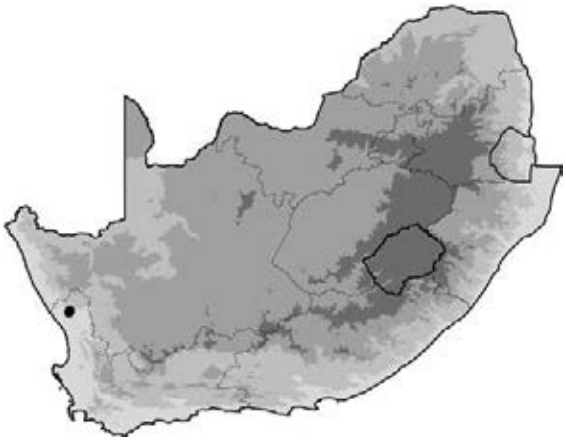
14c. subsp. **serpentina** *Goldblatt & J.C.Manning* in Bothalia 41: 37 (2011). Type: Northern Cape, NE of Kotzesrus, road to Garies, 16 Sept. 2001, *Goldblatt & Porter 11900* (NBG, holo.; K, MO, PRE, iso.).

Plants either like subsp. *macrochlamys* without aerial stem and branches crowded close to base or with short aerial stem and branching above ground, thus rounded. *Leaves* in a loose fan, linear, (2–)3–4 mm wide, without main vein, blades serpentine (loosely wavy in concertina fashion, sometimes appearing coiled when pressed); margins plane, not thickened. *Rhipidial spathes*: inner 37–45 mm long, outer $^{2}/_{3}$ as long, sheathing in lower $^{2}/_{3}$. *Flowers* on pedicels 10–15 mm long; tepal claws forming a narrow cup, 9–11 mm deep, ± 5 mm wide at rim; outer tepal limbs 16–18 mm long, tips attenuate and twisted, inner tepal limbs ± 16 mm long, slightly reflexed, claws of both whorls 10–12 mm long. *Filaments* united in a column 10–11 mm long, free in upper 1 mm; anther thecae ± 2.2 mm long. *Ovary* 15–28 mm long, with a beak 7–18 mm long; style branches diverging, with style arms ± 1 mm long. *Flowering time*: late August and September, rarely to mid-October.

Distribution and ecology: restricted to central southern Namaqualand, from near Komaggas and Killian's Pass south to Kotzesrus; on low, sandy or stony hills inland of the coast in gravelly soils, either on stony slopes or in deep, red, quartzitic sand.

Diagnosis: the flowers of subsp. *serpentina* closely resemble those of subsp. *macrochlamys* and subsp. *kamiesbergensis* and differ if at all only in their slightly smaller size, and the subspecies is distinguished by its leaves, the narrow blades of which are wavy in a loose concertina fashion, with plane, smooth margins not at all thickened. This contrasts with the straight leaves of subsp. *macrochlamys*, which have strongly thickened, crisped or crenate margins, and in some populations, shortly velvety. The flowers of subsp. *serpentina* have a floral cup, 9–11 mm deep, ± 5 mm wide at the rim, outer tepals 26–28 mm long, and filaments 10–11 mm long, thus slightly smaller than in most populations of subsp. *macrochlamys*, which have a cup, 11–13 mm deep, 6–7 mm wide at the rim, outer tepals 28–32 mm long, and filaments ± 12 mm long. The inner spathes are 37–45 mm long, compared to 45–62 mm in subsp. *macrochlamys*, and the flowers have pedicels 10–15 mm long (versus 20–23 mm in subsp. *macrochlamys*), reflecting the shorter spathes. A particularly narrow-leaved form of subsp. *serpentina* has been recorded in the Komaggas area west of Springbok, the blades ± 2 mm wide and when dry, showing the outline of a raised central vein.

15. **Ferraria brevifolia** *G.J.Lewis* in Annals of the South African Museum 40: 119 (1954); Goldblatt & Manning: 37 (2011). Type: South Africa, [Western Cape], 2 miles [± 3 km] south of Nuwerus, Sept. 1945, *Lewis 1374* (SAM, holo.).



[*Ferraria namaquensis* Schltr. ms: *Schlechter 11031* (SAM)].

Plants 70–120(–180) mm high, usually ± acaulescent. *Stem* with 2 to 4 short, subequal branches borne close to ground. *Leaves* overlapping to form a tight fan, sheaths completely enclosing stem and much exceeding blades, blades oblong, 7–15 × 5–7(–10) mm, obtuse or acute, often hooked at tips; margins thickened especially abaxially, thickenings often crenate to slightly crisped. *Rhipidia* 2-flowered; inner spathe mostly 45–55 mm long, outer ± $^{2}/_{3}$ as long, sheathing in lower $^{2}/_{3}$, arching outward distally. *Flowers* on pedicels 15–23 mm long; pale to watery yellow with darker yellow to brown or orange margins, nectaries small, at base of tepals, claws forming a narrow cup, ± 12 mm deep, ± 7 mm wide at rim, faintly sweet-scented; outer tepals 32–40 × ± 9 mm, attenuate, tips slightly coiled, claws slender, 10–13 mm long, inner tepals 30–37 mm long. *Filaments* united in column ± 10 mm long, free in upper ± 1 mm; anther thecae divergent, ± 2.5 mm long, shorter after dehiscence; pollen orange. *Ovary* ellipsoid, (15–)18–25 mm long, with beak 8–12 mm long; style branches ± 1.5 mm long, diverging into prominently fringed arms, ± 1.5 mm long; stigmas on small lobes below tips of style arms and arching over anthers. *Capsules* ovoid, 15–25 mm long. *Seeds* angular, irregularly 5- or 6-sided, ± 3 mm diam., brown, shiny. *Chromosome number* 2*n* = 20. *Flowering time*: August and September; lasting two days.

Distribution and ecology: restricted to southern Namaqualand in Western Cape, South Africa, with a

range covering a linear distance of ± 40 km from near Bitterfontein in the north to a short distance south of Nuwerus; on slopes of gritty, granite-derived gravel.

Diagnosis: distinctive in *Ferraria*, the leaves of *F. brevifolia* form a tight, 2-ranked fan, with elongate sheaths 40–80 mm long, much exceeding the short, ovate, obtuse blades, 7–15 mm long. The blades, usually less than half as long as the sheaths, have relatively thick margins and oblique, acute or apiculate, hooked tips. The pale yellow flowers are virtually identical to those of *F. macrochlamys*, with a narrow floral cup, ± 12 mm deep, and tepal limbs, 22–28 mm long, with crisped, light brown or rarely reddish brown margins. The flowers produce a faint, slightly sweet scent. They can be distinguished from those of *F. macrochlamys*, if at all, by their somewhat longer outer tepals with long, tapering loosely coiled tips.

Distribution of ***Ferraria brevifolia***.

UNCERTAIN SPECIES

Ferraria fimbriata Burman in Nova acta physico-medico Academiae Caesareae Leopoldino-Carolinae germaniae naturae curiosorum 2: 201 (1761). Type: South Africa, without precise locality, illustration in Burman, l.c.: t. 3, f.. 2 (1761). The woodcut illustration is inadequate to identify this plant to species. It may represent *Ferraria divaricata* or *F. variabilis*.

EXCLUDED SPECIES

Ferraria blanda Salisb., Prodromus stirpium in horto ad Chapel Allerton vigentium: 42 (1796), superfluous name for *Moraea iridioides* L. = *Dietes iridoides* (L.) Sweet ex Klatt.

Ferraria lugubris Salisb., Prodromus stirpium in horto ad Chapel Allerton vigentium: 42 (1796) = *Moraea lugubris* (Salisb.) Goldblatt

Ferraria ocellaris Salisb., Prodromus stirpium in horto ad Chapel Allerton vigentium: 41 (1796) = *Moraea aristata* (D.Delaroche) Asch. & Graebn.

Ferraria tricuspis Willd., Enumeratio plantarum horti regii berolinensis: 691 (1809), illegitimate superfluous name = *Moraea tricuspidata* (L.f.) G.J.Lewis

Ferraria tristis (L.f.) Salisb., Prodromus stirpium in horto ad Chapel Allerton vigentium: 42 (1796). *Iris tristis* L.f., Supplementum plantarum: 97 (1782) = *Moraea vegeta* L.

36. **Moraea**

Moraea *Miller*, Figures of Plants 2: 159, t. 238 (1758) [as *Morea*], name and spelling conserved. Type also conserved: *M. vegeta* L.

Vieusseuxia D.Delaroche: 31 (1766). Type: *V. spiralis* D.Delaroche, lecto., designated by Goldblatt: 8 (1976a) = *Moraea bellendenii* (Sweet) N.E.Br.

Galaxia Thunb.: 50 (1782a). Type: *G. ovata* Thunb., lecto. designated by Goldblatt: 396 (1979a) = *Moraea galaxia* (L.f.) Goldblatt & J.C.Manning).

Homeria Vent.: no. 2 (1808). Type: *H. collina* (Thunb.) Salisb. = *Moraea collina* Thunb.

Hexaglottis Vent.: no. 3 (1808). Type: *H. longifolia* (Jacq.) Salisb. = *Moraea longifolia* (Jacq.) Pers.

Phaianthes Raf.: 30 (1838). Type: *P. lurida* (Ker Gawl.) Raf. = *Moraea lurida* Ker Gawl.

Plantia Herbert.: 89 (1844). Type: *P. flava* Herb. (probably = *Moraea virgata* Jacq.)

Hymenostigma Hochst.: 24 (1844). Type: *H. schimperi* Hochst. = *Moraea schimperi* (Hochst.) Pic.-Serm.

Gynandriris Parl.: 49 (1854). Type: *G. sisyrinchium* (L.) Parl. = *Moraea sisyrinchium* (L.) Ker Gawl.

[*Iridopsis* Welw. ex Baker: 270 (1878), invalid name only in synonymy.]

Helixyra Salisb. ex N.E.Br.: 348 (1929b) [*Helixyra* Salisb.: 305 (1812), invalid name], illegitimate superfluous name for *Gynandriris*. Type: not indicated by author.

Barnardiella Goldblatt: 312 (1976c). Type: *B. spiralis* (N.E.Br.) Goldblatt(= *Moraea herrei* (L.Bolus) Goldblatt

Roggeveldia Goldblatt: 840 (1979b). Type: *R. fistulosa* Goldblatt = *Moraea fistulosa* (Goldblatt) Goldblatt

Rheome Goldblatt: 92 (1980a). Type: *R. maximiliani* (Schltr.) Goldblatt = *Moraea maximiliani* (Schltr.) Goldblatt

Sessilistigma Goldblatt: 156 (1984a). Type: *S. radians* Goldblatt = *Moraea radians* (Goldblatt) Goldblatt

Revisionary accounts: Goldblatt: 681 (1976a) & 20 (1986a), both partial; Goldblatt: 239–260 (1980b, sect. *Gynandriris*); Goldblatt: 413–503 (1981, sect. *Homeria*).

[*Freuchenia* Eckl.: 14 (1827), invalid name without description.]

Named by Philip Miller for the English botanist Robert More and originally spelled *Morea* but later changed by Linnaeus to *Moraea*, thus honouring his wife, Elisabeth Moraea and her father, Johan Moraeus, physician in Falun, Sweden.

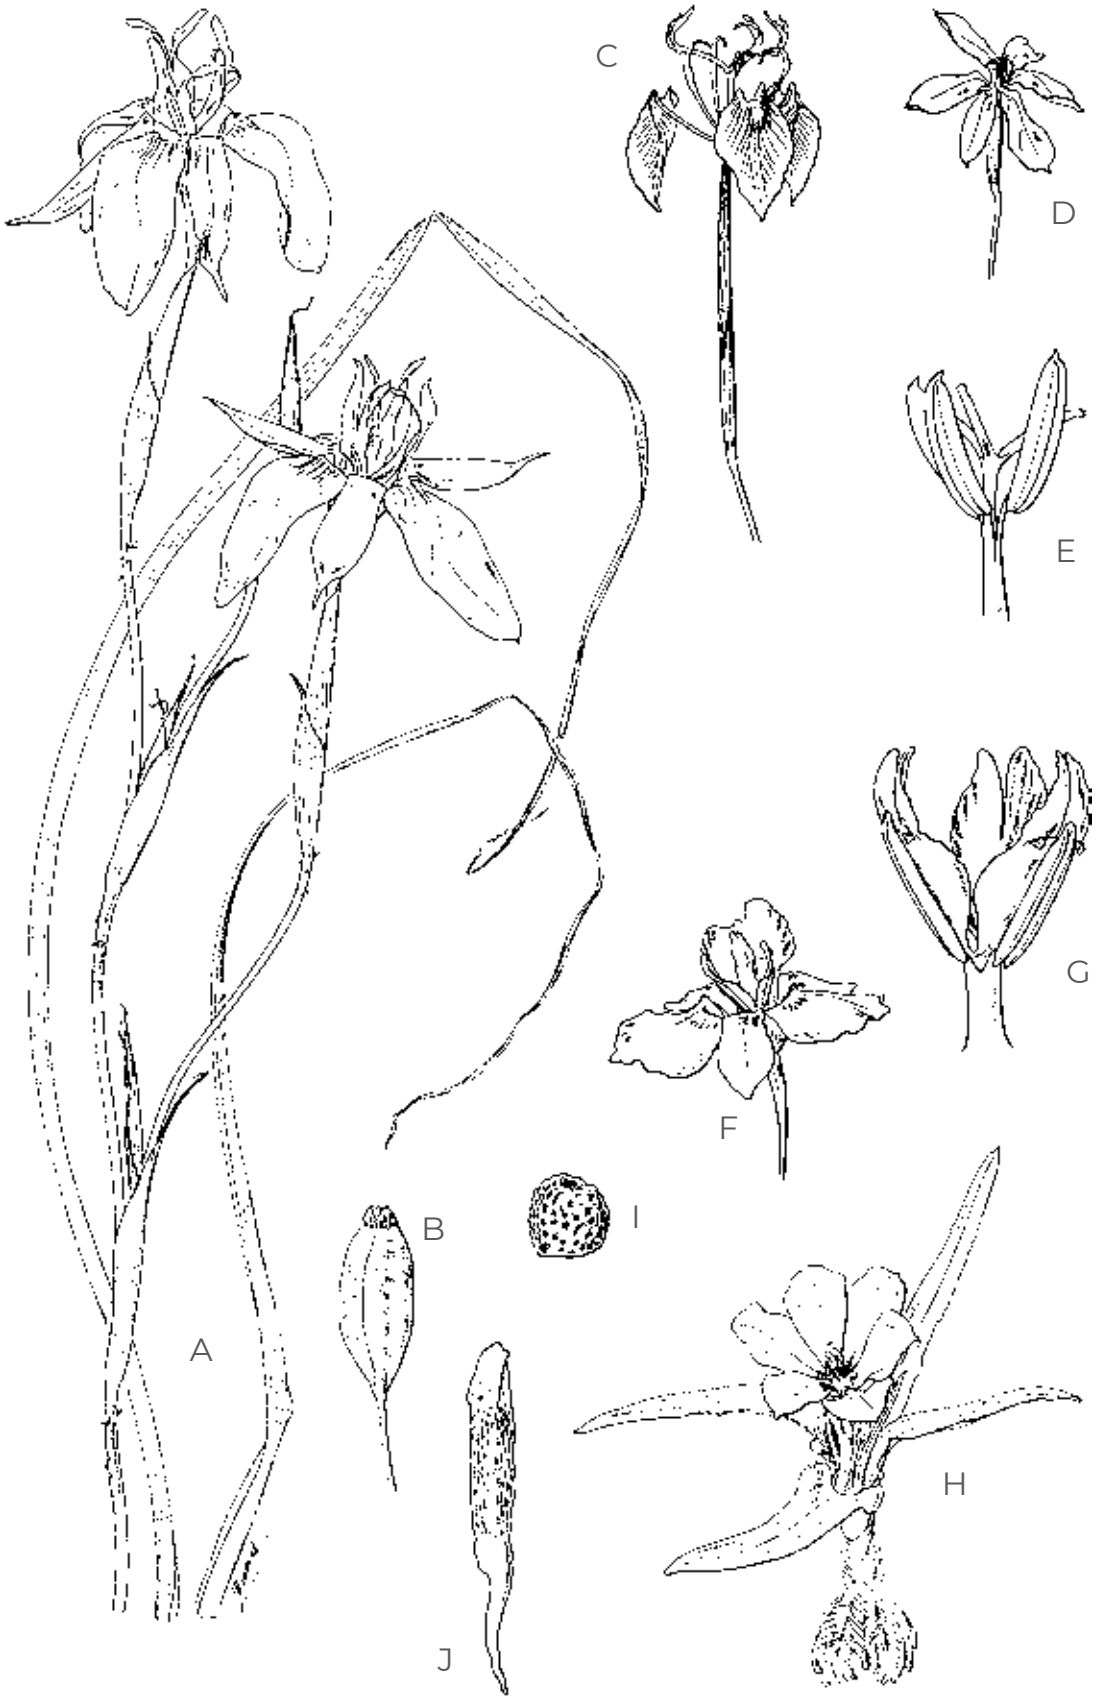
Large to small seasonal perennials, sometimes acaulescent. *Rootstock* a tunicate corm consisting of a single internode, roots arising from base of shoot at apex of corm; tunics coarsely to finely fibrous or woody with layers unbroken or fragmenting irregularly. *Leaves* few to several, lowermost without blades, thus cataphylls, these usually membranous and pale, turning brown with age, occasionally coarsely fibrous; foliage leaves several to solitary, blades bifacial, channelled to flat, or margins inrolled, or sometimes terete, without central vein; 1 to several sheathing bract-like leaves without blades usually present, up to 1 internode long. *Flowering stem* simple or branched, sometimes with 1 long terminal internode, then branches and foliage leaf (or leaves) crowded apically, entirely subterranean in several species. *Inflorescences* 1 to several rhipidia usually enclosed by large paired opposed bracts (spathes), usually entirely sheathing one another, occasionally outer free distally (rarely rhipidia indistinguishable from leaves; rhipidia 1- to several-flowered; spathes green or becoming dry, usually firm to leathery, inner spathe usually longer, both tightly sheathing or outer spathe curving outward distally, obtuse to attenuate at apex; floral bracts enclosed, shorter than spathes, membranous, with 2 green keels. *Flowers* radially symmetric, mostly ± *Iris*-like, fugaceous or lasting up to 3(4) days, pedicellate (rarely sessile), often blue to violet or yellow, also white, pink, red, usually with a yellow (white) mark (nectar guide) at base of outer tepal limbs, sometimes sweetly or unpleasantly scented, often producing nectar from perigonal nectaries at bases of outer or all tepals; tepals usually free, or united in a solid tube, usually clawed, claws ascending or short and clasping base of filament column, outer tepals often larger than inner or tepals subequal, limbs spreading to reflexed or those of inner tepals erect to suberect, inner sometimes tricuspidate to hair-like, or inner tepals occasionally lacking. *Stamens* symmetrically arranged with filaments partly to completely united, occasionally ± free; anthers mostly appressed to style branches (rarely alternate with them). *Ovary* exserted or included in spathes, sometimes extending upward as hollow tube (beak); style slender below, dividing near base or at apex of filament column into 3 branches, these often compressed, petal-like and wider than anther, terminating in large paired, entire, petaloid crests (crests single and fringed in *M. lugubris*), stigma usually transverse, sometimes 2-lobed or 2, at base of crests, or style branches reduced and narrow, 2-lobed sometimes with stigma terminal and crests vestigial or lacking, rarely style branches filiform or each divided into paired filiform arms extending between anthers, then stigmatic at tips. *Capsules* globose to ovoid or club-shaped, apex truncate or shortly beaked (rarely beak elongate), leathery to woody or submembranous, usually exserted, or included when ovary ± sessile. *Seeds* angular and prismatic, ± globose or compressed and discoid; surface cells domed, plane

or concave, outlines ± smooth to reticulate. *Pollen grains* monosulcate, exine reticulate to retipilate. *Basic chromosome number x* = 10, but a wide range of other numbers present (Goldblatt 1971c).

Species ± 230, 209 in southern Africa; mainly sub-Saharan Africa, also Mediterranean Basin and Middle East, most diverse and species-rich in western southern Africa, and with marked secondary centres in the mountains of eastern southern Africa and the East African highlands, favouring open habitats, including desert scrub, rocky grassland, rock outcrops, and shrubland, often flowering well only after fires.

Although remarkably diverse in floral morphology, *Moraea* is immediately recognised by the cormous rootstock comprising a single internode and produced annually, that of the past season being completely resorbed, and the dorsiventral leaf (unless terete). Plants are almost universally seasonal, thus deciduous in the dry season. Flowers range from the typical *Iris*-type, with larger outer tepals bearing markings at the base of the limbs, smaller inner tepals usually spreading to reflexed, and petaloid style branches with paired, plane appendages or crests. The filaments are typically at least partially united, sometimes entirely so, and each anther is appressed to a style branch and typically held below the transverse, simple or bilobed stigma. Departures from this apparently ancestral condition include reduction of the style branches, then often lacking crests, and the associated development of subequal inner and outer tepals, both whorls of which usually bear markings, as in all members of subg. *Homeria* and several species of other subgenera. In *M. lugubris* (subg. *Plumarieae*) the style crests are fringed and feathery, and the stigmatic surfaces are located at the tips of apically divergent style branches, both features reminiscent of *Ferraria*. The style branches are further reduced in sect. *Hexaglottis* and a few unrelated species into paired filiform arms extended horizontally between the stamens. In the *Roggeveldia* group of sect. *Pseudospicatae* and in *M. simplex* (subg. *Visciramosae*) the style branches are each reduced to a single filiform arm extended between the stamens.

The tepals are typically divided into an ascending claw and a spreading or reflexed limb, the claw varying from about as long as the limb and concealing the anthers to much shorter than the limbs, thus leaving the stamens exposed and often prominently displayed. The tepals in *Moraea* are usually free (unlike *Iris* in which they are typically joined basally in a cup or tube) but are united in a short, solid tube in subg. *Galaxia* plus a few other species scattered across the genus. Species of subg. *Acaules* have an underground stem and the flowers are raised well above the ground on a contractile stipe (possibly the pedicel) that contracts after fertilisation to pull the developing capsule back to ground level. In most species of subg. *Vieusseuxia* the inner tepals are reduced to three-lobed structures, often with a prominent central lobe, but in the *M. tripetala* species group they are further reduced into a thread- or cusp-like structure or may even be absent.



Leaf number is variable, ranging from several (e.g. *Moraea ramosissima*) to a single foliage leaf, with other foliar organs represented by large, often dry, bract-like leaves sheathing the stem. Leaves are occasionally finely hairy, notably in *M. villosa* and its close allies. The nodes and upper internodes of the stem are sticky and viscid in subg. *Visciramosae*. Molecular studies (Goldblatt et al., 2013) using both plastid and nuclear gene sequences confirm that *Moraea* is monophyletic and that *Ferraria* is its closest relative. The infrageneric classification used here, which includes 11 subgenera, is based on the phylogeny obtained from the molecular study.

Pollination is diverse and directly related to flower structure. Species with *Iris*-like flowers are pollinated by bees foraging for nectar produced from small nectaries at the bases of the outer tepals. Species with anthers displayed prominently above the tepals are pollinated by pollen-collecting female bees. Other species are pollinated by hopliine beetles (notably the *Moraea villosa* group) and a few have been shown to be pollinated mainly by mud wasps.

Largely sub-Saharan African, *Moraea* is centred in western southern Africa where it is most diverse but several species of subg. *Grandiflorae* and a few species of subg. *Polyanthes* occur in tropical Africa. Two species of the otherwise southern African sect. *Gynandriris* occur in the Mediterranean area and Middle East.

Key to subgenera

1a Style branches petaloid with fringed, feathery crests; stigmatic surfaces at tips of apically divergent style branches; foliage leaves usually 2 . . . . . Subg. 1. *Plumarieae* (only 1. *M. lugubris*)
1b Style branches not as above, often petaloid with paired entire crests above stigmatic lobes or crests reduced but never fringed, or style branches filiform; foliage leaves solitary to several:
2a Stem branched and sticky at or below nodes; rhipidial spathes unequal and acute or ± subequal and subobtuse, then often torn apically; foliage leaves 2 to several. . . . . Subg. 2. *Visciramosae*
2b Stem branched or not, not sticky at or below nodes; rhipidial spathes subequal or unequal, acute to attenuate; foliage leaves solitary to several:
3a Plants acaulescent with 2 or more leaves crowded at ground level (rarely shortly above ground) and style branches not filiform; leaves hardly differing from rhipidial spathes:
4a Flowers with tepals united below in a perianth tube; style with ± vestigial branches, entire or fringed and stigmatic distally. . . . . Subg. 5. *Galaxia*

MORAEA. M. vespertina: A, flowering stem and leaves; B, capsule. ***M. regalis***: C, flower. ***M. simplex***: D, flower; E, detail of stamens and style. ***M. cantharophila***: F, flower; G, details of stamens and style. ***M. melanops***: H, flowering plant. ***M. ciliata***: I, seed. ***M. cooperi***: J, seed.

4b Flowers with tepals free to base, borne on a hollow, contractile stalk retracting during capsule maturation; style with well-developed, petaloid branches with paired, petaloid crests. . . . . Subg. 7. *Acaules*
3b Plants usually caulescent with leaves solitary to several, sometimes crowded near stem apex, sometimes acaulescent but style branches various, sometimes filiform; leaves differing from inflorescence spathes:
5a Corm tunics dark brown, initially unbroken, later splitting irregularly, sometimes ultimately fibrous; rhipidial spathes blunt or truncate to obtuse, outer spathe often diverging apically; flowers pale yellow to ± beige (rarely brown) usually with dark venation:
6a Foliage leaf solitary, inserted above ground; blade channelled below, terete or narrowly linear distally; plants unbranched and with single rhipidium with outer spathe always sheathing; ovary triangular to prominently 3-winged. . . . . Subg. 6 *Monocephalae*
6b Foliage leaves two or more, lowermost basal or leaves clustered at first aerial node; blades channelled or terete distally; plants usually branched with multiple rhipidia and outer spathe often free and diverging distally; ovary round in section . . . . . Subg. 3. *Umbellatae*
5b Corm tunics light to dark brown, usually coarsely to finely fibrous; rhipidial spathes acute to attenuate with outer spathe always sheathing; flowers variously coloured:
7a Plants with 2 or more foliage leaves and flowers fugaceous; flowers usually yellow (rarely red, salmon-pink or, if blue, then plants dwarf, < 50 mm high at flowering); flowers mostly with well-developed style branches with crests or, if style branches reduced, then flowers tiny with subequal tepals . . . . . Subg. 4. *Moraea*
7b Plants with 1 or more foliage leaves and flowers either fugaceous or long-lasting; flowers various colours: flowers with style branches well developed or reduced, with short or lacking crests or filiform:
8a Flowers always long-lived; style branches usually well-developed with short to long crests (if crests lacking, inner and outer tepals spreading); inner tepals often reduced, with limbs either 3-lobed or linear, or limbs lacking and inner tepal cusp-like or absent . . . . . Subg. 10. *Vieusseuxia*
8b Flowers fugaceous or long-lived; style branches well developed with paired crests or branches narrow and crests vestigial or lacking; inner tepals with well-developed entire limbs:
9a Flowers always fugaceous; perianth mostly blue to violet or white or sometimes yellow but then style branches filiform, paired or single and ascending to horizontal . . . . . Subg. 8. *Polyanthes*
9b Flowers long-lasting or fugaceous; perianth variously coloured, rarely blue to violet but then style branches well-developed:
10a Flowers mostly long-lasting; style branches well-developed inner tepal limbs erect or suberect to spreading; foliage leaves always solitary (or lacking at anthesis). . . . . Subg. 9. *Grandiflorae*
10b Flowers long-lived or fugaceous; style branches variously reduced, usually narrower than subtending anthers and with crests weakly developed or vestigial; inner tepals mostly similar in orientation to outer tepals, with limbs spreading to half reflexed, usually with nectar guides; foliage leaves several to solitary . . . . . Subg. 11. *Homeria*

Subg. 2. *Visciramosae*

1a Foliage leaves 3 or more; rhipidial spathes acute, unequal with outer ± half as long as inner:
2a Flowers white or pale blue; outer tepals 40–45 mm long; foliage leaves 4 to 6 . . . . . 2. *M. vespertina*
2b Flowers dull yellow to beige or light brown; outer tepals 22–33 mm long; foliage leaves 3(4):
3a Tepal claws forming a wide cup and limbs half reflexed . . . . . 3. *M. bubalina*
3b Tepal claws suberect forming a narrow cup and limbs fully reflexed. . . . . 4. *M. striata*
1b Foliage leaves 2; rhipidial spathes subacute to obtuse, often lacerate at tips, subequal or outer slightly shorter than inner:
4a Style branches filiform, extending between stamens; tepals with short erect claws ± 2 mm long . . . . . 10. *M. simplex*
4b Style branches flattened, opposite anthers and appressed to them; tepals with longer ascending claws:
5a Style branches shorter than anthers; style branches with crests vestigial or absent. . . . . 9. *M. elsiae*
5b Style branches ± as long as anthers; style branches with short to long crests:
6a Flowers relatively large with outer tepals 23–31 mm long; style branches with crests 6–12(–15) mm long; inner rhipidial spathe 25–40 mm long. . . . . 5. *M. bituminosa*
6b Flowers fairly small with outer tepals mostly < 23 mm long (rarely up to 30 mm); style branches with crests (1.5)2.0–6.0(–10.0) mm long; inner rhipidial spathe 15–30 mm long:
7a Flowers white, sweetly scented; tepals spreading to half reflexed. . . . . 7. *M. viscaria*
7b Flowers yellow, slate blue, or white (occ. flushed pink), usually not scented; tepals usually fully reflexed (or half reflexed):
8a Flowers yellow, brown, rarely white or flushed pink; outer tepals 12–18(25) mm long with claws ± half or less than half as long as limbs. . . . . 6. *M. inconspicua*
8b Flowers slate blue; outer tepals ± 18 mm long with claws slightly longer than limbs. . . . . 8. *M. saldanhensis*

Subg. 3. *Umbellatae*

1a Stem subterranean; leaves and rhipidia clustered at ground level:
2a Tepals unequal, outer larger and with nectar guides at limb bases; style branches well developed with prominent crests . . . . . 16. *M. longiflora*
2b Tepals subequal, outer ± as long as inner and both with nectar guides at limb bases; style branches divided almost to base into paired filiform arms, thus lacking crests. . . . . 20. *M. singularis*

1b Stem aerial; either lowermost leaf inserted at ground level or all leaves and branches clustered at ground level but then rhipidia stalked:
3a Foliage leaves clustered at stem apex well above ground (leaves not basal):
4a Style branches filiform and extended between stamens, lacking crests . . . . . 19. *M. nana*
4b Style branches flattened, appressed to opposed anther, with or without prominent crests:
5a Style branches bearing prominent crests 10–12 mm long; filaments united in column 8–10 mm long . . . . . 14. *M. intermedia*
5b Style branches without crests; filaments in column 5–7 mm long, united or free distally:
6a Plants 150–450 mm high; outer tepals 19–27 × 9–12 mm; inner rhipidial spathes 30–40 mm long 17. *M. umbellata*
6b Plants 90–150 mm high; outer tepals 15–24 × 6–10 mm; inner rhipidial spathe 20–35 mm long 18. *M. maximiliani*
3b At least 1 foliage leaf or all leaves clustered at ground level:
7a Branches (when present) produced at ground level . . . . . 13. *M. margaretae*
7b Branches produced above ground level:
8a Branches crowded at stem apex; tepals free. . . . . 11. *M. linderi*
8b Branches borne along stem, not crowded above:
9a Tepals free to base; inner tepals present . . . . . 12. *M. orthrosantha*
9b Tepals united in short tube; inner tepals lacking . . . . . 15. *M. cooperi*

Subg. 4. *Moraea*

1a Plants dwarf, rarely exceeding 50 mm at flowering; flowers blue-violet . . . . . 29. *M. nubigena*
1b Pants rarely less that 100 mm high; flowers yellow, brownish, red or salmon-pink:
2a Filaments as long as or longer than tepal claws; anthers displayed above outer tepal limbs; pollen red:
3a Lowermost leaves inserted well above ground and clustered together at or shortly above first aerial node; inner tepal claws ± 5 mm long and limbs spreading . . . . . 22. *M. indecora*
3b Lowermost leaves basal, not crowded together; inner tepal claws 10–12 mm long and limbs ascending to erect . . . . . 27. *M. garipensis*
2b Filaments shorter than tepal claws; anthers partly to entirely concealed by subtending tepal claw; pollen yellow to white, blue or red:
4a Style branches reduced, concealed by anthers and lacking crests . . . . . 24. *M. vlokii*
4b Style branches well developed, broader than anthers and bearing prominent crests:
5a Plants 0.5–1.2 m high; bearing numerous small cormlets at base of corm and in lowermost leaf axils . . . . . 26. *M. ramosissima*
5b Plants usually < 0.5 m high; without basal or axillary cormlets:
6a Outer spathes $^{2}/_{3}$ to nearly as long as inner and margins free to base or almost so; pollen usually blue . . . . . 21. *M. vegeta*
6b Outer spathes ± half as long as inner and margins united in lower $^{1}/_{3}$ or more; pollen white to yellow or red:
7a Stem sparsely hairy to velvety; leaves and spathes velvety to glabrous . . . . . 28. *M. papilionacea*
7b Stem smooth; leaves and spathes glabrous:
8a Foliage leaves (1)2 or 3; outer tepals mostly 12–24 mm long . . . . . 23. *M. gawleri*
8b Foliage leaves several (at least 4); outer tepals mostly 25–28 mm long . . . . . 25. *M. namaquamontana*

Subg. 5. *Galaxia*

1a Style branches short, margins deeply fringed:
2a Corm tunics entire (not fibrous), pith-like to ± cartilaginous; foliage leaves terete in upper half . . . . . 46. *M. angulata*
2b Corm tunics fibrous, foliage leaves bifacial or unifacial, sometimes terete in upper half:
3a Filaments free in upper $^{2}/_{3}$; tepals yellow below fading to white in upper half . . . . . 39. *M. luteoalba*
3b Filaments free and diverging in upper $^{1}/_{3}$ or united entirely; tepals yellow, sometimes with darker cup edged with dark markings or white with yellow cup then with filaments united:
4a Flowers white with yellow centre; filaments entirely united. . . . . 43. *M. albiflora*
4a Flowers yellow; filaments free distally for ± 1 mm or fully united:
5a Leaves narrow, linear, ± unifacial or ± terete distally; margins smooth or sparsely and obscurely ciliate:
6a Perianth tube 10–24 mm long; tepals (11–)15–19 mm long; style usually exceeding anthers . . . 44. *M. fugacissima*
6b Perianth tube 5–10 mm long; tepals 10–15 mm long; style dividing opposite anther apices . . . . . 45. *M. stagnalis*
5b Leaves oblong to ± ovate; leaf margins ciliate to minutely velvety or smooth:
7a Flowers with deeper yellow cup edged with dark markings. . . . . 42. *M. vuvuzela*
7b Flowers uniformly yellow:
8a Perianth tube 4.5–10.0 mm long; tepals 6–10 mm long. . . . . 41. *M. pilifolia*
8b Perianth tube mostly 10–25 mm long; tepals 16–30 mm long:
9a Tepals 16–20 mm long; anthers 2–3 mm long. . . . . 40. *M. galaxia*
9b Tepals 22–30 mm long; anthers 4–5 mm long. . . . . 38. *M. kamisensis*
1b Style branches with entire margins; flowers often pink to purple, or red, white or yellow:
10a Flowers predominantly white or yellow sometimes with brown markings in midline of tepals (rarely orange):
11a Flowers yellow, sometimes with brown markings in midline of tepals (rarely orange); tepals 18–28 mm long . . . . . 31. *M. citrina*

11b Flowers white with yellow cup; tepals 10–12 mm long . . . . . 34. *M. minima*
10b Flowers pink or purple to red, with pale or dark purple centre:
12a Flowers small, perianth tube 8–10 mm long; tepals 10–15 mm long:
13a Leaves narrow, shallowly channelled to plane, uniformly green; tepals 10–12 mm long . . . . . 30. *M. kamiesmontana*
13b Leaves terete, green with translucent adaxial line; tepals ± 15 mm long . . . . . 37. *M. fenestralis*
12b Flowers larger, perianth tube (10–)12–30 mm long; tepals 14–25 mm long:
14a Flowers with dark purple centre:
15a Tepals spreading from base, 18–25 mm long; filaments 4.0–6.5 mm long, united in lower $^{2}/_{3}$; style dividing opposite apex of filaments . . . . . 33. *M. barnardiella*
15b Tepals ascending but not cupped, ± 16 mm long; filaments ± 3 mm long, free or united in lower half; style dividing ± 1 mm beyond anther apices . . . . . 32. *M. melanops*
14b Flowers with yellow centre:
16a Leaves with ± straight margins; style dividing opposite anthers apices. . . . . 36. *M. variabilis*
16b Leaves with undulate margins; style dividing well above anthers . . . . . 35. *M. versicolor*

Subg. 6. *Monocephalae*

1a Filaments joined at least 2 mm and up to half their length; stems usually with (1)2 sheathing leaves . . . . . 48. *M. anomala*
1b Filaments joined at the base for up to 2 mm; stems usually with 1(2) sheathing leaf:
2a Leaf linear-folded, trailing; flowers relatively small with outer tepals 20–24 mm long; anthers 5–6 mm long . . . . . 50. *M. vallisavium*
2b Leaf terete, ± stiffly erect; flowers usually larger with outer tepals 30–50 mm long; anthers 7–10 mm long:
3a Nectar guides clear yellow, circled with darker pigment; style crests slightly longer than style branches 47. *M. angusta*
3b Nectar guides consisting of lines of dark dots on deep yellow background; style crests slightly shorter than style branches . . . . . 49. *M. neglecta*

Subg. 7. *Acaules*

1a Stem extending well above ground with leaves clustered at first aerial node . . . . . 55. *M. longipes*
1b Stem subterranean with leaves borne at ground level:
2a Plants usually with multiple flower clusters (rhipidia), sometimes growing in tufts; leaves 5 or more, ± falcate or spreading horizontally; flowers white with yellow nectar guides at base of outer tepal limbs and usually a violet to purple mark near top of inner tepal claws or base of limbs; filaments ± 6 mm, united in lower half; corm tunics dark and coarsely fibrous; leaves glabrous or rarely ciliate on margins:
3a Leaves tapering from broad base to slender acute apex, mostly 30–50 mm long, laxly twisted with acute apex; floral bracts not evident, retained within spathes; outer tepals 18–22 mm long . . . . . 51. *M. falcifolia*
3b Leaves oblong, up to 20 mm, straight with obtuse apex; floral bracts extending above leaves as dry white-membranous threads; outer tepals ± 14 mm long . . . . . 52. *M. filamentosa*
2b Plants usually growing singly with solitary flower cluster (sometimes 2 or 3 in *M. ciliata*); leaves (not including sheathing inner spathe of rhipidium) mostly 3 or 4(6), suberect or falcate, sometimes twisted; flowers predominantly blue, mauve, pink, red, yellow or white, with yellow nectar guides, inner tepals usually without markings; filaments 3–18 mm long, united only basally or for up to half their length; corm tunics pale, fibrous (sometimes coarsely so) or consisting of layers of spongy tissue:
4a Outer tepals 40–60 mm long with claws 25–40 mm long, ± twice as long as limbs; filaments 12–18 mm long, united in lower half; flowers predominantly yellow, sometimes with white inner tepals. . . . . 57. *M. macronyx*
4b Outer tepals 18–25 mm long with claws 9–18 mm long, ± as long as or shorter than limbs; filaments 3–10 mm long and united basally for $^{1}/_{5}$–$^{1}/_{2}$ their length; flowers blue to violet, white, yellow, pink or red:
5a Style branches 4–5 mm long, with broadly triangular crests, 8–10 × 4–5 mm at base, ± twice as long as style branches; filaments 3–4 mm long; flowers yellow, red, purple or violet. . . . . 56. *M. tricolor*
5b Style branches 6–16 mm long with lanceolate to narrowly wedge-shaped or ± linear crests, 7–15 × 2–3 mm at base; filaments 4–10 mm long; flowers blue to mauve, white, yellow or pink to dull red:
6a Leaves twisted distally with margins thickened, strongly undulate to crisped and usually smooth; flowers pale yellow or with white inner tepals; seeds small, angular-prismatic, 1.3–1.5 × 1.0–1.3 mm. . . . . 54. *M. flava*
6b Leaves usually ± straight to falcate and often partly hairy (rarely twisted distally and ciliate) with margins straight, undulate or lightly crisped, sometimes thickened and ciliate to long hairy; flowers blue, deep yellow often brown outside, or white rarely with pink flush; seeds (where known) relatively large, softly angular to ± globose, 1.4–2.5 mm diam.. . . . . 53. *M. ciliata*

Subg. 8. *Polyanthes*

1a Flowers with filiform style branches, either simple or forked to base into paired filiform arms extending between anthers; both inner and outer tepals usually with contrasting markings:
2a Style branches simple, filiform, extending between anthers; tepals predominantly blue to violet:
3a Foliage leaf channelled, 5–7 mm wide, margins thickened . . . . . 111. *M. marginata*
3b Foliage leaf terete, without margins:
4a Leaf straight, hollow, ± 3 mm diam., ± as long as stem . . . . . 112. *M. fistulosa*

4b Leaf falcate, and somewhat twisted, not hollow, ± 1 mm diam., longer than stem, often trialing distally . . . . . 111. *M. monticola*
2b Style branches with paired filiform arms; flowers yellow or blue to violet:
5a Perianth blue to violet:
6a Stem 80–100 mm high, weakly flexuose; foliage leaf solitary; stem 1- or 2-branched; plants of southern Namibia . . . . . 71. *M. hexaglottis*
6b Stem 200–450 mm high, straight; foliage leaves 2 or more; stem usually with 1 to 4 primary branches each with (1)4 to 6 sessile lateral flower clusters at upper nodes; plants of interior Western Cape . . . . . 109. *M. pearsonii*
5b Perianth yellow to beige:
7a Tepals united basally in a perianth tube:
8a Perianth tube (3–)4–9 mm long; ovary entirely included. . . . . 82. *M. virgata*
8b Perianth tube 1.5–2.0 mm long; upper part of ovary sometimes emerging from spathes:
9a Leaf margins straight; plants with several to many sessile lateral rhipidia; anther 6–7 mm long . . . 81. *M. brevituba*
9b Leaf margins undulate (sometimes crisped); plants unbranched or with 1 or 2 shortly stalked lateral rhipidia; anthers ± 3 mm long. . . . . 77. *M. thermarum*
7b Tepals free to base:
10a Lateral rhipidia stalked; leaves comparatively broad and short, up to 11 mm wide, spreading and twisted, with margins undulate and often crisped . . . . . 76. *M. namaquana*
10b Lateral rhipidia sessile, spicately arranged on the main or primary branches:
11a Capsules narrowly ellipsoid to cylindric-trigonous, rarely > 3 mm at widest; plants of open and dry habitats . . . . . 78. *M. lewisiae*
11b Capsules obovoid to club-shaped, truncate above; 4–8 mm at the widest point; plants of moist habitats, stream sides and seeps:
12a Capsules 12–16(–23) mm long and 6–8 mm wide; inner spathe of lateral rhipidia usually shorter than outer and concealed by the sheathing bract leaves . . . . . 79. *M. longifolia*
12b Capsules 6–10(–12) mm long and ± 4 mm wide; inner spathe of the lateral rhipidia usually longer than outer and not concealed. . . . . 80. *M. riparia*
1b Flowers with flattened style branches appressed to opposed anthers, with or without obvious crests:
13a Ovary subsessile and perianth raised above spathes on sterile tubular extension of ovary AND style branches broad, petaloid and bearing prominent crests; rhipidial spathes translucent between veins:
14a Foliage leaves 2; leaf blades ± helically coiled or rarely laxly twisted, with median band of translucent tissue . . . . . 87. *M. pritzeliana*
14b Foliage leaves 1 or 2; leaf blades linear straight or laxly twisted, usually channelled, uniformly green:
15a Flowers small, outer tepals 12–18 mm long; anthers 2.5–4.0 mm long . . . . . 84. *M. setifolia*
15b Flowers moderate-sized, outer tepals (17–)19–30 mm long; anthers (4–)5–8 mm long:
16a Flowers white; inner tepal limbs erect . . . . . 85. *M. cedarmontana*
16b Flowers blue to blue-mauve or violet; inner tepal limbs half reflexed:
17a Foliage leaves 2; flowers crepuscular, opening after 17:00 . . . . . 89. *M. hesperantha*
17b Foliage leaves usually solitary or 2; flowers diurnal, collapsing in late afternoon:
18a Plants of summer-rainfall southern Africa; tepals blue-mauve mottled darker with age; outer tepals 17–28 mm long. . . . . 86. *M. simulans*
18b Plants of western winter-rainfall southern Africa; tepals blue-mauve to violet, not mottled darker with age; outer tepals 21–30 mm long:
19a Claws of outer tepals 11–12 mm long; tepals pale blue to blue-mauve . . . . . 83. *M. australis*
19b Claws of outer tepals 7–8 mm long; tepals blue-violet. . . . . 88. *M. contorta*
13b Ovary subsessile or on long pedicels with or without beaked ovary AND style branches reduced or broad, petaloid and bearing crests; rhipidial spathes not translucent between veins:
20a Foliage leaves 2 or more:
21a Style branches with prominent, erect paired crests; outer tepals with nectar guides at bases of limbs:
22a Ovary and capsules included in rhipidial spathes:
23a Lower or all foliage leaves ± basal, with blades twisted or coiled:
24a Inner tepals spathulate with limbs erect; leaves twisted or coiled and narrowly channelled. . . 58. *M. serpentina*
24b Inner tepals ± obovate, with limbs of both whorls half-reflexed:
25a Leaves 2 or 3, with blades terete and helically coiled. . . . . 59. *M. tortilis*
25b Leaves 2, with blades channelled or terete but not coiled:
26a Foliage leaves terete, < 1 mm diam., straight, possibly trailing distally; outer tepals ± 18 × 8 mm . . . . . 61. *M. teretifolia*
26b Foliage leaves channelled, shorter than stem with margins undulate (crisped); outer tepals 25–30 × 10 mm . . . . . 60. *M. geminifolia*
23b Leaves inserted well above ground, ± opposed at first aerial node:
27a Stems and leaves fairly sturdy, stem mostly 2–4 mm diam.; flowers moderate-sized to large, outer tepals 30–50 mm long; capsules mostly 12–30 mm long . . . . . 72. *M. fugax*
27b Stems and leaves ± filiform, stem rarely > 1 mm diam.; flowers moderate-sized, outer tepals 20–33 mm long; capsules 9–13(–15) mm long. . . . . 74. *M. filicaulis*
22b Ovary and capsules exserted from rhipidial spathes:
28a Outer tepals 16–30 mm long; inner rhipidial spathes 20–45 mm long:
29a Foliage leaves 2(3); inner rhipidial spathes mostly 30–45 mm long; plants of northern Namibia and Botswana . . . . . 92. *M. carsonii*

29b Foliage leaves (2)3 or 4; inner rhipidial spathes 20–40(–45) mm long; plants of southern Western and Eastern Cape . . . . . 90. *M. bipartita*
28b Outer tepals 36–60 mm long; inner rhipidial spathes 40–60 mm long:
30a Ovary veined with red (not southern Cape populations); outer tepals 36–55 mm long; capsules 9–16 mm long, erect . . . . . 91. *M. polystachya*
30b Ovary uniformly green; outer tepals 45–60 mm long; capsules 16–20 mm long, often nodding . 93. *M. venenata*
21b Style branches reduced, as wide as or narrower than anthers, with crests vestigial or lacking; nectar guides present at bases of limbs of both tepal whorls:
31a Plants acaulescent or almost so; tepals united basally in a tube 5–6 mm long . . . . . .68. *M. graniticola*
31b Plants with well-developed aerial stem; tepals free to base:
32a Style dividing at top of filament column and diverging from base . . . . . 95. *M. polyanthos*
32b Style dividing at or above middle of anthers, hardly diverging:
33a Foliage leaves several (at least 4); leaf blades 20–40 mm wide; style branches 2–6 mm long . . . . .94. *M. speciosa*
33b Foliage leaves 2 or 3; leaf blades narrow, 2–5 mm wide; style branches ± 1 mm long:
34a Ovary veined with red; tepals ± 30–36 mm long; anthers 5.5–6.6 mm long, contiguous; style dividing opposite anther apices and overtopping them . . . . . 96. *M. deserticola*
34b Ovary uniformly green; tepals ± 22 mm long; anthers 4–5 mm long, exceeding style, branches ± 1 mm long . . . . . 97. *M. tanquana*
20b Foliage leaf solitary (sometimes absent at flowering), remaining leaves entirely sheathing stem:
35a Plants of eastern southern Africa:
36a Foliage leaf absent or dry at flowering time (or new leaf emergent), the blade terete without a longitudinal groove:
37a Style branches reduced, narrow, lacking crests . . . . . .101. *M. thomsonii*
37b Style branches not reduced, always bearing crests:
38a Flowers pale lilac to blue-mauve; outer tepals 18–20 mm long . . . . . .99. *M. stricta*
38b Flowers violet; outer tepals 12–15 mm long . . . . . 101. *M. alpina*
36b Foliage leaf present at flowering time, the blade channelled, sometimes margins tightly inrolled, seeming terete but with narrow longitudinal adaxial groove:
39a Leaf inserted at base or shortly above ground. . . . . 98. *M. elliotii*
39b Leaf inserted well above ground often at base of first branches; branches often short, somewhat crowded above first aerial node:
40a Inner rhipidial spathes 34–40 mm long; capsules globose, ± 5 mm diam.; outer tepals 25–30 mm long . . . . . .103. *M. inclinata*
40b Inner rhipidial spathes 25–35 mm long; capsules club-shaped up to 10 mm long; outer tepals 15–20 mm long . . . . . .102. *M. natalensis*
35b Plants of western, winter-rainfall southern Africa:
41a Style branches bearing prominent, erect paired crests; only outer tepals bearing nectar guides at bases of limbs:
42a Leaf inserted well above ground, often at base of first branches; branches often short, somewhat crowded above first aerial node:
43a Spathes short, 20–35(–40) mm long; capsules 10–12 mm long; branches many on extended stem . . . . . 73. *M. gracilenta* (see also 74. *M. filicaulis* above)
43b Spathes longer, (35–)40–65 mm long; capsules 15–28(–40) mm long:
44a Plants usually acaulescent and unbranched, rarely 1- or 2-branched; capsules 18–36 mm long; flowers white or blue to mauve or violet; outer tepals 20–40 mm long . . . . . .75. *M. macrocarpa*
44b Plants with aerial stem, several to many branched, branches often crowded; capsules 12–30 mm long; flowers white, blue or yellow, outer tepals 30–50 mm long . . . . . 72. *M. fugax*
42b Leaf inserted at ground level, plants branched or not:
45a Ovary and capsules exserted; rhipidial spathes green, sometimes dry toward tips:
46a Flowers small, outer tepals 14–17 × 4.5–6.0 mm; outer tepals reflexed up to 30º; inner rhipidial spathes 22–32 mm long . . . . . .105. *M. exiliflora*
46b Flowers moderate in size, outer tepals 20–30 mm long; outer tepals reflexed 45º or more; inner rhipidial spathes 33–60 mm long. . . . . .104. *M. lazulina*
45b Ovary and capsules included; rhipidial spathes partly dry, with broad membranous margins:
47a Foliage leaf terete, straight below, loosely to tightly coiled in distal $^1/_3$; flowers white to creamy white . . . . . .65. *M. acocksii*
47b Foliage leaf or leaves dorsiventral, channelled at least below, often twisted distally; flowers white, yellow or blue to blue-mauve (lilac):
48a Plants small, up to 150 mm high; outer tepals 22–28 mm long; outer tepal claws ± 8–10 mm long, thus ± half as long as limbs . . . . . 66. *M. quartzicola*
48b Plants usually exceeding 200 mm; outer tepals 26–40 mm long; outer tepal claws ± as long as limbs:
49a Filaments ± 15 mm long and anthers 3–4 mm long (< $^1/_3$ as long as filaments); outer tepals ± 30 × ± 8 mm. . . . . 67. *M. macgregoriorum*
49b Filaments 10–14 mm long and anthers 5–9 mm long (± $^1/_2$ to > $^1/_2$ as long as filaments); outer tepals 26–47 × 10–22 mm:
50a Foliage leaf narrowly channelled (sometimes appearing ± terete but with narrow adaxial groove), the margins straight; flowers blue-mauve or white . . . . . .63. *M. namibensis*
50b Foliage leaf twisted or straight, the margins straight or undulate to partly crisped; flowers pale or deep yellow, white or pale blue-mauve:

51a Leaf usually trailing almost from base, margins undulate to crisped; flowers usually yellow . . . . . 64. *M. bolusii*
51b Leaf falcate, thus erect in lower half, almost straight to undulate; flowers pale blue-mauve or white, rarely pale, watery yellow. . . . . 62. *M. saxicola*
41b Style branches reduced, mostly as wide as or narrower than anthers, with crests vestigial or lacking; inner and outer tepals usually bearing nectar guides at bases of limbs:
52a Ovary extended above as a sterile tube; leaves terete:
53a Leaf ± 3 mm diam., interior hollow and pithy, rigidly erect; tubular upper part of ovary ± 1 mm long . . . . . .69. *M. rigidifolia*
53b Leaf ± 1 mm diam., straight or loosely coiled helically; tubular upper part of ovary 7–10 mm long . . . . . .70. *M. herrei*
52b Ovary without sterile tubular extension above; leaves channelled (sometimes with narrow longitudinal groove) or terete:
54a Plants with 2 to 4 branches, all stalked; capsules ellipsoid-obovoid. . . . . .106. *M. crispa*
54b Plants with 1 or 2 stalked primary branches from base but bearing sessile lateral rhipidia above; capsules globose or spindle-shaped:
55a Capsules globose, 2–4 mm diam., membranous and semi-transparent, fragmenting irregularly; flowering December to March . . . . . 108. *M. pseudospicata*
55b Capsules ± spindle-shaped with a short sterile beak; flowering October to November. . . . . .107. *M. verecunda*

Subg. 9. *Grandiflorae*

1a Plants with single sheathing leaf; flowers yellow . . . . . .125. *M. unibracteata*
1b Plants with 2 to several sheathing leaves, usually overlapping one above; flowers yellow, white or pink or blue:
2a Leaves with narrow adaxial groove or appearing terete with margins tightly inrolled; flowers yellow:
3a Cataphylls decaying brown, entire or irregularly broken, ribbed . . . . . 124. *M. hiemalis*
3b Cataphylls decaying into firm, dark brown vertical fibres:
4a Flowers deep yellow; outer tepals 40–50 mm long; inner tepal limbs erect. . . . . 119. *M. galpinii*
4a Flowers pale yellow to almost white; outer tepals 55–65 mm long; inner tepal limbs erect to spreading . . . . . 118. *M. robusta*
2b Leaves plane to widely channelled; flowers yellow, white or pink or blue:
5a Flowers blue or pink then often with style crests darker pink:
6a Flowers blue to violet; filaments shorter than anthers. . . . . .121. *M. ardesiaca*
6a Flowers pink often with darker pink style crests; filaments longer than anthers . . . . . .122. *M. carnea*
5b Flowers yellow or white with style crests the same colour as the tepals or with dark purple markings:
7a Cataphylls forming a pale straw-coloured fibrous network distally:
8a Plants usually solitary; flowers deep yellow with orange nectar guides. . . . . 117. *M. reticulata*
8a Plants growing in clumps; flowers pale watery yellow with small, white to pale yellow nectar guides . . . . . 116. *M. alticola*
7b Cataphylls pale to brown, entire or frayed or torn at apex or decaying irregularly:
9a Style crests with dark purple-brown blotch at bases:
10a Plants growing mostly along steams and drainage lines, usually in clumps . . . . . .115. *M. huttonii*
10b Plants of open grassland, usually solitary . . . . . 123. *M. graminicola*
9a Style crests uniformly coloured:
11b Plants relatively small, up to 450 mm high, mostly solitary:
12a Leaf 5–6 mm wide; outer tepals 35–50 mm long. . . . . .120. *M. muddii*
12b Leaf mostly 8–25 mm wide; outer tepals 60–75 mm long . . . . . 123. *M. graminicola*
11b Plants tall, usually > 500 mm high, usually growing in clumps:
13a Leaves ± flat to widely channelled, deep green; flowers often with large orange nectar guide . . . . . 113. *M. spathulata*
13b Leaves with semi-circular channel, glaucous-green; flowers with small yellow nectar guide . . . . . 114. *M. moggii*

Subg. 10. *Vieusseuxia*

A. Species of summer-rainfall eastern southern Africa (Limpopo to Eastern Cape near East London):

1a Inner tepals reduced to short cusps (sometimes minutely divided at tips):
2a Flowers relatively large, pale yellow to creamy white; outer tepals 30–35 mm long; flowering in summer January to March . . . . . 149. *M. albicuspa*
2b Flowers small, white to pale mauve with purple style crests; outer tepals 20–27 mm long; flowering in late spring mostly October to November. . . . . 151. *M. modesta*
1b Inner and outer tepal claws subequal but limbs 3-lobed:
3a Inner tepal lobes unequal, inner lobe at least twice as long as short, rounded lateral lobes:
4a Foliage leaf dry at flowering or emergent; blade terete; flowers white to pale blue . . . . . 150. *M. marionae*
4b Foliage leaf present at flowering; blade channelled; flowers brown and creamy beige . . . . . .147. *M. trifida*
3b Inner tepal lobes ± equal, inner lobe slightly narrower than lateral lobes:
5a Flowers purple; outer tepals 25–30 mm long. . . . . .148. *M. dracomontana*

5b Flowers white to creamy white to pale mauve; outer tepals 18–30 mm long:
6a Outer tepals 27–30 mm long and velvety or scabrid outside; filaments 10–12 mm long. . . . . 152. *M. pubiflora*
6b Outer tepals 18–28 mm long and glabrous or sparsely puberulous outside; filaments 4–7 mm long:
7a Outer tepal limbs oblanceolate and half reflexed, with claws 9–11 mm long; stamens 11–12 mm long . . . . . 153. *M. brevistyla*
7b Outer tepal limbs broadly ovate to orbicular and spreading, with claws 7–9 mm long; stamens ± 8.5 mm long. . . . . 154. *M. vigilans*

B. Species of winter-rainfall western southern Africa (Richtersveld to Grahamstown):

1a Plants with 2 or more foliage leaves (but see 160. *M. tripetala*); filaments united in lower $^{2}/_{3}$ or entirely:
2a Foliage leaves only 2, blades narrow, up to 1 mm wide with narrow adaxial groove, distally twisted to coiled . . . . 134. *M. helicoidea*
2b Foliage leaves 3 or more, blades 3–10 mm wide, widely channelled, straight to slightly twisted but never coiled 133. *M. fergusoniae*
1b Plants with solitary foliage leaf; filaments variously united or free to base or almost so:
3a Inner tepals with well-developed, lanceolate to ovate or ellipsoid limbs mostly as long as or longer than claws (but see *M. tulbaghensis*); stems and foliage leaves glabrous:
4a Filaments united only near base; flowers yellow. . . . . 126. *M. thomasiae*
4b Filaments united in a smooth slender column, sometimes free in upper $^{1}/_{3}$; flowers variously coloured but not yellow:
5a Tepal claws < $^{1}/_{3}$ as long as limbs and ± spreading; markings on tepals similar on inner and outer tepals:
6b Flowers orange or greenish cream-coloured with brown centre; pollen orange. . . . . 131. *M. insolens*
6a Flowers blue to mauve or dark purple with white or yellow nectar guides on inner and outer tepals; pollen yellow:
7a Flowers purple with yellow nectar guides; outer tepals 15–17 mm long . . . . . 132. *M. worcesterensis*
7b Flowers pale blue to mauve with white nectar guides; outer tepals 17–20 mm long . . . . . 167. *M. amissa*
5b Tepal claws ± half as long as to longer than limbs and ascending to ± erect; markings only on outer tepal limbs:
8a Inner tepal limbs erect and usually curving inward distally:
9a Flowers pale pink to almost white flushed pink outside. . . . . 128. *M. barkerae*
9b Flowers violet to blue:
10a Inner tepals 18–20 mm long. . . . . 127. *M. incurva*
10b Inner tepals 6–10 mm long. . . . . 138. *M. algoensis*
8b Inner tepal limbs spreading:
11a Flowers dark maroon, sometimes with creamy yellow highlights (rarely largely creamy yellow), foul smelling; outer tepal claws longer than limbs . . . . . 129. *M. lurida*
11b Flowers white to creamy yellow, usually odourless; outer tepal claws ± as long as limbs:
12a Outer tepals 25–30 mm long; inner tepals 18–25 mm long . . . . . 130. *M. cantharophila*
12b Outer tepals 19–21 mm long; inner tepals ± 14 mm long . . . . . 145. *M. deltoidea*
3b Inner tepals with reduced limbs either 3-lobed or linear-filiform or lacking and claws reduced to filiform cusps sometimes 3-forked at apex, sometimes absent; stem and abaxial leaf surface glabrous, velvety or hairy:
13a Inner tepals with limbs linear-filiform (sometimes slightly wider near limb bases or rarely forming obscure rounded lobes up to 2 mm long) or lacking and claws reduced to filiform cusps or absent entirely:
14a Filaments united in lower $^{1}/_{3}$–$^{2}/_{3}$:
15a Flowers blue or violet, outer tepal limbs with small white nectar guides . . . . . 143. *M. regalis*
15b Flowers white veined and spotted with blue, outer tepal limb with dark purple nectar guides:
16a Inner tepals absent; filaments 8–9 mm long. . . . . 140. *M. barnardii*
16b Inner tepals filiform cusps 13–15 mm long; filaments 12–15 mm long. . . . . 139. *M. longiaristata*
14b Filaments united for < $^{1}/_{3}$ their length or free and flowers predominantly blue to violet or purple (rarely white):
17a Inner tepals 7.5–15.0 mm long, linear throughout or expanded and lobed in middle:
18a Foliage leaf usually shorter than stem, sometimes only half as long, blade distally at most shallowly channelled or ± plane and laxly twisted, mostly 3.5–5.0 mm wide; leaf and/or stem or spathes and sheathing leaves sometimes hairy; inner tepals 7.5–12.5 mm long, often expanded in middle, sometimes into small rounded lobes at base of spreading distal half; ovary 7–8 mm long . . . . . 158. *M. mutila*
18b Foliage leaf as long as or more often exceeding stem, sometimes twice as long; leaf blade narrowly channelled with edges often folded together, 1.5–3.0 mm wide; vegetative parts never hairy; inner tepals 8–15 mm long, linear for entire length, spreading in distal $^{1}/_{3}$–$^{1}/_{2}$; ovary 11–15 mm long. . . . . 159. *M. cuspidata*
17b Inner tepals (1–)2–6 mm long or occasionally absent, either 3-lobed in upper $^{1}/_{3}$ or reduced to hair-like or lanceolate to linear cusps, acute and usually widest at base:
19a Axil of foliage leaf bearing several dark-coloured cormlets breaking through leaf sheath; plants never forming mature capsules or seeds; anthers pale blue and pollen blue or white to yellow; plants restricted to Western Cape West Coast near Saldanha on limestone pavement or calcareous sands . . . . . 162. *M. hainebachiana*
19b Axil of foliage leaf rarely with a solitary cormlet enclosed in sheath or without cormlets; anthers and pollen orange-red or white (rarely yellow); plants always forming mature capsules and fertile seeds; plants widespread from the Western Cape coast and Western Karoo on various soils:
20a Filaments usually united for 0.5–1.5 mm (rarely free); plants not forming colonies, occasionally a single cormlet present in axil of foliage leaf; leaves narrowly channelled and edges often closely appressed; stems and abaxial leaf surface glabrous:
21a Ovary narrowly ellipsoid, mostly 4–9 mm long; capsules ellipsoid, 8–14 mm long; foliage leaf (or leaves) usually as long as or longer than stem; axillary cormlets absent; pollen usually orange-red, occasionally white; plants of slopes and flats . . . . . 160. *M. tripetala*

21b Ovary linear-cylindric, 10–13 mm long; capsules ± cylindric (15–)20–24 mm long; foliage leaf often shorter than stem, sometimes half as long; bearing a single cormlet in axil of foliage leaf; pollen white; plants of seasonal wetlands ..... 161. *M. ogamana*
20b Filaments ± free or united basally for up to 0.4 mm; plants usually forming colonies due to vegetative reproduction by axillary cormlets and/or two new cormlets replacing parent corm; leaves widely channelled, often ± plane distally; plants sometimes velvety on stems and abaxial surface of leaves:
22a Outer tepal limbs (9–)11–18 × 10–14 mm, always as long as or longer than wide; anthers 4.5–7.0(–8.0) mm long and up to one and a half times as long as filaments; corm tunics usually of hard, coarse, light brown (occasionally dark brown) fibres ..... 163. *M. amabilis*
22b Outer tepal limbs 15–20(–23) × 15–20 mm, often ± as long as wide; anthers 8–11 mm long and ± twice as long as filaments; corm tunics usually of soft, fine (rarely medium-textured), light to dark brown fibres ..... 164. *M. grandis*
13b Inner tepals 3-lobed distally with central lobe longest and acute, outer lobes short and obtuse:
23a Stems velvety and abaxial (outer) leaf surface shortly hairy to velvety; inner tepals 3-lobed with innermost lobe laxly spreading at least 3× as long as lateral lobes:
24a Anthers exceeding style branches and often exceeding crests; style crests very short, 0.5–2.0 mm long:
25a Flowers blue to mauve; style crests 0.5 mm long, ± as long as stigmatic lobes and appressed to them; pollen ± white to pale yellow ..... 172. *M. gigandra*
25b Flowers orange to red or rarely white; style crests 1–2 mm long, exceeding stigmatic lobes; pollen orange ..... 169. *M. tulbaghensis*
24b Anthers not exceeding style branches, usually reaching to just below stigmatic lobes; style crests short, 2–8 mm long:
26a Outer tepals claws yellow with or without dark spotting, shortly hairy or glabrous:
27a Outer tepals 28–40 mm long, nectar guides on limbs prominent, semi-circular, dark purple, dark turquoise or navy blue, sometimes edged with thin yellow line; anthers 6–10 mm long ..... 168. *M. villosa*
27b Outer tepals 22–28 mm long, nectar guides on limbs small, yellow sometimes edged with dark spots or consisting of small dark spots; anthers 5–6 mm long ..... 166. *M. caeca*
26b Outer tepals claws not yellow, densely covered with long, blackish hairs:
28a Outer tepal limbs orbicular, as wide as or wider than long ..... 170. *M. calcicola*
28b Outer tepal limbs oblong to obovate, longer than wide ..... 171. *M. loubseri*
23b Stems glabrous but abaxial (outer) leaf surface glabrous or shortly hairy; inner tepals 3-lobed with innermost lobe spreading, erect or coiled inward, mostly 2× as long as lateral lobes, sometimes longer:
29a Flowers dark maroon, sometimes with white to creamy yellow highlights; outer tepal limbs shorter than claws ..... 129. *M. lurida*
29b Flowers variously coloured but never maroon; outer tepal limbs as long as or longer than claws:
30a Leaves hairy on abaxial surface or at least margins visibly short- to long-ciliate:
31a Flowers shades of blue; leaves velvety on abaxial surface or only ciliate on margins ..... 141. *M. debilis*
31b Flowers dull white, tepals red-brown on reverse; leaves glabrous with margins long-ciliate ..... 137. *M. atropunctata*
30b Leaves glabrous including margins:
32a Central lobe of inner tepals spreading, at least 3× as long as lateral lobes:
33a Outer tepal limbs lanceolate, longer than wide ..... 156. *M. petricola*
33b Outer tepal limbs ± orbicular, ± as wide as long:
34a Outer tepals 30–35 mm long, limbs white with dark blue to turquiose markings at base; style brances 7–8 mm long ..... 165. *M. aristata*
34b Outer tepals 22–28 mm long, limbs mauve-lilac or pink (rarely almost white) with small yellow or dark markings at base; style brances ± 5 mm long ..... 166. *M. caeca*
32b Central lobe of inner tepals upright or curved inward and mostly up to 2× as long as lateral lobes:
35a Flowers predominantly blue to purple:
36a Inner tepals ± 4 mm long, < half as long as outer tepal claws; outer tepal claws 8–10 mm long, with a pair or shallowly raised marginal teeth shortly below apex ..... 157. *M. helmei*
36b Inner tepal > 6 mm long, as long as or longer than outer tepal claws; outer tepal claws not toothed:
37a Outer tepals 24–28 mm long ..... 138. *M. algoensis*
37b Outer tepals 12–23 mm long:
38a Filaments 3.5–4.0 mm long, united in lower half ..... 155. *M. decipiens*
38b Filaments 4–6 mm long, united almost to apex ..... 135. *M. unguiculata*
35b Flowers white to yellow, creamy green, beige or pink:
39a Outer tepal limbs 20–33 mm long, orbicular, ± as wide as to wider than long
40a Flowers yellow; filaments 3–5 mm long. ..... 146. *M. bellendenii*
40b Flowers white to creamy white (rarely pale watery yellow); filaments 4–7 mm long .... 144. *M. tricuspidata*
39b Outer tepals limbs 8–22 mm long, ovate to lanceolate, longer than wide:
41a Outer tepals 12–20(–22) mm long; outer tepal claws densely velvety ..... 135. *M. unguiculata*
41b Outer tepals (20–)22–40 mm long; outer tepal claws hairless or velvety:
42a Flowers creamy white, yellow-green or ± beige; outer tepal claws hairless; plants of Namaqualand, Northern Cape. ..... 136. *M. rivulicola*
42b Flowers pale pink; outer tepal claws densely velvety; plants of Little Karoo, Western Cape ..... 142. *M. lilacina*

Subg. 11. *Homeria*

1a Foliage leaves 2 or more, uppermost leaves green and usually free distally or sometimes entirely sheathing:
2a Flowers with distinct style crests 2–3 mm long, clearly extending beyond the stigma lobes, and either erect or incurved:
3a Anthers 2–5 mm long:
4a Tepal claws 7–10 mm long; anthers ± 5 mm long. . . . . 182. *M. flexicaulis*
4b Tepal claws obsolete or up to 2 mm long; anthers 2–3 mm long:
5a Tepals spreading from base; outer rhipidial spathe entirely sheathing . . . . . 180. *M. schlechteri*
5b Tepal claws ± 2 mm long, appressed to filament column with limbs outspread; outer inflorescence spathe free in upper part and arching outward . . . . . 181. *M. knersvlaktensis*
3b Anthers 6–10 mm long; tepal claws erect, forming a cup enclosing at least lower half of filaments, or stamens entirely within cup:
6a Style and stamens entirely included in floral cup; plants 700–1 000 mm tall . . . . . 183. *M. cedarmonticola*
6b Only lower $^{2}/_{3}$ of filament column included in floral cup; plants to mostly 200–250 mm tall . . . . . 195. *M. serratostyla*
2b Flowers without distinct style crests (and style branches often not markedly flattened):
7a Filament column ± cylindric; anthers erect or divergent:
8a Plants 350–750 mm tall; tepals 30–40 mm long; anthers 4.5–8.0 mm long, diverging from base. . . 185. *M. ochroleuca*
8b Plants up to 300 mm tall; tepals 15–24 mm long; anthers 2.0–3.5 mm long, erect or barely diverging:
9a Ovary ± 4 mm long; filament column 6 mm long . . . . . 207. *M. fenestrata*
9b Ovary 10–12 mm long; filament column 7–9 mm . . . . . 204. *M. karooica*
7b Filament column with a bulbous base; anthers ± erect and contiguous, usually concealing style branches:
10a Tepals reflexed at maturity; flowers nodding to pendent. . . . . 203. *M. pendula*
10b Tepals spreading or slightly cupped; flowers upright:
11a Stem minutely scabrid; leaves 2–4 mm wide, laxly coiled in loose spiral in upper half . . . . . 201. *M. aspera*
11b Stem smooth; leaves 5–10 mm wide, ± straight. . . . . 202. *M. miniata*
1b Foliage leaf solitary, other leaves entirely sheathing and bract-like, ± attenuate with dry tips:
12a Filaments free, diverging; style branches sessile . . . . . 193. *M. radians*
12b Filaments united entirely or free and diverging in distal 1–2 mm; style present, dividing shortly above apex of filament column or opposite base to middle of anthers:
13a Foliage leaf ± basal, often sheathing lower half of stem; stem ± straight, not flexed outward above leaf sheath:
14a Tepal claws ± $^{1}/_{3}$–$^{1}/_{2}$ as long as limbs, forming a narrow or wide cup; filaments and sometimes lower part or all of anthers included in cup:
15a Floral cup relatively narrow; enclosing filaments:
16a Ovary 15–24 mm long; capsules mostly 25–40 mm long. . . . . 178. *M. britteniae*
16b Ovary 8–12 mm long; capsules < 20 mm long:
17a Stem usually bearing cormlets at aerial nodes; flowering August to November; capsules 17–20 mm long, usually at least partly included in spathes. . . . . 194. *M. bulbillifera*
17b Stem never bearing cormlets at aerial nodes; flowering April to June; capsules 8–15 mm long, well exserted from spathes. . . . . 184. *M. autumnalis*
15b Floral cup wide and basin-like, not enclosing filaments:
18a Tepals pandurate-spathulate, widest in upper $^{1}/_{3}$; filaments 7–8 mm long; anthers 8–13 mm long, usually not reaching the top of the style branches; ovary 18 mm long. . . . . 191. *M. comptonii*
18b Tepals oblong-lanceolate, widest in middle or lower $^{1}/_{3}$; filaments 5–6 mm long; anthers 8–10 mm long, usually exceeding the style branches; ovary 12–14 mm. . . . . 192. *M. elegans*
14b Tepal claws < $^{1}/_{3}$ as long as limbs, ascending to suberect, including or clasping base of filament column:
19a Anthers not or barely exceeding style branches; outer tepals 30–43 mm long. . . . . 173. *M. cookii*
19b Anthers exceeding style branches, these reaching to about middle of anthers; outer tepals 18–34 mm long:
20a Flowers nodding to pendent; tepal limbs fully reflexed . . . . . 177. *M. reflexa*
20b Flowers upright; tepals spreading to slightly reflexed:
21a Leaves relatively broad, (5–)7–15 mm wide, and clasping lower part of stem:
22a Style crests present, ± 2 mm long:
23a Tepals, mostly 18–25 × 5–10 mm; leaves 5–15 mm wide. . . . . 174. *M. pallida*
23b Tepals oblong obovate, mostly 27–34 × 11–17 mm; leaves 15–35 mm wide . . . . . 176. *M. marlothii*
22b Style crests lacking:
24a Flowers usually pink; tepal claws ± 2 mm long and clasping bulbous base of filament column . . . 205. *M. bifida*
24b Flower pale yellow; tepal claws ± 8 mm long and diverging not clasping hardly swollen base of filament column . . . . . 206. *M. fragrans*
21b Leaves narrow, 2–4 mm wide, clasping lower part of stem or not:
25a Plants 350–450 mm tall; tepals 25–27 mm long; style crests ± 1.5 mm long. . . . . 175. *M. doleritica*
25b Plants 150–300 mm tall; tepals 18–24 mm long; style crests absent . . . . . 204. *M. karooica*
13b Foliage leaf inserted some distance above ground, never sheathing stem for significant distance; stem flexed outward above sheath of foliage leaf:
26a Tepal claws $^{1}/_{2}$–$^{2}/_{3}$ as long as limbs, forming a narrow or wide cup; filaments and sometimes all or part of anthers included in cup:
27a Tepal claws 9–15 mm long ± erect; claws forming a narrow tubular cup including the filaments and anthers:
28a Style dividing at or above apex of filament column, always below middle of anthers; style branches erect or diverging; tepal claws 9–15 mm long forming a narrow tubular cup including the filaments and anthers:
29a Filament column 4–5 mm long; leaf fairly short, seldom over 200 mm long, usually straight, the apex swollen and acute. . . . . 188. *M. pyrophila*

29b Filament column 6–7 mm long; leaf long, bent and trailing, seldom < 250 mm long, apex often dry at flowering. . . . . 187. *M. collina*
28b Style dividing at or above middle of anthers, sometimes barely divided; style branches erect:
30a Ovary usually partly or entirely enclosed in the spathes, the capsules often enclosed; style branches well developed, 2–3 mm long, barely or not reaching apex of anthers . . . . . 190. *M. minor*
30b Ovary usually exserted from the spathes, the capsules exserted; style branches very short, 1–2 mm long or not developed. . . . . 189. *M. longistyla*
27b Tepal claws widely diverging; claws forming a wide basin-like cup including filaments:
31a Outer tepals 28–33 mm long, with claws 13–16 mm long; anthers 5–11 mm long:
32a Ovary 17–20 mm long; capsules 25–55 mm long . . . . . 186. *M. flaccida*
32b Ovary 13–16 mm long; capsules 20–40 mm long . . . . . 185. *M. ochroleuca*
31b Outer tepals 16–26 mm long, with claws 5–10 mm; anthers 3–4 mm long:
33a Tepals 16–24 mm long with claws 5–6 mm long . . . . . 199. *M. flavescens*
33a Tepals 25–27 mm long with claws 9–10 mm long:
34a Style branches diverging, 3–4 mm long, with acute crests ± 1 mm long; anthers shortly exceeding style branches . . . . . 196. *M. patens*
34b Style branches suberect (to slightly diverging), ± 2.5 mm long, without crests; anthers not reaching tips of style branches . . . . . 198. *M. vallisbelli*
26b Tepal claws < 1/3 as long as limbs, often < 1/4 as long; filaments partly exserted from cup, or prominently displayed:
35a Outer tepals 10–12 mm long; anthers ± 2 mm long . . . . . 200. *M. demissa*
35b Outer tepals 20–28 mm long; anthers ± 3–5 mm long:
36a Style branches with short, acute crests ± 1 mm long; anthers diverging 3–5 mm long:
37a Tepals 20–25 mm long; filaments ± 5 mm long, free in upper 1 mm; flowers pale ivory-yellow. . . 179. *M. eburnea*
37b Tepals 25–28 mm long; filaments completely united in column 5–6 mm long; flowers bright yellow . . . . . 197. *M. louisabolusiae*
36b Style branches lacking crests, hidden by coherent anthers ± 3 mm long:
38a Tepals pale yellow with green markings at bases of tepals limbs; filament column ± 6 mm long, minutely pubescent in lower half . . . . . 208. *M. fuscomontana*
38b Tepals pink salmon with pink to red makings at bases of limbs; filament column 6–8 mm long, prominently long-papillate in lower 2/3 . . . . . 209. *M. brachygyne*

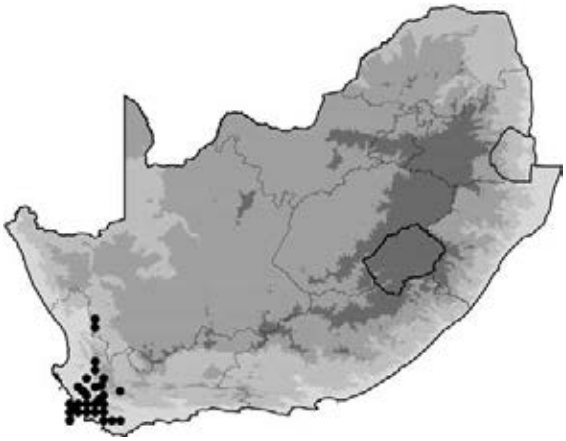
Subg. 1. **Plumarieae**

Subg. **Plumarieae** *Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 43: 36 (2013). Type: *M. lugubris* (Salisb.) Goldblatt

Plants with branched stems. *Foliage leaves* several, channelled. *Flowers* fugaceous, blue; tepals subequal but outer larger and with nectar guides, limbs laxly spreading; filaments united in lower half; style branches diverging at tips and stigmatic apically, crests plumose. *Capsules* ± globose. *Basic chromosome number x* = 10.

1. **Moraea lugubris** *(Salisb.) Goldblatt* in Annals of the Missouri Botanical Garden 63: 18 (1976a); Goldblatt: 66 (1986a). *Ferraria lugubris* Salisb.: 42 (1796), as a new name for *Iris plumaria* Thunb.: no. 16 (1782b), illegitimate superfluous name for *M. iriopetala* L.f., *M. juncea L.*, *M. vegeta* L. *M. plumaria* Ker Gawl.: 240 (1804a). *Vieusseuxia plumaria* Eckl.: 14 (1827). Type: South Africa, [Western Cape], below Devil's Peak, Cape Town, *Thunberg s.n.* [UPS–THUNB 1153, lecto. Designated by Goldblatt: 706 (1976a)].

Moraea mira Klatt: 202 (1885). Type: South Africa, [Western Cape], slopes of Caledon Swartberg near the Baths, *Templemann sub MacOwan 2162* (K, S, syn.).



[*Vieusseuxia geniculata* Eckl.: 12 (1827), invalid name without description.]

Plants 60–160 mm high. *Corm* ± globose, up to 20 mm diam., corm body enclosed in large basket-like, ± woody tunics, with cormlets produced round the base. *Stem* 2 internodes long, flexuose, usually 2- to 4-branched, branches arising from same aerial internode. *Foliage leaves* 2 or 3, linear, channelled, lowermost basal, upper inserted well above ground. *Rhipidial spathes* pale green, sometimes with brown apices; inner 30–50 mm long, outer seldom > half as long as inner. *Flowers* fugaceous, blue to violet, outer tepal limbs with yellow nectar guides at bases; outer tepals 16–18 mm long, claws ± 5 mm long, reflexed to ± 45°; inner tepals ± as long but narrower, similarly reflexed. *Filaments* ± 6 mm long, united in lower 1/2, free above; anthers ± 3 mm long, long-apiculate; pollen usually red. *Ovary* narrowly ovoid, 2–3 mm long, usually exserted; style branches plane, bearing stigmatic areas at lateral tips, with single prominent crest and feathery outgrowths from distal surface. *Capsules* ± globose, 6–8 mm long. *Seeds* angular prismatic. *Chromosome number* 2*n* = 20. *Flowering time*: mainly August and September.

Distribution and ecology: restricted to the southern African winter-rainfall zone, extending from the Bokkeveld Mtns in Northern Cape, South Africa, in the north to the Cape Peninsula and Caledon District in Western Cape

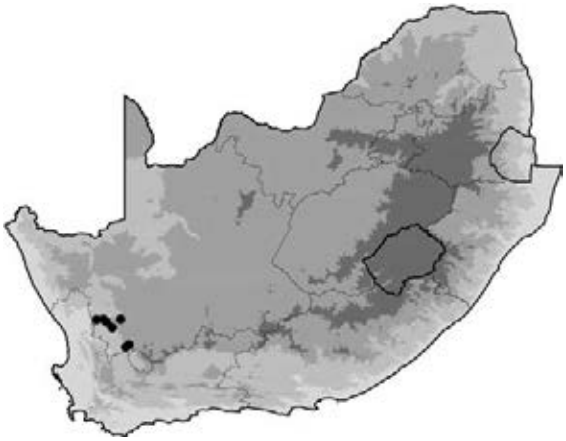
in the south; usually in wet sites in sandy ground or outcrops of Cape Sandstone at low to middle elevations, especially common after fire.

Diagnosis: *Moraea lugubris* is immediately recognised by the small, violet to pale blue flower with feathery or fringed style crests, unique in *Moraea* and reminiscent of the related genus *Ferraria*. The species also recalls *Ferraria* in the stigmatic surfaces located at the lateral tips of style branches. Both floral morphology and molecular phylogenetic studies place *M. lugubris* close to the base of phylogenetic trees, in some it is retrieved as sister to the remaining species of *Moraea*. The corm is of the *Moraea* type, thus consisting of a single internode with an apical bud and enclosed by well-developed tunics. The tunics of coarse fibres loosely enclosing the corm body are, however, unique in the genus.

Distribution of ***Moraea lugubris***.

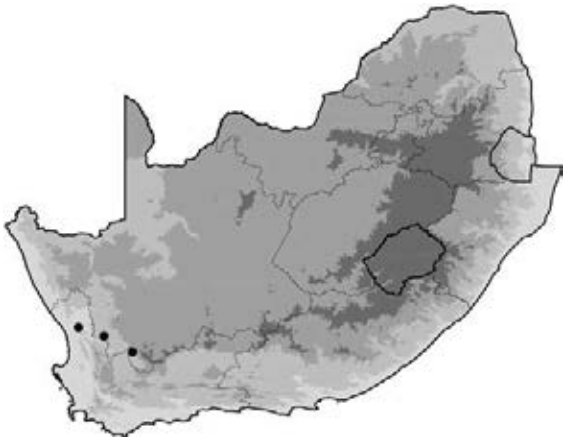
Subg. 2. **Visciramosae**

Subg. **Visciramosae** *Goldblatt* in Annals of the Missouri Botanical Garden 63: 7 (1976b). Type: *M. bituminosa* (L.f.) Ker Gawl.



Plants with branched stems, sticky on and below nodes; corm tunics ± woody, sticky on adaxial surface. *Stem* branched, bearing cauline sheathing leaves. *Foliage leaves* several or 2, channelled. *Rhipidial spathes* acute or obtuse to truncate, outer entirely sheathing. *Flowers* fugaceous, variously coloured; tepals subequal and all with nectar guides or outer larger and with nectar guides, limbs spreading to reflexed; filaments united in lower half or free but contiguous; style branches broad with abaxial stigmatic lobe bearing a forked or entire appendage in centre, style crests paired and prominent or style branches reduced, lacking crests, then flattened or filiform. *Capsules* ± globose. *Basic chromosome number x* = 10.

Sect. 1. **Multifoliae** *Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 43: 36 (2013). Type: *Moraea vespertina* Goldblatt & J.C.Manning



Foliage leaves several. *Rhipidial spathes* ± acute, inner exceeding outer. *Flowers* white, pale blue or predominantly buff-brown; style branches and crests moderately or well developed.

2. **Moraea vespertina** *Goldblatt & J.C.Manning* in Novon 10: 14 (2000a). Type: South Africa, Northern Cape, Calvinia District, rocky hills east of Nieuwoudtville, 31 Oct. 1996, *Goldblatt & Manning 10580* (NBG, holo.; K, MO, PRE, iso.).

Plants 0.7–1.1 m high. *Corm* globose, 15–25 mm diam.; tunics of coarse, red-brown fibres. *Stem* slightly flexuose, sticky below nodes for half an internode, bearing entirely sheathing leaves 40–65 mm long, green below, dry and brown above, tips dry, attenuate, with 1 or 2 lateral branches at upper 3 or 4 nodes, branches parallel to stem below, flexed outward above sheathing leaf. *Foliage leaves* usually 4 to 6 in 2 ranks, lower 3 to 5 basal, channelled, arching outward, mostly 5–8 mm wide, uppermost cauline, shorter than basal. *Rhipidial spathes* dull green, becoming ± purplish with age, margins dry and membranous, with dry, brown attenuate tips, inner 40–50 mm long, outer ± half as long. *Flowers* fugaceous, white fading bluish or to pale slate-blue, outer tepal limbs with yellow nectar guide streaked with darker veins at bases, either slightly lemon-scented or a sweet clove scent, tepal claws arching upward and forming a cup enclosing filaments and anther bases; outer tepals 40–45 × 15–20 mm, claws arcuate, erect above, 10–12(–16) mm long, with large basal nectary, limbs lanceolate, often ± attenuate, spreading horizontally or dipping up to 45° below horizontal; inner tepals 36–42 × 8–15 mm. *Filaments* 7–10 or ± 12 mm long, free but parallel and connivent below, forming a slender column, diverging in upper 1.5 mm; anthers 6–8 mm long, ovate, white; pollen white. *Ovary* exserted, narrowly club-shaped, ± 10 mm long; style branches 7–10 × 8–9 mm, ascending, stigma bilobed with sterile acute appendage between lobes, crests ± linear, erect, 15–20 mm long. *Capsules* narrowly ovoid to oblong, 18–25 mm long. *Seeds* angular, angles ± ridged to winged, ± 4–5 × 3 mm, dark brown. *Flowering time*: October to mid-November in the Calvinia District; opening 16:00–16:30 and wilting ± 19:30–20:00; September in the Tanqua Karoo population, opening 17:00–17:30.

Distribution of ***Moraea vespertina***.

Distribution of ***Moraea bubalina***.

Distribution and ecology: endemic to the western Karoo in Northern Cape, South Africa, extending from the western edge of the Bokkeveld Plateau to Calvinia and locally in the northeastern Tanqua Karoo to the south; in heavy red clay soil in low outcrops of dolerite, sites that are poorly drained and remain waterlogged for most of the growing season, sometimes even until flowering time in October and November.

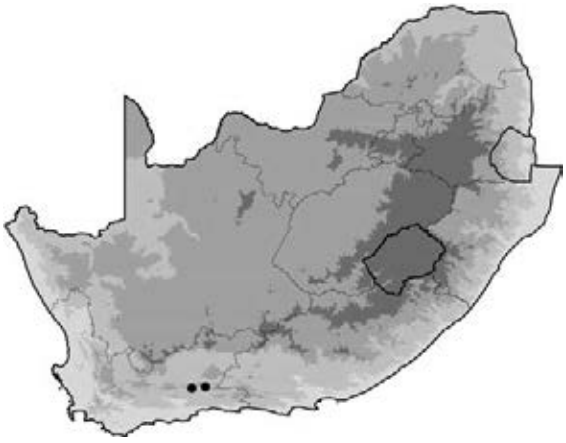
Diagnosis: distinguished by the tall stature and relatively large white or pale blue flowers, the outer tepals 40–45 mm long, and the well-developed style branches and style crests, *Moraea vespertina* is also distinctive in subg. *Visciramosae* in having 4 to 6 foliage leaves, a characteristic shared in the subgenus with *M. bubalina* and *M. striata*, the three species constituting sect. *Multifoliae*. The remaining species of subg. *Visciramosae* have two foliage leaves and comprise sect. *Visciramosae.*

The populations in the Calvinia area have white flowers, sometimes flushed blue on fading and bloom late October to November whereas plants from the Tanqua Basin have a slate-blue perianth, slightly larger flowers and bloom in September (possibly into October). The flowers last a few hours from late afternoon to early evening and are pollinated by settling moths.

3. **Moraea bubalina** *Goldblatt* in Annals of the Missouri Botanical Garden 63: 733 (1976a); Goldblatt: 28 (1986a). Type: South Africa, [Western Cape], Vanrhynsdorp, Farm Zandkraal, *Barker 5667* (NBG, holo.).

Plants (250–)400–700 mm high. *Corm* 15–20 mm diam.; tunics dark brown, inner layers unbroken, outer becoming partly fibrous, sticky inside. *Stem* usually several-branched from upper nodes, sticky below nodes, with cauline sheathing leaves 25–60 mm long, green below, dry and brown above, tips dry, acute-attenuate; with up to 3 branches per node, branches parallel to stem below, flexed outward above sheathing leaf. *Foliage leaves* usually 3, lower 2 basal, channelled, arching, becoming trailing and broken distally. *Rhipidial spathes* green, apices acute, dry and brown, inner 25–40 mm long, outer $^{1}/_{2}$–$^{2}/_{3}$ as long. *Flowers* fugaceous, buff-coloured to light brown with yellow, crescent-shaped nectar guides at bases of outer and inner tepal limbs, claws darkly striped, tepal claws forming a wide cup ± 10 mm deep, limbs reflexed to ± 35°; outer tepals 22–33 × 7–9 mm, claws slightly shorter than limbs, inner tepals shorter, up to 20–28 mm long. *Filaments* 8–12 mm long, free but parallel and contiguous in lower $^{3}/_{4}$, diverging distally; anthers 4–7 mm long, brown; pollen light brown. *Ovary* ovoid, 5–7 mm long; style branches 6–7 mm long, diverging, stigma bilobed with sterile, erect appendage between lobes, crests erect, 3–6 mm long. *Capsules* and *seeds* not known. *Chromosome number* 2*n* = 20. *Flowering time*: September to October, flowers opening 15:30–16:00 and fading at dusk.

Distribution and ecology: mainly from the Western Karoo of South Africa and evidently rare, extending from Loeriesfontein in Northern Cape in the north to Lambert's Bay in the south and inland to the southern end of the Bokkeveld Plateau in Western Cape; mainly on shale, gravel flats and slopes.



Diagnosis: *Moraea bubalina* is distinct in subg. *Visciramosae* in having more than two leaves and acute rhipidial spathes, features it shares with *M. striata* and *M. vespertina* but it differs from these species in the buff-coloured to brown perianth with spreading claws forming a wide cup, the subequal tepals all bearing nectar guides, and the relatively short style branches and crests.

4. **Moraea striata** *Goldblatt & J.C.Manning* in Bothalia 43: 153 (2013). Type: South Africa, Western Cape, Rust en Vrede, road from gate to waterfall, dry clay slope, 8 Oct. 2012, *Goldblatt & Porter 13858* (NBG, holo.; MO, iso.).

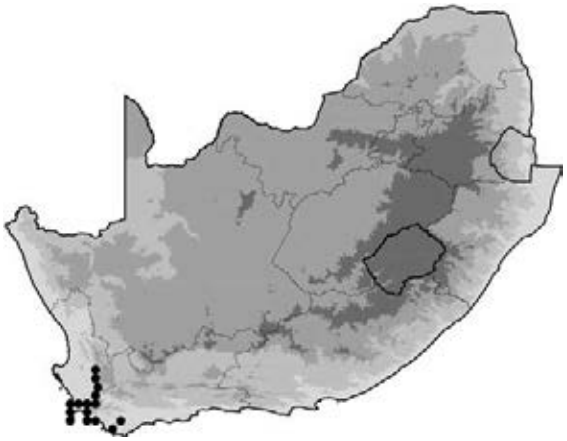
Plants 450–600 mm high. *Corm* including tunics 20–25 mm diam., with several large cormlets around base; tunics brown, sticky internally, accumulating as coarse matted fibres forming a collar around base. *Stem* 2- to

5-branched from upper nodes, sticky below nodes; branches short, arching outward above sheathing leaf, erect distally, with cauline sheathing leaves 30–40 mm long, acute to obtuse or truncate. *Foliage leaves* 3, all ± basal, linear, falcate, often trailing distally, channelled, V-shaped in cross section with pronounced keel, 4–5 mm wide when opened flat. *Rhipidial spathes* grey-green, becoming dry distally, acute-attenuate, inner 30–40 mm long, inner ± ½ as long. *Flowers* fugaceous, dull khaki-coloured, tepal limbs fully reflexed, with several longitudinal dark brown-grey lines for entire length, outer tepal limbs with pale yellow nectar guides at bases, fully reflexed, with clear dull yellow nectar guides at bases, claws darkly lined; outer tepals 25–30 × 10–11 mm, claws ± 7 mm long, with dark basal nectary; inner tepals 22–25 × ± 8 mm. *Filaments* ± 10 mm long, free but contiguous in lower 6 mm, diverging in distal 4 mm; anthers ± 4 mm long, buff-yellow, shortly exceeding stigmatic lobes; pollen orange-red. *Ovary* ± cylindric, 5–6 mm long; style branches ± 6 × 5 mm, crests erect, broadly wedge-shaped, 6–7 mm long, outer margins lightly serrated, with broad, entire petaloid stigmatic appendage ± 4 mm long. *Capsules* and *seeds* unknown. *Flowering time*: October, probably also November; opening ± 14:00–14:30, collapsing at sunset.

Distribution and ecology: evidently a local endemic of the southern foothills of the Great Swartberg near Oudtshoorn in Western Cape, South Africa; on clay flats and slopes.

Distribution of ***Moraea striata***.

Diagnosis: *Moraea striata* stands out in subg. *Visciramosae* in having three foliage leaves and acute rhipidial spathes, features it shares with *M. bubalina* and *M. vespertina* but it differs from these species in the dull khaki-coloured flowers with several longitudinal dark brown-grey lines along their entire length. The tepal limbs have pale yellow nectar guides at the base and are fully reflexed. The ascending tepal claws form a narrow cup enclosing the lower half of the filaments and the anthers are displayed well above the claws. *Moraea inconspicua* has similarly coloured, but smaller flowers with suberect tepal claws and usually fully reflexed limbs.



Sect. 2. **Visciramosae** *Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 43: 36 (2013). Type: *Moraea bituminosa* (L.f.) Ker Gawl.

Foliage leaves 2. *Rhipidial spathes* ± subacute to obtuse or truncate and often dry-tipped and lacerate, inner hardly longer than outer. *Flowers* yellow, blue or brown, occasionally white; style branches and crests moderately well developed or reduced and without crests (in *M. simplex* filiform and extending between the stamens).

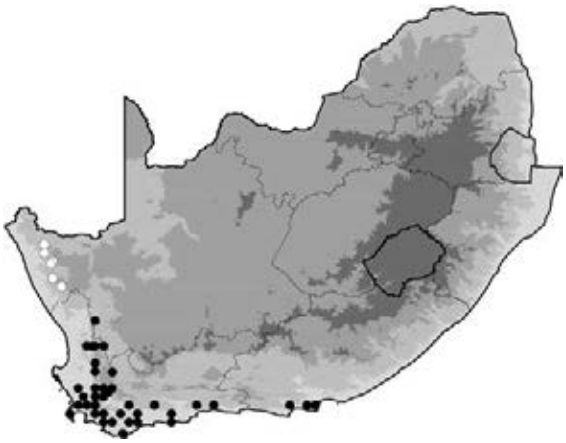
5. **Moraea bituminosa** *(L.f.) Ker Gawl.* in König & Sims, Annals of Botany 1: 240 (1804a); Goldblatt: 30 (1976b); Goldblatt: 30 (1986a). *Iris bituminosa* L.f.: 98 (1782). *Vieusseuxia bituminosa* (L.f.) Eckl.: 14 (1827). *M. viscaria* var. *bituminosa* (L.f.) Baker: 15 (1896). Type: South Africa, [Western Cape], 'prope Bergrivier, Vierentwintigrivieren et alibi', *Thunberg s.n.* [UPS–THUNB 1114, lecto., designated by Goldblatt: 732 (1976a)].

Plants 250–500 mm high, flexuously branched. *Corm* 15–20 mm diam.; tunics dark brown, ± woody or becoming fibrous, sticky-bituminous on inner surfaces. *Stems* with up to 3 branches at most aerial nodes, viscous below nodes, with cauline entirely sheathing leaves ± obtuse to truncate. *Foliage laves* 2, lower basal, upper inserted at lowest aerial node, linear, falcate to trailing, occasionally loosely coiled. *Rhipidial spathes* green, becoming dry and conspicuously veined with age, apices acute to obtuse, brown, occasionally lacerated, 25–40 mm long, subequal or outer only slightly shorter. *Flowers* fugaceous, usually pale to deep yellow with outer tepal limbs with darker yellow nectar guides at bases often speckled with black (rarely blue-mauve with white nectar guides), sweetly scented; outer tepals 23–31 × 8–12 mm, claws 5–8 mm long, limbs ± spreading to reflexed up to ± 35°; inner tepals 20–25 mm long, oriented as outer tepals. *Filaments* mostly 6–12 mm long, free but parallel and contiguous in a slender column, or united, diverging in upper 1–2 mm; anthers 4–7 mm long, yellow (rarely dark purple); pollen yellow (rarely red). *Ovary* ovoid, ± 6 mm long, usually at least partly exserted, style branches 4–9 mm long, crests 6–12(–15) mm long, lanceolate to linear, stigmatic appendage ± 1 mm long. *Capsules* ovoid, 10–13 mm long. *Seeds* angular-prismatic. *Chromosome number* 2*n* = 20. *Flowering time*: late September to mid-December; flowers open soon after midday and last until ± sunset but those of the blue-flowered morph open earlier in the day.

Distribution and ecology: fairly widespread in Western Cape, South Africa, from Porterville and Tulbagh south

Distribution of ***Moraea bituminosa***.

to the Cape Peninsula and east to Swellendam and the Bredasdorp Mtns; on stony sandstone derived soils in fynbos vegetation but also on stony clay or granitic gravel in renosterveld.



Diagnosis: *Moraea bituminosa* is distinguished from its allies in subg. *Visciramosae* by its relatively large, usually yellow flowers with spreading to half-reflexed tepals with only the outer bearing nectar guides, and by the large, often obtuse spathes, 25–40 mm long. Confusion between *M. bituminosa* and *M. bubalina* is possible as the latter has equally large tepals and spathes, but the spathes in *M. bubalina* are acute with the outer spathe half to two-thirds as long as the inner (subequal in *M. bituminosa*). In addition, *M. bubalina*, from dry areas in the Western Karoo and Clanwilliam District, has dull buff- to khaki-coloured flowers, the tepal claws forming a wide cup, and relatively short style crests only 2–3 mm long. Currently included in *M. bituminosa*, plants from the Tulbagh Valley and Jonkershoek have larger flowers than are typical of the species and a blue-mauve perianth with white nectar guides. The taxonomic status of these plants remains to be established.

6. **Moraea inconspicua** *Goldblatt* in Annals of the Missouri Botanical Garden 63: 737 (1976a); Goldblatt: 36 (1986a). Type: South Africa, [Western Cape], Wilderness, *Van Niekerk 181* (BOL, holo.; PRE, iso.).

Plants 200–450 mm high. *Corm* 15–20 mm diam.; tunics brown, ± woody or becoming fibrous, sticky-bituminous on inner surfaces, often persisting with cataphylls to form a collar around base. *Stem* with up to 3 branches at most aerial nodes, viscous below nodes, with cauline sheathing leaves, ± obtuse or truncate. *Foliage leaves* 2, linear, either channelled and falcate to trailing or coiled with plane surface, 2–3 mm wide. *Rhipidial spathes* acute to ± obtuse, becoming dry above, often becoming lacerated, inner 15–30 mm long, outer slightly shorter. *Flowers* fugaceous, yellow, creamy pink, white or brown, outer tepal limbs with yellow nectar guides at bases; outer tepals 12–18(25) × 5–7 mm, usually reflexed ± 90° (sometimes less), claws 4–8 mm long, $^{1}/_{2}$–$^{2}/_{3}$ as long as limbs, scented of vanilla; inner tepals narrower, usually slightly shorter than outer, limbs similarly reflexed. *Filaments* 3.5–8.0 mm long, free but contiguous or united in lower part; anthers 2–4 mm long; pollen yellow or orange-red. *Ovary* ± 3 mm long, included or exserted, style branches 3–6 mm long, crests (1.5–)3.0–10.0 mm long. *Capsules* broadly ovoid-globose, (6–)7–10 mm long. *Chromosome number* 2*n* = 20. *Flowering time*: September to December (January).

Distribution and ecology: the most widespread species in subg. *Visciramosae*, extending from northern Namaqualand in Northern Cape through Western Cape to Port Elizabeth in Eastern Cape, South Africa, thus almost throughout the winter-rainfall area; on a variety of soils, usually in dry, exposed habitats, sometimes in granite outcrops.

Diagnosis: with the smallest flowers in subg. *Visciramosae, Moraea inconspicua* is distinguished by its flowers with fully reflexed tepals, the outer mostly 12–18 mm long (rarely up to 25 mm), the limb at least twice as long as the claw. In addition the rhipidial spathes are short, usually less than 28 mm long and sometimes only 18 mm. Flower colour is variable, mostly yellow or partly to completely brown, but white-flowered morphs occur in the Biedouw Valley near Clanwilliam and on the Agulhas Plain near Elim, the latter with the smallest flowers recorded in the species. In Namaqualand flowers are sometimes ivory-coloured or pink, but also yellow or brown as elsewhere. The foliage leaves are usually straight and erect below but often trailing distally, and have channelled blades, but plants from Namaqualand have distinctive spirally coiled leaves with a plane surface and on this basis have been segregated as subsp. *namaquensis*. Populations from the northern Cederberg and Biedouw Valley have unusually large flowers for the species, the outer tepals up to 25 mm long, thus matching those of closely allied *M. bituminosa*. The narrow leaves, short style crests and almost fully reflexed tepal limbs conform to *M. inconspicua*.

Distribution of ***Moraea inconspicua*** subsp. ***inconspicua***, ●; subsp. ***namaquensis***, ○.

Superficially similar *Moraea viscaria*, is a white-flowered species with spreading tepals 15–23 mm long, a strong floral odour, and relatively well-developed style crests up to 6 mm long, half as long to ± as long as the style branches. *Moraea saldanhensis* may also be confused with *M. inconspicua* but has slate-blue flowers with the tepal claws as long as to slightly longer than the limbs, the latter usually reflexed to ± 45°.

Key to subspecies

1a Leaves channelled, falcate to trailing; outer tepals 12–18(–25) mm long; filaments 3.5–6.0 mm long; plants from Bokkeveld Mtns to Port Elizabeth . . . . . 6a. subsp. *inconspicua*

1b Leaves plane, coiled; outer tepals 15–18 mm long; filaments 6–8 mm long; plants from Namaqualand. . . . . 6b. subsp. *namaquensis*

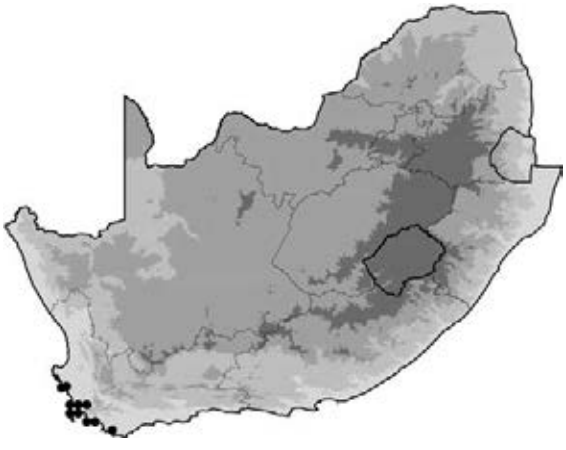
6a. subsp. **inconspicua**

Foliage leaves linear, channelled, falcate to trailing. *Rhipidia* with inner spathes 15–26 mm long. *Flowers* mostly yellow to brown, occasionally white; outer tepals 12–18(25) mm long, claws 4–6 mm long. *Filaments* 3.5–6.0 mm long; anthers 1.5–3.3 mm long; pollen usually yellow (red when perianth white). *Style crests* 1.5–10.0 mm long. *Flowering time*: mostly October to December (January).

Distribution and ecology: widespread in the winter-rainfall zone, from the Bokkeveld Mtns to Port Elizabeth; mostly on sandy or stony ground.

6b. subsp. **namaquensis** *Goldblatt & J.C.Manning* in Bothalia 42: 212 (2012a). Type: Northern Cape, Springbok, SE of Driekoppie farmhouse, 3 Oct. 1981, *Van Berkel 439* (NBG, holo.; MO, iso.)

Foliage leaves coiled, surface plane. *Rhipidia* with inner spathes mostly 19–28 mm long. *Flowers* ivory-coloured, creamy yellow, creamy pink, pale yellow or brown; tepals usually reflexed to lie vertically, outer 15–18 mm long, claws 5–7 mm long. *Filaments* 6–8 mm long; anthers 3–4 mm long; pollen usually red. *Style crests* 3–4 mm long. *Flowering time*: mid-September to late November.



Distribution and ecology: restricted to the higher-lying edge of the western escarpment in Namaqualand, between Steinkopf and the Kamiesberg; growing in gritty, granite-derived ground.

Diagnosis: subsp. *namaquensis* is distinguished from typical subsp. *inconspicua* by the coiled leaves with flat blades up to 3 mm wide. Other vegetative and floral features differ only quantitatively, with considerable overlap but on average subsp. *namaquensis* has slightly larger rhipidial spathes and floral features than subsp. *inconspicua*. In subsp. *namaquensis* the outer rhipidial spathes are 19–28 mm long, outer tepals 15–18 mm long, and anthers 3–4 mm long compared with rhipidial spathes 15–26 mm long, outer tepals 12–15 mm long and anthers 1.5–3.3 mm long in subsp. *inconspicua*.

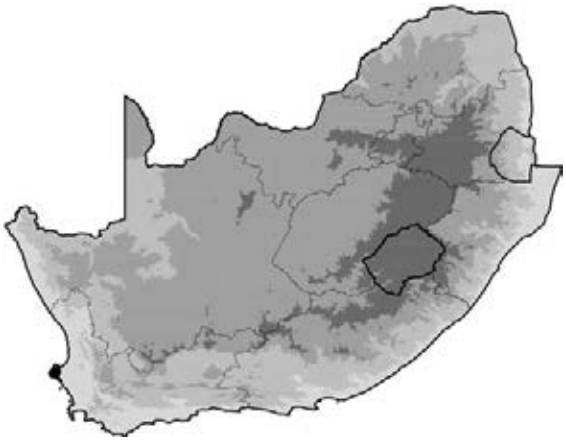
7. **Moraea viscaria** *(L.f.) Ker Gawl.* in König & Sims, Annals of Botany 1: 240 (1804a), name misapplied to *M. inconspicua*. *Iris viscaria* L.f.: 98 (1782); Goldblatt: 735 (1976a); Goldblatt: 34 (1986a). *Vieusseuxia viscaria* (L.f.) Eckl.: 12 (1827). Type: South Africa, Cape, 'Lospers farm,' near Saldanha, *Thunberg s.n.* (UPS–THUNB 1200, holo.).

Moraea odorata G.J.Lewis: 53 (1941). Type: South Africa, [Western Cape], Cape Town, Rondebosch Common, *Barnard s.n.* (BOL[*20341*], holo.; PRE, SAM, iso.).

Plants 200–450 mm high. *Corm* 15–20 mm diam., bearing numerous small cormlets at base; tunics brown, ± woody or becoming fibrous, sticky-bituminous on inner surfaces. *Stem* usually with 2 or 3 branches at most aerial nodes, viscous below nodes, bearing cauline sheathing leaves obtuse to truncate. *Foliage leaves* 2, linear, channelled, falcate to trailing, 2–4 mm wide. *Rhipidial spathes* green, becoming dry above, acute to obtuse, 18–24 mm long, prominently veined when dry, outer usually slightly shorter. *Flowers* fugaceous, white, sometimes flushed brown to purple outside, outer tepal limbs with small pale yellow nectar guides at bases, sweetly scented; outer tepals 15–23 × ± 8 mm, ± spreading (or limbs slightly reflexed), claws ascending, 5–8 mm long; inner tepals 14–20 mm long, oriented as outer tepals. *Filaments* 5–6 mm long, parallel and contiguous in a slender column, diverging near apices; anthers 4–5 mm long, acuminate; light brown; pollen light brown to red. *Ovary* ± 5 mm long, ± ovoid, exserted, style branches ± 5 mm long, crests mostly as long to slightly longer, occasionally reduced to ± 1 mm. *Capsules* broadly ovoid, 7–10 mm long. *Seeds* angled. *Chromosome number* 2*n* = 20. *Flowering time*: late September to October in the Saldanha area, elsewhere November to December; flowers open ± 16:00 and fade soon after nightfall.

Distribution of ***Moraea viscaria***.

Distribution and ecology: coastal Western Cape, South Africa, extending from the vicinity of Saldanha Bay in the north to Cape Agulhas in the southeast; on sandy flats at low elevations.



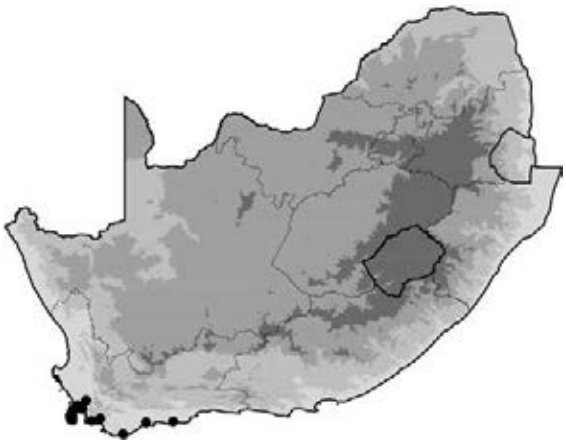
Diagnosis: a relatively short species, 200–400 mm tall, characterised by its white flowers with laxly spreading tepals marked with nectar guides only on the outer tepal limbs, a strong, rich floral scent, and well-developed style crests. Confusion is perhaps possible with *Moraea inconspicua* but that species has a smaller flower, occasionally with white tepals but more often yellow to brown or creamy pink, with the tepal limbs always sharply reflexed, at least to 45° and more often to ± 90°.

8. **Moraea saldanhensis** *Goldblatt & J.C.Manning* in Bothalia 42: 210 (2012a). Type: Western Cape, Vredenburg, rocky coastal sandveld near Jacobsbaai at Mauritzbaai, 20 Oct. 2011, *Manning 3310* (NBG, holo.; MO, iso.).

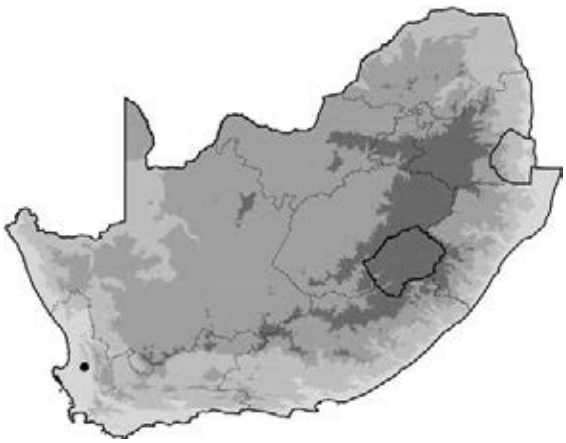
Plants 150–350 mm high. *Corm* obconic-subglobose, 25–40 mm diam., bearing numerous small cormlets at base; tunics brown, outer layers becoming fibrous, with strong vertical ribs joined by fine fibres. *Stem* sticky below nodes, usually branching at all nodes, with 2, rarely 3, branches per node, with cauline sheathing leaves up to 28 mm long, dry and brown in distal 5–6 mm, ± truncate or subacute. *Foliage leaves* 2, lowermost up to 40 × 4–6 mm (opened flat), inserted below ground, linear, channelled, longest, initially suberect, trailing above, upper leaf somewhat shorter. *Rhipidial spathes* subacute to ± truncate, purple near tips, aging dry and brown, inner 22–25 mm long, outer $^{1}/_{2}$–$^{2}/_{3}$ as long. *Flowers* fugaceous, slate blue-grey to purple, outer tepals coppery pink outside and limbs with off white nectar guides minutely speckled with blue dots at bases, claws whitish, minutely speckled grey-blue; outer tepals ± 18 × 5.5–7.0 mm, initially spreading, later half reflexed often recurving distally, claws ± 10 mm long, thus slightly exceeding limbs, suberect; inner tepals up to 14 × 3 mm, oblanceolate, limbs spreading horizontally or later half reflexed. *Filaments* ± 8 mm long, free but closely cohering in smooth, cylindric column ± 6.5 mm long, diverging near apex; anthers 3–4 mm long, dark purple; pollen orange-red. *Ovary* ± 8 mm long, usually included; style branches ± 6 × 2 mm, sharply diverging and extended horizontally, white, flushed purple distally; stigma lobe transverse, with prominent stigmatic appendage ± 2 mm long, acute or apex forked, crests arching upward, 4–5 mm long, purple. *Capsules* and *seeds* unknown. *Flowering time*: late September to November; flowers opening ± 9:45 and collapse ± 17:00.

Distribution and ecology: a local endemic of the Atlantic Coast of Western Cape, South Africa, between Jacobsbaai and Vredenburg; in sandy ground among granite rocks.

Diagnosis: *Moraea saldanhensis* has relatively small, slate-blue flowers, the outer tepals ± 18 mm long with



Distribution of ***Moraea saldanhensis***.



spreading and ultimately half reflexed limbs ± 8 mm long thus shorter than the claws ± 10 mm long. It is most easily confused with *M. inconspicua* which has similarly small flowers (outer tepals 12–18 mm long), usually yellow to brown, occasionally white to cream-coloured, but the tepal limbs are almost always fully reflexed and somewhat to twice as long as the upright claws. *Moraea saldanhensis* also has a slightly longer filament column, ± 6.5 mm long (vs 3.5–6.0 mm in southern populations of *M. inconspicua*), orange-red pollen and the ovary is included whereas in *M. inconspicua* the ovary is usually exserted and the pollen is typically yellow, although populations with red pollen are known, notably among the Namaqualand populations, segregated as subsp. *namaquensis*.

9. **Moraea elsiae** *Goldblatt* in Annals of the Missouri Botanical Garden 63: 18 (1976b), as a new name for *Homeria simulans* Baker: 529 (1896) [not *M. simulans* Baker (1892)]; Goldblatt: 32 (1986a). Type: South Africa, [Western Cape], sandy places near Kenilworth, *H. Bolus 7931* (BOL, lecto., designated by Goldblatt: 739 (1976a); K, MO, isolecto.).

Plants 20–40 mm high. *Corm* mostly 20–35 mm diam.; tunics brown, ± woody or becoming fibrous, sticky-bituminous on inner surfaces, persisting with cataphylls as a collar around base. *Stem* with up to 3 branches at most aerial nodes, viscous below nodes, with cauline sheathing leaves, ± obtuse to truncate. *Foliage leaves* 2, linear, channelled, falcate to trailing, 3–5 mm wide. *Rhipidial spathes* green, dry above, usually ± obtuse, often becoming lacerated, inner 19–30 mm long, outer slightly shorter. *Flowers* fugaceous, yellow, rarely white, flushed brown outside, with darker yellow nectar guide specked with black at bases of all tepal limbs, limbs reflexed to ± 45°; outer tepals 15–22 × 5–9 mm, claws ± 5.5 mm long, inner slightly smaller, 14–19 × 4 mm. *Filaments* 4–7 mm long, free but parallel and contiguous below, diverging near apices; anthers 2.5–4.0 mm long, yellow; pollen yellow. *Ovary* 5–6 mm long, ovoid; style branches 3–4 mm long, overtopped by anthers, bilobed,

Distribution of ***Moraea elsiae***.

Distribution of ***Moraea simplex***.

crests vestigial, shorter than stigma lobes. *Capsules* ovoid, up to 10 mm long. *Seeds* unknown, *Chromosome number* 2*n* = 20. *Flowering time*: November to December (January).

Distribution and ecology: endemic to Western Cape, South Africa, from the Cape Peninsula and vicinity east to the Potberg and Still Bay; usually on sandy or loamy flats, typically in sites waterlogged during the winter months.

Diagnosis: although vegetatively typical of subg. *Visciramosae, Moraea elsiae* is immediately recognised by the flowers with subequal tepals, all with nectar guides at the bases of the limbs, and the reduced style branches with vestigial crests overtopped by the anthers. Flowers of *M. elsiae* are usually yellow but white-flowered plants have been recoded at Kleinmond and near Elim, the latter with flowers slightly smaller than elsewhere.

10. **Moraea simplex** *Goldblatt & J.C.Manning* in Novon 14: 294 (2004). Type: Western Cape, 21 km N of Piketberg, 18 Sept. 2002, *Goldblatt & Porter 12231* (NBG, holo.; MO, PRE, iso.).

