Arquivos de Neuro-Psiquiatria is a periodic registered in the Departamento de Imprensa e Propaganda (11795), Departamento Nacional de Propriedade Industrial (97414) and 1º Ofício de Títulos e Documentos de São Paulo, Brasil. Its owner and publisher is the Academia Brasileira de Neurologia, no provide society registered in the 1º Oficial de Registro de Títulos e Documentos e Civil de Pessoa Jurídica, in the Ministério da Fazenda (CNPJ 43.185.230/0001-85) and in the Secretaria de Finanças do Município de São Paulo (CCM 9.129.811-3). It is the Official Journal of the Academia Brasileira de Neurologia / (Brazilian Academy of Neurology) since 1970. It is published monthly since 2012, with absolute regularity over these 70 years since its foundation in 1943.

CONTENTS

"De novo" absence status epilepticus: case report with 8-year follow-up . 1

"De novo" mutations in cadasil: a systematic review 1

Effect of the anti-inflammatory action of β-carbolines on SH-SY5Y cell line (human neuroblastoma) and modulation of TMPRSS11 and Furin receptors 1

Eyes: a window to the cerebellum 1

Management of uncontrolled epileptic seizures in the emergency setting in the southeast region from 2013 to 2023 2

"Split-hand like" syndrom in X-linked form of Charcot-Marie-Tooth disease (CMTX1) caused by GJB1 mutation: a comparative study of eletrophisiologic features 2

Ataxic sensory ganglionopathy secondary to Sjogren's: a case report 2

"My brain Robbie": translation to Portuguese to promote a healthy brain . 3

"Rede ELA": a Brazilian initiative on transdisciplinary and interinstitutional research on amyotrophic lateral sclerosis (ALS) 3

"Rete collaterals" at callosomarginal artery: a rare case report 3

18q21,2q23 deletion syndrome associated with agenesis of the corpus callosum 3

2 siblings with autosomal dominant Alzheimer's disease secondary to PSEN1 gene mutation: a case report 4

80 years of Leão's cortical spreading depression: a historical overview of its impact on neurology 4

A brain connectivity study associated with peritraumatic dissociation (PTD) in women with posttraumatic stress disorder (PTSD) 4

A Brazilian neuromuscular center experience in diagnosis of rare diseases patients 5

A case of congenital myasthenic syndrome-0,22 responsive to pyridostigmine (so far...) 5

A case of refractory epileptic seizures induced by glufosinate ammonium poisoning 5

A case of spinal dural arteriovenous fistula 6

A case report of complex neurological manifestations associated with polycythemia vera 6

A case report of erdheim-chester disease with neurological manifestations: the relevance of PET-CT scan 6

A case report of super-refractory status epilepticus with a good response to intravenous human immunoglobulin 6

A challenge: anti-GAD-related limbic encephalitis 7

A challenger case report: septic-embolic stroke or ischemic stroke due to aortitis syphilitic? 7

A clinical alert on the evolution of a patient with Guillain-Barré syndrome and dengue treated with therapeutic plasma exchange: case report 7

A clinical case of migraine and probable cluster headache in a patient with tuberous sclerosis 8

A cluster of Creutzfeld-Jakob disease VV2 phenotype in 2024 in São Paulo 8

A comprehensive analysis of ATRX and IDH1 expression in gliomas: associations with tumor grade and prognostic implications 8

A congenital slow channel myasthenic syndrome in two sisters: case report 8

A "de novo" KIF1A mutation in a patient with spastic paraplegia, peripheral neuropathy and intellectual disability: case report 9

A diagnostic challenge: is mixed connective tissue disease enough to explain difficult-to-control epilepsy? 9

A dysarthria, dysphagia, and sialorrhea: impacts on the quality of life in patients with Parkinson's disease 9

A epidemiological analysis of the hospitalization of meningococcal infection in Brazil from 2013-2023 10

A family with ALS and simultaneous mutations in C9ORF72 and OPTN genes 10

A gabapentin-induced edema in a patient with mesial temporal lobe epilepsy: a case report 10

A huge bilateral paraphalccine cerebral meningioma case report treated in a multimodal way: endovascular and microsurgery 10

A mechanistic analysis of the neural modulation of the inflammatory system through vagus nerve stimulation: a systematic review and meta-analysis 11

A non-internuclear cause of walled-eye ophthalmoplegia 11

A novel pattern of voxel-based morphometry is associated with focal cortical dysplasia: the "boomerang sign" 11

A novel variant of GJB1 related to demyelinating CMTX1 with tremor 11

A portable device for assessing ankle angles during gait in post-stroke individuals: a prototyping study 12

A pure dysautonomic variant case of Guillain-Barré syndrome 12

A rare adult-onset leukoencephalopathy as a likely etiology of neurocognitive decline: a case report 12

A rare case of anti-MOG antibody positive encephalomyelitis following dengue infection 13

A rare case of cerebellar progressive multifocal leukoencephalopathy in a patient with HIV and subacute ataxia 13

A rare case of cryoglobulinemia associated with hepatitis B virus infection 13

A rare case of hemichorea secondary to giant perivascular space: a case report 13

A rare case of hypnic headache after meningitis in a patient with HIV, primary or secondary? Case report 14

A rare case of spontaneous hypertensive pneumocephalus due to neurotuberculosis 14

A rare case report: central venous thrombosis associated with a thoracic spontaneous cerebrospinal fluid fistula 14

A rare cause of clival mass: giant cell tumor case report and review of literature 15

A rare cause of fecal and urinary incontinence after cerebrospinal fistula surgery: lumbosacral radiculopathy and cauda equina syndrome caused by intrathecal fluorescein - a case report 15

A rare differential diagnosis of bilateral optic neuropathy 15

A rare form of genetic X-linked intellectual disability: case report 15

A relapse of coccidioidomycosis meningitis without pulmonary involvement associated with obstructive hydrocephalus and ischemic stroke successfully treated with voriconazole and amphotericin B: a case report 16

A slow and complex neurodegenerative disorder with predominant primary lateral sclerosis features in a patient with a erbb4 variant 16

A strengthening protocol based on core tasks in Parkinson's disease: a pilot study 16

A telehealth approach to developmental delays: assessing outpatient children in São Carlos, São Paulo 17

A US vs Brazil comparison of mild cognitive impairment conversion to Alzheimer's disease 17

Abetalipoproteinemia: a case report of a diagnostic challenge 17

Access to rehabilitation for people with spinal muscular atrophy undergoing treatment with disease-modifying drugs 18

Acetazolamide in the treatment of idiopathic intracranial hypertension: a real-world study 18

Acquired hepatocerebral degeneration accompanied by recurrent episodes of hepatic encephalopathy secondary to chronic hepatitis c virus (HCV) infection, presenting as the initial manifestation of hepatitis C in a young patient 18

Active workspace volume combined with trunk inclination upon standing predicts fshd clinical severity 18

Acute bilateral hippocampal swelling in transient global amnesia triggered by sexual orgasm 19

Acute carotid web thrombosis and early reocclusion after successful thrombectomy: a case report 19

Acute denervation findings on electromyography in patient with central lesion: case report 19

Acute disseminated encephalomyelitis (ADEM) associated with dengue infection: a case report 20

Acute disseminated encephalomyelitis (adem) following recent rabies vaccine 20

Acute disseminated encephalomyelitis as a concomitant presentation of anti-mog, covid and hiv: case report 20

Acute disseminated encephalomyelitis secondary to tuberculosis in a pediatric patient: a case report 20

Acute hyponatremia secondary to polydipsia provoking seizure after physical exercise: a case report 21

Acute intermittent porphyria in siblings: a case report 21

Acute intermittent porphyria mimicking guillain-barré syndrome: a case report 21

Acute intermittent porphyria presenting with encephalopathy and osmotic demyelination syndrome 22

Acute intermittent porphyria: identification of novel variant in the HMBS gene 22

Acute myelorradiculitis after dengue infection 22

Acute spinal cord compression due to extramedullary hematopoiesis 22

Acute vestibular syndrome in the emergency department: be alert! 23

Acute weight loss and alexythymia after stroke in the right caudate nucleus 23

ADEM as the first manifestation of HIV in a young adult presented at a Brazilian tertiary hospital 23

ADEM refractory to immunoglobulins as a presentation of mogad in a young woman 24

ADEM-like presentation in an immunocompetent host after disseminated tuberculosis: TB or not TB? 24

Adherence to AHA life's essential 8 criteria in stroke patients: an observational study 24

Admission trends for epilepsy in the Northeast region over the last 10 years and the impact of the COVID-19 pandemic 24

Advances in modulation of the microbiota-gut-brain axis: treatment of neuropsychological disorders and functional gastrointestinal disorders 25

Advances in the treatment of glioblastoma: traditional therapeutic strategies vs. modern therapies - systematic review 25

Advantage of FilmArray® over conventional methods in the diagnosis of acute bacterial infections of the central nervous system, including meningitis caused by listeria monocytogenes 25

Aerobic physical exercise improves quality of life in temporal lobe epilepsy 25

Age of onset and clinical characteristics of neuromyelitis optica spectrum disorder: a cross-sectional study in Espírito Santo 26

Age profile of mortality in viral and bacterial meningitis cases: an epidemiological study (2012-2022) 26

Albendazole plus praziquantel versus albendazole alone in the treatment of neurocysticercosis: a systematic review and meta-analysis 26

Alien hand syndrome associated with lesion in the corpus callosum and frontal lobe 26

Alterations in the motor development of children with autism spectrum disorder level 2, according to the portage inventory: a cross-sectional study 27

Altered cerebral vasoreactivity on transcranial color-coded sonography related to akinetic-rigid phenotype of Parkinson's disease and individuals with Parkinson's disease and risk factors for cerebrovascular disease ... 27

Alternating hemiplegia in childhood associated with epilepsy, a rare disease related to ATP1A3 gene mutation: case report 27

Alzheimer's disease and antipsychotics, a troublesome match 27

Alzheimer's disease and Parkinson's disease: prolonged work absence in Brazilian public university employees in ten years 28

Amyloid angiopathy-related inflammation: more than amyloid spells 28

Amyotrophic lateral sclerosis and multiple sclerosis: a uncommon association 28

Amyotrophic lateral sclerosis associated with a rare pathogenic VCP gene variant: a case report 29

An atypical case of hereditary distal motor neuropathy (HDMN) associated with mutation on DCTN1 gene 29

An atypical presentation of neuroleptospirosis: a case report and literature review 29

An atypical presentation of stiff person spectrum disorder: a case report 30

An epidemiological analysis of Guillain-Barré syndrome in the neurology service of the UNIMED BH hospital 30

An epidemiological analysis of hospitalizations due to epilepsy in Brazil from 2013 to 2023 30

An epidemiological analysis of hospitalizations due to transient ischemic attack and non-specific strokes (hemorrhagic or ischemic) in Ceará from 2013 to 2023 30

An epidemiological analysis of hospitalizations due to viral encephalitis in Ceará from 2013-2023 31

An epidemiological analysis of hospitalizations due to viral meningitis in Ceará from 2013-2023 31

An epidemiological analysis of incidence of brain cancer in brazil from 2013 to 2023 31

An epidemiological analysis of viral encephalitis in children in Northeast Brazil between 2018 and 2023 31

An extradural hematoma case report of the posterior fossa treated conservatively 32

An ominous complication: explosive mucormycosis initially mimicking optic neuritis 32

An overview of multiple sclerosis associated comorbidities 32

An uncommon neurological presentation of dengue fever: spinal subdural hematoma 32

An under-recognized case of mioclonic epilepsy: NUS1 33

An unusual case of variegate porphyria with nerve enlargement, conduction block and idiopathic intracranial hypertension 33

An unusual presentation of small vessel disease: NIT1 gene mutation 33

Anabolic androgenic steroids triggering reversible cerebral vasoconstriction syndrome 33

Analgesics overuse in patients with headache in the neurology outpatient clinic of a university center: clinical-epidemiological profile 34

Analysis of admissions by stroke in Southeast region since 2020 to 202334

Analysis of contraindications to chemical thrombolysis in patients within the therapeutic window for stroke in a public tertiary neurology service in the state of Pernambuco 34

Analysis of deaths due to cerebrovascular diseases in the state of São Paulo between 2010-2022: an ecological study 35

Analysis of efficiency between the cost, length of stay and clinical outcomes for stroke in the states of the Northern region of Brazil 35

Analysis of epilepsy cases in Brazil in the last five years 35

Analysis of four attention tests and the influence of education and intelligent coefficients 35

Analysis of functional/dissociative seizures (FDS) semiology based on video-electroencephalography (VEEG) 36

Analysis of hospitalizations for carpal tunnel syndrome surgery in Brazil from 2014 to 2023 36

Analysis of hospitalizations for stroke before and during the COVID-19 pandemic in Bahia: an epidemiological approach 36

Analysis of hospitalizations for the treatment of polyneuropathies in Brazil between 2019 and 2023 37

Analysis of melatonin as a therapeutic tool in the treatment of neurologically-originated insomnia: a systematic review 37

Analysis of morbidity due to dementia in elderly individuals in Southeast Brazil (2008-2024): an ecological study 37

Analysis of mortality due to intracranial trauma in São Paulo from 2020 to 2023: an ecological study 37

Analysis of prevalence and vaccination coverage against bacterial meningitis in Brazil from 2013 to 2022 38

Analysis of spina bifida hospitalizations in the northeast region of Brazil over the last ten years 38

Analysis of the correlation between trunk control and quality of life in individuals with post-stroke hemiplegia: a cross-sectional study 38

Analysis of the effects of melatonin in astrocytes in a mouse model of Parkinson's disease 39

Analysis of the epidemiological profile of epilepsy in the Southeastern region of Brazil over the last five years 39

Analysis of the epidemiological profile of hospitalizations for epilepsy in Brazil between 2019 and 2023 39

Analysis of the epidemiological profile of migraine cases in Brazil between 2018 and 2023 39

Analysis of the incidence of hospitalizations and deaths due to cerebral palsy and other paralytic syndromes in Brazil from 2019 to 2023 40

Analysis of the incidence of Parkinson's disease inpatients and deaths in brazil during the years 2019 to 2023 40

Analysis of the morbidity and mortality of muscular dystrophies in Brazil: 2019 to 2023 40

Analysis of the prevalence of diagnoses and age group impact of brain cancer in Brazil over the last 5 years 40

Analysis of the prevalence of tuberculous meningitis in the state of São Paulo between 2012 and 2022 41

Analysis of the profile and therapeutic response of Parkinson's disease patients undergoing deep brain stimulation 41

Analysis of the profile of demyelinating and autoimmune diseases at the first specialized referral center in the state of Alagoas 41

Analysis of the profile of hospitalizations due to multiple sclerosis in the sus in 2023 42

Analysis of the profile of patients who died due to post-stroke infection in a reference hospital in Salvador-BA 42

Analysis of the strategies involved in the management of epilepsy in the hospital emergency environment 42

Analysis of the use of benzodiazepines and cognitive changes 42

Anatomopathological features of MRI negative epilepsies in a cohort from Southern Brazil 43

Anatomy of vertical hemispherotomy: a study in cadaveric brains 43

Angioedema induced by thrombolytic therapy in stroke: a case series from Brazilian Northeast 43

Anterior temporal lobectomy vs amygdalohippocampectomy in the treatment of mesial temporal pole epilepsy: a functional connectivity analysis 43

Anti-AMPAR encephalitis in a patient with rapidly progressive dementia and ataxia: a case report 44

Anticholinisterasic, antidepressant, antipsychotic e hypnotic use in a sample of individuals with dementia: comparison between patient and caregiver report and plasma levels 44

Anticoagulation strategy for patients presenting with ischemic strokes while using a direct oral anticoagulant: a systematic review and meta-analysis 44

Anticonvulsant potential of phenolic compounds in animal models of epilepsy: a systematic review 45

Antiganglioside antibody screening accuracy and sensitivity in a tertiary neuromuscular outpatient clinic 45

Anti- IgLON5 disease presenting with bulbar dysfunction, ocular paralysis and facial myokymias 45

Anti-MAG: an important differential diagnosis of CIDP 45

Anti- MDA5 dermatomyositis with severe myopathy: an unusual presentation 46

Anti-MDA5 dermatomyositis: two phenotypic extremes 46

Antiseizure drugs impair fine motor dexterity in people with epilepsy without lesions in the motor areas 46

Anti-seizure prophylaxis and electroencephalographic changes in bulsufan therapy: a case report 47

Anti-SOX1 antibody-positive caused by small-cell lung cancer presenting with chorea: a case report 47

Anxiety, depression, and excessive daytime sleepiness in patients with parkinson's disease: a possible association? 47

Aphasic status in a patient with serous ovarian carcinoma and CNS recurrences: case report and narrative literature review 47

Application of artificial intelligence algorithms in the diagnosis of temporal lobe epilepsy compared to conventional methods: a systematic review 48

Application of artificial intelligence and mass spectrometry for biomarker discovery in plasma and CSF of patients with cognitive decline 48

Application of the new criteria for optic neuritis in a patient seronegative for anti-AQP4 and anti-mog antibodies 48

Application of the proposed criteria for the diagnosis of mog- associated disease (MOGAD) in a population from Rio de Janeiro 49

AQP4-IGG-seropositive neuromyelitis optica spectrum disorder (NMOSD) associated with teratoma and parotid tumor: a case report 49

Aquaporin-4 positive NMOSD patients have worse quality of life 49

Arboviruses evolving with Guillain-Barré syndrome and impact on immunoglobulin stock: a case report 49

Area postrema syndrome as an initial manifestation of AQP4 -AB negative NMO spectrum disease treated with rituximab: a case report 50

Arnold-Chiari malformation type I and chronic vocal cord paralysis: case report 50

Arquivos de Neuro-Psiquiatria: a bibliographic study of the first 20 years (1943-1963) 50

Artificial intelligence algorithms to detect cerebral small vessel disease tomography markers and their association with clinical outcomes in patients with acute ischemic stroke undergone thrombectomy 51

Artificial intelligence algorithms to differentiate between contrast extravasation and hemorrhagic transformation in tomography of acute ischemic stroke after thrombectomy 51

Aseptic meningoventriculitis after spinal anesthesia and Epstein Barr finding as a differential diagnosis of rapidly progressive dementia: case report 51

Assesment of the quality of life of elderly individuals attending a senior community center 51

Assessing dysphagia and ventilatory dysfunction in inclusion body myositis: clinical insights and muscle ultrasound findings 52

Assessing stroke awareness in Aparecida-SP city: a cross-sectional study from 2023 and 2024 52

Assessing the efficacy of donanemab in reducing amyloid plaque levels in Alzheimer's disease: a systematic review and meta-analysis of randomized clinical trials 52

Assessing the impact of serological profiles on clinical outcomes in suspected paraneoplastic neurological syndromes 52

Assessment and management of patients with syndromic craniosynostosis associated with hydrocephalus 53

Assessment of changes in the sleep/wake cycle of medical students at a private university 53

Assessment of disability in patients with progressive multiple sclerosis in a Brazilian hospital 53

Assessment of respiratory function in Friedreich's ataxia 53

Assessment of the accuracy of stroke protocol screening by the emergency medical services 54

Assessment of the pain perception threshold by electrical algometry in migraine and healthy individuals: preliminary study 54

Assessment of trigeminal nerve integrity in young adults 54

Assistive technology for communication accessibility in Machado Joseph disease 55

Association between age and time from symptom onset to admission to a stroke unit in Northeastern Brazil 55

Association between alpha-1-antitrypsin levels and intracranial aneurysms: a case-control study 55

Association between cannabis exposure and stroke: a systematic review and meta-analysis 55

Association between diffuse glioma and ischemic stroke in a pediatric patient: a case report 56

Association between early ictus-admission time in a stroke unit and functional outcome in hyperacute stroke patients not eligible for reperfusion therapies 56

Association between microembolic signals on transcranial doppler and brain atrophy in patients with Chagas disease 56

Association between migraine and autism spectrum disorder: a case series of 10 patients 56

Association between risk of obstructive sleep apnea and stroke recurrence: a cohort study 57

Association between stroke etiology and functional outcomes 57

Association of neuromyelitis optica and rapidly progressive IgA glomerulonephritis: a case report 57

Ataxia and Parkinsonism related with CAG expansion size in a cohort of Huntington's disease in the Brazilian Amazon region 58

ATP1A3 related disorders: a case series 58

Atrophy of the frontal lobe after white matter ischemia due to occlusion of the cervical portion of the internal carotid artery 58

Attention deficit hyperactivity disorder and autism spectrum disorder in adults 58

Atypical case of HaNDL syndrome: an unusual presentation in a man 59

Atypical cryptococcosis with restricted diffusion mimicking radiological features of ischemic stroke: a case series 59

Atypical features of epileptic seizures 59

Atypical initial manifestations of multiple sclerosis: a case report 59

Atypical presentation of hypertensive cerebral lobar hemorrhage in a puerperal woman 60

Atypical presentation of Rasmussen's encephalitis as progressive hemispheric atrophy syndrome without epilepsy: an unusual case report and the diagnostic challenge of a rare condition 60

Atypical presentation of rhabdomyolysis due to epilepsy in a patient with McArdle disease 60

Atypical presentation of Turner-type X-linked syndromic intellectual developmental disorder: a pediatric case report 61

Atypical presentations of MUSK-congenital myasthenia syndrome 61

Aura change in migraine: be careful! 61

Autoimmune necrotizing myopathy associated with 3-hydroxy-3-methylglutaryl-coa reductase (HMGCR) antibody after COVID infection: a case report 61

Autoimmune optic neuritis in a patient with hiv on irregular treatment: case report 62

Automatic prediction of ASPECTS for patients with posterior circulation infarcts 62

Autosomal recessive spinocerebellar ataxia type 8 and associated non-cerebellar features 62

B12 vitamin deficiency and dementia in the elderly 63

Bacterial meningitis in the Brazilian public health system: a regional comparison over the last decade 63

Balint syndrome in the three-territory sign outbreak 63

Basal ganglia calcification associated with hypocalcemia and hypomagnesemia: a case report of Fahr's disease 63

Basal ganglia encephalitis with fulminant Parkinsonian features and dysautonomia in a child: look no further than levodopa 64

Behavioral variant frontotemporal dementia and the DYSF gene: causal relationship or coincidence? A case report 64

Beneficial nucleosides reposition at TK2d: the first Brazilian cohort of treated patients 64

Beyond cataplexy: which parameters could help differentiate narcolepsy type 1 from narcolepsy type 2? 64

Beyond myelopathy: neuromuscular manifestations of HTLV-1 65

Bilateral asynchronous lateralized periodic discharge in a patient with intraparenchymal hemorrhage 65

Bilateral facial palsy secondary to dengue fever: a case report 65

Bilateral fusiform internal carotid artery aneurysms: case report and challenges in the approach 66

Bilateral optic neuritis and probable MOG-associated demyelinating syndrome in pediatric patient: a case report 66

Bilateral petrosal apex cephalocele and empty sella turcica - case report 66

Bilateral profound sensorineural hearing loss due to cerebrovascular event 66

Bilateral schwannomas: a case of schwannomatosis 67

Bilateral third nerve palsy as a manifestation of pituitary apoplexy: a case report 67

Bilateral vestibulopathy due to aminoglycoside otoxicity in patients with chronic kidney disease: a series of cases 67

Bilateral wrist drop revealing symmetric polyradiculoneuropathy and optic neuritis secondary to dengue infection successfully treated with human immunoglobulin - a case report 68

Biopsy diagnosis of fungal infections affecting the central nervous system 68

Biopsy-proven myosistis and myocarditis due to immune checkpoint inhibitor treatment 68

Bisegmental angioplasty of the right vertebral artery: case report 68

Bladder pattern profile of children with Zika virus congenital syndrome. 69

Body composition in older adults with mild cognitive impairment: effect of 6 months of resistance training 69

Botulinum toxin as a therapeutic option in Graves' orbitopathy: a case report ... 69
Botulinum toxin as an ally in the treatment of belly dancer syndrome: a case report ... 70
Botulinum toxins on muscular spasticity rehabilitation in a reference center in Northern Brazil ... 70
Bow Hunter's syndrome in a patient with paroxysmal vertigo: case report ... 70
Brachial plexitis: an unusual presentation in dengue virus infection ... 70
Brachial plexus axonotmesis after coronary artery bypass surgery: a case report ... 71

Case report: pericallosal artery stroke with multiple executive dysfunctions ... 87
Case report: progressive encephalopathy associated with BSCL2 gene mutation ... 87
Case report: progressive supranuclear palsy like of vascular etiology ... 87
Case report: reversible cerebral vasoconstriction syndrome in a young patient using thermogenic supplements and hormonal therapy for high-performance exercise ... 88

Case report: rhombencephalitis by varicella-zoster virus (VZV) in an elderly and immunosuppressed patient 88

Case report: sensory neuronopathy secondary to paraneoplastic syndrome 88

Case report: Takayasu arteritis leading to stroke 88

Catatonia as first presentation of anti-NMDA receptor encephalitis: a case report 89

Catatonia due to herpetic encephalitis: a case report 89

Cathepsin A-related arteriopathy with strokes and leukoencephalopathy (CARASAL): a systematic review 89

Cauda equina syndrome as an initial manifestation of Burkitt leukemia . 90

CEBALID syndrome: a rare cause of genetic-based intellectual disability 90

Cenobamate for refractory epilepsy in a Brazilian private practice setting: a preliminary report 90

Central foot drop: a clinical case of a patient with SPG 83 90

Central pontine myelinolysis not related to rapid sodium correction: a case report 91

Central retinal artery occlusion in a young woman associated with isolated ophthalmic artery arteritis 91

Cerebellar ataxia as a presentation of neuro-Behçet: case report 91

Cerebellar stroke secondary to bow Hunter's syndrome: a case report ... 92

Cerebral amyloid angiopathy-related inflammation (CAARI): a case report and review 92

Cerebral compliance patterns during normal sleep. 92

Cerebral metastasis of lung cancer mimicking multiple sclerosis lesions 93

Cerebral perivascular space abnormalities after COVID19 93

Cerebral schistosomiasis due to Schistosoma mansoni infection: a rare case presentation in Brazil 93

Cerebral superficial siderosis: challenges in diagnosis 93

Cerebral tuberculoma as a differential diagnosis for an extra axial lesion in an immunocompetent patient: a case report 94

Cerebral vascular accident: epidemiology of hospital admissions for ischemic and hemorrhagic stroke 94

Cerebral vasculitis and pachymeningitis as the first manifestation of rheumatoid arthritis 94

Cerebral venous thrombosis as a cause of subarachnoid hemorrhage and thunderclap headache: a very uncommon presentation 94

Cerebral venous thrombosis associated with the use of testosterone implant: a case report 95

Cerebral venous thrombosis due to ChadOx1-s vaccine against COVID-19: pitfalls of VITT syndrome and response to factor-X inhibitors 95

Cerebral venous thrombosis following lumbar puncture: case report and considerations 95

Cerebral venous thrombosis secondary to protein s deficiency: a case report ... 96

Cerebrospinal fluid AD biomarkers in patients with suspected normal pressure hydrocephalus 96

Cerebrospinal fluid HIV viral escape 96

Cerebrospinal fluid hypotension presenting atypically and with different types of headache: a case report 96

Cerebrotendinous Xanthomatosis: electrophysiological and ultrasonographic characterization in a Brazilian study 97

Cerebrovascular diseases by place o death: investigating associated factors and trends in an ecological time series study 97

Cervical and dorsal pain are more prevalent in individuals with headache: preliminary data from a Brazilian cohort 97

Cervical compressive myelopathy due to ossification of the posterior longitudinal ligament: a case report 98

Cervical dural arteriovenous fistula presenting as acute extensive longitudinal transverse myelopathy: a case report 98

Challenges and decisions at the start of Pompe disease treatment: case report ...98

Challenges in diagnosing of inclusion body myositis (IBM) in Brazil: revisiting the new diagnostic criteria 98

Challenges in differential diagnosis of demyelinating diseases: a clinical and laboratory review and comparison of four cases 99

Challenges in managing acute hepatic porphyrias with comorbid conditions: a case series 99

Challenges in the immunocompromised patient: a case of ureaplasma meningoencephalitis 99

Challenging visual acuity measurement in a child with MOGAD syndrome: a case report 100

Changing the natural course of hereditary transthyretin amyloidosis: the importance of early diagnosis 100

Charcot-Marie-Tooth disease in a patient with long-chain 3-hydroxyacyl-coa dehydrogenase (LCHAD) deficiency 100

CHD8 and autism spectrum disorder: genomic advances and clinical implications for neurological practice 100

Chediak-Higashi syndrome presenting as pure juvenile Parkinsonism . 101

Chorioretinitis, bilateral optic neuritis and pachymeningitis as manifestation paraneoplastic probable of esophageal squamous cell carcinoma 101

Chronic Chagas heart disease presented as comma-shaped stroke 101

Chronic dengue virus encephalitis diagnosed by metagenomic analysis: a case study 101

Chronic inglammatory demyelinating polyneuropathy (CIDP): a case series from a tertiary center 102

Chronic inflammatory demyelinating polyradiculoneuropathy related to neurofascin-155 IgG4 with response to rituximab: case report 102

Chronic lymphocytic inflammation with pontine perivascular enhancement responsive to steroids (CLIPPERS): case presentation 102

Chronic meningitis neurobrucellosis: case report 103

Chronic pelvic inflammatory context leading to migraine exacerbation: a case report 103

Clinical acute manifestations in the multiple sclerosis onset associated with worse functional outcomes 103

Clinical and electroneuromyographic assessment in lepromatous leprosy: the confirmation of an asymmetrical and non-length-dependent pattern 104

Clinical and epidemiological aspects of patients attended at a reference center for movement disorders 104

Clinical and epidemiological aspects of patients with myasthenia gravis in a tertiary center 104

Clinical and epidemiological characteristics of patients with Parkinson's disease being investigated for obstructive sleep apnoea: an observational analysis in the Brazilian Amazon 104

Clinical and epidemiological characterization of myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD) in a tertiary center in Amazonas 105

Clinical and epidemiological characterization of patients with Guillain-Barré syndrome (gbs) attended at a university hospital, 2014-2018 105

Clinical and epidemiological evaluation of sleep disorders in chronic kidney patients at a dialysis center in Amazonas, Brazil 105

Clinical and epidemiological profile of hospital admissions due to cerebral venous thrombosis in a reference hospital 105

Clinical and functional profile of patients with ischemic stroke secondary to arterial dissections 106

Clinical and genetic characterization of limb-girdle muscular dystrophy 2G/R7 in a large cohort of Brazilian patients 106

Clinical and genetic profile of patients with chanalopathies in a reference center for neuromuscular diseases: retrospective observational study 106

Clinical and genetic spectrum of the ZFYVE26 gene: an analysis of 7 patients 107

Clinical and genotypic characteristics of patients with Nonaka distal myopathy at a specialized clinic in Salvador, BA..... 107

Clinical and imaging findings in language-predominant dementia syndromes: a case series 107

Clinical and laboratory profile of thrombotic microangiopathy following gene therapy for 5q-spinal muscular atrophy in Brazil 107

Clinical and molecular profile of Duchenne muscular dystrophy in a single center in Brazil..... 108

Clinical and molecular spectrum of TK2-deficiency: a large Brazilian cohort 108

Clinical and motor functional evaluation of patients with bi-allelic disease-causing variants in SMN1 gene and two copies of SMN2 treated in the pre-symptomatic stage 108

Clinical and neuroimaging features of corticobasal degeneration..... 109

Clinical and neurophysiological characterization of patients with ganglionopathies: case series..... 109

Clinical and neurophysiological epidemiology of brain death..... 109

Clinical and polysomnographic characteristics associated to excessive daytime sleepiness in obstructive sleep apnea 109

Clinical and radiological improvement of oligodendrocyte myelin syndrome with combined treatment of rituximab and plasmapheresis. 110

Clinical and ultrasonographic evaluation of dysphagia in patients with LAMA2-CMD 110

Clinical challenges and multidisciplinary management in Takayasu's arteritis: a case report 110

Clinical characteristics of patients with positive genetic testing for peripheral neuropathies at a tertiary Brazilian neuromuscular outpatient clinic in an university hospital 111

Clinical evaluation of dysphagia as a prognosis factor in stroke patients: preliminary results 111

Clinical factors associated with constipation in patients with Parkinson's disease: a Brazilian cross-sectional study in Bahia 111

Clinical features and quality of life of patients with amyotrophic lateral sclerosis at a specialized care service in Salvador-BA..... 111

Clinical features on Friedreich's ataxia patients in São Paulo, Brazil 112

Clinical outcomes and safety of repetitive transcranial magnetic stimulation in the treatment of Alzheimer's disease: a scoping review . 112

Clinical spectrum of the PLA2G6 gene 112

Clinical study of patients with familial amyloidotic polyneuropathy at Pedro Ernesto University Hospital 112

Clinical variant of Nasu-Hakola disease associated with frontotemporal dementia and absence of osteodysplasia: case report 113

Clinical, epidemiological, and genetic profile of late onset Pompe disease in a tertiary hospital in the Northeast of Brazil 113

Clinical, epidemiological, serological, and neurophysiological data of patients with myasthenia gravis from a reference center in Northeast of Brazil.....113

Clinical-epidemiological aspects of patients with myasthenia gravis in an outpatient of the public health system in northeast of brazil 113

Clinical-epidemiological profile and correlations with arboviruses of inpatients with Guillain-Barré syndrome at a hospital in the Northeast of Brazil 114

Clinical-radiological mismatch in patient with moyamoya syndrome and seronegative rheumatoid arthritis..... 114

Clinicogenetic characterization and response to disease-modifying therapies in spinal muscular atrophy: real-world experience from a reference center in Southern Brazil 114

CLIPPERS syndrome: case report..... 115

Cluster analysis reveals diversity among the neuropsychological phenotypes of SARS-Cov-2 infected subjects 115

Cluster phenotyping and genomic correlation of motor neuronopathies115

Cluster tic syndrome: the duel of two excruciating headaches 115

c-NORSE score identifies patients with cryptogenic NORSE in a Brazilian cohort 116

Coexisting anti-NMDAR and MOG antibody-associated encephalitis: case report..... 116

Cognition and endothelial function in hypertensive individuals with and without a history of COVID-19: a cross-sectional study 116

Cognitive and neuropsychiatric analysis of patients with myotonic dystrophy type I 117

Cognitive and theory of mind impairment in sporadic and familial amyotrophic lateral sclerosis patients 117

Cognitive assessment in patients with spinocerebellar ataxia type 6 ... 117

Cognitive changes in patients with concentric Baló sclerosis: a systematic review 117

Cognitive decline in patients with Chagas and non-Chagas etiology heart failure: a prospective cohort study 118

Cognitive impairment following leptospirosis encephalitis: case report and literature review..... 118

Cognitive impairment: clinical presentation of an immunocompetent patient with neurosyphilis 118

Cognitive multisensory rehabilitation (cmr perfetti): improving motor function in chronic stroke patients..... 118

Cognitive symptoms in long COVID patients: clinical and epidemiological analysis 119

Cognitive training associated with transcranial direct current stimulation in the treatment of age-related mild cognitive impairment: a systematic review of randomized clinical trials 119

Coinfection of neurotuberculosis and neurocryptococcosis in an immunocompetent patient: a case report..... 119

Collet-sicard syndrome: a clue to occult malignancy in an elderly female - a case presentation 120

Communication problems are not associated with cognitive decline in people with Parkinson's disease 120

Companion's knowledge on stroke and symptoms-to-door time in reference hospital 120

Comparative analysis of emergency assistance for stroke in the interior of Pernambuco to national guidelines 120

Comparative analysis of prognosis between patients with wake-up stroke and patients with acute ischemic stroke with defined onset time..... 121

Comparative analysis of the clinical and epidemiological profile of patients with ischemic stroke according to age in a referral hospital in Bahia 121

Comparative analysis of the management and prognosis of ischemic cerebral stroke patients according to age in a referral hospital in Bahia 121

Comparative analysis of the spatio-temporal distribution of acute ischemic stroke treatment with thrombolytic therapy in Brazil from 2019 to 2023..... 122

Comparative efficacy of different pharmacotherapies for muscular dystrophy: a systematic review and network meta-analysis 122

Comparative spatial analysis of leprosy cases in the North and Southeast regions..... 122

Comparison between conventional physiotherapy rehabilitation and virtual reality in Parkinson's disease: a systematic review 123

Comparison of disability level between early and late onset Parkinson's disease using WHODAS-2 123

Comparison of electrochemical skin conductance and skin biopsies tests for detection of neuropathy in patients with hereditary transthyretin amyloidosis-polyneuropathy (ATTRv-PN) 123

Comparison of Kappa index and oligoclonal bands detection positivity in cerebrospinal fluid samples of patients with suspected multiple sclerosis (MS) 123

Comparison of mortality rate and length of stay between intracranial aneurysm treatment by endovascular surgery vs. microsurgery in Northeastern Brazil over the past 5 years 124

Comparison of open-loop and closed-loop transcutaneous auricular vagus nerve stimulation on autonomic control in healthy individuals: new directions for epilepsy treatment 124

Comparison of quality indicators in a stroke unit during and after the COVID-19 pandemic 124

Comparison of stroke awareness between Aparecida (SP) and São Paulo (SP): a cross-sectional study from 2023 and 2024 124

Comparison of the efficacy of monotherapy with bevacizumab versus combined therapies or monotherapies with other drug classes in the treatment of recurrent glioblastoma 125

Comparison of the incidence and mortality of intracranial trauma in children under 1 year old in the Southeast region of Brazil during 2020 and 2021 125

Comparison of the prevalence of hospitalizations due to Alzheimer's disease in the federal regions of Brazil and the mortality rate 125

Comparison of the prevalence of hospitalizations due to Parkinson's disease in the federal regions of Brazil and the mortality rate 126

Comparison of years of life lost due to ischemic stroke between two countries with a public health system: 5-year analysis 126

Compensated idiopathic intracranial hypertension due to traumatic cerebrospinal fluid fistula: a case report 126

Complex case of trismus, ischemic stroke and neuromuscular disorder: a diagnostic challenge 126

Complex dementia case: overlapping symptoms of vascular, Alzheimer's, and frontotemporal dementia with adult leukoencephalopathy 127

Complex neurological manifestations in a case study of narcolepsy and autosomal dominant ataxia 127

Complication of herpetic encephalitis: Klüver-Bucy syndrome: clinical case 127

Comprehensive analysis of the clinical and genetic features of RYR1-related myopathies 128

Comprehensive step-by-step clinical assessment for managing action-induced focal dystonia after bilateral gpi deep brain stimulation for Parkinson's disease 128

Concomitant elevation of pro-inflammatory cytokines IL-6, IL-10 and neurodegeneration biomarkers neurofilament light chain (NFL) as potential biomarkers for severe COVID-19 outcomes 128

Congenital insensitivity to pain due to SCN9A gene mutation: a case report 129

Congenital limb-girdle muscular dystrophy: case report with molecular diagnosis 129

Congenital miopathy presenting as mitocondrial miopathy: the relevance of genetic testing and semiological findings in chronic progressive external ophtalmoplegia 129

Congenital myasthenia gravis: a case report from the perspective of neurology 129

Congenital myopathy due to a mutation in the ACTA1 gene: case report 130

Contrast-induced encephalopathy: a mimicker in the ICU 130

Contribution of nerve biopsy in leprosy and other neuropathies: 26 years of experience at a reference center 130

Co-occurrence of multiple sclerosis and autism spectrum disorder: a case series of 9 patients 131

Co-occurrence of nmo spectrum disorder (nmosd) anti- AQP-4positive and a history of low-grade glioma in childhood: a case report 131

Correlation between Guillain-Barré syndrome and COVID-19 infection or vaccination in patients undergoing therapeutic plasmapheresis 131

Correlation between median motor latency and complementary sensory tests on the 1st and 4th fingers for early diagnosis of carpal tunnel syndrome 131

Correlation between meningitis vaccination and mortality rates in Brazil: a retrospective analysis 132

Correlation between microvascular changes in the retina and choroid with disease duration, severity, and cognitive deficits in migraine with and without aura 132

Correlation between motor development and cognitive development in children with cerebral palsy 132

Correlation between motor, non-motor, and cognitive functions with optical coherence tomography (OCT) in Parkinson's disease 132

Correlation between postural control and sleep quality in patients with parkinson's disease: a cross-sectional study 133

Correlation between severity of ischemic stroke and levels of disability and functional dependence: a cohort study 133

Correlation between sleep and kinematic gait parameters in people with parkinson's disease 133

Correlation between vitamin d deficiency and post-stroke depression: an updated meta-analysis 134

Cortical correlations of CSF neurogranin, VILIP-1, alpha-synuclein, and NFL in SCD and MCI according to amyloid status 134

Cortical laminar necrosis and its characteristics in a patient with systemic hypoperfusion: a case report 134

Cost analysis of amyotrophic lateral sclerosis according to clinical protocols and therapeutic guidelines compared to real-world clinical practice: application of time-driven activity-based costing methodology in a specialized service 134

Costs of hospitalizations for the treatment of acute ischemic and hemorrhagic stroke in the state of São Paulo between 2019 and 2023 .. 135

Could coinfection accelerate htlv-1-associated myelopathy/tropical spastic paraparesis (HAM/TSP) onset? 135

COVID-19 and vascular complications: case analysis of ischemic stroke in the artery of percheron 135

COVID-19 pandemic and sleep quality in medical students at university of Ribeirão Preto 135

Cranial nerve syndrome in a MOG-AB positive patient 136

Cranial nerves palsy due to pneumococcal meningitis: a case report 136

Creation of a university EEG study group to collaborate with medical education in electroencephalography with the democratic Republic of Congo, Africa 136

Creutzfeldt-Jakob disease (CJD): two-cases report 137

Creutzfeldt-Jakob disease Heidenhain variant: case report with progressive cognitive decline recorded by videos 137

Creutzfeldt-Jakob disease in Brazil: a review of its profile and notification mechanisms 137

Creutzfeldt-Jakob disease, a series of cases in a public hospital in Paraíba, Brazil 137

Creutzfeldt-Jakob disease: a case report 138

Creutzfeldt-Jakob disease: a case report 138

Creutzfeldt-Jakob disease: a Heidenhain variant case report 138

Crossed cerebellar diaschisis: a report of presentation with tardive ataxia and diagnosis with PET-CT and tractography 138

Crucial role of the ApoE4 variant in the pathogenesis of Alzheimer's disease in homozygous patients: a systematic review 139

Cryptococcal meningoencephalitis in an immunocompetent patient: case report 139
CSF1R-related leukoencephalopathy: case report 139
Cutaneous anaplastic large cell lymphoma in a multiple sclerosis patient receiving natalizumab 139
Cyclic stereotypic catatonia revealing anti-nmda encephalitis 140
Cytotoxic lesions of the corpus callosum (CLOCC): a neurological complication of dengue fever 140
Dabigatran reduced the length of hospital stay for cerebral venous thrombosis 140
DBS of the Meynert basal nucleus for patients with Lewy body dementia: a meta-analysis of randomized clinical trials 141
Deaths to epilepsy in Brazil: a comparison between sex and age group from 2018 to 2022 141
Deciphering the TBK1 mutation: a key to unlocking the mysteries of frontotemporal dementia and als in Brazilian families 141
Deep learning for neuroimage classification in Alzheimer's disease: barriers to clinical relevance 141
Deep phenotyping of hereditary amyloidosis I107V in a Brazilian cohort 142
Delirium phenotype in acute stroke 142
Delirium post-stroke: does the cognitive phenotype impact the patient's functional outcome? 142
Dementia in public health in Brazil: epidemiological analysis regarding hospitalizations and mortality between 2012 and 2022 143
Dementia syndrome in multiple sclerosis 143
Dementia syndrome secondary to postherpetic encephalitis: a sequelae lesion 143
Demographic, genetic and clinical profile of patients with hereditary transthyretin amyloidosis from a reference center in Brazil 143
Demyelinating impairment in leprosy and the importance of the differential diagnosis with inflammatory neuropathies 144
Dengue encephalitis and the differential diagnosis of bilateral thalamic lesions ... 144
Dengue encephalitis: a reality in an endemic country 144
Dengue fever and neurological complications: a report of acute disseminated encephalomyelitis (ADEM) with good response to plasmapheresis 145
Dengue meningoencephalitis: a case of neurological manifestations and diagnostic challenges in pediatrics 145
Dengue virus-induced encephalitis leading to new-onset refractory status epilepticus 145
Description of a cohort of patients with Baló concentric sclerosis from Rio de Janeiro/Brazil 145
Description of prevalence of hospitalizations for brain neoplasms and the mortality among Brazilian federative regions 146
Description of the prevalence of epilepsy hospitalizations in the federative regions of Brazil and the mortality rate 146
Description of the prevalence of migraines and other pain syndromes hospitalizations in the federative regions of brazil and the mortality rate 146
Descriptive analysis of cerebrovascular disease patients at a public hospital in São Paulo - Ipiranga Hospital 146
Descriptive analysis of ischemic stroke patients undergoing thrombolysis in a São Paulo metropolitan public hospital 147
Desmopressin effects in patients with antiplatelet associated intracranial haemorrhage: a systematic review and meta-analysis 147
Desmopressin in hematoma expansion in patients with intracranial hemorrhage and prior use of antiplatelet agents: a systematic review and meta-analysis 147
Detailed neurological examination in people living with HTLV-1 148
Detection of latent tuberculosis infection in patients at a reference center for demyelinating diseases in Recife-PE 148
Development of an instrument for the assessment of compensatory strategies in individuals with stroke 148
Diabetes insipidus associated with infundibuloneurohypophysitis: case report 148
Diagnoses of overlapping cases of neuromuscular junction disorders: myasthenia gravis and Lambert Eaton syndrome 149
Diagnosis and treatment of a case of functional (conversion) disorder: the importance of neurology-psychiatry collaboration 149
Diagnosis and treatment of anaplastic supratentorial cortical ependymoma in an adult patient: a case report 149
Diagnosis and treatment of myasthenia gravis in a pregnant patient with suspected head and neck tumor: case report 150
Diagnosis journey of Brazilian Friedreich's ataxia patients 150
Diagnosis of Chediak-Higashi syndrome in the neurology ward 150
Diagnosis of exclusion in progressive idiopathic ganglionopathy: a case report 150
Diagnostic and treatment pathways for adult patients with brain cancer in bahia: a comparative analysis in 2013 and 2023 151
Diagnostic and treatment pathways for pediatric patients with brain cancer in Bahia: a comparative analysis in 2013 and 2023 151
Diagnostic challenge in neuromyelitis optica in the pediatric population: case report 151
Diagnostic challenges in Behçet's disease: a case report with multisystemic manifestations 152
Diagnostic challenges of longitudinally extensive transverse myelitis: unveiling an uncommon culprit 152
Diagnostic imaging of spontaneous intracranial hypotension: a case series 152
Diagnostic pathway of Noonan-like syndrome with loose anagen hair 1: case report 152
Diagnostic tools in the diagnosis of pure neural leprosy 153
Diagnostic value of intraepidermal nerve fiber density (IENFD) in lower limb skin biopsies of patients with hereditary transthyretin amyloidosis-polyneuropathy (ATTRv-PN) in a Brazilian centre 153
Diagnostic value of voxel-based morphometry in MRI negative epilepsies and focal cortical dysplasia: correlation with electrocorticography and surgical results 153
Diagnostic yield of autosomal dominant cerebellar ataxia by whole exome sequencing in an undetermined ataxia cohort 154
Diagnostic yield of distinct next generation sequencing approaches in adult patients with suspected genetic myopathy 154
Did Thomas Willis describe narcolepsy? 154
Differences between triggers of migraine and tension-type headache in southern brazilian patients 154
Differential diagnoses of inflammatory myopathies with positive biopsy for dysferlin 155
Differential diagnosis between ischemic stroke and mitochondrial myopathy, encephalopathy with lactic acidosis and stroke-like episodes (MELAS): a case report 155
Differential diagnosis for sudden visual deficits: a case series and literature review on Anton-Babinski syndrome 155
Differential diagnosis of cluster headache: a systematic review 156
Differential diagnosis of epilepsy and the importance of the video-electroencephalography: a case report 156
Differential diagnosis of neuromyelitis optica and brainstem glioma in a pediatric patient: a case report and how to differentiate between them 156

Difficult-to-control epilepsy due to germ cell brain tumor and asymmetric hippocampal atrophy: case report 156

Diffuse and extensive intracranial calcifications in a patient with systemic lupus erythematosus: an atypical case of Fahr's syndrome 157

Diffuse brain involvement in lymphomatoid granulomatosis 157

Diffuse cortical laminar necrosis in dengue encephalitis and status epilepticus: rare complications of a common disease in a climate crisis scenario 157

Digital analysis of immunostaining and tissue distribution of the R132H mutant form of isocitrate dehydrogenase 1 in diffuse low or high-grade adult astrocytomas 157

Digital tool validation for syndromic and topographic diagnosis in vascular neurology: LouiS 158

Directional deep brain stimulation in the management of Parkinson's disease: efficacy and constraints - an analytical appraisal 158

Discontinuation of disease-modifying drugs in older patients with multiple sclerosis: an observational study 158

Disease burden and outcomes in adult patients with Duchenne muscular dystrophy 158

Disorders of nerves, nerve roots and plexuses in Brazil: an epidemiological analysis over the last 5 years 159

Dissection of the common carotid artery and anatomical variant of anterior cerebral artery leading to ischemia in multiple cerebral vascular territories 159

Disseminated cryptococcosis in immunocompetent patients: a therapeutic challenge 159

Dissemination of leptomeningeal non-Hodgkin lymphoma in a patient with Sézary syndrome: a case report 159

Distal hereditary motor neuropathy with HSJ1 chaperone mutation presenting with movement disorders 160

Distinct patterns of CNS damage along the spectrum of ATXN2-related disorders 160

Distribution of antiepileptic drugs by specialized component of pharmaceutical assistance (ceaf): a time series analysis 160

DNMT1 mutation cerebellar ataxia in rare expression in a Brazilian family: a report of 2 cases 161

Do not neglect sudden paresthesia: a case report of cheiro-oral syndrome 161

Do Parkinson's disease subtypes impact an individual's ability during the functional task of boarding a bus? 161

Do sleep distubances impact the qualrity of life and cognition similarly in men and women with Parkinson's disease? 161

Does antidepressant use interfere with multiple sclerosis patient's outcome? 162

Does COVID-19 impact the modulation of the cardiac autonomic nervous system in patients with systemic arterial hypertension? 162

Does Ginkgo Biloba extracts really have any impact on patients with moderate to low acute ischemic stroke (NIHSS ≤15) ?: an updated meta-analysis of Chinese randomized clinical trials 162

Does midbrain atrophy distinguish progressive supranuclear palsy from frontotemporal dementia? A multimodal neuroimaging investigation ... 163

Does posterior callosotomy reduces secondary bilateral synchrony? A proof-of-concept video-EEG study 163

Does postural control influence kinematic parameters of normal and dual-task gait in individuals with Parkinson's disease? 163

Does the upper limb strength exerted to board a bus correlate to gait in individuals with Parkinson's disease? 163

Don't close your eyes for this diagnosis: prevalence and characteristics of Jeavons' syndrome in an epilepsy monitoring unit in Southern Brazil 164

Dopa-responsive cervical dystonia: case report 164

Dorsal root ganglia and spinal cord imaging in genetic and acquired sensory neuronopathies 164

Dosage of botulinum toxin in hemifacial spasm patients: a referral center experience 164

Driver's license eligibility in adult patients with epilepsy 165

Drug candidate prototypes for Parkinson's disease treatment: an in silico, in vitro, and in vivo study 165

Drug-resistant epilepsy related to PPP2R5D 165

Dual pathology in neurodegenerative dementias: when idiopathic normal pressure hydrocephalus diagnosis masks and modifies other dementias 165

Dural fistula and trigeminal autonomic headache 166

Dystonia caused by atp1a3 gene mutation: report of two cases 166

Early and long-term programming characteristics in Parkinson's disease patients submitted to subthalamic deep brain stimulation 166

Early diagnosis of epidermoids cysts in the pontocerebellar angle up to age of 24 years: a challenge for managing neural tube defects - systematic review of the last 20 years 167

Early diagnosis of laing myopathy with neuromuscular ultrasound: a case report and future directions 167

Early fecal metabolomic alterations in pilocarpine-induced status epilepticus: insights into tle pathophysiology and resistance mechanisms 167

Early reactivation of Chagas disease in the central nervous system after heart transplant: case report 167

Early stroke as a primary manifestation of inborn error of immunity 168

Early vs classical facioscapulohumeral muscular dystrophy onset: a specialized muscular center profile 168

Early-onset myopathy, areflexia, respiratory distress, and dysphagia (EMARDD): a case report and description of a novel variant 168

Eaton Lambert myasthenic syndrome with cerebellar ataxia misdiagnosed as Guillain-Barré spectrum 169

Ecological study of hospitalization for dementia in Brazilian regions, 2014 - 2023 169

Ecological study of meningococcal infection in the Southeast region of Brazil from 2015 to 2022 169

Ecological study of migraines and other headache syndromes in Southern Brazil, 2014 - 2023 169

Ecological study: analysis of morbidity and mortality of bacterial meningitis in preschool children in the Southeast region 170

Effect of a 12-week protocol of strength and functional exercises on the treatment of motor symptoms in individuals with hereditary spastic paraparesis: adaptive crossover randomized clinical trial 170

Effect of organic purple grapes on behavioral tests of self-grooming and social interaction in an animal model of Valproic acid-induced autism . 170

Effect of organic purple grapes on brain antioxidant enzyme activity in an animal model of autism induced by Valproic acid 171

Effect of theta burst transcranial magnetic stimulation associated with transcranial direct current stimulation to improve unilateral spatial neglect after stroke: a randomized controlled trial study protocol 171

Effect of transcranial direct current stimulation on the cognitive function of individuals with Alzheimer's disease: a systematic review with meta-analysis and meta-regression 171

Effect of vitamin D3 isolated or associated with donepezil on the spatial memory of adult and aged ovariectomized rat 171

Effective management of diabetic peripheral neuropathy associated with wound healing: a case report 172

Effective use of botulinum toxin for neuropathic pain management in a neuroma: a case report 172

Effectiveness of botox (onabotulinumtoxin) in the treatment of migraines: a systematic review 172

Effectiveness of DBS as a treatment for Alzheimer's disease: meta-analysis 173

Effectiveness of deep brain stimulation in Huntington's disease: a comprehensive literature review 173

Effectiveness of dordaviprone in H3 K27M-mutant diffuse glioma: a systematic review and proportional meta-analysis 173

Effectiveness of dual task in a combined training on quality of life and concern about falling in individuals with Parkinson's disease: randomized controlled trial 173

Effectiveness of GLP-1 receptor agonists in Parkinson's disease: a systematic review and meta-analysis 174

Effectivity of tafamidis in the control of neurological deficits in patients with familial amyloid polyneuropathy: a systematic review and meta analysis 174

Effects of cannabigerol on neuroinflammation and spatial memory in mice with cerebral ischemia 174

Effects of laser and ultrasound therapies on sciatic nerve axonotmesis: an experimental study 175

Effects of melatonin use in children with sleep disorders: a systematic review 175

Effects of mental practice on fog in people with Parkinson's disease: a randomized clinical trial 175

Effects of neuromodulation in patients with multiple sclerosis: a systematic review 175

Effects of non-invasive neuromodulation on food cravings and executive functions in health professionals 176

Effects of trans-spinal direct current stimulation combined with motor training in traumatic spinal cord injuries: a case study 176

Efficacy and complications of lumboperitoneal shunt for idiopathic normal pressure hydrocephalus in elderly patients: a systematic-review and meta-analysis 176

Efficacy and safety of argatroban in treatment of acute ischemic stroke in patients not receiving endovascular treatment: a systematic review and meta-analysis 176

Efficacy and safety of atogepant for migraine prevention: a systematic review and meta-analysis of randomized controlled trials 177

Efficacy and safety of botulinum toxin type a (bont-a) use in the treatment of chronic migraine: a systematic review and meta-analysis 177

Efficacy and safety of galcanezumab for cluster headache preventive treatment: a systematic review and meta-analysis 177

Efficacy and safety of hematopoietic stem cells transplantation in Krabbe disease: a systematic review 178

Efficacy and safety of inotersen and eplontersen in hereditary transthyretin amyloidosis: a systematic review and meta-analysis 178

Efficacy and safety of mechanical thrombectomy in posterior circulation ischemic strokes: a systematic review 178

Efficacy and safety of melatonin for migraine prevention in children and adolescents: a systematic review and meta-analysis 178

Efficacy and safety of mycophenolate in AQP4-AB negative neuromyelitis optica spectrum syndrome associated with encephalopathy: report of a case 179

Efficacy and safety of rituximab in a Brazilian cohort of patients with refractory myasthenia gravis 179

Efficacy and safety of tacrolimus for myasthenia gravis: a systematic review and meta-analysis 179

Efficacy and safety of tirofiban in acute ischemic stroke patients not receiving endovascular treatment: a systematic review and updated meta-analysis 180

Efficacy and safety of vamorolone in improvement of muscle function in Duchene muscle dystrophy: a systematic review and meta-analysis 180

Efficacy of botulinum toxin in the management of trigeminal neuralgia: a systematic literature review 180

Efficacy of injectable sustained-release and autogel lanreotide for tumor reduction in pituitary adenomas: a systematic review and single-arm meta-analysis 180

Efficacy of pimavanserin for patients with psychosis in Alzheimer's disease: a systematic review 181

Efficacy of subcutaneous apomorphine in Parkinson's disease: a meta-analysis of randomized controlled trials 181

Eight-and-a-half syndrome due to pontine stroke: a case report 181

Electroencephalography findings in a girl with Zellweger syndrome: case report 181

Electroencephalography findings in Landau-Kleffner syndrome: case report 182

Elevated plasma levels of miR-206 in adult spinal muscular atrophy patients: a potential biomarker 182

Endovascular thrombectomy versus standard medical treatment alone in patients with acute ischemic stroke with large infarct (aspects ≤5): a systematic review and meta-analysis of randomized controlled trials .. 182

Enhanced RNA extraction and qPCR for microrna quantification in REM sleep behavioral disorder: potential biomarkers and methodology comparison 182

Enhancing postoperative epilepsy assessment with Resectvol DL: a novel deep learning tool for brain lacuna segmentation 183

Epidemiologic analysis of the hospitalization of Parkinson's disease in Brazil from 2013-2023 183

Epidemiologic analysis of the hospitalization of viral encephalitis in Brazil from 2013-2023 183

Epidemiologic profile of hospitalizations and deaths by brain neoplasms in the state of Bahia between 2013 and 2021 184

Epidemiological analysis of admissions, treatment, mortality and costs of cerebrovascular diseases in Brazil between 2017 and 2022 184

Epidemiological analysis of deaths due to inflammatory polyneuropathies from 2018 to 2022 184

Epidemiological analysis of deaths due to tuberculosis of the central nervous system in Brazil by geographic regions from 2013 to 2023 184

Epidemiological analysis of deaths from neuromuscular junction and muscle diseases from 2018 to 2022 185

Epidemiological analysis of epilepsy cases in the state of Pará between 2018 and 2022: an ecological study 185

Epidemiological analysis of Hansen's disease in the pediatric population in the state of Goiás: from 2010 to 2023 185

Epidemiological analysis of hospitalizations due to Alzheimer's disease in the Brazilian population between 2019 and 2023 186

Epidemiological analysis of hospitalizations due to multiple sclerosis in the Northeast of Brazil from 2018 to 2023 186

Epidemiological analysis of hospitalizations for facial paralysis and other paralytic syndromes across Brazilian regions 186

Epidemiological analysis of hospitalizations for microsurgery for intracranial tumors in Brazil between the years 2013 and 2022 187

Epidemiological analysis of hospitalizations from viral encephalitis in Brazil from 2019 to 2023: an ecological study 187

Epidemiological analysis of intracranial hemorrhage cases in Goiás over the past five years 187

Epidemiological analysis of meningococcal disease in children up to 14 years old 187

Epidemiological analysis of meningo-encephalic tuberculosis in vulnerable populations in Brazil: 2014-2023 188

Epidemiological analysis of migraine hospitalizations in the state of São Paulo from 2019 to 2023: an ecological study 188

Epidemiological analysis of mortality rate and treatment cost of uncontrolled epileptic seizures in the state of São Paulo 188

Epidemiological analysis of patients with epilepsy in Brazil..... 189

Epidemiological analysis of pediatric hospitalizations for epilepsy in the state of São Paulo: an overview of the last 10 years..... 189

Epidemiological analysis of spina bifida in Brazil and of maternal factors 189

Epidemiological analysis of strokes in the elderly in the southeast region of brazil: incidence and mortality 190

Epidemiological analysis of the prevalence and mortality of viral meningitis in the southeast region of Brazil..... 190

Epidemiological analysis of traumatic brain injury in the Brazilian unified health system, 2012 to 2022 190

Epidemiological analysis of traumatic brain injury in the Northern region of Brazil from 2019 to 2023 191

Epidemiological analysis of zika virus infections associated with cases of microcephaly in the Brazilian regions between 2015 and 2023..... 191

Epidemiological and clinical characteristics of patients with Guillain-Barré syndrome in a hospital in the Northeast of Brazil after pandemia: preliminary results 191

Epidemiological and clinical features of patients admitted for stroke in an emergency department in the interior of Pernambuco 191

Epidemiological and clinical profile of patients with Guillain-Barré syndrome at a university hospital in Mato Grosso do sul, from 2018 to 2023 192

Epidemiological and healthcare indicators analysis of the stroke line of care within the emergency and urgency healthcare network..... 192

Epidemiological aspects of bacterial and viral meningitis in Brazil: a retrospective analysis from 2018 to 2023 192

Epidemiological aspects of hospital admissions for Alzheimer's in Brazil from 2015 to 2019..... 193

Epidemiological aspects of patients affected by stroke in the Southeast region between Jan/2018 to Jan/2024 193

Epidemiological aspects of patients affected by viral encephalitis in the Southeast between 2019 and 2023..... 193

Epidemiological aspects of pediatric patients affected by viral meningitis in the Southeast region between 2019 and 2023..... 194

Epidemiological assessment of microcephaly in Brazil from 2015 to 2023 194

Epidemiological characterization of polio vaccination in Brazil and in the state of São Paulo during the 21st century 194

Epidemiological disparities in hospitalizations for multiple sclerosis in the face of the COVID-19 pandemic..... 194

Epidemiological factors implicated in Parkinson's disease: a preliminary study of patients from an outpatient clinic with a standardized routine questionnaire 195

Epidemiological overview of migraine hospitalizations in Brazil: profile of hospitalized individuals and costs..... 195

Epidemiological profile analysis of hospital admissions for viral encephalitis in Brazil from 2019 to 2023..... 195

Epidemiological profile and comorbidities of patients with Parkinson's disease at an university hospital 196

Epidemiological profile and impact of hospitalizations for complicated migraine in Brazil (2019-2023)..... 196

Epidemiological profile and mortality of hospitalizations for epilepsy in the state of Pará from 2014 to 2023 196

Epidemiological profile and public expenditure of hospital admissions for migraines in Brazil 196

Epidemiological profile and temporal trends of meningococcemia in Brazil between 2010 and 2023 197

Epidemiological profile and treatment efficacy of cladribine in a single Brazilian multiple sclerosis center 197

Epidemiological profile of admissions for brain neoplasm in Northeast Brazil between 2008 and 2023 197

Epidemiological profile of central nervous system neoplasms in the last decade..... 198

Epidemiological profile of deaths due to brain cancer in Brazil between 2017 and 2021..... 198

Epidemiological profile of deaths from hereditary ataxias in Brazil from 2013 to 2022 198

Epidemiological profile of epilepsy hospitalizations among young people in Northeastern Brazil from 2013 to 2023 199

Epidemiological profile of hospitalization for mental and behavioral disorders due to alcohol use in Brazil between the years 2019-2024..... 199

Epidemiological profile of hospitalization for Parkinson's in Brazil between the years 2014-2024..... 199

Epidemiological profile of hospitalizations and deaths from multiple sclerosis in Brazil from 2019 to 2023 199

Epidemiological profile of hospitalizations due to Alzheimer's disease between 2019 and 2023 200

Epidemiological profile of hospitalizations due to viral meningitis during the COVID-19 pandemic 200

Epidemiological profile of hospitalizations for central nervous system tuberculosis: a half-decade study across regions of Brazil..... 200

Epidemiological profile of hospitalizations for epilepsy in childhood in Brazil from 2019 to 2023 200

Epidemiological profile of hospitalizations for neurocysticercosis by regions of Brazil 2013-2022 201

Epidemiological profile of hospitalizations for Parkinson's disease in brazil from 2012 to 2022 201

Epidemiological profile of hospitalizations for viral encephalitis in Brazil from 2014 to 2023 201

Epidemiological profile of hospitalizations for viral meningitis in Brazil between the years 2019-2024..... 202

Epidemiological profile of meningitis in Brazil from 2014 to 2023 202

Epidemiological profile of meningitis in the South region of Brazil from 2019 to 2023 202

Epidemiological profile of multiple sclerosis in Brazil: an analysis of the last 5 years (2019-2023)..... 202

Epidemiological profile of multiple sclerosis inpatients in Brazil in the last 10 years 203

Epidemiological profile of muscle disorders: insights from a specialized service in São Paulo 203

Epidemiological profile of Parkinson's disease in Brazil: an analysis of the last 10 years 203

Epidemiological profile of patients hospitalized for tetanus in Brazil over the last 10 years 204

Epidemiological profile of patients who death from Alzheimer's disease in Salvador – Bahia: 2013 to 2023..... 204

Epidemiological profile of patients with Guillain-Barré syndrome from 2013 to 2023 in the Federal District, Brazil 204

Epidemiological profile of patients with headache in neurology outpatient clinics in the Southern region of Santa Catarina..... 204

Epidemiological profile of patients with multiple sclerosis from 2013 to 2023 in the Federal District, Brazil..... 205

Epidemiological profile of patients with neurotuberculosis in Brazil over the last 5 years 205

Epidemiological profile of pediatric patients hospitalized for multiple sclerosis in Brazil: 2014-2023 205

Epidemiological profile of transient ischemic stroke (CVA) and related syndromes in adults and elderly people in Northeast Brazil from 2018 to 2023 205

Epidemiological profile of traumatic cervical spinal cord injury in Northern Brazil: a 10-year retrospective analysis. 206

Epidemiological study of cases of ischemic stroke in a hospital of Minas Gerais: an observational study 206

Epidemiological study of live births with spina bifida in Brazil 206

Epidemiological study on multiple sclerosis hospitalization in Brazil comparing sex, age and region between January 2008 to December 2023 206

Epidemiological study on the prevalence of Parkinson's disease, parkinsonism, and rem sleep behavior disorder in the community of Candangolândia - DF 207

Epidemiology of Alzheimer's disease in Ceará: an analysis of hospitalized patients (2008-2022) 207

Epidemiology of Alzheimer's disease hospitalizations in Brazil: analysis regarding color/race, age group and sex 207

Epidemiology of encephalocele in newborns in Brazil: an analysis of the last decade 208

Epidemiology of multiple sclerosis mortality in Brazil over the last 20 years 208

Epidemiology of patients followed by the post-stroke palliative care team in a reference hospital for stroke treatment in Santa Catarina 208

Epilepsy during the COVID-19 pandemic: an analysis of trends in hospitalizations and deaths in Brazil 209

Epilepsy in the Brazilian pediatric population: an ecological study between 2018 and 2023 209

Epilepsy mortality trends in Brazil (2001-2022): a joinpoint analysis 209

Epilepsy prevalence as a cause of hospitalization for central nervous system diseases in Brazil: an epidemiological study 209

Epilepsy: inference of quantitative data on hospitalizations in Brazil between 2019 and 2023 210

Epileptic and developmental encephalopathy secondary to a mutation on gene STXBP1: a case report 210

Erdheim-Chester manifesting purely as a neurological disease: case report 210

Erenumab for migraine: a systematic review and meta-analysis 211

Erenumab for treatment of episodic migraine with previous treatment failures: a systematic review and meta-analysis 211

Escobar syndrome associated with arthrogryposis multiplex congenita: a rare case presentation 211

Etiological profile and outcome of people with optic neuritis treated at a neurological clinic between 2005 and 2022 in the interior of the Brazilian Amazon 211

Evaluating the impact of mechanical thrombectomy availability on ischemic stroke outcomes in Brazil's public health system 212

Evaluation along a comparison within Brazil's regions of factors linked to hospital internment from cerebral infarction and number of chemical thrombolysis used to treat them over the period of 2014-2023 212

Evaluation and differentiation of edema and tumor infiltration in patients with high-grade glioma: initial experience using T2 relaxometry tests .. 212

Evaluation of atypical festinating gait in a patient with Wilson's disease 213

Evaluation of benign multiple sclerosis beyond the EDSS: cognitive, fatigue and mood disorders 213

Evaluation of brain morphometry by magnetic resonance imaging in patients with psychogenic nonepileptic seizures 213

Evaluation of cerebello-cortical pathways using the virtual brain in a patient with cerebellar mutism: study methodology 213

Evaluation of cognitive impairment in long-severe COVID patients 214

Evaluation of epidemiological factors in patients diagnosed with meningitis in 2023 in Mato Grosso do Sul, Brazil 214

Evaluation of facial expressions for the recognition of parkinsonian fasciations based on artificial intelligence learning 214

Evaluation of gait and balance in patients with spinocerebellar ataxia type 1 using wearable inertial sensors 214

Evaluation of micrornas as biomarkers of malignant evolution in patients with diagnosis of glioma 215

Evaluation of motor results in patients with Parkinson's disease undergoing deep brain stimulation implantation at the neurological institute of Curitiba 215

Evaluation of MRI findings associated with benign multiple sclerosis .. 215

Evaluation of prognosis from admission data in patients diagnosed with stroke accident in a reference hospital in Bahia 215

Evaluation of pulse therapy with intravenous methylprednisolone on leprosy neuritis: an observational study on a Brazilian referral center .. 216

Evaluation of quantitative muscle ultrasound in monitoring the progression of Duchenne muscular dystrophy 216

Evaluation of rAAVrh74 antibodies seroprevalence: report from the first tested cohort of Duchenne patients in Brazil 216

Evaluation of sleep perception and presence of daytime sleepiness and its impact on the quality of life of patients with Fabry disease: a case series 216

Evaluation of the functional capacity of patients with CADASIL in the state of Rio de Janeiro 217

Evaluation of the hospitalization landscape for multiple sclerosis in children and adolescents aged 1 to 19 across Brazilian regions over the past 5 years 217

Evaluation of the prevalence of functional neurological symptom disorder in an outpatient epilepsy clinic of a tertiary hospital in Cuiabá and the importance of its recognition 217

Evaluation of the results of transcranial magnetic stimulation protocol in the rehabilitation of patients post-stroke 218

Evaluation of the select score as a predictor of risk for epilepsy development in patients with ischemic stroke 218

Evidence of cortical thinning in patients with hereditary transthyretin amyloidosis 218

Evolutionary profile of the Walking test and Rotterdam scale in a group of patients with late-onset Pompe disease undergoing enzyme replacement therapy 218

Evolutive course of recovery of transcortical motor aphasia following focal resections in the frontal lobe for refractory epilepsy 219

Excessive daytime sleepiness in Parkinson's disease: an observational analysis 219

Excruciating pain during exercise reveals colloid cyst: a case of potential life-threatening risk 219

Experience in the switch from alglucosidase to avalglucosidase in real-life late-onset Pompe disease treatment 219

Experience with the use of cladribine in patients with multiple sclerosis at the neuroimmunology outpatient clinic of Faculdade de Medicina ABC 220

Experience with use of rituximab in a patient with Susac syndrome: a case report 220

Exploratory study of cognitive dysfunction and brain mri correlates in hereditary transthyretin amyloidosis 220

Exploring differentiation of common demyelinating CMT subtypes: a pilot study using supervised machine learning 221

Exploring how cognitive components influence social cognition in patients with dementia 221

Exploring ITPR3 mutations in Charcot-Marie-Tooth neuropathy: a case report from Brazil 221

Exploring the medication use: a comparative study of HTLV-1 patients facing HAM/TSP and those without 221

Exploring transient global amnesia: insights from demographic, clinical, cognitive and neuroimaging profiles..... 222

Explosive onset of non-epileptic seizures following levetiracetam introduction – is there a possible association 222

Expression of cellular pluripotency regulated micrornas associated with tumor recurrence in meningiomas 222

Expression of micrornas: miR-27A, miR-636, miR-1229 associated with memory in tonsils, hippocampus and blood of patients diagnosed with epilepsy 222

Expression of miR-19B and miR-7 in serum samples from patients with probable rbd as potential biomarkers..... 223

Eye movement patterns and decision-making in soccer: an eye-tracking study of professional athletes 223

Fabry disease, a diagnostic challenge: case report..... 223

Facial diplegia, sixth nerve palsy and hyperreflexia: rare variant of Guillian-Barré syndrome and response to plasmapheresis 224

Factors associated with intensive care unit admission for patients with acute stroke: a cohort study in a reference hospital in Bahia..... 224

Fahr's syndrome: a case report 224

False negative genetic panel for spinocerebellar ataxias: a case report 225

Familial amyloidosis with compound heterozygosity of the V122I and V30M: a case report 225

Familial amyloidotic polyneuropathy: an epidemiological study at a university hospital..... 225

Familial distal amyotrophy sord related 225

FDG-PET changes in LGI1-encephalitis..... 226

Feasibility analysis of using non-invasive monitoring technology to assess brain compliance during sleep..... 226

Femoral neuropathy secondary to compression by retroperitoneal hematoma: a rare differential diagnosis for neuroschistosomiasis 226

Finding the spot: results of a noninvasive strategy in MRI negative patients submitted to epilepsy surgery guided by ECoG..... 227

Findings from the illuminate prospective natural history study (NHS) in individuals with adult-onset leukoencephalopathy with axonal spheroids and pigmented glia (ALSP)..... 227

Findings in optical coherence tomography in patients with Wilson's disease: a cross-sectional study..... 227

Fine motor dexterity impairment in a large group of people with epilepsy without lesions in the motor areas..... 227

FIREFISH parts 1 and 2: 5-year efficacy and safety of risdiplam in type 1 SMA 228

First Brazilian study in central disorders of hypersomnolence using precision medicine: high-resolution hla sequencing and hypocretin levels in patients with narcolepsy and idiopathic hypersomnia..... 228

Five-year experience in spinal muscular atrophy treatment with nusinersen: a single-center experience..... 228

Fluctuating scoliosis due paravertebral dopa-responsive dystonia 229

Focal impaired awareness seizures in patient with choroidal fissure cyst 229

Foot drop as the predominant symptom in facial onset sensory and motor neuronopathy (FOSMN) 229

Foramen ovale electrodes can identify a focal seizure onset when surface EEG fails in mesial temporal lobe epilepsy?..... 229