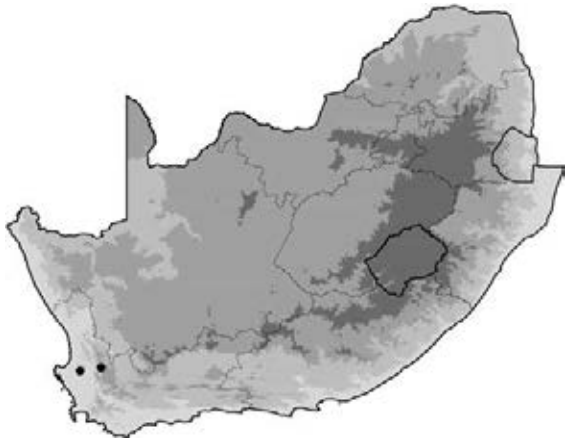
Plants 280–400 mm high. *Corm* ovoid, ± 10 mm diam.; tunics of coarse, light brown fibres, with collar of ± fine fibres around base. *Stem* lightly flexuose, sticky below nodes for half internode length, cauline sheathing leaves 24–35 mm long, green, becoming dry and light brown above, ± acute; bearing 2 or 3 short branches at upper 3 or 4 nodes, lowermost sometimes also branched. *Foliage leaves* usually 2, lowermost inserted below ground, upper inserted at first aerial node, blades channelled, ± 2 mm wide, exceeding stem, arching outward or trailing distally. *Rhipidial spathes* green, with dry, brown tips, 18–22 mm long, inner slightly shorter than outer. *Flowers* fugaceous, pale creamy yellow, outer tepal limbs with pale yellow mark at bases, unscented, tepal claws ascending, forming a cup enclosing filament bases; tepals with limbs initially spreading later reflexed to ± 30°, outer 18–20 × 7.5–8.5 mm, claws ± 2 mm long, ± erect, limbs ovate, obtuse; inner slightly shorter, ± 18 × 7 mm. *Filaments* ± 5 mm long, free but parallel and connivent below forming slender column, diverging in upper 1 mm; anthers ± 3 mm long, erect, contiguous, white; pollen white. *Ovary* narrowly ovoid, ± 3 mm long, exserted; style dividing shortly below base of anthers into 3 filiform arms, each stigmatic apically and extended between filaments, ± 4 mm long. *Capsules* and *seeds* unknown. *Flowering time*: in mid- to late September, probably into mid-October; opening ± 14:00 and wilting shortly after nightfall.

Distribution and ecology: known only from a single site at the eastern foot of the Piketberg Mtns in Western Cape, South Africa; in stony loamy clay, flowering after a fire the previous summer.

Diagnosis: the growth habit, corm tunics, characteristic branching with sticky internodes, and the free but parallel and coherent filaments all place *Moraea simplex* firmly in subg. *Visciramosae* but its simple filiform, apically stigmatic style branches extending outward between the top of the filaments, and short, suberect tepals claws ± 2 mm long are unique in the subgenus and remarkable in *Moraea*, in which just two species of subg. *Polyanthes* have similar style branches. Vegetatively, *M. simplex* may be mistaken for the common and widespread *M. inconspicua* in both habit and the short rhipidial spathes, but the flowers of *M. inconspicua*, although small, conform to the conventional type in the genus in their flattened style branches bearing paired erect, style crests.

Subg. 3. **Umbellatae**

Subg. **Umbellatae** *Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 43: 36 (2013). Type: *Moraea margaretae* Goldblatt

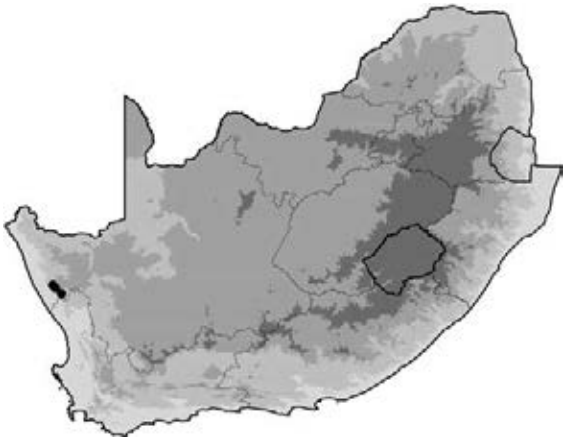


Plants with branched stems, sometimes acaulescent, branches and leaves sometimes clustered at first aerial node or remote from one another; corm tunics dark brown, initially unbroken, later splitting irregularly, sometimes ultimately fibrous. *Leaves* several or solitary. *Rhipidial spathes* blunt or truncate, with outer spathe often diverging apically. *Flowers* fugaceous, pale yellow to ± beige (rarely pale pink) with dark venation, sometimes with perianth tube; stamens united in lower half; style branches well developed or reduced and lacking crests (in *M. nana* with paired filiform arms extended horizontally). *Capsules* ± club-shaped. *Basic chromosome number x* = 10.

11. **Moraea linderi** *Goldblatt* Annals of the Missouri Botanical Garden 69: 352 (1982); Goldblatt: 58 (1986a). Type: South Africa, [Western Cape], Piketberg Mtn, Moutonshoek, *Linder 638* (MO, holo.).

Plants 350–450 mm high. *Corm* 15–18 mm diam., bearing numerous pale cormlets at base; tunics brown, initially unbroken, breaking from below into sections, ultimately becoming fibrous. *Stem* branching well above ground, flexed above insertion of second leaf, 2- to 4-branched. *Leaves* 3, lowermost basal, suberect to ± falcate, terete but with narrow adaxial groove, exceeding stem, other leaves inserted well above ground, shorter than basal, channelled, up to 4 mm wide. *Rhipidial spathes* green with brown tips, truncate to acute, inner 35–40 mm long, slightly shorter or longer than outer, diverging in upper half. *Flowers* fugaceous, pale yellow, outer tepal limbs with darker yellow nectar guides at bases; outer tepals ± 35 mm long, claw ± 15 mm long, ascending, limb spreading to slightly reflexed; inner tepals ± 25 × 4 mm, spreading when fully expanded. *Filaments* 6–8 mm long, united in lower ± 1 mm (or evidently free), diverging above; anthers ± 6 mm long; pollen yellow. *Ovary* ± 7 mm long, club-shaped; style branches 10–12 × ± 3 mm, crests prominent ± 10 mm long. *Capsules* and *seeds* unknown. *Chromosome number* 2*n* = 30, i.e. triploid [diploids probably also present in the population]. *Flowering time*: December.

Distribution and ecology: known only from two sites in Western Cape, South Africa, one in the Piketberg Mtns and the other in the Cold Bokkeveld; in seasonally moist sites near streams or seeps in sandy soils, flowering well only after fire. The type locality on the Piketberg is now inundated by a dam.



Diagnosis: an unusual species, *Moraea linderi* has the brown, woody, initially entire corm tunics and outer rhipidial spathes free distally, that characterise subg. *Umbellatae* but stands out in having a well-developed basal leaf (leaves in the subgenus are often inserted well above ground) and filaments united for ± 1 mm (± one sixth of their length). The flowers have well-developed style branches and prominent crests ± 10 mm long.

Distribution of ***Moraea linderi***.

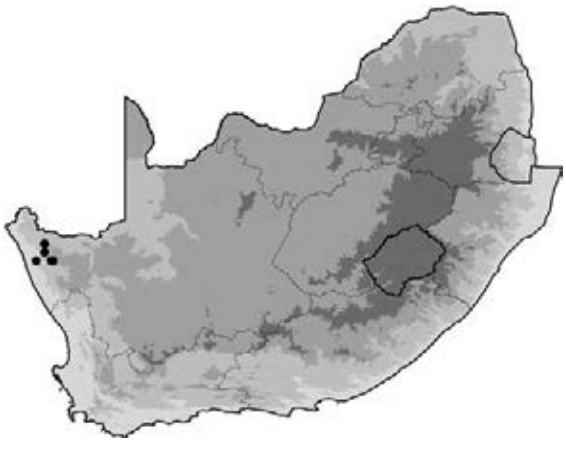
12. **Moraea orthrosantha** *Goldblatt & J.C.Manning* in Bothalia 44: 18 (2014a). Type: South Africa, Northern Cape, 15.5 km N of Garies, sandy slopes at 2 110 ft [± 645 m], 10 Oct. 2013, *Goldblatt & Porter 13990* (NBG, holo.; K, MO, PRE, iso.).

Plants up to 350 mm high. *Corm* 8–11 mm diam.; tunics brown, ± woody, inner layers entire, outer splitting from base. *Stem* mostly 3 or 4(5) internodes long, with 1 or 2 branches at each node, branches slightly flexed above sheath of subtending leaf. *Leaves* 3 to 5, lowermost longest, inserted 10–20 mm above ground, linear, channelled, ± straight or loosely twisted, up to 450 mm long, upper leaves progressively shorter, none entirely sheathing. *Rhipidial spathes*: inner 35–40 mm long, ± truncate, apex brown, somewhat lacerated, outer $^{1}/_{2}$–$^{2}/_{3}$ as long, with acute, brown apex. *Flowers* buff-yellow, lightly brown-veined, outer tepals darkly veined abaxially, limbs with deep yellow nectar guides at bases edged brown, spreading slightly below horizontal, inner tepals with reddish brown spot at bases of limbs, similarly spreading, outer tepals 30–32 mm long, limbs 20–22 × 10–12 mm, claws ± 10 mm long, inner tepals oblanceolate, ± 22 × 5–6 mm. *Filaments* 8–9 mm long, united in lower 5–6 mm, diverging distally; anthers dark purple, 3.5–5.0 mm long; pollen red. *Ovary* exserted, oblong-elliptic, 5–6 mm long; style branches ± 10 mm long, crests 10–14 mm long, erect, narrowly wedge-shaped. *Capsules* narrowly obovoid, 9–11 mm long. *Seeds* softly angular, ± 1 mm long, with rugulo-reticulate surface, light yellow-brown. *Flowering time*: late September to late October; flowers opening ± 7:00 and collapsing ± 12:00.

Distribution of ***Moraea orthrosantha***.

Distribution and ecology: known only from a small area north of Garies in Northern Cape, South Africa, in the higher country south of Garagams; apparently restricted locally to wetter sites in granite-derived sand or stony ground. Plants in trampled or drier situations are much smaller than normal.

Diagnosis: one of few species of subg. *Umbellatae* with leaves basal and cauline rather than crowded at the first aerial node, *Moraea orthrosantha* has a flower typical of the genus, with well-developed style branches and crests and nectar guides only on the outer tepals. The flowers are dull yellow with conspicuous dark veins and closely resemble those of *M. margaretae*. As the specific epithet suggests, flowers open soon after sunrise and collapse about noon (Greek, *orthros* = morning, *anthos* = flower). The flowers of most species of subg. *Umbellatae* open in the mid- to late morning and wilt and collapse in the late afternoon, and only a few other examples of morning flowering phenology are known in *Moraea*, notably in *M. vlokii* and three Namaqualand species of subg. *Homeria*, *M. flexicaulis, M. knersvlaktensis* and *M. schlechteri*. Records for *M. margaretae*, with which *M. orthrosantha* is most easily confused, indicate flowers open midmorning and collapse toward sunset.



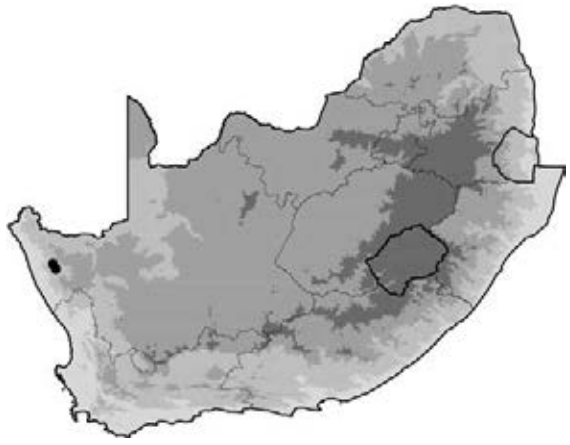
13. **Moraea margaretae** *Goldblatt* in Annals of the Missouri Botanical Garden 63: 19 (1976b); Goldblatt: 60 (1986a). Type: South Africa, [Northern Cape], Namaqualand, pipeline track SW of Nababeep, *Goldblatt 628* (BOL, holo.; K, MO, PRE, S, iso.).

Plants up to 150 mm high. *Corm* 5–7 mm diam.; tunics brown, inner layers ± woody and entire, outer becoming coarsely fibrous. *Stem* with 1 long above-ground internode, usually 1- or 2-branched from close to ground level. *Leaves* usually 3, linear, all inserted at ground level, channelled below, terete and often twisted to coiled distally. *Rhipidial spathes* green, leathery, with dark brown tips, acute or lacerated tips; inner 30–45 mm long, often lacerated at apex, outer ± $^{2}/_{3}$ as long, acute, entirely sheathing. *Flowers* fugaceous, pale buff-yellow, finely veined with brown, flushed brown outside, outer tepal limbs with deep yellow nectar guides at bases edged with brown, rarely inner tepals with a small brown spot at limb bases; tepals lanceolate, with laxly spreading to half reflexed limbs, outer 20–30 mm long, claws 5–8 mm long, suberect; inner tepals ± 20 mm long, initially erect, limbs later half-reflexed. *Filaments* ± 5 mm long, united in lower 3–4 mm; anthers 4–5 mm, dull purple; pollen red. *Ovary* ± cylindric, 5–6 mm long, usually ultimately exserted; style branches 7 mm long, stigma lobe transverse, crests erect, lanceolate, 6–10 mm long. *Capsules* and *seeds* unknown. *Chromosome number* $2n = 40$. *Flowering time*: September; flowers open midmorning and collapse near sunset.

Distribution and ecology: restricted to northern Namaqualand in Northern Cape, South Africa, from Steinkopf in the north to the escarpment west of Springbok near Spektakel Pass in the south; in coarse, granite-derived gravel, sometimes near streams or seeps.

Diagnosis: *Moraea margaretae* has the brown, ± woody corm tunics, leathery rhipidial spathes with brown tips and flowers with finely brown-veined yellow tepals characteristic of subg. *Umbellatae*, and is distinguished in the subgenus by its habit and flowers with well-developed style branches and prominent style crests. The leaves and branches (when present) are crowded close to ground level and the aerial stem and branches comprise a single internode. The species is tetraploid, $2n = 40$ (two populations counted), one of the few exclusively polyploid species known in *Moraea*.

Moraea margaretae seems to be most closely related to *M. orthrosantha* of central Namaqualand but this species has aerial stems of three or four internodes, with two or three branches at the aerial nodes. The flowers of the two are similar in size and colour but those of *M. margaretae* have shorter filaments ± 5 mm long vs. filaments 8–9 mm long in *M. orthrosantha*. Both species have red anthers and pollen. Hybrids between *M. margaretae* and *M. intermedia* occur at a site west of Springbok.



Distribution of ***Moraea margaretae***.

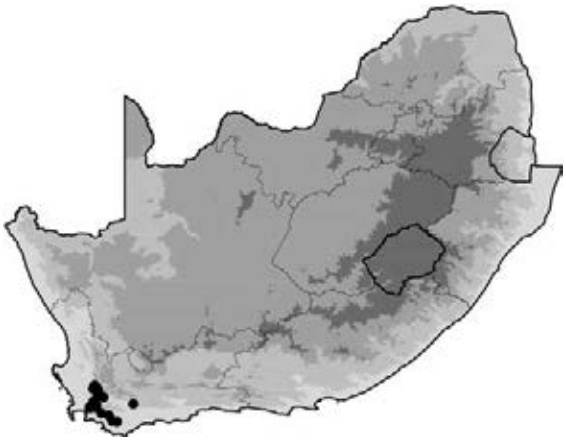
14. **Moraea intermedia** *Goldblatt & J.C.Manning* in Bothalia 40: 147 (2010). Type: Northern Cape, Farm Ghoop (Modderfontein), west of Springbok, granitic gravel slope, 18 Sept. 2009, *Goldblatt, Manning & Porter 13405* (NBG, holo.; K, MO, PRE, iso.).

Plants 150–450 mm high. *Corm* ovoid, 12–15 mm diam., asymmetric with a fibrous downward extension on one side; tunics brown, inner layers unbroken, outer fragmented into vertical sections held together by cross fibres, sometimes ± fibrous with age. *Stem* ± erect, firm, with long basal internode, branched, branches crowded above first aerial node 80–150 mm above ground, main stem sometimes also branched. *Leaves* 2 to 4, inserted above ground, clustered above first aerial node, linear, channelled, lowermost longest, arching to trailing, up to 400 mm long, upper leaves progressively smaller. *Rhipidial spathes* green, acute to ± truncate, turning brown with age, inner 38–45 mm long, outer ± $^{2}/_{3}$ as long, sheathing entirely. *Flowers* fugaceous, pale dull yellow with darker veins, outer tepal limbs with bright yellow, green spotted nectar guides at bases edged brown distally; tepals with limbs spreading, undulate, and claws forming a narrow cup ± 4 mm deep clasping base of filament column, outer tepals 27–30 × 9–12 mm, claws narrow, ± 4 mm long, erect, inner tepals 23–26 × 8–9 mm. *Filaments* 8–10 mm long, united in smooth, cylindric column; anthers 6–8 mm long, overtopping stigma lobe, dark purple; pollen orange-red. *Ovary* ± 8 mm long, included or exserted; style branches ± 6 × 2 mm, narrowly diverging, with terminal, transverse, semi-circular stigma lobes ± 3 mm wide, crests erect, 10–12 mm long. *Capsules* ± cylindric, ± 9 mm long. *Seeds* unknown. *Flowering time*: mid-September to mid-October; flowers open soon after sunrise at ± 7:00 and fade in late afternoon, ± 15:30–16:00.

Distribution and ecology: restricted to the granite hill country of north-central Namaqualand west and southwest of Springbok in Northern Cape, South Africa, and currently known from only two sites; in open, granitic sandy ground.

Distribution of ***Moraea intermedia***.

Diagnosis: the asymmetric corm with brown, ± woody corm tunics, relatively blunt, brown-tipped rhipidial spathes, and yellow, darkly veined tepals place *Moraea intermedia* in subg. *Umbellatae*. The long basal internode with leaves clustered at the first aerial node recalls *M. nana* of the subgenus, but the flowers have typical *Moraea*-like style branches with terminal, transverse stigma lobes and prominent, paired petaloid style crests. Unlike the typical *Moraea* flower, however, all six tepals of *M. intermedia* have short claws clasping the base of the filament column, the claws all bearing basal nectaries, and the limbs each have a nectar guide at the base. Other *Moraea*-type flowers have inner tepals lacking both nectaries and nectar guides. The similarly marked inner and outer tepals recall the *Homeria*-type flower as found in subg. *Umbellatae* in *M. maximiliani* and *M. umbellata*, whereas *M. cooperi, M. linderi*, *M. longiflora* and *M. margaretae* have more-or-less typical *Moraea*-type flowers. The remaining member of the alliance, *M. nana*, has spreading, subequal tepals with short claws clasping the base of the filament column but the style branches are reduced to paired filiform arms extending between the anthers.



At the type locality, *Moraea intermedia* is parapatric with the closely related *M. margaretae*, which favours somewhat wetter sites, and a range of hybrids between the two species occurs there.

15. **Moraea cooperi** *Baker,* Handbook of the Irideae: 54 (1892); Goldblatt: 729 (1976a); Goldblatt: 102 (1986a). Type: South Africa, Cape, Worcester, *Cooper 1661* [K, lecto., designated by Goldblatt: 729 (1976a)].

Moraea stenocarpa Schltr.: 93 (1900). *Gynandriris stenocarpa* (Schltr.) R.C.Foster: 47 (1939). Type: South Africa, [Western Cape], between Bain's Kloof and Ceres Road, *Schlechter 9082* (B, lecto., designated by Goldblatt: 729 (1976a); BOL, GRA, MO, PRE, S, SAM, isolecto.).

Moraea apetala L.Bolus: 385 (1929a). *Gynandriris apetala* (L.Bolus) R.C.Foster: 48 (1939). Type: South Africa, [Western Cape], Stellenbosch Flats, *Duthie 1770* (BOL, holo.; K, iso.).

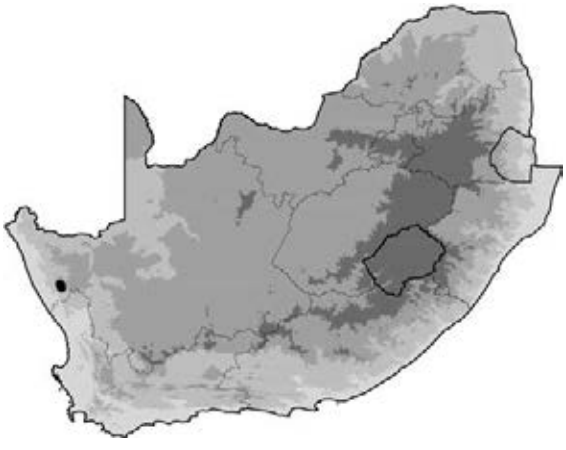
Plants 150–250 mm high. *Corm* 10–15 mm diam.; tunics of dark brown, coarse fibres. *Stem* flexuose, usually 2- or 3-branched from upper nodes, with cataphylls forming a brown, fibrous collar around base. *Foliage leaves* 2 or 3, lowermost basal and longest, exceeding stem, remaining leaves cauline and progressively smaller, blades linear, channelled, ± 3 mm wide when opened flat; leaves subtending ± bract-like and dry distally not sheathing above. *Rhipidial spathes* green, at anthesis becoming dry and brown distally, attenuate; inner spathe 30–50 mm long, outer ± half as long, entirely sheathing. *Flowers* fugaceous, solitary in spathes, pale

Distribution of ***Moraea cooperi***.

yellow finely veined with dull brown-purple, outer tepal limbs with yellow nectar guides at bases; tepals united in tube ± 10 mm long, limbs laxly spreading, lanceolate, 33–40 × 20 mm, claw ± 10–14 mm long (inner tepals absent). *Filaments* ± 6 mm long, united in lower 1–2 mm; anthers 7–9 mm long, light purple; pollen yellow. *Ovary* 10–12 mm long, included in middle of spathes; style branches 12–15 mm long, crests up to 10 mm long. *Capsules* narrowly ellipsoid, 25–30 mm long. *Seeds* compressed, elongate, winged at opposite ends, ± 4 mm long. *Chromosome number* 2*n* = 20. *Flowering time*: late September and October, occasionally in November at higher elevations; flowers lasting a single day.

Distribution and ecology: local in Western Cape, South Africa, between Tulbagh and Caledon but absent from the Cape Peninsula; usually on well-watered, stony flats and flowering well only after fire. Largely a lowland species, *M. cooperi* has lost much of its range to agriculture and urban development.

Diagnosis: immediately recognised in *Moraea* by the yellow, finely veined flowers and perianth of only three tepals, united basally in a short perianth tube. In addition, the narrowly fusiform ovary is included within the spathes and the compressed seeds are winged at both ends. The relationships of *M. cooperi* remain puzzling and it is provisionally included in subg. *Umbellatae*, with which its brown corm tunics, pale yellow, finely veined tepals and chromosome number, *n* = 10 are consistent. A perianth tube is also found in *M. longiflora* of the subgenus and the two species were placed together in sect. *Tubiflorae* of subg. *Moraea* in earlier studies. Molecular phylogenetic studies do not place *M. cooperi* among other species of subg. *Umbellatae* but show it to be isolated, at least with the plastid DNA loci so far sequenced.



The presence of a floral tube prompted Foster (1939) to transfer both *Moraea cooperi* and *M. longiflora* to *Gynandriris* (now sect. *Gynandriris* of *Moraea*) but the members of sect. *Gynandriris* do not actually have a perianth tube but rather a tubular extension of the ovary and are not closely related to *M. cooperi*.

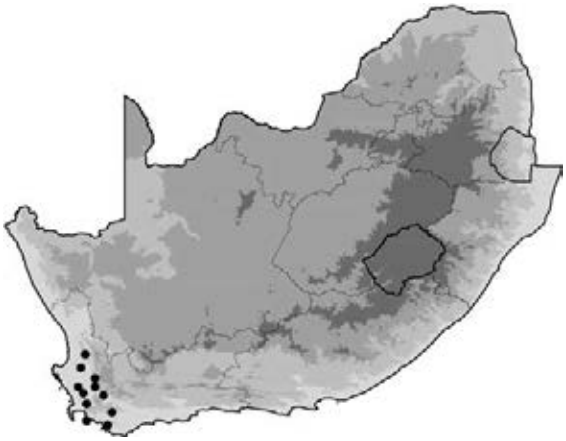
16. **Moraea longiflora** *Ker Gawl.* in Curtis's Botanical Magazine 19: t. 712 (1804b); Goldblatt: 731 (1976a); Goldblatt: 124 (1986a). *Helixyra flava* Salisb.: 305 (1812), illegitimate superfluous name for *M. longiflora* Ker Gawl. *Helixyra longiflora* (Ker Gawl.) N.E.Br.: 349. (1929b). *Gynandriris longiflora* (Ker Gawl.) R.C.Foster: 40 (1936). Type: South Africa, without precise locality, illustration in Ker Gawl.: t. 712 (1804b).

Plants small, ± 50 mm high. *Corm* spindle-shaped, ± 10 mm diam.; tunics dark brown, very hard, breaking into ± netted fibres. *Stem* subterranean, with 2 to 4 ± sessile branches clustered at ground level, with cataphylls pale, becoming fibrous and forming a collar around base. *Leaves* several, basal longest, 40–60 mm long, linear-filiform, narrowly channelled, rigid, remaining leaves similar but shorter, clustered at ground level. *Rhipidial spathes* green, 25–30 mm long, inner entirely sheathing, outer somewhat leaf-like, sheathing for ± 5 mm, free distally. *Flowers* fugaceous, yellow, outer tepal limbs with yellow-orange nectar guides at bases; tepals united in tube 20–30 mm long, outer 23–30 mm long, claw 7–10 mm long, ascending, limb spreading to laxly reflexed, inner tepals 17–22 mm long, also spreading or becoming reflexed. *Filaments* 5–6 mm long, united in lower $^1/_3$; anthers ± 5 mm long, yellow; pollen yellow. *Ovary* 4–5 mm long, subsessile, included; style branches 10–12 mm long, crests ± 10 mm long. *Capsules* and *seeds* unknown. *Chromosome number* 2*n* = 20. *Flowering time*: October.

Distribution and ecology: a rare species restricted to the Kamiesberg in Namaqualand, Northern Cape, South Africa; local in moist sandy sites.

Diagnosis: *Moraea longiflora* is distinctive in its acaulescent habit and yellow, long-tubed flowers. The combination of a flower with long perianth tube and underground stem is unique in subg. *Umbellatae* but the brown corm tunics, yellow flowers with brown-veined tepals, and outer rhipidial spathes free and diverging

Distribution of ***Moraea longiflora***.



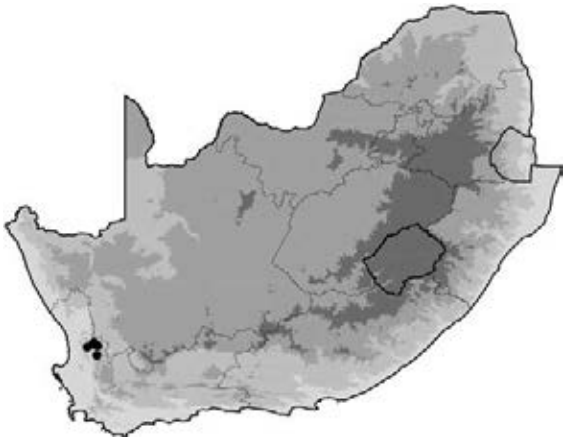
distally, are consistent with this placement. The species bears more than a passing resemblance to *M. cooperi*, also with a perianth tube but with a well-developed aerial stem. Molecular phylogenetic studies place *M. longiflora* closest to *M. margaretae* and *M. intermedia* of subg. *Umbellatae*, but *M. cooperi* is not included in that alliance rendering its relationships uncertain.

17. **Moraea umbellata** *Thunb.*, Dissertatio de *Moraea*: 13 (1787). *Aristea umbellata* (Thunb.) Spreng.: 158 (1824). *Bobartia umbellata* (Thunb.) Ker Gawl.: 31 (1827). *M. edulis* var. *umbellata* (Thunb.) Baker: 21 (1896). *Homeria umbellata* (Thunb.) G.J.Lewis: 86 (1948). *Rheome umbellata* (Thunb.) Goldblatt: 92 (1980a). Type: South Africa, Cape, near Piketberg, *Thunberg s.n.* '*Moraea umbellata* a' [UPS–THUNB 1230, lecto., effectively designated by N.E.Br.: 54 (1928)].

Homeria bobartioides L.Bolus: 12 (1931a). Type: South Africa, [Western Cape], Mulder's Vlei, Stellenbosch distr., *L. Bolus s.n.* (BOL [19085], lecto., K, isolecto).

Plants 150–450 mm high. *Corm* globose-ovoid, up to 20 mm diam., slightly asymmetric with a fibrous downward extension on one side, with many cormlets clustered around base; tunics brown, inner layers unbroken, outer layers becoming partly fibrous, sometimes entirely with age. *Stem* erect, with long, basal internode and branches clustered in umbellate fashion. *Leaves* 2 to 4, inserted well above ground, clustered at bases of branches, lowermost up to 400 mm long, others shorter, channelled, falcate to trailing. *Rhipidial spathes* green with brown tips, ± truncate or lacerate at apex, rarely acute, inner 30–40 mm long, outer ± half to nearly as long, sheathing entirely or free distally. *Flowers* fugaceous, pale yellow flushed brownish outside, bases of all tepal limbs with dull yellow nectar guides at bases, tepal claws forming a windowed cup below enclosing filaments, limbs spreading horizontally, somewhat undulate; outer tepals 19–30 × 9–12 mm, claws narrow, 5–7 mm long; inner 17–28 × 8–10 mm long. *Filaments* 6–7 mm long, united entirely or free and diverging in upper 1.0–1.5 mm, column smooth; anthers 3.0–3.5 mm long, narrowly diverging; pollen yellow. *Ovary* ovoid, 5–7 mm long, exserted or partly(–entirely) included; style branches ± 2 mm long, narrow, appressed to and shorter than anthers, bilobed at tips, lacking crests. *Capsules* and *seeds* unknown. *Chromosome number* $2n = 20$ (or 30). *Flowering time*: late September to November (to early December); flowers opening ± 14:00 or even later, fading by 19:00.

Distribution and ecology: relatively widespread in Western Cape, South Africa, from the Piketberg south to the Cape Peninsula and east to Stormsvlei Kloof west of Riviersonderend; usually in deep rocky sandstone derived soil on flats or level sites in montane areas, most often found in seasonally moist situations.



Distribution of ***Moraea umbellata***.

Diagnosis: *Moraea umbellata* has the vegetative morphology typical of subg. *Umbellatae*, viz. a stem comprising a long basal internode, leaves clustered well above ground at the first aerial node where branching occurs, and several subequal branches clustered in semi-umbellate manner. Plants can be robust, reaching as much as 450 mm in height and can often be distinguished by size alone. The flowers are also distinctive with the tepal claws 5–7 mm long and enclosing the filaments, which are either united entirely or free near the apex, and reduced and narrow style branches appressed to but shorter than the anthers and lacking crests. The outer inflorescence spathes may be entirely sheathing or free distally as in several other species of the subgenus. The fugaceous flowers last only a few hours, opening in the late afternoon, fading in early evening and completely collapsed by 19:00.

Individuals of three of four populations so far examined cytologically are triploid, $2n = 30$, hence sexually sterile, and only one diploid population is known, $2n = 20$. It seems likely that many populations of the species are triploid as plants often fail to set seed, and most collections lack developing capsules. Reproduction in the sexually sterile plants is evidently by the numerous tiny cormlets produced around the base of the mother corm.

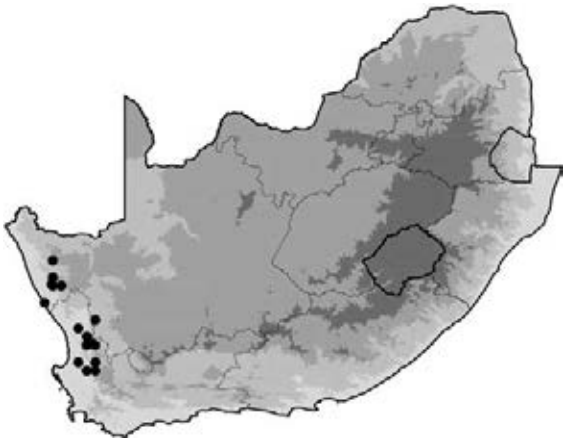
18. **Moraea maximiliani** *(Schltr.) Goldblatt & J.C.Manning* in Novon 5: 269 (1995). *Homeria maximiliani* Schltr.: 94 (1900). *Rheome maximiliani* (Schltr.) Goldblatt: 92 (1980a). Type: South Africa, [Western Cape], Clanwilliam District, near Hoek, *Schlechter 8700* (B, lecto., designated by Goldblatt: 92 (1980a); BOL, E, G, K, M, MO, P, PRE, S, US, isolecto.).

Plants 90–150 mm high. *Corm* ± globose, 9–12 mm diam., slightly asymmetric with a lateral downward ridge; tunics dark brown, inner layers unbroken, outer of flat sections held together by cross fibres, sometimes becoming ± fibrous with age. *Stem* erect or inclined,

Distribution of ***Moraea maximiliani***.

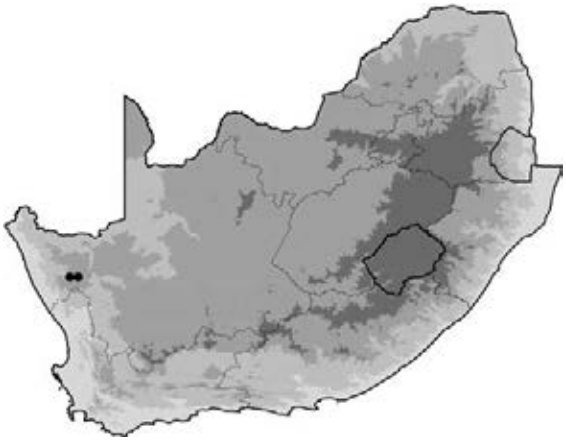
with long basal aerial internode, leaves and branches crowded at first aerial node, with fibrous cataphylls sometimes accumulating as a collar around base. *Leaves* 2 or 3, inserted well above ground and clustered at first aerial node, lowermost much longer than others, narrowly channelled, linear to filiform, straight to strongly falcate or trailing distally. *Rhipidial spathes* on short to nearly sessile branches, with acute, brown-tipped apices, inner 20–35 mm long, outer $^1/_2$ to ± as long, sheathing below, usually free and diverging distally. *Flowers* fugaceous, pale yellow to beige, tepals veined with dark brown, bases of all tepal limbs with deeper yellow nectar guides edged distally with red-brown; tepals subequal, oblanceolate-pandurate, limbs spreading to laxly reflexed, outer 15–24 × 6–10 mm, claws ascending, ± 6 mm long, inner narrower and slightly shorter than outer. *Filaments* united in smooth, slender column 6–8 mm long; anthers ± erect, contiguous, 2.0–2.5 mm long, yellow; pollen yellow. *Ovary* narrowly top-shaped, 3–6 mm long, usually exserted; style branches short, ± 1 mm long, narrow, forked apically with tips diverging and extending between anthers, without crests. *Capsules* club-shaped to oblong, 6–10 mm long. *Seeds* small, angular-prismatic. *Chromosome number* 2*n* = 20. *Flowering time*: late August to mid-October; opening midmorning and collapsing ± 15:00.

Distribution and ecology: a narrow endemic restricted to the eastern slopes of the Pakhuis Mtns and Biedouw Valley in the Clanwilliam District in Western Cape, South Africa; in sandy, stony ground, sometimes in shallow soil on sandstone pavement.



Diagnosis: distinguished by the small, pale yellow flowers with subequal tepals, all with short, ascending claws and small, deeper yellow nectar guides at the bases of the tepals, *Moraea maximiliani* also has short, reduced style branches appressed to the anthers with the stigmatic tips extending between them. The slender, almost filiform leaves are crowded at the top of the elongated based internode. The outer rhipidial spathes clasp the inner only in the lower half and arch outward distally.

19. **Moraea nana** *(L.Bolus) Goldblatt & J.C.Manning* in Novon 5: 269 (1995). *Hexaglottis nana* L.Bolus: 326 (1932a). Type: South Africa, [Western Cape], foot of the Cederberg at Algeria, 25 Sept. 1030, *Weintroub s.n.* (BOL [*19972*], lecto., designated here [not holo. As previously cited]; K, isolecto.).



Plants 100–300 mm high. *Corm* globose-ovoid, 10–15 mm diam., slightly asymmetric with a fibrous downward extension on one side; tunics brown, inner layers unbroken, outer layers fragmenting in sections held together by cross fibres or ± fibrous with age. *Stem* consisting of one long aerial internode with leaves and branches clustered close to first aerial node, with ± dry, fibrous cataphylls. *Leaves* 3 or 4, inserted close together at and above first above ground aerial node, lowermost longest, blades leathery, up to 400 mm long, channelled, straight or falcate to trailing. *Rhipidial spathes* green, leathery, 25–40 mm long, apices often dark brown, sometimes truncate or lacerate, outer slightly longer or shorter than inner, usually sheathing below, distally free and recurved. *Flowers* fugaceous, yellow to buff-coloured or salmon-orange, tepals finely veined dark brown, often flushed brown outside, limbs of all or only outer tepals with brighter yellow nectar guides at bases edged brown; outer tepals 19–25 × 10–14 mm, claws narrow, 2–4 mm long, ascending, forming a narrow cup around base of filaments, limbs spreading, ± undulate, inner tepals shorter, up to 10 mm wide. *Filaments* 4–5 mm long, united in lower 1.5–3.0 mm; anthers 4–5 mm long, initially erect and parallel, arching inward after anthesis, yellow; pollen yellow. *Ovary* ± cylindric, 4–6 mm long, exserted or partly (entirely) included in spathes; style branches divided almost to base into two slender ascending arms, ± 5 mm long, extending either side of subtending filament. *Capsules* 6–10 mm long, ± barrel-shaped, 3–4 mm wide. *Seeds* small, angular. *Chromosome number* 2*n* = 20. *Flowering time*: late September to October (to early November); flowers opening usually ± 12:30, fading at dusk; rarely opening ± 8:00 and fading 13:00 (Pakhuis Mtns).

Distribution and ecology: relatively widespread along the Atlantic Coast of South Africa, from the Spektakel Mtns west of Springbok in Namaqualand, Northern Cape, to the Olifants River Valley south of Citrusdal in Western Cape; on stony, sandy ground. The species is probably more common than the record indicates as plants are easily overlooked and little collecting is done in late spring when it flowers.

Diagnosis: flowers of *Moraea nana* are of the *Hexaglottis*-type and closely resemble those of *Moraea* sect. *Hexaglottis* in their spreading, subequal tepals with short erect claws and style branches reduced to paired filiform arms, but the resemblance is convergent and *M. nana* has a vegetative form almost identical to that of some species of subg. *Umbellatae*, with leaves and branches crowded together above the ground. Chromosome number *n* = 10, also matches subg. *Umbellatae*

Distribution of ***Moraea nana***.

Distribution of ***Moraea singularis***.

(subg. *Hexaglottis* has *x* = 6). *Moraea nana* is probably most closely allied to *M. maximiliani* and the two can only be distinguished by examination of the floral parts: *M. maximiliani* has tepal claws ± 6 mm long, entirely united filaments, and short, apically diverging style branches partly hidden by the short erect and contiguous anthers, whereas *M. nana* has shorter tepal claws, 2–4 mm long, filaments free in the upper half, and filiform, spreading style branches extending between the filaments. *Moraea nana* and *M. maximiliani* are interfertile but neither can be crossed with species of sect. *Hexaglottis*.

Flowers typically open after midday, ± 12:30 and collapse after 18:00 but in plants from the Pakhuis area of the northern Cederberg flowers open at ± 8:00 and deliquesce at ± 13:00. Flowers of these populations are slightly smaller than is typical but otherwise do not appear to differ significantly.

20. **Moraea singularis** *Goldblatt & J.C.Manning* in Bothalia 43: 154 (2013). Type: Northern Cape, Kamiesberg, Vaalputs, *NECSA* site, Platbakkies Succulent Karoo, 2 Aug. 2011, *Van Rooyen 2827* (PRU, holo.).

Plant small, acaulescent 30–40 mm high. *Corm* spindle-shaped, ± 10 mm diam., tunics of grey-brown, wiry, reticulate fibres. *Stem* with 1 to 4 sessile branches clustered at ground level. *Leaves* 3, clustered at ground level, lowermost longest, inserted on stem at ground level, falcate, terete, 50–80 mm long, 0.8–1.0 mm diam., upper 2 leaves much shorter, recurved, bifacial, channelled or with short terete blade up to 20 mm long. *Rhipidial spathes* green, 25–30 mm long, outer leaf-like, spreading distally, ± as long as inner. *Flowers* rotate, pale to golden-yellow, limbs of all tepals with brown, spear- or lozenge-shaped nectar guide near bases, tepal claws ascending, forming a cup enclosing base of filament column, limbs spreading, inner usually twisted through 90° distally; tepals united for 2 mm, claws ± 1 mm long, limbs obovate-pandurate, truncate, outer ± 12 × 6 mm, inner slightly smaller. *Filaments* ± 5 mm long, connate in a smooth, cylindric column ± 4 mm long, free and diverging in upper 1 mm; anthers ± 3 mm long, arched, yellow; pollen yellow. *Ovary* cylindric, ± 10 mm long, included; style branches divided almost to base into paired terete arms extending either side of each anther, ± 1.5 mm long, stigmatic at apices, crests reduced, ± 1 mm long. *Capsules* and *seeds* unknown. *Flowering time*: late July to early August.

Distribution and ecology: known from two sites along the eastern foothills of the Kamiesberg massif in central Namaqualand, Northern Cape, South Africa, but possibly with a wider range than is presently known; on gravel flats derived from granite bedrock.

Diagnosis: an acaulescent species, *Moraea singularis* also stands out in the short, terete leaf blades. The yellow flowers, with both inner and outer tepals limbs bearing brown nectar guides, have tepal claws only ± 1 mm long that form a narrow cup including the base of the smooth filament column. The tepal limbs are oblanceolate-pandurate, the inner three slightly smaller than the outer and twisted through 90°. The asymmetric corms with brown corm tunics accord best with subg. *Umbellatae*, as do the outer rhipidial spathes, which sheath the inner only in the lower half and arch outward distally, and also the yellow flowers with darkly veined tepals and brown nectar guides. Unique to the subgenus is the terete blade of the basal leaf, while the upper leaves are channelled entirely or for part of their length and terete distally.

Subg. 4. **Moraea**

Moraea [unranked] *Corymbosae* Baker: 10 (1896), illegitimate superfluous name. Type: *M. juncea* L. = *M. vegeta* L., type of the genus.

Plants with stems usually branched, sometimes repeatedly; corm tunics finely to coarsely fibrous or ± woody. *Foliage leaves* several to (1)2. *Flowers* mostly yellow to buff-brown, occasionally pink to red, or partly white (blue in *M. nubigena*); filaments united in lower half; style branches and crests well developed (reduced in *M. vlokii*). *Capsules* ± globose, exserted. *Basic chromosome number x* = 10.

Sect. 3. **Moraea**

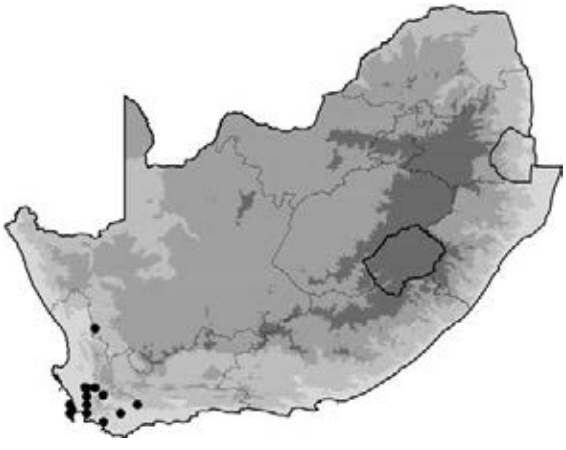
Corms often asymmetric; tunics of pale, coarse or fine fibres. *Foliage leaves* several to (1)2. *Flowers* yellow, sometimes pink to red or brown; filaments partially united; style branches and crests usually well developed (reduced in *M. vlokii*).

21. **Moraea vegeta** *L.*, Species plantarum: 59 (1753); Goldblatt: 693 (1976a); Goldblatt: 54 (1986a). *M. iriopetala* var. *vegeta* (L.) L.f.: 100 (1782). Type: South Africa, without precise locality or collector, illustration in Miller: t. 238 (1758).

Iris tristis L.f.: 97 (1782). *Ferraria tristis* (L.f.) Salisb.: 42 (1796). *Moraea tristis* (L.f.) Ker Gawl.: 241 (1804a). *Vieusseuxia tristis* (L.f.) Eckl.: 11 (1827). Type: South Africa, [Western Cape], below Devil's Peak near Cape Town, *Thunberg s.n.* [UPS–THUNB (1190), lecto., designated by Goldblatt: 693 (1976a)].

Moraea sordescens Jacq.: t. 225 (1795). Type: illustration in Jacq.: t. 225 (1795).

Vieusseuxia graminifolia Eckl.:. 11 (1827). Type: South Africa, Cape, 'Groene Berg,' *Zeyher 1068* (S, lecto.).



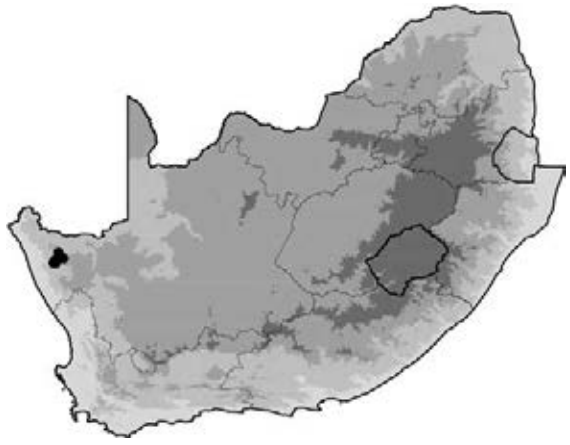
[*Vieusseuxia rivularis* Eckl.: 11 (1827), invalid name without description.]

[*Vieusseuxia juncea* Eckl. ex Steud.: 765 (1841), invalid name without description.]

Plants (100–)150–300 mm high, usually several branched. *Corm* 10–20 mm diam.; tunics of fine, pale fibres. *Stem* several-branched, finely velvety. *Leaves* several, basal and cauline, ± linear, lower exceeding stem, often trailing distally, channelled, glaucous, progressively shorter above. *Rhipidial spathes* green, apices sometimes brown, inner 20–40 mm long, outer ± $^{2}/_{3}$ as long. *Flowers* fugaceous, dull yellow to light brown, flushed with blue or purple, outer tepal limbs with yellow nectar guides at bases; outer tepals 20–25 mm long, limbs up to 18 mm long, lanceolate, weakly reflexed, inner slightly smaller, also weakly reflexed. *Filaments* 5–6 mm long, united in lower $^{1}/_{3}$; anthers 3–4 mm long, blue; pollen yellow or blue. *Ovary* ± ovoid, ± 4 mm long, exserted, style branches 7–8 mm long, crests 7–10 mm long, lanceolate. *Capsules* ± globose, soft walled, showing outline of seeds, pendent when mature, ± 12 × 8 mm. *Seeds* round to angular. *Chromosome number* 2*n* = 20. *Flowering time*: September and October.

Distribution and ecology: extending from Darling to the Cape Peninsula and eastward to Tulbagh and Swellendam in Western Cape, South Africa, with outlying populations in the Koebee Valley well to the north; typically on heavy soils derived from clays or granites and often in shade, in light bush or on forest margins.

Diagnosis: *Moraea vegeta* with its several characteristic glaucous leaves, velvety stem, and somewhat pendulous capsules is not easily confused with related species with similar flowers such as *M. papilionacea* and *M. gawleri* (the latter its closest relative according to molecular data). *Moraea indecora*, restricted to northern Namaqualand, has similar drooping capsules but rather different habit and flowers, and may be immediately related but molecular evidence on the question is lacking. *Moraea vegeta* is one of the few species of the genus that has adapted to human settlement and it is most common, almost weedy, in parts of the Constantia area of the Cape Peninsula where it thrives under the naturalised oaks and pines. *Moraea vegeta* is also one of few species of *Moraea* that is self-compatible and autogamous in the absence of insect-mediated pollen transfer. The dull-coloured and inconspicuous flowers are consistent with this mode of reproduction.



Distribution of ***Moraea vegeta***.

22. **Moraea indecora** *Goldblatt* in Annals of the Missouri Botanical Garden 63: 695 (1976a); Goldblatt: 57 (1986a). Type: South Africa, [Northern Cape], sandy flats, 8 km east of Nababeep, Oct. 1974, *Goldblatt 3053* (MO, holo.; NBG, PRE, S, iso.).

Plants large, 350–600 mm high, with collar of fine fibres around base. *Corm* deep seated, up to 250 mm below ground, compressed-globose, ± 20 mm diam.; tunics of fine fibres. *Stem* leafless for 100–150 mm above ground, several-branched. *Leaves* 3 to 6, inserted well above ground level, lower exceeding stem, linear, channelled, trailing distally, ± 10 mm wide. *Rhipidial spathes* green below, dry and brown distally, attenuate, inner 40–50 mm long, outer ± $^2/_3$ as long. *Flowers* fugaceous, large, yellow, outer tepal limbs with deeper yellow nectar guides edged with light brown at bases; outer tepals 25–40 mm long, limbs lanceolate, ± spreading, claw short, ± 5 mm long; inner tepals 22–35 mm long, spreading. *Filaments* ± 8 mm long, united near base; anthers 8–10 mm long, exceeding stigma lobes; pollen bright red. *Ovary* ovoid, 6–8 mm long, style branches ± 12 mm long, crests 15–20 mm long. *Capsules* subglobose, up to 15 × ± 8 mm diam., showing outline of seeds, ± nodding. *Seeds* ± globose, slightly angled by pressure. *Chromosome number* 2*n* = 16. *Flowering time*: October; flowers opening near midday and fading at sunset.

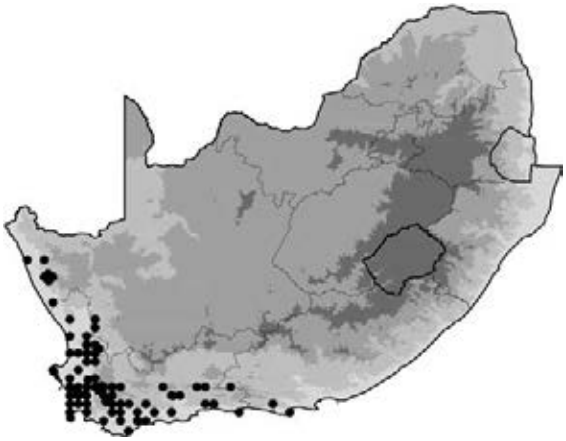
Distribution and ecology: local in central Namaqualand west and east of Springbok in Northern Cape, South Africa, and known from just four sites and evidently extremely rare; in deep gritty, granitic sand.

Diagnosis: *Moraea indecora* is distinctive in having several foliage leaves, all inserted well above the ground just below the first branch, large yellow flowers with bright red anthers that extend beyond the stigmas, and nodding capsules. The large corms of *M. indecora* are particularly deep seated, buried at least 200 mm below the ground, partly wedged in bed rock. The nodding, soft-walled capsules and fibrous corm tunics recall *M. vegeta*, perhaps its closest ally. The chromosome number of 2*n* = 16 is unusual in subg. *Moraea* (*x* = 10) but at least *M. papilionacea* (*n* = 9 and 8) also departs from that base number.

Distribution of ***Moraea indecora***.

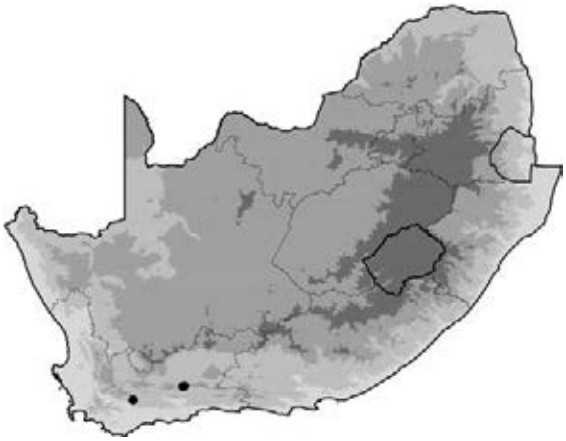
23. **Moraea gawleri** *Spreng.*, Systema vegetabilium 5: 462 (1828), as a new name for *M. crispa* (L.f.) Ker Gawl.: t. 1284 (1810a), illegitimate homonym not Thunb. (1787); Goldblatt: 689 (1976a) ; Goldblatt: 52 (1986a). *Iris crispa* L.f.: 98 (1782). *M. undulata* Ker Gawl.: 43 (1827), illegitimate new name for *M. crispa* (L.f.) Ker Gawl., not *M. undulata* (L.) Thunb. (1787). *Vieusseuxia crispa* (L.f.) Eckl.: 12 (1827). Type: South Africa, [Western Cape], hills near Cape Town, *Thunberg s.n.* (UPS–THUNB 1120, lecto., designated by Goldblatt: 689 (1976a); S, isolecto.).

Moraea decussata Klatt: 367 (1882). Type: South Africa, without precise locality, *Krauss 1447* (V, holo., presumed destroyed, authentic specimens at S).



Moraea crispa var. *rectifolia* Baker: 16 (1896). Type: South Africa, [Western Cape], Table Mtn, *H. Bolus 4718* (BOL, syn.).

Moraea sulphurea Baker: t. 7658 (1899). Type: South Africa, without precise locality or collector, illustration in Baker: t. 7658 (1899).



[*Vieusseuxia angustifolia* Eckl.: 12 (1827), invalid name without description.]

Plants 150–450 mm high. *Corm* 5–15 mm diam.; tunics light brown, with coarse, vertically ridged fibres. *Stem* few–several-branched, rarely simple, bearing acute sheathing leaves at upper nodes. *Foliage leaves* (1)2, lower basal, upper inserted from lowest aerial node, linear, ± falcate to weakly coiled, channelled, margins plane, undulate or crisped, mostly 3–6 mm wide. *Rhipidial spathes* green, becoming dry and brown apically, ± acute (attenuate), inner (8–)10–25 mm long, outer ± half as long. *Flowers* fugaceous, yellow, ± white, or pale brick-coloured, or combinations of these colours, outer tepal limbs ± spreading to reflexed to 40°, with yellow nectar guides at bases, often vanilla-scented; outer tepals 12–28 × 5–14 mm, claws slightly < $^1/_2$ as long as limbs, inner tepals 10–20 mm long, similarly oriented. *Filaments* ± 6 mm long, united for ± half their length; anthers 2–3 mm long, red or yellow; pollen red or yellow. *Ovary* narrowly ovoid, 2–3 mm long, style branches 5–8 mm long, mostly held above tepals, crests lanceolate. *Capsules* ± globose to broadly elliptic, 5–10 × 4–5 mm. *Seeds* angular prismatic. *Chromosome number* 2*n* = 20 + 0–6B (*x* = 10). *Flowering time*: July to September, to October in the south; opening midmorning, fading late afternoon.

Distribution and ecology: widespread and sometimes locally common in southwestern South Africa, from Namaqualand in Northern Cape to Humansdorp in Eastern Cape in the east; on clay flats and slopes, usually in renosterveld, occasionally in sandy habitats.

Distribution of ***Moraea gawleri***.

Distribution of ***Moraea vlokii***.

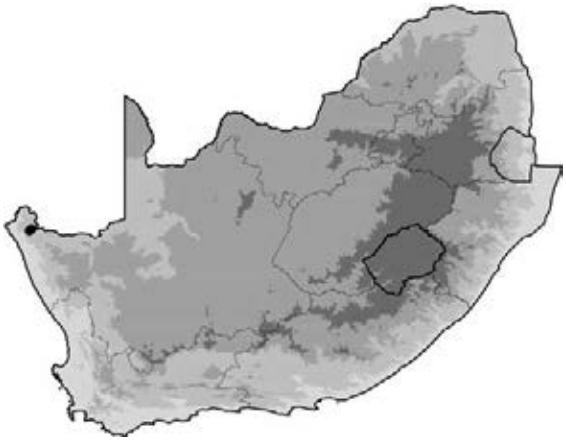
Diagnosis: a relatively small plant, *Moraea gawleri* is most easily recognised by its short rhipidial spathes, the inner seldom more than 20 mm long and the outer about half as long, and the two or rarely solitary foliage leaf, the blades sometimes loosely coiled and the margins undulate to crisped, although plane-margined forms (var. *rectifolia* Baker) occur, often in moister habitats. The small flowers are unexceptional except for their variable colouring, sometimes brick-red, white or yellow or combinations of these colours. Both morphology and molecular studies show the species is closely allied to other members of subg. *Moraea*, in particular *M. vegeta* and *M. vlokii*. This last species is almost identical to *M. gawleri* vegetatively but has flowers with reduced style branches that lack crests, and usually a solitary foliage leaf.

24. **Moraea vlokii** *Goldblatt* in South African Journal of Botany 58: 209 (1992). Type: South Africa, [Western Cape], Swartberg Mts, Gamkaspoort, near road to Grootberg, 18 Oct. 1985, *Vlok 1149* (NBG, holo.; K, MO, PRE, iso.).

Plants 140–330 mm high. *Corm* ± 12 mm diam.; tunics light brown, with coarse, vertically ridged fibres. *Stem* 2- to 6-branched, rarely simple, sheathing leaves at upper nodes ± 10 mm long. *Foliage leaves* 1(2), lower ± basal, upper when present inserted from lowest aerial node, linear, channelled, usually slightly longer than stem, mostly 1.5–2.5 mm wide, margins straight. *Rhipidial spathes* green, becoming dry and brown apically, ± acute, inner ± 10 mm long, outer slightly shorter. *Flowers* fugaceous, yellow, limbs of all tepals with yellow nectar guides at bases, ± spreading to reflexed to 30°, unscented; claws ascending, ± 2.5 mm long, forming a cup enclosing lower half of filaments; outer tepals ± 14 × 9 mm, inner tepals ± 10 × 7 mm. *Filaments* ± 7 mm long, united in a smooth column, diverging in upper 1 mm; anthers ± 2 mm long, yellow; pollen yellow. *Ovary* narrowly obovoid, ± 2 mm long, style branches ± 2 mm long, appressed to and reaching upper $^1/_3$ of anther, forked apically, without crests. *Capsules* ± globose to broadly ovoid, ± 4 mm long. *Seeds* angled. *Chromosome number* $2n = 20$. *Flowering time*: September to mid-October; opening early morning, fading ± 13:00.

Distribution and ecology: known from two sites some 150 km apart in Western Cape, South Africa, one in the Great Swartberg near Gamkaskloof and the other in the Waboomsberg between Montagu and Ouberg Pass (other populations undoubtedly exist but the species is inconspicuous and easily overlooked even in bloom just a few mornings a year); in stony, sandstone ground.

Diagnosis: closely resembling the common and widespread *Moraea gawleri* in all vegetative features, notably the strongly vertically ribbed corm tunics, and short rhipidial spathes with the outer much shorter than the inner, *M. vlokii* usually has a single foliage leaf (occasionally a second much shorter one), always with straight margins, and pale yellow flowers with short tepal claws less than one quarter as long as the limbs, and vestigial style branches shorter than and concealed by the anthers and lacking crests. By contrast, *M. gawleri* has tepal claws only slightly shorter than the limbs and style branches with prominent, petaloid crests. Both species have broadly obovoid to almost globose capsules. Flowers open in early morning and collapse at ± 13:00, whereas those of *M. gawleri* open in mid- to late morning and last through late afternoon.



25. **Moraea namaquamontana** *Goldblatt* in Annals of Kirstenbosch Botanic Gardens 14: 50 (1986a). Type: South Africa, [Northern Cape], Richtersveld, Stinkfontein Mtns, *Oliver, Tölken & Venter 627* (PRE, holo.; NBG, iso).

Plants 220–350 mm high. *Corm* 10–14 mm diam.; tunics brown, with coarse, vertically ridged fibres. *Stem* 3- to 6-branched, rarely simple, with short, partly sheathing bracts subtending branches. *Leaves* several (up to 9), mostly basal, ± falcate to trailing, often loosely twisted, widely channelled, 10–16 × 10–15 mm, margins undulate. *Rhipidial spathes* ± acute, inner 22–28 mm long, outer ± $^1/_3$ as long. *Flowers* fugaceous, yellow, ± orange outside, outer tepal limbs ± spreading to reflexed to 40°, with

deep yellow nectar guides at bases; outer tepals 22–28 × ± 12 mm, claws 8–9 mm long, inner tepals 23–25 mm long, similarly oriented. *Filaments* 6–7 mm long, united ± in lower half; anthers ± 4 mm long, red; pollen red. *Ovary* narrowly ovoid, 3.5–4.0 mm long, style branches ± 7 mm long, crests lanceolate, 9–13 mm long. *Capsules* ± globose, 5–7 × ± 5 mm. *Seeds* angular, up to 2 mm long. *Chromosome number* 2*n* = 20. *Flowering time*: September; flowers opening midmorning, fading late afternoon.

Distribution and ecology: exceedingly rare, *Moraea namaquamontana* is known from a few isolated populations in the Richtersveld in Northern Cape, South Africa; evidently on stony slopes.

Diagnosis: with flowers typical of the genus, *Moraea namaquamontana* has moderate-sized, yellow flowers with outer tepals up to 28 mm long and inner up to 25 mm long, both whorls with half reflexed limbs. It stands out particularly in having several, mostly basal, relatively broad leaves, falcate and slightly twisted. The stems usually have one or two branches, these subtended by short, partly sheathing bract-like leaves. The

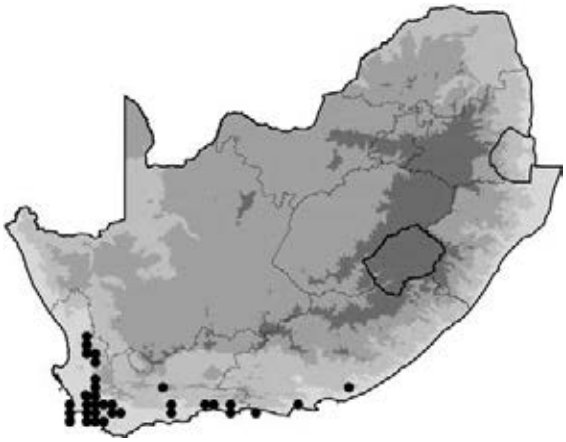
Distribution of ***Moraea namaquamontana***.

fairly short rhipidial spathes, the outer about one third as long as the inner, recall those of *M. gawleri* and the corms of the two species are similar, having relatively coarse fibres with prominent vertical members.

Sect. 4. **Polyphyllae** *Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 43: 36 (2013). Type: *M. ramosissima* (L.f.) Ker Gawl.

Plants usually many-branched. *Corm* tunics brown, fragmenting irregularly. *Foliage leaves* several to many, broad and widely channelled. *Flowers* yellow; filaments united in lower half or only at base; style branches and crests well developed.

26. **Moraea ramosissima** *(L.f.) Druce* in Botanical Society Exchange Club of the British Isles 4: 636 (1916); Goldblatt: 687 (1976a); Goldblatt: 46 (1986a). *Iris ramosissima* L.f.: 99 (1782). *Iris ramosa* Thunb.: 18 (1782b), illegitimate superfluous name for *I. ramosissima* L.f. *Moraea ramosa* Ker Gawl.: t. 771 (1804c), illegitimate superfluous name. *Vieusseuxia ramosa* Eckl.: 12 (1827), illegitimate superfluous name. Type: South Africa, [Western Cape], sandy places in the Swartland, *Thunberg s.n.* [UPS–THUNB 1169, lecto., designated by Goldblatt: 687 (1976a)].



Moraea bulbifera Jacq.: 38, t. 197 (1797). Type: South Africa, without precise locality or collector, illustration in Jacq.: 38, t. 197 (1797).

[*Freuchenia bulbifera* Eckl.: 14 (1827), invalid name without description.]

[*Vieusseuxia freuchenia* Steud.: 765 (1841), invalid name.]

[*Moraea racemosa* Drège ex Baker: 131 (1877), invalid only in synonymy.]

Plants large, 500–1 200 mm. *Corm* 20–30 mm diam., with numerous small cormlets round base, enclosed in a network of hard, spiny roots. *Stem* branched repeatedly from base to apex, bearing green sheathing leaves with margins free to base. *Foliage leaves* many, in 2 ranks, channelled, falcate, up to 300 × 15 mm. *Rhipidial spathes* green with dry, acute to attenuate apices; inner spathe 20–25 mm long, outer much shorter, < 10 mm long. *Flowers* fugaceous, yellow, outer tepal limbs with deeper yellow nectar guides at bases, tepal limbs reflexed 35°–45°; outer tepals ± 30 × 15 mm, inner slightly smaller. *Filaments* 12–15 mm long, free, sometimes contiguous near bases; anthers ± 10 mm long; pollen yellow or red. *Ovary* broadly ovoid, ± 4 mm long, style branches 20–25 mm long, crests narrowly triangular, 15–20 mm long. *Capsules* ± globose, truncate above, ± 6 mm diam.

Distribution of ***Moraea ramosissima***.

Seeds angled. *Chromosome number* 2*n* = 20. *Flowering time*: October to December, typically late blooming; flowers open ± 11:00 and fade in late afternoon.

Distribution and ecology: a widespread species of the Cape Floristic Region of South Africa, extending from the Gifberg Plateau in the north of Western Cape to the Cape Peninsula in the south and to Grahamstown in Eastern Cape in the east; in sandy soils, both on mountains and flats, most often in moist sites, thus near streams or south-facing slopes, flowering only after fire.

Diagnosis: *Moraea ramosissima* is one of the taller species in the genus, plants often exceeding 1 m in height, and exhibits such ancestral features as multiple foliage leaves and an unspecialised yellow flower. Notably the filaments are free or barely united at the base, evidently a derived condition. Peculiar to the species are the hard, spiny roots that enclose the corm and hundreds of cormlets produced around the base. The spiny roots probably have a protective function but they evidently do not prevent massive depredation by baboons and porcupines that uproot large numbers of plants in search of the edible corms. The survival of such populations is assured by the production of cormlets which are shed in large numbers from the base of the main corm and also from the lower aerial nodes. The corm tunics, often decayed at flowering, consist of firm, leathery, brown layers that split from the base.

Its immediate relationships are with the south Namibian and Richtersveld species, *Moraea garipensis*, also relatively tall with multiple leaves but with the filaments united in the lower half and unusually long style branches but short style crests. Molecular study has confirmed their immediate sister relationship.

27. **Moraea garipensis** *Goldblatt* in Annals of Kirstenbosch Botanical Garden 14: 48 (1986a). Type: Namibia, Orange River Valley near Aussenkehr, rock crevices, *Goldblatt 7153* (MO, holo.).

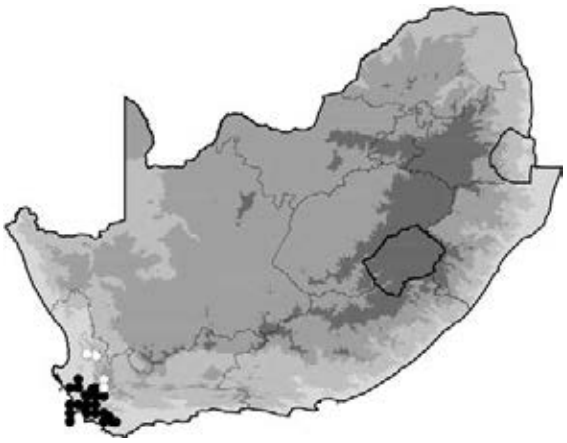
Plants 250–500 mm high. *Corm* 15–20 mm diam.; tunics of brown, leathery layers splitting from base and near apex. *Stem* mostly 2- to 6-branched, rarely simple, bearing acute sheathing leaves at upper nodes. *Foliage leaves* several, lowermost basal, about as long as stem, upper leaves inserted on stem above ground, ± linear, ascending, channelled, 8–10 mm wide, margins straight. *Rhipidial spathes* ± acute or rarely attenuate, inner 25–35 mm long, outer $^{2}/_{3}$ to ± as long. *Flowers* fugaceous, yellow, outer tepal limbs half to almost fully reflexed, with scattered dark spotting at bases; outer tepals ± 36 × 15 mm, claws ± 12 mm long, inner tepals 16–18 × 4–6 mm, suberect. *Filaments* ± 16 mm long, united for ± half their length; anthers ± 8 mm long, red, held above tepal limbs; pollen orange. *Ovary* ± globose, ± 4 mm long, exserted; style branches ± 12 mm long, crests wedge-shaped, ± 5 mm long. *Capsules* broadly obovoid, 8–10 mm long. *Seeds* angular, ± 2 mm long, with loose testa. *Chromosome number* 2*n* = 20. *Flowering time*: July, possibly also August; flowers opening ± 14:00, fading at sunset.

Distribution of ***Moraea garipensis***.

Distribution and ecology: known from two sites, the type locality in southern Namibia and another in the northern Richtersveld of Northern Cape, South Africa; in rock outcrops with corms wedged in rock crevices.

Diagnosis: *Moraea garipensis* is distinguished by its tall stature and normally several-branched stem, and relatively large, yellow, fugaceous flowers, all unique in species from Namibia or the adjacent Richtersveld in Northern Cape. The flowers are also somewhat unusual in having relatively long filaments, ± as long as the outer tepal claws, and the anthers in consequence are presented above the limbs of the outer tepals, where the bright orange pollen is conspicuously displayed. The several leaves and branched stem recall the Cape species, *M. ramosissima,* and molecular phylogenetic studies confirm their immediate relationship.

Provisionally assigned to sect. *Polyphyllae*



28. **Moraea papilionacea** *(L.f.) Ker Gawl.* in Curtis's Botanical Magazine 20: t. 750 (1804d); Goldblatt: 699 (1976a); Goldblatt: 62 (1986a); Goldblatt *et al*: 73 (2015). *Iris papilionacea* L.f.: 98 (1782). *Xiphion papilionaceum* (L.f.) Schrank: 174 (1822). Type: South Africa, [Western Cape], hills near Cape Town, *Thunberg s.n.* [UPS-THUNB 1145, lecto., designated by Goldblatt: 699 (1976a)].

Plants 60–160 mm high. *Corm* 8–13 mm diam.; tunics of flat, brown, woody sections separated by cross fibres, ultimately decaying into fibrous mass. *Stem* roughly hairy to ± smooth, usually (1)2 internodes long above insertion of basal foliage leaf or leaves, several-branched from base or from upper node (rarely unbranched), basal internode elongating in fruit. *Foliage leaves* 2 to 4, linear to falcate but spreading distally,

sometimes loosely twisted, lowermost ± basal or inserted at first above ground node, channelled below, ± as long or longer than stem, finely to roughly hairy on veins, rarely smooth, occasionally veins prominently thickened, intervein areas ± smooth or papillate, margins undulate, long-ciliate. *Rhipidial spathes* often with dry brown apices or entirely green, acute, usually hairy on veins and margins, inner 24–30 (subsp. *Glabrescens*) or (35–)40–60 (subsp. *Papilionacea*) mm long, outer usually slightly shorter than inner, rarely ± 1/2 as long, sometimes not sheathing distally. *Flowers* fugaceous, yellow or salmon-pink, occasionally yellow with salmon-pink inner tepals and style branches, outer tepal limbs with yellow nectar guides at bases edged green or red, ± spreading, sweetly scented; outer tepals 20–30 × 8–9 mm, claws suberect, inner tepals lanceolate, 19–23 × 10 mm. *Filaments* 3–6 mm long, united in lower 1/3–1/2; anthers 3–5 mm long, dark purple; pollen red or yellow. *Ovary* narrowly obovoid, smooth or finely velvety, 3–6 mm long, exserted; style branches 5–8 mm long, crests lanceolate, 6–7 (subsp. *Glabrescens*) or 10–15 (subsp. *Papilionacea*) mm long. *Capsules* broadly elliptic-oblong, 5–9 × ± 5 mm long. *Seeds* angular, reticulate. *Chromosome number* 2*n* = 18, 16. *Flowering time*: August to late September.

Distribution and ecology: endemic to Western Cape, South Africa, extending from the northern Cederberg to Ceres (subsp. *glabrescens*) and from Porterville south to the Cape Peninsula and east to Caledon and Hermanus (subsp. *papilionacea*); on flats and slopes in clay, clay loam or granitic gravel soils or in peaty sand.

Diagnosis: *Moraea papilionacea* is readily distinguished by the hairy to velvety stems and usually hairy undersides of the leaves with long-ciliate margins, and its fugaceous, yellow or deep salmon-pink flowers, sometimes pink with yellow style branches. Plants have at least two and sometimes three or four foliage leaves, the two longest inserted at the base or at the first above-ground node. The remaining foliage leaves are much shorter, the uppermost subtending the branch or branches at the uppermost aerial node. Plants are typically branched and the stem consists of just two well-developed internodes above the lowermost leaves. Nested among species with the ancestral base for the genus, *x* = 10, *M. papilionacea* is dysploid , with 2*n* = 18 in subsp. *papilionacea* and 2*n* = 16 in subsp. *glabrescens*. Its relationships are uncertain and molecular study has failed to provide a satisfactory placement. It has provisionally been assigned to sect. *Polyphyllae* of subg. *Moraea* although the brown corm tunics appear to better match those of subg. *Umbellatae.*

Distribution of ***Moraea papilionacea*** subsp. ***papilionacea***, ●; subsp. ***glabrescens***, ○.

We do not recognise var. *maythamiae* G.J.Lewis, named for plants with salmon-pink flowers from the Cape Peninsula with subglabrous leaves and flowers opening in the late afternoon. The type form, also from the Cape Peninsula, has yellow flowers opening in late morning. A few populations of subsp. *papilionacea* consist of plants with either yellow or salmon-pink flowers, some with yellow tepals and salmon-pink style branches.

Key to subspecies

1a Flowers larger, often salmon-pink, the outer tepals 25–30 mm long and inner 22–23 mm long . . . . . 28a. subsp. *papilionacea*

1b Flowers smaller, pale yellow, the outer tepals 20–22 mm long and inner 19–20 mm long. . . . . 28b. subsp. *glabrescens*

28a. subsp. **papilionacea**

Moraea pilosa J.C.Wendl.: 42 (1798). Type: unknown.

Iris hirsuta Licht. ex Roem. & Schult.: 478 (1817). *Moraea hirsuta* (Licht. ex Roem. & Schult.) Ker Gawl.: 43 (1827). Type: South Africa, [Western Cape], Tulbagh District, *Lichtenstein s.n.* (location unknown, possibly originally at B, now lost).

Moraea papilionacea var. *maythamiae* G.J.Lewis in Salter *et al.*: 37 (1949). Type: South Africa, [Western Cape], Cape Town, Rondebosch Common, *Salter 8989* (SAM, lecto., designated by Goldblatt: 699 (1976a); BOL, NBG, isolecto.).

[*Vieusseuxia intermedia* Eckl.: 12 (1827), invalid name without description.]

[*Vieusseuxia nervosa* Eckl.: 12 (1827), invalid name without description.]

Plants 100–160 mm high. *Stem* usually roughly hairy, or ± glabrous, usually (1)2 internodes long above insertion of basal foliage leaf or leaves, several-branched from base or from upper node (rarely unbranched), basal internode elongating in fruit. *Foliage leaves* 2 to 4, sometimes loosely twisted, lowermost ± basal, channelled below, ± as long as or longer than stem, finely to roughly hairy on veins or sometimes glabrous, margins undulate, long-ciliate. *Rhipidial spathes* usually hairy on veins and margins, inner (35–)40–60 mm long, outer usually slightly shorter than inner, rarely ± 1/2 as long, sometimes

not sheathing distally. *Flowers* yellow or salmon-pink, occasionally yellow with salmon-pink inner tepals and style branches, outer tepal limbs with yellow nectar guides at bases edged green or red, ± spreading; outer tepals 25–30 × 8–9 mm, inner tepals lanceolate, ± 23 × 10 mm. *Filaments* 4–6 mm long; anthers 3–5 mm long, dark purple; pollen red or yellow. *Ovary* smooth or finely velvety, 5–6 mm long, style branches 6–8 mm long, crests 10–15 mm long. *Capsules* broadly elliptic-oblong, 7–9 × ± 5 mm long. *Chromosome number* 2*n* = 18. *Flowering time*: August to late September.

Distribution and ecology: extending from Porterville south to the Cape Peninsula and east to Caledon and Hermanus; on flats and slopes in clay, clay loam or granitic gravel soils.

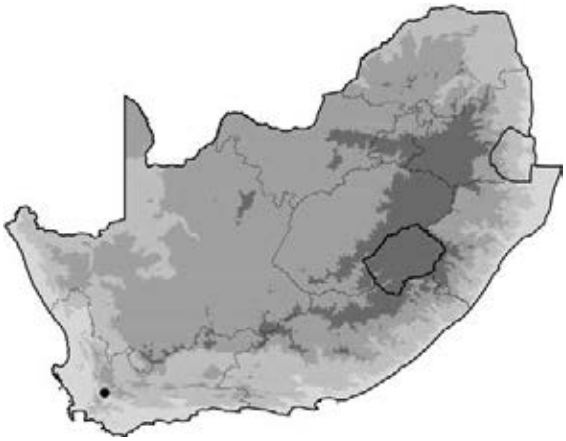
Diagnosis: subsp. *papilionacea* is distinguished from subsp. *glabrescens* by the larger flowers, the outer tepals 25–30 mm long and inner 22–23 mm long. The flowers are often salmon-pink whereas those of subsp. *Glabrescens* are consistently yellow.

An unusual morph of subsp. *papilionacea* occurring only in seasonally inundated habitats in the near southwestern corner of Western Cape, has narrow, hairless leaves, 2–3 mm wide, hairless spathes and sparsely hairy stems, recalling those of subsp. *glabrescens* but the flowers are typical of *M. papilionacea*, although consistently salmon-pink as far as known. It is not clear whether these plants merit taxonomic recognition but they are currently regarded as an ecological race.

28b. subsp. **glabrescens** *Goldblatt & J.C.Manning* in Goldblatt et al. in South African Journal of Botany 99: 73 (2015) Type: Western Cape, Cederberg, near top of Cederberg Pass, Driehoeks River Valley, along seeps and streams, 28 Sept. 1981, *Goldblatt 6408* (NBG, holo.; K, MO, iso.).

Plants 60–100 mm high. *Stem* ± inclined, with basal internode extended up to 30 mm above ground, leaves and branches crowded at first aerial node, sparsely hairy or evidently glabrous. *Leaves* 2 or 3, then uppermost much smaller, falcate, lowermost inserted shortly above ground, narrowly channelled, smooth, main veins and margins thickened, abaxially papillate between veins, margins sparsely long-ciliate. *Rhipidial spathes* subacute, glabrous, inner 24–30 mm long, outer ± $^1/_2$ as long. *Flowers* pale yellow, outer tepal limbs with deep yellow nectar guides at bases edged dark brown, scent unknown; outer tepals 20–22 × 9 mm, spreading to weakly reflexed, inner tepals lanceolate, 19–20 × 5 mm, limb spreading. *Filaments* 3–4 mm long; anthers ± 3.5 mm long; pollen yellow. *Ovary* smooth, 3.0–4.5 mm long; style branches ± 5 mm long, crests 6–7 mm long. *Capsules* ovoid, 5–8 × ± 3 mm long. *Chromosome number* 2*n* = 16. *Flowering time*: late September to mid-October.

Distribution and ecology: restricted to middle and higher elevations in the Cederberg and Cold Bokkeveld Mtns as far south as Ceres in Western Cape; on wet, peaty, sandy flats somewhat marshy in winter, flowering for up to three or four years after fire after which their habitat becomes overgrown with taller grasses and restiads.



Diagnosis: subsp. *glabrescens* has the same distinctive habit and corms as subsp. *papilionacea* and is recognised by its smaller, consistently pale yellow flowers, the outer tepals 20–22 × 9 mm and the inner 19–20 × 5 mm. Flowers of subsp. *papilionacea* have either yellow or salmon-pink flowers (or sometimes a combination of both colours) with outer tepals 25–30 × 8–9 mm and inner ± 23 × 10 mm. Similarly the rhipidial spathes, style branches, crests and capsules are consistently smaller than those of subsp. *papilionacea*. Both species have villous stems but those of subsp. *glabrescens* are sparsely so, becoming ± smooth with age, whereas typical *M. papilionacea* has prominently hairy stems. Equally significant, the leaves of subsp. *glabrescens* are narrowly channelled, smooth beneath with a pair of veins and the margins prominently thickened and the margins are ciliate. Curiously, the intervein epidermis is minutely papillate on the underside (under 10× magnification), an unusual feature, occasionally weakly developed in subsp. *papilionacea*. Undersides of the leaves of subsp. *papilionacea* are usually prominently hairy on the veins, which are seldom thickened, and the leaf blades are shallowly channelled to ± flat in the distal half, slightly twisted and have undulate margins rather than being channelled throughout. Chromosome number supports the recognition of subsp. *glabrescens* which has a diploid number of 2*n* = 16 while several counts for subsp. *papilionacea* are 2*n* = 18.

29. **Moraea nubigena** *Goldblatt* in Annals of the Missouri Botanical Garden 63: 749 (1976a); Goldblatt: 68 (1986a). Type: South Africa, [Western Cape], Worcester District, near Fonteintjiesberg hut, 1 400 m, Oct. 1976, *Goldblatt 4208* (MO, holo.; K, NBG, PRE, S, iso.).

Plants tiny, 30–50 mm high at anthesis, taller in fruit. *Corm* globose, 8–10 mm diam.; tunics of fine, pale fibres accumulating in a thick mass. *Stem* unbranched, 2 internodes long, middle node bearing a short sheathing, bract-like leaf ± 10 mm long. *Foliage leaf* solitary, inserted at ground level, somewhat succulent, channelled, falcate, 30–40 mm long. *Rhipidial spathes* firm, often flushed red, entirely sheathing; inner spathe 12–14 mm long, outer slightly shorter. *Flowers* fugaceous, blue, outer tepal limbs with small, yellow nectar guides at bases and claws streaked with red transverse marks; outer tepals 10–14 mm long, limbs 6–8 mm long, reflexed to ± 35°; inner tepals 8–10 mm long, limbs also reflexed. *Filaments* ± 3 mm long, united in smooth column in lower $^2/_3$, diverging above; anthers 1.5–2.0 mm long; pollen white. *Ovary* ovoid, ± 2 mm long, style branches broad, 3 mm long, crests erect, ± 2 mm long. *Capsules* subglobose, ± 5 mm diam. *Seeds* unknown. *Chromosome number* 2*n* = 20. *Flowering time*: late September to mid-October.

Distribution and ecology: known only from Fonteintjiesberg at ± 1 400 m in the Brandwacht Mtns near Worcester in Western Cape, South Africa; on wet, moss-covered sandstone pavement close to streams.

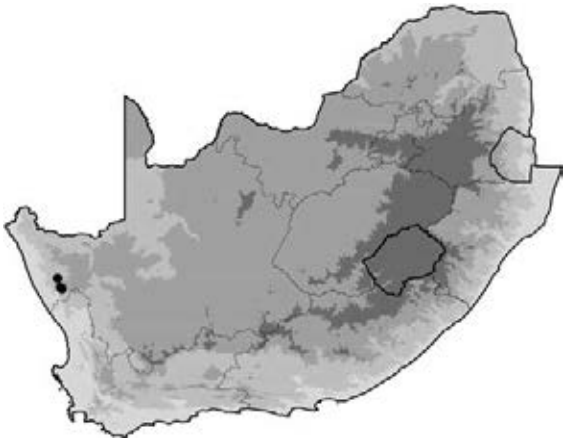
Diagnosis: *Moraea nubigena* is immediately recognised by its low stature, no more than 50 mm high when in bloom, an unbranched stem, solitary foliage leaf, and blue, fugaceous flowers. The flower itself is unexceptional and helps little in understanding its relationships. The species was originally assigned to sect. *Polyanthes* (now subg. *Polyanthes*), but its chromosome number $2n = 20$ is inconsistent with that placement. Molecular study places *M. nubigena* in an isolated position but embedded among species with the same chromosome number. It is provisionally placed in sect. *Polyphyllae* of subg. *Moraea*, where it is notable for being the only blue-flowered species of the subgenus.

Distribution of ***Moraea nubigena***.

Subg. 5. **Galaxia**

Subg. **Galaxia** *(Thunb.) Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 43: 37 (2013). *Galaxia* Thunb.: 50 (1782a). *Moraea* sect. *Galaxia* (Thunb.) Goldblatt: 376 (1998). Type: *G. graminea* Thunb., lecto., designated by Phillips: 213 (1951) = *M. fugacissima* (L.f.) Goldblatt

Plants acaulescent at anthesis; corm tunics pale, finely to coarsely fibrous. *Leaves* several, often plane and ± prostrate, narrowly channelled or terete. *Rhipidial spathes* hardly or not at all distinct from leaves, enclosing one flower. *Flowers* fugaceous, sessile, with solid perianth tube, yellow, white, or shades of pink to purple; tepals mostly without narrow claws (not *M. kamiesmontana*); style branches much reduced with crests obscure, stigma lobes entire or irregularly fringed. *Capsules* ± globose. *Basic chromosome number* $x = 9$.



Individual flowers are subtended by two foliar structures, a shorter inner and longer outer one, both with closed sheaths and inserted a short distance below the base of the ovary, i.e., at the base of a pedicel. The flower and these two foliar structures share a short stalk, a branch or peduncle. At the base of the branch there is a scale-like membranous prophyll with two keels.

Ser. **Unguiculatae** *Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 43: 37 (2013). Type: *Moraea kamiesmontana* (Goldblatt) Goldblatt

Flowers pink with white cup; tepals prominently clawed; filaments partly united; style and stigma lobes undivided.

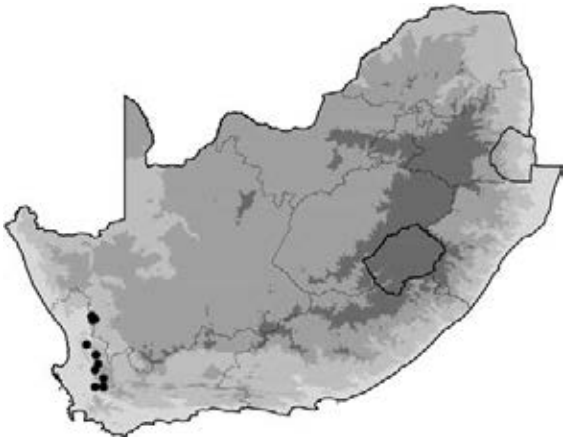
30. **Moraea kamiesmontana** *(Goldblatt) Goldblatt* in Novon 8: 377 (1998). *Galaxia kamiesmontana* Goldblatt: 1084 (1984b). Type: South Africa, [Northern Cape], Namaqualand, Kamiesberg Mtns, Rooiberg, shallow soil on rock shelves, *Goldblatt 5560* (MO, holo.; K, NBG, PRE, S, WAG, iso.).

Plants tiny, up to 20 mm high when in bloom. *Corm* ovoid, 3–5 mm diam.; tunics of light brown, netted fibres with prominent vertical ribs. *Stem* underground at flowering, reaching up to 50 mm above ground in fruit. *Leaves* 2 to 5, falcate, shallowly channelled to plane, up to 30 × 1 mm, acute, with broad transparent sheathing bases below ground, margins smooth. *Rhipidial spathes* hardly distinct from leaves. *Flowers* fugaceous, bell-shaped, light purple with yellow claws and nectar guides at bases of tepal limbs; perianth tube 5–10 mm long, cylindric; tepals 10–12 mm long, clawed, claws ascending, forming a narrow cup including filament column, limbs extended horizontally, outer up to 5 mm wide, inner up to 4 mm wide. *Filaments* ± 5 mm long, united below in a cylindric column, free and diverging in upper 0.5–1.0 mm, yellow; anthers just < 2 mm long, diverging, yellow.

Distribution of ***Moraea kamiesmontana***.

Ovary oblong-cylindric, ± 3 mm long, style diverging into three lobes at midanther level, stigma lobes shorter than or barely overtopping anthers, margins entire, minutely ciliate, incurving opposite anther, radial margins slightly raised. *Capsules* 6–7 mm long. *Seeds* angular, < 0.5 mm diam. *Chromosome number* 2*n* = 18. *Flowering time*: May and June.

Distribution and ecology: local at higher elevations in the Kamiesberg of central Namaqualand in Northern Cape, South Africa, and currently known only from above 1 200 m elevation on Rooiberg and Sneeukop; in shallow, seasonally waterlogged places on rocky pavement.



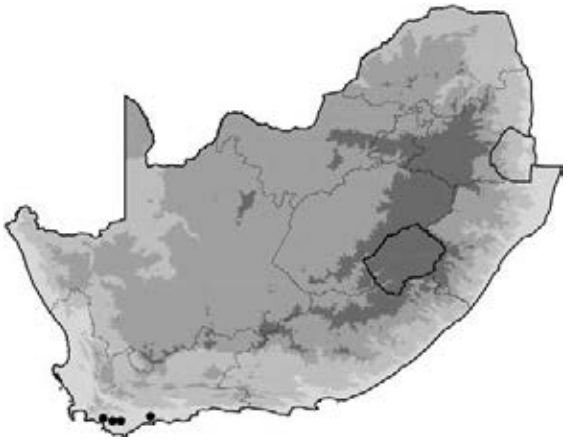
Diagnosis: *Moraea kamiesmontana* stands out in subg. *Galaxia* not only in its particularly small size but in the structure of its flowers. In other species of the subgenus the flowers have flaccid, widely cupped tepals that lack distinct claws, but in *M. kamiesmontana* the ascending tepal claws form a narrow cup enclosing the filaments and the limbs are sharply flexed at right angles to the cup, thus extended horizontally. The chromosome number, 2*n* = 18, is the ancestral number for the subgenus, and we interpret *Moraea kamiesmontana* as a relict species, surviving in specialised, seasonally moist, montane habitats.

Ser. **Eurystigma** *(Goldblatt) Goldblatt* in Novon 8: 377 (1998). *Galaxia* subg. *Eurystigma* Goldblatt: 398 (1979a). *Galaxia* ser. *Eurystigma* (Goldblatt) Goldblatt: 376 (1998). Type: *G. versicolor* Salisb. ex Klatt = *Moraea versicolor* (Salisb. ex Klatt) Goldblatt

Flowers pink to purple or white (yellow or orange in *M. citrina*); filaments united entirely or free and diverging distally; style branches with stigma lobes undivided.

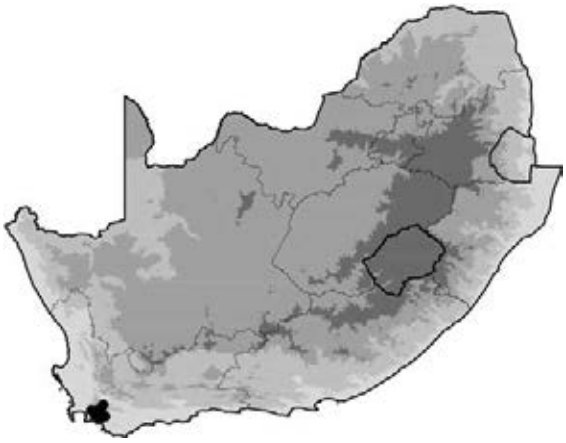
31. **Moraea citrina** *(G.J.Lewis) Goldblatt* in Novon 8: 377 (1998). *Galaxia citrina* G.J.Lewis: 4 (1938); Goldblatt: 405 (1979a). Type: South Africa, [Western Cape], between De Keur and Gydo, *Martin s.n.* (BOL, holo.; NBG, iso.).

Plants up to 50 mm high. *Corm* 8–12 mm diam.; tunics coarsely fibrous with prominent vertical ribs. *Stem* underground at flowering. *Foliage leaves* channelled, lowermost 30–70 mm long, spreading or lowermost prostrate, upper shorter, smooth, glossy, margins hyaline, minutely ciliate. *Rhipidial spathes* not distinct from leaves; with 3 to 5 flowers per plant. *Flowers* fugaceous, ± salver-shaped with tepals cupped below, usually uniformly yellow, sometimes with blackish markings at edge of floral cup, rarely orange-red with yellow centre; perianth tube 13–28 mm long; tepals ± equal, obovate, mostly 18–28 × 9–11 mm. *Filaments* united in a column up to 6 mm long; anthers sessile, 3.5–5.0 mm long, yellow; pollen yellow. *Ovary* ovoid, ± 4 mm long; style straight, dividing above anther tips, stigma lobes entire. *Capsules* and *seeds* unknown. *Chromosome number* 2*n* = 16, 14, 34. *Flowering time*: mainly August to late September.



Distribution of ***Moraea citrina***.

Distribution and ecology: extending from the Bokkeveld Mtns in Northern Cape, South Africa, south through the Cederberg to Gydo Pass near Ceres in Western Cape; typically on sandy ground, sometimes on shallow soil over sandstone pavement.



Diagnosis: the only yellow-flowered species of ser. *Eurystigma*, *Moraea citrina* has relatively large flowers with tepals usually 20–28 mm long and rarely wider than 10 mm. The glossy leaves are channelled and have straight margins. It is one of just two species of the series with sessile anthers, the other being *M. versicolor*. Orange-flowered plants are known from the Bokkeveld Mtns at the northern end of its range. Hybrids have been recorded near Ceres between *M. citrina* and *M. variabilis*. These plants have larger flowers in a range of colours, mostly pale orange, not recorded in either species.

32. **Moraea melanops** *Goldblatt & J.C.Manning* in Novon 10: 19 (2000a). Type: South Africa, Western Cape, Bredasdorp District, Fairfield Farm, 18 Aug. 1995, *Goldblatt & Nänni 10249* (NBG, holo.; K, MO, iso.).

Plants acaulescent, up to 40 mm high. *Corm* globose, asymmetric below, 10–15 mm diam.; tunics of cartilaginous layers, with age decaying into fibres arranged in herringbone pattern, or with hard vertical claw-like ribs separated by fine cross fibres, accumulating in a dense mass around base. *Stem* underground at flowering. *Leaves* several, lowermost inserted below ground shortly above corm, others in a basal cluster, ± prostrate, obovate to lanceolate, shallowly channelled, 20–35 × 10–14 mm, slightly undulate, margins occasionally crisped. *Rhipidial spathes* not distinct from leaves; with 2 to 5 flowers per plant. *Flowers* fugaceous, ± salver-shaped with tepals shallowly cupped, light to dark purple, dark purple-black at bases; perianth tube cylindric, 18–27 mm long; tepals subequal, laxly spreading, obovate, ± 16 × 9–10 mm. *Filaments* ± 3 mm long, free or united in lower half, initially erect and contiguous, later diverging, yellow; anthers ± 3 mm long, purple; pollen yellow. *Ovary* oblong-cylindric, ± 4 mm long; style straight,

Distribution of ***Moraea melanops***.

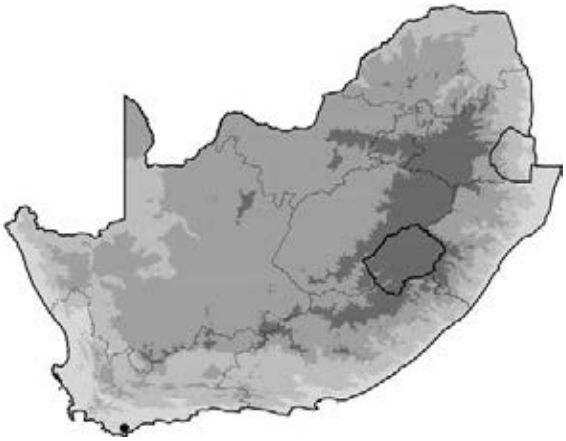
Distribution of ***Moraea barnardiella***.

reaching ± 1 mm beyond anther tips, dividing into three short lobes, initially upright and appressed to one another, later spreading and lying just above anthers. *Capsules* and *seeds* unknown. *Chromosome number* 2*n* = 16. *Flowering time*: late July to mid-September.

Distribution and ecology: a rare endemic of Western Cape, South Africa, occurring in the Caledon and Bredasdorp Districts, from the southern slopes of Shaw's Mtns to the Potberg; in heavy clay soil in renosterveld, flowering well only in disturbed sites or after fire.

Diagnosis: the purple flower with a dark centre and shallowly cupped tepals recall particularly *Moraea barnardiella*, and it is to that species that *M. melanops* is evidently most closely allied. Vegetatively, they appear to be identical but *M. melanops* has free to partly united filaments diverging distally and the style exceeds the anthers and has fairly narrow branches, whereas *M. barnardiella* has filaments free in the upper $^1/_3$ and strongly diverging above, and the style divides opposite the apex of the filament column, with broader branches than in *M. melanops*.

33. **Moraea barnardiella** *Goldblatt* in Novon 8: 377 (1998), as a new name for *Galaxia barnardii* Goldblatt: 398 (1979a) [not *M. barnardii* L.Bolus (1933)]. Type: South Africa, [Western Cape], Caledon Division, clay slopes between Eseljacht and Queen Anne, *Goldblatt 2499* (MO, holo.; BOL, K, NBG, PRE, S, WAG, iso.).



Plants acaulescent, up to 50 mm high, including flowers. *Corm* up to 18 mm diam.; tunics of brown, knotted fibres. *Stem* underground at flowering. *Leaves* lowermost inserted below ground shortly above corm, others in a basal cluster, channelled, 40–60 mm long, margins undulate to slightly crisped, minutely ciliate. *Rhipidial spathes* not distinct from leaves; with 2 to 5 flowers per plant. *Flowers* fugaceous, salver-shaped, purple-pink with dark purple-black centre; perianth tube 15–30 mm long, cylindric, purple-black; tepals spreading from base, broadly obovate, obtuse or bluntly acute, mostly 18–25 mm long, outer 10–14 mm wide, inner tepals slightly narrower. *Filaments* 4.0–6.5 mm long, united below in cylindric column, free and diverging in distal 1–2 mm; anthers 3.0–3.5 mm long, curving upward distally, exceeding style branches, yellow; pollen yellow. *Ovary* ovoid, ± 4 mm long; style dividing opposite apex of filament column, branches short, bearing broad, erect, undulate stigmatic lobes appressed to each other. *Capsules* and *seeds* unknown. *Chromosome number* 2*n* = 16. *Flowering time*: late August to late September.

Distribution and ecology: restricted to the Caledon District of Western Cape, South Africa, from near Villiersdorp to Caledon; on shale and clay flats and slopes.

Diagnosis: *Moraea barnardiella* is recognised by the purple flowers with a purple-black centre and spreading rather than cupped tepals, and the partly united filaments, free in the distal 1–2 mm. The yellow anthers exceed the unusually broad style branches. *Moraea barnardiella* is vegetatively almost identical to *M. melanops* but the latter has shallowly cupped tepals, free to partly united filaments diverging distally, and the style exceeds the anthers and has fairly narrow branches.

34. **Moraea minima** *Goldblatt* in Novon 8: 377 (1998), as a new name for *Galaxia parva* Goldblatt: 1085 (1984b) [not *M. parva* N.E.Br. (1929)]. Type: South Africa, [Western Cape], Farm Mierkraal, SSW of Bredasdorp, *Goldblatt 6181A* (MO, holo.; K, NBG, PRE, iso.).

Plants solitary, small, 20–30 mm high. *Corm* up to 10 mm diam.; tunics brown, with prominent woody vertical ribs. *Stem* underground, extending 20–40 mm above ground in fruit. *Foliage leaves* 3 or 4, bifacial, ± flat or shallowly channelled, outer ± prostrate, acute and acuminate, undulate, 15–35 × ± 8 mm, margins hyaline, smooth. *Rhipidial spathes* not distinct from leaves; with (1)2 or 3 flowers per plant. *Flowers* fugaceous, bell-shaped, white with yellow centre, tepals with turquoise markings in midlines; perianth tube 7–10 mm long, cylindric; tepals 9–12 × 5–6 mm. *Filaments* 3–4 mm long,

Distribution of ***Moraea minima***.

united below in a cylindric column, free and diverging in upper 0.6–1.5 mm, yellow; anthers 1.5–2.0 mm long, yellow; pollen yellow. *Ovary* ± globose, ovoid, ± 4 mm long; style diverging near anther bases, arms reaching ± middle of anthers, stigma lobes with entire, minutely ciliate margins, lobes separate or ± continuous at edges. *Capsules* and *seeds* not known. *Chromosome number* 2*n* = 12. *Flowering time*: late July to early September.

Distribution and ecology: known only from clay flats at Mierkraal Farm, SSW of Bredasdorp in Western Cape, South Africa; in light loamy clay in coastal renosterveld (recorded just once and critically rare if not extinct).

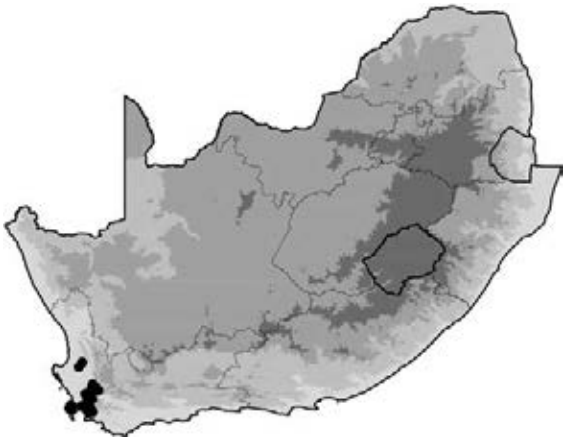
Diagnosis: with very small, white flowers, *Moraea minima* has nearly prostrate leaves with flat or shallowly channelled blades and style branches with entire stigmatic lobes. The flowers have a perianth tube only 7–10 mm long and tepals 9–12 mm long. Possibly most closely related to *M. melanops* or *M. versicolor*, both of which have larger, pink to purple flowers, *M. minima* differs significantly in having a short style so that the stigma lobes reach only to the middle of the anthers, the pollen thus in direct contact with the stigmas, and the species is self-compatible and, under greenhouse conditions, autogamous. The similarity of the small white flowers of *M. minima* to those of *M. albiflora*, which is also autogamous, is superficial and *M. albiflora* has the fringed style branches typical of ser. *Galaxia*.

Moraea minima has a unique chromosome number in subg. *Galaxia*, a derived diploid number of 2*n* = 12, the lowest number in the genus (base number is *x* = 9 in subg. *Galaxia*). The karyotype is structurally heterozygous and because the species produces ample seed, its embryology will undoubtedly prove to be of unusual interest.

35. **Moraea versicolor** *(Salisb. ex Klatt) Goldblatt* in Novon 8: 377 (1998). *Galaxia versicolor* Salisb. ex Klatt: 783 (1864); Goldblatt: 400 (1979a). Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 291, lower right (1792).

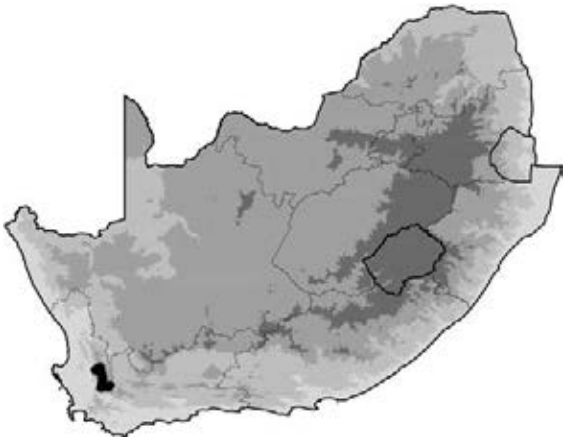
Galaxia ovata var. *purpurea* Ker Gawl.: t. 1516 (1812). *Galaxia purpurea* (Ker Gawl.) Klatt: 385 (1882). Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 1516 (1812).

Galaxia ovata var. *ecklonii* Baker: 97 (1892). Type: South Africa, [Western Cape], Cape Town, Devil's Peak, *Ecklon 308* (S, lecto., designated by Goldblatt: 401 (1979a); K, MO, PRE, isolecto.).



[*Galaxia mucronularis* Salisb.: 315 (1812), invalid name without description.]

[*Galaxia violacea* Eckl.: 17 (1827), invalid name without description.]



Plants acaulescent, up to 40 mm high. *Corm* ± globose, 10–15 mm diam.; tunics of dark brown, reticulate fibres arranged in herringbone pattern, vertical ribs often thick and woody, often accumulating in a dense mass. *Stem* underground at flowering. *Leaves* in a basal tuft, lowermost inserted below ground shortly above corm, short and inconspicuous, laxly spreading to ± prostrate, lanceolate, widely channelled to flat, 30–50 × 3–6 mm, undulate, margins occasionally crisped, minutely ciliate. *Rhipidial spathes* hardly distinct from leaves, with up to 5 flowers per plant. *Flowers* fugaceous, salver-shaped with tepals cupped in lower half, pink to purple or red, usually yellow in cup with dark pigment at edge of cup and yellow stamens and style OR tepals dark blue to purple in centre and usually with purple-black stamens and style; perianth tube cylindric, (10–)18–27 mm long; tepals subequal, spreading distally, obovate, 14–22 × 7–14 mm. *Filaments* 5–6 mm long, united below in cylindric or bottle-shaped column slightly wider in lower half, free and ascending in distal 1.0–1.5 mm; anthers ± erect, 2.5–4.0 mm long, shorter after dehiscing, yellow or purple; pollen yellow. *Ovary* oblong-cylindric, ± 4 mm long; style straight, dividing 2–3 mm above anther tips into 3 short, spreading stigmatic lobes with undulate margins, yellow. *Capsules* and *seeds* unknown. *Chromosome number* 2*n* = 16, 14. *Flowering time*: late July to mid-September; flowers open ± 12:30 and collapse ± 16:30.

Distribution and ecology: restricted to the southwestern Western Cape, South Africa, from the Olifants River Mtns and Piketberg inland in the Tulbagh and Breede River Valleys and south to Gordon's Bay and the Cape Peninsula; typically on heavy soils derived from shales or granite.

Diagnosis: *Moraea versicolor* has pink to purple flowers with tepals forming a cup in the lower half, usually with a yellow centre but populations with a blue to violet centre occur locally. The leaves are usually somewhat glaucous and widely channelled and often somewhat twisted, with undulate margins. The filaments are free and diverging in the upper 1.0–1.5 mm and united in the lower part, usually forming a bottle-shaped column wider in the lower half but populations with a cylindric filament column occur in the Breede River Valley. The style divides above the anthers, often exceeding them

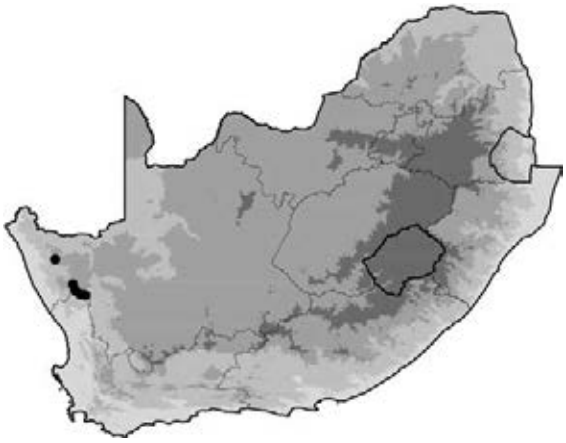
Distribution of ***Moraea versicolor***.

Distribution of ***Moraea variabilis***.

by 3–4 mm. *Moraea variabilis* has similarly coloured flowers but glossy, channelled leaves with straight margins, and filaments united entirely or rarely free distally for less than 1 mm, with the style dividing just above the anther tips. The species is variable for chromosome number and most populations have a diploid number of $2n = 16$ but plants from the northern Cape Peninsula and from the Tulbagh Valley have $2n = 14$.

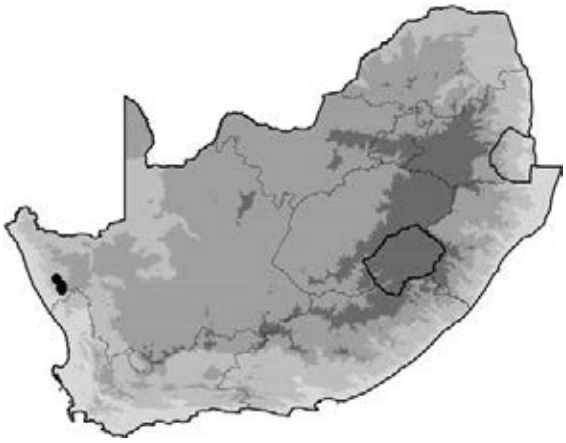
36. **Moraea variabilis** *(G.J.Lewis) Goldblatt* in Novon 8: 377 (1998). *Galaxia variabilis* G.J.Lewis: 6 (1938); Goldblatt: 403 (1979a). Type: South Africa, [Western Cape], between De Keur and Gydo Pass, *Compton & party s.n.* as *Nat. Bot. Gard. 2080/36* (BOL, holo.; NBG, iso.).

Plants acaulescent, up to 40 mm high. *Corm* ± globose, 10–15 mm diam.; tunics of dark brown, netted fibres arranged in herringbone pattern, vertical ribs often thick and woody, often accumulating in a dense mass. *Stem* underground at flowering. *Leaves* in a basal tuft, ± straight, spreading, lowermost often ± prostrate, oblong to lanceolate, channelled to flat, 30–50 × ± 6 mm, margins ± straight, minutely ciliate. *Rhipidial spathes* hardly distinct from leaves, with up to 5 flowers per plant. *Flowers* fugaceous, salver-shaped with tepals cupped in lower halves, usually dark pink-purple with yellow cup and darkly pigmented at edge of cup; perianth tube cylindric, 12–30 mm long; tepals subequal, spreading distally, obovate, 20–35 × 10–13 mm. *Filaments* ± 6 mm long, united in smooth, straight column, rarely free in distal ± 1 mm, usually yellow; anthers sessile (or nearly so), ± erect, 3–4 mm long before splitting, yellow or purple; pollen yellow. *Ovary* oblong-cylindric, ± 4 mm long; style straight, dividing above anther tips into 3 short, spreading stigmatic lobes, margins undulate. *Capsules* and *seeds* unknown. *Chromosome number* $2n = 14$. *Flowering time*: September to mid-October.



Distribution and ecology: restricted to interior Western Cape, South Africa, from the Cold Bokkeveld near Eland's Kloof southward to Lakenvlei southeast of Ceres in the Warm Bokkeveld; in heavy clay soils.

Diagnosis: with a reddish purple flower with yellow cup, *Moraea variabilis* most resembles *M. versicolor* but differs in the glossy, dark green leaves, channelled with straight margins, filaments usually united entirely or rarely free for less than 1 mm, thus with the anthers sessile or almost so, and the style dividing just above the anther tips. *Moraea versicolor* has the leaves usually glaucous and with wavy margins, the filaments free and diverging in the upper 1.0–1.5 mm, and the style dividing 2–3 mm above the tips of the anthers. The ranges of the two species are complimentary.



Apparent hybrids with *Moraea citrina* have been recorded at a few sites and have large orange or pink flowers. The variation in flower size and colour among the hybrids suggests that they are interbreeding.

37. **Moraea fenestralis** *(Goldblatt & E.G.H.Oliv.) Goldblatt* in Novon 8: 377 (1998). *Galaxia fenestralis* Goldblatt & E.G.H.Oliv.: 406 (1993). Type: South Africa, [Northern Cape], Namaqualand, Kliprand, valley northwest of Farm Matjiesfontein toward Farm Middelpos, low granite outcrop, 960 m, June 1991, *Oliver 9847* (NBG, holo.; K, MO, PRE, iso.).

Plants up to 25 mm high. *Corm* ± ellipsoid, 6–8 mm diam.; tunics of light brown, netted fibres with prominent vertical ribs. *Stem* underground at flowering. *Leaves* in a basal tuft, 3 or 4, falcate, terete, 10–35 × 0.6–1.0 mm, with transparent adaxial band. *Rhipidial spathes* not distinct from leaves; with 1 to 3 flowers per plant. *Flowers* fugaceous, salver-shaped with tepals slightly cupped, pale pink to lilac or ± white with yellow at bases; perianth tube ± 8 mm long, cylindric; tepals ± 15 mm long, narrowed below into claws ± 6 mm long, inner tepals joined to filament column for ± 2 mm. *Filaments* ± 7 mm long, united below in a cylindric column, free and diverging in upper ± 1 mm; anthers ± 2 mm long, erect, yellow; pollen yellow. *Ovary* ± ovoid, ± 4 mm long; style branches short, dividing into 3 broad, stigmatic lobes at midanther level, margins undulate, entire. *Capsules* ovoid-ellipsoid, ± 6 mm long. *Seeds*

Distribution of ***Moraea fenestralis***.

Distribution of ***Moraea kamisensis***.

globose, 0.6 mm diam., dark brown. *Flowering time*: June and July; opening ± 10:00 and collapsing ± 15:30.

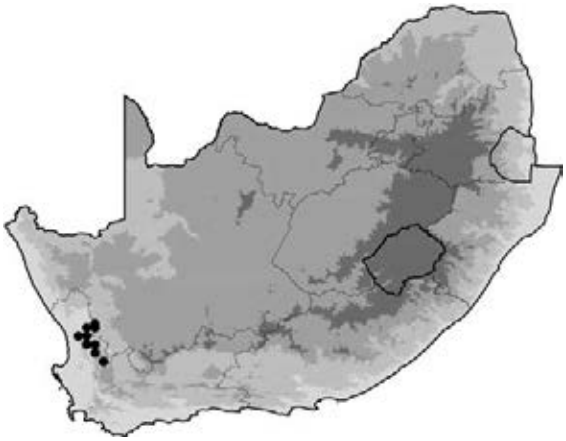
Distribution and ecology: a poorly documented species recorded from the low hills near Kliprand and the interior Kamiesberg to near Okiep in Namaqualand, Northern Cape, South Africa; restricted to exposed granite outcrops.

Diagnosis: one of the smallest species of subg. *Galaxia*, *Moraea fenestralis* has falcate, terete leaves with a transparent band of tissue on the upper (adaxial) surface. Plants bloom early in the season, mostly in June but also July, and the small flowers have tepals ± 15 mm long. An unusual feature of the flowers is that the inner tepals are joined to the filament column for ± 2 mm. The short style branches bear broad stigmatic lobes with entire, undulate margins, the ancestral condition for the subgenus. The relationships of *M. fenestralis* are uncertain but it is assigned here to ser. *Eurystigma* based on DNA sequence data.

Ser. **Galaxia** *(Thunb.) Goldblatt* in Novon 8: 376 (1998). *Galaxia* Thunb.: 50 (1782a). Type: as for subgenus.

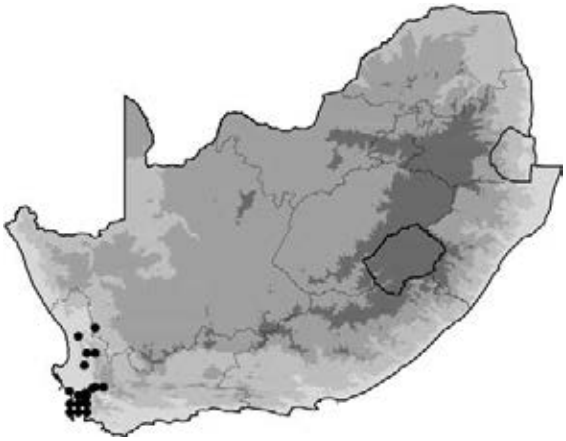
Flower yellow or white, filaments united in a column, sometimes free and diverging distally or spreading from base (*M. luteoalba*); style branches with fringed stigma lobes.

38. **Moraea kamisensis** *Goldblatt* in Novon 8: 377 (1998), as a new name for *Galaxia grandiflora* Andrews: t. 164 (1801) [not *M. grandiflora* (Cav.) Pers. (1805)]; Goldblatt: 407 (1979a). Type: South Africa, without precise locality, possibly collected by J. Niven, illustration in Andrews: t. 164 (1801).



Plants up to 45 mm high, including flowers. *Corm* 6–8 mm diam.; tunics of brown, reticulate fibres. *Stem* underground at flowering. *Foliage leaves* few, not clearly distinguished from rhipidial spathes, inserted at ground level, lower spreading to ± prostrate, oblong, ± plane, obtuse, margins thickened, ± translucent, ciliate. *Rhipidial spathes* not distinct from leaves; with 2 to 5 flowers per plant. *Flowers* fugaceous, salver-shaped with tepals cupped below, yellow; perianth tube 15–25 mm long, cylindric; tepals obovate, 22–30 × 11–15 mm, obtuse, usually apiculate. *Filaments* ± 6 mm long, united in a cylindric column; anthers 4–5 mm long, erect, yellow; pollen yellow. *Ovary* ovoid, ± 5 mm long; style ± 8 mm long, dividing into short, horizontal, deeply fringed stigmatic lobes. *Capsules* and *seeds* unknown. *Chromosome number* $2n = 18$. *Flowering time*: September to early October; flowers opening ± 11:30 and collapsing after 16:00.

Distribution and ecology: restricted to middle elevations of the Kamiesberg in Northern Cape, South Africa; locally common in sandy, granitic gravel, flowering particularly well after fire.



Diagnosis: largest member of ser. *Galaxia*, *Moraea kamisensis* has large yellow flowers, the perianth tube up to 25 mm long and tepals 22–30 mm long. The spreading to nearly prostrate foliage leaves have conspicuously thickened, ± translucent margins (hyaline when dry) that are fairly densely ciliate, similar to those of leaves of *M. galaxia*.

39. **Moraea luteoalba** *(Goldblatt) Goldblatt* in Novon 8: 377 (1998). *Galaxia luteoalba* Goldblatt: 410 (1979a). Type: South Africa, [Western Cape], Pakhuis Pass, *Goldblatt 2205* (MO, holo.; K, NBG, PRE, iso.).

Plants up to 50 mm high, often growing in small clumps. *Corm* 12–16 mm diam.; tunics of fine fibres accumulating in a dense mass. *Stem* underground at flowering. *Foliage leaves* not clearly distinguished from rhipidial spathes, inserted at ground level, ovate, lower 2 prostrate, ovate-oblong, ± plane, 20–40 × up to 6 mm, margins hyaline, densely ciliate. *Rhipidial spathes* not distinct from leaves; with 2 to 5 flowers per plant. *Flowers* fugaceous, ± salver-shaped, usually deep yellow in centre with tepals grading to creamy white distally or uniformly yellow;

Distribution of ***Moraea luteoalba***.

Distribution of ***Moraea galaxia***.

perianth tube cylindric, 7–16 mm long; tepals obovate, ± obtuse, 15–21 × 7–10 mm. *Filaments* 5.5–7.5 mm long, united in lower ± 2 mm, diverging above; anthers 2–3 mm long, yellow; pollen yellow. *Ovary* ovoid, ± 3 mm long; style slender, initially erect, dividing above anther tips, later eccentric, stigma lobes fringed. *Capsules* and *seeds* unknown. *Chromosome number* 2*n* = 18. *Flowering time*: mid-August to September.

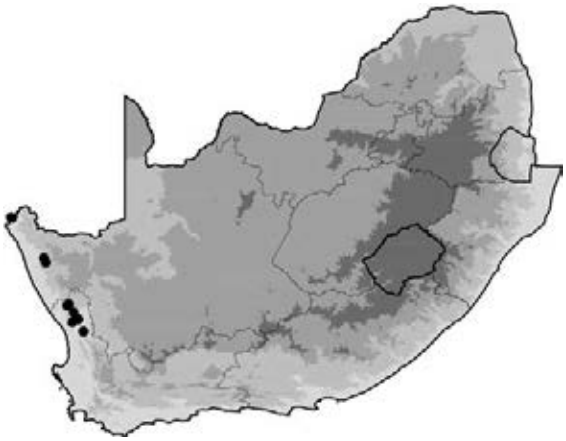
Distribution and ecology: restricted to the Gifberg–Matsikamma Mtns and the Cederberg in Western Cape, South Africa; often on sandstone outcrops, sometimes at the edge of seasonal pools or in moss beds in shallow ground.

Diagnosis: the ovate to oblong, ± prostrate leaves of *Moraea luteoalba* are like those of the more common *M. galaxia* but it has sharply different flowers with tepals deep yellow in the centre typically grading to creamy white distally or sometimes uniformly yellow, and filaments united only in the lower third and diverging distally. *Moraea galaxia* always has uniformly yellow flowers with the filaments united entirely in a bottle-shaped column, with the anthers appressed to the style.

40. **Moraea galaxia** *(L.f.) Goldblatt & J.C.Manning* in Strelitzia 9: 714 (2000b). *Ixia galaxia* L.f.: 93 (1782). Type: South Africa, without precise locality, *Sparrman s.n.* [S, lecto., designated by Goldblatt: 412 (1979a)].

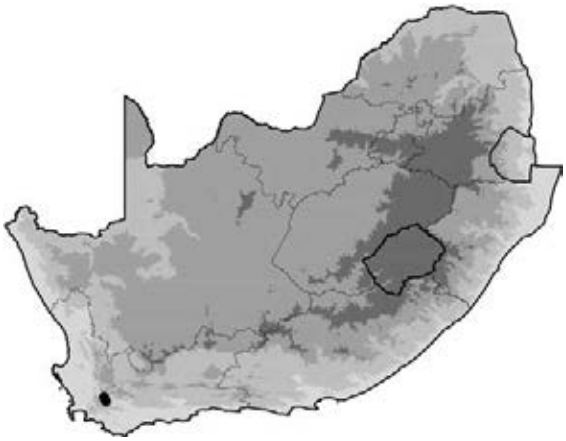
Galaxia ovata Thunb.: 51 (1782a); Goldblatt: 412 (1979a). *Moraea ovalifolia* Goldblatt: 377 (1998), as a new name for *G. ovata* Thunb. (1782a) [not *M. ovata* Thunb. (1800)]. Type: South Africa, [Western Cape], vicinity of Cape Town, *Thunberg s.n.* (UPS-THUNB 15450, lecto., designated by Goldblatt: 412 (1979a); C, S, isolecto.).

Galaxia multiflora Spreng.: 251 (1820). Type: unknown.



Plants solitary or several in cushion-like tufts. *Corm* ± 10 mm diam.; tunics of brown, netted fibres, sometimes with prominent vertical ridges. *Stem* underground at flowering. *Foliage leaves* prostrate, ± plane, lowermost 20–30 mm long, often slightly undulate, margins thickened, pale, ciliate in a single row or densely ciliate over thickened area. *Rhipidial spathes* not distinct from leaves; with 2 to 5 flowers per plant. *Flowers* fugaceous, salver-shaped with tepals cupped below, uniformly yellow; perianth tube (5–)10–20 mm long, cylindric; tepals ± ovate or obovate, 16–20 × 6–8 mm. *Filaments* united in a column 4–5 mm long, often bottle-shaped, yellow; anthers sessile, 2–3 mm long, erect, yellow; pollen yellow. *Ovary* ovoid, ± 3 mm long; style slender, initially erect, dividing above anther tips, stigma lobes fringed. *Capsules* and *seeds* unknown. *Chromosome number* 2*n* = 18, 36. *Flowering time*: late July to mid-September; opening after 10:30 and collapsing after 16:00.

Distribution and ecology: relatively widespread in Western Cape, South Africa, from the Cederberg and Piketberg Mtns south to the Cape Peninsula and east to the Caledon District; on sandstone pavement and rock crevices, occasionally in open sandy ground.



Diagnosis: one of the most common species of subg. *Galaxia*, *Moraea galaxia* has the yellow flowers and fringed style lobes typical of ser. *Galaxia* and is best distinguished by the broad, ± ovate leaves prostate or nearly so and with thickened, usually densely ciliate margins. The filaments are united in a bottle-shaped column with the sessile anthers appressed to the style. Over most of its range *M. galaxia* is tetraploid, 2*n* = 36, but diploid plants, 2*n* = 18 occur in the southeast of its range in the Caledon District.

41. **Moraea pilifolia** *Goldblatt* in Novon 8: 377 (1998), as a new name for *Galaxia ciliata* Pers.: 41 (1805) [not *M. ciliata* (L.f.) Ker Gawl.]. Type: South Africa, without precise locality or collector, illustration in Andrews: t. 94 (1800b).

Plants solitary or several in small tufts, up to 50 mm high. *Corm* 8–12 mm diam.; tunics of fine, netted fibres accumulating with age in a dense mass around base.

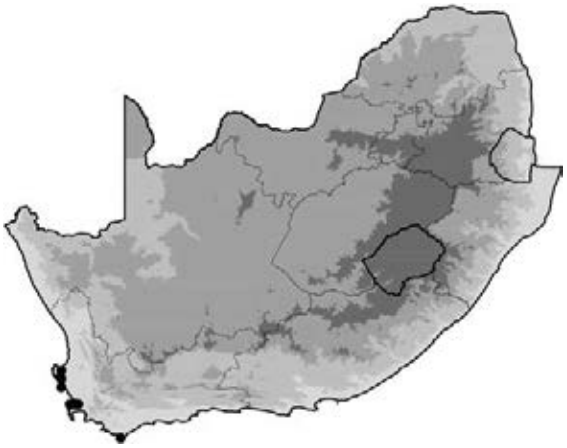
Distribution of ***Moraea pilifolia***.

Distribution of ***Moraea vuvuzela***.

Stem underground at flowering. *Foliage leaves* ascending below, recurving distally, oblong, obtuse, shallowly channelled, often slightly undulate, lower, up to 20 × 9 mm, margins thickened, hyaline when dry, densely long-ciliate. *Rhipidial spathes* not distinct from leaves; with 1 to 3 flowers per plant. *Flowers* fugaceous, uniformly yellow, salver-shaped with tepals cupped below; perianth tube cylindric, 4.5–10.0 mm long; tepals subequal, ovate-obovate, 6–10 mm long. *Filaments* united in a cylindric tube 3.5–4.0 mm long; anthers sessile, diverging, 2.5–3.5 mm long, yellow; pollen yellow. *Ovary* ± 2.5 mm long; style dividing opposite anther tips, stigma lobes short, deeply fringed, spreading above anthers. *Capsules* and *seeds* unknown. *Chromosome number* 2*n* = 18. *Flowering time*: June and July, rarely in early August.

Distribution and ecology: largely a Northern Cape species, extending from near Beauvalon in the Richtersveld and Nababeep in northern Namaqualand to the slopes of the Gifberg in Western Cape, South Africa; usually on clay substrates, often wedged in rock crevices.

Diagnosis: a relatively small plant, *Moraea pilifolia* has pale yellow flowers with a perianth tube up to 10 mm long and tepals 6–10 mm long, otherwise typical of ser. *Galaxia*, thus with united filaments, sessile anthers and short, fringed style branches. The leaves are distinctive in their oblong shape with thickened, densely long-ciliate margins. It most closely resembles *M. galaxia*, which has broader, usually prostrate leaves, the margins with short cilia, and larger flowers with tepals 16–20 mm long.



42. **Moraea vuvuzela** *Goldblatt & J.C.Manning* in Bothalia 40: 148 (2010). Type: South Africa, Western Cape, Rawsonville, hills between Breede River and Brandvlei Dam, burnt clay slope, 21 July 2009, *Le Roux & Manning 591* (NBG, holo.; K, MO, PRE, iso.).

Plants up to 40 mm high, forming small tufts. *Corm* subglobose, 10–15 mm diam.; tunics of alternating layers of fine fibres and hard, cartilaginous material, with thickened vertical ribs, accumulating with age in collar around base. *Stem* underground or reaching up to 10 mm above ground. *Leaves* ± 3, lowermost inserted well below ground shortly above corm, short and inconspicuous, remaining 2 leaves inserted at ground level, ± prostrate, narrowly lanceolate, 20–35 × 3–4 mm, shallowly channelled, margins hyaline, smooth or minutely ciliate. *Rhipidial spathes* not distinct from leaves; with 2 to 4 flowers per plant. *Flowers* fugaceous, salver-shaped, pale yellow with median brown or purplish markings at top of darker yellow cup 7–10 mm deep; perianth tube cylindric, 8–10(–15) mm long; tepals obovate, 20–25 × 7–10 mm. *Filaments* ± 7 mm long, united in a baluster-shaped column, free and diverging in upper ± 1 mm; anthers 2.0–2.5 mm long, yellow; pollen yellow. *Ovary* ± 4 × 2 mm; style erect, reaching 1.5–2.0 mm above anther tips, branches deeply fringed spreading above anthers. *Capsules* and *seeds* unknown. *Flowering time*: late July to September, rarely in early October.

Distribution and ecology: known from a handful of sites between Rawsonville and Villiersdorp in Western Cape, South Africa; in loamy clay soils in renosterveld vegetation, typically on cooler south- or southeast-trending slopes, flowering best after removal of the surrounding vegetation or after fire.

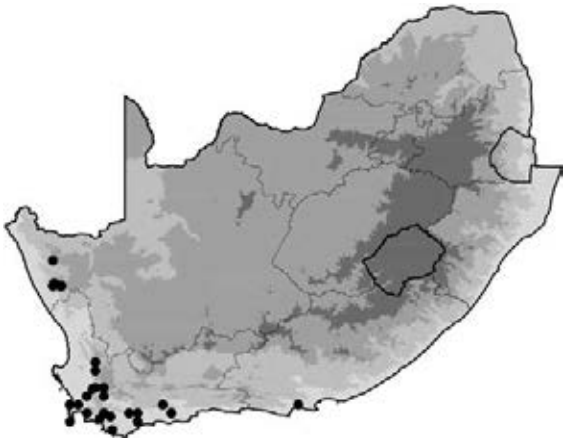
Diagnosis: with the spreading, ± fringed stigmatic lobes of ser. *Galaxia*, *Moraea vuvuzela* stands out in its pale yellow flowers with brown or purplish markings at the top of the darker yellow floral cup. Most of the remaining members of the series have uniformly bright yellow flowers. The corm tunics of *M. vuvuzela* are ± woody with prominent, thickened longitudinal ribs only partially separated from one another by transverse fibres. The corm tunics in most other species are less woody, with the longitudinal ribs separated by transverse fibres, with the exception of *M. angulata*, which has unique, woody or corky tunics with wing-like longitudinal ribs.

43. **Moraea albiflora** *(G.J.Lewis) Goldblatt* in Novon 8: 376 (1998). *Galaxia albiflora* G.J.Lewis: 44 (1941); Goldblatt: 421 (1979a). Type: South Africa, [Western Cape], Rondebosch Common, *Lewis s.n.* (SAM *54289*, holo).

Distribution of ***Moraea albiflora***.

Plants small, inconspicuous, mostly up to 30 mm high. *Corm* 8–12 mm diam.; tunics fibrous with prominent vertical ribs. *Stem* underground at flowering. *Leaves* in a basal cluster, spreading to ± prostrate, linear, channelled, 30–60 × ± 3 mm, margins hyaline, sparsely ciliate. *Rhipidial spathes* hardly distinct from leaves, with 2 to 4 flowers per plant. *Flowers* fugaceous, salver-shaped with tepals cupped below, white with yellow cup; perianth tube 10–13 mm long; tepals subequal, obovate, spreading in upper half, 9–12 × 3–4 mm. *Filaments* united in ± cylindric column ± 4 mm long; anthers sessile, erect, ± 1.5 mm long. *Ovary* ovoid, ± 3 mm long; style slender, dividing ± opposite lower $^1/_3$ to middle of anthers, branches deeply and irregularly fringed, tangled in anthers. *Capsules* and *seeds* unknown. *Chromosome number 2n* = 18. *Flowering time*: July to early September; flowers open ± 13:00 and collapse ± 15:30.

Distribution and ecology: restricted to coastal Western Cape, South Africa, from near Saldanha Bay to Cape Agulhas; on rocky granite outcrops and on wet, sandy flats.



Diagnosis: an inconspicuous plant, *Moraea albiflora* has the fringed style branches characteristic of ser. *Galaxia* and is recognised by its small white flowers with a yellow cup, the tepals only 9–12 mm long, and style dividing below the apex of the anthers so that the fringed stigma lobes are tangled in the anthers. The leaves are ± straight and spreading to nearly prostrate, with finely ciliate, hyaline margins. *Moraea albiflora* is autogamous, the pollen shed directly onto the stigmatic surfaces during the few hours that each flower remains open. Despite its autogamy, hybrids with *M. fugacissima* have been recorded where the two co-occur on Rondebosch Common on the Cape Peninsula.

44. **Moraea fugacissima** *(L.f.) Goldblatt* in Novon 8: 376 (1998). *Ixia fugacissima* L.f.: 94 (April 1782); Goldblatt: 416 (1979a). *Galaxia graminea* Thunb.: 50 (July 1782a), illegitimate superfluous name [based on type of *Ixia fugacissima* L.f.] [*G. graminifolia* Harv.: 376 (1868), orthographic variant]. *Galaxia fugacissima* (L.f.) Druce: 624 (1917). Type: South Africa, [Western Cape], Cape Town, *Thunberg s.n.* [UPS-THUNB 15449, lecto., designated by Goldblatt: 416 (1979a)].

Plant solitary or several in tufts, up to 70 mm high. *Corm* mostly 10–12 mm diam.; tunics fibrous, often with prominent vertical ribs. *Stem* underground at flowering. *Leaves* in a basal tuft, ± upright or lower ± prostrate, ± linear, narrowly channelled at least in lower half, often terete distally, 30–80 × ± 2 mm, margins of channelled part smooth or rarely sparsely minutely ciliate. *Rhipidial spathes* hardly distinct from leaves, with 2 to 5 flowers per plant. *Flowers* fugaceous, salver-shaped with tepals cupped below, uniformly yellow, sweetly scented; perianth tube cylindric, (10–)15–24 mm long; tepals subequal, obovate, (11–)15–19 × 4–9 mm. *Filaments* usually entirely united (free in upper $^1/_3$), 3–6 mm long; anthers usually sessile, 1.5–4.0 mm long, yellow; pollen yellow. *Ovary* ± 2.5 mm long; style usually dividing ± 2 mm above anther tips, branches short, deeply fringed. *Capsules* and *seeds* unknown. *Chromosome number* 2*n* = 18, 36. *Flowering time*: July to September; opening after 10:30 and collapsing ± 16:00.

Distribution and ecology: occurring in Northern, Western and Eastern Cape, South Africa, from south of Springbok in Namaqualand to the Cape Peninsula and east to Humansdorp, the furthest east record; mostly in seasonally wet sites, often on poorly drained sandy flats but sometimes on loamy clay soils.

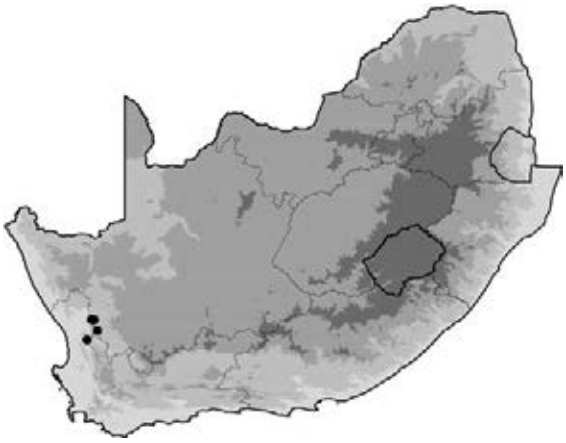
Diagnosis: *Moraea fugacissima* is distinguished primarily by the relatively long, grass-like, linear leaves up to 80 mm long and usually terete distally. The fugaceous flowers are typical of ser. *Galaxia*, having a yellow perianth, filaments usually entirely united, and fringed style branches. Occasionally the filaments are free in the upper third and the style may divide opposite the anthers rather than above them, possibly a developmental aberration. *Moraea fugacissima* is most easily confused

Distribution of ***Moraea fugacissima***.

with *M. stagnalis* but that species has broader leaves and smaller flowers with a perianth tube 5–10 mm long, a short style dividing opposite the anthers, and filaments typically free in the upper third.

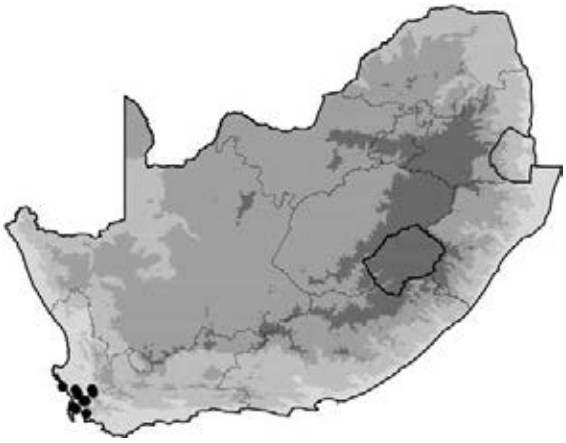
45. **Moraea stagnalis** *(Goldblatt) Goldblatt* in Novon 8: 377 (1998). *Galaxia stagnalis* Goldblatt: 414 (1979a). Type: South Africa, [Northern Cape], pools at the top of Vanrhyns Pass, *Goldblatt 3888* (MO, holo.; K, NBG, PRE, S, iso.).

Plant small, inconspicuous, usually solitary, mostly up to 25 mm high. *Corm* 8–10 mm diam.; tunics finely fibrous with prominent vertical ribs. *Stem* underground at flowering. *Leaves* ascending or lower ± prostrate, ± linear or narrowly lanceolate, channelled, 20–40 × ± 2 mm, margins smooth or rarely sparsely and minutely ciliate. *Rhipidial spathes* hardly distinct from leaves, with 1 to 3 flowers per plant. *Flowers* fugaceous, yellow, cup-like; perianth tube 5–10 mm long; tepals subequal, obovate, spreading in upper half, 10–15 × 5–8 mm. *Filaments* 4.5–5.0 mm long united in ± cylindric column or free in upper $^1/_3$; anthers erect, 1.5–2.0 mm long, diverging, yellow; pollen yellow. *Ovary* ovoid, ± 3 mm long; style slender, dividing ± opposite upper $^1/_3$ of anthers, branches deeply and irregularly fringed, tangled in anthers. *Capsules* and *seeds* unknown. *Chromosome number 2n* = 36. *Flowering time*: June to mid-August; opening ± 11:30 and collapsing ± 16:30.



Distribution and ecology: extending from Garies in Namaqualand and the Bokkeveld Mtns of Northern Cape, South Africa, to the northern Cederberg in Western Cape; in seasonally wet sites, including shallow pools in sandstone pavement, banks of seasonal streams and wet seeps on sandy ground.

Diagnosis: the wet habitat is distinctive for *Moraea stagnalis*, which has flowers almost identical with those of other members of ser. *Galaxia* but with the filaments usually free in the upper third. The style divides opposite the anthers and the stigmatic fringes of the style branches are always in contact with the anthers and pollen. The narrow, shallowly channelled leaves have smooth to minutely ciliate margins. *Moraea stagnalis* is polyploid, 2*n* = 36, and in the laboratory is autogamous. The species is most easily confused with *M. fugacissima*, which has larger flowers with a perianth tube mostly 15–24 mm long, anthers up to 4 mm long, and the style usually exceeding the anthers rather than tangled among them. The filaments of *M. fugacissima* are usually completely united whereas those of *M. stagnalis* are typically, though not invariably, free in the upper third.



46. **Moraea angulata** *Goldblatt* in Novon 8: 376 (1998), as a new name for *Galaxia alata* Goldblatt: 418 (1979a) [not *M. alata* Vahl (1805)]. Type: South Africa, [Western Cape], roadside 20 km south of Malmesbury at Klein Dassenberg intersection, *Goldblatt 2176* (MO, holo.; K, NBG, PRE, S, iso.).

Plant small, usually solitary, 20–40 mm high. *Corm* 5–8 mm diam.; tunics pale, composed of pith-like, soft layers with conspicuous vertical wings. *Stem* underground at flowering. *Leaves* spreading to ± prostrate, channelled near base, terete in upper half, 15–30(–60) mm long, channelled part with ciliate margins. *Rhipidial spathes* hardly distinct from leaves, with 1 to 3 flowers per plant. *Flowers* fugaceous, yellow or white, salver-shaped with tepals cupped below; perianth tube cylindric, 5–20 mm long; tepals subequal, obovate, 13–19 × 6.5–8.0 mm. *Filaments* united in a cylindric column 4–5 mm long; anthers sessile, 2.0–2.5 mm long, slightly diverging, yellow or white. *Ovary* globose, ± 2 mm diam.; style slender, dividing ± 4 mm above anther tips, branches short, deeply fringed. *Capsules* and *seeds* unknown. *Chromosome number 2n* = 18 (27). *Flowering time*: July and August; flowers opening ± 12:00 and collapsing ± 15:30.

Distribution and ecology: restricted to the lowlands of the southwestern corner of Western Cape, South Africa, and known from a few sites between Yzerfontein, the Cape Peninsula and Somerset West, most of them now lost to agriculture, urban development and the spread

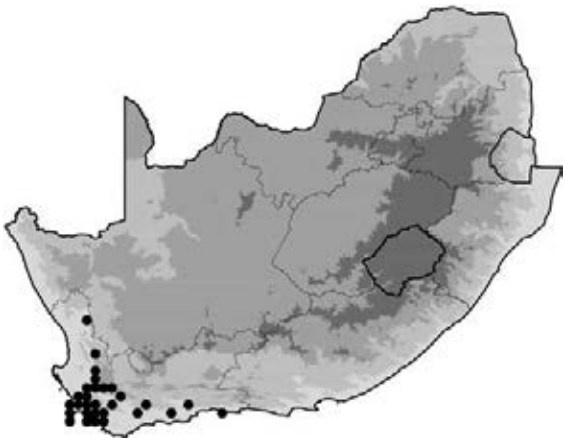
Distribution of ***Moraea stagnalis***.

Distribution of ***Moraea angulata***.

of alien vegetation and not recorded since the 1970s; in seasonally waterlogged, sandy ground.

Diagnosis: seemingly a typical member of ser. *Galaxia, Moraea angulata* has relatively small flowers with tepals 13–19 mm long, and is distinctive in the short, terete, fleshy leaves, usually grey in colour, and unique corm tunics of soft, pith-like material with wide vertical wings, for which the species is named. The filaments are completely united in a column enclosing the style, which divides above the tips of the diverging anthers into fringed stigmatic lobes.

Subg. 6. **Monocephalae**



Subg. **Monocephalae** *(Baker) Goldblatt* in Annals of the Missouri Botanical Garden 63: 7 (1976b). *Moraea* [unranked] *Monocephalae* Baker: 10 (1896). Type: *M. angusta* (Thunb.) Ker Gawl., lecto., designated by Goldblatt: 7 (1976b).

Plants unbranched, often sticky at and below nodes. *Foliage leaf* solitary, distally terete or channelled almost to apex. *Flowers* fugaceous, yellow to buff-brown; stamens united only near base; style branches well developed; ovary sharply 3-angular. *Capsules* ovoid-oblong in outline, 3-lobed. *Seeds* usually flattened and discoid or somewhat angular and depressed. *Basic chromosome number x* = 10.

47. **Moraea angusta** *(Thunb.) Ker Gawl.* in König & Sims, Annals of Botany 1: 240 (1804a); Goldblatt: 740 (1976a); Goldblatt: 40 (1986a). *Iris angusta* Thunb.: 19 (1782b). Type: South Africa, [Western Cape], slopes below Devil's Peak and Lion's Head, Cape Peninsula, *Thunberg s.n.* [UPS-THUNB, lecto., designated by Goldblatt: 740 (1976a)].

Moraea obtusa N.E.Br.: 195 (1931). Type: South Africa, [Western Cape], Cape Flats, marsh at Crawford, *Weintraub sub Moss 18185* (BM, K, syn.).

Plants mostly 200–400 mm high. *Corms* 10–18 mm diam.; tunics pale to dark brown, soft textured, inner layers ± entire, outer becoming vertically split, eventually fibrous. *Stem* with long above-ground internode, flexed above sheath of foliage leaf, with 1(2) sheathing leaves 25–40 mm long, usually ± obtuse, rarely sticky below upper nodes. *Foliage leaf* solitary, inserted shortly above ground level, firm to rigid, exceeding stem, terete. *Rhipidial spathes* dark green, distal margins brown, mostly truncate or obtuse at apex, inner 50–80 mm long, outer ± half as long. *Flowers* fugaceous, usually pale yellow, sometimes flushed brown throughout, rarely pale blue-grey, veined purplish or brown outside, outer tepal limbs with clear yellow nectar guide at base, outer tepals 30–50 mm long, limbs spreading to laxly reflexed, claw 10–20 mm long, suberect; inner tepals 25–35 mm long, erect, often becoming reflexed later. *Filaments* 5–12 mm long, almost free ± to base (united for ± 1 mm); anthers 7–10 mm long, yellow; pollen usually orange-red, rarely yellow. *Ovary* ± 8–12(–18) mm long, cylindric-triangular to ± 3-winged, exserted, style branches 11–20 mm long, crests 13–23 mm long, slightly exceeding style branches. *Capsules* cylindric, somewhat 3-lobed, 15–20 mm long. *Seeds* large, flat, discoid. *Chromosome number* 2*n* = 20. *Flowering time*: late August to November.

Distribution of ***Moraea angusta***.

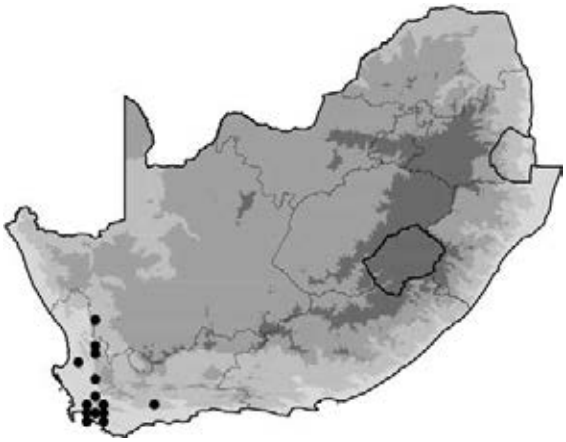
Distribution and ecology: extending in Western Cape, South Africa, from the Gifberg south to the Cape Peninsula and east to Knysna; on stony flats and slopes, usually in sandy ground at middle to low elevations.

Diagnosis: with the typical features of the subgenus, viz. a solitary foliage leaf with a terete blade and narrowly 3-winged ovary, *Moraea angusta* is recognised by darkly veined yellow to almost brown flowers with prominent nectar guides edged with dark pigment, filaments that are united basally for ± 1 mm, and relatively narrow style crests ± as long as but usually slightly longer than the style branches. The stem usually bears a single sheathing leaf (rarely two) and is not normally sticky below the upper nodes. Related *M. neglecta* also has filaments united only near the base but the firm-textured tepals are not darkly veined and the nectar guides consist of longitudinal lines of dark dots. In addition the style crests are ± half to $^{2}/_{3}$ as long as the style branches. In *M. anomala* the filaments are united for (2–)4–8 mm and the stem almost always has two sheathing leaves and is rarely sticky below the nodes. The red pollen colour of *M. angusta* is shared with *M. anomala* but *M. neglecta* has yellow to white pollen.

Unusually small-flowered plants collected on the Langeberg may be confused with *Moraea vallisavium* from the Klein River Mtns but can be recognised by the relatively short, stiff, terete leaf.

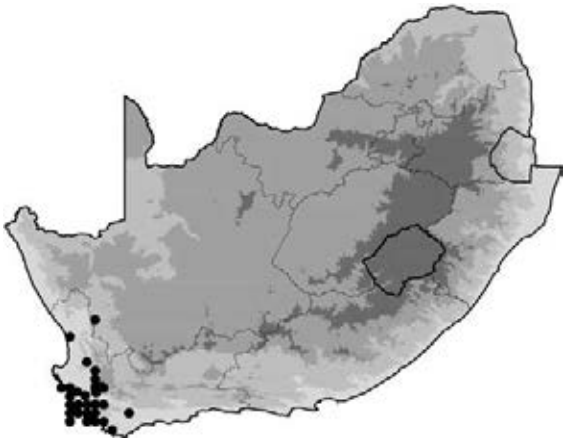
48. **Moraea anomala** *G.J.Lewis* in Journal of South African Botany 15: 119 (1949); Goldblatt: 743 (1976a); Goldblatt: 42 (1986a). Type: South Africa, [Western Cape], Houw Hoek Pass, Caledon District, *Lewis s.n.* (SAM [58100], holo.).

Plants mostly 300–500 mm high. *Corms* 10–18 mm diam.; tunics pale to dark brown, soft textured, inner layers ± entire, outer becoming vertically split, eventually fibrous. *Stem* flexed above sheath of foliage leaf, with long above-ground internode, bearing (1)2 sheathing leaves 30–50 mm long, usually ± obtuse, rarely sticky below upper nodes. *Foliage leaf* solitary, inserted shortly above ground level, firm to rigid, exceeding stem, terete. *Rhipidial spathes* dark green, distal margins brown, mostly truncate or obtuse at apex, inner 28–40(–60) mm long, outer ± half as long. *Flowers* fugaceous, pale yellow, outer tepal limbs with darker yellow nectar guides at bases; outer tepals 30–45 mm long, limbs ± as long as claws, inner tepals 25–35 mm long, initially erect, becoming reflexed to 40° at maturity. *Filaments* 6–14 mm long, united for at least 2 mm and usually 4–8 mm; anthers 4–8 mm long; pollen usually red. *Ovary* ± 10–15 mm long, cylindric-triangular to ± 3-winged, exserted, style branches 9–14 mm long, crests ± as long to slightly longer than style branches, 10–15 mm long, cylindric, somewhat 3-lobed, 15–20 mm long. *Seeds* large, flat, discoid. *Chromosome number* 2*n* = 20. *Flowering time*: late September to November.



Distribution and ecology: endemic to the western half of Western Cape, South Africa, from Pakhuis Pass and the northern Cederberg to Elim on the Agulhas Plain and the Langeberg at Grootvadersbos in the southeast; typically on clay or clay loam, both in montane and lowland habitats.

Diagnosis: *Moraea anomala* can usually be distinguished from its close allies by the stem bearing two sheathing leaves (rarely one) and with nodes smooth rather than sticky, as well as by the pale yellow flower with filaments united for at least 2 mm and usually 4–8 mm long. Flowers usually open in the late morning, and last till ± 17:00 the same day, but those of the Cederberg populations only to open at ± 16:00 and evidently represent a distinct race of the species. It is most easily confused with *M. angusta* which has similar nectar guides but usually a single sheathing leaf on the stem and filaments united for ± 1 mm.

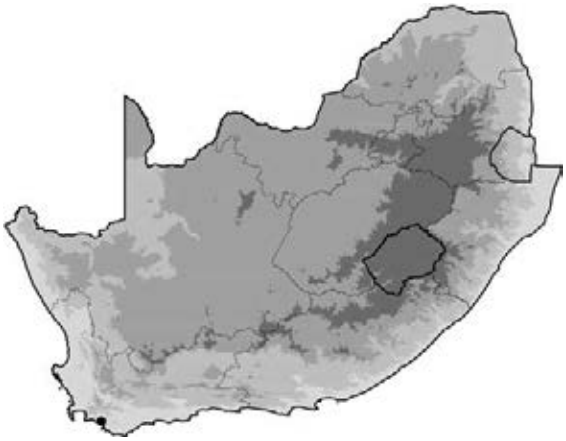


49. **Moraea neglecta** *G.J.Lewis* in Journal of South African Botany 15: 118 (1949); Goldblatt: 744 (1976a); Goldblatt: 44 (1986a). Type: South Africa, [Western Cape], near Sirkels Vlei, Cape Peninsula, *Lewis s.n.* (SAM [57107], holo.).

Plants mostly 300–500 mm high. *Corms* 10–18 mm diam.; tunics pale to dark brown, soft textured, inner layers ± entire, outer becoming vertically split, eventually fibrous. *Stem* flexed above sheath of foliage leaf, with long above-ground internode, sticky below upper nodes (rarely not sticky), with 1(2) sheathing leaves, 30–50 mm long, usually ± obtuse. *Foliage leaf* solitary, inserted shortly above ground level, firm to rigid, exceeding stem, terete. *Rhipidial spathes* dark green, distal margins brown, mostly truncate or obtuse at apex, inner 50–75 mm long, outer ± half as long. *Flowers* fugaceous, bright yellow, outer tepal limbs with nectar guide consisting of longitudinal lines of dark dots and yellow background; outer tepals 38–50 mm long, limbs slightly longer than claws; inner tepals 25–35 mm long, usually erect, obtuse. *Filaments* 6–12 mm long, united at base for ± 1 mm; anthers 7–9 mm long; pollen yellow (white). *Ovary* 9–15 mm long, exserted, cylindric-triangular to ± 3-winged, style branches 14–18(–22) mm long, crests slightly to significantly shorter than style branches, 14–22 mm long. *Capsules* cylindric, shallowly 3-lobed, mostly 15–20 mm long. *Seeds* large, flat, discoid. *Chromosome number* 2*n* = 20. *Flowering time*: middle September to November.

Distribution and ecology: from the Bokkeveld Mtns of Northern Cape, South Africa, in the north to the Caledon District in the southwest; mainly on sandy flats near the coast but also on mountain slopes and plateaus.

Distribution of ***Moraea anomala***.



Distribution of ***Moraea neglecta***.

Diagnosis: *Moraea neglecta* is readily distinguished when alive from *M. angusta* by its bright yellow flower with nectar guides consisting of longitudinal lines of black dots across the lower third of the outer tepal limbs. It can also be recognised by its usually sticky nodes, single sheathing leaf, and style crests usually slightly shorter than the style branches. It is frequently the most robust member of the alliance with stems up to 500 mm tall (although sometimes much shorter).

50. **Moraea vallisavium** *Goldblatt* in Annals of the Missouri Botanical Garden 69: 357 (1982); Goldblatt: 40 (1986a). Type: South Africa, [Western Cape], Vogelgat, Hermanus, 1 500 ft [± 460 m], *Goldblatt 5394* (MO, holo.; K, NBG, iso.).

Plants 100–340 mm high. *Corm* small, 4–6 mm diam., with corms of past seasons persisting beneath; tunics of fine netted fibres usually accumulating as a collar around base. *Stem* ± erect to inclined, unbranched, bearing a single sheathing leaf 15–40 mm long with margins free to base. *Foliage leaf* solitary, linear, unifacial, inserted above ground level, ± 2 mm wide, exceeding stem and falcate to trailing. *Rhipidial spathes* green, inner 30–40 mm long, obtuse to truncate, outer ± half as long. *Flowers* fugaceous, yellow, claws darkly speckled, outer tepal limbs with deep yellow nectar guides at bases; outer tepals 20–24 × 8–10 mm, claws ascending, 9–10 mm long, limb horizontal to slightly reflexed; inner tepals 16–19 × 7 mm, claw 6–8 mm long, slightly reflexed. *Filaments* ± 5 mm long, united in lower 2 mm; anthers 5–6 mm long; pollen red. *Ovary* 8–10 mm long, triangular in section; style branches ± 8 × 4 mm, crests 6–10 mm long, erect. *Capsules* narrowly top-shaped, slightly 3-lobed, 12–17 mm long, dehiscent in upper $^1/_3$. *Seeds* ± angular, 2 × 1 mm. *Chromosome number* unknown. *Flowering time*: late December to January.

Distribution of ***Moraea vallisavium***.

Distribution and ecology: a rare local endemic, *Moraea vallisavium* is restricted to the Klein River Mtns near Hermanus in Western Cape, South Africa; in relatively moist sites, often on steep south-facing slopes and flowering well only after fire unless in open rocky sites.

Diagnosis: although evidently a member of subg. *Monocephalae*, *Moraea vallisavium* has some unusual features for the alliance, particularly the finely fibrous corm tunics, the persistent old corms that accumulate beneath the current corm, and the leaf blade compressed and unifacial rather than terete. Also unusual, the margins of the sheathing leaf and outer rhipidial spathes are free to the base, whereas those of other species of the subgenus are united basally for a short distance. Like other members of the subgenus *M. vallisavium* has a solitary foliage leaf, an unbranched stem and fairly large yellow flowers. The seeds are unusual for subg. *Monocephalae* in their relatively large size ± angular shape, quite unlike the flattened discoid seeds of other species of the subgenus.

Subg. 7. **Acaules**

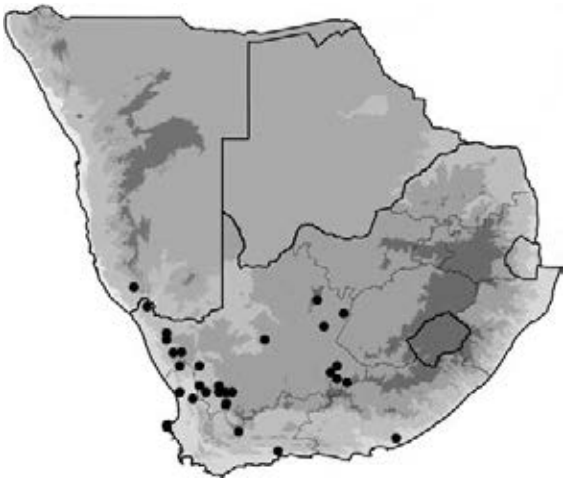
Subg. **Acaules** (*Baker*) *Goldblatt & J.C.Manning* in Bothalia 43: 37 (2013). *Moraea* [unranked] *Acaules* Baker: 8 (1896) [as 'sect. *Acaules* Baker' in Goldblatt: 7 (1976b)]. Type: *M. ciliata* (L.f.) Ker Gawl.

Plants usually acaulescent (not *M. longipes*), usually unbranched, often with a single rhipidium; corm tunics usually pale and coarsely fibrous. *Foliage leaves* several to few, hardly distinct from spathes, channelled. *Flowers* fugaceous, retracted after anthesis to base of rhipidium, various colours; stamens united in lower half; style branches well developed. *Capsules* concealed in spathes. *Basic chromosome number x* = 10.

51. **Moraea falcifolia** *Klatt* in Abhandlungen der Naturforschenden Gesellschaft zu Halle 15: 366 (1882); Goldblatt: 709 (1976a); Goldblatt: 77 (1986a). Type: South Africa, [Northern Cape], Hantam Mts, 1869, *Meyer s.n.* (B, lecto., designated by Goldblatt: 709 (1976a); S; isolecto.).

Moraea fasciculata Klatt: 366 (1882). *Galaxia pedunculata* Bég.: 211 (1909), illegitimate superfluous name for *M. fasciculata* Klatt [based on the same type]. Type: South Africa, [Western Cape], 'Langevaley', *Drège 2600* (B, holo.; K, P, S, iso.).

Moraea galaxioides Baker: 49 (1892). Type: South Africa, 'Transvaal', 1872, *Barber s.n.* (K, holo.).



[*Moraea polyphylla* Baker: 130 (1877), invalid name without description]

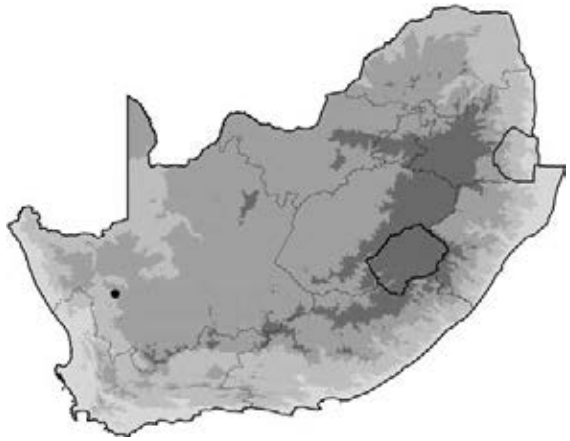
Plants small, up to 60 mm high, forming a dense sessile rosette. *Corm* 14–20 mm diam., bearing small cormlets at base; tunics of coarse, dark fibres. *Stem* subterranean, produced above ground in fruit, usually with few

branches, each bearing an inflorescence. *Foliage leaves* clustered at base, several, some indistinguishable from rhipidial spathes, up to 100 mm long, linear to lanceolate, falcate or loosely twisted, channelled, margins often undulate, sometimes crisped. *Rhipidial spathes*, especially the outer, sheathing only at base, with unifacial tip, not clearly distinct from leaves, inner usually entirely sheathing, up to 25 mm long, margins membranous. *Flowers* fugaceous, white, outer tepal limbs with yellow nectar guides at bases often edged purple, inner tepals usually with purple or grey mark at top of claws and sometimes crests purple in lower half, limbs of all tepals spreading; outer tepals 15–22 × 12–15 mm, claws 8–11 mm long, ascending; inner tepals 13–20 mm long. *Filaments* up to 6 mm long, united in lower half; anthers 3–4 mm long. *Ovary* sessile, cylindric-ovoid, 4–5 mm long, style branches ± 8 mm long, crests 5–8 mm long, outer margins often obscurely serrated. *Capsules* globose-ovoid, up to 10 mm long. *Seeds* rounded-angular, surface reticulate. *Chromosome number* 2*n* = 20. *Flowering time*: May to August (September).

Distribution and ecology: widespread in southern Africa, extending from southwestern Namibia southward through Namaqualand and Bushmanland in Northern Cape, South Africa, to the Vanrhynsdorp District with outliers as far south as Jacobsbaai near Saldanha, thence through interior Western Cape from Worcester to Laingsburg, the western Karoo and Great Karoo to the Alexandria District in Eastern Cape; in dry, open habitats in karroid or semi-karroid scrub and semi-desert (records from 'the Transvaal' are probably from near Kimberley).

Diagnosis: *Moraea falcifolia* is a small, tufted plant seldom reaching 60 mm when in flower, producing several smooth, falcate leaves, sometimes with ciliate margins, surrounding one or more sessile inflorescences, the spathes of which differ hardly at all from the leaves except by their position subtending the fugaceous blooms. The flowers are white with prominent yellow nectar guides on the outer tepals and dark purple or sometimes grey markings on the inner tepals and frequently dark purple on the lower half of the otherwise white style crests. Plants from the eastern end of its range, from near Kimberley and Barkly West, were treated by J.G. Baker as *M. galaxioides* but grade without noticeable discontinuity into those from Western Cape and the western Northern Cape, which include the types of *M. falcifolia* from the Calvinia District and *M. fasciculata* from Langvlei, on the Atlantic Coast near Lambert's Bay.

Distribution of ***Moraea falcifolia***.



Dwarf plants from the dry country north of Loeriesfontein with leaves 10 mm long, with obtuse apices and parallel, minutely ciliate margins, once included in *Moraea falcifolia* are now regarded as a separate species, *M. filamentosa*.

52. **Moraea filamentosa** *Goldblatt & J.C.Manning* in Bothalia 43: 154 (2013). Type: [Northern Cape], 22 miles [± 34 km] north of Loeriesfontein, May 1958, *Hall 1385* (NBG, holo.).

Plants acaulescent, ± 20 mm high, including flowers. *Corms* ± 12 mm diam.; tunics of medium-textured, shaggy fibres. *Foliage leaves* several, clustered at base, blades up to 10 mm long, falcate, channelled, up to 1.2 mm wide when opened flat, with thickened, hyaline main vein on abaxial surface, apex obtuse, margins hyaline, minutely ciliate. *Rhipidial spathes*: outer not distinct from leaves, with broad, membranous sheaths, inner ± membranous, floral bracts membranous, dry, elongate, often irregularly torn, ± as long as leaves. *Flowers* fugaceous?, possibly white, markings and orientation of tepals not known; outer tepals lanceolate, ± 14 × 4 mm, claws ± 5 mm long, limbs probably spreading, inner tepals ± 12 × 2 mm, possibly erect. *Filaments* ± 4.5 mm long, united in lower half; anthers ± 2.5 mm long, evidently yellow. *Ovary* elongate, fertile part club-shaped, ± 5 mm long; style branches broad, ± 4 mm long, crests triangular, ± 4 mm long, erect. *Capsules* and *seeds* unknown. *Flowering time*: May.

Distribution and ecology: known from a single collection from north of Loeriesfontein in Northern Cape, South Africa; the habitat is not known.

Diagnosis: the acaulescent *Moraea filamentosa* is a dwarf plant, reaching no more that 20 mm high, including the flowers. The small leaves are distinctive, having broad, membranous sheaths and falcate, channelled blades with obtuse apices. The hyaline margins are minutely ciliate and the blades have a thickened ridge in the midline of the abaxial surface. A remarkable feature not known in any other species of *Moraea* is that the floral bracts are elongate, membranous, and ± as long as the leaves, thus visible as pale filamentous threads among the leaf blades The small flowers have outer tepals ± 14 mm long, with filaments united in the lower half, and with broad style branches and erect, petaloid crests. It is evidently most closely related to *M. falcifolia,* which

Distribution of ***Moraea filamentosa***.

has a similar habit but is a larger plant with larger flowers, the outer tepals mostly 18–22 mm long, and longer, often twisted, tapering leaves up to 100 mm long with acute tips.

53. **Moraea ciliata** *(L.f.) Ker Gawl.* in König & Sims, Annals of Botany 1: 241 (1804a); Goldblatt: 79 (1986a); Goldblatt & Manning: 111 (2015). *Iris ciliata* L.f.: 98 (1782). *Vieusseuxia ciliata* (L.f.) Eckl.: 11 (1827). Type: South Africa, [Western Cape], hills near Cape Town, *Thunberg s.n.* [UPS-THUNB, lecto., designated by Goldblatt: 711 (1976a)].

Plants acaulescent, mostly 100–200 mm high. *Corm* mostly 12–15 mm diam.; tunics of medium to coarse pale or rarely dark brown fibres, sometimes (subsp. *ciliata*) extending upward as a collar of fibres. *Stem* subterranean even in fruit, occasionally with 1 or 2 sessile branches at ground level, sometimes with axillary cormlets. *Leaves* 3 or 4 (rarely up to 6) including leaf-like outer spathe, inserted at ground level, often exceeding inflorescence, usually slender, ± ascending to falcate and somewhat twisted, usually exceeding inner spathe, channelled, 5–12(–25) mm wide when opened flat, smooth or softly hairy, margins often undulate, rarely slightly crisped, short to long ciliate, straight, undulate or crisped. *Rhipidia* solitary (or 2 or 3); inner spathe usually sparsely hairy (smooth), 35–140 mm long. *Flowers* fugaceous, blue to blue-grey, white, yellow or pale pink, outer tepal claws sometimes dark blue to purple, limbs with small yellow nectar guides at bases outlined dark blue to violet, purple or brown, heavily scented of vanilla; outer tepals lanceolate, (18–)20–35 mm × 5–8 mm, claws (7.5–)10.0–17.0 mm long (slightly shorter to ± as long as limb); inner tepals 15–32 mm long, linear-spathulate to narrowly lanceolate, limbs spreading to half reflexed. *Filaments* 5–10 mm long, united basally for 1.5–2.0 mm or for almost half their length; anthers 4–8 mm long, blue or white; pollen white to yellow. *Ovary* spindle-shaped, (6–)10–14 mm long, retracted after flowering; style branches (7–)9–16 mm long, crests (6–)8–15 mm long. *Capsules* 10–28 mm long, enclosed in bases of spathes, walls ± membranous-translucent. *Seeds* ± globose, 1.4–2.5 mm diam. *Chromosome number* $2n$ = (18)20, 40. *Flowering time*: mainly late July to mid-September, occasionally earlier to October at high elevations, rarely in May or June.

Distribution and ecology: widespread in South Africa, extending from the Richtersveld and northern Namaqualand in Northern Cape to the Cape Peninsula and Swellendam in Western Cape and east through the Roggeveld to isolated sites in the Upper Karoo in Eastern Cape.

Diagnosis: distinguished in subg. *Acaules* by the often pubescent leaves and spathes, and most frequently blue flowers with relatively slender inner tepals, either linear-spathulate or narrowly lanceolate, and slender style crests. The capsules of *Moraea ciliata* are the longest in the subgenus, 10–28 mm long, and the seeds are more-or-less globose or somewhat angled by pressure and ± 2 × 2–3 mm. Two additional subspecies are recognised, yellow-flowered subsp. *lutescens* and white- or pale pink-flowered subsp. *cuprina*. The subspecies have separate but complimentary ranges and are weakly differentiated from one another. *Moraea ciliata* is easily distinguished from *M. tricolor*, which has broad style crests longer than the style branches, and tepal claws shorter than the limbs. Closely related *M. macronyx* has the tepal claws much longer than the limbs, whereas in *M. ciliata* the claws are slightly shorter than to about as long as the limbs. Basic chromosome number for *M. ciliata* is x = 10, known for several populations of subsp. *ciliata* and subsp. *lutescens*, although populations of subsp. *ciliata* from the Caledon and Bredasdorp Districts are polyploid, $2n$ = 40. Subsp. *cuprina* remains uncounted.

In the Roggeveld, Klein Roggeveld and nearby *Moraea ciliata* co-occurs with closely related *M. flava*, which blooms some weeks earlier and has smaller, white and yellow flowers, leaves with thickened and crisped margins, and smaller capsules, 8–12 mm long with small angular seeds. May-flowering *M. longipes*, confused in the past with *M. ciliata*, has the leaves and rhipidia borne on an elongate stem well above ground and sheathed at the base by a prominent collar of stiff fibres.

Key to subspecies

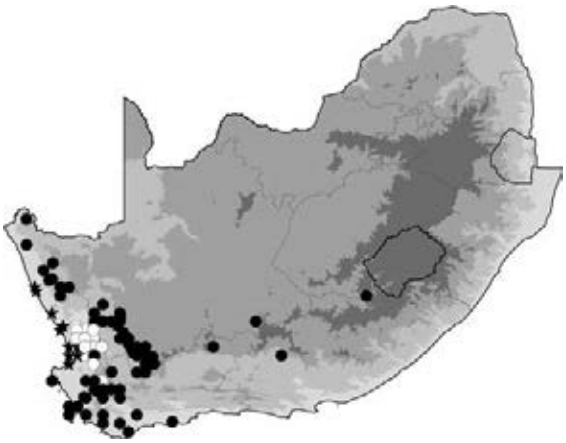
1a Flowers yellow to beige often flushed brown outside and nectar guides edged brown; filaments 4–7 mm long, united for 2.0–2.5 mm ($^1/_3$ to almost half their length) . . . . . 53b. subsp. *lutescens*

1b Flowers blue or white often flushed grey outside or translucent white to pink flushed coppery pink outside and nectar guides edged dark blue to violet or purple; filaments 4.5–10.0 mm long, united for 1–2 mm < $^1/_3$ their length):

2a Flowers shades of blue or white; plants nearly always with single inflorescence . . . 53a. subsp. *ciliata*

2b Flowers translucent white to pink flushed coppery pink outside; plants sometimes with 2 or 3 inflorescences . . . . . 53c. subsp. *cuprina*

53a. subsp. **ciliata**



Moraea hantamensis Klatt: 365 (1882). Type: South Africa, [Northern Cape], Hantam Mts, *Meyer s.n.* (B, holo.).

Moraea macrochlamys Baker: 49 (1892). Type: South Africa, [Eastern Cape], Graaff-Reinet, Sneeuberge, *Drege 2186* (K, lecto., designated by Goldblatt: 711 (1976a); B, S, iso.).

Plants often quite tall but also dwarfed in dry habitats, leaves up to 300 mm long, usually with axillary cormlets. *Leaves* 3 or 4, often exceeding inflorescence, usually slender, ± straight to falcate and somewhat twisted, channelled, 3–8 mm wide when opened flat, glabrous or softly hairy, margins usually ciliate, straight, undulate or crisped. *Rhipidia* solitary; inner spathe smooth or sparsely hairy, 35–55(75) mm long. *Flowers* blue to blue-grey, outer tepal claws often dark blue to purple, limbs with small yellow nectar guides at bases outlined dark blue (or rarely white with yellow nectar guides); outer tepals 24–34 mm long, claws 12–17 mm long (slightly shorter to ± as long as limb); inner tepals 25–32 mm long. *Filaments* 5–10 mm long, united for 1.5–2.0 mm (± $^1/_4$–$^1/_5$ their length); anthers 5–8 mm long, blue or white. *Ovary* 6–16 mm long; style branches 9–16 mm long, crests 9–15 mm long. *Capsules* 12–20 mm long. *Seeds* ± globose, 2.0–2.5 mm diam. *Flowering time*: mainly late July to mid-September, occasionally earlier.

Distribution and ecology: widespread across the southern African winter-rainfall zone, from the Cape Peninsula north to Saldanha Bay and east to Caledon and Bredasdorp in Western Cape, and then in an arc from the Richtersveld and interior Namaqualand through the Bokkeveld Plateau to the Roggeveld in Northern Cape, with isolated records from the Great Karoo near Richmond, the Sneeuberge near Graaff-Reinet, and near Lady Grey in Eastern Cape; mostly in renosterveld shrubland on heavier, clay soils.

Diagnosis: with flowers in shades of blue, less often white, subsp. *ciliata* remains variable for plant and flower size depending on season in the arid parts of its range. The leaves and spathes are usually hairy and with undulate to crisped margins, these rarely thickened, but always ciliate. Flowers typically have tepals 24–34 mm and filaments 5–10 mm long. Notable variants are white-flowered plants from the Cold Bokkeveld and the Hex River Pass, and early-flowering plants from sandy soils in the lower Breede River Valley west and south of Swellendam. These have relatively small white flowers unusual in having a purple mark at the base of the inner tepal limbs and have outer tepals 18–20 mm long. The two known populations were collected in flower in May and June, respectively. Additional collections are needed to better understand these plants which may merit taxonomic recognition at some level. The blue- and white-flowered populations bloom from July to September, even later at high elevations. Cormlets are often produced in lower leaf axils, absent in the other subspecies. Subsp. *ciliata* is diploid over most of its range but blue-flowered populations from the Caledon and Bredasdorp Districts are tetraploid, $2n = 40$.

Distribution of ***Moraea ciliata*** subsp. ***ciliata***, ●; subsp. ***cuprina***, ★; subsp. ***lutescens***, ○.

53b. subsp. **lutescens** *Goldblatt & J.C.Manning* in South African Journal of Botany 99: 112 (2015). Type: South Africa, [Western Cape], 6 km from Klipfonteinrand to Doornbos, *Nordenstam & Lundgren 1117* (NBG, holo.; MO, S, iso.).

Like subsp. *ciliata* but often more slender, stem usually without axillary cormlets. *Leaves* 3 or 4, often exceeding inflorescence, usually ± straight to loosely twisted, narrowly channelled, mostly up to 4 mm wide in middle when opened flat, smooth or sparsely hairy, margins usually ciliate. *Rhipidia* solitary; inner spathe smooth or sparsely hairy, 35–55(–75) mm long. *Flowers* yellow to beige or light brown, usually flushed brown outside, outer tepal limbs with small yellow nectar guides at bases edged with brown; outer tepals 24–32 mm long, claws 12–16 mm long, thus ± as long as limb; inner tepals 19–22 mm long. *Filaments* 4–7 mm long, united for 2.0–2.5 mm ($^1/_3$ to almost $^1/_2$ their length); anthers 4–6 mm long; pollen yellow. *Ovary* 6–9 mm long; style branches 7–11 mm long, crests 9–11 mm long. *Capsules* 10–14 mm long (as far as known). *Seeds* ± globose, ± 1.8 mm diam. *Flowering time*: late July to mid-September.

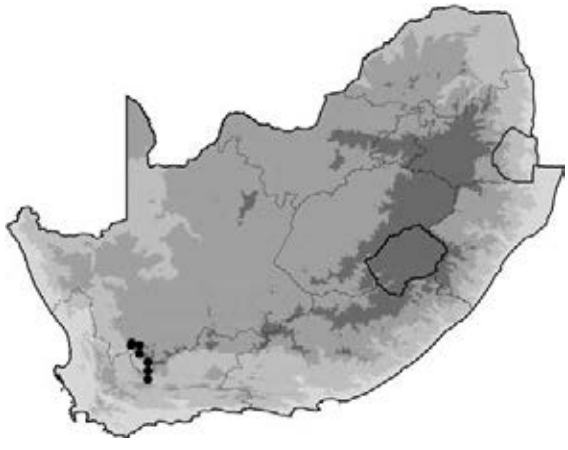
Distribution and ecology: extending in Western Cape from near Goudini north through the Olifants River Valley and Cederberg to the Gifberg (possibly also on the Knersvlakte); on stony, sandstone or loamy clay ground.

Diagnosis: distinguished in *Moraea ciliata* by the yellow to beige flowers, the tepals usually flushed or veined brown outside, a comparatively slender habit, and leaves that are hairless or sparsely hairy and often straight but with ciliate margins. The flowers are often relatively small for *M. ciliata* with outer tepals 24–32 mm long and filaments 4–7 mm long united for one third to almost half their length. In subsp. *ciliata* the filaments are 5–10 mm long but united only up to 2 mm, thus no more that one third their length but often less.

53c. subsp. **cuprina** *Goldblatt & J.C.Manning* in South African Journal of Botany 99: 113 (2015). Type: South Africa, Western Cape, Koekenaap to coast, Farm Kommandokraal, sandveld vegetation, in sandy depression, 15 July 2013, *Manning & Parker 3406* (NBG, holo.).

Plants like subsp. *ciliata* but often with 2(3) rhipidia, without axillary cormlets. *Leaves* usually 4 or 5, falcate or ± erect, channelled, 4–6 mm wide opened flat, margins straight to undulate (rarely crisped), usually ciliate. *Rhipidia* 1 to 3; inner spathe 80–140 mm long, usually smooth including margins, with evident angular keel sometimes ciliate. *Flowers* translucent white flushed coppery outside or pink to dull translucent red, outer tepal limbs with small yellow nectar guides at bases; outer tepals 25–32 mm long, claws 9–12 mm long, thus slightly shorter than limbs; inner tepals 20–24 mm long. *Filaments* 4.5–5.5 mm long, united for ± 2 mm, thus < $^1/_2$ their length; anthers 4–5 mm long; pollen white. *Ovary* 10–16 mm long; style branches 8–9 mm long, crests 12–15 mm long. *Capsules* 18–28 mm long. *Seeds* ± globose, 1.4–1.8 mm diam. *Flowering time*: late July to late August.

Distribution and ecology: extending along the Western Cape Atlantic Coast and near interior from Redelinghuys and Rocher Pan to central Namaqualand near Hondeklipbaai and Garies in Northern Cape; in deep quartzitic sands along the coast or inland on sandy, granite-derived ground.



Diagnosis: the unusual flower colour, translucent white flushed pink outside or pale pink to dull red, is unique in the complex and this together with the frequent presence of two or three rhipidia in mature plants makes subsp. *cuprina* easy to recognise. Fruiting plants are notable in their particularly long capsules, mostly 20–25 mm long, occasionally slightly shorter or longer. Plants bloom relatively early for the complex, from mid-July to mid-August along the coast but somewhat later in interior Namaqualand. Plants evidently lack axillary cormlets which are common in subsp. *ciliata*.

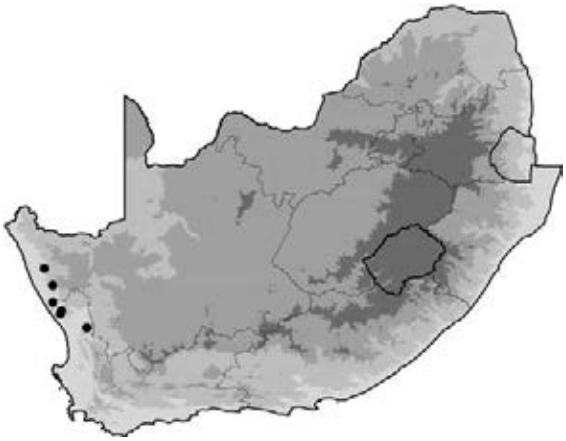
54. **Moraea flava** *Goldblatt & J.C.Manning* in South African Journal of Botany 99: 110 (2015). Type: South Africa, Northern Cape, 57 km S of Sutherland, below Komsberg Pass, sandy valley bottom, 31 Aug. 1993, *Goldblatt & Manning 9672A* (NBG, holo.; MO, iso.).

Plants 50–70 mm high, acaulescent. *Corm* ± globose, 10–15 mm diam.; tunics of pale straw-coloured, coarsely netted fibres with heavily thickened vertical ridges. *Stem* subterranean, bearing a single rhipidium. *Leaves* mostly 3 (including leaf-like outer spathe), ascending to spreading, loosely twisted below, often tightly so distally, channelled, grey-green, smooth, 40–80 mm long, margins thickened, undulate to crisped, usually minutely papillate, rarely ciliate. *Rhipidia* solitary, mostly 2(–4)-flowered; spathes smooth, inner 35–40 mm long. *Flowers* yellow or inner tepals and style crests pale yellow to white, outer tepal limbs with deeper yellow nectar guides at bases speckled with blue or black dots, spreading at ± 45°, inner tepal claws sometimes blue-grey and limbs often remaining suberect, scented of vanilla; outer tepals lanceolate, 18–28 × 6–8 mm, claws ascending, 9–11 mm long, channelled, shortly hairy in midline, inner tepals 18–28 mm long. *Filaments* 5–8 mm long, united for 1.5–2.0 mm, diverging distally; anthers 4.5–5.5 mm long, reaching to base of stigma lobes, pale blue; pollen white. *Ovary* elongate, fertile part oblong-cylindric, 5.0–7.5 mm long, partly included or exserted; style branches diverging, 7–10 mm long, crests erect, linear to narrowly wedge-shaped, 7–10 mm long. *Capsules* ovoid, 8–12(–15) mm long, retracted to ± base of spathes, near ground level. *Seeds* straw-coloured, angular-prismatic. *Flowering time*: August to mid-September.

Distribution and ecology: local in the western Karoo in Northern and Western Cape, South Africa, occurring in the central and southern Roggeveld, Klein Roggeveld and the Matjiesfontein–Laingsburg Karoo; in stony, sandy or clay ground.

Diagnosis: *Moraea flava* is distinguished from *M. ciliata* by its consistently relatively low stature, seldom exceeding 65 mm, smooth, twisted leaves with crisped and thickened margins minutely papillate to ciliate, and moderately sized yellow or yellow and white perianth, the outer tepals 18–28 mm long with shorter claws 9–11 mm long. The relatively short capsules, 8–12 mm long contain small, angular seeds. The leaves are typically hairless with only the leaf margins sometimes minutely papillate to ciliate. The species is sympatric with *M. ciliata* in the southern Roggeveld and Klein Roggeveld where *M. ciliata* has larger (elsewhere the flowers may be smaller), consistently blue flowers, the outer tepals 28–32 mm long with claws 15–16 mm long, inner tepals 24–26 mm long, filaments 8–9 mm long, united for ± 1 mm, anthers 5–7 mm long and style branches ± 12 mm long with crests 11–12 mm long. Although usually a taller plant, typically with straight

Distribution of ***Moraea flava***.



to undulate leaf margins, *M. ciliata* in the Roggeveld is occasionally only 50 mm high (most likely the result of a poor season) and may have crisped leaf margins, thus approaching *M. flava* in appearance, but the leaves are usually pubescent with the margins always ciliate, with hairs at least 0.5 mm long.

55. **Moraea longipes** *Goldblatt & J.C.Manning* in Bothalia 39: 5 (2009). Type: Western Cape, Namaqualand, 6 km NW of Bitterfontein on road to Kotzesrus, in stony granitic ground, 1 June 2008, *Manning 3172* (NBG, holo.; MO, iso.).

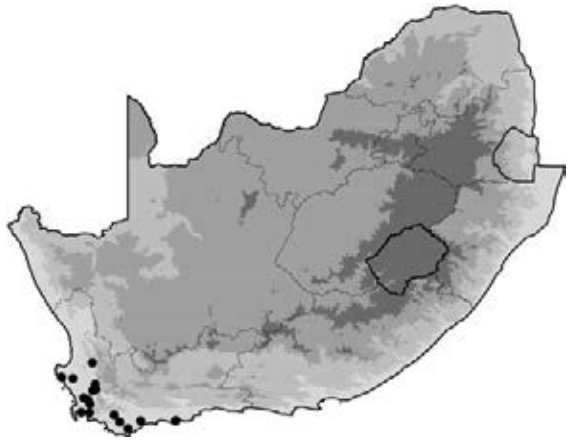
Plants 100–180 mm high. *Corm* globose, 15–20 mm diam.; tunics of ± straw-coloured, coarse fibres often with thickened vertical ridges. *Stem* unbranched, consisting of a single internode extending from the corm to well above ground level, sheathed by fibrous collar around base. *Foliage leaves* 3 (including leaf-like outer spathe), subopposite, inserted at base of inflorescence, suberect, straight, 45–85 mm long, channelled, margins smooth or sparsely ciliate. *Rhipidial spathe* with broad, transparent membranous margins, 50–70 mm long. *Flowers* fugaceous. Pale yellow or translucent white with pale copper-pink margins of outer tepals, inner tepals and outside of tepals, outer tepal limbs with yellow nectar guides at bases speckled with black dots, laxly spreading; outer tepals ± 30 × 19 mm, claw suberect, ± 10 mm long, hairy in midline, inner tepals ± 28 × 2–4 mm, claws suberect, ± 9 mm long, limbs laxly spreading. *Filaments* suberect, 7–9 mm long, united basally for ± 1.5 mm; anthers 7.5–9.0 mm long, reaching base of stigma lobes. *Ovary* elongate, fertile part ovoid, 5–9 mm long, usually at least partly included; style branches ascending, 13–16 mm long, crests erect, narrowly triangular, outer margins slightly and unevenly serrated, 8–10 × 2.5–3.0 mm at base. *Capsules* and *seeds* unknown. *Flowering time*: late May to mid-June.

Distribution and ecology: with a scattered distribution along the Atlantic Coast of South Africa, from Sannagas near Springbok in Northern Cape in the north to the Knersvlakte and the flats below the Gifberg in Western Cape in the south; on granitic or sandy gravel flats.

Diagnosis: flowering in mid-winter in May and June, *Moraea longipes* has the general aspect of *M. ciliata* and *M. tricolor* except that the stem is not subterranean at flowering but extends up to 180 mm above ground. Like most species of subg. *Acaules* the ovary is retracted to the base of the inflorescence spathes after flowering. The flowers are most like those of *M. ciliata* but have slightly broader style crests, triangular with the base 2.5–3.0 mm wide (± linear in *M. ciliata*) and the filaments are united basally for ± 1.5 mm, about one fifth of their length, as are those of most other species of subg. *Acaules*. The anthers of *M. longipes* are the longest in the subgenus, 7.5–9.0 mm long (5–8 mm in *M. ciliata*) and are held above the nectar guides on filaments as long as the tepal claws. A notable feature of *M. longipes* is the collar of fibres around the underground part of the stem, uncommon but not unique in the subgenus.

Distribution of ***Moraea longipes***.

The species flowers early in the season, May to early July, and grows in places where *M. ciliata* has been found in bloom six to eight weeks later. Flower colour in *M. longipes* is either pale, watery yellow or translucent white, then with the edges of the outer tepal limbs and the inner tepal limbs a pale coppery pink colour and with the tepals flushed the same colour outside.



56. **Moraea tricolor** *Andrews* in The Botanist's Repository 2: t. 83 (1800a); Goldblatt: 714 (1976a); Goldblatt: 84 (1986a). *M. ciliata* var. *tricolor* (Andrews) Baker: 11 (1896). Type: South Africa, without precise locality or collector, illustration in Andrews: t. 83 (1800a).

Iris fugax Pers.: 54 (1805), illegitimate superfluous name for *Moraea tricolor* Andrews (1800a). Type: unknown, possibly as for *M. tricolor*.

Moraea barbigera Salisb.: 306 (1812). *M. ciliata* var. *barbigera* (Salisb.) Baker: 49 (1892). Type: South Africa, without precise locality or collector, illustration in Curtis's Botanical Magazine t. 1012 '*Moraea ciliata* var.'

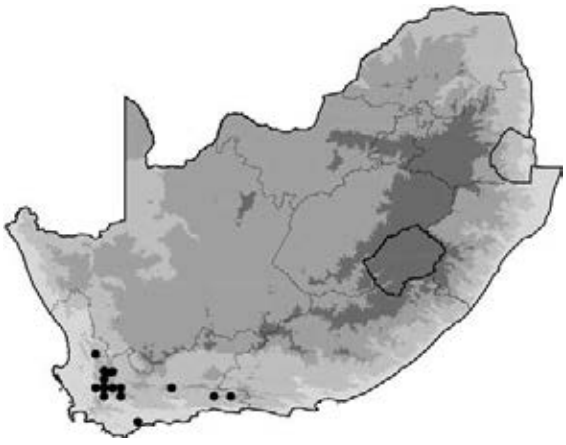
Moraea duthieana L.Bolus: 113 (1927a). Type: South Africa, [Western Cape], 15 km west of Stellenbosch, *L. Bolus s.n.* (BOL [18529], holo.; K, iso.).

Plants small, 50–150 mm high. *Corm* ± 15 mm diam.; tunics of medium to coarse, pale fibres. *Stem* subterranean, unbranched, bearing cormlets at nodes. *Foliage leaves* usually 2(3) (excluding opposed leaf-like spathe enclosing flowers), subopposite, inserted at ground level, suberect to falcate, exceeding inflorescence, smooth or lightly hairy or velvety, margins ciliate, straight or slightly undulate. *Rhipidial spathe* smooth or sparsely hairy, inner 20–60(–100) mm long, outer not distinct from leaves. *Flowers* fugaceous, yellow, red, pink, light purple or violet, outer tepal limbs with yellow (rarely orange) nectar guide at bases edged in darker pigment; outer tepals 20–25 mm long, lanceolate, spreading to slightly reflexed, claws 12–14 mm long; inner tepals 20–25 mm long, lanceolate, limbs like the outer. *Filaments* 3–4 mm long, united at base; anthers 2.5–3.0 mm long;

Distribution of ***Moraea tricolor***.

pollen yellow. *Ovary* ± cylindric, 8–10 mm long, usually exserted; style branches 4–5 mm long, crests 8–10 × 4–5 mm, broadly triangular, outer margins irregularly serrated. *Capsules* included bases of spathes and leaves, (7–)10–12 × 6 mm, soft walled. *Seeds* angular to subglobose, 1.0–1.4 × 1.3–2.0 mm, light brown with reticulate sculpturing. *Chromosome number* 2*n* = 18, 20. *Flowering time*: late July to middle September in the west, May and June in the east.

Distribution and ecology: extending in Western Cape, South Africa, from Hopefield and Piekenierskloof Pass south to the Cape Peninsula (now extinct there) and east as far as De Hoop and Still Bay; preferring seasonally wet sites in sandy ground, but the unusually early blooming populations from De Hoop and Still Bay occur on well-drained sandy ground.



Diagnosis: *Moraea tricolor* is recognised by its broadly triangular style crests 8–10 × 5 mm and relatively short style branches, up to 5 mm long, ± half as long as the crests. In the Atlantic Coast forelands of Western Cape flowers are either predominantly deep pink to brick-red (flower colour in the type of the species) or yellow or, in the Saldanha area, violet, and have virtually hairless leaves and spathes. In the Caledon District plants grow in renosterveld on clay ground and have pale purple flowers, and the leaves and spathes are velvet. Added to these differences is a difference in chromosome number, 2*n* = 18 in the west but 20 in the Caledon District. Populations further east in the De Hoop area and near Still Bay have yellow flowers and resemble the western populations morphologically but bloom earlier in the year, in May and June versus July to September in the west.

57. **Moraea macronyx** *G.J.Lewis* in Annals of the South African Museum 40: 115 (1954); Goldblatt: 714 (1976a); Goldblatt: 82 (1986a). Type: South Africa, [Western Cape], Gydo Pass, *Lewis s.n.* (SAM [61920], holo.).

Plants acaulescent, 90–180(–250) mm high. *Corm* 10–15 mm diam.; tunics of pale fibres or entire spongy, pith-like layers, bearing cormlets at base, producing slender stolons. *Stem* subterranean, unbranched, bearing cormlets at nodes, with single rhipidium. *Foliage leaves* 2(3) (excluding opposed leaf-like spathes enclosing flowers), subopposite, channelled, suberect to falcate, smooth or lightly hairy, 120–250 mm long, margins ciliate, straight to undulate. *Rhipidial spathes* glaucous-green, smooth or lightly hairy, inner 80–110 mm long, outer not distinct from leaves, clasping inner only at base. *Flowers* fugaceous, pale yellow or sometimes style branches and crests white, outer tepal limbs with nectar guides of dark spots on a yellow field at bases often edged yellow-brown distally, spreading or recurved distally; outer tepals 40–60 × 14–20 mm, claws 25–40 mm long, half again to ± twice as long as limbs; inner tepals 30–45 × 7 mm, linear-lanceolate, obtuse, initially erect, limbs later spreading. *Filaments* 12–18 mm long, united in lower ± 6 mm; anthers linear, 8–10 mm long, apiculate; pollen yellow or white. *Ovary* cylindric, 11–15 mm long; style branches 18–20 × 5 mm, crests up to 25 mm long. *Capsules* and *seeds* not known. *Chromosome number* 2*n* = 20. *Flowering time*: September to mid-October.

Distribution and ecology: largely a montane species of Western Cape, South Africa, extending from the southern Cold Bokkeveld to Robertson and Matjiesfontein in the west through the Little Karoo to the upper Long Kloof near Avontuur in Eastern Cape, and on the Potberg in the south; usually in clay ground but also limestone outcrops.

Diagnosis: allied to the well-known and widespread *Moraea ciliata* and occurring entirely within the range of this species, *M. macronyx* can be distinguished by its larger flowers with the outer tepal claws one and a half to twice as long as the limbs. The larger outer tepals are 40–60 mm long with the claws 25–40 mm long and the style branches are ± 20 mm long with crests up to 25 mm long. The outer tepals of *M. ciliata* are mostly 25–35 mm long with the claws 12–15 mm long, thus about half as long as the limbs, and the style branches are typically 8–15 mm long. Vegetatively *M. macronyx*

Distribution of ***Moraea macronyx***.

and *M. ciliata* are nearly identical although the corm tunics may differ, those of *M. macronyx* sometimes unusual in being entire and peculiarly soft, of an almost spongy, pith-like texture. Some populations, however, have fibrous corm tunics no different from those of *M. ciliata*.

Subg. 8. **Polyanthes**

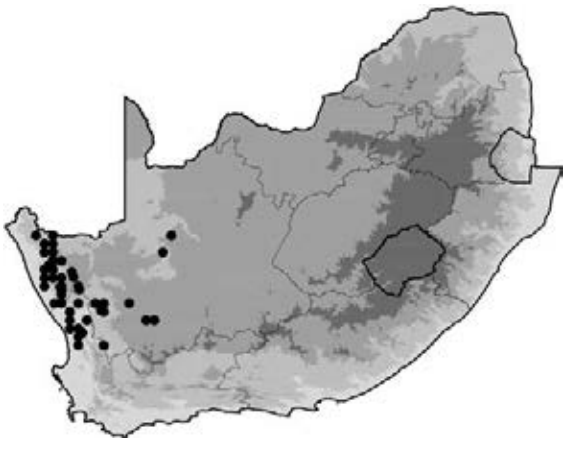
Subg. **Polyanthes** *(Goldblatt) Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 43: 37 (2013). *Moraea* sect. *Polyanthes* Goldblatt: 8 (1976b). Type: *M. polystachya* (L.f.) Ker Gawl.

Corm tunics mostly of hard, black fibres. *Foliage leaves* several to solitary. *Flowers* fugaceous, mostly blue to mauve, also yellow or white; stamens united in lower half; ovary often included, style branches well developed with prominent crest or much reduced, sometimes as paired or single filiform arms. *Capsules* oblong-ellipsoid, sometimes beaked, exserted or included. *Basic chromosome number* $x = 10$ but four of the six sections have $x = 6$.

Sect. 5. **Serpentinae** *Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 43: 37 (2013). Type: *Moraea serpentina* Baker

Foliage leaves (1)2 or 3(4), twisted or coiled. *Flowers* blue, yellow or mostly white; style branches and crests well developed. *Ovary* and *capsules* included.

58. **Moraea serpentina** *Baker*, Handbook of the Irideae 52 (1892); Goldblatt: 701 (1976a); Goldblatt: 69 (1986a). Type: South Africa, [Northern Cape], Okiep, *H. Bolus 6572* (K, lecto., designated by Goldblatt: 701 (1976a); GRA, isolecto.).



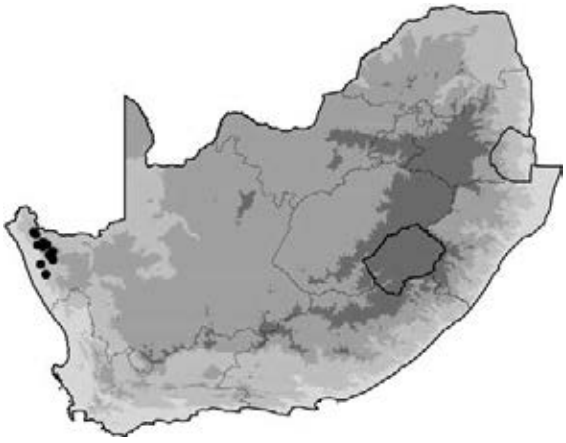
Moraea arenaria Baker: 52 (1892). Type: South Africa, [Western Cape], sand hills, Ebenezer, 1840, *Drège 8324* (K, holo.; MO, S, iso.).

Moraea framesii L.Bolus: 418 (1927b). Type: South Africa, [Northern Cape], near Calvinia, *P. Ross Frames s.n.* (BOL, holo.).

Plants (40–)70–200 mm high, usually branched. *Corm* 8–20 mm diam., asymmetric at base; tunics of tough coarse, usually dark fibres, often persisting as a collar around base. *Stem* 2 or 3 internodes long, branching from base or upper nodes, with 1 or 2 sheathing leaves 15–25 mm long, drying brown from tips. *Foliage leaves* basal only, or occasionally cauline, usually 3, occasionally 2 (or 1 in depauperate plants), channelled or ± flat, loosely coiled, margins ± undulate, sometimes lightly hairy on margins or on abaxial surface. *Rhipidial spathes* green or partly to largely dry, acute, often becoming lacerated, inner 15–30 mm long, outer entirely sheathing, ± $^1/_2$ as long. *Flowers* fugaceous, either white to yellow, tepals then often flushed with violet or pink, OR blue-violet, outer tepal limbs with large yellow nectar guides at bases, laxly spreading to reflexed; outer tepals 24–30 × 15–25 mm long, claw ± 12 mm long, limb obtuse to retuse; inner tepals 15–30 mm long, usually ± erect, spathulate. *Filaments* 5–7 mm long, united near base or up to middle; anthers 3–5 mm long, violet or white; pollen white. *Ovary* ellipsoid, 5–6 mm long, included, style branches ± 6 mm long, crests 4–8 mm long, lanceolate. *Capsules* enclosed in spathes, club-shaped sometimes tapering to short beak, 8–10 mm long. *Seeds* angled. *Chromosome number* $2n = 20$. *Flowering time*: September to October, occasionally in November.

Distribution and ecology: extending from the Richtersveld in Northern Cape, South Africa, south to Vanrhynsdorp and Klawer in Western Cape, also in Bushmanland and inland through the Upper Karoo as far east as Prieska; in sandy gravel, usually in stony places, sometimes in limestone outcrops.

Diagnosis: a small plant, *Moraea serpentina* rarely attains 200 mm in height and 90–120 mm is usual. It is readily distinguished by the typically three, rarely two or four foliage leaves, the blades channelled or flat and always at least loosely twisted, sometimes tightly so. The flowers are either partly yellow with pale yellow or white style branches and crests or white with the inner tepals and style branches flushed with violet. The inner tepals are held erect, a striking feature of the species. In the Kamiesberg populations the leaves are hairy on the margins or abaxial surface. Closely related *M. tortilis,* restricted to northern Namaqualand, has a broadly



Distribution of ***Moraea serpentina***.

similar appearance but the leaf blades are terete and tightly coiled in corkscrew fashion, and the violet or white flowers have both outer and inner tepal limbs invariably half reflexed.

Populations of *Moraea serpentina* from the western Knersvlakte, north of Vredendal, stand out in having consistently smaller, pale blue-violet flowers and two or even a single leaf but evidently do not otherwise differ from white-flowered plants. One- or two-leaved plants are occasionally found elsewhere across its range rendering taxonomic recognition of the blue-flowered plants impractical.

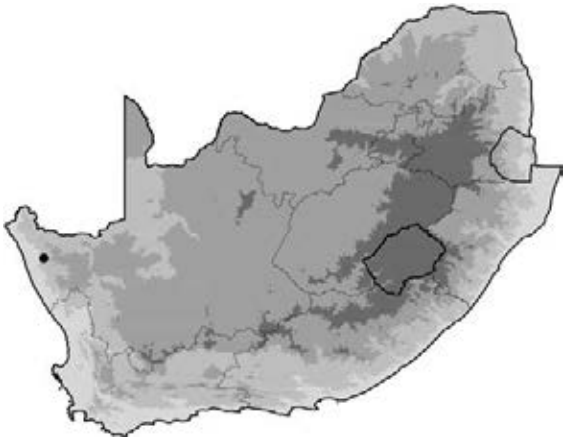
59. **Moraea tortilis** *Goldblatt* in Annals of the Missouri Botanical Garden 63: 705 (1976a); Goldblatt: 72 (1986a). Type: South Africa, [Northern Cape], between Okiep and Steinkopf, *Goldblatt 2771* (MO, holo.; K, NG, PRE, iso.).

Plants 10–15 mm high. *Corm* ± 10 mm diam., asymmetric at base; tunics of tough, dark fibres, sometimes as accumulating in a fibrous collar around base. *Stem* 2 or 3 internodes long, branched at base and upper nodes, sheathing leaves green or brown entirely, 12–20 mm long. *Foliage leaves* basal and sometimes cauline, (1)2 or 3, terete (flattened adaxially when dry), coiled helically like a corkscrew. *Rhipidial spathes* green to brown below, becoming completely dry and lacerated, inner 25–40 mm long, outer ± half as long, sheathing entirely. *Flowers* fugaceous, blue or white, outer tepal limbs with small yellow nectar guides at bases often edged dark violet, half reflexed; outer tepals 25–35 × ± 20 mm, limb ± $^{2}/_{3}$ as long as claws, obtuse to retuse; inner tepals to 22–30 mm long, limbs also reflexed. *Filaments* ± 8 mm long, united in lower half; anthers 5 mm long, yellow; pollen yellow. *Ovary* narrowly ovoid-ellipsoid, ± 9 mm long, included, style branches ± 10 mm long, crests narrow, ± 10 mm long, erect. *Capsules* ± ellipsoid, 12–13 mm long, included. *Seeds* angled. *Chromosome number* 2*n* = 20. *Flowering time*: September and October.

Distribution of ***Moraea tortilis***.

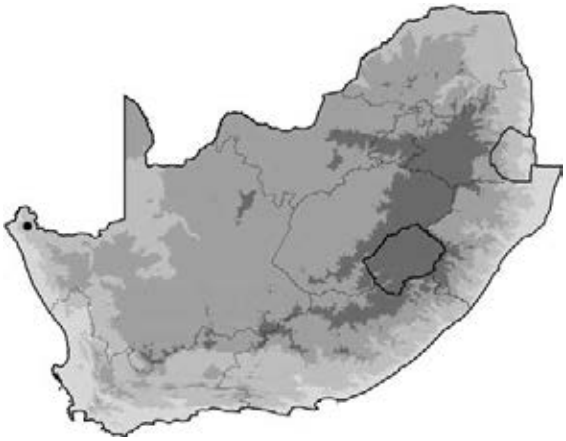
Distribution and ecology: rarely and local in Northern Cape, South Africa, extending from the southern Richtersveld to Springbok; confined to stony sandy places, frequently associated with quartzite outcrops.

Diagnosis: rarely exceeding 120 mm in height, *Moraea tortilis* is distinguished by tightly coiled, corkscrew-like leaves terete in section. Plants are usually branched and the flowers, violet or sometimes white with yellow nectar guides, are distinctive in the broad, half reflexed tepal limbs. The ovary and capsules remain enclosed in the spathes as in the closely allied *M. serpentina,* which has loosely coiled to twisted leaves, the blades channelled or flat, and predominantly yellow or white flowers with erect or suberect, spathulate inner tepals.



Sect. 6. **Deserticolae** *Goldblatt* in Annals of the Missouri Botanical Garden 63: 7 (1976b). Type: *Moraea bolusii* Baker

Moraea [unranked] *Subracemosae* Baker: 9 (1896) [as 'sect. *Subracemosae* Baker' in Goldblatt: 7 (1976b)]. Type: *M. edulis* (L.f.) Ker Gawl., lecto., designated by Goldblatt: 7 (1976b) = *M. fugax* (D.Delaroche) Ker Gawl.



Plants unbranched or branched, branches sometimes sessile. *Foliage leaves* solitary or 2. *Flowers* usually blue to mauve or violet or white, occasionally yellow; tepal claws short or ± as long as limbs; stamens united in lower half or entirely; style branches well developed with erect crests or reduced, without crests (as paired or filiform arms extended horizontally in *M. hexaglottis*). *Ovary* and *capsules* included, sometimes beaked.

60. **Moraea geminifolia** *Goldblatt & J.C.Manning* in South African Journal of Botany 91: 79 (2014b). Type: South Africa, Northern Cape, Springbok, near Nigramoep Mine on private mining company road on low ridge in scattered bush with *Ornithogalum pruinosum*, 29 Sept. 2013, *Goldblatt, Porter & Burger 13945* (NBG, holo.; MO, PRE, iso.).

Plants 70–100 mm high. *Corm* globose, 15–20 mm diam.; tunics forming dense, fibrous mass, dark grey-brown, usually accumulating in a collar around base. *Stem* simple or 1- or 2-branched, bearing sheathing leaves 15–20 mm long, sometimes overlapping. *Foliage leaves* 2, middle green, basal, ± linear, channelled, loosely twisted, ± trailing distally, 50–80 mm long, ± 3 mm wide opened flat, margins hyaline when dry, margins undulate, rarely partly crisped. *Rhipidial spathes* with broad, dry, transparent margins, inner 25–30 mm long, outer ± $^{2}/_{3}$ as long. *Flowers* fugaceous, mostly white, sometimes pale blue, outer tepal limbs with large pale yellow nectar guides edged distally with purple marks

Distribution of ***Moraea geminifolia***.

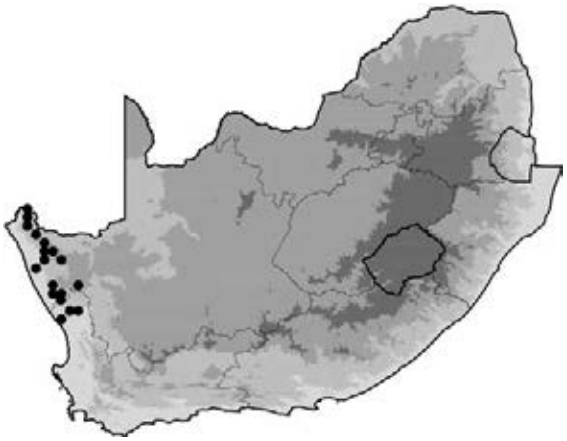
Distribution of ***Moraea teretifolia***.

at bases, odourless or faintly scented of vanilla; outer tepals 25–30 mm long, limbs ± 22 × 10 mm, claws ascending, ± 12 mm long, inner ± 28 × 6 mm. *Filaments* ± 8 mm long, united below in smooth, cylindric column ± 3 mm long; anthers ± 6 mm long, pale mauve; pollen white. *Ovary* narrowly ellipsoid, ± 6 mm long, included; style ± 4 mm long, branches diverging, ± 10 mm long, crests broadly wedge-shaped, 10–12 × 3.5 mm. *Capsules* and *seeds* unknown. *Flowering time*: late September to mid-October; opening ± 14:30 and collapsing ± 19:00.

Distribution and ecology: known only from ridge tops near the edge of the escarpment near Nigramoep west of Springbok in Northern Cape, South Africa; in stony flat ground with hard, clay substrate.

Diagnosis: immediately recognised by the two foliage leaves inserted below ground, more-or-less equal in size and with undulate margins, *Moraea geminifolia* is otherwise unremarkable in the *M. saxicola* complex. The white or pale blue-mauve flowers broadly resemble those of *M. saxicola*, although smaller in all features, with outer tepals 25–30 mm long and claws half to $^{2}/_{3}$ as long as the limbs. The filaments are ± 8 mm long and anthers ± 6 mm long. In *M. saxicola* the outer tepals are 34–45 mm long with claws about as long as the limbs, the filaments are 12–14 mm long, and anthers 6–9 mm long. *Moraea geminifolia* and *M. saxicola* are ecologically separated, growing adjacent to one anther just a few metres apart but on different soils.

61. **Moraea teretifolia** *Goldblatt & J.C.Manning* in South African Journal of Botany 91: 79 (2014b). Type: South Africa, Northern Cape, Richtersveld, slopes of Ploegberg, 27 Oct. 2008, *Nicholson s.n.* (NBG, holo. [with photo.]).



Plants up to 200 mm high. *Corm* globose, 15–20 mm diam.; tunics forming dense, fibrous mass, dark grey-black. *Stem* simple or 1-branched, 3 internodes long, bearing sheathing leaves ± 25 mm long. *Foliage leaves* 2, basal, ± linear, evidently narrowly channelled, straight, possibly ± trailing distally, ± as long as stem, slightly < 1 mm diam. margins plane. *Rhipidial spathes* with broad, dry, transparent margins, inner ± 25 mm long, outer ± $^{1}/_{2}$ as long. *Flowers* fugaceous, white with style branches flushed pale mauve, outer tepal limbs with large pale yellow nectar guides at bases white in middle, inner tepal claws speckled yellow, scent unknown; outer tepals ± 18 × 8 mm, claws ascending, ± 8 mm long, inner tepals ± 15 × 6 mm. *Filaments* ± 8 mm long, united below in smooth, cylindric column ± 4 mm long; anthers ± 4.5 mm long, pale mauve; pollen white. *Ovary* spindle-shaped, ± 7 mm long, included; style branches diverging, ± 6 mm long, crests broadly wedge-shaped, ± 7 mm long. *Capsules* ellipsoid, 9–10 mm long, without beak. *Seeds* unknown. *Flowering time*: October; recorded open in late afternoon.

Distribution and ecology: known only from the slopes of the Ploegberg in northwestern Richtersveld in Northern Cape, South Africa; in sandy, stony ground.

Diagnosis: superficially a small-flowered morph of *Moraea saxicola*, *M. teretifolia* stands out in having two basal foliage leaves with straight, terete blades ± as long as the stem. Both closely related *M. geminifolia* and *M. saxicola* also have branched stems but larger flowers, the outer tepals of *M. geminifolia* 25–30 × 10 mm and those of *M. saxicola* 34–45 × 10–16 mm, whereas in *M. teretifolia* the outer tepals are ± 18 × 8 mm. The white flowers have large nectar guides at the base of the outer tepal limbs, the nectar guides with a white centre bracketed by broad yellow borders. The capsules of *M. teretifolia* are 9–10 mm long and differ from those of *M. saxicola* in lacking a beak. Capsules of *M. saxicola* are 12–14 mm long with short beak up to 1 mm long.

62. **Moraea saxicola** *Goldblatt* in Annals of the Missouri Botanical Garden 63: 717 (1976a); Goldblatt: 86 (1986a); Goldblatt: 76 (2014b). Type: South Africa, [Northern Cape], 5 km west of Steinkopf, *Goldblatt 3057* (MO, holo.; K, NBG, PRE, S, iso.).

Plants mostly 200–500 mm high. *Corms* 16–20 mm diam.; tunics dark brown, finely netted, extending

Distribution of ***Moraea saxicola***.

upward in a thick collar around base. *Stem* (4)5 to 8 internodes long, branched, sometimes with 1 or 2 longer branches from lower nodes, upper nodes bearing ± sessile rhipidia or branches short and concealed by attenuate sheathing leaves, mostly 35–45 mm long. *Foliage leaf* solitary, usually exceeding stem, channelled to ± flat, 4–9 mm wide, falcate or trailing distally, sometimes twisted or loosely coiled distally, margins pale, thickened, straight or undulate, occasionally partly crisped, (juvenile leaves straight or somewhat twisted, narrowly channelled, up to 2 mm wide, or terete). *Rhipidial spathes* becoming dry at flowering time, often lacerated, inner 40–60 mm long, outer ± 10 mm shorter. *Flowers* fugaceous, pale blue or white to pale watery yellow, outer tepal limbs with long yellow to orange nectar guides white in middle at bases, faintly scented; outer tepals 34–45 mm long, limbs mostly 15–22 × 10–16 mm, half reflexed, claws ± as long or slightly shorter than limbs; inner tepals 30–36 mm long, limbs reflexed. *Filaments* 12–14 mm long, united in lower half; anthers 6–9 mm long, slightly exceeding stigma lobe, pale mauve; pollen white. *Ovary* ± cylindric, 8–10 mm long; included, style branches 8–15 mm long, crests ± lanceolate, 12–18 mm long. *Capsules* ellipsoid, mostly 12–14 mm long, with short beak up to 1 mm long. *Seeds* angular. *Chromosome number* 2*n* = 20. *Flowering time*: September to October; opening after 15:00 and sometimes only after 16:00, collapsing soon after sunset.

Distribution and ecology: extending from the Richtersveld in Northern Cape, South Africa, to the northern Knersvlakte in Western Cape; relatively common on various soils but often on gritty granitic gravel in rocky ground or on clay and shale substrates.

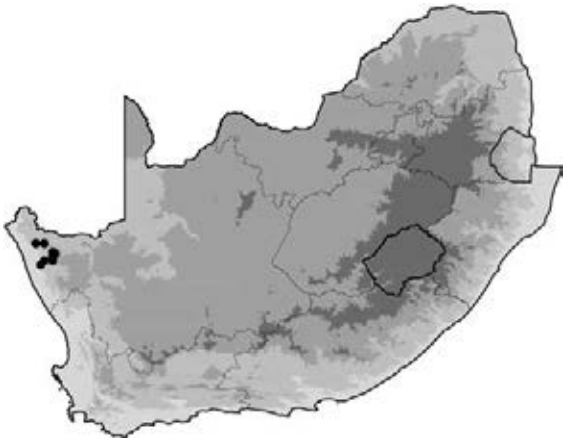
Diagnosis: late-flowering *Moraea saxicola* is recognised by the solitary foliage leaf with thickened, straight to undulate margins, and relatively large flowers with outer tepals 34–45 mm long and the limbs of both whorls half reflexed. The tepals are usually pale blue in the north of its range, white to palest yellow elsewhere, and the outer tepal limbs bear pale yellow nectar guides. The foliage leaf is fairly broad and slightly undulate with occasionally slightly crisped margins. Unusual for *Moraea*, the juvenile leaves are narrow and sometimes terete and coiled near the apex. By the time these plants reach flowering age, the leaf is usually broad, channelled and trailing. *Moraea saxicola* is allied to the yellow-flowered *M. bolusii* of northern Namaqualand, which also has an undulate leaf.

63. **Moraea namibensis** *Goldblatt* in Annals of the Missouri Botanical Garden 63: 721 (1976a); Goldblatt: 98 (1986a); Goldblatt: 77 (2014b). Type: Namibia, sandy flats near Udabib, *Merxmüller & Giess 3299* (WIND, holo.; M, PRE, iso.).

Plants erect, 120–400 mm high. *Corm* 15–20 mm diam.; tunics of dark, medium-textured fibres extending upward around base as a fine network. *Stem* erect, usually 2- or 3-branched. *Foliage leaf* solitary, ± basal, linear, falcate, narrowly channelled, longer than and trailing distally, margins straight. *Rhipidial spathes* with dry, brown, attenuate apices, inner 40–65 mm long; outer ± $^{2}/_{3}$ as long. *Flowers* fugaceous, white or blue-mauve, outer tepal limbs with yellow nectar guides at bases, reflexed to ± 40°; outer tepals 40–47 × 12–14 mm, limbs lanceolate, claws 20–22 mm long; inner tepals narrowly lanceolate, 35–40 × ± 7 mm, subacute. *Filaments* 10–12 mm long, united in lower half; anthers ± 6 mm long. *Ovary* ± ellipsoid, 8–18 mm long, included; style branches 10–12 mm long, crests lanceolate, 15–25 mm long. *Capsules* club-shaped, 12–20 mm long, beaked. *Seeds* unknown. *Chromosome number* 2*n* = 20. *Flowering time*: late August to October.

Distribution and ecology: poorly collected, *Moraea namibensis* is known from two sites in southwestern Namibia near Rosh Pinah and from near Port Nolloth in Northern Cape, South Africa; on sandy slopes and flats.

Diagnosis: *Moraea namibensis* stands out in the solitary basal leaf with a long, narrowly channelled blade, straight margins and relatively large, blue or white



Distribution of ***Moraea namibensis***.

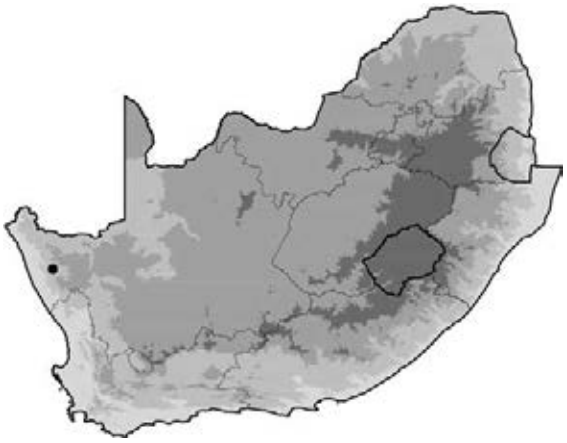
flowers. Typical of sect. *Deserticolae*, the ovary is included in the spathes and as far as known, the capsules are beaked, a feature of some members of the *M. saxicola* complex. When described only white-flowered plants were known but the population from near Port Nolloth has blue-mauve flowers somewhat larger that those of those from Namibia, the outer tepals up to 47 mm long and the inner up to 40 mm long. Other features of the Port Nolloth population are similarly slightly larger that previously recorded, particularly the style crests, up to 25 mm long.

64. **Moraea bolusii** *Baker*, Handbook of the Irideae: 57 (1892); Goldblatt: 721 (1976a); Goldblatt: 88 (1986a); Goldblatt: 78 (2014b). Type: South Africa, [Northern Cape], near Okiep, Sept. 1883, *H. Bolus 6574* (K, lecto., designated by Goldblatt: 721 (1976a); BOL, isolecto.).

Plants 70–200 mm high. *Corm* mostly 12–20 mm diam.; tunics of coarse black fibres usually extending upwards in a collar around base. *Stem* simple or few-branched, branches ascending, exserted from subtending sheathing leaf, sheathing leaves dry, ± membranous, 20–30 mm long. *Foliage leaf* solitary, smooth, longer than stem but usually ± trailing, shallowly channelled, usually laxly twisted for entire length, margins undulate to crisped. *Rhipidial spathes* partly green, drying from above at flowering, acute or lacerated distally, margins membranous, translucent; inner spathe 30–40 mm long, outer ± half as long. *Flowers* fugaceous, yellow, outer tepal limbs with large, deep yellow nectar guides at bases, inner tepals, style branches and crests paler yellow than outer tepals or white; outer tepals 26–33 × 11–13 mm, broadly lanceolate, ± half reflexed; inner tepals ± 25 mm long, limbs also reflexed. *Filaments* 10–12 mm long, united in lower ± $^{2}/_{3}$; anthers ± 6 mm long, yellow; pollen white. *Ovary* narrowly ellipsoid, 6–8 mm long, included; style branches ± 10 mm long, crests 10–15 mm long, broadly lanceolate. *Capsules* narrowly ellipsoid, 12–15 mm long. *Seeds* not known. *Chromosome number* 2*n* = 20. *Flowering time*: mostly September to middle October; opening 13:00 to 14:00 and collapsing at sunset.

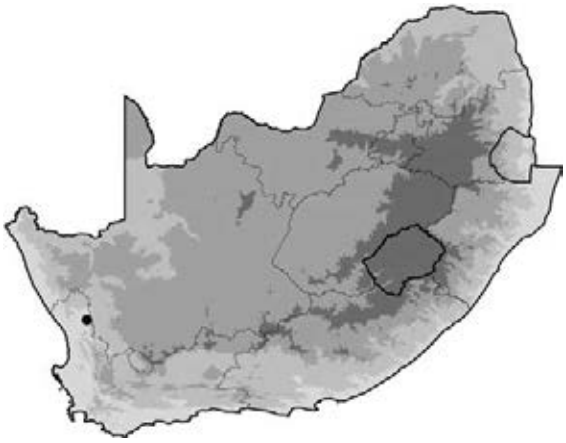
Distribution of ***Moraea bolusii***.

Distribution and ecology: centred in northern Namaqualand, Northern Cape, South Africa, from Steinkopf southward to Garies; in shallow sandy and stony soils.



Diagnosis: relatively common in northern Namaqualand, *Moraea bolusii* is distinguished by its solitary, fairly broad, undulate and loosely twisted leaf with somewhat thickened margins, and pale yellow flowers with relatively broad tepals up to 12 mm wide, both the inner and outer tepals limbs reflexed to ± 45°. The inner tepals, style branches and crests are typically paler than the outer tepals, often almost white. Flowers of related *M. saxicola* are usually white, sometimes pale blue, and open later than those of *M. bolusii*, between 15:00 and 16:00, also collapsing at sunset. The range of *M. bolusii* falls entirely within that of *M. saxicola.*

65. **Moraea acocksii** *Goldblatt & J.C.Manning* in South African Journal of Botany 91: 80 (2014b). Type: South Africa, Northern Cape, 31 miles [± 50 km] SW of Springbok, granite hills, 25 Sept. 1957, *Acocks 19584* (NBG, holo.; K, M, PRE, iso.).



Plants 120–150 mm high, evidently without a collar of fibres at base. *Corms* obconic, ± 10 mm diam.; tunics of medium-textured, black fibres. *Stem* simple or rarely 1-branched, branch exserted from sheathing leaf, 3 aerial internodes long, bearing attenuate, partly dry sheathing leaves 15–18 mm long. *Foliage leaf* solitary, usually shortly exceeding stem, terete, ± 1 mm diam. when alive, straight below, loosely to tightly coiled in distal $^{1}/_{3}$. *Rhipidial spathes* becoming dry at flowering time, often lacerated, inner 28–35 mm long, outer ± half as long to slightly less. *Flowers* fugaceous, white to creamy white, outer tepal limbs with yellow nectar guides at bases, evidently half reflexed; outer tepals ± 22 × 8 mm, limb ± as long as claw; inner tepals ± 15 mm long, limbs also half reflexed. *Filaments* 8–10 mm long, united in lower 3–4 mm; anthers ± 4 mm long; pollen ?white. *Ovary* subcylindric, ± 7 mm long, included, style branches ± 8 mm long, crests 6–8 mm long, wedge-shaped, ± 2 mm wide at base. *Capsules* ± ellipsoid, 8–9 mm long. *Seeds* unknown. *Flowering time*: October; flower phenology unknown.

Distribution and ecology: known from the type collection from central Namaqualand in Northern Cape, South Africa; on gravelly slopes of granite hills.

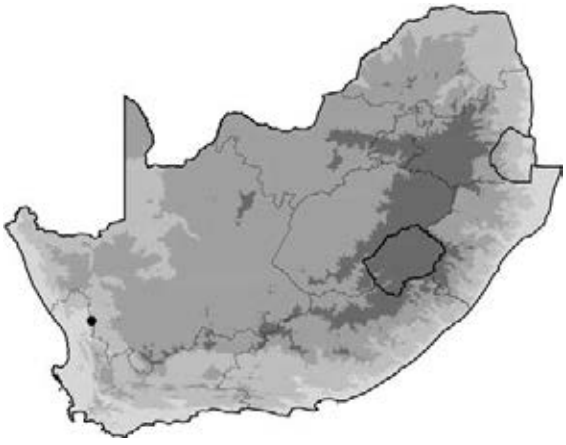
Diagnosis: the most striking feature of *Moraea acocksii* is the very slender, terete leaf, straight and ± erect for most of its length but with the distal third loosely to relatively tightly coiled and then straight again near the tip. Still poorly known, plants are usually unbranched but a few plants have a single branch, this relatively long and exserted from the subtending sheathing leaf. Plants are relatively low in stature, the tallest specimens up to 150 mm high, and the aerial part of the stem consists of four internodes, each node bearing an attenuate sheathing leaf up to 18 mm long. The white or creamy white flowers are relatively small for the

Distribution of ***Moraea acocksii***.

Distribution of ***Moraea quartzicola***.

M. saxicola complex with outer tepals ± 22 mm long (34–45 mm in *M. saxicola*), filaments 8–10 mm long and anthers ± 4 mm long.

66. **Moraea quartzicola** *Goldblatt & J.C.Manning* in South African Journal of Botany 91: 82 (2014b). Type: South Africa, Western Cape, low hills near Grootdrif west of Vanrhyns Pass, among quartzite stones, 9 Oct. 2013, *Goldblatt & Porter 13989* (NBG, holo.; K, MO, PRE, iso.).



Plants 70–150 mm high. *Corms* 12–15 mm diam.; tunics wiry, dark brown, accumulating in a dense mass, becoming finely netted distally. *Stem* simple or 1- or 2-branched, branches usually shortly emerging from subtending sheathing leaf, ascending, bearing ± dry, attenuate sheathing leaves ± 20 mm long. *Foliage leaf* solitary, usually slightly longer than stem, channelled to ± flat, mostly 3–5 mm wide, laxly twisted, trailing to ± prostrate, margins pale, thickened, undulate to crisped. *Rhipidial spathes* becoming dry at flowering time, often lacerated, inner 25–30 mm long, outer ± $^{2}/_{3}$ as long. *Flowers* fugaceous, pale blue-mauve to almost white, outer tepal limbs with large yellow nectar guides with white centre at bases, half reflexed; outer tepals 22–28 × ± 12 mm, limbs 15–18 mm long, claws 8–10 mm long (thus ± half as long as limbs); inner tepals 18–25 × ± 5 mm, limbs ultimately half reflexed. *Filaments* 8–9 mm long, united in lower half; anthers 3.5–5.0 mm long, pale mauve; pollen white. *Ovary* narrowly ellipsoid, ± 7 mm long, included; style branches ± 7.5 mm long, crests 8–12 mm long, lanceolate. *Capsules* ± ellipsoid, 8–9 mm long, with beak ± 1 mm long. *Seeds* unknown. *Flowering time*: October; opening 16:30 to 17:00 and collapsing ± 19:00.

Distribution and ecology: restricted to the southern edge of the Knersvlakte close to the foot of the Bokkeveld, Koebee and Gifberg Mtns in Western Cape, South Africa; on flat or gently sloping ground in clay loam among quartzite stones, a habitat common in the area.

Diagnosis: with a solitary, twisted and trailing leaf with undulate to crisped margins, *Moraea quartzicola* appears to be closely allied to the Namaqualand species *M. saxicola* but is distinguished by its smaller stature, up to 150 mm high, and smaller spathes and flowers, the outer tepals 22–24 mm long with short claws 8–10 mm long, the limbs thus almost twice as long. *Moraea saxicola*, always a taller plant, rarely < 250 mm high, has inner rhipidial spathes 40–60 mm long (vs. 25–30 mm), and outer tepals 30–40 mm long with the claws about as long as the limbs. Other floral parts of *M. saxicola* are likewise larger that those of *M. quartzicola*.

67. **Moraea macgregoriorum** *Goldblatt* [as *macgregorii*] in Annals of the Missouri Botanical Garden 63: 719 (1976a); Goldblatt: 92 (1986a) & 82 (2014b). Type: South Africa, [Western Cape], foot of Vanrhyns Pass, *Goldblatt 3097* (MO, holo.; NBG, iso.)

Plants 120–250 mm high. *Corm* ± 20 mm diam.; tunics of light brown, finely netted fibres extending upward in a collar around base. *Stem* flexuose, with several short branches, sheathing leaves attenuate, ± 20 mm long. *Foliage leaf* solitary, much exceeding stem, trailing distally, 3–4 mm wide, channelled, margins thickened.

Distribution of ***Moraea macgregoriorum***.

Rhipidial spathes dry distally at anthesis, apices sometimes lacerated; inner spathe 30–35 mm long, outer slightly shorter. *Flowers* fugaceous, pale blue-lilac, outer tepal limbs with prominent orange nectar guides in proximal half, reflexed to ± 40º; outer tepals ± 30 mm long, claws ± 15 mm long, linear, channelled below; inner tepals narrowly lanceolate, ± 25 mm long, claws ± linear, channelled, limbs similarly reflexed. *Filaments* 15 mm long, united in lower half; anthers 3–4 mm long, mauve; pollen ± white. *Ovary* ellipsoid, 7–8 mm long, included, style branches ± 12 mm long, crests narrow, up to 10 mm long. *Capsules* ± 15 mm long, ± obovoid, shortly beaked for ± 15 mm long, partly to fully included in spathes. *Seeds* small, angled. *Chromosome number* 2*n* = 20. *Flowering time*: October; opening ± 16:00 and collapsing ± 19:30.

Distribution and ecology: a narrow endemic restricted to the lower slopes of the Bokkeveld Mtns east of Vanrhynsdorp in Western Cape, South Africa; on rocky clay ground.

Diagnosis: although vegetatively there is little to distinguish *Moraea macgregoriorum* from related species, including *M. saxicola* and it allies, in the solitary, rather narrow undulate leaf, branched stem and ± dry spathes, the flower is, however, striking: the pale blue-lilac tepals are held well apart from one another and have long, very narrow claws, narrow, spreading to reflexed limbs and characteristic orange nectar guides. Particularly distinctive are the elongate filaments ± 15 mm long and disproportionately short anthers ± 4 mm long (*M. saxicola* has filaments 12–14 mm long and anthers 6–9 mm long). As in other members of sect. *Deserticolae* the ovary is included in the spathes. Molecular phylogenetic studies show that *M. macgregoriorum* is closely allied to *M. saxicola* and *M. bolusii*.

68. **Moraea graniticola** *Goldblatt* in Annals of the Missouri Botanical Garden 73: 107 (1986c). Type: Namibia, southern Namib, Aus townlands, sand around granite dome (ex hort. Kirstenbosch), *Lavranos & Pehlemann 20007* (WIND, holo.; MO, iso.).

Plants acaulescent or nearly so, up to 50 mm high. *Corm* 25–35 mm diam.; tunics of dark brown, coarse fibres accumulating in a dense mass around base, live corm up to 8 mm diam. *Stem* subterranean or produced just above ground, usually with 1 to 3 branches clustered near base. *Foliage leaves* 2(3), lowermost longest, up to 200 × ± 6 mm, shallowly channelled, spreading, white in midline, somewhat twisted, margins undulate, upper leaves similar but shorter. *Rhipidial spathes* with inner 25–30 mm long, outer somewhat membranous, slightly shorter than inner. *Flowers* fugaceous, blue-violet, outer tepal limbs with yellow nectar guides at bases; tepals united in a short tube 5–6 mm long, claws ± 3 mm long, ascending, forming a cup enclosing lower part of filament column, limbs spreading horizontally; outer tepals obovate, 18–20 × 9–11 mm; inner tepals ± 17 × 9 mm. *Filaments* 5–6 mm long, white, united below in

Distribution of ***Moraea graniticola***.

cylindric column, free and diverging in upper 1 mm; anthers ± 3.5 mm long, diverging, creamy white; pollen ± white. *Ovary* narrowly ellipsoid, 7–8 mm long, included, with a short sterile beak up to 2 mm long; style branches diverging, 2 mm long, deeply bilobed, ± 1 mm long, stigmatic towards apices, without crests. *Capsules* and *seeds* unknown. *Chromosome number* 2*n* = 20. *Flowering time*: September to early October (in cultivation).

Distribution and ecology: known only from near the town of Aus in southern Namibia; in sandy ground around granite outcrops.

Diagnosis: the small, blue-violet flowers of *Moraea graniticola* with subequal, spreading, shortly clawed tepals stand out in the genus and sect. *Deserticolae* in having a shortly beaked ovary and tepals united in a short perianth tube. The species is also unusual in being more-or-less acaulescent. Molecular DNA sequence studies show the species to be closely allied to *M. rigidifolia* and *M. herrei*, which have broadly similar flowers, both with an ovary beak, particularly well developed in *M. herrei*. Both the latter species have aerial stems, a solitary foliage leaf, and free tepals.

69. **Moraea rigidifolia** *Goldblatt* in Annals of the Missouri Botanical Garden 73: 109 (1986c). Type: Namibia, southern Namib, Farm Süd Witpütz, rocky granite flats, *Goldblatt 7016* (WIND, holo.; MO, NBG, PRE, S, US, WAG, iso.).

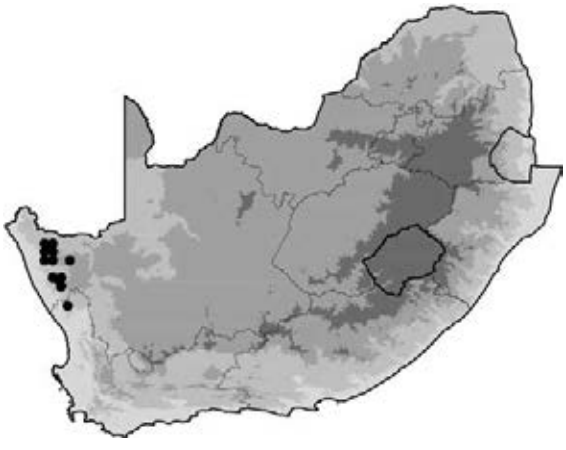
Plants slender, 70–120 mm high. *Corm* 20–30 mm diam.; tunics of dark brown, coarse fibres tunics accumulating in a dense mass extending upwards in a collar around base. *Stem* simple or branched from below, bearing several sessile lateral rhipidia above, sheathing leaves ± dry, brown, up to 25 mm long. *Foliage leaf* solitary, basal, terete, ± 3 mm diam., fistulose, pithy inside, falcate to recurved. *Rhipidial spathes* becoming dry and brown above, inner 17–22 mm long, outer slightly shorter. *Flowers* fugaceous, blue-mauve, outer tepal limbs with ± white nectar guides at bases, claws forming

Distribution of ***Moraea rigidifolia***.

a shallow cup around base of filament column, limbs spreading horizontally; tepals lanceolate, outer 14–18 × 6–7 mm, claws 3–4 mm long, inner 13–15 × 5–6 mm. *Filaments* 4.0–5.5 mm long, united below in a slender smooth column, free in upper 1.3–2.0 mm and diverging; anthers 2.2–3.0 mm long, diverging, white; pollen white. *Ovary* ± sessile, narrowly ellipsoid, 5–7 mm long, with sterile beak ± 1 mm long, included; style branches diverging, 2.0–2.5 mm long, bilobed above and stigmatic apically, reaching to midanther level, crests lacking. *Capsules* and *seeds* unknown. *Chromosome number* 2*n* = 20. *Flowering time*: late September to October; opening ± 16:30 and collapsing ± 19:00.

Distribution and ecology: known only from a single locality in southern Namibia, some 35 km north of the mining settlement of Rosh Pinah; in thin soil on low outcrops of weathered granite, the corms often wedged in cracks in rock.

Diagnosis: the small, pale blue-mauve flowers of *Moraea rigidifolia* have subequal tepals with short claws that enclose the lower part of the filaments, and divergent anthers appressed to short, narrow style branches that lack crests. The Namaqualand species *M. herrei* has similar flowers apart from the ovary, which although also subsessile has a sterile, tubular, apical beak 7–10 mm long. The beak is poorly developed in *M. rigidifolia* and only ± 1 mm long. The leaf of *M. herrei* is slender, terete and often spirally coiled, very different to the straight, relatively thick, hollow leaf of *M. rigidifolia*. Molecular studies confirm that the two species are closely related.



70. **Moraea herrei** *(L.Bolus) Goldblatt* in Novon 8: 374 (1998). *Homeria herrei* L.Bolus: 367 (1931b). Type: South Africa, [Northern Cape], Namaqualand, Breekpoort, Steinkopf, *Herre s.n.* (BOL, holo.).

Moraea spiralis Baker: 57 (1892), illegitimate homonym, not *M. spiralis* L.f. (1782). *Helixyra spiralis* N.E.Br.: 349 (1929b). *Gynandriris spiralis* (N.E.Br.) R.C.Foster: 41 (1936). *Barnardiella spiralis* (N.E.Br.) Goldblatt: 312 (1976c). Type: South Africa, [Northern Cape], 'Namaqualand', *Drège 2604* (K, lecto., designated by Goldblatt: 312 (1976c); BOL, isolecto.).

Plants 6–14 mm high. *Corm* up to 20 mm diam.; tunics of dark brown fibres, vertical members heavily thickened, accumulating in a dense mass, extending upward as a collar around base. *Stem* simple or few-branched near base, usually bearing 1 to several sessile lateral rhipidia, sheathing leaves ± 15 mm long, ± dry at flowering. *Foliage leaf* solitary, basal, terete, ± straight and falcate to loosely or tightly coiled in corkscrew-fashion. *Rhipidial spathes* dry, pale brown, inner 15–20 mm long, outer $^{2}/_{3}$ to ± as long, margins membranous. *Flowers* fugaceous, nearly sessile, perianth borne on an ovary tube, blue-mauve to violet, inner and outer tepal limbs with small yellow nectar guides at bases; outer tepals ± 14, claws short, ± 4 mm long, forming a cup including filament column, limbs spreading ± horizontally, 10 × 7 mm, inner with limbs 9 × 6 mm. *Filaments* ± 5.5 mm long, united in a slender column minutely scabrid in lower half, free and diverging in upper ± 1 mm; anthers ± 3.5 mm long, white, initially concealing style branches; pollen pale yellow. *Ovary* cylindric, 12–15 mm long, fertile in lower ± 5 mm, prolonged distally as a sterile, tubular beak; style branches short, ± 1 mm long, dividing into two diverging, narrow, apically stigmatic arms without crests, reaching to middle of anthers. *Capsules* and *seeds* unknown. *Chromosome number* 2*n* = 20. *Flowering time*: mainly September and October; opening ± 14:30 and collapsing at sunset.

Distribution and ecology: fairly widespread in Namaqualand in Northern Cape, South Africa, from near Steinkopf in the north to Bitterfontein in Western Cape in the south, and common west of Springbok; in hard, stony sandy gravel or clay.

Diagnosis: *Moraea herrei* stands out in its slender, terete leaf, often loosely spirally coiled, and in the small, violet flower with subequal tepals with spreading to reflexed

Distribution of ***Moraea herrei***.

limbs and short, almost vestigial style branches lacking crests. The flower is subsessile and the perianth is raised above the spathes on a sterile, tubular extension of the ovary, a structure that is paralleled in sect. *Gynandriris*. *Moraea herrei* is allied to two southern Namibian species, *M. graniticola* and *M. rigidifolia,* both of which have a shortly beaked ovary with the beak much shorter than in *M. herrei*. *Moraea graniticola* differs additionally in having a true perianth tube and a stem barely reaching above ground.