Foreign accent syndrome in a patient with stroke at pons: case report . 230

Frequency and characterization of facial pain in individuals with hemifacial spasm in an outpatient clinic of a public tertiary center 230

Frequency of GAA-FGF14 ataxia in a large cohort of brazilian patients with unsolved adult-onset cerebellar ataxia..... 230

From independent to incapacitated: a case of antiepileptic drug-induced rapidly progressive dementia 231

From reversible cerebral vasoconstriction syndrome to subarachnoid hemorrhage, a continuum presentation of the same pathology: a case report associated analgesic abuse in kidney transplant recipient..... 231

Frontotemporal dementia (FTD) and amyotrophic lateral sclerosis (ALS): is clinical diagnosis sufficient? A case report 231

Functional connectivity of brain networks in patients with mild cognitive impairment after 24 weeks of resistance training 232

Functional recovery following resections of focal cortical dysplasia for epilepsy in the primary motor cortex (M1) 232

Functional/dissociative seizures in the pediatric/hebiatric population: videoelectroencephalography results from Santa Casa de Belo Horizonte 232

Functionality and disability according to whodas 2.0 in people with stroke: a cross-sectional study 232

Fungal encephalitis by Kluyveromyces marxianus (Candida kefyr) associated with pyelonephritis in an immunocompetent patient..... 233

GABA-B encephalitis as a paraneoplastic manifestation of malignant neoplasm..... 233

GAD-linked cerebellar ataxia and chronic use of phenytoin 233

Gamma-delta T cells suppress microbial metabolites that activate striatal neurons and induce repetitive/compulsive behavior in mice 233

Ganglionopathy and leprosy: a rare clinical presentation or overlapping pathologies? 234

Gene expression analysis of the WNT and mtor pathways from brain tissue of patients with focal cortical dysplasia type II 234

Gene therapy for Duchenne muscular dystrophy in Brazil: a case report234

Gene therapy for spinal muscular atrophy amid the dengue outbreak in Brazil: a case report..... 235

General evaluation of drugs used by post-stroke patients in the city of Marabá/Pará..... 235

Genetic migration dynamics: unraveling the influence of internal migration on Huntington's disease prevalence in the Amazonas state .. 235

Genetic search: techniques that resulted in the discovery of the Huntington's disease gene..... 235

Genetic testing in patients with oligo: or asymptomatic elevated CK 236

Genotype/phenotype correlation and peripheral neuropathy in Wilson's disease (WD) in the state of Ceará, Brazil..... 236

Genotype-phenotype correlations of FGFR2/3 variations: beyond craniosynostosis - a systematic review 236

Gerstmann syndrome as a rare presentation of cerebral venous thrombosis 237

Giant axonal neuropathy: case report of an intermediate form with late manifestations 237

Girdle muscular dystrophy, severe LGMD 2F subtype in a pediatric patient: case report 237

Globus pallidus internus deep brain stimulation for severe Tourette's syndrome: a case report 237

Glossopharyngeal neuralgia secondary to bone fibrodisplasia: a case report..... 238

Glossopharyngeal neuralgia: a case report..... 238

Glossopharyngeal neuralgia: case report..... 238

Glycemic imbalance, but not diabetes mellitus (DM), increases the risk of infection in patients with acute stroke admitted to a stroke unit: a cohort study in a reference hospital in Bahia..... 239

Gradenigo syndrome secondary to mucormycosis in an elderly patient: a case report 239

Graves' ophthalmopathy from the neurologist's perspective: a case report 239
Guillain-Barré syndrome after dengue infection: case report 239
Guillain-Barré syndrome after dengue virus infection: an unusual association 240
Guillain-Barré syndrome in children: a 10-year retrospective analysis of a Brazilian electrophysiology diagnostic center archive 240
Guillain-Barré syndrome succeeding dengue infection: a case series of three patients 240
Guillain-Barré syndrome: an uncertain etiology between influenza and acute contagious gastroenteritis - a case report 241
GYG1 gene mutation causing a mild phenotype of polyglucosan body myopathy type 2 241
HACD1-related congenital myopathy in four unrelated patients 241
Haloperidol versus atypical antipsychotics in the management of delirium: a systematic review and meta-analysis of randomized controlled trials 241
Has Creutzfeldt-Jakob disease become more frequent in Brazil? A case report and mini literature review 242
Headache and epilepsy in a female young patient: MELAS 242
Health profile of elderly people with probable cognitive impairment of primary health care 242
Healthcare journey for patients with amyotrophic lateral sclerosis (ALS) in a specialized service in Salvador-Bahia 243
Healthcare professionals perspectives on palliative care for stroke patients: the passar study 243
Heidenhain variant of Creutzfeldt-Jakob disease hiding in plain sight: clinical evolution and sequential MRI analysis of brain degeneration ... 243
Hemiballism-hemichorea as the initial presentation of type II diabetes refractory to adequate glycemic control: a case report 243
Hemiconvulsion-hemiplegia epilepsy syndrome associated with variant in the CACNA1A gene 244
Hereditary coproporphyria: misdiagnosis and iatrogenesis - a case report 244
Hereditary gelsolin amyloidosis: a case report and brief review of the literature 244
Hereditary neuropathy with liability to pressure palsies (HNPP): a diagnostic challenge 245
Hereditary spastic paraparesis associated with SPG11 gene: a case report 245
Hereditary spastic paraplegia 76 an extremely rare disease with challenging diagnosis 245
Hereditary spastic paraplegia, Kjellin syndrome: clinical findings that may go unnoticed 245
Hereditary transthyretin amyloidosis (ATTRv) mimicking motor neuron disease: importance of considering this differential diagnosis 246
Hereditary transthyretin amyloidosis: a diagnostic challenge 246
Herpes zoster-related hospitalizations and mortality in brazil over 5 years: an epidemiological study 246
Herpetic encephalitis as a differential diagnosis of ischemic stroke 247
Heterozygous GRIN2B mutation as a cause of intellectual developmental disorder: a case report 247
Hidden focal cortical dysplasia in the frontal lobe: value of repeated mri correlated with electroclinical hypothesis 247
High values of glycated hemoglobin are associated with the severity of acute cerebral ischemia 247
High-resolution ultrasound in the diagnosis of ischemic neuropathy post-arteriovenous fistula surgery: a case report and review 248
Hirayama disease: a rare case report 248
Histopathological substrate of increased T2 signal intensity of the anterior temporal lobe white matter in temporal lobe epilepsy due to hippocampal sclerosis 248
History of polyneuropathy and musculoskeletal manifestations in patients with transthyretin-mediated amyloidosis with cardiomyopathy in APOLLO-B 249
HIV-associated neuromuscular weakness syndrome: report of two cases presenting with neuromuscular weakness associated with hyperlactatemia 249
Home protocol proposal for increased activity in individuals after stroke based on specific and task-oriented motor training 249
Hopkins syndrome, a breath of mystery: a case report 249
Horner's syndrome as a complication of interscalene brachial plexus block: a case report 250
Hospital admissions and deaths due to Alzheimer's disease in Brazil: epidemiological analysis 2019-2023 250
Hospital admissions for migraine and other pain syndromes among children and teenagers in Brazil between 2018 and 2023: an analysis of DATASUS 250
Hospital admissions for viral encephalitis: a critical analysis 250
Hospital costs associated with malignant brain neoplasms in Brazil: an analysis of the last 5 years 251
hospitalization due to alzheimer's disease in brazil between 2019 and 2023 251
Hospitalization period in a stroke unit associated with worse functional outcome at 90 days: a cohort study in a reference hospital in Bahia 251
Hospitalizations for Alzheimer's disease in the southeast region of Brazil: an epidemiological study (2013-2023) 252
Hospitalizations for multiple sclerosis in the Brazilian Northeast: an analysis of DATASUS 252
Hospitalizations for neurotic, stress-related, and somatoform disorders in Brazil from 2019 to 2023: an epidemiological study 252
Hospitalizations for transient ischemic stroke in women under 60 in the period from 2020 to 2023: an analysis of risk factors and lifestyle habits of women in the pandemic and post-pandemic period 252
Hospitalizations for viral encephalitis in the northern region of Brazil in the pre-pandemic and pandemic period (2016-2019/2020-2023) 253
Hospitalizations in Brazil due to schizophrenia spectrum disorder in childhood 253
Hospitals costs, average length of stay and numbers of hospitalizations non-specific stroke from 2018 to 2023 in the regions of Brazil 253
Hsan type VII in a family from northeastern brazil 254
HSPB8-associated mutation resulting in myopathy with rigid spine with multiple muscle contractures and multiminicores in biopsy 254
Huntington's disease in a 24-year-old male patient: a case report 254
Huntington's disease: a two-cases report of atypical presentations 254
Huntington's disease mortality in Brazil: an epidemiological overview from 2013 to 2022 255
Hyperactivity symptoms are related to functional connectivity alterations in dopaminergic and noradrenergic networks in Alzheimer's disease 255
Hypereosinophilic syndrome associated with polyneuropathy: a case report 255
Hyper-religiousness as a clinical manifestation in Charles Bonnet's syndrome 256
Hypertrophic pachymeningitis secondary to granulomatosis with polyangiitis: case report 256
Hypocalcemia and functional outcomes in stroke patients post-thrombolysis 256

Hypoglossal nerve injury resulting from traumatic brain injury 256

Hypoglossal paralysis secondary to paraganglioma in the right carotid bulb: a case report 257

Hypoglossal paresis in a relapse of multifocal acquired demyelinating sensory and motor neuropathy: a case report 257

Hypokalemic periodic paralysis secondary to primary hyperaldosteronism: a case report 257

Hypothalamic atrophy and textural changes in polyglutamine ataxias.. 257

Hypothalamic dysfunctions in patients victims of traumatic brain injury: a systematic review 258

Idiopathic hypertrophic cranial pachymeningitis: a journey from clinical presentation to histological diagnosis 258

Idiopathic hypertrophic pachymeningitis: still a diagnostic challenge .. 258

Idiopathic intracranial hypertension preceding multiple sclerosis: a case report 259

Idiopathic intracranial hypertension presenting with facial palsy: a case report 259

Illiteracy and low education levels affect Parkinson's disease screening in an epidemiological study in the administrative region of candangolândia. 259

Imaging pattern in hypoglycemic encephalopathy: an important differential diagnosis to remember 259

Imbalance in a 44-year-old woman with atrophy cerebelar in MRI: a case report of spinocerebellar ataxia type 42 (SCA42) 260

Immunosuppression in neuromyelitis optica spectrum disorder: a trial sequential analysis and updated meta-analysis 260

Impact of ambient temperature in Teresina/Piauí on multiple sclerosis: an analysis of quality of life, severity of fatigue, sexual performance, and self-medication 260

Impact of benzodiazepine use on quality of life, mental health and cognitive function in the elderly population 261

Impact of delirium and its timing of onset on stroke outcomes 261

Impact of glucagon-like-peptide-1 receptor agonists on non-motor symptoms in Parkinson's disease: a systematic review and meta-analysis 261

Impact of neurodegenerative diseases in Brazil: an analysis of mortality from Alzheimer's and Parkinson's from 2012 to 2022 261

Impact of obstructive sleep apnea in post thrombolysis context of stroke patients: a transversal study 262

Impact of obstructive sleep apnea on immediate outcomes in stroke patients 262

Impact of oxyhemoglobin desaturation on cerebral compliance in patients with obstructive sleep apnea syndrome: a pilot study 262

Impact of physical activity on the evolution of symptoms in patients with Parkinson's disease 263

Impact of renal dysfunction on post-stroke rehabilitation in patients at high risk for obstructive sleep apnea 263

Impact of sars-cov-2 infection on the development of multiple sclerosis 263

Impact of sleep deprivation on neurological and cognitive functions 263

Impact of the duration of obstructive sleep apnea on cerebral compliance in humans: a pilot study 264

Impacts of dysarthria on quality of life in Parkinson's disease 264

Impacts of hepatic encephalopathy on transplant patients: a systematic review 264

Impacts of maternal immune activation on neuroinflammation in adult offspring after sepsis: an experimental study 264

Impacts of non-prescribed use of methylphenidate by university students: a systematic review 265

Impacts of the COVID-19 pandemic on the epidemiological profile of stroke in Brazil between 2016 and 2023 265

Implications of detecting clinical manifestations of dysphagia in Parkinson's disease 265

Importance of the neurological examination: delayed diagnosis of tropical spastic paraparesis with atypical evolution in a young adult 265

Improvement clinic to an unusual drug treatment in short-lasting unilateral neuralgiform headache attacks with cranial autonomic symptoms (SUNA): a case report 266

Improvement of neuropathic pain related to spinal cord injury using combined transcranial direct current stimulation and neuromuscular electrical stimulation: a case report 266

Impulse control disorder in patients with Parkinson's disease: a life quality analysis 266

In addition to Parkinson's disease, a different presentation of the LRRK2 mutation 267

In silico study for optimizing magneto hyperthermia for cancer treatment using the glioblastoma-on-a-chip model, comparing heat dissipation in tumoral versus healthy vascular networks 267

Inborn errors of immunity: neurological phenotypes, clinical features and genetics of a cohort of 27 patients 267

Incidence and mortality of congenital malformations of the nervoussysteminbrazil in children under 1 year of age 267

Incidence and predictors of late seizure after cerebral venous thrombosis: an ambispective cohort 268

Incidence and risk factors of viral neuroinfections in children in the Northern region of Brazil 268

Incidence of atrial fibrillation in patients with ischemic stroke due to large vessel occlusion undergoing chemical thrombolysis in a stroke reference unit in 2022 268

Incidence of hemorrhagic transformation in patients with ischemic stroke due to large vessel occlusion, undergoing chemical thrombolysis in a stroke unit in 2022 269

Incidence of meningitis in bahia from 2013 to 2023: an age group analysis ... 269

Incidence of stroke in pediatric population in Joinville (Santa Catarina, Brazil) 269

Incidental finding of acute disseminated encephalomyelitis in an elderly person: case report 269

Inclusion body myopathy with dysphagia and its expressive improvement with the use of immunoglobulin 270

Inclusion body myositis with exceptional response to immunosuppressive treatment 270

Inclusive neuroanatomy education for visually impaired students: development of 3D printed models of the spinal cord 270

Infantile cerebral venous thrombosis associated with basal ganglia hemorrhage due to protein's deficiency: case report 271

Infection sites most associated with the occurrence of delirium during hospitalization in a stroke unit: a cohort study in a reference hospital in Bahia....271

Inflammatory polyneuropathy in the state of São Paulo: a comparative analysis of of the pre-pandemic and post-pandemic period 271

Influence of gender on IBM: analysis of epidemiological and clinical characteristics 271

Influence of ischemic stroke on intestinal permeability and systemic immune response: a preclinical study 272

In-hospital mortality rate due to meningitis in Brazil, from 2008 to 2022: a joinpoint analysis 272

Initial neurological manifestations of cryptococcosis in non-HIV adults 272

Integrating objective and subjective data in a new outcome scale for epilepsy surgery in people with severe epilepsies (PWSE): the Porto Alegre seizure impact scale (PASIS) 272

Intellectual disability and neuropsychomotor delay in a patient with a rare variant 49,XXXXY of Klinefelter syndrome 273

Intensive blood pressure lowering for intracerebral hemorrhage: a systematic review and updated meta-analysis of randomized controlled trials 273

Interferon gamma, IL-18 and NFL as potential biomarkers for COVID-19 severity and lethality 273

Interleukin-6 inhibitors in neuromyelitis optica spectrum disorder: a systematic review and meta-analysis 274

Interoperable platform for surveillance of amyotrophic lateral sclerosis cases in Brazil 274

Interregional mapping of stroke in Ceará (IMISC): a proposal of a georeferencing methods of stroke analysis in Northeastern Brazil 274

Interventional neuroradiology: epidemiological profile and clinical outcomes in Southern Santa Catarina 274

Intestinal microbiome and multiple sclerosis: dysbiosis as a trigger or a reflex of the autoimmune response? 275

Intracranial hemorrhage in Brazil 275

Intracranial hypotension secondary to dural fistula and complicated in cerebral venous thrombosis (CVT) 275

Intraoperative electrocorticography (ECOG) tailored resection in nonlesional epilepsy and focal cortical dysplasia 276

Intrathecal pemetrexed for leptomeningeal carcinomatosis in EGFR-mutated NSCLC with severe renal impairment 276

Intravenous delivery of human dental pulp stem cells provides neuroprotection and attenuates disease progression in a murine model of amyotrophic lateral sclerosis 276

Intravenous thrombolysis in a patient with embolism in the left middle cerebral artery following recent postoperative osteosynthesis of the distal radius and thoracic spine arthrodesis after severe spinal cord trauma 277

Invasive fungal rhinosinusitis: a case report 277

Investigating proteomic and metabolomic signatures in mesial temporal lobe epilepsy: insights into neurotransmitter dynamics and pharmacoresistance 277

Irreversible bilateral ischemic optic neuropathy in the post-operative myocardial revascularization setting: case report 277

Irreversible paraplegia following benzathine penicillin injection: a case report 278

Is artificial intelligence ready to teach epilepsy through images? 278

Is Lhermitte's sign in the first acute episode associated with earlier diagnosis of multiple sclerosis? 278

Is there a relationship between atopic dermatitis and stroke? A systematic review and meta-analysis is there a relationship between atopic dermatitis and stroke? 279

Ischemic myelopathy, a rare vascular syndrome: case report and literature review 279

Ischemic or hemorrhagic unspecified stroke: an analysis of death profile and mortality rate in the Northern region of Brazil, 2019 - 2023 279

Ischemic stroke as a diagnostic key for takayasu's arteritis: case report 279

Ischemic stroke due to free-floating internal carotid thrombus in a patient with COVID-19: case report 280

Ischemic stroke in young adult and left ventricular non-compaction cardiomyopathy: a case report 280

Ischemic stroke secondary to dissection of the right common carotid artery resulting from clamping during pre-hospital care for a stab wound in cervical zone II 280

Ischemic stroke with bilateral internal carotid artery dissection in a 30-year-old woman: a case report 280

Isolated conus medullaris infarction: a case report 281

Isolated oculomotor nerve palsy, stroke and syphilis: a reported case .. 281

Isolated oculomotor nerve paralysis after mild traumatic brain injury .. 281

Isolated ophthalmoplegia in a patient with Miller-Fisher syndrome 282

Isolated optic neuritis: an atypical manifestation of bartonellosis 282

Isquemic stroke concomitant with pulmonary thromboembolism: when to anticoagulate ? 282

James Parkinson's legacy on child abuse two centuries after his passing. 283

Journey of value of raras (JAV RARAS): cost analysis of the treatment of amyotrophic lateral sclerosis (ALS) using the time-driven activity-based costing (TDABC) methodology in a specialized service in Salvador-Bahia 283

Juvenile Huntington's disease: the influence of CAG repeat number on clinical manifestations - 2 case reports 283

Juvenile myasthenia gravis positive acetylcholine anti-receptor in a male child: a case report 283

Kennedy disease: a case report 284

Kennedy's disease (X-linked spinal and bulbar muscular atrophy): follow-up of 18 patients in a neuromuscular outpatient clinic 284

Ketogenic diet applied to myoclonic status epilepticus in progressive myoclonic epilepsy 284

Kleine-Levin syndrome after COVID-19: a clinical report of the use of clarithromycin during the crisis of hypersomnia 284

Knowledge of patients about the risk factors of ischemic stroke 285

Laminopathy diagnosis: the importance of clinical correlation when considering a VUS mutation 285

Langerhans cell histiocytosis involving the corpus callosum and spinal cord in an elderly patient 285

Langerhans cell histiocytosis presenting with pachymeningitis and epilepsy: a case report 285

Late onset ataxia: Gerstmann-Straussler-Scheinker disease a diagnosis to consider 286

Late onset multiple acyl-coenzyme a dehydrogenase deficiency mimicking inflammatory myopathy: a case report 286

Late onset Pompe's disease as a differential diagnosis in muscular dystrophy in young adults: a case report 286

Late onset Tay-Sachs disease in bBahia's countryside: a case report 287

Late-life education's impact on adult executive functions 287

Late-onset biotinidase deficiency mimicking adult leigh syndrome: case report 287

Late-onset GM2 gangliosidosis due to mutations in GM2A gene mimicking spinal muscular atrophy type 3 288

Late-onset Pompe's disease in children: case report and genetic particularities 288

Lateralized periodic discharges (LPDS) with identical periods 288

Left arm palsy and cerebellar ataxia revealing mycobacterium avium infection in a patient with HIV and systemic lupus erythematosus: a case report 288

Left oculomotor nerve paralysis after dengue infection: a rare neuroinfectious journey 289

Left temporal arteritis associated with ipsilateral amaurosis 289

Leptomeningeal disease in genitourinary tract cancer manifesting as intracranial hypertension: case reports 289

Levamisole-induced leukoencephalopathy 290

Light chain neurofilament in biofluids and its application as a potential biomarker in amyloidosis: preliminary findings 290

Limb girdle muscular dystrophy: autosomal recessive calpainopathy, case report ... 290

Limb levitation and alien limb as a rare initial manifestation of high grade glioma (glioblastoma multiforme) ... 291

Limb-girdle muscular dystrophy TRAPPC11 related (LGMDR18) and central nervous system involvement ... 291

Linfoproliferative malignancy recidive as a stroke mimics ... 291

Livedo reticularis as a dysautonomic manifestation in bulbar ischemia 291

Lively contributions: 150 years after Johannes (Jan) Evangelist Purkinje passing ... 292

Logopenic variant of primary progressive aphasia: case report ... 292

Longitudinal analysis of 173 long-COVID subjects reveals worsening of work capacity and neuropsychiatric symptoms 20 months after diagnosis ... 292

Longitudinal analysis reveals the persistence of reduced work capacity and neuropsychiatric symptoms 25 months after infection in post-survivors ... 293

Longitudinal clinical and spinal cord imaging in adult patients with SMA type 3 ... 293

Longitudinal evaluation of fatigue in adult patients with spinal muscular atrophy and the impact of treatment with disease-modifying drugs ... 293

Longitudinal T2-weighted MRI relaxometry in patients with temporal lobe epilepsy ... 293

Longitudinally extensive myelitis secondary to neuroschistosomiasis: case report ... 294

Longitudinally extensive transverse myelitis after hand-foot-and-mouth disease in an adult, immunocompetent patient: a case report ... 294

Longitudinally extensive transverse myelitis as a manifestation of systemic lupus erythematosus ... 294

Long-term cardiac magnetic resonance imaging study in Friedreich's ataxia ... 295

Long-term effect of subthalamic nucleus deep brain stimulation on freezing of gait in Parkinson's disease: a single-arm meta-analysis of prospective studies ... 295

Overdrainage syndrome after idiopatic intracranial hypertension: a case report 352

Overlap of Guillain-Barré syndrome variants: a case report 352

Overlap of neuroectodermal syndromes: Sturge-Weber syndrome, Klippel-Trenaunay syndrome, and pigmentary vascular phakomatosis in a pediatric patient - a case report 352

Overlap of neuromyelitis optica spectrum disorder and systemic lupus erythematosus: a case report 352

Overlap syndrome: systemic lupus erythematosus and dermatopolymyositis 353

Overview of admissions and deaths due to meningococcal infection in patients aged 0 to 14 in the Southeast between 2018 to 2023 353

Overview of bacterial meningitis in brazil: analysis of variables in the last five years 353

Overview of childhood stroke by regions of Brazil in the pre- and post-COVID-19 pandemic periods 354

Overview of Parkinson's hospitalizations in Brazil from 2019 to 2023 354

Overview of the number of pediatric hospitalizations due to bacterial meningitis and vaccination coverage in Brazil from 2013 to 2022 354

Overview of traumatic brain injury in young adults 355

Oxidative stress and mitochondrial dysfunction contributes to postoperative cognitive dysfunction in elderly rats dependent on NLRP3 activation 355

P2Y12 inhibitors plus aspirin versus aspirin in patients with stroke or transient ischemic attack: an updated meta-analysis of randomized controlled trials 355

P3 event-related potentials before and after lumbar puncture as auxiliary tool in the diagnosis of idiopathic normal pressure hydrocephalus: preliminary results 355

Pain and fatigue in amyotrophic lateral sclerosis: a multi-method study 356

Pain-related evoked potentials uncovers small fiber damage in hereditary transthyretin amyloidosis with polyneuropathy 356

PAR-2 monoclonal antibody as a treatment for migraine: a systematic review 356

Paradoxical worsening of gait due to l-dopa induced dystonia: a case report 356

Paraneoplastic cerebellar degeneration syndrome associated with breast cancer: a case report 357

Paraneoplastic polyradiculopathy secondary to papillary renal cell carcinoma with detection of anti-MGT30: a case report 357

Paraneoplastic subacute cerebellar degeneration associated with invasive ductal breast carcinoma: a case report 357

Paraproteomic polyneuropathy linked to antimyelin antibody: a case report 358

Parechovirus encephalitis in a Brazilian adult: an extremely rare case report in the world 358

PARK ON - proposal for a computational decision support system for assessing the eligibility of patients with Parkinson's disease for functional neurosurgery, including dbs system implantation and ablative procedures 358

Parkinson's disease in Brazil and its hospital morbidity in 1 decade 358

Parkinson's disease: a baseline tremor (electrocardiographic change in Parkinson's disease) 359

Parkinsonism in bipolar mood disorder: a new look at an old problem 359

Paroxysmal kinesigenic dyskinesia associated with a pathogenic variant in the PRRT2 gene: a case report 359

Paroxysmal kinesigenic dystonia: a misdiagnosed condition 359

Paroxysmal kinesiogenic dyskinesia: a case report 360

Paroxysmal tonic upward gaze mimicking occipital epilepsy 360

Pathogenic mtDNA variants at low-level heteroplasmy may induce mitochondrial dysfunction and cause exercise intolerance 360

Pathological jealousy as an initial symptom of Alzheimer's disease: anatomy clinical study of a case 361

Pathophysiology of olfactory disorders related to COVID-19 infection .. 361

Patient with hereditary diffuse leukoencephalopathy axonal with spheroids requiring gastrostomy 361

Patterns of response to antiseizure medication over decades in a cohort of patients with mesial temporal lobe epilepsy with hipocampal sclerosis 361

Pediatric Guillain-Barré syndrome in a 27-year cohort 362

Pediatric ischemic stroke in a sickle cell patient with patent foramen ovale and Moya-Moya syndrome: the challenges of selecting a secondary prevention strategy 362

Perception of quality of life and social support of patients with amiotrophic lateral sclerosis followed up at a tertiary outpatient in Fortaleza 362

Performance of a Brazilian population with mild cognitive impairment and Alzheimer's disease in the three words: three shapes (3W3S) test 362

Performance of a cost-effective olfactory test to evaluate hyposmia in Parkinson's disease patients 363

Performance of a healthcare line stroke and its impact on stroke mortality in the Brazil's central arid Northeast countryside 363

Peripheral facial paralysis post-viral dengue infection: a case report ... 363

Persistent hypoglossal artery stroke presenting as alternating hemiparesis with fourth nerve palsy, internuclear ophthalmoplegia, and dissociated torsional-vertical nystagmus 363

Persistent MRI contrast enhancement in calcified neurocysticercosis and its association with refractory epilepsy: a case report 364

Pharmaceutical and non-pharmaceutical treatments for migraine: a systematic review of efficacy and safety 364

Phelan-McDermid syndrome, autism spectrum disorder and intellectual disability in a pediatric patient: a case report 364

Phenotypes associated with autosomal recessive polg in adults: description of a series of cases 365

Phenotypic and genotypic profile of Brazilian patients with hereditary spastic paraplegia type 76 365

Physical disabilities in leprosy patients in Brazil: twenty years of analysis 365

Physiotherapeutic treatment with motor imagery and tdcs on essential tremor: a case presentation 365

Pisa syndrome induced by brexpiprazole: a case report 366

Pituitary tumor simulating cluster headache 366

Plasma Aβ42/p-Tau ratio predicts csf amyloid status in subjective cognitive decline and mild cognitive impairment 366

Plasma miRNAs correlate with structural brain and cardiac damage in Friedreich's ataxia 366

PLP-1 spectrum disease: two female cases of a X-linked inheritance ... 367

Poliomyelitis sequelae in Brazil: an analysis of hospitalizations and deaths according to age groups in the eradication era 367

Polyneuropathy and folate deficiency: a case report 367

Polyneuropathy as an initial manifestation of adrenal neoplasia: case report 367

Polyneuropathy secondary to Rocky Mountain spotted fever: a case report 368

Polyradiculoneuritis due to HSV-2 mimicking miller Fisher syndrome: a case report 368

Polyradiculoneuropathy and multisystem complications in a Chikungunya-infected patient: a case report 368

Polysomnographic findings in patients with Parkinson's disease 369

Polysomnography and simplified sleep apnea test devices: mixing water and oil in the cup of the new cfm resolution 369

Pompe disease diagnosed in a neurology clinic in the interior of the Amazon: first adult case in the state of Pará 369

Porphyria variegata: a case report 370

Positive outcome of natalizumab therapy in multiple sclerosis with leptomeningeal lesion: a case report 370

Possible co-occurrence of CNS demyelination and subdural haematoma caused by TNF-alpha inhibitors 370

Post radiculomedullary trauma intracranial hypertension 370

Post-endoscopy bilateral cortical infarction presenting as a stroke chameleon: a case report 370

Posterior reversible encephalopathy syndrome (PRES) in an infant: case report 371

Post-irradiation internal carotid artery vasculopathy: a case report 371

Post-pump chorea: a rare and persistent neurological complication of cardiopulmonary bypass 371

Post-stroke delirium in younger is associated with worse long term functional outcome 372

Post-traumatic epilepsy: biological and social description 372

Post-vaccinal dengue encephalitis and dengue shock syndrome: case report 372

Potentials and limitations of genetic testing in autism spectrum disorder 372

Precision medicine in the FGF12 gene related to refractory epilepsy responsive to phenytoin: a case report 373

Predictors of azathioprine therapeutic success in patients with neuromyelitis optica spectrum disorder 373

Predictors of death during internmnent in patients with hemorrhagic stroke and high risk of obstructive sleep apnea: a transversal study 373

Predictors of fast visual recovery in idiopathic intracranial hypertension: a cohort study 373

Predictors of hemorragic transformation in patients with stroke and high risk of obstructive sleep apnea: a transversal study 374

Predictors of quality of life in patients with myasthenia gravis treated in the unified health system 374

Preliminary analysis of clinical and neurophysiological data of patients with Charcot-Marie-Tooth disease 374

Preliminary assessment of the use of the virtual brain in the study of patients with brain gliomas: a descriptive approach 374

Preliminary baseline characteristics from evoke and evoke+: two phase 3 randomized placebo-controlled trials of oral semaglutide in patients with early Alzheimer's disease 375

Preliminary data on the validation of the comprehensive coordination scale for individuals with Parkinson's disease 375

Preliminary study evaluating the structures of medial temporal lobe in epilepsy with hippocampal sclerosis using transcranial sonography 375

Pre-surgical hippocampus and amygdala volumes do not present relationship with seizure freedom after surgery in temporal lobe epilepsy patients 376

Prevalence of comorbidities in patients admitted to a stroke care unit in a reference hospital in the state of Pernambuco 376

Prevalence of gastrointestinal symptoms in patients with autism spectrum disorder: a systematic review 376

Prevalence of hypertension and its impact on NIHSS scores in ischemic stroke patients at a tertiary hospital 376

Prevalence of incidental findings in the brains of non-sedated nonclinical population of full-term neonates undergoing MRI scans 377

Prevalence of leprosy in the state of Maranhão from 2013 to 2023 377

Prevalence of meningitis by case evolution in Brazil between the years 2013 and 2023 377

Prevalence of zika virus in pregnant women as a risk factor for microcephaly in babies: an epidemiological analysis of the Northern region of Brazil 377

Primary amebic meningoencephalitis caused by free-living amoeba: report of 2 fatal cases in Natal/RN, Brazil 378

Primary central nervous system lymphoma presenting as demyelinating disease 378

Primary presentation of demyelinating polyneuropathy in POEMS syndrome: a case report 378

Probable bickerstaff encephalitis due to dengue fever: a case report ... 379

Problematic of neurocysticercosis in Angola: a systematic review 379

Professor, how is your mental health? 379

Profile and outcome post-rehabilitation of patients with vertigo in a clinic in Southern Santa Catarina 379

Profile of deaths and hospitalizations of elderly patients affected by stroke in Northeastern Brazil: analysis of a 12-year epidemiological overview 380

Profile of hospitalizations by traumatic brain injury in elderly in Brazil from 2014 to 2023 380

Profile of hospitalizations for viral encephalitis in children and teenagers under 14 years old in the Southern region of Brazil from 2013 to 2023 .. 380

Profile of hospitalizations of patients affected by multiple sclerosis in Northeastern Brazil: a 12-year epidemiological overview 381

Profile of hospitalizations, deaths and mortality rate in Brazil due to malignant brain neoplasms from 2008 to 2023 381

Profile of meningitis mortality in Brazil from 2010 to 2022: an ecological study 381

Profile of mortality due to viral meningitis in Brazil between 2014 and 2023 381

Profile of multiple sclerosis in Brazil over the last 12 years in an epidemiological and cost analysis: an underestimated disease ? 382

Profile of neurological complications in patients treated with CAR-T cell therapy at a Nove de Julho Hospital in são Paulo 382

Profile of patients affected by movement disorders in subspecialized outpatient clinics of a tertiary hospital in Southern Brazil 382

Profile of patients who underwent intravenous thrombolysis after ischemic stroke at a stroke care unit 382

Profile of patients with chronic demyelinating polyneuropathy (CIDP) according to the 2021 diagnostic criteria in a reference center: a series of cases 383

Profile of renal function in stroke patients with high risk of obstructive sleep apnea: a transversal study 383

Progressive encephalomyelitis with rigidity and myoclonus (PERM) associated with anti-GAD antibodies 383

Progressive multifocal leukoencephalopathy as a differential diagnosis for rhombencephalitis in an HIV-positive patient: a case report 384

Progressive proximal weakness in an adult female: a case of spinal muscular atrophy type III with p.Ala2Gly variant 384

Progressive supranuclear palsy with predominant cerebellar ataxia: clinical and neuroimaging manifestations of two cases 384

Prospective randomized study to evaluate the efficacy of additional dopaminergic replacement in cociceptive pain in patients with Parkinson's disease 384

Pro-thrombotic antibodies in patients with post-infection or post-COVID-19 vaccine stroke 385

Protocols for analyzing effective connectivity in patients with refractory frontal and temporal lobe epilepsies 385

Pseudo-INO in Steinert myotonic dystrophy: a case series 385

Pseudotumoral lesion mimicking glioblastoma in a patient with multiple sclerosis 386

Pseudotumoral manifestation of primary central nervous system vasculitis: a case report 386

Psychiatric comorbidity in Moyamoya disease: a case presentation 386

Psychiatric symptoms and cognitive impairment in patients with idiopathic cervical dystonia 386

Psychiatric-onset multiple sclerosis: case report 387

Psychosocial impact of narcolepsy on the health-related quality of life of late-diagnosed patients: a systematic literature review of the last 10 years 387

Puerperium as a risk factor for immunocompetent patients with neurotuberculosis? 387

Pulmonary arteriovenous microfistulas as an uncommon cause of stroke in a young adult 388

Pure ataxia related to CACNA1A: report of a non-episodic and non-migrainous case 388

Pure transverse myelitis secondary to multiple sclerosis: an unusual case 388

Pyridostigmine in the management of dropped head syndrome following botulinum toxin injection: case report 388

Quality of life of patients with amyotrophic lateral sclerosis (ALS) and satisfaction with the care and treatment received in a specialized service for rare diseases 389

Quality of life of patients with ATTRV amyloidosis and satisfaction with the care and treatment received in a specialized rare disease service .. 389

Quantifying ataxia in RFC1-related disorder using wearable sensor technology 389

Quantifying myelin loss with [11C]PIB PET and MTR: predicting cognitive and functional decline in MS 390

Quantitative study of hospital admissions for Alzheimer's disease in Brazil from 2019 to 2023 390

Racemose neurocysticercosis and cerebral venous thrombosis: case report 390

Radiation therapy-induced plexopathy: a case report 390

Radiation-induced mesial temporal and frontobasal lesions mimicking viral encephalitis 391

RAINBOWFISH: primary efficacy and safety data in risdiplam-treated infants with presymptomatic spinal muscular atrophy (SMA) 391

Rapidly progressive and reversible dementia: an abnormal finding in MRI not to be missed for dural arteriovenous fistula diagnosis 391

Rapidly progressive dementia with focal deficits and seizures in a 35-year-old male: from behavioral changes to CNS vasculitis diagnosis amidst HIV infection 392

Rapsyn-associated congenital myasthenic syndrome: distinctive phenotype mimicking limb-girdle dystrophy 392

Rare association between CADASIL and multiple system atrophy: a report of three Brazilian cases and literature review 392

Rare early onset CSF-1R-related leukodystrophy 393

Rare presentation of giant cell arteritis following COVID-19 infection ... 393

Rare simultaneous bilateral thalamic hemorrhage with the presence of the Austregésilo-Esposel sign: a case report and literature review 393

Realistic simulation training in stroke care: a systematic review 393

Real-world experience with Fabry disease: case series in a neuromuscular center 394

Reasons for ketogenic diet therapy discontinuation in pharmacoresistant adult epilepsy patients 394

Reccurent epilepsy seizures in carriers of a heterozygous variant of the PIGN gene 394

Recurrence of epilepsia partialis continua on the opposite side after hemispherectomy: an uncommon yet severe outcome of focal cortical dysplasia 395

Recurrent anti-LGI1 limbic encephalitis: a case report..... 395

Recurrent encephalopathy with extensive brain lesions associated with mog antibody: a case report..... 395

Recurrent hemorrhagic stroke with associated use of lurasidone: a case report..... 395

Recurrent Takotsubo cardiomyopathy associated with recurrent status epilepticus: a clinical case report 396

Red flags in dermatomyositis diagnosis: a pilot study 396

Refractory chronic inflamatory demyelinating polyneurophaty (CIDP) syndrome in a pregnancy patient: a case report 396

Refractory intracranial hypertension associated with the use of all-trans-retinoic acid: a case report 397

Refractory post-herpetic anti-NMDA receptor autoimmune encephalitis: case report 397

Regional epidemiological analysis and costs associated with admissions for headache in the unified Brazilian health system: notifications from 2019 to 2023 397

Relapse comparison between parenchymal and non-parenchymal forms of Neuro-Behçet 398

Relapse frequency and predictors in immune-mediated hypertrophic pachymeningitis 398

Relapse of neuromyelitis optica with atypical presentation of painful tonic spasms and area postrema syndrome: a case report 398

Relapse rate and associated factors in multiple sclerosis: a Brazilian cross-sectional study 398

Relation between childcare centers and neuropsychomotor development: an experience report from the “conviver” project 399

Relationship between anxiety and stroke: experience report from the world stroke campaing 399

Relationship between motor and respiratory function in Duchenne muscular dystrophy patients..... 399

Relationship between the presence and subtypes of auras and extrahippocampal cortical and subcortical atrophy in patients with temporal lobe epilepsy associated with hippocampal sclerosis 399

Reliability of perfusion measured by non-contrast magnetic resonance imaging (arterial spin labeling) in patients with ischemic stroke: a systematic review and meta-analysis 400

REM sleep: definition and relevance..... 400

Remarkable response to capecitabine, trastuzumab, pertuzumabe and radiotherapy in a woman with brain metastasis from breast cancer 400

Renal biomarkers in the evaluation of patients with hereditary amyloidosis related to ttr gene mutation..... 401

Renal predictors of mortality in stroke patients with risk of obstructive sleep apnea: a transversal study 401

Repercussions of the use of oral contraceptives in women with migraine 401

Report of a series of patients with mosaic trisomy 18: Edwards syndrome 402

Report of two new cases of the extremely rare Cluster-Tic syndrome.... 402

Resistance training can influence episodic memory performance in elderly people with mild cognitive impairment..... 402

Restless legs syndrome/Willis-Ekbom disease in Parkinson’s disease: a cross-sectional analysis..... 403

Rethinking hot cross bun sign: an uncommon finding on spinocerebellar ataxia type 2 403

Retinal neurodegeneration and brain atrophy in patients with Chagas disease: a cross-sectional study 403

Retrospective analysis of data from thrombectomies performed from january to march 2024 in a public hospital in João Pessoa/PB..... 403

Rett’s syndrome: a case report 404

Reversible cerebral vasoconstriction syndrome associated with probable drug poisoning: case report 404

Reversible posterior encephalopathy syndrome (PRES) after endovenous iron infusion: unusual case in the literature..... 404

Reversible posterior leukoencephalopathy syndrome after intravenous iron infusion..... 405

Rhino-cerebral mucormycosis presenting with ophthalmoplegia and intracerebral hemorrhage..... 405

Rhino-orbital mucormycosis presenting as orbital apex syndrome: a case report..... 405

Rhomboencephalitis as a differential diagnosis of stroke: a case report 405

Right peripheral facial paralysis in a 1-day-old neonate: a case report . 406

Risdiplam treatment for spinal muscular atrophy: real life data from a Brazilian cohort 406

Risk factors and prognosis of myelomeningocele associated with holoprosencephaly: a case report..... 406

Risk stratification for stroke among professionals in a hospital network 406

Rockstar hands: a complex pattern of hand dystonia in Wilson’s disease 407

Role of Cannabidiol as an adjuvant in the treatment of refractory cryptogenic epilepsy: a case report 407

Role of skin biopsy in the etiological diagnosis of multiple mononeuritis 407

Safety and efficacy of alternative vascular accesses in mechanical thrombectomy for large occlusion vessel strokes: a systematic review and meta-analysis..... 407

Safety and efficacy of batoclimab for generalized myasthenia gravis: a systematic review and meta-analysis 408

Safety and efficacy of dabrafenib and trametinib in pediatric patients with glioma: a systematic review and meta-analysis 408

Safety and efficacy of duloxetine for low back pain: a meta-analysis of randomized controlled trials 408

Safety and efficacy of stellate ganglion block in patients with subarachnoid hemorrhage: a single-arm meta-analysis 409

Safety and efficacy of tixagevimab/cilgavimab for COVID-19 prophylaxis in immunosuppresed patients with multiple sclerosis or related disorders: a meta-analysis..... 409

Safety and efficacy of topiramate in migraine prophylaxis in younger patients: a meta-analysis 409

Safety of magnetic resonance-guided focused ultrasound in Parkinson’s disease: a meta-analysis of randomized controlled trials 409

SAH: analysis of a sample from a prospective study in a Brazilian hospital 410

Saliva whole exome sequencing utility for the molecular diagnosis of CPEO..... 410

Same-day discharge or postoperative day 1 in patients who underwent brain tumor resection: a systematic review and meta-analysis..... 410

Scar dancing syndrome: a rare presentation of a unique condition 410

Schistosomal myelopathy mimicking longitudinally extensive myelitis in neuroimaging..... 411

Screening for SCA27B in a cohort of Brazilian patients with unsolved ataxias 411

Seasonality of fatigue in Parkinson's disease in a high temperature location 411

Secondary epileptogenesis in acquired hemispheric lesions: a case of too-little-too-late? 412

Secondary nummular headache: a case report 412

Seizure outcome in patients with malformations of cortical development other than focal cortical dysplasia in a tertiary center 412

Seizure outcomes in patients with burned-out hippocampus syndrome operated after noninvasive investigation 412

Seizures and myoclonus in systemic lupus erythematosus: an uncommon neurological presentation in a young woman 413

Sensory aphasia as sole manifestation of focal status epilepticus 413

Sensory motor axonal polyneuropathy in association with granumatosis with polyangiitis and secondary Sjogren's syndrome: a case report 413

Sensory-motor polyneuropathy due to the use of antiparasitic drugs: a case report 413

Sepsis compromises post-ischemic stroke neurological recovery and is associated with sex differences 414

Sepsis secondary to ischemic stroke results in sex-dependent potentiation of hypothalamic inflammation in rats 414

Sequential optic neuritis secondary to aspergillosis mimicking Foster Kennedy syndrome: a case report 414

"De novo" absence status epilepticus: case report with 8-year follow-up

Luma Hussein Salem[1], Felipe Guimarães Kanda[1], Raquel Guimarães Kanda[2], Rafael Guimarães Kanda[3], Paulo Afonso Medeiros Kanda[4]

Correspondence: Luma Hussein Salem; Email: lumasalem2345@gmail.com.

Case presentation: A 53-year-old woman went to the emergency room (ER) confused for four days. Lab tests and a CT scan were normal, so, she was referred to a routine psychiatric evaluation. However, her family went to a neurologist, who found a disoriented patient unable to count to 10, perform calculations, remember date or own address. She didn't show focal signs. History of rare seizures in adolescence. The electroencephalogram (EEG) showed continuous, generalized, 3-5 Hz spike-and-wave discharges (SWD). The diagnosis was late-onset absence status epilepticus. Two hours after 5 drops of clonazepam 2.5 mg/ml, she woke up with normal cognition but no recollection of the past week. EEG recorded the next day showed posterior dominant rhythm (PDR) at 7.5 Hz, with brief bursts of fragmented 3 Hz SWD. Upon questioning, she reported having "startles" since adolescence, suggesting idiopathic generalized epilepsy (IGE). Subsequent EEGs on 10/05/2017, 11/21/2018, 02/12/2020, 12/21/2022, and 12/21/2023 had normal background activity with PDR at 10 Hz. All of them showing brief bursts of fragmented, generalized 3-5 Hz SWD. She occasionally has myoclonic seizures but has not had any new absence seizures or convulsions. **Discussion:** Late-onset absence status epilepticus (LO-ASE) is rare and can occur in adults and the elderly as a late relapse of IGE or in de novo patients without a seizure history. De novo LO-ASE is frequently described in women, often triggered by benzodiazepine withdrawal, alcohol or psychotropic drug intoxication, none of which in this history. LO-ASE is characterized by a prolonged and fluctuating confusional state, with or without minor abnormal motor components. The EEG shows various ictal patterns, from typical or atypical generalized spike-and-wave discharges to complex asymmetric irregular sharp and slow waves with anterior predominance. The evolution of our case revealed the persistence of mild and rare morning myoclonic seizures. This LO-ASE likely emerged on a substrate of juvenile myoclonic epilepsy. The eight-year follow-up evidenced the chronic nature of this IGE with a good response to anti-seizure medication. This report provides a detailed view of the clinical and EEG evolution of a rare case of LO-ASE in a middle-aged woman over 8 years period. It emphasizes the need to consider this condition in the differential diagnosis of confusional states in ERs, especially in patients with history of seizures to prevent complications and improve clinical outcomes in such cases. **Final comments:** This case of absence status epilepticus in a middle-aged patient, highlighs the importance of clinical suspicion of ASE and IGE in ER, and the use of EEG in such diagnosis.

"De novo" mutations in cadasil: a systematic review

Karoline de Alvarenga Leandro Lobo[1], Saulo Machado Moreira Sousa[2], Ralph Lettieri Manhães[1], Vanderson Carvalho Neri[1]

[1]Faculdade de Medicina de Campos, Campos dos Goytacazes RJ, Brazil.
[2]Universidade Estadual do Norte Fluminense Darcy Ribeiro, Campos dos Goytacazes RJ, Brazil.

Correspondence: Karoline de Alvarenga Leandro Lobo; Email: alvarengalobo@gmail.com.

Background: CADASIL is a genetic disease caused by mutations in the NOTCH3 gene. While it is traditionally considered hereditary, recent research indicates the presence of "de novo," mutations. **Objective:** To investigate the latest discoveries regarding "de novo" mutations in CADASIL. **Methods:** A comprehensive systematic review was conducted using: PubMed, Google Scholar, BVS, Jstage, KoreaMed, IMSEAR, MJM, Mycite, WPRIM, LILACS, SciELO, Cochrane Library, and MDPI. Only indexed journals published between 2000 and 2022 were analyzed, resulting in a selection of 41 articles. Duplicated papers (12), non-original articles (3), non-English publications (2), studies not focused on CADASIL and "de novo" mutations (15), and those lacking confirmed mutations (1) were excluded. **Results:** This systematic review presents a collection of case studies concerning non-hereditary NOTCH3 cysteine-altering variants. The described mutations included a heterozygous missense variant NOTCH3 c.1320C> G p.(Cys440Trp) in exon 8, and two heterozygous missense mutations in exon 4 (cys128 to gly and a C-to-T mutation at nucleotide 622). No significant differences in gender prevalence were observed. The mean age of symptom onset was 30.6 ± 9.8 years. Although CADASIL typically manifests between the ages of 10 and 50, the mean age of symptom onset for common hereditary NOTCH3 mutations was 36.7±12.9 years, suggesting a possible anticipation of symptoms in these variant cases. The youngest patient was 15 years old, while the oldest was 40 years old. Migraine was present in 89% of the patients at symptom onset, with 66% experiencing speech changes. However, only 33% reported ocular symptoms, and 22% reported fatigue/asthenia and/or facial asymmetry. In terms of psychomotor and cognitive domains, 33% exhibited psychomotor slowness, and 22% showed changes in concentration, attention, memory, mood, and executive functions, with or without mental confusion. Additionally, 33% presented hemiplegia/paresis. Imaging investigations revealed bilateral white matter lesions in all patients. Parietal lobe lesions were observed in 89% of cases, while 56% exhibited lesions in the temporal lobe and/or basal ganglia, and 33% had periventricular lesions. No significant changes were observed in other regions. No explicit correlations were found between CADASIL and pre-existing comorbidities unless a SARS-CoV-2 infection. **Conclusion:** Although CADASIL is recognized as an hereditary disease caused by mutations in the NOTCH3 gene, "de novo" mutations variants have increasingly been identified as responsible for CADASIL. This review provides insights into "de novo" mutations in CADASIL. These findings emphasize the importance of investigating non-inherited factors and triggering events in CADASIL, because they may contribute to reducing the risk factors associated with this condition.

Effect of the anti-inflammatory action of β-carbolines on SH-SY5Y cell line (human neuroblastoma) and modulation of TMPRSS11 and Furin receptors

Laura Seixas Bianco[1], Alessandra Linardi[1], Roberta Sessa Stilhano[1]

[1]Santa Casa de São Paulo, Faculdade de Ciências Médicas, São Paulo SP, Brazil.

Correspondence: Laura Seixas Bianco; Email: laura.bianco@aluno.fcmsantacasasp.edu.br.

Background: Harmine and harmaline are β-carbolines found in the Banisteriopsis caapi, a vine found in the Amazon rainforest and used with Psychotria viridis to prepare Ayahuasca. β-carbolines are potent MAO-A enzyme inhibitors. Literature has suggested their therapeutic potential due to their immunomodulatory, anti-inflammatory, antidepressant and anxiolytics action. Harmine and harmaline promote neurogenesis in neurospheres and can stimulate the proliferation, migration and differentiation of neural stem cells to adult neurons, indicating possible therapeutic benefits. The SH-SY5Y cell line (human neuroblastoma) is commonly used in neuronal, biochemical and functional properties and as a model for neuroinflammation. High levels of pro-inflammatory cytokines, such as TNF-α and IL-6, are found in COVID-19 patients. Despite the blood-brain barrier, SARS-CoV-2 can cross it and trigger an excessive immune response, releasing cytokines in the CNS, potentially worsening the neurological symptoms of COVID-19, referred to as neuro-COVID. **Objective:** To evaluate the potential anti-inflammatory effects of β-carbolines on the SH-SY5Y cell line and their modulation of TMPRSS11 and Furin receptors, which facilitate viral entry into neuronal cells. **Methods:** β-carbolines (Sigma-Aldrich) were prepared with DMSO and stored at -20°C. SH-SY5Y were cultured in DMEN/F12 supplemented with 10% fetal bovine serum and 1% penicillin and streptomycin. Neuroinflammation was induced by treating cells with LPS (130 ug/mL) for 48 hours. Harmine and harmaline (3-30 μM) were added 24 hours before LPS. **Results:** Harmine (30 μM) reduced basal IL-6 (25 pg/mL) and LPS-induced IL-6 (54.7 pg/mL) to zero. Harmaline (3 μM) significantly reduced basal IL-6 to 2.7 pg/mL and LPS-induced IL-6 to 26.7 pg/mL. Harmine also reduced basal TNF-α (43.1 pg/mL) and LPS-induced TNF-α (103 pg/mL) to practically zero, while harmaline (3 μM) significantly reduced basal TNF-α to zero and LPS-induced TNF-α to 56.6 pg/mL. However, there was no change in the expression of TMPRSS11 and Furin receptors, both in cells induced by LPS or basal and in cells treated by β-carbolines. **Conclusion:** β-carbolines reduced the production of both basal and LPS-induced inflammatory cytokines in the SH-SY5Y cell line, suggesting a potential neuroprotective role in neuroinflammation-induced disorders. Although there were no significant effects on the expression of SARS-CoV-2 receptors, the compounds still show promise in preventing neuro-COVID symptoms caused by neuroinflammation.

Eyes: a window to the cerebellum

Emanuelly Victória Andrade Fonseca[1], Luma Santos de Oliveira[1], Fabio Victor Vieira Rocha[1], Daniel Mariani Favalessa[1], Igor Flavio Gonçalves do Vale[1], Melissa dos Santos Matos[1], Renann Nunes Pirola[1]

[1]Universidade Federal do Espírito Santo, Vitória ES, Brazil.

Correspondence: Emanuelly Victória Andrade Fonseca; Email: mn.andradeduarte@hotmail.com.

Case presentation: A 28-year-old male patient presented with ataxia at the age 1 year and 2 months and never acquired unsupported gait. He currently only gait with bilateral support. He denied other comorbidities and a similar family history. He had suffered a fall from his own height, associated with head trauma, with no warning signs. On examination, he had ocular telangiectasias, atrophy of the interosseous muscles, more prominent on the left, abolished osteotendinous reflexes, grade IV global muscle strength, bilateral facial choreo-dystonia, more pronounced on the left, severe bilateral ataxia, and was in a wheelchair. Facial mimicry and extrinsic ocular muscles were preserved. Evoked nystagmus, slowed saccades and slurred speech were observed. Computed tomography of the skull revealed marked cerebellar atrophy, most evident in the cerebellar vermis, and ectasia of the IV ventricle. After genetic testing, the diagnosis of Ataxia-telangiectasia was confirmed. Laboratory tests showed leukocytosis of 16,230/mm3 and platelet count of 502,000/mm3. **Discussion:** Louis Barr Syndrome or

Ataxia-telangiectasia (A-T) is a rare autosomal recessive disorder, with an incidence of 1:100,000, which usually begins in the first 5 years of life. Its etiology is related to mutations in the ATM gene, whose encoded protein plays a crucial role in cell signaling in response to DNA damage, oxidative stress and genotoxic agents. Patients present with cerebellar degeneration, telangiectasia, immunodeficiency, sensitivity to radiation and a tendency to neoplasms, especially lymphoid ones. In the case in question, TA was suspected due to the presence of neurological signs, such as cerebellar ataxia since childhood, postural instability, fine motor incoordination, abnormal eye movements, involuntary movements, loss of osteotendinous reflexes, ocular telangiectasia and motor neuropathy. In addition, AT can also manifest with sensory neuropathy, cognitive disorders, cutaneous telangiectasia, repetitive sinopulmonary infections, immunoglobulin deficiency, lymphopenia or leukocytosis, and increased alpha-fetoprotein. Nuclear Magnetic Resonance often reveals cerebellar degeneration with atrophy of the vermis and its hemispheres. It is therefore essential to consider AT in any ataxic child when other diagnoses are unlikely. Diagnosis is based on clinical assessment, laboratory tests and genetic testing. Treatment is symptomatic, as there are still no therapies that prevent or slow down neurodegeneration. **Final comments:** The diagnosis of A-T involves clinical data, laboratory tests and genetic testing. Continuous surveillance and early interventions are essential due to immunodepression, marked by low levels of IgA, IgM and IgG production in response to vaccines and infections, generating increased susceptibility to diseases such as recurrent pneumonia, bronchiectasis, interstitial lung disease and cancer. Multidisciplinary care is essential to improve patients' life qualities.

[4]Universidade Anhembi Morumbi, São Paulo SP, Brazil.
[5]Centro Universitário Novafapi; Teresina PI, Brazil.

Correspondence: Letícia Dardes Barbosa; Email: leticiadardes@hotmail.com.

Background: The rate of untreated epileptic seizures in the Southeast region has increased in recent years, posing a threat to the population, as death can be a consequence. Given that epileptic seizures are sudden and temporary events caused by abnormal electrical activity in the brain, resulting in convulsions, changes in behavior, or unusual sensations, there is a need for prompt emergency team control to avoid gaps, which were not observed between 2013 and 2023. **Objective:** To conduct an epidemiological analysis of the treatment of uncontrolled epileptic seizures as urgent care for the inhabitants of the Southeast region. **Methods:** It consists of an ecological study involving data collection through the Hospital Information System (SIH/SUS). The study population consisted of individuals from the Southeast Region who received treatment for uncontrolled epileptic seizures urgently during the period from 2013 to 2023. The variables analyzed included the number of hospitalizations, average length of stay, and deaths. Data were collected using descriptive statistical analysis techniques. **Results:** During the period from 2013 to 2023, a total of 195,911 cases were reported in the Southeast region. The year 2022 recorded the highest number of hospitalized patients, with 20,902 cases (10.66%), followed by the year 2023 with 19,915 (10.16%), while the year 2020 had the lowest, with 16,475 cases (8.40%). Regarding the average length of stay, it was 5.5 days over the decade. In 2022, the longest stay was recorded, with an average of 5.9 days, while in 2014, the shortest was registered, with an average of 5.0 days. During this period, a total of 6,306 deaths were reported, accounting for 3.21% of the affected population, with the year 2023 recording the highest number of notifications, with 714 episodes (11.32%), and the year 2022 with 707 occurrences (11.21%), while in 2014, there was the lowest number, with 425 episodes (6.73%). **Conclusion:** The prevalence of untreated epileptic seizures is evident, underscoring the need to understand the etiology and classification for better management. It is crucial to control them to improve the patient's routine and habits, in order to address the increasing number of hospitalizations and deaths observed during the studied years (2013/2023). Finally, an initiative from the Ministry of Health (MS) to constantly monitor the patient, while noting the particularities observed in each case, is necessary to achieve a satisfactory holistic response to the patient's health.

"Split-hand like" syndrom in X-linked form of Charcot-Marie-Tooth disease (CMTX1) caused by GJB1 mutation: a comparative study of eletrophisiologic features

Ricardo Vergara Gianvechio[1], Wilson Marques Junior[1], Pedro José Tomaselli[1], Lucas Gondim Briand Vieira[1], Brenda Cristina Nava[2], Gabriela Rodrigues Ramos[2]

[1]Universidade de São Paulo, Faculdade de Medicina de Ribeirão Preto, Hospital das Clínicas, Ribeirão Preto SP, Brazil.
[2]Universidade de São Paulo, Faculdade de Medicina de Ribeirão Preto, Ribeirão Preto SP, Brazil.

Correspondence: Ricardo Vergara Gianvechio; Email: ricardo.gianvechio@alumni.usp.br.

Background: The X-linked form of Charcot-Marie-Tooth disease (CMTX1) is a common form of inherited neuropathy. It's caused by mutations in the GJB1 gene. Some reports in the literature suggest that a "split hand syndrome-like" condition can be found in patients with CMTX1, characterized by more prominent atrophy in the abductor pollicis brevis (APB) than in the abductor digiti minimi (ADM). Nonetheless, we found no studies numerically describing this possible predilection by means of neurophysiologic parameters. **Objective:** This retrospective study was conducted to objectively evaluate the possible predilection of involvement of the APB (in detriment of ADM) in CMTX1, comparing them to CMT1A patients and to control patients without evidence of peripheral neuropathy and with normal nerve conduction studies (NCS). **Methods:** We analyzed the data from electroneuromyography of 59 patients (21 patients with GJB1 mutations, 26 patients with PMP22 duplication - CMT1A group, and 12 patients without peripheral neuropathy and with normal values of NCS). The epidemiological and clinical baseline characteristics were also collected for comparison. The mean age of the patients undergoing electroneuromyography was 36.1 years in the CMT1X group and 35.5 years in the CMT1A group. The ratio APB/ADM (the ratio between the CMAPs in the APB and in the ADM, respectively) was calculated in each patient. In patients where it was possible to calculate the ratio from both hands, we conventionally used the smaller ratio. We then compared the results from the three groups using a two-tailed Student's t-test. **Results:** The mean APB/ADM in the CMT1X group was 0.646 with a standard deviation of 0.444, while in the CMT1A group, the mean APB/ADM was 1.286 with a standard deviation of 0.578. The mean APB/ADM ratio was significantly lower in patients in the CMTX1 group compared to patients in the CMT1A group (p-value=0.0001) and to patients in the control group (p-value=0.04). There was no statistical difference between the CMT1A group and the control group (p=0.06). **Conclusion:** Although this is a preliminary study, the results suggest a significant predilection for more pronounced atrophy in the APB compared to the abductor digiti minimi ADM in patients with CMTX1. This finding was quantitatively supported by the significantly lower APB/ADM ratios in the CMT1X group compared to both the CMT1A and control groups. The absence of a significant difference between the CMT1A and control groups suggests that this phenomenon is specific to CMTX1. This could be useful to generate hypotheses surrounding the pathophysiology of the disease. Further prospective and/or longitudinal studies should be conducted to evaluate the reproducibility of these results in larger samples and to determine the predictive values of the clinical and neurophysiological findings of "split hand-like syndrome," and the APB/ADM ratio in patients with suspected inherited neuropathies.

Ataxic sensory ganglionopathy secondary to Sjogren's: a case report

Ana Clara Rodrigues Santos[1], Lucas Porto Ferreira[1], Luiza Serafini Balestrassi[1],Joselene Sales Costa[1], Tamiris Araújo Silva[1], Augusto Cesar Marrafon[1], Franciane Couto Soares[1], João Batista Macedo Vianna[1]

[1]Hospital de Clínicas de Itajubá, Itajubá MG, Brazil.

Correspondence: Ana Clara Rodrigues Santos; Email: anaclaraa.14@hotmail.com.

Case presentation: Patient JRAS, at the age of 45, began suffering from paresthesia in the hands bilaterally, which progressed to the lower limbs, and in three weeks he developed difficulty in walking and tetraparesis. She sought care at the emergency room in her city of origin, with a clinical hypothesis of Guillain Barret Syndrome, where an outpatient electroneuromyography was requested. The examination, carried out in March 2019, showed purely sensory neurogenic impairment and an axonal pattern (lack of response in all nerves studied) in the upper and lower limbs, without changes in the motor nerves, nor signs of conduction block, thus suggesting, ganglionopathy or marked sensory axonal polyneuropathy. Subsequently, during the etiological investigation, the Schirmer test was moderate and severe, and the Rose Bengal Test showed impregnation on the eyelid margin. With the diagnosis of Sjogren's syndrome, therapy was instituted with 3 cycles of pulse therapy during a quarter and symptomatic therapy, such as Gabapentin, with a favorable response. **Discussion:** Sjogren's syndrome is a chronic autoimmune disease that results in inflammation of the exocrine glands, with keratoconjunctivitis sicca and xerostomia being the common manifestations. The extra glandular presentation is multisystemic and may present neurological manifestations, with involvement of the central and peripheral nervous system. Among neurological manifestations, peripheral neuropathy is the most common complication and can be found in 25% of patients. Symptoms may be associated with small fiber neuropathy, mononeuropathy multiplex, cranial neuropathy and, more recently, sensory ataxic neuronopathy associated with immunological attack on the dorsal root ganglion. Sensory ganglionopathies are a subgroup of peripheral neuropathies whose common feature is primary damage to the cells of the bodies of neurons located in the dorsal root ganglia. Among the complications associated with the peripheral nervous system, sensory ataxic ganglionopathy is a rare and severe form that affects less than 5% of patients with Sjogren's. **Final comments:** This case report aims to explore the

characteristics of ataxic sensory neuronopathy, which presents clinically with changes in proprioception, ataxic gait, pseudoathetosis, positive Romberg test and changes in thermal and pain sensitivity. Ganglionopathies are considered rare diseases, whose error and delayed diagnosis are commonly relevant problems, which impacts patient care and can cause irreversible damage with severe functional impact.

"My brain Robbie": translation to Portuguese to promote a healthy brain

Vivian Proença Lara[1], Glaucia Muniz Proença Lara[2], Eléonore Bayen[3]

[1]Faculdade de Ciências Médicas de Minas Gerais, Belo Horizonte MG, Brazil.
[2]Universidade Federal de Minas Gerais, Belo Horizonte MG, Brazil.
[3]Global Brain Health Institute/Sorbonne Université, Hôpital de La Pitié-Salpêtrière, Paris, France.

Correspondence: Vivian Proença Lara; Email: vi.prlara@gmail.com.

Background: Scientific research in Neurology and in Epidemiology has shown that early prevention and a healthy lifestyle can mitigate the risk that chronic diseases, including dementia, will develop. A character called "Robbie" was created and a video based on scientific knowledge about brain health prevention was produced as a fun and engaging narrative. Robbie, the brain, explains to us what we can do every day to keep our brain in good shape. This French initiative is a creative way to raise awareness and to promote a better understanding of brain health in children aged 6 to 12 and more broadly to increase awareness among the general public about the importance of brain health for all age groups and in different languages. **Objective:** The goal of this project is to empower children (as well as teenagers, adults and seniors) to keep their brains healthy throughout their lives by providing them with simple public health messages. **Methods:** The video was released in 01/10/18 and was later translated from French into Brazilian Portuguese as "Um cérebro saudável!". The translation was performed during the Alzheimer's Association International Conference on 12/04/2019, in São Paulo. The text was revised by a portuguese teacher. Robbie's voice was interpreted in a simple recorder. The final portuguese video lasts approximately 7 minutes and can be broadcast in different environments, including schools. To support public health interventions on brain health in primary and secondary schools, an educational kit that complements the project was created and translated. It contains activity sheets that can be used by teachers, students and volunteers. The video and the educational material are free to access and cannot be used for commercial purposes. The video is distributed via the YouTube platform (channel @mybrainrobbie1810) and the website https://mybrain-robbie.org. The video is also avaliable in English, Spanish, Mandarin, Greek, Turkish, Slovenian and Lithuanian. On 15/01/2024 a second video was released: "An inclusive world", now available in English and French with a planned translation into Portuguese and other languages soon. **Results:** The eight healthy habits presented in the video that should be observed every day throughout life are: 1. Learning; 2. Exercise; 3. Avoid blows to the head; 4. Have a good diet; 5. Avoid dangerous substances; 6. Sleep well; 7. Taking care of your health; 8. Having time for friends and family. Each one of them is shown and explained by Robbie in the video. Until 26/05/2024 the video was seen 186.518 times in YouTube, in different languages (including Portuguese), in many countries. **Conclusion:** This is as a fun and simple effort to promote global health and also to reduce inequalities all over the world. The eight good brain habits mentioned by Robbie correspond to risk factors for cognitive decline and dementia that can be modified.

https://doi.org/10.5327/CBN240009

"Rede ELA": a Brazilian initiative on transdisciplinary and interinstitutional research on amyotrophic lateral sclerosis (ALS)

Luna Lila Fernandes de Faria[1], Julia Costa Nacif Santos[1], Maria Goreti de Almeida Oliveira[1], Tiago Antônio de Oliveira Mendes[1], Ricardo Luis de Sousa[1], Clodoaldo Irineu Levartoski de Araújo[1], Lucas Vilas Boas Magalhães[1]

[1]Universidade Federal de Viçosa, Viçosa MG, Brazil.

Correspondence: Lucas Vilas Bôas Magalhães; Email: lvbmagalhaes@ufv.br.

Background: Amyotrophic Lateral Sclerosis (ALS) is a heterogeneous group of fatal neurodegenerative diseases, characterized by involvement of the upper and lower motor neurons in the spinal and bulbar pathways. About 90% of ALS cases are sporadic, with a polygenic pattern, while the remaining 10% comprise monogenic forms, implicated in the development of familial ALS (fALS). The mutation of VAPB gene is associated with the majority of fALS cases in Brazil, but it has an almost insignificant prevalence in developed countries, leading to limited research on the disease caused by this variant. This fact reinforces the need for studies that explore the particularities of ALS in Brazil. **Objective:** To establish a transdisciplinary and interinstitutional research network, in order to expand and integrate knowledge regarding ALS in its multiple dimensions: clinical, diagnostic, therapeutic, epidemiologic, genetic, biochemical and cellular. **Methods:** To establish our network, we initially counted on virtual platforms to recruit professionals from different areas and institutions. In sequence, a questionnaire was used to select and better access each participant's areas of research and potential contributions to the net. Based on this information, 9 working groups were established with defined lines of study, including epidemiology, diagnosis, treatment, alternative therapies and administrative support, each with it's own coordinator. In order to compile knowledge on the topic, define gaps in scientific literature and develop original research projects, weekly meetings took place in each group. Meanwhile, monthly reunions were organized to update the network on the projects. **Results:** The network got its accreditation on 05/10/2024, and has been able to gather 24 researchers from different Brazilian and international institutions, from fields that include medicine, physics and biochemistry. To this moment, there are 12 research projects ideas in process of being developed/registered on cellular and animal ALS models, epidemiology, diagnostic tools and interventions, including stem-cells studies, immunotherapy, and alternative medicine. Furthermore, from the net's foundation, there are ALS patients actively participating in its administrative aspects, which provides the organization a unique perception of the disease's impacts. **Conclusion:** ALS is a complex multifactorial disease, which results in a need for an interdisciplinary approach, both on patient care and on the research perspective of the disease. Our project has given the first steps towards systematically expanding and integrating knowledge on the disease. Despite its advances, "Rede ELA" is still in its early stages and it's our belief that the continuous expansion of contributors from different areas and institutions is essential to its progress and could lead to significant impact on knowledge about ALS.

https://doi.org/10.5327/CBN240010

"Rete collaterals" at callosomarginal artery: a rare case report

Angelo Ponte de Freitas Campos[1], Rodrigo de Paiva Bezerra[1], Maurício Elias Nunes da Silva[1], Marcel Ken Uehara[1], Lívia Almeida Dutra[1], Gisele Sampaio Silva[1]

[1]Hospital Israelita Albert Einstein, São Paulo SP, Brazil.

Correspondence: Angelo Ponte de Freitas Campos; Email: campos_angelo@hotmail.com.

Case presentation: We describe the case of a 32-year-old female patient with a history of episodic migraine without aura. She reported a new headache episode that began in the morning, strong intensity, pulsating type, associated with dizziness, nausea, photophobia, and phonophobia. The pain was localized in the right frontal region with progressive evolution, without thunderclap characteristics, but worsened with postural changes. Neurologic examination was unremarkable. She was admitted for diagnostic elucidation and underwent a brain MRI, which showed a nodular cortical/juxtacortical formation in the right frontal region with peripheral blood residues, closely related to the right callosomarginal artery, of vascular nature, suggesting differential diagnoses of pseudoaneurysm or arteriovenous malformation/fistula. Further investigation with cerebral angiography revealed a nodular formation originating from the left callosomarginal artery in the projection of the superior frontal gyrus, characterized by a network of tortuous arterial vessels from which the anterior and middle internal frontal arteries originate. This is likely a remnant of an embryological artery called "Rete mirabile." She didn't undergo a neurosurgery procedure at that time, due to lack of hemorrhage or aneurysm. She was discharged with guidance for analgesia for episodic migraines and scheduled a follow-up and radiological monitoring in three months. **Discussion:** Anatomical variations called "rete-like or rete mirabile" are a rare group of vascular abnormalities. They consist of a complex arterial network primarily found in some mammals such as cows, goats, pigs, and cats. "Rete-like" variations are rare in humans, with an estimated prevalence of 0.01%, and the Asian population seems to be more affected. When present, they are most frequently found in the carotid vascular territory, the middle cerebral arteries, and less commonly described in the posterior circulation. Subarachnoid hemorrhage is the most common clinical presentation (34.2%), usually secondary to aneurysms formed by vessel wall fragility, followed by incidental diagnoses (20%). When indicated, treating aneurysms secondary to rete-like formations can be difficult. Expectant management and serial radiological follow-up are considered in patients with incidental diagnoses. **Final comments:** Despite being an extremely rare variation, they can cause intracranial hemorrhages secondary to aneurysm rupture. High clinical suspicion coupled with selective cerebral angiography is necessary for a correct diagnosis since even MRI can sometimes make a diagnostic mistake. Furthermore, further studies are needed to define the best therapeutic option considering the topography, dimensions, and other epidemiological characteristics of patients.

18q21,2q23 deletion syndrome associated with agenesis of the corpus callosum

Jessica Vargas Lopes[1], Caroline Dresch Sabadin[2], Laís Machado de Oliveira[3], Rhanna Carolina de Oliveira[3], Vitor Zubeldia[3], Júlia Mascarello[3], Ana Paula Schuur[3], Juliana Dourado Grzesiuk[3], Thyara Boechat[4]

[1]Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre RS, Brazil.
[2]Universidade Estadual do Oeste do Paraná, Cascavel PR, Brazil.
[3]Centro Universitário Assis Gurgacz, Cascavel PR, Brazil.
[4]Dra. Thyara Boechat Neuropeditaria, Cascavel PR, Brazil.

Correspondence: Jessica Vargas Lopes; Email: jessicavargasl@outlook.com.

Case presentation: A female patient, aged 1 year and 1 month, born by cesarean section with a birth weight of 2905 gr. and an Apgar score of 8. She was admitted to the Neonatal Intensive Care Unit (NICU) following birth due to cardiorespiratory arrest, seizures and neonatal sepsis, with a diagnosis of congenital cytomegalovirus infection and epilepsy. At physical examination she presented with axial hypotonia, asymmetrical spontaneous movements, appendicular hypertonia, inability to follow visual objects and bilateral horizontal nystagmus. Electroencephalography (EEG) indicated disorganized brain activity with hemispheric asymmetries, in addition to a fast of medium to high voltage in the central and anterior temporal regions. The speech therapy evaluation revealed hypotonia of speech articulatory structures, and lack of coordination between the tongue, sucking, breathing and swallowing. Cranial magnetic resonance imaging (MRI) showed agenesis of the corpus callosum. A G-band karyotype revealed a partial deletion of the long arm of chromosome 18 present in all the 20 metaphases analyzed. The genomic microarray test identified the position of the terminal chromosomal alteration as 18q21,2q23. The deletion involved a 24.4 Mb segment and was present in most cells (mosaic). An intervention plan was established with a multidisciplinary team, aiming to prevent and mitigate the signs and symptoms of global developmental delay presented by the patient. **Discussion:** Chromosome 18q deletion syndrome (OMIM 601808) is a rare chromosomal disease and most case reports present common findings as impaired intellectual disability, microcephaly, short stature, congenital aural atresia, hearing loss, ophthalmological abnormalities, palatal defects, short frenulum, foot deformities, hypotonia and delayed myelination, in addition to cardiac anomalies. There are a few studies reporting individuals affected with chromosome 18q deletion having neuroradiological findings as smaller corpus callosum, therefore, the present case is one of the rare cases associated with agenesis of the corpus callosum, a congenital malformation which could also contribute to the developmental delay found in the patient. The deletion detected in the reported patient involves 70 coding genes, and two of them are possibly involved with corpus callosum malformations: RTTN and NEDD4L. As alterations in NEDD4L gene have a dominant inheritance it may play an important role in corpus callosum malformations. **Final Comments:** Chromosome 18q deletion syndrome has a low incidence and a high phenotype variability. Axial hypotonia and bilateral horizontal nystagmus were the main findings in the reported patient that are commonly associated with 18q deletions. However, her agenesis of the corpus callosum is a highly rare pathology. Few reports discuss this association, therefore, it is encouraged that more research be done, considering the possible correlation of both disorders, such as observed in this case.