71. **Moraea hexaglottis** *Goldblatt* in Annals of the Missouri Botanical Garden 73: 108 (1986c). Type: Namibia, Huib Plateau, Farm Aub, 80 km N of Rosh Pinah, *Lavranos & Pehlemann 21704* (MO, holo.; WIND, iso.).

Plants small, 80–100 mm high. *Corm* 10–15 mm diam.; tunics of coarse brown fibres. *Stem* weakly flexuose below nodes, 1- or 2-branched, bearing sheathing leaves 12–18 mm long, green becoming dry above. *Foliage leaf* solitary, basal, slender, apparently terete but linear and channelled, with tightly inrolled margins, sometimes slightly twisted above, ± twice as long as stem. *Rhipidial spathes* becoming dry and pale straw-coloured above, inner 16–19 mm long, outer ± half to nearly as long. *Flowers* fugaceous, blue-violet, outer tepal limbs with pale yellow nectar guides at bases; outer tepals 12–14 × 6–7 mm, claw ± 1 mm long, clasping filament column, limb obovate, spreading ± horizontally, obovate; inner tepals smaller than outer, 10–12 mm long, lanceolate. *Filaments* ± 4 mm long, united in lower half in a smooth cylindric column, diverging in upper half; anthers 3–4 mm long, ascending, yellow; pollen yellow. *Ovary* ± cylindric, ± 3 mm long, at least partly exserted; style branches divided almost to base into paired slender tapering arms extending upwards between filaments, style arms ± 2.7 mm long, apically stigmatic, crests lacking. *Capsules* globose, 4–6 mm diam. *Seeds* angular. *Chromosome number* 2*n* = 20. *Flowering time*: September to October, opening ± 16:00, fading at sunset.

Distribution of ***Moraea hexaglottis***.

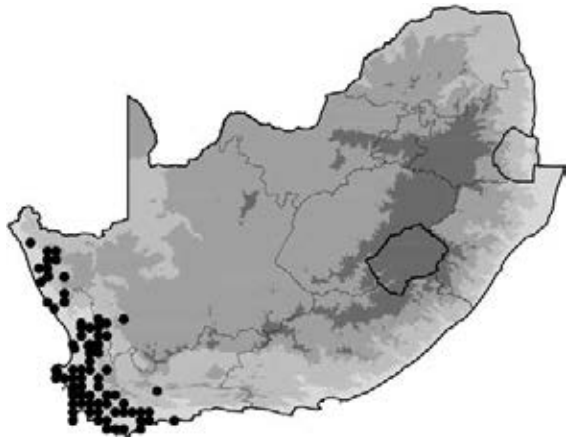
Distribution and ecology: restricted to southern Namibia and known from only one site on the Huib Plateau at ± 1 300 m; in silt on black limestone.

Diagnosis: named for the six, filiform style branches, *Moraea hexaglottis* has small, blue-violet flowers with spreading, subequal tepals very like those of *M. rigidifolia* and the widespread *M. crispa* but with short style branches, each divided almost to the base into a pair of slender, ascending arms resembling those of the species of sect. *Hexaglottis*, except that in sect. *Hexaglottis* the filaments are united only near the base, the style arms are stouter, and the flowers are always yellow. The blue flowers and chromosome number $x = 10$ suggest that *M. hexaglottis* is allied to the *M. herrei* group of sect. *Deserticolae*. Blue-flowered *Moraea pearsonii* of sect. *Pseudospicatae* has remarkably similar paired, filiform style branches.

72. **Moraea fugax** *(D.Delaroche) Jacq.*, Hortus botanicus vindobonensis 3: 14 (1776); Goldblatt: 98 (1986a, incl. *M. filicaulis*). *Vieusseuxia fugax* D.Delaroche: 33 (1766). Type: South Africa, without precise locality or collector, illustration in Van Hazen: 67 (1759).

Iris edulis L.f.: 98 (1782). *Moraea edulis* (L.f.) Ker Gawl.: t. 613 (1803a). *Vieusseuxia edulis* (L.f.) Link: 56 (1821). Type: South Africa, without precise locality, *Thunberg s.n.* [UPS-THUNB, lecto., designated by Brown 1928: 38].

Moraea corniculata Lam.: 115 (1791). Type: South Africa, without precise locality, *Sonnerat s.n.* [P, lecto., designated by Goldblatt: 725 (1976a)].



Iris longifolia Schneev.: t. 20 (1793). *Moraea longifolia* (Schneev.) Sweet: 497 (1830), illegitimate homonym, not *M. longifolia* (Jacq.) Pers. (1805). *M. edulis* var. *longifolia* (Schneev.) Baker: 21 (1896). Type: South Africa, without precise locality or collector, illustration in Schneev.: t. 20 (1793).

Moraea odora Salisb.: t. 1, 10 (1805). *M. edulis* var. *odora* (Salisb.) Baker: 21 (1896). Type: South Africa, without precise locality or collector, illustration in Salisb.: t. 1, 10. (1805).

[*Iris imberbis* van Hazen ex Ker Gawl.: t. 1238 (1809), invalid name only in synonymy. *Iris imberbis, etc.* van Hazen: 67 (1759) polynomial.]

[*Vieusseuxia longifolia* Eckl.: 14 (1827), invalid name without description.]

Plants medium to large, mostly 200–500 mm high. *Corm* 15–30 mm diam.; tunics of light, rarely dark brown, medium-textured fibres. *Stem* mostly 2–3 mm diam., suberect to inclined, with long basal internode, sheathing leaves mostly 15–30 mm long, dry and brown distally. *Foliage leaves* inserted at first node above ground, solitary or 2, ± opposite and subequal or unequal, linear, much exceeding stem, ± falcate, trailing distally, channelled, (1.5–)3.0–7.0 mm wide, margins sometimes

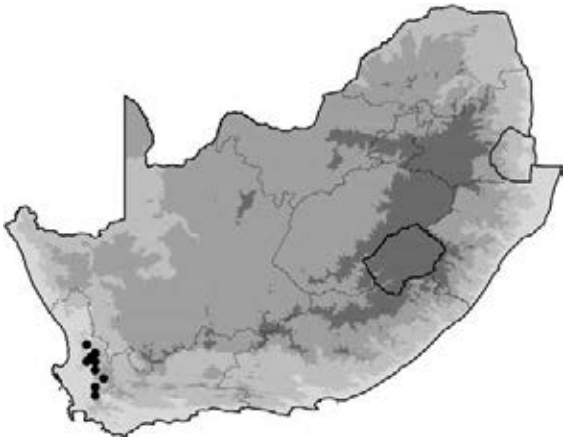
Distribution of ***Moraea fugax***.

tightly inrolled, then evidently terete. *Rhipidial spathes* with age dry and membranous distally, inner 35–80 mm long, outer entirely sheathing, ± 1/3 as long. *Flowers* fugaceous, white, blue or yellow, outer tepal limbs with yellow or white nectar guides at bases, strongly vanilla-scented; tepals lanceolate, limbs ± spreading, claws ascending; outer tepals 30–50 mm long, limb ± as long as claw or slightly shorter; inner tepals 26–43 × 5–9 mm. *Filaments* 7–13 mm long; anthers 6.5–10.0 mm long, usually white; pollen usually white. *Ovary* ellipsoid, 10–20 mm long with beak ± 1.5 mm, included; style branches (10–)12–20 mm long, crests lanceolate, 10–20 mm long. *Capsules* club-shaped to ± cylindric, shortly beaked, mostly 12–30 mm long. *Seeds* many, angled. *Chromosome numbers* 2*n* = 20, 18, 16, 14, 12, 10. *Flowering time*: mainly late August to October; usually opening ± 13:00 (later in some populations), collapsing near sunset.

Distribution and ecology: relatively widespread along the western and southern coasts and near interior of South Africa, extending from the Bokkeveld Mtns in Northern Cape through Western Cape to the Cape Peninsula and east to Albertinia, as well as northwards along the coast into central Namaqualand; in sandy ground and rock outcrops, both in rocky sites and deep sands, from coastal sites to mountains at middle elevations.

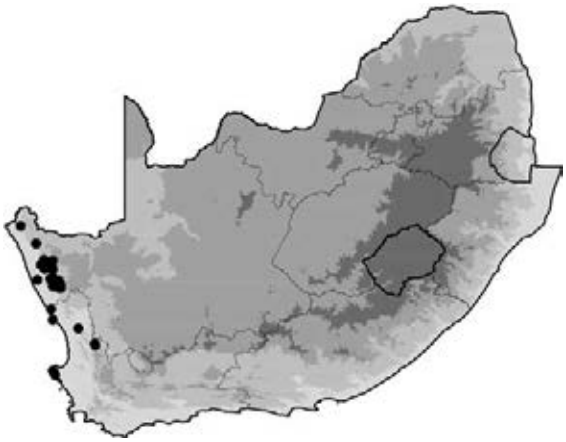
Diagnosis: usually easy to recognise by the long basal internode with the leaf or leaf pair inserted at the first node above ground, *Moraea fugax* has a few- to several-branched stem and relatively large flowers. Also distinctive, the ovary and capsules are included in the spathes and have a short beak, conspicuous in fruit. The species includes three main morphs. The typical form with yellow flowers and relatively broad inner tepal limbs is often early flowering, mainly in August to the middle of September, and occurs mostly on stony sandstone slopes. A second morph has white to blue flowers with narrower inner tepals and is largely coastal, occurring in deep sands and extending from Namaqualand to Hermanus but inland for some distance and occasional in the Olifants River Valley. A third morph from interior southwestern Cape has smaller, white flowers with unusually narrow inner tepals. The tall, white to blue-flowered morph has been recognised as *M. longifolia* (or as *M. edulis* var. *longifolia*) [under the assumption that *M. edulis* represented yellow-flowered plants]. Another unusual variant is represented by yellow flowered plants from the Pakhuis Mtns and nearby flowering in late September and October, with inner tepals erect (unique in the complex) and particularly slender stems and filiform, tightly rolled leaves.

Not only is *M. fugax* diverse morphologically but chromosome numbers are strikingly varied, with diploid numbers ranging from 2*n* = 20 to 10, the lower numbers usually associated with yellow-flowered populations. Further investigation at population level is necessary to resolve variation in the complex into a more refined taxonomy.



73. **Moraea gracilenta** *Goldblatt* in Annals of the Missouri Botanical Garden 63: 724 (1976a); Goldblatt: 94 (1986a). Type: South Africa, [Western Cape], sandy flats south of Piekenierskloof Pass, *Goldblatt 3279* (MO, holo.; K, NBG, PRE, S, iso).

Moraea edulis var. *gracilis* Baker: 56 (1892). Type: South Africa, [Western Cape], Tulbagh Kloof to Piekenierskloof, *Zeyher 1647* (K, lecto., designated by Goldblatt: 724 (1976a); PRE, S, isolecto.).



Plants 300–800 mm high. *Corm* 15–20 mm diam.; tunics of fine to medium-textured, pale or dark brown fibres. *Stem* with long basal internode, many-branched, sheathing leaves 25–35 mm long, dry and brown distally. *Foliage leaf* solitary, channelled, linear, exceeding stem and trailing distally, inserted well above ground at first aerial node. *Rhipidial spathes* becoming dry above, apices brown, acute; inner 25–35(–40) mm long, outer slightly < 1/2 as long. *Flowers* fugaceous, pale blue-mauve, outer tepal limbs with yellow nectar guides at bases, strongly vanilla-scented; outer tepals 20–30 × ± 8 mm, lanceolate, laxly spreading; inner tepals 18–28 × 5–6 mm, limbs laxly spreading. *Filaments* ± 5 mm long, united in lower half; anthers 4–6 mm long, white; pollen white. *Ovary* narrowly ellipsoid, 8–10 mm long, usually partly included at anthesis; style branches 7–9 mm long, crests linear-lanceolate, 7–12 mm long. *Capsules* mostly 10–12 mm long, shortly beaked. *Seeds* angular. *Chromosome number* 2*n* = 20. *Flowering time*: late September to November, extending to December at higher altitudes; opening ± 15:30 and collapsing ± 19:00.

Distribution and ecology: local in Western Cape, South Africa, from Clanwilliam in the north to Tulbagh and Piketberg: on sandy flats, often in deep sandy ground (many of the known sites for the species are degraded or lost to agriculture).

Diagnosis: *Moraea gracilenta* differs consistently from all morphs of the very variable *M. fugax* in its distinctive

Distribution of ***Moraea gracilenta***.

Distribution of ***Moraea filicaulis***.

extended stem, multi-branched habit, and smaller pale blue to almost white flowers, the outer tepals 20–30 mm long. The rhipidial spathes are also relatively short, the inner spathe, 25–40 mm long, and the capsules are only ± 10 mm long. Timing of anthesis is also different in the two species. Flowers of *M. gracilenta* open ± 15:30 and last until 19:00, whereas those of *M. fugax* open between 11:00 and 13:00 and collapse by 18:00. The flowering phenology of *M. gracilenta* appears to vary hardly at all in wild populations.

74. **Moraea filicaulis** *Baker* in Bulletin de l'Herbier Boissier, sér. 2: 1005 (1904b). *M. fugax* subsp. *filicaulis* (Baker) Goldblatt: 155 (1986b). Type: South Africa, [Northern Cape], Kamiesberg between Roodeberg and Ezelskop, *Drège 2605* (K, lecto., designated by Goldblatt: 725 (1976a); MO, P, isolecto.).

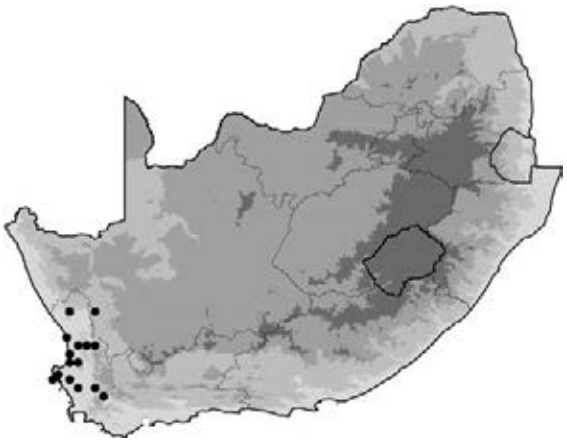
Moraea diphylla Baker: 42 (1906). Type: South Africa, [Western Cape], Olifants River, *Penther 734* [K, lecto., designated by Goldblatt: 725 (1976a)].

Plants (60–)120–200 mm high. *Corm* 7–16 mm diam.; tunics usually pale, rarely dark brown, of fine to medium fibres. *Stem* slender, up to 1 mm diam., with long basal internode, few- to several-branched, sheathing leaves 12–20 mm long, green, becoming dry above. *Foliage leaves* usually 2, inserted at first above-ground node, subopposite, occasionally solitary, linear-filiform, narrowly channelled, 1–2 mm wide, subequal or unequal in length, occasionally loosely spiralled distally. *Rhipidial spathes* green or becoming dry distally, inner 20–35(–40) mm long, outer ± $^{1}/_{3}$–$^{1}/_{2}$ as long. *Flowers* fugaceous, white, sometimes shaded blue or pink, or blue-mauve, rarely violet or purple, vanilla-scented, outer tepal limbs with yellow nectar guides at bases, limbs of both whorls reflexed up to 40º; tepals lanceolate, outer 20–30(–35) × 8–12 mm, claws ± 8 mm long; inner 18–30 × 5–7 mm. *Filaments* 5–6 mm long, united in lower half; anthers 4–6 mm long, usually white; pollen white. *Ovary* narrowly ellipsoid, 8–11 mm long, included, style branches 8–10 mm long, crests lanceolate 8–15 mm long. *Capsules* 8–13(–15) mm long, shortly beaked. *Chromosome number* 2*n* = 18, 12, 10. *Flowering time*: August to October.

Distribution and ecology: extending from the Richtersveld of Northern Cape, South Africa, to Vanrhynsdorp in Western Cape and along the Atlantic Coast as far south as Saldanha; in stony or hard sandy ground.

Diagnosis: closely resembling *Moraea fugax* in general appearance except smaller in all features, *M. filicaulis* has a slender, almost filiform stem ± 1 mm in diam., and one or more often two subequal or unequal, filiform, narrowly channelled leaves inserted at the first above ground internode. The flowers are usually white, but occasionally pink or blue-mauve or even violet, and have outer tepals mostly 20–35 mm long (occasionally longer) and inner tepals 18–30 mm long. Flowers of *M. fugax* have outer tepals mostly 30–45 mm long and inner tepals 25–35 mm long. The inner rhipidial spathes, a useful measure of plant size, are 20–35(–40) mm long in *M. filicaulis* but 40–65 mm long in *M. fugax*.

Moraea filicaulis has been treated as a subspecies of *M. fugax* and an important reason for recognising it as a separate species is that it sometimes co-occurs with typical *M. fugax* but always showing slightly different habitat preferences.



75. **Moraea macrocarpa** *Goldblatt* in Annals of the Missouri Botanical Garden 73: 151 (1986b). Type: South Africa, [Western Cape], Piketberg Mtns, south of Redelinghuys, *Acocks 24359* (PRE, holo.; MO, iso.).

Plants 40–80 mm high, usually stem ± underground. *Corm* 8–12 mm diam., deeply seated 115 mm or more; tunics of fine pale fibres. *Stem* sometimes initially underground or barely above ground, in fruit well above ground (not known for subsp. *virginea*); filiform, simple or 1 or 2 (rarely 3 or 4) shortly stalked inflorescences. *Foliage leaf* solitary, often inserted shortly below

ground or at ground level, linear-filiform, narrowly channelled or entirely terete, 0.4–1.5 mm wide, much exceeding stem, up to 600 mm or more (subsp. *virginea*). *Rhipidial spathes* becoming dry above, tips brown, acute, inner (34–)40–50(–65) mm long, outer ± $^1/_3$–$^1/_2$ as long incl. dry tapering tip. *Flowers* fugaceous, either pale to middle blue-mauve with yellow nectar guides at outer tepal limb bases edged violet or purple and claws yellow with dark spots, or white with yellow guides without dark edges and claws with yellow midline, vanilla-scented, limbs of both whorls slightly reflexed or spreading; outer tepals lanceolate, limb 12–26 × 7–15 mm, claws 8–12 mm long; inner tepals 18–32 × 5–8 mm. *Filaments* 5–9 mm long, united in lower half; anthers 4–9 mm long, ± white pale violet inside; pollen off white. *Ovary* ± cylindric, 17–22 mm long, included, style branches 6–10 mm long, crests narrowly lanceolate, 12–18 mm long, suberect. *Capsules* ± cylindric, 18–36 mm long, shortly beaked. *Chromosome number* $2n = 20$ (subsp. *Macrocarpa*). *Flowering time*: mainly August to early October; opening ± 12:00 and collapsing ± 19:00 or (subsp. *virginea*), or opening ± 10:00 and collapsing 16:30.

Distribution and ecology: extending from the Bokkeveld Mtns in Northern Cape, South Africa, south through Western Cape to Saldanha and Darling and locally inland in the Breede River Valley near Worcester or (subsp. *virginea*) in the De Hoop hills; always in deep sandy ground.

Diagnosis: until 1986 associated with the widespread *Moraea fugax, M. macrocarpa* is immediately recognised by its low stature, mostly 40–80 mm in height with stem underground or barely exserted at flowering, single narrow, falcate to trailing foliage leaf, and elongate, included ovary, 17–22 mm long. The capsules are even longer, up to 36 mm long and remain largely included in the spathes. Apart from the unusually long ovary, the flowers differ little from those of *M. fugax* and *M. filicaulis* and it has the beaked ovary of those two species. Capsules of *M. filicaulis* are usually 8–15 mm long and those of *M. fugax* typically 15–27 mm long vs 18–36 mm in *M. macrocarpa*. The tepals of *M. macrocarpa* are either blue-mauve, the outer with deep yellow nectar guides at the bases of the limbs edged in dark purple or in subsp. *virginea* white, also with yellow nectar guides, but lacking dark edges.

Distribution of ***Moraea macrocarpa*** subsp. ***macrocarpa***, ●; subsp. ***virginea***, ○.

Key to the subspecies

1a Flowers pale to middle blue-mauve with yellow nectar guides at bases of outer sepals edged in dark purple; outer tepals mostly 20–30 mm long; foliage leaf channelled almost to apex and mostly ±1.5 mm wide when opened flat (though margins often inrolled) . . . . . 75a. subsp. *macrocarpa*

1b Flowers white with yellow nectar guides without dark edges; outer tepals mostly 32–38 mm long; leaves usually terete throughout (occ. channelled for some distance) and ± 1 mm diam. . . . . 75b. subsp. *virginea*

75a. subsp. **macrocarpa**

Foliage leaf solitary, linear-filiform, narrowly channelled or with margins inrolled, 0.4–1.5 mm wide, much exceeding stem. *Rhipidial spathes* acute, inner (34–)40–50(–65) mm long, outer ± $^1/_3$–$^1/_2$ as long incl. dry tapering tip. *Flowers* pale to middle blue-mauve with yellow nectar guides at bases of outer tepals edged violet or purple and claws yellow with dark spots; outer tepal limbs 12–15 × 5–10 mm, claws 8–11 mm long; inner tepals 18–28 × 5–7 mm. *Filaments* 5–6 mm long, united in lower $^1/_2$; anthers 4–5 mm long. *Ovary* ± cylindric, 17–21 mm long, included, style branches 6–7 mm long. *Capsules* ± cylindric, 18–35 mm long, shortly beaked. *Flowering time*: mainly August to early October; opening ± 12:00 and collapsing ± 19:00.

Distribution and ecology: the range of *Moraea macrocarpa* except for the De Hoop hills.

Diagnosis: distinguished from subsp. *virginea* by the smaller, blue-mauve perianth with outer tepals 17–25 mm long, inner 18–28 mm long, and the channelled foliage leaf, the margins sometimes closely inrolled but always with a narrow adaxial groove.

75b. subsp. **virginea** *Goldblatt & J.C.Manning*, new subspecies. Type: South Africa, Western Cape, 3.5 km along road to De Hoop, wide valley in deep sandy loam, burned (?the previous summer), 30 Sept. 2016, *Goldblatt & Porter 14181* (NBG, holo.; K, MO, PRE, iso.).

Foliage leaf solitary, usually terete above base, rarely narrowly channelled for up to half its length, up to 600 mm or more. *Rhipidial spathes* acute, inner 50–55 mm long, outer ± $^1/_2$ as long incl. dry tapering tip. *Flowers* fugaceous, white with yellow guides without dark edges and claws white, yellow in midline, limbs of both whorls ± spreading; outer tepal limbs 20–26 ×

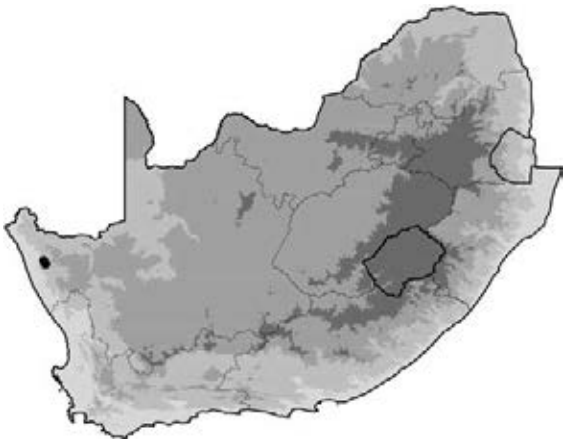
12–15 mm, claws ± 12 mm long; inner tepals 24–32 × 6–8 mm. *Filaments* 7–9 mm long, united in lower half; anthers ± 9 mm long, ± white; pollen off white. *Ovary* ± cylindric, 20–22 mm long, included, style branches ± 10 mm long, crests narrowly lanceolate, 12–18 mm long, suberect. *Capsules* ± cylindric, 33–36 mm long, shortly beaked. *Flowering time*: mainly mid-September and October; opening ± 10:00 and collapsing ± 16:30.

Distribution and ecology: currently known from a single shallow, sandy valley in the hills east of the road to De Hoop National Park.

Diagnosis: immediately distinguished by the relatively large, white flowers with outer tepals 32–38 mm long, inner tepals 24–32 mm long, and the terete leaf blade, rarely partly channelled in the lower half.

Sect. 7. **Hexaglottis** *(Vent.) Goldblatt* in Novon 8: 376 (1998). *Hexaglottis* Vent.: 6 (1808). Type: *H. longifolia* (Jacq.) G.J.Lewis, lecto., designated by Lewis: 219 (1959) = *Moraea longifolia* (Jacq.) Pers.

Plantia Herbert: 89 (1844). Type: *P. flava* Herb. (probably = *Moraea virgata* Jacq.)



Plants usually branched, secondary branches usually sessile. *Flowers* yellow, with tepals subequal with claws short; tepals united in tube in two species; style branches reduced to paired filiform arms extended either side of opposed stamen, ovary exserted or included and ± sessile in species with perianth tube. *Ovary* and *capsules* exserted or included.

76. **Moraea namaquana** *(Goldblatt) Goldblatt* in Novon 8: 376 (1998). *Hexaglottis namaquana* Goldblatt: 554 (1987). Type: South Africa, [Northern Cape], Namaqualand, top of Spektakel Pass, clay in quartzite patches, *Goldblatt 3059* (MO, holo.; K, NBG, iso.).

Plants 150–300 mm high. *Corm* 10–15 mm diam.; tunics of dark brown to black fibres, extending upward into short stiff bristles. *Stem* several-branched, all stalked, sheathing leaves 17–21 mm long. *Foliage leaves* 2 or 3, all ± basal, 80–150 mm long, up to 11 mm wide, spreading to ± prostrate, undulate and loosely twisted, margins undulate or crisped. *Rhipidial spathes* green or becoming dry from tips, acute, inner 25–30 mm long, outer ± half as long. *Flowers* fugaceous, stellate, yellow, tepal limbs spreading; tepals ± 20 mm long, claws ± 2 mm long, erect and clasping filament bases, outer tepals up to 5 mm wide, inner narrower. *Filaments* united only at base (seeming free), 3–4 mm long; anthers ± 3 mm long, straight and suberect before dehiscence, yellow. *Ovary* 4–5 mm long, usually barely exserted from spathes, style arms paired, filiform, spreading, ± 4 mm long. *Capsules* narrowly oblong-ellipsoid, 8–10 mm long. *Seeds* angular, ± 1 mm diam. *Chromosome number* 2*n* = 12. *Flowering time*: late September to October; opening ± 15:00 and collapsing near sunset.

Distribution and ecology: known only from the eastern slopes of Spektakel Pass west of Springbok in Northern Cape, South Africa; in stony, clay ground mostly covered with white quartzite pebbles.

Diagnosis: *Moraea namaquana* stands out in sect. *Hexaglottis* in the spreading to prostrate basal leaves, undulate and twisted leaf blades with crisped margins, and

Distribution of ***Moraea namaquana***.

branched stem with all lateral inflorescences stalked. Other species have linear, upright leaves with straight margins and sessile or very shortly stalked lateral inflorescences. The flowers are virtually identical with those of *M. lewisiana* and *M. rupicola* except for their slightly smaller size, with tepals ± 20 mm long. The capsules are ellipsoid and well exserted from the spathes. *Moraea lewisiana* growing nearby at the type locality has linear leaves and tall stems but no intermediates between the two species are known.

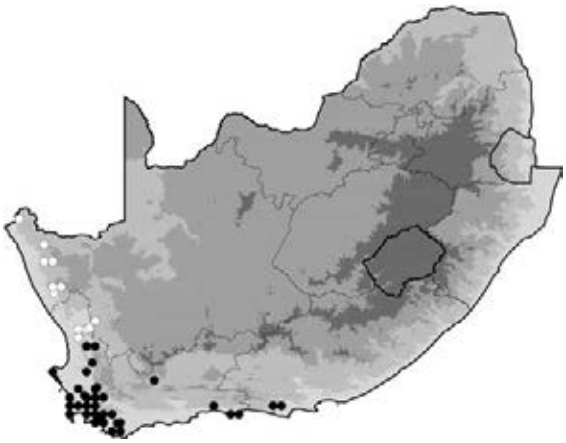
77. **Moraea thermarum** *Goldblatt & J.C.Manning* in Bothalia 43: 156 (2013). Type: Namibia, Karas, Ai-Ais Hotsprings Game Park, along Orange River, on cliff face, 13 Sept. 2012, *A. Burke 12035* (WIND, holo.).

Plants 30–100 mm high. *Corm* 10–15 mm diam.; tunics of dark brown to black fibres, extending upward as short stiff bristles. *Stem* simple or 1- or 2-branched; branches shortly stalked; sheathing leaves 1 or 2, 11–17 mm long. *Foliage leaves* 3 or 4, all ± basal, trailing or pendent, 80–120 × 1–3 mm, undulate and loosely twisted, margins crisped, with 1 conspicuous lateral vein per side. *Rhipidial spathes* becoming dry from tips, acute, inner 15–25 mm long, outer ± half as long. *Flowers* fugaceous, stellate, yellow, tepals connate basally in short cylindric tube ± 1.5 mm long, limbs spreading, elliptic,

Distribution of ***Moraea thermarum***.

± 15 × 5 mm, shortly clawed, claws 0.5–1.0 mm long. *Filaments* united only at base (seeming free), ± 5 mm long; anthers ± 3 mm long, straight and suberect before dehiscence, yellow. *Ovary* included, style arms paired, filiform, spreading, 4–5 mm long. *Capsules* and *seeds* unknown. *Flowering time*: mid- September to October.

Distribution and ecology: known from two collections fringing the Huib Hoch Plateau in southwestern Namibia, one from the summit of the Aurusberg and the other along the Orange River near Ai-Ais; confined to shaded cliff faces, growing wedged in cracks in the rocks.



Diagnosis: resembling *Moraea namaquana* in its trailing, undulate or crisped leaves and stalked lateral inflorescences, *M. thermarum* is distinguished by its narrower, linear leaves, 1–3 mm wide with a single lateral vein on each side and somewhat smaller flowers with a distinct perianth tube ± 1.5 mm long, and the ovary included in the spathes. *Moraea namaquana*, which grows in open rocky ground, is a more robust plant, with leaves 5–11 mm wide with two conspicuous lateral veins per side, and tepals free to the base.

78. **Moraea lewisiae** *(Goldblatt) Goldblatt* in Novon 8: 376 (1998). *Hexaglottis lewisiae* Goldblatt: 234 (1971a), as a new name for *M. flexuosa* L.f.: 100 (1782), illegitimate superfluous name for *Ixia longifolia* Jacq. (1776); Goldblatt: 554 (1987). *Sisyrinchium flexuosum* Spreng.: 167 (1824). *Homeria flexuosa* Sweet: 395 (1826a). *Hexaglottis flexuosa* Sweet: 498 (1830). Type: South Africa, [Western Cape], without precise locality, *Thunberg s.n.* [UPS-THUNB 1217, lecto., designated by Goldblatt: 234 (1971a)].

Plants variable in size, (120–)200–700 mm high. *Corm* 15–20 mm diam.; tunics (pale) dark brown, fibrous. *Stem* bearing 1 to 3 secondary branches near base (rarely simple), often flexuose, with sessile lateral rhipidia, usually overlapping one above, sheathing leaves concealing at least lower part of rhipidia, usually 25–30 mm long. *Foliage leaves* 1 to 3(4), ± basal (or inserted shortly above ground), linear, channelled, ascending but trailing distally, normally much exceeding stem, sometimes shorter, margins often inrolled, straight, rarely undulate. *Rhipidial spathes* usually dry above, 30–45 mm long, attenuate, outer slightly shorter than inner. *Flowers* fugaceous, stellate, pale to deep yellow, often feathered brownish outside, inner and outer tepal limbs with deeper yellow nectar guides at bases, usually edged with small dark green to black spots, with strong sweet scent; outer tepals 19–24 × 7–10 mm (subsp. *lewisiae*), 24–30 × 9–13 mm (subsp. *secunda*), claws 1.5–2.0 mm long, clasping filament column, limbs spreading, outer ovate, inner ± wedge-shaped, ± as long to 2 mm shorter but narrower than outer. *Filaments* 4–6 mm long, united in lower 1.0–1.5 mm; anthers 5–7 mm long, shorter after releasing pollen, yellow; pollen yellow. *Ovary* cylindric-ellipsoid, (5.5–)6.5–12.0 mm long, usually partly to entirely exserted, rarely included; style branches divided almost to base into paired filiform arms 6–7 mm long, extended horizontally. *Capsules* narrowly triangular-cylindric, 11–16(–20) mm long (subsp. *lewisiae*) or ovoid-ellipsoid, 8–13(–15) mm long (subsp. *secunda*), often shortly beaked, splitting in upper $^1/_3$ to half. *Seeds* angular, sometimes narrowly, tapering at both ends, 1.2–2.0 × 0.7–1.0 mm, winged in northern populations. *Chromosome number* 2*n* = 12. *Flowering time*: (September) October and November; usually opening between 15:00 to 16:00 in the south, collapsing ± 19:00, opening later in Namaqualand populations and fading at ± 20:00.

Distribution and ecology: widespread in the southern African winter-rainfall zone, from the Richtersveld in Northern Cape, South Africa, south through Western Cape and as far east as Humansdorp in Eastern Cape, sometimes common; usually in dry, exposed sites, often in stony ground, on both sandy and clay soils.

Diagnosis: the flowers of *Moraea lewisiae* are typical of sect. *Hexaglottis* in the yellow tepals with short erect claws and it is distinguished mainly by the capsules

Distribution of ***Moraea lewisiae*** subsp. ***lewisiae***, ●; subsp. ***secunda***, ○.

either cylindric but triangular to 3-lobed in section and 11–20 mm long or ovoid-ellipsoid and round in section, 8–15 mm long, and usually with a short beak up to 1 mm long. The tepal limbs bear yellow nectar guides at their bases dotted with fine, green to black spots. Taller *M. longifolia* has paler yellow tepals of similar size but lacking spotted nectar guides and the flowers have none or little scent and slightly shorter style branches, and characteristic obovoid, club-shaped capsules with obviously truncate apex and larger seeds. Two subspecies of *M. lewisiae* are recognised, typical subsp. *lewisiae* with elongate capsules 3-lobed to 3-angled in section and often slightly smaller upright flowers, and subsp. *secunda* with larger, nodding flowers and ovoid-ellipsoid capsules round in section, often with a short beak.

Key to subspecies

1a Capsules cylindric or nearly so, 11–16(–20) mm long, not beaked; outer tepals 19–24 mm long; flowers ± upright ..... 78a. subsp. *lewisiae*

1b Capsules obovoid-ellipsoid, 8–13(–15) mm long, often distinctly beaked; outer tepals 24–30 mm long; flowers usually nodding ..... 78b. subsp. *secunda*

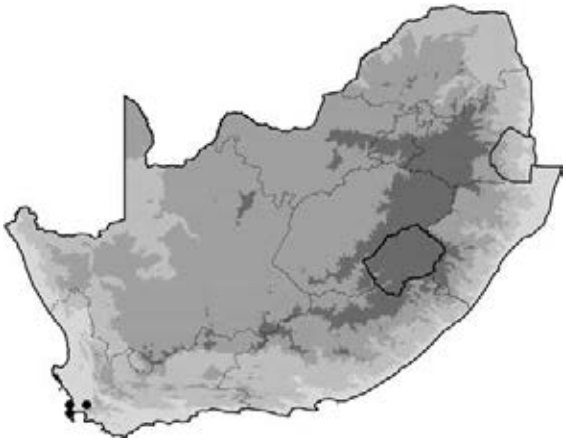
78a. subsp. **lewisiae**

Plants mostly 200–600 mm high. *Flowers* usually upright; tepals 19–24 × 7–10 mm. *Ovary* 8–10 mm long, usually partly to entirely exserted at flowering, rarely included. *Capsules* ± cylindric, triangular in section, 11–15(–20) mm long, dehiscing in upper $^1/_3$–$^1/_2$. *Seeds* angular-ellipsoid, tapering at both ends, 1.2–1.4 × 0.7 mm.

Distribution and ecology: extending from the Atlantic coast of Western Cape east through the southern Cape to Humansdorp in Eastern Cape; evidently common only in the west and records are very scattered east of Bredasdorp, possibly because of inadequate collecting.

78b. subsp. **secunda** *(Goldblatt) Goldblatt* in Goldblatt & Manning in Novon 14: 296 (2004). *Hexaglottis lewisiae* subsp. *secunda* Goldblatt: 558 (1987). Type: South Africa, [Northern Cape], near the top of Spektakel Pass, *Goldblatt 6673* (PRE, holo.; K, MO, NBG, S, US, WAG, iso.).

Plants 200–600 mm high. *Flowers* usually nodding; outer tepals 24–30 × 9–13 mm. *Ovary* 5.5–9.5 mm long, usually at least partly exserted at flowering. *Capsules* ovoid-ellipsoid, 8–13(–15) mm long, often distinctly beaked, dehiscing for at least $^1/_2$ its length. *Seeds* angular, narrowly winged on ridges, ± 2 × 1 mm.



Distribution and ecology: scattered through Northern Cape and northern Western Cape, from the Richtersveld southward to the Olifants River Valley near Clanwilliam; in rocky ground, either in clay ground, less often in sand.

Diagnosis: particularly variable, subsp. *secunda* usually has two foliage leaves and produces 1 to 3 long branches from the base. It may be a tall plant up to 600 mm high, but plants from the dry foothills of the Bokkeveld and Koebee Mtns may be only 200 mm high and have only a single leaf. Also unusual, flowers in these populations open later than elsewhere, usually after 16:30. Plants from dolerite outcrops in the Calvinia District may have up to four leaves and appear very different vegetatively.

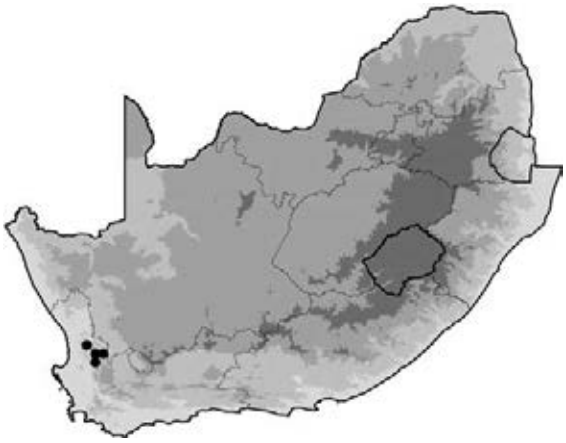
79. **Moraea longifolia** *(Jacq.) Pers.*, Synopsis plantarum 1: 49 (1805). *Ixia longifolia* Jacq.: 47 (1776). *Hexaglottis longifolia* (Jacq.) Salisb.: 313 (1812); Goldblatt: 560 (1987). Type: South Africa, without precise locality or collector, illustration in Jacq.: 47 (1776).

Hexaglottis longifolia var. *angustifolia* G.J.Lewis: 222 (1959). Type: South Africa, [Western Cape], Du Toit's Kloof, *Pillans 8436* (BOL, holo.).

Plants 600–2 000 mm high. *Corm* 15–20 mm diam.; tunics of fine, light brown fibres. *Stem* ± straight, simple or 1- to 3-branched from lower nodes, lateral rhipidia sessile, each subtended by sheathing leaf often entirely concealing rhipidia. *Foliage leaves* 3 or 4(5), linear, ascending below, bent and trailing distally, lowermost longest, 250–600 mm long, progressively shorter above, 6–12(–20) mm wide, ± flat or channelled. *Rhipidial spathes* attenuate, dry at tips, inner 3.5–5.5(–7.5) mm long, outer slightly shorter. *Flowers* fugaceous, stellate, pale yellow, usually only outer tepal limbs with inconspicuous, slightly darker yellow nectar guides, odourless or faintly scented; tepals with claws ± 2 mm long, clasping filament column, limbs spreading, outer with limbs 19–27 × 8–11 mm, inner 16–23 × 6–9 mm. *Filaments* 4–6 mm long, united in lower 2–3 mm; anthers 5–6 mm long before anthesis, yellow; pollen yellow. *Ovary* 8–12 mm long, exserted, style branches divided to base in filiform, horizontally extended arms 4–6 mm long. *Capsules* obovoid-clavate, truncate, 12–16(–23) mm long, exserted, splitting for $^1/_2$ to $^3/_4$ their length. *Seeds* angular, 2.0–2.3 mm long. *Chromosome number* $2n = 24$. *Flowering time*: mid-October and November; opening ± 14:00–14:45, collapsing after 18:00.

Distribution of ***Moraea longifolia***.

Distribution and ecology: restricted to the Cape Peninsula and surrounds in Western Cape, South Africa; in relatively moist situations, along streams and in marshes or shady places close to bush or forest.



Diagnosis: particularly tall for sect. *Hexaglottis* and standing up to 2 m high, *Moraea longifolia* is distinguished by the pale yellow flowers with faint nectar guides without dark spotting, comparatively short style branches, 4–6 mm long, and large, obovoid to club-shaped capsules. *Moraea longifolia* is tetraploid and known to be self-compatible and autogamous, whereas the other species of the section are diploid and self-incompatible (compatibility relations are not known for *M. brevituba*). Closely related and similar *M. lewisiae* has cylindric 3-lobed capsules, slightly larger, deeper yellow flowers with prominently spotted nectar guides, and style branches 6–7 mm long. Also sometimes confused with *M. longifolia*, *M. riparia* has smaller capsules and bright yellow, strongly scented flowers, and is self-incompatible.

80. **Moraea riparia** *(Goldblatt) Goldblatt* in Novon 8: 376 (1998). *Hexaglottis riparia* Goldblatt: 559 (1987). Type: South Africa, [Western Cape], Olifants River at Citrusdal, after fire, *Goldblatt 6706* (NBG, holo.; K, MO, NBG, PRE, iso.).

Plants 450–900 mm high. *Corm* 13–20 mm diam.; tunics of fine, light brown fibres. *Stem* straight, simple or 1- to 3-branched from lower nodes, bearing sessile lateral rhipidia at upper nodes, subtended by sheathing leaves often concealing rhipidial spathes, 32–35 mm long, often exceeding node above. *Foliage leaves* (2)3, linear, ascending, usually bent and trailing above, lowermost longest, ± as long or longer than stem, 3–5 mm wide, channelled, upper leaves progressively shorter and narrower. *Rhipidial spathes* with attenuate dry apices, inner 33–38 mm long, outer slightly shorter. *Flowers* fugaceous, stellate, deep yellow, strongly scented; tepals 16–21 × 6–8 mm, claws ± 2 mm long, clasping filament column, limbs spreading, inner slightly shorter but as wide as outer. *Filaments* 4–6 mm long, united in lower 1.5–2.5 mm; anthers initially 5–6 mm long, yellow; pollen yellow. *Ovary* cylindric, 5–7 mm long, exserted; style branches divided to base in paired, filiform arms 5–6 mm long, extended horizontally. *Capsules* obovoid–club-shaped, ± truncate, 6–10(–12) × ± 4 mm. *Seeds* angular, 1.0–1.5 × ± 1 mm. *Chromosome number* $2n = 12$. *Flowering time*: October and November; opening ± 17:00, collapsing after 19:30.

Distribution and ecology: restricted to Western Cape, South Africa, from Clanwilliam in the north and Wolseley in the south; restricted to riverbanks and possibly the edges of marshes, habitats frequently overgrown with tall vegetation, thus blooming in such places only after fires or clearing of surrounding bush.

Diagnosis: with yellow flowers typical of sect. *Hexaglottis*, *Moraea riparia* is distinctive largely in its small obovoid to club-shaped capsules and comparatively

Distribution of ***Moraea riparia***.

slender, often willowy stems. The capsules, 6–10 mm long (occasionally up to 12 mm long in robust plants), recall those of *M. longifolia* but this species has much larger capsules, usually 16–23 mm long. *Moraea riparia* is diploid, $2n = 12$, whereas *M. longifolia*, usually a taller plant, is tetraploid, $2n = 24$. The flowers of *M. riparia* are deep yellow and scented in contrast to the pale yellow, usually odourless flowers of *M. longifolia.*

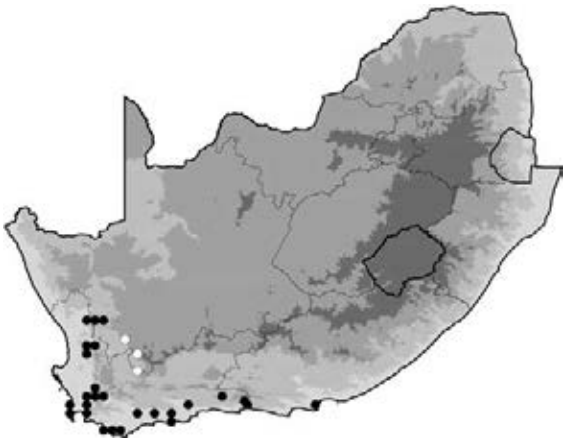
81. **Moraea brevituba** *(Goldblatt) Goldblatt* in Novon 8: 376 (1998). *Hexaglottis brevituba* Goldblatt: 562 (1987). Type: South Africa, [Northern Cape], Richtersveld, Sabiesies, road to Cornellsberg, *Viviers s.n.* (NBG, holo.; K, MO, PRE, iso.).

Plants 400–550 mm high. *Corm* 12–18 mm diam. or larger if surrounded by accumulated tunic layers; tunics of coarse, dark brown to blackish fibres. *Stem* simple or with 2 or 3 diverging secondary branches from near base, straight or slightly flexuose, bearing several sessile lateral rhipidia at upper nodes partly enclosed by slightly shorter sheathing leaves mostly 18–25 mm long. *Foliage leaves* 2 to 4, basal or inserted low on stem, linear, ascending, longer than stem and trailing distally, channelled with margins incurved. *Rhipidial spathes* usually partly to entirely dry and pale at flowering, attenuate, inner (20–)25–30 mm long, outer half to $^2/_3$ as long, exserted from subtending sheathing leaf. *Flowers* fugaceous, rotate, upright to nodding, pale yellow, evidently odourless; tepals united below in a short closed tube 1–2 mm long, tepals 16–19 × 5–8 mm long, claws ± 1 mm long, suberect, clasping bases of filament column, limbs extended horizontally, narrowly ovate, inner slightly smaller than outer. *Filaments* 3–4 mm long, united below for ± 1 mm; anthers initially 7–8 mm long, yellow; pollen yellow. *Ovary* included, cylindric, often curved outward distally, 8–11 mm long, upper 1 mm narrow and sterile, usually half exserted; pedicel (4–)7–10 mm long; style branches divided to base into filiform, horizontal arms ± 6 mm long. *Capsules* included, ellipsoid, shortly beaked, ± 15 mm long including beak ± 2 mm long. *Seeds* evidently angular, dark brown,

Distribution of ***Moraea brevituba***.

± 2 mm long. *Chromosome number* 2*n* = 24. *Flowering time*: September to October; opening middle afternoon ± 16:00 and collapsing after 19:00.

Distribution and ecology: evidently fairly rare and known from only a few sites in central and northern Namaqualand, Northern Cape, South Africa, from the Richtersveld south to Garies but apparently centred in the Springbok–Richtersveld area, with a sterile collection from Witputz in southern Namibia that requires confirmation; in arid, stony places.



Diagnosis: the yellow flowers with a short perianth tube only 1–2 mm long distinguish *Moraea brevituba* from close allies in sect. *Hexaglottis,* particularly the widespread *M. virgata*, which has similar vegetative morphology but flowers with a well-developed perianth tube some 4–7 mm long, and the ovary entirely included on short pedicels 4–6 mm long. The ovary of *M. brevituba* is often partly exserted and the pedicels are (4–)7–10 mm long. Like other species of the section, the flowers open in the middle of the afternoon and last just a few hours.

82. **Moraea virgata** *Jacq.*, Collectanea 3: 194 (1791). *Ixia virgata* (Jacq.) Willd.: 202 (1797). *Homeria virgata* (Jacq.) Sweet: 395 (1826a). *Hexaglottis virgata* (Jacq.) Sweet: 498 (1830); Goldblatt: 563 (1987). Type: South Africa, without precise locality or collector, illustration in Jacq.: t. 228 (1792).

Plants variable in size, 120–850 mm high. *Corm* 13–18 mm diam., or larger if surrounded by accumulated tunic layers; tunics of coarse, dark brown to blackish fibres. *Stem* with simple or with 1 to 3(6) long, diverging secondary branches, straight to slightly flexuose, bearing sessile lateral rhipidia at upper nodes, each partly to almost entirely enclosed by subtending sheathing leaf, usually as long or longer than rhipidia. *Foliage leaves* usually (1)2 or 3(4), ± basal, linear, ascending, longer than stem, trailing distally, channelled with margins curving inward, occasionally loosely coiled above. *Rhipidial spathes* partly to entirely dry and pale at anthesis, attenuate, inner 22–30(–37) mm long, $^{1}/_{2}$–$^{2}/_{3}$ as long. *Flowers* fugaceous, rotate, pale yellow, with tepals united below in a closed tube, upright or secund, evidently odourless, tepal limbs with deeper yellow nectar guides at bases; perianth tube cylindric, narrow, usually slightly curving outward, 4–7(–9) mm long, usually included; tepals 14–25 (subsp. *virgata*), 23–32 (subsp. *karooica*) mm long, with short, erect claws 1.0–1.5 mm long, limbs extended horizontally, 4–8(–11) mm wide; outer larger, lanceolate to ovate, inner lanceolate to wedge-shaped. *Filaments* 3.3–6.0 mm long, united for 1–2 mm; anthers initially 6–9 mm long, yellow; pollen yellow. *Ovary* 8–16(–20) mm long, upper 1–2 mm a narrow, sterile beak, cylindric, included, on pedicels 5–6 mm long; style branches divided almost to base in paired filiform arms 5–6 mm long, extending horizontally. *Capsules* narrowly ellipsoid, shortly beaked, 9–13 × 2–3 mm (subsp. *virgata*), or 16–22 × 4 mm (subsp. *karooica*), only 1 (rarely 2) developed in each rhipidium. *Seeds* narrowly angular, 1–2 × 0.7–1.0 mm. *Chromosome number* 2*n* = 12, 10 (subsp. *virgata*), or 2*n* = 14 (subsp. *Karooica*). *Flowering time*: (late September) October to December (mid-January); opening 15:00–15:30 (up to 16:00 on cooler days), collapsing after 18:30.

Distribution and ecology: widespread through the Cape Floristic Region of South Africa, from the Bokkeveld Mtns in Northern Cape in the northwest through Western and Eastern Cape to Port Elizabeth in the east; most often on heavier soils, particularly shales of the Malmesbury System, but also on granitic substrates and occasionally on sandy soils of the Cape System.

Diagnosis: *Moraea virgata* is unmistakable in its relatively straight stems with strongly diverging lateral branches, and tepals united in a relatively long perianth tube 4–7 mm in length. Associated with the development of a perianth tube, the ovary is entirely included in the spathes and borne on a short pedicel 5–6 mm long. The

Distribution of ***Moraea virgata*** subsp. ***virgata***, ●; subsp. ***karooica***, ○.

capsules remain included in the spathes even as they ripen. Related *M. brevituba* has a much shorter perianth tube only 1–2 mm long. Two subspecies of *M. virgata* are recognised, subsp. *virgata* and larger flowered subsp. *karooica*.

Key to subspecies

1a Outer tepals 14–25 × 5–7(–11) mm; foliage leaves 1 to 3; spathes, at least terminal, 22–32 mm long . . . . . 82a. subsp. *virgata*
1b Outer tepals 23–32 × 7–11 mm; foliage leaves usually 4 or 5; spathes, at least terminal, 32–37 mm long. . . . . 82b. subsp. *karooica*

82a. subsp. **virgata**

Plantia flava Herbert in Lindl. in Edwards's Botanical Register 30 (misc.): 89 (1844). Type: uncertain.

Hexaglottis virgata var. *lata* G.J.Lewis: 228 (1959). Type: South Africa, [Western Cape], Biedouw Valley, Welbedacht, *Lewis 2514* (SAM [61821], holo.; BOL, PRE, SAM, iso.).

Plants 120–500(–700) mm high. *Foliage leaves* 1 to 3(4). *Rhipidial spathes* 22–28(–32) mm long. *Flowers* with perianth tube (3.0–)4.0–5.5(–7.0) mm long; tepals 14–22(–25) mm long. *Filaments* 3.3–6.0 mm long; anthers 5–8 mm long. *Ovary* 8–12 mm long. *Capsules* 9–13 mm long. *Chromosome number* 2*n* = 12, 10.

Distribution and ecology: as for the species but absent from the Roggeveld Escarpment.

Diagnosis: fairly uniform across its range, subsp. *virgata* is distinguished by slightly shorter rhipidial spathes mostly 22–28 mm long and flowers with a perianth tube mostly 4.0–5.5 mm long and tepals 14–25 mm long. The capsules are shorter than in subsp. *karooica*, 9–13 mm long.

82b. subsp. **karooica** *(Goldblatt) Goldblatt* in Goldblatt & Manning, Novon 14: 296 (2004). *Hexaglottis virgata* subsp. *karooica* Goldblatt: 568 (1987). Type: South Africa, [Northern Cape], 22 km W of Middelpos, Farm Blomfontein, *Snijman 765* (NBG, holo.; K, MO, PRE, iso.).

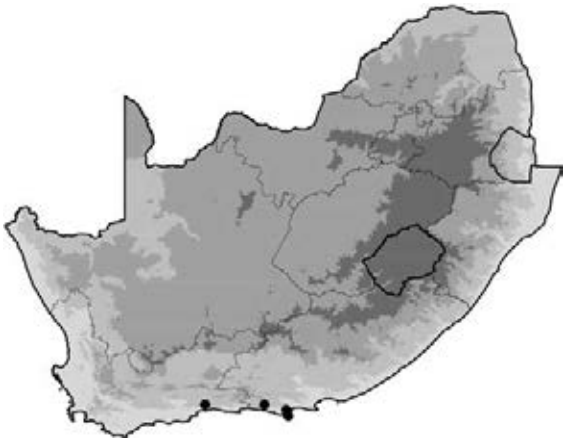
Plants robust, 300–850 mm high. *Leaves* usually 4 or 5, rarely 2 or 3. *Rhipidial spathes* 32–37 mm long. *Flowers* with perianth tube 6.5–9.0 mm long; tepals 23–32 × 7–11 mm. *Filaments* 4–6 mm long; anthers 6–8 mm long. *Ovary* 15–20 mm long. *Capsules* 16–22 mm long. *Chromosome number* 2*n* = 14.

Distribution and ecology: known from three widely separated sites on the Roggeveld Escarpment in Northern Cape, extending from west of Middelpos south to the Farm Blesfontein, SW of Sutherland; in stony ground or dolerite outcrops.

Diagnosis: subsp. *karooica* has larger rhipidial spathes 32–37 mm long and flowers with a perianth tube 6.5–9.0 mm long and tepals 23–32 mm long. Other features of the flowers are likewise slightly larger than in subsp. *virgata*, particularly the capsules 16–22 mm long vs. 9–13 mm in subsp. *virgata*.

Sect. 8. **Gynandriris** *(Parl.) Goldblatt* in Novon 8: 376 (1998). *Gynandriris* Parl.: 49 (1854). *Iris* subg. *Gynandriris* (Parl.) Baker: 2 (1892). *I.* sect. *Gynandriris* (Parl.) Dykes: 229 (1913). Type: *M. sisyrinchium* (L.) Ker Gawl.

Moraea subg. *Helixyra* Salisb. ex Baker [as a combination but *Helixyra* Salisb. an invalid name]: 48 (1892). Type: *M. simulans* Baker, lecto., designated by Goldblatt & Manning in Goldblatt et al.: 38 (2013).



Plants few-branched, occasionally simple; spathes membranous-translucent with prominent veins. *Flowers* fugaceous, blue to purple or white; stamens united in lower half; style branches well developed with erect crests; ovary ± sessile and with sterile tubular beak. *Capsules* with transparent walls, remaining enclosed in spathes.

83. **Moraea australis** *(Goldblatt) Goldblatt* in Novon 8: 376 (1998). *Gynandriris australis* Goldblatt: 251 (1980b). Type: South Africa, [Eastern Cape], Jeffrey's Bay, duineveld, *Fourcade 3309* (BOL, holo.; K., iso.).

Plants 60–250 mm high. *Corm* ± 1.5 mm diam.; tunics of soft, pale fibres. *Stem* usually branched, elongate or barely produced above ground, then with branches clustered near base; upper nodes with sheathing leaves ± as long as spathes. *Foliage leaf* solitary, channelled, erect to trailing, exceeding stem. *Rhipidial spathes* ± dry, membranous with prominent veins, inner 35–60 mm long, outer slightly shorter. *Flowers* fugaceous, pale blue to blue-lilac, outer tepal limbs with white nectar guides edged orange distally, spreading horizontally to slightly reflexed; outer tepals lanceolate, 23–30 × 8–10 mm, claws ± 10 mm, inner tepals 18–22 × 4–5 mm, suberect, ultimately half reflexed. *Filaments* 5–6 mm long, united in lower 1 mm; anthers ± 5 mm long. *Ovary* included; style branches 8–9 mm long, crests 8–12 mm long. *Capsules* and *seeds* not known. *Chromosome number* 2*n* = 12. *Flowering time*: late September to early November; opening ± 13:00 and collapsing ± 19:30.

Distribution and ecology: endemic to the south coast of Western and Eastern Cape, South Africa, between Mossel Bay and Jeffrey's Bay; in coastal dunes and flat sandy ground.

Diagnosis: distinguished in sect. *Gynandriris* by the relatively large flower, the outer tepals 23–30 mm long

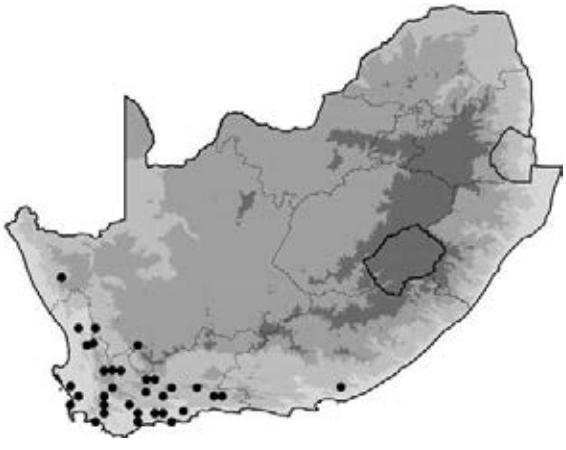
Distribution of ***Moraea australis***.

and style crests 8–12 mm long, *M. australis* otherwise closely resembles the widespread *M. setifolia*. The latter, an autogamous, weedy species has smaller flowers with outer tepals 12–18 mm long and style crests 4–7 mm long.

84. **Moraea setifolia** *(L.f.) Druce* in Botanical Society Exchange Club of the British Isles 4 (suppl. 2): 636 (1917). *Iris setifolia* L.f.: 99 (1782). *Helixyra setifolia* (L.f.) N.E.Br.: 39 (1928). *Gynandriris setifolia* (L.f.) R.C.Foster: 40 (1936); Goldblatt: 251 (1980b). *Iris setacea* Thunb.: 20 (1782b), illegitimate superfluous name for *I. setifolia* L.f. *Moraea setacea* Ker Gawl.: 240 (1804a), illegitimate superfluous name. *Vieusseuxia setacea* Eckl.: 13 (1827), illegitimate superfluous name. Type: South Africa, without precise locality, *Thunberg s.n.* (UPS–THUNB 1163, holo.).

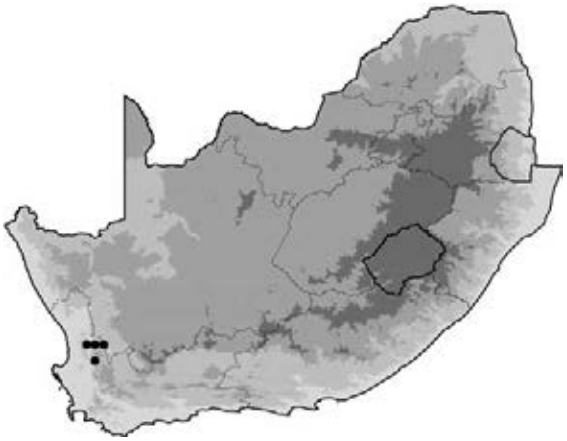
Moraea rogersii Baker: 57 (1892). *Helixyra rogersii* (Baker) N.E.Br.: 349 (1929b). *Gynandriris rogersii* (Baker) R.C.Foster: 40 (1936). Type: South Africa, [Western Cape], Mossel Bay, *Rogers s.n.* (K, holo.).

Moraea xerospatha MacOwan ex Baker: 529 (1897). Type: South Africa, [Western Cape], Cape Town, *MacOwan 3118* (K, lecto., designated by Goldblatt: 251 (1980b); BOL, isolecto.).



Moraea xerospatha var. *monophylla* J.M.Black: 113 (1922). Probable type: South Australia (introduced from South Africa), without precise locality or collector, illustration in Black: 113 (1922).

[*Moraea humilis* Eckl.: 15 (1827), invalid name without description.]



Plants small, 50–180(–250) mm high. *Corm* 10–15 mm diam.; tunics of pale, netted fibres. *Stems* usually branched, either very short with nodes condensed, or elongated, sheathing leaves 25–35 mm long. *Foliage leaves* 1 or 2, linear, channelled, much longer than stem, 2–3 mm wide, margins straight; upper nodes with sheathing leaves ± as long as spathes. *Rhipidial spathes* membranous with prominent veins, becoming dry and transparent at flowering, inner 20–35(–40) mm long, outer slightly shorter. *Flowers* fugaceous, small, pale blue-mauve (rarely white), outer tepal limbs with white nectar guides edged orange distally, half reflexed; outer tepals 12–18 × 5–9 mm, claws as long or slightly shorter than limbs; inner tepals 12–16 mm long, limbs half reflexed. *Filaments* 3.5–6.0 mm long, united in lower $^1/_3$–$^1/_2$; anthers 2.5–4.0 mm long. *Ovary* ± cylindric, included, 16–23 mm long, fertile part ± 6 mm long; style branches 4–7 mm long, diverging, crests 4–7 mm long, erect. *Capsules* ellipsoid, ± 10 mm long. *Seeds* dark brown, angular. *Chromosome number* $2n = 12$. *Flowering time*: late spring, September to early November; opening 12:00–13:00 and collapsing after 17:00.

Distribution and ecology: widespread in southwestern and southern South Africa, extending from the Kamiesberg of central Namaqualand in Northern Cape south and east through Western Cape to Grahamstown in Eastern Cape, but evidently absent from the south coast between Mossel Bay and Port Elizabeth; weedy and adventive, it often occurs in waste places, trampled sites, roadsides and even lawns in a variety of soils. It is naturalised in Australia.

Diagnosis: *Moraea setifolia* is readily distinguished in sect. *Gynandriris* by its low stature and small flowers. The blue-mauve flowers have orange and white nectar guides on the outer tepals, 12–18 mm long, and the limbs of both outer and inner tepals are half reflexed. The small flower size is reflected in the short filaments 3.5–6.0 mm long and short anthers up to 4 mm long. The flowers open between noon and 13:00 and fade shortly before sunset. Several populations examined for chromosome number are diploid, $2n = 12$, and plants have been found in the greenhouse to be reproductively self-compatible and autogamous. They thus produce ample seed wherever they occur. This mode of reproduction is unusual in *Moraea* but explains its success as a weed.

Distribution of ***Moraea setifolia***.

Distribution of ***Moraea cedarmontana***.

85. **Moraea cedarmontana** *(Goldblatt) Goldblatt* in Novon 8: 376 (1998). *Gynandriris cedarmontana* Goldblatt: 250 (1980b). Type: South Africa, [Western Cape], Biedouw Valley, Welbedacht, *Goldblatt 4287* (MO, holo.; K, NBG, PRE, S, US, WAG, iso.).

Plants 100–300 mm high. *Corm* 10–15 mm diam.; tunics of stiff, dark, coarse fibres covered by mealy substance. *Stem* with one main axis and few to several ± sessile, lateral branches; sheathing leaves 40–55 mm long. *Foliage leaves* 2, linear, channelled, ± erect or trailing, longer than stem. *Rhipidial spathes* membranous with prominent veins, ± dry at flowering, attenuate, inner 40–60 mm long, outer slightly shorter. *Flowers* fugaceous, white, outer tepal limbs with small, yellow nectar guides at bases, ultimately ± half reflexed; outer tepals lanceolate, 24–27 × 10–12 mm, claws suberect, 10–12 mm long, inner tepals 20–25 × 3–5 mm, erect. *Filaments* 5–6 mm long, united in lower $^1/_3$–$^1/_2$; anthers 5–6 mm. *Ovary* ± cylindric, included, ± 50 mm long, fertile in lower 10 mm; style branches 7–11 mm long, ascending, crests erect, 11–13 mm long. *Capsules* and *seeds* not known. *Chromosome number* 2*n* = 12. *Flowering time*: September and October.

Distribution and ecology: a narrow endemic of Western Cape, South Africa, restricted to the interior valleys of the northern Cederberg and Nardouw Mtns; associated with wet sites such as along streams and drainage lines.

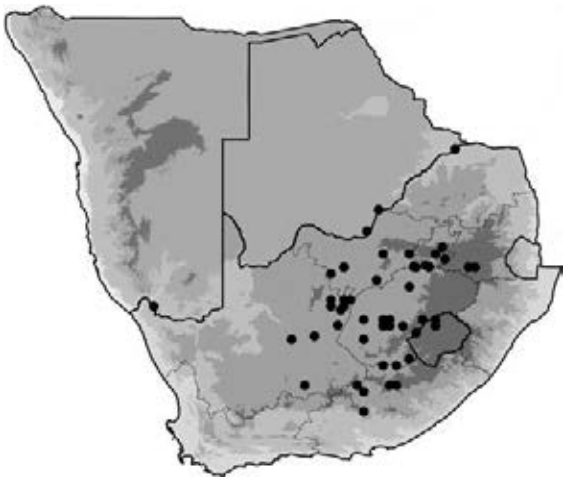
Diagnosis: recognised by the relatively small, white flowers, *Moraea cedarmontana* has outer tepals 24–27 mm long and the inner 20–25 × 3–5 mm, relatively narrow in proportion to the length. Plants are usually fairly slender and up to 300 mm tall.

86. **Moraea simulans** *Baker*, Handbook of the Irideae 58 (1892). *Helixyra simulans* (Baker) N.E.Br.: 350 (1929b). *Gynandriris simulans* (Baker) R.C.Foster: 40 (1936); Goldblatt: 252 (1980b). Type: South Africa, [North West], Bloemhof, *Nelson 203* [K, lecto., designated by Goldblatt: 252 (1980b)].

Moraea burchellii Baker: 57 (1892). *Helixyra burchellii* (Baker) N.E.Br.: 349 (1929b). *Gynandriris burchellii* (Baker) R.C.Foster: 40 (1936). Type: South Africa [as Bechuanaland], [Northern Cape], Jabrin's Fountain, *Burchell 2250* (K, holo.).

Moraea cladostachya Baker: 58 (1892). *Helixyra cladostachya* (Baker) N.E.Br.: 349 (1929b). *Gynandriris cladostachya* (Baker) R.C.Foster: 40 (1936). Type: South Africa, [Northern Cape], Verleptpram, Orange River, *Drège 2610* (K, lecto., designated by Goldblatt: 252 (1980b); BM, L, LE, MO, S, isolecto.).

Helixyra elata N.E.Br.: 349 (1929b). *Gynandriris elata* (N.E.Br.) R.C.Foster: 40 (1936). Type: South Africa, [Mpumalanga], Standerton, *Rogers 14799* (K, holo.).



Helixyra mossii N.E.Br.: 350 (1929b). *Gynandriris mossii* (N.E.Br.) R.C.Foster: 40 (1936). Type: South Africa, [Gauteng], Gedult, 15 Oct. 1927, *Moss 15607* (K, holo.; P, S, iso.).

Helixyra propinqua N.E.Br.: 349 (1929b). *Gynandriris propinqua* (N.E.Br.) R.C.Foster: 40 (1936). Type: South Africa, [Limpopo], Soutpansberg, *DvS s.n.* (PRE, holo.).

Helixyra spicata N.E.Br.: 349 (1929b). *Gynandriris spicata* (N.E.Br.) R.C.Foster: 41 (1936). Type: South Africa, [Northern Cape], Griqualand West, *Burchell s.n.* (K, holo.).

Plants (100–)140–450 mm high. *Corm* 15–20 mm diam.; tunics of pale to dark coarse fibres, often with a cormlet in leaf axil. *Stems* either contracted, sometimes with many basal branches or extended, with short to ± sessile aerial branches and sometimes longer basal branches; upper nodes with sheathing leaves ± as long as spathes. *Foliage leaves* 1 or 2, linear, channelled, longer than the stem, often trailing distally, 2–4 mm wide. *Rhipidial spathes* usually dry at flowering time, sometimes green toward base; inner (25–)35–55 mm long, outer slightly shorter. *Flowers* fugaceous, pale blue-mauve mottled darker mauve to violet, outer tepal limbs white nectar guides at bases edged orange proximally, half reflexed; outer tepals (17–)20–28 × ± 8 mm, claws slightly shorter than limbs, inner tepals 15–19 × 3–4 mm, spreading, ultimately half reflexed. *Filaments* 5–6 mm long, united for 1.0–1.5 mm; anthers 4–8 mm long. *Ovary* ± cylindric, included, 15–25 mm long, fertile in lower ± 6–8 mm; style branches 8–12 mm long, crests 3–6 mm long, erect. *Capsules* ± ovoid, 13–20 mm long. *Seeds* large, dark brown, elongate-angular. *Chromosome number* 2*n* = 24, 36. *Flowering time*: mainly August and September, at the end of the dry season; opening after 15:30, collapsing after 19:00.

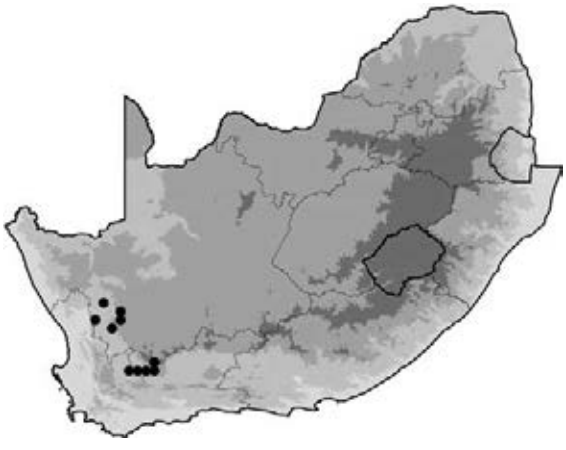
Distribution and ecology: widespread across summer-rainfall southern Africa, extending from Victoria West in South Africa north through eastern Northern Cape, Free State, North West Province, Gauteng and

Distribution of ***Moraea simulans***.

interior Mpumalanga, as well as western Lesotho and eastern Botswana, with isolated populations in the lower Orange River in the Richtersveld, probably also in Namibia; usually in dry grassland, open bushveld and karroid scrub.

Diagnosis: living plants of *Moraea simulans* are readily recognised by their distinctive flowers with the tepals speckled throughout with darker mauve to violet blotches on a pale blue-lilac background, a feature unique in the section but unfortunately not visible when dry. The flowers are moderate in size, having outer tepals 17–28 mm long and both inner and outer tepals are rather narrow with laxly spreading to half reflexed limbs. Flowers open in the middle of the afternoon, usually after 15:30 and last just a few hours, collapsing after 19:00. Despite its several synonyms, *M. simulans* is not particularly variable except in height and the number of branches, features dependent on growing conditions rather than genetically determined.

The species is evidently polyploid but chromosome numbers are known from only two collections, one tetraploid, $2n = 24$, and the other hexaploid, $2n = 36$.



87. **Moraea pritzeliana** *Diels* in Botanische Jahrbücher für Systematik 44: 117 (1909). *Gynandriris pritzeliana* (Diels) Goldblatt: 781 (1976a) & 248 (1980b). Type: South Africa, [Northern Cape], Calvinia District, *Diels 694* (B, holo.).

Moraea torta L.Bolus: 418 (1927b). *Helixyra torta* (L.Bolus) Barnard: 52 (1932). *Gynandriris torta* (L.Bolus) R.C.Foster: 41 (1936). Type: South Africa, [Northern Cape], near Calvinia, *Compton s.n.* (BOL, holo.).

Plants mostly 120–350 mm high. *Corm* 15–20 mm diam.; tunics of coarse, dark, rigid fibres often covered with white, mealy substance. *Stem* either contracted, with branches produced near ground, or extended with branches produced from base and at aerial nodes; upper nodes with sheathing leaves ± as long as spathes; stem becoming loosely coiled in fruit. *Foliage leaves* 2, linear, flat but helically coiled from base or middle, either upright and exceeding stem, or spreading, 2.5–5.0 mm wide, with broad translucent band on adaxial midline, usually with prominent submarginal veins. *Rhipidial spathes* becoming dry above or completely, then ± translucent with prominent veins, inner (34–)37–45 mm long, outer slightly shorter. *Flowers* fugaceous, dark blue-violet, outer tepal limbs with white nectar guides at bases, ± half reflexed, odourless; outer tepals 21–30 × 10–15 mm, claws ± $^1/_3$ as long as limbs, inner tepals 20–26 × 7 mm long, limbs half reflexed. *Filaments* 5–6 mm long, united in lower 1.5–3.0 mm; anthers 4.5–6.5 mm long; pollen yellow. *Ovary* ± cylindric, subsessile, 32–38 mm long, fertile part ± 10 mm long; style branches 8–10 mm, diverging, crests (4–)7–11 mm long, ± linear. *Capsules* ellipsoid, 15–20 mm long. *Seeds* angular, relatively large. *Chromosome number* $2n = 12$. *Flowering time*: middle September to November; opening 1:00–12:00, collapsing after 16:00.

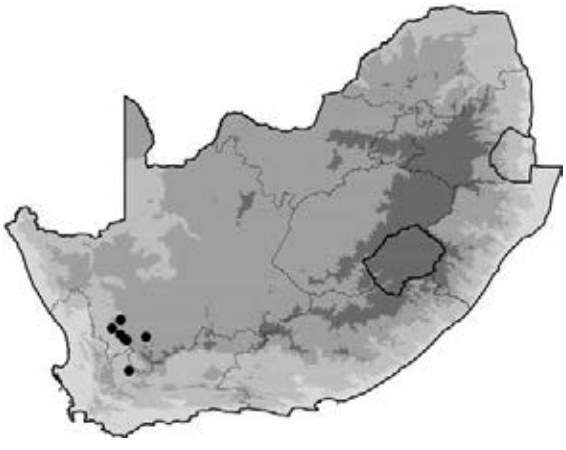
Distribution and ecology: widespread in the western Karoo, extending from near Loeriesfontein in Northern Cape, South Africa, across the Bokkeveld Plateau and Roggeveld to the Koedoes Mtns and the Komsberg Escarpment in the south; in dry stony ground in karroid succulent scrub or mountain renosterveld.

Diagnosis: *Moraea pritzeliana* is unmistakable in having two opposed, strongly coiled leaves, each with a broad, translucent central band along the midline. The translucent, prominently veined spathes and subsessile, cylindric ovary with a sterile tubular beak are typical of sect. *Gynandriris*, in which the large, dark blue to violet flowers with broad reflexed inner and outer tepal limbs, the latter 21–30 × 10–15, are also distinctive. *Moraea pritzeliana* and *M. contorta* share an unusual feature, viz. as the capsules mature at the end of the growing season the stem becomes loosely coiled. This feature as well as the similar, large dark blue to violet flowers suggests a close relationship between the two, a hypothesis that is supported by molecular studies which retrieve the two as sister species.

Distribution of ***Moraea pritzeliana***.

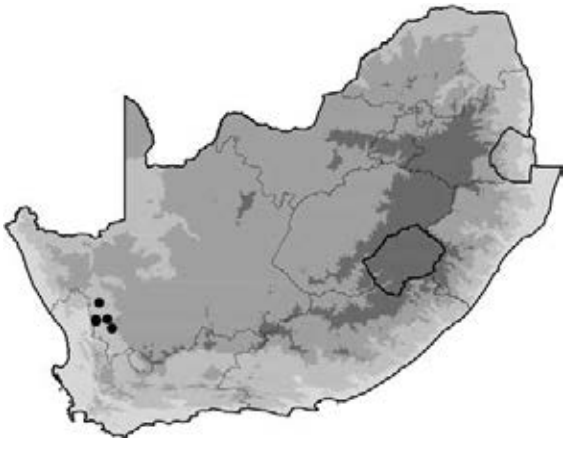
88. **Moraea contorta** *Goldblatt* in Novon 8: 376 (1998), as a new name for *Gynandriris anomala* Goldblatt: 250 (1980b) [not *M. anomala* G.J.Lewis]. Type: South Africa, [Northern Cape], Roggeveld, west of Middelpos, *Goldblatt 4396* (MO, holo.; K, NBG, PRE, iso.).

Plants 250–300 mm high. *Corm* 15–18 mm diam.; tunics of coarse, dark, rigid fibres often covered with white, mealy substance. *Stem* erect, with short, lateral branches at upper nodes; with sheathing leaves ± as long as spathes; stem becoming loosely coiled in fruit. *Foliage leaf* usually solitary, linear, channelled, much longer than stem, erect below, trailing distally, 5–7 mm wide. *Rhipidial spathes* ± membranous, dry or sometimes green below, with prominent hyaline veins, inner 36–45 mm long, outer slightly shorter. *Flowers* fugaceous, dark blue, outer tepal limbs with white nectar guides at bases, limbs of both whorls half reflexed, with a strong spicy-sweet scent; outer tepals 21–26 × 10–12 mm long, claws 8–9 mm, ± $^1/_3$ as long as limbs, inner tepals ± 22 × 7 mm. *Filaments* 4.5–6.0 mm long, united for ± $^1/_2$ their length; anthers 5–7 mm long. *Ovary* ± cylindric, 30–38 mm long, fertile part ± 10 mm long; style branches 8–10 mm long, crests ± 10 mm long, erect. *Capsules* narrowly ellipsoid, 15–18 mm long. *Seeds* lozenge-shaped, dark brown. *Flowering time*: October to mid-November; opening 1:00–12:00, collapsing in late afternoon.



Distribution and ecology: recorded on the Hantamsberg at Calvinia in Northern Cape, South Africa, at scattered sites to the south and in the Roggeveld close to the escarpment edge, as well as in the Koedoes Mtns; in relatively well-watered sites.

Diagnosis: recognised by the large dark blue flowers with relatively broad tepals, the outer 21–26 × 10–12 mm long, with the claws ± a third as long as the limbs, *Moraea contorta* is most closely related to the more widespread *M. pritzeliana* and its range falls entirely with that of the latter. The flowers of *M. contorta* have a strong sweet, coconut-like scent while those of *M. pritzeliana*, often darker in colour, are apparently unscented. Vegetative differences are more pronounced, and *M. contorta* typically has a single, linear, channelled leaf in contrast to the very distinctive pair of opposed, helically coiled leaves of *M. pritzeliana.* The two species share a unique feature, as the capsules ripen and the stems dry out they become loosely coiled, speculatively an adaptation for dispersal by becoming entangled in the feet of passing antelope or other animals.



89. **Moraea hesperantha** *(Goldblatt) Goldblatt* in Novon 8: 376 (1998). *Gynandriris hesperantha* Goldblatt: 248 (1980b). Type: South Africa, [Northern Cape], Nieuwoudtville, Glenlyon, rocky hills, *Goldblatt 4371* (MO, holo.; NBG, PRE, iso.).

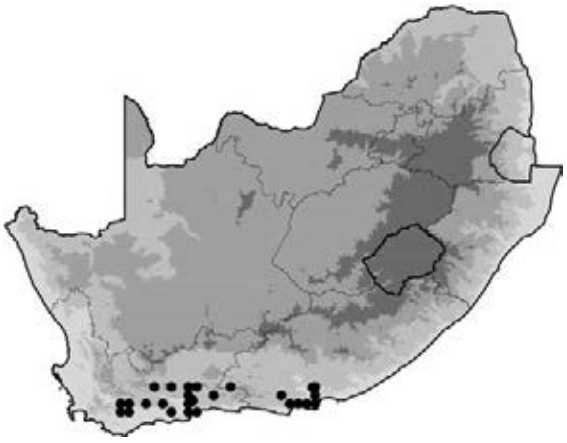
Plants 400–650 mm high. *Corm* 20–30 mm diam.; tunics of wiry, pale, mealy fibres. *Stem* suberect, sometimes with 1 or more long branches from near base and with short, subsessile lateral branches; upper nodes with sheathing leaves ± as long as spathes. *Foliage leaves* 2, linear, much longer than stem, suberect, trailing distally, channelled, 6–8 mm wide, margins straight. *Rhipidial spathes* becoming membranous with fine longitudinal veins, inner 45–60 mm long, outer slightly shorter. *Flowers* fugaceous, violet, outer tepal limbs with yellow nectar guides at bases, half reflexed; outer tepals 26–29 × 10 mm, claws diverging, ± 10 mm long, inner tepals narrowly lanceolate, suberect, 22–26 × 5 mm. *Filaments* 5.0–6.5 mm long, united in lower $^1/_3$–$^1/_2$; anthers 7–8 mm long, violet; pollen yellow. *Ovary* ± cylindric, 40–55 mm long, fertile in lower ± 12 mm; style branches 9–12 mm long, diverging, crests 7–9 mm long. *Capsules* and *seeds* unknown. *Chromosome number* 2*n* = 12. *Flowering time*: October to mid-November; opening 16:00–16:30, collapsing after 19:00.

Distribution and ecology: restricted to the western Karoo and known from less than a handful of sites between Nieuwoudtville and Loeriesfontein in Northern Cape, South Africa; in heavy red clay in dolerite outcrops.

Distribution of ***Moraea contorta***.

Distribution of ***Moraea hesperantha***.

Diagnosis: one of the tallest and most robust species of sect. *Gynandriris,* stems of *Moraea hesperantha* may reach up to 650 mm high and bear several, short lateral branches. The two long, suberect, channelled leaves trail distally. The dark violet flowers recall those of *M. pritzeliana* but have suberect inner tepals vs. reflexed in *M. pritzeliana*, which has characteristically coiled leaves and is a much shorter plant. *Moraea hesperantha* stands out in particular in being evening blooming: the flowers open at 16:00–16:30, about the time that flowers of *M. pritzeliana* begin to fade, and the flowers last till well after dark, usually collapsing by 19:30. The evening blooming habit is unique in sect. *Gynandriris*.



Sect. 9. **Polyanthes** *Goldblatt* in Annals of the Missouri Botanical Garden 63: 8 (1976b). Type: as for subgenus.

90. **Moraea bipartita** *L.Bolus* in Journal of Botany, British and foreign 71: 122 (1933); Goldblatt: 107 (1986a). Type: South Africa, [Western Cape], Riversdale Karoo, on road to Adams Kraal, *Ferguson s.n.* (BOL [20068], holo.).

Plants mostly 200–350 mm high. *Corm* ± 15 mm diam.; tunics of hard, dark brown to black fibres. *Stem* several-branched, sheathing leaves green, becoming dry at tips, mostly 25–35 mm long. *Foliage leaves* usually 3 or 4, rarely only 2, linear, channelled, 2–6 mm wide, lowermost ± basal and usually exceeding stem, upper leaves shorter. *Rhipidial spathes* often becoming dry and brown above, attenuate; inner (20–)25–45 mm long, outer ± $^1/_2$ as long. *Flowers* fugaceous, pale blue to blue-mauve or violet, scented of burned vanilla or unscented, outer tepal limbs with small to large yellow nectar guides at bases sometimes edged white, ± half reflexed; tepals lanceolate, outer 16–30 mm long, claws ± $^1/_3$ as long as limbs; inner smaller, 14–25 mm long. *Filaments* 4–6 mm long, united in lower $^2/_3$; anthers ± 5 mm long, pale mauve; pollen white. *Ovary* ovoid, 4–5 mm long, usually partly exserted at flowering; style branches ± 5 mm long, crests 5–8 mm. *Capsules* ellipsoid broadly ovate, ± 9 mm long. *Seeds* angular. *Chromosome number* 2*n* = 12. *Flowering time*: mainly August to October (to November); flowers open after midday and fade after 17:30, sometimes shortly after dark.

Distribution and ecology: common in the Little Karoo but extending from near Swellendam and Robertson in southern Western Cape, South Africa, through the Little Karoo and southern Cape to Uitenhage in Eastern Cape.

Diagnosis: *Moraea bipartita* is distinguished by the two or more foliage leaves, the blades linear, channelled and up to 6 mm wide, and the relatively small, *Moraea*-type flower with well-developed, broad style branches and prominent, erect crests. The stems have several branches in mature plants in seasons of adequate rainfall and the flowers are usually blue to blue-mauve with yellow nectar guides only on the outer tepal limbs, the outer tepals 16–30 mm long and the inner 14–25 mm long. Plants from the Perdebont Valley in the southern Little Karoo near the northern end of Robinson Pass have pale yellow flowers otherwise exactly like those of blue-flowered plants. This is a striking exception not only for *M. bipartita* but for the entire sect. *Polyanthes*.

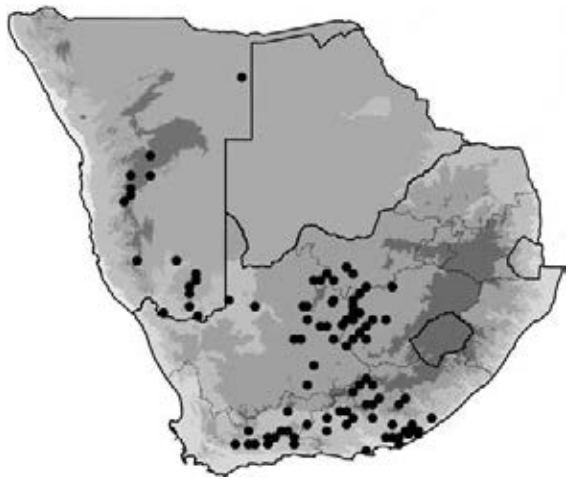
Distribution of ***Moraea bipartita***.

Closely related *Moraea polyanthos* is virtually identical vegetatively to *M. bipartita* but has subequal tepals, the limbs of both whorls spreading horizontally and bearing small white to yellow nectar guides, and the style branches, ± as wide as the anthers, lack crests. The filaments of *M. polyanthos* are united in a slender column whereas those of *M. bipartita* are free in the upper third. Hybrids between *M. bipartita* and *M. polyanthos* have been recorded where the two species co-occur, and plants with a range of flowers intermediate between the two indicate introgression among the hybrids.

Moraea polystachya has flowers of similar form to those of *M. bipartita*, thus with broad style branches and crests, but plants are larger as are the flowers, the outer tepals 36–55 mm long. The ovary is often veined dark red in *M. polystachya* but is uniformly green in *M. bipartita*.

91. **Moraea polystachya** *(Thunb.) Ker Gawl.* in König & Sims, Annals of Botany 1: 240 (1804a); Goldblatt: 746 (1976a); Goldblatt: 118 (1986a). *Iris polystachya* Thunb.: 25 (1782b). *Iris lacera* Lam.: 304 (1789), illegitimate superfluous name for *I. polystachya* Thunb. Type: South Africa, without precise locality, *Thunberg s.n.* (UPS–THUNB, syn.).

Moraea toxicaria Dinter: 237 (1923). Type: Namibia, Entemba, Walthers Farm, Okongue, *Dinter 3414* (SAM, holo.).



[*Vieusseuxia multiflora* Eckl.: 12 (1827), invalid name without description.]

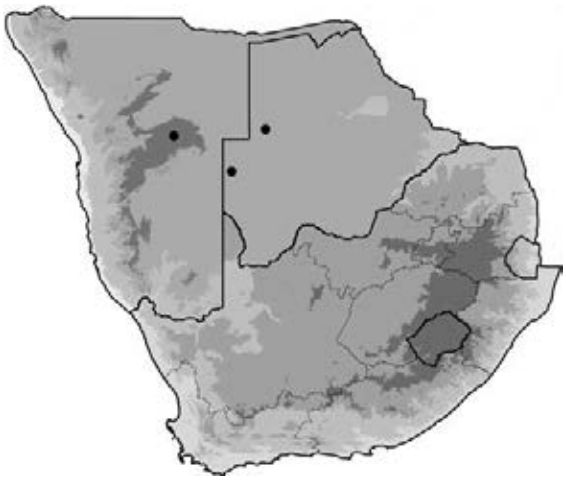
[*Moraea multiflora* Sol. ex Baker: 18 (1896), invalid name only in synonymy.]

Plants medium to large, up to 800 mm high. *Corm* 25–50 mm diam.; tunics of hard, dark coarse fibres. *Stem* several-branched, with green to partly to completely dry sheathing leaves at upper nodes 60–80 mm long. *Foliage leaves* 3 to 5, ± linear, channelled, usually as long as or longer than stem, trailing distally, 6–12(–20) mm wide. *Rhipidial spathes* green or turning brown and dry above, attenuate, inner 50–70 mm long, outer ± $^{2}/_{3}$ as long. *Flowers* fugaceous, blue to mauve or violet, outer tepal limbs with yellow to orange nectar guides at bases, limbs of both whorls reflexed up to ± 40° or erect (Little Karoo populations), claws suberect; outer tepals 36–55 × 13–25 mm, inner 36–55 × 13–21 mm, claws 15–21 mm long. *Filaments* ± 10 mm long, united in lower $^{3}/_{4}$; anthers 8–10 mm long, pale mauve; pollen white. *Ovary* ± ellipsoid, conspicuously veined red, mostly 7–12 mm long; style branches ± 10 mm long, crests up to 20 mm long. *Capsules* obovoid, 9–16 mm long. *Seeds* angular-prismatic, 1.2–1.6 mm long. *Chromosome number* 2*n* = 12. *Flowering time*: autumn and winter (December to) March to July (August).

Distribution and ecology: widespread in interior southern Africa, extending from the Little Karoo in Western Cape, South Africa, north into the eastern Upper Karoo, Eastern Cape, and western Free State to northern Namibia; most often on rocky slopes and flats and typically flowering in late summer and autumn but in winter in the Little Karoo.

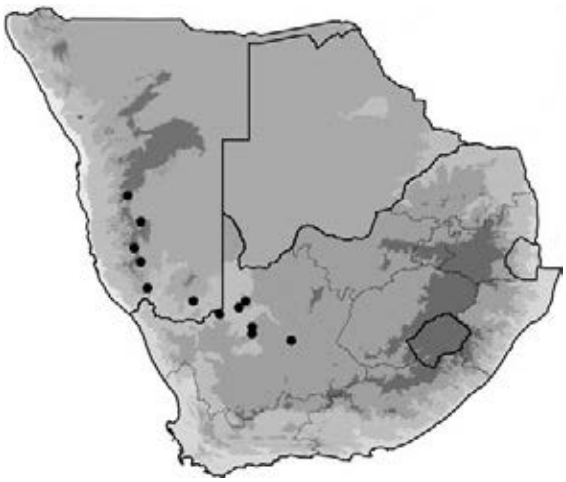
Diagnosis: widespread and relatively common in interior southern Africa, *Moraea polystachya* is recognised by the combination of several foliage leaves, branched stem, and large blue-mauve to violet flowers. The limbs of both tepal whorls are half reflexed but only the outer tepals bear nectar guides, and the tepal claws form a narrow cup enclosing the filaments and broad style branches, leaving the style crests prominently displayed. An unusual and particularly distinctive feature of most populations is the red veining on the ovary, this absent in plants from the Little Karoo. Once regarded as an ecological variant of *M. polystachya*, *M. venenata* is now regarded as a separate, but closely related species. A shorter plant, *M. venenata* has somewhat larger flowers with inner tepals usually held ± erect, the ovary also typically red-veined. The larger capsules, up to 16–20 mm long, are nodding when mature and contain larger seeds, ± 2 mm long. Capsules of *M. polystachya* are held erect, are 9–16 mm long and the smaller seeds are 1.2–1.6 mm long. Both *M. polystachya* and *M. venenata* are poisonous to stock.

Distribution of ***Moraea polystachya***.



Moraea polystachya in the Little Karoo is distinctive not only in lacking red veining on the ovary but in having blue rather than violet flowers with the inner tepals held erect for most of the flowering cycle. No other features appear to distinguish these plants, which flower in the winter months rather than in late summer and autumn.

92. **Moraea carsonii** *Baker* in Bulletin of Miscellaneous Information Kew 1894: 391 (1894); Goldblatt: 252 (1977a); Goldblatt: 126 (1986a). Type: Zambia, Mbala, 'Fwambo', *Carson s.n.* (K, holo.).



Moraea homblei De Wild.: 7 (1932). Type: Congo, Shaba, near Kolwezi, *Homblé 1024* (BR, holo.).

Plants 200–400 mm high. *Corm* 10–15 mm diam.; tunics of fine to medium, dark brown fibres. *Stem* usually with 1 or 2 (several) ascending branches, sheathing leaves 25–60 mm long, green with dry, brown, attenuate apices. *Foliage leaves* 2(3), exceeding stem, linear, channelled, 2–5 mm wide, lowermost basal or inserted shortly to well above the ground, often trailing distally, upper 1 or 2 leaves shorter than basal. *Rhipidial spathes* attenuate, becoming dry and brown apically, sometimes flushed red, inner 30–40(–50) mm long, outer ± 10 mm shorter. *Flowers* fugaceous, blue-violet, outer tepal limbs with white to yellow nectar guides at bases; outer tepals 20–30 mm long, lanceolate, limb slightly longer than claw, spreading at ± 30° below horizontal; inner tepals 17–28 mm long, narrowly lanceolate to nearly linear, limb also spreading. *Filaments* ± 7.5 mm long, united below, free in upper $^{1}/_{3}$; anthers 4.5–5.5 mm long, yellow. *Ovary* narrowly ovoid, 3.5–7.0 mm long, exserted, style branches 8–10 mm long, crests 7–10 mm long, ± erect. *Capsules* ± globose, 7–9 mm long. *Chromosome number* 2*n* = 12. *Flowering time*: February to April (also December and January in tropical Africa).

Distribution and ecology: largely tropical African, extending from northern Namibia and northern Botswana through Zambia, Mozambique and Zimbabwe to Congo, Malawi and southern Tanzania; in grassland, especially rocky sites.

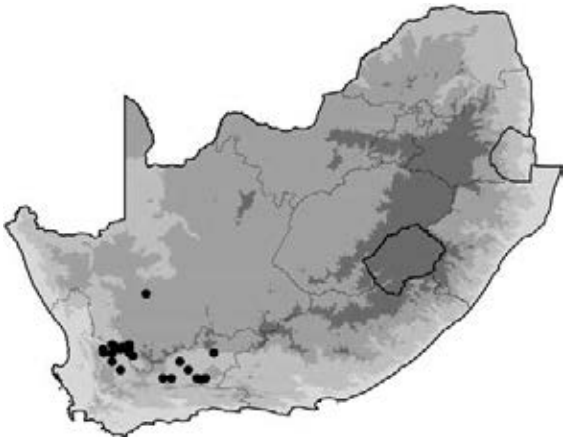
Distribution of ***Moraea carsonii***.

Distribution of ***Moraea venenata***.

Diagnosis: the two or three foliage leaves and relatively small, violet flowers with yellow nectar guides on the lower tepals and broad, well-developed style branches and crests are diagnostic for *Moraea carsonii*. It is the only tropical member of sect. *Polyanthes*, the other species all southern African and mostly occurring in the winter-rainfall zone of the subcontinent. The fugaceous flowers last a single day.

93. **Moraea venenata** *Dinter* in Repertorium specierum novarum regni vegetabilis 19: 238 (1923); Goldblatt: 121 (1986a). Type: Namibia, Bullspoort Flats, *Dinter 2141* [SAM, lecto., designated by Goldblatt: 121 (1986a)].

Moraea polystachya var. *brevicaulis* E.Phillips: 16 (1926). Type: South Africa, without precise locality, *Stent & Curton s.n.* [illustration in Phillips: fig. 2 (1926)].



Plants medium to large, 200–300 mm high. *Corm* globose, 20–35 mm diam.; tunics of hard, dark medium-textured to coarse fibres. *Stem* several-branched, with green to partly to completely dry, attenuate sheathing leaves at upper nodes 30–50 mm long. *Foliage leaves* 3 to 6, lanceolate to linear, channelled to ± flat, as long or longer than stem, falcate, usually trailing distally, 8–30 mm wide, margins often thickened, hyaline. *Rhipidial spathes* green or turning brown and dry above, long attenuate, with broad, translucent margins, inner mostly 40–60 mm long, outer almost as long, margins free nearly to base. *Flowers* fugaceous, blue-violet, outer tepal limbs with yellow to orange nectar guides at bases, reflexed up to ± 40º; outer tepals mostly 45–60 × 18–25 mm, claws ± 22 mm long, inner 35–50 × 9–12 mm, evidently ± erect. *Filaments* 10–15 mm long, united in lower $^{2}/_{3}$; anthers 8–9 mm long. *Ovary* ± cylindric, mostly 15–20 mm long, sometimes veined red, usually included; style branches ± 12 mm long, crests up to 15 mm long. *Capsules* narrowly obovoid, 16–20 mm long, nodding when mature. *Seeds* angular, ± 2 mm long. *Chromosome number* 2*n* = 12. *Flowering time*: mainly autumn and early winter, mostly March to July.

Distribution and ecology: occurring in central and southeastern Namibia and the adjacent Upper Karoo of Northern Cape, South Africa; in dry stony ground, sometimes with limestone substrate.

Diagnosis: *Moraea venenata* has the several leaves, a branched stem, and blue-violet flowers much like those of *M. polystachya*, but is a more robust species, although often not as tall. The flowers have outer tepals 40–60 mm long with the claws 22–30 mm long, and as far as known the inner tepals are erect. The widest of the several leaves are up to 30 mm wide near the middle [vs. 6–12(–20) mm in *M. polystachya*] and the outer spathes are up to 60 mm long and the inner about half as long but with unusually broad, translucent margins, free almost to the base, an unusual feature among the southern African members of the genus.

94. **Moraea speciosa** *(L.Bolus) Goldblatt* in Botaniska Notiser 133: 92 (1980a); Goldblatt: 122 (1986a). *Homeria speciosa* L.Bolus: 10 (1920). Type: South Africa, [Western Cape], near Prince Albert, *Krige s.n.* (BOL [13486], lecto., designated by Goldblatt: 122 (1986a); BOL, PRE, isolecto.).

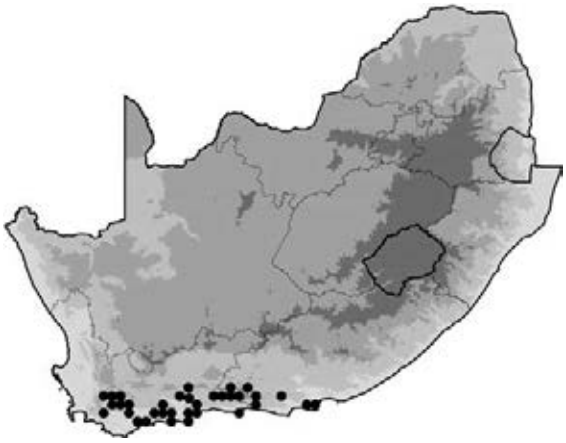
Plants medium to large, 400–700 mm high. *Corm* globose, 30–40 mm diam.; tunics of hard, dark medium-textured to coarse fibres. *Stem* several-branched, with green to partly to completely dry sheathing leaves at upper nodes 30–40 mm long. *Foliage leaves* several, narrowly lanceolate (to ± linear), channelled to ± flat and twisted distally, ± $^{1}/_{2}$–$^{2}/_{3}$ as long as stem, up to 40 mm wide, margins undulate. *Rhipidial spathes* green, turning pale and membranous later, inner 50–70 mm long, outer ± $^{2}/_{3}$ as long. *Flowers* fugaceous, sometimes half nodding, pale blue-mauve with yellow cup, limbs of inner and outer tepals with yellow to orange nectar

Distribution of ***Moraea speciosa***.

guides at bases edged violet, spreading to slightly reflexed, claws diverging, forming a wide cup including filaments; outer tepals 35–45 × 18–25 mm, claws 12–15 mm long, inner ± as long but slightly narrower. *Filaments* united in a cylindric column finely hairy below, mostly 9–13 mm long; anthers (8–)12–17 mm long, initially contiguous, becoming slightly divergent in upper half, orange or yellow; pollen orange. *Ovary* ± cylindric, 8–12 mm long, green, sometimes included; style dividing opposite middle of anthers, branches 3–6 mm long, narrowly diverging, not reaching anther tips, without crests. *Capsules* ± club-shaped, 12–22 mm long, nodding to pendent when mature. *Seeds* angular, ± 2 mm long. *Chromosome number* 2*n* = 12. *Flowering time*: mainly autumn and early winter, mostly March to July.

Distribution and ecology: centred in the Tanqua Karoo of Western Cape, South Africa, and extending to the east in the Great Karoo as far as Prince Albert and to the west into the dry interior valleys of the Cederberg and locally north near Calvinia in Northern Cape; on dry, stony flats, flowering irregularly, only in years of adequate rainfall.

Diagnosis: *Moraea speciosa* is easily recognised by the large, pale blue-mauve flowers with a deep, wide, pale yellow floral cup that includes the filaments, these entirely united in a cylindric column. The anthers are initially contiguous and appressed to the style, later becoming slightly divergent distally. The style divides opposite the middle of anthers and the slender branches lack crests and do not reach the tips of the anthers. Plants have several, relatively broad leaves up to 40 mm wide, trailing distally and with undulate margins.



95. **Moraea polyanthos** *L.f.*, Supplementum plantarum: 99 (1782); Goldblatt: 746 (1976a); Goldblatt: 108 (1986a). Type: South Africa, [Western Cape], near the Kore River, *Thunberg s.n.* (UPS–THUNB 1126, holo.).

Homeria lilacina L.Bolus: 9 (1920). Type: South Africa, [Western Cape], near Matjiesfontein, *Beattie & H. Bolus s.n.* (BOL [15186], holo.).

Plants mostly 150–450 mm high. *Corm* 10–15 mm diam.; tunics of hard, dark brown to black fibres. *Stem* several-branched, with attenuate sheathing leaves dry at tips, mostly 35–45 mm long. *Foliage leaves* usually 3 or 4, rarely only 2, linear, channelled, lowermost ± basal, usually exceeding stem, trailing distally, upper leaves shorter, 2–6 mm wide. *Rhipidial spathes* often becoming dry and brown above, attenuate; inner 33–45 mm long, outer ± $^1/_2$ as long. *Flowers* fugaceous, blue to blue-mauve or white, scented of burned vanilla or unscented, all tepal limbs with small to yellow to orange nectar guides at bases sometimes edged white, spreading ± horizontally, claws diverging to form a cup including filaments and sometimes anthers; tepals lanceolate, outer 23–40 × 8–10 mm long, claws 10–12 mm long; inner smaller, 20–35 × 6–9 mm. *Filaments* united in a smooth, slender column (5–)6–9 mm long; anthers 4–7 mm long, pale mauve or white; pollen usually white. *Ovary* narrowly obovoid, 5–7 mm long, usually partly exserted at flowering; style branches 4–5 mm long, ± as wide as anthers, bilobed at tips, without crests. *Capsules* ellipsoid–obovoid, 7–11 mm long. *Seeds* angular. *Chromosome number* 2*n* = 12. *Flowering time*: mainly September and October (November); opening after midday and collapsing at nightfall.

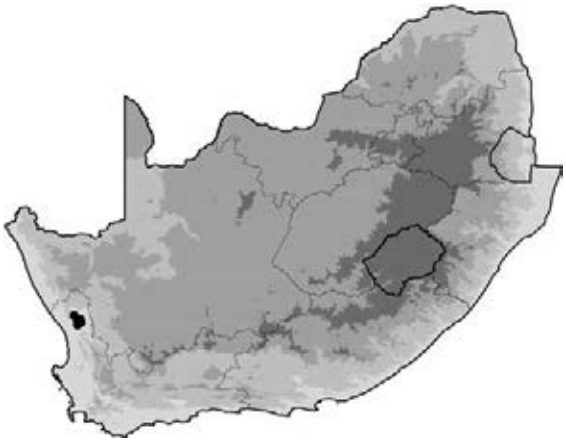
Distribution and ecology: relatively common and widespread in southern and interior Western Cape and coastal Eastern Cape, South Africa, from near Worcester though the Little Karoo and Long Kloof to Uitenhage and in the south from Stormsvlei to Mossel Bay.

Diagnosis: *Moraea polyanthos* is recognised by the branched stem bearing two to four foliage leaves, and moderate-sized, blue to blue-mauve, violet or rarely white flowers with style branches as narrow and as long as or slightly longer than the anthers and lacking style crests. The ascending tepal claws diverge slightly to form a relatively narrow cup that includes the filaments and the lower part of the anthers or all of the anthers, and the tepal limbs spread more-or-less horizontally. The filaments are united in a slender, smooth column usually 7–9 mm long. A notable variant of

Distribution of ***Moraea polyanthos***.

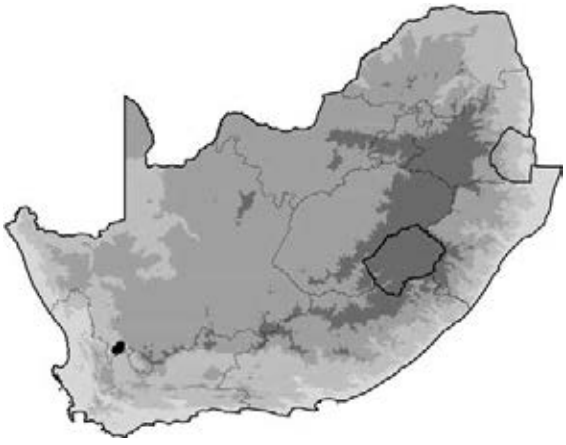
the species from near Albertinia and Herbertsdale in southern Western Cape has slightly smaller, white or pale blue flowers with the filaments only 5–6 mm long, and both filaments and anthers are included in the floral cup whereas the anthers are usually fully excluded from the cup in typical *M. polyanthos*. The species is closely allied to *M. bipartita*, which has conventional *Moraea*-type flowers with broad style branches with prominent crests but the two are identical in vegetative features. Hybrids between these two species have been recorded where they co-occur.

96. **Moraea deserticola** *Goldblatt* in Annals of the Missouri Botanical Garden 73: 113 (1986c). Type: South Africa, [Western Cape], Knersvlakte, Farm Quaggasfontein, *Hall 5089* (NBG, holo.; MO, iso.).



Plants 350–450 mm high. *Corm* ± 10 mm diam.; tunics of hard, dark brown to blackish fibres. *Stem* simple or 1- to 3-branched from upper nodes, sheathing leaves 25–40 mm long. *Foliage leaves* 2 or 3, linear, channelled, 2–3 mm wide, ± as long as the stem, margins becoming tightly inrolled when dry, lowermost basal and largest. *Rhipidial spathes* becoming dry and brown above, inner 33–40 mm long, outer ± $^{2}/_{3}$ as long. *Flowers* fugaceous, pale blue or white with pale blue outside, limbs of all tepals with yellow nectar guides at bases, tepal claws ascending and forming a wide cup including the filament column, limbs extended horizontally; tepals 30–36 × 11–12 mm, claws ± 12 mm long, inner slightly smaller than outer. *Filaments* 8–10 mm long, united in a smooth slender cylindric column; anthers 5.5–6.5 mm long, erect, contiguous, appressed to and initially concealing style branches. *Ovary* 6–7 mm long, narrowly obconic, exserted, conspicuously red-veined; style dividing into 3 short horizontal lobed branches just above apex of anthers ± 1 mm long, crests lacking. *Capsule* ± obovoid, 9–10 mm long, red-veined. *Seeds* many, angular. *Chromosome number* 2*n* = 12. *Flowering time*: June to August.

Distribution and ecology: a narrow endemic of the Knersvlakte between Vanrhynsdorp and Nuwerus in Western Cape, South Africa; on stony slopes and flats on and around outcrops of marble or other limestone type rocks, sometimes in fine clay-like soil.



Diagnosis: *Moraea deserticola* is distinguished by the large, deeply cupped, pale blue to white flowers with subequal tepals, 30–36 mm long, horizontally spreading tepal limbs, and long conspicuous, erect and contiguous anthers. It most closely resembles *M. speciosa*, which has somewhat larger flowers of similar morphology with tepals 36–45 mm long, and several broad leaves up to 40 mm wide unlike the two or three narrow foliage leaves of *M. deserticola,* only 2–3 mm wide, with the margins often tightly inrolled. The ovary of *M. deserticola* is veined dark purple whereas *M. speciosa* has a uniformly green ovary.

97. **Moraea tanquana** *Goldblatt & J.C.Manning* in Bothalia 39: 4 (2009). Type: South Africa, Northern Cape, Tankwa National Park, small koppie east of Leeuberg, 404 m, 4 Aug. 2006, *Steyn 872* (NBG, holo.; PRE, iso.).

Plants up to 500 mm high. *Corm* subglobose, ± 20 mm diam.; tunics of coarse, dark brown to blackish fibres. *Stem* up to 3-branched from upper nodes, sheathing leaves green, attenuate. *Foliage leaves* 3, lowermost basal, linear and channelled, 2–5 mm wide, ± $^{3}/_{4}$ as long as stem, upper 2 leaves cauline, ± as long as basal. *Rhipidial spathes* green but dry and membranous apically with brownish cusps; inner ± 30 mm long, outer ± half as long. *Flowers* fugaceous, pale blue or mauve with a yellow cup, and small, rounded, yellow nectar guides at bases of all tepal limbs, tepal claws minutely pubescent at base, 8–9 mm long, ascending and forming wide cup, limbs spreading horizontally; outer tepals obovate, ± 25 mm long, limb 15–16 × 12 mm, inner tepals slightly shorter, ± 22 mm long. *Filaments* ± 10 mm long, reaching to mouth of floral cup or exserted ± 1 mm, united, column cylindric, minutely pubescent at base; anthers erect, contiguous, 4–5 mm long at anthesis (shrinking to 3 mm after dehiscence), yellow, concealing style branches. *Ovary* ovoid, 4–5 mm long, exserted from spathes; style

Distribution of ***Moraea deserticola***.

Distribution of ***Moraea tanquana***.

branches ± 1 mm long, concealed by anthers; stigma lobes bifid, crests lacking. *Capsules* and *seeds* unknown. *Flowering time*: August, probably also in late July.

Distribution and ecology: a rare species known from a single hill in the Tanqua Karoo National Park east of Leeuberg in Western Cape, South Africa; on clay soils on a dolerite outcrop.

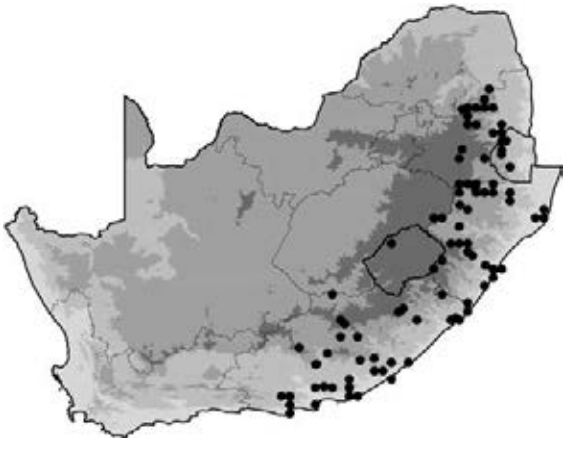
Diagnosis: closely related to *Moraea deserticola* from the Knersvlakte, *M. tanquana* is distinguished by the three linear foliage leaves up to 5 mm wide, pale blue to mauve flowers with subequal tepals ± 22 mm long, united filaments, and short, contiguous anthers, 4–5 mm long that exceed the style branches and enclose them. The style divides opposite the lower third of the anthers so that the stigmatic tips of the short style branches, ± 1 mm long, emerge from between the middle of the ± contiguous anthers, and the branches lack crests. A smaller plant, *M. deserticola* has narrow foliage leaves 2–3 mm wide, tepals 30–36 mm long, and anthers 6.0–6.5 mm long (shrinking after anthesis to 5 mm) that remain contiguous around the style with their bases held within the floral cup. The ovary is conspicuously veined with dark red in *M. deserticola* but uniformly green in *M. tanquana*.

Sect. 10. **Pseudospicatae** *Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 43: 38 (2013). Type: *Moraea pseudospicata* Goldblatt

Plants unbranched or branched, secondary branches sometimes sessile. *Foliage leaves* solitary (2 in *M. callista* which may be misplaced here). *Flowers* usually blue to mauve or violet; tepal claws short or ± as long as limbs; stamens united in lower half; style branches will developed with erect crests or reduced, without crests, sometimes as paired or single filiform arms extended horizontally. *Ovary* and *capsules* exserted or included.

98. **Moraea elliotii** *Baker*, Handbook of the Irideae: 58 (1892); Goldblatt: 127 (1986a). *Vieusseuxia elliotii* (Baker) Klatt: 154 (1894). Type: South Africa, [Mpumalanga], marshes near Lake Chrissie, *Scott Elliot 1592* (K, holo.).

Moraea macra Schltr.: 377 (1898). Type: South Africa, [Eastern Cape], Queenstown, *Galpin 2193* (B, holo.; BOL, PRE, iso.).



Moraea violacea Baker: 863 (1901). Type: South Africa, [KwaZulu-Natal], Byrne, *Wood 5220* (Z, holo.; BM, iso.).

Moraea juncifolia N.E.Br.: 346 (1929b). Type: South Africa, [Mpumalanga], Saddleback, *Galpin 8539* (K, holo.; SAM, iso.).

Moraea stewartiae N.E.Br.: 346 (1929b). Type: Swaziland, Hlatikulu, *Stewart 44* (K, holo.; PRE, iso.).

Plants mostly 300–500 mm high. *Corm* 12–20 mm diam.; tunics of dark brown fairly coarse fibres often forming a collar around base. *Stem* simple or with several (up to 8) branches, these suberect, flexed away from axis, sheathing leaves 40–60 mm long. *Foliage leaf* solitary, ± basal or inserted above ground, sometimes ± in middle of stem, linear, channelled or seeming terete with margins tightly inrolled with narrow adaxial groove, longer than stem, initially ± erect often becoming trailing above. *Rhipidial spathes* attenuate, green with brown membranous tips or becoming largely dry and brown, inner 40–60 mm long, outer shorter by ± 10 mm. *Flowers* fugaceous, blue to violet, occasionally pale lilac to ± white, outer tepal limbs with yellow-orange (or ± white) nectar guides at bases edged purple or violet, ± laxly spreading or reflexed to ± 45°; outer tepals 20–30 × 10–12 mm, claws ascending, ± $^1/_3$ as long as limbs; inner tepals 15–24 × 2–4 mm, narrowly lanceolate, initially suberect, either limbs becoming half-reflexed OR entirely spreading and twisted through 90°, claws 2–3 mm long. *Filaments* 3.4–4.5 mm long, united in lower 1–2 mm; anthers 5–6 mm long, white, pale grey-blue or yellow; pollen white or yellow. *Ovary* ovoid-ellipsoid, 6–8 mm long; style branches 8–10 mm long, crests erect, 5–9 mm long. *Capsules* club-shaped, 9–12 mm long. *Seeds* small, angled. *Chromosome number* 2*n* = 12, 24. *Flowering time*: September to March, usually late spring, from September in the south, and summer to autumn, from December to March in the north.

Distribution and ecology: widespread through the eastern half of the country, from near Mossel Bay in Western Cape north through Eastern Cape and KwaZulu-Natal to Mpumalanga and Limpopo in South Africa, also in Lesotho and Eswatini; in tropical Africa in Malawi and probably Mozambique; typically in open grassland, in a variety of soils, often in stony sites where corms are protected from predation.

Distribution of ***Moraea elliotii***.

Diagnosis: with relatively small flowers, *Moraea elliotii* currently includes plants from the Mpumalanga highveld with a linear leaf inserted high up on the stem but not immediately under the inflorescence, as well as those with a more-or-less basal leaf. The leaf is channelled but sometimes with margins tightly inrolled and appearing subterete or terete (the type of the synonym *M. juncifolia*). Plants from Gauteng, Mpumalanga and Eswatini mostly flower from December to March, whereas those from the KwaZulu-Natal Midlands generally flower in late spring, and those in the Eastern Cape may bloom as early as September. The flowers are small, with outer tepals 20–30 mm long and those from the north of its range are blue to violet with yellow-orange nectar guides and have inner tepals with half reflexed limbs. Populations from KwaZulu-Natal and Eastern Cape are variable in colour, sometimes pale violet to lilac or even white, often with the inner tepals spreading almost from the base and twisted through 90° and the filaments united for only ± 1 mm, vs 2.0–2.5 mm elsewhere. There appear, however, to be no consistent floral differences between the southern and northern populations and this makes formal recognition of subspecies impossible.

Populations of *Moraea elliotii* with the leaf inserted high on the stem can be confused with *M. natalensis*, but the latter is a more slender plant usually with smaller flowers, and the leaf is inserted higher on the stem at the base of the crowded branches.

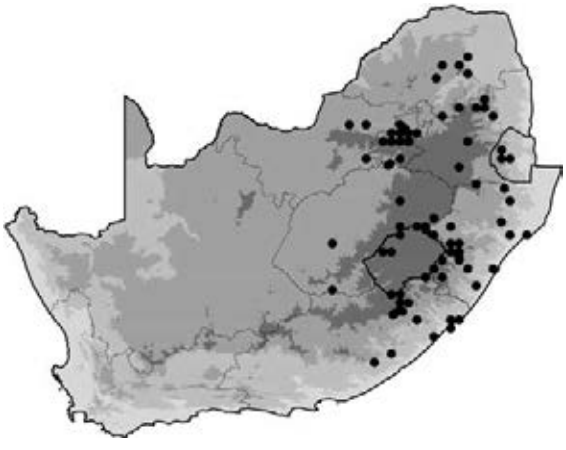
99. **Moraea stricta** *Baker* in Vierteljahrsschrift der Naturforschenden Gesellschaft Zürich 49: 178 (1904a); Goldblatt: 134 1986a). Type: South Africa, [Limpopo], Shilouvane, *Junod 563* (Z, holo.; K, LD, iso.).

Moraea tellinii Chiov.: 138 (1911). Type: Ethiopia, Semien, Debarek, *Chiovenda 3007* [F, lecto., designated by Goldblatt: 262 (1977a)].

Moraea mossii N.E.Br.: 347 (1929b). Type: South Africa, [Gauteng], Johannesburg, *Moss 15805* (K, holo.; PRE, iso.).

Moraea parva N.E.Br.: 347 (1929b). Type: South Africa, [Limpopo], Woodbush, *Moss 15564* (K, holo.).

Moraea trita N.E.Br.: 345 (1929b). Type: South Africa, [Mpumalanga], Lydenburg, *Wilms 1419* (K, holo.; P, PRE, iso.).



Moraea trita var. *foliata* N.E.Br.: 347 (1929b). Type: several specimens cited, no lectotype designated.

Moraea curtisiae R.C.Foster: 46 (1939). Type: Kenya, near Noyrosera, 40 miles [64 km] SE of Narok, *Curtis 676* (GH, holo.).

Plants mostly 150–250 mm high, excluding leaf. *Corm* 10–30 mm diam.; tunics of medium to coarse, dark brown fibres, often bearing cormlets at base. *Stem* usually with 2 or 3 branches, these held close to main axis on short stalks, and with sessile rhipidia at upper nodes, sheathing leaves 30–60 mm long, dry, papery, brown; apices often lacerated. *Foliage leaf* solitary, usually absent, dry and broken, or emergent at flowering, basal, ultimately up to 600 mm long or longer, terete, strongly ribbed, ± 1.5 mm diam., becoming dry and broken before flowering. *Rhipidial spathes* dry, papery, rarely green near base, apices speckled darker brown, sometimes lacerate, attenuate; inner 30–40 mm long; outer slightly smaller or ± as long. *Flowers* fugaceous, pale lilac to blue-mauve, outer tepal limbs with yellow to orange nectar guides at bases edged purple or violet; outer tepals obovate to lanceolate, ± 20 × 4–7 mm, claws ± as long as limbs, ascending, narrow; inner tepal ± usually suberect, ± 15–18 × 2–4 mm, linear-lanceolate. *Stamens* united basally, filaments ± 3.5 mm long; anthers 5 mm long, yellow (?or white). *Ovary* obovoid, 6–8 mm long; style branches 7–8 mm long, appressed to outer tepal claws, crests lanceolate, suberect, ± 3 mm long. *Capsules* ± club-shaped, ± 10 mm long. *Seeds* angular, yellow-brown. *Chromosome number*: $2n$ = 24, 36, 48, 60. *Flowering time* (in southern Africa): (July–)September to November.

Distribution and ecology: the most widespread species of *Moraea*, extending in South Africa from near Stutterheim in Eastern Cape through KwaZulu-Natal, Gauteng, Mpumalanga and Limpopo into tropical Africa as far north as Ethiopia; flowering at the end of the dry season in dry grassland, often in rocky sites on thin soils.

Diagnosis: *Moraea stricta* is recognised by the combination of a dry (or absent) foliage leaf at flowering, a fairly short stem up to 250 mm high, and small, pale blue-mauve to lilac flowers. Only the outer tepals bear nectar guides and the style branches are relatively well developed and bear short, erect crests ± 3 mm long. The foliage leaf, also distinctive, is emergent at or soon after flowering, and has a terete, prominently ribbed blade with a thickened apex. Ultimately the leaf may be up to 600 mm long or longer, then trailing through low, grassy vegetation. At the end of the growing season the leaf turns dry and brown and the flowering stem to which it is attached begins to elongate in preparation for flowering the following spring. Flowering at the end

Distribution of ***Moraea stricta***.

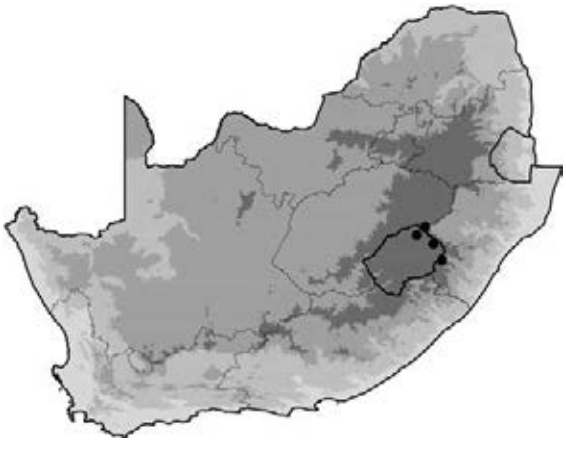
of the dry season, the rhipidial spathes and sheathing leaves are, like the foliage leaf, usually dry and brown.

Moraea stricta is one of relatively few polyploid species. Tetraploid, hexaploid and octoploid populations, $2n$ = 24, 36 and 48, have been recorded in southern Africa and a population from Malawi is decaploid, $2n$ = 60.

100. **Moraea alpina** *Goldblatt* in Annals of the Missouri Botanical Garden 60: 225 (1973); Goldblatt: 136 (1986a). Type: South Africa, [KwaZulu-Natal], Mont-aux-Sources, *Galpin 10361* (PRE, holo.).

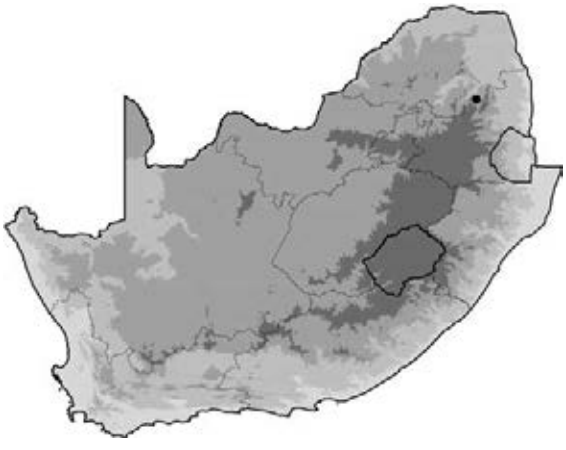
Plants 50–120 mm high. *Corm* 7–10 mm diam.; tunics of fine, light brown fibres. *Stem* few-branched or simple; contracted, sheathing leaves green or becoming dry and brown. *Foliage leaf* absent or emergent at flowering, attached to corm not flowering stem, when fully developed slender, terete, 0.5 mm diam. *Rhipidial spathes* usually green with translucent margins, attenuate, inner ± 25 mm long, outer ± $^2/_3$ as long. *Flowers* fugaceous, dark blue to violet, outer tepal limbs with yellow nectar guides at bases, claws ascending, limbs reflexed to ± 35°; outer tepals ± 12–15 × 3–4 mm; inner tepals shorter and narrower than outer. *Filaments* ± 6 mm long, united in lower ± 1.5 mm; anthers ± 3 mm long, yellow. *Ovary* obovoid, ± 4 mm long; style branches ± 6 mm long, style crests ± 1.5 mm long. *Capsules* ± obovoid to subglobose, ± 5 mm long. *Seeds* angular. *Chromosome number* $2n$ = 12. *Flowering time*: December and January.

Distribution and ecology: a high elevation species, occurring on the upper slopes and summit plateau of the Drakensberg in KwaZulu-Natal, South Africa, and Lesotho; in mixed grassland.



Diagnosis: most remarkable for its small size, *Moraea alpina* stands no more than 120 mm high and is distinguished by the solitary, terete basal leaf, which is absent or emergent from a separate shoot at flowering, as in *M. stricta*. That species blooms early in the season before the new leaf has emerged, and the leaf attached to the flowering stem is dry or absent. *Moraea alpina* has deep blue to violet flowers somewhat larger than those of *M. stricta* and ± globose capsules ± 5 mm long, whereas capsules of *M. stricta* are club-shaped and up to 10 mm long.

101. **Moraea thomsonii** *Baker*, Handbook of the Irideae: 57 (1892); Goldblatt: 137 (1986a). Type: Tanzania, 'plateau north of Lake Nyassa', Oct. 1880, *Thomson s.n.* (K, holo.).



Plants mostly 150–300 mm high, excluding leaf. *Corm* 10–20 mm diam.; tunics of medium to coarse, dark brown fibres. *Stem* usually with 3 to 6 branches held close to main axis on short stalks or ± sessile, sheathing leaves 30–60 mm long, dry, papery, brown, often lacerated. *Foliage leaf* solitary, usually absent, dry and broken, or emergent at flowering, basal, ultimately up to 500 mm long or longer, terete, ribbed, ± 1.5 mm diam., becoming dry and broken before flowering. *Rhipidial spathes* dry, papery, rarely green near base, apices speckled darker brown, sometimes lacerate, attenuate; inner 25–40 mm long; outer ± $^2/_3$ as long. *Flowers* fugaceous, pale blue-mauve, limbs of all tepals with yellow to orange nectar guides at bases; outer tepals obovate to lanceolate, 20–24 × 5–8 mm, claws slightly shorter than limbs, ascending, narrow; inner tepals 16–18 × ± 7 mm, lanceolate. *Filaments* 3–4 mm long united in lower $^1/_3$; anthers ± 5 mm long, white or yellow. *Ovary* narrowly ellipsoid, ± 4.5 mm long; style branches 7–8 mm long, crests vestigial, shorter than stigma lobes. *Capsules* ± club-shaped, ± 10 mm long *Seeds* angular. *Chromosome number* $2n$ = 12. *Flowering time*: August to September (to November in tropical Africa).

Distribution and ecology: recorded only once in southern Africa, on Mt Sheba in Mpumalanga, South Africa, otherwise occurring in eastern Zimbabwe, adjacent Mozambique, Malawi and southern Tanzania; in dry grassland, blooming early in the season, usually before the first rains.

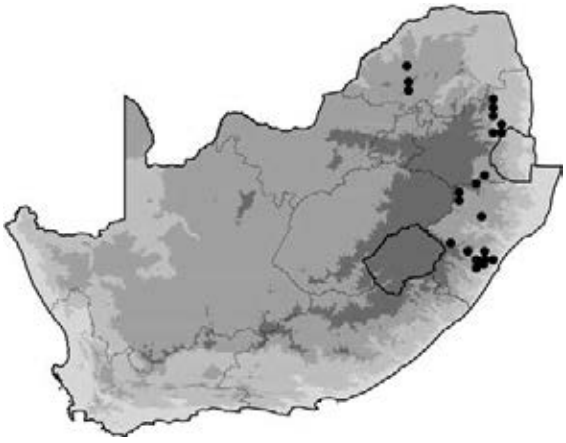
Diagnosis: virtually identical to the relatively common *Moraea stricta* in vegetative features and life history,

Distribution of ***Moraea alpina***.

Distribution of ***Moraea thomsonii***.

M. thomsonii is distinguished only by the flowers. The blue-mauve tepals have nectar guides on both the outer and inner tepal limbs and the inner tepals, ± 7 mm wide, are broader than in *M. stricta*. The style branches are poorly developed and have vestigial crests shorter than the stigma lobes. In *M. stricta* the style crests are 3–4 mm long and held erect above the nectar guides and the inner tepals are only 3–4 mm wide. As in *M. stricta*, the leaf is terete, usually dry and broken at flowering time and the sheathing leaves and spathes are more-or-less dry.

102. **Moraea natalensis** *Baker*, Handbook of the Irideae: 56 (1892); Goldblatt: 221 (1973) & 130 (1986a). Type: South Africa, [KwaZulu-Natal], without precise locality, *Sanderson 253* (K, lecto., designated by Goldblatt: 221 (1973); S; isolecto.).

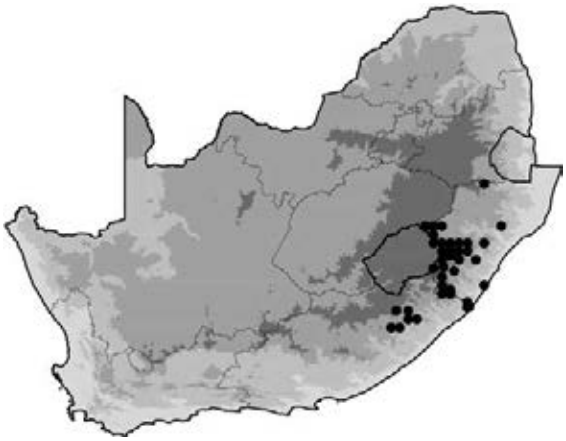


Moraea erici-rosenii R.E.Fr.: 234 (1916). Type: Zambia, Kalambo, *Fries 1345* (UPS, holo.; Z, iso.).

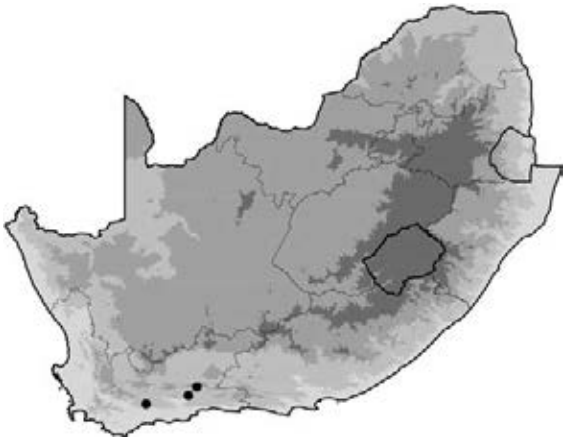
Moraea parviflora N.E.Br.: 346 (1929b). Type: South Africa, [Limpopo], Nylstroom, Tomson's Vlei, *Pole-Evans 19668* (K, holo.; PRE, iso.).

Plants 150–450 mm high, including leaf. *Corm* globose, 12–15 mm diam.; tunics of dark brown to black fibres. *Stem* erect or inclined, lowermost internode elongate with foliage leaf inserted well above ground, upper internodes much shorter, flexuous, few-branched, rarely simple, sheathing leaves green to dry, light brown, 25 mm long. *Foliage leaf* solitary, inserted well above ground, usually shortly exceeding stem, up to 200 mm long, narrowly channelled or terete. *Rhipidial spathes* green or becoming brown and dry above, attenuate, apices becoming lacerated, inner 25–35 mm long, outer ± 10 mm shorter. *Flowers* fugaceous, blue-mauve to violet, outer tepal limbs with yellow nectar guides edged dark mauve at bases, limbs reflexed to ± 35°; outer tepals 15–20 × ± 10 mm, claws ± $^1/_3$–$^1/_2$ as long as limbs; inner tepals linear-lanceolate, up to 15 × 4 mm. *Filaments* 4–5 mm long, united in lower 2–3 mm; anthers 4–5 mm long, yellow. *Ovary* ± ovoid, ± 4 mm long; style branches 5–6 mm long, crests ± 6 mm long. *Capsules* ovoid to club-shaped, 5–10 mm long. *Seeds* angled. *Chromosome number* 2*n* = 12. *Flowering time*: mostly November to January.

Distribution and ecology: extending in South Africa from coastal KwaZulu-Natal to higher elevations in Mpumalanga and Limpopo, also in Zambia and Zimbabwe; in open grassland, often in stony sites.



Diagnosis: with moderate-sized, blue-mauve to violet flowers, only the outer tepals with nectar guides, and well-developed style branches and crests, *Moraea natalensis* has unexceptional flowers for subg. *Polyanthes* but stands out in having a solitary foliage leaf inserted well above the ground on a stem with a long basal internode. The leaf is green at flowering and narrowly channelled, sometimes with the margins tightly inrolled and thus apparently terete. The few to several branches are short and somewhat crowded above the axil of the foliage leaf. This distinctive growth form is shared among the eastern southern African species of the subgenus only with *M. inclinata*, a taller plant, usually with darker violet flowers, green rhipidial spathes with the outer only about half as long as the inner, and nearly globose capsules. In *M. natalensis* the rhipidial spathes are often almost dry at flowering with the outer spathe only slightly shorter than the inner, and the capsules are obovoid to club-shaped. The plants from Zambia described as *M. erici-roseni* differ hardly at all from typical *M. natalensis*, but those described as *M. parviflora* from the Nylstroom area of Limpopo and currently included in *M. natalensis* are distinctive in their particularly slender habit and apparently smaller capsules.



Distribution of ***Moraea natalensis***.

103. **Moraea inclinata** *Goldblatt* in Annals of the Missouri Botanical Garden 60: 222 (1973): Goldblatt: 132 (1986a). Type: South Africa, [KwaZulu-Natal], Cathkin Park, *Galpin 11847* (BOL, holo.; PRE, iso.).

Plants 400–900 mm high, including leaf. *Corm* 10–15 mm diam.; tunics of brown fibres sometimes extending upwards in a collar around base. *Stem* slender, smooth or rarely woolly, usually inclined, with long basal internode and leaf inserted just below rhipidia; with up to 4 short branches, rarely simple, sheathing leaves 12–20 mm long, becoming dry and light brown distally. *Foliage leaf* solitary, inserted well above ground, channelled, mostly 150–400 mm long, up to 3 mm wide, sometimes seemingly terete with margins closely inrolled. *Rhipidial spathes* becoming dry and speckled brown distally; inner 34–40 mm long, outer ± $^1/_2$ as long. *Flowers* fugaceous, blue to violet, outer tepal limbs with yellow nectar guides at bases, claws ascending, limbs reflexed ± 45°; outer tepals 25–30 × 10 mm; inner tepals 20–25 × ± 6 mm. *Filaments* ± 5 mm long, united in lower $^1/_3$; anthers ± 7 mm long. *Ovary* ovoid, 4–5 mm long, style branches ± 6 mm long, up to 3 mm wide, crests 4–5 mm long. *Capsules* ± globose, 5–6 mm diam. *Seeds* angular. *Chromosome number* 2*n* = 12, 22. *Flowering time*: mostly November to February.

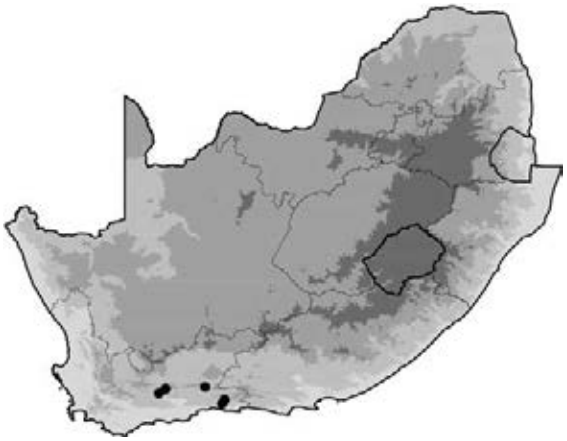
Distribution of ***Moraea inclinata***.

Distribution of ***Moraea lazulina***.

Distribution and ecology: extending from the southern Drakensberg near Cala in Eastern Cape, South Africa, northward to KwaZulu-Natal, eastern Free State and Lesotho; mainly montane in grassland, mostly above 1 200 m elevation.

Diagnosis: although confused in the past with *Moraea natalensis*, which has a similar habit with the leaf inserted on the stem just below the inflorescence, *M. inclinata* is taller and more robust, sometimes up to 900 mm tall, with the inner rhipidial spathes 34–40 mm long and the outer only about half as long. Other differences include the globose capsules, ± 5 mm in diam., and the larger flowers with outer tepals 25–30 mm long vs. capsules club-shaped, up to 10 mm long, and outer tepals 15–20 mm long in *M. natalensis*.

104. **Moraea lazulina** *Goldblatt & J.C.Manning* in Bothalia 43: 158 (2013). Type: South Africa, Western Cape, Oudtshoorn, Schoemanshoek, Kranskloof, eastern foot of rocky hill, in stony sandstone ground, 8 Oct. 2012, *Goldblatt & Porter 13859* (NBG, holo.; MO, PRE, iso.).



Plants 160–350 mm high. *Corm* ± conical, 12–18 mm at widest diam., with numerous small cormlets round base; tunics of medium-textured, matted, dark grey fibres. *Stem* flexuose, 1- to 5-branched, rarely simple, bearing sheathing leaves 32–38 mm long. *Foliage leaf* solitary, linear, longer than stem, erect to falcate, narrowly channelled, 2–3 mm wide opened flat. *Rhipidial spathes* with brown, attenuate tips, inner 33–45 mm long, outer ± half as long. *Flowers* fugaceous, blue, outer tepal limbs with white nectar guides at bases sometimes edged with dark blue, limbs of both whorls ± half reflexed, inner often more so than outer, unscented; outer tepals ± lanceolate, 22–27 × 8–9 mm, limbs 15–18 mm long, claws 7–8 mm long, inner tepals 17–20 × 5–7 mm. *Filaments* ± 8 mm long, united in lower half; anthers ± 5 mm long, grey-blue; pollen white or pale blue. *Ovary* ± cylindric, 5–6 mm long; style branches ± 7 × 5 mm, crests narrowly wedge-shaped, 7–8 mm long. *Capsules* and *seeds* unknown. *Flowering time*: mid-September to late October; opening ± 15:00, collapsing at dusk.

Distribution and ecology: relatively widespread in the Little Karoo, from near Barrydale and the Rooiberg to De Rust east of Oudtshoorn in Western Cape, South Africa; in rocky sandstone ground, sometimes on limestone slopes near the Cango Caves.

Diagnosis: resembling a second Little Karoo species, *Moraea exiliflora*, also with a solitary, narrowly channelled basal leaf, *M. lazulina* has significantly larger flowers and is typically a taller plant, usually with a moderately branched stem. The flowers are always blue with large, white nectar guides on the outer tepals, 22–27 × 8–9 mm, whereas *Moraea exiliflora* has smaller, pale blue, mauve or white flowers with yellow (or white) nectar guides and outer tepals 14–17 × 4.5–6.0 mm. Other features of *M. lazulina* are likewise larger than in *M. exiliflora*. The shape of the flowers also differs to some extent, the tepal limbs of *M. lazulina* being reflexed more than 45°, the inner sometimes more so than the outer whereas the tepal limbs of *M. exiliflora* are laxly spreading to reflexed up to 30°.

105. **Moraea exiliflora** *Goldblatt* in Annals of Kirstenbosch Botanical Garden 14: 128 (1986a). Type: South Africa, [Western Cape], Swartberg Mtns, Ladismith, path to Towerkop, rock faces in pockets of soil, ± 1 000 m, *Esterhuysen 36122* (BOL, holo.; K, MO, NBG, PRE, S, US, WAG, iso.).

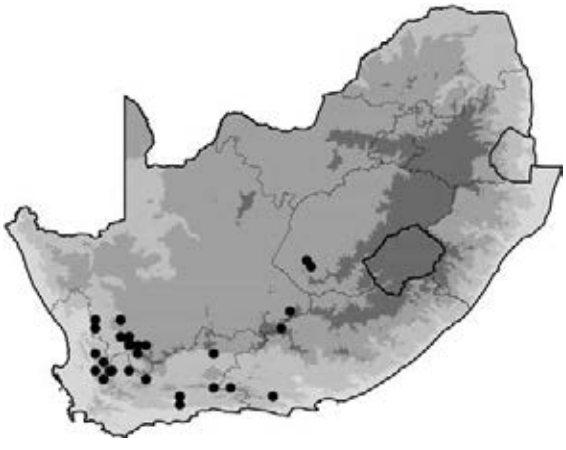
Plants 150–250 mm high. *Corm* ± obconic to subglobose, 5–8 mm diam.; tunics of fine to medium textured, dark brown to blackish fibres. *Stem* usually 3 or 4 internodes long, simple or 1- or 2-branched, branches erect, held close to main axis with rhipidia diverging; sheathing leaves 25–30 mm long, attenuate. *Foliage leaf* solitary, ± basal, slightly longer than stem, narrowly channelled, leaf halves folded together when dry, then seeming terete, ± 2–3 mm wide alive opened flat. *Rhipidial spathes* attenuate with dry brown apices, inner 22–32 mm long, outer ± $^1/_2$ as long. *Flowers* fugaceous, pale

Distribution of ***Moraea exiliflora***.

blue-grey, blue or white, outer tepals with yellow nectar guides at bases; tepals unequal, broadly oblanceolate, subobtuse, claws ascending, limbs spreading to reflexed up to 30º below horizontal, outer 14–17 × 4.5–6.0 mm, claws 5–7 mm long, < $^{1}/_{2}$ as long as limbs, inner 12–14 × ± 2 mm. *Filaments* ± 4.5 mm long, united in lower $^{2}/_{3}$; anthers 3.0–3.5 mm long, pale blue-mauve to white; pollen white. *Ovary* narrowly ovoid, 3–5 mm long, included or barely exserted; style branches ± 5 × 2 mm, crests narrowly wedge-shaped, ± 5 mm long. *Capsules* obovoid, 5–6 mm long. *Seeds* unknown. *Chromosome number* 2*n* = 12. *Flowering time*: late September and October; opening ± 16:00, collapsing soon after nightfall.

Distribution and ecology: extending from Towerkop in the Klein Swartberg and Touwsberg in the Little Karoo of Western Cape, South Africa, eastward to the upper Long Kloof southwest of Uniondale in Eastern Cape; on relatively dry, well-drained, rocky sandstone slopes.

Diagnosis: a slender plant with a solitary, narrow, channelled leaf and small, fugaceous flowers, *Moraea exiliflora* is recognised primarily by flower size, the outer tepals 14–17 × ± 4.5 mm and the inner 12–14 × ± 2 mm with the limbs of both whorls spreading to laxly reflexed up to 30º. The rhipidial spathes are proportionately small, the inner 22–32 mm long and, like all members of sect. *Pseudospicatae,* are long-attenuate with brown tips. *Moraea lazulina*, has similarly proportioned but larger flowers with the outer tepals 22–27 × 8–9 mm, the tepal limbs being reflexed more than 45º, the inner sometimes more so than the outer. The species is inconspicuous even when in bloom after 16:00 and may be more common than the present record indicates.



106. **Moraea crispa** *Thunb.*, Dissertatio de *Moraea* no. 13 (1787); Goldblatt: 112 (1986a). *M. undulata* Ker Gawl.: 43 (1827), illegitimate superfluous name for *M. crispa* Thunb. Type: South Africa, [Northern Cape], 'Roggeveld', *Thunberg s.n.* (UPS–THUNB 1214, holo.).

Homeria rogersii L.Bolus: sub t. 306 (1928a). Type: South Africa, [Eastern Cape], Naauwpoort, *Rogers 12078* (BOL, lecto., designated by Goldblatt: 93 (1980a); K, PRE, Z, isolecto.).

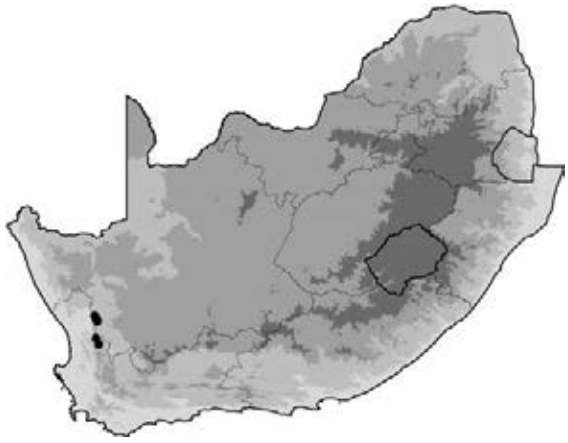
Plants usually small, 80–120(–250) mm high. *Corm* 10–20 mm diam.; tunics of tough, blackish fibres often accumulating in a thick mass, usually with small cormlets around base. *Stem* flexuose, usually with 2 to 4 branches, sheathing leaves attenuate, becoming dry, brown, 15–40 mm long. *Foliage leaf* solitary, basal, up to 250 mm long, either linear and channelled, often slightly twisted, sometimes margins undulate to crisped, or terete, then sometimes hollow. *Rhipidial spathes* becoming dry and straw-coloured above, inner 24–40 mm long, outer $^{2}/_{3}$ as long. *Flowers* fugaceous, blue-mauve (rarely white) with deep yellow (or yellow and blue) nectar guides at bases of limbs of inner and outer tepals, limbs ± spreading, claws ± 3 mm long, suberect, forming a shallow cup around base of filament column; tepals oblanceolate, outer 12–21 × 4–8 mm, inner tepals 11–18 × 5–6 mm. *Filaments* 3.5–8.0 mm long, united in slender, smooth column, free in upper $^{1}/_{4}$–$^{1}/_{2}$; anthers 2–5 mm long, diverging, yellow; pollen yellow. *Ovary* ovoid-globose, 3–6 mm long, usually exserted; style branches narrow, ascending, 2–3 mm long, reaching to ± middle anther level, forked and stigmatic apically, white or yellow; crests lacking. *Capsules* ovoid to ± globose, 6–7 × 3–4 mm. *Seeds* brown, angular. *Chromosome number* 2*n* = 12, 24, 36. *Flowering time*: late September to November, sometimes in December; opening late afternoon, mostly after 15:30, fading in early evening.

Distribution and ecology: with an unusually wide range in South Africa, extending from Free State and the Upper Karoo near Hanover in Eastern Cape, west to Nieuwoudtville and the Western Karoo in Northern Cape and through the interior mountains of Western Cape to the Baviaans Kloof near Humansdorp in the east; in relatively dry, exposed sites in stony ground.

Diagnosis: one of several species of sect. *Pseudospicatae*, *Moraea crispa* has small, pale blue-mauve flowers with small yellow nectar guides at the bases of the limbs of both inner and outer tepals, and short tepal claws

Distribution of ***Moraea crispa***.

forming a cup around the bases of the filaments. The style branches are much reduced, 2–3 mm long, appressed to and reaching only to about the middle of the anthers. The single foliage leaf is unusually variable, usually channelled and somewhat twisted, occasionally with undulate and even crisped margins (the type form from near Calvinia), sometimes ± filiform and tightly rolled with straight margins or somewhat twisted. White-flowered plants from the Baviaanskloof open at ± 18:00 in contrast to ± 16:00 for blue-flowered plants and need further investigation.



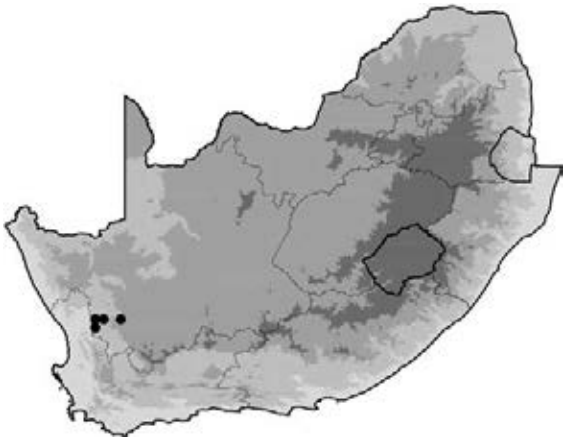
Moraea crispa is unusual in being heteroploid. Populations from the Western Karoo are mostly diploid, 2*n* =12, but tetraploid and hexaploid populations have been recorded from the Cederberg and Cold Bokkeveld and these plants have the longest anthers in the species.

107. **Moraea verecunda** *Goldblatt* in Annals of Kirstenbosch Botanical Garden 14: 116 (1986a). Type: South Africa, [Northern Cape], Nieuwoudtville, rocky outcrop west of town, *Goldblatt 7391* (MO, holo.; K, NBG, PRE, S, iso.).

Plants usually small, 150–200 mm high, occasionally growing in clumps, often with collar of fibres around base. *Corm* 12–15 mm diam.; tunics of blackish fibres often accumulating in a thick layer. *Stem* flexuose, often with 1 or 2 branches from below, rhipidia in upper axils sessile, sheathing leaves attenuate, partly to entirely dry and brown at anthesis, 15–20 mm long. *Foliage leaf* solitary, basal, up to 250 mm long, linear, narrowly channelled, margins tightly inrolled (often evidently terete but with narrow adaxial groove), often trailing distally. *Rhipidial spathes* becoming dry and straw-coloured, inner 15–20 mm long, outer ± $^{2}/_{3}$ as long. *Flowers* fugaceous, violet, tepal limbs of both whorls with small yellow nectar guides at bases, ± spreading, claws ± 1.8 mm long, ascending to form a shallow cup; tepals lanceolate, outer 10–13 × 4–5 mm, inner 9–12 × ± 3 mm. *Filaments* 3–4 mm long, united below in a slender, smooth column, free and diverging near apices; anthers ± 2 mm long before dehiscence, later 1.2–1.5 mm long, suberect, yellow; pollen yellow. *Ovary* narrowly ellipsoid, 4.5–6.0 mm long, exserted; style branches ± 1.5 mm long, appressed to anthers, reaching to ± middle anther level, forked and stigmatic apically, crests lacking. *Capsules* ellipsoid, 10–12 mm, long, beaked in upper 1 mm. *Seeds* brown, ± ovoid, 1.8–2.0 mm diam. *Chromosome number* 2*n* = 12. *Flowering time*: October to late November; flowers opening late afternoon, mostly after 15:30, fading in early evening.

Distribution and ecology: poorly collected and evidently rare, occurring in the immediate area of Nieuwoudtville in Northern Cape, South Africa, but also some 80–100 km to the south in the Biedouw Valley–Wuppertal area of the northern Cederberg in Western Cape; restricted rocky sandstone ground.

Diagnosis: *Moraea verecunda* is recognised by the combination of small, pale blue-violet flowers with subequal



Distribution of ***Moraea verecunda***.

tepals 10–13 mm long, all bearing yellow nectar guides, and short tepal claws ± 1.8 mm long diverging to form a wide, shallow cup around the filament bases. The filaments are united in a smooth column and diverge only near the tips. In general the flowers resembles those of *M. crispa* and its close allies, both in form and in the short style branches that lack crests and are appressed to the subtending anthers but it differs from that species in having sessile lateral rhipidia and unusual capsules, ± spindle-shaped with a short sterile beak, unique in sect. *Pseudospicatae*. The solitary foliage leaf is linear, narrowly channelled and usually more-or-less trailing distally, thus typical of the section.

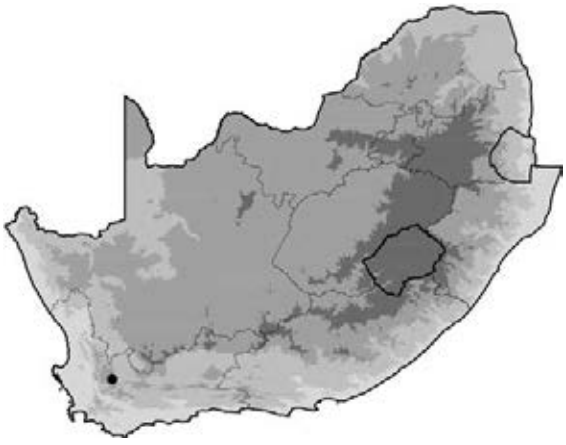
108. **Moraea pseudospicata** *Goldblatt* in Annals of the Missouri Botanical Garden 73: 111 (1986c); Goldblatt: 114 (1986a). Type: South Africa, [Northern Cape], Glenlyon, E of Nieuwoudtville, dry Dwyka Tillite flats, *Snijman 783* (NBG, holo.; K, MO, PRE, S, NBG, WAG, iso.).

Plants slender, 150–400 mm high, enclosed by collar of fibres around base. *Corm* 30–50 mm diam., but live corm ± 10 mm diam.; tunics of tough, blackish fibres. *Stem* simple or with 1 or 2 long branches from near base, bearing several sessile rhipidia at upper nodes, sheathing leaves dry, brown, up to 25 mm long, darker on veins. *Foliage leaf* solitary, basal, slender, apparently terete but narrowly grooved on adaxial surface with margins tightly inrolled, straight or weakly twisted. *Rhipidial spathes* subequal, dry and straw-coloured at anthesis, also darker on veins, 20–25 mm long. *Flowers* fugaceous, blue-mauve, tepal limbs of both whorls with deep yellow nectar guides at bases, claws forming a shallow cup around base of filament column, limbs spreading; tepals lanceolate, outer 15–17 × ± 3.5 mm, claw ± 2 mm, inner tepals ± 1 mm shorter than outer. *Filaments* 4.0–6.5 mm long, united entirely or free in upper $^{2}/_{3}$ but contiguous, forming a slender, smooth cylindric column; anthers 2.0–4.5 mm long, erect and contiguous, yellow; pollen yellow. *Ovary* globose, ± 2 mm long; style dividing ± opposite middle of anthers, branches vestigial, narrow, ascending, 1.0–1.5 mm long, stigmatic

Distribution of ***Moraea pseudospicata***.

apically, initially concealed by anthers, reaching to upper 1/3 or slightly exceeding anther apices; crests lacking. *Capsules* globose, 2–4 mm diam., membranous and semi-transparent, fragmenting irregularly. *Seeds* dark brown, angular, ± 1 mm long. *Chromosome number* 2*n* = 12. *Flowering time*: December to March; flowers opening ± 16:00 and fading in early evening.

Distribution and ecology: restricted to the Bokkeveld Plateau from near Nieuwoudtville south to Lokenberg and inland to the Hantamsberg at Calvinia in Northern Cape, South Africa, but poorly documented and undoubtedly with a wider range; on stony flats and slopes, in karroid bush and renosterveld.



Diagnosis: resembling the more common and widespread *Moraea crispa* in both flower structure and general aspect, *M. pseudospicata* has pale blue-mauve flowers with subequal tepals with short erect claws that form a short, narrow cup including the lower part of the filament column. The anthers are nearly erect and so concealing the narrow and short style branches, whereas in *M. crispa* the anthers and style branches diverge, exposing the style branches. *Moraea pseudospicata* differs also in its taller stature, up to 400 mm high, sessile lateral inflorescences with dry, chaffy sheathing leaves and rhipidial spathes, and in its globose capsules with almost membranous walls, apparently dehiscing irregularly rather than along the locule sutures. Flowering middle to late summer in an area of summer drought, the leaves are usually dry and broken at flowering time.

109. **Moraea pearsonii** *Goldblatt & J.C.Manning* in Bothalia 39: 2 (2009). Type: South Africa, Western Cape, Farm Vrede, dry wash west of junction between Touws River and Ceres–Sutherland roads, 15 Dec. 2007, *Manning 3128* (NBG, holo.; K, MO, iso.).

Plants 200–450 mm high, with collar of fine fibres around base. *Corm* globose, 20–30 mm diam., deeply buried; tunics of coarse black fibres. *Stem* erect, usually with 1 to 4 ascending branches, dull purplish where exposed, bearing (1)4 to 6 sessile lateral flower clusters at upper nodes, sheathing leaves dry, attenuate. *Foliage leaf* solitary, basal, much longer than stem, trailing, partially or entirely dry at flowering, linear, channelled but margins inrolled when dry and appearing terete, 2–3(–4) mm wide, up to 1 m long. *Rhipidial spathes* dry and papery at flowering, pale buff-coloured or lightly flushed with purple, attenuate, inner 20–33 mm long, outer ± as long. *Flowers* fugaceous, pale lilac flushed buff-coloured on reverse; inner and outer tepal limbs with small, oblong, yellow nectar guides at bases, unscented, claws erect, clasping filament bases, 1.0–1.5 mm long, limbs spreading or slightly reflexed; outer tepals oblong-elliptic, ± 13 × 4.5–5.0 mm, inner tepals 13 × 4 mm. *Filaments* free, contiguous at base, 3.5–4.0 mm long, mauve; anthers erect, 4.5–5.0 mm long, yellow, curving inwards distally at anthesis; pollen yellow. *Ovary* ovoid, 2.5–3.0 mm long; style erect, filiform, mauve, ± 2.5 mm long, branches each divided to base into two filiform arms 3.5–4.0 mm long and spreading to ascending between anthers. *Capsules* barrel-shaped, 4–5 × 3–4 mm. *Seeds* angular, ± 1.5 mm diam., red-brown. *Flowering time*: late November to late December; flowers opening at ± 17:30 and wilting at ± 20:30.

Distribution and ecology: a narrow endemic of interior Western Cape, South Africa, known only from the roadside between Karoo Poort and the Farm Hottentotskloof at the southern end of Swartruggens; in sandy alluvium over shale in washes in open shrubland transitional between renosterveld and arid fynbos.

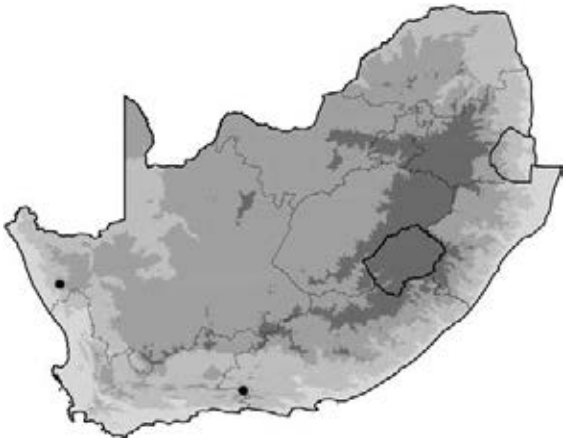
Diagnosis: flowering in the dry season, the solitary, long, trailing leaf up to 1 m long is dry or almost so when flowering begins. The relatively small, blue flowers are distinctive, resembling those of sect. *Hexaglottis* in having subequal tepals with short erect claws, free stamens, and style branches divided to the base into filiform arms extending between the stamens. Plastid DNA data confirm an alliance with *Moraea crispa* and *M. pseudospicata*, both of which have small, blue flowers with partly united filaments and flattened style branches forked at the tips and appressed to the subtending anthers. The leaf of *M. pearsonii* is linear and

Distribution of ***Moraea pearsonii***.

narrowly channelled when fresh, but with the margins tightly inrolled on drying so that the leaf then appears to be terete. The main stem and branches bear sessile rhipidia at the upper nodes, a pattern found in several species of the section, including *M. pseudospicata* and *M. verecunda*, both Western Karoo endemics.

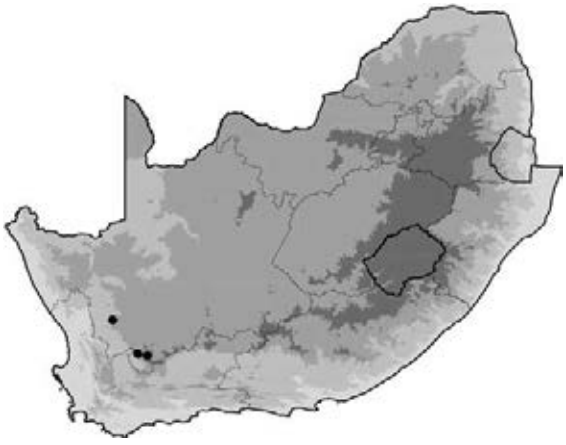
110. **Moraea monticola** *Goldblatt* in Novon 8: 374 (1998), as a new name for *Roggeveldia montana* Goldblatt: 211 (1992) [not *M. montana* Schltr. (1900)]. Type: South Africa, [Northern Cape], Namaqualand, Kamiesberg near Leliefontein, *Goldblatt 6696* (NBG, holo.; K, MO, PRE, S, iso.).

Plants 100–150 mm high. *Corm* globose, 10–15 mm diam.; tunics of dark brown, coarse, wiry fibres. *Stem* ± flexuose, usually few-branched from upper nodes, sheathing leaves 25–35 mm long, dry, pale below with dark attenuate apices. *Foliage leaf* solitary, basal, terete, ± falcate to trailing distally, longer than stem, ± 1 mm diam. *Rhipidial spathes* initially green, drying and brown from apex, inner 20–25 mm long, outer ± ½ as long. *Flowers* fugaceous, blue or white, all tepal limbs spreading to slightly reflexed, with yellow nectar guides at bases; tepals subequal, outer ± 15 × 6 mm, inner 13–14 × ± 4, claws ± 1 mm long, suberect, enclosing bases of filaments. *Stamens* free, filaments ± 3.5 mm long, diverging; anthers ± 6 mm long, straight in bud, becoming incurved after anthesis, yellow. *Ovary* ovoid-elliptic, ± 3.5 mm long; style branches undivided, filiform, extending between bases of anthers, ± 3.5 mm long. *Capsules* ± broadly elliptic-ovoid, ± 9 mm long. *Seeds* angular. *Chromosome number* 2*n* = 24. *Flowering time*: October and November; flowers opening ± 16:00 and wilting at dusk, ± 19:30.



Distribution and ecology: known from two widely separated populations in South Africa, one in the Kamiesberg, Northern Cape, and the other near Willowmore at the foot of the Great Swartberg in Eastern Cape.

Diagnosis: one of three species of subg. *Polyanthes* with filiform, undivided style branches extending between the anthers, *Moraea monticola* is distinguished by the single, falcate to trailing foliage leaf with a terete blade. Related *M. marginata* has a broad, channelled leaf with thickened margins and slightly smaller flowers, the tepals 9–13 mm long vs. 13–15 in *M. monticola*.

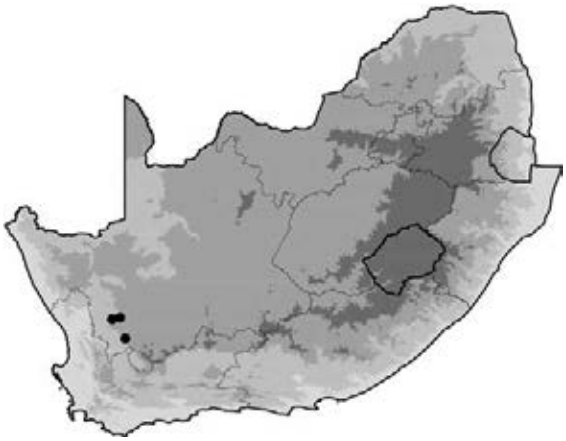


111. **Moraea marginata** *J.C.Manning & Goldblatt* in Bothalia 36: 141 (2006). Type: South Africa, Northern Cape, Sutherland, 200 m along Bo-Visrivier road south of town, Farm Tweefontein, stony flats in open karroid scrub, 15 Nov. 2005, *Manning 2997* (NBG, holo.; K, MO, iso.).

Plants 100–150 mm high. *Corm* globose, 15–20 mm diam.; tunics of coarse black fibres. *Stem* usually 1- to 4-branched at upper nodes, dull purplish where exposed, with 3 or 4 sheathing leaves ± dry and papery at flowering, imbricate, attenuate. *Foliage leaf* solitary, basal, longer than stem, trailing and slightly twisted and coiled, firm-textured, grey-green, ± dry at flowering, linear, channelled, 20–25 × 5–7 mm, margins conspicuously thickened, cartilaginous. *Rhipidial spathes* becoming dry above, inner 25–30 mm long, outer ± ½ as long. *Flowers* fugaceous, blue-violet, all tepal limbs with small, oblong, yellow nectar guides at bases, unscented; tepals oblanceolate, shortly clawed, claws erect, 1.0–1.5 mm long, clasping base of filaments, limbs spreading or slightly reflexed, inner twisted slightly counter-clockwise distally; outer 10–13 × 3.5–4.0 mm, inner 9–12 × 2.5–3.0 mm. *Stamens* free, filaments contiguous at base, 4–5 mm long, suberect, mauve; anthers erect, 4.5–5.0 mm long, yellow, curving inwards above at anthesis. *Ovary* narrowly ellipsoid, 4 mm long; style branches filiform, 4 mm long, spreading to ascending, emerging between anthers, mauve. *Capsules* barrel-shaped, 6–8 × 5 mm. *Seeds* subglobose or angled by pressure, ± 2 mm diam., reddish brown, testa surface rugulose. *Flowering time*: November; flowers opening ± 16:00 and wilting at ± 20:00.

Distribution and ecology: poorly documented and known from the foot of the Hantamsberg and from two sites at the southern end of the Roggeveld Escarpment near

Distribution of ***Moraea monticola***.



Distribution of ***Moraea marginata***.

Sutherland in Northern Cape, South Africa; in fine alluvium over shale in open, succulent karroid scrub.

Diagnosis: recognised by the combination of stellate, blue-violet flowers with subequal tepals, free stamens and undivided, filiform style branches, *Moraea marginata* also has a solitary, linear, channelled leaf with conspicuous, maroon margins that are very conspicuously thickened when dry. As with related *M. fistulosa* and *M. monticola*, the style branches are filiform, undivided and extend between the stamens. The leaves of *M. marginata* are dry and withered at flowering, and the attractive, blue-violet flowers, 20–25 mm in diam., open in early summer in the late afternoon for just a couple of hours, withering near sunset, a phenology shared with several other species of the *M. crispa* alliance.

112. **Moraea fistulosa** *(Goldblatt) Goldblatt* in Novon 8: 374 (1998). *Roggeveldia fistulosa* Goldblatt: 840 (1979b). Type: South Africa, [Northern Cape], between Calvinia and Middelpos, *Goldblatt 4163* (MO, holo.; K, NBG, iso.).

Plants 300–500 mm high. *Corm* 10–15 mm diam.; tunics of dark brown, wiry fibres. *Stem* few-branched at upper nodes, sheathing leaves 25–35 mm long, dry, pale below, with dark attenuate tips. *Foliage leaf* solitary, terete, hollow, usually straight, ± 3 mm diam., exceeding stem. *Rhipidial spathes* usually becoming dry above, attenuate, dark brown, inner 30–35 mm long, outer ± $^{2}/_{3}$ as long. *Flowers* fugaceous, blue-mauve, all tepals with yellow-orange nectar guides at bases of spreading limbs; tepals subequal, 16–18 mm long, inner slightly smaller than outer, claws ± 2 mm long, ascending. *Stamens* free, filaments ± 4 mm long, suberect; anthers ± 4.5 mm long, straight in bud, becoming incurved after anthesis. *Ovary* ± 3 mm long; style branches filiform, extending between filaments, ± 2.5 mm long. *Capsules* and *seeds* unknown. *Chromosome number* 2*n* = 12. *Flowering time*: December; flowers opening ± 16:30 and wilting at dusk, ± 19:00.

Distribution of ***Moraea fistulosa***.

Distribution and ecology: poorly collected and known only from Calvinia Distinct in the Western Karoo, Northern Cape, South Africa; in rocky flats in red, dolerite-derived clay.

Diagnosis: one of three species of the *Roggeveldia* group of sect. *Pseudospicatae, Moraea fistulosa* has the characteristic blue to violet flowers of the alliance with subequal, ± spreading tepals all bearing yellow nectar guides, free stamens, and filiform style branches extending between the stamens. Of the three species of the group, *M. fistulosa* is recognised by the straight, hollow, terete leaf blade, ± 3 mm in diam. and relatively tall stem, up to 500 mm high. The smaller *M. monticola* also has a terete leaf, but only ± 1 mm in diam., solid internally and slightly smaller flowers, the tepals 13–15 mm long (vs. 16–18 mm in *M. fistulosa*). As in allied species in sect. *Pseudospicatae*, the flowers open in the later afternoon, after 16:00 and fading and collapsing at dusk, usually between 18:00 and 19:00.

Subg. 9. **Grandiflorae**

Subg. **Grandiflorae** *Goldblatt* in Annals of the Missouri Botanical Garden 63: 8 (1976b). Type: *Moraea spathulata* (L.f.) Klatt

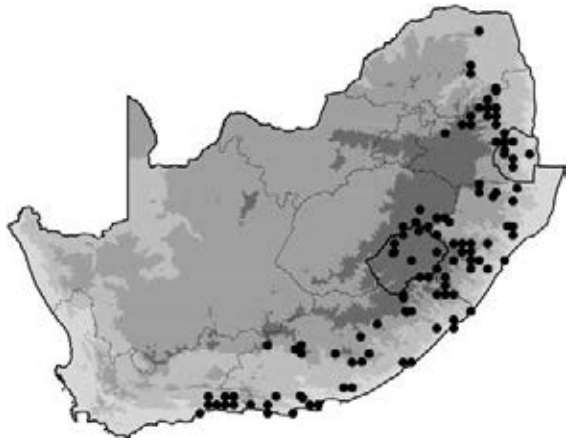
Plants usually unbranched, rarely with a short branch from upper node. *Flowers* yellow (white), blue to violet pale pink; stamens united in lower half; ovary usually 3-angled; style branches well developed with prominent crests. *Capsules* large, exserted. *Seeds* flattened, usually discoid. *Basic chromosome number x* = 6.

113. **Moraea spathulata** *(L.f.) Klatt* in Conspectus Florae Africae 5: 152 (1894); Goldblatt: 250 (1973) & 207 (1986a). *Iris spathulata* L.f.: 99 (1782). *Iris spathacea* Thunb.: 17 (1782b), illegitimate superfluous name for *I. spathulata* L.f. *M. spathacea* Ker Gawl.: sub t. 1103 (1808), illegitimate superfluous name. Type: South Africa, [Eastern Cape], Wolwekraal [Long Kloof near Keurboomsrivier], *Thunberg s.n.* (UPS–THUNB 1172, holo.).

Moraea longispatha Klatt: 560 (1866). Type: South Africa, [Eastern Cape], 'Tambukiland', banks of the Kei River, *Ecklon & Zeyher Irid. 3* (MO, syn.).

Moraea spathulata subsp. *autumnalis* Goldblatt: 254 (1973). Type: South Africa, [KwaZulu-Natal], Nyameni Mouth, Port Edward, *Strey 8619* (PRE, holo.; NH, iso.).

Moraea spathulata subsp. *saxosa* Goldblatt: 254 (1973). Type: South Africa, [Mpumalanga],



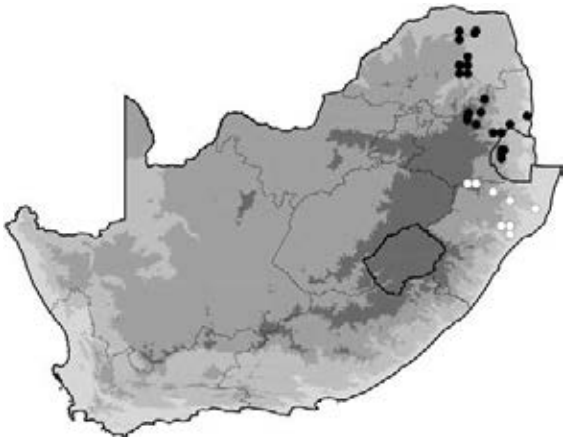
summit, Long Tom Pass, *Goldblatt 612* (BOL, holo.; PRE, iso.).

Moraea spathulata subsp. *transvaalensis* Goldblatt: 253 (1973). Type: South Africa, [Mpumalanga], near Sabie, *Goldblatt 610* (BOL, holo.; MO, iso.).

Plants up to 1 m high, usually in clumps, rarely solitary, evergreen. *Corm* 15–20 mm diam.; tunics brown, fibrous, often accumulating in a loose mass. *Stem* sheathed below by brown, sometimes netted cataphylls, simple, rarely with a sessile lateral rhipidium from penultimate node, sheathed entirely by pale green, ± inflated, sheathing leaves 90–180 mm long, tips usually dry and brown. *Foliage leaf* solitary, much longer than stem, linear, flat to shallowly channelled, 18–24 wide. *Rhipidial spathes* acute to attenuate, inner 100–180 mm long, outer slightly shorter. *Flowers* long-lasting, yellow often with dark veins, outer tepal limbs with deeper yellow to orange nectar guides at bases, reflexed to ± 45°, faintly honey-scented; outer tepals 35–50 × 20–25 mm, claws ± $^1/_3$ as long as limbs; inner tepals 30–60 mm long, suberect or curving inward distally. *Filaments* 8–16 mm long, united in lower half; anthers 7–15 mm long, purple or white. *Ovary* cylindric, 20–30 mm long, cylindric-triangular; style branches 20–30 mm long, crests erect, up to 20 mm long. *Capsules* oblong-cylindric, broadly 3-lobed, mostly 30–45 mm long. *Seeds* flattened, discoid, ± 3 mm diam. *Chromosome number* $2n = 12$. *Flowering time*: mainly November to February, sometimes later; September to November in southern Eastern Cape.

Distribution and ecology: widespread though eastern southern Africa, from George in Western Cape along the coast and interior mountains to Limpopo in South Africa, as well as Lesotho, Eswatini and eastern Zimbabwe; in more-or-less open sites in grassland or low open bush, often in rocky places.

Diagnosis: somewhat variable across its wide range, *Moraea spathulata* typically forms large tufts, thus it is not unusual to see several flowers open at once. Each flowering stem bears a single broad leaf, shallowly channelled to almost flat. The species can be distinguished by its large yellow flowers, the outer tepals up to 50 mm long, tall stems, and clump-forming habit. Plants flower in late winter and spring along the coast but in summer and autumn inland. The species comprises numerous local races, but owing to the small differences between them, it is difficult to define many of them. Four subspecies were described in Goldblatt (1973) but are not currently recognised.



Distribution of ***Moraea spathulata***.

114. **Moraea moggii** *N.E.Br.* in Transactions of the Royal Society of South Africa 17: 346 (1929b); Goldblatt: 237 (1973). Type: South Africa, [Limpopo], probably Haenertsburg (as Struben's Farm), *Mogg s.n.* (PRE, holo.).

Plants 500–700 mm high, always solitary. *Corm* 15–20 mm diam.; tunics of matted, brown fibres. *Stem* unbranched, covered by (2)3 or 4, green sheathing leaves, not usually overlapping, apices dry, brown. *Foliage leaf* linear, channelled, exceeding stem, trailing distally, mostly 11–15 mm wide. *Rhipidial spathes* green, with acute, dry tips, inner 9–16 mm long, inner slightly shorter. *Flowers* long-lived, yellow, creamy yellow or white, outer tepal limbs with bright yellow nectar guides at bases edged with a ring of purple veins; outer tepals broadly lanceolate, obtuse, 40–75 × 30–35 mm, claws ± $^2/_3$ as long as limbs; inner tepals broadly lanceolate with tapering base, obtuse to retuse, up to 40–60 × 20–25 mm long, erect. *Filaments* ± 10 mm long, united in lower $^1/_2$; anthers ± 10 mm long. *Ovary* cylindric, 20–30 mm long; style branches 18–20 mm long, crests 10–20 mm long, erect. *Capsules* cylindric-3-lobed, 30–40 mm long. *Seeds* flattened, disc-like. *Chromosome number* $2n = 12$. *Flowering time*: mainly December to April.

Distribution and ecology: South Africa, extending from the Haenertsburg area of Limpopo along the eastern escarpment of Mpumalanga to northern KwaZulu-Natal; in open grassland.

Diagnosis: distinguished in subg. *Grandiflorae* by its solitary habit, long, narrow, channelled leaf 11–15 mm wide, often with a grey blush, and very large, pale yellow to white flowers. The outer tepals are up to 75 mm long and the inner up to 60 mm long. It is most easily confused with *M. spathulata*, some forms of which are similar, but the two can usually be distinguished by the solitary habit of *M. moggii* compared with typically clump-forming *M. spathulata,* which has broader leaves often flat or very widely channelled and usually darker yellow flowers. Apart from this, *M. moggii* is generally a late flowering species, while *M. spathulata* flowers in spring or summer, except for some southern KwaZulu-Natal populations that also flower late in the season. Two subspecies are recognised, northern subsp. *moggii*, with pale yellow flowers, and southern subsp. *albescens* which typically has white or creamy yellow flowers.

Distribution of ***Moraea moggii*** subsp. ***moggii***, ●; subsp. ***albescens***, ○.

Key to subspecies

1a Flowering in late February to April; flowers pale yellow; Limpopo, Mpumalanga and Eswatini . . . . . 114a. subsp. *moggii*

1b Flowering in December or January, occasionally later; flowers usually white, sometimes creamy yellow; southern Mpumalanga and northern KwaZulu-Natal . . . . . 114b. subsp. *albescens*

114a. subsp. **moggii**

Cataphylls: uppermost rarely < 150 mm long. *Foliage leaf* grey-green, glaucous, 4–10 mm wide, not ribbed when fresh. *Flowers* yellow, veined purple-brown; style branches and crests ± uniformly coloured. *Flowering time*: late February to April.

Distribution and ecology: extending from Haenertsburg in Limpopo through the Mpumalanga Escarpment to central Eswatini; in short, montane grassland.

Geographically separated from subsp. *albescens*, subsp. *moggii* has a narrower, glaucous foliage leaf 4–10 mm wide and not obviously ribbed, particularly well-developed cataphylls, the uppermost usually exceeding 15 mm, and uniformly yellow flowers. Late flowering, subsp. *moggii* blooms from late February to April, later than subsp. *albescens,* which typically flowers from December to February.

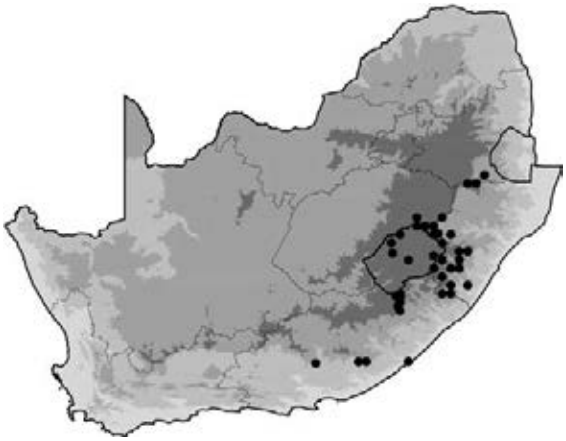
114b. subsp. **albescens** *Goldblatt* in Annals of the Missouri Botanical Garden 60: 239 (1973). Type: South Africa, [Mpumalanga], Wakkerstroom, Tafelkop, *Mauve & Tölken 4524* (PRE, holo.; BOL, iso.).

Cataphylls: uppermost usually < 100 mm long (rarely > 150 mm). *Foliage leaf* 10–15 mm wide, light green to slightly glaucous, veins often prominent even in fresh material. *Flowers* white to creamy yellow, veined green, purple or brown; style branches and crests often suffused with purple. *Flowering time*: December to February, occasionally later.

Distribution and ecology: extending from Wakkerstroom in southern Mpumalanga to Melmoth and Stanger in KwaZulu-Natal; in well-watered montane and coastal grassland.

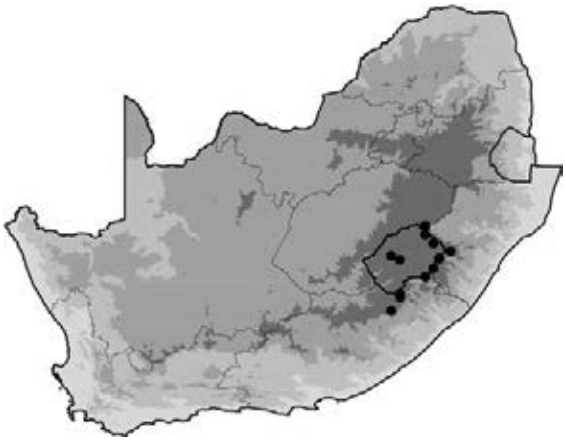
Diagnosis: subsp. *albescens* can only with some difficulty be distinguished from subsp. *moggii* and even subspecies rank may be undeserved. The white to creamy yellow, slightly smaller flowers, shorter cataphylls, and a broader foliage leaf 10–15 mm long, relatively prominently veined separate it from subsp. *moggii*. Associated with these features is flowering time from December to February, with subsp. *moggii* flowering later, mainly March and April, occasionally in February.

115. **Moraea huttonii** *(Baker) Oberm.* in Flowering Plants of Africa 40: t. 1581 (1970a); Goldblatt: 256 (1973). *Dietes huttonii* Baker: t. 6174 (1875). Type: South Africa, [Eastern Cape], without precise locality, *Hutton s.n.* (K, holo.).



Moraea baurii Baker: 50 (1892). Type: South Africa, [Eastern Cape], Baziya, along streams, *Baur 247* (K, holo.).

Moraea rivularis Schltr.: 90 (1907). Type: South Africa, [KwaZulu-Natal], Ifafa, *Rudatis 100* (B, holo.).



Plants 0.8–1.1 m high, growing in clumps. *Corm* ± 15–20 mm diam.; tunics, soft, ± entire or ± fibrous, brown. *Stem* sheathed by brown cataphylls rarely becoming fibrous distally, simple or bearing 1 or 2 short to ± sessile branches held close to main axis; sheathed entirely or almost so by 5 or 6 sheathing leaves, these green with dry, brown tips. *Foliage leaf* solitary, linear, usually exceeding stem, 5–10(–25) mm wide, ± flat to widely or rarely narrowly channelled. *Rhipidial spathes* green, with dry acute tips, inner 80–140 mm long, outer ± $^{3}/_{4}$ as long. *Flowers* long-lived, yellow, outer tepal limbs with large, deep yellow nectar guides at bases and a dark, brown to purple crescent at bases of style crests, sweetly scented; outer tepals oblanceolate, 45–55 × ± 20 mm, claws ± $^{1}/_{3}$ as long as limbs, inner tepals lanceolate 40–45 mm long, erect. *Filaments* ± 13 mm long, united in lower $^{1}/_{3}$–$^{1}/_{2}$; anthers 7–9 mm long. *Ovary* ± 15 mm long, ± cylindric; style branches ± 15 × 8 mm, crests 10–13 mm long. *Capsules* oblong-cylindric, ± 30 mm long. *Seeds* flattened, triangular to discoid. *Chromosome number* $2n = 12$. *Flowering time*: spring to early summer.

Distribution and ecology: widespread in eastern southern Africa, extending from the Boschberg and Winterberg to Kentani in Eastern Cape, South Africa, through Lesotho and KwaZulu-Natal to extreme southern Mpumalanga, also in eastern Free State; in wet places along streams and the edges of marshes.

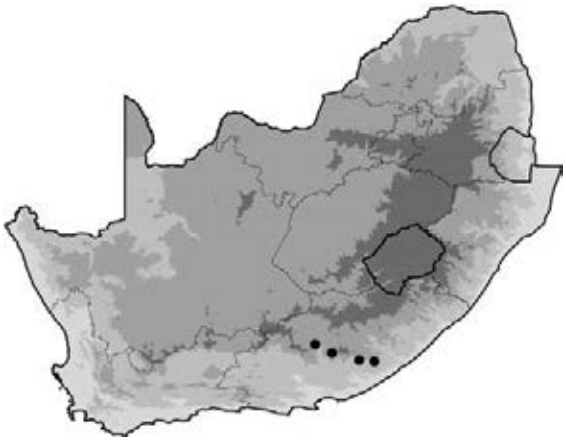
Diagnosis: apart from its unusual habitat, *Moraea huttonii* is distinguished among the several yellow-flowered

Distribution of ***Moraea huttonii***.

Distribution of ***Moraea alticola***.

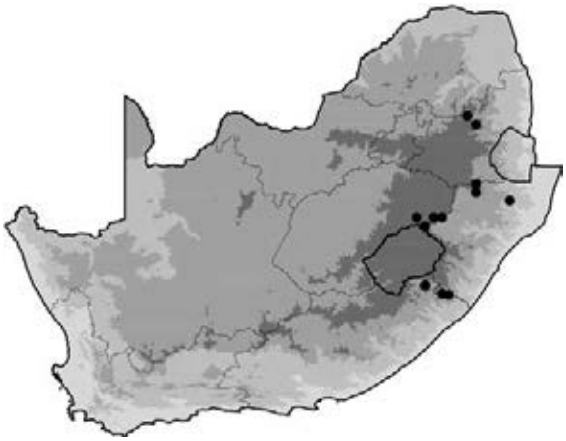
species of the subgenus by the conspicuous purple to brown blotches on the style crests. The flowers are typical of subg. *Grandiflorae* in their large size, yellow colour and well-developed style branches and crests. Plants typically grow in clumps, as does the related *M. spathulata*, but *M. huttonii* usually has narrower leaves mostly 4–10 mm wide (rarely to 25 mm) and usually deeply channelled. Unlike most species of the subgenus, stems of *M. huttonii* are occasionally branched from the upper nodes.

116. **Moraea alticola** *Goldblatt* in Annals of the Missouri Botanical Garden 60: 255 (1973); Goldblatt: 210 (1986a). Type: South Africa, [KwaZulu-Natal], Drakensberg, Mont-aux-Sources, *Schweickerdt s.n.* (PRE [28588], holo.; NH, iso.).



Plants up to 1 m high, forming clumps, evergreen. *Corm* 15–20 mm diam.; tunics of coarse, brown fibres. *Stem* sheathed by brown cataphylls, uppermost forming a pale, well-developed fibrous network, simple or with 1 or 2 short branches or sessile rhipidia at upper nodes, enclosed by 3 to 5 overlapping sheathing leaves 140–180 mm long, green with dry, light brown tips. *Foliage leaf* exceeding stem, flat or shallowly channelled, 14–25 mm wide, erect below, trailing distally, margin often thickened and hyaline. *Rhipidial spathes* green, usually with dry, brown apices, inner 120–150 mm long, outer ± equal or slightly shorter. *Flower* long-lived, pale, watery yellow, outer tepal limbs with small darker yellow nectar guides at bases, reflexed to ± 40°; outer tepals 50–80 × 25–40 mm, claws 20–30 mm long, ± erect, inner tepals 50–70 mm long, ± erect. *Filaments* ± 20 mm long, united in lower half, anthers ± 15 mm long, pale yellow; pollen white. *Ovary* cylindric, 20–30 mm long; style branches 18–20 mm long, crests ± 15 mm long. *Capsules* ± cylindric-3-lobed, 30–45 mm long. *Chromosome number* 2*n* = 12. *Flowering time*: mainly December to February, occasionally from October to March.

Distribution and ecology: restricted to the plateau and upper slopes of the Drakensberg in KwaZulu-Natal and Eastern Cape, South Africa, and Lesotho; in rocky grassland.



Diagnosis: a clump-forming species, *Moraea alticola* is distinguished by its habit and broad, more-or-less plane foliage leaf 14–15 mm wide, both features shared with *M. spathulata*. Despite its occurrence in an alpine area, at high elevations in the Drakensberg, it is easily the largest, most robust species in the genus. Although size alone makes *M. alticola* easy to recognise it is also distinctive in its uppermost cataphyll, which forms a well developed, pale, basket-like network well above the ground. Similar net-like cataphylls are found in some other species of subg. *Grandiflorae* but never as well developed. The pale, watery yellow flowers have rather narrow nectar guides on the outer tepals, unlike the large, yellow to orange nectar guides of most of the many forms of *M. spathulata*.

117. **Moraea reticulata** *Goldblatt* in Annals of the Missouri Botanical Garden 60: 249 (1973); Goldblatt: 212 (1986a). Type: South Africa, [Eastern Cape], Katberg Pass, Mar. 1972, *Goldblatt 682* (BOL, holo.; MO, PRE, iso.).

Plants 450–700 mm high, solitary, rarely in small clumps, possibly evergreen. *Corm* up to 20 mm diam.; tunics of medium-textured fibres. *Stem* sheathed below by pale fibrous cataphyll up to 200 mm long forming a basket-like network, unbranched (rarely with a sessile lateral rhipidium), covered by 3 or 4 overlapping sheathing leaves, 120–150 mm long, green or becoming dry distally. *Foliage leaf* solitary, linear, channelled to ± flat, much exceeding stem, 12–15 mm wide, suberect, later trailing distally. *Rhipidial spathes* green with dry brown tips, inner 120–150 mm long, outer slightly shorter. *Flowers* long-lived, bright yellow, outer tepal limbs with large, orange nectar guides at bases, reflexed to ± 45°; outer tepals 65–70 × 25 mm; inner tepals 50–60 × 15 mm, ± erect. *Filaments* ± 13 mm long, united in lower $^1/_2$; anthers ± 15 mm long, white; pollen white. *Ovary* cylindric, 20–30 mm long; style branches ± 20 mm long, crests 15–18 mm long. *Capsules* cylindric-3-lobed, 30–40 mm long. *Seeds* flattened, discoid. *Flowering time*: March to May.

Distribution of ***Moraea reticulata***.

Distribution of ***Moraea robusta***.

Distribution and ecology: restricted to central Eastern Cape, South Africa, in the Amatole, Hogsback and Elandsberg Mtns, from Bedford to near Cathcart; on seasonally moist grassy slopes.

Diagnosis: allied to the widespread *Moraea spathulata*, the flowers of *M. reticulata* are almost identical in size and general aspect but the plants themselves differ in being almost invariably solitary. *Moraea spathulata* occurs in the same areas as *M. reticulata* but blooms from November to January, whereas *M. reticulata* flowers later, from March to May. The species is also recognised by the distinctive cataphylls, the uppermost of which extends well above the ground as a grey or brown basket-like network around the base of the leaf and stem. Occasionally also seen in *M. spathulata*, the cataphylls are never as prominently developed.

118. **Moraea robusta** *(Goldblatt) Goldblatt* in Annals of the Missouri Botanical Garden 69: 368 (1982); Goldblatt: 214 (1986a). *M. galpinii* subsp. *robusta* Goldblatt: 248 (1973). Type: South Africa, [KwaZulu-Natal], Utrecht, Naauwhoek, *Devenish 109* (PRE, holo.).

Plants up to 400 mm high, solitary or in small clumps. *Corm* 10–18 mm diam.; tunics of coarse, brown fibres. *Stem* sheathed below by dark brown to black, fairly rigid vertical fibres often reaching above ground, unbranched, enclosed by 3 to 8 overlapping sheathing leaves 70–100 mm long. *Foliage leaf* solitary, ultimately much exceeding stem and trailing distally, channelled to flat, 4–10 mm wide or with margins tightly inrolled, then narrowly channelled adaxially, and 2.5–3.0 mm diam. (± 5 mm wide when opened flat), much exceeding stem but ultimately trailing distally. *Rhipidial spathes* green with dry brown tips, slightly inflated, inner 90–120 mm long, outer ± $^{2}/_{3}$ as long. *Flowers* lasting 3 days, pale yellow to ± white, outer tepal limbs with yellow nectar guides at bases, laxly spreading, sweetly scented; outer tepals 55–65 × 22–26 mm, limbs up to 40 mm long, acute; inner tepals lanceolate, 50–58 × 12–15 mm long, ± retuse, limbs laxly spreading to half reflexed. *Filaments* 10–15 mm long, united in lower $^{2}/_{3}$; anthers 10–14 mm long, yellow or white. *Ovary* cylindric, 12–16 mm long; style branches ± 15 mm long, crests 7–18 mm long. *Capsules* narrowly ellipsoid, 25–45 × ± 10 mm, tapering and narrowed in upper 4 mm into a beak. *Seeds* angular-prismatic, 2.5–3.0 mm at longest axis, in two rows per locule. Flowering time: August to November, later at higher elevations.

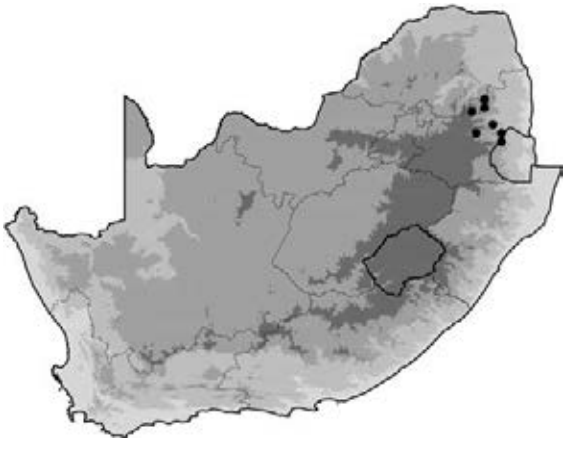
Distribution and ecology: South Africa, extending from Machadodorp to Wakkerstroom in Mpumalanga through eastern Free State to southern KwaZulu-Natal; on rocky mountain slopes up to 2 500 m elevation.

Diagnosis: like its apparent close relative, *Moraea galpinii*, *M. robusta* has distinctive coarsely fibrous corm tunics forming a collar around the stem base but it differs from *M. galpinii* in its larger, white or pale yellow flowers with the limbs of both the inner and outer tepals at length spreading to laxly reflexed, the outer tepals 55–65 mm long vs. ± 40 mm in *M. galpinii*. The leaf is channelled and wider than in *M. galpinii,* 4–10 mm wide but in some populations the margins are closely inrolled. Populations on the slopes of The Sentinel in the northern KwaZulu-Natal Drakensberg have the upper portion dry and broken suggesting emergence before winter, whereas the lower portions are green, evidently having emerged in the spring. The narrowly ellipsoid capsules are up to 45 mm long and up to 10 mm at the widest. The capsules contain numerous angular seeds arranged in two rows per locule. The narrow capsules with a prominent beak and angular seeds stand in marked contrast to the ± ovoid capsules and flattened, discoid seeds of *M. spathulata* and other species of the subgenus for which these characters are known.

119. **Moraea galpinii** *(Baker) N.E.Br.* in Transactions of the Royal Society of South Africa 17: 346 (1929b); Obermeyer: t. 1582 (1970b); Goldblatt: 246 (1973); Goldblatt: 213 (1986a). *M. spathacea* var. *galpinii* Baker: 14 (1896). Type: South Africa, [Mpumalanga], Saddleback Range, *Galpin 459* (K, holo.; BOL, PRE, iso.).

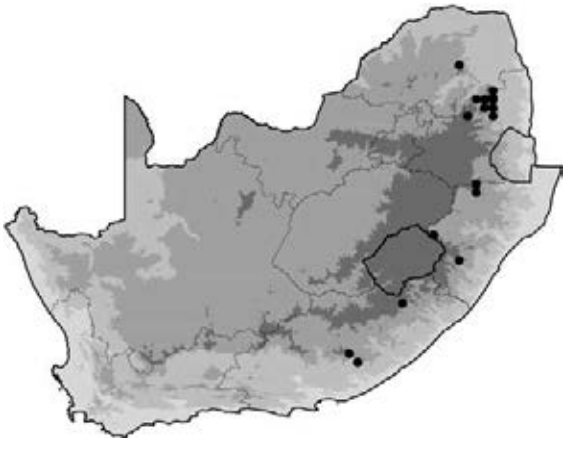
Plant up to 300 mm high, solitary or forming small clumps. *Corm* 15–18 mm diam.; tunics of coarse, dark brown fibres, often accumulating in a dense mass. *Stem* sheathed below by dark brown cataphylls, with age forming a collar of ± black, rigid vertical fibres around base, unbranched, enclosed by (2)3(4), ± overlapping sheathing leaves 50–70 mm long, green with dry, brown tips. *Foliage leaf* absent or emergent at flowering time, ultimately exceeding stem, narrowly channelled with margins tightly folded together, seeming terete but with narrow adaxial groove, ± 2.5–3.5 mm diam. *Rhipidial spathes* green with dry, brown tips, inner 90–110 mm long, outer ± ¾ as long. *Flowers* long-lived, yellow, outer tepal limbs with orange-gold nectar guides at bases, reflexed to ± 40º; outer tepals lanceolate, ± 40– 50 × 18–22 mm, claws suberect, ± ⅔ as long as limbs; inner tepals narrowly lanceolate, erect, ± 35 × 10 mm, obtuse to retuse. *Filaments* up to 8 mm long, united in lower ⅔; anthers 7–9 mm long. *Ovary* cylindric, ± 10 mm long; style branches ± 7 mm long, crests 10–15 mm long. *Capsules* cylindric-3-lobed, up to 25 mm long. *Seeds* unknown. *Chromosome number* 2*n* = 12. *Flowering time*: August to early October.

Distribution and ecology: a narrow endemic of the northern Mpumalanga Drakensberg in the Mt Anderson area, South Africa; on stony slopes, flowering late in the dry season when the single, narrow foliage leaf is just emerging from the ground.



Diagnosis: the rare *M. galpinii* is distinguished by the single, slender foliage leaf, usually barely emergent at flowering time but ultimately exceeding the stem. The blade appears at first to be terete but has a narrow adaxial groove separating the two closely appressed leaf halves. The flowers, fairly typical of subg. *Grandiflorae*, are bright yellow and have outer tepals 40–50 mm long with spreading limbs and erect inner tepals ± 35 mm long. Particularly distinctive is the collar of hard, blackish vertical fibres enclosing the base of the stem and extending a short distance above ground. This feature is shared with *M. robusta,* which is distinguished by paler, larger flowers with erect to spreading inner and outer tepal limbs. Young plants not yet of flowering age have rather soft, unbroken ± membranous cataphylls.

120. **Moraea muddii** *N.E.Br.* in Transactions of the Royal Society of South Africa 27: 346 (1929b); Goldblatt: 239 (1973) & 198 (1986a). Type: South Africa, [Mpumalanga], MacMac Creek, *Mudd s.n.* (K, holo.).



Plants 150–450(–700) mm, solitary. *Corm* ± 15 mm diam.; tunics brown, softly fibrous. *Stem* sheathed by irregularly broken, brown cataphylls, unbranched, enclosed by 2 or 3 ± overlapping sheathing leaves 80–120 mm long, green with dry, brown tips. *Foliage leaf* solitary, linear, channelled, mostly 5–6 mm wide, ultimately exceeding stem. *Rhipidial spathes* green with dry, brown tips, inner 70–120 mm long, outer ± ⅔ as long. *Flowers* long-lived, pale yellow, outer tepal limbs with deeper yellow nectar guides at bases, spreading to half reflexed; outer tepals 35–50 × 12–20 mm, claws 15–20 mm long; inner tepals lanceolate, erect, 35–40 × 5–7 mm. *Filaments* ± 10 mm long, united in lower ⅔; anthers ± 9 mm long, white; pollen white. *Ovary* ± cylindric, ± 15 mm long; style branches ± 13 mm long, crests erect, ± 10 mm long. *Capsules* ovoid-oblong, 18–22 mm long, on elongate pedicels up to 300 mm long. *Seeds* flattened, disc-shaped, with spongy testa, in a single row per locule. *Chromosome number* unknown. *Flowering time*: October to December, sometimes later.

Distribution and ecology: occurring in the mountains of summer-rainfall eastern South Africa, extending from Haenertsburg in Limpopo through Mpumalanga to KwaZulu-Natal, with isolated populations in the Amatole Mtns of Eastern Cape; on grassy slopes and flats.

Diagnosis: one of the smallest of the yellow-flowered species of subg. *Grandiflorae, Moraea muddii* stands 150–600 mm tall and is normally a solitary plant with soft, brown, irregularly broken cataphylls. The pale yellow flowers have tepals up to 50 mm long, thus of moderate size for the subgenus. Similar *M. unibracteata* is also of relatively low stature but has slightly smaller

Distribution of ***Moraea galpinii***.

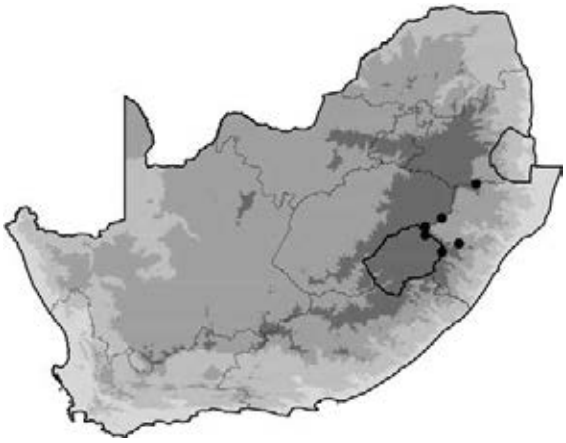
Distribution of ***Moraea muddii***.

flowers and is easily distinguished by its single sheathing leaf inserted in the upper part of the stem, leaving the lower half visible vs. two or three overlapping sheathing leaves in *M. muddii*.

Plants from Eastern Cape flowering somewhat later in the season and currently included in *M. muddii* probably represent a separate subspecies or even species but too little is known about them to permit an informed decision about their status. The leaves stand out in having a V-shaped keel instead of the rounded keel elsewhere in subg. *Grandiflorae*.

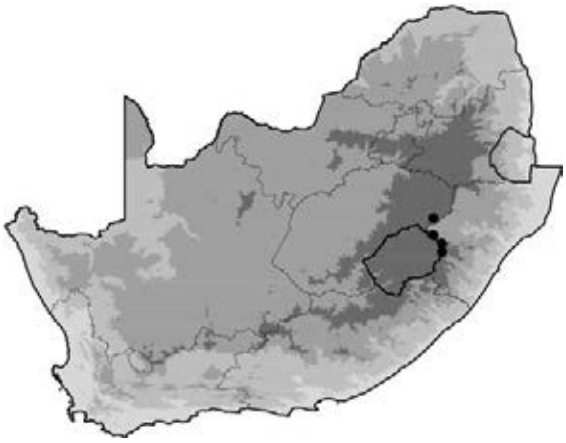
121. **Moraea ardesiaca** *Goldblatt* in Annals of the Missouri Botanical Garden 60: 243 (1973); Goldblatt: 202 (1986a). Type: South Africa, [KwaZulu-Natal], Royal Natal National Park, *Trauseld 84* (PRE, holo.).

Plants 500–700 mm high, usually solitary. *Corm* ± 15 mm diam.; tunics of medium-textured, netted fibres. *Stem* sheathed below by light brown, broken cataphylls, unbranched, partly covered by sheathing leaves 2(3), ± 100 mm long, lower part often exposed. *Foliage leaf* linear, channelled, usually exceeding stem, 5–10(–25) mm wide. *Rhipidial spathes* grey-green with light brown tips, inner 90–140 mm long, outer ± $^{2}/_{3}$ as long. *Flowers* long-lived, slate-blue to pale blue-mauve, outer tepal limbs with linear, pale yellow nectar guides at bases, half reflexed; outer tepals 65–75 × 25–35 mm, limb 45–50 mm long; inner tepals 50–60 mm long. *Filaments* 8–10 mm long, united in lower half; anthers 10–12 mm long, as long or longer than filaments. *Ovary* cylindric, up to 25 mm long; style branches ± 15 mm long, crests 15–20 mm long. *Capsules* cylindric-3-lobed, ± 20 mm long, shortly beaked. *Seeds* unknown. *Flowering time*: November to January.



Distribution and ecology: restricted to the northern Drakensberg of KwaZulu-Natal and adjacent Free State, South Africa, from Van Reenen to Lotheni and with an outlying population in the vicinity of Utrecht; occurring along streams and drainage lines at elevations of 1 800–2 200 m.

Diagnosis: the only blue-flowered member of subg. *Grandiflorae* in southern Africa, *Moraea ardesiaca* is immediately recognised by the large flowers either slate-blue to blue-mauve. Confusion with *M. carnea* is possible but this species has pale pink flowers with darker pink to purple style crests and smaller, narrower tepals 55–60 mm long vs. 65–70 mm in *M. ardesiaca*. *Moraea carnea* also occurs along streams on open slopes at relatively high elevations, usually above 2 300 m, whereas *M. ardesiaca* is generally found at lower elevations along streams and drainage lines.



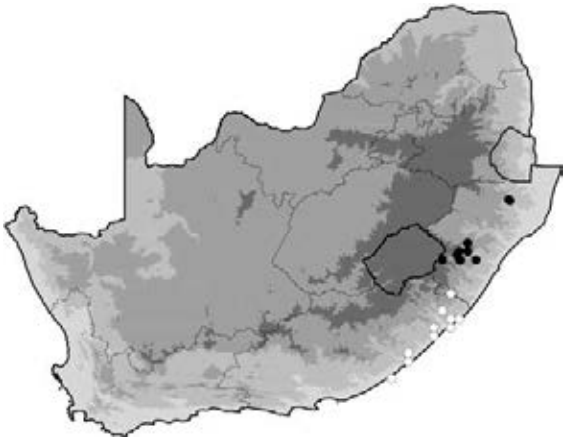
122. **Moraea carnea** *Goldblatt* in Annals of the Missouri Botanical Garden 60: 242 (1973); Goldblatt: 200 (1986a). Type: South Africa, [KwaZulu-Natal], Giants Castle, *Trauseld 481* (PRE, holo.; CPF, NU, iso.).

Plants 400–500 mm high, solitary. *Corm* ± 15 mm diam.; tunics of moderately fine fibres. *Stem* sheathed below by irregularly broken brown cataphylls, unbranched, bearing 3 or 4 overlapping sheathing leaves 40–80 mm long, green with dry acuminate apices. *Foliage leaf* linear, longer than stem, 5–6 mm wide, channelled, erect or bent and trailing distally. *Rhipidial spathes* green with brown attenuate tips, inner 70–100 mm long, outer ± $^{2}/_{3}$ as long. *Flower* long-lived, yellowish pink to creamy pink with dark pink to brown veins, outer tepal limbs with yellow nectar guides at bases edged with dark pink and style crests uniformly deep pink to purple; outer tepals 55–60 × 20–25 mm, claws ± 25 mm long, limbs laxly spreading; inner tepals 45–50 × 10 mm, suberect. *Filaments* 10–12 mm long, united in lower $^{2}/_{3}$, diverging above; anthers ± 10 mm long. *Ovary* ± cylindric, ± 20 mm long; style branches 15–17 mm long, crests up to 15 mm long. *Capsules* cylindric-3-lobed, ± 25 mm long, shortly beaked. *Seeds* unknown. *Flowering time*: mainly November and December.

Distribution and ecology: a narrow endemic of the northern and central KwaZulu-Natal Drakensberg, South Africa, and adjacent Lesotho, recorded from Witsieshoek to Sani Pass; at relatively high elevations, mostly above 2 000 m in grassland and cliffs along streams.

Distribution of ***Moraea ardesiaca***.

Distribution of ***Moraea carnea***.



Diagnosis: among the smallest of the southern Africa species of subg. *Grandiflorae*, *Moraea carnea* stands no more than 500 mm high. It is also the only pink- to creamy pink-flowered species of the subgenus and is also unusual in having darker pink to purple style crests and sometimes darker inner tepals. *Moraea ardesiaca* is a larger plant up to 700 mm tall with larger, slate-blue to blue-mauve flowers. The two species also differ in relative anther length, shorter than the filaments in *M. carnea* but longer than the filaments in *M. ardesiaca*.

123. **Moraea graminicola** *Oberm.* in Flowering Plants of Africa 39: t. 1526 (1968); Goldblatt: 244 (1973); Goldblatt: 203 (1986a). Type: South Africa, [KwaZulu-Natal], Clovelly Farm, Mooi River, *Mauve 4466* (PRE, holo.; BOL, iso.).

Plants 250–600 mm high, solitary. *Corm* up to 15 mm diam.; tunics of medium-textured fibres, sometimes extending upward in a collar around base. *Stem* sheathed below by light brown cataphylls, simple (rarely branched in subsp. *notata*), enclosed by 1 or 2 (subsp. *graminicola*) or 3 (subsp. *notata*), overlapping, green, attenuate sheathing leaves 120–150 mm long. *Foliage leaf* usually shortly exceeding stem at flowering time, linear, channelled, 7–25 mm wide. *Rhipidial spathes* green entirely or with dry brown apices, inner 140–180 mm long, outer ± $^{2}/_{3}$ as long. *Flowers* long-lived, pale yellow to grey conspicuously veined with mauve, especially on crests, these sometimes mauve at base, outer tepal limbs with yellow nectar guides at bases; outer tepals ovate with narrow, tapering claws, 60–75 × ± 30 mm, claws ± $^{2}/_{3}$ as long as limbs, inner tepals lanceolate, 40–45 × ± 15 mm, erect. *Filaments* 8–12 mm long, united in lower half; anthers ± 13 mm long. *Ovary* cylindric, ± 20 mm long; style branches ± 20 mm long, crests erect, 10–15 mm long, erect. *Capsules* cylindric-3-lobed, 25–30 mm long. *Seeds* flattened, discoid. *Chromosome number* 2*n* =12. *Flowering time*: August to November (subsp. *graminicola*), September to December (January) (subsp. *notata*).

Distribution and ecology: occurring at middle elevations from Ngome in northern KwaZulu-Natal to near East London in Eastern Cape, South Africa; in open grassland, flowering early in the season.

Diagnosis: *Moraea graminicola* is recognised by its solitary habit and relatively large flowers with the outer tepals 60–75 mm long. Populations from KwaZulu-Natal are usually only 250–400 mm high and the stem bears a single sheathing leaf but Eastern Cape populations, treated as subsp. *notata*, are usually taller, up to 600 mm high, with two or three sheathing leaves, and the style crests stained with mauve near the bases, thus bicoloured. Subsp. *graminicola* may be confused with *M. unibracteata* which also has a single sheathing leaf and flowers early in the season but in *M. unibracteata* the foliage leaf is 2–10 mm wide, the sheathing leaf is inserted close to the base of the inflorescence, leaving the lower part of the stem visible, and the flowers are smaller than those of subsp. *graminicola*, the lower tepals 30–45 mm long and anthers 7–9 mm long vs. ± 13 mm in *M. graminicola*.

Distribution of ***Moraea graminicola*** subsp. ***graminicola***, ●; subsp. ***notata***, ○.

Key to subspecies

1a Sheathing leaves 1 or 2; style crests uniformly yellow; occurring in KwaZulu-Natal . . . . . 123a. subsp. *graminicola*

1b Sheathing leaves 3; style crests darkly blotched at base; occurring in Eastern Cape. . . . .123b. subsp. *notata*

123a. subsp. **graminicola**

Plants seldom exceeding 450 mm. *Stem* unbranched, bearing 1 or 2 overlapping bract leaves. *Flowers* pale yellow to grey, veined with mauve; style crest sometimes flushed a pale mauve, but not darkly marked at the base. *Flowering time*: August to November.

Distribution and ecology: restricted to central KwaZulu-Natal, from Ngome in the north to Nottingham Road and Underberg in the south.

123b. subsp. **notata** *Goldblatt* in Annals of the Missouri Botanical Garden 60: 245 (1973). Type: South Africa, [Eastern Cape], Transkei, east of Libode, *Codd 10691* (BOL, holo.; PRE, iso.).

Plants 400–600 mm high, more robust than subsp. *graminicola*. *Stem* usually simple, occasionally branched, bearing 3 sheathing leaves. *Flowers* pale yellow to creamy white; style crest marked dark brown to mauve at base. *Flowering time*: September to January.

Distribution and ecology: Eastern Cape, mainly northern parts but extending from Umtata and Port St Johns south to East London.

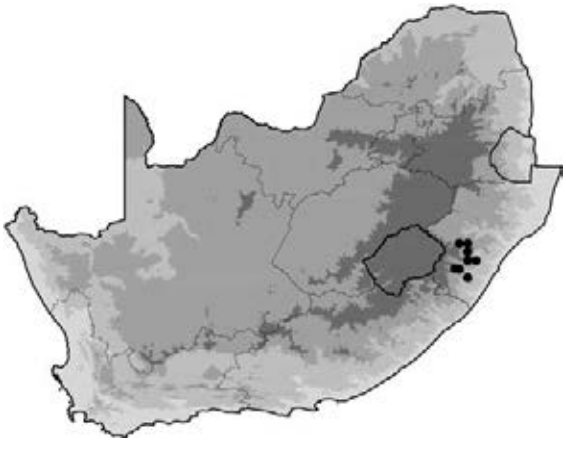
Resembling subsp. *graminicola* in most features, particularly the pale, truncate, submembranous cataphylls and pale yellow, darkly veined tepals, subsp. *notata* usually flowers later in the year, is more robust and has unusual dark markings at the bases of the style crests. More investigation is needed before its taxonomic status is confirmed. There is an unusual break in the range

of *M. graminicola*, with subsp. *graminicola* occurring in northern and central KwaZulu-Natal and subsp. *notata* restricted to Eastern Cape south of Umtata and Port St Johns.

124. **Moraea hiemalis** *Goldblatt* in Annals of the Missouri Botanical Garden 60: 248 (1973); Goldblatt: 204 (1986a). Type: South Africa, [KwaZulu-Natal], Lions River, *Obermeyer s.n.* (PRE [33562], holo.).

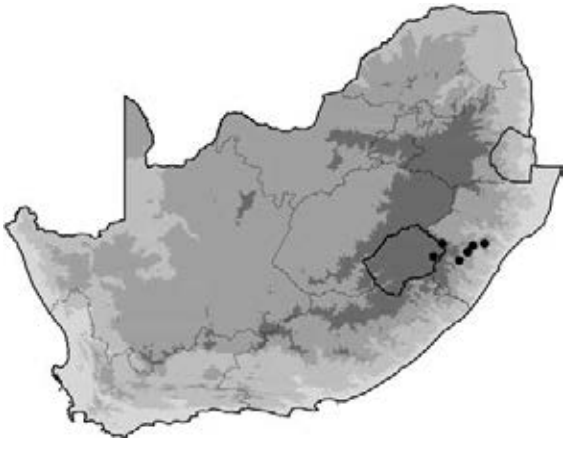
Plants mostly 380–450 mm high, solitary. *Corm* ± 10 mm diam.; tunics not known. *Stem* sheathed below by brittle, entire, or irregularly broken cataphylls ribbed silver and purple below, unbranched, covered by (3)4 or 5 usually overlapping sheathing leaves 12–14 mm long. *Foliage leaf* solitary, exceeding stem, terete with narrow adaxial groove, ± 5 mm diam. *Rhipidial spathes* green with dry, brown tips, inner 80–140 mm long, outer ± as long or slightly shorter. *Flowers* probably long-lived, deep yellow, tepals often ± darkly veined, outer tepal limbs with darker yellow nectar guides at bases; outer tepals 45–50 × ± 24 mm, claws ± $^{2}/_{3}$ as long as limbs; inner tepals ± 40 × 15 mm long, ascending to erect. *Filaments* ± 8 mm long, united in lower $^{2}/_{3}$; anthers ± 10 mm long, yellow. *Ovary* cylindric, ± 15 mm long; style branches ± 13 mm long, crests ± 10 mm long. *Capsules* cylindric-3-lobed, 20–25 mm long. *Chromosome number* unknown. *Flowering time*: July and August.

Distribution and ecology: restricted to central KwaZulu-Natal, South Africa; in dry grassland.



Diagnosis: a particularly distinctive member of the *Moraea spathulata* complex, *M. hiemalis* is unusual in flowering in winter, July and August. It is distinguished by its cylindrical leaf with the margins tightly inrolled, and its solitary habit. The plants are also generally smaller in most features than typical *M. spathulata* and its immediate allies, the outer tepals 45–50 mm long and the inner ± 40 mm long.

125. **Moraea unibracteata** *Goldblatt* in Annals of the Missouri Botanical Garden 60: 241 (1973); Goldblatt: 200 (1986a). Type: South Africa, [KwaZulu-Natal], Nottingham Road, *Galpin 9457* (PRE, holo.; CPF, NU, iso.).



Plants up to 350 mm high, solitary. *Corm* ± 10 mm diam.; tunics of fine, pale fibres. *Stem* sheathed below by brown cataphylls, unbranched, bearing a single, green sheathing leaf inserted in upper part of stem, often overlapping rhipidial spathes, lower part of stem exposed. *Foliage leaf* solitary, shortly exceeding stem, channelled, (2–)4–10 mm wide. *Rhipidial spathes* green, apices dry and brown, inner spathe 60–80 mm long, outer ± $^{3}/_{4}$ as long. *Flowers* ?long-lived, pale yellow to nearly white (sometimes drying pale blue), when dry veined with purple, outer tepal limbs with darker yellow nectar guides at bases, spreading to half reflexed; outer tepals lanceolate, 30–45 mm long, claws suberect, ± $^{2}/_{3}$ as long as limbs; inner tepals 30–40 mm long, narrowly lanceolate, ± erect. *Filaments* ± 8 mm long, united in lower half; anthers 7–9 mm long, yellow. *Ovary* 15–18 mm long; style branches ± 10 mm long, crests 10–13 mm long. *Capsules* and *seeds* unknown. *Chromosome number* unknown. *Flowering time*: October to November.

Distribution and ecology: restricted to the Midlands and lower elevations of the Drakensberg in KwaZulu-Natal, South Africa; in montane grassland.

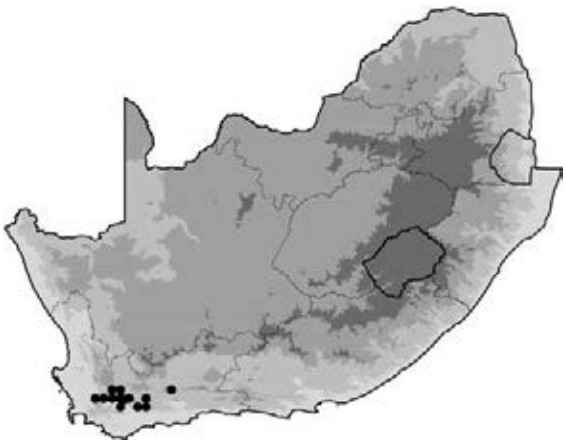
Diagnosis: poorly known, *Moraea unibracteata* is one of the smallest members of subg. *Grandiflorae.* It can always be recognised by the stem bearing a single sheathing leaf, this inserted in the upper half of the stem and usually reaching or overlapping the rhipidial spathes. The pale yellow to almost white flowers are unremarkable in the subgenus, although relatively small, with outer tepals 30–45 mm long and anthers 7–9 mm long. The tepals are reported to have dark veins, especially evident when dry.

Distribution of ***Moraea hiemalis***.

Distribution of ***Moraea unibracteata***.

Subg. 10. **Vieusseuxia**

Subg. **Vieusseuxia** *(D.Delaroche) Baker*, Handbook of the Irideae: 48 (1892). *Vieusseuxia* D.Delaroche: 31 (1766). Type: *V. spiralis* D.Delaroche, lecto., designated by Goldblatt: 8 (1976b) = *Moraea bellendenii* (Sweet) N.E.Br.



Sect. 11. **Integres** *Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 43: 39 (2013). Type: *Moraea thomasiae* Goldblatt

Plants often unbranched. *Foliage leaf* solitary, basal. *Flowers* yellow, inner tepals spathulate, entire; filaments free or barely united at base; style branches united to style only near base.

126. **Moraea thomasiae** *Goldblatt* in Annals of the Missouri Botanical Garden 63: 20 (1976b); Goldblatt: 138 (1986a). Type: South Africa, [Western Cape], Worcester, Karoo Garden, *Goldblatt 2422* (NBG, holo.; BOL, K, MO, PRE, S, iso.).

Plants slender, 150–300 mm high. *Corm* ± 10 mm diam.; tunics of firm, pale to dark brown fibres. *Stem* mostly 3 internodes long, rarely with 1 branch, sheathing leaves green with dry attenuate tips, 35–40 mm long. *Foliage leaf* solitary, ± basal, linear, channelled, 3–6 mm wide, exceeding stem, ± erect or trailing distally. *Rhipidial spathes* green with dry, brown attenuate apices, inner 35–60 mm long, outer ± $^1/_2$ as long. *Flowers* long-lived, pale yellow often with conspicuous dark veins, outer tepal limbs with large deep yellow nectar guides at bases, usually edged dark brown, half reflexed; outer tepals 26–35 mm long, claws narrow, 12–15 mm long; inner tepals narrowly lanceolate, initially erect, limbs later spreading, 18–22 mm long. *Filaments* 4–5 mm long, free almost to base; anthers ± 6 mm long, brown; pollen yellow. *Ovary* narrowly ovoid, 8–11 mm long; style branches 12–15 mm long, crests ± linear, 7–10 mm long. *Capsules* ellipsoid, 12–15 mm long. *Seeds* angular. *Chromosome number* 2*n* = 12. *Flowering time*: August to middle September.

Distribution and ecology: a fairly narrow endemic of Western Cape, South Africa, extending from the foothills of the Brandwag Mtns near Worcester eastward to Robertson and from the Waboomsberg near Koo to Barrydale; typically on cooler and moister south-facing shale and clay slopes.

Distribution of ***Moraea thomasiae***.

Diagnosis: superficially like *Moraea angusta* (subg. *Monocephalae*) in its pale yellow flowers with lanceolate, entire inner tepals, stamens united only near the base, and unbranched stem, *M. thomasiae* otherwise has a single channelled leaf inserted near the stem base and long-lasting flowers. These two features, as well as the chromosome number, 2*n* = 12, accord best with subg. *Vieusseuxia* and molecular phylogenetic studies also place *M. thomasiae* among the species of this subgenus but without close relatives. Most other species of the subg. *Vieusseuxia* have reduced inner tepals, most often with 3-lobed limbs, sometimes a linear cusp, or even lacking. On the basis of the entire inner tepals and yellow flowers, also unusual in the subgenus, *M. thomasiae* is placed in a separate section.

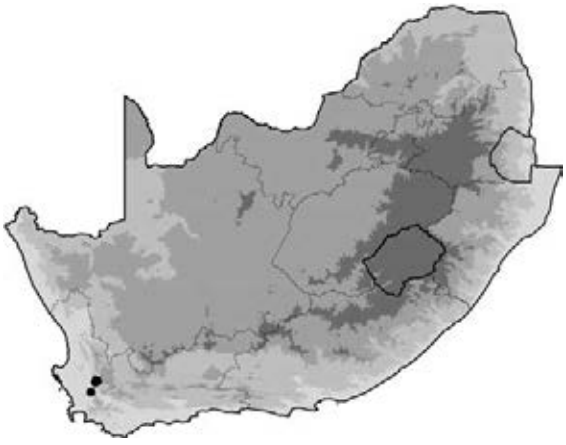
Sect. 12. **Vieusseuxia** *(D.Delaroche) Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 43: 39 (2013). *Vieusseuxia* D.Delaroche: 31 (1766). Type: *Moraea bellendenii* (Sweet) N.E.Br.

Foliage leaf usually solitary (not *M. fergusoniae,* some *M. tripetala* subsp. *violacea*). *Flowers* mostly blue to violet or purple, sometimes pink, orange, maroon, white, rarely yellow; inner tepals often tricuspidate, hair-like and linear, sometimes absent, or entire; filaments usually united in lower half to entirely, barely united at base or rarely free.

127. **Moraea incurva** *G.J.Lewis* in South African Gardening and Country Life 23: 167 (1933a); Goldblatt: 144 (1986a). Type: South Africa, [Western Cape], between Wellington and Tulbagh, *K. Stanford s.n.* (BOL [20185], holo.).

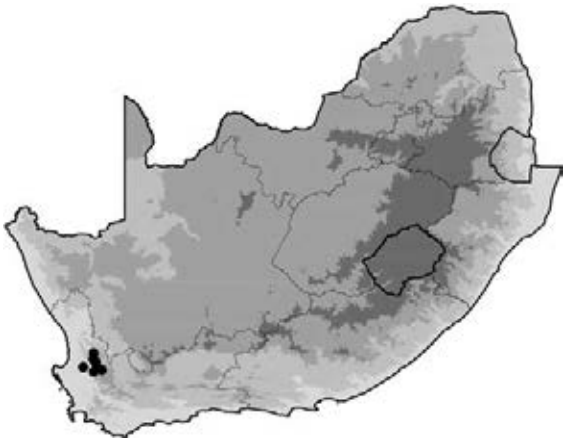
Plants slender, 250–400 mm high, often with fibrous collar around base. *Corm* ± 15 mm diam.; tunics of dark brown fibres. *Stem* usually unbranched, 3 or 4 internodes long, sheathing leaves, green with dry attenuate apices, 40–45 mm long. *Foliage leaf* solitary, basal, linear, narrowly channelled or margins inrolled and sometimes seeming terete, ± 2 mm diam. (± 3.5 mm wide when opened flat), longer than stem and trailing distally.

Rhipidial spathes with dry, attenuate apices; inner 40–70 mm long, outer ± $^1/_2$ as long. *Flower* long-lasting, pale blue-mauve to violet, outer tepal limbs with yellow nectar guides at bases edged dark blue, reflexed ± 45°, curling inward near tips; outer tepals lanceolate, 25–32 × 9–11 mm long, claws ascending, 10–12 mm long, velvety, limb ± 20 mm long, inner tepals either ± lanceolate and entire, attenuate or 3-lobed with rounded lateral lobes and linear central lobe, 18–20 × 4–6 mm, ± erect, curving inward distally. *Filaments* 10–13 mm long, united in a slender, almost smooth or puberulous column, free in upper ± 2 mm; anthers 3–4 mm long, slightly exceeding stigma lobes, displayed above tepal limbs, violet; pollen orange. *Ovary* narrowly ovoid, ± 10 mm long, sometimes included; style branches ± 4 mm long, crests ± 4 mm long, erect. *Capsules* ellipsoid, 15–17 mm long. *Seeds* angular, prismatic. *Flowering time*: October to November, as late as January at higher elevations.



Distribution and ecology: a narrow endemic of the upper Tulbagh Valley and Klein Winterhoek Mtns in Western Cape, South Africa (rare and poorly documented); on rocky slopes in loamy sandstone ground at elevations up to 1 800 m.

Diagnosis: *Moraea incurva* has blue to violet flowers with the inner tepals either 3-lobed with the inner lobe linear and 18–20 mm long, or entire and thus exceptional but not unknown in subg. *Vieusseuxia*. The inner tepal limbs are abruptly curved inward (hence the name *incurva*) on suberect claws. The species otherwise conforms to subg. *Vieusseuxia* in the solitary basal leaf, modest size of the flowers, and in the filaments united in a slender column with only the tips free. The filament column, 10–11 mm long, raises the anthers above the bases of the inner tepal limbs and the orange anthers are thus prominently displayed. The immediate relationships of *M. incurva* are uncertain but molecular studies place it close to *M. unguiculata* and *M. tripetala*. The entire to 3-lobed inner tepals with incurved limbs and long filament column recall *M. barkerae* and the two species may be, on this basis, closely related. A relationship with *M. tripetala* seems less likely in view of the nearly free filaments and reduced inner tepals of that species.



128. **Moraea barkerae** *Goldblatt* in Annals of the Missouri Botanical Garden 63: 757 (1976a); Goldblatt: 144 (1986a). Type: South Africa, [Western Cape], Cederberg, above Algeria Forest Station on trail to Middelberg, 1 400 m, *Goldblatt 3245* (MO, holo.; K, NBG, PRE, S, iso.).

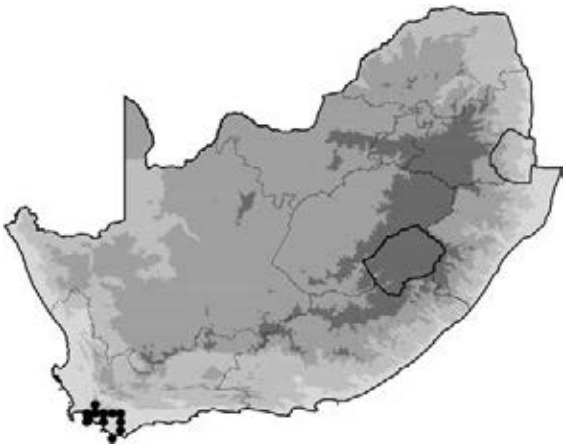
Plants mostly 200–400 mm high, with fibrous collar around base. *Corm* 12–20 mm diam.; tunics of coarse, grey to light brown fibres, often with thickened vertical members. *Stem* usually simple or with 1 branch, 2 or 3(4) internodes long, sheathing leaves (25–)35–60 mm long, with dry, brown attenuate apices. *Foliage leaf* solitary, basal, linear, ± as long as stem or up to 100 mm longer, suberect to falcate, but often trailing distally, narrowly channelled or leaf halves folded together thus blade seeming terete, 1.0–2.5 mm wide opened flat. *Rhipidial spathes* green with dry, dark brown, attenuate apices; inner spathe 33–70 mm long, outer ± half as long. *Flowers* long-lived, opening pale pink fading to almost white, outer tepal limbs with white or pink nectar guides at bases edged at both ends with broad purple margins, spreading to slightly reflexed; outer tepals 24–30 × 8–10 mm, lanceolate-attenuate, claws 6–10 mm long, lightly hairy; inner tepals 18–25 × 4–6 mm, ± erect, apex attenuate entire or obscurely 3-lobed. *Filaments* 10–15 mm long, united in lower $^1/_2$–$^2/_3$ in a smooth column; anthers 5 mm long, apiculate, purple, slightly exceeding stigma lobes; pollen red. *Ovary* ± cylindric, 7–10 mm long, exserted or initially partly included; style branches ± 10 × 2 mm, crests narrowly wedge-shaped to linear, 5–10 mm long. *Capsules* ovoid-ellipsoid, 13–17 mm long. *Seeds* angular, prismatic. *Chromosome number* 2*n* = 12. *Flowering time*: late September to November or early December at higher elevations.

Distribution and ecology: a montane species, occurring at middle to upper elevations in the Cederberg, Cold Bokkeveld Mtns and Piketberg in Western Cape, South Africa; on well-drained, rocky sandstone slopes.

Distribution of ***Moraea incurva***.

Distribution of ***Moraea barkerae***.

Diagnosis: *Moraea barkerae* is unusual in subg. *Vieusseuxia* in the pale pink (sometimes almost white) flower, the outer tepals with white or pink nectar guides with broad purple edges, and the unusually long filaments, united in a slender column 10–15 mm long and free for 5 mm, thus raising the anthers well above the tepal limbs so that the bright, orange-red pollen is clearly visible. The well-developed inner tepals, ± 15 mm long, are held almost erect, the limbs curving inward and with attenuate apices or sometimes obscurely 3-lobed, with the central lobe particularly prominent and the lateral lobes no more than small obtuse lateral projections. The slender, typically unbranched stem and often nearly entire inner tepals suggest a possible relationship with violet-flowered *M. incurva*, which shares these features, as well as having unusually long filaments and the anthers prominently displayed above the outer tepal limbs.



129. **Moraea lurida** *Ker Gawl.* in The Botanical Register 4: t. 312 (1818); Goldblatt: 762 (1976a); Goldblatt: 174 (1986a). *Vieusseuxia lurida* (Ker Gawl.) Sweet: 395 (1826a). *Phaianthes lurida* (Ker Gawl.) Raf.: 31 (1838). Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 312 (1818).

Moraea montana Schltr.: 92 (1900). Type: South Africa, [Western Cape], Onrus River Mouth, *Schlechter 9494* (B, holo.; BOL, GRA, K, PRE, iso.).

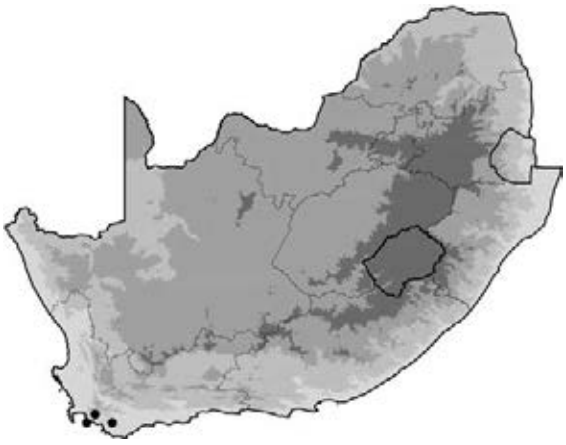
Moraea fusca Baker: 24 (1906). Type: South Africa, [Western Cape], Caledon, *Penther 762* (K, holo.; BOL, iso.).

Plants mostly 250–350 mm high. *Corm* 10–15 mm diam.; tunics of coarse, often ± woody fibres. *Stem* usually 2- or 3-branched, branches diverging from the axis, sheathing leaves green with dry, brown attenuate apices, 40–50 mm long. *Foliage leaf* solitary, basal, linear, channelled, exceeding stem, often trailing distally, 3–5 mm wide. *Rhipidial spathes* green with dry, brown attenuate apices, inner (35–)40–55(–70) mm long, outer ± 1.2 as long. *Flowers* long-lived, often dark maroon, or partly yellow, rarely entirely creamy yellow, outer tepal limbs often with a pale spot near base, ± spreading, claws ascending and margins overlapping, forming a deep cup enclosing stamens, foul-smelling; outer tepals 22–30 × 10 mm, claws broad, 13–17 mm long, lightly papillate; inner tepals either entire with limbs short, apiculate or ± 3-lobed, 12–15 mm long, spreading. *Filaments* 5–6 mm long, united in a smooth column, free and diverging in upper ± 1 mm; anthers 4–6(–8) mm long, brown, apiculate; pollen orange. *Ovary* ± cylindric, 8–9 mm long; style branches up to 6 × ± 2 mm, crests 2–3 mm long, triangular. *Capsules* club-shaped, 12–15 mm long. *Seeds* angular, prismatic. *Chromosome number* 2*n* = 12. *Flowering time*: October to November.

Distribution and ecology: centred in the Caledon District of Western Cape, South Africa, but extending from the Hottentots Holland Mtns in the west to the Bredasdorp Mtns in the east; largely montane, on rocky, sandstone slopes, rarely blooming except after fire.

Distribution of ***Moraea lurida***.

Diagnosis: variable in flower colour and to some extent in tepal shape, the perianth of *Moraea lurida* is typically an unusual dark liverish maroon and unpleasantly scented but is sometimes marked with yellow, through orange, violet, brown to creamy white. Both the dark and the lighter coloured flowers, the latter evidently unscented, seem equally attractive to muscid, dung and game flies that visit them in large numbers and are likely the legitimate pollinators. Also unusual in *Moraea*, the bases of the tepal claws lack discrete nectaries and nectar is secreted over the claw surface along vein lines. While the outer tepals are fairly uniform in shape, with the limbs shorter than the claws, the inner tepal limbs vary from fairly broad and entire to truly tricuspidate with a fairly long coiled central cusp and shorter, obtuse lateral lobes. *Moraea lurida* is probably most closely allied to *M. insolens*, a local endemic of the southern slopes of Caledon Swartberg, as well as to *M. cantharophila*, also endemic to the Caledon District.



130. **Moraea cantharophila** *Goldblatt & J.C.Manning* in Novon 12: 353 (2002). Type: South Africa, Western Cape, Sandy's Glen, Farm Vredehoek, loamy clay slope, 16 Sept. 2000, *P. Goldblatt & J.C. Manning 11542* (NBG, holo.; K, MO, PRE, iso.).

Plants 200–450 mm high. *Corm* globose, 15–20 mm diam.; tunics of coarse, pale straw-coloured, netted fibres. *Stem* straight or flexed at nodes, arching outward below inflorescence, 2 or 3 internodes long, sheathing leaf 45–55 mm long, green with ± dry, attenuate apex, simple or with 1(2) branches. *Foliage leaf* solitary, linear, channelled, arching outward, overtopping the stem and often dry distally, mostly 2.5–3.5 mm wide, ± basal. *Rhipidial spathes* green with dry attenuate apices, inner 45–65 mm long, outer ± $^2/_3$ as long. *Flowers* long-lived, white or cream-coloured, darkly veined on reverse of tepals, outer tepal limbs with a yellow or orange nectar guide outlined in dark purple at bases, claws mostly yellow, inner tepals each with a broad, dark purple-brown central band and pinkish edge, tepal limbs spreading ± horizontally or the tips curving upward,

claws ascending, forming a cup ± 12 mm wide at mouth, enclosing filament column and anther bases; outer tepals larger than inner, limbs obovate, (15–)18–20 × 14–19 mm, claws ± 10 mm long, smooth or papillate; inner tepal limbs 8–15 × 5–11 mm. *Filaments* 4–5 mm long, united almost to apices in a smooth, cylindric column, free in upper 0.5–1.0 mm, greenish to dark purple; anthers ± 6 mm long, purple; pollen orange. *Ovary* oblong–3-lobed, 7–12 mm long, exserted; style branches 6–7 × ± 3 mm, ascending, yellow to pink, crests triangular, uniformly salmon-pink, ± erect, 2.5–4.0 mm long. *Capsules* ± ovoid-ellipsoid, 16–18 mm long. *Seeds* unknown. *Chromosome number* unknown. *Flowering late* August and September, rarely early October.

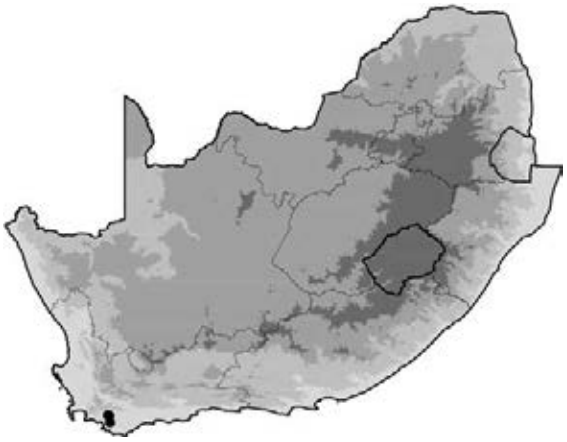
Distribution and ecology: restricted to the southwestern corner of Western Cape, South Africa, between the foot of Sir Lowry's Pass near Somerset West and Sandy's Glen in the Bredasdorp Mtns near Napier; on loamy clay slopes, flowering well only after fire.

Diagnosis: *Moraea cantharophila* has the solitary, long, channelled foliage leaf and branched stem typical of the subg. *Vieusseuxia* but unlike most species of the subgenus the inner tepals are not tricuspidate but broadly lanceolate with an entire, acute apex. The filaments are united to the apex, also uncommon in the subgenus. The dark central streak on the inner tepals is distinctive and is directly related to the pollination by hopliine beetles. *Moraea cantharophila* is evidently most closely related to *M. lurida* and *M. insolens*, both of which also have entire inner tepals with well-developed limbs. Fly-pollinated *M. lurida* typically has dark maroon flowers in which both the inner and outer tepals produce nectar over the entire inner surface of the claws, and the outer tepals are usually without contrasting markings. It has relatively long tepal claws, 13–17 mm that exceed the limbs, compared to claws ± 10 mm in *M. cantharophila*, thus shorter than the limbs. The tepal cup is thus deeper in *M. lurida* and includes both stamens and style branches, whereas the anthers are partly exserted in *M. cantharophila*.