Case presentation: This study is a report of 2 individuals from the same family who were being followed up as outpatients in a neurology department of a tertiary hospital. A 45-year-old woman presented with amnestic symptoms that began at the age of 36 and progressed to functional impairment, aphasia, social isolation, sphincter dysfunction, visual hallucinations, and significant irritability. Cranial magnetic resonance imaging (MRI) showed signs of diffuse cortico-subcortical atrophy, in addition to discrete hippocampal atrophy, findings that were not expected for her age. Her brother, a 51-year-old man, had amnestic symptoms onset at the age of 45, progressing to irritability, mood swings, and loss of functionality. Cranial MRI showed findings similar to those of his sister. In the family history, similar symptoms were observed in other members, including the grandmother, father, and two sisters, all of whom are now deceased. Sequential genetic analysis of both individuals revealed the presence of a pathogenic mutation in the PSEN1 gene (c552A> C [p.Glu184Asp]), confirming the diagnosis of Autosomal Dominant Alzheimer's Disease (ADAD). **Discussion:** The PSEN1 gene, located on chromosome 14, encodes a protein with the same name that acts as a transmembrane molecule, performing several functions of neurological importance. Its mutation can result in several alterations, including modifications in amyloid metabolism and neurogenesis. Mutations in this gene are the main cause of ADAD, accounting for approximately 50% of cases. In the case report in question, considering that the sister's exome confirmed the existence of the aforementioned mutation, there was an indication to perform genetic screening on all of the patient's first-degree relatives, where her brother would be diagnosed early, increasing the chance of trying to reduce the progression of the disease. Comparative studies between ADAD and late-onset sporadic Alzheimer's disease (DAEIT) indicate that ADAD tends to have presenile onset of symptoms (before age 65), with a more rapid and severe clinical progression, in addition to the presence of cortical symptoms, such as aphasia, and greater loss of hippocampal volume, when compared to DAEIT, which tends to have a more indolent course and without the evident presence of cortical symptoms. Early diagnosis of ADAD in older family members can facilitate management and improve long term outcome and quality of life in younger family members that have ADAD without symptom onset. **Final comments:** It is concluded that these cases highlight the importance of early genetic investigation in cases of presenile onset Alzheimer's disease, especially when associated with a family history of first-degree relatives with similar symptoms. This leads to an accurate and early diagnosis of the disease, which can improve management of the pathology in other family members, in addition to improving quality of life and allowing appropriate genetic counseling.

80 years of Leão's cortical spreading depression: a historical overview of its impact on neurology

José Antonio Vieira da Silva Calsoni[1], Sofia Gameiro de Souza[1], Raimundo Marcial de Brito Neto[1], Ana Luiza Morgado Costa[1], Rodrigo Amorim Jorge[2], Cristiana Pessoa de Queiroz Faria Goes[3], Jano Alves de Souza[1]

[1]Universidade Federal Fluminense, Niterói RJ, Brazil.
[2]Unigranrio, Duque de Caxias RJ, Brazil.
[3]Universidade Estadual do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: José Antonio Vieira da Silva Calsoni; Email: calsoni.jose@gmail.com.

Background: Aristides Azevedo Pacheco Leão (1914-1993) was born in Rio de Janeiro and entered the medical school at the University of São Paulo. When he was in his 2nd year, he contracted tuberculosis and had to interrupt his course. Although cured he never went back to medical school. Determined to be a scientist, he was accepted at Harvard University (1941), earning his master's degree (1942) and PhD (1943). Then, he became an assistant researcher at the Department of Anatomy at Harvard, where he was able to identify the phenomenon of Cortical Spreading Depression (CSD), which this year marks the 80th anniversary of its publication in the Journal of Neurophysiology. Its discovery by Aristides Leão ushered in a new era of understanding in neurology. This phenomenon, characterized by a wave of neuronal depolarization followed by prolonged suppression of cortical activity, revolutionized the comprehension of migraine pathophysiology, and other neurological disorders. **Objective:** Provide a comprehensive exploration of the historical significance and enduring impacts of Aristides Leão's discovery of cortical spreading depression over the past 80 years. **Methods:** A critical and objective narrative review of literature, including Leão's original research publications, historical archives, and contemporary bibliography. Through a analysis of these sources, we aim to construct a coherent narrative elucidating the evolution of the knowledge surrounding CSD. **Results:** Leão's discovery of CSD in 1944 fundamentally transformed the landscape of neurology. Initially observed in experimental rabbit models, the phenomenon was first described as being related to epilepsy and then there were several studies on this matter. Soon CSD's implications extended to other human conditions like migraine. In 2001, Hadjikhani et al. used fMRI to demonstrate that migraine aura is associated with the propagation of CSD in the visual cortex. Recent studies evaluate the phenomenon of CSD in many aspects such as: spreading depression and cortical hemodynamics; how estrogen and stimulation of the vagus nerve modulate CSD; and the characteristics of CSD in sleep and wake states. Now, non-invasive methods to detect spreading depression is awaited in clinical research. From elucidating the pathophysiology of migraine to informing approaches for other neurological disorders, the impact of Leão's discovery echoes across neurology and his work laid the foundation for future research, inspiring methodological innovations and theories that still influence neuroscience. **Conclusion:** The description of CSD stands as a testament to the transformative power of scientific inquiry. Over the past 80 years, Leão's work has catalyzed paradigm shifts in our understanding of neurological phenomena, paving the way for innovative diagnostic and therapeutic strategies. As we continue to unravel the intricacies of CSD, Leão's legacy endures as an inspiration for future generations of neuroscientists.

Correspondence: Giovana Fontanella Pileggi; Email: giovana.pileggi@gmail.com.

Sexual violence against women, including sexual assault, is endemic, and more than 50% of the victims will develop PTSD. A PTD could happen when the violence is happening, being a marker of a worse outcome and worse response to treatment. Functional magnetic resonance (fMRI) is a tool to study brain activity and connectivity using the resting state. However, studies of PTD were scarce. To compare the connectivity between brain areas using the resting state in women with diagnostic PTSD after sexual assault, that present or not PTD, and health controls. We executed seed-to-voxel analysis in target brain areas related to PTSD studies in literature: hippocampus, amygdala, para-hippocampus, insula, and Default Mode Network (DMN) areas, using the CONN software. We found significant differences between PTSD patients with or without PTD. The women with PTD showed increased connectivity between the DMN average and the right and

left frontal cortex, right areas of the cerebellum, right precentral gyrus, lateral areas of the occipital lobe, superior frontal gyrus, precuneus, and supramarginal gyrus. The patients with PTD also showed increased connectivity between the insulae and angular and supramarginal gyrus, lateral occipital cortex and right parietal lobule. Furthermore, increased connectivity was found between the parahippocampus and the supramarginal and angular gyrus, cerebellum, and occipital cortex. On the other hand, women with PTD showed decreased connectivity between the DMN (RLP) and the precuneus, lateral occipital and cuneal cortex. Also, decreased connectivity was found between the insulae and Heschl's, supramarginal, and postcentral gyrus. Finally, decreased connectivity was found between the anterior parahippocampal gyrus and the cerebellum, angular and supramarginal gyrus, and the lateral occipital cortex. These findings suggest that patients with PTD exhibit distinct patterns of brain connectivity, which can be related with their symptoms and experiences. The increased connectivity in the right parietal lobe and lateral occipital cortex suggests heightened sensitivity and intensified interpretation of visual stimuli, potentially linked to re-experiencing the traumatic event. Also, an increased activity in the precuneus and left cuneus indicates intensified retrieval of these traumatic visual perceptions. In addition, reduced activity in the prefrontal cortex and superior frontal gyrus suggests decreased self-reflection and emotional regulation, possibly due to emotional disconnection. The reduced activity in the right precentral gyrus implies a decrease in motor action preparation. These results contribute to a better understanding of the physiological mechanisms associated with PTD on PTSD, which makes it relevant in the development of possible new treatments and further investigations into the implications of PTD in PTSD.

A Brazilian neuromuscular center experience in diagnosis of rare diseases patients

Erica Nogueira Coelho[1], Laura Alonso Matheus Montouro[1], Eduardo de Paula Estephan[1], João Aris Kouyoumdjian[1], Charles Marques Lourenço[1], Amadeu José Rorigues Queiróz[1], Maria da Penha Ananias Morita[1]

[1]Faculdade de Medicina de São José do Rio Preto, São José do Rio Preto SP, Brazil.

Correspondence: Laura Alonso Matheus Montouro; Email: lauramontouro@hotmail.com.

Background: Rare diseases patients management has been a challenge to Brazilian public healthy providers, especially with regards to etiological diagnosis of genetic disorders in gene therapy era. Difficulties relate mainly to cost and availability of molecular genetic techniques. **Objective:** This study main goal is to share our experience in diagnosis of rare genetic diseases in Neuromuscular Diseases Service of São José do Rio Preto State Medicine School. **Methods:** The 10th edition of International Diseases Classification (CID10) was used to search for patients matching rare diseases codes in the medical data records from 01-Jan-2018 to 15-Apr-2024. The following codes were selected: G11.0, G11.1, G11.2, G11.3, G11.4, G11.8, G11.9, G12.0, G12.1, G12.2, G12.8, G12.9, G23.8, G23.9, G24.1, G24.8, G24.9, G60.0, G60.1, G60.2, G60.8, G60.9, G71.0, G71.1, G71.2 e G71.8. They represent five major groups of rare neurological diseases: Inherited Ataxias/Spastic Hereditary Paraplegia, Motor Neuron Diseases, Dystonic Disorders, Inherited Neuropathies and Primary Inherited Muscular Diseases. Data about those patients and final diagnosis is presented bellow. **Results:** In the Ataxia/Paraplegia group, 179 patients went through evaluation at the Medicine School public outpatient clinic, 68 (38%) of then in our referral Neuromuscular Service, 56 (82,4%) were suspected to have a genetic cause, 25 (36,8%) had access to molecular genetic test and 15 (22,1%) reached the final etiological diagnosis. The genes found were: FXN, ATP1A3, ATXN1, ATXN3, COQ7, SPG11, CACNA1A, ALDH18A1 and SLC16A2. For Motor Neuron Diseases: 197 patients evaluated, 154 (78,2%) by the neuromuscular team, 38 (24,7%) with suspected genetic etiology, 29 (18,8%) tested and 22 (14,3%) with positive results. Described genes: SMN1, SPG11, COQ7, VWA1, TFG and POLG. 13 (9,5%) of a total of 137 patients with dystonic features had appointment in Neuromuscular Diseases Service, 12 (92,3%) with suspected inherited disease, 7 (53,8%) had genetic tests performed and 6 (46,2%) had final diagnosis defined: GCH1, SPR and WDR45. In Inherited Neuropathies group, 339 total patients were evaluated, 251 (74%) in Neuromuscular Service, 55 (21.9%) had the previous diagnosis suspected, 41 (16.3%) tested and 24 (9.6%) confirmed. Following genes: PMP22, FXN, SLC12A6, COQ7, AARS1, GAN, HINT1, LMNA, PRX, SPG11, TFG, TTR, VWA1, DNMT1 and DYNC1H1. Primary Inherited Muscular diseases were suspected in 102 (87.2%) of the 117 patients evaluated, 56 (47.9%) had access to genetic test and 37 (31.00006%) positive results. The genes were: DMD, CAPN3, DYSF, TTN, DMPK, CLCN1, D3Z4, GAA, GMPPB, LAMA2, LMNA, PYGM, RYR1, SGCG, TCAP and VCP. **Conclusion:** Despite genetic disorders may represent an important part of neuromuscular diseases, the access to molecular genetic test is a problem to public healthy services in Brazil, making the final etiological diagnosis a distant reality for the majority of these patients.

A case of congenital myasthenic syndrome-0,22 responsive to pyridostigmine (so far...)

Wesley Alfredo Gawlinski de Arruda[1], Naiana Posenato[1], Querem Hapuque Zeferini Neves[2], Gabriella Frattari de Araujo Rondon Borges[2], Amanda Martinez Lafetá[2]

[1]Hospital São Vicente de Paulo, Passo Fundo RS, Brazil.
[2]Universidade de Cuiabá, Cuiabá MT, Brazil.

Correspondence: Wesley Alfredo Gawlinski de Arruda; Email: wesley.alfredo@hotmail.com.

Case presentation: A 2-year and 6-month-old girl was referred from her pediatrician due to neurodevelopmental delay. Born by vaginal birth, full-term delivery, with normal metrics at birth and neonatal screening tests within normal limits, she did not require intensive care or resuscitation maneuvers. On physical examination, she was alert, active, and responsive to the examiner, presenting normal growth parameters. However, she had difficulty remaining in the supine position (tended to lateralize), generalized hypotonia (especially cervical), loss of proximal strength, weak palmar and plantar grasp reflexes. Due to presentation as a hypotonic infant, laboratory screening was requested to rule out possible myopathies, brain MRI, and genetic testing for Spinal Muscular Atrophy (SMA), in addition to initiating motor physiotherapy. Initial complementary tests were negative, so an expanded genetic panel was requested, revealing a pathogenic variant chr2:44,328,938 G> A (p.Arg421*) in homozygosis in the PREPL gene (OMIM #609557; 2p21), compatible with a diagnosis of Congenital Myasthenic Syndrome type 22 (CMS22). Subsequently, treatment with pyridostigmine was initiated, resulting in notable clinical improvement and increased speed in developmental milestones acquisition. **Discussion:** Congenital Myasthenic Syndrome (CMS) corresponds to a rare and heterogeneous group of hereditary neuromuscular disorders characterized by involvement of the neuromuscular junction due to autoantibodies acting against Acetylcholine (ACh). It is characterized by muscle weakness, hypotonia, dysphagia, ptosis, facial weakness, and delayed neuropsychomotor development. Among these disorders, CMS-22 is a rare recessive genetic disease caused by mutations in the PREPL gene, which encodes the protein Prolyl Endopeptidase-Like (PREPL), involved in vesicular transport and filling synaptic vesicles with acetylcholine and other neurotransmitters. Symptoms are generally moderate and often respond to pyridostigmine, particularly during childhood. **Final comments:** Although rare, congenital myasthenic syndromes should be suspected in children with hypotonia suggestive of peripheral nervous system disorders, with genetic testing being essential for diagnosis.

A case of refractory epileptic seizures induced by glufosinate ammonium poisoning

Michelle Zonkowski Ribas[1], Gustavo Zonkowski Ribas[1], Rodrigo Fadel Simão[1], Ricardo Ribeiro Homem Landi[1], Sofia Santos Lima Figueiredo[1], Felipe Cardoso Garcia[1], Theodora Turkot Antunes Pereira[1], Izabella Zgoda[1], Diego Schuster Paes[1]

[1]Hospital Universitário Cajuru, Curitiba PR, Brazil.

Correspondence: Michelle Zonkowski Ribas; Email: michelle.z.ribas@gmail.com.

Case presentation: A 50-year-old man with a history of chronic alcoholism reported ingesting glufosinate ammonium (GLA), an herbicide, associated with alcohol intake on May 16th. Upon admission, he presented with nausea, dizziness, and hallucinations. He experienced an episode of greenish vomiting and subsequently became diaphoretic, tachycardic, and cyanotic, with desaturation and a decreased level of consciousness, requiring orotracheal intubation. During transportation to a tertiary hospital, he developed supraventricular tachycardia, which spontaneously reverted, and had three episodes of epileptic seizures, which only ceased after the administration of 2 vials of diazepam. Upon admission to the hospital, the patient continued to experience epileptic seizures despite sedation with midazolam and fentanyl, leading to the initiation of phenobarbital and continuous sedation with propofol. Following these measures, a video electroencephalogram was performed, which did not identify any seizures. The patient subsequently developed rhabdomyolysis and acute kidney injury, with persistent anuria and metabolic acidosis, requiring hemodialysis sessions. After being off sedation since May 20th, the patient was successfully extubated on May 26th. **Discussion:** The initial symptoms of GLA intoxication are gastrointestinal, primarily due to its irritative effect on mucous membranes. Neurological effects include mental confusion, seizures, memory loss, and coma. Most epileptic seizures are generalized, and more than 50% of them are not controlled solely with benzodiazepines, as demonstrated in our case, where phenobarbital and propofol were necessary. The mechanism underlying these seizures is still poorly understood, but studies indicate hyperstimulation of N-methyl-D-aspartate (NMDA) receptors by glufosinate and its metabolites, such as ammonia. However, it is unknown whether hyperammonemia is a cause or consequence of neurotoxicity. While some studies suggest alcohol may offer protection when combined with GLA ingestion, our case demonstrates severe symptoms despite alcohol consumption. To this day, there is no antidote for this intoxication, and the mechanisms of toxicity remain unclear. While hemodialysis can assist in removing glufosinate from the body, there is no evidence of it preventing neurotoxicity. Additionally, renal excretion proves to be 1.6 to 1.8 times more effective than hemodialysis. Consequently, hemodialysis is reserved for cases of acute renal failure, such as in our situation, and most cases are managed solely with supportive care. **Final comments:** GLA intoxication is rare but presents significant neurological symptoms, necessitating prompt identification for adequate support. Regarding seizures, it is important to note that they are difficult to control and often require additional measures, such as phenobarbital and anesthetics.

https://doi.org/10.5327/CBN240018

A case of spinal dural arteriovenous fistula

José Víctor Filho de Oliveira[1], Luiz Felipe Mota Freitas[1], Leopoldo Antonio Pires[1], Thiago Cardoso Vale[1]

[1]Universidade Federal de Juiz de Fora, Hospital Universitário, Juiz de Fora MG, Brazil.

Correspondence: José Víctor Filho de Oliveira; Email: victorr_oliveira@hotmail.com.

Case presentation: Type 2 diabetic patient, 65 years old, presents with progressive worsening of neuropathic burning pain in the soles of the feet over the last 2 years. Within 2 months it progressed to ascending pain in the posterolateral region of the lower limbs. Additionally, he reported numbness in the anogenital region. Initially diagnosed with musculoskeletal disease, motor physiotherapy was recommended for 6 months. During this period, symptoms worsened during exertion and reports of erectile dysfunction. Proximal weakness in the lower limbs progressed to relatively symmetric crural paraparesis over 8 months, leading to paraplegia and urinary incontinence after intense exertion. In the emergency room, prolonged corticosteroids were prescribed, worsening the condition with notable sphincter dysfunction. Upon admission to our service, cauda equina syndrome was diagnosed. Signs of upper motor neuron involvement were observed asymmetrically in the left lower limb, suggesting conus medullaris syndrome, with sensory dysfunction more pronounced at the L1 level. Symptoms worsened with the Valsalva maneuver. Cerebrospinal fluid analysis and laboratory tests for inflammatory, infectious and autoimmune etiologies were negative. Dural arteriovenous fistula (DAVF) was suspected. Magnetic resonance imaging of the spine revealed extensive signal changes in the spinal cord, from the lower thoracic segments to the conus medullaris, with contrast enhancement and swelling effect. Numerous intradural and extramedullary flow voids were noted, centered at the T11 level. Subsequent spinal angiography demonstrated DAVF at the T12 level, fed by dural branches of the T12 left radicular artery originating from the T12 left intercostal artery, causing extensive venous reflux to L1 with tortuosity of the posterior spinal vein to high medullary levels. **Discussion:** Spinal DAVFs are characterized by an abnormal connection between a radiculomeningeal artery and a radicular vein. This anomaly results in venous congestion and spinal cord ischemia. The vague symptoms associated with DAVFs often lead to diagnostic delay. The slow progression of symptoms can result in extensive myelopathy and irreversible symptoms despite adequate therapeutic intervention. DAVFs should be considered among the differential diagnoses in middle-aged men who present with pain, numbness or weakness in the lower limbs with gradual progression of symptoms associated with bladder, sexual and intestinal dysfunction. Asymmetric onset of symptoms and worsening with exertion and Valsalva maneuver help in the diagnosis. Worsening with the use of corticosteroids is described. MRI typically shows T2 hyperintense lesions and intramedullary flow voids. Catheter angiography is the gold standard for confirmation. **Final comments:** The patient was treated with endovascular therapy, showing notable improvement despite the delay in diagnosis and the use of corticosteroids.

https://doi.org/10.5327/CBN240019

A case report of complex neurological manifestations associated with polycythemia vera

João Victor Meneses de Aguiar[1], Eduardo Rosa da Silva[1], Bruna Macena Cutti[1], Isadora Oliveira Côrrea[1], Laís Bissoli Perini[2], Edson Pilotto Duarte[1], Bruna Garcia da Silveira[3], Adaucto Wanderley da Nóbrega Junior[1]

[1]Hospital Homero de Miranda Gomes, São José SC, Brazil.
[2]Instituto de Assistência Médica ao Servidor Público Estadual de São Paulo, São Paulo SP, Brazil.
[3]Universidade do Sul de Santa Catarina, Palhoça SC, Brazil.

Correspondence: Laís Bissoli Perini; Email: laisbperini@hotmail.com.

Polycythemia vera is a myeloproliferative disorder of hematopoietic cells characterized by increased blood viscosity due to abnormal and excessive production of erythrocytes, leukocytes, and platelets. It is a rare disease with an annual incidence of 3/100,000 people. Erythrocytosis is the most clinically relevant manifestation, contributing significantly to thrombotic and hemorrhagic events. Neurological complications may occur, primarily due to its association with cerebral ischemic events. **Case presentation:** A 67-year-old male presented with sudden onset paresis in the left upper limb. He reported previous similar episodes, associated with cyanosis in the left hand and bilaterally in the feet, as well as a sensation of "pins and needles". His medical history included a previous ischemic stroke and partial gastrectomy for gastric adenocarcinoma, without requiring chemotherapy or radiotherapy. The patient was also under investigation in the Neurology outpatient clinic for asymmetric tremors in the upper limbs. Neurological examination revealed grade III paresis in the left upper limb with dystonic posture of the 2nd to 4th fingers, hyperreflexia of the left brachioradialis, and a positive Hoffman sign. He exhibited rapid frequency tremors in the hands, bilateral blepharospasm, and adductor-type laryngeal dystonia. Abdominal examination noted a palpable spleen 4 cm below the left costal margin. Admission cranial computed tomography (CT) showed a new ischemic lesion in the right superior frontal gyrus, consistent with recent stroke, and an old ischemic lesion in the right parietal lobe. Additional tests revealed polycythemia (Hb 17.1 g/dL), thrombocytosis (608,000 x 10^9/L), negative serologies, atrial fibrillation on electrocardiogram, and abdominal ultrasound confirming splenomegaly. A JAK2 mutation test confirmed polycythemia vera, supporting our clinical suspicion. Treatment included hydroxyurea to reduce hemoglobin levels, aspirin due to high risk of new ischemic events, and anticoagulation with a factor Xa inhibitor. Following therapy, there was clinical and laboratory improvement. **Final comments:** Increased blood viscosity due to elevated hematocrit is considered the primary factor predisposing polycythemia vera patients to thrombotic events. This case report highlights concurrent neurological symptoms associated with the disease, emphasizing the risk of cerebral infarcts and subsequent neurological manifestations. We highlight in this report the occurrence of dystonic phenomena, previously reported in other polycythemia vera cases. Our primary hypothesis revolves around cortical injury contralateral to the patient's phenomenology, given recent studies emphasizing specific central nervous system activation patterns in dystonia patients. This case underscores the importance of early diagnosis and appropriate therapeutic intervention to mitigate neurological risks associated with polycythemia vera.

A case report of erdheim-chester disease with neurological manifestations: the relevance of PET-CT scan

Hedra Marques Santos[1], João Henrique Fregadolli Ferreira[2], Lívia Almeida Dutra[2]

[1]Faculdade Israelita de Ciências da Saúde Albert Einstein, São Paulo SP, Brazil.
[2]Hospital Israelita Albert Einstein, São Paulo SP, Brazil.

Correspondence: Hedra Marques Santos; Email: hedra.marques@gmail.com.

Case presentation: A 77-year-old male presented with a subacute onset of dizziness, imbalance, intentional tremor of the left arm, dysarthria, and diplopia. He denied any sleep disorders or dysphagia. Additionally, he reported weight loss and was a former heavy smoker. Physical examination revealed ataxic gait, ocular ataxia, normal extrinsic eye movements, normal muscle strength, brisk reflexes, appendicular ataxia, and left hypoesthesia. Brain MRI showed T2 FLAIR lesion at the dorsal pontomesencephalic junction and the left superior cerebellar peduncle, with contrast enhancement, along with small enhancing foci at the right pons, as well as in the deep white matter of the cerebellar hemispheres, and right lateral wall of the fourth ventricle. Perfusion MRI was normal, and spectroscopy revealed an increase in the choline/creatine ratio, and reduction in the N-acetyl-aspartate/creatine ratio. Laboratory results showed normal renal and hepatic function, CRP 1.3, ESR 19mm, serum neurofilament light chain (NfL) of 22.60 pg/mL, normal immunofixation of serum proteins. CSF analysis revealed < 1 cell/mm^3, protein 36 mg/dL, OBC negative, CSF Nfl 1304 pg/mL, IgG index 0.48, negative metagenomic analysis and negative CSF immunophenotyping. Additionally, high-risk paraneoplastic antibodies panel was negative. PET-CT showed an increased in fluorodeoxyglucose-18F (FDG) metabolism in several bilateral bone lesions, and in the pituitary gland. Bone lesions were suggestive of multiple infarcts. A bone biopsy was performed and showed intertrabecular spaces containing fibrous connective tissue, surrounded by rare aggregates of histiocytes with large and foamy cytoplasm. There was no evidence of granulomas or necrosis in the evaluated sections. Immunohistochemistry was positive for CD138 in rare plasma cells, CD20 in rare lymphocytes, CD3 and CD43 in some lymphocytes, and CD68 and CD163 in foamy histiocytes. The patient was diagnosed with ERD. **Discussion:** ERD is a rare histiocytosis characterized by uncontrolled proliferation of histiocytes due to mutations in the MAPK pathway. The presence of CD68+ CD1a- foamy histiocytes is essential for the diagnosis. ECD usually occurs in males between 40 and 70 years of age. Central nervous system involvement may be the only manifestation of ECD and occurs in 40% of patients. The PET-CT in this context enables the detection of metabolic abnormalities throughout the body, including lesions in bones and other organs. This is particularly relevant in cases of ERD, where manifestations can be multifaceted and involve multiple organ systems. Moreover, PET-CT played a crucial role in guiding the bone biopsy, providing information on the location and extent of lesions. **Final comments:** This case report underscores the importance of PET-CT in the evaluation of patients with granulomatous involvement of the central nervous system, providing critical insights for diagnosis and management.

https://doi.org/10.5327/CBN240021

A case report of super-refractory status epilepticus with a good response to intravenous human immunoglobulin

Rayanne Pereira Mendes[1], Guilherme Bitencourt Barbosa[1], Renato Morais Bueno[1], Victor Ezaki Alves Silva[1]

[1]Faculdade de Medicina do ABC, Santo André SP, Brazil.

Correspondence: Rayanne Pereira Mendes; Email: rayannepmendes@gmail.com.

Case presentation: A 23-year-old female with irregularly treated epilepsy presented to the emergency room complaining of headaches, muscle twitching in limbs, and cognitive changes over the past three days. On admission, she appeared drowsy with no physical abnormalities noted. She developed intense psychomotor agitation, cognitive impairment, opsoclonus, myoclonus, and worsening consciousness, progressing to refractory status epilepticus as confirmed by electroencephalogram showing epileptiform

activity in the left medial temporal region. Cranial CT scan and initial cerebrospinal fluid analysis showed no abnormalities. Serological tests for HIV, syphilis, and viral hepatitis were negative, and rheumatological tests were normal. Subsequent cerebrospinal fluid analysis revealed a cell count of 55 (45% lymphocytes, 55% neutrophils) with normal protein and glucose levels. Despite seven days of anti-seizure medication adjustments and deep sedation, she remained in super-refractory status epilepticus as confirmed by subsequent electroencephalogram. Due to suspicion of autoimmune encephalitis, intravenous human immunoglobulin therapy was initiated, resulting in resolution of status epilepticus; however, she continued to experience a slow awakening process. A repeat cycle of intravenous human immunoglobulin significantly improved her level of consciousness. **Discussion:** Status epilepticus is a condition where mechanisms responsible for terminating seizures fail, potentially leading to neuronal injury or death. Super-Refractory Status Epilepticus persists for 24 hours or more despite anesthesia, including cases where seizures recur after anesthesia reduction or withdrawal. Clear treatment protocols for Super-Refractory Status Epilepticus are lacking, with intravenous human immunoglobulin proposed as a therapeutic option. It is thought to flood the system with non-reactive antibodies, attenuating inflammation through direct interactions with leukocytes and catabolism of pathological antibodies. A systematic review of 33 global Super-Refractory Status Epilepticus cases, including unspecified encephalitis and antibody-defined etiology, found that 42.4% responded to intravenous human immunoglobulin with complete seizure resolution. **Final comments:** While evidence of intravenous human immunoglobulin's superiority over conventional therapies for Super-Refractory Status Epilepticus is lacking, cases like this one, showing significant response to treatment, underscore the need for randomized clinical trials to better assess its efficacy.

Correspondence: Ana Letícia Manso Assakawa; Email: ra128765@uem.br.

Case presentation: A 25-year-old female patient presented with hyperthyroidism, confirmed by elevated TRAb (TSH Receptor Antibody) levels and TSH< 0.01, along with a diffuse goiter on thyroid scintigraphy characteristic of Graves' disease. Following iodine therapy, six months post-diagnosis, she developed hypothyroidism with TSH levels elevated, requiring levothyroxine treatment. During this period, the patient experienced epileptic seizures with mesial temporal semiology and secondary generalization and anterograde amnesia. MRI which revealed T2 and FLAIR hyperintensity affecting the amygdaloid bodies and bilateral hippocampal formations. A SPECT scan showed reduced uptake in the temporal and parietal lobes, anterior and posterior cingulate regions. EEG demonstrated focal epileptiform paroxysms in the bilateral temporal region. Despite treatment with lamotrigine, the patient continued with seizures. Serum anti-GAD levels were markedly elevated (> 2000 IU/mL), suggesting a diagnosis of anti-GAD autoimmune encephalitis. Confirmation was achieved through positive results of cerebrospinal fluid analysis using both cell-based assay and immunohistochemistry. Paraneoplastic investigations were negative. Treatment was a six-month course of immunoglobulin therapy combined with levetiracetam and lacosamide. While there was a slight improvement in seizure frequency with immunotherapy, episodes of secondary generalization ceased. Immunoglobulin therapy discontinued in favor of Rituximab as ongoing immunotherapy. **Discussion:** Limbic encephalitis include autoimmune, infectious, paraneoplastic and systemic etiologies. Among the autoimmune causes, anti-GAD antibodies are notable for their impact on glutamic acid decarboxylase, disrupting GABAergic transmission and causing neuronal hyperexcitability. It is associated with autoimmune diseases such as type 1 diabetes, Graves' disease, and Hashimotos thyroiditis. Neurological manifestations typically present as limbic encephalitis, cerebellar ataxia or stiff person syndrome. Diagnosis relies on clinical suspicion supported by inflammatory findings in cerebrospinal fluid, elevated anti-GAD titers in serum or CSF and characteristic temporal lobe hyperintensity on MRI. PET-FDG and EEG contribute to diagnosis. Treatment challenges arise due to the condition's refractory nature; 80% of patients do not respond adequately to first-line therapies like immunoglobulin. In this case, despite initial treatment, the patient's seizures persisted until anti-GAD autoimmune encephalitis was identified in conjunction with Graves' disease and subsequent hypothyroidism. **Final comments:** This case highlights the importance of considering anti-GAD autoimmune encephalitis in patients presenting with refractory epilepsy. Early diagnosis facilitated prompt initiation of immunotherapy, critical for improving prognosis and minimizing long-term complications. Enhancing access to specific laboratory tests is essential to reduce diagnostic delays.

https://doi.org/10.5327/CBN240023

A challenger case report: septic-embolic stroke or ischemic stroke due to aortitis syphilitic?

Igor Pereira Matos de Oliveira[1], Patrícia Marques Mendes[2], Yan da Silva Raposo[2], Matheus de Paula Batista[2], Caio Augusto de Martha Santos[2], Enzo Barreto Viana[2], Maycon Melo Lopes[2], Vitor Hugo Machado Silva[2], Eduardo Mendonça Werneck da Silva[2], Laís Aparecida Machado de Siqueira[2]

[1]Santa Casa da Misericórdia de Belo Horizonte, Belo Horizonte MG, Brazil.
[2]Hospital das Clínicas Samuel Libânio, Pouso Alegre MG, Brazil.

Correspondence: Igor Pereira Matos de Oliveira; Email: igorpmoliveira@outlook.com.

Case presentation: A 43-year-old woman attended emergency service with respiratory symptoms and a recent diagnosis of tuberculosis. She presented also aphasia and right brachial mono paresis. She was evaluated for ischemic stroke, and computed tomography (CT) of the brain evidenced bilateral hypodensity (left temporoparietal cortico-subcortical and right temporal subcortical). Serum FTA-ABS test was positive, and VDRL 1:8. In Cerebrospinal fluid analysis, VDRL was negative, bacterial and fungus culture without growth, and cryptococcal antigen test was negative. Transesophageal echocardiogram showed 0.5x0.6 cm thrombus vegetation in the pulmonary valve. Blood culture in three pairs with the finding of Bacillus altudinis/pumilus. CT angiography of the abdominal and thoracic Aorta reported thrombosis in the subclavian artery and aortic arch. Transesophageal Doppler Echocardiography added a filamentary hyperechogenic image in the right ventricular outflow tract, adhered to the pulmonary valve, with random movement. Carotid Doppler ultrasound, and transthoracic echocardiography without abnormalities. Treatment consisted of anticoagulants, antibiotic therapy for endocarditis, COXCIP (tablets containing isoniazid, pyrazinamide, ethambutol, and rifampicin), Crystalline Penicillin 4,000,000 IU, Benzathine Penicillin 2,400,000 IU. He evolved with complete improvement in neurological, cardiac, and respiratory symptoms. **Discussion:** Syphilitic aortitis is an inflammatory condition of the aortic wall, resulting from the hematogenous dissemination of the bacterium Treponema pallidum. Central nervous system involvement may also occur in tertiary syphilis. The presence of nonspecific systemic symptoms, such as fever, asthenia, and weight loss, initially obscured the diagnosis and led to an extensive investigation to determine the underlying cause. A history of smoking and use of illicit substances, including crack and alcohol, may have contributed to the progression of vascular disease and worsening of neurological symptoms. The probable TOAST of ischemic stroke was due to large vessel and cardioembolic involvement, with partial thrombosis of the aortic arch and the formation of septic emboli resulting in bilateral cortico-subcortical cerebral infarctions, evidenced by magnetic resonance imaging. The presence of positive VDRL in serum and hyperproteinorrhaquia in the cerebrospinal fluid also point to the diagnosis of neurosyphilis. Treatment of syphilitic aortitis and its complications involves the administration of antibiotics combined with anticoagulant therapy in cases of arterial thrombosis. Surgical intervention may be necessary in cases of serious vascular complications, such as aneurysms or aortic dissection. **Final comments:** It is important to carry out continuous surveillance and public education about syphilis and its complications and the management of the disease is multidisciplinary.

https://doi.org/10.5327/CBN240024

A clinical alert on the evolution of a patient with Guillain-Barré syndrome and dengue treated with therapeutic plasma exchange: case report

Eduarda Leitzke[1], Marco Antônio da Croce[1], Júlia Hasegawa Rodrigues[1], Ketelin Roos Tirloni[1], Bianca Tessele[1], Jaqueline Solda Palaoro[2], Bruna Accorsi Machado[2], Gisele de Oliveira Doring[2], Aline Ferreira de Miranda[2], Cristiane da Silva Rodrigues de Araújo[1]

[1]Universidade de Passo Fundo, Passo Fundo RS, Brazil.
[2]Hospital São Vicente de Paulo, Passo Fundo RS, Brazil.

Correspondence: Eduarda Leitzke; Email: leitzkeeduarda@gmail.com.

Case presentation: 23-year-old patient, treated in the emergency room of a hospital in the north of Rio Grande do Sul in November 2013, reporting pain and paresthesia in the lower limbs for 30 days, after a viral illness and a recent trip to Bahia. Physical examination indicated Guillain-Barré syndrome (GBS), confirmed by lumbar puncture. Requested evaluation of the Hemotherapy Service for the therapeutic plasmapheresis (TPE) procedure. After starting the procedure, within three hours the patient had urinary difficulty, requiring a bladder catheter and with greenish urine; six hours later, he developed respiratory failure, hypoxemia, sweating and hypotension, requiring mechanical ventilation. Patient was sent to the Intensive Care Unit with suspected septic shock. Laboratory tests revealed an increase in hematocrit from 43% to 60%. The patient progressed to acute renal failure and underwent renal replacement therapy, but could not tolerate hemodialysis due to clinical instability, progressing to multiple organ failure and death 4 days after the procedure. Cause of death: hemoconcentration shock after TPE. Multidisciplinary review discussed possible causes. Pre-procedure sample confirmed positive IgM for Dengue. **Discussion:** GBS is an autoimmune inflammatory demyelinating polyradiculoneuropathy, which leads to loss of the myelin sheath and tendon reflexes. Symptoms are sensory loss, hypo- or areflexia and limb paresis and/or plegia, mostly symmetrical. Most patients have an infectious disease prior to the onset of symptoms.

Treatment of GBS includes plasmapheresis and intravenous immunoglobulin (IVIg) performed within four weeks of the onset of neurological symptoms, which can slow the progression of the disease by removing harmful antibodies. Dengue is an arboviral infection, the symptoms of which are fever, joint pain, headache, flushed skin and morbilliform rashes. The incidence of neurological symptoms and complications in dengue varies from 1 to 25%, including GBS. In the current dengue scenario, with 4.7 million probable cases by May 2024, it is necessary to evaluate a possible association of dengue with GBS. **Final comments:** Understanding the immunological mechanisms triggering GBS following dengue infection and the increasing incidence of dengue cases in various regions of Brazil, along with the association of these two pathologies, highlights the importance of continuous epidemiological surveillance and the implementation of vector control measures to prevent outbreaks of these diseases and its neurological complications.

A clinical case of migraine and probable cluster headache in a patient with tuberous sclerosis

Giuseppe Dick Bonato[1], Marco Antônio Delazeri[1], Vanise Grassi[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Hospital São Lucas, Porto Alegre RS, Brazil.

Correspondence: Giuseppe Dick Bonato; Email: g.d.bonato@hotmail.com.

Case presentation: We present a 35 year-old male with tuberous sclerosis following referred to headache-specialized evaluation. He has been treated for focal epilepsy since age of 4, which was well controlled with lamotrigine 300 mg/day. Diagnosis of tuberous sclerosis was made after skin biopsy a few years before, and brain MRI confirmed generalized dispersed cortical and subcortical tuberous lesions, and small subependymal nodules in left lateral ventricle wall. Skin lesions included hypercromic right forehead plaque and left hallux ungual fibroma. He denied further health issues and previous neurologist had started verapamil 240 mg/day and amitriptyline 75 mg/day for headache. He described two types of headache. Migrainous episodes first presented at 10 year-old, as a moderate bilateral frontal 1-2 hours-long pulsating pain with associated nausea, vomiting, photo- and phonophobia. In such episodes, he needs to stop what he is doing and quietly lie down. The second type of headache started at age of 20 and was a stabbing, acute, severe, left orbital pain. These episodes were associated with marked ipsilateral autonomous symptoms: lacrimation, conjunctival injection, sweating, ptosis and rhinorrhoea. While presenting these second-type episodes, the patient also has photophobia and prefers to lie down, though remains unrestful in bed. They tend to occur in colder months and take up to 8 hours when severe. He had no relevant headache episodes in the previous 10 months under current therapies. Reduction and discontinuation of verapamil was discussed, but patient was very resistant due to good response. As needed subcutaneous sumatriptan was introduced and patient was taught to how to use it. MRI focused on pituitary gland showed possible hypocaptant microadenoma. The patient was then referred to a neuroendocrine team and waits for endocrine screening results. **Discussion:** We present a case with two very distinct headache types: migraine without aura and probable cluster headache - as duration feature of ICHD-3 cluster headache criteria is not fulfilled. Headache associated with tuberous sclerosis can have various causes. In the presented case, however, cluster headache qualities are more closed related to the possible adenoma. Association between both conditions have been described, and it is hypothesized that both hypothalamic activation and local structural changes play a role in developing autonomic features. Cutaneous lesions alone would not fulfill clinical diagnostic criteria for tuberous sclerosis complex updated in 2012, bur radiologic neurologic features do in fact fulfills two major features in said criteria and consequently closes the diagnosis. **Final comments:** Cluster headache is a debilitating diagnosis that can be related to adenomas and pituitary lesions. There is however a question whether subependymal periventricular nodes can play a role in the presented case trigeminal autonomic headache.

Correspondence: Fernanda Lustosa Cabral Gomez; Email: fernandalustosacg@gmail.com.

Case presentation: Case 1 A 58-year-old man was admitted with a one-month history of progressive dizziness and nausea. Neurological exam revealed signs of cerebellar ataxia. Brain MRI and cerebrospinal fluid analysis were unremarkable. He underwent empirical treatment with intravenous immunoglobulin but showed no signs of improvement. Two months later he maintained progressive worsening of cerebellar symptoms along with visual hallucinations and involuntary movements of the head and upper limbs. At this time, his exam revealed worsening of cerebellar signs, global hyperreflexia and choreic movements. A new brain MRI was performed and revealed bilateral T2-hyperintensity in caudate nucleus and putamen with restricted diffusion. 14-3-3 CSF assay was positive and established criteria for probable sporadic Creutzfeldt-Jakob disease (sCJD). The patient died one month later at the palliative care facility. Case 2 A 53-year-old man with a history of chronic alcoholism was admitted with one month of progressive dizziness and headache. Neurological exam revealed central nystagmus and dysmetria. Laboratory and brain image were unremarkable. He was discharged on Thiamine under the hypothesis of Wernicke's encephalopathy. One month later his symptoms worsened, along with visual hallucinations and global rigidity. His exam revealed akinetic mutism and hyperekplexia. Brain MRI showed restricted diffusion of right parietooccipital cortex and protein 14-3-3 from CSF was positive, establishing probable sCJD. The patient died three weeks later at the palliative care facility. **Discussion:** CJD is a rare, fatal and rapidly progressive neurological disease, caused by misfolded prion protein in the brain. The reported prevalence in Brazil per year is 1 to 2 cases per million. CJD is classified in four subtypes: sporadic (sCJD), variant, iatrogenic and familial. Sporadic form is the most common (85%) and is further classified into four subtypes according to prion protein features and genotype: MM1/(MV)1, MM2, VV1, VV2 and MV2. Both our patients had clinical features consistent with the VV2 subtype that most commonly presents prominent progressive ataxia. Patients lived 30 kilometers from each other and were admitted to the same facility within two months. Both cases were reported to the Ministry of Health. **Final comments:** Our article addresses a temporo-spatial cluster of sCJD with the VV2 phenotype in São Paulo. Similar clusters of sCJD have been reported in the past. One possible explanation for this phenomenon is the exposure to a common external factor or, less likely, direct transmission between cases. Our work highlights the need for future research on transmission events and environmental factors that may increase the occurrence of CJD.

Correspondence: Leslie Mateus de Sousa Nunes; Email: leslienunes@alu.ufc.br.

Background: Management of brain tumors has evolved due to the identification of molecular changes, allowing greater diagnostic accuracy, understanding of the biological behavior of tumors, definition of prognostic factors, and identification of therapeutic targets. IDH mutation is a common change in primary and recurrent gliomas, but the role of ATRX is not yet fully understood. Studies highlight the association between IDH mutations and ATRX inactivation, attributed to deletions, gene fusion, or a combination of these causes. **Objective:** To analyze the expression of wild ATRX and IDH1 mutant in gliomas, looking for possible associations with tumor grade. Understanding these relationships can contribute to more accurate management strategies. **Methods:** An epidemiological, descriptive, transversal, and retrospective study was carried out by reviewing the records of patients diagnosed with gliomas in a tertiary hospital over a period of 10 years. The analysis included 97 patients with different histological types of gliomas, classifying them according to the expression of ATRX and IDH1, in addition to tumor grade. **Results:** The analysis of the records showed a varied distribution of gliomas: 43 cases of astrocytomas (44.3%), 1 case of ganglioglioma (1%), 41 cases of glioblastoma (42.2%), 11 cases of oligodendroglioma (11.3%), and 1 case of pleomorphic xanthoastrocytoma (1%). As for tumor grade, 2 cases of grade I (2%), 31 cases of grade II (31.9%), 9 cases of grade III (9.2%), and 54 cases of grade IV (55%) were identified. Evaluation of ATRX expression revealed preservation of this protein in 79 cases (81.4%): 26 cases of grade II (26.8%), 5 cases of grade III (5%), and 48 cases of grade IV (49.4%). In 18 cases (18.5%), silenced ATRX was observed: 5 grade II cases (5.1%), 4 grade III cases (4.1%), and 9 grade IV cases (9.2%). The analysis of the IDH1 marker showed positivity in 74 cases (76.2%): 1 case of grade I (1%), 33 cases of grade II (34%), 12 cases of grade III (12.3%), and 28 cases of grade IV (28.8%). Negativity for IDH1 was identified in 23 cases (23.7%): 3 cases of grade II (3%), 1 case of grade III (1%), and 19 cases of grade IV (19.5%). In the 74 cases with positive IDH1, ATRX was preserved in 61 cases (82.4%) and silenced in 13 cases (17.5%). In the 23 cases with negative IDH1, the distribution was equal: 11 cases of preserved ATRX (47.8%) and 12 cases of silenced ATRX (52.1%). **Conclusion:** The immunohistochemical analysis of the expression of wild ATRX and mutant IDH1 in diffuse gliomas showed association with tumor grade, corroborating the profile described in the medical literature. When IDH1 is positive, ATRX is often preserved; in cases of negative IDH1, there is equal distribution between preserved and silenced ATRX. The most commonly observed histological types were astrocytomas and glioblastomas, with a prevalence of grade IV tumors. These correlations help in understanding tumor biology and its prognostic value.

A congenital slow channel myasthenic syndrome in two sisters: case report

Laura Altomare Fonseca Campos[1], Jéssica Cristina Silveira Damasceno[1], Marcelo Sobrinho Mendonça[1], Thiago Cardoso Vale[1]

[1]Hospital e Maternidade Therezinha de Jesus, Juiz de Fora MG, Brazil.

Correspondence: Laura Altomare Fonseca Campos; Email: lauraaltomare8@gmail.com.

Case presentation: Female siblings, aged 31 and 16, with early childhood onset of eyelid ptosis that worsened throughout the day, associated with falls and weakness, with impairment in school and basic activities of daily living were evaluated. Pregnancy and childbirth were uneventful, and there were no cognitive or neurological deficits or other comorbidities. One of them had dysphagia for liquids during adolescence, which improved after being monitored by a speech therapist. Physical examination showed proximal weakness in the upper and lower limbs, as well as bilateral eyelid ptosis, with no other alterations. Family history included a father and paternal grandfather affected by congenital myasthenia, without consanguinity. The hypothesis of congenital muscle disease was raised, and investigations were carried out with imaging, laboratory and electroneuromyography (ENMG) tests, which showed postsynaptic neuromuscular junction dysfunction, with the occurrence of double action potentials in the motor conduction study in all assessed nerves, bilaterally, suggesting a slow channel mechanism. A genetic test (neuromuscular panel) showed a mutation in the cholinergic receptor nicotinic alpha 1 subunit (CHRNA1) gene in heterozygosity, confirming the diagnosis of Congenital Myasthenic Syndrome 1A (OMIM #601462). Brain MRI was normal. Ophthalmologic and cardiologic evaluations were unrevealing. Spirometry has also been carried out periodically and, to date, mild restrictive disorder has been monitored. Fluoxetine and salbutamol were tried but discontinued due to side effects. **Discussion:** Slow-channel congenital myasthenic syndrome (CMS) consists of a dynamic alteration of the acetylcholine ion channel of the neuromuscular junction, with an autosomal dominant inheritance pattern and a high degree of penetrance. Symptoms vary from mild weakness, which worsens throughout the day, intolerance to physical exercise, to incapacitating weakness, respiratory failure and bulbar symptoms. Unlike Myasthenia Gravis, an important differential diagnosis, slow channel CMS does not respond well to corticotherapy and acetylcholinesterase inhibitors and may worsen with their use. However, it does respond to drugs such as fluoxetine and quinidine, which act on the affected sodium channels. **Final comments:** This report exposes an important differential diagnosis of neurological diseases that present with ptosis and fatigable muscle weakness.

https://doi.org/10.5327/CBN240029

A "de novo" KIF1A mutation in a patient with spastic paraplegia, peripheral neuropathy and intellectual disability: case report

Aline Yumi Sato Yamazaki[1], Fernanda Nunes Maria[1], Aline Geisler[1], Juliana Cardoso Fiquene[1]

[1]Hospital Santa Isabel, Blumenau SC, Brazil.

Correspondence: Aline Yumi Sato Yamazaki; Email: aline.yumi-andra@hotmail.com.

The KIF1A gene encodes a Kinesin-related protein involved in the anterograde transport of synaptic-vesicle precursors along the axon. Since 2011 several KIF1A-related disorders have been described such as hereditary spastic paraparesis, hereditary sensory and autonomic neuropathy, severe neurodegenerative condition, progressive encephalopathy with edema, hypsarrhythmia, and optic atrophy (PEHO) and NESCAV syndrome. We report a patient presenting spastic paraplegia, peripheral neuropathy and intellectual disability with gene KIF1A mutation. A 58-year-old man presented to our hospital with a progressive gait disorder and peripheral neuropathy. According to his sister, he was born by home birth with no medical assistance. During his childhood, the family observed that he had intellectual delay, as he did not learn to read or to write and dropped out of school after the second grade. He was able to do daily living activities (eg. take a shower, eat by himself), but he did not have a social life, nor a job. Until 15 years old, he had no difficulty walking, then he began to experience gait changes and frequent falls. Currently, he has been walking with the aid of a walker for about 5 years. He had no seizures, dysautonomia, dysphagia, or dysarthria. A neurological examination revealed coherent speech, although intellectual disability. He also presents spastic paraparesis, muscle weakness in the lower limbs, Medical Research Council (MRC) sum score 49/60, deep tendon reflexes (biceps 0, brachioradialis 1, patellar 2, Achilles 0), bilateral Babinski sign. In the investigation, brain MRI was normal, electroneuromyography showed axonal sensitive and motor polyneuropathy with a predominance of the lower limbs, and the genetic panel found a pathogenic heterozygous mutation in the KIF1A gene (p.Arg11Trp). Despite this wide phenotypic spectrum, KIF1A-related disorders as a whole remain extremely rare with many patients receiving a misdiagnosis. In this case reported, the disorder was probably attributed to poor assistance during birth, retarding the diagnosis. Several types of mutations in the same protein have been observed, which leads to the possibility of new variants in these KIF1A-related disorders.

https://doi.org/10.5327/CBN240030

A diagnostic challenge: is mixed connective tissue disease enough to explain difficult-to-control epilepsy?

Leticia Machado Dumont, Renan Brandão Rambaldi Cavalheiro[1], Paulo Sgobbi[2], Wladimir Bocca Vieira de Rezende Pinto[2], Cristine Mella Cukiert[1], Rafael Chaves Claudino de Queiroga[1]

[1]Irmandade Santa Casa de Misericordia de São Paulo, São Paulo SP, Brazil.
[2]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Leticia Machado Dumont; Email: leticiamachadodumont@gmail.com.

Case presentation: 27 year-old female patient with a complex clinical presentation, recently diagnosed with GLUT1 deficiency and scleroderma type mixed connective tissue disease (DMTC). The patient had treatment-resistant seizures since childhood, in addition to rheumatological symptoms that began at the age of 16. Since DMTC alone could not explain the occurrence of seizures, the patient was referred from rheumatology to neurology, leading to a investigation and subsequent diagnosis of overlapping GLUT1 deficiency. At 1 year of age, the patient presented with her first seizures, exhibiting different phenomenologies, including myoclonic seizures (the most frequent type). At the age of 3 started treatment with valproic acid, without seizure control. During childhood, the patient presented with learning difficulties, repeating some school years. At the age of 16, she began to experience significant weight loss and muscle weakness in her upper limbs. On neurological examination, she presented with grade IV motor strength in the upper limbs. On ectoscopy, she presented with stigmas of scleroderma. At rheumatological investigation with laboratory tests was confirmed the diagnosis of scleroderma type DMTC (ANA speckled nuclear >1/654, Anti RNP antibody reactive). Treatment with Leflunomide was introduced, with control of the rheumatological condition. Despite DMTC control, the seizures persisted, even with the use of 2500mg/day of valproic acid. That way, the patient was referred to neurology for further investigation. EEGs and cranial MR were performed, without identifying the cause of the seizures. Therefore, it was decided to perform an epilepsy genetic panel, which did not find pathogenic variants, but identified a variant of uncertain significance (VUS) in the SLC2A1 gene, responsible for encoding the GLUT1 protein. Literature review indicated that the VUS in question may be related to GLUT1 deficiency. GLUT1 deficiency is a rare genetic disorder that affects glucose transport to the brain and can lead to a range of neurological problems, including seizures, developmental delay and intellectual disability. DMTC, on the other hand, is a group of autoimmune diseases that affect connective tissue. The association between GLUT1 deficiency and DMTC is rare but has been described in the literature. The VUS identified in the patient's SLC2A1 gene has also been associated with GLUT1 deficiency in other studies. Thus, the combination of GLUT1 deficiency and DMTC in this patient is even rarer than the isolated occurrence of these diseases and represents a diagnostic and therapeutic challenge. **Final comments:** This case illustrates the importance of a comprehensive investigation in patients with refractory epilepsy. The diagnosis of GLUT1 deficiency in adults can be challenging due to the variety of symptoms, but genetic testing has contributed to the elucidation of such cases, allowing for appropriate treatment and patient follow-up.

https://doi.org/10.5327/CBN240031

A dysarthria, dysphagia, and sialorrhea: impacts on the quality of life in patients with Parkinson's disease

Arthur Jun Deguti Hata[1], Vivian Kaori Segawa[1], Ana Luiza Fabris Moraes[1], Emerson Gisoldi[1], Alice Estevo Dias, Margarete de Jesus Carvalho[1]

[1]Faculdade de Medicina do ABC, Santo André SP, Brazil.

Correspondence: Arthur Jun Deguti Hata; Email: arthur.deguti@gmail.com.

Background: Idiopathic Parkinson's disease (IPD) is a chronic neurodegenerative disease with slow progression and motor and non-motor manifestations, it affects between 1-2% of the population over 65 years old. Dysarthria, dysphagia, and sialorrhea can compromise patients' quality of life and lead to clinical complications. **Objective:** To evaluate the perception of a group of IPD patients regarding speech, swallowing, and saliva control alterations, as well as their impact on quality of life. **Methods:** Observational cross-sectional study with the application of the Radboud Oral Motor Inventory (ROMP) questionnaire in IPD patients. The questionnaire consists of 23 questions, seven related to speech, seven to swallowing, and nine to salivation. Each question contains 5 response (options from 1 to 5), with 1 being normal and 5 being severe alteration. The results were obtained by summing the points of each question, with total scores ranging from 23-115 for speech and swallowing, and 9-45 for salivation. All patients were evaluated using the Hoehn & Yahr (H&Y) and Unified Parkinson's Disease Rating Scale (UPDRS I, II, III, IV, and V) scales for Spearman's correlation analysis with ROMP, using a significance level of ($p \leq 0.05$). **Results:** 25 IPD patients aged 40 to 80 years, including 11 men (44%) and 14 women (56%), H&Y 1-5 and UPDRS 9-96 were evaluated. The mean total points across all patients were 44.08 (SD 16.4), with mean scores for speech was 17.16 (SD 7.5) , 13.56 (SD 6.7) for saliva, and 13.36 (SD 7.7) for swallowing. When separated by sex, men had a total mean of 47.36 (SD 17.3) and women 41.50 (SD 15.8). Spearman correlation of ROMP with UPDRS showed a coefficient of 0.43 ($p=0.03$) and ROMP with H&Y scale was 0.25 (p 0.11). **Conclusion:** This study showed that speech, swallowing, and saliva disorders seriously affect quality of life in IPD, particularly in interpersonal relationships and patients' food safety. Thus, the application of ROMP in IPD patients was useful both for quickly identifying alterations and for guiding appropriate assessment and timely multidisciplinary rehabilitation, aiming to alleviate disease complications and improve well-being.

A epidemiological analysis of the hospitalization of meningococcal infection in Brazil from 2013-2023

Paulo Wendel Moura de Souza[1], Júlia Viana de Castro[1], Matheus Henrique Brustolim Marcucci[1], Lucas Frigo[1], Cássia Caroline Aguiar da Ponte[1], Yasmin Dantas Babadopulos[1], Amanda Mendes das Neves[1], Sofia Santana de Figueirêdo[1], Rodrigo Guimarães Bandeira[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Júlia Viana de Castro; Email: juliaviana2020@alu.ufc.br.

Background: Meningococci (Neisseria meningitidis) are gram-negative diplococci that cause meningitis and meningococcemia. Symptoms include headache, nausea, vomiting, photophobia, lethargy, rash, multiple organ failure, shock, and disseminated intravascular coagulation. Carriers (and infected patients) may transmit the organism to people who have direct contact with respiratory secretions or who inhale large-droplet nuclei from a carrier or patient. Diagnosis is clinical, confirmed by culture. **Objective:** To analyze the epidemiological profile of confirmed cases of meningococcal infection in Brazil between the years 2013 and 2023. **Methods:** This study is an epidemiological investigation of the hospitalization of meningococcal infections cases between 2013 and 2023 in Brazil. Data were collected from the Sistema de Informação de Agravos de Notificação (Sinan Net) do Departamento de Informática do Sistema Único de Saúde (DATASUS), and data analysis was performed using Jamovi® software. **Results:** From 2013 to 2023, approximately 13,008 cases of meningococcal infection were recorded in Brazil. Of these, approximately 42.91% (≅ 5,582) were in the Southeast region and only 7.92% (≅ 1,031) in the North region. During the pre-pandemic period of SARS-CoV-2 (2013 to 2019), the mean number of cases was 1,464 per year, while during the pandemic (2020 to 2022), it was 602 cases per year, a reduction of 58.86%. From 2019 to 2020, there was a reduction of 44.24%, and from 2020 to 2021, a reduction of 14.59%. The year 2022 had an increase of 59.38% compared to 2021 in terms of the number of cases, and from 2022 to 2023 a small increase of 6.4%. The age group that suffered the most reduction in the mean number of cases in the pandemic period compared to the pre-pandemic period was 10 to 14 years old (0.76%), and the one that was least affected were those from 70 to 79 years old and 80 years old or older (14% and 12%, respectively). **Conclusion:** According to the data analysis, there has been a considerable reduction in the number of cases during the pandemic period (58%) compared to the pre-pandemic period. This is due to social isolation, as well as the restrictive and preventive hygiene measures imposed during the pandemic period to control COVID-19, which may have contributed to lowering the rates of bacterial infections, directly influencing the drop in the number of cases of meningococcal infections. In addition, this difference can also be explained by a reduction in the notification of cases, as well as in hospital demand during the pandemic period, a setting also seen in other diseases, such as encephalitis. This phenomenon can be evidenced by the sharp reduction between 2019 and 2020 and an increase that was also exacerbated between 2021 and 2022, as well as a only slight change between 2022 and 2023, the first post-pandemic year.

https://doi.org/10.5327/CBN240033

A family with ALS and simultaneous mutations in C9ORF72 and OPTN genes

Francisco de Assis Aquino Gondim[1], Rodrigo Fagundes da Rosa[1], José Marcelino Aragão Fernandes[1], Nayana Freire de Almeida Fontes[1], João Marcelo Albuquerque Beserra de Sousa[1], Wilson Marques Júnior[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Rodrigo Fagundes da Rosa; Email: rodrigofdarosa@gmail.com.

C9ORF72 mutations are the most common identified genetic cause of ALS. The role of OPTN mutations in ALS is less certain. To our knowledge, there is only one report of simultaneous mutations in C9ORF72 and OPTN genes leading to ALS. Here, we report a family with 3 ALS patients, 2 of them with simultaneous C9ORF72 and OPTN mutations. **Case presentation:** Case 1: 62 year-old, male, with history of hypertension and Restless Legs Syndrome, began experiencing dysphonia and dysarthria in January 2020, followed by weakness in the left arm. After four months, he developed weakness in the right arm and fasciculations. EMG performed revealed lower motor neuron disease. In January 2021, he developed leg weakness and falls and in April 2021, riluzole was started. Neurological examination revealed preserved cognitive functions, predominantly left-sided tetraparesis, diffuse hyperreflexia, and proximal and distal arm atrophy. He died on late 2022. Case 2: 56 year-old, female began experiencing dysphonia and dysarthria in September 2019, followed by arm weakness. She underwent gastrostomy in March 2021. She was treated with riluzole and Revised El Escorial, Awaji and Gold Coast criteria. She died in January 2023. Their father had died with a disease pattern consistent with ALS and similar to their children (Cases 1 and 2). Genetic testing revealed that both patients in Case 1 and 2 had simultaneous mutations in the C9ORF72 and OPTN genes (C.1691A> G; p.aSP564Gly, variant of uncertain significance. **Discussion:** Familial Amyotrophic Lateral Sclerosis (fALS) may comprise 10-20% of ALS cases. More than 40 genes have been associated with ALS. The most common genetic cause is a hexanucleotide repeat expansion in the C9orf72 gene, responsible for 30%-50% of familial ALS cases. Optineurin (OPTN) is a cytosolic protein ubiquitously expressed, primarily located in the perinuclear region of the cell, where it associates with the Golgi apparatus and interacts with various molecules. Mutations in OPTN are also known to cause primary open-angle glaucoma (POAG) and Paget's disease. **Final comments:** To our knowledge, our present report with simultaneous mutations in OPTN and C9orf72 genes in ALS patients was previously evidenced only in a single family from England (Bury et al. 2016).

A gabapentin-induced edema in a patient with mesial temporal lobe epilepsy: a case report

Vanessa Conceição Saar Mautone Lima[1], Ricardo Cezare Araujo[1], Victória Nunes Alvares[1], Lucas Gonçalves Coelho[1], Clara Ribeiro Rizzo[1], Bernardo Leal Cupello[1], Melina da Silva Bernardes[1], Glenda Corrêa Borges de Lacerda[1]

[1]Universidade Federal do Estado do Rio de Janeiro, Hospital Universitário Gaffrée e Guinle, Rio de Janeiro RJ, Brazil.

Correspondence: Victória Nunes Alvares; Email: victoriaalvares@edu.unirio.br.

Case presentation: A 50 year-old female with a previous diagnosis of Mesial Temporal Lobe Epilepsy and on active treatment with lamotrigine, gabapentin, topiramate, phenobarbital, valproate and fluoxetine, was admitted with generalized edema and arthralgia in our hospital. On physical examination, the patient presented with hands, heels and facial edema, as well as warmth in the joints of her hands, claudication and a distented abdomen with referred pain on deeper palpation of the right hypochondriac region. Laboratory exams were within the normal limts and the abdominal computed tomography (CT) scan did not show any significant alterations. An in-depth cardiologic investigation was performed in the patient to analyze a possible cardiac-induced edema. However, the Electrocardiogram (EKG), the Transesophageal Echocardiogram (ECOTT), Ambulatory Blood Pressure Monitoring (ABPM) and Lower Limbs Venous Doppler US exams did not show any pathological changes. Therefore, the main hypothesis raised was an antiseizure drug-induced edema, specifically a gabapentin major side effect. **Discussion:** Gabapentin is an antiseizure medication (ASM) mainly used as an adjunct to more potent ASM for managing focal seizures, as it binds to presynaptic voltage-dependent calcium channels, stabilizing the neuronal excitability. Among its various aderse effects, there is weight gain associated with peripheral edema, Although the exact mechanism of its inducing edema remains unknown, some studies suggest that gabapentin might induce peripheral edema in a similar way as calcium channel blockers, such as Amlodipne, do: stimulating arterial dilation without venous compensation. In the presented case, as most frequent causes of edema, such as cardiac, nephrologic and hepatic originated edema, were ruled out, gabapentin was considered as a culprit. A dosis reduction resultued in the edema resolution on our patient. **Final comments:** In conclusion, we emphasize that, among the vairous causes that can possibly induce a peripheral edema, medical providers should always look for pharmacological causes, specially in those patientes on polypharmacy. Even though it isn't a common side effect, neurologists and other healthcare workers should be fully aware of the association between gabapentin and edema so that unecessary interventions can be avoided as the medication can be easily adjusted or even discontued on our patients.

[2]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Maria Cândida Barros Arantes Romano; Email: candinha_barros-ar@hotmail.com.

This article presents the case of a bilateral, median, solid and volume (5x8x7cm), causing sinus thrombosis at this level, with symptoms non-specific, as the patient only had a headache, with no improvement following conservative treatment, and was submitted to a computerized tomography that showed the lesion. Due to the large extracranial vascular and bone afferent, prior embolization was performed of its main afferent right middle meningeal artery, and discusses its pathophysiology, its image findings, treatment and evolution. Parafalcine cerebral meningiomas represent 7.7% of all neoplasms meningoepithelial. They are currently divided according to their parallel relationship to the superior sagittal sinus into anterior, median (between coronal and lambdoid suture) and posterior. They may appear with non-specific symptoms, and may have differential diagnoses, migraine, tension headache, and psychiatric disorders, according to their location, due to slow growth and brain accommodation mechanisms, respecting the monro-kelly doctrine. The severity of the expansive lesion presented is evident, thanks to the technological advancement, hemodynamic techniques, intraoperative management of hemostasis of the lesion occurs in a more succinct and abbreviated manner, due to the embolization of the tumor previously at first, reducing the morbidity and

mortality of surgery, which in other times was extremely high. Currently, there are still more studies on the topic required in order making the more precise and cost-effective technique, as the technology is new and very costly for the public health system.

Background: Current preliminary evidence suggests that VNS modulates the inflammatory system through intricate routes, including neuroendocrine mediated and immunologic communication. Numerous studies have delved into the anti-inflammatory effects of VNS, particularly with cervical and auricular stimulation. Moreover, to the best of our knowledge, despite various studies on the antiinflammatory effects of VNS, a comprehensive review and analysis pooling the results of these studies is currently lacking. **Objective:** To conduct a systematic review and meta-analysis assessing the antiinflammatory effects of various VNS methods while exploring multiple antiinflammatory pathways. **Methods:** We included clinical trials that used electrical stimulation of the vagus nerve and assessed inflammatory markers up to October 2022. We excluded studies lacking control groups, those with combined interventions, or abstracts without full text. We adhered to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines and the Cochrane Handbook for Systematic Reviews. For each inflammatory marker, a random-effects meta-analysis using the inverse variance method was performed. Methods used include transcutaneous auricular VNS (taVNS), transcutaneous cervical VNS (tcVNS), invasive cervical VNS (iVNS), and electroacupuncture VNS (eaVNS). Main reported outcomes included tumor necrosis factor (TNF)-α, interleukin (IL)-6, IL-1ß, C-reactive protein (CRP), and IL-10. Risk of bias was evaluated using the Cochrane Collaboration Tool (RoB 2.0). **Results:** This review included 15 studies, involving 597 patients. No statistically significant general VNS effect was observed on TNF-α, IL-6, and IL-1ß. However, CRP, IL-10, and interferon (IFN)-γ were significantly modulated by VNS across all methods. Subgroup analysis revealed specific stimulation techniques producing significant results, such as taVNS effects in IL-1ß and IL-10, and iVNS in IL-6, whereas tcVNS and eaVNS did not convey significant pooled results individually. Cumulative exposure to VNS, higher risk of bias, study design, and pulse width were identified as effect size predictors in our meta-regression models. **Conclusion:** Pooling all VNS techniques indicated the ability of VNS to modulate inflammatory markers such as CRP, IL-10, and IFN-γ. Individually, methods such as taVNS were effective in modulating IL-1ß and IL-10, whereas iVNS modulated IL-6. However, different VNS techniques should be separately analyzed in larger, homogeneous, and powerful studies to achieve a clearer and more consistent understanding of the effect of each VNS method on the inflammatory system.

A non-internuclear cause of walled-eye ophthalmoplegia

João Vitor Gerdulli Tamanini[1], Sofia Monaco Gama[1], Gabriel Casella Speltri[1], Fernanda Abreu[1], Clara Moreira[1], Guilherme Ribeiro[1], Jackeline Neves Pereira[1], Luccas Almeida[1], Larissa Mendes[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: João Vitor Gerdulli Tamanini; Email: jvgtamanini@yahoo.com.br.

Case presentation: A 60-year-old patient presented with a history of two days of facial palsy and binocular diplopia. Past medical history included an upper respiratory infection 1 week before. He presented right-sided hemifacial paralysis involving the superior and inferior quadrants, bilateral exotropia on primary gaze position, adduction restriction of the left eye when looking to the right, and of the right eye when looking to the left. Due to these findings, we made a hypothesis of wall-eyed bilateral internuclear ophthalmoplegia (WEBINO). However, on further examination it was noticed that the patient did not have any form of gaze-evoked nystagmus and presented with up-gaze and convergence palsy. Furthermore, the patient also presented with ataxic gait, absent osteotendinous reflexes and was unable to perform a tandem walk. Considering laboratory assessment, serum examinations were unremarkable, whereas spinal fluid analysis presented 0 cells and 57mg/dL of protein. Motor conduction studies showed reduced amplitude in the right facial nerve potential in the platism and the eye orbicularis muscles. There were no sensitive alterations. The F wave latency was increased in the tibial and normal in the ulnar nerves. The H reflex was absent bilaterally. Regarding the blink reflex, the R1 latency was increased on the right, whereas latency of the left R1 and bilateral R2 and R2c were within normal ranges. Given the clinical, laboratory and nerve conduction study findings we put forward a hypothesis of Miller Fisher syndrome (MFS). **Discussion:** MFS is a rare form of acute-onset immune-mediated neuropathy and is characterised by the triad: ophthalmoparesis, ataxia and areflexia. Specifically, MFS is highly associated with anti-GQ1b antibody. In that sense, both anti-GQ1b antibody and MFS have been associated with internuclear ophthalmoplegia and WEBINO. Our patient presented with several findings suggestive of MFS. Particularly, WEBINO consists of a form of bilateral internuclear ophthalmoplegia with large, wide-angle, exotropia in the primary position, bilateral adduction impairment and nystagmus of the abducting eye. Moreover, WEBINO typically presents with a wide range of vertical gaze alterations such as vertical gaze-evoked nystagmus, skew deviation and vestibular ocular reflex alterations. Lesions that cause WEBINO are frequently located in the pons and/or midbrain and are usually of inflammatory or ischemic aetiology. Particularly, the damaged structure is classically described as the middle longitudinal fasciculus. In a first assessment our patient seemed to present with WEBINO. However, the adduction paralysis,, as well as lack of abduction and gaze evoked nystagmus made the diagnosis of true WEBINO less likely. Normal MRI and alteration in nerve conduction corroborated the pseudo-WEBINO of peripheral nature. **Final comments:** Our patient presented with a pseudo-WEBINO of non-internuclear cause.

A novel pattern of voxel-based morphometry is associated with focal cortical dysplasia: the "boomerang sign"

William Alves Martins[1], Eliseu Paglioli[1], Ricardo Paganin[1], Thomas More Frigeri[1], Rafael Paglioli[1], Ricardo Bernardi Soder[1], Natalie da Silveira Donida[1], Bibiana Liberman Thomé[1], Tais Michele Werle[1], Andre Palmini[1]

Correspondence: William Alves Martins; Email: walvesm.br@gmail.com.

Background: More than 30% of patients with epilepsy have seizures refractory to medication and epilepsy surgery remains the only hope of sustained seizure-freedom. It has been shown that complete resection of an epileptogenic structural abnormality seen on MRI is the best predictor of surgical success3, yet a visible MRI lesion is not found in a significant number of patients. Post-processing MRI techniques may harbor a way to correctly identify previously undetected lesions. In this study, we report a relatively specific pattern of VBM abnormalities using the MAP program. **Objective:** To describe a new pattern of MAP positivity associated with focal cortical dysplasia (FCD) **Methods:** We studied all patients in the Porto Alegre Surgery Program (PAESP) who underwent surgery from 2006-2020, selecting patients with MRI negative or FCD positive MRI. All patients had a T1 volumetric sequence analysed using the MAP program, providing statistical maps of cortical-subcortical junction. A cut-off of > 4 SD with exclusion of artefacts upon MRI review was applied. Of 141 patients, MAP was positive in at least one region in 93 patients (66%) (83% in those with lesional MRI and 43% in nonlesional patients. A peculiar, previously undescribed pattern was observed in 29 (31%) of the MAP+ patients, consisting of a Z score > 4 in the "blurring map" at the depth of a sulcus, assuming the shape of a boomerang, its convex portion turned towards the subcortical white matter. Pathology was available in 22 of these patients and the "boomerang pattern" was significantly associated with FCD II (16/22 [73%], p=0.018;), with a trend both for better surgical outcome (55% x 42%, p =0.2) and to lesional MRI (34.8% x 22.2%, respectively; p=0.2). The "boomerang sign" was also linked to total resection of MAP+ region (69% x 42.2%, p=0.017; OR: 2.2 [1.1- 4.3]) and better surgical outcome when completely resected (70% x 22%, p=0.041). **Results:** We have described a new pattern of MAP positivity at the bottom of a sulcus in the format of a "boomerang". Huppertz el al had briefly mentioned a half ring- or horseshoe-shaped pattern in the extension map, but no further investigations were reported. In a study of 5 patients, Stecher et al suggested that a U-shaped asymmetry may underlie FCD in very young children. Here we further characterized this pattern of MAP positivity, showing that the "boomerang sign" is associated with FCD II in 73% of cases and its presence associates with higher rates of complete resection of MAP+ regions. **Conclusion:** The boomerang sign pattern may be a reliable visual clue of MAP positivity, perhaps increasing confidence in lesion localization. Furthermore, it may be a marker of bottom of sulcus dysplasia (BOSD), a peculiar type of FCD. Crucially, because subtle blurring is often seen at the bottom of sulci in patients with otherwise normal MRI, MAP may resolve the issue of whether those represent true abnormality.

A novel variant of GJB1 related to demyelinating CMTX1 with tremor

Ana Beatriz Bataglia Sperandio[1], Laura Alonso Matheus Montouro[1]

[1]Centro Universitário Padre Albino, Faculdade de Medicina de Catanduva, Catanduva SP, Brazil.

Correspondence: Ana Beatriz Bataglia Sperandio; Email: anabsperandio@gmail.com.

Case presentation: Male, 55 years-old, of consanguineous parents (second cousins). After a fracture in his right ankle at the age of 34, he presented progressive foot deformities associated with paresthesias and weakness. After a few years, the condition progressed to the distal upper limbs associated with intense hand tremors. At

fifties, he needs a walking stick support. The patient has also morbid obesity, systemic arterial hypertension, diabetes mellitus type 2. He denies similar cases in family. On physical examination: atrophy of the thenar and predominantly hypothenar region, claw posture of fingers IV and V on the right and distal interphalangeal joint in swan head on fingers II, III, IV. Atrophy and weakness of legs and feet. High-frequency, medium-amplitude postural tremor in the upper limbs. Global areflexia. Severe sensory ataxia. Distal anormal proprioception. Electroneuromyography: no sensory action potential obtained in the four limbs, motor neuropathy with a primarily demyelinating pattern in the upper limbs (prolongation of distal motor latency and velocity of the compound muscle action potential < 20m/s) and severe neuropathy by non obtained motor potentials in lower limbs. Commercial panel of hereditary neuropathies reveals a hemizygous mutation in the GJB1, variant NM_000166 .6:c.120dup:p.(Glu41Argfs*6). **Discussion:** A large cohort with 160 cases of CMTX1, motor nerve conduction velocity (MNCV) of ulnar and median ranged to 35.0±5.7 and 33.7±5.0, respectively. Therefore, the present case has MNCV far below compared to the majority, reiterating the electrophysiological heterogeneity present in CMTX1. Patients with classic CMT disease phenotype plus tremor were known as Rossy-Lévy Syndrome, usually associated with CMT1A. Tremor is unusual in CMTX1 and has been described in some diseases variants. The c.-17G> A variant, referred by Tomaselli et al, was described in 5 male patients who had postural tremor. Other variants in literature associated with tremor: c.-170T> G, c.-17+1G> T, p.Ala39Val, c.278T> A, p.Arg-164Trp, p.Ile202Asp, p.Trp132Valfs*14, p.A271Lfs*121, p.R183S, c.303dup. By contrast, the Korean cohort by Hong et al, points out that 35% have tremor (21 different variants, some of which are Korean-specific). In Brazil, tremor in the lower limbs in two siblings with p.Trip132Arg was described by Nishiyama. Therefore, this present case has high-frequency postural tremor as one of his symptoms. This variant leads to a change in the reading frame by replacing a glutamic acid with an arginine and consequently early arrest of protein translation, resulting in a truncated protein. This variant is absent in gnomAD, scientific literature and ClinVar. By correlating the phenotype with the type of variant, the potential of its pathogenicity is very high. **Final comments:** This case contributes with a new variant of GJB1, corroborates the electrophysiological heterogeneity and reinforces the phenotypical association of CMTX1 with tremor.

https://doi.org/10.5327/CBN240040

A portable device for assessing ankle angles during gait in post-stroke individuals: a prototyping study

Tatiana Souza Ribeiro[1], Raiff Simplício da Silva[1], Daiane Carla Rodrigues Cardoso[1], Vitor Vale Pereira[1], Lígia Pablícia Lopes Dantas[1], Maria Amanda Ferreira Quirino[1], Larissa Araujo Gomes[1], Aline Braga Galvão Silveira Fernandes[1], Jefferson Doolan Fernandes[2]

[1]Universidade Federal do Rio Grande do Norte, Natal RN, Brazil.
[2]Instituto Federal do Rio Grande do Norte, Parnamirim RN, Brazil.

Correspondence: Tatiana Souza Ribeiro; Email: tatiana.ribeiro@ufrn.br.

Background: Individuals after a stroke commonly experience gait alterations. Limitations in ankle range of motion are among the most common, particularly reduced dorsiflexion during the pre-swing phase and initial contact. Assessing ankle joint angles during gait can assist rehabilitation professionals in planning therapies to improve gait. Portable devices using inertial sensors offer excellent cost-effectiveness for this assessment. However, to the best of our knowledge, no studies have used this technology for this purpose in this population. **Objective:** This study aims to develop and preliminarily test the "Portable device for kinematic gait assessment of individuals post-stroke: DAMA" - a portable device using inertial sensors to obtain ankle angle measurements during the gait of post-stroke individuals. **Methods:** This is a cross-sectional prototyping study. It preliminarily included 3 healthy individuals aged between 20 and 70 years. For the test, the participants were equipped with the DAMA device and Qualisys system® markers for simultaneous data collection by both systems. They walked 4 meters at their usual speed 10 times to collect data on the maximum dorsiflexion angle (MD), maximum plantar flexion angle (MPF), and ankle angles at initial contact (IC) and toe-off (TO). The averages of these measurements were recorded. In the statistical analysis, we compared the data obtained by the two systems using the Wilcoxon test. We also examined the correlations between the averages obtained by the device and those obtained by the Qualisys system® using Spearman's correlation coefficient. **Results:** The means obtained with Qualisys were: IC = -1.93(±0.39); TO= -8.11 (±1.57); MPF= -15.75 (±1.77); MD= 10.90 (±0.55). The means obtained with Qualisys were: IC =5.87 (±4.60); TO= 2,83(±1,96); MPF= -23.56 (±2.78); MD= 12.73 (±2.88). There was no statistical difference between the outcomes collected by the device and those collected by Qualisys: IC (p=0.109); TO (p=0.109); MPF (p=0.109); MD (p=0.285). There was a negative correlation for IC (r=-1.000; p< 0.01) and a positive correlation for MPF (r=1.000; p< 0.01), and a not statistically significant correlation for TO and MD (r=0.5; p=0.667). **Conclusion:** Comparing the two analysis methods revealed no statistical difference between them. However, the limited sample size hinders making precise inferences about their accuracy. The correlation found may suggest good performance of the device for MPF. A larger sample size will be needed for further validation of DAMA in measuring ankle joint angles.

A pure dysautonomic variant case of Guillain-Barré syndrome

Olga Cassol Silva[1], Joana Laurindo da Silva[1], André Luiz Pereira Martins[1], Carolina Aparecida Donofrio Santos Costa[1], Maria Eduarda Andreatta[1], Mariana Costa Borges[1], Cristine Koehler[1], Gabriela da Silva Cremonese[1], Rafael Marques Mendes[1], Ana Magda da Silva Bruscato[1]

[1]Hospital Governador Celso Ramos, Florianópolis SC, Brazil.

Correspondence: Olga Cassol Silva; Email: olgacassol@hotmail.com.

Case presentation: A 17 year-old female was transferred to a tertiary hospital due to orthostatic intolerance. She was previously healthy. 20 days before the presentation, she had an episode of abdominal pain with diarrhea, was evaluated in a local hospital, diagnosed with urinary infection and discharged with a 3 day course of Ciprofloxacin. After 2 days, she progressed with intense myalgia, fever, nausea and retro orbital pain and a day later with cough and odynophagia. She also had an episode of loss of consciousness that made her come to the ER and be admitted due to hyponatremia and leukocytosis. After laboratory analysis and thorax and abdomen TC exams, she was diagnosed with Chikungunya and atypical pneumonia, treated with Azithromycin and Ceftriaxone and discharged with only residual cough and mild myalgia. After 2 days, she was again transferred to the hospital with episodes of loss of consciousness related to orthostatic position. Her physical exam was normal (including sensitivity, strength and reflexes), except for orthostatic hypotension with no compensation of heart rate. Her blood pressure in lying position was 100x70mmHg and in sitting position after 1 and 3 minutes was 60x40mmHg. She didn't tolerate stand up position and had syncope episodes when tried. Laboratory analysis, head CT, electrocardiogram and echocardiography did not show abnormalities. Cerebrospinal fluid (CSF) analysis showed proteino-cytologic dissociation (1 cell to 90 proteins), glucose of 56 and 10 red blood cells. Electroneuromyography (EMG) revealed slowing of late responses (F waves) associated with incipient signs of sensory, axonal and asymmetric peripheral neuropathy. She was diagnosed with an atypical Guillain-Barré Syndrome (GBS) secondary to Chikungunya infection and treated with a 5 day course of intravenous Immunoglobulin with little improvement. She was discharged with Duloxetin and Fludrocortison for orthostatic hypotension, regarding a mild anxiety underlying condition, and oriented to wear compression socks. At her one-month revaluation consult, she had improved and was well tolerating sitting position and progressing with attempts of upright position during physiotherapy. **Discussion:** This case presents an atypical presentation of GBS, confirmed by typical CSF and EMG findings. Literature data estimates an autonomic dysfunction in ⅔ of all SGB, but the prevalence of a 'pure' dysautonomic syndrome is unknown. Regarding these patients, mortality rate is up to 7%, which reinforces the importance of early monitoring for respiratory or cardiovascular collapse. This patient had had 2 episodes of loss of consciousness at home and a few during medical evaluation, with no evidence of arrhythmias or respiratory dysfunction. **Final comments:** This case report reinforces the importance to keep a close eye on patients with atypical presentations after an infection condition in order to make a correct diagnosis to provide appropriate management and treatment.

A rare adult-onset leukoencephalopathy as a likely etiology of neurocognitive decline: a case report

Allefy Beltrão Albano[1], Alvaro José Porto Moreira[1], Ana Dolores Firmino Santos do Nascimento[2], Luziany Carvalho Araújo[1], Breno José Alencar Pires Barbosa[1], Fabrício Martins Veras[1], Letícia Klabinske Marques Monteiro[1], Clélia Maria Ribeiro Franco[1], Mariana de Almeida Cruz Silva[1], Matheus Goiana Novaes Correia Carvalho[1]

[1]Universidade Federal de Pernambuco, Hospital das Clínicas, Recife PE, Brazil.
[2]Hospital da Restauração, Recife PE, Brazil.

Correspondence: Allefy Beltrão Albano; Email: allefymed@gmail.com.

Case presentation: 28-year-old female patient presented to our service, in 2024, for investigation of a cognitive condition characterized by progressive memory loss and difficulty of planning and executing routine activities that has evolved over the last year, accompanied by depersonalization, infantilism, loss of self-care, minimal social provision and urinary and fecal incontinence. Family members reporting two short-term paroxysmal events in the last three months, characterized by sudden loss of consciousness accompanied by hypertonia, with no report of limb shocks. Companion reports the absence of similar cases in the family and the patient was previously functional for daily and instrumental activities of living, with no previous reports of cognitive dysfunction. On physical examination, she presented preserved strength and trophism, with hyperreflexia in the lower limbs, non-straight tandem gait, unmotivated and constant laughter (pseudobulbar affect), distal stereotypical movements with the hands and teeth grinding, with previous self-mutilation in the dental arches. Cognitive examination has made difficult by lack of cooperation, showing temporospatial disorientation, telegraphic speech, significant executive dysfunction, without aphasia and apraxia. Magnetic resonance imaging of the brain was performed, which showed involvement of the periventricular white matter with anterior predominance, symmetrical in sagittal T2/FLAIR sequences.

Complementary tomographic study demonstrated small calcifications adjacent to the anterior horns of the lateral ventricles. **Discussion:** Adult-onset leukoencephalopathy with axonal spheroids and pigmented glia (ALSP) is a rare degenerative disease (prevalence less than 1/1.000.000) of the white matter, with onset in the third decade, characterized by axonal and glial damage due to mutations in the CSF1R gene. Age at onset of less than 60 years, associated with at least two of the following findings: cognitive decline, pyramidal syndrome, extrapyramidal signs and epilepsy, associated with typical findings on brain neuroimaging demonstrating bilateral white matter lesions, periventricular, with frontal predominance associated to specific calcifications, make the diagnosis probable even in the absence of a confirmatory genetic test for the specific mutation. However, such diagnostic criteria for ALSP have limited overall sensitivity along with modest specificity, requiring a comprehensive approach based on Magnetic Ressonance patterns, as classic patterns such as the case in question. **Final comments:** ALSP can represent a unique diagnostic challenge, given its particular adult-onset presentation and the low number of cases described in the literature, with early recognition being essential given the poor prognosis and the potential for familial genetic testing with goal of genetic counseling.

https://doi.org/10.5327/CBN240043

A rare case of anti-MOG antibody positive encephalomyelitis following dengue infection

Raquel Maria Ayres Monteiro[1], Luis Otavio Caboclo[1]

[1]Faculdade Israelita de Ciências da Saúde Albert Einstein, São Paulo SP, Brazil.

Correspondence: Raquel Maria Ayres Monteiro; Email: raquelmamonteiro@gmail.com.

Case presentation: A 42-year-old female with history of breast cancer and currently on tamoxifen, was admitted for investigation of neurological complications following a recent symptomatic dengue infection. Seven days after onset of dengue, she began to exhibit bladder hesitation followed by urinary retention, abdominal pain, and absence of bowel movement. As her condition progressed, she developed lower limbs and hand grip weakness, and diplopia when looking to the left. Neurological examination indicated tetraparesis with muscle strength grade 4+, hyperesthesia and allodynia in T6 level, diplopia, horizontal conjugate gaze paresis, brisk reflexes, and no cognitive or language alterations. Brain MRI revealed high T2/FLAIR signal in the right cerebral peduncle and thalamus. Spinal MRI revealed extensive lesions with discrete high T2 signal along the cervical and thoracic cord, suggesting infectious, immune, or demyelinating etiology. Cerebrospinal fluid (CSF) showed lymphocytic pleocytosis and elevated protein. Viral panel in CSF was negative. Serum analysis revealed presence of anti-myelin oligodendrocyte glycoprotein (MOG) antibodies. Patient received high-dose methylprednisolone therapy for five days and underwent four sessions of plasmapheresis. After these interventions, the patient fully recovered, showing improved strength, normal balance and gait, and complete recovery of bladder function. **Discussion:** Dengue has been associated with neurological complications, directly through viral infection or indirectly through dysregulated immune responses. This is a rare of a patient with myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD) following dengue infection. MOGAD symptoms include optic neuritis, extensive transverse myelitis, acute disseminated encephalomyelitis, brainstem or cerebellar features, or cerebral cortical encephalitis. MOGAD can present as either a monophasic or relapsing disease course, and MOG-IgG cell-based assays are important for diagnostic accuracy. Most patients experience good to excellent visual and motor recovery following corticosteroid and plasmapheresis therapy. However, permanent bladder, bowel, or sexual dysfunction can occur. The effective management of this patient underscores the potential for immune-mediated processes in post-dengue neurological disorders and suggests that early intervention can lead to significant recovery. **Final comments:** Autoimmune encephalomyelitis following dengue infection, particularly when associated with anti-MOG positivity, is rare and underscores the complexity of neurological manifestations in dengue. Early recognition and appropriate treatment are essential for a good prognosis.

A rare case of cerebellar progressive multifocal leukoencephalopathy in a patient with HIV and subacute ataxia

Pedro Schmidt dos Reis Matos Figueiredo[1], Johnatan Felipe Ferreira da Conceição[1], Flávia de Aguiar Machado[1], Lucas Ladeira de Lucas[1], Helena do Amaral Barreto[1], Caroline Bittar Braune[1]

[1]Universidade Federal Fluminense, Hospital Universátio Antonio Pedro, Departamento de Neurologia, Niterói RJ, Brazil.

Correspondence: Pedro Schmidt dos Reis Matos Figueiredo; Email: pedrosch2010@gmail.com.

Case presentation: A 40-year-old female presented with a one-week history of uncoordinated movements and difficulty walking, accompanied by brief episodes of vertigo. She was diagnosed with HIV approximately 3 months before and since then was regularly on antiretroviral therapy (TDF + 3TC + DTG) and sulfamethoxazole-trimethoprim for neurotoxoplasmosis treatment. On neurological examination, she exhibited debilitating imbalance while standing, significant ataxia on finger-to-nose and heel-to-shin tests bilaterally and bilateral horizontal nystagmus. Laboratory tests showed a viral load of 600 copies/ml and a CD4 cell count of 113 cells/ml. Brain magnetic resonance imaging (MRI) revealed a lesion hyperintense on T2 and FLAIR sequences in the left cerebellar hemisphere, sparing the dentate nucleus, suggestive of the "shrimp sign" described in cases of progressive multifocal leukoencephalopathy (PML) (Figure 1A). Initial cerebrospinal fluid (CSF) analysis was normal, including PCR for John Cunningham (JC) virus and, therefore, no specific treatment was started, and the patient remained hospitalized for follow-up. One month after admission, a new brain MRI was performed, now showing bilateral cerebellar lesions with the "shrimp sign" appearance (Figure 1B), and a new CSF PCR for JC virus was requested and returned positive, thus establishing the diagnosis of PML. **Discussion:** Cerebellar ataxia in HIV patients can have metabolic, infectious, vascular, or autoimmune etiologies, and may or may not be related to the presence of the retrovirus itself. PML is an opportunistic demyelinating disease of the central nervous system, associated with the presence of the JC polyomavirus typically in patients with CD4 counts < 200 cells/ml, and can manifest as an ataxic syndrome due to asymmetric involvement of the cerebellum. The shrimp sign on brain MRI has high sensitivity and specificity for the diagnosis of cerebellar PML. The diagnosis of PML without histopathological findings is based on a combination of typical clinical and neuroimaging findings associated with JC virus positivity in the CSF. When these three criteria are met, the diagnosis is definitive, according to AAN criteria. The treatment of HIV-associated PLM typically involves improving the patients immune status with the use of antiretroviral drugs, although the neurological deficits observed are usually irreversible. **Final comments:** New-onset cerebellar ataxia in HIV patients can be an uncommon clinical manifestation of PML and should be considered among the differential diagnoses, especially in patients with low CD4 cell counts. Despite the improved survival of these patients with the initiation of effective antiretroviral therapy, this condition remains serious and usually has a poor neurological prognosis.

A rare case of cryoglobulinemia associated with hepatitis B virus infection

Carolina Braga Moura[1], Ana Maria Porto Cortines Laxe Martins da Silva[1], Ana Luiza Morgado[1], Camila Castelo Branco Pupe[1], Osvaldo J. M. Nascimento[1]

[1]Universidade Federal Fluminense, Niterói RJ, Brazil.

Correspondence: Ana Maria Porto Cortines Laxe Martins da Silva; Email: analaxe@id.uff.br.

Case presentation: A 48-year-old Brazilian woman reported progressive numbness along the lateral aspect of her right leg, evolving into constant numbness in her left foot and intermittent hand numbness, accompanied by weakness in writing. Her medical history included a neonatal blood transfusion, HBV diagnosis at age 20, and recent entecavir initiation. She also had skin lesions diagnosed as urticaria, a thyroid nodule, and a family history of Charcot-Marie-Tooth disease type 1A (CMT1A). Upon neurological examination, the patient exhibited normal gait and muscle strength but presented with distal hypoesthesia, particularly in the lower limbs, asymmetry, and hyperchromic skin lesions. Nerve conduction studies indicated asymmetric sensory axonal polyneuropathy, predominantly in the lower limbs. Laboratory tests confirmed active HBV replication (reactive Anti-HBe, HBV DNA: 759 IU/mL) and cryoglobulinemia. Complement levels were notably reduced (C3: 83 mg/dL, CH50: < 12.8 IU/mL). Genetic testing for CMT1A was negative. Initial treatment with oral prednisone (1 g/kg) and entecavir was ineffective, leading to the initiation of plasma exchange. After one month, the patient experienced persistent numbness in her left foot, but her overall neurological condition improved. Sensory responses, including vibration, tactile, and pain sensation, showed slight improvement. Post-treatment, cryoglobulins were undetectable, and complement levels normalized. **Discussion:** Cryoglobulins are often associated with underlying conditions such as chronic viral infections, chronic liver or kidney disease, autoimmune diseases, lymphoproliferative disorders and genetic factors. Hepatitis C virus (HCV) infection has been the most common etiology associated with cryoglobulinemia, with over 90% of mixed cryoglobulinemias (MCs) linked to HCV. This case underscores the rare occurrence of cryoglobulinemia due to HBV. The presentation with axonal polyneuropathy and skin lesions mimicked other neuropathies, complicating diagnosis. The persistence of symptoms despite initial treatment highlights the necessity for alternative therapeutic strategies such as plasma exchange. **Final comments:** This case contributes to the understanding of cryoglobulinemia associated with HBV, emphasizing the importance of considering HBV in differential diagnoses of cryoglobulinemia. It also underscores the need for vigilant monitoring and flexible treatment approaches to manage this rare but significant complication. The findings highlight the necessity for further research to better understand the pathophysiology and optimal management of HBV-related cryoglobulinemia, potentially improving outcomes for similar patients in the future.

A rare case of hemichorea secondary to giant perivascular space: a case report

Rafael Saliba Helmer[1], Mayko Nascimento Merscher[1], Camila Caroso Lobo[1], Verena Miranda de Souza[1], Maria Paula Oiticica de Jesus[1], Thiago Ganho[1], Luiz Fernando de Oliveira Urzeda[1], Laura Araujo Paulino[1], Walderico Silva Machado Filho[1], Raissa Gomes Castro e Souza[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Rafael Saliba Helmer; Email: rsalibahelmer@gmail.com.

Case presentation: A 67-year-old male patient was brought to the emergency department due to his daughter's observation of involuntary movements in his right hemibody. The onset of symptoms remained uncertain as the patient had not initially perceived the movements. His medical history included multiple myeloma, which had shown a complete response to chemotherapy and autologous bone marrow transplant in 2022, as well as chronic obstructive pulmonary disease and hypertension. Neurological examination revealed choreiform movements predominantly affecting the distal aspect of the right hemibody, including the ipsilateral hemiface. Brain CT and angio-CT revealed no significant findings apart from an oval hypodensity in the left nucleocapsular region. Subsequent 3T brain MRI revealed an enlarged perivascular space in the left nucleocapsular and sublenticular regions, measuring 1.6x1.6 centimeters. All laboratory tests, including metabolic, hematological, and rheumatological profiles, showed no alterations. Further investigation failed to identify additional conditions justifying the observed symptoms. **Discussion:** Perivascular spaces, typically asymptomatic, may lead to neurological symptoms when extremely enlarged, termed tumefactive Virchow-Robin spaces. Despite the limited literature discussing the consequences of such enlargement, rare symptomatic cases, including chorea, have been documented. The mechanism linking perivascular space enlargement to movement disorders remains unclear, potentially involving proximity to the basal ganglia or disruption of adjacent white matter tracts. This case underscores the importance of considering enlarged perivascular spaces in the differential diagnosis of unilateral movement disorders, urging further research into their pathophysiology for improved diagnostic and management strategies. **Final comments:** Our case highlights that giant perivascular spaces, particularly near the basal ganglia, can present as unilateral movement disorders, such as chorea, despite typically being asymptomatic. This underscores the importance of considering this rare etiology in the differential diagnosis of such conditions, emphasizing the need for comprehensive evaluation and awareness among clinicians.

A rare case of hypnic headache after meningitis in a patient with HIV, primary or secondary? Case report

Juan Sebastián Sánchez León[1,2], Marcela Nataly Parra Alvarez[1,2], Renato Dumba Monteiro de Castro[1,2], Tais Luise Denicol[1,2], Julian Gomez Gonzalez[1,2], Carolina Matte Dagostini[1,2], Karla Sarai Sandoval[1,2], Pedro Hall Ruschel[1,2], Liselotte Menke Barea[1,2]

[1]Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre RS, Brazil.
[2]Irmandade da Santa Casa de Misericórdia de Porto Alegre, Porto Alegre RS, Brazil.

Correspondence: Juan Sebastián Sánchez León; Email: juansebastian1516@hotmail.com.

Case presentation: A 76 year old female started 5 years ago with holocranial headache during sleep that cause awakening between 3 and 4 hours in the morning with duration of 20 to 30 minutes without response to treatment with simple analgesic, significantly affecting her quality life. Patient didn't have previous history of headache. One year before starting headache, she had an bacterial meningitis and was diagnosed with HIV, after treatment of meningitis she started antiretroviral therapy. First she started with intermittent bilateral temple headache from mild to moderate intensity, but after few months, headache change presentation to current characteristics. For these symptoms was decided to make a cerebrospinal fluid analysis that was normal and an brain MRI that showed ventricular enlargement disproportionate to cerebral atrophy, being suspected of normal pressure hydrocephalus; however, she didn't have compatible clinical characteristics, so that diagnosis was ruled out. Due to the characteristics of the headache we diagnosed of hypnic headache and started treatment with Indomethacin 25 milligrams once at night. After treatment the patient improved significantly and she didn't have more episodes of headache. **Discussion:** Hypnic headache is a rare primary headache that is characterized by equal or more than 10 headache episodes for month during sleep that cause awakening, with duration from 15 minutes to 4 hours without cranial autonomic symptoms and without better accounted for other ICHD-3 diagnosis. It generally occurs after the age of 50, in the medical literature there are some reports of secondary hypnic headache cases being associated with brain tumors, vascular pathologies, obstructive sleep apnea, low glucose, nocturnal hypertension or associated with medications which in this case were discarded. Headache associated with meningoencephalitis according to ICHD-3 need a temporal association, parallel or on the onset of disease which contrasts with our case, reducing the probability of being secondary, even though there is no greater evidence of this probable association because hypnic headache is a rare type of headache. **Final comments:** Although hypnic headache is rare, it must be suspected in cases of headache during sleep that causes awakening in order to initiate treatment that improves the quality of life of the patients.

A rare case of spontaneous hypertensive pneumocephalus due to neurotuberculosis

Mayara Romero Canal[1], Mariana Tonon Giovannone[1], Natália Furlani Kassouf[1], Beatriz Gadel Medeiros[1], Natasha Soares Cutolo[1], Ana Luisa Vilela Sá Fortes[1], Fernando Pierini Costa[1], William Thiago Almeida Leite[1], Mauro Gomes Araujo[1], Eduardo de Almeida Guimarães[1]

[1]Santa Casa de Misericórdia de São Paulo, São Paulo SP, Brazil.

Correspondence: Mayara Romero Canal; Email: academico.mayara.canal@gmail.com.

Case presentation: A 78-year-old patient seeks emergency care due to a severe, pulsating headache associated with rhinorrhea that started 14 days ago and worsened over the last 2 days. He had hypertension, DM II, obesity and treatment for neurotuberculosis in childhood. On physical examination, translucent liquid was noted flowing through the nasal cavity associated with signs of meningeal irritation without other changes. initially a head tomography and CSF collection were performed which showed pneumocephalus with frontal air level and bone discontinuation in the E. sphenoid bone (Figure 1 and 2) in the presence of meningoencephalitis (More than 3600 cells with neutrophilic predominance). **Discussion:** Intracerebral aerocele is defined by the presence of gases in regions of the central nervous system and is most commonly observed after trauma, surgery and neoplasms, but rarely spontaneously in infections caused by gas-producing bacteria. Its evolution can be good (asymptomatic) or dramatic to the most aggressive form (hypertensive pneumocephalus) representing a medical emergency. Symptoms are varied (depending on intensity and location) with non-specific neurological deficits, convulsions and changes in the level of consciousness. When located in the posterior fossa, it can displace important structures and result in neurological shock, coma and brain death. For proper diagnosis, a cranial tomography is considered, the change is revealed by the Mount Fuji sign (pathognomonic). The mechanisms of the disease are explained by two main theories: Dandy ("ball valve") which highlights the compaction of gas due to an imbalance of external and intracranial pressure associated with the rupture of dural fissures at the base of the skull that are obstructed by brain structures once opened. And the second Horowitz ("inverted bottle effect") which points to the increase in negative pressure due to the reduction of CSF by external mechanisms with compensation of air entry to balance the pressure differential. **Final comments:** In the case described above, we hypothesized that cerebrospinal fluid rhinorrhea was one of the causes of the pneumatocele, which occurred due to the destruction of brain space connections and also to cerebrospinal fluid loss, involving both mechanisms described. These events can occur in diseases such as tuberculosis and histoplasmosis. The Nasal/sinusoidal infectious manifestation of Mycobacterium Tuberculosis causing the above findings is poorly documented in the medical literature. In general, we observe masses or granulomas in lesion sites associated with B symptoms. In the present case, the pulmonary form was previously treated in childhood, with reactivation occurring in adulthood as an extrapulmonary form, later progressing to sphenoid bone erosion, meningoencephalitis and spontaneous hypertensive pneumocephalus.

A rare case report: central venous thrombosis associated with a thoracic spontaneous cerebrospinal fluid fistula

Angelo Ponte de Freitas Campos[1], Rodrigo de Paiva Bezerra[1], Marcel Ken Uehara[1], Gisele Sampaio Silva[1]

[1]Hospital Israelita Albert Einstein, São Paulo SP, Brazil.

Correspondence: Gisele Sampaio Silva; Email: giselesampaio@hotmail.com.

Case presentation: We describe the case of a 35-year-old female patient with a history of spontaneous lower back pain for three weeks, accompanied by nausea, vomiting, and one episode of diarrhea. She denied any history of trauma. The day after the onset of symptoms, she developed an intense, oppressive headache, associated with photophobia and blurred vision. The headache worsened when upright and improved when lying down. Cerebral spinal fluid demonstrated only slight hyperproteinorachia, without pleocytosis and no increase in lactate. Cisternoscintigraphy demonstrated marked delay in cerebrospinal fluid circulation through the usual pathways. She underwent MRI and cranial angio-MRI, which, in addition to the signs suggestive intracranial hypotension, also demonstrated venous thrombosis in subacute evolution, partially recanalized, in the superior sagittal sinus, transverse sinuses, and more recent thrombosis in the cortical veins of the parietal convexities. Further investigation with myelotomography confirmed a ventral median cerebrospinal fluid fistula at the T1-T2 level. The patient underwent a blood-patch and fibrin glue procedure via bilateral foraminal T2-T3 and interlaminar blood-patch at L4-L5. For treatment of CVT she was anticoagulated with apixaban every 12 hours. **Discussion:** Cerebrospinal fluid hypotension headache is a rare and currently underdiagnosed condition. It is generally a cause of chronic headache, which can be spontaneous, more rarely, or secondary to other causes such as trauma, surgeries, cancers, or even congenital diseases. The diagnosis is challenging, as neuroimaging findings can be subtle. Therefore, a high level of suspicion is required, along with image evaluation by experienced radiologists. Magnetic resonance imaging (MRI) of the brain is preferable and could show some indirect and nonspecific signs. Myelotomography is considered the gold standard, although very limited. This exam can identify the exact site of epidural CSF leakage. The timing of diagnosis is crucial for the occurrence of complications, most of which are severe. Treatment involves clinical measures such as hydration and increased caffeine intake, with or

without the use of corticosteroids (conflicting data in the literature). Epidural Blood Patch (EBP) should be considered in patients refractory to clinical measures. **Final comments:** Cerebrospinal fluid hypotension is a rare and still underdiagnosed entity, but it is responsible for high morbidity associated with potentially severe complications. High clinical suspicion combined with insightful radiological interpretation is crucial for diagnosing this disease. Early diagnosis and therapeutic intervention can alter the natural history of the disease and reduce unfavorable outcomes.

A rare cause of clival mass: giant cell tumor case report and review of literature

Ligia Henriques Coronatto[1], Hennan Salzedas Teixeira[1], Roberto Sobocinski Castro[1], Thaís Rodrigues Barbosa Geraldo[1], Bruna Gutierres Gambirasio[1], Adrialdo José Santos[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Ligia Henriques Coronatto; Email: liscorona@hotmail.com.

Case presentation: A 16-year-old male referred horizontal binocular diplopia two months after a new-onset occipital headache started. Neurological examination revealed right eye abduction paresis. CT scan and later MRI evidenced an expansive lesion that seemed to originate from the clivus, partially calcified in the periphery, that occupied the suprasellar, sellar, and chiasmatic region, also affecting the nasal fossa and paranasal sinuses. MRI confirmed a non-enhancing heterogeneous lesion at this site. He was submitted to endoscopic transsphenoidal partial resection of the clival mass. Pathology discloses giant cells marked for CD68 at immunochemistry (osteoclasts). Histiocytosis markers such as S100 were negative; desmin (a myogenic marker present in myofibroblastic tumors and some sarcomas) was also negative. Ki67 was present in less than 1% of cells, indicating indolent growth. The tissue pattern and immunochemistry were compatible with Giant Cell Tumor of the Clivus. Two months after surgery, the patient's double vision resolved. Adjuvant radiotherapy was performed. In the following months, brain imaging showed tumor shrinkage. Eight months after the end of radiotherapy, the patient remains asymptomatic and MRI remains stable. **Discussion:** Giant Cell Tumor (GCT) is a benign osteolytic neoplasm, most common in young adults between 20 and 40 years old, mainly affecting the metaphyseal or epiphyseal region of the tibia and femur. It represents 4-10% of all primary bone tumors and presents locally aggressive behavior with, rarely, metastases. The pathophysiology is uncertain. Involvement of the skull is rare, accounting for less than 1% of all GCT cases. The sphenoid and temporal bones are more commonly affected. Clivus involvement is rare with very few reports in the literature. The most frequently reported symptoms of GCT of the clivus are headache and diplopia, often associated with increased intracranial pressure and sixth cranial nerve palsy. Total resection of the lesion is generally unfeasible requiring adjuvant therapy. Radiotherapy is most often used for residual tumors and local control. Despite the known efficacy of Denosumab (anti-RANKL monoclonal antibody) for the treatment of extracranial GCTs, little is known about the effectiveness of chemotherapy treatment for giant cell tumors of the clivus. Lines of adjuvant chemotherapy have been described using Doxorubicin, Cisplatin, Methotrexate, Zolendronate, and Raloxefin. **Final comments:** GCT of the clivus remains a diagnostic and therapeutic challenge due to its rarity and locally aggressive behavior. The difficulty in achieving total resection of the lesion requires adjuvant therapies for treatment optimization. Due to the rarity of this disease in the clivus, we describe this interesting case report with excellent response to resection and radiotherapy.

https://doi.org/10.5327/CBN240052

A rare cause of fecal and urinary incontinence after cerebrospinal fistula surgery: lumbosacral radiculopathy and cauda equina syndrome caused by intrathecal fluorescein - a case report

Amanda Miranda de Mendonça[1], Matheus Alves da Silva[1], Ana Luisa Vieira de Faria[1], Eduardo Mesquita de Souza[1], Rafael Bragança Rodrigues Matias[1], Alex Araujo Fernandes[1], Matheus Luís Braga Munareto[1], Christiane Monteiro de Siqueira Campos[1], Alex Machado Baeta[1], Marcelo Freitas Schmid[1]

[1]Hospital Beneficência Portuguesa, São Paulo SP, Brazil.

Correspondence: Amanda Miranda de Mendonça; Email: amanda.miranda.dv@gmail.com.

Case presentation: A 23 years-old female patient presented with hyaline rhinorrhea, compatible with spontaneous cerebrospinal fluid fistula, which was confirmed through a cisternography, and the patient underwent microsurgical correction of skull base fistula via endoscopic endonasal approach which required a lumbar puncture and intrathecal fluorescein injection . The patient presented epileptic seizures during weaning from sedation, controlled with intravenous lacosamide. During the postoperative care, the patient presented urinary and fecal retention, as well as hypoesthesia in the gluteal region. Her neurological exam showed no muscle weakness, and the only alteration was a hypoesthesia on the gluteal region. Abdomen and pelvis CT showed no alterations. Cerebrospinal fluid (CSF) analysis revealed 12 cells with lymphocytic predominance, 52mg/dL of proteins and 64mg/dL of glucose. Pelvic and lumbosacral plexus MRI revealed hypersignal in the left sciatic nerve, compatible with acute denervation. Electroneuromyography revealed acute motor axonal impairment of the pudendal nerves bilaterally, favoring the hypothesis of radiculopathy from S2 to S4. Infection and rheumatologic diseases were ruled out. Due to the CSF with an inflammatory pattern and the electroneuromyography and MRI, corticosteroid therapy was started with intravenous methylprednisolone 500mg for 3 days associated with urologic physiotherapy, with clinical improvement. **Discussion:** Lumbosacral radiculopathy is most commonly caused by nerve root compression. Noncompressive mechanisms, such as infection, trauma, inflammation, neoplasm and vascular disease are rare. Signs and symptoms vary with which nerve root is affected. The cauda equina syndrome is caused by an injury of two or more nerve roots constituting the cauda equina. Its typically associated with marked neurologic disability, presenting with bilateral leg weakness in multiple root distributions and perineal sensory symptoms, as well as bowel, bladder and sexual dysfunction due to involvement of the S2-S4 spinal nerve roots. Fluorescein is used intrathecally to localize with more precision cerebrospinal fluid fistulas on skull base. Fluorescein can cause weakness in the extremities, epileptic seizures, numbness and cranial nerve deficits, but these are rare and reversible. Studies show that intrathecal fluorescein can cause discrete meningeal reactions, such as an increase in cells between 24 and 48 hours after the procedure and an increase in neutrophils within 24 hours, with a subsequent decrease within 48 hours, usually asymptomatic. **Final comments:** We present a case report of a lumbosacral radiculopathy and cauda equina syndrome caused by the use of fluorescein, a rare case not found by our group in the literature.The use of fluorescein is usually safe, but unusual reactions may be present.

https://doi.org/10.5327/CBN240053

A rare differential diagnosis of bilateral optic neuropathy

Matheus Hisamitsu Facine[1], Humberto Ramos Crispim[1], Lucas Do Rego Barros Correa Martins[1], Caique Alberto Dosualdo[1], Gabriel Pina Paiva[1], Andressa Regina de Mello Galego[1], Marina Gaglione Teodoro da Silva[1], Murilo Wendeborn Rodrigues[1], Ricardo Kendy Nishiuchi Paiva[1], Renato Arantes Lima Simoes[1]

[1]Faculdade de Medicina de São José do Rio Preto, São José do Rio Preto SP, Brazil.

Correspondence: Humberto Ramos Crispim; Email: hrcrispim.uni@gmail.com.

Case presentation: A forty years old woman, started within 04 days before admission a new onset headache, pulsatile, high intensity, associated to conjunctival hyperemia and lacrimation. Evolving in 02 days, with bilateral blurred vision acuity, with central scotoma, which was progressively getting worse and affiliated to pain when moving her eyes. She denied any other symptom. Her background history was unremarkable as well as her family history.The general and neurological examination was normal, except by the central scotoma and conjunctival hyperemia. She could count fingers at 10 inches bilateral, pupillary reflex was normal and she has no Relative Afferent Pupillary Defect (RAPD) or dyschromatopsia. The intraocular pressure(IOP) and extrinsic eye movement was normal as well. There was no apparent corneal deposit. Fundus examination (FE) noticed diffuse bilateral serous retinal detachment and pockets of fluid in the outer retinal on the left eye. No dermatologic or hearing alteration was seen. Her blood exams, serology and rheumatological tests were normal. Sedimentation velocity was slightly high (49mm/h).Cerebrospinal fluid (CSF) shows pleocytosis and proteinorrachia with normal opening pressure. Confirmed intrathecal production of Immunoglobulin G (IgG). Serum Antibody Anti aquaporin-4 receptor (AQP-4) negative and Oligoclonal Band (BOC) CSF was negative? The Brain Magnetic Resonance Imagem (MRI) showed diffuse parietal thickening with gadolinium enhancement and deposit on eyeball, as well as, posterior wall vitreous chamber thickening. Optical Coherence Tomography (OCT) showed retinal detachment in a bullous serous pattern. Fundus Flurouscein Angiography (FFA) showed multiple bacilar detachment and typical pinpoint leaks - presuming Vogt-Koyanagi-Harada (VKH) syndrome. The patient filled criteria for VHK incomplete syndrome. The treatment was promptly started using Methylprednisolone 1 gram/day for 5 days. She had an excellent improvement in headache and visual acuity: 20/60 left eye and 20/80 right eye was discharged using prednisone 1mg/kg/day. On the 14 days follow up the FE showed resolution of serous detachment and the control OCT showed presence of pigmentary detachment in the right eye, and improvement of retinal detachment. **Discussion:** VKH is rare systemic disease involving various melanocyte-containing organs. This exact cause remains unknown, but there are evidences of an autoimmune process against an antigenic component on the melanocyte configuring an inflammatory T-cell-mediated immune response. The early treatment is essential to avoid complications and permanent vision loss. In this case the patient filled criteria for Incomplete VHK, she had a good improvement on visual acuity after using corticosteroid, confirmed on OCT returned of foveal depression and restored retinal parallelism layer. **Final comments:** This case report highlighted the importance of fast diagnosis VHK to a better prognosis and recovery.

https://doi.org/10.5327/CBN240054

A rare form of genetic X-linked intellectual disability: case report

Ana Beatriz Landim Ribeiro[1], Luciana Amorim de Matos[1], Giovana Rodrigues França[1], Lisandra Mesquita Batista[2], Carlos Alexandre Gomes Farias[1], Paulo Victor Zattar Ribeiro[2], Lucca Biolcati Palavani[3]

[1]Universidade Nove de Julho, São Paulo SP, Brazil.
[2]Universidade de São Paulo, Faculdade de Medicina de Ribeirão Preto, Hospital das Clínicas, Ribeirão Preto SP, Brazil.
[3]Max Planck University Center, Berlim, Germany.

Correspondence: Ana Beatriz Landim Ribeiro; Email: ablr2016@icloud.com.

Case presentation: We presented a 12-year-old boy who started a genetic investigation because of speech and facial dysmorphisms. He was born at 40 weeks of gestation without any complications via Cesarean operation. His birth length was 49cm, and his birth weight was 3.100. During his childhood he was presented with development delay, and still does not speak sentences, he only says the word "no". Today he remains with mild intellectual disabilities. As for other important manifestations, he presented with supratentorial ventriculomegaly, short stature, and behavior alterations such as aggressivity. He also presented with normal initial investigation for FMR1 disorders and karyotype revealing 46XY as result. As dysmorphic findings, we could notice short stature, malar flattening, thick vermillion of the lips, large mouth, sparse eyebrows, and micrognathia. He has no history of genetic diseases in her family, but his mom and his two brothers also had mild intellectual disabilities. He was submitted to a CGH array analysis, and it was found a pathogenic variant XQ25(123832142_124348427)X2 compatible with the diagnosis of Xq25 duplication syndrome. **Discussion:** It's known that Xq25 duplication syndrome is an X-linked neurodevelopmental disorder, characterized by delayed development and intellectual disability associated with abnormal behavior and dysmorphic facial features. To date, there are only thirty-two documented cases in scientific literature. We have described the clinical case of a patient presenting with many of the common features of the Xq25 duplication syndrome. A comparison of our patients phenotype with those previously reported showed similarities, including severe speech delay, facial features and intellectual disabilities. With that being said, it's known that the Xq25 duplication syndrome seems to be a complex condition mainly characterized by neuro psychomotor delay, intellectual disabilities, speech disturbances, epilepsy, brain abnormalities, and organ defects. Multiple X-linked intellectual disabilities are described every year and this reminds us of the importance of differential diagnosis when encountering a boy with intellectual disabilities. **Final comments:** Further detailed reports are certainly needed to better characterize the spectrum associated with this condition and, ultimately, help physicians to assist these patients comprehensively.

https://doi.org/10.5327/CBN240055

A relapse of coccidioidomycosis meningitis without pulmonary involvement associated with obstructive hydrocephalus and ischemic stroke successfully treated with voriconazole and amphotericin B: a case report

Ana Luisa Vieira de Faria[1], Matheus Alves da Silva[1], Amanda Miranda de Mendonça[1], Eduardo Mesquita de Souza[1], Rafael Bragança Rodrigues Matias[1], Alex Araujo Fernandes[1], Matheus Luís Braga Munareto[1], Christiane Monteiro de Siqueira Campos[1], João Antonio Garreta Prats[1], Alex Machado Baeta[1]

[1]Hospital Beneficência Portuguesa, São Paulo SP, Brazil.

Correspondence: Ana Luisa Vieira de Faria; Email: alfaria96@gmail.com.

Case presentation: A 17-year-old male patient presented with a history of persistent headache. He was previously diagnosed and treated in the USA for coccidioidomycosis meningitis. His infection was complicated with obstructive hydrocephalus that demanded a ventriculoperitoneal shunt and also he developed an ischemic stroke. He was discharged back to Brazil with Fluconazol 1000 mg/day as a maintenance treatment presenting to our hospital after the new headache. His initial neurological examination was unremarkable. The initial CT scan revealed recurrence of the hydrocephalus, and the valve was regulated by the neurosurgery team. Suspecting of relapse of meningitis causing the valve dysfunction, an MRI was made and revealed dilation of the supratentorial ventricular system, diffuse leptomeningeal thickening and impregnation of the basal cisterns, including mesial temporal structures, third ventricle, midbrain, pons, trigeminal, abducens, facial and vestibulocochlear nerves. Also, a cerebrospinal fluid analysis revealed 308 cells with lymphocytic predominance, 188 mg/dL of proteins and 5 mg/dL of glucose. His initial opening pressure was 27 cmH2O. An initial infectious and immunodeficiency screening was negative. We associated Amphotericin B 5 mg/kg, with a subsequent switch from Fluconazole to Voriconazole. He evolved with clinical, radiological and cerebrospinal fluid improvement, being discharged with Voriconazole as a maintenance treatment. **Discussion:** Coccidioidomycosis meningitis is caused by a dimorphic fungus. They are endemic in regions of the southwestern United States, some areas of Central and South America. Spread occurs hematogenously after initial pulmonary infection and can cause destructive meningeal lesions. Meningitis is the most lethal complication of coccidioidomycosis infection. The most common clinical manifestation is persistent headache, present in 75% of patients. Signs of meningeal irritation on physical examination are usually absent; neck stiffness is rarely present. The cerebrospinal fluid presents an increase in cellularity, with a lymphocytic predominance. Glucose is usually reduced and is associated with a significant increase in proteins. We rarely find the organisms in direct microscopic examination of the CSF, if present it is an indication of a high fungal disease burden. On imaging examination we can find leptomeningeal enhancement, cerebral infarction resulting from vasculitis of small and medium vessels, in addition to hydrocephalus, which is the most common complication of coccidioidomycosis meningitis. **Final comments:** We present a case report of a rare infection in Brazil, to highlight the importance of correct follow up of these patients to manage the complications and infectious relapses.

https://doi.org/10.5327/CBN240056

A slow and complex neurodegenerative disorder with predominant primary lateral sclerosis features in a patient with a erbb4 variant

Case presentation: A 69-year-old woman began experiencing symptoms in 1998 with rigidity in her toes, hands, and legs, as well as unspecified headaches. Her condition progressed to a gradual loss of movement, resulting in occasional falls and domestic accidents. She was diagnosed with Primary Lateral Sclerosis (PLS) in 2005 and started the use of riluzole. By 2006, she started to need a cane, progressed to a walker in 2012, and has been wheelchair-dependent since 2017. Current complaints include occasional paresthesias, pulsating headaches and persistent sharp pains in the lower limbs (predominantly left), starting in 2024. She performs basic daily activities with grab bars. She also developed nighttime hallucinations, consisting of hands entering through the window and rats on the ceiling, nausea before and during lunch, and urinary urge incontinence for 16 years. Her appetite and sleep are preserved. Past medical history includes congestive heart failure (CHF), arrhythmia and generalized anxiety disorder (GAD). She reports an extensive family history of dementia and psychiatric diseases and denies cases of cancer in relatives. Riluzole was discontinued in 2013 after repeated Electromyography (EMG) did not reveal involvement of lower motor neurons. The neurological examination revealed normal Mini-Mental State Examination (MMSE), mild hypomimia, mixed dysarthria (cerebellar and pyramidal) with voice and head tremor and hypophonia, slight saccadic dysmetria with ocular instability, spastic tetraparaparesis with action tremor predominantly on the left, cerebellar symptoms (index-finger to nose test dysmetria, dysdiadochokinesia), postural arm tremor, mild parkinsonism (bradykinesia, intention, and postural tremor) and rare fasciculations, global hyperreflexia (grade 4) with Babinski and Hoffman signs. She does meet criteria for essential tremor and with abnormal bilateral tremor on Archimedes spiral test. Genetic testing (June 2022) reveals the c.3182G> A variant in the ERBB4 gene, in heterozygosity, with uncertain significance. Neuromagnetic resonance (11/03/22) showed Fazekas score 2 for leukoaraiosis, MTA score 1 for hippocampal atrophy, and GCA score 1 for global cortical atrophy, with no hot bun cross sign in the brainstem. **Discussion:** Current knowledge about the ERBB4 gene indicates that it encodes a cell surface tyrosine kinase protein for neuregulins and EGF family members, regulating the development of the Central Nervous System. Although its significance is uncertain, the ERBB4 variant found suggests it may cause complex pathologies, including pyramidal involvement, parkinsonism, and cerebellar findings **Final comments:** This related case seems to expand the spectrum of ERBB4 related neurodegenerative disease, whose gene is currently associated with HER4 and ALS19. The case report was obtained with the patients understanding and written consent, agreeing to the publication of their clinical information

A strengthening protocol based on core tasks in Parkinson's disease: a pilot study

Clara Rezende Rocha[1], Maria Eduarda Salum Aveiro[1], Caroline Rodrigues Osawa[1], Pedro Henrique Souza de Andrade[1], Artur Souza dos Santos[1], Daniel Alves de Menêzes[1], Thiago de Andrade[1], Gustavo José Luvizutto[1], Luciane Aparecida Pascucci Sande[1]

[1]Universidade Federal do Triângulo Mineiro, Uberaba MG, Brazil.

Correspondence: Clara Rezende Rocha; Email: d202010477@uftm.edu.br.

Background: Parkinson's disease (PD) is a neurodegenerative disease whose progression impairs the performance of activities of daily living (ADLs). Its main symptoms are tremor, bradykinesia, muscle rigidity and postural instability, making neurofunctional rehabilitation important for these individuals. Physical exercises are essential for reducing the PD progression and optimize the social participation of individuals. Despite numerous studies on the dose and type of exercise to be performed in PD, no strengthening protocol was found aimed the rehabilitation of core tasks. **Objective:** This is a pilot study that proposes a strengthening protocol aimed at maintaining the independence of PD patients in performing ADLs, with a focus on training core tasks (standing, walking, stepping up/down, and reaching/grasping/manipulating objects). **Methods:** This is a longitudinal study and case report with a 70-year-old man with PD for 12 years and stage 3 on the Hoehn and Yard scale. The protocol contains 9 exercises to be performed in ambulatorial environment and is divided into five weeks with the possibility of progression and regression in terms of difficulty and intensity. Fifteen sessions were realized and the volunteer was assessed using the Unified Parkinson's Disease Rating

Scale adapted by the Movement Disorder Society (MDS-UPDRS), the Dynamic Gait Index (DGI), the Montreal Cognitive Assessment (MoCA) and the Parkinson's Disease Questionnaire (PDQ - 39). **Results:** The protocol included exercises for reaching (anterior, superior and diagonal), step up and down (with and without resistance), free and resisted lower limb exercises aimed at postural transfers, trunk strengthening, gait and balance. The sessions lasted 40 minutes and for each exercise was performed 3 series of 8 to 12 repetitions, which were associated with cognitive double tasks. After five weeks, improvements were seen in the UPDRS (12 points) and DGI (1 point) scores, as well as in the Mobility (12.5%), ADLs (2.5%), cognition (16.67%) and communication (6.25%) domains of the PDQ-39. There was a worsening in the scores of the other domains of the PDQ-39 (emotional well-being, stigma, social support and bodily discomfort) and the MoCA. **Conclusion:** This study developed a strengthening protocol for PD rehabilitation. The protocol was applied for five weeks, three times a week, for 40 minutes to an individual with PD. Improvements were seen in dynamic balance, motor symptoms, mobility, performance of ADLs, cognition and communication, as recorded by the DGI, UPDRS and PDQ-39 scales. No improvement was observed in executive functions and memory (MoCA), as well as in emotional well-being, stigma, social support and bodily discomfort. The protocol can be applied in an outpatient setting and needs to be applied to more volunteers to assess its effectiveness and feasibility.

A telehealth approach to developmental delays: assessing outpatient children in São Carlos, São Paulo

Guillermo Andrey Ariza Traslaviña[1], Melissa Giannina Sueros Torres[2] , Giovanni Scuracchio Baccala[2], Amanda Dourado Souza Akahosi Fernandes[2]

[1]Universidade de São Paulo, Faculdade de Medicina de Ribeirão Preto, Ribeirão Preto SP, Brazil.
[2]Universidade Federal de São Carlos, São Carlos SP, Brazil.

Correspondence: Guillermo Andrey Ariza Traslaviña; Email: gtraslavina@fmrp.usp.br.

Background: On March 11, 2020, the World Health Organization officially declared COVID-19 a global pandemic. This announcement precipitated both individual and substantial collective challenges. In response, governments across the globe implemented specific regulations, which included strengthening regulatory frameworks and expanding remote healthcare services. Concurrently, there was a markedly high suppressed demand for outpatient services, particularly for children experiencing developmental delays. Consequently, in acknowledgment of the potential advantages of telehealth for multidisciplinary evaluations, a hybrid approach-integrating both remote and face-to-face methods-was instituted to assess children with suspected neurodevelopmental disorders. **Objective:** describe the clinical and demographic profiles of children evaluated through a multidisciplinary protocol, including neuropediatric, occupational therapy and psychology, between March 2021 and February 2023 at the Federal University of São Carlos. **Methods:** A general online invitation was sent to public and private health clinics, as well as schools. Each participant underwent at least three independent remote consultations, conducted by a team consisting of specialists in each specialty and undergraduate students. Each interview was scheduled according to the availability of the family members and followed a pre-established guide. After completing the initial interview process, a subsequent meeting involving only specialists was scheduled to elucidate the primary diagnostic hypotheses. Following this, a direct consultation with all the specialists was arranged, during which a physical and behavioral assessment was conducted in a controlled environment. At the end of the process, a final document was produced summarizing the consultation, primary diagnosis, and recommendations for treatment or follow-up. The activity concluded in February 2023. **Results:** A total of 94 children were evaluated, including 66 males (70.2%) and 28 females (29.8%). The majority (63%) were of White race, with an average age of 35.7 months. A high percentage had prenatal follow-up (88%), born at term (63%), and had a normal birth weight (63%). Approximately 75.8% were attending school. The evaluation revealed that 39.1% of the children showed delays in motor milestones, 75.8% in language development, and 65.2% in social skills. Subsequent follow-ups diagnosed 64% of the children with autism spectrum disorder. Other diagnoses included developmental delays due to lack of stimulation, epilepsy, reactive disorders, and other developmental and language conditions. **Conclusion:** This research highlights the effectiveness of a hybrid telehealth model, as a strategy to mitigate the high demand for specialized pediatric evaluations. The observed high frequency of autism among the participants may be attributed to preliminary screening by pediatricians or other health professionals prior to their inclusion in the activity.

[4]Hospital Alemão Oswaldo Cruz, São Paulo SP, Brazil.

Correspondence: Gabriella Chinaglia Zanin; Email: gabriella.zanin@aluno.fcmsantacasasp.edu.br.

Background: Mild Cognitive Impairment (MCI) is considered a transitional stage between the expected effects of aging in the patient's cognition, and the pathological changes of Alzheimer's disease. The early detection of this transitional stage has grown in importance recently, as new therapies, mainly monoclonal antibody, have been approved by the FDA for Alzheimer treatment, and have shown better efficacy when introduced in early stages of the disease progression. Furthermore, several modifiable quality-of-life related factors influence the conversion rate. **Objective:** The present study's aim was to compare the conversion rate of MCI to Alzheimer in the last 5 years between a US and a Brazilian cohort of patients originally diagnosed with MCI. **Methods:** An electronic medical record aggregator called TriNetX was used to anonymously obtain the patient data used in the study, using exclusively hospital related records. The US cohort was built using a US-only database via selecting patient above 50 years old, who received the MCI diagnosis in the last 5 years time frame and had never received an MCI or Alzheimer diagnosis before. The Brazilian cohort was built using the same criteria as the US but pulled data from the database of a reference neurology center in São Paulo. The MCI diagnosis was considered the index event, while the outcome was an Alzheimer's disease diagnosis within 5 years of the index event. Risk was obtained by calculating the fraction of patients with the selected outcome from the cohort's total. **Results:** Test results were a US cohort of N=204,396, of whom 18,624 patients had the selected outcome, with a risk of conversion of 9,112% and a mean follow-up of 1,5 years. Mean age of cohort was 76 with standard deviation of 10. The Brazilian cohort had N=260 patients, whom 20 had the selected outcome, with a risk of conversion of 7,692% with a mean follow-up of 1 year. Mean age of cohort was 71 with a standard deviation of 10. **Conclusion:** A lot of the variability in risk of conversion result from demographic factors, mainly age, and health factors, such as cardio-embolic events. While the Brazilian cohort showed a lower risk than its US counterpart, it had both a shorter follow-up and had a cohort mean age lower by 5 years. This possibly indicates a higher MCI to Alzheimer conversion rate in Brazilian cohort, a finding that would be congruent with the overall lower educational attainment compared to the US.

Abetalipoproteinemia: a case report of a diagnostic challenge

Yasmin Ramalho Mandarino[1], Nicole D'Orazio Schilipacke[1], Éder Rodrigues Pereira[1], Victoria Heloina Machado[1], Raul Rodrigues Vilar[1], Laíse Koenig de Lima[2], Maria Eduarda Angelo de Mendonça Fileti[2], Thábata Emanuelle Martins Nunes[2], Carla Heloísa Cabral Moro[2], Alexandre Luiz Longo[2]

[1]Universidade da Região de Joinville, Joinville SC, Brazil.
[2]Hospital Municipal São José, Joinville SC, Brazil.

Correspondence: Yasmin Ramalho Mandarino; Email: yasminramalhoo@gmail.com.

Case presentation: A 45-year-old female patient, previously diagnosed with acanthocytosis, consulted a neurologist due to difficulty walking and frequent falls since the age of 15. She also reported decreased visual acuity for 20 years and childhood steatorrhea, which improved with a low-fat diet. As for the familial history, the pacient reported that her brother had similar symptoms without a defined diagnosis and that her parents were consanguineous. On examination, the patient presented with right-sided dysmetria, gait ataxia, global areflexia, grade IV+ muscle strength in the limbs, a positive Romberg sign, impaired proprioception, and vibration sense deficit. Fundus examination revealed optic atrophy and retinitis pigmentosa. Additional tests showed acanthocytosis and extremely low levels of cholesterol and triglycerides, with no other significant abnormalities. Cranial MRI results were within normal limits. Given the family history, the patient's symptoms, and laboratory findings, treatment for abetalipoproteinemia was initiated, including supplementation with vitamins A, D, and E, medium-chain triglycerides, and dietary adjustments. Following the commencement of treatment, the progression of the patient's disease stabilized. **Discussion:** Abetalipoproteinemia is an extremely rare condition, occurring in fewer than 1 in 1 million individuals. For the disease to manifest, an individual must possess two defective alleles, as abetalipoproteinemia is a recessive and hereditary disorder (1). Children presenting with steatorrhea, vomiting, and growth retardation are suspected of having abetalipoproteinemia, which may also be incidentally detected in adulthood through health screenings due to extremely low plasma cholesterol levels (3).The diagnosis of abetalipoproteinemia is established in a proband with absent or extremely low levels of LDL cholesterol, triglycerides, and apolipoprotein B (apo B), alongside biallelic pathogenic variants in the microsomal triglyceride transfer protein gene identified through molecular genetic testing (2). Supplementing high doses of fat-soluble vitamins, such as vitamins E and A, can prevent, delay, or alleviate disease complications and improve prognosis, potentially allowing survival into the eighth decade of life. Without treatment, systemic complications due to fat-soluble vitamin deficiencies may occur within the first decade of life (3). **Final comments:** Abetalipoproteinemia, a rare genetic disease, is a complex disorder resulting in the malformation and inadequate secretion of lipoproteins. While there is no cure, treatment can mitigate complications and improve the quality of life for those affected. Early diagnosis is crucial for prompt intervention. Although access to genetic testing can be limited, diagnosis should not be delayed. It is primarily clinical and may not require genetic testing if the characteristic symptoms are clearly present.

Access to rehabilitation for people with spinal muscular atrophy undergoing treatment with disease-modifying drugs

Eduardo Vital de Carvalho[1], Graziela Jorge Polido[1], Rodrigo de Holanda Mendonça[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Departamento de Neurologia, São Paulo SP, Brazil.

Correspondence: Eduardo Vital de Carvalho; Email: duvital1983@gmail.com.

Background: Spinal muscular atrophy (SMA) is a neurodegenerative disease caused by mutations in SMN1 (which encodes the survival motor neuron protein). Reduced expression of SMN leads to loss of motor neurons that manifests clinically with severe muscle weakness. The severity of the disease varies from early onset, with respiratory failure during the first months of life, to a mild type, with onset in adulthood, with slow progression. In the last decade, new drug treatment options have been developed, such as modulating the splicing of the SMN2 and SMN1 gene replacement by gene therapy. The first medications were approved for the treatment of patients with SMA and, if started early, can significantly modify the natural course of the disease. Faced with this new era of medicine, new phenotypes emerged and functional demands were reestablished. Since 2007, multidisciplinary care standards have been established, ensuring increased survival and improved quality of life for patients with SMA. New perspectives for early diagnosis, such as neonatal screening, have been recommended, but in Brazil it is not yet well established, so many patients are diagnosed with some degree of active neuronal degeneration and clinical manifestations of the disease. Rehabilitation is essential and plays an extremely important role associated with available treatments. **Objective:** Describe the access that patients with SMA have to rehabilitation with a multidisciplinary team. **Methods:** Retrospective and descriptive study with analysis of medical records. Demographic characteristics such as age, sex, weight and height were collected from patient records. Clinical characteristics such as type of SMA and medication treatment used. Characteristics about rehabilitation such as access, specialties and frequency. **Results:** 104 medical records of patients with SMA were reviewed, 14 (13.4%) of type 1, 56 (53.8%) of type 2 and 34 (32.6%) of type 3. The average age was 12. 97±9.97 years old, average height of 1.02±0.58 and average weight of 35±23. 71 (68.2%) patients have access to some type of drug treatment, 54% to Spinraza, 0.07% to Risdiplan and 0.05% to combined therapy. 38 (36.5%) of patients do not have access to rehabilitation. Of the patients who have access to rehabilitation, 85% undergo motor physiotherapy, 48% respiratory physiotherapy, 30% aquatic physiotherapy, 33% speech therapy, 0.06% psychology, 19% occupational therapy and 0.06% nutritional monitoring. **Conclusion:** We conclude that some patients who receive some drug treatment do not have access to rehabilitation. There is no standard prescription of a rehabilitation program for patients with SMA undergoing drug treatment. Access to some specialties of the multidisciplinary team is still restricted. The multidisciplinary team is extremely important in the follow-up of patients with SMA and aims to minimize complications resulting from muscle weakness.

Acetazolamide in the treatment of idiopathic intracranial hypertension: a real-world study

Ana Carolina Montouro Storarri[1], Annelise Akemi Higa Lee[1], Lorrane Campidelli Arthuzo[1], Luis Armando Sawada[1], Beatriz Marques dos Santos[1], Thassia Cavalcante de Oliveira Moraes Marques[1], Bruno Pissolati Mattos Gonzaga[1], Renan Barros Domingues[1]

[1]Santa Casa de Misericórdia de São Paulo. São Paulo SP, Brazil.

Correspondence: Ana Carolina Montouro Storarri; Email: anastorarri@gmail.com.

Background: Acetazolamide is a carbonic anhydrase inhibitor widely used in the treatment of idiopathic intracranial hypertension (IIH), a condition characterized by increased intracranial pressure without detectable apparent cause, often resulting in symptoms such as headache, papilledema, and transient visual loss. The efficacy of acetazolamide in managing IIH has been demonstrated in various clinical studies, notably improving patients' symptoms and playing a crucial role in preventing long-term visual complications. The therapeutic approach with acetazolamide is generally well-tolerated, although side effects such as paresthesia, fatigue, and changes in taste may occur. **Objective:** In the present study we aimed to assess the results with Acetazolamide in a real-life cohort of Brazilian patients. **Methods:** The data of IIH patients treated at Santa Casa since 2019 were evaluated, with information obtained during consultations and from medical records. Sociodemographic and clinical data were collected. The outcomes assessed were headache attributed to HII, pulsatile tinnitus, reduced visual acuity, diplopia, and papilledema before and after treatment with acetazolamide. Comparisons were made using the chi-square test. **Results:** Forty patients were included, all of them were female. The mean age was 33.9±11.5 years. Twenty-two patients were obese, 10 were overweight, and in 8 this information was not obtained. The mean BMI was 33,5±4,3. The mean follow-up time was 55.4±48.4 days. The mean Acetazolamide dose was 972.2±523.6. Six patients reported side effects (paresthesias=6 and dizziness and tinnitus=1) with four of them discontinuing acetazolamide, which was replaced by topiramate. The frequencies of observed evaluated outcomes were: headache (90%x0%, P< 0.0001); low visual acuity (75% x 50%, P=0.02); papilledema (75.7% x 54.5%, P=0.001); diplopia (33.3% x 25%, P=0.006); and tinnitus (27.8% x 0%, P=0.0007).

https://doi.org/10.5327/CBN240064

Acquired hepatocerebral degeneration accompanied by recurrent episodes of hepatic encephalopathy secondary to chronic hepatitis c virus (HCV) infection, presenting as the initial manifestation of hepatitis C in a young patient

Tainá Fátima Ramos Gonçalves[1], Ingrid Lorena da Silva Gomes[1], Guilherme Lago Miranda[1], Pedro Almeida Martins Pontes[1], Giovanni Caniçali Simões[1], Henrique de Moraes Bernal[1], Sephora Sabrina Candido de Almeida[1], Marcele Schettini de Almeida[1], Herval Ribeiro Soares Neto[1], Sônia Maria César de Azevedo[1]

[1]Instituto de Assitência Médica ao Servidor Público Estadual de São Paulo (IAMSPE), São Paulo SP, Brazil.

Correspondence: Tainá Fátima Ramos Gonçalves; Email: taina_goncalves1@hotmail.com.

Case presentation: A 36-year-old previously healthy woman presented with a seven-month history of progressively worsening cognitive and behavioral fluctuations, subsequently developing headaches, mental confusion, psychomotor agitation, and speech and language alterations. Neurological examination revealed fluctuating levels of consciousness, difficulty understanding commands, incoherent speech, dysarthria, and extrapyramidal symptoms. Her family history included a mother who died from liver cirrhosis secondary to hepatitis C infection. An extensive evaluation began with neuroimaging. Brain MRI showed spontaneous hyperintensity on T1-weighted sequences in the basal ganglia, consistent with hypermanganesemia. Cerebrospinal fluid analysis was unremarkable. Serum tests, including serologies for HIV, hepatitis B, and syphilis, were negative. Renal and thyroid functions, rheumatologic markers, and serum manganese levels were normal. Positive serology for hepatitis C (anti-HCV reactive with a viral load of 339,000) and laboratory tests revealed altered liver function markers and hyperammonemia (187 µmol/L, reference range: 11-51 µmol/L). Further investigation with abdominal CT and ultrasound indicated chronic liver disease with portal hypertension. A diagnosis of liver cirrhosis (Child-Pugh A6, MELD: 24), hepatic encephalopathy (EH), and hepatocerebral degeneration (AHD) secondary to hepatitis C virus infection was established. Treatment for hepatitis C with velpatasvir/sofosbuvir and management of cirrhosis symptoms with lactulose and ornithine aspartate were initiated and maintained for 12 weeks. The patient continued follow-up with neurology and gastroenterology after hospital discharge, showing improved consciousness and resuming daily activities. **Discussion:** HCV is a leading cause of cirrhosis in Brazil. Acquired hepatocerebral degeneration is one of the neurological conditions linked to chronic liver dysfunction. While hepatic encephalopathy is more common and reversible, AHD is rare and irreversible. HE results from the livers inability to detoxify neurotoxic substances like ammonia, and evidence suggests that multiple HE episodes increase the risk of AHD. The primary cause of AHD is manganese deposition in the basal ganglia, though serum manganese levels can be normal, and other pathophysiological mechanisms may be involved. **Final comments:** Multiple episodes of hepatic encephalopathy in the context of hepatitis C infection are mostly a consequence of cirrhosis and liver dysfunction, as well as the potential neurotoxic effects of HCV. These events are associated with hepatocerebral degeneration, characterized by irreversible basal ganglia manganese deposition. This chronic condition necessitates symptomatic clinical management and control of complications. Additionally, patients with hepatic encephalopathy require careful treatment to reduce the risk of acquired hepatocerebral degeneration and to mitigate symptoms associated with hyperammonemia.

Correspondence: Eduardo Inacio Nascimento Andrade; Email: neduardoinacio@gmail.com.

Background: Facioscapulohumeral muscular dystrophy (FSHD) is one of the most common muscular dystrophies, and the validation of longitudinal clinical assessments that reflect disease progression are needed for future clinical trials. ACTIVE Workspace Volume (WSV) and OpenCap provide complementary measures to capture 3D motion of the joints and perform kinematic analyses. WSV uses a game to engage patients in a series of tasks using the arms and trunk while measuring the upper limb accessible space. OpenCap uses two iPhones to capture and analyze movements of the upper and lower extremities in space while the patient performs a task. **Objective:** To explore the ability of WSV and OpenCap to predict clinical severity in patients with FSHD. To develop a model using different parameters obtained from ACTIVE and OpenCap that could be used as reliable biomarkers for FSHD therapeutic trials. **Methods:** As part of an ongoing pilot study, we aim to recruit a total of 10 FSHD and

5 control subjects. Here we present the WSV results of 5 initial subjects with FSHD as summarized by the percentage of predicted reachable workspace for each patient's age and height. In addition, the maximum degree of trunk bending when standing from a chair was measured using OpenCap for each patient. FSHD Clinical Severity Scale (Ricci score) was obtained from each patient by a neuromuscular trained neurologist. A multiple linear regression model was performed using the Ricci score as the dependent variable and the first two measures as covariants. **Results:** The mean degree of lumbar bending when standing was 16.4 degrees (SD=10.3). The mean % of predicted reachable workspace achieved by patients was 116% (SD=68%). The mean Ricci score was 2.3 (SD=1.35). The normality of the variables was confirmed using the "Shapiro-Wilk" test. The multiple linear regression model was statistically significant, ($F2,2 = 10337$, $p<0.001$). The model R^2 was 1.00. The percentage of the predicted workspace achieved by each patient was inversely correlated and statistically significant predictor ($b=-0.1$, $SE=0.01$, $t=-7.28$, $p<0.01$) of the dependent variable. The maximum degree of lumbar bending when standing had a positive correlation and was also a significant predictor ($b=0.13$, $SE= 9.078\times10\text{-}4$, $t=143.78$, $p<0.001$) of the Ricci score. **Conclusion:** As muscle weakness progresses, patients with FSHD experience compromise of upper extremity reachable volume. Patients may also need to lean more forward to stand from a chair. ACTIVE Workspace and OpenCap can capture these changes and when combined they may predict the overall severity of disease in patients with FSHD. A larger patient cohort needs to be tested to confirm the use of this model as a clinical biomarker of disease progression.

Acute bilateral hippocampal swelling in transient global amnesia triggered by sexual orgasm

Gustavo Henrique Tomasi[1], Paula Gasperin[1], Carolina Heck Haubrich[1], Ricardo Bernardi Soder[1], Lucas Porcello Schilling[1], William Alves Martins[1], André Palmini[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Hospital São Lucas, Porto Alegre RS, Brazil.

Correspondence: Carolina Heck Haubrich; Email: carolhhaubrich@gmail.com.

Case presentation: A 50-year-old woman presented with acute disorientation, disordered speech, and repetitive questioning, alongside retrograde and anterograde amnesia. The retrograde amnesia spanned 15 hours before presentation. Her symptoms began seconds into an orgasm during sexual intercourse. Despite attempting to continue her routine, including going to work, her memory dysfunction worsened, leading to multiple timecard punches within a short span (at 11:31h, 11:48h, 11:56h, 11:59h, 12:06h, 12:40h, and 12:41h). She had a history of controlled hypothyroidism and episodic migraine with aura. Neurological exam was normal except for a significant deficit in newly acquired information. Her symptoms improved over the next 10 hours, leading to a complete recovery. Brain CT scan and general laboratory tests were normal. Eight years earlier, she had experienced a similar event triggered by orgasm, with full recovery in approximately six hours, requiring no further investigation. Due to the recurrence and the Valsalva-related nature of her transient global amnesia (TGA), further work-up included electroencephalogram and CTA, both of which were unremarkable. However, brain MRI displayed bilateral hippocampal swelling without diffusion-weighted-imaging restriction. She was discharged two days later, completely asymptomatic and has had no other episodes since. **Discussion:** TGA is characterized by a sudden inability to retain new information and recall recent events, accompanied by repetitive, anxious questioning. Anterograde and retrograde amnesia can persist for variable durations but typically last a few hours. Underlying pathophysiology of TGA remains a mystery, especially the convergence of diverse triggering phenomena into acute memory dysfunction. Investigations are usually non-revealing. Previous studies show involvement of mesial temporal structures and/or thalami, with focal hyperintensity and restricted diffusion on diffusion-weighted MRI. In our case, acute imaging immediately following a recurrent episode of TGA showed bilateral hippocampal swelling without restricted diffusion, suggesting a non-ischemic mechanism of hippocampal insult. These findings support the hypothesis that TGA may result from acute venous congestion of the mesial temporal lobe, which requires a combination of longstanding insufficiency of the internal jugular vein (IJV) and acute, intense Valsalva maneuvers associated with emotionally or physically charged events. The IJV, which continues from the lateral sinus and drains the mesial temporal lobe, has a single valve proximal to its termination in the subclavian vein. Insufficiency of this valve can lead to retrograde venous congestion. In our patient, the swelling was restricted to the hippocampus and disappeared promptly upon recovery. We propose that the Valsalva maneuver during sexual intercourse and orgasm triggered venous congestion with possible IJV insufficiency, leading to bilateral hippocampal edema and amnesia.

Acute carotid web thrombosis and early reocclusion after successful thrombectomy: a case report

João Paulo Bello dos Santos[1], Letícia Escorse Requião[1], Vinícius Paulo Lima de Menezes[1], Amanda Sanae Esaki[1], Luis Henrique de Castro Afonso[1], Maria Clara Zanon Zotin[1], Giulia Maria Ximenes Verdi[1], Frederico Fernandes Alessio Alves[1], Millene Rodrigues Camilo[1], Octávio Marques Pontes Neto[1]

[1]Universidade de São Paulo, Ribeirão Preto SP, Brazil.