Distribution of ***Moraea cantharophila***.

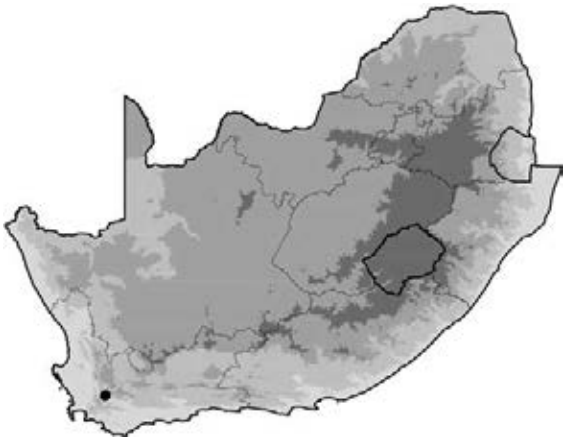
There is considerable variation in *M. cantharophila*, the type population from Sandy's Glen with larger inner tepals, 12–15 × 9–11 mm, with a broad brown central band on the claws, whereas plants from Sir Lowry's Pass have smaller inner tepals, 8–9 × 5–6 mm, and lack the prominent band of colour on the claws. Possible hybrids between *M. cantharophila* and *M. lurida* have been recorded near Elgin.

131. **Moraea insolens** *Goldblatt* in Flowering Plants of Africa 41: t. 1639 (1971b); Goldblatt: 176 (1986a). Type: South Africa, [Western Cape], Caledon, Drayton Siding, *Goldblatt 570* (BOL, holo.; K, PRE, iso.).



Homeria maculata Klatt: 627 (1866) [not *M. maculata* Sessé & Moc. (1893)]. Type: South Africa, [Western Cape], 'Langehoogte, Boontjieskraal', Caledon, *Ecklon & Zeyher Irid. 38* (B, lecto., designated by Goldblatt: 763 (1976a); S, isolecto.).

[*Vieusseuxia auranticata* Eckl.: 13 (1827), invalid name without description.]



Plants mostly 270–400 mm high, sometimes in small clumps, often with collar of fibres around base. *Corm* ± 10 mm diam.; tunics of coarse, brown fibres extending upwards in a collar around base. *Stem* 2 or 3 internodes long, usually 2- or 3-branched, sheathing leaves 50–60 mm long, green with dry, brown attenuate tips. *Foliage leaf* solitary, linear, channelled, as long or shortly exceeding stem, erect below, often trailing distally, 3–4 mm wide. *Rhipidial spathes* with dry, attenuate apices, inner spathe 50–60 mm long, outer ± $^{2}/_{3}$ as long. *Flowers* long-lived, 45–50 mm diam., either bright orange or creamy green, limbs of all tepals with narrow yellow band edged brown distally and claws uniformly brown; outer tepals 26–30 × 20 mm, limbs spreading ± horizontally, claws poorly differentiated from limbs, 6–7 mm long; inner tepals similar but smaller, 23–25 × ± 15 mm. *Filaments* ± 4 mm long, united below in a slender column, free and diverging in distal 0.4 mm; anthers 6–8 mm long, exceeding style crests, brown; pollen orange. *Ovary* ± cylindric, ± 10 mm long; style branches 4 × 1–2 mm, narrow, brown, crests short, ± 1.5 mm long, triangular, orange. *Capsules* club-shaped to elliptic, 12–15 mm long. *Seeds* angled, prismatic. *Chromosome number* $2n = 12$. *Flowering time*: late September and October.

Distribution and ecology: a narrow endemic of the Caledon District of Western Cape, South Africa, currently known from two sites, one at the western end of Caledon and the other at Drayton Siding east of Caledon (its original range was somewhat wider, possibly extending the length of the Swartberg, some 20 km); on lower, south-trending slopes of Caledon Swartberg in loamy clay-gravel, flowering well after fire.

Diagnosis: with its open, poppy-like flowers, either bright orange-red or creamy green with a brown centre, *Moraea insolens* is one of the most striking species in the genus. The filaments are united in a smooth, dark brown column and the large anthers, ± 8 mm long

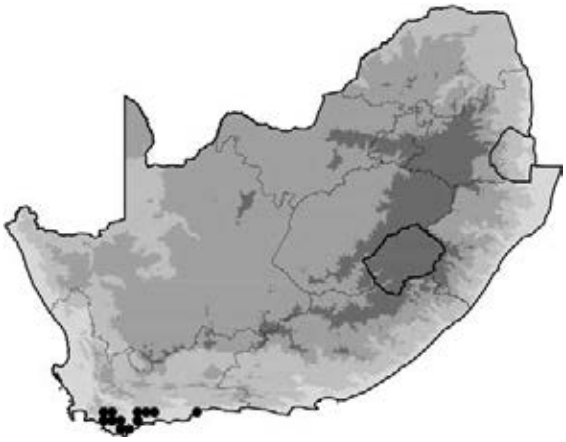
Distribution of ***Moraea insolens***.

Distribution of ***Moraea worcesterensis***.

are closely appressed to and exceed the narrow style branches with their tiny crests. The inner tepals closely resemble the outer in colour and orientation and are only slightly smaller. *Moraea insolens* is probably most closely related to *M. lurida*, a species of sandstone soils which usually has dark maroon flowers, sometimes with contrasting white markings, and similarly reduced style branches and crests but smaller inner tepals often with 3-lobed limbs. The two species share an unusual karyotype, unique in sect. *Vieusseuxia.*

132. **Moraea worcesterensis** *Goldblatt* in Annals of the Missouri Botanical Garden 73: 115 (1986c); Goldblatt: 142 (1986a). Type: South Africa, [Western Cape], sandstone flats at Worcester West, *Goldblatt & Snijman 6977A* (NBG, holo.; K, MO, PRE, S, US, iso.).

Plants 120–250 mm high, with fibrous collar around base. *Corm* globose, 15–20 mm diam.; tunics of brown, coarse fibres, often thickened into claw-like ridges, eventually accumulating in a dense mass. *Stem* simple or 1-branched, straight or flexed at upper nodes, sheathing leaves green in lower half, becoming dry and brown distally, attenuate, 30–40 mm long. *Foliage leaf* solitary, basal, linear, channelled, ± as long to ± twice as long as stem, ± 2.5 mm wide. *Rhipidial spathes* dry and dark brown above, attenuate, inner 28–35 mm long, outer ± $^1/_2$ as long. *Flowers* long-lived, dark violet-purple, limbs of all tepals with small yellow nectar guides at bases, spreading horizontally; outer tepals 15–17 × ± 9 mm, claws diverging, ± 3 mm long; inner tepals 13–15 × 4–5 mm, claws diverging. *Filaments* 5–6 mm long, purple, united below, free in upper 2 mm; anthers ± 4 mm long, exceeding style branches, purple; pollen yellow. *Ovary* ± 5 mm long, ± cylindric, tapering toward base; style branches narrow, < 1 mm wide, diverging, appressed to opposed anther, bilobed apically, crests vestigial. *Capsules* narrowly obovoid, ± 10 mm long. *Seeds* angular, prismatic. *Chromosome number* 2*n* = 12. *Flowering time*: September.



Distribution and ecology: a rare and evidently threatened species of Western Cape, South Africa, currently known from only two sites in the low hills north of Worcester; in dry sites on stony, clay slopes and flats.

Diagnosis: a remarkable member of subg. *Vieusseuxia*, *Moraea worcesterensis* has small, star-like, violet-purple flowers with spreading outer and inner tepals both with small yellow nectar guides at the limb bases. The style branches, held well above the tepals, are much reduced, < 1 mm wide and ± as wide as the anthers, and lack true crests. The purple filaments are united in a cylindric column but free distally and the purple anthers slightly exceed the style branches. The relationships of *M. worcesterensis* are uncertain but molecular studies confirm its assignment to subg. *Vieusseuxia,* originally placed there on the basis of the solitary leaf, long-lived flower and chromosome number of 2*n* = 12 (basic chromosome number in the subgenus is *x* = 6).

133. **Moraea fergusoniae** *L.Bolus* in South African Gardening and Country Life 19: 294 (1929b); Goldblatt: 64 (1986a). Type: South Africa, [Western Cape], Riversdale, *Ferguson s.n.* (BOL [18970], holo.).

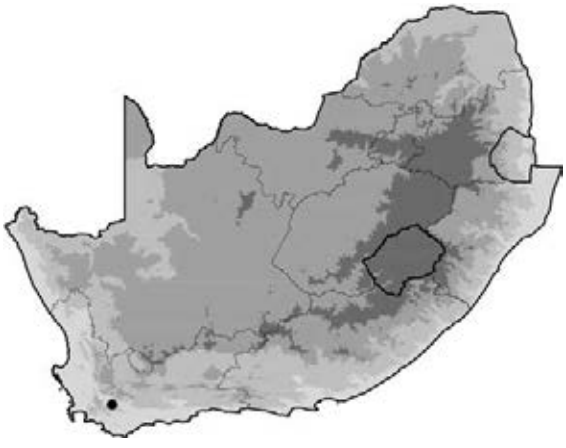
Moraea fimbriata Klatt: 561 (1866), illegitimate homonym, not *M. fimbriata* Loisel (1822). Type: South Africa, [Western Cape], Caledon, *Ecklon & Zeyher Irid. 42* [SAM, lecto., designated by Goldblatt: 697 (1976a)].

Plants 100–200 mm high. *Corm* 5–15 mm diam.; tunics of pale medium fibres. *Stem* usually 2- to 4-branched from base, rarely simple, mostly (1)2 internodes long, sheathing leaves 1 per branch, green with dry, brown apices, 16–22 mm long. *Foliage leaves* 3 to 6, basal, shallowly channelled, shorter to ± as long as stem, 5–10 mm wide, dark green, falcate or loosely twisted, margins ciliate, undulate to crisped. *Rhipidial spathes* with dry, brown, attenuate apices, inner 26–38 mm long, outer ± half as long. *Flowers* long-lived, white to creamy white or blue, often flushed purple to brown outside, outer tepal limbs with yellow nectar guides at bases, spreading to half reflexed; outer tepals lanceolate, ± 20 mm long, claws ascending, slightly shorter than limbs; inner tepals

Distribution of ***Moraea fergusoniae***.

erect, 8–12 mm long, either entire, narrowly lanceolate or 3-lobed with a long central cusp and 2 small, rounded lateral lobes. *Filaments* ± 4 mm long, united or free in upper 1 mm; anthers 3 mm long, yellow; pollen yellow. *Ovary* ellipsoid, ± 5 mm long; style branches 3–5 mm long, crests linear, 5–7 mm long. *Capsules* club-shaped, ± 7 mm long. *Seeds* angular, prismatic. *Chromosome number* 2*n* = 12. *Flowering time*: late July and August.

Distribution and ecology: relatively widespread in southern Western Cape, South Africa, from near Bot River east to Robinson's Pass near Mossel Bay; typically on clay soils in renosterveld.



Diagnosis: unique in subg. *Vieusseuxia,* the diminutive *Moraea fergusoniae* has 3 to 6 foliage leaves, all basal, and the short stems consist of only one or two aerial internodes. The flowers are usually white to creamy white but very attractive blue-flowered populations occur in the vicinity of Swellendam. The flowers are long-lived and have either entire and lanceolate or 3-lobed inner tepals, then with a longer acute central cusp and short lateral lobes. Because of the multiple foliage leaves *M. fergusoniae* was long thought to be allied to species of subg. *Moraea*, in particular *M. papilionacea*, but this now appears incorrect. Both the long-lived flower and often 3-lobed inner tepals accord with subg. *Vieusseuxia* as does the chromosome number, 2*n* = 12, and molecular phylogenetic studies place the species in that subgenus among a cluster of species with solitary leaves. The presence of multiple leaves in *M. fergusoniae* thus presumably represents a striking evolutionary reversal to the ancestral state in *Moraea.* In the subgenus only *M. helicoidea* also consistently has more than one leaf, and flowers similar in shape and size to those of *M. fergusoniae*, and the two are evidently immediately related.

134. **Moraea helicoidea** *Goldblatt & J.C.Manning* in South African Journal of Botany 99: 70 (2015). Type: South Africa, Western Cape, Farm Droogeriviersberg, SE of Worcester, in Breede Shale Renosterveld, 500 m, 14 Sept. 2014, *Manning & Le Roux 1172* (NBG, holo.; K, MO, iso).

Plants ± 50–150 mm high. *Corm* ± globose, 7–10 mm diam.; tunics of pale brown, netted fibres. *Stem* consisting of 2 aerial internodes, simple or 1-branched from aerial node, solitary sheathing leaf green with dry, brown apices, 9–15 mm long, sometimes reaching almost to base of inflorescence, with cataphylls forming collar around base. *Foliage leaves* 2, subequal, inserted at base, suberect, exceeding stem, blades narrow, apparently terete with narrow adaxial groove, ± 1 mm diam. when opened flat, distal half of blade loosely coiled to almost straight in shade. *Rhipidial spathes* green with dry brown, acute tips, inner 16–25 mm long, outer entirely sheathing, ± half as long. *Flowers* long-lived, largely white, speckled outside with brown spots, outer tepal limbs spreading, with large yellow nectar guide at bases and brown inner tepals, with light, fruity scent; tepals unequal, outer ± 16–18 mm long, limb ± broadly obovate-orbicular, 10 × 10 mm, claws suberect, ± 7 mm long, inner 8–9 mm long, limbs much reduced, ± 4 mm long, ± deltoid to obscurely 3-lobed with longer central lobe curving inward. *Filaments* ± 4.5 mm long, united in lower 3 mm in a cylindric column enclosing style, free and diverging above; anthers ± 3 mm long, pale mauve; pollen white. *Ovary* ellipsoid, ± 5 mm long; style branches 4.5–5.0 mm long, suberect, crests erect, ± 5 mm long. *Capsules* ± ellipsoid, 7–8 × 5 mm. *Seeds* unknown. *Flowering time*: late August and September.

Distribution and ecology: extremely local and known only from the Farm Droogeriviersberg, ± 30 km SW of Worcester in Western Cape, South Africa; in a transition zone between the Witteberg- and Dwyka geological groups, in renosterveld.

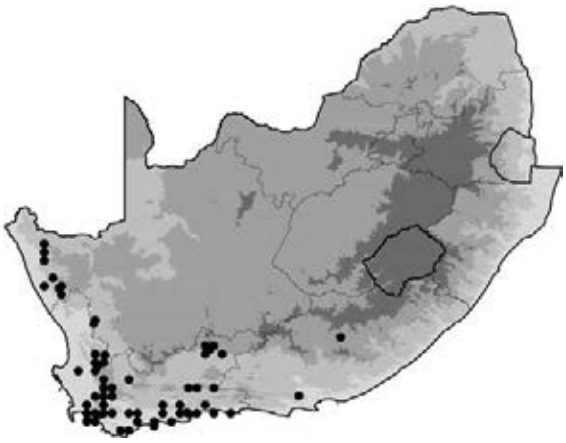
Diagnosis: *Moraea helicoidea* is immediately distinguished in subg. *Vieusseuxia* by the presence of two subequal foliage leaves inserted near the base and loosely coiled in corkscrew fashion. More than one foliage leaf is rare in the subgenus and consistent only in *M. fergusoniae*, which has three to six foliage leaves, the blades channelled, shorter than the stem and 3–10 mm wide, slightly twisted and with undulate, minutely ciliate margins. *Moraea tripetala* subsp. *violacea* sometimes

Distribution of ***Moraea helicoidea***.

has two foliage leaves but very different flowers with inner tepals represented by minute cusps. Flowers of *M. helicoidea* are predominantly white with outer tepals bearing large, deep yellow nectar guides at the limb bases and with small dark spots on the reverse. The brown inner tepals have reduced, 3-lobed limbs, common in the subgenus, and are comparable in shape to those of *M. fergusoniae* which has either pale blue or white flowers. Branching in *M. fergusoniae* is usually basal whereas branches in *M. helicoidea*, when present, are cauline, borne at the first aerial node.

135. **Moraea unguiculata** *Ker Gawl.* in Curtis's Botanical Magazine 16: t. 593 (1802a); Goldblatt: 759 (1976a); Goldblatt: 155 (1986a). Type: South Africa, without precise locality, illustration in Ker Gawl.: t. 593 (1802a).

Iris tricuspis var. *minor* Jacq.: t. 222 (1792). Type: South Africa, without precise locality, illustration in Jacq.: t. 222 (1792).



Moraea tenuis Ker Gawl.: t. 1047 (1807). *Vieusseuxia tenuis* (Ker Gawl.) Roem. & Schult.: 491 (1817). Type: South Africa, without precise locality, illustration in Ker Gawl.: t. 1047 (1807).

Iris gracilis Licht. ex Roem. & Schult.: 477 (1817). *Moraea gracilis* (Licht. ex Roem. & Schult.) A.Dietr.: 478 (1833). Type: South Africa, without precise locality, *Lichtenstein s.n.* (Type unknown, identity based on description).

Moraea ceresiana G.J.Lewis: 57 (1941), as a new name for *M. violacea* L.Bolus: 116 (1928b), illegitimate homonym, not *M. violacea* Baker (1900). Type: South Africa, [Western Cape], Ceres, *Cook s.n.* (BOL 17020], holo.).

[*Vieusseuxia gracilis* Eckl.: 12 (1827), invalid name without description.]

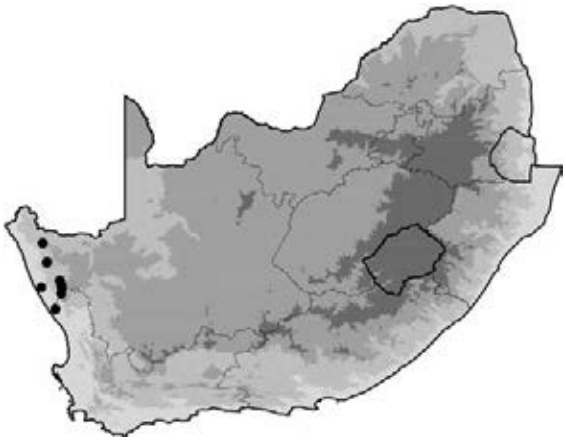
Plants 150–600 mm high. *Corm* 10–18 mm diam.; tunics light brown to dark grey, fine to coarse fibres. *Stem* usually few branched, usually 3 internodes long, bearing green, attenuate sheathing leaves 40–55 mm long. *Foliage leaf* solitary, basal, linear, up to half again as long as stem, erect below, trailing distally, channelled, glabrous, glaucous-grey, 2–3(–4) mm wide. *Rhipidial spathes* green, becoming dry and dark brown near tips, attenuate, inner spathe 30–40 mm long, outer ± half as long. *Flowers* long-lived, white, creamy to dull yellow, brown or deep blue, outer tepal limbs with yellow to brown nectar guides at bases, sometimes speckled brown or purple over surface, half to fully reflexed, inner tepals often darkly speckled; outer tepals lanceolate, 12–20 mm long, claw ± half as long as limb, densely hairy; inner tepals ± erect, 7–12 mm long, usually tricuspidate with long, central, symmetrically incurved cusp and 2 short obtuse lateral lobes (rarely ± linear, filiform or expanded in middle). *Filaments* 4–6 mm long, united almost to apex; anthers 3–4 mm long, apiculate, usually white. *Ovary* ± ellipsoid-ovoid, 7–9 mm long; style branches ± 5 mm long, crests 2.5–4.0 mm long.

Distribution of ***Moraea unguiculata***.

Capsules ± club-shaped, 13–15 mm long. *Seeds* small, angular. *Chromosome number* 2*n* = 12. *Flowering time*: late August to early December.

Distribution and ecology: widespread throughout the South African winter-rainfall region, from Steinkopf in Namaqualand, Northern Cape, south through Western Cape to Grahamstown in Eastern Cape in the east and with isolated populations in the mountains of the Great and Upper Karoo (absent from the Western Cape Atlantic Coast and Cape Peninsula); usually on clay soils but also on granite-derived or sandy gravels.

Diagnosis: *Moraea unguiculata* is a slender plant with one of the smallest flowers in subg. *Vieusseuxia*, the outer tepals typically 12–18 mm long with limbs ± 8–10 mm long. Flowers are unusually varied in tepal orientation and colour. The most common morph has outer tepal limbs half reflexed and white to creamy yellow, darkly speckled near the base, but populations in the Ceres area of the Western Cape have attractive dark blue-violet tepals. A second morph, corresponding to the synonym, *M. tenuis*, has the outer tepal limbs fully reflexed and the tepals dull pinkish brown with pale yellow, velvety nectar guides. These morphs may represent separate taxa but so far attempts to refer all herbarium collections to one or other morph have failed owing to the presence of apparent intermediates. Plants consistently have filaments united in a slender, smooth column with only their tips free, comparatively narrow style branches, short narrow crests, and 3-lobed inner tepal limbs, the longer central lobe linear and symmetrically coiled inward. Evidently closely related, *M. bellendenii* and *M. tricuspidata* have larger flowers, also with 3-lobed inner tepals but with the central lobe asymmetrically coiled. Also easily confused with *M. unguiculata*, *M. rivulicola* has somewhat larger flowers of very similar structure but with outer tepals up to 24 mm long, unbearded tepal claws, and a larger ovary and capsule, the latter 25–32 mm long vs. 13–15 mm in *M. unguiculata*. The two species co-occur at some sites in Namaqualand in slightly different habitats.



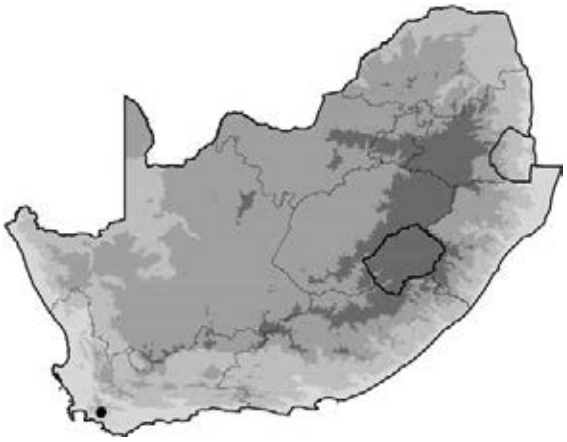
An odd variant of *Moraea unguiculata* from the Kamiesberg of central Namaqualand has linear, filiform inner tepals but otherwise seems to conform to the species. Typical *M. unguiculata* with 3-lobed inner tepals also occurs in the Kamiesberg.

136. **Moraea rivulicola** *Goldblatt & J.C.Manning* in Novon 5: 262 (1995). Type: South Africa, [Northern Cape], Springbok District, streambed at eastern end of Spektakel Pass, 11 Sept. 1993, *Goldblatt & Manning 9710* (NBG, holo.; K, MO, PRE, WAG, iso.).

Plants 500–900 mm high. *Corm* globose, 14–18 mm diam.; tunics of pale, coarse vertical fibres connected by fine cross strands. *Stem* of 4(5) internodes, simple or usually 1- to 3-branched, sheathing leaves 50–65 mm long, with dry, attenuate-filiform apices. *Foliage leaf* solitary, basal, ± twice as long as stem, channelled, 3–10 mm wide (when opened flat). *Rhipidial spathes* with dry brown attenuate apices, inner 55–70(–90) mm long, outer 45–65 mm long. *Flowers* long-lived, cream-coloured, yellow-green or ± beige, outer tepal limbs with large, darkly spotted dull yellow nectar guides at bases, claws similarly dotted, inner tepals light to reddish brown; outer tepals 20–28 × 10–13 mm, claws ascending, channelled, 7–14 mm long, with large basal nectary opposed by a lobe ± 2 mm long, limbs 14–19 mm long, reflexed 45°–60°, inner tepals 13–19 × 4–5 mm, ascending, channelled below, usually trilobed, median lobe linear, curving inward, laxly asymmetrically coiled, lateral lobes rounded, obtuse, up to 2 mm long, or limb ovate-attenuate. *Filaments* 8–12 mm long, united in lower ± 5.5–10.0 mm, diverging in upper 1.8–2.5 mm; anthers 4–6 mm long, shortly exceeding stigma lobes, orange. *Ovary* ellipsoid-3-lobed, 11–14 mm long, exserted; style branches ± 6 × 2 mm, diverging, crests lanceolate, 3–5 mm long. *Capsules* cylindric, 25–32 mm long. *Seeds* angular. *Flowering time*: mid-August to late September.

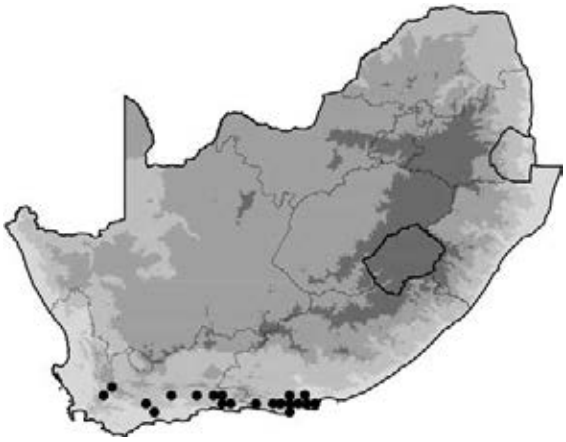
Distribution and ecology: a fairly rare endemic of Namaqualand, Northern Cape, South Africa, with a scattered range extending from the Spektakel Mtns west of Springbok in the north to the Kamiesberg and the heights south of Kotzesrus in the south; usually along the banks and beds of seasonal streams, in drainage lines and seasonal marshes.

Diagnosis: resembling *Moraea unguiculata*, *M. rivulicola* has larger, pale, creamy green, yellow-green or beige flowers, the outer tepals up to 28 mm long with limbs typically held at 60° below horizontal and smooth claws. The inner tepals are also distinctive in having the central lobe of the typically 3-lobed limb drawn into a slender, obliquely coiled cusp, while the lateral lobes are rounded and very short. The ovary is oblong-cylindric and 11–14 mm long, and gives rise to large cylindric capsules 25–32 mm long. *Moraea unguiculata* has smaller flowers with the outer tepals seldom exceeding 16 mm and with densely pubescent or bearded claws. The inner tepals, 7–10 mm long, are also 3-lobed but



Distribution of ***Moraea rivulicola***.

the long central cusp is coiled inward symmetrically. Flower colour in *M. unguiculata* ranges from white to creamy white, brownish, and even blue, and the outer tepal limbs may be half reflexed or, in some populations outside Namaqualand, may be completely reflexed.



A population from the rocky hills west of Bitterfontein and south of Kotzesrus stands out in the particularly large flowers with the inner tepals ± 19 mm long, and with an ovate-attenuate limb. Other organs are also larger, with the filaments united in a column up to 10 mm long and free for an additional 2.5 mm and the anthers are 5.5–6.0 mm long. This population represents a significant variant and distinctive race, perhaps deserving of infraspecific recognition.

137. **Moraea atropunctata** *Goldblatt* in Annals of the Missouri Botanical Garden 69: 362 (1982); Goldblatt: 172 (1986a). Type: South Africa, Caledon District, Farm Vleitjies, Eseljacht Mtns, *Goldblatt 5635* (MO, holo.; K, NBG, PRE, S, US, iso.).

Plants 150–200 mm high. *Corm* 9–12 mm diam.; tunics of light brown, netted fibres. *Stem* erect, simple or 1-branched, usually consisting of only 2 internodes, bearing long-attenuate sheathing leaves 25–40 mm long, dry and brown above. *Foliage leaf* solitary, basal, linear, channelled, margins ciliate-hairy, 4–8 mm widest, usually erect, slightly longer than to twice as long as stem. *Rhipidial spathes* long-attenuate, brown above, inner 45–65 mm long, outer ± half as long. *Flowers* dull creamy white, red-brown on reverse of outer tepals, spotted dark brown or blue towards base of outer tepal limbs on yellow background, tepals claws brown; outer tepals 20–24 mm long, claw 5–7 mm, bearded, limbs spreading, 17–25 mm wide; inner tepals 9–15 mm long, 3-lobed, inner lobe longest, acute, straight or twisted, lateral lobes short, obtuse, yellow, speckled brown. *Filaments* ± 5 mm long, united in a smooth column, free in upper 0.5 mm; anthers ± 4 mm long, purple-brown; pollen orange. *Ovary* 10–14 mm long; style ± 5 mm long, branches ± as long as anthers, crests ± 4 mm long, dull

Distribution of ***Moraea atropunctata***.

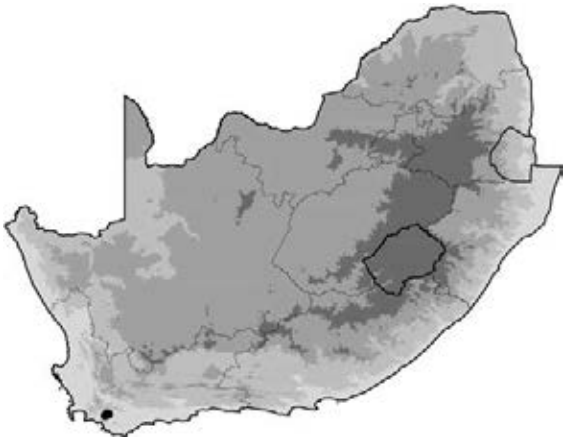
Distribution of ***Moraea algoensis***.

orange. *Capsules* oblong, 25–35 mm long, somewhat inflated. *Seeds* unknown. *Chromosome number* 2*n* = 12. *Flowering time*: mid-August to late September.

Distribution and ecology: known only from a small area of the Eseljacht Mtns in the Caledon District in Western Cape, South Africa; on stony clay ground.

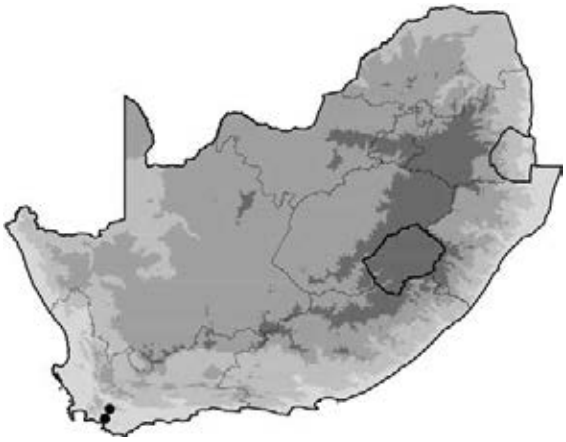
Diagnosis: a striking and unusual species both in flower and vegetative morphology, *Moraea atropunctata* has dull coloured flowers with broad outer tepal limbs reddish brown outside, and 3-lobed inner tepals with the longer median lobe laxly spreading. The nectar guides consist of small dark spots at the bases of the outer tepals while the claws are dark brown. The leaves are relatively short, not or hardly exceeding the stems, and unusually broad, with prominently ciliate-hairy margins. Although evidently related to the *M. tricuspidata* and *M. unguiculata* groups in general, the foliage and flowers easily separate it from the several species of these alliances. The unusually large, inflated capsules, 25–35 mm long, are also unusual for these two groups and recall the *M. villosa* species group.

138. **Moraea algoensis** *Goldblatt* in Annals of the Missouri Botanical Garden 60: 226 (1973); Goldblatt: 750 (1976a); Goldblatt: 140 (1986a). Type: South Africa, [Eastern Cape], Port Elizabeth, *Batten 7* (NBG, holo.).



Plants 200–400 mm high. *Corm* 10–15 mm diam.; tunics of medium to coarse, netted fibres. *Stem* 2- to 4-branched, branches flexed away from axis and often all facing to one side, sheathing leaves 35–40 mm long, with dry, brown, long attenuate tips. *Foliage leaf* solitary, linear, ± basal, channelled, exceeding stem and trailing distally, mostly 2.5–3.5 mm wide. *Rhipidial spathes* attenuate, with brown membranous margins and tips, inner 40–50 mm long, outer spathe ± $^1/_2$ as long. *Flowers* dark blue to violet, outer tepal limbs with yellow nectar guides at bases, ± half reflexed; outer tepals 25–28 × 9–10 mm, claws slightly shorter than limbs, inner tepals blue to purple to brown, 6–10 mm long, with ovate or broadly 3-lobed limbs ± 3 mm long. *Filaments* ± 4 mm long, united in lower 3 mm, diverging in upper 1 mm; anthers ± 4 mm long; pollen usually orange-red. *Ovary* ± ellipsoid, ± 6 mm long; style branches ± 5 mm long, crests linear, 6–8 mm long. *Capsules* and *seeds* unknown. *Chromosome number* 2*n* = 12. *Flowering time*: August and September, rarely in June or July.

Distribution and ecology: extending from the hills near Worcester in Western Cape, South Africa, to Humansdorp and Port Elizabeth in Eastern Cape; mostly on stony slopes in loamy clay, often on the interface between sandstone and shale substrates.



Diagnosis: with relatively small, blue to violet flowers and orange-red pollen, *Moraea algoensis* is distinguished primarily by the characteristic inner tepals, often dark violet to brown, with a broad, relatively short limb, sometimes entire or 3-lobed with a long, incurved central lobe. The filaments are united in the lower $^2/_3$ in a slender, smooth column, arching outward distally, and bearing pale blue anthers with bright orange pollen. Flowers of some populations may be confused with *M. unguiculata*, but that species rarely has blue flowers and more strongly reflexed outer tepal limbs, the inner tepals darkly speckled on a yellow to white background, and a consistently trilobed inner tepal limb with the longer, narrow central cusp coiled inward. Bright red to orange pollen is not known in *M. unguiculata*.

139. **Moraea longiaristata** *Goldblatt* in Annals of the Missouri Botanical Garden 69: 360 (1982); Goldblatt: 140 (1986a). Type: South Africa, [Western Cape], Caledon Swartberg above the Gardens, *Goldblatt 5883* (MO, holo.; C, E, K, NBG, PRE, S, US, WAG, iso.).

Plants 150–300 mm high. *Corm* 8–12 mm diam.; tunics of pale, coarse fibres. *Stem* simple or 1-branched, with 3 aerial internodes, sheathing leaves 30–40 mm long, with dry, attenuate apices. *Foliage leaf* solitary, basal, erect, channelled, exceeding stem, often dry near apex, ± 2 mm wide. *Rhipidial spathes* attenuate, apices dry

Distribution of ***Moraea longiaristata***.

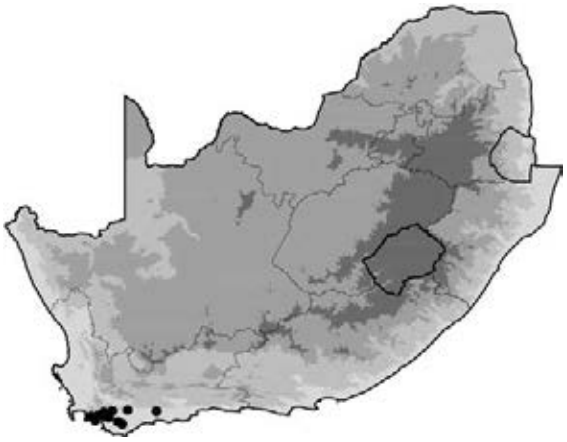
Distribution of ***Moraea barnardii***.

and brown, inner 45–55 mm long, outer ± 1/2 as long. *Flowers* long-lived, white, outer tepal limbs with white nectar guides ringed in dark blue near bases, with faint, dark blue radiating veins, half reflexed, margins undulate; outer tepals 23–30 mm long, limbs 11–14 × 11–16 mm, claws 12–16 mm long, suberect, slightly longer than limbs; inner tepals 13–15 mm long, linear, < 1 mm wide, erect, curving inward toward apex. *Filaments* 12–15 mm long, united in lower 1/2–2/3; anthers 3–4 mm long, dark blue-purple; pollen red. *Ovary* ± cylindric, 8–10 mm long, entirely or partly enclosed; style branches ± 10 mm long, crests ± 5 mm long. *Capsules* and *seeds* unknown. *Chromosome number* unknown. *Flowering time*: September to mid-October.

Distribution and ecology: a local endemic of the Caledon Swartberg above the town of Caledon in Western Cape, South Africa; on rocky slopes in coarse sandy ground, flowering well after fire or when the surrounding vegetation is cleared.

Diagnosis: *Moraea longiaristata* and *M. barnardii* have a superficially similar flower but the inner tepals of *M. longiaristata* are linear and erect, ± 15 mm long and the outer tepals have claws 12–16 mm long, whereas *M. barnardii* lacks inner tepals entirely, and the outer tepal claws are ± 7 mm long and shorter than the tepal limbs. Associated with the longer tepals claws, the filaments of *M. longiaristata* are up to 15 mm long but only 8–9 mm long in *M. barnardii*. In other respects, including broad, white outer tepal limbs with undulate margins, nectar guides consisting of dark blue spots, the short, purple anthers and red pollen, the two species are very alike.

140. **Moraea barnardii** *L.Bolus* in Journal of Botany, British and foreign 71: 122 (1933); Goldblatt: 150 (1986a). Type: South Africa, [Western Cape], top of Shaw's Pass, Caledon, *Barnard s.n.* (BOL [20067], holo., NBG, SAM, iso.).



Plants slender, rarely exceeding 300 mm high. *Corm* ± 10 mm diam.; tunics of brown, coarse fibres. *Stem* usually simple or 1-branched, 3 internodes long, sheathing leaves 25–40 mm long, attenuate. *Foliage leaf* solitary, linear, channelled, usually exceeding stem or trailing distally, ± 1.5 mm wide. *Rhipidial spathes* attenuate, dry and brown in upper half, inner ± 45 mm long, outer up to 25 mm long. *Flowers* long-lived, white, outer tepal limbs with dark blue nectar guides at bases edged with radiating blue lines, spreading to weakly reflexed; outer tepals ± 20 mm long, limbs 12–13 mm long and ± as wide, margins undulate; inner tepals lacking. *Filaments* 8–9 mm long, united in lower 1/3, free and diverging above; anthers oblong, 3–4 mm long, dark blue; pollen orange-red. *Ovary* narrowly elliptic, 7–9 mm long, red, exserted; style branches ± 6 mm long, crests 6–7 mm long. *Capsules* club-shaped, usually flushed red, ± 10 mm long. *Seeds* angular, prismatic. *Chromosome number* 2*n* = 12. *Flowering time*: mid-September and early October.

Distribution and ecology: a rare local endemic of the Caledon District of Western Cape, South Africa, on Shaw's Mtn and possibly near Gansbaai and to the west at Palmiet River Mouth (both latter records in need of confirmation); in outcrops of sandstone rocks, flowering best after fire.

Diagnosis: a slender species standing up to 300 mm tall, *Moraea barnardii* is immediately distinguished by the white flowers faintly blue-veined on the underside, with broad, spreading to laxly reflexed outer tepal limbs with undulate margins and nectar guides consisting of a ring of dark blue edged with radiating blue lines. Flowers lack inner tepals and have short filaments 8–9 mm long, united in the lower third, dark blue anthers and red pollen. Plants are usually unbranched. The immediate relationships of *M. barnardii* are with the Caledon Swartberg endemic *M. longiaristata* and the several differences between then are discussed under that species.

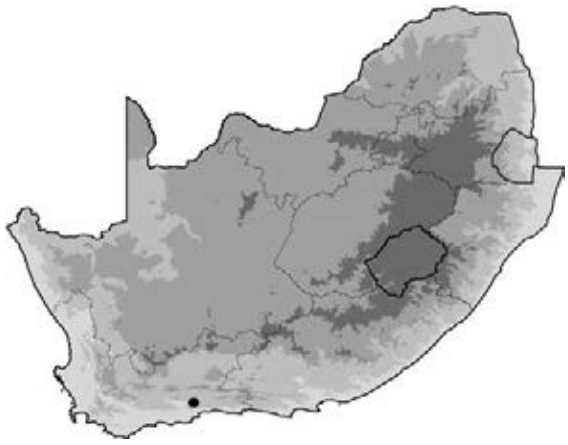
141. **Moraea debilis** *Goldblatt* in Annals of the Missouri Botanical Garden 63: 21 (1976b); Goldblatt: 146 (1986a). Type: South Africa, [Western Cape], clay slopes SW of Caledon, *Goldblatt 673* (BOL, holo.; K, MO, PRE, S, iso.).

Plants slender, 150–400 mm high. *Corm* ± 10 mm diam.; tunics of light brown, relatively fine fibres. *Stem* 2 or

Distribution of ***Moraea debilis***.

3 internodes long, laxly 1- to 3-branched, rarely simple, sheathing leaves becoming dry at flowering, 45–60 mm long. *Foliage leaf* solitary, basal, linear, softly hairy on abaxial surface, exceeding stem and trailing distally, 2.5–3.5 mm wide, margins ciliate. *Rhipidial spathes* becoming dry and brown near tips, long attenuate, sometimes ± lacerated, inner 40–55 mm long, outer ± half as long. *Flowers* long-lived, ± violet fading to pale mauve and becoming speckled, outer tepal limbs with white nectar guides with purple central spot at bases, ± half reflexed; outer tepals ± lanceolate, ± 20 mm long, claws ± $^1/_2$ as long, velvety; inner tepals ± 10 mm long, erect, slender, usually 3-lobed distally with central cusp much exceeding lateral lobes. *Filaments* ± 4.5 mm long, united in lower half; anthers ± 5 mm long, pale mauve; pollen yellow. *Ovary* ± cylindric, 6–8 mm long; style branches ± 7 mm long, crests ± 3 mm long. *Capsules* narrowly ovoid-club-shaped, 10–12 mm long. *Seeds* small, angled. *Chromosome number* 2*n* = 12. *Flowering time*: September to October.

Distribution and ecology: restricted to the Caledon District of Western Cape, South Africa, from Bot River to the Ruens near Bredasdorp; in clay soils among low shrubs in renosterveld.



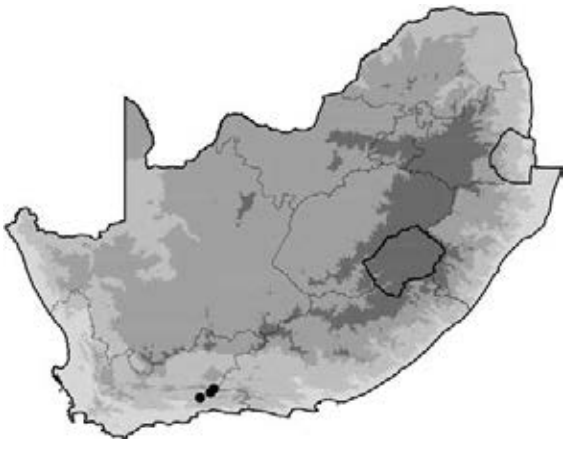
Diagnosis: a slender plant, *Moraea debilis* has small flowers initially violet, fading to pale blue-mauve and becoming mottled, spreading to reflexed outer tepal limbs and trilobed inner tepals. The filaments are united for half their length in a column ± 2.5 mm long. Somewhat unusual in sect. *Vieusseuxia*, the linear leaf is softly hairy on the outer surface and the margins are usually ciliate.

142. **Moraea lilacina** *Goldblatt & J.C.Manning* in Novon 12: 355 (2002). Type: South Africa, Western Cape, northern foothills of the Langeberg, near Perdebont, Farm Graskloof, 23 Sept. 1999, *Goldblatt & Nänni 11587* (NBG, holo.; K, MO, iso.).

Plants 200–350 mm high. *Corm* ± globose, 12–16 mm diam.; tunics of light brown, netted fibres. *Stem* usually unbranched, with 3 aerial internodes, sheathing leaves 40–45 mm long, with dry, attenuate apices. *Foliage leaf* solitary, ± basal, linear, narrowly channelled, ± 1.5 mm wide, trailing and often dry distally. *Rhipidial spathes* with dry, attenuate apices, inner 40–45 mm long, outer ± $^2/_3$ as long. *Flowers* long-lived, pale pink, fading darker pink, outer tepal limbs with bright yellow nectar guides at bases, flushed lilac-pink on reverse, reflexed at ± 45°; outer tepals 27–30 mm long, claws ± 10 mm long, yellow, densely hairy; inner tepals 16–18 mm long, 3-lobed with linear, suberect central lobe ± 9 mm long, lateral lobes short, obtuse. *Filaments* 7–8 mm long, united in lower $^2/_3$ in a cylindric column, smooth or papillate, free and diverging above; anthers ± 3.5 mm long, pink. *Ovary* oblong, 7–8 mm long, exserted; style branches diverging, ± 5 × 2 mm, crests slender, erect, 5–8 mm long. *Capsules* and *seeds* unknown. *Flowering time*: September.

Distribution and ecology: known from just one site in the northern foothills of the Langeberg northwest of Robinson's Pass in Western Cape, South Africa; in sandy loam, mostly wedged in crevices in sandstone outcrops.

Diagnosis: *Moraea lilacina* is recognised by the pink to lilac flowers with outer tepals 27–30 mm long, and 3-lobed inner tepals 16–18 mm long. The inner tepals have a narrow, channelled claw but the 3-lobed limb consists of an erect central cusp ± 9 mm long and shorter rounded lateral lobes. The filaments are 7–8 mm long with a papillate or smooth column, The species is clearly allied to the widespread southern African winter-rainfall *M. unguiculata*, a remarkably variable species, both as regards perianth colour and size, but its critical features are inner tepals 10–12 mm long and trilobed with the central cusp linear and coiled inward, filaments usually 3–5 mm long with the column lightly to densely papillate, and the outer tepals are typically 12–16 mm long, rarely up to 24 mm long in northern Namaqualand populations. The stems in *M. unguiculata* are almost always branched unless depauperate due to environmental conditions but typically unbranched in *M. lilacina*. The outer tepals of *M. unguiculata* may be white to cream-coloured, brown, violet, or even dull yellow and usually have a contrasting mark at the base



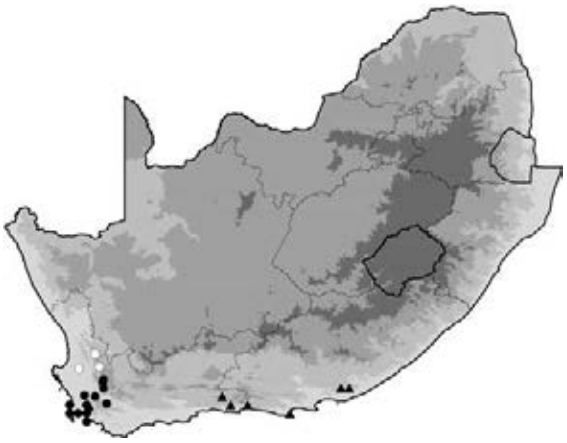
Distribution of ***Moraea lilacina***.

of the limb, and the style branches are narrow and spreading as in *M. lilacina*, but with erect crests 2.0–4.0(–5.5) mm long vs. 5–8 mm in *M. lilacina*.

143. **Moraea regalis** *Goldblatt & J.C.Manning* in Novon 5: 266 (1995). Type: South Africa, [Western Cape], Little Karoo, De Rust, rocky hillside near old cemetery, 19 Sept. 1994, *J.A. Vlok & A.L. Schutte 345* (NBG, holo.; K, MO, PRE, WAG, iso.).

Plants 180–350 mm high. *Corms* globose, 12–14 mm diam.; tunics of medium to coarsely textured, light brown, netted fibres. *Stem* 3 internodes long, ± straight, usually unbranched, sheathing leaves green with dry, attenuate tips, 25–40 mm long. *Cataphylls* dry and brown. *Foliage leaf* solitary, basal, up to twice as long as stem, linear, channelled, ± 3 mm wide (when opened flat), erect below, trailing distally. *Rhipidial spathes* green with dry brown attenuate tips, inner 45–65 mm long, outer ± $^1/_2$ as long. *Flowers* violet (? or pale blue), outer tepal limbs with small triangular, minutely pubescent, white nectar guides at bases outlined with dark purple, fully reflexed, claws densely dark violet pubescent, scentless; outer tepals (26–)30–40 mm long, claws ascending, ± $^1/_3$ as long as limbs; inner tepals erect, ± 24 mm long, linear to wider just below the midline, then with 2 obscure rounded lateral lobes 1–2 mm long and central, linear cusp ± 10 mm long, 20–24 mm long. *Filaments* 12–15 mm long, united below in a cylindric column 9–10 mm long, diverging in upper 3–5 mm; anthers 6–9 mm long, sometimes exceeding stigma lobes; pollen orange. *Ovary* cylindric-3-lobed, 8–10 mm long, exserted; style branches 10–12 × 2 mm, diverging, crests narrowly lanceolate-linear, 5–8 mm long. *Capsules* ellipsoid-oblong, 12–16 mm long. *Seeds* angular, prismatic, ± 1.5 mm long. *Flowering time*: mid-August to mid-September.

Distribution and ecology: a local endemic known with certainty only from south-trending slopes of a rocky hill south of De Rust in the Little Karoo, Western Cape, South Africa, but possibly also from south of Oudtshoorn; on red, sandy ground derived from Enon Conglomerate.



Distribution of ***Moraea regalis***.

Diagnosis: *Moraea regalis* is distinguished in subg. *Vieusseuxia* by the comparatively large, dark violet-purple flowers, the outer tepals 26–40 mm long with unusually long claws 10–12 mm long, and narrow, either ± linear or 3-lobed inner tepals. It is closely related to *M. unguiculata*, which has smaller flowers and almost always trilobed inner tepals with a large incurved central cusp and small but broadly obtuse lateral lobes. The slender filament column and narrow style branches are also characteristic of the *M. unguiculata* group of species. Typical plants south of De Rust have violet flowers but a collection from south of Oudtshoorn with pale blue flowers may also belong here.

144. **Moraea tricuspidata** *(L.f.) G.J.Lewis* in Journal of South African Botany 14: 89 (1948); Goldblatt 63: 765 (1976b); Goldblatt: 167 (1986a); Goldblatt et al.: 70 (2015). *Iris tricuspidata* L.f.: 98 (1782). *I. tricuspis* Thunb.: 14 (1782b), illegitimate superfluous name for *I. tricuspidata* L.f. *M. tricuspis* Ker Gawl.: 19: t. 696 (1803b), illegitimate superfluous name. *Vieusseuxia tricuspis* Fisch. ex Spreng., illegitimate superfluous name: 165 (1824); *Moraea tricuspis* Willd.: 691 (1809), illegitimate superfluous name. Type: South Africa, [Western Cape], probably foot of Devil's Peak, *Thunberg s.n.* [UPS–THUNB 1183, lecto., designated by Goldblatt 63: 765 (1976a)].

Plants 250–1 200 mm high. *Corms* 10–20 mm diam.; tunics of pale to dark brown, medium to coarse fibres. *Stem* simple or more often branched from upper axil, branches slender, held away from main axis, sheathing leaves with dry, brown, long attenuate tips, 50–70 mm long. *Foliage leaf* solitary, basal, channelled, 4–7 mm wide, exceeding stem, often trailing distally, sometimes with a large axillary cormlet. *Rhipidial spathes* green, sometimes brown in upper half, with dry attenuate apices, inner (30–)40–70 mm long, outer ± half as long. *Flowers* long-lived, white to pale creamy yellow, outer tepal limbs with brown to yellow-speckled nectar guides at bases, spreading, outer tepal claws yellow-speckled ± black, inner tepals ± brown, faintly vanilla-scented; outer tepals 17–30 × ± 15 mm, claws ± > $^1/_2$ as long as limbs, 3–5 mm wide at midpoint, pubescent, inner tepals 10–12 mm long (excluding central cusp), 3-lobed, lateral lobes obtuse, central lobe slender, obliquely coiled inward, 3–5 mm long. *Filaments* 6–7 mm long, united in lower $^2/_3$ to almost entirely in minutely papillate column; anthers ± 5 mm long. *Ovary* ± ellipsoid-ovoid, 8–12 mm long; style branches 4–7 mm long, crests 4–7 mm long. *Capsules* club-shaped, (12–)18–25 mm long. *Seeds* angular, prismatic. *Chromosome number 2n* = 12, 24. *Flowering time*: September to mid-November.

Distribution and ecology: relatively widespread in southwestern South Africa, extending from the Cederberg and Cape Peninsula to Caledon in Western Cape and from the Kammanassie Mtns in the Little Karoo through the Long Kloof to Grahamstown in Eastern Cape; usually on clay or loamy soils; flowering is stimulated by fire or clearing of surrounding vegetation. The disjunction in

Distribution of ***Moraea tricuspidata*** subsp. ***tricuspidata***, ●; subsp. ***cormifera***, ▲; subsp. ***parviflora***, ○.

the range between the western and eastern populations appears to be a true one.

Diagnosis: *Moraea tricuspidata* is readily distinguished in sect. *Vieusseuxia* by the comparatively large, white or sometimes pale creamy yellow flowers with spreading, comparatively broad tepal limbs forming a wide cup. The inner tepal limbs are 3-lobed with rounded lateral lobes and a slender central lobe up to 5 mm long, usually obliquely coiled inward (sometimes straight in subsp. *parviflora*). Closely allied to *M. bellendenii* and sometimes barely distinguishable from it without knowledge of flower colour, *M. tricuspidata* is a shorter plant, rarely exceeding 500 mm in height, whereas *M. bellendenii* has deep yellow flowers and is a taller, more slender species, 500–1 000 mm high. Slight but apparently consistent differences in size of floral parts can usually be relied upon to distinguish them. Although they have somewhat different habitat preferences and flowering times, the two occasionally grow close to one another at sites on the Cape Peninsula, where hybrids between the two occur, these intermediate in height and with pale yellow flowers.

Three subspecies are recognised. The northwestern populations, assigned to subsp. *parviflora*, have smaller flowers, sometimes pale yellow, and are often taller, standing up to 1.2 m high with up to six branches at each aerial node. The eastern populations, subsp. *cormifera*, were first mistakenly assigned to *M. bellendenii* as subsp. *cormifera*, and are distinguished by the presence of a cormlet in the axil of the foliage leaf and often slightly smaller flowers. Subsp. *cormifera* is tetraploid, $2n = 24$ (based on two population counts), while subsp. *tricuspidata* is diploid, $2n = 12$ (based on plants from the Cape Peninsula).

Subsp. *cormifera* has outer tepals ± 25 mm long (vs. up to 30 mm in subsp. *tricuspidata*) and somewhat shorter filaments, 4–5 mm long united almost entirely (vs. 6–7 mm long and united in the lower two thirds) and style branches ± 4 mm long (vs 6–7 mm).

Key to subspecies

1a Outer tepals 17–22 mm long with limbs ± elliptic, < $^1/_2$ as wide as long, 10–13 × 6–10 mm; anthers 3.5–4.0 mm long; plants of the Cederberg, Cold Bokkeveld and Piketberg. . . . . 144b. subsp. *parviflora*

1b Outer tepals 23–30 mm long with limbs ± orbicular, ± as wide as long, 13–15 × 13–15 mm; anthers ± 5 mm long; plants of the southern Western Cape and southern Eastern Cape:

2a Foliage leaf axil without with an axillary cormlet; style branches 6–7 mm long; filaments 6–7 mm long, united below, free in upper $^1/_3$. . . . . 144a. subsp. *tricuspidata*

2b Foliage leaf axil usually bearing a solitary cormlet; style branches 4–6 mm long; filaments 4–6 mm long, united ± entirely 144c. subsp. *cormifera*

144a. subsp. **tricuspidata**

Moraea confusa G.J.Lewis: 89 (1948). Type: South Africa, without precise locality or collector, illustration in Ker Gawl: t. 696 (1803b).

Plants 250–600 mm high. *Stem* simple or more often branched from upper axils. *Rhipidial spathes*: inner (30–)40–70 mm long, outer ± half as long. *Flowers* white to creamy white, outer tepal limbs with brown to yellow-speckled nectar guides at bases, outer tepal claws yellow-speckled ± black, inner tepals ± brown; outer tepals 25–30 × ± 15 mm, limbs orbicular, nearly as wide as long, claws 3–5 mm wide at midpoint, pubescent, inner tepals 10–12 mm long (excluding central cusp), central lobe of limb slender, obliquely coiled inward, 3–5 mm long. *Filaments* 6–7 mm long, united in lower $^2/_3$ to almost entirely; anthers ± 5 mm long. *Ovary* ± ellipsoid-ovoid, 8–12 mm long; style branches 4–7 mm long, crests 4–7 mm long. *Capsules* 18–25 mm long. *Chromosome number* $2n = 12$.

Distribution: restricted to the extreme southwest, from Malmesbury to Caledon.

Diagnosis: subsp. *tricuspidata* has mostly larger flowers with outer tepals up to 30 mm long and with orbicular limbs about as wide as long, and inner tepals with the central lobe 3–5 mm long and obliquely coiled inward.

144b. subsp. **parviflora** *Goldblatt & J.C.Manning* in Goldblatt et al. in South African Journal of Botany 99: 70 (2015). Type: South Africa, Western Cape, Piketberg, southern end of plateau, burned sandstone slope, 655 m, 9 Oct. 2014, *Goldblatt & Porter 14064* (NBG, holo.; K, MO, PRE, iso.).

Plants 500–1 200 mm high. *Stem* several branched, branching at all 3 or 4 aerial nodes with 2 to 6 branches at each node, branches slender, ± erect, sheathing leaves with dry, brown, long attenuate tips, 50–70 mm long. *Rhipidial spathes*: inner 40–50 mm long, outer ± half as long. *Flowers* white to creamy white, outer tepal limbs pale yellow at bases, claws darkly speckled on

pale yellow ground, inner tepals brown with yellow tips; outer tepals 17–22 mm long, claws 6–10 mm long, ascending, limbs elliptic, 10–13 × 6–10 mm, inner tepals 8–12 mm long, narrow central lobe 1–3 mm, straight or twisted. *Filaments* 3.5–5.5 mm long, free in upper 1–2 mm; anthers ± 3.5 mm long. *Style* branches ± 3 mm long, crests 4–6 mm long. *Capsules* 12–14 mm long.

Distribution and ecology: restricted to the northwestern mountains of Western Cape, occurring at the southern end of the Piketberg, the Cederberg and Cold Bokkeveld; mostly on stony sandstone slopes, flowering well after fire.

Diagnosis: subsp. *parviflora* is distinguished by the relatively small, white or pale yellow flowers with outer tepals 17–22 mm long, the spreading limb 6–10 mm wide (less than half as wide as long), filaments united almost to the apex in a column, and short style branches ± 3 mm long. The inner tepals are brown with yellow tips and shortly trilobed with a slender central cusp 1–3 mm long.

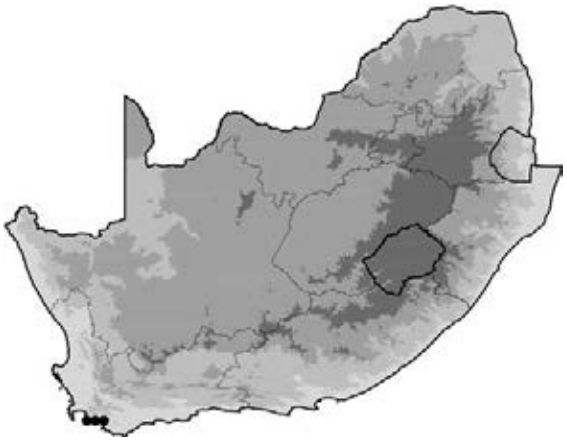
Subsp. *parviflora* bears some resemblance to *M. unguiculata* in its small flower size and tepal shape but not in the style branches nor the inner tepals, 7–12 mm long, which although similar in length have a long slender inner cusp that is usually curved inward and never twisted. The style branches of subsp. *parviflora* likewise do not accord with those of *M. unguiculata.* Apart from differences in height and floral organs, subsp. *parviflora* has capsules 12–16 mm long, also smaller than those of subsp. *tricuspidata*, mostly 18–24 mm long.

144c. subsp. **cormifera** *(Goldblatt) Goldblatt & J.C.Manning* in Goldblatt et al. in South African Journal of Botany 99: 72 (2015). *Moraea bellendenii* subsp. *cormifera* Goldblatt: 236 (1973). Type: South Africa, [Eastern Cape], Albany Division, Atherstone, *Jacot-Guillarmod 6706* (GRA, holo.; GRA, iso.).

Plants 250–350 mm high. *Stem* few-branched, at the 2 or 3 aerial nodes with 1 to 3 branches at each node, bearing a single large cormlet at foliage leaf axil. *Rhipidial spathes*: inner 30–60 mm long, outer ± half as long. *Flowers* white to creamy white, outer tepal limb bases and claws speckled brown to gold; outer tepals 23–30 mm long, limbs orbicular, 13–15 × 13–15 mm; inner tepals 11–15 mm long, 3-lobed with narrow inner lobe incurved or spirally coiled. *Filaments* united to base of anthers, 4–6 mm long; anthers ± 5 mm long. *Style branches* 4–6 mm long, crests 5–6 mm long. *Capsules* 12–13 mm long. *Chromosome number 2n* = 24. *Flowering time*: late September and October.

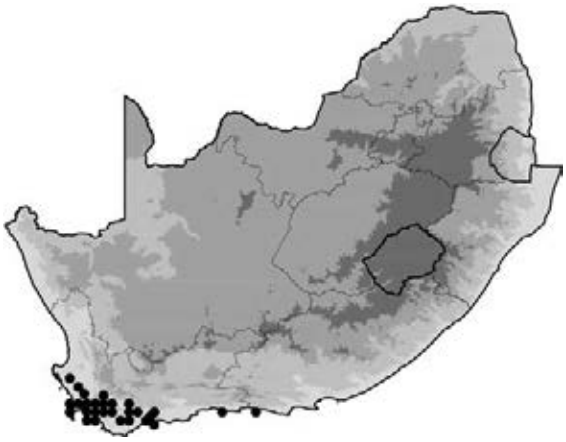
Distribution and ecology: extending from the Kammanassie foothills in Western Cape to Port Elizabeth and Grahamstown in Eastern Cape, mainly along the coast; mostly on sandy loam in grassland.

Diagnosis: subsp. *cormifera* is immediately distinguished by the single, relatively large cormlet in the axil of the single foliage leaf, a feature rare in subg. *Vieusseuxia* and not otherwise known in *Moraea tricuspidata.* The white to creamy white flowers are similar to those of subsp. *tricuspidata* in size and shape, the outer tepal limbs orbicular, 13–15 × 11–15 mm, thus as wide as long or almost so. The filaments, somewhat shorter than in subsp. *tricuspidata*, are united for their entire length, whereas they are free apically elsewhere in the species. Capsules of subsp. *cormifera*, so far as known, are smaller than in subsp. *tricuspidata*, 12–13 mm long (vs. 18–25 mm). The disjunction in the ranges of subsp. *cormifera* and subsp. *tricuspidata* appears true and not an artifact of inadequate collecting.



We note that at least populations of subsp. *cormifera* are tetraploid, $2n = 24$ (two counted, including the type population), whereas subsp. *tricuspidata* on the Cape Peninsula is diploid, $2n = 12$ (Goldblatt & Manning 2013).

145. **Moraea deltoidea** *Goldblatt & J.C.Manning* in Novon 10: 16 (2000a). Type: South Africa, Western Cape, Klein River Mtns, Vogelgat Nature Reserve, near Mainstream, 23 Nov. 1996, *Hanekom s.n.* (NBG, holo.; MO, PRE, iso.).



Plants 300–400 mm high. *Corm* globose, 8–14 mm diam.; tunics of light brown, fine fibres. *Stem* usually flexed outward at nodes, usually 3 internodes long, several-branched, with up to 3 branches per node, sheathing leaves 35–45 mm long, with dry, attenuate tips. *Foliage leaf* solitary, linear, channelled, exceeding stem, usually trailing above, 1.5–2.2 mm wide. *Rhipidial spathes* attenuate, dry and brown toward apices, inner 45–50 mm long, outer ± $^1/_2$. *Flowers* long-lived, pale creamy yellow, outer tepal limbs with dark spots at bases and on claws, slightly reflexed, claws diverging at ± 60°, forming a wide cup including stamens and style branches; outer tepals broadly obovate, 19–21 × 8–9 mm, claws ± 9 mm long; inner tepals oblanceolate, ± 14 × 4 mm. *Filaments* 4–5 mm long, united in lower $^2/_3$ in a slender column, free and diverging in upper ± 1.5 mm; anthers 4–6 mm long, diverging, slightly exceeding style branches and sometimes crests, creamy white; pollen orange. *Ovary* ± cylindric, ± 4 mm long, included or partly exserted; style branches slightly wider than anthers, 5–6 mm long, crests broadly deltoid, slightly < 1 mm long. *Capsules* club-shaped to ellipsoid, 8–10 mm long, well exserted. *Seeds* narrowly angular-prismatic, ± 2 mm long. *Flowering time*: October and November.

Distribution and ecology: restricted to the southern coast of Western Cape, South Africa, so far recorded only near Kleinmond and in the Klein River Mtns near Hermanus; on stony sandstone slopes, flowering well only after fire.

Diagnosis: a slender plant with solitary, narrow leaf, 1.5–2.0 mm wide, *Moraea deltoidea* is allied to *M. unguiculata* and *M. tricuspidata* and significant differences between them are restricted to the flowers. *Moraea deltoidea* has

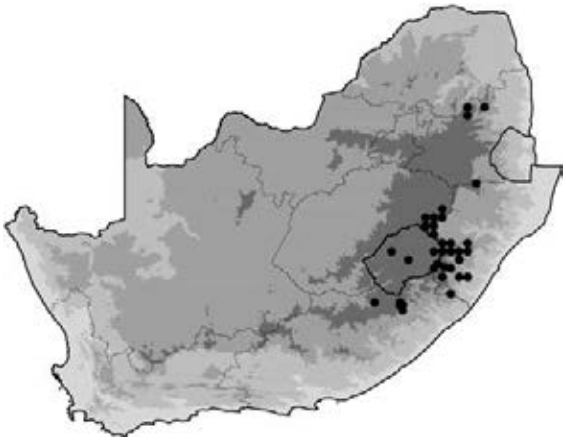
Distribution of ***Moraea deltoidea***.

Distribution of ***Moraea bellendenii***.

oblanceolate inner tepals with a broad claw and short, somewhat attenuate limb extending outward or reflexed to the same degree as the outer tepal limbs. In *M. unguiculata* the inner tepals consistently have a fairly narrow claw and trilobed limb consisting of two shorter, obtuse lateral lobes and a slender, tapering central lobe that coils inward. The style crests of *M. unguiculata* are usually well developed and lanceolate, thus longer than wide whereas in *M. deltoidea* they are deltoid, thus wider than high. *Moraea deltoidea* may also be confused with *M. tricuspidata*, which has larger, creamy white flowers with 3-lobed inner tepals in which the lateral lobes are fairly broad and obtuse and the narrow central lobe curves inward obliquely.

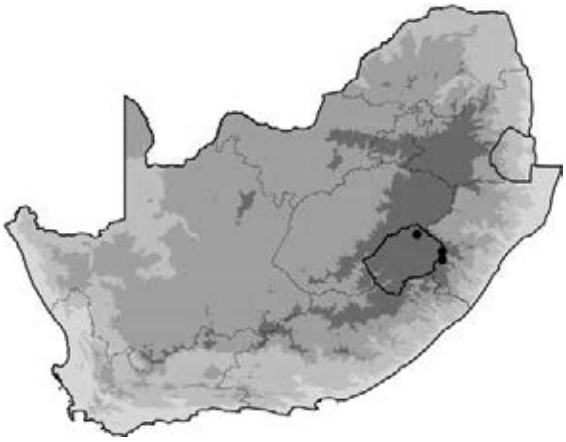
146. **Moraea bellendenii** *(Sweet) N.E.Br.* in Bulletin of Miscellaneous Information Kew 1929: 139 (1929a); Goldblatt: 767 (1976a); Goldblatt: 170 (1986a). *Vieusseuxia bellendenii* Sweet: 395 (1826a), as a new name for *M. tricuspis* var. *lutea* Ker Gawl.: t. 772 (1804e). *M. pavonia* var. *lutea* (Ker Gawl.) Baker: 59 (1892). Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 772 (1804e).

Vieusseuxia spiralis D.Delaroche: 31 (1766). Type: South Africa, without precise locality or collector, illustration in D.Delaroche: 31 (1766) [not *Moraea spiralis* L.f. (1782)].



Plants slender, 500–1000(–1200) mm high. *Corms* 14–20 mm diam.; tunics of medium to coarse, light brown fibres. *Stem* several-branched mostly from upper nodes, branches slender, upright, sheathing leaves with dry, brown, attenuate apices, 60–100 mm long. *Foliage leaf* solitary, basal, linear, 5–10 mm wide, exceeding stem, erect below, trailing distally. *Rhipidial spathes* long attenuate, with dry, brown tips, inner 50–70 mm long, outer ± $^1/_2$ as long. *Flowers* long-lived, yellow, darkly speckled on tepal claws, outer tepal limbs with speckled markings at bases, ± spreading, curving upward distally; outer tepals 22–33 × 14–18 mm, claw 9–13 mm long, broad, veined and speckled, limb ± as long as wide, inner tepals 3-lobed, 8–10 mm long (excluding inner cusp), usually ± 4 mm at widest, lateral lobes short and obtuse, inner linear, 2–4 mm long, coiled inward obliquely. *Filaments* 3–5 mm long, united in a column, diverging in upper 1 mm; anthers 4–5 mm long, dull yellow-brown; pollen yellow. *Ovary* ± cylindric, 8–10 mm long, exserted; style branches ± 6 mm long, crests 3–5(–8) mm long, narrowly triangular. *Capsules* club-shaped, 12–15 mm long. *Seeds* angular, prismatic. *Chromosome number* 2*n* = 12. *Flowering time*: October to November.

Distribution and ecology: relatively widespread in southwestern South Africa, extending from Darling on the Western Cape Atlantic Coast eastward to Knysna and Keurbooms River in Eastern Cape; most often on gravelly, granite-derived ground, but occasionally on heavy clay soils.



Diagnosis: closely allied to *Moraea tricuspidata* and often difficult to distinguish from it as dry specimens, *M. bellendenii* is a taller plant often exceeding 1 m in height with yellow flowers darkly spotted in the centre. The flowers have broad outer tepal limbs laxly spreading and curving upward distally, and 3-lobed inner tepals. As in white- to pale creamy yellow-flowered *M. tricuspidata*, the inner tepals have short, obtuse lateral lobes and a linear central cusp-like lobe that curves inward obliquely. The inner tepals of *M. bellendenii* are 8–10 mm long, whereas those of *M. tricuspidata* are 10–12 mm long. The two may also be distinguished by the filaments, 6–7 mm long in *M. tricuspidata* vs. 3–5 mm in *M. bellendenii.*

147. **Moraea trifida** *R.C.Foster* in Contributions from the Gray Herbarium 114: 40 (1936), as a new name for *M. rogersii* N.E.Br.: 344 (1929b), illegitimate homonym, not *M. rogersii* Baker (1892); Goldblatt: 233 (1973); Goldblatt: 156 (1986a). Type: South Africa, [Mpumalanga], Pilgrims Rest, *Rogers s.n.* (K, holo.).

Moraea culmea Killick: 436 (1954). Type: South Africa, [KwaZulu-Natal], Cathedral Peak, *Killick 1558* (PRE, holo.; BOL, K, LD, NBG, NU, P, iso.).

Distribution of ***Moraea trifida***.

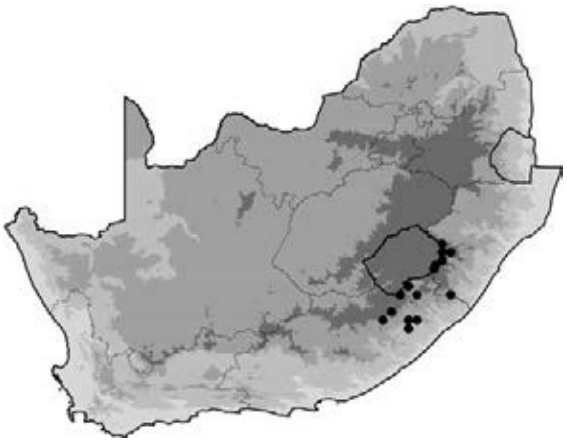
Distribution of ***Moraea dracomontana***.

Plants mostly 250–500 mm high. *Corm* 10–20 mm diam.; tunics of medium-textured, straw-coloured fibres. *Stem* simple or several branched, branches suberect, sheathing leaves 1 or 2(3), 50–60 mm long, with dry, brown, attenuate apices. *Foliage leaf* solitary, inserted well above ground; varying in length at flowering, ultimately up to 600 mm long, linear, channelled, 3–4 mm wide. *Rhipidial spathes* with dry, brown, apices, inner 40–70 mm long, outer 10–20 mm shorter. *Flowers* long-lived, pale yellow to creamy white, dotted brown to green; outer tepals lanceolate, 15–20 × 5–10 mm, limb 8–10 mm long reflexed to 60º, claws suberect; inner tepals up to 15 mm long, 3-lobed, lateral lobes, short, obtuse, inner linear, ± erect, 5–7 mm long. *Filaments* 7–9 mm long, free in upper 1.5 mm; anthers ± 4 mm long, often exceeding style branches, brown; pollen yellow. *Ovary* ± cylindric, 7–10 mm long; style branches ± 4 mm long, crests ± linear, up to 4 mm long. *Capsules* ovoid-elliptic, 18–20 mm long. *Seeds* angular prismatic. *Chromosome number* 2*n* = 12. *Flowering time*: mostly November to March.

Distribution and ecology: widespread in eastern South Africa, from Qacha's Nek in Eastern Cape to Pilgrim's Rest in northern Mpumalanga, also in Lesotho; on grassy slopes, up to 2 800 m.

Diagnosis: one of several eastern southern African species of sect. *Vieusseuxia* with 3-lobed inner tepals, *Moraea trifida* is distinguished by the dull-coloured, pale yellow to creamy brown flowers, dotted brown to green. The outer tepal limbs are strongly reflexed and the foliage leaf is distinctive in being inserted well above ground. The dull flower colouring recalls some morphs of the winter-rainfall species, *M. unguiculata,* but the resemblance is superficial. The foliage leaf in *M. unguiculata* is basal and the flowers are usually smaller.

148. **Moraea dracomontana** *Goldblatt* in Annals of the Missouri Botanical Garden 60: 231 (1973); Goldblatt: 164 (1986a). Type: South Africa, [KwaZulu-Natal], Giant's Castle, Langalibalele Pass, *Trauseld 500* (PRE, holo.; CPF, NU, iso.).



Plants 200–300 mm high, often with a collar of fibres around base. *Corm* ± 10 mm diam.; tunics of fine, light brown fibres. *Stem* simple, rarely 1-branched, 3 internodes long, sheathing leaves 2, with dry, brown, attenuate apices, 35–55 mm long. *Foliage leaf* solitary, basal, linear, narrowly channelled, sometimes appearing ± terete but with adaxial grove, ± as long as stem, 2–3 mm wide. *Rhipidial spathes* with dry, brown, attenuate apices, inner ± 50 mm long, outer slightly < $^{1}/_{2}$ as long. *Flowers* long-lived, purple, outer tepal limbs with yellow nectar guides at bases, half reflexed; outer tepals 25–30 mm long, limb 16–18 mm long, claws ± $^{2}/_{3}$ as long; inner tepals 5–10 mm long, 3-lobed, lateral lobes linear with expanded apex, obtuse, inner lobe linear, acute, either shorter or longer than lateral lobes. *Filaments* 5–6 mm long, united in lower half; anthers ± 6 mm long, mauve; pollen yellow. *Ovary* cylindric-ellipsoid, 6–9 mm long; style branches ± 8 mm long, crests lanceolate, 5–6 mm long. *Capsules* ellipsoid, 9–11 mm long. *Seeds* angular-prismatic. *Flowering time*: December to January.

Distribution and ecology: restricted to high elevations in the central Drakensberg of KwaZulu-Natal, South Africa, and adjacent Lesotho; usually in moist sites, often near streams or in the shelter of rock outcrops.

Diagnosis: *Moraea dracomontana* is distinctive among the eastern southern African species of sect. *Vieusseuxia* in its attractive dark purple flowers with yellow nectar guides, and 3-lobed inner tepals, the linear central lobe shorter or sometimes longer than the lateral lobes which have rounded, expanded tips.

149. **Moraea albicuspa** *Goldblatt* in Annals of the Missouri Botanical Garden 60: 230 (1973); Goldblatt: 163 (1986a). Type: South Africa, [KwaZulu-Natal], Drakensberg, source of Tina River, Mar. 1904, *Galpin 6846* (BOL, holo.; PRE, SAM, iso.).

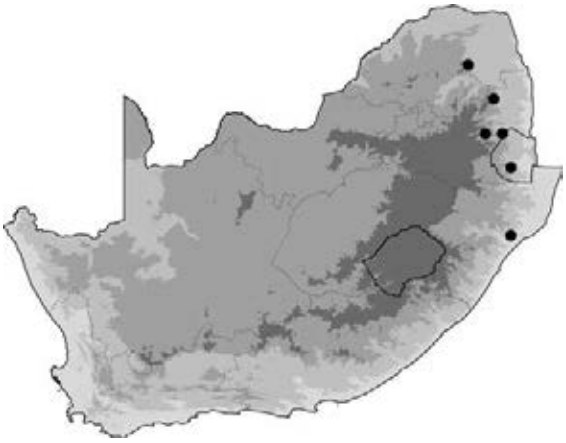
Moraea jarmilae J.J.Halda: 69, fig. 79 (2002). Type: Lesotho, Drakensberg, vicinity of Ox Bow, ± 3 100 m, 10 Mar. 1989, *J.J. & J. Halda s.n. PR4710* (PR, holo.).

Distribution of ***Moraea albicuspa***.

Plants 400–600 mm high, often with fibrous collar around base. *Corm* 14–20 mm diam.; tunics of brown fibres. *Stem* simple or 1- or 2-branched, sheathing leaves 3 or 4, with dry brown, attenuate apices, 40–60 mm long. *Foliage leaf* solitary, basal, channelled, linear, exceeding stem, often dry and broken distally. *Rhipidial spathes* with dry, brown, attenuate apices, inner 50–70 mm long, outer ± $^{2}/_{3}$ as long. *Flowers* long-lived, white to creamy yellow, outer tepal limbs with narrow, deep yellow nectar guides at bases, spreading or laxly reflexed; outer tepals 30–35 × ± 15 mm, limb 15–20 mm long, claws as long to slightly shorter, darkly speckled, smooth; inner tepals vestigial, 5–7 mm long, hair-like, sometimes obscurely 3-lobed distally. *Filaments* ± 7 mm long, united below, free and diverging in upper 1 mm; anthers 5–6 mm, white; pollen white. *Ovary* ± cylindric, 7–9 mm long; style branches ± 7 mm long, crests ± linear, 7–8 mm long. *Capsules* and *seeds* unknown. *Flowering time*: January to March.

Distribution and ecology: relatively widespread, extending from Ox Bow in Lesotho south though interior KwaZulu-Natal, South Africa, to the Drakensberg of Eastern Cape above Engcobo; in rocky sites.

Diagnosis: *Moraea albicuspa* is readily distinguished by its relatively large white to pale yellow flowers, the outer tepals with narrow, deep yellow nectar guides, and the much reduced inner tepals, hair-like cusps just 5–7 mm long, usually entire, or obscurely 3-lobed at the apex. One of the taller species of eastern southern African species of sect. *Vieusseuxia*, it stands up to 600 mm high.



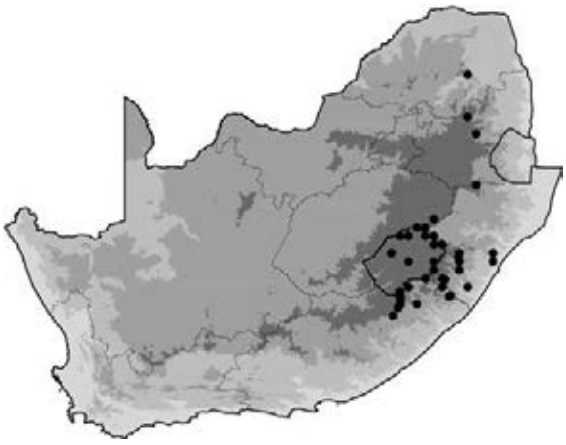
150. **Moraea marionae** *N.E.Br.* in Transactions of the Royal Society of South Africa 17: 347 (1929b); Goldblatt: 235 (1973); Goldblatt: 159 (1986a). Type: South Africa, [Limpopo], Woodbush, *Blenkiron sub Moss 15565* (K, holo.).

Moraea exilis N.E.Br.: 348 (1929b). Type: South Africa, [Mpumalanga], Saddleback, *Galpin 467* (K, holo.; PRE, iso.).

Plants small, mostly 200–300 mm high, often with a collar of fibres around base. *Corm* ± 10 mm diam.; tunic of pale straw-coloured fibres. *Stem* slender, simple, 2 internodes long, sheathing leaves green with dry, brown, attenuate apices, 24–45 mm long. *Foliage leaf* lacking or emergent at flowering, solitary, ultimately exceeding stem, terete. *Rhipidial spathes* with attenuate, brown apices, inner 33–50 mm long, outer ± $^{2}/_{3}$ as long. *Flowers* long-lived, white to pale blue, marked with lilac veins, outer tepal limbs with deep yellow nectar guides at bases, reflexed to 30–50°, claws speckled with purple spots on a broad median yellow band; outer tepals 10–20 × 6.5–7.5 mm, lanceolate, claws ascending, slightly shorter than limbs; inner tepals 7.5–12.0 mm long, erect, 3-lobed, lateral lobes short, ovoid, obtuse, inner cusp-like, linear, 3–4 mm long, curving inward, brown-dotted. *Filaments* 4–5 mm long, united or free in upper 0.5 mm; anthers 3–4 mm long, shortly exceeding style branches. *Ovary* club-shaped, ± 5 mm long; style branches diverging, ± 4 mm long, crests slender, 2–3 mm long. *Capsules* barrel-shaped, up to 10 mm long. *Seeds* unknown. *Flowering time*: August to October.

Distribution and ecology: South Africa, extending from the Woodbush near Haenertsburg in Limpopo through Mpumalanga and Eswatini to eastern KwaZulu-Natal near Eshowe; usually in montane grassland.

Diagnosis: spring-flowering *Moraea marionae* is an inconspicuous plant and even in bloom the small, white to pale blue flowers are difficult to spot in the resprouting grass. As a result it remains poorly documented over its relatively wide range. The outer tepals are only 10–20 mm long, the limbs rarely longer than 12 mm, and the inner tepals are 3-lobed with small, rounded lateral lobes and a linear central cusp that is coiled inward. The terete leaf is often absent or just emergent at flowering time and attains its full length during the summer after the capsules have ripened. No plants with fully developed leaves are known. Its relationships are most likely with *M. trifida*, also of eastern southern Africa but with larger, brown to greenish flowers, also with 3-lobed inner tepals, but a channelled leaf present at flowering.



Distribution of ***Moraea marionae***.

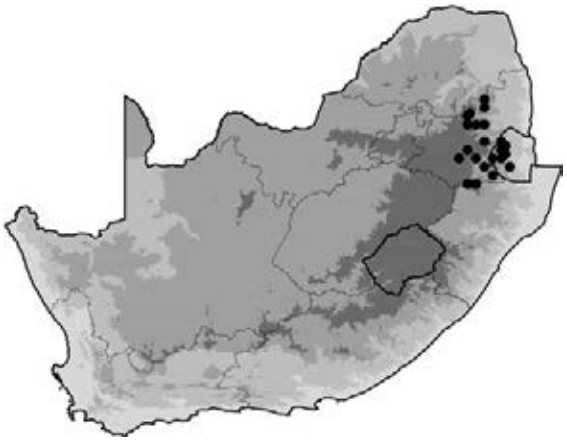
151. **Moraea modesta** *Killick* in Bothalia 6: 437 (1954); Goldblatt: 232 (1973); Goldblatt: 166 (1986a). Type: South Africa, [KwaZulu-Natal], Cathedral Peak Forest Station, *Killick 1028* (PRE, holo.).

Plants small, mostly 100–200 mm high, with fibrous collar around base. *Corm* ± 10 mm diam.; tunics of very fine, light brown fibres. *Stem* slender, rarely branched, mostly with 2(3) aerial internodes, sheathing leaves with dry, brown attenuate apices, 40–50 mm long. *Foliage leaf* solitary, basal, usually dry at flowering or absent, new leaf sometimes emergent, ultimately exceeding stem, evidently terete but with narrow adaxial groove. *Rhipidial spathes* with dry brown apices, inner 30–50 mm long, outer ± $^{2}/_{3}$ as long. *Flowers* long-lived, white to pale mauve, veined with purple, style branches and crests dark purple, outer tepal limbs with small, pale yellow nectar guides at bases, spreading; outer tepals 20–27 × 12–15 mm, limbs 12–15 mm long; inner tepals minute, 5–6 mm long, linear or trifid with inner cusp ± 1 mm long. *Filaments* 3–6 mm long, usually united for ± half their length, rarely ± free to base or free only in upper ± 0.5 mm; anthers ± 6 mm long. *Ovary* ± cylindric, 7–8 mm long, style branches ± 7 mm long, narrow, crests linear, ± 6 mm long. *Capsules* obovoid-ellipsoid, 10–12 mm long. *Seeds* angular. *Flowering time*: mainly September to November.

Distribution and ecology: occurring in Lesotho and South Africa where it extends from Machadodorp and Wakkerstroom in Mpumalanga, through eastern Free State to Mount Fletcher in Eastern Cape, especially common in KwaZulu-Natal; mainly in montane grassland at elevations of 1 500–3 000 m, most often flowering after fire.

Diagnosis: readily recognised by its small, predominantly white flowers with outer tepals up to 27 mm long, and dark purple style branches and crests, *Moraea modesta* is a low-growing species, seldom reaching more than 200 mm in height. The vestigial inner tepals are 5–6 mm long, either hair-like cusps or obscurely 3-lobed at the apex. It is one of several species that flower after the foliage leaf, produced the previous summer, is dry and dead. The leaf is sometimes retained at flowering, still attached to the base of the flowering stem but more often has decayed and is no longer evident. A new, emergent leaf is sometimes present at flowering, extending well above the stem later in the growing season.

Distribution of ***Moraea modesta***.



Populations from near Machadodorp in central Mpumalanga have more-or-less free filaments, unusual for the species, and require additional study. In other populations the filaments are united for at least half their length.

152. **Moraea pubiflora** *N.E.Br.* in Transactions of the Royal Society of South Africa 17: 348 (1929b); Goldblatt: 227 (1973) & 160 (1986a). Type: Swaziland, Hlatikulu, *Stewart s.n.* (K, holo.; PRE, iso.).

Plants mostly 450–600 mm high. *Corm* 14–20 mm diam.; tunics of dark brown netted fibres. *Stem* with 2 or 3 aerial internodes, up to 10-branched, rarely simple, sheathing leaves with dry brown, attenuate apices, 50–80 mm long. *Foliage leaf* solitary, ± basal, linear, channelled, 3–4 mm wide, either exceeding stem or trailing distally. *Rhipidial spathes* with dry, attenuate apices, inner 60–80 mm long, outer ± $^{1}/_{2}$ as long. *Flowers* long-lived, white to pale blue or lilac, outer tepal limbs with nectar guides of small brown dots at bases, lanceolate, half reflexed, inner tepals and style branches dotted green or brown; outer tepals 25–30 mm long, claws ascending, ± as long as limbs, velvety on inner surface, velvety to scabrid outside; inner tepals 3-lobed, lobes laxly spreading, subequal, ± linear, 5–7 mm long, obtuse. *Filaments* 13–15 mm long, united in a slender column, free in upper ± 2 mm; anthers 5–6 mm long, often exceeding stigma lobes, yellow; pollen white to yellow. *Ovary* ± cylindric, 6–8 mm long, usually exserted; style branches ± 6 mm long, crests linear, 4–5 mm long. *Capsules* club-shaped, 9–11 mm long. *Seeds* angular-prismatic. *Flowering time*: December to March.

Distribution and ecology: occurring in northeastern southern Africa along eastern the Escarpment, from Dullstroom in Mpumalanga south through Eswatini to Wakkerstroom; in stony grassland and low bush.

Diagnosis: up to 600 mm tall, *Moraea pubiflora* is a fairly robust species of sect. *Vieusseuxia* and most easily distinguished by inner tepals divided into 3 subequal slender, spreading, brown-speckled lobes, the outer two expanded at the tips and obtuse, and the inner slender with a ± acute apex and curving upward distally. The outer tepal limbs are typically white but the claws, inner tepals and style branches and crests are densely dotted with dark brown on a pale yellow to greenish background. A particularly unusual feature of the species is the scabrid to velvety surface of the outside of the outer tepals. Similar in flower structure, although smooth or

Distribution of ***Moraea pubiflora***.

papillate on the outside of the outer tepals, *M. brevistyla* has similarly coloured but much smaller flowers, the outer tepals 18–20 mm long and the filaments just 5–7 mm long compared with outer tepals 25–30 mm long and filaments 13–15 mm long in *M. pubiflora*.

153. **Moraea brevistyla** *(Goldblatt) Goldblatt* in Annals of Kirstenbosch Botanical Garden 14: 162 (1986a). *M. pubiflora* subsp. *brevistyla* Goldblatt: 229 (1973). Type: South Africa, [KwaZulu-Natal], Cathkin Park, *Galpin s.n.* (BOL [30823], holo.).

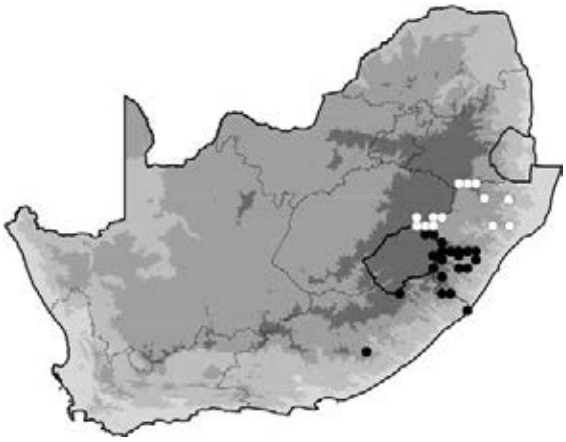
Plants mostly 250–500 mm high. *Corm* ± 15 mm diam.; tunics of dark brown, relatively fine, netted fibres. *Stem* of 2 to 4 aerial internodes, several-branched, sheathing leaves with dry brown, attenuate apices, 35–70 mm long. *Foliage leaf* solitary, ± basal, linear, channelled, 2–4 mm wide, ± erect, exceeding stem, trailing distally. *Rhipidial spathes* with dry, attenuate apices, inner 40–75 mm, outer ± $^1/_2$ as long. *Flowers* long-lived, predominantly white, sometimes flushed blue to mauve with age, tepals grey to pale purple on reverse, outer tepal limbs with nectar guides of small brown dots at bases, lanceolate, spreading to half reflexed, claws smooth or papillate, inner tepals and style branches yellow finely dotted green or brown; outer tepals 16–30 mm long, claws ascending, ± as long as claws, bearded on inner surface, papillate or smooth on outer surface; inner tepals 3-lobed, lateral lobes slender, laxly spreading, lateral lobes slender, 4–10 mm long, obtuse, erect, inner lobe linear, acute, 4–6 mm long, arching outward. *Filaments* 5–7 mm long, united in a slender column, free in upper 0.5–3.0 mm; anthers 4–5 mm long, often exceeding stigma lobes, yellow; pollen yellow. *Ovary* ± cylindric, 5–6 mm long, usually exserted; style branches 4 mm long, crests linear, 2–5 mm long. *Capsules* club-shaped-ovoid, 6–10 mm long. *Seeds* unknown. *Flowering time*: late November to March.

Distribution and ecology: eastern South Africa, Lesotho and Eswatini from the Mpumalanga/northern KwaZulu-Natal Border through western Free State and Lesotho to Kokstad in southern KwaZulu-Natal and to the Elandsberg and Katberg in Eastern Cape; fairly common in middle and upper elevation grassland.

Diagnosis: *Moraea brevistyla* is recognised but the moderate-sized to small white, sometimes blue to mauve flushed flowers, the outer tepals only 16–30 mm long and with a spreading to half reflexed limb 9–20 mm long, and characteristic inner tepals with the limbs consisting of three linear, subequal lobes with the inner lobe spreading and arching upward distally. It is closely allied to the Mpumalanga and Eswatini *M. pubiflora*, with strikingly similar but substantially larger white flowers, the outer tepals 25–30 mm long and disproportionately long filaments with a column ± 13 mm long vs. 4 to 9 mm in *M. brevistyla*. *Moraea pubiflora* also has unusual scabrid or velvet outer surfaces of the large outer tepals, whereas in *M. brevistyla* the reverse of the outer tepal claws is smooth or minutely papillate. The ranges of the two overlap in the Wakkerstroom area of the Mpumalanga–KwaZulu-Natal Border, but the two species remain distinct morphologically. *Moraea brevistyla* is parapatric in the Sentinel area of the northern high Drakensberg with the very similar *M. vigilans* and their differences are outlined below. Two subpecies are recognised, the typical extending from Royal Natal National Park and Lesotho to Eastern Cape, and subsp. *papillosa* in the northern part of the range, from the Sentinel and Golden Gate National Park to Eswatini.

Key to subspecies

1a Outer tepals 16–22 mm long; outer tepal claws smooth (rarely papillate) outside; outer rhipidial spathe 40–50 mm long; filaments 4–6(7) mm long. . . . . 153a. subsp. *brevistyla*



1b Outer tepals 25–30 mm long; outer tepal claws papillate outside; outer rhipidial spathe (50)60–80 mm long; filaments 8–9 mm long. . . . . 153b. subsp. *papillosa*

153a. subsp. **brevistyla**

Plants with outer rhipidial spathes 40–50 mm long; *Flowers* with outer tepals 16–22 mm long, with claws smooth (rarely papillate) outside; inner tepal claws 3–5 mm long. *Filaments* 4–6(7) mm long, free in upper 0.4–1.5 mm; anthers 4–5(6) mm long.

Distribution and ecology: extending from Royal Natal National Park near Tendele to the KwaZulu-Natal Midlands and southern Lesotho, and Elandsberg and Katberg in Eastern Cape; in rocky grassland.

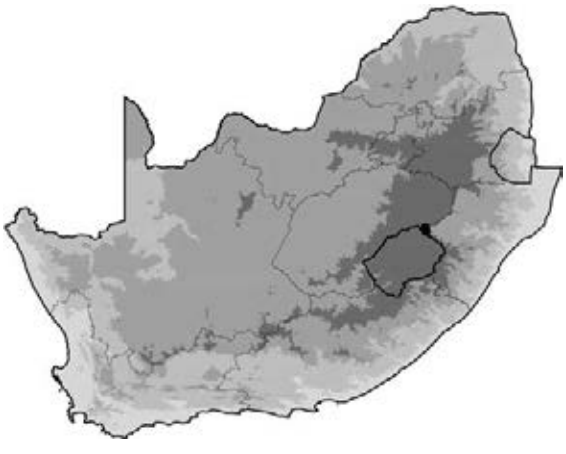
Diagnosis: subsp. *brevistyla* is the smaller-flowered subspecies, thus distinguished by the outer tepals 16–22 mm long with the claws smooth outside (rarely minutely papillate), inner tepal claws short, 3–5 mm long, and filaments 4–6(–7) mm long. The inner rhipidial spathes are also relatively short, 40–50 mm long.

Distribution of ***Moraea brevistyla*** subsp. ***brevistyla***, ●; subsp. ***papillosa***, ○.

153b. subsp. **papillosa** *Goldblatt & J.C.Manning*, new subspecies. Type: South Africa, Free State, Mont aux Sources, slopes, *Flanagan 2037* (PRE, holo.; BOL, SAM, iso.)

Plants with outer rhipidial spathes (50)60–80 mm long; *Flowers* with outer tepals 25–30 mm long, with claws papillate outside; inner tepal claws 5.0–7.5 mm long. *Filaments* 7–9 mm long, free in upper 2–3 mm; anthers 4–5 mm long.

Distribution and ecology: extending from eastern Free State at Golden Gate National Park north to Wakkerstroom and the Mpumalanga–KwaZulu-Natal border area in rocky grassland.



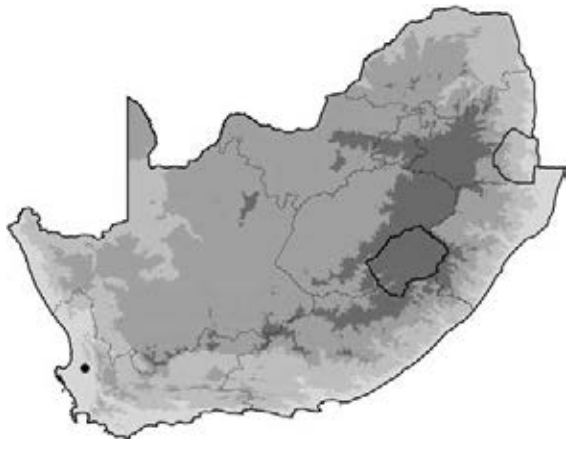
Diagnosis: subsp. *papillosa* is distinguished by the larger flowers with outer tepals 25–30 mm long with the claws always papillate outside, inner tepal claws 5.0–7.5 mm long, and filaments 7–9 mm long. The inner rhipidial spathes are also longer, mostly 60–80 mm long, occasionally only 50 mm long.

154. **Moraea vigilans** *Goldblatt & J.C.Manning* in Novon 10: 17 (2000a). Type: South Africa, Free State, slopes of The Sentinel, 15 Feb. 1999, *Goldblatt & Manning 11046* (NBG, holo.; K, MO, PRE, iso.).

Plants 500–700 mm high. *Corm* globose, 8–15(–20) mm diam.; corms with tunics of fine, light brown fibres. *Stem* 3 or 4 internodes long, usually branched at 2 upper internodes, with up to 4 branches per node, sheathing leaves 42–50 mm long, green with dry, brown, attenuate apices. *Foliage leaf* solitary, ± basal, linear, channelled, erect, often ± as long as stem, often bent and trailing above, 3–4 mm wide. *Rhipidial spathes* with dry, brown, acute(–attenuate) apices, inner 50–55 mm long, outer ± $^2/_3$ as long. *Flowers* long-lived, white, often faintly tinged with mauve especially reverse of tepals, outer tepal limbs with bluish bands or spots toward bases, speckled with mauve over lower $^1/_3$–$^2/_3$, rarely over entire surface, claws banded with mauve lines, inner tepals brown with ± white dots, sweetly scented; outer tepals 24–28 × 14–17 mm, claws ascending, 7–9 mm long, limb ± broadly ovate, spreading; inner tepals erect, 8.5–10.0 mm long, 3-lobed, lateral lobes spathulate, 5–6 mm long, inner lobe filiform, arching outward, 4–6 mm long. *Filaments* 4.0–4.5 mm long, united in a column ± 3 mm long, diverging in upper 1.0–1.5 mm; anthers ± 4 mm long, bluish, apiculate; pollen yellow. *Ovary* oblong-cylindric, 5–6 mm long; style branches 4–5 mm long, crests narrowly triangular 3–4 mm long, brown. *Capsules* oblong, 12–15 × ± 5 mm. *Seeds* angular-prismatic, ± 1.2 mm long. *Flowering time*: January to mid-February.

Distribution and ecology: a narrow endemic of the northern high Drakensberg, so far recorded only on the slopes of The Sentinel, which lies close to the borders of KwaZulu-Natal and Free State in South Africa (probably also in Lesotho); locally common on steep, moist slopes on basalt outcrops in peaty loam.

Diagnosis: *Moraea vigilans* is evidently closely related to the widespread *M. brevistyla* but the two are readily distinguished when alive. They grow within a few metres of one another on the slopes of The Sentinel where *M. brevistyla* grows on deeper soils on grassy slopes and *M. vigilans* is confined to basalt outcrops. The most striking difference between them is the broadly ovate to orbicular outer tepal limbs of *M. vigilans*, spreading or ascending up to 30°, whereas the narrower, oblanceolate-obovate outer tepal limbs of *M. brevistyla* are weakly to strongly reflexed and the limbs are usually pinched downward in the proximal third. Less apparent are the shorter outer tepal claws of *M. vigilans*, 7–9 mm long, and shorter filament column and style branches, the latter reaching opposite the apex of the outer tepal limb. The short, brownish crests extend upward above the base of the tepal limbs for up to 4 mm. The outer tepal claws of *M. brevistyla* are 9–11 mm long, the filaments and anthers are longer than those of *M. vigilans* (11–12 mm combined length in *M. brevistyla* vs. ± 8.5 mm in *M. vigilans*), and the style branches usually exceed the outer



Distribution of ***Moraea vigilans***.

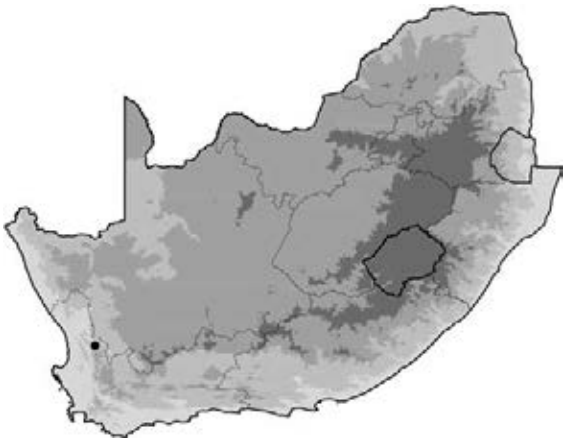
tepal limbs by up to 3.5 mm, while the white style crests extend upward a further 5 mm. Vegetatively the two species appear virtually identical but the stems of *M. vigilans* are somewhat willowy and incline toward the ground, whereas the stems of *M. brevistyla* are usually stiffly erect.

155. **Moraea decipiens** *Goldblatt & J.C.Manning* in Bothalia 42: 115 (2012b). Type: Western Cape, Piketberg, Farm Noupoort, south-trending, rocky sandstone slope in shallow pockets of soil, 2 Nov. 2011, *Goldblatt & Porter 13709* (NBG, holo.; K, MO, PRE, iso.).

Plants 300–450 mm high. *Corm* 9–12 mm diam.; tunics of pale, fine fibres. *Stem* simple, rarely 1-branched, sheathing leaves 45–55 mm long, green with dry attenuate apices. *Foliage leaf* solitary, linear, channelled but with margins folded together, 0.7–1.5 mm diam., exceeding stem, often trailing above, sometimes with cormlet in axil. *Rhipidial spathes* with dry, brown, attenuate tips, inner 35–40 mm long, outer ± half as long. *Flowers* long-lived, purple, outer tepal limbs with white, wedge- or V-shaped, minutely papillate nectar guides at bases, dark purple in centre, laxly spreading; outer tepals 20–23 mm long, claws 8–9 mm long, with wide, dark violet median stripe, limb 12–15 × 6–8 mm; inner tepals 7–10 mm long, ± erect, 3-lobed, lateral lobes rounded, central lobe 3–4 mm long, tapering to attenuate, laxly twisted apex. *Filaments* 3.5–4.0 mm long, united in lower ± 2 mm; anthers 4.5–6.0 mm long, sometimes shortly exceeding stigma lobe, dark purple-black; pollen orange-red. *Ovary* narrowly oblong, 7–9 mm long, usually exserted in mature flower; style branches 7–9 × 1–2 mm, crests narrowly wedge-shaped, ± 5 mm long, erect. *Capsules* narrowly ovoid, 8–11 mm long. *Seeds* angular, 1.2–1.5 mm long, angles forming raised, pale, ± spongy ridges. *Flowering time*: late October to mid-November.

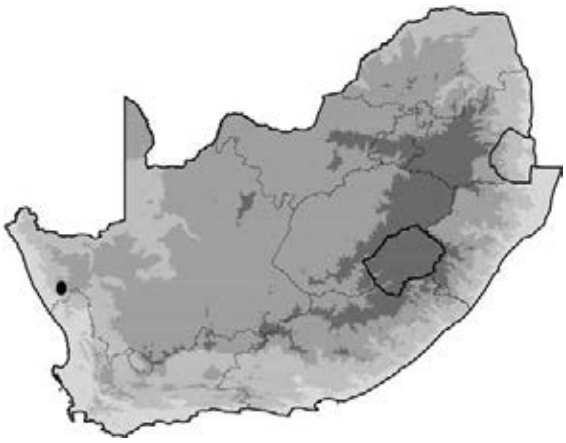
Distribution and ecology: restricted to the eastern half of the Piketberg in Western Cape, South Africa, evidently at middle elevations; on stony sandstone slopes in shallow pockets of soil among restiads and low shrubs.

Distribution of ***Moraea decipiens***.



Diagnosis: named for the deceptive appearance of the flowers to those of the common and widespread *M. tripetala*, *M. decipiens* differs in having the inner tepal claws distinctly expanded distally, sometimes into three rounded lobes, with the limb linear-attenuate and curved inward distally. The inner tepals recall those of *M. unguiculata* and *M. algoensis* but unlike those species, the filaments of *M. decipiens* are ± 3.7 mm long and shortly united for ± 2 mm and the style branches diverge above the fused part of the filaments whereas in *M. unguiculata* and *M. algoensis* the filaments are united almost to their apices in a well-developed thick column. The style branches of *M. decipiens* are relatively short, ± 7 mm long, whereas those of *M. tripetala* are usually 9–12 mm long. The markings on the outer tepal limbs are also notable, consisting of a wedge- or V-shaped white zone surrounding a dark purple basal mark continuous as a wide, longitudinal purple streak on the claws. Typical *M. tripetala* occurs at higher elevations on the Piketberg but flowers some two to four weeks earlier.

156. **Moraea petricola** *Goldblatt & J.C.Manning* in Bothalia 43: 158 (2013). Type: South Africa, Western Cape, Pakhuis peaks, ± 5 km NW of Kliphuis, Rheboksvlei Extension 185, 925 m, 25 Oct. 2008, *Helme 5726* (NBG, holo.).



Plants ± 30 mm high. *Corm* globose, ± 12–16 mm diam.; tunics of grey-brown, medium-textured, netted fibres, accumulating in fibrous collar around base of stem. *Stem* with 3 aerial internodes, unbranched, sheathing leaves with dry attenuate apices, 35–40 mm long. *Foliage leaf* solitary, basal, linear, narrowly channelled, $^{2}/_{3}$ to ± as long as stem, ± 2 mm wide opened flat. *Rhipidial spathes* with dry, attenuate apices, inner ± 40 mm long, outer ± half as long. *Flowers* lasting 3 days, purple, outer tepal limbs with white, wedge-shaped nectar guides at bases, laxly spreading to weakly reflexed; outer tepals ± 20 mm long, claws ± 6 mm long, ascending; inner tepals ± 9 mm long, limbs spreading, ± 4 mm long, 3-lobed with long, tapering central cusp and short, rounded, obtuse lateral lobes, claws ± 5 mm long, ascending, tapering from narrow base to wide apex. *Filaments* ± 8 mm long, united in smooth cylindric column in lower ± 3 mm, diverging in upper 5 mm; anthers ± 5 mm long, dark purple; pollen red. *Ovary* ± cylindric, ± 8 mm long, exserted; style branches ± 8 × 2 mm long, ascending, held above subtending limbs, crests narrowly wedge-shaped, ± 4 mm long. *Capsules* and *seeds* unknown. *Flowering time*: October to mid-November.

Distribution and ecology: evidently restricted to higher elevations in the mountains to the north of Pakhuis Pass in the northern Cederberg in Western Cape, South Africa; on stony, sandstone slopes.

Diagnosis: *Moraea petricola* is a typical member of subg. *Vieusseuxia* in its solitary basal leaf and 3-lobed inner tepals. The purple flowers are assumed to be long-lasting and the outer tepal limbs have narrow, white, wedge-shaped nectar guides edged with dark purple. The

Distribution of ***Moraea petricola***.

Distribution of ***Moraea helmei***.

inner tepals have unusually broad, 3-lobed limbs with a prominent, linear, reflexed central cusp and rounded lateral lobes. The flowers in general recall *M. decipiens,* particularly in the flower colour and shape but have much longer filaments, ± 8 mm long vs. 3.5–4.0 mm in *M. decipiens*, a style ± 5 mm long (vs. ± 2 mm) and shorter tepal claws, 5–6 mm (vs. 8–9 mm). The relatively long style branches are held well above the subtending outer tepals limbs, whereas in *M. decipiens* the style branches are appressed to the tepal claws and the inner tepals curve upward rather than having reflexed limbs with the central cusp directed downward. Additional collections of this rare species are needed to confirm current observations based on limited material.

157. **Moraea helmei** *Goldblatt & J.C.Manning* in Bothalia 42: 116 (2012b). Type: South Africa, Northern Cape, Kamiesberg south of Farm Karas, near top of Langkloof, 1 125 m, 28 Oct. 2011, *Goldblatt & Porter 13688* (NBG, holo.; MO, iso.).

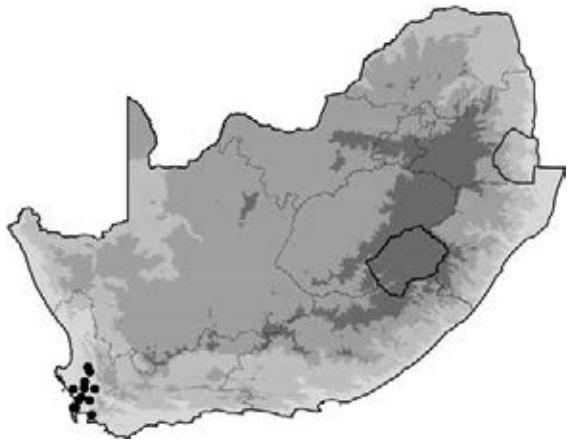
Plants 250–350 mm high. *Corm* 9–12 mm diam. with pale, fibrous tunics. *Stem* simple or with 1 or 2 short branches. *Foliage leaf* solitary, linear, channelled, remaining ± erect, ± 2 mm wide when opened flat; sheathing leaves 2 or 3, attenuate, becoming dry at tips, 35–45 mm long. *Rhipidial spathes* with dry, attenuate tips, inner 40–45 mm long, outer ± $^{2}/_{3}$ as long. *Flowers* pale blue to violet, outer tepal limbs darkly veined, with narrowly triangular, shortly velvety, yellow nectar guides at bases of outer tepal limbs outlined pale blue to dark violet; outer tepals 21.0–23.5 mm long, claw 8–10 mm long, with a shallow raised marginal tooth shortly below apex, limbs 12.5–13.5 × 7–8 mm; inner tepals short, ± 4 mm long, 3-forked in upper 1 mm, inner lobe slightly larger than laterals, ± puberulous. *Filaments* ± 4 mm long, united in puberulous column in lower 1.5 mm; anthers ± 6.5 mm long, dark violet; pollen yellow. *Ovary* narrowly ellipsoid, ± 7 mm long, initially partly included, ultimately fully exserted; style branches linear, 9 × 1 mm, crests ± 7 mm long, erect. *Capsules* and *seeds* unknown. *Flowering time*: late October to mid-November.

Distribution and ecology: known from only two sites in the Kamiesberg in central Namaqualand in Northern Cape, South Africa, at the upper end of the Langkloof; in seasonally moist places at ± 1 125 m elevation.

Diagnosis: the filaments, united for 1.5 mm and slightly more than one third their length, and the short style, ± 2 mm long, place *Moraea helmei* among the several species of the *Moraea tripetala* complex, but its inner tepals are relatively well developed, ± 4 mm long, and expanded distally into three short, subequal lobes (vs. linear and usually cusp-like in *M. tripetala* and its immediate allies). The puberulous filament column appears to be unique in the complex. The trilobed inner tepals of *M. helmei* recall those of *M. unguiculata*, which has a longer, narrow, coiled central lobe and rounded lateral lobes, but the filaments of this species are united in a prominent column for more than half their length. A peculiarity of the outer tepal claws of *M. helmei* is the pair of shallow tooth-like marginal projections just below the apices – the tepal claws in other species are straight or bowed outward and usually have plane margins.

158. **Moraea mutila** *(C.H.Bergius ex Eckl.) Goldblatt & J.C.Manning* in Bothalia 42: 119 (2012b). *Vieusseuxia mutila* C.H.Bergius ex Eckl.: 12 (1827). *M. tripetala* var. *mutila* Baker: 23 (1896), as new name for *V. mutila* Licht. ex Klatt: 621 (1866), illegitimate homonym, not *V. mutila* C.H.Bergius ex Eckl. (1827). Type: South Africa, [Western Cape], vicinity of Camps Bay, *Bergius 15* (S [7238], holo.).

Iris tripetala Thunb.: 13 (1782b, Dec.), illegitimate superfluous name for *M. tripetala* L.f. (1782, Apr.). Type: South Africa, without precise locality, *Thunberg s.n.* (UPS–THUNB, syn.).



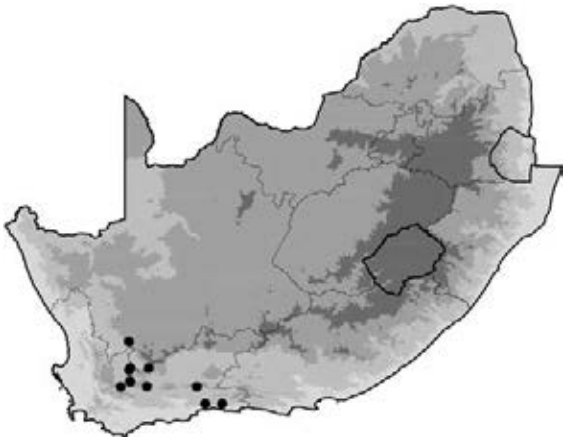
Moraea punctata Baker: 1003 (1904b). Type: South Africa, [Western Cape], Piketberg Road [Gouda], 17 Aug. 1897, *Schlechter 4851* (K, lecto., designated by Goldblatt: 751 (1976a); B, GRA, PRE, isolecto.).

Moraea monophylla Baker: 24 (1906). Type: South Africa, [Western Cape], Olifants River, Clanwilliam, Aug. 1894, *Penther 685* [K, lecto., designated by Goldblatt: 751 (1976a)].

Plants 150–300 mm high, usually with fibrous collar around base. *Corm* mostly 10–15 mm diam.; tunics of medium to coarse fibres, vertical members often thickened below into claw-like ridges. *Stem* simple, rarely 1-branched, sometimes pilose, sheathing leaves usually 2, with dry, attenuate apices, 20–40 mm long. *Foliage leaf* solitary, linear, shallowly channelled below, often becoming flat and slightly twisted in distal $^1/_3$, ± $^1/_2$ to as long as stem, 3–5(–7) mm wide, smooth or hairy abaxially or on margins. *Rhipidial spathes* with dry, attenuate apices, sometimes velvety, inner 35–40(–45) mm long, outer ± $^1/_2$ as long. *Flowers* long-lived, pale blue or white, outer tepal limbs with triangular, white to pale yellow nectar guides with dark blue dots at bases, often edged with darker colour, velvety (or smooth?), reflexed ± 45°, outer tepals 23–27 × ± 10 mm, claws ascending, 9–12 mm long, limbs ovate, margins recurving later; inner tepals sublinear slightly expanded in middle, sometimes as rounded lobes, 7.5–12.5 mm long. *Filaments* 3.0–3.5 mm long, united for 0.5–1.5 mm; anthers 4.5–6.5(–7.5) mm long; pollen red or yellow. *Ovary* narrowly ellipsoid, 7–8 mm long; style branches 7–9 mm long, crests linear, 8–10 mm long. *Capsules* ellipsoid, 15–17 × ± 5 mm. *Seeds* angular, light brown, ± 1.8 mm long, testa spongy, angles narrowly winged. *Chromosome number* 2*n* = 12. *Flowering time*: August to mid-September.

Distribution and ecology: centred in the western lowlands of Western Cape, South Africa, from the Cape Peninsula to the Piketberg and locally inland to the Tulbagh Valley; on shale and loamy clay soils, probably also on granites, usually in renosterveld.

Diagnosis: early-blooming *Moraea mutila* is recognised by the pale blue, rarely white flowers with linear to narrowly lanceolate inner tepals 7.5–12.5 mm long, erect below and spreading distally. Often difficult to see in preserved specimens, the inner tepals are usually slightly wider in the midline and sometimes expanded into rounded lobes near the base of the spreading distal half. The flowers otherwise seem little different from those of the more common *M. tripetala*, but the pilose nectar guides are usually white or palest yellow and dotted with dark blue to purple, whereas the nectar guides of *M. tripetala* are more often yellow, edged with dark blue or purple. The leaf is typically relatively short, in most collections shorter than the stem, and widely channelled, sometimes plane in the distal half. Plants sometimes have leaves velvety on the abaxial surface and velvety spathes. The pubescence is evidently variable in populations, thus a character of limited value for identification. Leaves of *M. tripetala* are almost invariably hairless.



Distribution of ***Moraea mutila***.

Possibly belonging here are pale blue-flowered plants from the western lower slopes of Sir Lowry's Pass with the inner tepals trilobed as in *Moraea mutila* but the filaments united for ± 2.5 mm and the style 4 mm long. Alternatively these plants may be hybrids between *M. tripetala* and *M. unguiculata*.

159. **Moraea cuspidata** *Goldblatt & J.C.Manning* in Bothalia 42: 120 (2012b). Type: South Africa, Western Cape, near Farm Fortuin, north of Matjiesfontein, near shaded rest stop (co-blooming with *M. amabilis*), 28 Sept. 2009, *Goldblatt & Porter 13462* (NBG, holo.; MO, iso.).

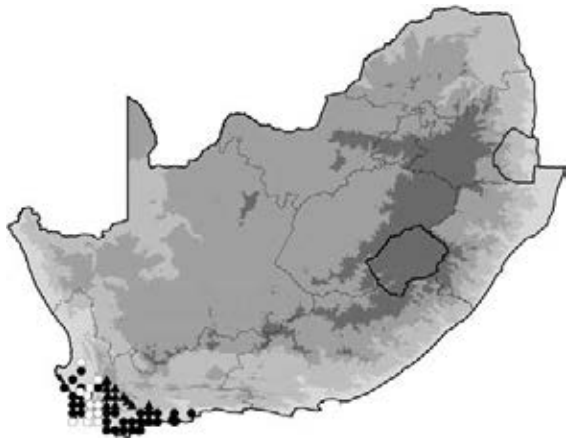
Plants 180–300 mm high, with collar of tough fibres around base. *Corm* 15–25 mm diam., without cormlets at base; tunics of brown to ± black, tough, medium to coarse fibres. *Stem* simple or 1(2)-branched exceptionally with up to 6 branches, sheathing leaves with dry attenuate tips, (30–)40–55 mm long. *Foliage leaf* solitary, linear(–linear-filiform), channelled, usually V-shaped in section, leaf halves closely appressed in dry conditions, 1.5–3.0 mm wide (opened flat), erect or trailing distally. *Rhipidial spathes* with attenuate, dry tips, inner (40–)50–80 mm long, outer ± half as long. *Flowers* long-lived, pale blue, mauve or violet blue, outer tepal limbs with large white, velvety nectar guides dotted and usually edged with dark violet at bases, lanceolate, half reflexed; outer tepals (20–)26–34 × 10–16 mm, claws (8–)10–12 mm long, usually speckled with dark blue to violet dots or purple in midline; inner tepals linear, (8–)10–15 mm long, ascending below, distal $^1/_3$–$^1/_2$ usually spreading (± erect when short). *Filaments* (3–)4–6 mm long, united basally for 0.5–1.8 mm; anthers 4–8 mm long, violet; pollen red (rarely white). *Ovary* ellipsoid, 11–15 mm long; style branches 8–10 mm long, crests 5–8 mm long, linear. *Capsules* ovoid-ellipsoid, 14–16 mm long. *Seeds* angular, 1.8–2.0 mm long, light brown, testa spongy, thickened on angles. *Chromosome number* 2*n* = 12. *Flowering time*: mid-September and October.