Correspondence: Letícia Escorse Requião; Email: leticiaescorse@gmail.com.

Case presentation: A 58-year-old Black woman presented with sudden onset aphasia, right-sided weakness, and numbness 11 hours prior to admission at the Emergency Unit. On examination, her NIHSS score was 13, indicating a left middle cerebral artery (MCA) stroke. She had a history of smoking but no other cardiovascular diseases. CT revealed loss of gray-white differentiation in the left insular and frontal regions, with an Alberta Stroke Program Early CT Score (ASPECTS) of 8. CT angiogram of the head showed a left MCA occlusion and a small wedge-shaped hypodense filling defect along the posterior margin of the left internal carotid artery (ICA), suggestive of a carotid web (CW). Thrombolytic therapy was not administered. Endovascular mechanical thrombectomy (MT) using combined use of contact aspiration and stent-retriever technique was performed, achieving successful recanalization (TICI score 3) within 124 minutes Door-to-Recanalization time. The NIHSS score after the procedure was 17. Blood tests, transthoracic echocardiography, continuous ECG monitoring and evaluation for hypercoagulability testing and vasculitis was performed to investigate the etiolgy. Subsequent CT at 24 hours showed hypodensity in the left deep nuclei and left frontoparietal areas and left hyperdense MCA sign. Carotid doppler ultrasound (CDUS) revealed a hypoechoic mass, suggestive of acute thrombus formation on the CW. Cerebral angiography performed prior to carotid angioplasty, identified reocclusion of the ipsilateral MCA. Due to the risk of hemorrhagic complications, a second MT was not performed. The patient was treated with aspirin 300 mg and clopidogrel 75 mg, followed by angioplasty with stent placement 10 days post-stroke. She was subsequently transferred to a stroke rehabilitation center, the NIHSS score was 14 and the RANKIN score was 4. **Discussion:** Carotid web is a recognized cause of cryptogenic stroke. Our findings are consistent with previous studies describing a higher prevalence of CW in young Black female patients, often ipsilateral to ischemic strokes of undetermined cause. Symptomatic CW is associated with a high rate of recurrent stroke (17% to 40%), particularly in cases involving morphological and hemodynamic changes such as local flow turbulence or in situ thrombus formation. Acute CW thrombosis and early reocclusion following successful MT are rarely reported. Early neurological deterioration (within 3 days) and hemodynamic disturbances related to CW are important red flags in these cases. Follow-up with CDUS may be useful for monitoring thrombus formation. Carotid stenting immediately after MT could be considered to prevent recurrent strokes given the elevated short-term risk post-MT. **Final comments:** The optimal management to prevent recurrent stroke in patients with carotid web remains uncertain. Observational studies generally favor interventional therapy over medical management, but randomized trials are needed to provide more definitive guidance.

Acute denervation findings on electromyography in patient with central lesion: case report

Eduardo Barbosa de Albuquerque Maranhão[1], Alexandre Medeiros Sampaio Januario[2]

[1]Faculdade de Ciências Médicas de Jaboatão, Jaboatão dos Guararapes PE, Brazil.

[2]SOS NEURO.

Correspondence: Eduardo Barbosa de Albuquerque Maranhão; Email: maranhao.eduardo@hotmail.com.

Background: A subacute isolated deficit in the upper limb can be challenging to characterize in some cases, particularly regarding central versus peripheral nervous system localization. Here, we present the case of a 70-year-old male patient with prostate cancer under investigation for bone metastasis, who developed a subacute isolated weakness in the right upper limb. The symptom onset occurred during a magnetic resonance imaging (MRI), which was complicated by contrast extravasation and difficulty in peripheral venous access. Subsequent electrodiagnostic evaluation performed 45 days after symptom onset revealed symmetric sensory nerve action potentials in the median and ulnar nerves. Motor nerve action potentials of the median, ulnar, and axillary nerves showed significant reduction only in the axillary nerve innervated muscles of the affected limb. During needle electromyography, fibrillations and positive sharp waves were observed in nearly all muscles of the right upper limb, except for rare occurrences in the deltoid and biceps, and frequent findings in muscles such as the flexor carpi radialis, pronator teres, and extensor digitorum communis. During voluntary muscle contraction, muscles including the dorsal interosseous, flexor carpi radialis, pronator teres, and extensor digitorum communis showed markedly reduced motor unit potentials, while muscles like deltoid, biceps, triceps, brachioradialis, and flexor pollicis longus exhibited relatively normal motor unit potentials. Subsequent contrast-enhanced cranial MRI revealed an expansive metastatic lesion involving the lateral aspect of the left precentral gyrus. **Discussion:** The presence of acute denervation findings (such as fibrillations and positive sharp waves) on electromyography in patients with central lesions is a well-documented phenomenon in the literature. One of the prevailing theories for these findings implicates disruption in transsynaptic transmission between the first and second motor neurons, leading to anterior horn degeneration. Typically, abnormal spontaneous activity begins approximately one month after injury onset, becomes less frequent by six months, and is rare after one year, contrasting with upper motor neuron signs. Regarding the predominantly affected muscle groups, as observed in this case, distal muscles in the affected limb often exhibit a higher proportion of acute denervation

compared to proximal muscles. **Conclusion:** Therefore, vigilance is warranted when electromyography reveals signs of denervation in patients presenting with subacute flaccid monoparesis. As exemplified in this case, it still may indicate ongoing pathology involving the first motor neuron, the critical importance of meticulous evaluation for guiding accurate diagnosis and clinical management.

Acute disseminated encephalomyelitis (ADEM) associated with dengue infection: a case report

Beatriz Pires Paes[1], Bruna da Silva Lima[1], Poliana Lima Campos[1], Beatriz Ballarin Costa[1], Anthony Magalhães Morais Santiago[1], Camilo Carvalho[1], Larissa Lucas Schloicka[1], Andre Gustavo Fonseca Ferreira[1]

[1]Hospital de Base do Distrito Federal, Brasília DF, Brazil.

Correspondence: Beatriz Pires Paes; Email: beatrizpirespaes@gmail.com.

Case presentation: A 48-year-old man was diagnosed with dengue fever confirmed by a positive serology, and after fifteen days, developed paraparesis and a tingling sensation in both legs associated with urinary retention. Ten days after the onset of the condition, he was transferred to the neurological department. At admission, there was asymmetric sensorimotor paraparesis, worse on the left, with sensory level at T10, with tactile, thermal, and palesthetic hypoesthesia. Cerebrospinal fluid analysis showed normal protein levels and a slight increase in opening pressure (27 cmH2O); polymerase chain reaction did not detect dengue virus, and the research for oligoclonal bands was negative. Neuroimaging (MRI) revealed supratentorial and infratentorial intraparenchymal lesions of probable inflammatory/demyelinating etiology, T2 hyperintensity, and gadolinium enhancement in a lesion in the cervical cord (C4-C5), in addition to multiple small peripheral oval lesions, also with T2 hyperintensity and gadolinium impregnation, from T1 to T9. He underwent pulse therapy with methylprednisolone for five days, and his condition improved significantly. Considering the extent of his lesions, we prescribed a four-week-long course of oral corticosteroids afterward. **Discussion:** Acute disseminated encephalomyelitis (ADEM) is a rare immune-mediated central nervous system disorder that determines a rapidly demyelinating process. It can occur during the acute or post-infectious phase of dengue, usually affects young children and has an identifiable trigger. Characterized by acute-onset polyfocal neurological deficits, its symptoms generally appear within 2-21 days after an infection. Encephalopathy is an obligatory feature, and it includes behavioral changes and/or alterations in consciousness, including irritability, not explained by systemic febrile illness or posticta symptoms. Our patient presented with significant irritability. There are no consensus diagnosis criteria for adults but it is usually based on the clinical manifestations described above, along with evidence of demyelination on MRI, which shows hyperintense abnormalities in T2-weighted/FLAIR, with typically bilateral, asymmetrical, large (> 2 cm) and poorly demarcated lesions. Gadolinium enhancement is reported in up to 30% of cases. Clinical manifestations may vary widely but usually include motor and sensory deficits, pyramidal signs, ataxia, brainstem symptoms, and transverse myelitis. CSF pleocytosis and elevated protein levels are typically seen, yet oligoclonal bands are found in less than 10%. Treatment usually consists of IV methylprednisolone for 3-5 days, followed by oral prednisone for 4-6 weeks. **Final comments:** In conclusion, we presented a rare case of ADEM associated with dengue fever in an older male. The diagnosis was based on the clinical manifestations, imaging findings, and laboratory tests. ADEM is a challenging diagnosis, and early treatment is crucial to a better outcome.

Acute disseminated encephalomyelitis (adem) following recent rabies vaccine

Isabella Nascimento Guedes[1], Matheus Pinto Munoz[1], Lilian Eduarda Bastos da Silva[1], Karoline da Silva Guimarães[1], Gilvan Pires de Castro Junior[1], William Corá[1], Darah Fontes da Silva Assunção, Natasha Pryanka de Araújo Bessa, Roger Santana de Araújo[2], Marina Buldrini Filogonio Seraidarian Seraidarian[2]

[1]Universidade Estácio de Sá, Rio de Janeiro RJ, Brazil.
[2]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Isabella Nascimento Guedes; Email: isabellaguedes21@icloud.com.

Case presentation: Acute disseminated encephalomyelitis (ADEM) following recent rabies vaccine. Clinical case: A 23-years-old female veterinary student was admitted with a history of 3 days weakness, dyspnea, diarrhea and vomiting, and more recently speech impairment and decreased level of consciousness. Emergency department CT showed important cerebellum edema and a decompressive surgery was performed to reduce intracranial pressure. Further head MRI demonstrated abnormalities in cortical and subcortical regions and tumefactive demyelinating lesions diffusely affecting cerebellar and cerebral hemispheres. Patient medical history reveled thar she was submitted to a prophylactic immunization process and the second dose of antirabic vaccine was taken a few days before the illness. As acute disseminated encephalomyelitis (ADEM) can be triggered by preceding infection or immunization, the patient was managed with corticosteroids and immunoglobulin therapy, which led to overall improvement in both radiological and clinical findings. **Discussion:** Rabies is a viral disease transmitted by infected mammals with high neurotropism. Although there is no specific treatment, rabies pre-exposure vaccination is recommended for veterinary staff. The vaccine has inactivated virus and the immunization schedule consists of 3 doses given on days 0, 7 and 28. The hallmarks of rabies encephalitis are primary cortex and basal ganglia lesions, while this case reports affections in white matter and periventricular areas that could be explained by an immune-mediated process. Neurologic impairment is a serious post-vaccination adverse event and its incidence is 1 in 8000 people. The main neurological conditions related to the immunization are: encephalomyelitis, transverse myelitis, cranial nerve neuropathy, peripheral mononeuropathy and Guillain-Barré syndrome. **Final comments:** This case reports acute and severe neurological impairment, probably related to an autoinflammatory response triggered by rabies vaccine. Differential diagnosis could be other autoimmune encephalitis, infectious meningoencephalitis, neurovascular 2 / 2 syndromes or neoplastic lesions. However, taking into account clinical findings, radiological images and patient's evolution those hypotheses were considered less probable.

Acute disseminated encephalomyelitis as a concomitant presentation of anti-mog, covid and hiv: case report

Juliana Magalhães Leite[1], Thaís Magalhães Lima Leite[2], Lucas Silva Barbosa Bezerra[2], Lívia Gonçalves Santos Costa[2], Ana Lívia de Andrade Rangel[2], Matheus Saraiva Gurgel[2], Rafael de Souza Andrade[1], Assis Martins Maia[1]

[1]Hospital Metropolitano Dom José Maria Pires, João Pessoa PB, Brazil.
[2]Centro Universitário UNIPE, João Pessoa PB, Brazil.

Correspondence: Thaís Magalhães Lima Leite; Email: thaismlleite@gmail.com.

Case presentation: A 21-year-old male patient, a student from Itabaiana-PB, presented with thoracic/lumbar dorsalgia that began 5 days before admission. His condition progressively worsened to paraparesis, and subsequently paraplegia with urinary and fecal retention, with a sensory level at T10, along with drowsiness. He denied any trauma, infectious symptoms, or exposure to river or lake water. Cranial MRI revealed subtle ovoid lesions affecting the deep periventricular white matter of the cerebral hemispheres at the callosal-septal interface of the frontoparietal regions. Cervical spine MRI showed extensive signal alteration affecting the cervical and thoracic spinal cord, associated with mild medullary expansion. Cerebrospinal fluid (CSF) culture was negative, with 14.3 leukocytes (10% polymorphonuclear, 90% mononuclear), glucose 82, protein 68.8, and a negative viral panel. HIV and COVID tests were not performed in the CSF due to lack of availability. Anti-aquaporin-4 antibody was negative, Herpes IgG/IgM was reactive. HIV was reactive with CD4 298 / CD8 692 / VL 102,000 copies/ml, COVID positive. He received 1g of methylprednisolone for 7 days and immunoglobulin for 5 days. The patient showed improved upper limb strength, sensory level improvement, remaining hypoesthesia in the thigh root, and significant radiological improvement. He was discharged on oral corticosteroids and regular antiretroviral therapy (ART). One month after discharge, anti-MOG results were positive. A new cycle of immunoglobulin was administered, and anti-MOG was repeated 3 months post-discharge, remaining positive. **Discussion:** When anti-MOG antibody disease involves the brain, the phenotype resembles acute disseminated encephalomyelitis (ADEM), with mental status changes and good outcomes following treatment with corticosteroids and intravenous immunoglobulins. Unlike ADEM, which is classically monophasic, MOG antibody seropositivity indicates a high probability of relapse. Transverse myelitis is a known manifestation of primary HIV infection. Speculated factors in the formation and infiltration of post-infectious MOG antibodies into the CNS include molecular mimicry and the breakdown of the blood-brain barrier due to prior viral inflammation, although the precise mechanisms of post-infectious demyelinating disease remain to be elucidated. **Final comments:** The presentation of anti-MOG-associated encephalomyelitis in a patient with asymptomatic COVID co-infection, along with a recent HIV diagnosis, sparked significant discussion regarding the possibility of a false-positive anti-MOG result and the appropriate long-term therapeutic approach. Given the severity of the clinical condition, cycles of immunoglobulin were chosen, and anti-MOG antibody levels are being monitored. This case report is highly relevant for academic discussion due to its uniqueness and therapeutic evolution.

Acute disseminated encephalomyelitis secondary to tuberculosis in a pediatric patient: a case report

Júlio César Soares Barros[1], Antonia Cardoso Silva[1], Guilherme Carvalho de Souza[1], Larissa da Silva Almeida[1], Adriano Cardozo Silva[2], Glicia Florêncio Medeiros[3], João Eduardo Gondim Mendes Leite[3], Bárbara Letícia Figueiredo Fonseca[3]

[1]Universidade Federal de Alagoas, Maceió AL, Brazil.
[2]UniFTC, Feira de Santana BA, Brazil.
[3]Hospital Geral do Estado Professor Osvaldo Brandão Vilela, Maceió AL, Brazil.

Correspondence: Júlio César Soares Barros; Email: julio.barros@famed.ufal.br.

Case presentation: A female patient, 11 years old, with a history of dysuria and a diagnosis of hydronephrosis for 2 months, was under follow-up with a pediatric nephrologist. The mother initiated treatment with sulfamethoxazole + trimethoprim on her own, but the patient developed drowsiness associated with paresis in the right

lower limb. She was admitted to the hospital with paresis in the left lower limb and transferred to another service. Her condition worsened, with paresis in the upper limbs and desaturation, leading to transfer to the pediatric ICU. MRI revealed transverse myelitis at various levels, and brain MRI showed acute disseminated encephalomyelitis (ADEM). Infectious etiology investigation revealed a positive rapid molecular test for tuberculosis (TB) in the cerebrospinal fluid, confirming the diagnosis of ADEM caused by TB. The patient underwent pulse therapy with methylprednisolone (later transitioned to prednisolone), followed by human immunoglobulin (4 days), and started TB treatment with rifampicin, isoniazid, pyrazinamide, and ethambutol (RHZE). Azathioprine was also initiated later. The patient received intensive follow-up with motor physiotherapy and occupational therapy, showing satisfactory progress. She improved neurologically and had a favorable clinical evolution, being discharged with general care instructions and outpatient and multidisciplinary follow-up. **Discussion:** ADEM is an inflammatory demyelinating disease of the central nervous system that usually occurs after infections or, less commonly, after vaccination. It is most commonly associated with viral infections, but can also occur following bacterial infections, although these are rare. This case is notable for the association of ADEM with TB, a bacterial infection caused by Mycobacterium tuberculosis. Clinically, ADEM typically presents with an acute onset of multifocal neurological symptoms, including encephalopathy, ataxia, and motor or sensory deficits. In more severe cases, there may be impaired consciousness. In this case, the patient presented with progressive neurological symptoms requiring intensive care. The diagnosis of ADEM was confirmed by MRI, and the infectious etiology was confirmed with a rapid test in the cerebrospinal fluid. The management of ADEM includes immunosuppression with corticosteroids and, in some cases, intravenous immunoglobulin, as performed in this patient. Specific treatment for tuberculosis with the RHZE regimen is crucial to control the underlying infection. The inclusion of azathioprine aimed to prevent relapses and promote long-term remission. **Final comments:** ADEM is a rare condition, especially when associated with TB infection. This highlights the importance of differential diagnosis in patients with acute and progressive neurological symptoms. Rapid and accurate identification of the etiology is crucial for appropriate management and a positive prognosis, as demonstrated by the patients progressive recovery.

Acute hyponatremia secondary to polydipsia provoking seizure after physical exercise: a case report

Mário Vicente Guimarães[1], Josué Andrade Martins[2], Lawani Rigopoulos[3], Guilherme Requião Radel Neto[2], Julia Souza e Costa[2], Raquel Maria Ayres Monteiro[4], Ana Beatriz Lima Pedroza[2], Tatiana Quintanilha Soares da Silva[2], Bruany Antoniolli Bianchi[2], Natália Moreno Coelho[2]

[1]Universidade de São Paulo, São Paulo SP, Brazil.
[2]Universidade Anhembi Morumbi, São Paulo SP, Brazil.
[3]Hospital Israelita Albert Einstein, São Paulo SP, Brazil.
[4]Faculdade Israelita de Ciências da Saúde Albert Einstein, São Paulo SP, Brazil.

Correspondence: Raquel Maria Ayres Monteiro; Email: raquelmamonteiro@gmail.com.

Case presentation: A 50-year-old man presented at the emergency center with malaise, sweating, abdominal and thoracic pain, followed by a generalized tonic-clonic seizure. He had played an exhaustive tennis game and consumed 4 liters of water. His medical history includes recent gastroplasty and depression, currently treated with quetiapine, trazodone, and melatonin. Post-seizure, he was disoriented with a Glasgow Coma Scale score of 9 and bilateral mydriasis, prompting orotracheal intubation. At the emergency center, he experienced another seizure, treated with intravenous phenytoin, and showed signs of sinus bradycardia, managed with atropine. Imaging tests, including CT and MRI, revealed no abnormalities. His sodium level was critically low at 117 mEq/L, and D-Dimer was elevated at 2400 ng/mL. Upon hospital admission, he was hypertensive and agitated despite sedation. AngioCT found calcified plaques in several arteries but no stenosis. AngioMR and transcranial Doppler results were unremarkable, and EEG indicated disorganized brain activity. The echocardiogram showed no abnormalities. The primary diagnosis is a seizure resulting from hyponatremia due to excessive water intake. **Discussion:** Acute hyponatremia occurs when symptoms develop within 48 hours, often leading to severe cerebral edema and poor prognosis, while chronic hyponatremia develops over a longer period. This patients condition likely resulted from dilutional hyponatremia due to excessive low-sodium fluid intake and increased ADH during intense exercise, leading to symptoms such as cellular edema and increased intracranial pressure. The case underscores the importance of carefully correcting acute hyponatremia to avoid osmotic demyelination syndrome, with a recommended increase in serum sodium of no more than 8 to 10 mEq/L per day. Additionally, differential diagnoses like hyperthermia or hypoglycemia should be considered in athletes presenting with seizures after strenuous activities. **Final comments:** This case highlights the importance of promptly recognizing and understanding the variations of exercise-associated hyponatremia (EAH) to manage it appropriately based on its specific cause. Hyponatremia should always be considered in patients presenting with seizures following intense activity and excessive fluid intake.

https://doi.org/10.5327/CBN240074

Acute intermittent porphyria in siblings: a case report

Lucas Gonçalves Coelho[1], Victoria Nunes Alvares[1], Clara Ribeiro Rizzo[1], Isabella Navarro Diaz Horta[1], Maria Eduarda Braz Ferreira Leão Caldas dos Santos[1], Bernardo Leal Cupello[1], Isadora Gomes Mesquita[2], Patricia Gomes Pinheiro[2], Clarissa de Araujo Davico[2], Karina Lebeis Pires[2]

[1]Universidade Federal do Estado do Rio de Janeiro, Rio de Janeiro RJ, Brazil.
[2]Universidade Federal do Estado do Rio de Janeiro, Hospital Universitário Gafrée e Guinle, Rio de Janeiro RJ, Brazil.

Correspondence: Lucas Gonçalves Coelho; Email: lucasgcoelho@edu.unirio.br.

Case presentation: Two sisters, 49 and 54 years old, are followed up at the neurology outpatient clinic due to the diagnosis of Acute Intermittent Porphyria since 2001, detected by family screening. The younger sister reports periods of abdominal pain associated with menstruation, which awaken her and radiate to the left lower limb. In addition, the patient refers to anxiety, chronic fatigue, frequent cramps and a "strange sensation" in her hands and feet, which is relieved by biting her nails or wearing socks. Genetic molecular testing was performed and confirmed a mutation of uncertain significance in the HMBS gene (c.1004G> T). The older sister has a similar clinical presentation, characterized by intermittent abdominal cramps since 2014, associated with sporadic numbness in the fingers and depression. On physical examination, distal hypopalesthesia is observed in the four limbs. Her genetic molecular test also demonstrated a mutation of uncertain significance in the HMBS gene (c.100G> T). Both patients reported improvement in pain over the use of 5% glucose solution, increased intake of carbohydrates in the diet or use of ibuprofen. **Discussion:** Acute Intermittent Porphyria (AIP) is a rare disease caused by a deficiency of the enzyme Porfobilinogen deaminase, leading to accumulation of neurotoxic precursors of the heme group (porphyrins). The clinical manifestations of AIP are diverse and nonspecific, including abdominal, neuropsychiatric and autonomic symptoms. In the cases presented, additionally to the similarity of the symptoms presented by the sisters, there is a family history of the condition, emphasizing the importance of genetic screening for the early diagnosis of the disease, ensuring fulfilled monitoring and treatment, especially in courses of crisis which come from the disease. **Final comments:** The incorporation of Acute Intermittent Porphyria in the differential acute neurovisceral diagnosis disease is crucial, especially in patients with family history. Besides, it is necessary to emphasize the importance of genetic counseling in the family of those patients, aiding early detection and treatment. Therefore, implementing strategies that prevent acute thus is important to improve the quality of life of patients with AIP.

Acute intermittent porphyria mimicking guillain-barré syndrome: a case report

Iasmim Portela Maifrede[1], José Víctor Filho de Oliveira[1], Luiz Felipe Mota Freitas[1], Stephania Neves Scapim[1], Leopoldo Antonio Pires[1], Thiago Cardoso Vale[1]

[1]Universidade Federal de Juiz de Fora, Hospital Universitário (EBSERH), Juiz de Fora MG, Brazil.

Correspondence: Iasmim Portela Maifrede; Email: iasmimportela@hotmail.com.

Case presentation: Woman, 18-year-old, previously healthy, presented with a history of mild to moderate recurrent colic abdominal pain associated with pollakiuria, diarrhea and depressed humor since november 2023. After a month, the pain became more intense and was associated with constipation, palpitations, diaphoresis, and dark urine. The symptoms worsened after episodes of alcohol intake, prompting visits to the emergency room. In early March 2024, she was hospitalized in her hometown due to intestinal subocclusion, followed 4 days later by dysautonomia, proximal predominant crural paraparesis, episodes of intermittent mental confusion and urinary incontinence. Laboratory tests revealed electrolyte disturbances (hypocalcemia, hypomagnesemia, and hypokalemia) associated with leukocytosis. The condition rapidly progressed to tetraparesis and peripheral facial diparesis with dysphagia and hypophonia, requiring orotracheal intubation. The diagnosis of Guillain-Barré syndrome was considered, despite normal cerebrospinal fluid findings, and immunoglobulin was initiated without improvement. Due to the presence of abdominal pain associated with acute flaccid paralysis with dysautonomia, the possibility of polyneuropathy secondary to acute intermittent porphyria (AIP) was raised and confirmed by 24-hour urine delta-aminolevulinic acid (ALA) and quantitative porphobilinogen levels, with results exceeding 12.0 mg/L and 3.1 mg/24h, respectively. Intravenous glucose support was initiated, and the patient progressed with partial improvement of symptoms, but with persistent bulbar muscle weakness and symmetrical distal paresis, currently showing progressive gains with rehabilitation. **Discussion:** AIP is a rare metabolic disorder with an estimated prevalence of 0.5 to 10 per 100,000 individuals worldwide. Up to 23% of carriers have polymorphic neurological manifestations. This case report describes an acute presentation of abdominal pain with neurological manifestations, such as proximal-predominant paresis, associated with dysesthesias, areflexia, autonomic manifestations, and facial paralysis. The dark urine color present in the picture is one of the most characteristic aspects of AIP. Among the laboratory alterations, hyponatremia, hypocalcemia and leukocytosis are possible findings in patients with AIP. The neurological manifestations of AIP attacks can assume a character similar to Guillain-Barré Syndrome,

however, central nervous system manifestations (such as in the case, confusional syndrome), in addition to recurrent abdominal pain and association of symptom onset with medication and/or alcohol intake, can help differentiate the two pathologies. **Final comments:** AIP is a rare disease that is difficult to diagnose, but it should be considered in patients with diverse neurological manifestations, especially those with recurrent abdominal pain, as an alternative diagnosis.

https://doi.org/10.5327/CBN240076

Acute intermittent porphyria presenting with encephalopathy and osmotic demyelination syndrome

Rafael Bragança Rodrigues Matias[1], Eduardo Mesquita[1], Ana Luisa Vieira de Faria Donadon[1], Amanda Miranda de Mendonça[1], Alex Araujo Fernandes[1], Matheus Luís Braga Munareto[1], Alex Machado Baeta[1], Hennan Salzedas Teixeira[1], Karlla Danielle Ferreira Lima[1]

[1]Beneficência Portuguesa de São Paulo, São Paulo SP, Brazil.

Correspondence: Rafael Braganca Rodrigues Matias; Email: rafaelwaa@gmail.com.

Case presentation: A 28-year-old female, previously healthy with an unclear early paternal death, presented with abdominal and right flank pain, constipation, and was treated for urinary infection. She was hospitalized for 11 days, during which hyponatremia and hypokalemia were observed, and discharged with a serum sodium level of 110. She returned with seizures and rhabdomyolysis, sodium at 104, and underwent a rapid correction of 30 mEq in 24 hours. Admitted to our service with suspected encephalopathy and new abdominal pain, examination revealed diffuse hypotonia and areflexia, with proximal strength graded III. Acute intermittent porphyria was suspected; hematin was initiated. MRI showed central pontine myelinolysis signs, hyperintensity in bilateral striatum, cerebral cortex, cerebellum, dorsolateral thalamus aspects, especially in the pons. Laboratory tests indicated porphobilinogen in urine, isolated ALA of 6.2, ALA/creatinine ratio of 32.5 mg (limit 4.5). Genetic studies found no abnormalities in mother and sisters. Gastrostomy and tracheostomy were performed; the patient improved with hematin but remains bedridden. Early identification of porphyria is vital for treatment and outcome; initial misidentification and erroneous sodium correction led to encephalopathy, complicating the diagnosis with overlapping osmotic demyelination syndrome during an acute porphyria attack. **Discussion:** Porphyrias are a group of rare metabolic disorders affecting the heme biosynthetic pathway. Depending on the defective enzyme, these disorders can manifest with neurovisceral and/or cutaneous symptoms. Neurovisceral porphyrias are characterized by acute attacks triggered by excessive heme production. During an acute attack, patients typically experience severe abdominal pain, vomiting, and tachycardia. Other possible symptoms include hypertension, hyponatremia, peripheral neuropathy, and mild mental symptoms. In severe cases, symptoms may escalate to seizures and psychosis. If left untreated, the attack can become very severe, affecting the peripheral, central, and autonomic nervous systems, potentially leading to paralysis, respiratory failure, coma, and even death. **Final comments:** In this case the failure to identify classic signs of porphyria led to misdiagnosis and a delay in the correct treatment. Additionally, the mechanism of hyponatremia was not considered, leading to an incorrect correction and complications such as osmotic demyelination syndrome. This case report highlights the importance of disseminating information about the classic clinical presentation and the factors clinicians should consider when including porphyria in their diagnostic hypotheses. Early treatment has the potential to interrupt the damage process.

https://doi.org/10.5327/CBN240077

Acute intermittent porphyria: identification of novel variant in the HMBS gene

Camila Rodrigues Nepomuceno[1], Nayara de Paula Guerreiro[1], Maria Fernanda Hamamoto Leati[1], Andre Vinicio Cruz Mesias[1], Gabriella Corrêa Dousseau[1], Daniel Thomas Pereira Lopes[1], Cristiane de Araújo Martins Moreno[1], Arthur de Medeiros Dias[2], Ana Claudia Piccolo[2], Maria Sheila Guimarães Rocha[1]

[1]Hospital Santa Marcelina, São Paulo SP, Brazil. [2]Hospital Dr Alipio Corrêa Neto, São Paulo SP, Brazil.

Correspondence: Camila Rodrigues Nepomuceno; Email: camilarnepomuceno@gmail.com.

Case presentation: A 19-year-old woman has made multiple visits to the emergency room this year due to recurring abdominal pain. In April 2024, she was admitted to another hospital due to ascending areflex flaccid paralysis, where she was initially diagnosed and treated for Guillain-Barré syndrome (GBS). However, cerebrospinal fluid showed no cytoprotein dissociation. Her upper limbs were more severely affected than her lower limbs, and she also experienced seizures, confusion, and reduced level of consciousness. Electrolyte disturbances, particularly hyponatremia, were consistently observed during hospitalization. Given this context, porphyria was suspected, and a 24-hour urine analysis was conducted, revealing: Uroporphyrins 3078 mcg, Heptaporphyrins 183 mcg, Hexaporphyrins 48 mcg, Pentaporphyrins 98 mcg, Coproporphyrins I 153 mcg, and Coproporphyrins III 261 mcgall exceeding the laboratory reference values. She was then transferred to our service and qualitative analysis of ALA and PBG in urine was also positive. Subsequently, genetic sequencing revealed the variant c.751del: p. (Arg251Glyfs*4) in heterozygosity in exon 11 of the HMBS gene. This variant was classified as probably pathogenic (ACMG evidence: PM2, PVS1) and has not been previously described; it is absent in ClinVar and Gnomad databases. The patient received targeted treatment with hematin and glucose, which effectively controlled the crisis. **Discussion:** Acute intermittent porphyria (AIP), the most prevalent and severe form of hepatic porphyrias, is an autosomal dominant disorder caused by mutations in the HMBS gene. These mutations lead to a deficiency in hydroxymethylbilane synthase (HMBS), the third enzyme in heme biosynthesis. Common disease-causing mechanisms associated with the HMBS gene include missense, frameshift, splice site, and nonsense mutations. Symptoms of AIP include severe diffuse abdominal pain, headache, muscle weakness (often presenting as areflex flaccid paralysis, which can clinically mimic GBS), autonomic neuropathy, neuropsychiatric symptoms, hyponatremia, myoglobinuria, seizures, and coma. The penetrance rate of AIP is low, and the condition exhibits high clinical heterogeneity. Some mutations may influence the penetrance or severity of clinical manifestations, and several modifying genes have been identified over the years, including the PEPT2 gene, PPARA gene, cytochrome P450 gene, and ABCB6 gene. As mentioned above, we identified a novel frameshift variant in the HMBS gene. This variant has not been previously described and is absent from both the ClinVar and Gnomad databases. **Final comments:** Early diagnosis of AIP is crucial. This can be achieved through quantitative and qualitative porphyrin tests. Prompt diagnosis can prevent the progression to severe acute attacks, as well as chronic manifestations. Advances in genetic sequencing have led to the identification of numerous variants, aiding in genetic counseling and crisis prevention.

https://doi.org/10.5327/CBN240078

Acute myelorradiculitis after dengue infection

Bárbara Luisa Coraspe Gonçalves[1], Luiz Guilherme Gerhardt Fernandes[1], Maria Luiza Levindo Coelho Martinis[1], Ana Carolina Andorinho de Freitas Ferreira[1], Bárbara França Amorim[1], Cristiane Borges Patroclo[1], Marina Brasileiro Cesar Leitao[1], Marcelo Cagy[1], Osvaldo Pantoja de Oliveira[1]

[1]Hospital Federal dos Servidores do Estado, Rio de Janeiro RJ, Brazil.

Correspondence: Barbara Luísa Coraspe Gonçalves; Email: barbaracoraspeg@gmail.com.

Case presentation: A 52-year-old man, living in Rio de Janeiro, presented with fever, headache, myalgia, retro orbital pain, nausea, vomiting and fatigue. He sought emergency care and received symptomatic medication. After 5 days, he evolved with severe sensory ataxia, strap-like pain in the flanks level with irradiation to lower limbs. There was mild proximal paraparesis with a sensory loss level at T10, in addition to urinary and fecal retention, leading to hospitalization. Blood analysis disclosed hyponatremia (118mmol/L), positive NS1 and leukopenia (3,310/mm^3), negative C-reactive protein. CSF analysis pointed to 6 leukocytes/mm^3 (100% mononuclear), glucose 62mg/dL and protein 240 mg/dL, no growth of bacteria or fungi. Electromyography and MR were unremarkable. The neurological examination was compatible with myeloradiculitis, which was regarded as an acute arboviral complication. The patient received treatment with methylprednisolone for 5 days, physiotherapy and motor rehabilitation. He was discharged after partial clinical improvement. After 2 months, patient had recovered completely from ataxic gait, however, it remained light neuropathic pain in a waistcoat pattern. **Discussion:** In the first half of 2024, Brazil surpassed the mark of 2 million dengue (DENV) cases. According to data from the Ministry of Health, the country registered 2,010,896 cases in the first 11 weeks of this year, and more than 500 deaths. Symptoms of DENV fever include headache, retro-ocular pain, severe myalgia, arthralgia, rash, hemorrhagic manifestations and leukopenia. Although neurological manifestations might be rare, they reach up to 21% in Brazil. They encompass examples of direct invasion, immunemediated response and metabolic disturbance with neurological repercussion, such as: encephalopathy in parallel to cerebral edema and secondary to hyponatremia, fulminant hepatic failure or hypoxia; Guillain-Barré syndrome; encephalitis and myelitis. Myelitis is a rare neurological complication. It involves mostly males and presents usually with lower limbs sensorimotor impairment and sphincter disturbances within 2 weeks of dengue onset. The outcome is favorable in general, and the recovery may be full. It is caused by autoimmune reaction or direct invasion. The direct infection of the nervous system may stem from sequential infection, notably considering the hyperendemicity (the cocirculation of multiple dengue serotypes) and the neurotropic properties. The DENV2 and DENV3 viruses have been proved to cross the blood-brain barrier and invade the CNS. Our case fits in the most prevalent profile and seemingly derives from direct invasion. However, it was associated to normal MRI. This condition has been punctually reported, especially in MOGrelated disorders. **Final comments:** This report depicts a case of acute myeloradiculitis sparked during DENV infection presenting with normal MRI. The outcome resulted in full recovery of gait and residual thoracic radicular pain.

Acute spinal cord compression due to extramedullary hematopoiesis

João Victor Cabral Correia Férrer[1], Maria Eduarda Slhessarenko Fraife Barreto[1], Ruan Gambardella Rosalina de Azevedo[1], Victor Cardoso de Faria[1], Rafael Tuzino Leite Neves Maffei[1], Adriel Rego Barbosa[1], Andre Felipe Candêas Amorim[1], Marianna Pinheiro Moraes de Moraes[1], José Luiz Pedroso[1], Orlando Graziani Povoas Barsottini[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Maria Eduarda Slhessarenko Fraife Barreto; Email: madusfbarreto@gmail.com.

Case presentation: A 26-year-old man with beta-thalassemia major presented with paresthesia in lower limbs, genital numbness, urinary retention, constipation and erectile dysfunction, without low back pain, one day after falling from his own height. Physical examination disclosed tactile hypoesthesia on the posterior territory of the thigh and leg on the left and absent left Achilles reflex. Spinal cord magnetic resonance imaging (MRI) revealed T2 hyperintense and T1 heterogeneous contrast- enhancing soft tissue mass in the presacral region and in the lumbosacral epidural space, compressing the spinal cord and its roots. Electroneuromyography showed signs of acute denervation in myotomes S1-S4 on the left. He underwent decompressive laminectomy L5-S2 and radiotherapy sessions. Biopsy confirmed extramedullary hematopoiesis (EMH). **Discussion:** This condition occurs as a compensatory and physiological reaction in hemoglobinopathies and myeloproliferative disorders, such as thalassemia, sickle cell anemia, polycythemia vera and myelofibrosis. The most common sites are the liver, spleen and lymph nodes. EMH-induced spinal cord compression is rare and usually presents a subacute progression. Acute course is uncommon, and trauma can be a trigger. Low signal intensity on both T1- and T2-weighted MR images is characteristic of iron deposition and strongly suggests EMH. Treatment options are variable including blood transfusions, cytostatic agents, radiotherapy and decompressive surgery, this last option allowing an immediate decompression and an accurate histological diagnosis. **Final comments:** It is important to know about uncommon neurological complications of systemic diseases. The early diagnosis and correct treatment are essential to reduce clinical sequelae and to improve quality of life.

Correspondence: César Minoru Toita Koga; Email: cesarmtkoga@gmail.com.

Case presentation: A 76-year-old male with hypertension, dyslipidemia, and atrial fibrillation on edoxaban presented to the emergency department with sudden, complete right-sided sensorineural hearing loss, followed by vertigo, imbalance, nausea, and vomiting. He was treated symptomatically and discharged with oral prednisone. While vestibular symptoms improved, hearing loss remained. A neurology clinic evaluation after a month revealed an altered right head impulse test and ipsilateral anacusis, with normal strength, reflexes, coordination and sensory examination. Brain magnetic resonance imaging (MRI) taken 2 weeks after symptom onset revealed right labyrinth hemorrhage. **Discussion:** Labyrinthine hemorrhage (LH) is a rare condition involving bleeding within the intralabyrinthine compartment, presenting as sudden sensorineural hearing loss (SNHL) and any other dysfunction of the compartments of the labyrinth, such as vertigo, nausea, vomiting, nystagmus, and imbalance. While most LH cases are idiopathic, potential causes include hematological malignancies, autoimmune diseases, cerebral venous thrombosis, and anticoagulant therapy. However, LH associated with direct oral anticoagulants has not been reported. It is often characterized by profound hearing loss and resemble acute vestibular neuritis or labyrinthine ischemia, making the diagnosis challenging. The HINTS battery differentiates acute vestibular neuritis from stroke but may not adequately distinguish from LH or labyrinthine infarction. Furthermore, the HINTS plus battery, which includes acute hearing loss, could be used to differentiate LH from acute vestibular neuritis, but is limited in distinguishing LH from anterior inferior cerebellar artery (AICA) ischemic infarction, posing a risk of thrombolysis in patients with ongoing labyrinthine bleeding. Computed tomography (CT) alone lacks sensitivity in identifying intralabyrinthine disorders. Only brain MRI can detect labyrinthine hemorrhage in the acute phase, revealing hyperintensities in the labyrinth on T1 and FLAIR sequences. Treatment data for LH are limited. Common approaches include oral or systemic corticosteroids and intratympanic corticosteroid therapy. Discontinuing anticoagulants is recommended, but the risk-benefit balance is debated. In cases associated with anticoagulants, resuming therapy after 30 days and switching to a lower-risk agent like apixaban can be considered. Prognosis for hearing impairment in LH is generally poor, with most patients experiencing permanent hearing loss, while vestibular symptoms typically resolve within weeks due to central compensation. **Final comments:** LH is a rare cause of sudden SNHL and vestibular syndrome, often resulting in permanent ipsilateral deafness. Due to the scarcity of high-quality management data, treatment strategies should be individualized. Case reports such as this are important for raising awareness and acknowledgement of LH, since it may mimic acute vestibular neuritis.

Acute weight loss and alexythymia after stroke in the right caudate nucleus

Janaina Mariana de Araujo Miranda Brito Marques[1], Paulo Roberto de Brito Marques[1]

[1]Universidade de Pernambuco, Recife PE, Brazil.

Correspondence: Janaina Mariana de Araujo Miranda Brito Marques; Email: marianaaraujo6@gmail.com.

Case presentation: 78-year-old woman, admitted to a neurology outpatient clinic complaining of weight loss of 30 kg after an ischemic stroke 6 months ago. Refers to a patient who had chest pain 6 months ago and underwent cardiac catheterization in the emergency room with normal results. Immediately after the procedure, she presented left hemiparesis, followed by hyporexia and adipsia. She reported not feeling hungry or thirsty and when she ate felt disgust and a sensation of change in the texture and flavor of the food (as if she were drinking oil). Her behavior from extroverted and communicative changed to reclusive with a feeling of social inadequacy and difficulty identifying and expressing what she felt, her mood became depressed. The neurological examination showed left hemiparesis with hyperreflexia and the presence of striatal hand (Fig.1). Mini-Mental State Examination1 23/30, Montreal Cognitive Assessment2 13/30, Depression Scale3 (Zung) 46/80, Toronto Alexithymia Scale4 73/100. Brain magnetic resonance imaging (MRI) showed hyperacute ischemic insult in the right caudate nucleus (Fig. 2). **Discussion:** The Caudate Nucleus (CN) contains several neuronal clusters that are functionally connected to cortical areas that are part of networks involved in the cognitive and emotional process, whose lesions compromise multiple cognitive and behavioral domains. Personality change, psychiatric disorders, and cognition symptoms can do clinical syndrome. Lesions located in the right CN through their interconnections, with the orbitofrontal, medial and anterior prefrontal, and cingulate cortical areas, are involved in these behaviors. We report the case of a 78-year-old woman, who, in addition to the motor deficit, developed acute weight loss, mood changes, hyporexia, adipsia, bizarre taste perceptions, and alexithymia, which we infer as possible disconnection of networks with the right insula and hypothalamus. The cognitive and emotional consequences of CN lesions, as illustrated in the patient, emphasize the concept of network disturbance as a cause of cognition and behavioral manifestations of vascular disorders. **Final comments:** There are few studies on cognition and behavioral disorders caused by unilateral CN injury. Although these syndromes present strong similarities, there are subtle differences, which likely reflect the specific contribution of neuronal processing within each cognition and emotional network.

ADEM as the first manifestation of HIV in a young adult presented at a Brazilian tertiary hospital

Bruno Barros de Padua Andrade[1], Rodrigo Ferreira Faria[1], Giovanna Santos Rodrigues[1], Luiz Fernando Mohallem Reynaldo[1], Victoria Lot Avezum Mestriner[1], Elizardo Nogueira Junior[1], Marilia Mamprim de Moraes Perin[1], Matheus Spilari[1]

[1]Pontifícia Universidade Católica de Campinas, Campinas SP, Brazil.

Correspondence: Bruno Barros de Padua Andrade; Email: brndepadua@gmail.com.

Case presentation: A 28-year-old previously healthy male was admitted following a motorcycle crash. He reported asymmetric paraparesis and hypoesthesia with a sensory level at T6, both worse on the left side, since eight days prior to admission. Additionally, he described urinary incontinence and constipation during the initial assessment and had difficulty describing the chronological order of events, presenting as slightly drowsy. Initially, he underwent an MRI study based on the hypothesis of spinal cord syndrome and encephalopathy, which revealed tumefactive lesions with a pseudotumorous aspect in the right frontal (2), temporo-parietal (1) cortex, at the supratentorial level, and multiple coalescing lesions at the level of the cervico-thoracic transition. Due to the characteristics and topography of the lesions, serologies and CNS inflammatory markers were requested, revealing HIV+ (ELISA and Western blot), a pathology the patient was previously unaware of. Until the CD4 count and further serologies were realized, IVIG (0.4g/kg/d) was initiated. After subsequent exams came back negative (CD4 749 cells/mm^3), treatment was transitioned to Methylprednisolone 1g/d. Upon discharge, the patient had improved motor and sensory capacity in the upper limbs but retained motor and sensory deficits in the lower limbs. As treatment progressed, the patient also showed improvement in consciousness, achieved sphincter competency, and no longer required intermittent catheterization. **Discussion:** Acute disseminated encephalomyelitis (ADEM) is a rare inflammatory and demyelinating disorder of the central nervous system. Distinctively, ADEMs pathological changes tend to have a perivenous localization and commonly affect children following exposure to infections and vaccines. It has been associated with various viral infections including EBV, CMV, and less commonly HIV. There are few descriptions in the literature of patients with atypical manifestations of ADEM and HIV, generally presented in immunocompetent individuals or during seroconversion (CD4 counts > 500 cells/μL), due to the necessity of "autoreactive" circulating T-cells that predispose the development of an autoimmune response to HIV. **Final comments:** Although the initial approach to multifocal deficits of subacute onset should consider demyelinating disorders, particularly in HIV-infected patients, it must be distinguished from a spectrum of other opportunistic diseases that may present similarly, especially neuroinfections. Recognition and diagnosis must be prompt and should not delay treatment.

ADEM refractory to immunoglobulins as a presentation of mogad in a young woman

Adria Rodrigues da Silva[1], Bruna Beppler[1], Carol Zapelini[1], Lia Maki Hatisuka Imai[1], Luis Sidônio Teixeira da Silva[1], Lúcio Baena de Melo[1], Mônica Marcos de Souza[1], Gabriel Rodrigues Espelho Rossi[1]

[1]Universidade Estadual de Londrina, Londrina PR, Brazil.

Correspondence: Ádria Rodrigues da Silva; Email: adriarodriguess@hotmail.com.

Case presentation: Female patient, 43 years old, admitted to a tertiary hospital with a history of neck pain and sporadic holocranial headache for 2 years, worsening over the past 2 weeks. Symptoms included febrile episodes, paresthesia, and paresis in the left upper limb (LUL), followed by other limbs asymmetrically, confining her to a wheelchair. She also experienced tremors in the upper limbs, mental confusion, and urinary retention. Previously healthy, she had nodular skin lesions (neurofibromatosis type I). Neurological examination revealed inattentiveness, restlessness, aphasia, mild left facial paralysis, asymmetric tetraparesis, brisk reflexes, Hoffmann and Babinski signs present, bilateral exhaustible clonus, and predominant ataxia in the LUL. Cranial CT scan was normal. Cerebrospinal fluid (CSF) analysis showed 59 cells (88% lymphocytes) and 60 proteins. Serum serology for cytomegalovirus (CMV) IgM and IgG was positive, but negative in CSF with undetectable viral load. Oligoclonal bands were exclusively found in CSF. Neuroaxis MRI revealed T2/FLAIR signal abnormalities in the white matter adjacent to the left lateral ventricle body, left frontal lobe, and left amygdala, oval-shaped with contrast enhancement, and from C4 to T4 and lower dorsal levels/spinal cord cone, associated with pial surface enhancement. Despite switching from acyclovir to ganciclovir without improvement after 7 days of admission, intravenous human immunoglobulin 2g/kg was infused. The patient deteriorated, requiring therapeutic plasma exchange, and eventually discharged with improved consciousness, motor function, and ataxia, on Azathioprine 50 mg/day and Prednisone 10 mg/day. Subsequently, serum MOG-IgG test was positive (1:100), initiating periodic immunoglobulin therapy, weekly physiotherapy, and showing neurological improvement. **Discussion:** MOG antibody-associated disease (MOGAD) is an inflammatory demyelinating disease of the central nervous system (CNS) with heterogeneous clinical manifestations, ranging from isolated optic neuritis to multifocal CNS demyelination. Detection of MOG-IgG in serum confirms the diagnosis in patients with compatible clinical phenotypes and MRI findings. Concurrent infections such as rubella, CMV, and Epstein-Barr are reported, suggesting compromised blood-brain barrier during these exposures, leading to peripheral blood leakage of MOG antigens and substantial MOG-IgG production. In this case, however, the timing of CMV infection couldnt be determined. Crises often respond to high-dose corticosteroids, with plasma exchange reserved for refractory cases. Maintenance therapy relies on empirical immunosuppressants, though further studies are needed for treatment guidance. **Final comments:** MOGAD is a recently discovered, rare disease with variable phenotypes, challenging diagnosis, and uncertain treatment.

ADEM-like presentation in an immunocompetent host after disseminated tuberculosis: TB or not TB?

Jackeline Neves Pereira[1], Pedro Henrique Fraiman[1], Raphael Gusmao Barreto[1], Fernanda Ferreira Abreu[1], Gabriel Casela Speltri[1], Paula Massarani Peçanha-pietrobon[1], Marianna M. Moraes[1], Paulo Roberto Abrão Ferreira[1], Orlando Graziani Povoas Barsottini[1], Jose Luiz Pedroso[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Jackeline Neves Pereira; Email: jac.nevesp@gmail.com.

Case presentation: A 23-year-old woman in the late stages of pregnancy presented to the Hospital with fever and abdominal pain. She was diagnosed with pyelonephritis and underwent an emergency cesarean section due to fetal bradycardia. During the days following the surgery, she maintained abdominal pain and an abdomen computerized tomography (CT) scan revealed a pancreatic solid-cystic mass, signs of pyelonephritis, colonic swelling, and peritoneal implants. She developed pneumoperitoneum due to a cecum perforation, the histopathological analysis confirmed disseminated tuberculosis (TB), in addition to an incidental pancreatic tumor suggestive of pseudopapillary pancreatic neoplasm (later confirmed through biopsy). She tested negative for HIV and infectious hepatitis. After two weeks of standard TB treatment, she developed optic neuritis in the right eye, rapidly deteriorating to a hand movement perception. The first hypothesis was an effect of Ethambutol, which was then suspended. Nevertheless, one week later, the contralateral eye was also affected. The brain Magnetic Resonance (MR) revealed signs of bilateral optic neuritis. Cerebrospinal fluid (CSF) study was negative for TB and neoplasm cells, besides a normal glucose, protein, and cell count. Despite Methylprednisolone pulse therapy and plasmapheresis, she maintained bilateral visual loss and developed weakness in the right arm. A new brain MR revealed hyper-intensities in the frontal lobe, corpus callosum, and brain stem, compatible with demyelinating lesions. The brain biopsy was negative for TB and compatible with demyelination. The auto-immunity panel was negative for either surface or intranuclear antibodies, including anti-MOG antibodies. After hospital discharge, the patient presented a progressive partial recovery from her neurological deficits until the day of this report and could see the face of her child for the first time after 5 months of having given birth. **Discussion:** The presented case had a series of challenges to the correct diagnosis of her neurological symptoms: an immunocompetent patient, a pancreatic neoplasm, repetitive negative molecular tests for TB in the CSF, Ethambutol side effects similar to the initial visual deficit, and progression of neurological symptoms during treatment despite corticosteroids use. Indirect effects of TB in the central nervous system are not the most common presentation of the disease, especially of demyelinating nature, presenting as Acute Demyelinating Encephalomyelitis (ADEM) like syndrome, as we describe here. **Final comments:** ADEM-like syndrome related to TB has been reported before and should be kept in mind by neurologists, especially in countries with a high prevalence of the disease. The differential diagnoses are mostly Ethambutol side effects or direct TB effects in the CNS. The rapid progression and characteristics of lesions monitored by MRI should help to differentiate, in addition to the usual benign course with symptoms and image regression.

Adherence to AHA life's essential 8 criteria in stroke patients: an observational study

Catarina Dantas Corrêa[1], Eduarda de Almeida Joly[1], Gabriel de Camargo de Brito[1], Gabrielle Beatriz da Cruz Ferreira[1], Pedro Paulo Daniel Rocha[1], Renata Dal-prá Ducci[1], Valéria Cristina Scavasine[1], Juliano André Muzzio[1], Viviane de Hiroki Flumignan Zétola[1], Marcos Christiano Lange[1]

[1]Universidade Federal do Paraná, Curitiba PR, Brazil.

Correspondence: Catarina Dantas Correa; Email: catarinadcorrea@gmail.com.

Background: Cardiovascular diseases are a major cause of mortality and morbidity worldwide. In Brazil, cardiovascular diseases are the leading cause of non-traumatic death. The American Heart Association (AHA) Lifes Essentials 8 framework (comprising Diet, Physical Activity, Nicotine Exposure, Sleep Health, Body Mass Index, Blood Lipids, Blood Glucose, and Blood Pressure) provides a holistic approach to health, shifting the focus from merely treating cardiovascular diseases to promoting and preserving overall health. **Objective:** To evaluate the adherence of stroke patients to the American Heart Association (AHA) Lifes Essential 8 criteria. **Methods:** This observational study analyzed data from 41 patients admitted to a stroke unit over a four-month period. Data were collected on diet, physical activity, smoking, sleep, BMI, non-HDL levels, blood glucose, and blood pressure, with scores ranging from 0 to 100 according to the Lifes Essential 8 criteria. **Results:** The median overall Lifes Essential 8 score for the study population was 58 (IQR 50-65). Median scores for lifestyle habits were as follows: adherence to diet, 50 (IQR 25-50); physical activity, 0 (IQR 0-40); smoking, 75 (IQR 0-100); and sleep quality, 90 (IQR 40-100). For risk factors, the median scores were: BMI, 70 (IQR 70-100); non-HDL levels, 80 (IQR 60-100); blood glucose, 100 (IQR 60-100); and blood pressure, 30 (IQR 5-100). **Conclusion:** This study demonstrated low adherence scores for blood pressure, physical activity, and diet according to the Lifes Essential 8 criteria. These findings suggest that health intervention strategies and policies should focus on improving physical activity and diet among stroke patients.

https://doi.org/10.5327/CBN240086

Admission trends for epilepsy in the Northeast region over the last 10 years and the impact of the COVID-19 pandemic

Willian Alves Costa[1], Danilo Silva Nogueira[1], Juliana Alencar Isacksson Vieira[1], Vinícius Gabriel Nunes de Freitas[1], Pedro Antônio Tavares Pinto[1], Agnus Gabriel Bitencourt Magalhães[1], Francisco Edvan Batista Filho[1], Thiago da Costa Brito[2]

[1]Universidade Federal do Amapá, Macapá AP, Brazil. [2]Universidade Estadual do Pará, Belém PA, Brazil.

Correspondence: Danilo Silva Nogueira; Email: danilo-nogg@hotmail.com.

Background: Epilepsy is one of the most prevalent chronic neurological conditions in Brazil. It is characterized by recurrent epileptic seizures, related to abnormal electrical activity in the brain, without a readily defined or identified causal factor. **Objective:** this study aims to outline an epidemiological overview of hospital admissions due to epilepsy in the Northeast region over the past decade, as well as to evaluate the implications of the COVID-19 pandemic. This works aims to make. **Methods:** This is a descriptive, retrospective, and cross-sectional study involving the collection and analysis of data from the Hospital Information System (SIH/SUS), extracted from the Department of Health Informatics of the Unified Health System (DATASUS). The category "Epilepsy" was analyzed in the Northeast region from 2014 to 2023, considering variables such as Region, Federative Unit, year, race, age group, sex, and hospital admissions. The collected data were organized into tables using EXCEL 2016 software. **Results:** The Northeast region constitutes the second highest region in terms of epilepsy hospital admissions reported over the past 10 years (128,605 cases). The majority of cases were reported in the states of Pernambuco and Bahia (27.2% and 27.08% respectively). Conversely, Sergipe had the lowest number of recorded cases (2.31%). Over these 10 years, there was a progressive increase in cases, with 2022 and 2023 showing the highest prevalence (12.6% and 11.9% respectively). A sharp decline was observed in 2020, with a prevalence of 9.2%. In Pernambuco, there were variations in this

pattern regarding the peak years; instead of 2022 and 2023 , 2021 and 2022 showed the highest prevalence (3.3% and 3.4% respectively). Regarding demographic profile, males (58.6%) and individuals of mixed race (67.2%) constituted the majority of cases. In terms of age group, prevalence was highest among children aged 0 to 9 years (38.9%), particularly in the state of Ceará (25.12%). Conversely, individuals aged 15 to 19 years and those aged 80 years and above were the least affected (5.4% and 4% respectively). **Conclusion:** Therefore, based on the results obtained, it was observed that epilepsy has been on the rise in the Northeast region over the past 10 years, particularly in the state of Pernambuco and among males and individuals of mixed race. Regarding age groups, there was notable prevalence among children aged 0 to 9 years; however, these findings are closely linked to the high incidence rates affecting this age group in the state of Ceará. Additionally, it was noted that the Covid-19 pandemic had a significant impact on the number of hospital admissions, as evidenced by the significant decrease reported in 2020.

https://doi.org/10.5327/CBN240087

Advances in modulation of the microbiota-gut-brain axis: treatment of neuropsychological disorders and functional gastrointestinal disorders

Jocsã David Gomes Santos[1], Luan Kelves Miranda e Souza[1]

[1]Instituto de Educação Superior do Vale do Parnaíba, Parnaíba PI, Brazil.

Correspondence: Jocsã David Gomes Santos; Email: jocsadavid.jd@gmail.com.

Background: The bidirectional communication between the gastrointestinal system and the central nervous system, known as the microbiota-gut-brain axis, is important for the regulation of physiological and psychological functions. In this context, contemporary science has revealed the role of the gut microbiota in modulating this axis, offering new therapeutic perspectives for neuropsychological and gastrointestinal disorders. The influence of the microbiota on mental health and gastrointestinal function has attracted significant scientific interest, highlighting the need to explore interventions based on axis modulation. **Objective:** To review recent advances in the modulation of the microbiota-gut-brain axis, focusing on the application of microbiota-based interventions for the treatment of neuropsychological and functional gastrointestinal disorders. **Methods:** This is an integrative literature review with a cross-sectional, retrospective design, using the descriptors "Microbiome-Brain-Gut Axis", "Neurocognitive Disorders", and "Gastrointestinal Microbiome" from the Health Sciences Descriptors (DeCS), combined with the Boolean operator AND. The databases used were PubMed, Scielo, and Dynamed. The research included articles in Portuguese, English, and Spanish, within the time frame of 2020 to 2024. Original articles, systematic reviews, and meta-analyses were included, while articles unrelated to the topic, letters to the editor, editorials, and opinion articles were excluded. **Results:** The modulation of the microbiota-gut-brain axis through probiotics involving Bifidobacterium and Lactobacillus reduces cortisol levels and has shown efficacy in reducing symptoms of neuropsychological disorders, such as depression and anxiety, as well as functional gastrointestinal disorders, such as irritable bowel syndrome. Additionally, the administration of serotonin receptor agonists, such as psilocybin or 2,5-dimethoxy-methylamphetamine, has shown significant therapeutic potential, as elevated serotonin levels in the intestinal lumen promote the proliferation of bacteria like Turicibacter sanguinis, which can regulate genetic pathways in the gastrointestinal system and be used as treatments for depression, anxiety, and inflammatory bowel diseases. Studies also highlight the importance of personalizing interventions based on the individual microbiota profile of patients to increase efficacy. **Conclusion:** Microbiota-based therapies represent a significant advancement in the treatment of neuropsychological and gastrointestinal disorders, with a reduced side effect profile compared to traditional treatments. The incorporation of these interventions into clinical practice could revolutionize the management of various conditions, significantly improving patients' quality of life.

https://doi.org/10.5327/CBN240088

Advances in the treatment of glioblastoma: traditional therapeutic strategies vs. modern therapies - systematic review

Graziele Gleice da Silva[1], Ana Silvia Suassuna Carneiro Lúcio[1], Alexandre Jorge de Andrade Negri Júnior[1]

[1]Faculdade de Ciências Médica da Paraíba, João Pessoa PB, Brazil.

Correspondence: Graziele Gleice da Silva; Email: grazielle_gleice@hotmail.com.

Background: Glioblastoma (GBM) is a grade 4 astrocytoma (WHO), the most common primary malignant tumour of the central nervous system (CNS). It is responsible for about half of the malignant CNS tumours, with a 5-year survival rate of 7.2%. The standard GBM therapy includes neurosurgery, radiotherapy (radiation therapy), and chemotherapy. This type of therapy has not been very successful due to recurring side effects. There is however a promising, modern form of therapy consisting of immunotherapy and virotherapy, combining oncolytic viruses [OVs] and cancer vaccines. Additionally, significant progress is notable in tomo-, NanoTherm-, or individualized multimodal immunotherapy (IMI). Ongoing challenges in GBM treatment include insufficient resection, a high degree of heterogeneity, and an immunosuppressive microenvironment. **Objective:** To highlight the most modern therapies in the treatment of glioblastoma and their effectiveness compared to traditional therapies. **Methods:** This is a systematic review of the literature guided by the question: "What are the new therapies for glioblastoma?" The article selection took place between February and May 2024 carried out through the U.S. National Library of Medicine (PUBMED) database. The inclusion criteria were: primary original articles addressing new therapies in GBM treatment, available in Portuguese and in English. There were no restrictions on the study design, however, only articles from 2021 to 2023 were selected. Exclusion criteria included articles that did not address the theme. The following indexed descriptors from Health Sciences Descriptors (DeCS) were used: "Glioblastoma", "Immunotherapy", and "Virotherapy". **Results:** Immunotherapy combined with virotherapy and cancer vaccines is an innovative therapeutic regimen. Personalized medicine encompasses the patient as a whole in the context of immunotherapy, such as individualized multimodal immunotherapy (IMI). This is based on individual tumour-host immune interactions and the concept of OV-induced immunogenic tumour cell death (ICD). Ongoing challenges in GBM treatment include insufficient resection, a high degree of heterogeneity, and an immunosuppressive microenvironment. Treatment with OVs is more beneficial and safer than regular treatment, with fewer side effects, making it a promising course of treatment for GBM. **Conclusion:** Given that there are modern treatments available, a transformation in the clinical trials is needed, both to their specific approach and to individual patient approach. This will lead to more targeted guidelines and better humanization of GBM patients' treatment.

Advantage of FilmArray® over conventional methods in the diagnosis of acute bacterial infections of the central nervous system, including meningitis caused by listeria monocytogenes

Renan Domingues[1], Irineu Massaia[1], Camila Spinelli[1], Myrna Monteiro[1], Márcio Vega[1], Lais Guerra[1], Daiane Salomão[1], Carlos Senne[1]

[1]Senne Liquor Diagnóstico, São Paulo SP, Brazil.

Correspondence: Renan Barros Domingues; Email: contato@renandomingues.med.br.

Background: The etiological diagnosis of bacterial meningitis is fundamental for supporting accurate therapeutic decisions, making the early initiation of antimicrobials crucial. **Objective:** In this study, we evaluated the performance and utility of FilmArray® compared to conventional microbiological methods in the diagnosis of bacterial meningitis. **Methods:** We retrospectively evaluated CSF data from 2502 samples of patients suspected of having CNS infection, focusing on the CSF data from cases where a bacterial agent was identified. **Results:** Ninety cases were positive for bacteria, with the following agents identified: E. coli K1 = 3, H. influenzae = 17, L. monocytogenes = 8, N. meningitidis = 16, S. pneumoniae = 35. Of these, only 21 (23.3%) were positive with conventional microbiological methods, including culture and/or bacterioscopy, with the following distribution: E. coli K1 = 0/3 (0%), H. influenzae = 4/17 (23.5%), L. monocytogenes = 2/8 (25%), N. meningitidis = 5/16 (31.2%), S. pneumoniae = 8/35 (22.8%). For the 8 samples positive for L. monocytogenes, the cell count was 853.4 cells/mm3 (90-2560 cells/mm3), with neutrophils in CSF ranging from 17% to 78%. The protein level was 146.5 mg/dl (69-263 mg/dl), glucose was 30.5 mg/dl (12-238 mg/dl), and lactate was 82.1 mg/dl (44.9-160.3 mg/dl). Only two cases had a positive culture. **Conclusion** The study confirms previous data indicating that FilmArray® significantly increases the sensitivity of the etiological diagnosis of bacterial meningitis for all agents included in the panel, including L. monocytogenes. The results of this study corroborate the low sensitivity of conventional microbiological methods and suggest that molecular methods constitute the best tool for the etiological diagnosis of these cases.

Aerobic physical exercise improves quality of life in temporal lobe epilepsy

Shai Oisiovici Laks[1], Nathalia Volpato[1], Nikolas Coelho[1], Mateus Henrique Nogueira[1], Clarissa Lin Yasuda[1], Luciana Ramalho Pimentel da Silva[1], Fernando Cendes[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Shai Oisiovici Laks; Email: s243177@dac.unicamp.br.

Background: Aerobic physical exercise (APE) has been showing improvement of quality of life (QoL) and mood disorders in a series of chronic brain diseases [1]. A prior study from our group showed that people with temporal lobe epilepsy (TLE) with an active lifestyle present better QoL, but the influence of APE in the QoL of TLE is still unclear[2]. As drug-resistance is commonly associated with TLE, the possibility of seizures happening during the activities might prevent patients from benefiting from APE. **Objective:** We aimed to analyze the influence of APE in the QoL of TLE patients, also focusing on the seizure worry subitem of the QoL in epilepsy 31 (QOLIE-31) questionnaire. **Methods:** We selected and reviewed data from

51 individuals with TLE who participated in a 6-month APE program under the supervision of a board-certified physical trainer. TLE patients were divided into training (TLE-training) and control (TLE-control) groups. The TLE-training group went through an APE program of 6 months, while the TLE-control group was oriented to keep their routine. Both groups were assessed by the QOLIE-31 before and after the intervention (APE-time). A mixed-between subjects ANOVA was conducted to assess the impact of the APE intervention compared to TLE-control pre- and post-intervention on the QoL. We set p< .05 as statistically significant. **Results:** There was a significant interaction between intervention-groups and APE-time (p=.0005), showing that only patients on the TLE-training group presented with higher QoL after the intervention (p=0.001). As for seizure worry, we have not found any significant differences between groups (p=0.50). **Conclusion:** The APE improved QoL and did not increase the SW, which might be a feature of concern for both patients and healthcare practitioners. Further studies should focus on long term interventions to evaluate the long-term impact of APE in the QoL of TLE patients.

Age of onset and clinical characteristics of neuromyelitis optica spectrum disorder: a cross-sectional study in Espírito Santo

Vinícius Andreata Brandão[1], Igor Flavio Gonçalves do Vale[1] , Mackeyle Siqueira de Souza[1], Sávio Cesar Rodrigues Pestana[1], Victória Pagani Samora Sousa[1], Paula Zago Melo Dias[2], Bruno Batitucci Castrillo[2], Carlos Alberto Magirius Peixoto[2]

[1]Universidade Federal do Espírito Santo, Vitória ES, Brazil.
[2]Hospital Universitário Cassiano Antônio Moraes, Vitória ES, Brazil.

Correspondence: Vinícius Andreata Brandão; Email: viniciusandreatab@gmail.com.

Background: Neuromyelitis optica spectrum disease (NMOSD) is a rare autoimmune condition, usually associated with antibodies against aquaporin-4 (anti-AQP4), which leads to demyelination of the central nervous system, mainly affecting the optic nerve and spinal cord. Typically, the onset of these symptoms occurs between the third and fourth decades of life, although, less frequently, they can appear in any age group. **Objective:** To assess the age of onset of symptoms in patients diagnosed with NMOSD with positive IgGaquaporin-4. **Methods:** This is a cross-sectional study carried out at a neurology outpatient clinic in a public health service in Espírito Santo, Brazil. The electronic medical records of patients diagnosed with NMOSD were reviewed to assess the age of patients at the first disease attack. Data was categorized into late onset NMOSD (LONMOSD), after the age of 50; and very-late onset NMOSD (VLONMOSD), after the age of 70. **Results:** The average age of onset of symptoms among the 31 patients studied (28 women and 3 men) was 38.5 years, ranging from 13 to 79 years. Among these patients, six (19.3%) started their symptoms before the age of 20, while eight (25.8%) had their first symptoms after the age of 50. Of those who had their first symptoms after 50, 16.19% were classified as LONMOSD and 9.67% as VLONMOSD. Patients who experienced their first attack after the age of 50 had a lower incidence of optic neuritis, with an average of 0.6 attacks per person (standard deviation of 0.7) over two years of disease. In contrast, patients below the age of 50 had an average of 1 attack per person (standard deviation of 0.6). Regarding longitudinally extensive transverse myelitis (LETM), both age groups had an average of 1 attack over two years. **Conclusion:** The average age of onset found in this study aligns with global literature, which indicates a peak prevalence of NMOSD around the age of 40. However, the prevalence of NMOSD after the age of 50 is notably higher than the global average. The clinical characteristics observed in patients with LONMOSD demonstrates higher incidence of spinal cord lesions compared to optic neuritis (ON), often resulting in a poorer prognosis compared to patients with onset before age 50. Furthermore, older patients are more likely to have comorbidities and reduced immune function, which contribute to worse clinical outcomes and a lower life expectancy free from disability, despite aggressive immunosuppressive treatment.

Age profile of mortality in viral and bacterial meningitis cases: an epidemiological study (2012-2022)

Paulo Victor de Santiago Gonçalves[1], Leonardo José Rodrigues de Araújo Melo[1], Leslie Mateus de Sousa Nunes[1], Victor Domingueti Vallim Fonseca[1], Francisco Luciano Honório Barreto Cavalcante[1], Cássia Caroline Aguiar da Ponte[1], Cynthia Paz Rodrigues[1], Leonardo Elias Araujo[1], Lucas Soares Radtke[1], Heitor Rios de Medeiros Virginio[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Paulo Victor de Santiago Gonçalves; Email: paulo.santiago6571@gmail.com.

Background: Infections that affect the meninges, causing inflammation known as meningitis, can result from various bacterial and viral pathogens. These agents typically exhibit higher incidence rates across different age groups, capitalizing on the varying immunological characteristics of individuals at different life stages. **Objective:** This study aims to delineate the age profile of patients with confirmed deaths due to viral and bacterial meningitis between 2012 and 2022. **Methods:** We conducted an epidemiological investigation of confirmed fatal cases of viral and bacterial meningitis spanning the years 2012 to 2022. Data were collected from the DATASUS Notifiable Diseases Information System, and statistical analysis was performed using Jamovi software. **Results:** Based on epidemiological data from DATASUS for the period 2012 to 2022, deaths attributed to clinical complications of bacterial meningitis (6,613 deaths) significantly outnumbered those caused by viral meningitis (683 deaths). When examining patient age groups, we observed that 11.72% of deaths occurred in children under 1 year old due to bacterial infections, and 8.5% were related to viral infections. These findings indicate a declining trend up to age 19, followed by an increase with advancing age. The highest mortality rates occurred in the 50 to 69 years age group for bacterial meningitis (30.6% of deaths) and the 40 to 59 years age group for viral meningitis (26.2% of deaths). Similar to the first two decades of life, there is a decline in mortality beyond age 70. **Conclusion:** The collected data allows us to construct an age profile of meningitis victims. Notably, very young children face a higher risk of severe infection and mortality. As physiological development progresses (up to the end of adolescence), the death rate tends to decrease, only to rise again, peaking around age 50 for bacterial variants and age 40 for viral variants. However, after this peak, cases decline beyond age 70 for both studied variants.

Albendazole plus praziquantel versus albendazole alone in the treatment of neurocysticercosis: a systematic review and meta-analysis

Luísa Menegaz Veronese[1], Gabriela Oliveira Caetano[1], Jade Lingiardi Altoé[2], Laíse Lênin Leodoro Silva[1], Maria Eduarda Silva[1], Artur Menegaz de Almeida[1], Ítalo Barros Andrade[1], Michele Kreuz, Davi Tanajura Costa[3]

[1]Universidade Federal de Mato Grosso, Sinop MT, Brazil.
[2]Universidade Cesumar, Maringá PR, Brazil.
[3]Universidade Luterana do Brasil, Canoas RS, Brazil.

Correspondence: Artur Menegaz de Almeida; Email: arturomenegaz@gmail.com.

Background: Neurocysticercosis is a parasitic neurological disease, considered by the World Health Organization (WHO) as one of the most neglected tropical diseases in the world, also being an important public health concern in Brazil. The eggs of the Taenia solium hatch and the larvae spread through highly vascularized tissues, including the brain. Most patients are asymptomatic, but in some cases, cysts can cause inflammation, which can lead to headaches, seizures, and intracranial hypertension. The preferred treatment for neurocysticercosis remains unclear: the combination therapy of albendazole plus praziquantel has been associated with greater benefits than albendazole alone. **Objective:** To assess the safety and efficacy of albendazole plus praziquantel therapy for neurocysticercosis in comparison to albendazole alone. **Methods:** MEDLINE, Embase, and Cochrane databases were systematically searched until May 11, 2024. Data were examined using the Mantel-Haenszel method and 95% confidence intervals (Cls). Heterogeneity was assessed using I^2 statistics. Primary outcomes were the reduction of cysts, seizure recurrences, and possible adverse events. R, version 4.3.2, was used for statistical analysis. **Results:** A total of 4 randomized controlled trials and 313 patients, in which 129 (41%) were submitted to combined therapy. Compared to albendazole monotherapy, the combination of albendazole plus praziquantel regimen achieved better rates of cyst resolution (68% vs 42%; odds ratio [OR] 2.87; CI 95% 1.74-4.72; P = 0.00003; I^2 = 1%). Furthermore, no difference was seen regarding the occurrence of adverse events (18% vs 23%; risk ratio [RR] 1.17; CI 95% 0.76-1.79; P=0.481345; I^2= 12%). Seizure relapse endpoint did not reach a statistically significant difference between groups (10% vs 9%; risk ratio [RR] 1.36; CI 95% 0.68-2.72; P= 0.383208; I^2= 0%). **Conclusion:** In this meta-analysis, consistent results suggest that albendazole plus praziquantel combined therapy is associated with more beneficial outcomes than albendazole alone in treating neurocysticercosis.

Alien hand syndrome associated with lesion in the corpus callosum and frontal lobe

Sávio Roberto Silva Costa[1], Fernando Gabriel dos Santos Santiago[1], Gustavo Celeira de Sousa[1], Danusa Neves Somensi[1], Emanuel de Jesus Soares de Sousa[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Gustavo Celeira de Sousa; Email: gustavo.c.sousa0@gmail.com.

Case presentation: Male, 59 years old, describes complaints of involuntary movements in the right hand that began 1 year after a stroke. These movements have characteristics of grasping, strangling, or pulling. However, the movements can also precede the motor act, causing the limb to make gestural movements in relation to speech or perform movements that the patient intended to do with the contralateral limb. Additionally, it presents motor incoordination in the left upper and lower limbs after the stroke. MRI shows gliosis in the left frontal lobe from the superior frontal gyrus to the precentral gyrus, as well as signs of ischemia in the corpus callosum and cingulate gyrus. On the physical examination, he is in good general condition, scoring 20/30 on the mini-mental state examination. Neurological examination reveals pathological findings such as absence of movement in the right foot, hyperreflexia, and increased reflexogenic area in the right patellar reflex. Motor coordination is

altered in the index-nose test with the left hand, and cranial nerve evaluation shows right nasal hemianopsia. **Discussion:** This case represents a rare condition known as alien hand syndrome, defined as involuntary and seemingly purposeful autonomous activity, combined with the patients erratic perception, usually associated with difficulty recognizing the limb in the absence of visual cues. It is worth noting that the hand is the most commonly affected limb, but the alteration can be found in other limbs as well. The pathophysiology describes lesions in the frontal lobe or the anterior portion of the corpus callosum, and, more rarely, in the parietal region. The clinical presentation varies according to the affected location. Thus, lesions in the frontal lobe, such as the supplementary motor area, cingulate gyrus, and medial prefrontal cortex, mainly affect the dominant hand and are characterized by frontal release signs - grasping and groping. In lesions of the corpus callosum, intermanual conflict is presented, while parietal lesions provide a sensation of limb estrangement and the appearance, mainly, of the levitation phenomenon. Therefore, the similarity between the imaging findings of the patient in question and the characteristic clinical manifestations, mainly of the frontal lobe and corpus callosum lesion variants, is evident. **Final comments:** The onset of this syndrome is generally due to acute focal lesions, and in this condition, recovery occurs within 1 year. However, in chronic and degenerative brain lesions, the clinical symptoms may persist for life. Currently, there is no specific treatment or rehabilitation for the condition, but it does not cause any harm to the patient's physical integrity.

[2]Universidade Nove de Julho, São Paulo SP, Brazil.
[3]FisioPETI, São Bernardo do Campo, SP, Brazil.

Correspondence: Débora Bachin Carvalho; Email: dbachinc@gmail.com.

Background: Autism Spectrum Disorder (ASD) is classified into three levels of severity. At level 2, the child needs substantial support and is subject to motor skills delays. A frequently used instrument to assess these children is the Operationalized Portage Inventory (OPI). Although the OPI is widely used, studies describing the identified motor difficulties are still rare. **Objective:** To analyse the overall motor performance of children with ASD level 2, according to the OPI, and to check the correlation to their performance in language, cognition, self-care and socialization. **Methods:** This is a retrospective observational cross-sectional study, analyzing 47 medical records of children aged between three and six years old, seen at FisioPETI Rehabilitation Clinic, São Bernardo do Campo / SP. The project was approved by the Research Ethics Committee of the Faculdade de Medicina do ABC University Center, protocol no. 70421023.0.0000.0082. The following data was collected: age, gender, Childhood Autism Rating Scale (CARS) score, developmental classification (in years) and quantification of developmental delay (in months) in each dimension of the OPI. Pearson's correlation test was used to relate the delay in overall motor performance to the other dimensions. The sample power calculation to quantify the delay in global motor performance was 100%. **Results:** In the sample of 47 patients (CARS median: 33), 74.47% were male, 91.49% showed delay in global motor performance, 97.87% in self-care and 100% in language, cognition and socialization. The median age was 4.0 years old, the global motor development, 2.7 (years); self-care, 2.5; cognition, 1.7; socialization, 1.6 and language, 0.9. The quantification of developmental delay in months (average) was 19.93 in global motor, 21.06 in self-care, 29.76 in cognition, 31.52 in socialization and 36.87 in language. There was a significant correlation between developmental delay and all other dimensions: language ($p< 0.001$), cognition ($p< 0.001$), socialization ($p< 0.001$) and self-care ($p< 0.001$). **Conclusion:** The largest proportion of children with ASD level 2 showed delays in all neurodevelopmental dimensions assessed by the OPI, however, motor development was less severe. A correlation was found between the severity of the motor alteration and the impairment in all other developmental dimensions.

Altered cerebral vasoreactivity on transcranial color-coded sonography related to akinetic-rigid phenotype of Parkinson's disease and individuals with Parkinson's disease and risk factors for cerebrovascular disease

Rodrigo Tavares Brisson[1], Rita de Cássia Leite Fernandes[1], Josevânia Fulgêncio de Lima[1], Liene Duarte Silva[1], Marco Antônio Sales Dantas de Lima[1], Ana Lucia Zuma de Rosso[1]

[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Rodrigo Tavares Brisson; Email: quimicarod@hotmail.com.

Background: A correlation between worse functional outcomes in Parkinson's disease (PD) patients with cerebrovascular disease (CVD) or the Akinetic-rigid phenotype has been argued in recent studies. **Objective:** To evaluate the association of cerebral hemodynamics impairments, assessed by Transcranial Color-coded Doppler sonography (TCCS), on PD patients with different phenotypes of the disease and with risk factors for CVD. **Methods:** Idiopathic PD patients (n = 64) were divided into motor subtypes: Akinetic-rigid (AR) (n = 31) and Tremor-dominant (TD) (n = 33) and into two groups regarding vascular risk factors: when ≥2 were present (PDvasc) (n = 20) and < 2 (PDnvasc) (n = 44). In a parallel analysis, the Fazekas scale on brain magnetic resonance imaging (MRI) was applied to a sample to assess the degree of leukoaraiosis. TCCS examinations were prospectively performed obtaining middle cerebral artery Mean Flow Velocities (Vm), Resistance Index (RI), and Pulsatility Index (PI). The Breath-Holding Index (BHI) was calculated to assess cerebrovascular reactivity (cVR). Standardized functional scales were administered (UPDRS III and Hoehn&Yahr). **Results:** The phenotype groups were similar in age, disease duration and demographic parameters, but there were significantly higher H&Y scores on RA group (2,66±1,6 vs 2,21±0,78; p=0.05). cVR was impaired in 64% of AR vs. 36% of TD (odds ratio: 3,18). AR group exhibited lower BHI (0.56 ± 0.32 vs. 0.97 ± 0.60; $p = 0.001$), lower Vm after apnea (45.8 ± 10.9 cm/s vs. 53.18 ± 10.4 cm/s; $p = 0.008$), higher PI (0.91 ± 0.24 vs. 0.8 ± 0.15; $p = 0.029$). PDvasc group showed higher PI (0.97 ± 0.22 vs. 0.80 ± 0.18; $p = 0.001$), higher IR ($0.59 \pm 0,09$ vs. 0.54 ± 0.08 ; $p = 0.042$) and higher frequency of altered cVR (75% vs. 38%; $p = 0.007$ - odds ratio: 4,7). There was a significant predominance of higher values on Fazekas scale in the PDvasc group (p=0.004). We found no difference between the Fazekas scale when comparing motor subtypes groups but there was a trend toward higher scores in the AR phenotype. **Conclusion:** TCCS, a cost-effective method, displayed impaired cVR in Parkinsonian patients with risk factors for CVD with higher degree of MRI leukoaraiosis. PD patients with the AR disease phenotype also presented higher frequency of impaired cVR on TCCS and greater functional impairment, although with just a trend to higher scores on MRI Fazekas.

Alternating hemiplegia in childhood associated with epilepsy, a rare disease related to ATP1A3 gene mutation: case report

Vanessa Lopes Senssuliin[1], Andrea Senna Pessoto Serafin Gallina[1]

[1]Universidade Anhembi Morumbi, Piracicaba SP, Brazil.

Correspondence: Vanessa Lopes Senssulini; Email: vsenssulini@gmail.com.

Case presentation: A 3-year-old female patient, only child of non-consanguineous parents, began experiencing bilateral muscle spasms and rotary eye movements at three months of age. During that period, transfontanelle ultrasound and electroencephalogram (EEG) were both normal. Despite this, she was diagnosed with epilepsy and started treatment with Phenobarbital combined with oxcarbazepine. Over a year, attempts to taper medication resulted in worsened symptoms, including tonic-clonic seizures, persistent eye movements, and right-sided hemiplegia. Due to refractory symptoms and clinical deterioration, Levetiracetam was added, followed by Clobazam, yet seizures persisted. Various diagnostic tests were conducted, including cranial MRI and EEG, all yielding no significant abnormalities. A geneticist recommended genetic testing for ataxias and epilepsy, identifying a heterozygous pathogenic variant in the ATP1A3 gene (Gly947Arg). Flunarizine was subsequently added to the treatment plan based on genetic findings, alongside ongoing multidisciplinary management. **Discussion:** The patient was ultimately diagnosed with Alternating Hemiplegia of Childhood (AHC) associated with the ATP1A3 gene mutation, despite initial treatment for epilepsy. The link between AHC and this mutation is recent, with most cases identified post-2012. Diagnostic criteria for AHC, established since 1993, include onset before 18 months, autonomic phenomena, cognitive impairment, recurring episodes of hemiplegia involving both sides of the body, neurological abnormalities like choreoathetosis, symptom disappearance during sleep, and reoccurrence upon awakening. The patient exhibits five of these criteria. However, definitive diagnosis is hindered by the disease's rarity (annual incidence < 1 per 100,000 newborns), phenotypic variability, and limited genetic data in epidemiological studies. The significance of a definitive diagnosis resides in its capacity to guide optimal clinical management, even in the absence of a specific treatment, with current management focusing on symptomatic measures and multidisciplinary care to improve patient quality of life. **Final comments:** Prospective, randomized, controlled studies are needed to develop more effective treatments that not only alleviate symptoms but comprehensively address the disease. Increased research publication will deepen understanding of disease mechanisms, diagnosis, and clinical aspects, benefiting clinical practice and a broader patient population with this disease. Etics committee approval : 79893624.0.0000.5492

https://doi.org/10.5327/CBN240098

Alzheimer's disease and antipsychotics, a troublesome match

Gabriella Chinaglia Zanin[1], Caio Hussid de Góes[1], Diego Olympio Peixoto Lopes[2], Maria Tereza Martinez[3], Fernanda Herculano[4], Diogo Haddad Santos[4]

[4]Hospital Alemão Oswaldo Cruz, São Paulo SP, Brazil.

Correspondence: Gabriella Chinaglia Zanin; Email: gabriella.zanin@aluno.fcmsantacasasp.edu.br.

In the context of Alzheimer's disease, antipsychotic medications are used to treat behavioral and psychological symptoms of dementia, such as agitation, aggression, psychosis and delirium, with a prevalence between 40 to 50%. The choice of antipsychotic is particularly delicate, as they have important side effects, and some have been associated with higher mortality. While between 20 to 50% of patients with Alzheimer receive antipsychotic prescriptions, there are comparatively few studies with Brazilian data related to their usage. The present study's aim was to analyze antipsychotic drugs prescribed to patients with Alzheimer in the last 5 years in reference neurology center in São Paulo, while comparing it to the general Brazilian usage of antipsychotic in Alzheimer patients. An electronic medical record aggregator called TriNetX was used to anonymously obtain the patient data used in the study, using exclusively hospital related records. The Brazilian cohort was built using a database that coalesces patient records of several institutions throughout national territory, via selecting patient with Alzheimer diagnosis who were at least 50 years old when they received the diagnosis. The reference center cohort was built using the same criteria as the Brazilian but pulled data only from the database of a reference neurology center in São Paulo. Antipsychotic use event was defined as the first prescription of the drug, regardless of time of use or subsequent administrations. Test results were a Brazilian cohort of N=5,944, of whom 33% had been prescribed any type of antipsychotic, with 27% having received Quetiapine, 16% Haloperidol, 6% Risperidone and 4% Olanzapine. The reference center cohort had N=250 patients, whom 28% had been prescribed any type of antipsychotic, with 24% having received Quetiapine, 16% Haloperidol, 8% Risperidone and 4% Olanzapine. The main points of antipsychotics prescription in the context of any dementia are the increased mortality risk and side effects. While the prescription pattern is similar, the reference center administered antipsychotics to less patients. The most prescribed drug, Quetiapine, is an off-label prescription, as only Risperidone and Haloperidol are validated for usage in behavioral and psychological symptoms of dementia. This is possibly related to its less severe side effects compared to other antipsychotics, but it could also be a result from earlier evince of antipsychotics use where it appeared as the only drug to not increase mortality, a find contested by more recent review. An important find is the high usage of Haloperidol compared to other antipsychotics, as it is the drug most associated with increased mortality, especially when administered as injection, due to its neurotoxicity. As there is important evidence against its use in the context of dementia, and it should be viewed as a very restricted drug.

Background: In Brazil, around one hundred thousand new cases of Alzheimer's Disease are diagnosed each year. For Parkinson's disease, it is estimated that two hundred housand people are affected. The progressive aging of the population of public employees, associated with the change in legislation that allowed them to remain in active service until 74 years old, makes it important to know what the frequency of sickness is associated with the two most prevalent degenerative neurological diseases worldwide. **Objective:** Verify the frequency of Alzheimer's disease and Parkinson's disease associated with prolonged work absence in Brazilian public university employees in the last ten years. **Methods:** It was a cross-sectional study in which a retrospective survey was carried out, including work absences lasting fifteen days or more associated with Alzheimer's disease and Parkinson's disease, between 01/01/2014 and 12/31/2023. Gender, occupation and type of neurological disease were analyzed. The population was 5,564 public university employees, with a predominance of women (53.8%). The staff with age between 66 and 74 years old was 8.1%. **Results:** Alzheimer's diseases accounted for 0.12% of the total of 10,027 absences due to illness over the ten years. Parkinson's disease accounted for 0.18%. The frequency of absence from Alzheimer's disease in women when compared to the total number of absence by gender was 0.12% (12/7498) and 0.11 (3/2529) for men. The frequency of absence of Parkinson's disease in women when compared to the total number of absence by gender was 0.12% (12/7498) and 0.35 % (9/2529) for men. The workers most frequently affected by Parkinson's disease were teachers 55.5% (10/18) and administrative assistants 33.3% (6/18). For Alzheimer's disease, medical doctors were most affected 41.6% (5/12) and laboratory assistants 16.6% (2/12), professionals of the health sector were 66,6% (8/12). **Conclusion:** The present study found no difference in the frequency of sick leave between men and women for Alzheimer's disease. For Parkinson's disease, the frequency of absenteeism was higher in men compared to women. For Parkinson's disease, there was a predominance of sick leave for education professionals, while Alzheimer's disease was more common among health professionals.

Amyloid angiopathy-related inflammation: more than amyloid spells

Giuseppe Dick Bonato[1], Marciéli Gerhardt[1], Luis Del Carmen Vega Gutierrez[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Hospital São Lucas, Porto Alegre RS, Brazil.

Correspondence: Giuseppe Dick Bonato; Email: g.d.bonato@hotmail.com.

Case presentation: An 83 year-old woman is brought to a tertiary care hospital after being found with sensory impairment. The previous day she showed behavior change and had inespecific complaints. She also presented an episode of possible focal seizure. At first evaluation she was brad-psychic and presented mixed aphasia. Her blood pressure was elevated, being treated with parenteral antihypertensive drugs. Family denied previous history of hypertension, and she lived alone without need for help in daily activities. She presented major depression, being treated with citalopram. Moreover, she frequently took oral analgesics due to chronic back pain. First impressions of vascular event or hypertension encephalopathy were not confirmed. Brain MRI showed signs of amyloid angiopathy-related inflammation features, such as corticosubcortical assymetrical bleeds, white matter hyperintensities and leptomeningeal enhancement. Electroencephalogram showed asymmetric frontal epileptogenic activity. Lumbar puncture revealed 106mg/dl with no pleocytosis. Extensive infectious screening showed no other plausible cause for clinical presentation other than amyloid angiopathy-related inflammation, and we proceeded to administer methylprednisolone 1g per day during 5 days followed by oral corticoids with progressive dose tapering. Before being discharged, she had considerable improvement, presenting fully oriented and alert. In the next two months, she was admitted twice to the same hospital. At first, she presented urinary tract infection complicated by delirium, being discharged at basal cognitive level after treatment. A second admission was due to right femur fracture after falling, with surgical correction. She presented vomits at 7th postoperative day with possible bronchoaspiration and consequent cardiorespiratory arrest. She did not respond to intensive care measures and passed away the following day. **Discussion:** Amyloid angiopathy-related inflammation is an important differential of several more frequent medical conditions. Its potential treatability deem importance of identifying and diagnosing this disease. The two major proposed pathophysiological mechanisms involve primary angiitis-like features, and even if they are pathologically distinct, no clinical nor radiological characteristics seems to be able to differentiate them. Treatment basis involve immunomodulation, first line being high dose IV corticosteroids with progressive oral tapering. Response to treatment may be effective in more acute symptoms, while chronic impairments may be permanent. **Final comments:** The presented case conveys an older patient presenting inflammatory features associated with vascular changes compatible with the discussed disease. Our patient presented a good outcome after first hospitalization. Complications related to advanced age and worse prognosis-associated incidents (i.e. delirium and femur fracture) lead to patient's disease.

Amyotrophic lateral sclerosis and multiple sclerosis: a uncommon association

Jéssica Cristina Silveira Damasceno[1], Laura Altomare Fonseca Campos[1], Júlia Lima Vilela[1], Marcelo Sobrinho Mendonça[1], Thiago Cardoso Vale[1]

[1]Hospital e Maternidade Therezinha de Jesus, Juiz de Fora MG, Brazil.

Correspondence: Jéssica Cristina Silveira Damasceno; Email: drajessicadamasceno@gmail.com.

Case presentation: A 51-year-old woman, previously hypertensive, diabetic, and with a history of depressive disorder, began experiencing progressive weakness in her limbs, predominantly in her lower limbs, in 2019, leading to loss of ambulation and wheelchair dependence in 2023. She had a family history of amyotrophic lateral sclerosis (ALS) in her father and cousins, without genetic confirmation. In June 2022, she underwent electromyography of all four limbs and thoracic paravertebral muscles, revealing active denervation in all studied segments, consistent with motor neuron disease. Genetic testing revealed a mutation in the vesicle associated membrane protein B (VAPB) gene at position CHR20:58,418,318, confirming ALS diagnosis due to VAPB gene mutation. During diagnostic investigation, brain MRI made in 2021 showed hyperintense ovoid lesions on T2/FLAIR and hypointense ones on T1, suggestive of demyelinating lesions without contrast enhancement. She had no history suggestive of clinical relapses. Cervical and thoracic spinal cord MRI also revealed demyelinating lesions without contrast enhancement. She was diagnosed with radiologically isolated syndrome (RIS) and began undergoing periodic neuro-axis MRI scans. In September 2023, she experienced subacute worsening of strength, primarily in the upper limbs, and a repeat cervical spinal cord MRI showed a lesion in the right lateral C7-T1 with hyperintensity on T2 and STIR sequences, with contrast enhancement, suggestive of inflammatory activity. Cerebrospinal fluid showed oligoclonal bands. She underwent a 5-day course of methylprednisolone pulse therapy without clinical improvement. She was subsequently diagnosed with multiple sclerosis (MS) and started treatment with glatiramer acetate. **Discussion:** Familial

forms of ALS are associated with mutations in various genes. Mutations in the VAPB gene follow an autosomal dominant inheritance pattern and typically manifest as slowly progressive weakness, fasciculations, cramps, and preferential involvement of the lower motor neurons. Despite clinical, electrophysiological, and confirmatory genetic diagnosis of ALS due to VAPB gene mutation, the patient exhibited a faster progression rate since 2019 than typically observed for the disease. However, given the subacute worsening of strength, including in the upper limbs in September 2023, corresponding to the cervical spinal cord lesion, there was a possibility of a bout of MS rather than just ALS progression. There are no reports in the literature suggesting a causal association between ALS and MS, being the occurrence of both diseases in this patient likely coincidental. **Final comments:** This case highlights a rare association between familial ALS and MS and underscores the diagnostic challenge in this association, as motor symptoms from one condition can overlap with those of the other, complicating the differentiation between RIS and MS.

Amyotrophic lateral sclerosis associated with a rare pathogenic VCP gene variant: a case report

Yasmin Luíse Lucena e Silva[1], Samila Marissa Pinheiro Gomes[1], Aglagilson Fernandes Das Chagas[1], Moisés Vasco de Freitas[1], Emanuela Maria de Aguiar Azevedo[1], Gabriel Belo Cavalcante Linhares[1], Jonnathan Camara da Silva Vianna[1], Eduardo Martiniano de Lima[1]

[1]Universidade Federal Rural do Semi-Árido, Mossoró RN, Brazil.

Correspondence: Yasmin Luíse Lucena e Silva; Email: yasmin.silva43227@alunos.ufersa.edu.br.

Case presentation: Amyotrophic lateral sclerosis (ALS) is a motor neuron disease, affecting both upper and lower motor neurons. It is a progressive, paralytic, incurable condition of unknown etiology. Despite that, over 120 genes have been implicated in ALS. The following case report describes a patient who was diagnosed with ALS and was later found to have a rare pathogenic variant of the VCP gene. A 51-year old man, with a past medical history of lumbar hernia, acute myocardial infarction, hypertension and obesity, presented with progressive left lower limb weakness. He had no history of poliomyelitis and was initially evaluated by an orthopedist, who prescribed pregabalin. Unfortunately, the weakness progressed, later affecting the other lower limb and, eventually, both arms. The patient developed dysarthria and dysphonia. Currently bedridden, he is unable to speak and feeds via tube. Electroneuromyography, ordered about 7 months after symptom onset, was consistent with lower motor neuron disease, affecting the cervical, thoracic and lumbar regions. The condition was more evident on the left hemibody, mainly affecting the left lower limb. Split-hand index was decreased bilaterally, measuring 3.4 on the left and 5.0 on the right side. Finally, an oral swab sample was sequenced by next generation sequencing, which detected a heterozygous pathogenic variant of the VCP gene, namely NM_007126.5: c.277C> T: p. (Arg93Cys). The exact same variant was identified in close relatives, including a sibling and a cousin, who were diagnosed with slowly progressive motor neuron disease and inclusion body myositis, respectively. Furthermore, a case of Guillain-Barré syndrome and other neurological diseases with motor impairment in distant family members have been reported. **Discussion:** Pathogenic variants of the VCP gene have been linked to cases of ALS, as well as other conditions, such as inclusion body myopathy with early-onset Paget disease and frontotemporal dementia. This gene encodes the valosin-containing protein, an enzyme that mainly plays a role in protein degradation. Although ALS is a fairly common diagnosis, NM_007126.5: c.277C> T: p. (Arg93Cys) is a very rare variant of the VCP gene. It is considered a missense variant and studies indicate that it is expected to disrupt VCP protein function, but the exact mechanisms behind disease development are not fully understood. This case highlights an uncommon genetic abnormality detected in three related individuals, which is unusual considering that around 90% of ALS cases are sporadic. In addition, since these patients received different diagnoses, this report reinforces that the conditions mentioned here have an overlapping genetic basis. **Final comments:** This report features a rare genetic variant linked to ALS and other conditions. Further investigation is needed to better understand how this variant causes disease, which can aid genetic counseling and clinical management of patients.

An atypical case of hereditary distal motor neuropathy (HDMN) associated with mutation on DCTN1 gene

Roberto Pereira Santos[1], Rhanice Soares Huguenin Câmara[2], Amanda de Morais Affonso[2], Caio Tardin[1], Matheus Jorand Cecatto[1], Ana Carolina Leite[1], Barbara Pina Aiello[1], Filipi Britto[1], Victor Evangelista Rodrigues Pereira[1], Marcos Raimundo Gomes de Freitas[1]

[1]Universidade Federal do Rio de Janeiro, Hospital Universitário Clementino Fraga Filho, Serviço de Neurologia, Rio de Janeiro RJ, Brazil.
[2]Universidade Federal do Rio de Janeiro, Faculdade de Medicina, Rio de Janeiro RJ, Brazil.

Correspondence: Roberto Pereira Santos; Email: r.santos.ufrj@gmail.com.

Case presentation: A 20-year-old woman has presented with a scuffing gait since early childhood, bilateral dorsiflexion paresis worse on the left, and distal muscle atrophy in the lower limbs (LL), which has remained non-progressive. She shows no signs or symptoms of sensory, vocal, or parkinsonian issues. There were no similar cases in her family, and her asymptomatic, non-consanguineous parents were unaffected. Exon 29 of the DCTN1 gene revealed a heterozygous variant of uncertain significance (VUS) c.3502G> A (p.Val1168Ile). This gene typically follows an autosomal dominant pattern and is associated with Hereditary Distal Motor Neuropathy type 7B (dHMN7B) and Perry syndrome. Other pathogenic variants have also been linked to Amyotrophic Lateral Sclerosis (ALS). This case stands out due to its childhood onset, lack of progression, absence of vocal involvement, and negative family history of a dominant genetic variant that typically manifests in adulthood with vocal symptoms. Genetic testing of the parents will confirm the presence of this mutation. **Discussion:** Pathogenic variants in the DCTN1 gene typically exhibit an autosomal dominant inheritance pattern and are associated with Hereditary Distal Motor Neuropathy type 7B (OMIM#607641) and Perry syndrome (OMIM #168605). Some variants are also implicated in Amyotrophic Lateral Sclerosis (ALS), with both dominant and recessive inheritance patterns observed. Hereditary Distal Motor Neuropathy (dHMN) primarily affects distal motor function in the lower limbs, progressing to involve proximal limb regions and hands. Some variants may exhibit subclinical sensory and pyramidal signs, leading to differential diagnoses such as ALS, Spinocerebellar Ataxia, Hereditary Spastic Paraplegia, axonal Charcot-Marie-Tooth disease, and distal myopathies. A subgroup known as NMDh-plus may present additional features including bradykinesia, rigidity, retinitis pigmentosa, cognitive delay, hyperCKemia, and joint deformities. While mutations in over 30 genes have been linked to NMDh, identification of the specific pathogenic mutation occurs in fewer than half of cases (WU, 2022). The classification of NMDh variants and their related genes is detailed in Table 1, adapted from Zhang et al. (ZHANG, 2021). The dHMN7 subtype, encompassing types 7A and 7B, typically manifests in adulthood with vocal cord paralysis and follows an autosomal dominant inheritance pattern (ZHANG, 2021). **Final comments:** This case represents an unusual presentation of NMDh associated with a VUS in the DCTN1 gene. Further research is needed to elucidate the functional impact of this variant and its role in the pathogenesis of neurological disorders.

An atypical presentation of neuroleptospirosis: a case report and literature review

Ana Letícia Amorim de Albuquerque[1], Monique Blauth Tovo[1], Rhaná Carolina Santos[1], Giovanna Polo[1], Lorenna Lima Regueira Costa[1], Matheus Zschornack Strelow[1], Matheus Bernardon Morillos[1], Diógenes Guimarães Zan[1]

[1]Universidade do Vale do Rio dos Sinos, São Leopoldo RS, Brazil.

Correspondence: Ana Letícia Amorim de Albuquerque; Email: analeticia.neurologia@gmail.com.

Case presentation: Male, 43 years old, no known comorbidities. Presented with progressive caudal-cranial paresis in lower limbs. A week prior, he experienced acute urinary retention and episodes of intermittent fever. Neurological exam showed drowsiness, hypophonia, paraplegia associated with reduced strength in upper limb and cervical musculature. Tactile sensitivity was absent up to the T4 level, along with loss of sphincter control. Reflexes were increased in the upper limbs and absent in the lower limbs. Initial investigations revealed elevated hepatic and canalicular enzymes, elevated lactate dehydrogenase, and signs of systemic inflammation. Cerebrospinal fluid (CSF) had a total protein of 109 mg/dL, the ratio of CSF/Serum glucose was 0.86 and 640 cells/mm3, 80% lymphocytes. Magnetic resonance imaging revealed foci of hypersignal on T2 and subcortical FLAIR in the brainstem, middle cerebellar peduncles and at the level of the thalamus and basal nuclei with extension to the corona radiata, bilaterally, with minimal restriction in diffusion. MRI assessment of the cervical spine showed longitudinally extensive myelitis, with an incipient degenerative disc disease at C4-C5, C5-C6 and C6-C7, and T2 hyperintense lesion diffusely compromising the cervical spinal cord. The patient was initially treated with ceftriaxone and ampicillin for suspected CNS bacterial infection, and dexamethasone to reduce cerebral inflammation. A new detail emerged: the patient had contact with a dead rat without protective gear a week before symptom onset. Leptospirosis was confirmed by a positive serum IgM-ELISA. Clinical improvement was noted by day 9 of therapy as the patient was already receiving empirical ceftriaxone. He remained with lower limb plegia. The patient was discharged with physiotherapy and follow-up with neurology. **Discussion:** Leptospirosis is prevalent in tropical countries, such as Brazil, having episodic outbreaks after torrential rains and flooding, especially in precarious sanitary situations. Human contraction typically arises from exposure to contaminated soil, water and infected animals. Rodents are primary carriers. Humans may contract the infection through cuts and mucous membranes. Neurological involvement can lead to vasculitis, microcirculation and endothelial dysfunction, developing patchy demyelination in the CNS. Neurological manifestations occur in 15% of cases and can be manifested as encephalitis. This case underscores the importance of considering leptospirosis in the differential diagnosis of acute neurological syndromes, particularly in regions where the disease is endemic. **Final comments:** The case emphasizes the necessity for prompt recognition and treatment of leptospirosis to mitigate severe complications. Increased awareness and early intervention are paramount in managing such infections, particularly in tropical regions with poor sanitation and frequent rodent exposure.

An atypical presentation of stiff person spectrum disorder: a case report

Catarina Sodré de Castro Prado[1], Luiza de Aguiar Lima[1], Márcia Cristina Antunes Ribas[1], Gabriel R. de Freitas[1], Camila Pupe[1], Marco Antonio Araujo-leite[1], Caroline Bittar Braune[1]

[1]Universidade Federal Fluminense – Ebserh, Hospital Universitário Antonio Pedro, Departamento de Neurologia, Niterói RJ, Brazil.

Correspondence: Luiza de Aguiar Lima; Email: luizadealima@gmail.com.

Case presentation: A 25-year-old female presented with difficulty walking and dysarthria. After 4 months she developed dysphagia, convergent strabismus, urinary retention and vertigo. She had the previous diagnosis of congenital nephrogenic diabetes insipidus, Hashimotos disease and lichen planus. In the hospital the patient began with painful muscle spasms in the upper and lower limbs, along with tachycardia and profuse sweating, with no loss of consciousness, and a good response to treatment with benzodiazepines, baclofen and opioids. On neurological examination she exhibited involuntary contractions of the orbicularis oris muscle, spasticity and hyperreflexia of the upper and lower limbs, global reduction of strength with sarcopenia, convergent strabismus with bilateral lateral rectus paresis, worse on the right eye, and tongue paralysis. Neuroaxis magnetic resonance imaging showed no alterations that could justify her symptoms. The cerebrospinal fluid analysis was normal, including bacterial, viral and fungal panels and oncotic cytology, as was her serum screening for HIV, syphilis, toxoplasmosis, cytomegalovirus and hepatitis B and C. The antinuclear antibody (1:80) was positive with a fine speckled pattern. She deteriorated with respiratory failure and needed to undergo an orotracheal intubation. Her muscle weakness and ophthalmoplegia also progressed, and the patient could not lift her limbs against gravity or move her eyes. She remained oriented, with no alterations of cognition or behavior. She evolved with anisocoria, with her left pupil not reacting to light. Electromyography showed a sustained contraction of both agonist and antagonist musculature (biceps and triceps) simultaneously. The Anti-GAD-65 Antibody was requested and came back with a high titer of 29.541 UI/ml. The diagnosis of Stiff Person Spectrum Disorder (SPSD) was established and treatment with intravenous immunoglobulin was initiated with 0,4 grams per kilogram of weight during 5 days. After two weeks the patient began to improve, being able to stick out her tongue, move her head and eyes, remaining only with paresis of the right lateral rectus. Her right pupil also started responding to light and she was able to raise her lower limbs against gravity. **Discussion:** The diagnosis of SPSD was suspected based on the clinical scenario of painful muscle spasms, which became increasingly frequent, the good response to benzodiazepines and baclofen, the rigidity of extremities, the involvement of multiple cranial nerves bilaterally, and the personal history of autoimmune disease. It was further supported by electromyography findings, high titer of Anti-GAD-65 and the marked improvement after immunoglobulin. **Final comments:** This case highlights the importance to bear in mind the different clinical presentations of SPSD, and so to maintain a low threshold of suspicion for this treatable condition.

An epidemiological analysis of Guillain-Barré syndrome in the neurology service of the UNIMED BH hospital

Ana Luiza de Oliveira Batista Passos[1], Andréa Jerusa de Souza Santos[1], Glaucia Lara Resende[1]

[1]UNIMED, Belo Horizonte MG, Brazil.

Correspondence: Ana Luiza de Oliveira Batista Passos; Email: anaobps@hotmail.com.

Guillain-Barré Syndrome (GBS) is a rare immune-mediated condition that affects the peripheral nervous system and is characterized by an ascending flaccid paralysis, however, it sometimes presents in an atypical form with clinical variants. It has a diagnosis based on clinical, CSF and electrophysiological criteria. In this series of cases, we portray patients admitted to the Neurology service of the Unimed Hospital of the Contorno Unit (Belo Horizonte/MG) with a diagnosis of Guillain-Barré Syndrome between April 2022 and June 2024. 29 patients were included, 66% male and 34% female. The average age was 40.3 years (range 15 - 77 years). Of these, 27% had a respiratory or gastrointestinal infection preceding the condition; 38% had been vaccinated in the last 4 weeks and 80% of patients who had an infectious trigger in the gastrointestinal tract required transfer to the ICU. The months with the highest incidence of cases were December 2022 and November 2023. The majority received treatment with human intravenous immunoglobulin (86%) and none received treatment with plasmapheresis. Half had an Erasmus GBS Respiratory Insufficiency Score (EGRIS) ≤ 3 points and the other half EGRIS ≥ 4. Three patients developed respiratory failure in the first week after the onset of symptoms. Of those with EGRIS ≤ 3, 30% went to the ICU and did not require invasive ventilation. In relation to those with EGRIS ≥ 4, 70% went to the ICU, and of these 28% required invasive ventilation. There was 1 death. Our data and results presented are compatible with those described in the literature regarding triggers for autoimmunity and prognoses. We question whether the coronavirus pandemic could be an aggravating factor for the increase in the incidence of Guillain Barré Syndrome.

https://doi.org/10.5327/CBN240049

An epidemiological analysis of hospitalizations due to epilepsy in Brazil from 2013 to 2023

Matheus Henrique Brustolim Marcucci[1], Guilherme Ângelo Braga de Sousa[1], Leslie Mateus de Sousa Nunes[1], Matheus Sant'anna de Oliveira Gonçalves[1], Hurik Pontes Rocha[1], Paulo Wendel Moura de Souza[1], Leonardo Elias Araujo[1], Francisco Luciano Honório Barreto Cavalcante[1], Letícia da Costa Rios[1], Letícia Gadelha Caldas[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Matheus Henrique Brustolim Marcucci; Email: matheus.marcucci@alu.ufc.br.

Background: A temporary and reversible change in brain function, not caused by fever, drugs, or metabolic disorders, manifested by repeated epileptic seizures. The origins of seizures are often unidentified (idiopathic), but they can be related to various brain problems, such as structural abnormalities, strokes, or tumors. **Objective:** To analyze the epidemiological profile of epilepsy hospitalization cases in Brazil between 2013 and 2023. **Methods:** This study is an epidemiological investigation of confirmed epilepsy hospitalization cases between 2013 and 2023. Data was collected from the Sistema de Informação de Agravos de Notificação (Sinan Net) of the Departamento de Informática do Sistema Único de Saúde (DATASUS), and data analysis was performed using Jamovi® software. **Results:** After data analysis, 592,028 epilepsy cases were found in Brazil between 2013 and 2023. The highest numbers were in the Southeast with 249,189 cases (42.09%) and the Northeast with 138,242 cases (23.35%), followed by the South, Midwest, and North with 20.75%, 8.29%, and 5.52% respectively. Regarding temporal analysis, an average of 53,820.72 (±5196.94) cases per year was found, with a constant growth in diagnoses from 2013 to 2019, a turning point reducing the number of diagnoses in 2020, followed by another growth period until 2023. Of the observed cases, 57.90% of patients were male and 42.10% were female, with the predominant age group being 1-4 years old (16.68%), followed by 40-49 years old (10.14%) and 50-59 years old (10.13%). The most prevalent race was mixed race with 39% of the cases, and the least prevalent was indigenous with 0.16% of diagnoses. **Conclusion:** According to the data analysis, a concentration of cases was identified in the Southeast (42.09%), the Northeast (23.35%), and the South (20.75%), possibly due to the population concentration in these regions of Brazil. A possible underreporting of cases was found in 2020, likely caused by the COVID-19 pandemic, during which people avoided leaving their homes, making diagnoses more difficult. Regarding the patient profile, there was a prevalence of male individuals (57.90%) and patients aged 1-4 years (16.68%). This can be explained by the fact that children's brains are still developing, making them more susceptible to congenital or genetic anomalies. As for race, a low diagnosis rate was found in the indigenous population, which may be caused by both the concentration of this population in the country and the underreporting of cases in this population.

https://doi.org/10.5327/CBN240107

An epidemiological analysis of hospitalizations due to transient ischemic attack and non-specific strokes (hemorrhagic or ischemic) in Ceará from 2013 to 2023

Matheus Henrique Brustolim Marcucci[1], Guilherme Ângelo Braga de Sousa[1], Hurik Pontes Rocha[1], Paulo Wendel Moura de Souza[1], Matheus Sant'anna de Oliveira Gonçalves[1], Leonardo José Rodrigues de Araújo Melo[1], Cássia Caroline Aguiar da Ponte[1], Paulo Victor de Santiago Gonçalves[1], Oliver Reiks Miyajima[2], Júlia Viana de Castro[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.
[2]Universidade Estadual do Ceará, Fortaleza CE, Brazil.

Correspondence: Matheus Henrique Brustolim Marcucci; Email: matheus.marcucci@alu.ufc.br.

Background: Non-Specific Stroke (NS-Stroke) is brain damage causing a sudden, focal, neurological deficit from a vascular disease, lasting over 24 hours. In contrast, a Transient Ischemic Attack (TIA) is a temporary, reversible neurological deficit, usually lasting less than an hour, caused by a brief vascular blockage in the brain. **Objective:** To analyze the epidemiological profile of hospitalization cases of NS-Stroke and TIA in Ceará between 2013 and 2023. **Methods:** This study is an epidemiological investigation of the hospitalization of NS-Stroke and TIA cases between 2013 and 2023. Data were collected from the Sistema de Informação de Agravos de Notificação (Sinan Net) do Departamento de Informática do Sistema Único de Saúde (DATASUS), and data analysis was performed using Jamovi®. **Results:** According to the data found in DATASUS, between 2013 and 2023, approximately 74,400 cases of NS-Stroke were recorded in Ceará. A temporal analysis of NS-Stroke cases showed an average of 6,763.6 (±471.28) cases/year, with periods of increase (2013-2016, 2017-2019, 2020-2021 and 2022-2023) and years of decline (2017, 2020, 2022). Among the NS-Stroke diagnoses, 53.08% were male and 46.92% were female. Additionally, 60.67% of cases were from the metropolitan regions of Fortaleza and Cariri, while 39.32% were from outside the metropolitan region. The most prevalent race was mixed race at 70.36%, and the second least prevalent was black at 0.96%. Regarding TIA, during the analyzed period (2013-2023), 3,735 cases were recorded, with an average of 339.54 (±59.21) cases/year, with periods of increase (2013-2016, 2018-2019 and 2020-2023) and years of decline (2017, 2018, 2020). Among the TIA diagnoses, 51.91% were male and 48.09% were female. Moreover, 68.30% of cases were from the metropolitan regions of Fortaleza and Cariri, while

31.70% were from outside the metropolitan region. The most prevalent race was mixed race at 76.33%, and the least prevalent was black at 1.74%. **Conclusion:** According to the data analysis, significant differences were found in the reporting of Stroke cases, with NS-Stroke (74.400 cases) having a higher number than TIA (3,737 cases). This difference can possibly be explained by the underreporting of TIA cases, since, despite having symptoms similar to NS-Stroke, the rapid disappearance of symptoms often leads to not seeking medical attention. Additionally, there is the difficulty of recognizing symptoms by untrained individuals. In both cases, no significant gender differences were found. Higher hospitalization were found in metropolitan regions, both in NS-Stroke (60.67%) and TIA (68.30%), likely due to more hospitals and support networks for recognizing and treating these diseases in metropolitan areas. Regarding races, there was severe underreporting of cases in the black population (0.96% in NS-Stroke and 1.74% in TIA). This could be caused either by a lack of case reporting in this population or by a racial identification error.

https://doi.org/10.5327/CBN240108

An epidemiological analysis of hospitalizations due to viral encephalitis in Ceará from 2013-2023

Matheus Henrique Brustolim Marcucci[1], Oliver Reiks Miyajima[2], Guilherme ângelo Braga de Sousa[1], Matheus Sant'anna de Oliveira Gonçalves Matheus Gonçalves[1], Hurik Pontes Rocha[1], Paulo Wendel Moura de Souza[1], Lucas Soares Radtke[1], Emanuel de Assis Bertulino Martins Gomes[1], Pedro Vitor Ferreira Rodrigues[1], Sarah Braga de Castro[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.
[2]Universidade Estadual do Ceará, Fortaleza CE, Brazil.

Correspondence: Matheus Henrique Brustolim Marcucci; Email: matheus.marcucci@alu.ufc.br.

Background: Viral encephalitis is the most common type of encephalitis, characterized by inflammation of the brain caused when viruses like herpes simplex, herpes zoster, cytomegalovirus, or West Nile virus directly infect the brain. Alternatively, inflammation can be triggered by agents such as viruses, vaccines, or other stimuli. This inflammation can manifest with clinical symptoms including fever, headache, personality changes or confusion, seizures, paralysis or numbness, and drowsiness, which may progress to coma or death. **Objective:** To analyze the epidemiological profile of hospitalization cases of viral encephalitis in Ceará between 2013 and 2023. **Methods:** This study is an epidemiological investigation of hospitalization cases of viral encephalitis between 2013 and 2023. Data were collected from the Sistema de Informação de Agravos de Notificação (Sinan Net) of the Departamento de Informática do Sistema Único de Saúde (DATASUS), and data analysis was performed using Jamovi® software. **Results:** According to data analysis from 2013 to 2023, 863 cases of Viral Encephalitis were found in Ceará. In terms of temporal analysis, an average of 78.45 (±14.58) cases per year were identified. Regarding patient demographics, 57.24% were male and 42.76% were female. Moreover, 71.96% of cases were from metropolitan areas of Fortaleza and Cariri, while 28.04% were from non-metropolitan regions, predominantly affecting the age groups of 1-4 years (17.72%) and 5-9 years (12.97%). In terms of racial profile of hospitalizations, individuals of mixed race (parda) accounted for 761 (84.70%) of the hospitalizations, while individuals of black race accounted for only 1 (0.11%) case. **Conclusion:** According to the data analysis from 2013 to 2023 in Ceará, there was little variation in the number of hospitalizations per year, as evidenced by the low standard deviation (14.58), which was not significantly affected by the COVID-19 pandemic period. There was a slight predominance of male individuals (57.24%) and of individuals residing in metropolitan areas (71.96%), possibly influenced by factors such as population density and better access to healthcare systems, facilitating diagnosis. Regarding age groups, a higher number of cases were found among individuals aged 1 to 9 years (30.69%), possibly explained by children's naturally lower immunity and increased exposure to pathogens during activities such as play and school interactions. The racial profile indicates a potential underreporting of hospitalizations among black individuals or a misinterpretation of racial classification.

https://doi.org/10.5327/CBN240109

An epidemiological analysis of hospitalizations due to viral meningitis in Ceará from 2013-2023

Matheus Henrique Brustolim Marcucci[1], Lucas Frigo[1], Cynthia Paz Rodrigues[1], Ana Cecília Neves Rios Parente[1], Oliver Reiks Miyajima[2], Ana Luiza Souza Santos[1], Paulo Wendel Moura de Souza[1], Hurik Pontes Rocha[1], Matheus Sant'anna de Oliveira Gonçalves[1], Guilherme Ângelo Braga de Sousa[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.
[2]Universidade Estadual do Ceará, Fortaleza CE, Brazil.

Correspondence: Matheus Henrique Brustolim Marcucci; Email: matheus.marcucci@alu.ufc.br.

Background: Viral meningitis is an inflammation caused by a virus in the protective layers of the brain and spinal cord, the meninges, and the subarachnoid space (the space between the pia mater and arachnoid mater filled with cerebrospinal fluid). The condition includes symptoms similar to bacterial meningitis but milder, such as fever, headache, neck stiffness, nausea, vomiting, loss of appetite, irritability, drowsiness or difficulty waking up, lethargy, and photophobia. **Objective:** To analyze the epidemiological profile of hospitalziation cases due to viral meningitis between the years 2013 and 2023. **Methods:** This work is an epidemiological investigation study of confirmed hospitalization cases of viral meningitis between 2013 and 2023. Data were collected from the Sistema de Informação de Agravos de Notificação (Sinan Net) of the Departamento de Informática do Sistema Único de Saúde (DATASUS), and data analysis was performed using Jamovi® software. **Results:** The following data were found in DATASUS between 2013 and 2023: 2,776 diagnoses of meningitis in the state of Ceará, 909 of which were viral meningitis (32.74% of cases). The temporal analysis found an average of 82.63 (±26.79) annual cases of viral meningitis, maintaining an average of 90.42 cases/year from 2013-2019, which drastically reduced to 54 cases/year between 2020-2022, and increased again to 104 cases in 2023. Among the diagnoses, approximately 58.86% were male and 41.14% were female, 77.88% were from the metropolitan regions of Fortaleza or Cariri, and 22.12% were from non-metropolitan regions. The most affected age group was children aged 1-4 years, with 15.40% of the cases. The most prevalent race was mixed race with 801 cases (88.11%), and the least prevalent was black with 4 cases (0.41%). **Conclusion:** According to the analysis of the aforementioned data, a reduction in the number of cases was identified during the period from 2020-2022. This underreporting is possibly a result of the COVID-19 pandemic, during which people, fearing the virus, stayed indoors and away from hospitals, thus hindering diagnosis. A higher prevalence was found in males (58.86%) and in people from metropolitan regions (77.88%), which can possibly be explained by the greater number of hospitals and support networks for diagnosis. The age group most affected by viral meningitis is around 1-4 years, which may be due to individuals of this age having naturally weaker immune systems than adults and being more exposed to pathogens through play. Regarding races, the black race is drastically less reported than others, which may indicate underreporting or even a misidentification error.

An epidemiological analysis of incidence of brain cancer in brazil from 2013 to 2023

Paulo Victor de Santiago Gonçalves[1], Leonardo José Rodrigues de Araújo Melo[1], Pedro Vitor Ferreira Rodrigues[1], Victor Domingueti Vallim Fonseca[1], Cynthia Paz Rodrigues[1], Francisco Luciano Honório Barreto Cavalcante[1], Cássia Caroline Aguiar da Ponte[1], Paulo Wendel Moura de Souza[1], Letícia da Costa Rios[1], Leonardo Elias Araújo[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Paulo Victor de Santiago Gonçalves; Email: paulo.santiago6571@gmail.com.

Background: Brain neoplasms are serious clinical conditions with a high mortality rate. Tumors affecting the central nervous system are often of metastatic origin, meaning they initially arise in other parts of the body and later spread to the brain. **Objective:** To analyze the epidemiological profile of confirmed cases of brain neoplasms between the years 2013 and 2023. **Methods:** This study is an epidemiological investigation of confirmed brain tumor cases between 2013 and 2023. Data were collected from the DATASUS Notification of Diseases Information System, and data analysis was performed using Jamovi software. **Results:** According to the data from DATASUS, between 2013 and 2023, approximately 158.313 cases of malignant brain neoplasms were registered. Of these, 43.5% were recorded in the southeast region, 23.23% in the south, 20.8% in the northeast, 8.35% in the central-west, and 4.08% in the northern region of the country. Among the total cases, 47.75% of patients were female, and 52.24% were male. Regarding patients' race, approximately 3.15% of cases were in Black individuals, while 78.79% were in White and mixed-race individuals. The annual average of cases during the analyzed period was 14.392 (± 1019.492). **Conclusion:** Based on the collected data, a prevalence of cases was identified in the southeast region (43.5%), which can be attributed to the higher population density in that area. No significant difference in the number of cases was observed between genders. However, a limitation of this study was the low incidence observed in Black individuals (3.15%), possibly due to severe underreporting of neoplasm cases in this population or errors in racial identification.

An epidemiological analysis of viral encephalitis in children in Northeast Brazil between 2018 and 2023

Maria Cecília Leal Menezes[1], Luana Cristina de Oliveira Lima[1], Arthur Vinícius Feitosa Santos[1], Sabrina Sthéphanie Ataíde Martins[1], Vagner Costa da Cunha Júnior[1], Thiago Pariz da Silva Dumas[1], Arthur Aragão Nunes[1]

[1]Universidade Tiradentes, Aracaju SE, Brazil.

Correspondence: Maria Cecília Leal Menezes; Email:

Background: Viral Encephalitis (VE) is an inflammatory process that occurs in the brain parenchyma. It can result in permanent neurological sequelae and high morbidity rates, especially in children, although it can affect people of all ages. Therefore, a better understanding of its epidemiology can contribute to the construction of prevention and control strategies. **Objective:** To characterize the profile, according to epidemiological indicators, of hospitalizations due to VE in the Northeast of Brazil in the period from 2018 to 2023. **Methods:** This is a retrospective study with a quantitative approach, conducted based on an analysis of the secondary database from the SUS Hospital Information System (SIH/SUS) and the

Brazilian Institute of Geography and Statistics (IBGE), in the period between January 2018 and December 2023, regarding admissions due to VE in the Northeast region. Among the risk factors analyzed are age group, federative unit and color/ethnicity. As for the research numbers, they were organized in a spreadsheet in the Microsoft Excel program. **Results:** The sample studied consisted of 4,813 hospitalizations for viral encephalitis. The prevalence was in children aged 1 to 4 years, representing 15.41% of the total, followed by those aged 5 to 9 years (11.13%). In contrast, the lowest occurrence was among elderly people over 80 years old, corresponding to 2.28%. Among Brazilian states, Pernambuco recorded the highest number of cases (1,894 patients) and the highest prevalence per 100,000 inhabitants (20.9), with emphasis on hospitalizations among children aged 1 to 4 years. On the other hand, Alagoas had the lowest number of admissions (101), as well as the lowest rate per 100,000 inhabitants (3.2). Furthermore, viral encephalitis was more common among mixed race people, with 3,462 cases (71.93%), and less common among indigenous people, with only 4 cases (0.08%). **Conclusion:** The present study showed a higher occurrence of hospitalizations for VE in children aged 1 to 9 years in Northeast Brazil, possibly due to the immature immune system at this age, making them more susceptible to the disease. Moreover, there was an increase in admissions in the brown population and a drop in the indigenous population, suggesting a possible relationship with the majority number of brown people in the Northeast and the smaller number of indigenous people. Thus, racial, geographic and age factors were suggested in order to justify the distribution of viral encephalitis in the Northeast so that effective public policies can be created aimed at preventing the pathology, ensuring better control of it.

An extradural hematoma case report of the posterior fossa treated conservatively

Maria Cândida Barros Arantes Romano[1], João Lazaro da Silva Rodriguez Oquendo[1], Júlia Oliveira e Freitas[1], Fábio Serra Barbosa da Silva[2]

[1]Centro Universitário Tocantinense Presidente Antônio Carlos, Araguaína TO, Brazil.
[2]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Maria Cândida Barros Arantes Romano; Email: candinha_barros-ar@hotmail.com.

This article presents a case of posterior fossa epidural hematoma, of considerable volume, with non-specific symptoms and no signs of brain herniation or meningeal irritation, treated conservatively, without surgery, where there was good outcome, and discusses its pathophysiology, radiological findings, alternative treatments and their indications as well as the evolution of this patient. Epidural hematomas after trauma to the posterior fossa are very rare, representing only 0.3% of head injuries. The majority of extradural hematomas in the fossa posterior are venous, occurring based on fractures of the occipital bone with following injury to the sigmoid bone or transverse sinus. Venous bleeding may also occur as a result of arachnoid granulation or emissary veins rupturing. Due to its mild symptoms, and it being essential to perform a computed tomography in any suspected case. Early recognition is important so that you can reduce the time of brain herniation and thus reduce the morbidity and sequelae that the injury can cause.

Correspondence: Victor Alfonso Garcia Ortiz; Email: victorgarcia.or@gmail.com.

Case presentation: A 36 year-old male was transferred to our tertiary care hospital due to an extensive brain tumor. Two weeks prior to admission, he presented headache with right ocular pain and progressive vision loss. He was admitted to a secondary care facility with presumed optic neuritis. As previous medical history, he presented type 1 diabetes, hypertension and terminal chronic kidney disease. At the time, brain CT showed no lesions although angiography suggested a possible vasculitic process in the anterior circulation. He then received daily pulsetherapy with IV methylprednisolone 1g. On the sixth day of therapy, he progressed with consciousness impairment with a new brain CT showing extensive tumoral lesion at the right frontoparietal region and deep nuclei, as well as transtentorial and subfalcine herniations with diffuse cranial sinuses thickening. MRI further charactherized the lesions with extensive supra and infratentorial edema and water diffusion restriction in the anterior cerebral artery on the right. The patient underwent urgent decompression craniotomy but suffered progressive clinical deterioration. Rhinoscopy showed extensive inflammation of facial sinuses with infiltrative lesions. He receive empirically ceftriaxone, meropenem, vancomycin, anfotericin B, dexamethasone and acyclovir. Brain biopsy suggested infection by Rhyzopus spp. and extensive necrosis and inflammation, confirming mucormycosis. Despite all treatment efforts, he evolved with untreatable intracranial hypertension, evolving to brain death days after the procedure. **Discussion:** Mucormycosis is a rare fungal infection with high mortality and morbidity. It affects immunocompromised patients, but presents a high predilection for those with poorly-controled diabetes. Clinical syndromes englobe pulmonar and rino-orbit-cerebral mucormycosis. **Final comments:** We present a diabetic dialysis patient with invasive mucomycoses who underwent immunossupressant therapy due to presumed optic neuritis with ominous results. We highlight the imperative exclusion of infectious etiologies prior to starting immunossupressant therapy, particularly with possible previous immunosupression, and the need for close monitoring for neurological worsening during treatment. Mucormycosis is a serious and often unrecognized disease that demands prompt multidisciplinary treatment.

[3]CPQuali Pesquisa Clínica, São Paulo SP, Brazil.
[4]Hospital Alemão Oswaldo Cruz, São Paulo SP, Brazil.

Correspondence: Caio Hussid de Góes; Email: caio.goes@aluno.fcmsantacasasp.edu.br.

Multiple sclerosis is an inflammatory, autoimmune demyelinating disease of the central nervous system. Much like most chronic diseases, patients living with Multiple Sclerosis tend to develop associated comorbidities, resulting in decreased quality of life and increased economic burden of disease. The study's objective is to analyze the most common diagnosis received by Multiple Sclerosis patients before the initial Multiple Sclerosis diagnosis, as well as within 10 years of the diagnosis, without actively seeking the comorbidities. An electronic medical record aggregator called TriNetX was used to anonymously obtain the patient data used in the study, using exclusively hospital related records. The cohort was built using a Brazilian-only database via selecting patients who received the Multiple Sclerosis diagnosis in the last 10 years time frame, had never received a Multiple Sclerosis diagnosis before, and were at least 18 years at the time of the diagnosis. The associated diagnosis were gathered as the first instance per patient, regardless of subsequent frequency. Test results were a cohort of N=3,093 patients, with age at index of 40.2 ± 13.7 years and current age of 43.8 ± 13.8 years. Pre-Multiple Sclerosis most common comorbidity reported was headache at 8% of patients, followed by anxiety at 2%, fatigue at 2%, visual disturbances at 1%, and diabetes mellitus and hypothyroidism at less than 1%. Post Multiple Sclerosis diagnosis common comorbidity reported was headache at 10% of patients, followed by anxiety at 3%, fatigue at 2%, visual disturbances at 1%, and diabetes mellitus and hypothyroidism at 1%. Coexisting diseases increase the complexity of patient management, particularly with the increasing number of immunosuppressive disease-modifying therapies and the subsequent overlapping of their side-effects and comorbidity symptoms. The results obtained related to anxiety and depression post Multiple Sclerosis diagnosis were lower than the expected prevalence between 20 to 40% of patients. As most studies investigating these comorbidities actively seek them in patients via questionnaires, it is likely that spontaneous referral from the patient of symptoms typical of them occurs at a lower rate. Also, the prevalence of co-autoimmune diseases post Multiple Sclerosis diagnosis, hypothyroidism and diabetes mellitus, were lower than the expected. Hypothyroidism prevalence is reported as close to 20%, though it typically is subclinical in Multiple Sclerosis context, being diagnosed based on serum antibodies, which were not investigated in this research. Expected diabetes mellitus prevalence is between 5 and 7%, a discrepancy that may be a result from the age bias of the cohort, as most studies focusing on Multiple Sclerosis and Diabetes explore populations above 45 to 50 years. Thus, it can be concluded that comorbidities diagnosis in Multiple Sclerosis require patient referred symptoms, but also active seeking from the attending clinician.

An uncommon neurological presentation of dengue fever: spinal subdural hematoma

Maria Paula Oiticica de Jesus[1], Giovana Barros e Silva Ribeiro[1], Alberto Rolim Muro Martinez[1], João Luiz Mourão[1], Nivaldo Adolfo da Silva Junior[1], Marcondes Cavalcante França Junior[1], Raissa Gomes Castro e Souza[1], Rafael Saliba Helmer[1], Verena Miranda de Souza[1], Kaio Cezar Ferreira[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Maria Paula Oiticica de Jesus; Email: mpaulaoiticicaa@hotmail.com.

Case presentation: A 36-year-old woman with a previous history of cirrhosis due to an autoimmune hepatitis presented with insidious onset of back pain associated with limitating headache and nausea. A rapidly progressive symmetric paraparesis with lower limb areflexia and urinary retention took place two weeks later leading the patient to seek for medical attention. Laboratory workup disclosed thrombocytopenia (38,000) and mildly elevated INR (1.4). Initial cranial and thoracolumbar spine CT scans were unremarkable. Lumbar puncture revealed markedly elevated protein levels (> 1000 mg/dL) in the absence of pleocytosis. Initially suspected as Guillain-Barré syndrome, the patient did not respond to immunoglobulin therapy. Subsequent serological testing revealed positive IgM and IgG for dengue fever. The

patient's condition deteriorated with headache worsening and onset of tonic-clonic seizures. A new cranial CT scan revealed non-communicating hydrocephalus, necessitating external lumbar drainage (ELD). A subsequent MRI of the brain revealed leptomeningitis and arachnoiditis affecting basal cisterns, posterior fossa, and cervical spine segments. The patient progressed to flaccid tetraparesis and areflexia. Neuroaxis MRI was performed, revealing extensive heterogeneous collections occupying a significant portion of the intradural cerebrospinal fluid spaces within the vertebral canal, more pronounced at thoracic and lumbosacral levels. Signal characteristics suggest a likely subacute hemorrhagic nature. Notably, there was compressive effect on the spinal cord, most pronounced between T1 and T4 levels, with moderate narrowing of the cord caliber and extensive signal alteration spanning virtually the entire cervical cord and extending into the medulla, consistent with compressive myelopathy. **Discussion:** The patient, who was thrombocytopenic due to an underlying disease, along with dengue fever, experienced spontaneous spinal subdural hematoma complicated by hydrocephalus leading to severe hyperproteinorrachia due to the obstruction of CSF flow. The clinical course was further complicated by leptomeningitis and arachnoiditis, which may have arisen from local irritation secondary to hemorrhage or, considering the patient's immunosuppressed state, an infectious context (although a specific pathogen was not identified despite an extensive pathogens screening and lack of response to empirical treatment employed). **Final comments:** This case exemplifies a complex diagnostic challenge in a patient with autoimmune hepatitis-related cirrhosis and concurrent dengue infection, complicated by severe neurological manifestations. The diagnostic journey was marked by extensive imaging and laboratory investigations. This underscores the need for heightened vigilance and tailored therapeutic strategies in patients with overlapping immunosuppressive conditions and infectious complications.

This case reports a 13-year-old female of Japanese descent with distal tremors since she was seven months old. Her mother experienced an uneventful pregnancy, with eutocic vaginal labor. The patient's milestones of motor development were appropriate for the age, but there was speech delay and worsening of tremors with aging that made it difficult to perform some manual tasks. The parents informed learning disability since kindergarten, without social impairment. Physical examination was marked by: preserved language, slowed speech, dysmetria worse in the upper limbs, appendicular myoclonus that hindered walking, normoactive reflexes. There were no signs of: ocular motricity impairment, dystonia, parkinsonism. The neuropsychological test performed at the age of eight described mild intellectual disability and impairment of all skills assessed, including motor and visual skills. Laboratory tests resulted normal for renal, thyroid and liver function. There were normal blood levels of ammonia, lactate, total cholesterol, acid-base balance, and inflammatory markers. Brain magnetic resonance imaging was negative for malformations, anomalous enhancements and atrophies. Electroencephalogram revealed rare generalized interictal epileptiform activity of anterior predominance. Exome performed at nine years-old resulted on heterozygous NUS1 mutation, with 1.5mb deletion on the long arm of chromosome 6. This genetic testing was compatible with the hypothesis of Myoclonus, epilepsy, ataxia, intellectual disability syndrome (MEAID). This is a rare disease, often with de-novo occurrence, and early age onset (from a few months to 13 years). The phenotype is characterized by various combinations of epilepsy, intellectual disability, cerebellar ataxia, and cortical myoclonus. The patient is using valproic acid 30mg/kg/day and experiencing regular psychotherapy, with behavior and myoclonus control.

An unusual case of variegate porphyria with nerve enlargement, conduction block and idiopathic intracranial hypertension

Michelle Abdo Paiva[1], Andre Macedo Serafim Silva[1], Rodrigo de Holanda Mendonça[1], Ana Lucila Moreira[1], Nícolas Ruan dos Santos Cavalcante[1], José Pedro Soares Baima[1], Carlos Otto Heise[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Michelle Abdo Paiva; Email: michelle.abdop@gmail.com.

Acute hepatic porphyrias are a group of metabolic diseases where the main targets of neurotoxins ALA and PBG are the central and peripheral nervous system. Typical acute attack is characterized by an initial autonomic neuropathy, usually abdominal pain, followed by central nervous system symptoms or sensorimotor neuropathy. Chronic features have been suggested to be related to a small fiber neuropathy, but further investigation is still due. Here we report a patient with variegate porphyria with unusual findings during follow up, related to central and peripheral nervous systems. **Case presentation:** Female patient with previous history of acute attack (abdominal pain, urinary retention and tetraplegia) at age 27. She was evaluated at age 42 and as sequelae she had mild distal weakness and neuropathic pain in both hands and feet. She was diagnosed after genetic panel showed a pathogenic variant on PPOX - c.503G> A. Electrodiagnostic studies (EDX) were performed and revealed reduced compound motor action potential (CMAP) amplitudes in nerves of the lower limbs and both median nerves. Also, conduction block in both median nerves suggested acquired demyelinating neuropathy. Late responses showed absence of F waves and H reflexes in the tibial nerves. Sensory studies were normal. Neuromuscular ultrasound showed enlarged cross-sectional area in both median nerves in the forearm, consistent with neural thickening outside typical compression site. Six months later, she presented with psychosis and reported migrainous headache. Brain MRI suggested idiopathic brain hypertension. Lumbar puncture demonstrated increased opening pressure of 32 cmH2O. A new attack was discarded with biochemical exams. **Discussion:** Acute porphyric neuropathy is described as an axonal predominantly motor neuropathy. Secondary demyelinating findings have been described. A primary demyelinating neuropathy and partial conduction block, as seen in our case, have been reported in the acute phase and related to more severe acute attacks. A chronic distal axonal sensory-motor polyneuropathy can persist. Specific ultrasonography features of porphyric neuropathy have not been reported. **Final commentws:** This unpredicted finding can be a source of misleading diagnosis as inflammatory neuropathy. Finally, intracranial hypertension is not usually seen and further studies are needed to establish a relationship.

An unusual presentation of small vessel disease: NIT1 gene mutation

Camila Rodrigues Nepomuceno[1], Nayara de Paula Guerreiro[1], Maria Fernanda Hamamoto Leati[1], Felipe Cenicio Juliatti[1], Joao Roberto Ribeiro Pimenta[1], Larissa Neves de Lucena[1], Cristiane de Araujo Martins Moreno[1], Julian Leticia de Freitas[1], Maria Sheila Guimaraes Rocha[1]

[1]Hospital Santa Marcelina, São Paulo SP, Brazil.

Correspondence: Camila Rodrigues Nepomuceno; Email: camilarnepomuceno@gmail.com.

Case presentation: A 39-year-old woman presented at our hospital with a sudden neurological deficit characterized by disproportionate right hemiparesis and severe motor aphasia. When asked about past medical history, relatives reported that during the immediate postpartum period seven years ago, the patient had a similar condition, resulting in non-limiting motor and language sequelae. In childhood, the patient had a cognitive delay, which evolved over the years into cognitive dysfunction with amnestic and executive predominance. The family history included information about consanguinity (her parents were first-degree cousins); she has eight siblings without comorbidities. Brain MRI showed T2/FLAIR hyperintensity in periventricular white matter and bilateral middle cerebellar peduncle, also demonstrated diffusely widened perivascular spaces in the striatum and acute stroke in the left middle cerebral arterial territory. CSF, echocardiogram, and MR angiography showed no abnormalities. Whole exome sequencing revealed a homozygous pathogenic variant c.883C> T (p.Arg295*) in the NIT1 gene, consistent with small vessel disease. **Discussion:** Given the cognitive changes associated with white matter disease and stroke, leukoencephalopathy and its differential diagnoses were considered. Whole exome sequencing showed a mutation in the NIT1 gene responsible for small vessel disease. The Nitrilase1 (NIT1) protein belongs to the nitrilase protein family. Its role in human health and disease is not yet fully understood. Studies in mice have indicated that NIT1 functions as a metabolite repair enzyme. Additionally, NIT1 is believed to act as a tumor suppressor by activating the TGFβ-Smad and WNT signaling pathways. Rutten et al. demonstrated that biallelic loss-of-function variants in NIT1 cause genetic cerebral small vessel disease. In this study, all patients exhibited a distinct neuroimaging phenotype, with the extent of white matter hyperintensities varying among patients, even those of the same age. Our patient showed an image pattern similar to leukoencephalopathy on MRI. This condition brings to a newly identified cerebral small vessel disease inherited in an autosomal recessive manner. This type of inheritance can obscure the genetic nature of the disorder, as patients often appear to be sporadic cases. **Final comments:** We describe an uncommon cause of cerebral small vessel disease with a distinct neuroimaging phenotype consistent with diagnoses of leukoencephalopathy caused by biallelic NIT1 loss-of-function variants.

Anabolic androgenic steroids triggering reversible cerebral vasoconstriction syndrome

Cássia Marin Dapper[1], Natália Contini[1], William Alves Martins[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Natália Contini; Email: nataliacontini4@gmail.com.

Case presentation: A healthy 24-year-old male developed spontaneous and severe thunderclap headache (TCH), during low impact physical exercise. Neurological examination and vital signs were normal. Noncontrast brain computed tomography (CT), CT arteriography, laboratory tests and cerebrospinal (CSF) analysis displayed no

abnormal findings. The headache responded satisfactorily to intravenous analgesia. At the same day, after total pain improvement, patient requested to be discharged. One day after, he returned to the hospital after a new episode of TCH and severe nausea, not associated with physical effort. Once again, vital signs, neurological examination, and CT study were normal. Laboratory tests including blood count, lipid profile, prothrombin time, partial thromboplastin time, anti-nuclear antibody, anti-HBs, HBsAg, anti-HCV, anti-HIV and VDRL were unremarkable. Liver and renal function tests were above the limit of normality. Patient later revealed using an anabolic androgenic steroid (AAS) called oxandrolone in the past 6 weeks during gym time. At the same day of admission, a Brain MRI angiography revealed narrowing segments of P2 and P3 of posterior cerebral arteries, especially on the right side. There was no signs of bleeding or ischemia. Headache and nausea had gradual improvement after symptomatic medications. Liver and renal function tests came to normality and, after seven days, patient did not present any more episodes of headache. A MR angiography after four weeks demonstrated improvement in alternating stenotic areas in vessels. Thus, diagnosis of reversible cerebral vasoconstriction syndrome (RCVS) was established. **Discussion:** The features of RCVS are thunderclap headache, lack of subarachnoid hemorrhage by CSF and CT analysis, exclusion of cerebral vasculitis by CSF, and angiographic demonstration of multifocal segmental cerebral artery vasoconstriction that resolves with time. It is associated with some potential triggers. The most common are postpartum period, oral contraceptive medication, immunosuppressants drugs and vasoactive drugs, as antidepressants, nasal decongestants and illicit drugs. In the presented case, none of them was identified. The temporal relationship between the AAS initiation use and syndrome development can implicate the supplement as a contributing cause. Supraphysiologic doses of AAS have been associated with dyslipidemia, arrhythmias, cardiovascular remodeling and hypertension. Moreover, there is some evidence that androgen use is associated with thrombosis, which also increase the risk of cerebral venous or arteries events. The association between RCVS and AAS use has not previously been made. Indirect prothrombotic and proatherogenic mechanisms and direct cardiac effects can explain this possible correlation. **Final comments:** Thus, it is advisable to consider the potential roles of anabolic androgenic steroids in cases of otherwise unexplained cerebrovascular disease.

Analgesics overuse in patients with headache in the neurology outpatient clinic of a university center: clinical-epidemiological profile

Ana Beatriz Rezende dos Santos Correa[1], Bruna Verdelho Leite[1], Daniele Azevedo Valente[1], Celice Cordeiro de Souza Bergh Pereira[1], Walther Augusto de Carvalho[1]

[1]Centro Universitário do Pará, Belém PA, Brazil.

Correspondence: Daniele Azevedo Valente; Email: danieleazevedos84@gmail.com.

Background: Medication-overuse headache is a secondary headache that usually occurs in patients suffering from primary headaches, worsening the intensity and frequency of attacks and is often underdiagnosed and treated inappropriately because of the population's lack of knowledge about it and high frequency of self-medication with over-the-counter analgesic agents. **Objective:** To identify the prevalence of analgesics overuse by patients diagnosed with headache treated from June 2021 to June 2023 in a neurology outpatient clinic of a medical specialty center in the city of Belém/PA. **Methods:** A cross-sectional, observational, analytical-descriptive study was carried. **Results:** 166 medical records of patients with headache were included, in which there was a higher prevalence of females (85.5%), aged between 41-60 years (45.2%) and the main type being migraine with or without aura (61.4%). A prevalence of 28.3% of analgesic overuse was found, in wich dipyrone was the most associated acute analgesic (44.7%) and the prophylactic medciation most associated was amitriptyline (34%). It is noteworthy that in 51.2% of the medical records there was no adequate recording of information about the use of analgesics, which could lead to a possible underdiagnosis. **Conclusion:** It is concluded that a considerable portion of patients treated for headaches was doing analgesics overuse, predominantly females, the majority using dipyrone and amitriptyline. It was also revealed that there is a need for greater vigilance regarding the excessive use of analgesics in this population, either through greater encouragement for patients to use a headache diary or through the incorporation of specific forms for the care of patients with headache in the electronic medical records system.

Correspondence: Marcela Cristina de Souza Lemus; Email: marcelalemus47190@gmail.com.

Background: Cerebrovascular diseases are one of the principal causes of death in Brazil, in the last four years more than 106 thousand obits were registered by stroke (AVC), according to DATASUS. Recent studies have shown a relation between the grave acute respiratory syndrome caused by SARS-CoV-2 and the development of grave neurological manifestations, as the AVC. Due to the increase of cases of this disease after the pandemic, this study is important to understand the data of AVC admissions. **Objective:** Analyze the admissions by AVC in the southeast region between 2020 and 2023. **Methods:** Ecological study realized with Hospitals System Informations of SUS data, vinculated to DATASUS. It was evaluated the number of admissions of ischemic AVC or acute hemorrhagic AVC treatment (procedure: 0303040149) in the period of 2020 to 2023 in southeast region, including the variables: total of admissions, average cost, average time of hospitalization and mortality tax per year of service. As this was a study that uses secondary databases, it wasnt necessary the approval of the Ethics Committee. **Results:** In the period analyzed, the southeast region presents a total of 356,513 admissions to AVC treatment. During this period, there was a progressive growth of admissions, from 80,326 to 95,888 hospitalizations, which represents an increase of 19.37% between 2020 and 2023. The average cost per hospitalization increased from R$1,529.13 in 2020 to R$1,934.84 in 2023, without significant alterations between 2020-2021 and 2022-2023. The average time of hospitalization remained constant between the years analyzed, approximately 7.6 days. In relation of the mortality tax, in the first two years of COVID-19 pandemic, there was an increase of 16.68/100,000 habitants in 2020 to 17.61/100,000 habitants in 2021, while between 2022 and 2023 there was a reduction of mortality tax of 15.97 to 14.93 per 100,000 habitants, respectively. It is possible that the data presented here are underestimated by possible sub notifications. **Conclusion:** It was observed an increase in the total number of internations in the period analyzed, in addition to an increase of the average cost of hospitalizations. The tax values of mortality are consistent with the most critical phase of the first years of pandemic, being higher by 2021 and decreasing in the last two years.

Analysis of contraindications to chemical thrombolysis in patients within the therapeutic window for stroke in a public tertiary neurology service in the state of Pernambuco

Ana Caroline Paiva Simeao[1], Ana Caroline Paiva Simeao[1], Mayhara Rosany da Silva Santiago[1], Heloisy Maria Nunes Galvao[1], Nereu Alves Lacerda[1], Raissa Josefa Pereira de Moura[1], Luis Felipe Barros e Silva Pereira Ribeiro[1], Fernando Tenorio Travassos[1]

Correspondence: Ana Caroline Paiva Simeao; Email: carolpaivasimeao@gmail.com.