Distribution and ecology: fairly widespread in southwestern South Africa, extending from the southern

Distribution of ***Moraea cuspidata***.

Roggeveld and Klein Roggeveld in Northern Cape to the Bonteberg and Voetpadsberg near Touws River in Western Cape and in the Swartberg and higher mountains of the Little Karoo (an apparent gap in the range between the Roggeveld and the Swartberg may be the result of incomplete collecting); in fairly arid habitats, in mountain renosterveld and dry, marginal fynbos, usually in sandy or sandy loam soils derived from sandstones of the Cape and Karoo Systems.

Diagnosis: closely allied to *Moraea tripetala*, *M. cuspidata* is distinguished by the linear inner tepals up to 15 mm long (rarely less than 10 mm), spreading in the distal half, and usually with a particularly narrow foliage leaf with the halves usually tightly appressed in dry conditions. The brown to almost black corm tunics consist of thickened vertical fibres sometimes with raised ridges, and form a collar of stiff fibres around the base of the stem. The flowers are pale blue to violet with the large, velvety nectar guides spotted with dark blue on a white background. The filaments are usually united for 1.0–1.5 mm but occasionally less, and are ± as long as or slightly shorter than the dark purple anthers that bear red pollen. Capsules (where known) are relatively large, 14–16 mm long and the seeds are also relatively large, 1.8–2.0 mm long and unusual in having a pale, spongy testa much thickened into prominent ridges on the angles.



The species is sympatric at some sites and even co-blooming with smaller-flowered *Moraea amabilis* (also allied to *M. tripetala*) but that species has a broadly channelled foliage leaf, sometimes plane distally and often pilose on the abaxial surface, and consistently short, hair-like inner tepals typically 1.5–2.0 mm long. At sites where they have been recorded growing together pollen of *M. amabilis* is white, contrasting with the orange-red pollen of *M. cuspidata.* An outlying record of *M. cuspidata* from Perdekloof, southeast of Oudtshoorn, probably belongs here. The flowers are exceptionally small, the inner tepals are 8–9 mm long, otherwise consistent with the species.

160. **Moraea tripetala** *(L.f.) Ker Gawl.* in Curtis's Botanical Magazine 19: t. 702 (1803c); Goldblatt: 751 (1976a); Goldblatt: 152 (1986a) [including *M. amabilis, M. grandis* & *M. mutila*]; Goldblatt & Manning: 123 (2012b). *Iris tripetala* L.f.: 92 (1782). *Vieusseuxia tripetaloides* DC.: 138 (1803), illegitimate superfluous name for *Iris tripetala* L.f. (1782). *Vieusseuxia tripetala* (L.f.) Voigt: 602 (1845). Type: South Africa, [Western Cape], without precise locality, *Thunberg s.n.* [UPS–THUNB 1186, lecto., designated by Goldblatt: 751 (1976a)].

Plants (140–)250–450 mm high. *Corm* mostly 8–15 mm diam., without cormlets at base; tunics of moderately coarse, wiry, usually dark grey fibres. *Stem* simple or 1- or 2(6)-branched, sheathing leaves with dry, brown attenuate apices, mostly 45–60 mm long. *Foliage leaf* solitary (rarely 2 in subsp. *violacea*), leathery, narrowly channelled, C- or V-shaped in section, up to 5 mm wide, usually exceeding stem and trailing distally. *Rhipidial spathes* with dry attenuate apices, inner 35–65(–70) mm long, outer ± $^1/_2$ as long. *Flowers* long-lived, pale blue, purple or violet, outer tepal limbs with nectar guides at bases triangular, either yellow edged with violet, or white-dotted with dark blue and edged with darker blue, spreading at 45°, lightly honey-scented, unscented or strongly scented of carnation (subsp. *violacea*); outer tepals 20–30(–32) × ± 8–13 mm, claws 9–12 mm long, limbs obovate, 11–18 mm, inner tepals hair-like to ± linear, 1–4(–6) mm long, or lacking. *Filaments* 4–6 mm long, united for 0.5–1.5 mm, occasionally (southern populations) ± free; anthers 4–7 mm long; pollen usually orange-red, rarely white. *Ovary* 4–9 mm long; style branches 9–12 mm long, crests ± linear, 5–12 mm long. *Capsules* ellipsoid, 8–14 mm long. *Seeds* ± angular, 1.0–1.3 mm long, with raised, golden-brown ridges. *Chromosome number* 2*n* = 12. *Flowering time*: mainly August to December (January).

Distribution and ecology: widespread in Western Cape, South Africa, extending from Aurora on the west coast to near Knysna in the east, and inland to Ceres and the Little Karoo; in a variety of habitats including limestone flats in fynbos, to neutral and acid sands in sandveld, to loamy alluvium in coastal and montane fynbos; interior populations from the Warm Bokkeveld (Ceres) and western Little Karoo, here segregated as subsp. *violacea*, occur in significantly drier habitats on clay soils in renosterveld; populations segregated as subsp. *jacquiniana* are mostly montane and occur above 500 m but at lower elevations in the southern Cape Peninsula, and flower significantly later in the year.

Diagnosis: *Moraea tripetala* is distinguished by blue to violet flowers with inner tepals reduced to hair-like, filiform cusps mostly 2–4 mm long (rarely up to 6 mm long), and filaments united for up to 1.5 mm and occasionally free. The outer tepal limbs are broadly ovate, longer than wide and oriented ± 45° below horizontal. The corm tunics are dark brown to grey and usually composed of medium-textured fibres. The production

Distribution of ***Moraea tripetala*** subsp ***tripetala***, ●; subsp. ***jacquiniana***, ○; subsp. ***violacea***, ▲.

of cormlets is not known in *M. tripetala*. Nectar guides are often yellow edged with dark blue or purple, but occasionally white, then dotted with blue to purple. The seeds are small, and typical of the complex in being 5(6)-sided with the facets slightly wrinkled and showing the brown colour of the seed body. The angles are raised into narrow wings of paler colour. Related species including *M. amabilis*, *M. cuspidata* and *M. grandis* have larger seeds of more complex structure.

Among the plants included in *Moraea tripetala* are two important variants. Populations from the interior Western Cape on clays and shales from Ceres to the western Little Karoo are treated as subsp. *violacea*. These plants have dark violet outer tepals with yellow nectar guides, are usually relatively short in stature, and have short stiff, hair-like inner tepals, mostly ± 2 mm long. The flowers have an unusual strong clove or carnation-like scent. Unusual for the *M. tripetala* complex, and for subg. *Vieusseuxia* as a whole, several populations of this morph have two foliage leaves. A second set of populations flowering from November to January on the Cape Peninsula and surrounding mountains stand out in their softly fibrous corm tunics, slightly smaller flowers, and usually very narrow leaves, and are treated as subsp. *jacquiniana*. The flowers also often have inner tepals 4–6 mm long. Typical *M. tripetala* in the same area flowers from August to early October.

Key to subspecies

1a Plants mostly of montane habitats in rocky sandstone soils, flowering mainly November to January, occasionally in October; ovary 4–6 mm long; inner tepals often 5–6 mm long, reaching bases of anthers; tepals mostly dark violet . . . . . 160c. subsp. *jacquiniana*

1b Plants of clay, granitic or sometimes rocky limestone or sandstone soils, flowering mainly August to early October; ovary 6–9 mm long; inner tepals 1–3(–5) mm long (or absent), rarely reaching base of anthers; tepals pale to dark blue to violet:

2a Ovary 6–8 mm long; outer tepals 24–26 mm long and inner tepals 1–2 mm long; tepals violet with yellow nectar guides; foliage leaves 1 or 2; plants of clay soils in renosterveld in the Warm Bokkeveld, Bonteberg and Little Karoo . . . . . 160b. subsp. *violacea*

2b Ovary 8–9 mm long; outer tepals 23–30(–32) mm long and inner tepals absent or 1–3(–5) mm long; tepals pale blue or deep blue or purple usually with white (occasionally yellow) nectar guides; foliage leaf always solitary; plants of sandy flats and slopes, sometimes in limestone, extending from Aurora to Knysna . . . . . 160a. subsp. *tripetala*

160a. subsp. **tripetala**

Iris mutila Licht. ex Roem. & Schult., Systema vegetabilium secundum 1: 477 (1817). *Vieusseuxia mutila* (Licht. ex Roem. & Schult.) A.Dietr.: 494 (1833), illegitimate homonym, not *V. mutila* Eckl. (1827). Type: South Africa, [Western Cape], Lion's Head, as 'monti Leonis (Leeuwenrug),' *Lichtenstein s.n.* (location of specimens unknown, probably originally at B and now lost).

Plants 250–450 mm high, stem sometimes sheathed below by collar of brown fibres. *Corm* mostly 12–15 mm diam.; tunics of coarse, light to dark brown fibres *Foliage leaf* solitary, linear. *Inner rhipidial spathes* 45–65(–70) mm long. *Flowers* pale blue or purple with yellow or white nectar guides, faintly honey-scented or unscented; outer tepals 23–30(–32) mm long, claws 10–12 mm long, limbs 12–18 mm long; inner tepals usually hair-like, 1–3(–5) mm long, or absent. *Filaments* 4–6 mm long, united for 1.0–1.5 mm, occasionally (southern populations) ± free; anthers 4.5–7.0 mm long; pollen usually red, sometimes white. *Ovary* 8–9 mm long; style branches ± 12 mm long, crests mostly 8–12 mm long. *Capsules* 12–14 mm long. *Flowering time*: late August to mid-September, occasionally in October (exceptionally July).

Distribution and ecology: largely a plant of coastal forelands, extending from Aurora on the west coast of Western Cape to near Knysna in the east and inland on the Piketberg, the Hottentots Holland–Jonkershoek mountain complex, the Witzenberg at Ceres, and the lower southern slopes of the Langeberg; usually in sandy habitats or on coastal limestone, thus in sandveld, strandveld and fynbos vegetation, at low elevations but occasionally up to ± 700 m.

Diagnosis: subsp. *tripetala* has the largest flowers of the species, the outer tepals 23–30(–32) mm long and the inner tepals 1–3(–5) mm long or sometimes absent. The tepals are pale blue or deep blue or purple usually with white (occasionally yellow) nectar guides. The foliage leaf is always solitary and 4–5 mm wide. Populations along the southern Cape coast, notably in the De Hoop area, the Agulhas Peninsula and some from near Caledon, occasionally lack inner tepals or individual flowers may lack one or two of the inner tepals. Plants from the southern foothills and lower slopes of the Langeberg sometimes have free filaments.

160b. subsp. **violacea** *Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 42: 125 (2012b). Type: South Africa, Western Cape, Op-de-Tradouw, Barrydale to Montagu, south-facing clay slope in renosterveld, 26 Aug. 2000, *Goldblatt 11438* (NBG, holo.; K, MO, PRE, iso.).

Plants mostly 200–300 mm high, sometimes with collar of fine fibres around base. *Corm* mostly 8–10 mm diam., tunics of medium-textured, usually pale fibres, sometimes thickened below. *Foliage leaf* 1 or 2, linear, mostly 1.5–2.5 mm wide, leaf halves often folded together and blade appearing terete. *Inner rhipidial spathes* 35–45(–50) mm long. *Flowers* violet with yellow, velvety nectar guides, strongly scented of cloves (?always); outer tepals 24–26 mm long, claws ± 10 mm long, limbs 14–16 mm long, inner tepals hair-like, 1–2(3) mm long. *Filaments* 4.0–6.5 mm long, united for 0.5–1.2 mm; anthers 4.0–6.5 mm long, pale violet; pollen white. *Ovary* 6–8 mm long; style branches ± 12 mm long, crests 6–8(10) mm long. *Capsules* 8–11 mm long. *Flowering time*: late August to late October.

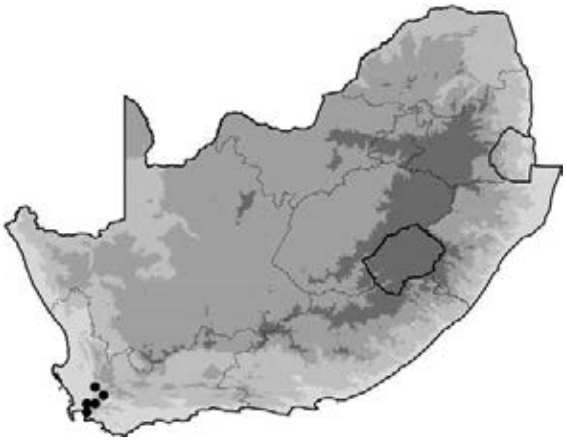
Distribution and ecology: occurring in interior Western Cape, extending from Gydo Pass and the Warm Bokkeveld though the southern foothills of the Hex River Mtns inland to Touws River and the western Little Karoo near Barrydale. Populations with two foliage leaves are scattered across its range; almost invariably on clay soils, usually in renosterveld but also among low succulent shrubs.

Diagnosis: subsp. *violacea* is distinguished by the violet perianth, the outer tepals with yellow nectar guides. The flowers are, as far as known, strongly scented of cloves. The leaves are unusually narrow, 1.5–2.5 mm wide when opened flat. Almost unique for subg. *Vieusseuxia*, some populations have two subequal, basal foliage leaves.

160c. subsp. **jacquiniana** *(Schltr. ex G.J.Lewis) Goldblatt & J.C.Manning* in Bothalia 42: 126 (2012b). *Moraea tripetala* var. *jacquiniana* Schltr. ex G.J.Lewis: 54 (1941). Type: South Africa, [Western Cape], Constantiaberg, December, *Wolley Dod 1919* (BOL, lecto. designated by Goldblatt: 751 (1976a); GRA, isolecto.).

Vieusseuxia pulchra Eckl.: 13 (1827). Type: South Africa, [Western Cape], 'Hottentotshollandkloof', *Ecklon & Zeyher s.n.* (S, holo.).

Plants 140–300 mm high, usually with collar of fine, loosely netted fibres around base. *Corms* ± 10 mm diam., tunics of relatively fine fibres. *Foliage leaf* solitary, narrowly channelled or leaf halves appressed together thus appearing terete, up to twice as long as stem, 2–3(–5) mm wide (when dry often apparently ± 1.5 mm diam.). *Inner rhipidial spathes* 40–50 mm long. *Flowers* usually purple or blue with triangular, white nectar guides spotted with dark blue and edged with darker colour, unscented, outer tepals 20–25 mm long, claws 9–11 mm long, limbs lanceolate, 11–16 × 8–11 mm, inner tepals hair-like, mostly 5–6 mm long, reaching or exceeding anther bases. *Filaments* 4–6 mm long, united for 1.0–1.5 mm; anthers 5–6 mm long; pollen usually (always?) red. *Ovary* 4–6 mm long; style branches 10–11 mm long, crests linear, 5–8 mm long. *Capsules* mostly 10–14 mm long. *Flowering time*: mid-November to January, rarely in late October.



Distribution and ecology: extending in Western Cape from Ceres and Piketberg to the Cape Peninsula and the Hottentots Holland and Houw Hoek Mtns; largely montane but at low elevations in the southern Cape Peninsula, in fynbos on stony sandstone slopes.

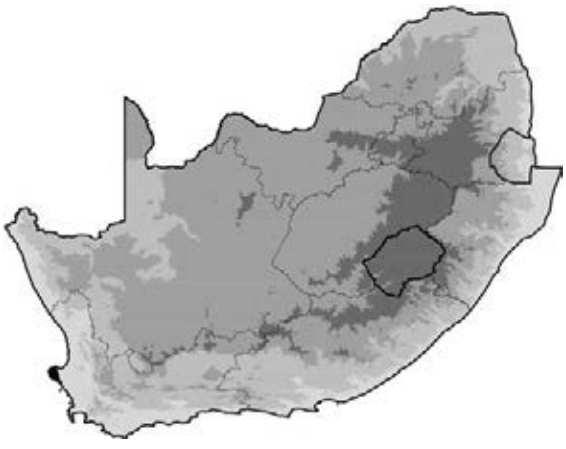
Diagnosis: subsp. *jacquiniana* is poorly differentiated from subsp. *tripetala*, but apart from the later flowering time it can be distinguished by the finely fibrous corm tunics, shorter rhipidial spathes 40–50 mm long and slightly smaller flowers, usually deep violet, consistently with inner tepals 4–6 mm long (usually shorter or absent in subsp. *tripetala*). The outer tepals are typically 20–25 mm long, the ovary 4–6 mm long, and the capsules 10–14 mm long, all smaller than in subsp. *tripetala*. The nectar guides are evidently always white whereas *M. tripetala* has yellow or less often white guides, then speckled with blue dots.

161. **Moraea ogamana** *Goldblatt & J.C.Manning* in Bothalia 42: 128 (2012b). Type: South Africa, Western Cape, Bo-Hermon, Elandsberg Farm, foot of Elandskloof Mtns, seasonally wet alluvial flats, in fynbos, 9 Sept. 2010, *Goldblatt & Manning 13520* (NBG, holo.; MO, iso.).

Plants 150–200(–380) mm high. *Corm* 6–12 mm diam.; tunics of hard, wiry, black fibres. *Stem* usually unbranched, 2 or 3 internodes long, sheathing leaves with dry attenuate tips, 30–45 mm long. *Foliage leaf* solitary, sometimes with second leaf from axillary cormlet, usually shorter than stem, rarely longer, 2–3 mm wide when opened flat, widely channelled or leaf halves almost folded together, inserted or shortly below ground level, usually bearing small axillary cormlet. *Rhipidial spathes* with dry, brown, attenuate tips, inner up to 55 mm long, outer ± $^1/_2$ as long. *Flowers* long-lived, pale blue, outer tepal limbs with triangular yellow nectar guides at bases and dark veins radiating from nectar guides; outer tepals 27–29 mm long, claws 12–14 mm long, limbs ovate, ± 15 mm long, inner tepals hair-like, up to 4 mm long. *Filaments* ± 5 mm long, united ± 1 mm; anthers ± 6 mm long, dark blue-black; pollen white. *Ovary* linear-cylindric, 10–13 mm long, darkly lined vertically on locules and septa; style branches ± 12 mm long, crests ± linear, 8–12 mm long. *Capsules* ± cylindric, (15–)20–24 × 2 mm. *Seeds* angular, 0.8–1.5 mm diam., golden-brown, shortly winged on angles. *Flowering time*: mid-August to mid-September.

Distribution and ecology: restricted to the lowlands of Western Cape, South Africa, from Voëlvlei near Gouda to Strand in the south and locally in the upper Breede River Valley between Wolseley and Botha; in seasonally waterlogged stony ground.

Distribution of ***Moraea ogamana***.



Diagnosis: a member of the *Moraea tripetala* complex of species, *M. ogamana* has hair-like inner tepals ± 4 mm long but is distinguished by the linear-cylindric ovary 10–13 mm long, often partly included in the spathes, and pale blue flowers with dark radiating venation and yellow nectar guides on the outer tepals. Associated with these features are the short stature, rarely exceeding 180 mm, fairly small corms, 7–12 mm diam., with wiry, black tunic fibres and a relatively short leaf, usually shorter than, but occasionally exceeding the stem. Unlike most populations of *M. tripetala* in the Western Cape forelands, which have orange-red pollen, the pollen of *M. ogamana* is white. An additional, but somewhat trivial distinction, the style crests, up to 12 mm, are unusually long for the relatively small flowers. Plants usually have a single small cormlet in the foliage leaf axil, and this modest level of vegetative reproduction results in plants sometimes growing in small clumps of three or four individuals. Correlated with the long, angular ovary, the capsules are ± cylindric and normally 20–24 mm long. Capsules of *M. tripetala* are ellipsoid-oblong and only 10–14 mm long. The seasonally waterlogged habitat is distinctive for *M. ogamana*.

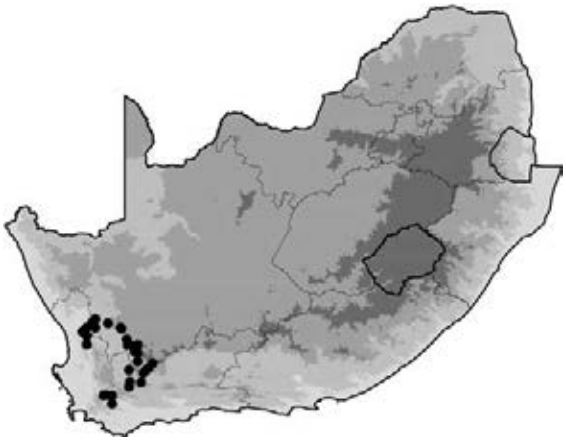
162. **Moraea hainebachiana** *Goldblatt & J.C.Manning* in Bothalia 42: 127 (2012b). Type: South Africa, Western Cape, Vredenburg, Jacobsbaai, 1 km E of town on calcrete ridge, Erf 890, 31 Aug. 2011, *Claassens 95* (NBG, holo.; MO, iso.).

Plants 180–280 mm high. *Corm* mostly 7–12 diam., usually with many cormlets at base; tunics of coarse, ± black, hard, wiry fibres, thickened below into claw-like ridges. *Stem* simple, rarely 1-branched, bearing several, dark-coloured cormlets just below ground level in foliage leaf axil, sheathing leaves with dry attenuate apices, ± 55 mm long, lowermost sometimes with axillary cormlets. *Foliage leaf* solitary, linear, channelled, inserted shortly above ground, trailing distally, (1.5–)2.0–4.0 mm wide, exceeding stem by 100–150 mm. *Rhipidial spathes* with dry attenuate tips, inner 60–65 mm long, outer ± $^1/_2$ as long. *Flowers* long-lived, pale violet to deep blue, outer tepal limbs with white nectar guides at bases with radiating lines of dark blue, scented of vanilla, outer tepals 24–25 mm long, claw ± 10 mm long, white-hairy on adaxial surface, limb 14–15 × 9 mm, usually ultimately recurving, inner tepals spindle-shaped, sometimes oblanceolate and obscurely 3-lobed, 5–6 × 0.5 mm, tapering distally with apex curving inward. *Filaments* ± 6 mm long, united in lower 1.0–1.5 mm; anthers 5–6 mm long, blue-grey; pollen ± white or yellow. *Ovary* narrowly oblong-truncate, included or exserted, 7–9 mm long; style branches wedge-shaped, 7–8 mm long; crests narrowly wedge-shaped (or sublinear), ± 10 × 1 mm. *Capsules* not developed, shed soon after flowers wilt. *Seeds* not produced. *Flowering time*: August to mid-September.

Distribution and ecology: a narrow endemic in the vicinity of Saldanha Bay in Western Cape, South Africa, including the West Coast National Park; restricted to rocky, limestone flats and slopes and calcareous sands along the coast and adjacent hills.

Diagnosis: *Moraea hainebachiana* shows several unusual features in the *M. tripetala* group. The first of these is the cluster of small, dark grey or bluish cormlets in the foliage leaf axil and at the base of the corm, the latter feature especially pronounced in non-flowering individuals. The foliage leaf is always inserted on the stem above ground level. Flowers are consistently pale violet to deep blue and have inner tepals 5–6 mm long, somewhat longer than is typical for *M. tripetala* and unusual in being expanded in the middle, thus spindle-shaped or sometimes oblanceolate and obscurely 3-lobed. More significantly, the filaments are as long as or slightly longer than the anthers, whereas the anthers are slightly longer than the filaments in *M. tripetala* and in some closely related species, often considerably so. The nectar guides are also somewhat unusual, consisting of lines of dots on a whitish background with the edges not clearly defined as they are in *M. tripetala* in which the yellow or white nectar guides are typically edged in darker blue to violet. Vegetative reproduction does not occur in *M. tripetala* and the production of multiple cormlets in leaf axils and at the base of the corm is unknown elsewhere in the *M. tripetala* complex.

Distribution of ***Moraea hainebachiana***.



Moraea hainebachiana is sterile and all capsules are shed soon after the flowers fade and seeds are not developed, thus it is evidently a vegetative apomict and propagation is effected by cormlets that plants produce liberally.

163. **Moraea amabilis** *Diels* in Botanische Jahrbücher für Systematik 44: 118 (1909). Type: South Africa, [Northern Cape], Bokkeveld, Calvinia, Oorlogskloof, *Diels 626* [B, lecto. [as holo.], designated by Goldblatt: 751 (1976a)].

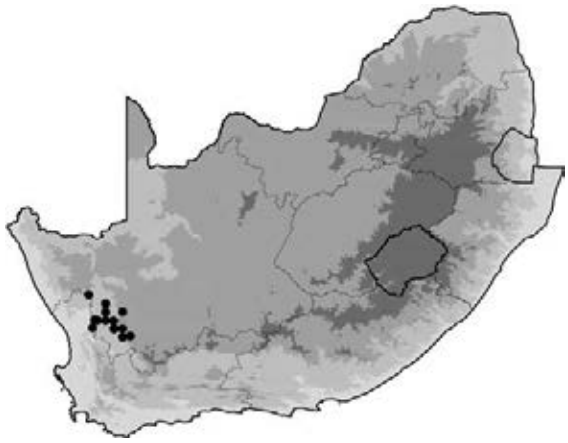
Plants 150–250 mm high, growing in clonal colonies. *Corm* mostly 7–12 mm diam., with tunics of pale, medium to fairly coarse fibres (rarely soft fine fibres), often replaced annually by two daughter corms. *Stem* simple or 1(2)-branched, glabrous or velvety, sometimes with cormlets in below-ground axils, sheathing leaves glabrous or velvety on outer surface, with dry, attenuate apices. *Foliage leaf* solitary, linear, channelled, often widely so, 2–5 mm wide, abaxial surface often velvety-pilose (or glabrous). *Rhipidial spathes* with dry and attenuate apices, smooth or velvety, inner mostly 45–55 mm long, outer ± $^{1}/_{2}$–$^{2}/_{3}$ as long. *Flowers* long-lived, mostly purple or violet to dark blue (rarely pink, dull yellow or buff-brown), outer tepal limbs with white, velvety nectar guides at bases speckled with purple or dark blue, often with larger dark mark at base, often slightly scented of honey or vanilla; outer tepals 20–31 × 10–14 mm, broadly lanceolate, claws pale mauve often with darker central line and spotted purple-black, 10–12 mm long, velvety, limbs (9–)11–18 mm long, apex obtuse-apiculate, inner tepals erect, hair-like, acute, 1.5–2.5 mm long. *Filaments* ± free, 3.5–6.0 mm long; anthers 4.5–7.0(–8.0) mm long; pollen red or white, rarely pale blue. *Ovary* narrowly ellipsoid, 6.0–9.5 mm long, usually flushed red, exserted; style branches ± 10 mm long; crests linear, often arching inward, 6–9 mm long. *Capsules* narrowly ellipsoid, 11–16 mm long, often with thickened apical rim. *Seeds* angular, 1.7–2.0 mm long, angles with spongy edges and prominent spongy micropylar crest. *Chromosome number* 2*n* = 12. *Flowering time*: mostly September to middle October.

Distribution and ecology: relatively widespread in southwestern South Africa, extending from the Bokkeveld Escarpment in an arc across the northern edge of the Roggeveld Escarpment and south through the Roggeveld and Klein Roggeveld in Northern Cape to Worcester, the western end of the Little Karoo and the Olifants River Valley; in light clay soils or sandy loam, sometimes in the Bokkeveld Mtns and Gifberg on shallow sandy ground on sandstone pavement.

Diagnosis: *Moraea amabilis* is recognised by the virtually free filaments (united for < 0.4 mm), inner tepals reduced to hair-like cusps up 2.5 mm long, and the distinctive mode of vegetative reproduction in which the parent corm is often replaced annually by two new corms. Plants also often have a cormlet in the leaf axil and as a result form clonal colonies. This unusual characteristic is only evident if the plants are carefully extracted from the ground. The species is most likely to be confused with *M. grandis*, which also has nearly free filaments but is larger

Distribution of ***Moraea amabilis***.

in all features, notably the ovary, 10–12(–15) mm vs. 6–9 mm long in *M. amabilis* and anthers 9–11 mm long, ± twice as long as the filaments vs. 4.5–7.0(–8.0) mm and up to half again as long as the filaments in *M. amabilis*. The corms of *M. amabilis* have pale (rarely dark) brown, coarsely fibrous tunics with prominent vertical elements in contrast to the finer tunic fibres in *M. grandis*. Apart from smaller flowers, *M. amabilis* often has white pollen in contrast to the consistently bright red-orange pollen of *M. grandis*. Capsules of *M. amabilis*, typically 11–16 mm long, contain relatively small, sharply angular seeds, ± 2 mm at longest axis, with a prominent, pale, spongy micropylar crest, whereas capsules of *M. grandis* are significantly larger, up to 19 mm long, with a thickened apical ridge and the large, dark brown seeds are up to 3 mm long. The velvety to pilose pubescence is universal on the leaves, stem and spathes of western Karoo populations of *M. amabilis* but those from the Bokkeveld Mtns, Gifberg and Cederberg–Olifants River mtns usually have glabrous leaves although there are some exceptions in the area. Only moderate confidence can be placed in the pubescence character as some other members of the *M. tripetala* complex occasionally have hairy leaves (notably *M. mutila*) although *M. grandis* is consistently glabrous. In the Nieuwoudtville area *M. amabilis* and *M. grandis* are sometimes difficult to distinguish, most likely due to hybridization. Plants from near Worcester included in *M. amabilis* have unusual, buff-yellow or dusty pink flowers and those from the Rabiesberg, not far distant, also with velvety stems and leaves, were described as having brown (we assume buff-brown) flowers.



164. **Moraea grandis** *Goldblatt & J.C.Manning* in Bothalia 42: 133 (2012b). Type: South Africa, Northern Cape, Wild Flower Reserve at Nieuwoudtville, around shrubs near top of dolerite slope, scented of vanilla, 22 Sept. 2011, *Goldblatt & Manning 13658* (NBG, holo.; MO, PRE, iso.).

Plants 200–400 mm high, usually in small colonies, usually with 1 or more cormlets in leaf or cataphyll axils, and sometimes with collar of fibres around base. *Corm*

mostly 10–15 mm diam.; tunics of light (rarely dark brown), relatively fine, firm or soft fibres; often producing two new corms to replace parent corm. *Stem* rarely velvety to pilose or glabrous, simple or 1(2)-branched, sheathing leaves or becoming dry from tips, attenuate, 55–70 mm long. *Foliage leaf* solitary, shallowly channelled, usually exceeding stem and up to twice as long, 3.5–5.5 mm wide, often trailing distally. *Rhipidial spathes* with dry, attenuate tips, inner 55–80 mm long, outer ± ½ as long. *Flowers* long-lived, pale blue to pale violet or light purple, outer tepal limbs with small, triangular yellow (rarely ± white) nectar guides at bases edged dark blue, short-velvety (rarely glabrous), spreading at 45–60°, scented of vanilla; outer tepals 30–40 × 15–20 mm, claws 12–18 mm long, velvety, limbs ± orbicular, widest above middle, 15–20(–23) mm long, usually ± as wide, inner tepals hair-like, erect, 1.5–3.5 mm long. *Filaments* ± free or united < 0.2 mm, 4.0–5.5 mm long; anthers 8–11 mm long, usually not reaching stigma lobes; pollen orange-red. *Ovary* ellipsoid, slightly narrowed below apex, (10–)12–15 mm long; style vestigial, branches ± 15 mm long, crests linear, 8–12 mm long. *Capsules* 16–19 mm long, narrowly ovoid-oblong with thickened rim. *Seeds* angular, relatively large, 2–3 mm long, angles forming wing-like ridges. *Chromosome number* 2*n* = 12. *Flowering time*: mainly late Aug. to late Sept.

Distribution and ecology: restricted to the northern end of the western Karoo in Northern Cape, South Africa, extending from the Langberg west of Loeriesfontein through the higher country between Loeriesfontein and Calvinia and along the Bokkeveld Plateau to the northern end of the Roggeveld Escarpment; usually in heavy clay soils, most often in heavy red clay among dolerite rocks but also in lighter soils derived from tillite and shale.

Diagnosis: the most striking of the species of the *Moraea tripetala* complex, *M. grandis* has relatively large corms up to 15 mm diam., with tunics usually of fine, soft (rarely firm) fibres, and the largest flowers in the alliance. The outer tepals are 30–40 mm long with ± orbicular limbs 18–23 × 15–20 mm, thus almost as wide as long, and have unusually small nectar guides, usually yellow (sometimes ± white) on a white background,

Distribution of ***Moraea grandis***.

minutely spotted with dark blue, and usually edged with darker blue or violet. The limbs are also widest in the upper third and usually have an abrupt, comma-like tip. The flowers have a pleasant, vanilla-like odour. Like its relative, *M. amabilis*, it typically grows in colonies resulting from vegetative reproduction by axillary cormlets and sometimes by the replacement of the parent corm by two daughter corms. It also resembles *M. amabilis* in having virtually free filaments (united for < 0.2 mm), but the anthers, 8–11 mm long, are at least twice as long as the filaments and sometimes 2.5 times as long, easily the largest in the *M. tripetala* complex. The pollen is consistently bright orange-red, not unusual for the complex, but contrasting with the white pollen in most western Karoo populations of *M. amabilis*, which has smaller anthers 4.5–7.0 mm long and ± as long as or up to 1.5 times as long as the filaments.

Moraea grandis sometimes grows in close proximity to *M. amabilis*, and the two can be seen flowering together at sites in the Calvinia District and occasionally elsewhere. Difficulty in distinguishing the two in the immediate vicinity of Nieuwoudtville is probably the result of hybridisation and introgression between the two species, which share the same large-bodied bees as pollinators.

Sect. 13. **Villosae** *Goldblatt & J.C.Manning* in Goldblatt et al. in *Bothalia* 43: 40 (2013). Type: *Moraea villosa* (Ker Gawl.) Ker Gawl.

Foliage leaf and stem usually pilose or velvety abaxially (not *M. aristata* and *M. caeca*). *Flowers* variously coloured, large with outer tepal limbs exceeding claws, limbs rotund, as wide or wider than long; inner tepals tricuspidate with central cusp long and trailing.

165. **Moraea aristata** *(D.Delaroche) Asch. & Graebn.*, Synopsis der Mitteleuropäischen Flora 3: 518 (1906); Goldblatt: 773 (1976a); Goldblatt: 182 (1986a). *Vieusseuxia aristata* D.Delaroche: 33 (1766). *M. candida* Baker: 59 (1892), as a new name for *V. aristata* D.Delaroche (mistakenly cited as *V. fugax* D.Delaroche). Type: South Africa, without precise locality or collector, cult. in Holland [L: Herb. van Royen, lecto., designated by Goldblatt: 773 (1976a)].

Ferraria ocellaris Salisb.: 41 (1796). Type: South Africa, without precise locality or collector, illustration in Curtis: t. 168 '*Iris pavonia*' (1791).

Vieusseuxia glaucopis DC.: 141 (1803). *Moraea glaucopis* (DC.) Drapiez: *Moraea* 6 (1833). Type: South

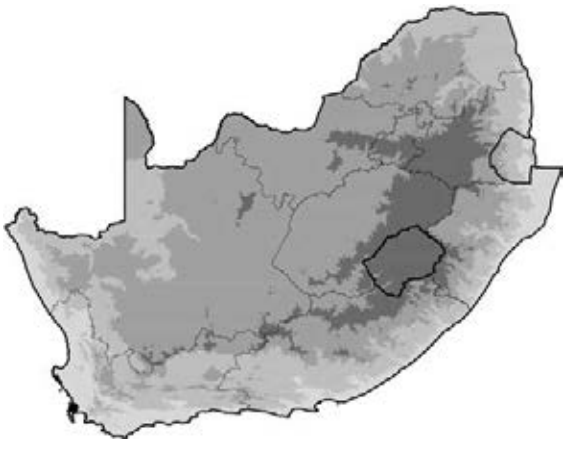
Africa, without precise locality or collector, illustration in Redouté: t. 42 (1803).

Moraea tricuspis var. *ocellata* D.Don in Sweet: t. 249 (1834). Type: South Africa, without precise locality or collector, illustration in Sweet: t. 249. (1834).

Plants 250–350 mm high. *Corms* ± 15 mm diam.; tunics of pale fibres. *Stem* glabrous, sometimes 1-branched. *Foliage leaf* solitary, basal, linear, glabrous, exceeding stem, channelled, often trailing distally. *Rhipidial spathes* with dry, brown, attenuate apices, inner 50–70 mm long, outer ± $^1/_2$ as long. *Flowers* long-lived, white, flushed blue-mauve outside, outer tepal limbs with prominent nectar guide of concentric crescents of dark purple, blue violet or green, spreading; outer tepals 30–35 × ± 25 mm, claws suberect, densely velvety, ± 12 mm long, limbs ± orbicular; inner tepals 15–20 mm long, 3-lobed, lateral lobes short, obtuse, central lobe ± linear, ± trailing. *Filaments* 3–4 mm long, united below in a glabrous column, free near apex; anthers ± 5 mm long, blue; pollen orange. *Ovary* ± cylindric, ± 10 mm long; style branches 7–8 mm long, crests 6–7 mm long, narrowly triangular. *Capsules* ± club-shaped, 15–20 nm long. *Seeds* angular, with spongy testa. *Chromosome number* 2*n* = 12. *Flowering time*: September.

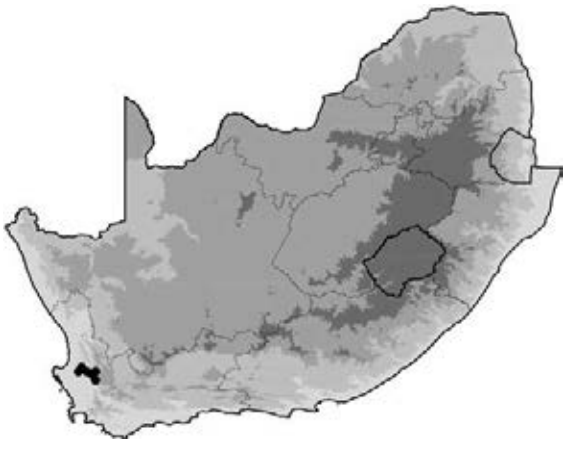
Distribution and ecology: known today only from the grounds of the Royal Observatory, Cape Town, in Western Cape, South Africa, but probably originally with a wider distribution on the lower slopes of Devil's Peak between Cape Town and Rondebosch; in loamy clay.

Diagnosis: it is no exaggeration to say that *Moraea aristata* is far more common in European herbaria than it is in the wild and it was in cultivation in Europe as early as the 1760s. Among the members of sect. *Villosae*, *M. aristata* is distinguished by the glabrous stem and leaf, rather than velvety or hairy as in *M. villosa*, and by the white flowers with striking nectar guides of dark purple or turquoise green. The outer tepals are up to 35 mm long with the limbs almost orbicular, thus nearly as wide as long, and the tepal claws are heavily bearded.



Moraea aristata is diploid with 2*n* = 12 in contrast to most populations of closely related *M. villosa*, which are tetraploid.

166. **Moraea caeca** *Barnard ex Goldblatt* in Annals of the Missouri Botanical Garden 63: 21 (1976b); Goldblatt: 178 (1986a). Type: South Africa, [Western Cape], top of Dasklip Pass, Porterville, *Goldblatt 678* (BOL, holo.; K, MO, PRE, S, iso.).



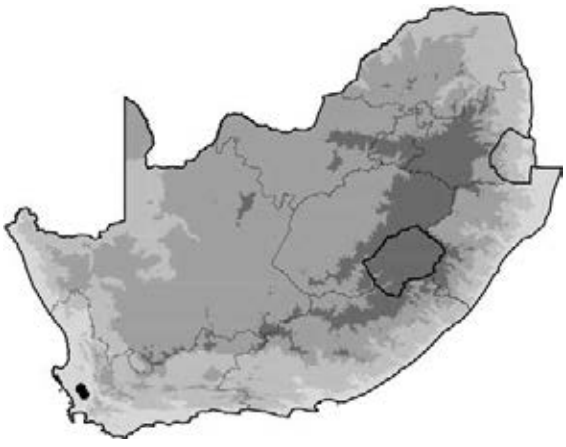
Plants slender, 200–400 mm high. *Corm* ± 10 mm diam.; tunics of pale, medium-textured fibres. *Stem* glabrous or sometimes velvety, simple or occasionally 1-branched, sheathing leaves dry and brown distally, 45–50 mm long. *Foliage leaf* solitary, linear, channelled, exceeding stem, often trailing distally, 3–4 mm wide. *Rhipidial spathes* green with dry, brown, attenuate apices; inner ± 50–60 mm long, outer ± half as long. *Flowers* long-lived, mauve-lilac to almost white, outer tepal limbs with small, triangular yellow or black nectar guides at bases, spreading; outer tepals 22–28 × 15–22 mm, claws ± erect, channelled, velvety, 8–12 mm long, limbs broadly ovate; inner tepals 3-lobed, channelled below, lateral lobes 1– 2 mm long, obtuse, central lobe 5–8 mm long, laxly spreading. *Filaments* 2–3 mm long, united ± in lower $^1/_2$; anthers 5–6 mm long, purple; pollen yellow or orange. *Ovary* ± cylindric, 10–18 mm long; style branches ± 5 mm long, flushed purple or black, crests 5–7 mm long, pale mauve to blue. *Capsules* club-shaped, 12–15 mm long. *Seeds* angular. *Chromosome number* 2*n* = 12. *Flowering time*: late September and October.

Distribution and ecology: restricted to the southern end of the Olifants River Mtns, Grootwinterhoek Mtns and Waaihoek Mtns, and on the Piketberg in Western Cape, South Africa; on stony sandstone slopes.

Diagnosis: *Moraea caeca* is recognised by the mauve-lilac to almost pink or whitish flowers with 3-lobed inner tepals, and broadly ovate outer tepals limbs with small, yellow or black nectar guides. Unlike most other members of the section the leaves and stems are usually glabrous, but at least a population from the Grootwinterhoek Mtns has

Distribution of ***Moraea aristata***.

Distribution of ***Moraea caeca***.



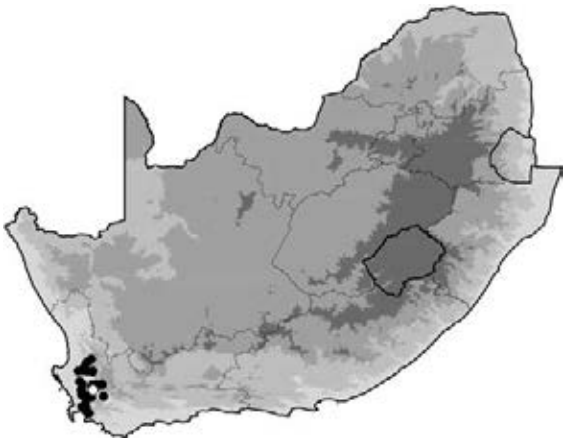
conspicuously velvety stems, and somewhat larger flowers, seemingly confirming the relationship of *M. caeca* to the *M. villosa* alliance. *Moraea caeca* is the only montane species of sect. *Villosae*. It is distinguished from *M. villosa* by its smaller flowers with reduced nectar guides.

167. **Moraea amissa** *Goldblatt* in Annals of the Missouri Botanical Garden 63: 774 (1976a); Goldblatt: 180 (1986a). Type: South Africa, [Western Cape], 10 km NW of Malmesbury, *Acocks 20739* (PRE, holo.).

Plants slender, 250–300 mm high. *Corm* 10–12 mm diam.; tunics or hard, brown, thickened fibres. *Stem* simple or occasionally branched, sheathing leaves with dry, brown apices, 35–40 mm long. *Foliage leaf* solitary, basal, linear, channelled, glabrous, exceeding stem or trailing, 1.5–2.5 mm wide. *Rhipidial spathes* with dry, brown attenuate apices, inner ± 40 mm long, outer ± $^1/_2$ as long. *Flowers* long lasting, pale violet, outer tepal limbs with white nectar guides edged with dark violet and dark, purple-brown claws, spreading; outer tepals lanceolate, 18–20 × ± 13 mm, claws ± 8 mm long; inner tepals either entire, ± lanceolate or with limbs becoming ± 3-lobed distally, ± 15 × 10 mm. *Filaments* 3–4 mm long, united in a slender column finely hairy at base; anthers ± 4 mm long, violet; pollen pale mauve. *Ovary* ovoid-cylindric, ± 7 mm long; style branches 4–5 mm long, crests 4–5 mm long, narrowly wedge-shaped. *Capsules* ovoid-elliptic, ± 12 mm long. *Seeds* unknown. *Flowering time*: early October.

Distribution and ecology: a narrow endemic of the Malmesbury District of Western Cape, South Africa; in granite-derived gravel in rocky habitats.

Diagnosis: *Moraea amissa* has broad, spreading, outer tepal limbs reminiscent of *M. villosa* but the pale blue flowers are much smaller and the inner tepals are either entire or imperfectly 3-lobed, thus inconsistent with *M. villosa*. The stems and leaves are glabrous, in contrast to the condition in most members of the *M. villosa* alliance. The immediate relationships of *M. amissa* remain uncertain.



Distribution of ***Moraea amissa***.

168. **Moraea villosa** *(Ker Gawl.) Ker Gawl.* in König & Sims, Annals of Botany 1: 240 (1804a); Goldblatt: 775 (1976a); Goldblatt: 184 (1986a). *Iris villosa* Ker Gawl.: t. 571 (1802b). *Vieusseuxia villosa* (Ker Gawl.) Spreng.: 166 (1824). *M. pavonia* var. *villosa* (Ker Gawl.) Baker: 59 (1892). Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 571 (1802b).

Plants 200–400 mm high. *Corm* 10–15 mm diam.; tunics with inner layers of fine and outer layers of pale, coarse, almost woody fibres. *Stem* simple or 1- or 2-branched, velvety, sheathing leaves with dry, brown, attenuate apices, 30–50 mm long. *Foliage leaf* solitary, linear, basal, velvety-hairy on abaxial surface, occasionally on margins only (rarely glabrous), exceeding stem, often bent and trailing distally. *Rhipidial spathes* with dry, brown attenuate apices; inner 40–60 mm long, outer ± $^2/_3$ as long. *Flowers* long-lived, shades of purple, lilac, pink or occasionally creamy green (subsp. *villosa*), or orange to peach (subsp. *elandsmontana*), outer tepal limbs with prominent dark purple, turquoise green or navy blue nectar guides at bases, sometimes edged with yellow, claws covered with orange, yellow or purple-brown hairs (rarely inner tepals with small nectar guide); outer tepals 28–40 mm long, limbs 22–38 × 20–35 mm, claws 8–12 mm long, diverging, limbs orbicular, ± as wide as long, spreading slightly below or above horizontal; inner tepals 16–30 mm long, tricuspidate with lateral lobes short, rounded, obtuse, central lobe ± linear, long, ± outspread. *Filaments* 4–5 mm long, united in a cylindric column, free near apices; anthers 6–10 mm long, occasionally exceeding stigma lobe, mauve; pollen orange or yellow. *Ovary* ± cylindric, 7–10 mm long, green or dull red; style branches 5–7 mm long, arching over outer tepal claws, crests (3–)5–8 mm long. *Capsules* ± cylindric, 20–30 mm long. *Seeds* angled with spongy testa. *Chromosome number* $2n = 12$ (subsp. *elandsmontana*), 24 (subsp. *villosa*). *Flowering time*: mid-August and September.

Distribution and ecology: relatively widespread in Western Cape, South Africa, from near Citrusdal in the Olifants River Valley to Somerset West and the Hottentots Holland Mtns and inland in the Tulbagh and Ceres Valleys but absent from the Cape Peninsula; on a variety of soils, including clay loam, granitic gravel and rocky flats in sandy ground.

Diagnosis: one of several species of the 'peacock moraea' group of species, characterised by their particularly broad, spreading outer tepals marked with large, contrasting markings, *Moraea villosa* is distinguished by the velvety stems and abaxial leaf surfaces, large flowers with outer tepals 28–40 × 20–25 mm and 3-lobed inner tepals with a long, spreading central lobe, and the well-developed style branches 6–8 mm long with crests 3–8 mm long. The anthers are usually shorter than the style branches, though occasionally slightly longer. The closely related *M. tulbaghensis*, which has orange to red (rarely white) flowers, has anthers exceeding the shorter and narrower style branches and significantly smaller flowers (outer tepals 28–31 mm long).

Distribution of ***Moraea villosa*** subsp. ***villosa***, ●; subsp. ***elandsmontana***, ○.

Two subspecies are recognised, widespread subsp. *villosa* with purple, lilac, creamy green or occasionally white flowers, large nectar guides, and yellow tepal claws is tetraploid, 2*n* = 24, and subsp. *elandsmontana* with orange to peach-coloured flowers with smaller, navy blue nectar guides is diploid, 2*n* = 12. The two are sympatric in the Elandsberg Nature Reserve north of Wellington.

Key to subspecies

1a Flowers predominantly purple, lilac, pink or creamy green; outer tepals 30–40 mm long, spreading to slightly reflexed; plants tetraploid . . . . . 168a. subsp. *villosa*

1b Flowers predominantly orange to peach-coloured; outer tepals 28–31 mm long, often slightly cupped to spreading; plants diploid . . . . . 168b. subsp. *elandsmontana*

168a. subsp. **villosa**

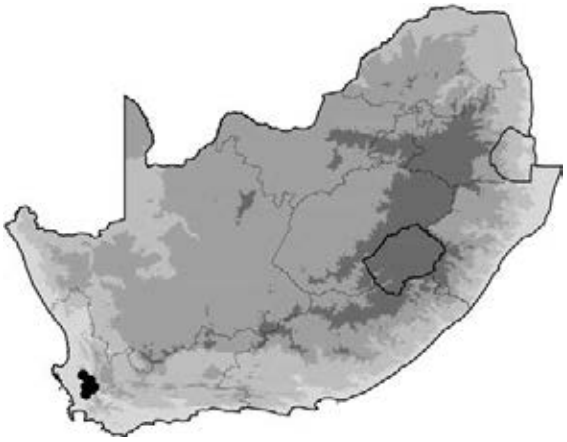
Stem usually unbranched. *Flowers* purple, lilac, pink or occasionally creamy green, outer tepals limbs with prominent purple or turquoise green nectar guides, spreading, often slightly below horizontal, claws yellow; outer tepals 30–40 × 20–25 mm, claws 8–12 mm long. *Filaments* ± 5 mm long; anthers 6–8 mm long, occasionally exceeding stigma lobe, mauve; pollen orange. *Ovary* often dull red. *Chromosome number* 2*n* = 24.

Distribution and ecology: as for the species.

168b. subsp. **elandsmontana** *Goldblatt* in Annals of the Missouri Botanical Garden 69: 366 (1982); Goldblatt: 186 (1986a). Type: South Africa, [Western Cape], foot of Elandskloof Mtns, Farm Elandsberg, *Goldblatt 6206* (MO, holo.; K., NBG, PRE, S, iso.).

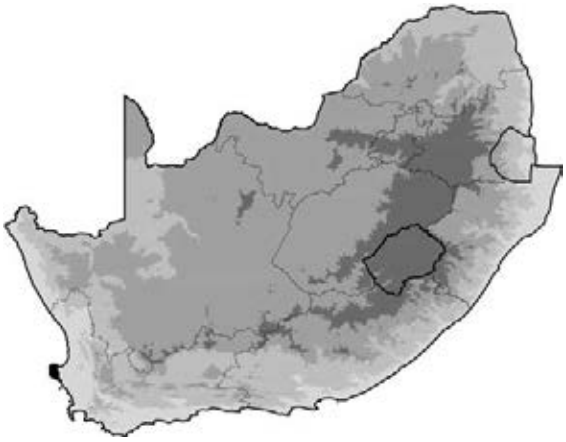
Plants like subsp. *villosa* in vegetative features but stem usually unbranched. *Flowers* bright orange to peach-coloured (exceptionally yellow), outer tepal limbs with navy blue nectar guides at bases, often slightly cupped or spreading, claws orange; outer tepals 28–31 mm long, claw 8–11 mm long, limb curving upward distally, margins curving upward. *Filaments* ± 4 mm long; anthers ± 6 mm long. *Ovary* usually green; style branches ± 6 mm long, orange. *Chromosome number* 2*n* = 12. *Flowering time*: September.

Distribution and ecology: restricted to lower western slopes of the Eland's Kloof Mtns in the Elandsberg Nature Reserve; in stony sandstone soil in fynbos.



Diagnosis: subsp. *elandsmontana* is almost identical to subsp. *villosa* except for the striking orange to peach-coloured flowers with contrasting navy blue nectar guides. The flowers are slightly smaller than in subsp. *villosa*, the outer tepals 28–31 mm long and usually curving upward, rather than spreading slightly below horizontal. It is diploid, 2*n* = 12 whereas several counts for subsp. *villosa* shows it to be tetraploid, 2*n* = 24.

169. **Moraea tulbaghensis** *L.Bolus* in South African Gardening and Country Life 22: 276 (1932c); Goldblatt: 778 (1976a); Goldblatt: 189 (1986a) [not including *M. neopavonia*]. Type: South Africa, [Western Cape], Saron, *H.M.L. Bolus s.n.* (BOL, holo.).



Iris pavonia L.f.: 98 (1782). *Vieusseuxia pavonia* (L.f.) DC.: 139 (1803). *Moraea neopavonia* R.C.Foster: 108 (1947), as a new name for *M. pavonia* (L.f.) Ker Gawl.: 240 (1804a), illegitimate homonym, not *M. pavonia* Thunb. (1787). Type: South Africa, [Western Cape], Swartland hills, *Thunberg s.n.* [UPS–THUNB 1148A, lecto., designated by Goldblatt: 769 (1976a)].

Plants 250–600 mm high. *Corm* 10–15 mm diam.; tunics of pale, coarse, ± woody fibres. *Stem* velvety-hairy, simple or 1-branched, sheathing leaves with dry attenuate apices, 45–60 mm long. *Foliage leaf* solitary, linear, basal, velvety on abaxial surface, exceeding stem, ± erect but often trailing distally. *Rhipidial spathes* with dry, brown, attenuate apices, inner 40–70(–80) mm long, outer ± $^1/_2$ as long. *Flowers* long-lived, bright orange, rarely red or white, outer tepal limbs with blue-green, navy blue, turquoise or darkly spotted nectar guides at bases, spreading, claws bearing orange hairs; outer tepals 22–40 mm long, limbs (12–)15– 21 × 15–23 mm, claws ± 10 mm long, diverging, densely velvety; inner tepals 15–25 mm long, either 3-lobed, with lateral lobes short, rounded, obtuse, central lobe linear, elongate, spreading or narrowly elliptic with acute apex. *Filaments* 4–5 mm long, united in a column, free near apices; anthers 7–10 mm long, reaching or exceeding style crests by up to 3 mm. *Ovary* ± 7–9 mm long; style branches 5–7 mm long, 2–5 mm wide, crests triangular, ± 2 mm long. *Capsules* cylindric, 20–40 mm long. *Seeds* large, angular, with spongy testa. *Chromosome number* 2*n* = 12, 24. *Flowering time*: September.

Distribution and ecology: a fairly narrow endemic of Western Cape, South Africa, extending from near Saron along the foothills of the Twenty Four Rivers and Elandskloof

Distribution of ***Moraea tulbaghensis***.

Distribution of ***Moraea calcicola***.

Mtns, in the upper Tulbagh Valley, Kasteelberg and on the hills of the Berg River Valley as far west as Koringberg; on clay and stony slopes and flats, mostly in renosterveld.

Diagnosis: resembling *Moraea villosa* in its velvety stems and outer leaf surfaces, *M. tulbaghensis* typically has bright orange flowers with navy blue to glossy, emerald green nectar guides. The flowers are usually somewhat smaller than those of *M. villosa*, the outer tepals 22–40 mm long, but the species is most easily distinguished by the anthers, 7–10 mm long and exceeding the style branches and often overtopping the particularly short crests ± 2 mm long. Western populations, recognised as *Iris pavonia* and later named *M. neopavonia*, sometimes have small, elliptic to obscurely three-lobed rather than the strongly tricuspidate inner tepals that characterise other populations, and are diploid, whereas the species is tetraploid elsewhere. Tepal markings in these populations are either navy blue or consist of small dark spots. Populations from Voëlvlei and at Elandsberg Nature Reserve have dark red rather than the more common orange flowers. Even more unusual, a white-flowered population occurs on the slopes of Kasteelberg.

170. **Moraea calcicola** *Goldblatt* in Annals of the Missouri Botanical Garden 69: 364 (1982); Goldblatt: 188 (1986a). Type: South Africa, [Western Cape], limestone hills above Saldanha, *Goldblatt 4118* (MO, holo.; BR, E, K, NBG, PRE, S, US, WAG, iso.).

Plants slender, 300–400 mm high. *Corm* 9–12 mm diam.; tunics of light brown, netted fibres. *Stem* simple or 1-branched, finely velvety, sheathing leaves green with dry, attenuate apices, 50–60 mm long. *Foliage leaf* solitary, basal, linear, channelled, exceeding the stem, villous on abaxial surface, 3–5 mm wide, often bent and trailing. *Rhipidial spathes* becoming dry from apices, attenuate, inner 50–70 mm long, outer ± $^{2}/_{3}$ as long. *Flowers* long-lived, blue or mauve, becoming paler with age, outer tepal limbs with small dark blue, triangular nectar guides at bases or ± without nectar guides, claws densely covered with black hairs, faintly scented; outer tepals 23–35 × 27–32 mm, limbs 15–25 mm long, spreading horizontally, claws 8–10 mm long, narrowly diverging; inner tepals 14–22 mm long, 3-lobed, lateral lobes short, obtuse, central lobed elongate, extended ± horizontally. *Filaments* 2–3 mm long, united in a glabrous column, free in upper 0.5 mm; anthers 5.5–6.5 mm long, dark blue-violet; pollen orange. *Ovary* ± cylindric, 10–15 mm long; style branches inclined, 6–8 mm long, ± 6 mm at widest point, crests ± 4 mm long, margins irregularly serrated. *Capsules* ellipsoid, 18–24 mm long. *Seeds* pale straw-coloured, angular. *Chromosome number* $2n = 12$. *Flowering time*: September.

Distribution and ecology: a narrow endemic of the Saldanha District of Western Cape, South Africa, extending from the Donkergat Peninsula northward to Paternoster, a distance of some 50 km; restricted to limestone outcrops along the coast and a short distance inland.

Diagnosis: *Moraea calcicola* resembles *M. villosa* in its velvety stems and outer leaf surfaces but differs in its clear blue to blue-mauve flowers, usually lacking markings on the tepal limbs and with dark, almost black tepal claws. *Moraea calcicola* is a more slender plant than *M. villosa* and has closer set outer tepals with darkly bearded claws 8–10 mm long and relatively short filaments 2–3 mm long. *Moraea villosa* has large dark nectar guides and contrasting yellow tepal claws 8–12 mm long, and filaments 4–5 mm long. The dark-coloured hairs on the outer tepal claws of *M. calcicola* are reminiscent of *M. loubseri*, which has outer tepals with a heavy beard covering the claws and proximal part of the limb, and the inner tepals are similarly coloured. The two species are most likely immediately related.

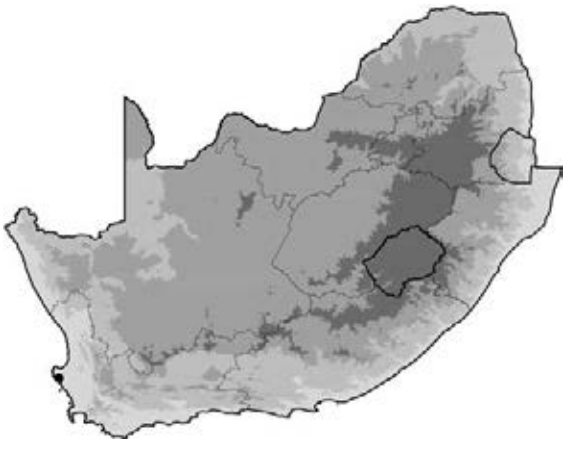
171. **Moraea loubseri** *Goldblatt* in Flowering Plants of Africa 44: t. 1724 (1977b); Goldblatt: 190 (1986a). Type: South Africa, [Western Cape], Olifantskop, Langebaan, *Goldblatt 2076* (MO, holo.; K, NBG, PRE, S, iso.).

Plants 150–200 mm high. *Corm* ± 10 mm diam.; tunics of pale, fairly coarse fibres. *Stem* minutely velvety,

simple or 1(2)-branched, sheathing leaves green, with dry, brown attenuate apices, 40–50 mm long. *Foliage leaf* solitary, basal, linear, channelled, hairy outside, exceeding stem and trailing distally. *Rhipidial spathes* with brown attenuate apices; inner 40–60 mm long, outer ± $^{2}/_{3}$ as long. *Flowers* long-lived, blue-violet, outer tepal claws and proximal $^{1}/_{3}$ of limbs densely covered with blue-black hairs, limbs laxly spreading to half reflexed; outer tepals 24–30 mm long, limbs 14–20 × 12–18 mm, claws broad, ± 10 mm long; inner tepals 3-lobed, 15–20 mm long, lateral lobes short, obtuse, central lobe linear-acuminate, ± 12 mm long, spreading to slightly reflexed. *Filaments* ± 4 mm long, united in lower ± 3 mm, free and diverging distally; anthers 5 mm long, violet; pollen orange. *Ovary* narrowly ovoid-cylindric, 8–10 mm long; style branches ± 6 mm long, ± horizontal, crests 8–10 mm long, wedge-shaped, spreading. *Capsules* ± club-shaped, 18–20 mm long. *Seeds* angular, testa inflated. *Chromosome number* 2*n* = 12. *Flowering time*: late August to late September.

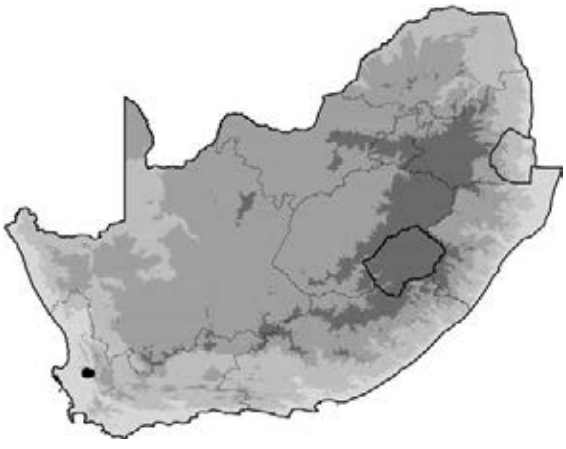
Distribution and ecology: an extremely local endemic, restricted to the upper slopes and summit of Olifants Kop, a low, granite hill on the outskirts of Langebaan south of Saldanha on the Atlantic Coast of Western Cape, South Africa; in sandy, rocky granitic ground.

Diagnosis: one of the so-called 'peacock moraeas', *Moraea loubseri* is readily recognised by the striking dark blue-violet flowers with the outer tepal claws and proximal parts of the limbs densely covered with dark blue-black hairs. The flowers are relatively large with outer tepals 24–30 × 12–18 mm. As in several other species of the *M. villosa* alliance, the solitary, linear leaf is velvety-hairy on the outer surface and the stem is minutely velvety. The inner tepals are 3-lobed with a particularly long, slender central lobe spreading to laxly reflexed and the style branches and crests are unusual in spreading horizontally rather than ascending as in other species of the *M. villosa* group.



The only known locality has subsequently been partially excavated and most of the original habitat of *Moraea loubseri* is destroyed. Only a few plants still survive in the wild but the species is now widely cultivated by bulb enthusiasts.

172. **Moraea gigandra** *L.Bolus* in South African Gardening and Country Life 17: 418 (1927b); Goldblatt: 771 (1976a); Goldblatt: 196 (1986a). Type: South Africa, [Western Cape], without precise locality, *Metelerkamp s.n.* (BOL, holo.).



Plants 200–400 mm high, usually unbranched. *Corms* ± 15 mm diam.; tunics of fine inner fibres and coarse woody outer fibres. *Stem* velvety, simple or 1-branched, sheathing leaves with attenuate, brown apices, 50–70 mm long. *Foliage leaf* solitary, basal, linear, sparsely hairy or glabrous on adaxial surface, usually exceeding stem, trailing distally. *Rhipidial spathes* with dry, dark brown attenuate apices, inner 50–80 mm long, outer ± $^{3}/_{4}$ as long. *Flowers* long-lived, blue-violet, (rarely white or orange), outer tepal limbs with narrow, dark blue-turquoise, crescent-shaped nectar guides at bases, spreading, claws densely hairy, dark brown; outer tepals 35–45 mm long, claw ± 6 mm long, broad, limbs 30–38 × 18–35 mm, inner tepals 9–15 mm long, 3-lobed, lateral lobes short, obtuse, central lobes linear, much longer, spreading to laxly reflexed. *Filaments* 2–4 mm long, free in upper 1 mm; anthers 13–15 mm long, dark blue, much exceeding style crests; pollen yellow. *Ovary* ± cylindric, 18–22 mm long; style branches ± 6 × 2 mm, crests vestigial, barely exceeding stigma lobe. *Capsules* 20–30 mm long, narrowly obovoid. *Seeds* unknown. *Chromosome number* 2*n* = 12. *Flowering time*: late September to mid-October.

Distribution and ecology: restricted to the lower slopes of the Piketberg and the Swartland hills to the east as far as Porterville in Western Cape, South Africa, now on the verge of extinction; on clay soil in renosterveld.

Diagnosis: with one of the largest and most striking flowers in the genus, *Moraea gigandra* has dark blue-purple, or rarely white or orange flowers with broad, shortly clawed outer tepals up to 45 mm long and 30–35 mm wide, the

Distribution of ***Moraea loubseri***.

Distribution of ***Moraea gigandra***.

limbs spreading horizontally and with dark blue to turquoise, crescent-shaped nectar guides. The flowers are distinctive not only in size but also for their extraordinarily long anthers, 13–15 mm long and exceeding the style branches. The style crests are barely developed and are about as long as the stigmatic lobes. The single, channelled leaf is usually hairy on the abaxial surface and the stems are velvety. Like other species in the *M. villosa* alliance the inner tepals are 3-lobed, with an elongate spreading to trailing central lobe. The species is comparatively late-flowering. *Moraea gigandra* was evidently once common north of the Berg River but is now on the verge of extinction, and the white- and orange-flowered populations have not been recorded since the 1930s.

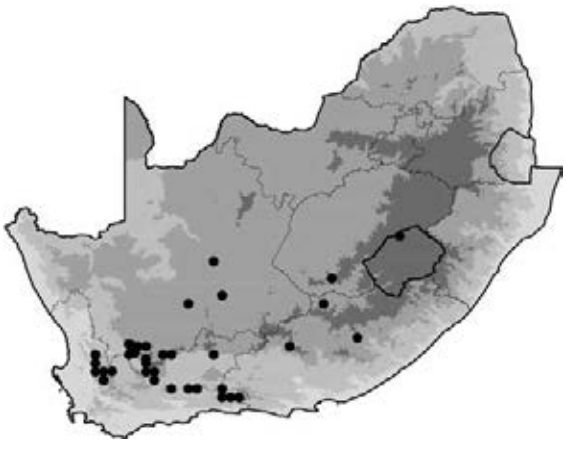
Subg. 11. **Homeria**

Subg. **Homeria** *(Vent.) Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 43: 40 (2013). *Homeria* Vent.: 2 (1808); Goldblatt: 431 (1981). Type: *H. collina* (Thunb.) Salisb. = *M. collina* Thunb.

Sessilistigma Goldblatt: 156 (1984a). Type: *S. radians* Goldblatt = *Moraea radians* (Goldblatt) Goldblatt

Plants simple or few–several-branched; corm tunics of wiry, black fibres. *Foliage leaves* few to solitary. *Flowers* fugaceous or long-lived, yellow, beige or pink to orange, sometimes with dark markings; outer and inner tepals mostly subequal, both whorls usually with nectar guides, claws as long as limbs or much shorter. *Filaments* united entirely or free near apices (free in *M. radians*); style branches reduced with crests vestigial or absent. *Capsules* ovoid-ellipsoid to cylindric, included or exserted. *Basic chromosome number* $x = 6$.

Sect. 14. **Stipantherae** *(Goldblatt) Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 43: 40 (2013). *Homeria* sect. *Stipantherae* [*Stipanthera*] Goldblatt: 426 (1981). Type: *Moraea cookii* (L.Bolus) Goldblatt



Leaf solitary, clasping stem below. *Flowers* yellow (rarely pink); tepals with claws much shorter than limbs, clasping or forming a cup including base of filament column. *Filaments* free near apices or fully united.

173. **Moraea cookii** *(L.Bolus) Goldblatt* in Novon 8: 375 (1998). *Homeria cookii* L.Bolus: t. 306 (1928a); Goldblatt: 440 (1981). Type: South Africa, [Western Cape], Concordia Valley, Montagu, *Cook s.n.* (BOL, lecto. designated by Goldblatt: 440 (1981); K, isolecto.).

Homeria pillansii L.Bolus: t. 684 (1938). Type: South Africa, [Western Cape], Gydo Pass, Ceres, *N. Pillans s.n.* (BOL [19882], holo.; K, PRE, iso.).

Plants (200–)300–600 mm high. *Corms* 15–30 mm diam.; tunics of coarse, black fibres. *Stem* branched from upper nodes, occasionally also near base, branches short, straight, but flexed below rhipidia, sheathing leaves acute, (40–)60–90 mm long. *Foliage leaf* solitary, basal, sheathing lower part of stem, falcate to trailing above, longer than stem, channelled, (6–)12–25 mm wide. *Rhipidial spathes* acute, inner elongating later to enclose capsules, (40–)50–90 mm long, outer slightly shorter to $^2/_3$ as long. *Flowers* fugaceous, pale yellow (rarely pale salmon-pink), darker towards centre, tepal limb bases minutely spotted dark yellow to green, faintly scented, spreading and twisted distally, claws erect, clasping filament column; outer tepals 30–43 × 14–18 mm, claws 4–6 mm long, limbs oblong to slightly obovate; inner tepals 30–35 × 12–14 mm. *Filaments* 6–10 mm long, united in cylindric column smooth or papillate in lower $^1/_3$, usually free in upper 1–2 mm; anthers 6–10 mm long, diverging, tips curving inward, yellow; pollen yellow. *Ovary* ± cylindric, 10–15 mm long, usually included; style branches diverging, 5–7 mm long, arching upwards distally, stigma bilobed, stigmatic laterally, crests 2–4 mm long, ± linear, arching inward. *Capsules* 15–22 mm long, cylindric to club-shaped. *Seeds* angular, light brown. *Chromosome number* $2n = 12, 24, 36$. *Flowering time*: late August to October.

Distribution and ecology: widespread in South Africa, mainly at high altitudes, from the Cederberg in Western Cape and the Roggeveld in Northern Cape east through the Karoo to Queenstown in Eastern Cape, and north in

Distribution of ***Moraea cookii***.

the mountains of the eastern Free State and western Lesotho; mainly montane, in grassland or fynbos on a variety of soils, flowering only after fire in Western Cape.

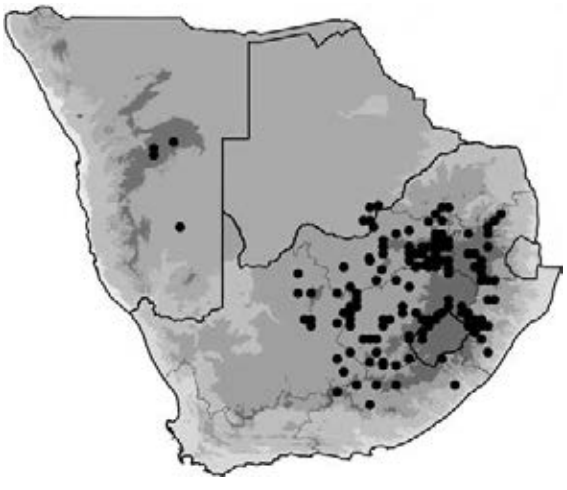
Diagnosis: *Moraea cookii* is distinguished by the large, usually pale yellow (rarely pale salmon-pink) flowers with short, erect tepal claws and broad spreading limbs mostly 25–35 mm long. The claws either clasp the filament column or form a narrow cup including the lower part of the filament column. The filaments are free distally for 1–2 mm, a feature shared with few other species of subg. *Homeria*, notably the closely related *M. elegans*. The broad leaves are grey-green and usually 15–25 mm wide (occasionally narrower) and clasp the lower part of the stem. The species is heteroploid, with diploids and tetraploids in the Karoo and interior but hexaploid in Western Cape.

174. **Moraea pallida** *(Baker) Goldblatt* in Novon 8: 375 (1998). *Homeria pallida* Baker: 75 (1892); Goldblatt: 445 (1981). Type: South Africa, [Northern Cape], Moshowa River near Old Litakun, *W. Burchell 2252-1* [K, lecto., designated by Goldblatt: 445 (1981)].

Moraea glauca J.M.Wood & M.S.Evans: 352 (1897). *Homeria glauca* (J.M.Wood & M.S.Evans) N.E.Br.: 350 (1929b). Type: South Africa, [KwaZulu-Natal], Mooi River, *Wood 4305* [K, lecto., designated by Goldblatt: 445 (1981)].

Homeria humilis N.E.Br.: 351 (1929b). Type: South Africa, [Gauteng], Pretoria District, *Mare s.n.* (K, lecto. designated by Goldblatt: 445 (1981); PRE, isolecto.).

Homeria mossii N.E.Br.: 351 (1929b). Type: South Africa, [Northern Cape], Concordia, *Moss 15606* (K, lecto. designated by Goldblatt: 445 (1981); LD, isolecto.).



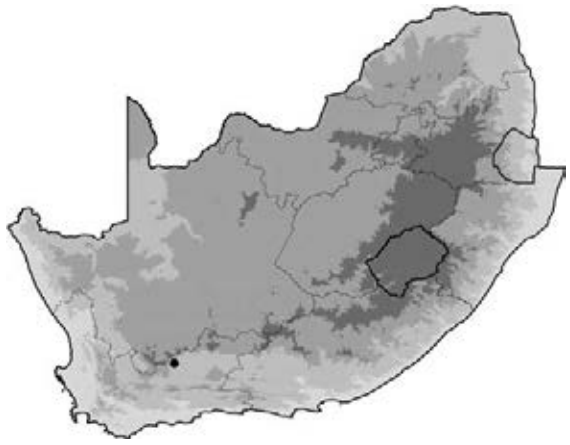
Homeria pura N.E.Br.: 351 (1929b). Type: South Africa, [Free State], Parys, *Young sub Moss 13494* [PRE, lecto., designated by Goldblatt: 434 (1981)].

Homeria townsendiae N.E.Br.: 351 (1929b). Type: South Africa, [Mpumalanga], Ermelo, *Townsend sub Moss 15810* (K, lecto., designated by Goldblatt: 434 (1981); PRE, isolecto.).

Plants 120–400 mm high, slender to robust. *Corms* 10–20 mm diam., sometimes with cormlets at base; tunics of black, wiry, coarse fibres. *Stem* straight or sometimes weakly flexed below nodes, several-branched, branches flexed below rhipidia; sheathing leaves attenuate with dry attenuate tips, 30–50 mm long. *Foliage leaf* solitary, basal, usually sheathing lower part of stem, distally falcate or suberect, often bent and trailing distally, channelled, longer than stem, usually 5–15 mm wide. *Rhipidial spathes* acute-attenuate, inner 35–50(–60) mm long, outer slightly shorter. *Flowers* fugaceous, yellow (rarely pink), tepal limbs with deep yellow nectar guides minutely speckled dark green at bases, spreading, claws erect, clasping filament column; outer tepals 18–24(–27) × 5–8(–12) mm long, claws narrow, ± 3 mm long, limbs ± oblong to obovate; inner tepals smaller, narrowly obovate, 5–8 mm wide. *Filaments* 5–7 mm long, united below in a smooth, cylindric column, free in upper 1.5–2.0 mm and diverging; anthers straight, arching inward after anthesis, 4–6 mm long, exceeding stigmas, yellow; pollen yellow. *Ovary* ± 10 mm long, ± cylindric; style branches diverging, 5–6 × ± 1 mm, stigma bilobed, crests ± 1 mm long, erect or arching inward. *Capsules* club-shaped, 10–20 mm long. *Seeds* angular, light brown. *Chromosome number* 2*n* = 12, 8. *Flowering time*: late August to October (rarely until December).

Distribution and ecology: widespread in South Africa, extending from central Namibia near Windhoek across southeastern Botswana, eastern Northern Cape, Free State to Gauteng and Mpumalanga as far east as Machadodorp and Lydenburg, and in the KwaZulu-Natal Midlands as far south as Lions River; in grassland often after the first spring rains, sometimes in vleis and seasonally wet sites.

Diagnosis: despite its several synonyms, *Moraea pallida* is relatively uniform both in the small yellow flowers and low stature with a solitary leaf clasping the lower half of the stem. The flowers have spreading tepal limbs 16–24 mm long and erect claws, ± 3 mm long, clasping the lower part of the filament column. Somewhat unusually for the genus, the filaments are free and diverging distally for 1–2 mm, a feature shared with *M. cookii* to which it appears to be closely related. The relatively short style branches reach only to the middle of the anthers but have short crests, either erect or curving inward. Populations from KwaZulu-Natal differ somewhat in having numerous small cormlets around the base of the parent corm and even in the axils of the foliage and sheathing leaves. Plants bloom in spring to early summer usually at the end of the dry winter, before the onset of the summer-rainfall season. It is extremely toxic to stock and is the cause of considerable debilitation and death among sheep and cattle.



Distribution of ***Moraea pallida***.

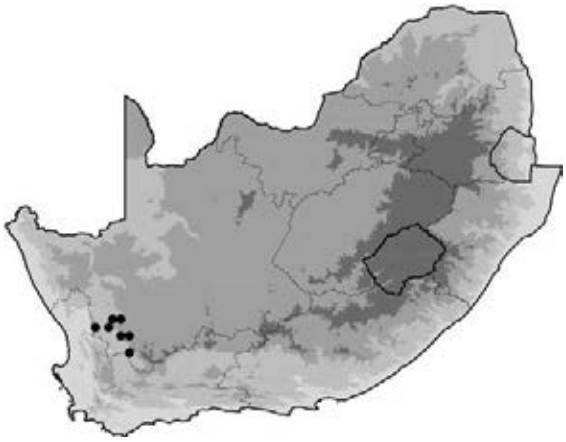
Cytologically *Moraea pallida* is unusual in being heteroploid. Northern populations have the typical $2n = 12$ for subg. *Homeria* but those sampled from Northern Cape and Free State are dysploid, $2n = 8$ and are complex heterozygotes, the chromosomes forming rings at meiosis.

175. **Moraea doleritica** *Goldblatt & J.C.Manning* in Bothalia 43: 160 (2013). Type: South Africa, Western Cape, Great Karoo, ± 52 km south of Fraserburg to Leeu Gamka, low dolerite outcrops below Great Escarpment, 27 Sept. 2012, *Goldblatt & Porter 13806* (NBG, holo.; MO, PRE, iso.).

Plants 350–450 mm high. *Corm* unknown. *Stem* with (1)2 or 3 branches from penultimate node, bearing a solitary sheathing leaf 45–55 mm long, attenuate, ± dry and light brown midway through flowering. *Foliage leaf* solitary, linear, fibrotic, falcate, longer than stem, narrowly channelled, 2–3 mm wide when opened flat. *Rhipidial spathes* pale grey-green, dry and light brown in upper half, attenuate, with fine white nerves evident, inner 50–65 mm long at anthesis, outer ± half as long, inner elongating after flowering to enclose ripening capsules. *Flowers* fugaceous, pale yellow, outer tepal limbs with deeper yellow nectar guides at base with fine dark dots; outer tepals obovoid-pandurate, 25–27 mm long, limbs ± 20 mm long, claws of both whorls ± 6 mm long, ascending to form narrow cup including lower half of filament column, limbs spreading and twisted through ± 45° distally, inner tepals ± 22 × 7 mm. *Filaments* 7–8 mm long, united for most of their length in smooth, cylindric column, free and diverging in upper 0.7 mm; anthers ± 8 mm long before anthesis, 5–6 mm after releasing pollen, then tips arching inward, exceeding style branches, yellow; pollen yellow. *Ovary* cylindric, usually exserted, ± 12 mm long; style branches ± 4 mm long, crests ± linear, erect, ± 1.5 mm long. *Capsules* and *seeds* unknown. *Flowering time*: mid-September and October; flowers opening early morning and collapsed by 11:00.

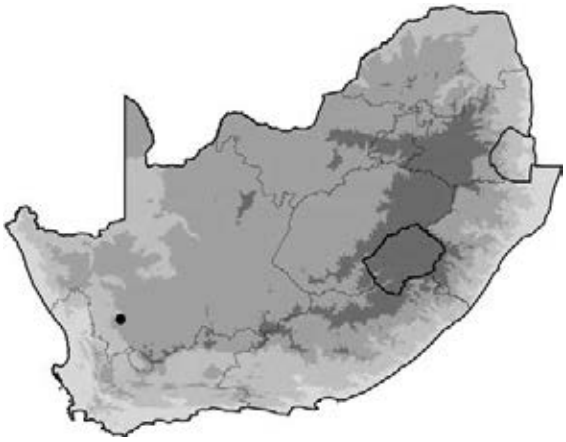
Distribution and ecology: known only from the western Great Karoo between Leeu Gamka and Fraserburg in Western Cape, South Africa; evidently restricted to low dolerite outcrops.

Distribution of ***Moraea doleritica***.



Diagnosis: the pale yellow flowers with relatively well-developed style branches and short, erect crests and, in particular, the filaments free distally for a short distance are somewhat unusual for subg. *Homeria* and recall *Moraea pallida* and *M. cookii*, also with a solitary foliage leaf. The spreading tepals twisted distally through ± 45° of *M. doleritica* are also found in *M. cookii* and *M. pallida*. Both *M. cookii* and *M. pallida* have a relatively broad leaf clasping the lower part of the stem, thus rather different to the particularly long, narrowly channelled, and relatively rigid, tough, fibrous leaf of *M. doleritica*. The range of *M. doleritica* in the Great Karoo is complimentary to that of *M. cookii* and *M. pallida*, with *M. cookii* extending from the Cederberg in Western Cape through the mountains of the Karoo to Lesotho, and *M. pallida* occurring across the Upper Karoo through Free State to Mpumalanga.

176. **Moraea marlothii** *(L.Bolus) Goldblatt* in Novon 8: 375 (1998). *Homeria marlothii* L.Bolus: 320 (1929c); Goldblatt: 443 (1981). Type: South Africa, [Northern Cape], Hantam Mts, *Marloth 12787* (BOL, lecto., designated by Goldblatt: 443 (1981); K, PRE, isolecto.).



Plants large, 500–750 mm high. *Corms* large, ± 35 mm diam.; tunics of coarse, wiry black fibres. *Stem* straight, several-branched from upper nodes, branches suberect, flexed upward below rhipidia, with sheathing leaves acute, 80–120 mm long. *Foliage leaf* solitary, basal, sheathing lower part of stem, channelled, falcate to trailing, 15–35 mm wide. *Rhipidial spathes* attenuate with brown, membranous tips, inner 50–70 mm long, outer slightly shorter. *Flowers* fugaceous, upright to half nodding, pale yellow (rarely pink), tepal limbs with dark yellow nectar guides at limb bases covered with tiny green dots, spreading, tepal claws erect, distally appressed to base of filament column, slightly bulbous below; outer tepals 27–34 × 11–17 mm, claws ± 4 mm long, limbs ± ovate; inner tepals slightly smaller, obovate. *Filaments* 7–10 mm long, united in cylindric to slightly bulbous column pubescent in lower $^1/_2$; anthers 8–11 mm long, diverging, exceeding style branches, arching inward distally; pollen yellow. *Ovary* cylindric-curved, 10–20 mm long; style branches diverging, 4–10 mm long, stigma lobe broad, fertile laterally; crests horizontal, 3 mm long. *Capsules* 20–25 mm long, club-shaped. *Seeds* angular, light brown. *Chromosome number* $2n = 24$. *Flowering time*: September and October.

Distribution and ecology: extending in Northern Cape, South Africa, from the Bokkeveld Mtns east to Calvinia and the Roggeveld as far south as Middelpos; mostly in rocky sites in heavy red clay but in sandstone outcrops in the west of its range.

Diagnosis: broadly resembling the widespread *Moraea cookii* in the solitary broad leaf clasping the lower half

Distribution of ***Moraea marlothii***.

Distribution of ***Moraea reflexa***.

of the stem, *M. marlothii* is a taller plant with slightly smaller, usually half nodding flowers with spreading to half reflexed tepals 27–34 × 11–17 mm and nearly equal vs. outer tepals 30–43 × 14–18 mm and markedly larger than the inner in *M. cookii*. The filaments are completely united whereas those of *M. cookii* are free in the upper 1–2 mm. A striking feature of *M. marlothii* is the slender, curved ovary up to 20 mm long. *Moraea marlothii* co-occurs on the Hantamsberg with vegetatively similar *M. reflexa,* which has pendent flowers with the tepals fully reflexed and a top-shaped ovary only 7–8 mm long.

177. **Moraea reflexa** *Goldblatt* in Novon 8: 375 (1998), as a new name for *Homeria hantamensis* Goldblatt & J.C.Manning: t. 2128 (1997) [not *M. hantamensis* Klatt (1882)]. Type: South Africa, [Northern Cape], Calvinia, Hantamsberg summit plateau, 11 Oct. 1995, *Goldblatt & Manning 10355* (NBG, holo.; K, MO, PRE, S, WAG, iso.).

Plants 700–1 100 mm high. *Corm* globose, 15–22 mm diam.; tunics of coarse, wiry, dark brown fibres. *Stem* straight, 3(4) internodes long, 2- to 4-branched from upper nodes, branches also sometimes branched, sheathing leaves with attenuate, dry apices, 60–100 mm long. *Foliage leaf* solitary, basal, sheathing stem in lower half, channelled below becoming ± plane above, falcate, 12–20 mm wide, slightly twisted distally. *Rhipidial spathes* nodding, with dry brown attenuate apices, inner 50–70 mm long, outer ± $^{2}/_{3}$ as long. *Flowers* fugaceous, nodding to nearly pendent, pale yellow, tepal limbs with creamy and darker yellow nectar guides minutely speckled dark green at bases, fully reflexed, claw tips clasping base of bulbous part of filament column, sweetly scented; outer tepals 28–34 × ± 8 mm, claws 3–4 mm long, erect; inner tepals oblong, 23–29 × ± 6 mm. *Filaments* ± 13 mm long, united in a bulbous column, cylindric and 2.5 mm at base, abruptly swollen to ± 3 mm diam., column tapering gradually to slender apex; anthers ± 6 mm long, diverging, pale yellow lined abaxially with grey; pollen pale yellow. *Ovary* ± top-shaped, 7–8 mm long, exserted, pedicel recurved; style branches ± 4 × 2 mm, diverging, expanded distally with stigmatic lobe wider than style branch and extended either side of anthers, crests straight, linear, 3–5 mm long. *Capsules* narrowly obovoid, 10–12 mm long. *Seeds* not known. *Flowering time*: late September to mid-November.

Distribution and ecology: a narrow endemic of the Hantamsberg at Calvinia, Northern Cape, South Africa; among dolerite rocks on the plateau above 1 300 m.

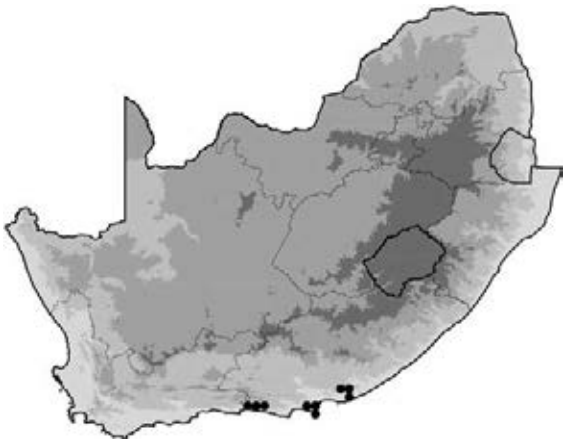
Diagnosis: *Moraea reflexa* is distinguished among the yellow-flowered species of subg. *Homeria* by the solitary, broad, glaucous leaf, the lower portion clasping the stem, and the half to fully pendent flowers with reflexed tepal limbs. The tips of the tepal claws clasp the thickened filament column but are slightly bowed toward the bases, which contain nectar. The style branches are relatively well developed and bear broad stigmatic lobes and straight linear crests. *Moraea reflexa* may be confused with superficially similar *M. marlothii*, a taller, more robust species that occurs widely across the western Karoo, but the tepals in that species, either yellow or pink, spread horizontally or are sometimes half reflexed, the filament column is usually narrow and cylindric or only slightly thickened below, and the ovary is long and slender and curved outward, whereas the shorter ovary of *M. reflexa* is straight, top-shaped and widest near the apex. Although the flowers of *M. marlothii* are comparable in size to those of *M. reflexa,* it has much larger anthers 8–11 mm long compared with anthers ± 6 mm long in *M. reflexa.*

178. **Moraea britteniae** *(L.Bolus) Goldblatt* in Novon 8: 374 (1998). *Homeria britteniae* L.Bolus: 11 (1931a); Goldblatt: 449 (1981). Type: South Africa, [Eastern Cape], Grahamstown, *Britten 2951* (BOL, lecto., designated by Goldblatt: 449 (1981); K, isolecto.).

Plants 200–450 mm high. *Corm* 10–15 mm diam.; tunics of coarse, black fibres. *Stem* straight, usually branched, branches ascending, held close to axis, sheathing leaves

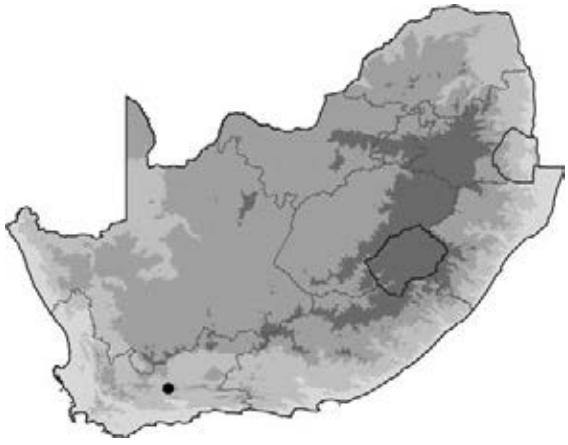
60–80 mm long, attenuate. *Foliage leaf* solitary, basal, often sheathing lower part of stem, longer than stem, erect or trailing distally, channelled, 6–9 mm wide, dark green. *Rhipidial spathes* attenuate, inner initially 60–80 mm long, elongating with age to enclose developing capsules, outer 40–60 mm long. *Flowers* fugaceous, creamy white to pale yellow, tepal limbs with deep yellow nectar guides at bases spotted with green, spreading horizontally, twisted distally, tepal claws suberect, forming a narrow tube enclosing filament column; outer tepals narrowly obovate to pandurate, 26–35 × 8–13 mm, claws 8–9 mm long, suberect; inner tepals smaller, 21–35 × 6–10 mm. *Filaments* 7–8 mm long, united below in a smooth, cylindric column, free in upper 0.5–1.5 mm (or virtually united entirely); anthers 6–7 mm, shortly exceeding stigma lobes, white; pollen white. *Ovary* cylindric, 15–24 mm long; style branches diverging and curved upward, 4–6 mm long, stigma bilobed, broad, receptive laterally, crests short, horizontal, ± 2 mm long. *Capsules* cylindric, (18–)25–45 mm long. *Seeds* angular. *Chromosome number* 2*n* = 12, 24. *Flowering time*: mid-September and October.

Distribution and ecology: occurring on the south coast of South Africa, from Knysna in Western Cape in the west to Grahamstown in Eastern Cape in the east; often in damp situations, most often in sandy soils, usually in low-lying areas that remain moist throughout the winter.



Diagnosis: often confused with other single-leaved species of subg. *Homeria*, *Moraea britteniae* is immediately recognised by the basal foliage leaf sheathing the lower half of the stem and the creamy white (to pale yellow) flowers. The tepal claws form a narrow cup including the filament column and sometimes the base of the anthers, with the apices of the filaments free for up to 1.5 mm. The ovary is relatively long, 15–24 mm, giving rise to capsules mostly 25–45 mm long. The apically free filaments and leaf sheathing the stem for some distance correspond with the critical features of the *M. cookii*–*M. pallida* group, although the long floral cup is unknown elsewhere in the group. DNA sequence data place the species closest to *M. ochroleuca* and *M. collina* (sect. *Homeria*) which also have unusually long capsules. Available information is thus conflicting and provisionally the species remains in *Stipantherae*.

179. **Moraea eburnea** *Goldblatt & J.C.Manning* in Bothalia 43: 160 (2013). Type: South Africa, Western Cape, Seweweekspoort to Laingsburg near Farm Vleiland, northern foothills of the Klein Swartberg Mtns, 25 Sept. 2004, *Goldblatt & Porter 12561* (NBG, holo.; K, MO, PRE, iso.).



Plants 150–200 mm high. *Corm* unknown. *Stem* mostly 2- to 4-branched, flexed above sheaths of basal and cauline leaves, sheathing leaves 30–40 mm long, attenuate, dry and light brown in distal half. *Foliage leaf* solitary, basal, linear, falcate, ± twice as long as stem, narrowly channelled, ± 2 mm wide opened flat, often dry and trailing distally. *Rhipidial spathes* dry and light brown in distal half, attenuate, inner 30–35 mm long, outer almost half as long. *Flowers* fugaceous, pale ivory-yellow, limbs of all tepals with deeper yellow nectar guides at bases, spreading; outer tepals narrowly obovate, 20–25 × 7–8 mm, limbs 18–22 mm long, claws of both whorls ± 2 mm long, ascending as a narrow cup including lower half of filament column, inner tepals 18–21 × 6–7 mm. *Filaments* ± 5 mm long, united in smooth, cylindric column 4 mm long, free and diverging in upper 1 mm; anthers ± 3 mm long before anthesis, ± 2 mm after releasing pollen, exceeding style branches, yellow; pollen yellow. *Ovary* spindle-shaped, usually exserted, ± 5.5 mm long; style branches flattened, 2.5 × 1.5 mm long, with broad stigmatic lobes, crests ± linear, erect, ± 1 mm long. *Capsules* obovoid, ± 10 mm long. *Seeds* unknown. *Flowering time*: September to mid-October.

Distribution and ecology: known only from the Farm Vleiland in the northern foothills of the Klein Swartberg Mtns in Western Cape, South Africa; on clay slopes.

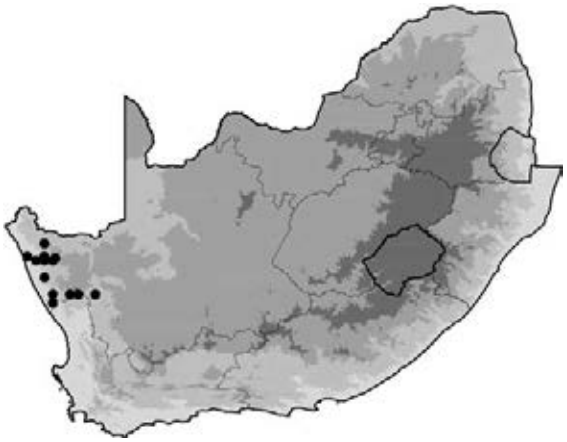
Diagnosis: the relatively small, pale yellow flowers of *Moraea eburnea* have moderately well-developed, flattened style branches terminating in unusually broad

Distribution of ***Moraea britteniae***.

Distribution of ***Moraea eburnea***.

stigmatic lobes and short, erect crests somewhat unusual in subg. *Homeria*, as are the filaments, united in a smooth, cylindric column ± 4 mm long but free and diverging in the upper 1 mm. The distally free filaments and moderately well-developed style branches suggest that *M. eburnea* may be most closely related to the *M. pallida* group (sect. *Stipantherae*) as most other species of subg. *Homeria* have the filaments completely united. If this assignment is correct *M. eburnea* is by far the smallest member of the alliance. The slender stem and narrow leaf place *M. eburnea* in an isolated position in the group. Relationships in subg. *Homeria* are difficult to assess by phenetic comparison and the affinities of *M. eburnea* remain to be established.

Sect. 15. **Flexuosae** *Goldblatt* in Annals of the Missouri Botanical Garden 69: 356 (1982). Type: *Moraea flexuosa* Goldblatt = *M. flexicaulis* Goldblatt



Homeria sect. *Namaquanae* Goldblatt: 425 (1981). Type: *H. schlechteri* L.Bolus = *Moraea schlechteri* (L.Bolus) Goldblatt

Leaves several, decreasing in size above. *Flowers* fugaceous, open only in the morning, yellow; tepals with claws much shorter than limbs, clasping or forming a cup including base of filament column. *Filaments* free near apices or ± fully united.

180. **Moraea schlechteri** *(L.Bolus) Goldblatt* in Novon 8: 375 (1998). *Homeria schlechteri* L.Bolus: sub t. 306 (1928a); Goldblatt: 434 (1981). Type: South Africa, [Northern Cape], Concordia, *Schlechter 11329* (BOL, lecto., designated by Goldblatt: 434 (1981); B, E, G, GRA, K, LD, MO, P, PH, PRE, S, US, Z, isolecto.).

Plants 150–350 mm high. *Corm* up to 30 mm diam.; tunics of coarse, wiry, black fibres. *Stem* flexuose, several-branched from upper nodes, fewer-branched in years of low rainfall, upper nodes sometimes with ± sheathing leaves, usually with expanded leafy tips. *Foliage leaves* 3 to several, lowermost ± basal (or inserted shortly above ground), up to 350 mm long, channelled, 8–20 mm wide, margins straight or slightly undulate. *Rhipidial spathes* with dry attenuate apices, inner 40–60 mm long, outer $^{2}/_{3}$ as long. *Flowers* fugaceous, half nodding, pale yellow, tepal limbs with darker yellow nectar guides as bases often edged grey or green, spreading, usually twisted through 90°; outer tepals 18–28 × 9–10 mm, narrowly obovate, to pandurate, claws poorly defined, ± 1 mm long, ascending, inner tepals slightly smaller. *Filaments* 4–5 mm long, united below in a slender, smooth column, free and diverging in upper 0.5–1.0 mm; anthers ± 2 mm long, strongly arched against style branches, yellow; pollen yellow. *Ovary* ± cylindric, 7–10 mm long, exserted; style branches diverging, ± 2 mm long, flattened, nearly horizontal, stigma lobes upright, appressed to crests, stigmatic laterally, crests arching inward to ± horizontal, ± 2 mm long. *Capsules* ± ovoid, 10–13 mm long. *Seeds* angular, light brown. *Chromosome number* $2n = 12$. *Flowering time*: August and September; flowers open early in the morning and begin to fade ± 12:30.

Distribution and ecology: fairly widespread in Namaqualand, South Africa, from Steinkopf in Northern Cape to south of Bitterfontein in Western Cape, with an outlying population near Loeriesfontein in the western Karoo; in open places on granite-derived sandy gravel.

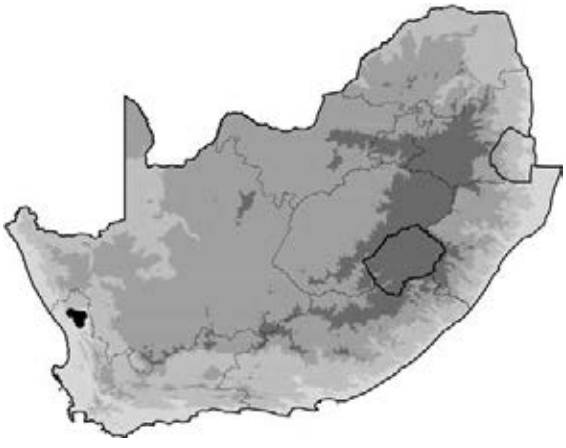
Distribution of ***Moraea schlechteri***.

Diagnosis: evidently one of the least specialised species of subg. *Homeria*, *Moraea schlechteri* has several foliage leaves, the lower longest, but even those on the upper nodes normally have expanded blades. The flowers are pale yellow and have small darker yellow nectar guides on all tepals, these with short, poorly differentiated claws ± 1 mm long. The filaments are united in a slender column but are free in the upper 0.5–1.0 mm, and the well-developed style branches are slightly wider than the anthers and have prominent crests 2 mm long. Closely related *M. knersvlaktensis* has a similar vegetative form, though with broader, undulate leaves, the lowermost inserted well above the ground and even the outer rhipidial spathes are somewhat leafy, sheathing the inner spathes only in the lower half. The flowers of the two species are structurally nearly identical but the nectar guides are more prominent in *M. knersvlaktensis*, the tepals claws 2 mm long, and the filament column sparsely and shortly hairy. Both *M. schlechteri* and *M. knersvlaktensis* have morning flowers that fade soon after midday.

181. **Moraea knersvlaktensis** *Goldblatt* in Novon 8: 375 (1998) as a new name for *Homeria ramosissima* Schltr.: 94 (1900); Goldblatt: 436 (1981) [not *M. ramosissima* (L.f.) Druce (1917)]. Type: South Africa, [Western Cape], banks of Sout River, Vanrhynsdorp, *Schlechter 8128* (B, lecto., designated by Goldblatt: 436 (1981); E, G, GRA, K, MO, P, PRE, US, Z, isolecto.).

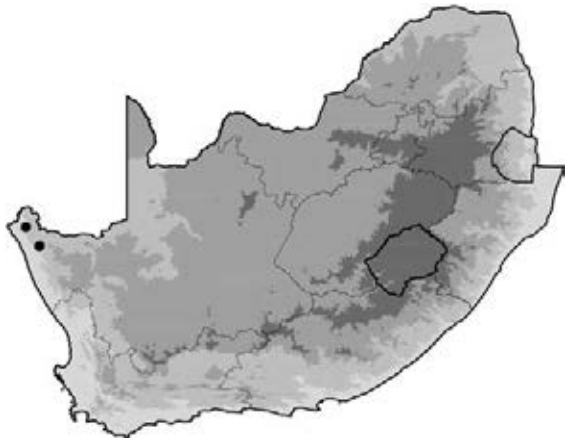
Plants small to medium, 80–200 mm high. *Corm* 10–20 mm diam.; tunics of hard, blackish fibres. *Stem* with

a long basal internode and first leaf inserted well above ground, flexed above each node, much-branched and rounded in shape. *Foliage leaves* several, lowermost inserted above ground, blades of all leaves channelled, lightly undulate, up to 150 mm long, 12–18 mm wide, leaves produced at all nodes. *Rhipidial spathes* grey-green, inner 35–50 mm long, ± attenuate, outer sheathing below with the upper half leafy and arching outward. *Flowers* pale yellow, all tepals limbs with dark yellow nectar guides at bases outlined in grey-green, spreading and often twisted through 90°, claws erect and clasping lower part of filament column; outer tepals obovate 17–19 × ± 8 mm long, claws ± 2 mm long, inner tepals slightly smaller. *Filaments* 6–7 mm long, united in a slender column papillate in lower $^1/_3$, free in upper ± 1 mm and diverging; anthers 2–3 mm long, arched, yellow; pollen yellow. *Ovary* ± narrowly club-shaped, 7–9 mm long; style branches flattened, ± 2 mm long, diverging, stigmatic lobes erect, crests ± 1.5 mm long, directed inward. *Capsules* oblong-club-shaped, 10–15 mm long. *Chromosome number* 2*n* = 12. *Flowering time*: late July to early September; flowers open in early morning and fade after ± 12:30.



Distribution and ecology: endemic to southern Namaqualand, mainly in the Knersvlakte, between Vanrhynsdorp and Nuwerus, in Western Cape, South Africa; on stony clay flats and slopes.

Diagnosis: *Moraea knersvlaktensis*, with its typical rounded form, is a distinctive plant of the Knersvlakte north of Vanrhynsdorp. It typically has slightly twisted leaves with undulate margins, and the outer inflorescence spathes are free distally and curve outward. The flowers of *M. knersvlaktensis,* which open early in the morning and fade after 12:30, are pale yellow with relatively prominent nectar guides bordered in pale grey-green, and the tepal claws, up to 2 mm long, clasp the base of the filament column. Closely related to *M. schlechteri*, the two species, as well as *M. flexicaulis*, are unusual for subg. *Homeria* in that every stem axil bears a foliage leaf, whereas other species bear attenuate, entirely sheathing leaves resembling the rhipidial spathes at the upper nodes. All three species have filaments with the apices free and diverging, and relatively well-developed style branches with relatively prominent crests.



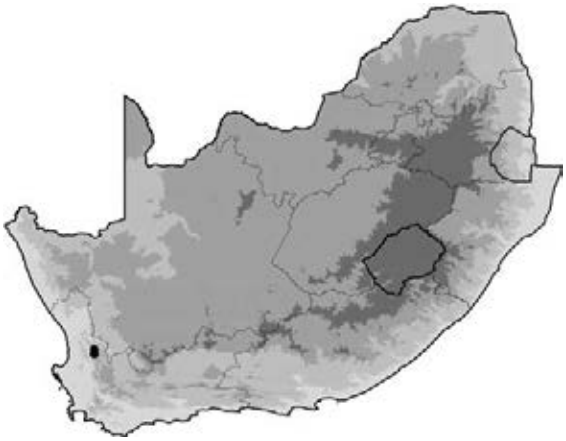
182. **Moraea flexicaulis** *Goldblatt* in Novon 12: 358 (2002), as a new name for *M. flexuosa* Goldblatt: 356 (1982) & 106 (1986a), illegitimate homonym, not *M. flexuosa* L.f. (1782). Type: South Africa, [Northern Cape], Richtersveld, Eksteenfontein road, *Goldblatt 6000A* (MO, holo.; K, NBG, PRE, S, WAG, iso.).

Plants 60–150 mm high. *Corm* 10–15 mm diam.; tunics of matted, relatively fine, dark brown (± black) fibres. *Stem* flexuose, flexed above sheathing base of each leaf, with up to 4 branches, rarely simple, without sheathing leaves. *Foliage leaves* 3 to 5, lowermost inserted shortly (up to 20 mm) above ground and largest, upper leaves progressively shorter, falcate, channelled, up to 60 mm long, 3–6 mm wide. *Rhipidial spathes* ± attenuate, with dry apices, inner 25–50 mm long, outer mostly ± $^1/_2$ as long, free and arching outward in distal $^2/_3$. *Flowers* fugaceous, pale yellow, limbs of all tepals with deeper yellow nectar guides at bases, spreading horizontally, outer tepal guides sometimes with numerous small dark green dots or clear yellow, faintly scented; outer tepals narrowly lanceolate, 28–30 × ± 8 mm, claws ± erect, ± 14 mm long, inner tepals 25–27 × 7 mm long, claws narrow ± as long as limbs, limbs twisted through 45°. *Filaments* 11–12 mm long, united in a cylindric column, free in upper ± 1.5 mm and diverging; anthers straight, ± 3.5 mm long, white; pollen white. *Ovary* ± 7 mm long, ± cylindric, flushed red; style branches 4 mm long, crests ± 2 mm long, erect. *Capsules* ovoid, 12–15 mm long. *Seeds* obovoid, ± smooth. *Chromosome number* 2*n* = 12. *Flowering time*: July and early August, opening near midday and fading in late afternoon.

Distribution and ecology: restricted to the Richtersveld of Northern Cape, South Africa, from the flats west of Anenous Pass north to Eksteenfontein and at the foot of the Ploegberg; in stony ground or loose fine sand.

Distribution of ***Moraea knersvlaktensis***.

Distribution of ***Moraea flexicaulis***.



Diagnosis: so unusual is *Moraea flexicaulis* that when first described it was assigned to a separate sect. *Flexuosae* of subg. *Moraea*, but molecular studies have shown it to be deeply nested in subg. *Homeria*, in which its chromosome number, $2n = 12$, and karyotype of exclusively acrocentric chromosomes are consistent, as are the largely united filaments forming a sturdy, cylindric column. *Moraea flexicaulis* is now considered to be most closely allied to two Namaqualand species of subg. *Homeria*, *M. schlechteri* and *M. knersvlaktensis*, all three with several leaves, even those in the upper part of the stem with free blades, and filaments free and diverging distally. The species remains a very distinctive member of the subgenus. Its particularly well-developed style branches and crests are exceptional in subg. *Homeria* but both its presumed close allies have style branches bearing moderately well-developed crests although they have much shorter style branches.

Blooming early in the season, in late June and July, *Moraea flexicaulis* comes into flower three to four weeks after the first soaking autumn or winter rains fall in this arid area of the southern African northwest coast. As with many plants of arid areas, plant size is very variable depending on rainfall. Plants from the base of the Ploegberg in the Richtersveld are unusually robust compared to other collections, up to 150 mm tall (vs. < 100 mm elsewhere) and with larger rhipidial spathes (45–50 mm vs. 20–40 mm) and broader leaves, leaving open the possibility that they may be a separate species but this remains uncertain until more material is available.

Sect. 16. **Homeria** *(Vent.) Goldblatt* in Novon 8: 374 (1998). Type: *H. collina* (Thunb.) Salisb. = *Moraea collina* Thunb.

Stem straight or flexed below nodes, upper leaves with expanded blades or entirely sheathing. *Foliage leaves* several to one. *Flowers* fugaceous or lasting 2(3) days; tepal claws short and erect or long and diverging to form a cup partly to entirely enclosing filaments and sometimes anthers; filaments usually united entirely (free in *M. radians*); style branches much reduced, usually narrower than anthers and with short to vestigial crests.

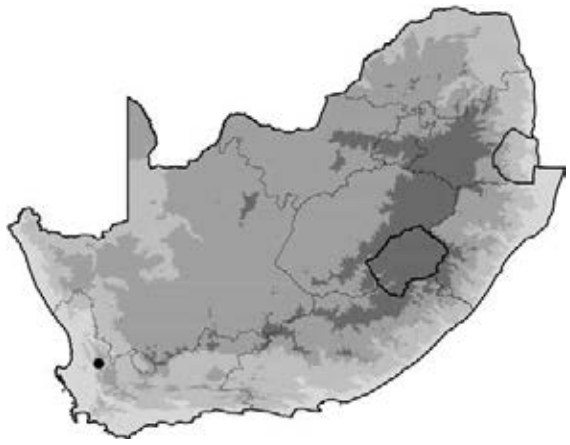
183. **Moraea cedarmonticola** *Goldblatt* in Novon 8: 374 (1998), as a new name for *Homeria cedarmontana* Goldblatt: 451 (1981) [not *M. cedarmontana* (Goldblatt) Goldblatt (1998)]. Type: South Africa, [Western Cape], Cederberg, half way up Uitkyk Pass [as Cederberg Pass], *Goldblatt 3871* (MO, holo.; K, NBG, PRE, S, US, WAG, iso.).

Distribution of ***Moraea cedarmonticola***.

Plants large, 700–1 000 mm high. *Corm* deep-seated, ± 20 mm diam.; tunics of coarse, hard black fibres. *Stem* straight, branched from upper nodes, branches short, held close to axis, all cauline leaves with short blades. *Foliage leaves* several, lower 1 or 2 ± basal, upper leaves progressively shorter above, all with channelled blades, lower leaves linear, up to 500 mm long, upright but often trailing distally, channelled, 15–20 mm wide, uppermost leaves up to 100 mm long. *Rhipidial spathes* attenuate, inner 60–80 mm long, outer ± $^3/_4$ as long. *Flowers* fugaceous, uniformly pale yellow, sweet-scented, tepal claws forming a narrow cup enclosing filament column, limbs spreading; outer tepals ± 40 mm long, claws ± 20 mm long; inner tepals slightly smaller. *Filaments* united in a column 16–20 mm long, minutely velvety in lower half, included in floral cup; anthers 9–10 mm long, initially erect, arching inward after dehiscence, exserted. *Ovary* ± cylindric, 11–14 mm long; style branches ± 7 mm long, diverging, stigma lobe upright, appressed to base of crests, stigmatic laterally, crests erect, 2–3 mm long, either exceeding or shorter than anthers. *Capsules* ± cylindric, mostly 20–25 mm long. *Seeds* angular, light brown. *Chromosome number* $2n = 12$. *Flowering time*: August and September, in October at higher elevations.

Distribution and ecology: a narrow endemic of Western Cape, South Africa, extending from the Cederberg at Middelberg above Algeria south to Elandskloof; on stony sandstone slopes, flowering well in the spring following a fire, rarely in other years.

Diagnosis: a tall species up to 1 m high with at least three well-developed leaves and the upper leaves with short, expanded blades, *Moraea cedarmonticola* is unmistakable even before flowering. The large yellow flowers have subequal tepals ± 40 mm long, the claws forming a narrow cup including the filament column but with the anthers exserted.



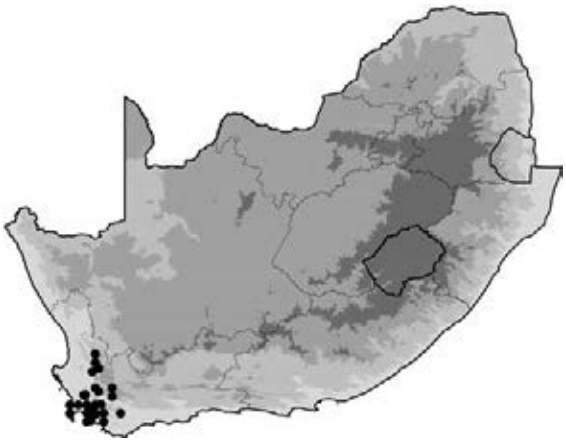
184. **Moraea autumnalis** *(Goldblatt) Goldblatt* in Novon 8: 374 (1998). *Homeria autumnalis* Goldblatt: 467 (1981). Type: South Africa,

[Western Cape], Elandskloof, 23 km east of Citrusdal, *Goldblatt 5504* (MO, holo.; BR, C, K, NBG, NSW, P, PRE, S, STE, US, WAG, iso.).

Plants 160–300 mm high. *Corm* globose, ± 20 mm diam.; tunics of coarse, black fibres. *Stem* slightly flexed below nodes, usually 2- to several-branched (rarely simple), bearing attenuate sheathing leaves 35–60 mm long. *Foliage leaf* solitary, basal, ± linear, flat to broadly channelled, sheathing base of stem, barely exceeding to slightly shorter than stem, with a prominent thickened, flat apical portion. *Rhipidial spathes* becoming dry and brown above, attenuate, inner 45–70 mm long, outer ± $^1/_2$ as long. *Flowers* probably long-lived, bright yellow, all tepal limbs with darker yellow nectar guides at bases, spreading, tepal claws erect, forming a narrow cup around filament column and bases of anthers; outer tepals 32–40 × ± 15 mm, claws 9–10 mm long, inner tepals 30–35 × 8–12 mm. *Filaments* united in a smooth, cylindric column 7–9 mm long; anthers narrowly diverging, 5–7 mm long, exceeding stigmatic lobes, curving inward above. *Ovary* ± cylindric, 8–9 mm long, exserted; style branches ± 3 mm long, crests triangular, 2 mm long. *Capsules* oblong, 8–15 mm long, exserted. *Seeds* unknown. *Chromosome number* 2*n* = 12. *Flowering time*: April to early June.

Distribution and ecology: known only from the mountains around Elandskloof, southeast of Citrusdal in Western Cape, South Africa; in stony, sandy mountain soil, apparently flowering well only after fire.

Diagnosis: unusual in the genus in its early flowering time, April to June (autumn and early winter), *Moraea autumnalis* is recognised by the solitary foliage leaf inserted close to the base of the sparsely branched (rarely simple) and slightly flexuose stem, and yellow flowers with the tepal claws ± erect and forming a narrow cup 9–10 mm long enclosing the filament column and bases of the anthers. The filaments are entirely united in a cylindric column minutely papillate in the lower half, and the anthers, 5–7 mm long, are twice as long as the style branches and arch inward after dehiscence. The style branches bear short, horizontal crests. When described *M. autumnalis* was thought to be closely allied to *M. pyrophila* (as *Homeria galpinii*) because they have a similar vegetative morphology and broadly similar flowers, but the claws of the pale yellow tepals of *M. pyrophila* form a cup enclosing both filaments and anthers, and the shorter filaments, 4–5 mm long, are conspicuously pubescent in the lower half. The anthers are usually shorter than the style branches, which bear short crests as in *M. autumnalis*. It is probably significant that the flowering in *M. pyrophila* is also relatively early in the season, mostly in July and August but as early as March and April.



Distribution of ***Moraea autumnalis***.

185. **Moraea ochroleuca** *(Salisb.) Drapiez*, Encyclographie du règne végétale 1: *Moraea* 3 (1833). *Homeria ochroleuca* Salisb.: 308 (1812); Goldblatt: 453 (1981). *H. collina* var. *ochroleuca* (Salisb.) Baker: 75 (1892). *H. exaltata* Sweet: 395 (1826a), illegitimate superfluous name for *H. ochroleuca* Salisb. *M. exaltata* Steud.: 160 (1841), illegitimate superfluous name. Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 1103 [1283 in error] (1808).

Homeria lucasii L.Bolus: 320 (1929c). Type: South Africa, without precise locality, *Lucas s.n.* (BOL [18572], holo.; K, iso.).

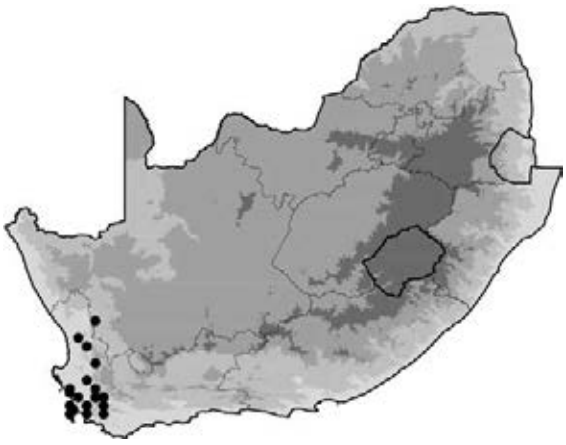
Plants medium to large, 350–750 mm high. *Corm* 15–25 mm diam.; tunics of coarse, black fibres. *Stem* 1- to several-branched from upper or all nodes, with attenuate sheathing leaves at upper nodes, 60–70 mm long. *Foliage leaves* usually solitary, sometimes 2(3), lowermost inserted above ground (sometimes up to 150 mm), channelled, exceeding stem, often trailing above, 6–15 mm wide, remaining leaves if present shorter. *Rhipidial spathes* attenuate, inner (50–)60–80 mm long, outer ± $^1/_2$ as long. *Flowers* long-lived, yellow entirely, or with orange floral cup, rarely orange entirely, strongly scented, tepal claws forming a wide cup and secreting nectar from veins on surface, limbs spreading; outer tepals obovate, 30–40 × 15–17 mm, claws 13–16 mm long, inner tepals similar, slightly smaller. *Filaments* united in a slender column 7–10 mm long, tapering from base to apex; anthers 4.5–8.0 mm long, ± straight, narrowly diverging, yellow; pollen yellow. *Ovary* cylindric, 13–16 mm long; style branches 5.0–6.5 mm long, slightly narrower than anthers, stigma bilobed, crests lacking. *Capsules* cylindric, 20–40 mm long, with short beak ± 1 mm long. *Seeds* angular. *Chromosome number* 2*n* = 12, 24 + 0–3B. *Flowering time*: mainly July to October, sometimes until December at higher elevations.