Background: Stroke is a significant cause of morbidity and mortality worldwide, being the second leading cause of death. Chemical thrombolysis is currently a major milestone for the acute treatment of ischemic stroke, with the greatest effectiveness within the first 3 hours, extending up to 4.5 hours. Currently, alteplase is the only approved chemical thrombolytic, but other thrombolytics like tenecteplase and other tissue reperfusion techniques are being studied to improve treatment response. **Objective:** To conduct an epidemiological profile of patients within the therapeutic window at a tertiary neurology hospital between February and May 2024, evaluating contraindications to the use of thrombolytics. **Methods:** A cross-sectional, observational study was conducted, including all patients within the therapeutic window for chemical thrombolysis at a public tertiary neurology service in the State of Pernambuco, observing the contraindications to thrombolysis. **Results:** A total of 71 thrombolysis protocol activations were evaluated at the institution, where 6 were patients outside the window or with an indeterminate onset, 27 underwent chemical thrombolysis (18 female and 9 male), and 44 did not undergo thrombolysis (22 female and 22 male). The reasons for not performing thrombolysis included: 11 cases of hemorrhagic stroke, 11 cases with a low NIHSS (≤4), 6 cases of extensive ischemic stroke with ASPECTS ≤8 or high NIHSS (> 23), 2 cases missed the window due to uncontrolled blood pressure for thrombolytic infusion, and 6 cases had other reasons, including patient refusal, issues with cranial CT, and recent stroke or traumatic brain injury. **Conclusion:** The majority of patients had some contraindication to chemical thrombolysis with alteplase, with hemorrhagic stroke and low NIHSS being the main reasons for not performing thrombolysis. Training the team on the importance and speed of indicating and contraindicating chemical thrombolysis is crucial. It is also important to evaluate that, in addition to chemical thrombolysis, there is the possibility of thrombectomy, which is not always available in public tertiary neurology services and could have been an alternative for patients with contraindications to chemical thrombolysis.

Analysis of deaths due to cerebrovascular diseases in the state of São Paulo between 2010-2022: an ecological study

Cristina de Souza Lemus[1], Maria Clara Missio dos Santos[2], Nivea de Mattos Amarante Rodrigues[1], Tainara Maria de Souza Abrão[3], Marjorie Correia de Andrade[4]

[1]Universidade Federal do Rio de Janeiro, Macaé RJ, Brazil.
[2]Universidade Nove de Julho, São Bernardo do Campo SP, Brazil.
[3]Pontifícia Universidade Católica de Minas Gerais, Poços de Caldas MG, Brazil.
[4]Universidade Potiguar, Natal RN, Brazil.

Correspondence: Marcela Cristina de Souza Lemus; Email: marcelalemus47190@gmail.com.

Background: Cerebrovascular diseases are among the main conditions responsible for deaths, physical disability, and impaired quality of life globally. According to data from the World Health Organization, six million individuals succumb annually to these diseases, making them the second leading cause of annual mortality. **Objective:** This study aims to analyze deaths from cerebrovascular diseases in São Paulo from 2010 to 2022. **Methods:** An ecological, observational study, using data from the Mortality Information System available on the website of the Department of Informatics of the Unified Health System (DATASUS). The information collected pertained to death notifications by residence with cause coded as "CID-BR-10: 070 - cerebrovascular diseases". Deaths were evaluated by age group, sex, year of occurrence, and color/race in the state of São Paulo between 2010 and 2022. Approval by the Ethics Committee was not required. A limitation of the study is the possible underreporting of cases. **Results:** In the analyzed period, 284,188 deaths from cerebrovascular diseases were recorded in the state of São Paulo. It was observed that between 2010 and 2020, the number of annual records did not exceed 22,308 deaths, in 2016. However, from the year 2021, a growing increase in these values was observed, reaching 23,058 deaths in 2022. The elderly, aged 60 years and older, represent 80.6% of the deaths during this period, with those over 80 years old being the most affected, accounting for 100,711 deaths (43.98%). Regarding sex, although male cases were predominant in the analyzed interval, deaths among men and women are close, totaling 144,064 and 140,110, respectively. In the analysis by color/race, a predominance of white color was observed, with 194,186 cases, representing 68.33% of the total deaths. The capital of São Paulo recorded 125,550 occurrences, corresponding to approximately 44% of the total of all analyzed regions, compared to 30% of the total cases registered outside the metropolitan region. **Conclusion:** The observed data indicated an increase in the number of deaths between 2021 and 2022, with the elderly being the majority of victims of cerebrovascular accidents. This phenomenon can be explained by the higher prevalence of comorbidities in this age group. Additionally, studies in the literature highlight the various disease mechanisms of SARS-CoV-2, such as vascular and nervous system involvement, which may be related to the increase in deaths from cerebrovascular diseases during the pandemic periods.

Analysis of efficiency between the cost, length of stay and clinical outcomes for stroke in the states of the Northern region of Brazil

Sávio Roberto Silva Costa[1], Emilly Alessandra Cruz dos Reis[1], Luan Nascimento Pereira de Amorim[1], Danusa Neves Somensi[1], Mariângela Moreno Domingues[1], Emanuel de Jesus Soares de Sousa[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Sávio Roberto Silva Costa; Email: saviorsc20@gmail.com.

Background: Stroke is one of the leading causes of morbidity and mortality across the globe, posing a significant challenge to healthcare systems. Characterized by the interruption of blood flow to the brain, stroke can result in severe and permanent neurological damage. Treating stroke patients involves high costs, including hospital expenses, medication, rehabilitation and long-term care. In addition, length of stay is a critical factor that influences both costs and patients' clinical outcomes. Thus, understanding these dynamics can provide valuable insight into improving treatment processes, reducing expenses and maximizing the quality of patient care. **Objective:** To evaluate the efficiency of stroke management in the northern region based on financial variables and the clinical outcome. **Methods:** This is a cross-sectional, observational study with a quantitative approach. The data was collected from the Department of Information and Informatics of the Unified Health System (DATASUS), in the hospital morbidity section (SIH/SUS). Variables related to the number of hospitalizations, total expenditure, average expenditure per hospitalization, average length of stay and mortality rate were analyzed; data was collected from 2014 to 2023. Bioestat 5.3 software was used for the statistical analysis. A p-value of less than 0.05 was considered statistically significant for this study. **Results:** In the period from 2014 to 2023, 17,018 hospitalizations for stroke were recorded in the Northern region, with 84.1% of the records occurring in Amazonas and Pará, where 11,839 and 2,479 hospitalizations were reported, respectively. Amapá had the lowest number of notifications in the period (73). The average regional cost per hospitalization was R$905.88; the states with the highest costs were Roraima (R$1,270.68) and Rondônia (R$1,227.31), while Acre had the lowest average cost per hospitalization (R$715.98). With regard to hospital stays, the North region had an average of 6.7 days, which was exceeded by four states, Amapá (12.1), Roraima (10.2), Acre (8.4) and Amazonas (6.9), while the lowest average was in Rondônia (4.9). The regional mortality rate during the period was 11.06, and the state with the highest death rate was Amapá (16.44), followed by Roraima (12.24) and Amazonas (11.84). The states with the lowest death rates were Rondônia (7.63%) and Tocantins (6.4%). **Conclusion:** Based on the data collected, there was a concentration of hospitalizations in Amazonas and Pará, which also had the highest total expenditure on hospitalizations for stroke in the North. Most of the costs were related to hospital services. The states of Amazonas, Acre, Amapá and Roraima stood out with average hospital stays and mortality rates higher than the regional average. In terms of efficiency, the most efficient state in the North was Tocantins, while Amapá was the least efficient in terms of expenditure and clinical outcomes for stroke.

Analysis of epilepsy cases in Brazil in the last five years

Caroline Patrícia Amaral Costa[1], Manuel Edmundo Teles Neto[2], Chan David Ribeiro[3], Rafael Reis de Oliveira[1], Moisés Cardoso Portilho[2], Laura Lino Gonçalves[3], Luiz Carlos Figueiredo Filho[3], Luan Nascimento Pereira de Amorim[3]

[1]Universidade Federal do Pará, Belém PA, Brazil.
[2]Centro Universitário Metropolitano da Amazônia, Belém PA, Brazil.
[3]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Caroline Patrícia Amaral Costa; Email: caroline.costa@ics.ufpa.br.

Background: Epilepsy is a serious syndrome in which the patient is in an imbalance of various modulators of the synaptic action potential, such as receptors, neurotransmitters, enzymes or the neurons themselves. These alterations result in episodes of focal or generalized cortical hyperexcitation. Acute symptomatic seizures affect around 29 to 39 people per 100,000 inhabitants, mainly children under the age of 1 and the elderly, who are predisposed to cardiovascular complications. Due to the complexity of epilepsy, it is crucial to analyze patient data in Brazil in order to identify risk groups, protective factors and strategies to reduce morbidity and mortality. **Objective:** To analyze the epidemiological profile of epilepsy cases over the last 5 years in Brazil. **Methods:** This is an epidemiological, ecological and temporal study, which used data collected from 2019 to 2023, available in the SUS Hospital Information System (SIH/SUS), provided by the SUS Information Technology Department (DATASUS). The following variables were selected: number of procedures, expenditure per hospital admission authorization (AIH), length of stay, average length of stay, deaths and mortality rate by Region/Federation Unit and Year of Processing. The data was tabulated using the Microsoft Excel 2021 program. **Results:** With regard to hospital admission authorizations (AIH), 228,181 cases were approved, with the Southeast region predominating with 41.54% (n=94777, p< 0.0001), while the North region had only 6.46%. In terms of average length of stay, the regions had an average of 5.8 days, with the Northeast having the longest with 6.1 days, while the Midwest had 5.1 days. In addition, with regard to the number of deaths, 6,901 deaths were recorded during this period, with the Southeast having 48.37% (n=3338, p< 0.0001), followed by the Northeast with 28.73%, while the total mortality rate for the period was 3.02, with the average rate by region predominating in the Southeast with 3.52. Finally, the average value per total hospitalization was R$876.32, and there was significant variation between the regions, with the Southeast region having an average of R$988.05 (p<0.0001) and the North having the lowest average with R$565.75. **Conclusion:** During the period analyzed, it should be noted that there was a significant predominance of the Southeast region in the number of hospitalizations and deaths, which may be associated not only with the demographic density of the region, but also with the high demand and complexity of the patients. Therefore, it is understood that the high cost per hospitalization associated with this region. Furthermore, based on the data obtained from the Northeast, it can be concluded that there is a greater need for prolonged treatment and intensive measures in this region, which may also be related to the considerable number of deaths.

Analysis of four attention tests and the influence of education and intelligent coefficients

Hellen Rose Maia Salazar[1], Ana Luiza Caldas Coutinho[2], Sergio Luis Schmidt[1]

[1]Universidade Federal do Estado do Rio de Janeiro, Programa de Pós Graduação em Neurologia, Rio de Janeiro RJ, Brazil.
[2]Universidade Federal do Estado do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Ana Luiza Caldas Coutinho; Email: analu.coutinho@edu.unirio.br.

The neurological circuit that involves attention includes prefrontal areas, thalamus, anterior cingulum, and brainstem. Other cognitive domains, such as memory, use more complex neocortical networks. When combined, all those networks form an individual's general intelligence. Although these cognitive domains can be affected even without attention deficits, the opposite is not true as attention is a prerequisite for them. Therefore, properly excluding attention deficits is a core process for the correct analysis of other cognitive processes. In this context, an ideal attention test would be one that can measure attention performance with minimal interference from

general intelligence. Currently, most attentional tests are anchored in years of formal education. However, to our knowledge, there aren't attentional tests standardized based on the Intelligent Quotient (IQ). Our main objective is to analyze if there was influence of intelligence scores on attentional performance through different neuropsychological tests. We also aimed to identify whether these attention tests were affected by different educational levels. This study age range was of 18 to 65 years. Education levels were divided as: elementary (0 to 8 years of instruction), high school (9 to 12) and higher education (13+). All participants were submitted to the following attention tests: Continuous Visual Attention Test (CVAT), Diffuse Attention Test for Drivers (TADIM), Discriminative Attention Test for Drivers (TADIS), and Pictorial Visual Memory Test (TEPIC). Intellectual performance was measured through the R-1 Non-Verbal Intelligence Test. R-1 raw points were divided into 3 clusters based on the percentile as: ≤ 25%; > 25% and < 75%; and ≥ 75%. For each attention test we analyzed the correlations between the R-1 raw scores and attention performance. A multivariate analysis of covariance (MANCOVA) was used to test the effect of R-1 clusters in the attention performance. Educational level was used as a covariate. The sample included 1036 participants (75.8% males). The mean age was 31.8 years. Education levels were represented as 17% elementary, 48% high school, 29% higher education and 5% not informed. The correlations indicated significant coefficients for TADIM (r = 0.486, P = 0.000), TADIS (r = 0.502, P = 0.000), and TEPIC (r = 0.311, P = 0.000). The CVAT variable that reached the highest correlation coefficient was the intrinsic alertness subdomain (r = 0.143, P = 0.000). A MANCOVA indicated a significant effect of the R-1 cluster for all the tests, excepted for the CVAT. The educational levels were also found equally significant for the TADIM, TADIS, and TEPIC except the CVAT. We concluded that TADIM, TADIS, and TEPIC test results were significantly affected by IQ and educational levels. Then, standardized data of these tests need to be corrected not only for the educational level, but also for the individual's IQ.

Analysis of functional/dissociative seizures (FDS) semiology based on video-electroencephalography (VEEG)

Luiza Barbosa de Oliveira[1], Gláucia Monteiro Oliveira[1], Vivian Proença Lara[1], Caio Cobucci Esteves[1], Igor Pereira Matos de Oliveira[1], Gustavo Barros Loureiro[1], Vanessa Alves Lobato[1], Aline Curcio de Moraes[1], Helena Barbosa Horta Santos[1], Maria do Carmo de Vasconcellos Santos[1]

[1]Santa Casa de Belo Horizonte, Belo Horizonte MG, Brazil.

Correspondence: Luiza Barbosa de Oliveira; Email: luiza.neurologia@gmail.com.

Background: Functional/dissociative Seizures (FDS) are episodes that may resemble epileptic seizures, but lack abnormal brain electrical activity. The gold standard for diagnosis is videoelectroencephalography (VEEG), however, diagnosis is often delayed due to limited centers offering VEEG facilities. Therefore, estimating the most frequent semiology in FDS can be an useful tool to help physicians in order to diagnose and manage these disorders. **Objective:** Detailed semiological analysis may assist in diagnosis. Then, the research focus is to analyze the semiology of documented FDS from our VEEG unit from 2020 to 2023. **Methods:** We retrospectively analyzed medical and VEEG records of patients with FDS with at least one typical event documented. Records were then reviewed for the presence or absence of semiological signs considered as potential discriminators between FDS and Epileptics Events according to the pertinent literature. Prevalence in our study allowed us to select 7 practical semiological features with potential to distinguish FDS from Epileptics Events. These items were: eyes closed, body position (opisthotonus), asynchronous limbs movement, head movements side-to-side, duration > 2 minutes, complete unresponsiveness and rapid postictal reorientation. Comparative analyses were carried out to identify significant differences between patients diagnosed with FDS and concomitant epilepsy from those with FDS and no concomitant epilepsy. For this, the Chi-square test (via simulation of Monte Carlo) was performed. In all analyzes carried out, the differences obtained were considered statistically significant when the p value< 0.05. Statistical analyzes were performed using the Stata® program. **Results:** In the period from 2020 to 2023, 828 patients were evaluated at the VEEG unit. Of these, 11.35% (n=94) documented FDS. Concomitant epilepsy was detected in 48.94% of patients positive for FDS. Considering the semiology of FDS the presence of asynchronous limb movements (23.89%), forced eye closure and duration greater than 2 minutes (15.79% each) were the most frequent signs. Data on semiology indicated a significant difference only in relation to the rate of forced eye closure. According to the results presented, this type of signal was observed at statistically lower rates in FDS patients and concomitant epilepsy, when compared to patients without epileptic events. **Conclusion:** The diagnosis of FDS can be challenging, therefore, an evaluation of semiology can help. When the patient has a normal interictal EEG, it may be possible to make a probable diagnosis of FDS, even without VEEG. For that, review of the clinical event suggestive of FDS by an experienced physician is needed.

https://doi.org/10.5327/CBN240128

Analysis of hospitalizations for carpal tunnel syndrome surgery in Brazil from 2014 to 2023

Laisa de Paula da Costa Lobato[1], Bárbara Alessandra Solano Silva[2] , José Antônio Solano Silva[1], Luan Victor Silva Ribeiro[1], Hálisson Ferreira Freitas Filho[3], Leandro Gabriel Costa Macedo[1], Ricardo Ferreira Silva[1], Dirceu Jose de Freitas Cardoso[1], Bárbara Coutinho Morgado[2]

[1]AFYA Faculdade de Ciências Médicas , Abaetetuba PA, Brazil.
[2]Centro Universitário do Pará, Belém PA, Brazil.
[3]Universidade Federal do Pará, Belém PA, Brazil.

Correspondence: Laisa de Paula da Costa Lobato; Email: laisaikilman@gmail.com.

Background: Carpal tunnel syndrome is a neuropathy characterized by compression of the median nerve at the wrist level, capable of affecting sensation in the region. It is one of the upper extremity disorders that generates substantial costs and disabilities, with an estimated prevalence between 4% and 5% of the population. In many cases, conservative treatment is ineffective, necessitating surgical intervention. Potential complications include suture dehiscence, infection, and tendon injuries, contributing to increased hospitalizations of these patients. **Objective:** To analyze the epidemiological profile of hospitalizations for carpal tunnel syndrome surgery in Brazil from 2014 to 2023. **Methods:** An ecological, retrospective, quantitative study using data collected from the Sistema de Informações Hospitalares (SIH/SUS) via Departamento de Informática do Sistema Único de Saúde (DATASUS). Variables were analyzed using descriptive statistics, focusing on surgical procedures for carpal tunnel release in Brazil during the study period, including annual hospitalization numbers by state, deaths, and average length of stay. **Results:** A total of 126,335 hospitalizations were reported, with the majority in 2023 (18,934 or 15%) and the fewest in 2020 (7,714 or 6.1%), potentially reflecting increased "home office" employment post-pandemic leading to repetitive strain injuries, such as typing. The Southeast region had the highest number of hospitalizations (60,745 or 48%), whereas the North had the lowest (1,802 or 1.42%), possibly due to higher rates of repetitive strain injuries in jobs involving finger and hand movements, such as typing, compared to predominantly manual labor in the North. Regarding deaths, 3 were recorded, which may be explained by the low complexity of carpal tunnel syndrome surgery. 2 deaths occurred in the South region and 1 in the Northeast. The average length of hospital stay in Brazil was 0.6 days, likely due to the straightforward postoperative course and low complication rates. The Central-West region had the highest average stay (1.3 days), while the Southeast had the lowest (0.4 days). **Conclusion:** Analysis of hospitalizations for carpal tunnel syndrome surgery revealed significant variations across Brazil. The peak in 2023 may be attributed to increased "home office" practices leading to repetitive strain injuries. The Southeast region experienced the highest number of hospitalizations, likely due to a higher prevalence of jobs involving repetitive finger and hand movements. The low mortality rate and short hospital stays highlight the safety and low complexity of this surgery. These findings underscore the importance of developing public policies aimed at treating and preventing this condition.

https://doi.org/10.5327/CBN240129

Analysis of hospitalizations for stroke before and during the COVID-19 pandemic in Bahia: an epidemiological approach

Victor Vale da Silva[1], Júlia Ribeiro Oliveira Campos[2]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.
[2]Afya Faculdade de Ciências Médicas de Itabuna, Itabuna BA, Brazil.

Correspondence: Victor Vale da Silva; Email: vitor.futebolclube@hotmail.com.

Background: Cerebrovascular accident (CVA) is one of the main causes of mortality and disability globally. In Bahia, the COVID-19 pandemic brought significant changes to the healthcare system, impacting the management of several medical conditions, including stroke. This objective study analyzes the profile of stroke hospitalizations in Bahia, comparing the pre-pandemic and during the pandemic periods, with the aim of identifying changes in hospitalization patterns and obtaining information to improve stroke management during periods of health emergencies. **Objective:** To evaluate the epidemiological profile of hospitalizations for stroke in Bahia between the pre-pandemic (2017-2019) and pandemic (2020-2022) periods. **Methods:** This is an epidemiological, retrospective and descriptive study that collected secondary data from the Hospital Morbidity System (SIH/SUS) to analyze the epidemiology of hospitalizations for stroke in the state of Bahia. The pandemic period analyzed was from January 2020 to December 2022, being compared to the pre-pandemic period, from January 2017 to December 2019. The variables studied included: number of hospitalizations, age group, sex, year and color /race. Data analysis was carried out in the Microsoft Excel program, using graphs to generate descriptive statistics. **Results:** In the period 2017-2020, there were 37,045 hospitalizations for stroke, rising to 41,842 during the pandemic (increase of 12.95%). Average hospital admissions decreased before the pandemic (7.6 days in 2017-2018, 7.3 days in 2019), but increased during the pandemic (7.3 days in 2020, 7.4 days in 2021, 7.7 days in 2022). The death rate, which was falling before the pandemic, increased during the pandemic. The number of hospitalizations for men increased from 18,673 to 21,061 (an increase of 12.8%) and for women from 18,372 to 20,781 (an increase of 13.1%). The male mortality rate reduced slightly (17.8 to 17.6), while the female mortality rate increased (17.91 to 18.18). The number of hospitalizations of black and brown people increased from 18,695 to 26,227 (an increase of 40.3%). In the elderly, hospitalizations increased by 10.9%, in adults aged 20 to 59, by 17.9%, and in young people under 20,

by 61.1%. **Conclusion:** The results indicate an increase in hospitalizations for stroke during the pandemic, with longer hospital stays and a change in the downward trend in the mortality rate. There were increases for both men and women, with variations in the death rate by sex. Analysis by race showed an increase in hospitalizations among black and mixed-race patients, possibly associated with the fact that these groups constitute the majority of those facing conditions of socioeconomic vulnerability. All age groups recorded an increase in hospitalizations, especially younger people. Therefore, these results highlight the need for prevention and treatment strategies adapted to each group in order to improve stroke management in challenging contexts.

[8]Universidade Estadual do Ceará, Fortaleza CE, Brazil.

Correspondence: Ana Clara Lacerda Freitas; Email: anaclf15@yahoo.com.br.

Background: Polyneuropathies are conditions that affect multiple peripheral nerves, causing a wide range of symptoms that vary depending on the nerves involved. These conditions can result from various causes, including metabolic diseases, nutritional deficiencies, toxins, infections, and autoimmune disorders. In the Brazilian context, the impact of polyneuropathies on public health is significant, with an increasing number of cases diagnosed each year. **Objective:** To analyze hospitalizations and healthcare costs related to the treatment of polyneuropathies in the Brazilian Unified Health System (SUS) between 2019 and 2023. **Methods:** This ecological study utilized data extracted by the Department of Informatics of the Brazilian Unified Health System (DATASUS). Data analysis was performed using Google Sheets, covering the number of cases and duration of hospitalizations for the treatment of polyneuropathies in Brazil, average cost per hospitalization, total cost, and mortality rate from 2019 to 2023. **Results:** Between 2019 and 2023, there were 37,810 hospitalizations for the treatment of polyneuropathies in Brazil, with 2022 having the highest number of hospitalizations (8,402), followed by 2019 (8,167), 2021 (7,509), 2023 (7,100), and 2020 with the lowest number of hospitalizations (6,632) in the period analyzed. There was a reduction in 2020, likely due to the impact of the COVID-19 pandemic, followed by a gradual recovery in subsequent years, until a decline again in 2023. The Southeast Region had the highest number of hospitalizations, with 13,412, followed by the Northeast (9,752), South (9,098), North (3,317), and Central-West with 2,231. The total expenditure for these hospitalizations was R$ 50,262,017.26, with the highest in 2022 (R$ 13,091,569.51) and the lowest in 2020 (R$ 7,554,768.12). The average cost per hospitalization increased from R$ 1,029.95 in 2019 to R$ 1,602.97 in 2023, reflecting an increase in costs over time. Additionally, the average hospital stay increased from 8.7 days in 2019 to 9.3 days in 2023, as well as the mortality rate, from 2.15% in 2019 to 2.66% in 2023. **Conclusion:** The year with the most hospitalizations was 2022, which consequently had the highest total expenditure. Additionally, the data indicate an increase in costs related to hospital resources and a rising mortality rate, highlighting significant challenges in the treatment of polyneuropathies. Through this analysis, it is possible to identify potential contributing factors, evaluate the effectiveness of existing interventions, and guide public health policies to improve the prevention, diagnosis, and management of these conditions.

Analysis of melatonin as a therapeutic tool in the treatment of neurologically-originated insomnia: a systematic review

Hálisson Ferreira Freitas Filho[1], João Victor Souza de Barros[1], Larissa Suzan Basilio e Silva[1], Felipe José Silva e Silva[1], Luan Víctor Silva Ribeiro[2] , Izabella Carolline Menescal Ferreira[1], Igor Moreira Miguez Godoy[3] , Kaliana Kennedy Oliveira Calixto[1], Antônio Marcos da Silva Henriques[1], Nathália Coimbra Coêlho[1]

[1]Universidade Federal do Pará, Belém PA, Brazil.
[2]Afya Faculdade de Ciências Médicas
[3]Centro Universitário Metropolitano da Amazônia, Belém PA, Brazil.

Correspondence: Hálisson Ferreira Freitas Filho; Email: halisson.filho@ics.ufpa.br.

Background: Insomnia, a common symptom among sleep disorders, is primarily characterized by difficulty sleeping due to mental or physical conditions. To determine the pathogenesis, a thorough analysis of the patients history is necessary to identify any underlying cause. The diagnosis refers to a symptom of insomnia that requires specific attention. The therapeutic approach can be cognitive-behavioral, which is the most commonly used, or pharmaceutical, which is also widely utilized and is the focus of this study. **Objective:** Explore the efficacy of using melatonin as a treatment for neurologically-originated insomnia. **Methods:** This involves conducting a systematic literature review of the past 10 years on the "PubMed" platform using the descriptors: "insomnia", "melatonin", and "neurological. Initially, 30 articles were selected, and of these, only 3 were included based on the following criteria: english language, systematic review, clinical trial, meta-analysis, and relevance to the topic. Twenty-six articles were excluded based on the exclusion criteria: not being in english, studies not aligned with the proposed theme, and incomplete articles. **Results:** Most studies assessed the effects of a specific dosage of slow-release melatonin on quantitative variables such as total sleep time, sleep latency, and wakefulness after sleep onset. In studies with elderly patients, in which insomnia is highly prevalent, as in other special populations like children, the results of melatonin use have been inconsistent. Although subjective improvement in sleep quality has been observed with the slow-release form, no benefit on total sleep time has been demonstrated using **Objective:** parameters. In a randomized, double-blind, placebo-controlled, crossover study with children affected by epilepsy and sleep problems, it was observed that slow-release melatonin improves sleep latency and wakefulness after sleep onset, a similar outcome of a systematic review with adults patients with neuropsychiatric disorders. However, these were small studies, so the results may not be generalizable to an open scope. **Conclusion:** Therefore, there is not enough evidence to recommend the use of melatonin for the treatment of insomnia, and a larger scale study is necessary to analyze the efficacy for secondary outcomes, safety, and tolerability in children with epilepsy.

Background: Dementia is a syndrome of degeneration of higher cortical functions, involving memory, thinking, comprehension, language, and judgment. It has become increasingly important as a public health problem due to the growth of the elderly population, projecting that these individuals may reach 23.8% by 2040, thus nearly a quarter of the Brazilian population. **Objective:** To analyze the morbidity and mortality due to dementia in the elderly population in the Southeast Region from January 2008 to March 2024. **Methods:** This is an ecological, cross-sectional, descriptive study with a quantitative approach, conducted in May 2024, using data collected from the Hospital Information System of SUS (SIH/SUS - Sistema de Informações Hospitalares do Sistema Único de Saúde), available from the Department of Informatics of the Unified Health System (DATASUS - Departamento de Informática do Sistema Único de Saúde). The variables used were hospitalizations, total diagnostic value, deaths, and mortality rate. The collected data were organized in Microsoft Excel spreadsheets and analyzed using descriptive statistics. **Results:** Mortality rates, deaths, hospitalizations, and total diagnostic value were observed, respectively, for each state in the Southeast Region. In Minas Gerais, it was 19.04% (626 deaths and 3,288 hospitalizations) totaling R$15,725,524.48; in Espírito Santo, it was 7.38% (9 deaths and 122 hospitalizations) totaling R$323,552.44; in Rio de Janeiro, it was 15.11% (950 deaths and 6,289 hospitalizations) totaling R$38,420,414.65; in São Paulo, it was 7.18% (511 deaths and 7,114 hospitalizations) totaling R$40,252,064.51. Hence, it was possible to verify that the mortality rate in the state of Rio de Janeiro is lower than that of Minas Gerais; additionally, it has an approximately 50% higher total value allocated compared to the number of hospitalizations that occurred in the state of Minas Gerais. Thus, there is an unequal distribution of funds in Brazil, resulting in avoidable deaths. **Conclusion:** The data examined highlight the discrepancy in resources allocated to Minas Gerais compared to Rio de Janeiro. Therefore, the lack of support professionals such as nurses, psychologists, and physiotherapists for this population exacerbates this situation, consequently requiring more investment in dementia prevention measures and care for diagnosed patients with comprehensive services. For example, early recognition of the disease and differential diagnosis to mitigate the impacts of this disease, improve the patients quality of life, and increase their survival.

Background: Intracranial Trauma is recognized as one of the leading causes of death and disability, constituting a significant public health issue. This trauma can impair consciousness and, depending on its severity, can affect physical, cognitive, emotional, or behavioral functioning. The Glasgow Coma Scale (GCS) and the pupillary light response are used to assess the severity of brain injury. According to the GCS score, trauma can be classified as mild, moderate, or severe. Falls are the most common cause of such injury, with motor vehicle incidents being the second leading cause. Several complications can arise, including intracranial hemorrhage, cerebral edema, elevated intracranial pressure, vasospasm, seizures, infection, hydrocephalus, memory loss, and hyponatremia. Early patient management and rapid intervention are crucial for a favorable prognosis. **Objective:** This study aims to analyze and present the epidemiology of intracranial trauma in the state of São Paulo from 2020 to 2023, identifying the factors and epidemiological characteristics of the affected patients. **Methods:** This is an ecological, retrospective, and descriptive study, with data collected from the Department of Informatics of the Unified Health System (DATASUS). The variables analyzed included mortality rate, race/ethnicity, sex, age group, and municipalities, focusing on intracranial trauma in the state of São Paulo from 2020 to 2023. **Results:** The mortality rate due to intracranial trauma in the state of São Paulo from 2020 to 2023 was 11.00 per 100,000 population. For males, the rate was 11.55 per 100,000, while for females it was 9.36 per 100,000. The age group with the highest rate was 80 years or older, with 21.45 per 100,000. Regarding race/ethnicity, the Indigenous population had the highest rate at 25.00 per 100,000, followed by Asians at 15.52 per 100,000. The municipality with the highest rate was Tapiratiba, with 100 per 100,000, followed by Queluz, with 50 per 100,000. **Conclusion:** Mortality due to intracranial trauma in the state of São Paulo during the evaluated period was higher among males, likely related to biological factors. The age group 80 years and older had the highest rates, suggesting the influence of factors associated with aging. Among municipalities, Tapiratiba had the highest rate at 100 per 100,000. Regarding race/ethnicity, Indigenous people were the most affected, indicating a possible relationship with socioeconomic and cultural factors. Understanding these data is crucial for developing strategies, such as public policies and programs, aimed at reducing the observed rates.

Analysis of prevalence and vaccination coverage against bacterial meningitis in Brazil from 2013 to 2022

Monyque Pinheiro Charchar[1], Rafaela Gruppi Rodrigues[1], Eloah Mourão Corrêa[1], Fabíola de Carvalho Chaves de Siqueira Mendes[1]

[1]Centro Universitário do Pará, Belém PA, Brazil.

Correspondence: Monyque Pinheiro Charchar; Email: mcharchar10@gmail.com.

Background: Meningitis is an inflammatory process of the meninges that can be infectious or non-infectious. Vaccination against its etiological agents is therefore an effective strategy for prevention and better prognosis. **Objective:** To analyze the prevalence of bacterial meningitis and its relationship with vaccination coverage in Brazil between 2013 and 2022. **Methods:** An ecological study was carried out using information available on the Notifiable Diseases Information System (SINAN) of the SUS Information Technology Department (DATASUS). We analyzed data on the number of cases of bacterial meningitis caused by Neisseria meningitidis, Streptococcus pneumoniae, and Haemophilus influenzae, and vaccination coverage for Pentavalent (VPenta), Pneumococcal (VPC), and Meningococcal C (VMC) by region of Brazil from 2013 to 2022. **Results:** The average vaccination coverage from 2013 to 2022 was 88.9%, 87.4%, and 84.3% for PCV, CMV, and VPenta, respectively. When analyzing coverage by year, in 2020 and 2021, the PCV and CMV vaccines showed a drop in coverage (below 80%) in most regions of Brazil, except for the South and Central-West regions only in 2020. As for VPenta, there was a drop in 2019 and 2021 in all regions, with average coverage of 71%, improving only in the Southern region in 2021 (80.8%). Regarding the prevalence of meningitis, there was a decrease in all regions when comparing the years 2019 (total of 16,684 cases), 2020 (7,076), and 2021 (6,867), with an increase in 2022 (12,238). Thus, considering the coincidence of low vaccination coverage and prevalence of bacterial meningitis with the most critical period of the SARS-CoV-2 pandemic, it is hypothesized that this may justify the low demand for health services, underreporting, as well as social isolation contributing to the reduction in contagion. It should also be noted that, as there was an increase in the number of cases in all regions in 2022, the hypothesis of the effect of social isolation during the pandemic is reinforced, as this year the distancing rules were less strict. On the other hand, vaccination coverage did not increase to the same extent in some regions, such as in the North of the country, where average coverage remained below 80% for all three vaccines, and in the Northeast and Southeast regarding CMV. **Conclusion:** The years 2020 and 2021 recorded low vaccination coverage and a reduction in the prevalence of bacterial meningitis, findings that may be related to the COVID-19 pandemic. However, in 2022, there was no significant resumption of coverage in some regions, suggesting that other factors interfered with vaccination. This highlights the need for the government to address issues negatively impacting immunization rates, such as flaws in production and distribution processes, unequal access between Brazilian regions, social inequality, and increasing misinformation in society.

https://doi.org/10.5327/CBN240135

Analysis of spina bifida hospitalizations in the northeast region of Brazil over the last ten years

Hálisson Ferreira Freitas Filho[1], Kaliana Kennedy Oliveira Calixto[1], Larissa Suzan Basilio e Silva[1], Felipe José Silva e Silva[1], Luan Víctor Silva Ribeiro[2], João Victor Souza de Barros[1], Igor Moreira Miguez Godoy[3], Izabella Carolline Menescal Ferreira[1], Antônio Marcos da Silva Henriques[1], Nathália Coimbra Coêlho[1]

Correspondence: Hálisson Ferreira Freitas Filho; Email: halisson.filho@ics.ufpa.br.

Background: Spina bifida is a congenital anomaly caused by failures in the neural tube closure mechanism during the fourth week of gestation. This condition can affect the spinal cord and meninges, leading to a range of neurological and orthopedic complications. The Northeast is the Brazilian region with the highest prevalence of hospitalizations due to this congenital malformation in the past ten years. **Objective:** To delineate the epidemiological profile of hospitalizations of patients with spina bifida in Northeast Brazil over the last ten years. **Methods:** This is a retrospective study using data obtained through the Department of Informatics of the Unified Health System (DATASUS), regarding hospitalizations for spina bifida in Northeast Brazil, between January 2014 and December 2023. **Results:** From the analysis of this period, a total of 4285 hospitalizations and 108 deaths were recorded in the Northeast region, representing 40.4% of hospitalizations and 44.8% of deaths due to spina bifida in Brazil. Among the states in the region, Bahia accounted for 29.1% of hospitalizations, followed by Maranhão with 20.8%. The highest number of hospitalizations occurred in 2015, with 15% of the total, showing a gradual decrease in the following years. Regarding age groups, individuals under 1 year old represented the age group with the highest number of hospitalizations (62.5%) and deaths (74.0%). Concerning sex, males predominated with 50.8% of hospitalizations and 55.5% of deaths. In terms of mortality rate, Alagoas had the highest rate (6.03), followed by Maranhão (4.36). The white race/color group was the most affected, with a mortality rate of 4.17. **Conclusion:** The data on hospitalizations and deaths reveal regional inequalities and vulnerabilities in the country. It is necessary to implement public policies with investments focused on improving health infrastructure and technologies for early detection and treatment of spina bifida, as well as on training health professionals for the proper management of patients from birth, in order to reduce the impact of hospitalizations and mortality in individuals under 1 year old.

Analysis of the correlation between trunk control and quality of life in individuals with post-stroke hemiplegia: a cross-sectional study

Marina Rigobello Muraro[1], Samuel Lidione da Silva[1], Wellington Felipe Conceição[1], Heloísa Freiria Tsukamoto[1]

[1]Centro Universitário Filadélfia, Londrina PR, Brazil.

Correspondence: Samuel Lidione da Silva; Email: lidione67@gmail.com.

Background: A stroke commonly leads to permanent dysfunctions such as hemiplegia/hemiparesis. These functional alterations significantly compromise the quality of life (QoL), potentially causing social and emotional impairment for affected patients. With the lesion, the motor incapacity of synergistic trunk muscles interferes with the execution of activities of daily living (ADLs), weakening the patient's subjective well-being. Literature results have shown that interventions aimed at improving trunk movement functionality favor an improvement in QoL, but it is still unclear whether trunk control is directly correlated with QoL in post-stroke individuals. **Objective:** To analyze the correlation between trunk control and aspects of QoL in individuals with post-stroke hemiplegia. **Methods:** This is a cross-sectional study with a quantitative approach, with a convenience and intentional sample composed of 16 individuals. The evaluation of trunk control and QoL variables was performed using the following questionnaires: Trunk Impairment Scale (TIS) and Stroke Impact Scale (SIS). Pearson and Spearman correlation analyses were used, according to data normality, considering a significance level of 5%. This study was approved by the Research Ethics Committee (CAAE: 67926323.2.0000.5217). **Results:** Participants had a mean age of 57±12.7 years. The final scores of the questionnaires were: TIS total 16.5±2.9 and SIS total 64.2±8.9. Statistically significant correlations were found in the following variables: with a moderate effect between the total scores of SIS and TIS (p=0.018 and r=0.582), in the ADLs domain and physical problems (p=0.004; r=0.674), and total TIS with the ADLs domain (p=0.003; r=0.685). For the SIS total and the ADLs domain variables, there was a strong correlation (p=0.00001; r=0.867). **Conclusion:** The lack of motor control in trunk movement adversely impacts the quality of life (QoL) in post-stroke individuals, with

a statistically significant correlation observed between these factors in this study's sample. Understanding these results underscores the importance of early clinical focus on addressing trunk control issues to enhance the subjective well-being prognosis for these individuals. Further research with larger sample sizes and objective measures of trunk control outcomes is necessary to validate the data presented.

[2]Centro Universitário Presidente Tancredo de Almeida Neves, São João del Rei MG, Brazil.

Correspondence: José Victor Ribeiro Silva Gomes; Email: josevrsgomes@gmail.com.

Background: Parkinson's disease (PD) is the second most common neurodegenerative disease in the world, only behind Alzheimer's. The etiology of PD is unclear, and the major pathological feature found in the brain is the loss of dopaminergic neurons in the substantia nigra (SN), part of the midbrain. The causes of those deaths are related to oxidative stress, mitochondrial dysfunction and protein abnormalities. Besides the neuronal cells, recent findings show an important role of glial cells in the development of neurodegenerative diseases. Among them, astrocytes are the most abundant and act, primarily, through a process called reactive astrogliosis in reaction to an abnormal or pathological state. In this process, astrocytes can change the brain environment, releasing cytokines and inflammatory mediators which, in dysfunctional situations, can damage and even kill neurons and other glial cells. In this context, melatonin can be used to attenuate this process, once its role in reducing oxidative stress and diminishing neuronal deaths has been shown. In addition, recent findings suggest that melatonin may play a role in astrogliosis. **Objective:** Evaluate the effects of melatonin in the population of astrocytes in a mouse model of Parkinson's disease. **Methods:** 32 male Wistar mice were used in the research, divided in 4 groups: submitted to an induction surgery of PD through the application of a toxin (6-OHDA) in the striatum or a sham surgery (control) and intraperitoneal injections of melatonin (20 mg/kg) or saline (0.5 mL/100 g, control) 5 days a week during 5 weeks before the surgery. One week after the surgery, the animals were euthanized and samples of their brains were used to make microscope slides for immunohistochemical analysis. Statistical analysis was performed using ANOVA one-way, p< 0.05. **Results:** We analyzed the process of astrogliosis comparing the quantity of astrocytes in the samples of each group. The count was made in two areas of the slide at 40x magnification. Two proteins were targeted in immunohistochemistry: GFAP (Glial Fibrilar Acid Protein) and vimentin. We evaluated astrogliosis in two regions of the mouse brain: SN and striatum. Although the astrogliosis was higher in the intervention group in all the analyses made, there was no statistically significant difference among the groups. The analysis made by GFAP in SN showed less astrogliosis in the control group (p=0.035). A larger number of astrocytes were identified using GFAP rather than using vimentin. **Conclusion:** Astrogliosis is an important process in the healthy brain. However, changes in it can contribute to the development of neurodegenerative diseases. Melatonin, as an antioxidant agent, may prevent the emergence of such damage. However, in this research, we did not find enough evidence to support the idea of a protective role of melatonin in PD. Further studies are necessary to elucidate this issue fully.

Analysis of the epidemiological profile of epilepsy in the Southeastern region of Brazil over the last five years

Marcelo Pereira de Souza[1], Bianca Amado Cardozo[1]

[1]Universidade Nove de Julho, Osasco SP, Brazil.

Correspondence: Marcelo Pereira de Souza; Email: marsouzz@hotmail.com.

Background: Epilepsy is a functional condition of the brain that results in epileptic seizures caused by an imbalance between the concentrations of the neurotransmitters GABA and glutamate. In the last five years, this condition was responsible for 28.54% of all hospitalizations for diseases of the nervous system in Brazil. Based on this result, it is important for a neurologist to know how to recognize epileptic events and treat refractory ones. **Objective:** To analyze the Brazilian epidemiological profile in the Southeast Region in relation to the prevalence of epilepsy cases associated with epileptic seizures. **Methods:** This is an ecological, retrospective, quantitative and descriptive study, whose data was obtained from consultations carried out on the Sistema de Informações Hospitalares (SIH/SUS), through the DATASUS platform, for the period from January 2019 to December 2023. The Southeast Region and its respective states were analyzed. **Results:** In relation to the Southeast region, this condition is present at all ages, with a distribution of 5,921 cases in Espírito Santo, representing 28.7% of total hospitalizations for nervous system diseases in the region (20,622); 33,885 in Minas Gerais, totaling 29.4% of hospitalizations (115,186); 14,492 in Rio de Janeiro, making up 26.1% of the total (55,484 hospitalizations) and 60,350 in São Paulo, corresponding to 27.6% (219,001 hospitalizations). In terms of age group, the prevalence is highest between 1 and 9 years old, which represents a total of 21.1% of hospitalizations in the region (24,196). Furthermore, it is clear that there is a significant decrease from the age of 10 in all the states in the region. **Conclusion:** Based on the analysis of this study, we can see the significant number of neurological hospitalizations associated with epilepsy, especially in children aged between 1 and 9 years, in Brazil over the last five years, with the southeast region standing out.

https://doi.org/10.5327/CBN240139

Analysis of the epidemiological profile of hospitalizations for epilepsy in Brazil between 2019 and 2023

Thairon Guilherme de Santana[1], Victória Maria Rabelo Lopes[1], Rayane Eunice Brandão de Lima[1], Gabriella de Oliveira Barboza[1], Maria Eduarda Garcia Marvulle[1]

[1]Universidade de Marília, Marília SP, Brazil.

Correspondence: Thairon Guilherme de Santana; Email: thaironguilherme@hotmail.com.

Background: Epilepsy is characterized as a chronic neurological disease associated with episodes of seizures resulting from spontaneous and abnormal electrical discharges of neurons. In addition, psychiatric comorbidities, such as depression and attention deficit hyperactivity disorder, are often associated with this pathology, which can have a significant impact on the quality of life of these individuals. **Objective:** This study aims to analyze the epidemiological profile of hospitalizations for epilepsy in Brazil between 2019 and 2023. **Methods:** This is an observational, descriptive, cross-sectional and retrospective study. We used data from the Department of Informatics of the Unified Health System (DATASUS) on hospitalizations for epilepsy in Brazil between 2019 and 2023. The variables used to classify the epidemiological profiles were: gender, age group and color/race. Cases that did not fit these variables were excluded. **Results:** Between 2019 and 2023 there were 239,393 cases of hospitalization due to epilepsy in Brazil, of which 42.18% (100,980) were female and 57.82% (138,413) male. Among male hospitalizations, there were more cases among brown men under the age of 20 with 34,693 (25.06%) cases, followed by brown men aged between 20 and 59 with 28,728 (20.75%) hospitalizations, and the third most frequent epidemiological profile among males was white men aged between 20 and 59 with 19,865 (14.35%). Among female hospitalizations, there were more brown women under the age of 20 with 27,400 (27.13%) cases, the second most common profile was white women under the age of 20 with 17,320 (17.15%), followed by brown women aged between 20 and 59 with 16,214 (16.05%) hospitalizations. **Conclusion:** Based on the analysis of the data, it can be concluded that the three main epidemiological profiles with the most hospitalizations due to epilepsy are brown men under 20 years of age and between 20 and 59 years of age, and brown women under 20 years of age, showing that with advancing age hospitalizations for this reason are decreasing.

https://doi.org/10.5327/CBN240140

Analysis of the epidemiological profile of migraine cases in Brazil between 2018 and 2023

Gabriella de Oliveira Barboza[1], Maria Eduarda Garcia Marvulle[1], Victória Maria Rabelo Lopes[1], Thairon Guilherme de Santana[1]

[1]Universidade de Marília, Marília SP, Brazil.

Correspondence: Gabriella de Oliveira Barboza; Email: gabriellaobz@gmail.com.

Background: Migraine is a type of primary headache, characterized by intense and pulsating pain, which may also be accompanied by photophobia, nausea, vomiting and other symptoms. The main triggers of this headache are stress, exposure to screens, sudden changes in temperature, poor quality of food and sleep, as well as anxiety and depression. Furthermore, it is a highly disabling and very prevalent condition worldwide, especially among women in the job market, and is an important cause of work absenteeism. Furthermore, because migraines are poorly understood and accepted in the workplace, many do not notify employers about this issue, resulting in the individual remaining unproductive in the workplace, a fact that generates important financial losses. **Objective:** This work aims to analyze the epidemiological profile of hospitalizations for migraine in Brazil, among individuals in the labor market, between the years 2018 and 2023. **Methods:** This is an epidemiological, retrospective, observational and descriptive study, using data from the Department of Informatics of the Unified Health System (DATASUS) from January 2018 to December 2023. The variables used were gender, age range from 20 to 69 years old, year of care and region. **Results:** The region with the highest prevalence of migraine cases was the northeast, followed by the southeast region, which together correspond to approximately 59.14% of the total. Furthermore, women experience more than double the rate of cases compared to men. Furthermore, there is also a higher frequency between the ages of 30 and 39 and a lower frequency between 60 and 69 years old. **Conclusion:** Based on the data presented, it is observed that, in fact, the prevalence of migraine is higher among women of reproductive age, a fact explained mainly by female neuroendocrine factors. Furthermore, the high frequency of cases in the northeast of Brazil may be related to the greater incidence of sunlight

in the region, the population's exposure to more intense temperatures and less access to specialized treatment health services. Finally, migraine is a health problem that generates both increased costs in the health sector and losses in the quality of life and work productivity of the Brazilian population, demonstrating the need for interventions mainly related to worker health.

Analysis of the incidence of hospitalizations and deaths due to cerebral palsy and other paralytic syndromes in Brazil from 2019 to 2023

Lucas Charuri de Andrade Castello Branco[1], Barbara Zorzi Sanfins[1], Francisca Isabelly Leite de Almeida[2], Moisés Cardoso Portilho[3], Fernando Gabriel Rodrigues Baia[4], Karolliny Amador Kzam[3], Vinícius Adriano Coelho Amaral[4], Bruno Kauê Rodrigues Vilhena[4], Paola Carolina Santos Foinkinos[4], Luan Nascimento Pereira de Amorim[4]

[1]Faculdade São Leopoldo Mandic, Campinas SP, Brazil.
[2]Centro Universitário Unifacisa, Campina Grande PB, Brazil.
[3]Centro Universitário Metropolitano da Amazônia, Belém PA, Brazil.
[4]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Lucas Charuri de Andrade Castello Branco; Email: julucascastellobranco@gmail.com.

Background: The Chronic Non-Progressive Encephalopathy, better known as cerebral palsy, is the most common disability in childhood and comprises a group of motor disorders due to permanent and non-progressive injuries to the fetal or childhood nervous system. In Brazil, a country with great heterogeneity and inequality in access to healthcare, the distribution of cerebral palsy is not homogeneous throughout the territory, which justifies carrying out epidemiological studies to analyze this disease in the country. **Objective:** Analyze the epidemiological profile according to hospitalizations and deaths from cerebral palsy and other paralytic syndromes in Brazil from 2019 to 2023. **Methods:** This is a quantitative, retrospective and cross-sectional study developed using data obtained from the Ministry of Healths Hospital Information System at DATASUS/TABNET, considering the variables: region, age group, gender and character of care of hospitalizations and deaths from cerebral palsy and other paralytic diseases in the period from 2019 to 2023. **Results:** A total of 39,118 hospitalizations for cerebral palsy and other paralytic syndromes were observed during the period, with the Southeast region having the highest percentage (45.24%), specifically the state of São Paulo (7,718), followed by the Northeast (24.2%) and Midwest (21.33%) regions, with a predominance of male patients aged between 20-29 years, with elective care, a profile similar to that of the other regions. Of all the deaths, there were 704 from the disease in the period, with the Southeast region accounting for 59.51% of cases, with a profile of male patients, but in the 50-59 age group, although in all states the most affected age group is the 60-69 age group, due to senility, predisposition to atherosclerotic events and hormonal factors. With regard to the mortality rate, the state of Mato Grosso do Sul has the highest rate for cerebral palsy and other paralytic syndromes (8.43), although the southern region leads the way (3.32). **Conclusion:** The study reveals that the majority of hospitalizations for cerebral palsy and other paralytic syndromes occurred in the Southeast, particularly in the state of São Paulo (7,718). Predominantly, the patients were young men (20-29 years old) and the care was elective, i.e. non-emergency, indicating that the hospitalizations were planned or programmed, which suggests a significant need for continuous and specialized care for this age group and demographic profile. As far as deaths are concerned, the Southeast again leads the prevalence (59.51%), although there is no relationship with the number of hospitalizations, since the age group of deaths is 50-59 years. These findings highlight the need for public health strategies focused on prevention, early diagnosis and appropriate management of the complications associated with these conditions, especially in the regions and age groups most affected.

Analysis of the incidence of Parkinson's disease inpatients and deaths in brazil during the years 2019 to 2023

Paola Carolina Santos Foinkinos[1], Karolliny Amador Kzam[2] , Matheus Prado dos Santos[1], Fernando Gabriel Rodrigues Baia[1], Vinicius Adriano Coelho Amaral[1], Bruno Kauê Rodrigues Vilhena[1], Luan Nascimento Pereira de Amorim[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.
[2]Centro Universitário Metropolitano da Amazônia, Belém PA, Brazil.

Correspondence: Paola Carolina Santos Foinkinos; Email: paola.csfoinkinos@aluno.uepa.br.

Background: Parkinson's disease is a degenerative disease of the central nervous system, characterized by motor, cognitive and autonomic alterations, which starts insidiously and causes socio-functional impairments, especially in the elderly population. Research shows that there is currently an increase in the mortality rate of the disease and that it could become a public health problem, due to the trend towards an ageing population in Brazil. Studies into the dynamics, course and impact of Parkinson's disease in the country are needed. **Objective:** To analyze the epidemiological profile of hospitalization and death rates due to Parkinson's disease in Brazil between 2019 and 2023. **Methods:** This is a cross-sectional, retrospective and quantitative study, in which secondary data were collected from the Department of Informatics of the Unified Health System (DATASUS), from the years 2019 to 2023. The following variables were analyzed: authorizations for hospital admissions, mortality rate, number of cases and average length of stay in hospital institutions. **Results:** There were a total of 4401 hospitalizations for Parkinson's disease in Brazil, from 2019 to 2023, with 46.76% of hospitalizations in the Southeast region, with emphasis on the state of São Paulo (22.47%). The average length of stay was 13.4 days. The longest average length of stay (33.4 days) was recorded in the state of Rio de Janeiro. The mortality rate was 7.84%, being more significant in the North region (10.29%), with emphasis on the state of Roraima (33.33%). **Conclusion:** Analysis of the study showed that the Southeast region accounts for almost half of all hospitalizations for Parkinson's disease in Brazil and that hospital stays require considerable maintenance costs, given the average length of stay of 13 days, which can reach a month in certain states. In addition, it is clear that less developed regions face obstacles in the management of Parkinson's disease, since it has a considerably higher mortality rate than the national average. It is therefore necessary to develop local measures to mitigate regional disparities with regard to the appropriate treatment of Parkinson's, with the aim of reducing the length of hospitalization and the number of deaths.

Analysis of the morbidity and mortality of muscular dystrophies in Brazil: 2019 to 2023

Lucas Charuri de Andrade Castello Branco[1], Barbara Zorzi Sanfins[1], Francisca Isabelly Leite de Almeida[2], Moisés Cardoso Portilho[3], Luan Daher Fernandes[4], Luiza da Paz de Souza[4], Suzana Gomes de Oliveira[4], Arley Nikson Oliveira Barreto[4], Luiz Carlos Figueiredo Filho[4], Luan Nascimento Pereira de Amorim[4]

[1]Faculdade São Leopoldo Mandic, Campinas SP, Brazil.
[2]Centro Universitário Unifacisa, Campina Grande PB, Brazil.
[3]Centro Universitário Metropolitano da Amazônia, Belém PA, Brazil.
[4]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Lucas Charuri de Andrade Castello Branco; Email: julucascastellobranco@gmail.com.

Background: Muscular dystrophies are neuromuscular diseases characterized by structural alterations or functional deficiency of the muscles. They fall into the group of myopathies, which are degenerative and hereditary diseases of genetic cause, transmitted as autosomal dominant, recessive or X-linked traits. The main clinical manifestations are: weakness, progressive degeneration of skeletal muscles, muscle fatigue and tiredness, atrophy, myotonia and cardiac and respiratory impairment, with fatigue being the symptom that most generates functional incapacity in the patient. Despite the fact that there is no cure for this condition, treatments are available from the health system to improve the patients quality of life. In this sense, it is important to evaluate the variables related to the treatment of this pathology. **Objective:** To analyze the morbidity and mortality of muscular dystrophies in the last 5 years (2019-2023) in Brazil. **Methods:** This is a cross-sectional, retrospective and quantitative study, in which data was collected from the Department of Informatics of the Unified Health System (DATASUS), referring to the years 2019 to 2023. Secondary data was collected from the SUS Hospital Morbidity database (SIH/SUS). **Results:** In the period considered, a total of 2,903 hospitalizations authorized for the treatment of muscular dystrophies were found in Brazil, all of which were of medium complexity. Among the regions, the Northeast predominated (38.04%), followed by the Southeast (37.13%), which also had a substantial number of hospitalizations. Of the total number of hospitalizations, the majority (76.6%) are urgent, while the remainder (23.3%) are elective. Finally, of the 2,903 hospitalizations, there were 68 deaths, which corresponds to a total mortality rate of only 2.34% associated with the clinical condition described. **Conclusion:** Therefore, based on the data analyzed about hospitalizations authorized for the treatment of muscular dystrophy, it not only affects secondary care, but also primary care, given the counter-referral that occurs in PHC. In addition, these hospitalizations occur differently throughout Brazil, highlighting the country's continental characteristics. For example, the Northeast Region concentrates the cases of hospitalizations, and the classification of these hospitalizations differs between elective and emergency cases. There was a recovery rate of 97.66% of the people who were hospitalized, meaning that the treatment of this problem is being efficient and promoting the reduction of these cases, which denotes a total of more than 2,500 people who suffered from these hospitalizations. It is important to note that the medium-complexity infrastructure, as well as the working conditions of health professionals, interfere with the outcome of hospitalizations of patients with muscular dystrophy.

Analysis of the prevalence of diagnoses and age group impact of brain cancer in Brazil over the last 5 years

Bernardo Caetano Novaes[1], Guilherme Galardino Santos[1], Samuel José Feres Ozava[1], Victor Bruno dos Santos Teixeira[1], Heloisa Magda Resende[1]

[1]Centro Universitário de Volta Redonda, Volta Redonda RJ, Brazil.

Correspondence: Bernardo Caetano Novaes; Email: bernardo16.novaes@gmail.com.

Background: Brain tumors include various malignant neoplasms that can originate from different types of cells in the central nervous system. They can be primary, developing within the brain tissue itself, or secondary, resulting from metastases of other neoplasms. The global incidence of the primary tumors is low, with approximately 3 cases per 100,000 people. Although rare, the prevalence of these tumors has been increasing in recent decades. They are highly incapacitating and have a high morbidity and mortality, with a 5-year relative survival rate of only 37%. **Objective:** To calculate the prevalence of brain cancer diagnoses over the last 5 years in the federative regions of Brazil and to analyze which age group is most affected. **Methods:** The methodology of this study involved data collecting from the Oncology Panel of DATASUS (Department of Information and IT of the Unified Health System) from 2019 to 2023 and population data from the 2022 IBGE (Brazilian Institute of Geography and Statistics) census to calculate prevalence. The age group analysis was conducted based on data from the Oncology Panel of DATASUS, defining the age groups as: 0-19 years; 20-39 years; 40-59 years; 60-79 years; and over 80 years. **Results:** This data collecting resulted in 29,958 cases of brain cancer diagnosed in Brazil. The federative region with the highest prevalence (per 100,000 inhabitants) was the South (21.50), followed by the Southeast (13.07), Central-West (13.03), Northeast (8.85), and North (6.49) regions. Regarding the most affected age groups, in the North region over the last 5 years: 0-19 years (330); 20-39 years (304); 40-59 years (519); 60-79 years (310); over 80 (16). In the Northeast: 0-19 years (946); 20-39 years (1,131); 40-59 years (2,172); 60-79 years (1,425); over 80 (48). Southeast: 0-19 years (1,758); 20-39 years (1,813); 40-59 years (4,386); 60-79 years (4,359); over 80 (169). South: 0-19 years (787); 20-39 years (1,071); 40-59 years (2,802); 60-79 years (2,703); over 80 (119). Central-West: 0-19 years (423); 20-39 years (465); 40-59 years (1,042); 60-79 years (830); over 80 (30). Thus, it can be observed that in Brazil, the most affected age group is 40-59 years. **Conclusion:** Based on the data collected over the last five years, the highest prevalence was observed in the South region (21.50/100,000 inhabitants) and the lowest in the North region (6.49/100,000 inhabitants). The most affected age group was 40-59 years in all regions, with 4,386 cases in the Southeast, 2,802 in the South, 2,172 in the Northeast, 1,042 in the Central-West, and 519 in the North. These results indicate a higher prevalence of cases in middle-aged individuals (40-59 years) and significant regional variation, suggesting the need for analysis of factors contributing to the development of brain cancer. Prevention and early diagnosis strategies are necessary nationwide, aiming to ensure equitable access to quality healthcare across all regions.

https://doi.org/10.5327/CBN240145

Analysis of the prevalence of tuberculous meningitis in the state of São Paulo between 2012 and 2022

Gabriel Pereira Silva Rocha[1], Letícia César de Oliveira[2] , Sofia Pereira Figueiredo[3], Mirella Simini Santolim[4], Michely Laiany Vieira Moura[5]

[1]Universidade de Mogi das Cruzes, Mogi das Cruzes SP, Brazil.
[2]AFYA Faculdade de Ciências Médicas, Palmas TO, Brazil.
[3]Centro Universitário Mauricio de Nassau de Barreiras, Barrareias BA, Brazil.
[4]Universidade Nove de Julho, São Paulo SP, Brazil.
[5]Universidade Federal do Piauí, Teresina PI, Brazil.

Correspondence: Gabriel Pereira Silva Rocha; Email: irineu33rocha@gmail.com.

Background: Meningitis is a morbidity that can lead to serious consequences for the infected person. Among the various etiologies, tuberculous meningitis stands out. It occurs when the Mycobacterium tuberculosis bacillus spreads from its primary site of infection to the Central Nervous System which can cause severe neurological damage, with a mortality rate of approximately 50%. It is therefore highly relevant to learn about the prevalence of such a serious disease, which is caused by the complication of a public health issue in Brazil and worldwide, such as tuberculosis. **Objective:** To describe the prevalence of tuberculous meningitis cases in the state of São Paulo, Brazil, from 2012 to 2022. **Methods:** It is characterized as an ecological, cross-sectional, descriptive and retrospective study of an epidemiological nature, supported by the database of the Department of Informatics of the Unified Health System (DATASUS), with information provided by the Notifiable Diseases Information System (SINAN). An analysis was conducted of confirmed cases of meningitis caused by Mycobacterium tuberculosis in the state of São Paulo between 2012 and 2022. The variables were reported using descriptive statistics. The electronic search was carried out employing the term "Tuberculous Meningitis" and "Brazil". **Results:** Between 2012 and 2022, 546 cases of meningitis caused by Mycobacterium tuberculosis were reported in the state of São Paulo. The highest prevalence among the cities in the state was recorded in Pariquera-Açu, with a rate of 0.0253%, 5 confirmed cases and a population of 19,723 inhabitants in the time period evaluated. The second highest incidence was detected in Louveira, with a rate of 0.0020%, followed by Ribeirão Preto, which recorded a rate of 0.0087% between 2012 and 2022. The low prevalence rates in the analyzed cities are justifiable by the fact that tuberculous meningitis is the most severe complication of all forms of tuberculosis, as well as by the decline in its lethality since 1945 with the discovery of chemotherapy drugs specific for tuberculosis. However, it is necessary to carry out a prevalence analysis with the aim of promoting the monitoring of notified cases, especially in the state of São Paulo, which has a population of 44.04 million during the period of analysis of the study, and is thus classified as a large center susceptible to the spread of the disease. **Conclusion:** Tuberculous meningitis has presented a reduced prevalence rate in the cities of the state of São Paulo, although tuberculosis continues to be a public health problem in Brazil and to affect patients who, once they are carriers of the Mycobacterium tuberculosis bacillus, are susceptible to developing a severe form of tuberculous meningitis. It is necessary to constantly monitor the prevalence of this comorbidity in the state of São Paulo in order to keep reported cases of the disease under control.

Analysis of the profile and therapeutic response of Parkinson's disease patients undergoing deep brain stimulation

Rhaymysom Jasmy Gomes Abreu[1], Rafaella Resplande Xavier[1], Beatriz Fulador[1], Helen Luiza Silvestrini[1], Letícia Lage Silva[1], Hingrid Cristine Arruda de Oliveira[1], Albérico Rocha Lima Neto[1], Victor Hugo de Souza Silva Gomes[1], Heloise Helena Siqueira Borge[1]

[1]Hospital Geral, Cuiabá MT, Brazil.

Correspondence: Beatriz Fulador; Email: beatriz_fulador@hotmail.com.

Background: Parkinson's disease (PD) is a neurodegenerative disorder characterized by cardinal motor symptoms such as bradykinesia, resting tremor, rigidity, and postural instability. Its pathophysiology results from degeneration of the nigrostriatal system, leading to decreased dopamine production. Deep Brain Stimulation (DBS) offers an innovative approach to managing the debilitating symptoms of PD. DBS involves implanting electrodes in specific areas of the brain, which receive stimulation through electrical currents, modulating neurotransmitters involved in the disease's etiopathogenesis. Proper patient selection for DBS must follow precise indications. **Objective:** To evaluate the effectiveness of deep brain stimulation indications in a reference service based on the response of motor symptoms in assisted patients. **Methods:** This is a retrospective study with data from patients with Idiopathic PD who underwent DBS from 2022 to 2024. Data were obtained from medical records, including variables such as sex, age, Mini-Mental State Examination (MMSE), Geriatric Depression Scale (GDS), Unified Parkinson's Disease Rating Scale (UPDRS) score, and levodopa (Prolopa) dosage. **Results:** The sample consisted of 7 patients, with an M:F ratio of 1:1.3, and a mean age of 55 years (50-61). Regarding the disease duration and DBS implantation, 57% of patients underwent surgery between the 4th and 6th year of the disease, and the rest between 7 to 10 years. Through the analysis of the MMSE, a screening and follow-up tool for cognitive impairment, it was found that 4 patients (57.14%) had preserved cognitive function, i.e., MMSE score ≥ 27, 2 patients (28.57%) had mild cognitive impairment (21-24), and 1 (14.28%) was classified with moderate cognitive impairment (10-20). Regarding the Geriatric Depression Scale, only 2 showed mild depression, while the others had no psychiatric abnormalities. All individuals in the analysis showed a reduction in the UPDRS percentage when compared before and after DBS implantation, with a variation between 45.45% and 88.88%, and an average reduction of 68.1%. Regarding the use of Prolopa, a significant reduction in dosage was observed. Before DBS implantation, patients used an average of 528 mg/day of Prolopa. Post-DBS, an average reduction of 32.38% in dosage was observed. **Conclusion:** The application of scales prior to DBS implantation aims to guide the indication. These yielded positive results for individuals with PD. Consequently, it is concluded that to achieve the expected outcomes, it is essential to establish a routine of continuous patient evaluation for correct and precise indications, thereby obtaining better results for the patients.

Analysis of the profile of demyelinating and autoimmune diseases at the first specialized referral center in the state of Alagoas

Túlio Marlus Castro Lucena[1], Assis Porfirio Furtado Nogueira[1], Vitor Gustavo Leão Souto[2], Samyra Melo Vital[3], Patrícia Pereira Nunes Ribeiro[1], Maria Júlia Tabosa de Carvalho[2], Geovane Brito Affonso[2], Érika Santos Machado[1], Darlan de Araujo Benevides[1], Nayra Roberta Sales Salvador[1]

[1]Hospital Geral do Estado, Maceió AL, Brazil.
[2]Hospital Universitário Professor Alberto Antunes, Maceió AL, Brazil.
[3]Hospital Metropolitano de Alagoas, Maceió AL, Brazil.

Correspondence: Túlio Marlus Castro Lucena; Email: tuliomarlus.neuro@gmail.com.

Background: In Maceió, the first specialized service for demyelinating and autoimmune diseases in the state of Alagoas was implemented for the screening, accurate diagnosis, appropriate treatment, and follow-up of affected individuals. **Objective:** To evaluate the epidemiological profile of patients treated at the referral outpatient clinic for demyelinating and autoimmune diseases in the state of Alagoas. **Methods:** A review of the medical records of patients seen at the service from its inauguration in August 2022 until June 2024 was conducted. Patients under investigation without a confirmed diagnosis were excluded from the analysis. **Results:** Currently, 65 patients with confirmed diagnoses are being followed at the demyelinating and autoimmune diseases outpatient clinic. Of these, 33 patients have been diagnosed with Multiple Sclerosis, including 24 women and 9 men, representing more than 50% of the clinic's patients, which aligns with global epidemiology as it is the most common demyelinating disease. Additionally, the proportion of approximately 70% women among those affected also

corroborates the literature on the disease. Among other demyelinating and autoimmune diseases, 13 patients are followed for Neuromyelitis Optica, with 8 women and 5 men. Regarding inflammatory myelitis of different causes, 13 patients are being followed, including 8 women and 5 men. Four patients are being followed for inflammatory optic neuritis, with 2 women and 2 men. One male patient is being followed for autoimmune encephalitis, and one male patient is being followed for MOG antibody-associated disease. **Conclusion:** Demyelinating and autoimmune diseases have always represented a diagnostic challenge within neurology. Therefore, the presence of specialized centers for accurate diagnosis and appropriate follow-up of patients is of utmost importance, providing earlier diagnosis, better care, and improved quality of life for patients affected by these diseases.

Background: Multiple sclerosis (MS) is an immune-mediated inflammatory demyelinating disease of the central nervous system that mainly affects women aged between 28 and 31 years. The progression of neurological disability in MS is highly variable. Its impact on individuals varies according to the severity of signs and symptoms, relapse frequency, rate of worsening, and residual disability. **Objective:** To assess the profile of hospitalizations for MS in the SUS (Brazilian Unified Health System) in the year 2023. **Methods:** The study consists of a retrospective and descriptive analysis of epidemiological data of patients hospitalized for MS in the SUS in 2023. The database used was the TABNET - DATASUS platform. The eligibility criteria included patients who were in SUS healthcare services, in the hospital admission modality, with ICD-10 (International Classification of Diseases) specified as MS. Regarding data representation, they were tabulated in Microsoft Excel, and inferential statistics were performed using BioEstat Software (Version 5.3). Due to the qualitative nature of the correlated data (gender, age group, type of hospitalization, and race), the Chi-Square test, with a significance level of 5%, was used. **Results:** During the year 2023, there were 1,369 hospitalizations for MS in the SUS. Of these, 938 (68.5%) were female. Regarding the type of hospitalization (TH), 688 (50.3%) patients were treated as emergencies. In terms of color/race, 700 (51.1%) were white, while 601 (43.9%) were brown. The most prevalent age group (AG) for hospitalizations was between 30 to 39 years (29.1%), with the majority (54.1%) of these hospitalizations being elective. On the other hand, in the AG between 10 to 19 years, emergency treatments (56.6%) prevailed. Concerning in-hospital mortality, the AG between 60 to 69 years old was the most prevalent (36.3%). Regarding statistical inference, significant correlations were found between being brown and emergency hospitalization ($p < 0.0001$), being white and elective hospitalization ($p < 0.0001$), AG (over 60 years) and mortality ($p < 0.0001$), and AG (between 30 to 59 years) and emergency hospitalization ($p = 0.0199$). Meanwhile, there were no correlations between AG and emergency hospitalization in those under 30 years ($p = 0.604$) and over 60 years ($p = 0.3222$). **Conclusion:** After a detailed analysis of this study, it is observed that women between 30 to 39 years old were more prevalent, as described in the literature. Despite recent advances in therapeutic options, MS is still a disease that can cause severe conditions requiring emergency hospitalization, especially in younger individuals. In addition, the mortality rate from MS remains significant, particularly among the elderly. Therefore, this research aims to encourage future studies and provide direction both for early diagnosis and treatment of MS, to optimize the quality of care and improve the prognosis for these patients in the SUS.

https://doi.org/10.5327/CBN240149

Analysis of the profile of patients who died due to post-stroke infection in a reference hospital in Salvador-BA

Ana Beatriz Brazileiro de Sant'anna[1], Joanna Sousa da Fonseca Santana[1], Amanda Hellen Sousa Leal[1], Ana Clara de Lemos Guimarães[1], Maria Clara Bastos de Sá[1], Giovanna Souza da Conceição Brito da Silva[1], Fabiana Oliveira de Araujo[1], Felipe Oliveira Costa[1]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.

Correspondence: Ana Clara de Lemos Guimarães; Email: anaguimaraes21.1@bahiana.edu.br.

Background: Stroke affects approximately 16 million patients annually, leading to sequelae and complications. Bacterial infections are the most common consequences of this condition and can exacerbate patient recovery post-stroke. Therefore, identifying high-risk groups for infections can expand knowledge about the topic and promote specialized care for this group. **Objective:** To analyze the patients profile due to post-stroke infection among patients admitted to the emergency department **Methods:** This is a cohort study, observational and retrospective, as a preliminary result from a major stroke study with 6,993 patients. The partial results are based on secondary data collected from electronic medical records of patients admitted to a reference hospital in Salvador, Bahia. The study population comprises patients diagnosed with stroke, aged over 18 years, admitted between 2020 and 2022. The study was analyzed using Excel and SPSS and was approved by the Ethics and Research Committee (CEP). Variables: age, sex, diagnosis [Ischemic Stroke (IS), Hemorrhagic Stroke (HS), Subarachnoid Hemorrhage (SAH), and Central Venous Thrombosis (CVT)], death, length of hospital stay, site of infection and admission window. **Results:** 62 out of 330 patients contracted a post-stroke infection (18.7%). Of those infected, 24 died (35.8%). The average age of the group with infection was 65 years (ranging from 19 to 94 years) with a slightly higher number of cases in women (59.7%). The distribution of stroke types among patients with infection, in ascending order, were: IS (65.7%), HS (22.4%), and SAH (4.5%). However, the highest incidence of infection was in the SAH group (37.5%). The most common comorbidities in patients with infection were hypertension (62.6%), diabetes mellitus (35.8%), and previous stroke (22.3%). The infections most associated with these patients were lower respiratory tract infections (53.7%), upper respiratory tract infections (43.2%), and urinary tract infections (25.3%). The average length of hospital stay was 29 days, and the admission window (time between the onset of symptoms and arrival at the hospital) had an average of 71 hours. **Conclusion:** The profile of patients is balanced between the sexes, with an average age of 65 years. It was more pronounced in cases of IS but prevalent in SAH. The most frequent infection sites (respiratory infection and urinary tract infections) align with what the literature reviews already identify as expected. The wide variation in the admission window and a longer length of hospital stay compared to the average of the sample and represented about 1/5 of the deaths in this study. Thus, there is a need for intensive clinical surveillance, preventive strategies for patients with comorbidities in order to improve clinical practices in these cases.

Analysis of the strategies involved in the management of epilepsy in the hospital emergency environment

Rafael Alvarenga de Oliveira Pereira[1], Pedro Battaglia Bonetti[1], Rafael Gonçalves Brandi[1], Vinicius Moreira Martins Couto[1], Gabriel Lucas da Costa Oliveira[1], Bruno Vasconcelos Stefanini[1], João Pedro Costa Romão[1], Vitor Fernando Bordin Miola[2], Luís Henrique dos Santos Sousa[3], Nicolas Minavia Delgadillo[1]

[1]Universidade Metropolitana de Santos, Santos SP, Brazil.
[2]Universidade de Marília, Marília SP, Brazil.
[3]Universidade de Pernambuco, Serra Talhada PE, Brazil.

Correspondence: Rafael Alvarenga de Oliveira Pereira; Email: rafael.oliva192@gmail.com.