Distribution and ecology: largely a montane species of Western Cape, South Africa, extending from the Cold Bokkeveld and Elandskloof south to the Cape Peninsula and east to Caledon and Hermanus; in rocky sandstone ground, flowering particularly well after fire but erratically in unburned sites.

Distribution of ***Moraea ochroleuca***.

Diagnosis: the large yellow or yellow and orange flowers of *Moraea ochroleuca* are distinctive in their wide cup formed by the tepal claws and spreading tepal limbs. The species is unusual in having nectar secreted from veins over the claw surface rather than from discrete nectaries at the tepal bases as in most other *Moraea* species. The style branches, relatively well developed and up to 6.5 mm long but only ± as wide as the anthers that are appressed to them, terminate in bilobed stigma lobes but lack discrete crests. The tall plants, up to 750 mm high, typically have a solitary foliage leaf but plants with two, or even three foliage leaves are known, these mostly from higher elevations. Flowers of *M. ochroleuca* last three days, opening in the morning on the first day and fading gradually during the third day. The flowers have a strong, rather sickly sweet, slightly fermenting odour, which attracts dung, game and muscid flies, the main pollinators of the species.

At lower elevations *Moraea ochroleuca* often co-occurs with *M. collina* and occasional natural hybrids between the two are known. Both diploid and tetraploid populations have been recorded.



186. **Moraea flaccida** *(Sweet) Steud.*, Nomenclator botanicus, edn. 2, 2: 160 (1841). *Homeria flaccida* Sweet: 395 (1826a); Goldblatt: 464 (1981). *H. collina* var. *flaccida* (Sweet) Klatt: 629 (1866). Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 1612 (1814).

Homeria collina var. *bicolor* Baker: 75 (1892). *H. bicolor* (Baker) Klatt: 157 (1894). Type: South Africa, [Western Cape], Stellenbosch, *Sanderson s.n.* (K, holo.).

Plants large, 300–600 mm high. *Corm* ± 20 mm diam.; tunics of hard, wiry, black fibres. *Stem* several-branched, slightly flexed above sheaths of foliage and sheathing leaves, these attenuate, 35–60 mm long. *Foliage leaf* solitary, usually inserted well above ground, linear, channelled, exceeding stem and trailing distally, 9–13 mm wide. *Rhipidial spathes* attenuate, inner 55–80 mm long, outer $^{1}/_{2}$–$^{2}/_{3}$ as long. *Flowers* long-lived, salmon-pink or yellow with yellow cup, all tepal limbs with deep yellow nectar guide at bases, ± spreading, tepal claws diverging, forming wide cup ± 12 mm deep including filaments and bases of anthers; outer tepals ± oblong to obovoid, 35–40 × 13–20 mm, claws up to 14 mm long, smooth or minutely papillate in lower part, inner tepals slightly smaller than inner. *Filaments* 7–8 mm long, united in a column smooth to sparsely papillate-pubescent in lower half, widest at base, tapering slightly to apex; anthers 8–11 mm long, contiguous for 3 mm, slightly diverging distally, yellow; pollen yellow. *Ovary* cylindric, 17–20 mm long; style branches slightly diverging, up to 7 mm long, stigmas bilobed, curved upward above apex of anthers, crests ± 1 mm long, erect, triangular. *Capsules* cylindric, mostly 30–55 mm long, tapering near apex, with a distinct beak ± 2 mm long. *Chromosome number* $2n$ = 24, 36. *Flowering time*: late August to October.

Distribution and ecology: widespread in Western Cape, South Africa, from the Cape Peninsula and Cape Flats north to Klawer and the Bokkeveld Mtns near Nieuwoudtville in Northern Cape; in seasonally waterlogged sites or marshes, mainly in sandy soils.

Diagnosis: *Moraea flaccida* is distinguished by its robust, several- to many-branched stem and characteristic flowers with the tepal claws widely diverging to form a shallow dish including the filaments and bases of the anthers. The tepals are usually salmon-pink with a yellow cup but populations with uniformly yellow flowers are not uncommon. When dry the shape of the flowers is often lost but its large size makes identification fairly easy. The tepals, ovary, filaments, anthers, and capsules are amongst the largest in the genus. The outer tepals are usually 35–40 mm long, and the filaments are ± 8 mm long with the anthers up to 11 mm long. The ovary, initially 17–20 mm long, elongates after fertilization and the capsules may reach a length of 55 mm. The capsules are notable in having a pointed beak some 2 mm long.

Distribution of ***Moraea flaccida***.

Earlier-flowering *Moraea collina* has been confused in the past with *M. flaccida* but is a shorter, few-branched species, the flowers with suberect tepal claws forming a narrow cup enclosing both filaments and anthers. The tepals of *M. collina* seldom exceed 35 mm, the filaments are 6–7 mm long, and the anthers are slightly shorter, 5–6 mm long. The ovary in *M. collina* is often as long as that of *M. flaccida* and the capsule may attain a length of over 35 mm. Capsules of *M. collina*, however, have a shorter, rather obtuse beak ± 1 mm long. Although *M. flaccida* flowers relatively late in the season, by which time *M. collina* is usually in fruit, their flowering times may overlap and natural hybrids have been recorded between the two species on the Cape Peninsula. *Moraea flaccida* is a polyploid species, either tetraploid, $2n$ = 24, or hexaploid, $2n$ = 36, as on the Peninsula and the sandveld to the north, whereas *M. collina* is consistently tetraploid. The hybrids recorded between the two species were pentaploid, $2n$ = 30, and completely sterile.

187. **Moraea collina** *Thunb.*, Dissertatio de *Moraea*: 11 (1787). *Sisyrinchium collinum* (Thunb.) Cav.: 346 (1788). *Homeria collina* (Thunb.) Salisb.: 307 (1812); Goldblatt: 471 (1981). Type: South Africa, [Western Cape], hills around Cape Town, *Thunberg s.n.* [UPS–THUNB 1209, lecto. designated by Goldblatt: 471 (1981)].

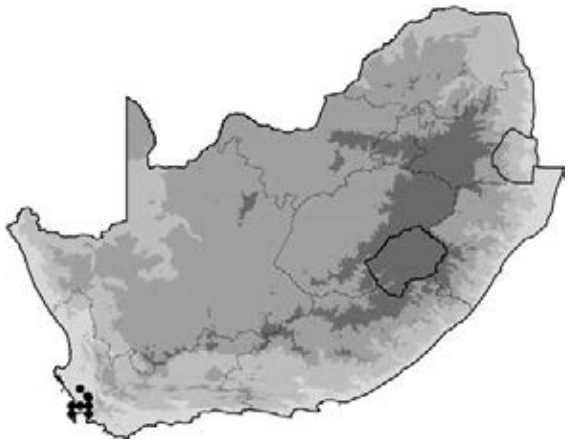
Sisyrinchium aurantiacum Zuccagni in Roem.: 145 (1806). *Homeria aurantiaca* (Zuccagni) Sweet: 498 (1830). *Moraea aurantiaca* (Zuccagni) A.Dietr.: 485 (1833). *H. collina* var. *aurantiaca* (Zuccagni) Baker: 75 (1892). *H. breyniana* var. *aurantiaca* (Zuccagni) G.J.Lewis: 232 (1950). Type: unknown, name often applied to *M. flaccida*.

Homeria collina var. *miniata* F.Muell.: 215 (1893). Type: unknown.

[*Moraea grandiflora* Eckl.: 14 (1827), invalid name without description.]

[*Vieusseuxia aurantiaca* Eckl.: 13 (1827), invalid name without description.]

[*Vieusseuxia collina* Eckl.: 12 (1827), invalid name without description.]



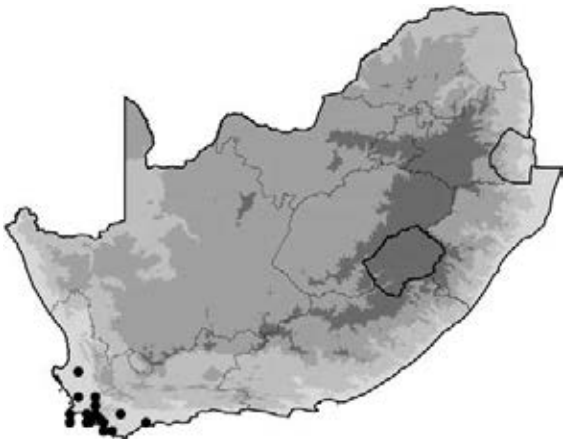
[*Vieusseuxia grandiflora* Eckl.: 14 (1827), invalid name without description.]

Plants 180–350 mm high. *Corm* 12–18 mm diam.; tunics of wiry, black fibres. *Stem* abruptly flexed outward above sheath of foliage leaf, simple or few-branched, branches also flexed outward, bearing attenuate sheathing leaves 20–40 mm long. *Foliage leaf* solitary, inserted well above ground, channelled, exceeding stem, usually trailing distally, 4–10 mm wide. *Rhipidial spathes* attenuate, inner 50–80 mm long, outer ± ½ as long. *Flowers* long-lived, pale yellow or salmon-pink, outer tepal limbs usually with deep yellow nectar guides at bases edged green, spreading, claws suberect, forming a narrow cup ± 12 mm deep, including filaments and anthers, ± 10 mm wide at mouth; outer tepals ± obovate, (25–)30–35 × 10–12 mm, claws 12–15 mm long, often papillate near bases, inner tepals 24–30 × 10 mm. *Filaments* united in a cylindric column 6–7 mm long, lightly pubescent in lower ½; anthers 5–6 mm long, slightly diverging above, yellow; pollen yellow. *Ovary* cylindric, (10–)14–19 mm long, often partly included; style branches (5–)6 mm long, diverging slightly and reaching anther tips, stigma lobe arched over anther tips, crests ± 1 mm long, erect to incurved. *Capsules* cylindric, (21–)30–40 mm long, short rounded beak ± 1 mm long. *Seeds* angular. *Chromosome number* $2n$ = 24. *Flowering time*: late June to early September.

Distribution and ecology: locally common in the south-western Western Cape, South Africa, from the Cape Peninsula east to Bot River and north to Bain's Kloof; mostly on sandy ground and flowering well following a fire or when the ground is cleared.

Diagnosis: *Moraea collina* is distinguished by the solitary leaf inserted on the stem well above ground, the stem flexed above the sheath of the foliage leaf, and yellow or pink flowers with the tepal claws forming a narrow cup including both filaments and anthers. The capsules are unusually long, even for sect. *Homeria*, typically 30–40 mm long and have a short blunt beak ± 1 mm long. It is often difficult to distinguish in herbaria from several other solitary-leaved species of sect. *Homeria*, in particular *M. minor* and *M. flaccida*. In *M. minor* the shorter anthers are 3–5 mm long, the style branches are 5–6 mm long and divide 2–3 mm above the anther bases, the ovary is shorter, up to 10 mm long, with capsules 18–28 mm long. Taller, more robust *M. flaccida* has tepals 35–40 mm long with claws that diverge to form a wide cup, elongate capsules, typically 30–55 mm long, with an acute beak ± 2 mm long.

Natural hybrids between *Moraea collina* and *M. flaccida* have been recorded from the Cape Peninsula. Because *M. flaccida* is hexaploid, $2n$ = 36 in this area (elsewhere sometimes tetraploid) and *M. collina* consistently tetraploid, $2n$ = 24, the resulting pentaploid hybrid with $2n$ ($5x$) = 30 is sterile.



Distribution of ***Moraea collina***.

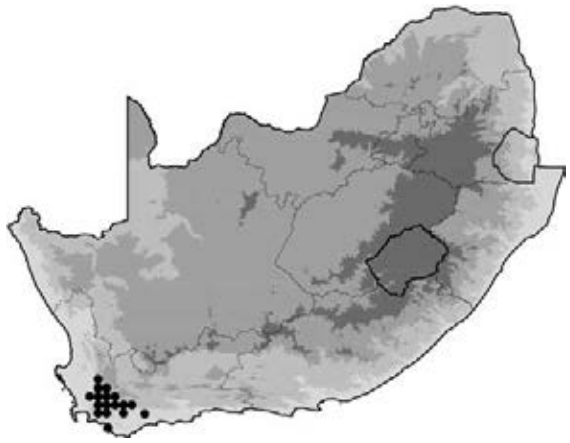
188. **Moraea pyrophila** *Goldblatt* in Novon 8: 375 (1998), as a new name for *Homeria galpinii* L.Bolus: t. 417 (1931d) [not *Moraea galpinii* (Baker) N.E.Br. (1929)]; Goldblatt: 469 (1981). Type: South Africa, [Western Cape], Klein Drakenstein Mtns above Salem, *Galpin 10600* (BOL [19420], holo.; K, iso.).

Plants 150–300 mm high. *Corm* 15–25 mm diam.; tunics of coarse, tough black fibres. *Stem* usually flexed above sheath of foliage leaf, simple or few-branched, branches also flexed, bearing attenuate sheathing leaves 40–50 mm long. *Foliage leaf* solitary, inserted well above ground, channelled, 100–200 mm long, often shorter but sometimes exceeding stem, 6–10 mm wide, usually rigid with a prominent thickened, unifacial apex. *Rhipidial spathes* attenuate, 40–50(–60) mm long, outer ± $^1/_2$ as long. *Flowers* long-lasting, pale yellow, tepal claws erect, forming a narrow cup 3–4 mm wide at mouth, enclosing stamens and style branches, limbs spreading horizontally; outer tepals ovate-oblong, 28–33 × 9–12 mm, claws 9–10 mm long; inner tepals obovate, slightly smaller. *Filaments* united in a puberulous column 4–5 mm long, broadest at base, tapering upward; anthers 5–6(–8) mm long, diverging slightly, yellow; pollen yellow. *Ovary* 6–10 mm long; style branches ± as long as anthers or slightly shorter, crests erect or curving inward, up to 1 mm long. *Capsules* 12–15(–20) mm long, ellipsoid. *Chromosome number* 2*n* = 12, 24. *Flowering time*: mainly July to September but also in March, April and November.

Distribution and ecology: restricted to southwestern Western Cape, South Africa, recorded on the Piketberg Mtns and from the southern Cape Peninsula and Bain's Kloof east to the Potberg; on sandstone derived soils, flowering rarely except after fire.

Diagnosis: *Moraea pyrophila* is recognised by the solitary foliage leaf inserted well above the ground, sparsely branched (rarely simple), flexuose stem, and yellow flower with the erect tepal claws forming a narrow cup ± 10 mm long completely enclosing the stamens. The filaments are entirely united in a cylindric column 4–5 mm long relatively densely hairy in the lower half, and the anthers, 5–8 mm long, are usually slightly shorter than the style branches. The nearly erect style branches, ± 5 mm long, bear short, horizontal crests, hardly visible in pressed flowers. *Moraea pyrophila* may be most closely related to *M. autumnalis*, which has the foliage leaf inserted close to ground level, and deeper yellow flowers with a floral cup including the filaments and only the bases of the anthers. *Moraea pyrophila* may also be confused with *M. collina* but that species has a longer leaf, usually trailing distally in contrast to the very short, apically thickened leaf of *M. pyrophila*, which seldom exceeds the stem.

Distribution of ***Moraea pyrophila***.



Both diploid and tetraploid populations have been recorded, tetraploids at Houw Hoek and Kleinmond and diploids at Hermanus and the Cape Peninsula. Although plants usually flower in late winter or early spring *M. pyrophila* has also been recorded in flower from March to September and in November.

189. **Moraea longistyla** *(Goldblatt) Goldblatt* in Novon 8: 375 (1998). *Homeria longistyla* Goldblatt: 475 (1981). Type: South Africa, [Western Cape], near bridge over Riviersonderend River east of Villiersdorp–Elgin road, *Goldblatt 4881* (MO, holo.; K, NBG, PRE, S, WAG, iso.).

Plants 150–300 mm high. *Corm* 8–14 mm diam.; tunics of wiry, black fibres. *Stem* flexed above leaf insertion, usually with several branches, or simple, with entirely sheathing leaves 30–50 mm long. *Foliage leaf* solitary, inserted shortly above ground, linear, channelled, longer than stem. *Rhipidial spathes* attenuate, inner 35–60 mm long, outer ± half as long. *Flowers* deep to pale orange-pink or pale yellow, with dark yellow nectar guides at bases of tepal limbs, tepal claws forming a cup 8–9 mm wide, including the filaments and anthers, limbs spreading, flaccid; outer tepals 25–35 × 10–14 mm, claws 11–15 mm long, limbs ± oblong, obtuse; inner tepals slightly smaller. *Filaments* united in a slender, cylindric column 7–9 mm long, minutely papillate-pubescent, smooth near apex; anthers erect, 4–7 mm long, contiguous or slightly diverging in upper $^1/_3$. *Ovary* 8–12(–15) mm long; style dividing opposite or beyond anther tips; branches short, 1–2 mm long or barely developed, stigma bilobed, crests minute, obscure or lacking. *Capsules* 15–20 mm long, cylindric, with short, acute beak ± 1 mm long. *Seeds* angular. *Chromosome number* 2*n* = 12. *Flowering time*: mid-August to October.

Distribution and ecology: endemic to Western Cape, South Africa, from Caledon north to Ceres and Tulbagh and east to Koo and Montagu; usually on clay soils in renosterveld.

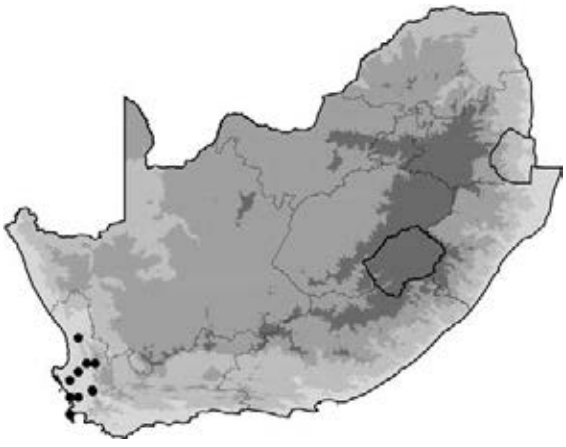
Diagnosis: *Moraea longistyla* is specialised in subg. *Homeria* in having the branches of the style almost or entirely suppressed, the style either dividing near the

Distribution of ***Moraea longistyla***.

apex of the anthers, with very short branches, 1–2 mm long, or essentially undivided with three apical stigmatic lobes. In other respects the species broadly resembles *M. collina* and particularly *M. minor* in the tepal claws forming a narrow cup including the stamens. In *M. minor* the style divides at or below the midline of the anthers, and the well-developed style branches are fairly broad and at least 3 mm long, bearing distinct crests. The ovary and capsules of *M. longistyla* are usually well-exserted from the spathes, while those of *M. minor* are typically enclosed, at least during development, although the ripe capsules are usually exserted. *Moraea longistyla* and *M. minor* have complementary distribution ranges, with *M. minor* always in sandy soils from the Cape Peninsula northward along the west coast into the Olifants River Valley. The morphological distinction between the two is supported by their reproductive biology: *M. longistyla* is self-incompatible, whereas the several populations of *M. minor* studied have proved to be self-compatible and autogamous.

190. **Moraea minor** *Eckl.*, Topographisches Verzeichniss der Pflanzensammlung von C.F. Ecklon: 15 (1827). *Homeria minor* (Eckl.) Goldblatt: 473 (1981). Type: South Africa, [Western Cape], sandy places in vineyards on eastern slopes of Table Mtn, *Ecklon Irid 7* [S, lecto., designated by Goldblatt: 473 (1981)].

Vieusseuxia curvata Eckl.: 13 (1827). Type: South Africa, [Western Cape], vineyards near Witteboom, *Ecklon s.n.* [S, lecto., designated by Goldblatt: 473 (1981)].

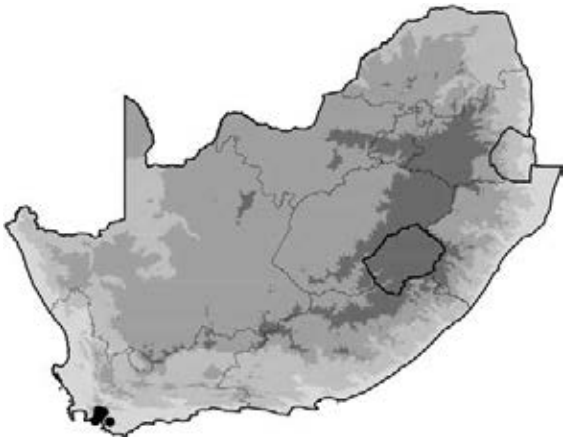


Homeria rhopalocarpa Schltr.: 95 (1900). Type: South Africa, [Western Cape], Vanrhynsdorp, Windhoek, *Schlechter 8366* (B, lecto., designated by Goldblatt: 473 (1981); BOL, C, E, G, GRA, K, M, MO, P, PRE, S, US, isolecto.).

Homeria framesii L.Bolus: 259 (1931c). Type: South Africa, [Western Cape], near Moorreesburg, *Ross-Frames s.n.* (BOL [19147], lecto., designated by Goldblatt: 473 (1981); K, PRE, isolecto.).

Plants 100–300 mm high. *Corm* 10–12 mm diam.; tunics of wiry, black fibres. *Stem* 1- to 3-branched, flexed above leaf insertion and at upper nodes, main axis of only 2 internodes above leaf, lowermost node bearing a sheathing leaf (sometimes with a short lamina). *Foliage leaf* solitary, inserted well above ground, linear, channelled, exceeding stem, 4–8 mm wide. *Rhipidial spathes* attenuate, inner initially ± 50 mm long with the outer ± $^{2}/_{3}$ as long, inner usually much elongating in fruit enclosing developing capsules, up to 80 mm long. *Flowers* fugaceous, usually dark pink with yellow nectar guides at bases of tepal limbs outlined in green, occasionally yellow, tepal claws forming a narrow cup including stamens and style branches, limbs spreading; outer tepals 22–38 × 9–16 mm, obovate; inner tepals 20–36 × 8–14 mm, often twisted. *Filaments* united in a cylindric column 6–9 mm, minutely pubescent in lower half; anthers erect 3–6 mm long, diverging in upper half. *Ovary* 9–15 mm long, enclosed in spathes; style branching opposite middle of anthers; branches erect, barely diverging, 2–3 mm long, usually reaching apex of anthers, or shorter, stigma lobe curved over anther tips, with short, erect crests < 1 mm long. *Capsules* cylindric, 25–28 mm long, without beak, enclosed in spathes during ripening. *Chromosome number* 2*n* = 12. *Flowering time*: mid-August and September.

Distribution and ecology: common along the Atlantic Coast of Western Cape, South Africa, from the Cape Peninsula north into the Olifants River Valley as far north as Klawer and locally into Elandskloof; on sandy soils, usually in sandveld.



Diagnosis: a diploid, self-compatible and autogamous species, *Moraea minor* has fugaceous flowers, opening in the late morning and fading in the middle of the afternoon of the same day. The flowers are similar to but slightly smaller that those of *M. collina,* having tepal claws forming narrow cup including the stamens and style branches, but the capsules are smaller, 25–28 mm long and without a beak, whereas the longer capsules of *M. collina* are typically 30–40 mm long, with an obtuse beak. On the Cape Peninsula, where both *M. collina* and

Distribution of ***Moraea minor***.

M. minor occur, the species are separated by a difference in flowering times, although they may be sympatric and have similar soil preferences. *Moraea minor* flowers in late August and September there, while *M. collina* blooms from June onwards and is usually in seed by August. *Moraea minor* is closely allied to *M. longistyla*, which occurs east of the range of *M. minor* and usually on clay or rocky ground, and their differences are discussed under that species. Flowers of *M. minor* are fugaceous, whereas those of *M. collina* and *M. longistyla* last two or three days.

191. **Moraea comptonii** *(L.Bolus) Goldblatt* in Novon 8: 375 (1998). *Homeria comptonii* L.Bolus: 294 (1929b); Goldblatt: 459 (1981). Type: South Africa, [Western Cape], near Villiersdorp, *Compton s.n.* (BOL, lecto., designated by Goldblatt: 459 (1981); K, isolecto.).

Distribution of ***Moraea comptonii***.

Plants 180–300 mm high. *Corm* 10–15 mm diam.; tunics of coarse, black fibres. *Stem* usually several-branched, bearing attenuate sheathing leaves 40–60 mm long. *Foliage leaf* solitary, inserted at or near ground level, linear, channelled, exceeding stem, often trailing distally, 3–7 mm wide. *Rhipidial spathes* attenuate, inner 70–100 mm long at flowering, much elongating after flowering and enclosing developing capsules, outer initially ± $^1/_2$ as long as inner. *Flowers* long-lived, yellow or pink to orange with yellow centre, sometimes with large dark green blotches on outer or both tepal whorls, tepals weakly divided into claws in lower half, but lower halves forming an open cup and upper halves ± spreading, heavily and sweetly scented; outer tepals 32–52 × 13–18 mm long, often pandurate or spathulate, widest in upper $^1/_3$; inner tepals 30–50 × 8–15 mm. *Filaments* united in a column tapering from wider base, 6–8 mm long, pubescent in lower $^2/_3$; anthers (8–)10–13 mm long, diverging, usually shorter than style branches, occasionally reaching or exceeding stigma lobes, yellow; pollen yellow. *Ovary* ± cylindric, ± 18 mm long, included or half exserted; style branches diverging, 6–10 mm long, crests erect to incurved, ± 1 mm long. *Capsules* initially cylindric, 25–30 mm long, included. *Seeds* angular. *Chromosome number* 2*n* = 12. *Flowering time*: late August and September.

Distribution and ecology: endemic to the Caledon District of Western Cape, South Africa, from near Villiersdorp and Bot River in the west to Caledon and Akkedisberg Kloof near Stanford in the east; on heavy clay soils in renosterveld.

Diagnosis: large-flowered *Moraea comptonii* is distinguished by the fiddle-shaped to spathulate tepals weakly divided into claw and limb, with the lower halves forming an open cup and upper halves spreading. The flowers are particularly strongly and sweetly scented and either entirely yellow, or salmon-pink to orange with a yellow cup, often with dark green markings in the lower third. Like its close relative *M. elegans*, plants have a solitary leaf, a partly to fully included ovary, and the inner rhipidial spathes become enlarged to enclose the developing capsules. Also like *M. elegans*, the filaments are fully united in a column tapering from a wide base but the anthers are usually shorter than the style branches in contrast to *M. elegans*, in which the anthers exceed the style branches. Another difference between the two is that the tepals of *M. elegans* are more-or-less ovate, widest in the lower third, and the tepal markings are confined to the outer tepals in the upper third, whereas tepals of *M. comptonii* are widest in the distal third and are either unmarked or have markings at the bases of the tepal limbs of both whorls. Both species have a pollination system using hopliine beetles, various flies and large-bodied bees, the dark markings serving to attract hopliines and the scent the flies and bees.

192. **Moraea elegans** *Jacq.*, Plantarum rariorum horti caesarei Schoenbrunnensis descriptiones et icones 1: 6 (1797). *Sisyrinchium elegans* (Jacq.) Willd.: 577 (1800). *Homeria elegans* (Jacq.) Sweet: 395 (1826a); Goldblatt: 462 (1981). Type: South Africa, without precise locality or collector, illustration in Jacq.: 6 (1797).

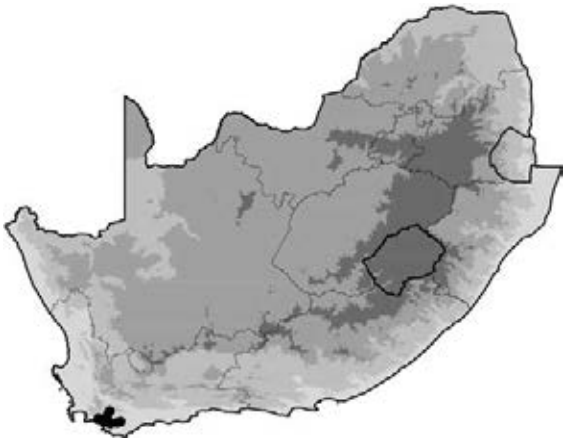
Moraea spicata Ker Gawl.: t. 1283 (1810b). *Homeria spicata* (Ker Gawl.) Sweet: 395 (1826a). Type: South Africa, without precise locality or collector, illustration in Ker Gawl.: t. 1283 (1810b).

Homeria metelerkampiae L.Bolus: 116 (1928b). Type: South Africa, [Western Cape], ex hort. Metelerkamp, Wellington, wild origin uncertain, *Metelerkamp s.n.* (BOL [31415], lecto., designated by Goldblatt: 462 (1981); K, isolecto.).

Plants 150–300 mm high. *Corm* 10–12 mm diam.; tunics of coarse wiry, black fibres. *Stem* few- to several-branched, bearing attenuate sheathing leaves 50–70 mm long. *Foliage leaf* solitary, inserted at or near ground level, linear, channelled, longer than stem, erect or trailing distally, 7–10 mm wide. *Rhipidial spathes* attenuate, inner 70–100 mm long, later elongating to enclose developing capsules, outer initially ± $^1/_2$ as long as outer. *Flowers* long-lived, predominantly yellow with large green blotch in middle or upper $^1/_3$ of outer tepals and usually orange distally, tepals spreading ±

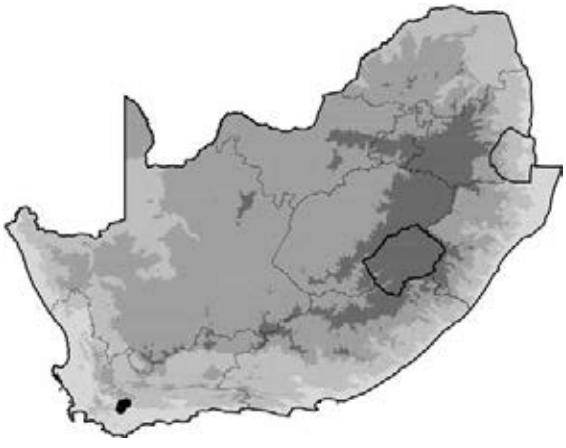
horizontally from base, weakly differentiated into claw and limb, strongly and sweetly scented; outer tepals 28–35 mm long, oblong or ovate, claws narrow, 13–15 mm wide, widest in lower $^1/_3$; inner tepals 26–38 mm long, ± as long or slightly longer than outer, 10–11 mm wide. *Filaments* 5–7 mm long, united in a column tapering from wider base, pubescent in lower $^1/_3$ or $^1/_4$; anthers 8–10 mm long, diverging, exceeding style branches, apices curving inward after dehiscence, yellow; pollen yellow. *Ovary* ± cylindric, 12–15 mm long, usually included; style branches diverging, ± 6 mm long, shorter than anthers, stigma lobe erect, appressed to anthers, crests 1–2 mm long, directed inward. *Capsules* cylindric, 20–25 mm long, included. *Seeds* angular. *Chromosome number* 2*n* = 12. *Flowering time*: late August to early October.

Distribution and ecology: restricted to the Caledon and Bredasdorp Districts of Western Cape, South Africa, extending from Genadendal and Caledon eastwards along the foot of the Caledon Swartberg to Napier and Bredasdorp, and in the Hemel-en-Aarde Valley to the south; on heavy clay soils in renosterveld, flowering well after fire or clearing of the surrounding vegetation.



Diagnosis: *Moraea elegans* is distinguished by the large flowers with predominantly yellow tepals spreading from the base, the tepals oblong and broadest in the lower half with the outer tepals strikingly marked with large green or green and orange blotches in the distal half. Plants have a solitary foliage leaf and bear few to several branches. The anthers, 8–10 mm long, are borne on a sturdy filament column wide at the base and tapering to a narrow apex, and exceed the style branches, an important distinction between *M. elegans* and closely allied *M. comptonii*, which has shorter anthers, either uniformly yellow or salmon to orange flowers with a yellow cup with or without green markings, these at the base of the spathulate or fiddle-shaped outer tepals, thus in the middle to lower third of the tepals. *Moraea elegans* and *M. comptonii* have complementary ranges in the Caledon and Bredasdorp Districts and are generally easy to distinguish, although some populations of *M. comptonii* approach *M. elegans* in appearance.

193. **Moraea radians** *(Goldblatt) Goldblatt* in Novon 8: 375 (1998). *Sessilistigma radians* Goldblatt: 156 (1984a). *Homeria radians* (Goldblatt) Goldblatt: 51 (1991). Type: South Africa, [Western Cape], between MacGregor and Stormsvlei at Steenbokvlakte turnoff, *P. Goldblatt 5903* (MO, holo.; K, PRE, S, iso.).



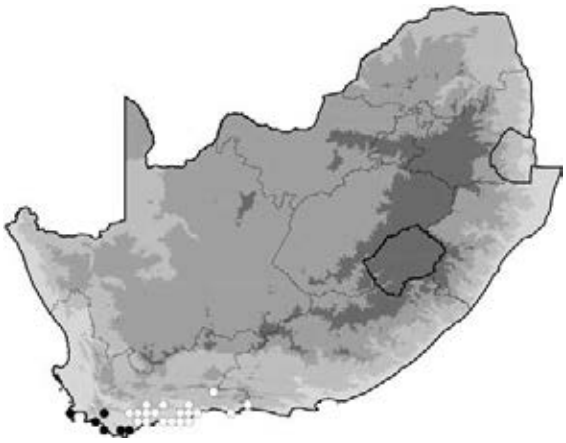
Plants 90–350 mm high. *Corm* 9–15 mm diam.; tunics of coarse, black, netted fibres. *Stem* with elongate basal internode, flexed above sheath of foliage leaf, usually 2- or 3-branched, sheathing leaves with brown attenuate tips, 20–35 mm long. *Foliage leaf* solitary, inserted 25–80 mm above ground, exceeding stem, arching outward, channelled, 2–5 mm wide. *Rhipidial spathes* attenuate, with dry brown tips, inner 30–50 mm long, outer ± half as long. *Flowers* fugaceous, beige-yellow, limbs of all tepals deep yellow at bases, spreading, tepal claws suberect, forming a small narrow cup ± 3 mm deep enclosing filaments; outer tepals obovate, 26–30 × 17 mm, claws 3–4 mm long; inner tepals 24–27 × ± 15 mm. *Filaments* free, ± 4 mm long, minutely papillate; anthers initially straight, suberect, ± 5 mm long, exceeding style branches, curving inward over style branches after anthesis, yellow; pollen yellow. *Ovary* ± cylindric, ± 10 mm long; style ± 1 mm long, branches diverging, ± 3 mm long, flattened and divided for half their length, stigmatic at tips of lobes, without crests. *Capsules* oblong-cylindric, 12–15 mm long. *Seeds* angular. *Chromosome number* 2*n* = 12. *Flowering time*: September to early October.

Distribution and ecology: a narrow endemic of the Robertson Karoo in Western Cape, South Africa, known from a few sites near MacGregor; on light clay or clay loam soils.

Diagnosis: although vegetatively resembling several other species of sect. *Homeria* in the solitary, somewhat glaucous leaf inserted above the ground and the few-branched stem, *Moraea radians* is so distinctive in its floral structures that it was at first referred to a

Distribution of ***Moraea elegans***.

Distribution of ***Moraea radians***.



separate genus, *Sessilistigma*. The beige-yellow flowers, with short, erect tepal claws and spreading limbs, are remarkable for the subgenus in their free stamens and almost vestigial style ± 1 mm long, dividing into three, flattened branches forked for half their length. Other species of subg. *Homeria* have filaments partly to entirely united and enclosing a well-developed style, the branches of which are each appressed to the opposed anther. The style branches of *M. radians* lack crests and are stigmatic at the tips of each lobe. Other features of the species, including the chromosome number and karyotype, $2n = 12$, are consistent with subg. *Homeria* and its assignment to the subgenus is fully supported by molecular evidence.

194. **Moraea bulbillifera** *(G.J.Lewis) Goldblatt* in Novon 8: 374 (1998). *Homeria bulbillifera* G.J.Lewis: 117 (1945); Goldblatt: 455 (1981). Type: South Africa, [Western Cape], Caledon Division, Riviera, *Purcell s.n.* (*SAM 54696*, holo.).

Plants 300–500(–600) mm high. *Corm* 10–20 mm diam., often with many small cormlets around base; tunics of coarse, black fibres. *Stem* sometimes ± trailing or suberect, usually much-branched, flexed above sheath of foliage leaf and above sheathing leaves, sometimes bearing several to many cormlets in aerial axils, with attenuate sheathing leaves 3.5–8.0 mm long. *Foliage leaf* solitary, usually inserted at or near ground level, rarely some distance above ground, exceeding stem, channelled, 5–10 mm wide. *Rhipidial spathes* attenuate, inner 40–80 mm long, elongating after flowering to enclose developing capsules, outer ± ½ as long at flowering. *Flowers* fugaceous, pale or deep yellow, occasionally pale pink or flushed orange-pink, all tepal limbs with dark yellow nectar guides at bases spotted green, spreading, tepal claws suberect, forming a small narrow cup 7–10 mm deep, enclosing filaments and lower part of anthers; outer tepals obovate, 23–38 × 10–16 mm, claws 9–11 mm long, inner tepals slightly smaller, 7–12 mm wide. *Filaments* united in a cylindric column 6–8 mm long, papillate or smooth; anthers 4–6 mm long, diverging, often slightly exceeding style branches, yellow; pollen yellow. *Ovary* 7–10(–13) mm long; style branches diverging, 2.5–6.0 mm long, stigma lobes upright, pressed against anthers, receptive laterally, crests 1–2 mm long, directed inward. *Capsules* 17–20(–22) mm long, narrowly club-shaped. *Seeds* angular. *Chromosome number* $2n = 12$, 18, 24. *Flowering time*: August to early October inland, September to early November along the coast.

Distribution and ecology: along the south coast of South Africa, extending from the Cape Peninsula in the west to the Albany District in Eastern Cape in the east, south of the Langeberg–Outeniqua Mtn axis, most frequent between Elim and Knysna; mostly in sandy ground.

Diagnosis: coastal populations of *M. bulbillifera* are unmistakable for the strongly cormiferous habit, but even plants lacking cormlets in the aerial axils are fairly easy to distinguish from other solitary-leaved species by their flowers with the narrow tepal cup enclosing only the filaments, with the anthers and well-developed style branches and crests extending well above the cup. The foliage leaf is usually inserted at or very close to the ground but plants from the drier valleys at the northern edge of its range are often confusing as the leaf may be inserted rather high above ground. Two subspecies are recognised. The typical subsp. *bulbillifera* is coastal and always found on sandy or limestone substrates. It is usually robust and has a well-developed cormiferous habit. Subsp. *anomala* occurs inland, mainly in renosterveld, on the rolling clay plains of the southern Cape, extending into the sandy and rocky valleys of the Langeberg and Riviersonderend Mtns. Sometimes as robust as subsp. *bulbillifera*, it is more often a much smaller plant, especially in drier habitats, with the dwarfing extending to the flowers as well.

Distribution of ***Moraea bulbillifera*** subsp. ***bulbillifera***, ●; subsp. ***anomala***, ○.

Key to subspecies

1a Stems with cormlets at aerial nodes conspicuous and breaking through leaf sheaths. . . . . 194a. subsp. *bulbillifera*

1b Stems without cormlets at aerial nodes (rarely a single cormlet developing at some nodes, always concealed by sheaths) . . . . . 194b. subsp. *anomala*

194a. subsp. **bulbillifera**

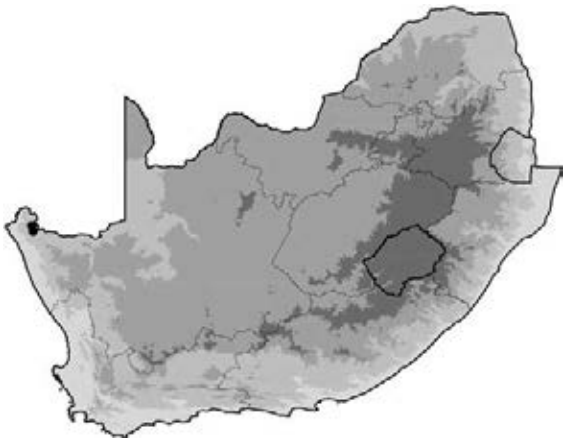
Foliage leaf basal, often trailing. *Stem* bearing multiple cormlets at nodes, (1)3- to 10-branched, usually from upper nodes, bearing attenuate sheathing leaves 35–60 mm long. *Rhipidial spathes* somewhat inflated, attenuate with dry, brown tips; inner 50–80 mm long. *Flowers* with outer tepals 23–38 × (10–)14–16 mm, inner tepals 22–32 mm long. *Filaments* 6–7 mm long; anthers 4.5–6.0 mm long, usually ± as long as style branches, or longer. *Chromosome number* $2n = 12$ (18). *Flowering time*: mid-September to November.

Distribution and ecology: entirely coastal, extending from the southern Cape Peninsula eastward to Cape

Agulhas in southern Western Cape; mostly in sandy soils, sometimes on limestone.

Distribution and ecology: subsp. *bulbillifera* is immediately recognised by the conspicuous production of small cormlets at the aerial nodes of the stem. Although plants are usually several-branched, the stems often appear attenuated and the lower nodes often lack branches, and the stem is sometimes ± trailing. Many collections of this subspecies lack developing capsules and it seems likely that at least some populations are sexually sterile. The copious cormlets presumably ensure propagation of such plants.

194b. subsp. **anomala** *(Goldblatt) Goldblatt* in Goldblatt & Manning in Novon 14: 296 (2004). *Homeria bulbillifera* subsp. *anomala* Goldblatt: 458 (1981). Type: South Africa, [Western Cape], Witsands near Ossekop, *Goldblatt 4885* (MO, holo.; BR, K, NBG, PRE, WAG, iso.).



Foliage leaf basal or inserted some distance above ground, usually erect, or trailing distally. *Stem* usually without cormlets at nodes, (1)10- to 20-branched, sheathing leaves 30–60 mm long. *Outer rhipidial spathe* 40–70 mm long, slender. *Flowers* usually smaller than subsp. *bulbillifera*; outer tepals 26–35 × 10–15 mm; inner tepals 23–32 mm long. *Filaments* 6–8 mm long; anthers 5–6 mm long, exceeding style branches, apices curving inward after anthesis. *Chromosome number* 2*n* = 12, 24. *Flowering time*: August to October.

Distribution and ecology: extending from Stormsvlei and Bredasdorp in the west, along the Langeberg–Outeniqua axis as far east as the Albany District; on clay or sand, and inland or coastal.

Diagnosis: flowers of subsp. *anomala* are usually smaller than those of subsp. *bulbillifera* with outer tepals rarely reaching 35 mm in length. The foliage leaf may be basal as in subsp. *bulbillifera* but is more often inserted shortly to well above the ground. Plants will on occasion produce one or two cormlets at some nodes, but this development is much less noticeable than in subsp. *bulbillifera*, where the many cormlets break through the bases of the sheathing leaves.

195. **Moraea serratostyla** *(Goldblatt) Goldblatt* in Novon 8: 376 (1998). *Homeria serratostyla* Goldblatt: 212 (1992). Type: South Africa, [Northern Cape], Richtersveld, foothills of Cornellsberg, *Viviers sub Goldblatt 7377* (NBG, holo.; MO, PRE, iso.).

Plants 160–250 mm high. *Corm* 12–18 mm diam.; tunics of wiry, medium-textured to fine, black fibres. *Stem* sharply flexed above sheaths of foliage leaves, 1- to few-branched. *Foliage leaves* (2)3, lowermost longest, inserted well above ground, suberect, exceeding stem, linear to falcate, channelled, 2–3 mm wide. *Rhipidial spathes* acute, inner initially 30–40 mm long, later elongating

Distribution of ***Moraea serratostyla***.

to enclose developing capsules, outer ± 15–25 mm long. *Flowers* fugaceous, pale yellow, limbs of all tepals with deep yellow nectar guides at bases, ± spreading, tepal claws ascending, forming a cup including lower $^{2}/_{3}$ of filament column; outer tepals obovate, 23–39 × ± 12 mm, claws ± 5 mm long, inner tepals lanceolate, 22–28 × ± 9 mm. *Filaments* united in a smooth, cylindric column ± 6 mm long or free distally for short distance; anthers ± 6 mm long, ascending, tips curving inward after dehiscence, yellow. *Ovary* ± cylindric, ± 7 mm long, usually included; style branches ascending, ± 2.5 × 1.5 mm, reaching to mid-anther level, margins serrated, stigma bilobed, appressed to anthers, receptive laterally, crests ± 0.5 mm long, arching inward, margins serrated. *Capsules* ± barrel-shaped, ± 9 mm long, included. *Seeds* angular. *Chromosome number* 2*n* = 12. *Flowering time*: July and August; flowers open 15:30 and fade at nightfall, ± 19:30.

Distribution and ecology: evidently rare and known from a few collections in the central Richtersveld in Northern Cape, South Africa; on stony flats and lower slopes.

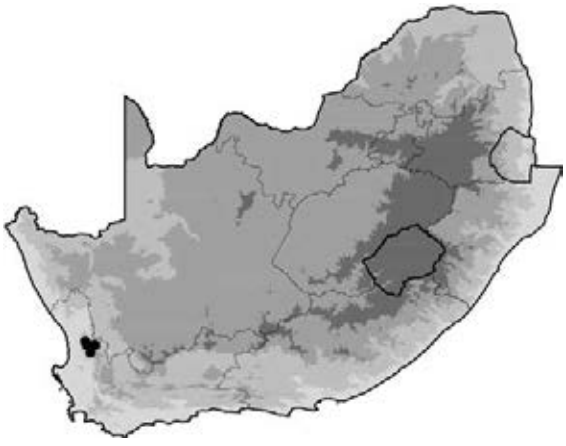
Diagnosis: *Moraea serratostyla* is recognised by the flexuose stem, two or three foliage leaves with the lowermost inserted on the stem well above ground, and relatively large, pale yellow flowers. Particularly unusual, the style branches are relatively well developed for subg. *Homeria*, ± 2.5 mm long with visible crests 0.5 mm long with the margins of both the style branches and crests serrated. The tepal claws, ± 5 mm long, form a wide cup that includes the lower part of the filament column while the tepal limbs spread outward, often slightly below the horizontal.

196. **Moraea patens** *(Goldblatt) Goldblatt* in Novon 8: 375 (1998). *Homeria patens* Goldblatt: 477 (1981). Type: [Western Cape], Clanwilliam Division, near Boontjies River, *Leipoldt s.n.* (BOL 20768], holo.; K, SAM, iso.).

Plants 250–450 mm high. *Corm* globose, ± 10 mm diam.; tunics of wiry, black fibres. *Stem* usually many-branched,

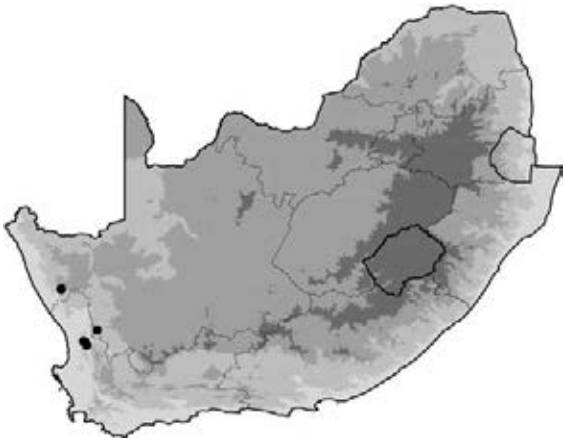
flexed outward above foliage leaf sheath and above sheathing leaves, these attenuate, 30–40 mm long. *Foliage leaf* solitary (rarely 2), inserted well above ground, linear, channelled, much exceeding stem, 3–5 mm wide. *Rhipidial spathes* attenuate, apices dry, brown, inner initially 40–60 mm long, elongating as capsules develop, inner ± half as long. *Flowers* fugaceous, bright yellow or orange, tepals limbs with dark yellow nectar guides at bases, laxly spreading, widely diverging, forming a wide, shallow cup including filaments; outer tepals pandurate, 25–27 × 9 mm, claw ± 9 mm long, inner tepals 20–24 × 7–8 mm. *Filaments* united in a cylindric column 7–8 mm long, papillate in lower half; anthers ± 4 mm long, diverging, yellow; pollen yellow. *Ovary* 9–10 mm long, exserted; style branches 3–4 mm long, ± as wide as anthers, reaching or slightly exceeding anther tips, crests erect, short (obscure in dry material). *Capsules* usually exserted or partly included, 12–15 mm long. *Chromosome number* 2*n* = 12. *Flowering time*: mid-August and September.

Distribution and ecology: a narrow endemic of the Clanwilliam District of Western Cape, South Africa, in valleys of the Olifants River, Nardouw and Pakhuis Mtns (poorly collected and evidently not common); on stony, sandy ground at relatively low elevations.



Diagnosis: with a relatively open flower, *Moraea patens* has tepal claws inclined gently upward forming a wide, shallow cup that includes the filament column and with the tepal limbs extending laxly outward. The filaments are united in a cylindric column 7–8 mm long and papillate in the lower half, and the diverging anthers are held well above the tepal cup. *Moraea patens* may be most closely related to the widespread *M. minor* but the two have quite different flowers, the tepal claws in *M. minor* forming a narrow cup completely including both the filaments and the suberect anthers. *Moraea vallisbelli*, occurring to the north on the Bokkeveld Mtns, is probably also closely allied but differs in its well-formed tepal cup, reduced style branches, and ovary and capsules enclosed by the accrescent rhipidial spathes.

197. **Moraea louisabolusiae** *Goldblatt* in Novon 8: 375 (1998), as a new name for *Homeria bolusiae* Goldblatt: 438 (1981) [not *M. bolusii* Baker (1892)]. Type: South Africa, [Western Cape], sandstone outcrop near Bulshoek, Olifants River Valley, *Goldblatt 5660* (MO, holo.; K, NBG, PRE, S, WAG, iso.).



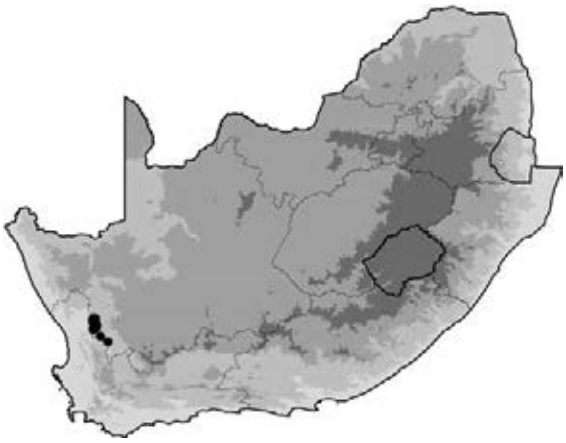
Plants slender, 150–400 mm high. *Corm* ± 10 mm diam.; tunics of wiry, black fibres. *Stem* flexed above leaf insertion, 1- to few-branched, bearing sheathing leaves 20–40 mm long. *Foliage leaf* solitary, inserted well above ground, channelled, exceeding stem, 2–4 mm wide, often broken and trailing above. *Rhipidial spathes* attenuate, inner 40–50 mm long, outer ± $^2/_3$ as long. *Flowers* fugaceous, pale yellow, limbs of all tepals with deeper yellow nectar guides at bases, spreading horizontally, claws short, appressed to lower part of filament column; outer tepals ± 28 × 12 mm, claws 1–2 mm long, limb pandurate-obovoid; inner tepals up to 20 × 8 mm. *Filaments* 5–6 mm long, partly united in a slender, smooth column, free and diverging in upper 0.5–1.0 mm; anthers ± 4 mm long, diverging and arching inward distally, exceeding stigmas, collapsing after anthesis, yellow. *Ovary* ± cylindric, 7–8 mm long, included; style branches broad, flattened, ± 2.5 mm long, stigmatic lobe upright, receptive laterally, crests 1.0–1.5 mm long. *Capsules* and *seeds* unknown. *Chromosome number* 2*n* = 12. *Flowering time*: late August and September, probably also in October.

Distribution and ecology: apparently with a scattered distribution along the Atlantic Coast of South Africa, recorded in Western Cape from the lower slopes of the Nardouw Mtns and in Northern Cape on the Bokkeveld Escarpment at Lokenburg and in the Kamiesberg; in rocky ground on sandstone or granite substrates.

Diagnosis: a fairly typical member of subg. *Homeria*, *Moraea louisabolusiae* has flowers with subequal tepals, all bearing nectar guides, short, erect tepal claws, and filaments largely united in a slender column but free in

Distribution of ***Moraea patens***.

Distribution of ***Moraea louisabolusiae***.



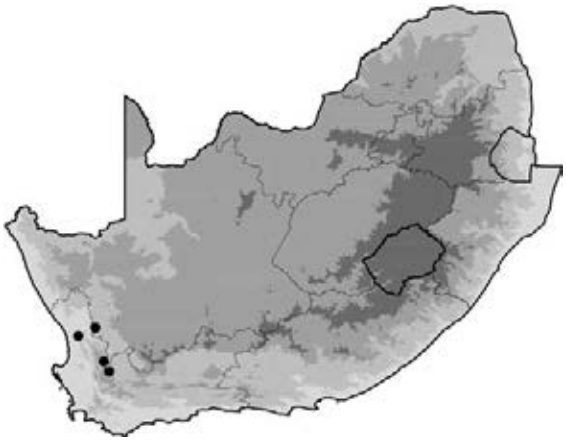
the distal 0.5–1.0 mm. The style branches are ± 2.5 mm long, shorter than the anthers, and bear short crests up to 1.5 mm long. Plants have a solitary, narrow foliage leaf inserted well above ground level and the stem is flexed outward above the sheathing part of the leaf. Apart from the single foliage leaf, the stem bears only sheathing leaves with attenuate apices. The flowers open early in the morning, at first light, and fade between 13:00 and 14:00. Molecular studies place *M. louisabolusiae* close to *M. patens*, which also has a solitary foliage leaf and the stem flexed above the leaf sheath but somewhat different flowers.

198. **Moraea vallisbelli** *(Goldblatt) Goldblatt* in Novon 8: 376 (1998). *Homeria vallisbelli* Goldblatt: 479 (1981). Type: South Africa, [Northern Cape], Oorlogskloof, *Schlechter 10947* (K, lecto., designated by Goldblatt: 479 (1981); B, BOL, M, isolecto.).

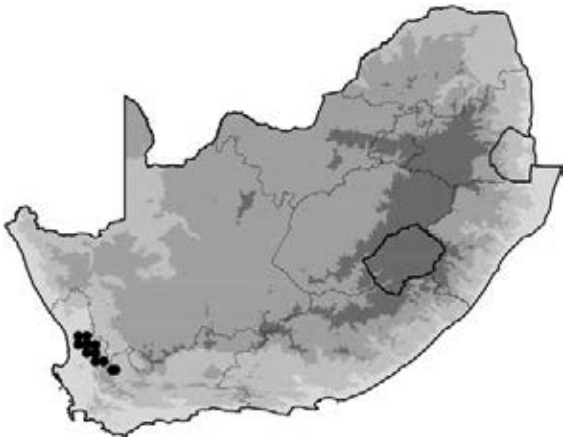
Plants 150–300 mm high. *Corm* subglobose, 8–15 mm diam.; tunics of fine to medium-textured, wiry, black fibres. *Stem* sharply flexed above sheath of foliage leaf and of sheathing leaves, usually several-branched (rarely simple), sheathing leaves attenuate, 25–50(–80) mm long, lowermost occasionally ± leaf-like. *Foliage leaf* solitary, inserted well above ground level, linear, ± erect or trailing distally, exceeding stem, channelled, margins inrolled. *Rhipidial spathes* attenuate with dry brown apices, inner initially 3.5–5.0(–7.0) mm long, later elongating to enclose developing capsules, outer initially ± $^1/_2$ as long. *Flowers* deep pink or pale yellow, with dark yellow nectar guides outlined in dark purple or green, tepal claws forming a wide cup, ± 8 mm deep, 10 mm wide at apex, including filament column, tepal limbs spreading; outer tepals ± 26 mm long, limbs 16–18 mm long, obovate, widest just below apex, claws ± 10 mm long, puberulous in lower part; inner tepals slightly shorter and narrower. *Filaments* united in a column 7–8 mm long, slightly narrowed toward apex, velvety in lower $^2/_3$; anthers ± 4.5 mm long, diverging, slightly overtopping style branches, yellow; pollen yellow. *Ovary* 9–12 mm long, included, rarely partly exserted; style branches narrow, ± 3 mm long, crests vestigial. *Capsules* cylindric, 12–14 mm long, usually included. *Seeds* angular-prismatic. *Chromosome number* 2*n* = 12. *Flowering time*: mostly August to mid-September.

Distribution and ecology: centred in the Bokkeveld Mtns north and south of Nieuwoudtville in Northern Cape, South Africa, but extending south to the lower Tanqua Karoo and Botterkloof; typically in stony sandstone soil in fynbos.

Diagnosis: *Moraea vallisbelli* is recognised by the solitary foliage leaf inserted on the stem well above ground, main stem and branches flexed above the sheaths of foliage or sheathing leaves, and a pink or yellow flower with the tepal claws diverging to form a relatively wide cup that includes the filaments. The filaments are united in a narrow column that is velvety



Distribution of ***Moraea vallisbelli***.



in the lower half, and the diverging anthers slightly exceed the style branches, the crests of which are vestigial. It is apparently related to the more widespread *M. minor* of the Western Cape Atlantic Coast and Olifants River Valley and the two are easily confused, especially when dried. However, in *M. minor* the tepal claws form a narrow cup including both filaments and anthers and the short style branches have larger, clearly visible crests. Both species are diploid but *M. minor* is autogamous and *M. vallisbelli* is self-incompatible. The species was first collected by Rudolf Schlechter in 1896 and his collections bear the manuscript name *Homeria tulipifera*.

199. **Moraea flavescens** *(Goldblatt) Goldblatt* in Novon 8: 375 (1998). *Homeria flavescens* Goldblatt: 481 (1981). Type: South Africa, [Western Cape], Cederberg, at turnoff to Krom River Farm, *Goldblatt 4058a* (MO, holo.; NBG, iso.).

Plants 120–300 mm high. *Corm* ± globose, 8–12 mm diam.; tunics of black, wiry fibres. *Stem* strongly flexed above sheath of foliage leaf, several-branched, sheathing leaves attenuate, 35–55 mm long. *Foliage leaf* solitary, inserted well above ground, linear, much exceeding stem, erect, trailing distally, channelled, up to 4 mm wide. *Rhipidial spathes* attenuate, apices dry, brown, inner initially 30–60 mm long, later elongating to enclose developing capsules, outer ± $^1/_2$ as long. *Flowers* fugaceous, pale yellow, tepal limbs with deep yellow nectar guides at bases edged grey-green, spreading, claws diverging, forming an open cup, ± 8 mm wide at mouth, including most of filament column; outer tepals obovate, 16–24 × 7–9 mm, often emarginate, claws 5–6 mm long, inner tepals 17–19 × 5–7 mm. *Filaments* united in a column ± 5 mm long, sometimes free in upper 0.5–2.0 mm, minutely papillate; anthers 3–4 mm long, diverging, yellow; pollen yellow. *Ovary* ± cylindric, 7–12 mm long, enclosed in spathes; style branches ± 2 mm long, flat, deeply bilobed, shorter than anthers, lobes extending between anthers. *Capsules* ellipsoid to cylindric, 8–16 mm long, enclosed until maturity. *Seeds* angular-prismatic. *Chromosome number* 2*n* = 9. *Flowering time*:

Distribution of ***Moraea flavescens***.

Distribution of ***Moraea demissa***.

September; flowers open in early morning and fade 13:00–14:00.

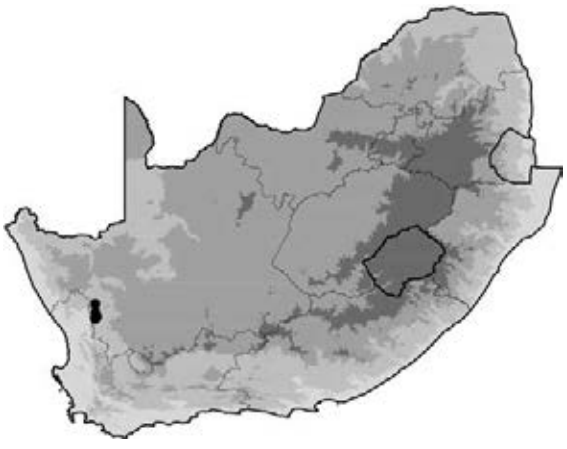
Distribution and ecology: restricted to the mountains along the West Coast of South Africa, in the Gifberg Mtn complex and in the southern Cederberg and Swartruggens; on stony sandstone slopes and flats in dry fynbos.

Diagnosis: relatively poorly documented, *Moraea flavescens* is rather variable as circumscribed at present. Plants in the south have smaller flowers than those in the north of its range and specimens from this area bear the manuscript name *H. klawerensis* L.Bolus. The species is characterised by its pale, watery yellow flowers with a wide tepal cup and emarginate outer tepals, and flat style branches shorter than the anthers. Populations from the southern Cederberg have the unusual diploid number of $2n = 9$, and form complex heterozygotes at meiosis. *Moraea flavescens* is closely related to a second Cederberg–Gifberg endemic, *M. demissa*, which also has unusual chromosome cytology with diploid numbers of $2n = 10$, 9 or 8. *Moraea demissa* has smaller flowers, also pale yellow, but the tepal claws are suberect and form a narrow cup around the lower half of the filament column. Flowers of *M. flavescens* open in the morning while those of *M. demissa* open after midday and last through the late afternoon.

200. **Moraea demissa** *Goldblatt* in Novon 8: 375 (1998), as a new name for *Homeria tenuis* Schltr.: 95 (1900) [not *M. tenuis* Ker Gawl. (1807)]; Goldblatt: 483 (1981). Type: South Africa, [Western Cape], Pakhuis Mtns, *Schlechter 8647* (B, lecto., designated by Goldblatt: 483 (1981); BOL, E, G, GRA, K, MO, P, PRE, US, Z, isolecto.).

Plants small, 70–200 mm high. *Corm* 5–10 mm diam.; tunics of black or brown, wiry or ± soft-textured fibres. *Stem* sharply flexed above sheath of foliage leaf, few- to several-branched, branches also flexed, bearing attenuate sheathing leaves 150–300 mm long. *Foliage leaf* solitary, inserted shortly to well above ground, linear, exceeding stem, channelled, 2–3 mm wide. *Rhipidial spathes* attenuate, inner initially 20–40(–60) mm long, later elongating to enclose developing capsules, outer 15–25 mm long. *Flowers* fugaceous, pale to deep yellow, tepals limbs with small deep yellow nectar guides at bases, spreading, claws suberect, forming a narrow cup ± 3 mm deep including lower $^1/_2$ of filament column; outer tepals oblong, 10–12 × ± 6 mm, claws 2–3 mm long, inner tepals lanceolate, 9–11 × 4 mm. *Filaments* united in a smooth cylindric column 5–6 mm long; anthers 1.5–2.0 mm long, diverging from base, yellow; pollen yellow. *Ovary* ± cylindric, 5–8 mm long, included; style branches 1.5–2.0 mm long, flattened, stigma bilobed, reaching middle to upper part of anthers, stigmatic laterally, crests very short, often obscured by anthers. *Capsules* clavate-cylindric, 8–11 mm long, included. *Seeds* angular. *Chromosome number* $2n = 10$, 9, 8. *Flowering time*: mid-August to early October; flowers open ± 14:00 and fade near nightfall.

Distribution and ecology: restricted to the mountains along the western coast of Western Cape, South Africa, extending from the Gifberg and Matsikamma Mtns through the Cederberg to the Cold Bokkeveld; on sandstone pavement, rocky sandstone slopes and on loamy clay.



Diagnosis: the smallest species of subg. *Homeria*, *Moraea demissa* has a solitary leaf, flexuose stem, and yellow flowers with tepals only 9–12 mm long. The tepal claws are suberect and form a narrow cup that includes the lower half of the filaments. Cytologically the species is of considerable interest as chromosome counts have revealed populations with diploid numbers of $2n = 10$, 9 and 8, with $2n = 9$ most common. The latter number, $2n = 9$, has also been recorded in the related *M. flavescens*. These two species contrast sharply with the basic $x = 6$ found in all other species of the genus except the unrelated *M. pallida*, a form of which has $2n = 8$. The significance of three different chromosome numbers in *M. demissa* has yet to be explained. Plants from sample populations grown in the greenhouse have proved to be autogamous.

Sect. 17. **Conantherae** *Goldblatt & J.C.Manning* in Goldblatt et al. in Bothalia 43: 40 (2013). *Homeria* sect. *Conantherae* [as *Conanthera*] Goldblatt: 427 (1981). Type: *Homeria miniata* (Andrews) Sweet = *Moraea miniata* Andrews

Stem straight or flexuose. *Foliage leaves* several to one. *Flowers* usually fugaceous (not *M. fuscomontana*), members of both whorls well developed and bearing nectar guides; tepal claws short, erect forming a cup enclosing base of filaments; filaments united entirely; anthers parallel and contiguous, stigmatic surfaces emerging between anthers.

201. **Moraea aspera** *Goldblatt* in Novon 8: 374 (1998), as a new name for *Homeria spiralis* L.Bolus: 260 (1931c) [not *Moraea spiralis* Baker (1892)]. Type: South Africa, [Northern Cape], Nieuwoudtville Waterfall, *H.M.L. Bolus s.n.* (BOL 19348], lecto., designated by Goldblatt: 498 (1981); GRA, K, PRE, isolecto.).

Plants 100–200 mm high. *Corm* ± globose, ± 10 mm diam.; tunics of coarse, black fibres. *Stem* flexuose, several-branched, minutely velvety, bearing attenuate, sheathing leaves 30–40 mm long. *Foliage leaves* 3, lowermost basal, remaining cauline, linear, ± falcate, channelled below, flat above and loosely coiled in upper half, 2–4 mm wide. *Rhipidial spathes* attenuate with dry apices, inner 25–50(–60) mm long, outer ± ½ as long. *Flowers* fugaceous, salmon-pink, all tepal limbs with yellow, darkly speckled nectar guides at bases, spreading, claws suberect, forming a shallow cup narrowly windowed between their bases, including base of filament column; outer tepals obovoid-oblong, 16–23 × ± 9 mm, claws ± 3 mm long, densely velvety 1 mm above bases; inner tepals smaller, obovate, 5–6 mm wide. *Filaments* united in a column 6 mm long, inflated above base, then gradually tapering to apex, densely velvety in bulbous part; anthers erect, contiguous, ± 2 mm long, shorter after dehiscence, yellow. *Ovary* ± ellipsoid, 6–7 mm long; style branches short, deeply forked, hidden by the anthers, apices emerging between anthers, crests absent. *Capsules* ± cylindric, 10–13 mm long. *Seeds* unknown.

Distribution of ***Moraea aspera***.

Chromosome number 2*n* = 12. *Flowering time*: August to mid-September.

Distribution and ecology: a narrow endemic restricted the northern end of the Bokkeveld Mtns, north and northeast of Nieuwoudtville in Northern Cape, South Africa; in stony clay soils in renosterveld.

Diagnosis: *Moraea aspera* is readily recognised by the three well-developed foliage leaves, relatively soft textured and loosely coiled distally, together with softly velvety, flexuose stems. Although always salmon-pink, the flowers are similar to those of *M. miniata* in having short, erect claws enclosing the base of the filament column, itself swollen above the base and densely velvety in the lower half. The two species are, however, easy to distinguish from vegetative morphology as *M. miniata* has straight, leathery leaves and a nearly straight, glabrous stem.

202. **Moraea miniata** *Andrews* in The Botanist's Repository 6: t. 404 (1804). *Homeria miniata* (Andrews) Sweet: t. 152 (1826b). Type: South Africa, without precise locality or collector, illustration in Andrews: t. 404 (1804).

Homeria lineata Sweet: t. 178 (1826c). *Moraea lineata* (Sweet) Steud.: 160 (1841). Type: South Africa, without precise locality or collector, illustration in Sweet: t. 178 (1826c).

Moraea gigantea Klatt: 381 (1867). Type: South Africa, [Northern Cape], between Great and Little Riet Rivers, *Burchell 1388* [K, lecto., designated by Goldblatt: 485 (1981)].

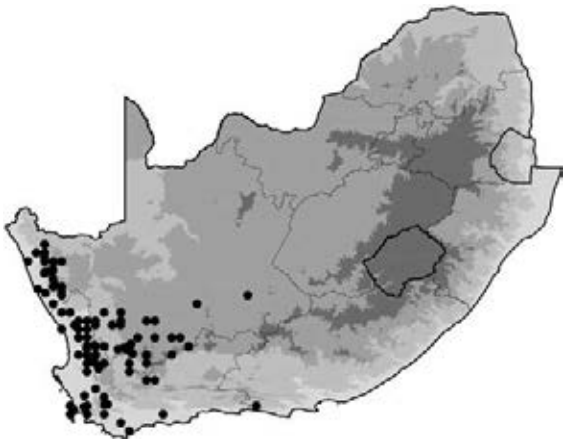
Homeria albida L.Bolus: 258 (1931c). Type: South Africa, [Western Cape], between Vanrhynsdorp and Vanrhyns Pass *L. Bolus s.n.* (BOL, holo.; K, iso.).

[*Homeria porrifolia* Sweet: 498 (1830), invalid name, without description. *Moraea porrifolia* Sweet ex Steud.: 160 (1841), invalid name, without description.]

Plants 150–600 mm high. *Corm* 10–25 mm diam., with few to many cormlets round base; tunics of medium-textured to coarse black fibres. *Stem* usually several- to many-branched, slightly flexed above sheaths of foliage and sheathing leaves, bearing attenuate sheathing leaves 30–45(–60) mm long. *Foliage leaves* 2 or 3, linear, channelled, usually exceeding stem, suberect, often trailing distally, (4)8–12(17) mm wide, lowermost basal, others cauline. *Rhipidial spathes* attenuate, dry and brown at apices, inner (30–)40–60 mm long, outer ± ⅔ as long. *Flowers* pink, yellow, occasionally white, tepal limbs with triangular yellow nectar guides dotted with green at bases, claws erect, ± 2 mm long, appressed to filament column, limbs spreading; outer tepals ovoid-ellipsoid,

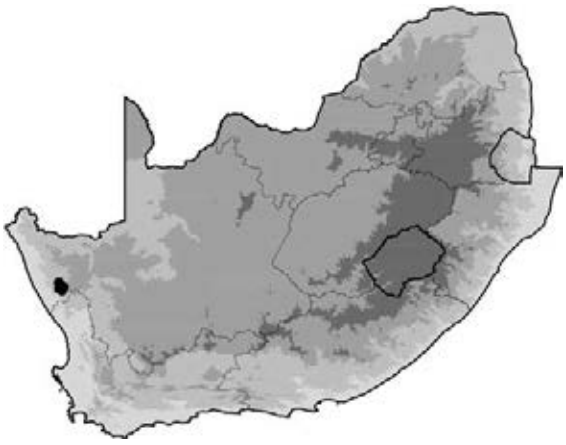
13–22(–27) × 6–10 mm, claws narrow, inner tepals slightly smaller. *Filaments* united in a column 6–8 mm long, narrow at base, swollen abruptly and then tapering gradually to apex, bulbous part pubescent; anthers ± 2 mm long, shorter after dehiscence, erect, contiguous. *Ovary* narrowly ellipsoid, 5–10 mm long, exserted; style branches short, obscured by anthers with tips emerging between anthers, crests absent. *Capsules* cylindric-ellipsoid, 12–16 mm long. *Seeds* angular-prismatic. *Chromosome number* 2*n* = 12 (2*n* = 18, 24 recorded in weedy plants of pastures and cultivated land). *Flowering time*: July to September(–October).

Distribution and ecology: common along the Atlantic and southern coasts of Western Cape, South Africa, extending as far north as Steinkopf and east into the western and Upper Karoo in Northern Cape, one of the most common and the most widespread species of subg. *Homeria*; on a variety of soils.



Diagnosis: one of several species of subg. *Homeria* with nearly identical flowers with short erect tepal claws clasping or enclosing the bulbous lower part of the filament column, spreading tepal limbs, and erect, contiguous anthers concealing the style branches, *Moraea miniata* is distinguished by its two, or more usually three, straight, linear leaves and several-branched stem. Flowers vary in colour, most often pink, especially in the south of its range, or yellow, or white in the immediate Vanrhynsdorp area. Plants in the Olifants River Mtns and valleys of the Cederberg are distinctive in their rather small, deep pink to almost orange flowers and shorter stature. Plants from the Upper Karoo are the most robust, reaching up to 600 mm high. *Moraea miniata* has become a serious weed in the southwestern Cape where it is often difficult to distinguish wild from adventive populations, the latter obvious on road verges and in overgrazed pastures. Plants reproduce readily from axillary cormlets and eradication is difficult. Some plants in old fields are obviously sterile, and these produce much larger numbers of cormlets than the wild plants. Causes of sterility appear to be chromosomal abnormalities, such as triploidy and dysploidy.

203. **Moraea pendula** *(Goldblatt) Goldblatt* in Novon 8: 375 (1998). *Homeria pendula* Goldblatt: 488 (1981). Type: South Africa, [Northern Cape], Namaqualand, Kamiesberg, *Goldblatt 4306* (MO, holo.; K, NBG, PRE, S, US, WAG, iso.).



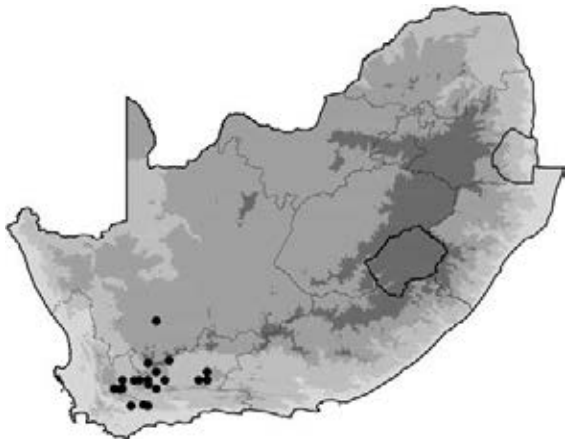
Plants 500–750 mm high. *Corm* ± globose, ± 20 mm diam.; tunics of coarse, wiry black fibres. *Stem* several-branched, branches ascending, flexed below rhipidia, with attenuate sheathing leaves with dry, brown tips. *Foliage leaves* 3 or 4, lowermost basal, remaining cauline, up to 600 mm long, channelled, falcate, bent and trailing distally, up to 20 mm wide. *Rhipidial spathes* attenuate, dry and brown distally, inner 40–50 mm long, outer ± $^{2}/_{3}$ as long. *Flowers* fugaceous, yellow (rarely orange), nodding to pendent, tepal limbs darkly speckled at bases, reflexed when fully open; outer tepals ± lanceolate, 24–28 × 7–8 mm, claws ± 4 mm long, clasping base of filament column, inner tepals slightly smaller. *Filaments* united in a column ± 15 mm long, swollen abruptly above base, tapering to apex, velvety in lower half; anthers 3–6 mm long, collapsing and shorter after anthesis, straight, contiguous, red; pollen orange-red (yellow). *Ovary* ± ovoid, 9–10 mm long; style branches 2.5–3.5 mm long, bifurcate, initially obscured by anthers, later apices extending between or above anthers, crests lacking. *Capsules* ± cylindric to club-shaped, 15–18 mm long. *Seeds* angular-prismatic. *Chromosome number* 2*n* = 12. *Flowering time*: October and November.

Distribution and ecology: locally common and conspicuous but restricted to middle elevations in the Kamiesberg of central Namaqualand in Northern Cape, South Africa; in wet places including streambanks, marshes and seeps, above 900 m.

Diagnosis: one of the tallest species of subg. *Homeria*, standing up to 750 mm, *Moraea pendula* has several, glaucous-grey foliage leaves and bright yellow, nodding to completely pendent flowers that are unusual in having the tepal limbs tightly reflexed against the pedicels. The filaments are fully united in a column abruptly

Distribution of ***Moraea miniata***.

Distribution of ***Moraea pendula***.



swollen above the base and tapering to a narrow apex, and the tepal claws, ± 4 mm long, clasp the bulbous part of the filament column. Typically the anthers and pollen are orange-red and provide a contrast to the yellow tepals. *Moraea pendula* is evidently closely related to the widespread *M. miniata*, which has smaller, spreading tepals but a similar filament column swollen at the base. Both occur in the Kamiesberg but *M. pendula* blooms later in the year and grows in wetter sites than *M. miniata*.

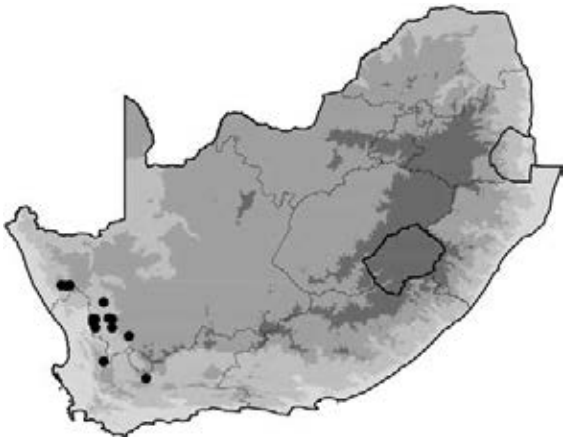
204. **Moraea karooica** [as *karrooica*] *Goldblatt* in Novon 8: 375 (1998), as a new name for *Homeria tricolor* G.J.Lewis: 266 (1933b) [not *M. tricolor* Andrews]. Type: South Africa, [Western Cape], between Jan de Boers and Bonteberg Karoo, *Compton 3778* (BOL, lecto., designated by Goldblatt: 493 (1981); NBG, isolecto.).

Plants usually small, 150–300 mm high. *Corm* 10–15 mm diam.; tunics of coarse, wiry black fibres. *Stem* usually flexed below each node, usually several-branched, bearing attenuate sheathing leaves 30–60 mm long. *Foliage leaf* usually solitary, basal (rarely 2 or 3, these cauline), linear, erect, often trailing distally, exceeding stem, channelled, 4–7 mm wide. *Rhipidial spathes* attenuate, inner initially 35–70 mm long, elongating in fruit to enclose ripening capsules, outer ± $^1/_2$ as long. *Flowers* salmon-orange, tepal limbs with a dark band near bases surrounding yellow zone, spreading, claws forming a wide cup 6–7 mm deep; outer tepals ± ovate, 18–24 × 7–8 mm, claws 5–6 mm long, ascending, inner tepals slightly smaller, obovate. *Filaments* united in a slender column 7–9 mm long, tapering slightly towards apex from wider base, smooth or sparsely and minutely papillate; anthers erect, contiguous, 3.0–3.5 mm long, after anthesis 2.0–2.5 mm long, yellow; pollen yellow. *Ovary* ± cylindric, 10–12 mm long; style branches short, 1.5–2.0 mm long, obscured by anthers, bifurcate, apices emerging between anthers; crests absent. *Capsules* ± cylindric, 9–15 mm long, usually enclosed by elongated inner spathe. *Chromosome number* 2*n* = 12. *Flowering time*: late September and October; opening early morning and collapsing in late afternoon.

Distribution and ecology: a fairly common, late-flowering species of the western Little Karoo and adjacent Tanqua Basin and western Karoo of South Africa, extending from Williston in the Upper Karoo of Northern Cape to Karoo Poort in the south, and east to Barrydale in the Little Karoo in Western Cape, also local in the Great Karoo; mostly in clay soils in dry renosterveld or karroid scrub.

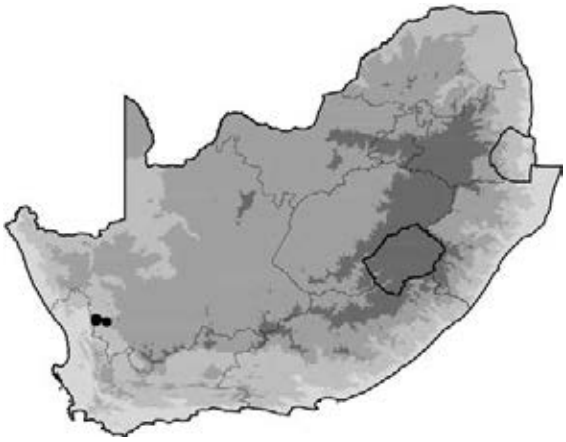
Diagnosis: broadly resembling the more common *Moraea miniata*, *M. karooica* may differ in leaf number, usually single (rarely two or three) vs. two or three in *M. miniata*, but more fundamentally in the flowers. *Moraea karooica* has ascending tepal claws that together form a shallow cup and a cylindric filament column, whereas in *M. miniata* the short tepal claws clasp the base of the bulbous filament column. *Moraea karooica* may be most closely allied to the rare *M. fenestrata* of the Tanqua Basin, which has a similar habit but consistently

Distribution of ***Moraea karooica***.



two or more leaves, and tepals conspicuously narrowed at the base, thus usually forming a windowed cup. Populations of *M. karooica* with more than one leaf are from the Koedoes Mtns and Verlatenkloof near Sutherland.

205. **Moraea bifida** *(L.Bolus) Goldblatt* in Novon 8: 374 (1998). *Homeria bifida* L.Bolus: 10 (1920). Type: South Africa, without precise locality or collector, ex Hort. Kirstenbosch, *Page s.n.* (BOL, holo.).



Homeria salmonea L.Bolus: 259 (1931c). Type: South Africa, [Northern Cape], near Nieuwoudtville, *H.M.L. Bolus s.n.* (BOL [19542], lecto., designated by Goldblatt: 495 (1981); K, PRE, isolecto.).

Plants 200–750 mm high. *Corm* 15–20 mm diam.; tunics of coarse, wiry black fibres. *Stem* with long basal internode, much-branched from upper nodes, branches short, flexed below rhipidia, with attenuate sheathing leaves 30–60 mm long. *Foliage leaf* solitary, basal, sheathing lower $^1/_2$ of stem, falcate distally, channelled but often flat distally, glaucous, 15–20 mm wide. *Rhipidial spathes* attenuate, inner 30–40 mm long, outer ± $^2/_3$ as long. *Flowers* fugaceous, pale yellow or pink, all tepal limbs with deep yellow nectar guides at bases usually spotted with green, spreading, claws erect, appressed to base of filament column; outer tepals oblong to narrowly obovate, 16–20 × 9–14 mm, claws narrow, ± 2 mm long, smooth, inner tepals slightly smaller, narrowly elliptic. *Filaments* united in a column 6–8 mm long, usually abruptly swollen above base, tapering in upper $^2/_3$ to narrow apex, smooth or velvety except at base and near apex; anthers initially 2.5–4.0 mm long, collapsing to 1.5–2.0 mm after dehiscence, erect, contiguous. *Ovary* ellipsoid, 7–9 mm long, usually included; style branches ± 1 mm long, deeply forked, apices stigmatic, emerging between anthers, crests lacking. *Capsules* ellipsoid, 10–12 mm long. *Chromosome number* 2*n* = 12, 12 + 4B, 24. *Flowering time*: August and September.

Distribution and ecology: South Africa, occurring in the eastern Kamiesberg in Namaqualand and from

Distribution of ***Moraea bifida***.

Distribution of ***Moraea fragrans***.

Loeriesfontein through the Bokkeveld Plateau and Roggeveld in Northern Cape south to Matjiesfontein in Western Cape; on a range of soils but most often in light clay and sandy ground.

Diagnosis: *Moraea bifida* is recognised by the solitary foliage leaf sheathing the lower half of the stem, short lateral branches borne in the upper half of the stem, and pink or yellow, star-like flowers with short tepal claws and spreading tepal limbs. The filament column is swollen and bulbous just above the narrow base and tapers in the upper third to a narrow apex. The tepal claws, ± 2 mm long, are erect and clasp the bulbous part of the filament column. The flowers are virtually identical to those of the widespread *M. miniata* but the latter is very different vegetatively, having at least two and often three or four foliage leaves, not clasping the stem for any distance. The two species can occasionally be found growing nearby but no intermediates are known and experiments have shown they cannot be crossed. The distinctive vegetative form of *M. bifida* is shared with *M. fragrans* but the flowers are rather different, the latter with tepal claws diverging from the base to form a shallow cup. Hybrids have been found in the wild between these two species in the Nieuwoudtville area where the two are common though confined to different soils. *Moraea bifida* is heteroploid and both diploid and tetraploid populations have been recorded.

206. **Moraea fragrans** *Goldblatt* in Novon 8: 375 (1998), as a new name for *Homeria odorata* L.Bolus: 326 (1932a) [not *M. odorata* G.J.Lewis (1941)]. Type: South Africa, [Northern Cape], Klipkoppies near Nieuwoudtville, *H.M.L. Bolus s.n.* (BOL, lecto., designated by Goldblatt: 496 (1981); K, isolecto.).

Plants 300–450 mm high. *Corm* 10–20 mm diam.; tunics of relatively soft, dark brown fibres. *Stem* straight, with long basal internode, several-branched above, branches short, held close to stem, flexed below rhipidia, bearing attenuate sheathing leaves 20–30 mm long, usually ± dry in upper half. *Foliage leaf* solitary, basal, sheathing lower $^1/_2$ of stem, falcate above, channelled, 12–20 mm wide. *Rhipidial spathes* attenuate, inner 35–40 mm long, outer $^1/_2$–$^2/_3$ as long. *Flowers* fugaceous, pale yellow (pale pink), tepal limbs with dark yellow nectar guides at bases outlined in faint grey-green, outspread, sweetly scented, claws ascending, forming a wide cup including filament column and anthers; outer tepals ± ovate, 23–25 × 9–11 mm, claws ± 8 mm long, inner tepals slightly smaller. *Filaments* united in a column 4–5 mm long, wider at base, tapering above, minutely velvety in lower half; anthers erect, contiguous, 1.5–2.0 mm long, yellow; pollen white. *Ovary* narrowly club-shaped, 6–7 mm long, often lightly dark speckled; style branches short, ± 1 mm long, deeply forked, tips stigmatic and emerging between or arching just above anthers, crests lacking. *Capsules* obovate-truncate, 7–10 mm long. *Chromosome number* 2*n* = 12. *Flowering time*: mid-August and September.

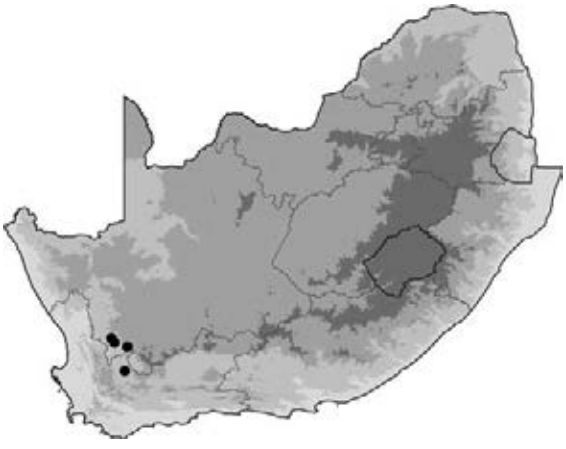
Distribution and ecology: a relatively narrow endemic of the Calvinia District in Northern Cape, South Africa, especially common in the hills east of Nieuwoudtville but also recorded to the east near Calvinia; restricted to heavy red clay soil derived from dolerite.

Diagnosis: in its vegetative form *Moraea fragrans* is nearly identical to *M. bifida,* both with a glaucous, falcate leaf with the lower half sheathing the stem almost to the base of the first branches. The flowers are, however, very different. The flowers of *M. fragrans* are nearly always pale yellow with darker yellow central cup and tepal claws ± 8 mm long, diverging to form a relatively wide cup that includes the stamens. The deep yellow nectar guides are edged with a band of grey-green. In *M. bifida* the tepal claws are short, only ± 2 mm long, erect and clasp the bulbous base of the filament column. Despite their different floral morphology, the two are likely closely related and hybrids have been recorded between them where their ranges come together. Greenhouse studies have shown the hybrids to be sterile.

207. **Moraea fenestrata** *(Goldblatt) Goldblatt* in Novon 8: 375 (1998). *Homeria fenestrata* Goldblatt: 491 (1981). Type: South Africa, [Northern

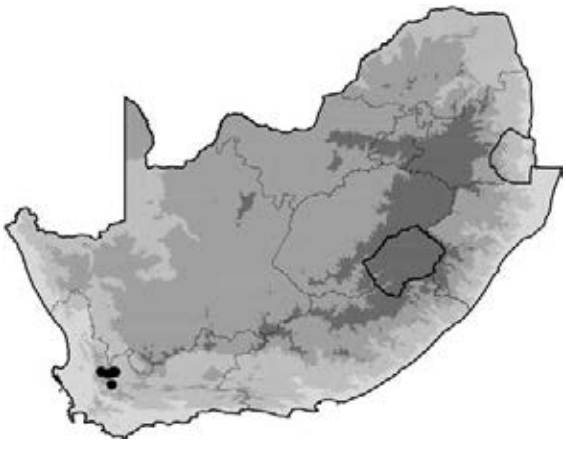
Cape], Tanqua basin 60 km south of Calvinia, *Goldblatt 3906* (MO, holo.; BR, K, NBG, PRE, S, US, WAG, iso.).

Plants small, 100–150 mm high. *Corm* ± 10 mm diam.; tunics of wiry, black fibres. *Stem* flexuose, bearing foliage leaves at all nodes below spathes, usually branched. *Foliage leaves* 2 to 4, lowermost inserted well above ground, exceeding stem, linear, channelled, upper leaves progressively shorter. *Rhipidial spathes* attenuate, inner 30–35 mm long, outer ± $^1/_2$ as long. *Flowers* fugaceous, pink with yellow cup, rarely uniformly yellow, tepal limbs with yellow nectar guides at bases edged dark pink, spreading, claws ascending, narrow at base and not contiguous, usually forming a wide cup windowed below, faintly scented; outer tepals oblong to narrowly obovate, 15–21 × 6–9 mm, claw ± 3 × < 1 mm, minutely papillate in middle; inner tepals slightly smaller, limbs ovate. *Filaments* united in a cylindric column ± 6 mm long, minutely papillate in lower half; anthers erect, contiguous, 3 mm long, collapsing to 2 mm after dehiscence. *Ovary* ± cylindric, ± 4 mm long, exserted; style branches 1 mm long, bifurcate, hidden by anthers, arms stigmatic apically and emerging between anthers; crests vestigial. *Capsules* and *seeds* not known. *Chromosome number* 2*n* = 12. *Flowering time*: July and early August.



Distribution and ecology: a poorly known species restricted to the arid Tanqua Karoo and the Koedoes Mtns in Western and Northern Cape, South Africa; on clay flats and slopes, flowering erratically depending on rainfall.

Diagnosis: *Moraea fenestrata* is recognised by the flexuose stem, sharply flexed above the sheaths of the two to four leaves, the lowermost of these inserted well above ground level. All nodes of the stem bear foliage leaves except for the terminal which bears the inflorescence. The pink (rarely yellow) flowers have a yellow cup formed by the diverging tepals claws, often so narrow at the base that the edges are gapped, the cup thus windowed near the base. Plants from the Koedoes Mtns lack these windows but in other respects match the type except that some plants have uniformly yellow flowers. The flowers have filaments united in a slender column, only slightly wider toward the base, and contiguous anthers, with the stigmatic tips of the forked style branches extending between the anthers.

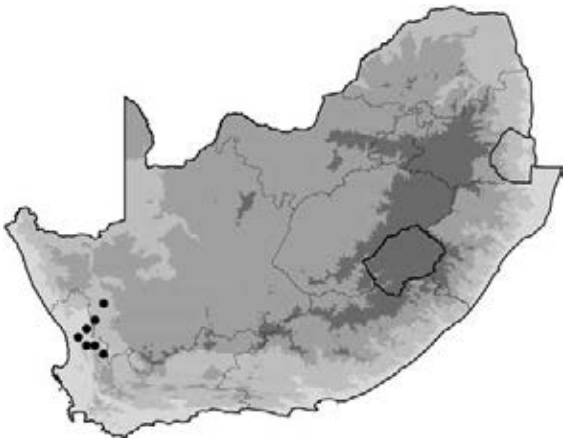


208. **Moraea fuscomontana** *(Goldblatt) Goldblatt* in Novon 8: 375 (1998). *Homeria fuscomontana* Goldblatt: 497 (1981). Type: South Africa, [Western Cape], Cold Bokkeveld, suurvlakte on plateau above Winkelhaaks River, *E. Esterhuysen 33951* (BOL, holo.; K, MO, PRE, S, iso.).

Plants 10–250 mm high. *Corm* 8–10 mm diam.; tunics of dark, wiry fibres. *Stem* erect below, flexed sharply above sheath of foliage leaf, 1- to several-branched, bearing attenuate sheathing leaves 20–30 mm long. *Foliage leaf* solitary, inserted well above ground, linear, channelled, erect below, trailing distally, 2–3 mm wide. *Rhipidial spathes* attenuate, inner initially 25–40 mm long, later elongating to enclose developing capsules, outer 14–25 mm long. *Flowers* long-lived, pale yellow, all tepal limbs with deep yellow nectar guides at bases edged or dotted with green, spreading, claws erect forming narrow cup enclosing lower $^1/_2$ of filament column; outer tepals oblong, 20–22 × ± 8 mm, claws ± 3 mm long, inner tepals ± 20 × 7 mm, ± wedge-shaped, widest in upper $^1/_3$. *Filaments* united in a cylindric column ± 6 mm long, velvety in lower $^2/_3$, wider at base, tapering and smooth above; anthers initially ± 3 mm long, erect, contiguous, collapsing after anthesis, then < 2 mm. *Ovary* cylindric, 4–5 mm long, enclosed; style branches short, ± 1.5 mm long, flat, bilobed, apices emerging between anthers, stigmatic and ciliate at tips. *Capsules* ovoid, ± 8 mm long, included. *Seeds* unknown. *Chromosome number* 2*n* = 12. *Flowering time*: September; flowers open between 10:00 and 11:00 and close in the evenings and fade midmorning two days later.

Distribution and ecology: restricted to the southern Cold Bokkeveld and Swartruggens in interior Western Cape, South Africa; on stony sandstone slopes and flats in dry fynbos vegetation.

Distribution of ***Moraea fenestrata***.



Distribution of ***Moraea fuscomontana***.

Diagnosis: relatively poorly known, *Moraea fuscomontana* has flowers resembling those of *M. miniata* except that the filament column is cylindric rather than bulbous below. This and the solitary foliage leaf and flexuose stem separate it from that species. *Moraea fuscomontana* may be most closely related to salmon-pink-flowered *M. brachygyne*, which also has the rhipidial spathes enclosing the developing capsules, but a longer, prominently papillate filament column ± 8 mm long, held well above the tepals, vs. 6 mm long and velvety below in *M. fuscomontana*. *Moraea fuscomontana* is also easily confused with *M. demissa* and *M. flavescens*, which are similar in size and vegetative morphology but differing in their flowers, especially in having divergent anthers and style branches with short crests.

209. **Moraea brachygyne** *(Schltr.) Goldblatt* in Novon 8: 374 (1998). *Homeria brachygyne* Schltr.: 94 (1900). Type: South Africa, [Western Cape], Bulshoek, Olifants River Valley, *Schlechter 8381* (B, lecto., designated by Goldblatt: 499 (1981); BOL, G, GRA, K, PRE, Z, isolecto.).

Homeria papillosa L.Bolus: 259 (1931c). Type: South Africa, [Western Cape], Vanrhyns Pass, *H.M.L. Bolus s.n.* (BOL [19541], holo.; K, PRE, SAM, iso.).

Plants mostly small, 80–250 mm high. *Corms* 7–10 mm diam.; tunics of coarse, wiry black fibres. *Stem* flexed outward above sheath of foliage leaf above each sheathing leaf, usually branched, sometimes repeatedly, with attenuate sheathing leaves 15–20(–30) mm long at upper nodes. *Foliage leaf* solitary, inserted well above ground, linear, channelled to ± flat, exceeding stem, 2–4 mm wide. *Rhipidial spathes* attenuate, inner 30–50 mm long, outer ± half as long. *Flowers* fugaceous, salmon-pink, all tepal limbs with yellow nectar guides at bases, spreading, claws erect, forming a shallow cup; outer tepals obovate to pandurate, 18–22 × 6–9 mm, claws ± 4 mm long, tapering to narrow base, inner tepals ± as long as outer, 5–6 mm wide. *Filaments* united in a slender, cylindric column 6–8 mm long, long-papillate in lower $^1/_2$; anthers 2.5–3.0 mm long, erect, contiguous, collapsing after anthesis, then ± 2 mm long. *Ovary* ± cylindric, 5–6 mm long, exserted; style branches concealed by anthers, short, bifurcate, stigmatic at tips, apices of style branches emerging between anthers, crests lacking. *Capsules* ellipsoid, 8–10 mm long. *Seeds* angular. *Chromosome number* 2*n* = 12. *Flowering time*: late July to early September.

Distribution of ***Moraea brachygyne***.

Distribution and ecology: restricted to western South Africa, from the Bokkeveld Mtns in Northern Cape through the Olifants River Valley to Citrusdal in Western Cape, with an outlying collection from the Kubiskou Mtns northwest of Loeriesfontein in Northern Cape provisionally assigned to this species; on rocky sandstone slopes often on wet sandstone pavement.

Diagnosis: *Moraea brachygyne* has a solitary, narrow leaf up to 4 mm wide, with the stem sharply flexed above the sheath, and small, salmon-pink flowers with short tepal claws and a slender filament column 6–8 mm long prominently papillate in the lower half. Yellow-flowered *M. fuscomontana* seems closest to *M. brachygyne* but has a shorter filament column ± 6 mm long, velvety in the lower two-thirds. The flowers themselves differ little from those of *M. miniata* except for the cylindric, rather than flask-shaped, filament column, but *M. miniata* is also readily distinguished by its multi-leaved habit.

UNCERTAIN SPECIES

Homeria breyniana (L.) G.J.Lewis in Journal of South African Botany 7: 59 (1941). *Tulipa breyniana* L.: 306 (1753). The name has been applied to *Moraea collina* but the type illustration is not identifiable to species (Goldblatt, 1981) although it is most likely a member of subg. *Homeria*.

Galaxia variabilis G.J.Lewis 987
Galaxia versicolor Salisb. ex Klatt 986
Galaxia violacea Eckl. 986
Geissorhiza adriaanii *Goldblatt & J.C.Manning* 453
Geissorhiza albens E.Mey. 336
Geissorhiza alticola *Goldblatt* 448
Geissorhiza altimontana *Goldblatt & J.C.Manning* . . . 428
Geissorhiza arenicola *Goldblatt* 482
Geissorhiza aspera *Goldblatt* 472
Geissorhiza aurea Eckl. 460
Geissorhiza barkerae *Goldblatt* 461
Geissorhiza bicolor N.E.Br. 460
Geissorhiza bicolor var. *macowanii* R.C.Foster. 460
Geissorhiza bolusii *Baker* 435
Geissorhiza bonaspei *Goldblatt* 454
Geissorhiza bracteata *Klatt* 430
Geissorhiza brehmii *Eckl. ex Klatt* 462
Geissorhiza brevituba *(G.J.Lewis) Goldblatt* 452
Geissorhiza bryicola *Goldblatt* 469
Geissorhiza burchellii *R.C.Foster* 466
Geissorhiza callista *Goldblatt* 467
Geissorhiza candida Eckl. 485
Geissorhiza cantharophila *Goldblatt & J.C.Manning* 481
Geissorhiza cataractarum *Goldblatt* 450
Geissorhiza cedarmontana *Goldblatt* 440
Geissorhiza ciliaris Salisb. 485
Geissorhiza ciliatula *Goldblatt* 470
Geissorhiza confusa *Goldblatt* 454
Geissorhiza corrugata *Klatt* 437
Geissorhiza cyanea Eckl. 466
Geissorhiza darlingensis *Goldblatt* 443
Geissorhiza delicatula *Goldblatt* 428
Geissorhiza demissa *Goldblatt & J.C.Manning* 473
Geissorhiza divaricata *Goldblatt* 478
Geissorhiza dregei Baker. 435
Geissorhiza dregei sensu auct. 436
Geissorhiza elsiae *Goldblatt* 424
Geissorhiza erecta Baker. 502
Geissorhiza erosa *(Salisb.) R.C.Foster* 484
Geissorhiza erosa var. *kermesina* (Klatt) R.C.Foster 485
Geissorhiza erubescens *Goldblatt* 486
Geissorhiza esterhuyseniae *Goldblatt* 440
Geissorhiza eurystigma *L.Bolus* 464
Geissorhiza excisa (L.f.) Ker Gawl. 437
Geissorhiza exilis *Goldblatt & J.C.Manning* 485
Geissorhiza exscapa *(Thunb.) Goldblatt* 456
Geissorhiza filifolia Baker. 445
Geissorhiza foliosa *Klatt* 426
Geissorhiza fourcadei *(L.Bolus) G.J.Lewis* 425
Geissorhiza furva Ker Gawl. ex Baker 446
Geissorhiza geminata Drège. 434
Geissorhiza geminata *E.Mey. ex Baker* 434
Geissorhiza gracilis Baker. 285
Geissorhiza graminifolia Baker 484
Geissorhiza graminifolia var. *bicolor* Baker 484
Geissorhiza grandiflora *Goldblatt* 467
Geissorhiza grandis Hook.f. 279
Geissorhiza helmei *Goldblatt & J.C.Manning* 451
Geissorhiza hesperanthoides *Schltr.* 449
Geissorhiza heterostyla *L.Bolus* 480
Geissorhiza heterostyla subsp. **heterostyla** 481
Geissorhiza heterostyla subsp. **rosea** *(Klatt) Goldblatt & J.C.Manning* 481
Geissorhiza hirta Ker Gawl. 484
Geissorhiza hirta var. *quinquangularis* (Eckl. ex Klatt) Baker 484
Geissorhiza hispidula *(R.C.Foster) Goldblatt* 443
Geissorhiza humilis *(Thunb.) Ker Gawl.* 442
Geissorhiza humilis var. *bicolor* Baker. 443
Geissorhiza humilis var. *grandiflora* Baker 442
Geissorhiza humilis var. *juncea* (Link) Baker 445
Geissorhiza imbricata *(D.Delaroche) Ker Gawl.* 459
Geissorhiza imbricata subsp. **bicolor** (N.E.Br.) Goldblatt 460
Geissorhiza imbricata subsp. **imbricata** 460
Geissorhiza imbricata var. *brehmii* (Eckl. ex Klatt) R.C.Foster. 462
Geissorhiza imbricata var. *concolor* Baker 460
Geissorhiza imbricata var. *obtusata* (Ker Gawl.) Baker . . . 460
Geissorhiza inaequalis *L.Bolus* 473
Geissorhiza inconspicua *Baker* 423
Geissorhiza inflexa *(D.Delaroche) Ker Gawl.* 484
Geissorhiza intermedia *Goldblatt* 444
Geissorhiza ixioides *Schltr. ex R.C.Foster* 487
Geissorhiza juncea *(Link) A.Dietr.* 445
Geissorhiza juncea var. *pallidiflora* (Schltr.) R.C.Foster. 446
Geissorhiza kamiesmontana *Goldblatt* 478
Geissorhiza karooica *Goldblatt* 438
Geissorhiza *Ker Gawl.* 416
Geissorhiza lapidosa *Goldblatt & J.C.Manning* 431
Geissorhiza larochei Loudon 465
Geissorhiza latifolia (D.Delaroche) Baker 775
Geissorhiza leipoldtii *R.C.Foster* 487
Geissorhiza lewisiae *R.C.Foster* 474
Geissorhiza lithicola *Goldblatt* 441
G**eissorhiza longifolia** *(G.J.Lewis) Goldblatt* 452
Geissorhiza longituba Klatt 521
Geissorhiza louisabolusiae *R.C.Foster* 462
Geissorhiza louisabolusiae var. *longifolia* R.C.Foster 462
Geissorhiza lutea Eckl. 543
Geissorhiza macra Baker 527
Geissorhiza malmesburiensis *R.C.Foster* 433
Geissorhiza marlothii R.C.Foster. 433
Geissorhiza mathewsii *L.Bolus* 465
Geissorhiza mathewsii var. *eurystigma* (L.Bolus) R.C.Foster. 464
Geissorhiza melanthera *Goldblatt & J.C.Manning* 455
Geissorhiza minima Baker 513
Geissorhiza minuta *Goldblatt* 464
Geissorhiza monantha Sweet 465
Geissorhiza monanthos *Eckl.* 475
Geissorhiza montana R.C.Foster. 469
Geissorhiza monticola *Goldblatt & J.C.Manning* 429
Geissorhiza namaquamontana *Goldblatt & J.C.Manning* 477
Geissorhiza namaquensis *W.F.Barker* 476
Geissorhiza nana *Klatt* 430
Geissorhiza nigromontana Eckl. 426
Geissorhiza nigromontana Eckl. 439
Geissorhiza nigromontana *Goldblatt* 427
Geissorhiza nubigena *Goldblatt* 449
Geissorhiza nutans *Goldblatt & J.C.Manning* 488
Geissorhiza obtusata Soland. ex Ker Gawl. 460
Geissorhiza ornithogaloides *(Licht. ex Roem. & Schult.) Klatt* 432
Geissorhiza ornithogaloides subsp. **flava** *(Klatt) Goldblatt & J.C.Manning* 433
Geissorhiza ornithogaloides subsp. *marlothii* (R.C.Foster) Goldblatt. 433
Geissorhiza ornithogaloides subsp. **ornithogaloides** 433
Geissorhiza outeniquensis *Goldblatt* 425
Geissorhiza ovalifolia *R.C.Foster* 435
Geissorhiza ovata *(Burm.f.) Aschers. & Graebn.* 437
Geissorhiza pallidiflora Schltr. 446
Geissorhiza pappei *Baker* 444
Geissorhiza parva *Baker* 436
Geissorhiza patersoniae L.Bolus 309
Geissorhiza pauciflora Baker 542
Geissorhiza platystigma *Goldblatt & J.C.Manning* 434
Geissorhiza pseudinaequalis *Goldblatt* 470

Geissorhiza pubescens Wolley-Dod 439
Geissorhiza pudica (Soland. ex Ker Gawl.) Klatt 863
Geissorhiza purpurascens *Goldblatt* 442
Geissorhiza purpureolutea *Baker* 461
Geissorhiza pusilla *(Andrews) Klatt* 439
Geissorhiza quadrangula (D.Delaroche) Ker Gawl. 327
Geissorhiza quinquangularis Eckl. ex Klatt 484
Geissorhiza quinquangularis var. *atrofaux* R.C.Foster . . . 484
Geissorhiza radians *(Thunb.) Goldblatt* 465
Geissorhiza ramosa *Ker Gawl. ex Klatt* 469
Geissorhiza reclinata *Goldblatt & J.C.Manning* 482
Geissorhiza recurvifolia (Poir.) Klatt 839
Geissorhiza rocheana Ker Gawl. 465
Geissorhiza rocheana var. *monantha* (Sweet) Baker 465
Geissorhiza rogersii N.E.Br. 481
Geissorhiza romuleoides Eckl. 433
Geissorhiza rosea (Klatt) Foster 481
Geissorhiza rosea Eckl. 484
Geissorhiza roseoalba *(G.J.Lewis) Goldblatt* 424
Geissorhiza rubicunda R.C.Foster 460
Geissorhiza rupestris Schltr. 435
Geissorhiza rupicola *Goldblatt & J.C.Manning* 471
Geissorhiza sabulosa Klatt 460
Geissorhiza saxicola *Goldblatt & J.C.Manning* 486
Geissorhiza schinzii *(Baker) Goldblatt* 452
Geissorhiza schlechteri Baker 527
Geissorhiza scillaris *A.Dietr.* 458
Geissorhiza scopulosa *Goldblatt* 479
Geissorhiza sect. Angustifoliae *Goldblatt* 441
Geissorhiza sect. **Ciliatae** *Goldblatt* 476
Geissorhiza sect. **Engysiphon** *(G.J.Lewis) Goldblatt* 451
Geissorhiza sect. **Geissorhiza** 459
Geissorhiza sect. **Includantherae** *Goldblatt* 440
Geissorhiza sect. **Intermedieae** *Goldblatt* 458
Geissorhiza sect. **Ixiopsis** *Goldblatt* 448
Geissorhiza sect. **Monticolae** *Goldblatt* 466
Geissorhiza sect. **Planifoliae** *Goldblatt* 472
Geissorhiza sect. **Pusillae** *Goldblatt* 439
Geissorhiza sect. **Tortuosae** *R.C.Foster* 437
Geissorhiza sect. **Weihea** *Eckl. ex Baker* 423
Geissorhiza secunda Ker Gawl. 472
Geissorhiza secunda var. *bicolor* Baker 460
Geissorhiza secunda var. *pusilla* (Andrews) Baker 439
Geissorhiza secunda var. *ramosa* (Ker Gawl. ex Klatt) Baker 469
Geissorhiza secunda var. *setifolia* Eckl. ex Baker 445
Geissorhiza setacea *(Thunb.) Ker Gawl.* 431
Geissorhiza setifolia Eckl. 446
Geissorhiza silenoides *Goldblatt & J.C.Manning* 471
Geissorhiza similis *Goldblatt* 458
Geissorhiza spiralis *(Burch.) M.P.de Vos ex Goldblatt* 438
Geissorhiza splendidissima *Diels* 483
Geissorhiza stenosiphon *Goldblatt* 447
Geissorhiza striata Eckl. 443
Geissorhiza subg. Geissorhiza 457
Geissorhiza subg. **Weihea** *(Eckl. ex Baker) Goldblatt* . . . 423
Geissorhiza sublutea (Lam.) Ker Gawl. 849
Geissorhiza subrigida *L.Bolus* 479
Geissorhiza subsect. *Filiformes* Foster 441
Geissorhiza subsect. *Foliosae* R.C.Foster 423
Geissorhiza subsect. *Pubescentes* Foster 476
Geissorhiza subsect. *Ventricosae* R.C.Foster 459
Geissorhiza sufflava *Goldblatt & J.C.Manning* 447
Geissorhiza sulphurascens *Schltr. ex R.C.Foster* 463
Geissorhiza sulphurea Schltr. 461
Geissorhiza sulphurea var. *arenicola* R.C.Foster 460
Geissorhiza tabularis *Goldblatt* 468
Geissorhiza tabularis var. *elatior* Eckl. 430
Geissorhiza tenella *Goldblatt* 456
Geissorhiza teretifolia G.J.Lewis 462
Geissorhiza tricolor *Goldblatt & J.C.Manning* 427
Geissorhiza tulbaghensis *F.Bolus* 475
Geissorhiza tulipifera Klatt 465
Geissorhiza uliginosa *Goldblatt & J.C.Manning* 426
Geissorhiza umbrosa *G.J.Lewis* 448
Geissorhiza unifolia *Goldblatt* 445
Geissorhiza vaginata Sweet 516
Geissorhiza violacea Baker 423
Geissorhiza wrightii Baker 460
Genlisia corymbosa (Ker Gawl.) Reichb. 50
Genlisia Reichenb. 44
Gladillus andrewsii Klatt 291
Gladilus maculatus subsp. *eburneus* Oberm. 331
Gladiolinae *Goldblatt* 218
Gladiolus × lewisiae Oberm. 359
Gladiolus abbreviatus *Andrews* 358
Gladiolus acuminatus *F.Bolus* 308
Gladiolus adlami Baker 263
Gladiolus aestivalis Ingram 351
Gladiolus aethiopicus Drapiez ex Jackson 359
Gladiolus affinis Pers. 272
Gladiolus alatus *L.* 322
Gladiolus alatus var. *algoensis* Herb. 322
Gladiolus alatus var. *meliusculus* G.J.Lewis 322
Gladiolus alatus var. *namaquensis* (Ker Gawl.) Baker 319
Gladiolus alatus var. *pulcherrimus* G.J.Lewis. 321
Gladiolus alatus var. *speciosus* (Thunb.) G.J.Lewis 320
Gladiolus alatus var. *uniflorus* Klatt 322
Gladiolus albens *Goldblatt & J.C.Manning* 331
Gladiolus albidus Jacq. 269
Gladiolus aletroides (Burm.f.) Vahl 101
Gladiolus algoensis (Herb.) Sweet 322
Gladiolus alopecuroides L. 153
Gladiolus alopecuroides Pers. 145
Gladiolus amabilis Salisb. 391
Gladiolus ambiguus Roem. & Schult. 613

Ixia emarginata Lam. 391
Ixia erecta P.J.Bergius 765
Ixia erecta Thunb. 749
Ixia erecta var. *lutea* Ker Gawl. 811
Ixia erecta var. *lutea-odorata* Ker Gawl. 749
Ixia erosa Salisb. 484
Ixia erubescens *Goldblatt* 806
Ixia esterhuyseniae M.P.de Vos 750
Ixia excisa L.f. 437
Ixia exiliflora *Goldblatt & J.C.Manning* 796
Ixia fabricii D.Delaroche 198
Ixia falcata L.f. 542
Ixia fenestrata Jacq. 713
Ixia filifolia F.Delaroche 849
Ixia filiformis Vent. 754
Ixia fimbriata Lam. 658
Ixia fistulosa (Jacq.) Sims 155
Ixia fistulosa Andrews 5554
Ixia flabellifolia D.Delaroche 719
Ixia flabelliformis Salisb. 633
Ixia flabellularis Vahl 704
Ixia flaccida (G.J.Lewis) Goldblatt & J.C.Manning. 791
Ixia flaccida Salisb. 754

Ixia flagellaris *Goldblatt & J.C.Manning*. 810
Ixia flava Hornem. 770
Ixia flava Lam. 839
Ixia flavescens Eckl. ex Baker 749
Ixia flavescens Eckl. 750
Ixia flexuosa *L.* 753
Ixia flexuosa Mill. 753
Ixia fragrans Jacq. 660
Ixia framesii L.Bolus 752
Ixia frederickii M.P.de Vos 761
Ixia fruticosa L.f. 48
Ixia fucata *Ker Gawl.* 746
Ixia fucata var. *filifolia* G.J.Lewis 787
Ixia fugacissima L.f. 991
Ixia fugax Hornem. 887
Ixia furva Banks ex Ker Gawl. 446
Ixia fuscocitrina Desf. ex DC. 770
Ixia galaxia L.f. 989
Ixia galaxioides Klatt 772
Ixia gawleri Schrad. 391
Ixia geminata Vahl. 434
Ixia gibba Salisb. 712
Ixia gladiata L.f. 919
Ixia gladiolaris Lam. 701
Ixia gloriosa *G.J.Lewis* 763
Ixia gracilis Salisb. 795
Ixia grandiflora (Andrews) Pers. 772
Ixia grandiflora D.Delaroche. 657
Ixia helmei *Goldblatt & J.C.Manning* 757
Ixia heterophylla Willd. 183
Ixia hirta Thunb. 484
Ixia holosericea Jacq. 658
Ixia humilis Thunb. 442
Ixia hyalina DC. 714
Ixia hyalina L.f. 713
Ixia hyalina Salisb. 713
Ixia hybrida Ker Gawl. 812
Ixia imbricata D.Delaroche 459
Ixia incarnata Jacq. 775
Ixia inflexa D.Delaroche 484
Ixia iridifolia (Jacq.) Link 128
Ixia iridifolia D.Delaroche 713
Ixia juncea Link 445
Ixia *L.* 732
Ixia lacera L. ex Ker Gawl. 658
Ixia lacerata *Goldblatt & J.C.Manning* 790
Ixia lancea Jacq. 780
Ixia lancea Thunb. 722
Ixia lapeirousia J.F.Gmel. 202
Ixia larochei Roem. & Schult. 465
Ixia latifolia *D.Delaroche* 775
Ixia latifolia var. *angustifolia* G.J.Lewis. 774
Ixia latifolia var. *curviramosa* G.J.Lewis 775
Ixia latifolia var. *parviflora* G.J.Lewis 777
Ixia leipoldtii *G.J.Lewis* 740
Ixia leucantha *Jacq.* 755
Ixia leucantha var. *aristata* (Thunb.) Baker 758
Ixia liliago DC. 658
Ixia linderi *Goldblatt & J.C.Manning* 743
Ixia linearifolia *Goldblatt & J.C.Manning*. 782
Ixia linearis Jacq. 553
Ixia linearis L.f. 327
Ixia longiflora Lam. 745
Ixia longiflora P.J.Bergius. 745
Ixia longifolia Jacq. 1016
Ixia longistylis *(M.P.de Vos) Goldblatt & J.C.Manning* 760
Ixia longituba *N.E.Br.* 740
Ixia longituba subsp. **longituba**. 741
Ixia longituba subsp. **macrosiphon** *Goldblatt & J.C.Manning* 741
Ixia longituba var. *bellendenii* (R.C.Foster) M.P.de Vos 741
Ixia lutea Eckl. 762
Ixia lutea var. *ovata* (Andrews) B.Nord. 762
Ixia macrocarpa *Goldblatt & J.C.Manning*. 744
Ixia maculata *L.* 770
Ixia maculata var. *amethystina* Ker Gawl. 768
Ixia maculata var. *caesia* Ker Gawl. 765
Ixia maculata var. *fuscocitrina* (DC.) G.J.Lewis. 770
Ixia maculata var. intermedia G.J.Lewis 771

This is the first complete taxonomic treatment for Iridaceae in southern Africa (including Botswana, Lesotho, Namibia, South Africa and Eswatini) since the publication of J.G. Baker's account in *Flora capensis* (1896). It treats a total of 1 210 species in 36 genera, classified in the four subfamilies **Aristeoideae** (*Aristea* 46 spp.), **Nivenioideae** (*Nivenia* 11 spp., *Klattia* 3 spp. and *Witsenia* 1 sp.), **Crocoideae** tribe Tritoniopsideae (*Tritoniopsis* 23 spp.), tribe Watsonieae (*Watsonia* 53 spp., *Pillansia* 1 sp., *Thereianthus* 11 spp., *Micranthus* 7 spp., *Codonorhiza* 7 spp., *Schizorhiza* 1 sp., *Lapeirousia* 27 spp. and *Afrosolen* 11 spp.) and tribe Ixieae subtribes Gladiolinae (*Gladiolus* 169 spp.), Melasphaerulinae (*Melasphaerula* 1 sp.), Freesiinae (*Xenoscapa* 3 spp., *Freesia* 16 spp., *Crocosmia* 7 spp. and *Devia* 1 sp.), Hesperanthinae (*Geissorhiza* 104 spp. and *Hesperantha* 87 spp.), Tritoniinae (*Babiana* 93 spp., *Chasmanthe* 3 spp., *Sparaxis* 16 spp., *Duthiastrum* 1 sp., *Dierama* 37 spp., *Tritonia* 30 spp. and *Ixia* 100 spp.), subtribe Radinosiphoninae (*Radinosiphon* 2 spp.) and Crocinae (*Romulea* 84 spp., *Afrocrocus* 1 sp. and *Syringodea*. 7 spp.), and Iridoideae (*Dietes* 5 spp., *Bobartia* 17 spp., *Ferraria* 15 spp. and *Moraea* 209 spp.). A revised, phylogeny-based tribal and subtribal classification is presented here for Crocoideae, correlating with corm ontogeny and seed characteristics. Keys are provided to subfamilies, tribes and genera (and in the case of larger genera to subgenera or sections) as well as to species and infraspececific taxa. Each species is fully described with complete nomenclature, geographic range and a distribution map. Genera are illustrated with line drawings, and nearly half of the species are illustrated with colour photographs. Four new species are described, **Bobartia vlokii** *Goldblatt & J.C.Manning*, **Geissorhiza adriaanii** *Goldblatt & J.C.Manning*, **Hesperantha mtamvunae** *Goldblatt & J.C.Manning* and **Romulea fuscomontana** *Goldblatt & J.C.Manning*, and a number of names are synonymised.