Background: Epilepsy is a chronic neurological disorder characterized by recurrent seizures, which are episodes of abnormal electrical activity in the brain. This activity can lead to a variety of symptoms, ranging from brief lapses in consciousness or involuntary movements to generalized seizures involving loss of consciousness and violent muscle contractions. The causes of epilepsy can vary, including brain injuries, congenital anomalies, genetic disorders, and underlying medical conditions. Treatment typically involves the use of antiepileptic medications to control seizures, although in some cases, surgery or other therapies may be recommended. This disorder is recurrent in emergencies, making it important to understand the management of epilepsy in this scenario. **Objective:** To carry out a systematic review of the literature on epilepsy and its management in emergency settings, with the purpose of analyzing the strategies involved in treating this condition in emergency hospital settings. **Methods:** Thus, managing epilepsy in an emergency requires swift and effective actions to control seizures and ensure patient safety. Key points include safeguarding the patient from injury during the seizure, ensuring an unobstructed airway, and administering antiepileptic medication, such as benzodiazepines, intravenously or intramuscularly, to halt seizures. Additionally, it is essential to assess and treat any underlying medical conditions that may be triggering seizures. Continuous monitoring of vital signs and maintaining a calm and safe environment are crucial during epilepsy management in the emergency setting. Following seizure control, investigating underlying causes and adjusting antiepileptic treatment are necessary to prevent recurrences. **Conclusion:** Hence, appropriate management of epilepsy in emergency situations is crucial to prevent severe complications, such as brain injuries, respiratory difficulties, and other medical emergencies associated with seizures. Moreover, effective management can help reduce the stigma surrounding epilepsy and enhance the long-term quality of life for the patient by ensuring adequate seizure control and minimizing negative impacts on physical and emotional health.

To evaluate the correlation between the use of BZD and the presence of cognitive changes among university employees in Southern Santa Catarina, data were collected from a sample of 122 individuals. Information was gathered through the application of the Montreal Cognitive Assessment (MoCA), a screening tool for detecting Mild Cognitive Impairment (MCI). Variables such as age, sex, race, education, marital status, BZD use, medication dosage, duration of use, and reason for prescription were also collected. The study found no statistically significant relationship between BZD consumption and cognitive decline (p=0.077). However, the executive function domain of the MoCA test showed a statistically significant difference between BZD users and non-users (p=0.010). A high prevalence of medication use was reported, at 21.3%. The general profile of users included women, Caucasians, in stable relationships or married, primarily prescribed for anxiety, with a prevalent duration of use ranging from 0 to 12 months.

Anatomopathological features of MRI negative epilepsies in a cohort from Southern Brazil

Fernanda Schuh Martins[1], William Alves Martins[1], André Luis Fernandes Palmini[1], Ricardo Paganin[1], Eliseu Paglioli[1], Rafael Paglioli[1], Thomas Frigeri[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Hospital São Lucas, Porto Alegre RS, Brazil.

Correspondence: Fernanda Schuh Martins; Email: fschuhmartins@gmail.com.

Background: Pharmacoresistant MRI-negative focal epilepsies present significant challenges for neurologists. While surgical intervention can potentially render patients' seizure-free, outcomes often vary significantly. The underlying pathology, aside from the localization of the epileptogenic zone, is a crucial factor influencing these outcomes. Certain etiologies are known to correlate with lower rates of post-surgery seizure freedom. **Objective:** This study evaluated the anatomopathological findings in a cohort of MRI-negative patients who underwent epilepsy surgery at the Porto Alegre Epilepsy Surgery Program (PAESP) from 2012 to 2019. **Methods:** The study included all MRI-negative patients who underwent surgery and had anatomopathological exams reviewed. Reports were available for 57 patients. Results showed Focal Cortical Dysplasia (FCD) I was the most common etiology, found in 18 (31.6%) patients. Mild Malformation of Cortical Development type II (MOGHE) was seen in 14 (21.1%), normal pathology in 10 (17.5%), FCD IIA in 9 (15.8%), mMCD I in 4 (6.5%), FCD IIB in 2 (3.2%), and FCD IIIA in 2 (3.5%). Rates of seizure-freedom were: 38.9% for FCD I, 22% for FCD IIA, 100% for FCD IIB, 33.3% for MOGHE, 20% for normal pathology, 25% for mMCD I, and 50% for FCD IIIA, with significant differences between etiologies (p=0.464). Median follow-up was 44 months (12-146). **Results:** In this cohort of MRI-negative patients, the pathology was consistent with previous studies, with FCD type I being the most common pathological substrate. Our 12-month seizure-free rate was 47.4%, with late recurrence in 30% of initially seizure-free patients. This could be due to more widespread underlying diseases, such as FCD type I, which is prevalent in nonlesional epilepsies. In a large cohort of MRI-negative patients, Wang et al. found FCD I in 40% of cases, corroborating our findings. Additionally, mild malformations of cortical development (mMCD) were a common finding in 27.6% of nonlesional cases. mMCD, as described in Palminis classification, includes heterotopic neurons in subcortical white matter (mMCD 1) or oligodendrocyte hyperplasia with blurring of the gray matter-white matter junction (mMCD II or MOGHE). Our study corroborates that mMCD II may be more common in nonlesional epilepsies than previously shown. **Conclusion:** In this southern Brazil cohort, FCD type I and MOGHE were the most common pathological substrates. These conditions may present a less distinct transition to normal cortex compared to other etiologies (e.g., FCD IIB), potentially leading to incomplete surgical resection of the epileptogenic zone and explaining late surgical recurrences in these patients.

Clinically intractable epileptic encephalopathies caused by hemispheric pathology can currently be treated by two surgical techniques, peri insular lateral hemispherotomy and vertical parasagittal hemispherotomy. Peri Insular hemispherotomy involves steps such as supra-insular and infra-insular windows and resection of the insula. The vertical parasagittal approach disconnects through a posterior frontal cortical window or the corpus callosum, continuing through the internal capsule and resecting the mesial temporal region. The vertical approach has advantages, such as complete disconnection at the level of the thalamus and lower risk of injury to the contralateral hemisphere. May result in seizure relief in patients with unilateral foci, although incomplete disconnections may occur, especially in extensive cortical malformations. Precise anatomical knowledge is crucial to the success of the procedure. It is essential to develop a universally acceptable hemispherotomy technique with consistent anatomical standards. In this sense, we carried out an anatomical study with photographic documentation of three adult cadaver heads in the Microneuroanatomy Laboratory of a University. Step-by-step disconnection of the hemisphere involves the steps: (1) Patient Position, Skin Incision, Craniotomy; (2) Resection (superior frontal rotation); step (3) Posterior callosotomy of the body; (4) approach to the Inferior Horn of the Lateral Ventricle; (5) disconnection of Projected Fibers from the anterior part of the Frontal Lobe; stage (6) the final disconnection of the Limbic System. It is essential to know the sequence of steps, know the anatomical landmarks and observe them all from different angles of vision, such as the steps (1): corpus callosum, foramen of monro, choroid plexus, collateral triangle, bulb callosum, falcotentorial junction and internal veins; stage (2): stria terminalis, fornix, choroid plexus, choroidal fissure and inferior choroidal point; stage (3): corpus callosum, septum pellucidum; stage (4): anterior cerebral artery (ACA), carotid bifurcation, olfactory triangle; stage (5): middle cerebral artery (MCA), corpus striatum, optic tract, posterior cerebral artery (PCA), and inferior choroidal point. The most challenging part is the final disconnection of the limbic system, requiring identification of the arteries through the arachnoid membrane, mainly the ACA, MCA and PCA, to avoid postoperative ischemic complications in the brainstem or thalamus. Vertical hemispherotomy surgery is established for intractable epilepsy secondary to diffuse, usually unilateral, hemispheric disease resistant to medical therapy. A solid anatomical understanding is a challenge even for neurosurgeons. Thus, a step-by-step understanding of the surgical procedure using cadaveric brains can serve as an intraoperative guide in disconnecting an entire cerebral hemisphere, beneficial for beginners in epilepsy surgery.

Angioedema induced by thrombolytic therapy in stroke: a case series from Brazilian Northeast

Raphael Pinheiro Camurugy da Hora[1], Manuela Magalhães Dardenne Tenório[1], Ana Dolores Fimino Santos so Nascimento[1]

[1]Hospital da Restauração, Secretaria de Saúde de Pernambuco, Recife PE, Brazil.

Correspondence: Raphael Pinheiro Camurugy da Hora; Email: raphaeldahora@hotmail.com.

Background: The advent of intravenous thrombolysis with rtPA has drastically changed the landscape of cerebrovascular diseases. However, this therapy is not without potential complications, one of which is orolingual angioedema, a local inflammatory reaction that can be life-threatening. **Objective:** To report and analyze cases of orolingual angioedema occurring during rtPA thrombolysis in patients with ischemic stroke, highlighting the clinical presentation, management, and outcomes. **Methods:** Four cases of orolingual angioedema were identified during a one-year period among patients receiving rtPA thrombolysis for ischemic stroke at a tertiary hospital in Northeast Brazil. Clinical data, including patient demographics, comorbidities, time to onset of symptoms, treatment administered, and outcomes, were collected and reviewed. **Results:** Case 1: A 66-year-old hypertensive and diabetic male presented with sudden hemiparesis and dysarthria. Edema of the lips and left hemi-tongue was noted 55 minutes into the infusion. The infusion was stopped, and hydrocortisone and adrenaline were administered. Orotracheal intubation was performed due to worsening edema. Case 2: A 65-year-old hypertensive and diabetic male developed right hemiparesis and dysarthria. Facial angioedema, particularly of the left lower lip, was observed 53 minutes into the infusion. The infusion was stopped, and hydrocortisone and diphenhydramine were administered, leading to improvement of the edema. Case 3: A 63-year-old obese and hypertensive female developed anterior and right tongue edema at the end of the alteplase infusion. Hydrocortisone, promethazine, and adrenaline were administered, resolving the condition after 24 hours. Case 4: A 58-year-old male with no comorbidities developed tongue edema and respiratory discomfort 58 minutes into the thrombolytic infusion. The infusion was stopped, and dexamethasone and supplemental oxygen were administered. **Conclusion:** Our study found a prevalence of angioedema similar to that reported in the literature (1.2% of thrombolysed cases over one year). There was a predominance of initial patterns involving half of the lips or tongue, and ACE inhibitor use in half of the cases. Notably, all events occurred near the end of the infusion. We recommend periodic oroscopy during the infusion to enable early detection of this adverse effect, thereby ensuring better care for patients.

The objective of this study was to differentiate the two most accepted approaches to surgically treat temporal lobe epilepsy, the Anterior Temporal Lobectomy (TPAH) and Selective Amygdalohippocampectomy (TSAH), from the perspective of functional connectivity of different areas of the brain with the healthy temporal lobe pre and postoperatively. The main hypothesis was that, from the

point of view of postoperative functional connectivity, Selective Amygdalohippocampectomy would behave like Anterior Temporal Lobectomy, which presumably has better seizure control. This is a retrospective study of 101 refractory mesial Temporal Lobe Epilepsy patients treated surgically at the Epilepsy Service of a University, 57 submitted to temporo-polar amygdalohippocampectomy (TPAH) and 44 submitted to transsylvian selective amygdalohippocampectomy (TSAH). We sought to investigate the consequences to global and contralateral temporal pole connectivity of each approach and compare both groups. In the analysis of patients undergoing TPAH, it was found that the preoperative healthy (right) temporal lobe was more connected to the regions of the left medial temporal gyrus, orbital part of the left inferior frontal gyrus, left superior frontal gyrus (medial segment), left frontal pole, left and right anterior cingulate gyrus, brainstem and right subcallosal area, when compared to the postoperative healthy temporal lobe. When the TSAH group was compared to the TPAH, no increase in connectivity was detected. When doing the inverse comparison, TPAH vs TSAH, the connectivity was only increased in the lingual gyrus. This study's findings showed an almost insignificant difference in how the neuroconnectivity of the brain was altered after surgery between the two distinct approaches. Thus, no benefit was shown for choosing one over the order, from a functional connectivity perspective. When comparing the selective access group to the post operative TPAH, the healthy temporal poles (right) in patients submitted to selective access surgery did not present any increase in connectivity when compared to the healthy temporal poles (right) of patients submitted to TPAH. This study's findings showed an almost insignificant difference in how the neuroconnectivity of the brain was altered after surgery between the two distinct approaches. Thus, no benefit was shown for choosing one over the order, from a functional connectivity perspective.

Correspondence: Pedro Cougo Samueli; Email: drpedrocougosamueli@gmail.com.

Case presentation: ISW, male, 75 years old, presenting complaints of 3 weeks onset of progressive cognitive decline. He showed a pattern of a multidomain impairment characterized by anterograde amnesia, visual spatial impairment, semantic paraphasia, visual and auditory hallucinations, irritability and compulsive smoking. No episodes of seizures or transient loss of consciousness reported. The patient had a previous history of postural tremor, long-term alcohol and tobacco consumption and colon cancer resection 30 years ago. On physical examination, He showed moderate disorientation regarding space and time and no language impairment, no signs of nystagmus or ophtalmoparesis. He had bilateral postural tremor, paratonic rigidity of the right upper limb and mild tandem gait ataxia, but no dysmetria or dysdiadokokinesia. He also had palpable right axillary lymph nodes. MRI showed only diffuse unspecific T2/FLAIR hyperintensities and no signs of cerebellar atrophy. 2h EEG recording was normal. CSF showed mild pleocytosis (6,5 WBC) 64% lymphomonocytic, normal glucose and negative oligoclonal bands. Also, tests for viral infection (CSF PCR panel for HHV-1, HHV-2, VZV and Enterovirus) resulted negative. B1 levels were normal (85 mcg/dL), as well as B12 and homocysteine (321 and 12mcg/dL, respectively). ANA titers were 1:320 nuclear fine speckled pattern, but no other autoimmune, rheumatological or infectious serology was positive. Chest, abdomen and pelvis CT resulted negative for malignancy screening, except for the right axillary nodes enlargement. CSF encephalitis antibody panel resulted positive for anti-AMPAR encephalitis. The patient evolved with bronchoaspiration, refractory respiratory arrest and death before biopsy and other diagnostic tests and therapeutics could be performed. **Discussion:** Anti-AMPAR encephalitis is an autoimmune encephalitis that was first described in 2009. Patients typically present features compatible with limbic encephalitis (altered mental status, cognitive impairment, psychiatric symptoms) with or without seizures. There is a moderate risk of association to neoplasm (breast, thymoma and small cell lung cancer). Although there is a description of one patient with anti-AMPA encephalitis who presented parkinsonism responsive to immunotherapy, other movement disorders, such as ataxia, are not characteristic of the disease. Although this case describes a patient with characteristics of limbic encephalitis, mild CSF monomorphic pleocytosis with a diagnosis of anti-AMPA-R encephalitis, the unfortunate outcome prevented a full assessment of paraneoplastic causes as well as the gait ataxia itself. **Final comments:** This case highlights the need for high diagnosis suspicion for autoimmune encephalitis in patients presenting rapid onset progressive cognitive symptoms, altered mental status, behavioral changes, seizures, or movement disorders, associated with CSF abnormalities, after the exclusion of other possible causes.

Background: Several psychotropic drugs play an importante role on dementia treatment, and polypharmacy is frequently observed among this population, as well as drug inadequate use **Objective:** To estimate anticholinesterasic drugs and memantine use in this population; to compare data about drug use obtained through medical history with those collected by plasma measure of antidepressants, antipsychotics, and hypnothics. **Methods:** This present sample is part of a study regarding plasma biomarkers through mass spectroscopy method and its relationship with oxidative stress markers. In this very sample, several drugs and its metabolites were studied and data was compared with clinical history. **Results:** A hundred and seven individuals were recruited to this study, all of them with some sort of cognitive impairment (CDR 0.5= 5.61%; CDR 1.0= 47.66%, CDR 2.0= 40.19%, CDR 3,0= 6,54%). About 46.73% of the sample did not use anticholinesterasic drugs; between the users, 9.35% used galantamine, 16.82% rivastigmine and 27.10% donepezil. Memantine use was observed in 12.15% of the sample. Antidepressant use was encountered in 44,86%, being the most common escitalopram (16.82%), duloxetine (5.61%), fluoxetine and bupropion (4.67% each). When compared to mass spectroscopy, only 36.45% did use antidepressants, being escitalopram found in 11.21%, fluoxetine in 7.48%, buproprione in 2.8% and duloxetine in none of the participants. 23.37% of the sample used antipsychotics, being quetiapine the most representative (18.69%); nevertheless, by mass spectroscopy method, only 4.67% showed detectable seric levels. Hypnothic use (benzodiazepines and zolpidem) were found in 1.87% of the sample. Inconsistencies between what was related by the participants and their caregivers, and mass spectroscopy were found in 36.45% of the sample. **Conclusion:** In this sample, inconsistencies were found between clinical history and mass spectroscopy on psychotropic drugs use. In this kind of patient, to which polypharmacy is of common occurrence, attention to correct drug use is imperative, in order to avoid adverse events related to drug use and thus morbidity increase, to assure correct adherence, and to be aware of non-prescribed drug use.

Background: This meta-analysis examines four therapeutic approaches following a stroke in patients already on DOACs: continuing with the same DOAC, changing to a different DOAC, increasing the current DOAC dosage, or switching to a vitamin K antagonist (VKA), such as warfarin. **Methods:** Systematic review of literature from the Medline, Embase, and Cochrane databases, conducted in line with PRISMA guidelines. The analysis focused on six studies with varied patient demographics, examining as outcomes as recurrent ischemic stroke, intracranial hemorrhage, other bleeding events, and mortality. **Results:** Four studies compared the same regimen of DOAC and the change to warfarin. The group that maintained the same DOAC regimen had a significantly decreased risk of ischemic stroke (RR, 0.55; 95% CI 0.43, 0.70; p< 0.001; I2= 0%), intracranial hemorrhage (RR, 0.37; 95% CI 0.25, 0.55; p< 0.001; I2= 0%), and hemorrhagic events (RR, 0.44; 95% CI 0.30, 0.63; p< 0.001; I2= 6%). Warfarin increased the risk of mortality (HR, 1.85; 95% CI 1.06, 3.24; p= 0.03; I2= 84%) compared to the same DOAC. Changing the DOAC was not superior to maintaining the same DOAC regarding ischemic stroke (RR, 0.97; 0.66,1.42; p= 0.88; I2= 74%), intracranial hemorrhage (RR, 1.10; 95% CI 0.76, 1.60; p= 0.62; I2= 0%), hemorrhagic events (RR, 1.03; 95% CI 0.78, 1.37; p= 0.82; I2= 0%), or mortality (HR, 0.98, 95% CI 0.85, 1.13; p= 0.78; I2= 0%). Switching DOAC dose was not superior compared to maintaining DOAC dose regarding ischemic stroke (RR, 0.88; 95% CI 0.66, 1.18; p= 0.39; I2= 0%), intracranial hemorrhage (RR, 1.04; 95% CI 0.64, 1.67; p= 0.88; I2= 0%), and hemorrhagic events (RR, 1.10; 95% CI 0.69, 1.74; p= 0.69; I2= 0%). DOAC change

was superior to warfarin concerning ischemic stroke (RR, 0.57; 95% CI 0.34, 0.95; p= 0.03; I2= 67%), intracranial hemorrhage (RR, 0.33; 95% CI 0.21, 0.52; p< 0.001; I2= 0), and hemorrhagic events (RR, 0.46; 95% CI 0.27, 0.81; p< 0.01; I2= 40%). Three studies compared the switch of DOAC dose and the switch to warfarin. Ischemic stroke (RR, 0.58; 95% CI 0.41, 0.83; p< 0.01; I2= 0%) and intracranial hemorrhage (RR, 0.36; 95% CI 0.21, 0.61; p< 0.001; I2= 0%) were significantly decreased in DOAC dose change group compared to the warfarin group. Regarding hemorrhagic events, DOAC dose change was also superior (RR, 0.37; 95% CI 0.22, 0.62; p< 0.001; I2= 0%) between these treatment groups. There was no difference between switching DOAC dose and changing DOAC agent regarding ischemic stroke (RR, 1.14; 95% CI 0.90, 1.44; p= 0.28; I2= 0%). Intracranial hemorrhage (RR, 1.05; 95% CI 0.63, 1.77; p= 0.84; I2= 0%) and hemorrhagic events (RR, 0.99; 95 % CI 0.60, 1.64; p= 0.98; I2= 0%) **Conclusion:** Post-stroke adjustments to anticoagulation therapy do not yield additional benefits. Additionally, the results suggest that warfarin may be less effective than DOACs for preventing stroke recurrence, bleeding complications, and death in this patient population.

https://doi.org/10.5327/CBN240159

Anticonvulsant potential of phenolic compounds in animal models of epilepsy: a systematic review

Rodrigo Esteves Lagares[1], Marcos Otávio Bueno[1], Mariana Siqueira Leite[1], Lucas Volpi Candido[1], Paola Ribas Gonçalves dos Santos[1], Igor Rodrigues de São Tiago[1], Alberto José Rodríguez Renfigo Valmorbida[1], Gustavo Colombo Dal-Pont[1]

[1]Universidade Alto Vale do Rio do Peixe, Caçador SC, Brazil.

Correspondence: Rodrigo Esteves Lagares; Email: rodrigolagares15@gmail.com.

Background: Epilepsy is a neurological condition of debilitating character marked by recurrent and spontaneous convulsions, affecting millions of people on a global scale. Despite the evolution of antiepileptic treatment, many patients continue to suffer from refractory seizures and the adverse effects of available drugs. Consequently, there is a continuous necessity to discover new treatment alternatives that may offer superior efficacy and less toxicity. In this context, phenolic compounds, widely found in plants, food and fruits, have stirred interest due to their antiepileptic properties. **Objective:** To investigate the pharmacological potential of the phenolic compounds in animal models of epilepsy. **Methods:** This is a systematic review carried out using PRISMA methodology. The database PubMed was used to search articles in the last 5 years (2020-2024), in English and Portuguese. As inclusion criteria, preclinical trials of rodents submitted to the induction protocol of convulsion/status epilepticus by pentylenetetrazol (PTZ) were defined. The articles were analyzed blindly by the authors, through the Rayyan® software. **Results:** Though the search strategy, 166 articles were found, and after careful filtration and analysis, 17 articles were included in this review. The experimental tests in mice demonstrated a significant reduction not only in the frequency of acute epileptic crisis, but also in the symptoms, after administration of the phenolic compounds. Research with resveratrol, ferulic acid, salvianolic acid B, quercetin, daidzin and genistein, among others, have highlighted their capacity to reduce convulsions induced by PTZ, attenuate cognitive and inflammatory deficits associated with epilepsy and protect against neuronal damage in animal models. These effects were attributed to the modulation of many signaling pathways, including AKT/CREB/BDNF, TLR4/NF- κB, JAK2/STAT3 and antioxidant pathways. Another relevant matter was the neuroprotective potential of some phenolic compounds, such as daidzin and quercetin, the latter also acting through the suppression of inflammatory cytokines like tumor necrosis factor alpha (TNF-α) and interleukin-1β (IL-1β), as well as the activity of the enzyme COX-2 (cyclooxygenase-2). **Conclusion:** Although promising, the results of these studies are mainly based on animal models, requiring more studies for better comprehension of these mechanisms. However, natural compounds present a significant therapeutic potential in epilepsy, offering an alternative and complementary approach to the conventional treatments.

Antiganglioside antibody screening accuracy and sensitivity in a tertiary neuromuscular outpatient clinic

Ana Flávia Andrade Lemos[1], Amanda Vitória Freire de Oliveira[1], Lucas Gondim Briand Vieira[1], Mariana Ribeiro Pereira[1], Mateus Gustavo Favaro[1], Rodrigo Siqueira Soares Frezatti[1], André Cleriston José dos Santos[1], Giuliana França Teixeira Mandia Grossi[1], Pedro José Tomaselli[1], Wilson Marques Junior[1]

[1]Universidade de São Paulo, Ribeirão Preto SP, Brazil.

Correspondence: Ana Flávia Andrade Lemos; Email: anaflaviaandradelemos@gmail.com.

Background: Gangliosides are glycosphingolipids highly abundant in the nervous system. They are composed of a ceramide lipid tail attached through glycosidic linkage to a glycan headgroup containing one or more sialic acid residues. They play important roles in the modulation of membrane proteins and ion channels, in cell signalling, and in communication among cells. Antibodies against ganglioside subtypes, such as GM1, GD1a, GT1a, and GQ1b gangliosides, have been associated with various neurological disorders. **Objective:** To analyse the association of anti-ganglioside antibodies (AGAs) and their subtypes with neuromuscular diseases in a tertiary neuromuscular outpatient clinic. **Methods:** Clinical and serological data were retrospectively gathered from patient records using a standardized proforma. We included patients evaluated from 2015 to 2024. Sera from 197 patients were tested using enzyme-linked immunosorbent assay (ELISA) for AGA. Patients were divided according to predefined clinical categories based on a review of the current literature on AGA. Final diagnoses were combined with the AGA results for statistical analysis. **Results:** From 197 patients included, 75 (38.26%) were female and 122 (61.92%) male. The average age at the onset of symptoms was 47.5 years for females and 45.4 years for males. Fifty-seven cases (28.93%) tested positive for one of the seven AGA subtypes (GQ1b, GT1b, GD1b, GD1a, GM3, GM2, GM1). A positivity rate of 20% for AGA GM1 and GM2 was observed in patients with multifocal motor neuropathy (MMN). Other correlations found were: 57% of patients diagnosed with Miller-Fisher Syndrome (MFS) tested positive for AGA, with 28% being GQ1b. Acute motor axonal neuropathy (AMAN) exhibited the highest positivity rate at 58%, with 23% for GM1. Chronic inflammatory demyelinating polyneuropathy (CIDP) showed a 29% positivity rate, with 57% being GQ1b. **Conclusion:** Antibodies against ganglioside complexes, or gangliosides and other glycolipid complexes, are emerging as useful markers of various clinical features and pathological subtypes; however, they lack specificity and accuracy.

Anti- IgLON5 disease presenting with bulbar dysfunction, ocular paralysis and facial myokymias

Carolina Heck Haubrich[1], Leticia Bassani Devens[1], Carollina Danezi Felin[1], Eduarda Rosa Fernandes[1], William Alves Martins[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Hospital São Lucas, Porto Alegre RS, Brazil.

Correspondence: Carolina Heck Haubrich; Email: carolhhaubrich@gmail.com.

Case presentation: A 65-year-old woman presented with acute severe dysphagia and stridor. The previous month, she had two aspiration pneumonias treated with antibiotics. Over the past year, she experienced unexplained falls and intermittent diplopia. Her medical history was unremarkable except for a thyroidectomy for stage I thyroid papillary carcinoma two years earlier. Neurological examination revealed supranuclear vertical palsy, slight bilateral facial weakness, facial myokymia, fasciculations, bilateral dysmetria, and an unsteady gait. She reported minor sleep problems, controlled with Zolpidem. Initially suspected of having myasthenia gravis, she showed subtle improvement with Pyridostigmine, but tests for MG were negative. She then developed acute respiratory distress, requiring mechanical ventilation. CSF revealed lymphocytic pleocytosis and increased protein. IVIG treatment stabilized her symptoms, but further tests for autoimmune and neoplastic causes were negative. A few months later, she experienced another episode of acute respiratory failure. Suspecting IgLON5, a Video-PSG demonstrated severe central and obstructive apneas, periodic complex movements, and undifferentiated NREM sleep. CSF tests (CBA) confirmed anti-IgLON5 antibodies. She was on a regimen of monthly IVIG and Rituximab, when she passed away 20 months after diagnosis. **Discussion:** Anti-IgLON5 is an auto-immune tauopathy recently identified as characterized by both REM and non-REM parasomnias, sleep apnea, and stridor. Its clinical features can resemble Parkinson's disease, MSA or Supranuclear Palsy, delaying the diagnosis. Initial presentations include sleep disorder, bulbar dysfunction, PSP-like syndrome, and cognitive impairment. Symptoms such as central hypoventilation and aspiration pneumonia due to dysphagia can be life-threatening. The presence of antibodies against extracellular IgLON5 epitopes is a hallmark of the disease. IgLON5 is a neuronal adhesion molecule whose function is not fully understood, yet it is widely expressed in the central nervous system. Neuropathology also reveals hyperphosphorylated tau protein accumulation in the hypothalamus, hippocampus and brainstem tegmentum, correlating with memory deficits, sleep disorders, and movement disorders. Associations with HLADRB1*10:01 and HLADQB1*05:01 alleles have been noted. Patients typically show a mild or no response to immunotherapy, likely due to irreversible IgLON5 antibodies. In a case series, half of the patients had a mean survival of 35 months post-diagnosis, with respiratory disturbances being the leading cause of death. **Final comments:** This case is notable due to the rarity of IgLON5 disease and its first reports in Latin America. The patient's acute respiratory failure and severe bulbar dysfunction prompted early gastrostomy and a broad differential diagnosis, initially considering myasthenia gravis. However, a sustained lack of improvement and unrevealing electroneuromyography led to the diagnosis of IgLON5.

Anti-MAG: an important differential diagnosis of CIDP

Adriana Alves Rapp[1], Filipe Nolasco de Souza e Silva[1], Marcel Leal Ribeiro[1], Rayanderson Nunes da Gama[1], João Gabriel Teixeira Mota[1], Julia Cordeiro Braga[1], Lucas Vergne Cheade Lins[1], Brenda Francisca Cardoso Brito[1], Victor Xavier da Silva[1], Diego Sant'ana Sodré[2]

[1]Hospital Santa Izabel, Salvador BA, Brazil.
[2]Universidade Federal da Bahia, Salvador BA, Brazil.

Correspondence: Adriana Alves Rapp; Email: adrianarapp15.2@bahiana.edu.br.

Case presentation: Patient, 77 years old, hypertensive with a history of prostate cancer, began experiencing weakness in the lower limbs in 2014 with progressive difficulty in walking, which worsened in 2016, requiring support for ambulation and the use of a cane since then. On physical examination, there was noticeable muscle weakness affecting the lower limbs with proximal strength graded as 4/5 and distal strength as 3/5, reduced vibratory sensation, and sensory ataxia. Osteotendinous reflexes were +/IV in the upper limbs and absent in the lower limbs. Other aspects of the neurological physical examination were unremarkable. During the investigation, in 2021, a electroneuromyography showed signs of demyelination such as reduced conduction velocity, temporal dispersion with conduction block, suggestive of chronic demyelinating sensory-motor polyradiculopathy. Concurrently, immunofixation of serum proteins revealed the presence of IgM. Due to the clinical presentation and complementary exams, AntiMAG antibody testing in 2022 was positive for IgM (titer 1/10). Initially, the patient was treated with prednisone but showed little response, also complaining of muscle pains during the treatment period. Currently, the patient is stable on Azathioprine, awaiting approval for Rituximab therapy with neurological stability. **Discussion:** AntiMAG neuropathy is predominantly a demyelinating disease characterized by a distally developed sensory or sensory-motor polyneuropathy in the context of IgM monoclonal gammopathy (sometimes of undetermined significance or secondary to lymphoplasmacytic lymphoma). The most common clinical manifestation involves weakness and altered sensation distally, primarily in the lower limbs, although some patients may experience gait instability and tremors. AntiMAG neuropathy is an important differential diagnosis of CIDP, particularly the distal variant (which accounts for 2/3 of patients with this phenotype), hence the mandatory need for adequate further investigation, including immunofixation of serum and urine proteins (often repeated if IgM is not initially detected). The confirmatory test is serological testing for AntiMAG antibodies. Traditionally, AntiMAG neuropathy does not respond to the usual treatments used for CIDP (such as corticosteroids or immunoglobulin), emphasizing the importance of correct differential diagnosis. The current optimal therapeutic option is sequential Rituximab infusion (anti-CD20 monoclonal antibody), with improvement seen in approximately 30-50% of cases. **Final comments:** Reinforcing that CIDP is a diagnosis of exclusion is essential for appropriately addressing possible differential diagnoses, among which is Anti-MAG neuropathy.

Correspondence: Elisa Gabriela Barros Cunha; Email: elisacunha4@gmail.com.

Case presentation: A 71-year-old woman with a history of hypertension,dyslipidemia, and hypothyroidism presented to our service with a 4-month history of dysphagia, dysphonia, muscle weakness, and spots on her face and hands. One month before the onset of symptoms, she had experienced a self-limited flu-like illness. She was taking losartan, hydrochlorothiazide, levothyroxine, and simvastatin. On general physical examination, hyperchromic lesions were observed on her lower eyelids and palms. Neurologically, she exhibited predominantly proximal muscle weakness in all four limbs (MRC 45), amyopathic gait, and required support from another person. Additional tests revealed CPK levels of 4705 U/L and ANA 1:5000 with a membrane-type nuclear pattern. Other rheumatological markers, including anti-SCL70, JO1, RO, LA, mitochondria, and RNP antibodies, were negative. Electroneuromyography indicated severe subacute myopathy with proximal predominance, fibrillations, and electrical myotonia. A muscle biopsy of the biceps brachii showed focal myositis with mild atrophy, and immunohistochemistry was positive for anti-CD68, CD3, CD4, CD8, and MHC-I antibodies, consistent with inflammatory myopathy. A serum antibody panel for myositis was positive for anti-MDA5 and anti-RO52. Neoplastic screening, including chest CT, upper digestive endoscopy, and thyroid ultrasound, showed no malignancy. Chest CT revealed thickening of the bronchial walls and posterior basal reticular opacities. During hospitalization, the patient received pulse therapy with methylprednisolone 1g for 5 days, and azathioprine was initiated. After discharge, based on the antibody panel results, monthly pulse therapy with gradual tapering was continued. At the last outpatient follow-up, 10 months post-discharge, the patient showed improvement in hyperchromic lesions and muscle strength (MRC 56), and was walking with a walker. The dose of azathioprine (2.1 mg/kg/day) was maintained, and methylprednisolone pulse therapy was gradually tapered. **Discussion:** Dermatomyositis (DM) has a global incidence of 5-10 per million per year and a prevalence of 6-7 per 100,000 per year. The most commonly associated antibodies are anti-Mi2, MDA5, NXP2, TIF1, and SAE. In DM associated with anti-MDA5, muscle involvement is generally less common than in other DM presentations, with skin rash, polyarthralgia, and interstitial lung disease being more frequent. This case is unusual in that the primary manifestation was muscle involvement. Anti-Ro52 is a non-specific antibody that can be present in various rheumatological diseases, occurring in 27-62% of anti-MDA5 DM cases and is associated with a worse prognosis due to increased lung involvement. **Final comments:** This case describes anti-MDA5 dermatomyositis with atypical severe muscle impairment. Early suspicion and therapeutic intervention in the context of inflammatory myopathy allowed for a relatively favorable outcome.

Correspondence: Caio César Alves Lins de Oliveira; Email: caiolins97@gmail.com.

Background: Dermatomyositis (DM) is an idiopathic inflammatory myopathy characterized by muscle weakness and typical skin lesions, with subgroups delimited by specific autoantibodies. Anti-MDA5 is associated to severe skin changes, including necrotic lesions, interstitial lung disease (ILD), normal CK and little or no weakness. In these cases, the muscle biopsy is usually normal or presents mild and nonspecific changes. **Methods**: We report a case of anti-MDA5+ DM (DM-MDA5) with atypical clinical and laboratory presentation, comparing it with a typical case. **Results:** Case 1: 40-year-old man came to medical attention due to skin lesions on his face 10 months ago. He then began to experience weakness in the lower limbs, progressing to the upper limbs, in addition to fever, dysphagia and dyspnea. On examination, he presented Gottron's papules, malar rash, shawl sign and proximal muscle strength grade 3 and distal grade 5. Laboratory tests revealed leukocytes of 2100/mm3, platelets 91,000/mm3, CK 77IU/L (< 171UI/L), aldolase: 8.7U/L (< 7.6U/L), ferritin 2855ng/mL (< 400ng/mL), ANA 1:80 (dotted cytoplasmic pattern). The following were negative: rheumatoid factor, anti-DNAds, anti-RNP, anti-Sm, anti-SSA/SSB, anti-Scl70, anti-centromere, anti-LKM1, anti-AMA, anti-TPO, anti-GAD, lupus anticoagulant and anti-cardiolipin (IgG/IgM). Serum immunofixationsuggested IgG/kappa monoclonal protein. Myelogram revealed granulocytic and megakaryocytic hyperplasia. Imaging evaluation showed splenomegaly and muscular edema with gadolinium enhancement in the right thigh and left arm. In neoplastic screening, thyroid infiltrative follicular papillary carcinoma was found. Electromyography showed a myopathic pattern with spontaneous activity. Muscle biopsy revealed necrotic and regenerating muscle fibers, perifascicular atrophy, perivascular inflammatory infiltrate, sarcolemmal C5b9 and sarcoplasmic immunoexpression for MXA. DM-specific autoantibody panel was positive for anti-MDA5. Case 2: 50-year-old man sought medical attention due to skin lesions. He presented Gottron's sign, palmar erythema, necrotic and scaly skin lesions on the back and shoulders and calcinosis cutis. On examination, he presented grade 4+ proximal weakness and dyspnea. Chest CT showed ILD. Muscle biopsy showed mild and nonspecific changes, without MHC-I immunoexpression. Myositis autoantibodies panel was positive por MDA5. **Conclusion:** we illustrate two extremes of the DM-MDA5 presentation spectrum: a hypomyopathic form and another with muscular involvement even with normal CK. Furthermore, case 1 presented characteristics of macrophage activation syndrome secondary to DM, and concomitant thyroid carcinoma. We highlight 1) wide phenotypic variability in DM-MDA5, 2) DM with severe weakness and normal CK and 3) DM-MDA5 with severe muscle involvement and associated with thyroid neoplasia.

Background: Several neuroimaging studies have demonstrated gray matter atrophy in the precentral gyri, basal ganglia and alterations of corticospinal tracts in focal and generalized epilepsies; however, little is known about the fine motor alterations in people with epilepsy (PWE). Besides, fewer studies have investigated the negative impact of adverse effects of drugs, symptoms of anxiety and depression on motor performance. **Objective:** Here, we aimed to analyze the impact of adverse effects of antiseizure medication on gross and fine motor dexterity in PWE and the relationship with associated factors such as depression and anxiety. **Methods:** We interviewed and tested 195 people with epilepsy (PWE, median of 35 years of age and 11 years of education) at a Tertiary Centre (before their outpatient appointment) and 252 healthy volunteers (HV, median of 35 years of age and 15 years of education) at the University Campus. All individuals performed the 9-hole peg test (9-HOLE), Box and Block Test (BBT), Tower of Hanoi (TH), the Block design subtest of the Wechsler Adults Intelligence Scale (BD-WAIS), Generalized Anxiety Disorder Questionnaire (GAD-7) and Neurological Disorders Depression Inventory for Epilepsy (NDDI-E). Patients also answered the Liverpool Adverse Events Profile (LAEP; 80% with adverse events and 20% without adverse events). PWE was separated into seizure-free (76 subjects), lower-frequency (13 subjects)

and pharmacoresistant (85 subjects). We used SPSS23 for statistical analyses with non-parametric tests for group comparisons (Mann-Whitney and Spearman correlation). We excluded subjects with intellectual or gross motor impairment. **Results:** Overall, the PWE performance was 15-22% worse than their age-paired controls ($p< 0.05$). Group with adverse events (AE_pos) was balanced to the group without adverse events (AE_neg) in terms of age ($p=0.8$) and education ($p=0.6$). However, the AE_pos presented higher proportion of patients with pharmacoresistant seizures ($p=0.03$), depression (NDDI, $p<0.001$) and anxiety (GAD-7, $p<0.001$). Interestingly, the two groups performed similarly for fine motor and complex tasks [9-HOLE (bimanual, $p>0.05$); tower of Hanoi ($p=0.5$) and BD-WAIS ($p=0.3$)]. On contrary, the AE_pos presented a poor bilateral performance on the gross motor test of Box and Block Test (average of 10% worse; $p<0.05$, bilaterally). We did not observe strong correlations between performance and intensity of anxiety or depression, regardless the higher scores. **Conclusion:** The impact of adverse events was mainly observed as higher intensity of anxiety and depression symptoms, and specifically on Box and Block Test. We speculate there is a 'floor effect" present in these groups of patients, associated with long duration of epilepsy, explaining similar performance on other tests. The treatment of anxiety and depression may improve motor performance. Future analyses with subtypes of epilepsies and the different medications are necessary.

Anti-seizure prophylaxis and electroencephalographic changes in bulsufan therapy: a case report

Luiza Gonçalves Fraga[1], Luís Guilherme Pacheco de Almeida[1], Mariane Panka[1], Patrícia Coral[1], Carlos Eduardo Soares Silvado[1], Marlon Wycliff Caeira[1], Luciano de Paola[1], Mayara de Rezende Machado[1]

[1]Universidade Federal do Paraná, Complexo Hospital de Clínicas, Curitiba PR, Brazil.

Correspondence: Luiza Gonçalves Fraga; Email: luizaag.fraga@gmail.com.

Case presentation: We present a case of a female patient aged 5 years old diagnosed at 16 months with Chediaki-Higashi syndrome (CHS), a rare primary immunodeficiency syndrome of autosomal recessive inheritance characterized by recurring infections and oculocutaneous albinism. During her disease course, she presented a first episode of bilateral tonic-clonic seizure (BTCS). Three years later, meanwhile a febrile illness, she presented a new seizure, and started on levetiracetam 30mg/kg/day. Due to disease's progression, she underwent bone marrow transplantation (BMT) receiving conditioning with bulsufan (BU) 19.6mg/kg, alongside fludarabine and antithymocyte globulin. Due to the neurotoxicity of BU and a history of epilepsy, levetiracetam dose was increased to 40 mg/kg/day. On the fourth day of infusion, the patient developed two episodes of seizures, and started phenytoin and phenobarbital as an add-on therapy to levetiracetam. Ancillary testing with a CT scan and electroencephalogram (EEG) showed only brain atrophy and diffuse and persistent slowing of background activity, predominantly in the delta range. Patient evolved with clinical improvement. **Discussion:** BU has been used since 1959 and is commonly used in the conditioning regime for BMT. It easily crosses the blood-brain barrier, reaching levels similar to those in blood or even higher. Neurotoxicity figures among its side effects, manifesting as seizures in around 7.5-10% of patients and due to this high incidence, antiseizure prophylaxis with phenytoin, phenobarbital, benzodiazepines or levetiracetam is reasonable. The first dose is given 12 hours before the first dose of BU and continues until 48 hours after the last dose. BTCS generally occurs during therapy, mainly between the third and fourth day, with myoclonus and muscle spasms also being reported. The ictal/interictal EEG may show generalized spike/polyspike-wave discharges, while follow up examinations show a persistent slowing of background with intermittent rhythmic delta activity, which may persist for 20-30 days. Even without an unequivocal seizure, encephalographic abnormalities can occur in up to 60% of patients. **Final comments:** Though seizures are rare in CHS patients, those on BU show a seizures' incidence of approximately 1.3%, being more common in patients with predisposing factors such as previous seizures/epilepsy or previous brain injury. Electroencephalographic changes can occur at any time during BU therapy and may persist for weeks, as the delta diffuse slowing presented by the patient in this case after treatment with 3 antiseizure medications. This report reinforces the importance of knowing potential side effects of drugs used in current medical practice and how antiseizure prophylaxis in selected cases can impact patients' prognosis.

Anti-SOX1 antibody-positive caused by small-cell lung cancer presenting with chorea: a case report

Victoria Lin[1], Victor Rebelo Procaci[2], João Henrique Fregadolli Ferreira[1], Livia Almeida Dutra[1]

[1]Instituto do Cérebro, Hospital Israelita Albert Einstein, São Paulo SP, Brazil.
[2]Hospital Israelita Albert Einstein, São Paulo SP, Brazil.

Correspondence: Victoria Lin; Email: vickylin1001@gmail.com.

Case presentation: A 60-year-old woman with liver metastasis and prior diagnosis of small-cell lung cancer, treated with radiotherapy, prophylactic cranial irradiation, and chemotherapy until 2022, was admitted in November 2023 to investigate involuntary movements she had experienced over the last year. In March 2023 she developed involuntary movements of the lips and, after three months, involuntary movements of the feet and legs as well. Neurological exam revealed chorea involving the face, legs, and feet. Hung-up knee jerk and motor impersistence were also present. Brain magnetic resonance imaging showed subtle brain volume reduction, subcortical white matter hyperintensities, and hemosiderin foci in the right thalamus. Upper abdominal magnetic resonance imaging revealed a hypovascular nodule in liver segment VII. Positron emission tomography-computed tomography indicated glycolytic hypermetabolism in a right peri-hilar lung mass and the hepatic nodule. She was treated with haloperidol 5 mg daily and intravenous immunoglobulin for five days, resulting in partial improvement. However, nine days later, she relapsed and the chorea progressively worsened. Cerebrospinal fluid and serum testing with a tissue-based assay and immunoblot revealed strong reactivity to anti-SOX1 antibodies. The haloperidol dosage was increased to 5 mg twice a day and oncology started durvalumab for the treatment of the small-cell lung cancer, which resulted in an almost complete resolution of the chorea. **Discussion:** Anti-SOX1 antibodies are partly characterized as onconeural due to their correlation with neoplastic diseases, particularly small-cell lung cancer. These antibodies are detected in up to 36% of patients with this neoplasm and are considered serological markers for this condition, an association reinforced by the present case. Chorea is not reported as a neurological symptom in anti-SOX1-positive patients with cancer, despite the common association of the antibody with intracellular antigens. Regarding treatment, the low prevalence of anti-SOX1-related paraneoplastic syndrome has precluded trials, resulting in a lack of guidelines. Syndromes associated with intracellularly targeted antibodies tend to be refractory to treatment. Moreover, given the probability of intracellular antigen, immune checkpoint inhibitor therapy was approached with caution, as it could increase the risk of aberrant T cell activation and immune-mediated adverse events, potentially aggravating the chorea, which did not occur in our case. **Final comments:** Anti-SOX1 antibodies are linked to small-cell lung cancer and chorea is associated with paraneoplastic syndromes, although a direct connection between them has rarely been documented. Further research is needed to recognize and treat these presentations.

Background: Parkinson's disease is a neurodegenerative disorder associated with the loss of nigrostriatal dopaminergic neurons, affecting 1% to 2% of the population over the age of 60. In addition to motor symptoms such as rigidity and postural instability, it manifests through non-motor symptoms including sleep disorders, anxiety, and depression, which can negatively impact the clinical course and quality of life of these patients. **Objective:** To analyse the association between anxiety, depression, excessive daytime sleepiness, and the stages of Parkinson's disease as determined by the Hoehn-Yahr scale. **Methods:** This was an observational, cross-sectional study conducted over 12 months at a tertiary referral hospital in Manaus, AM. The study was approved by the local ethics committee under CAAE n° 58684622.2.0000.0007. Inclusion criteria were patients with Parkinson's disease aged >18 years, diagnosed according to the London Brain Bank criteria, with staging of 1-3 on the Hoehn-Yahr scale. For the diagnosis of depression and anxiety, a single question was used, and for sleepiness, the Epworth Sleepiness Scale was used, with a score greater than 10 indicating excessive daytime sleepiness. **Results:** Among the 52 individuals, 33 (63.46%) were depressed and 19 (36.54%) were not; 42 (80.77%) were anxious and 10 (19.23%) were not; 34 (65.38%) were classified with excessive daytime sleepiness, and 18 (34.62%) were not. No significant association was observed between the stages of Parkinson's disease as per the Hoehn-Yahr scale and depression (X^2= 3.27; $p=0.65$), nor between Parkinson's disease and anxiety (X^2=3.54; $p=0.61$). No significant association was found between anxiety and sleepiness (X^2=4.28; $p=0.11$) or between depression and sleepiness (X^2=3.29; $p=0.19$). **Conclusion:** Our results support the literature, demonstrating that a large proportion of patients with Parkinson's disease exhibit anxiety, depression, and excessive daytime sleepiness. However, no significant association was found between the stages of Parkinson's disease and anxiety or depression, nor between anxiety and depression with excessive daytime sleepiness.

Aphasic status in a patient with serous ovarian carcinoma and CNS recurrences: case report and narrative literature review

Valdecir Boeno Spenazato Júnior[1], Thales Pardini Fagundes[1], Mayara Apolinário Januzzi[1], Isabela Rios Felix[2], Antonio Torrecilha Manfrinato[2]

[1]Fundação Pio XII, Barretos SP, Brazil.
[2]Faculdade de Ciências da Saúde de Barretos Dr. Paulo Prata, Barretos SP, Brazil.

Correspondence: Isabela Rios Felix; Email: isabelar.felix13@gmail.com.

A 51-year-old woman with a history of high-grade serous ovarian carcinoma stage IIIC had a CNS recurrence in 2019. She underwent resection and radiotherapy for lesions in the left frontal, temporal, and parietal lobes, followed by radiosurgery in July 2021 for a right frontal motor area lesion. The following year, a new nodule appeared in the right cerebellar hemisphere. By 2023, the cerebellar nodule increased in size, leading to multidisciplinary discussions about its nature, confirmed as radionecrosis in February 2024, with bevacizumab treatment initiated. In April 2024, the patient presented with acute onset speech difficulty, unable to pronounce several words, and was disoriented in time, person, and space. She had trouble understanding complex commands, could not repeat phrases, and had naming difficulties, along with ideomotor and ideational apraxia, partial alexia without agraphia, and echolalia. Cranial CT and lab tests showed no significant changes. A new MRI showed few evolutionary changes, with a slight increase in the edema of the left parietal lesion. The CSF analysis revealed no cells, and there were no signs of leptomeningeal disease. EEG findings were compatible with focal epilepsy and electrographic seizures, confirming Focal Non-Convulsive Status Epilepticus - Aphasic Status. The patient received levetiracetam, leading to complete improvement. Aphasic status does not present symptoms other than aphasia and is classified as an atypical seizure condition. Although rare, aphasia can occur in both focal seizures and status epilepticus, and it may be caused by multiple etiologies such as structural lesions, metabolic disturbances, and neurological diseases. In this case, despite the patient having a parietal lesion, it had no modifications and no disease progression. Moreover, laboratory abnormalities were absent. The diagnosis can be confirmed through EEG, however, a prolonged tracing is often necessary. Despite being challenging, early diagnosis is essential for the initiation of anticonvulsant treatment, as delays can lead to increased mortality. In this case, the patient began treatment with Levetiracetam and showed complete improvement, with no new seizures after one month of follow-up, reassuring the diagnosis. Treatment and changes in EEG patterns are important tools for retrospective diagnosis in such cases. Aphasic status is rare, likely due to underdiagnosis, and requires a high level of clinical suspicion. It should be considered in any patient with sudden aphasia or prolonged changes in fluency and comprehension. A simple EEG may not be suggestive, but it is an essential tool. Treatment should be initiated early with anticonvulsants to improve the status.

Application of artificial intelligence algorithms in the diagnosis of temporal lobe epilepsy compared to conventional methods: a systematic review

Sayros Akyro Soares Martins[1], Raphael Fernandes Casseb[1], Fernando Cendes[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Sayros Akyro Soares Martins; Email: sayrosakyro@gmail.com.

With the aim of evaluating the impact of artificial intelligence (AI) algorithms on the diagnosis of temporal lobe epilepsy (TLE), we conducted a systematic literature review of the past 10 years, assessing the performance of AI compared to conventional methods, the main data used (clinical or neuroimaging), and the algorithms employed. Studies included met the following criteria: published in English, included patients with TLE, evaluated the use of AI in diagnosing TLE in comparison to conventional methods, and reported performance metrics such as accuracy, sensitivity, and specificity. Studies focused on animal models or in vitro, not written in English, lacking comparison with a conventional diagnostic method, not published in peer-reviewed journals, and lacking performance metrics were excluded. The risk of bias in the studies was assessed using the QUADAS-2 bias scale. Statistical evaluation and meta-analysis of the data were performed using SPSS software. Literature searches were conducted using the databases PubMED, Scopus, Web of Sciences, Cochrane, and Embase. Search terms included "Epilepsy, Temporal Lobe/diagnostic imaging," "Artificial Intelligence," "Machine Learning," "Convolutional Neural Network," and "Magnetic Resonance Imaging." The initial search yielded 165 studies. Of these, 34 duplicate versions and 109 studies that did not meet the inclusion and exclusion criteria were removed, resulting in 22 studies being included. The study involved a total of 4,326 patients, of whom 2,114 had TLE and 2,212 were part of the control group (healthy individuals, patients with epilepsy other than TLE, or patients with neurodegenerative diseases). The median accuracy of the AI algorithms was 0.878. 63.64% of the studies used machine learning algorithms, 27.27% used deep learning algorithms, and 9.09% used both. The results showed the great potential of AI algorithms in assisting the diagnosis of temporal lobe epilepsy, with performance comparable to conventional methods. Deep learning algorithms have increasingly gained relevance in this issue, but the machine learning algorithm Support Vector Machine is still the most used (59.09% of the included studies). The main limitation of the study was the heterogeneity of the available performance metrics, with some studies not reporting relevant statistical information such as standard deviation or confidence interval, preventing the inclusion of half of the pre-selected studies in the initial search. When appropriate, future studies should report more robust statistical metrics, such as the sensitivity, specificity, and F1-score. Systematic review registration: https://www.crd.york.ac.uk/prospero/. Registration number: CRD42024545284

Correspondence: Leandro Cesar Monteiro; Email: lcesarmonteiro@gmail.com.

Background: The early diagnosis of cognitive decline, including Alzheimer's disease (AD), remains a significant challenge in neurology. Identifying reliable biomarkers in plasma and cerebrospinal fluid (CSF) can revolutionize diagnostic approaches and patient management. The integration of artificial intelligence (AI) with mass spectrometry (MS) offers a promising avenue for biomarker discovery due to its high sensitivity and specificity. **Objective:** This study aims to employ AI-driven analysis and MS to identify potential biomarkers in plasma and CSF of patients exhibiting cognitive decline. **Methods:** Plasma and CSF samples were collected from patients diagnosed with cognitive decline and matched controls. Mass spectrometry (LC-MS) was utilized to perform a comprehensive proteomic analysis of the samples. The resulting datasets were then processed and analyzed using AI algorithms tailored toward shortlisting patterns and identifying biomarkers correlated with cognitive decline. **Results:** Preliminary analysis has identified a set of proteins in both plasma and CSF that show significant differences between patients with cognitive decline and controls. The AI models have successfully highlighted potential biomarkers that may be involved in the pathophysiology of cognitive decline, offering promising targets for further validation. For example, in samples from AD patients, Beta Amyloid proteins (P05067) were found in quantities of around 270 spectral counts. A group spectral count can account for protein variants. In contrast, the analysis of samples from patients with cognitive decline (CD without AD identified) the same Beta Amyloid protein with a lower number of spectral counts, around 60. This preliminary finding suggests the potential of this differential biomarker in the analyzed samples. **Conclusion:** The integration of AI with MS in the analysis of plasma and CSF samples presents a robust methodology for biomarker discovery in cognitive decline. This approach not only enhances our understanding of the underlying mechanisms but also paves the way for the development of early diagnostic tools and personalized therapeutic strategies.

Application of the new criteria for optic neuritis in a patient seronegative for anti-AQP4 and anti-mog antibodies

Francyane Peixoto Ramos de Abreu[1], Luana Gomes Dias Pimentel[1], Marina Papais Alvarenga[1], Regina Maria Papais Alvarenga[1]

[1]Universidade de Vassouras, Vassouras RJ, Brazil.

Correspondence: Francyane Peixoto Ramos de Abreu; Email: francypra@gmail.com.

Case presentation: In 2022, a 46-year-old white male sought ophthalmological care complaining of visual alterations, mentioning a blurring of the central visual field in the right eye. Numerous tests were carried out and found to have mild dysfunction in the right eye. However, at the end of 2023, the patient reported a worsening of the condition, which led him back to the ophthalmologist, who ordered angiofluorescein, retinal mapping, MRI of the skull/orbits and visual field, in which loss of the temporal visual field in the right eye was detected. In April 2024, the patient noticed bilateral blurriness and sought medical assistance. On examination of the fundus of the eye, bilateral papillary oedema was identified, and corticosteroids were prescribed for a month, during which 50% of the condition improved. In May 2024, the patient went to the neurologist with a report specifying the alterations in the fundus of the eye and the presence of visual deficit bilaterally, with greater involvement of the right side. The suspicion of optic neuritis arises considering the papilla oedema. The neurologist requests a skull CT scan, optical coherence tomography, and visual evoked potential and asks the ophthalmologist for a new opinion to rule out ophthalmological causes. The skull CT was normal, and the ophthalmological causes were ruled out, but the visual evoked potential confirmed the suspicion of optic neuritis, concluding that there was a conduction defect in the visual pathways on both sides, with the right side being the most affected and compatible with demyelinating and axonal involvement of the optic nerve. The patient was informed of the disease and expressed the wish to be investigated, so he was admitted to Rio de Janeiro to have his cerebrospinal fluid examined and the markers anti-aquaporin 4 (AQP4) and autoantibody against myelin oligodendrocyte glycoprotein (Anti MOG) measured. After the tests were carried out, the cerebrospinal fluid was found to be normal, with no oligoclonal bands and no AQP4 or MOG markers. The patient is currently waiting to complete one month of physiotherapy before undergoing a new MRI. **Discussion:** The absence of lesions in the brain, spinal cord and AQP4 and MOG antibodies speaks in favour of isolated optic neuritis. In this report, the patient initially presented with a visual field deficit on the right, and within more than a year had a worsening episode in which the visual loss became bilateral, as well as papilla oedema assessed bilaterally by fundoscopy. The

change in evoked potential showed demyelinating and axonal involvement of the optic nerve, confirming the diagnostic suspicion of optic neuritis. **Final comments:** It is therefore believed that this is relapsing isolated NO (RION), due to the recurrence of symptoms, involvement restricted to the optic nerve and the absence of autoantibodies typically related to the disease.

Application of the proposed criteria for the diagnosis of mog- associated disease (MOGAD) in a population from Rio de Janeiro

Gabriela Barroso Girafa[1], Kelma Macedo Pohlmann Simoes[1], Vanderson Carvalho Neri[1], Marina Papais Alvarenga[1], Marcos Papais Alvarenga[1], Claudia Cristina Ferreira Vasconcelos[1], Marcell Pourbaix Morrisson Guimarães[1], Cleonice Alves de Melo Bento[1], Priscila Mendonça do Sacramento[1], Regina Maria Papais-Alvarenga[1]

[1]Universidade Federal do Estado do Rio de Janeiro, Pós-Graduação da Neurologia, Rio de Janeiro RJ, Brazil.

Correspondence: Gabriela Barroso Girafa; Email: gabrielagirafa@hotmail.com.

Background: In 2023, an international panel proposed new criteria for MOG-associated disease (MOGAD) based on clinical and imaging data and titers of MOG-IgG antibodies. **Objective:** To apply the MOGAD criteria in a series of patients with positive serum antibodies against the myelin oligodendrocyte glycoprotein (MOG-IgG) from Rio de Janeiro. **Methods:** Between 2016 and 2023, Neuromielitis optica (NMO), high risk NMO and acute disseminated encephalomyelitis (ADEM) patients from Rio de Janeiro were tested for anti aquaporin 4 antibody (AQP4-IgG) and MOG-IgG by the cell-based assay (CBA) method. The new MOGAD criteria were applied in the cases positive to MOG-IgG. **Results:** From 516 patients tested, 94 were positive for AQP4-IgG. Among the 422 negative cases for AQP4-IgG, MOG-IgG was present in 28 patients, five under 18 years old and 23 adults. Sixty percent of the patients were female, 70% caucasians and 30% afro-descendants. The age ranged between eight and 47 years (median 31). Two patients were seropositive for both antibodies. Optic neuritis (ON) ocurred in twenty patients, myelitis in 11 and brainstem syndrome in two patients . Two pediatric patients presented with ADEM. We didnt have titration in our test, making it necessary to have additional supporting clinical or MRI features, such as bilateral simultaneous clinical ON (12 patients), longitudinal optic nerve involvement (six patients), optic disc oedema (four patients), perineural optic sheath enhancement (three patients), longitudinally extensive transverse myelitis (four patients), conus lesion (1 patient), central cord lesion (two patients), Ill-defined T2-hyperintensity involving pons, middle cerebellar peduncle or medulla (four patients), multiple ill-defined T2 hyperintense lesions in supratentorial and often infratentorial white matter (four patients), cortical lesions (two patients). In total 23 of 28 patients (82%) fullfield the 2023 MOGAD criteria. Didn´t met the criteria one case of isolated unilateral ON, one case of transerse myelites no-LETM, two case of double seropositivity and one case of optic neurits and transverse myelitis without additional supporting criteria. **Conclusion:** Eighty- two percent of the patients MOG-IgG positive met the new criteria for MOGAD, inspite of not having MOG-IgG titration.

AQP4-IGG-seropositive neuromyelitis optica spectrum disorder (NMOSD) associated with teratoma and parotid tumor: a case report

Gabriel Isaac Correia[1], Elisa Gouvea Gutman[2], Caio Faria Tardim[1], Anna Beatriz Scherer Vanzan[2], Ingrid Pereira Marques[1], Carlos Eduardo Ferreira Ramos[2], Larissa Araujo Duarte[1], Marcos Martins da Silva[1], Roberto Pereira Santos[1], Soniza Vieira Alves-Leon[2]

[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.
[2]Universidade Federal do Estado do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Elisa Gouvea Gutman; Email: gutman811@gmail.com.

57-year-old female patient presented paresis and paresthesia in the right lower limb, accompanied by gait disturbance and urinary incontinence. Upon examination, she exhibited proximal predominance paresis in the right lower limb, hyperreflexia in the lower limbs predominantly on the left side, and diminished vibratory, tactile, and thermal-analgesic sensations with a T6 spinal level. During the investigation of myelitis, right ovarian teratoma and lymphoepithelial cyst in the right parotid were identified. Magnetic resonance imaging (MRI) revealed an extensive spinal cord lesion with longitudinal hypersignal from T3 to T7, predominantly central, without contrast enhancement. Brain imaging identified nodular lesions in the periventricular, subcortical, and medulla white matter, with hypersignal in T2 and FLAIR, without contrast enhancement or diffusion restriction. The hypotheses of Neuromyelitis Optica Spectrum Disorder (NMOSD) or paraneoplastic syndrome were considered. General biochemistry and rheumatological panels were normal. Cerebrospinal fluid analysis had normal findings and excluded infectious diseases. Antibody testing for anti-aquaporin 4 (AQP4) and anti-MOG IgG by ELISA method was negative. She evolved with improvement of the neurologic symptoms during the investigation and was discharged with outpatient follow-up. Six months later she evolved with similar symptoms. She tested negative for a new anti-MOG test, but positive for anti-AQP4, using the CBA method, establishing the diagnosis of NMOSD. She received pulse therapy with 1g/day of methylprednisolone for 5 days followed by 5 sessions of plasmapheresis on alternate days that did not yield significant improvement in symptoms. Treatment with azathioprine 100mg (2mg/kg/day) + prednisone 40mg/day was initiated, considering access to disease-modifying therapies in the Unified Health System. The relationship between teratomas, parotid tumor and NMOSD has been previously reported in literature, although the mechanism is still unclear. AQP4 has been detected in human parotid excretory duct epithelia, and a tumor with overexpression of excretory duct epithelial cells may lead to upregulation of AQP4 production. Additionally, histopathologic analyses of the teratomas revealed AQP4 immunoreactivity and infiltration of lymphocytes in the neural tissue component. In genetic susceptible patients, this can be the trigger to produce anti-AQP4 antibodies that induce the acute NMOSD attack. The coexistence of autoimmune disease and tumor may be explained by the immunotolerant role of HLA-G expression, inhibiting the immune responses of MHC-unrestricted NK and MHC restricted T cells. Presence of anti-AQP4-IgG does not exclude a paraneoplastic nature of NMOSD; however, paraneoplastic cases are rare and most of them are secondary to CNS lymphoma and intramedullary tumors. This case illustrates one more association between these conditions and reinforces the demand for further translational searches.

Correspondence: Karina Nonato Pingituro Domingues; Email: karina.npd@gmail.com.

Objective: To report quality of life in a cohort of people with Neuromyelitis Optica Spectrum Disorder (NMOSD), comparing patients based on the results of the Aquaporin-4 test. **Methods:** We evaluated 68 patients in six reference centers over a period of 18 months. Inclusion criteria was diagnosis of NMOSD according to IPND 2015. Demograhic and clinical data were evaluated. To evaluate life quality we use the Brazilian version of life quality SF-36. The research is in progress and will be applied in several regions of Brazil. **Results:** 68 NMOSD patients in the states of São Paulo, Paraíba, Goiás, Ceará, Bahia and Rio Grande do Sul, with 82% of female preponderance were evaluated. Median age was 41 and disease duration was 4.63 years. 33% are Aquaporin-4 positive, 31% Aquaporin-4 negative and 36% do not know or did not want to inform. According to the instrument, results are seen on a scale ranging from 0 to 100, where zero is the worst state and 100 is the best. Results obtained: regarding the physical functioning domain, the mean value obtained was 34 in Aquaporin-4 positive patients, 52 in Aquaporin-4 negative patients and 46 in patients who did not know/want to inform; regarding the role limitations due to physical health domain, the mean value obtained was 5 in Aquaporin-4 positive patients, 38 in Aquaporin-4 negative patients and 31 in patients who did not know/want to inform; regarding the social functioning domain, the mean value obtained was 45 in Aquaporin-4 positive patients, 59 in Aquaporin-4 negative patients and 63 in patients who did not know/want to inform; regarding the role limitations due to emotional problems domain, the mean value obtained was 9 in Aquaporin-4 positive patients, 36 in Aquaporin-4 negative patients and 50 in patients who did not know/want to inform. **Conclusion:** In this research, it was demonstrated that all domains had a worse result in Aquaporin-4 positive NMOSD patients, in relation to Aquaporin-4 negative patients or patients who were unable to inform the result, with greater emphasis on the domains limitation due to physical aspects and limitation due to emotional aspects, demonstrating a reduction in the Quality of Life of people with Aquaporin-4 positive NMOSD.

Arboviruses evolving with Guillain-Barré syndrome and impact on immunoglobulin stock: a case report

Isadora Ribeiro Doria[1], Larissa da Cruz Cardoso[1], Sandy Karoline Carnaúba dos Santos[2], Augusto Costa Ataides[1], Beatriz Palladino Ferreira[1], Matheus Henrique Fonseca Melo[3], Agnaldo Queiroz Plaster[2], Maria Luísa Ribeiro Lima[4], Mireli Martins Montijo[1]

[1]Universidade do Estado de Mato Grosso, Cáceres MT, Brazil.
[2]Universidade Federal de Mato Grosso do Sul, Campo Grande MS, Brazil.
[3]AFYA, Itabuna BA, Brazil.
[4]Centro Universitário Governador Ozanam Coelho, Ubá MG, Brazil.

Correspondence: Isadora Ribeiro Doria; Email: isardoria@gmail.com.

Case presentation: There was a high incidence of arboviruses in this endemic region, with a significant number of cases progressing to a neurological condition, acute polyradiculoneuritis, also known as Guillain-Barré syndrome, with five cases in a one-month period. One patient remains hospitalized at this time, while the others have been discharged. EER, a 31-year-old female, reported 30 days of diffuse abdominal pain, high fever,

headache, tachycardia, dysphagia, right-sided hemiparesthesia, and subsequently bilateral hemiparesthesia. She arrived at the hospital in a wheelchair with the above-mentioned symptoms Chikungunya infection was identified in her history, as with most patients who developed this syndromic condition. They also denied drug allergies, comorbidities, alcohol use, and drug use, and all tested negative for Human Immunodeficiency Virus. On physical examination, she presented with tetraparesis predominantly on the left side, muscle strength grade II, with preserved tone and trophism. The patient developed proteinuria and leukopenia associated with polyneuropathy, with flaccid paraplegia, but remains hospitalized due to difficulties with treatment with IV Human Immunoglobulin. **Discussion:** Guillain-Barré syndrome is a rare but serious complication of arbovirus infections, and the recent surge in cases has overwhelmed the healthcare system. Specific treatment for this syndrome aims primarily to accelerate the recovery process, reduce complications associated with the acute phase, and involves the use of IV Human Immunoglobulin, compounded by the emergency situation of its supply at the state and national levels. Many patients in need of this treatment face challenges and clinical complications. **Final comments:** Therefore, it is crucial to study the etiology and pathophysiology of arbovirus progression to acute polyradiculoneuritis, along with developing alternative management protocols and treatments due to the persistent seasonal characteristics of this public health problem. This can directly impact the incidence of Guillain-Barré syndrome and its associated neurological syndromes, with socioepidemiological impacts that are still immeasurable.

Area postrema syndrome as an initial manifestation of AQP4 -AB negative NMO spectrum disease treated with rituximab: a case report

Renata de Andrada Santana[1], Marina Papais Alvarenga[1], Regina Maria Papais Alvarenga[1]

[1]Universidade de Vassouras, Vassouras RJ, Brazil.

Correspondence: Renata de Andrada Santana; Email: renata.andradaa@gmail.com.

Case presentation: A brown woman, currently 41 years old, reports that in 12/2012, at the age of 29, she suddenly felt intensely nauseous and developed incoherent vomiting. A few days later, she started having recurrent hiccups interspersed with vomiting and dyspnea. She was hospitalized for almost a month investigating gastric causes, and underwent endoscopy and radiological exams, being discharged without a diagnosis after improving. On January 30, 2013, she suddenly presented with urinary retention weakness of the lower limbs and imbalance, evolving within 72 hours with tetraplegia and numbness from the neck down. When she returned to the hospital, she underwent imaging tests. The MRI showed an extensive longitudinal lesion extending from the bulb to the lumbar spinal cord, with edema and contrast uptake. She was started on IV methylprednisolone (1 gram for five days) followed by human immunoglobulin and showed little improvement in her right upper limb deficit. In May 2013, she underwent four sessions of plasmapheresis, followed by exponential improvement in the paralysis of the lower limbs over the following months. The AQP4 antibody test was negative. The patient never showed any visual impairment. Preventive treatment was started with a monoclonal antibody, Rituximab, in 05/2013 at a dose of 500mg 1x a week for 4 weeks, followed by a dose of 500mg 1x in 6-6 months, accompanied by physiotherapy. Over the last 10 years, she has progressed with complete recovery of motor dysfunction and normalization of the MRI image of the spine. At the last assessment on 03/2024, she walked freely and the MRI study showed no lesions. The sequelae are neurogenic bladder and fecal urgency. **Discussion:** The area postrema is located around the IV ventricle in the medulla oblongata. Physiologically, it works as a chemosensitive vomiting/hiccupping center and an epicenter for monitoring and integrating systemic autonomic signals, together with the nucleus of the solitary tract and the dorsal motor nucleus of the vagus. Demyelination in this territory leads to episodes of nausea, vomiting, and incoercible hiccups lasting longer than two days and is known as Area Postrema Syndrome (APS). APS, optic neuritis, and longitudinally extensive myelitis constitute the three central signs of "Neuromyelitis Optica Spectrum Disorders" (NMOSD). These diseases are currently classified by serological status into AQP4 positive and negative. Treatment of these groups differs because the new FDA-approved drugs for NMOSD are only indicated for AQP4-positive cases. **Final comments:** In describing this rare case of AQP4-AB antibody-negative NMOSD initiated by APS, we emphasize the efficacy and safety of the off-label drug Rituximab. This CD 20 cell immunosuppressant shows excellent results for both AQP4-AB positive and negative NMOSD cases and is indicated by expert consensus as a first-line drug for these diseases.

[4]Escola Estadual de Educação Profissional Presidente Médici, Campos Sales CE, Brazil.

Correspondence: Kelly Rejane Leite Figueiredo de Oliveira; Email: krlfigueiredo@gmail.com.

Case presentation: MCOLS, 53 years old, born in Saboeiro, Ceará. 28 years ago, she gradually developed dysphonia. Eight years later, she developed symmetrical paresis in her hands and paresthesia and pain in all four limbs, asymmetrical, particularly on the left. From then on, she developed difficulty walking and recurrent attacks of neck pain and left-sided hemicranial headache, the latter appearing in stitches, with strong intensity for up to 10 minutes, triggered by coughing or throbbing, with at least five episodes per month. On examination: dysphonic speech, symmetric palate elevation and reduced amplitude. Muscle strength grade 4: deltoid, rhomboid, biceps brachii, triceps, pronator teres, extensor carpi radialis, flexor carpi radialis, interossei and abductor pollicis brevis bilaterally. Grade 1 reflexes: styloradial, bicipital and triceps bilaterally. In sensitivity assessment, there is "shawl" hypoesthesia of C4-C6. Complementary exams: 10/21/2011 Laryngoscopy: nodular formation in the middle third of both vocal folds compatible with an intrachordal cyst; presence of irregular glottal cleft with double spindle predominance. 04/03/2017 Magnetic resonance imaging of the cervical spine: posterolateral disc protrusions at levels C5-C7, determining an impression on the ventral surface of the dural sac, causing a reduction in the amplitude of the left intervertebral foramen at C6-C7; herniation of the cerebellar tonsils through the foramen magnum by approximately 0.9 cm; extensive syringomyelic cavity from C2 to the thoracic segment. 03/13/2018 Electroneuromyography of the upper limbs: acute and chronic radiculopathy of the C7 root on the left side, with signs of active and chronic denervation in the flexor carpi radialis, extensor carpi radialis and left triceps muscles; sensory and motor neuropathy of the median nerve at the level of the wrist, bilaterally, compatible with severe carpal tunnel syndrome bilaterally. **Discussion:** Arnold-Chiari malformations are defined as a spectrum of abnormalities of the posterior part of the brain, involving the cerebellum, brain stem, skull base and spinal cord. Type I is the most common and is characterized by the caudal displacement of the cerebellar tonsils and the medial and inferior part of the posterior lobe of the cerebellum through the spinal canal, above 3 to 5 mm from the foramen magnum. The patient presented multiradiculopathy from C5 to T1, bilateral preganglionic hypoesthesia, C4-C6 hypoesthesia, motor deficit of the upper limbs caused by type I malformation. It was associated with extensive syringohydromyelia, dysphonia related to bulbar paresis, cervicogenic paroxysmal headache and cyst on the vocal folds. After a surgical approach, the headache, dysphonia, sensory and motor deficits gradually resolved after surgical treatment of the Chiari malformation, as well as neurophysiological recovery from the assessed radiculopathy.

Arquivos de Neuro-Psiquiatria: a bibliographic study of the first 20 years (1943-1963)

Rodrigo Fagundes da Rosa[1], Francisco Duque de Paiva Giudice Junior[1], Francisco Luciano Honório Barreto Cavalcante[1], Leonardo Elias Araujo dos Santos[1], Emanuela Freire Caetano Davi[1], João Marcelo Albuquerque Beserra de Sousa[1], Mariana Alcântara Tavares[1], Wagner Patrik Sousa Silva[1], Caio Levi Mendes Costa[1], Francisco de Assis Aquino Gondim[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Rodrigo Fagundes da Rosa; Email: rodrigofdarosa@gmail.com.

Background: In 2023, the Arquivos de Neuro-Psiquiatria celebrated 80 years. Founded in June 1943 by Oswaldo Lange, Adherbal Tolosa, and Paulino Longo, it has been the official journal of the Brazilian Academy of Neurology (ABN) since 1970. Over the decades, it has undergone several upgrades, including indexing in international databases, peer review, and transitioning to open access, reaffirming its commitment to academic excellence and the internationalization of Brazilian research. This article, the first in a series of four, analyzes the first 20 years of Arquivos de Neuro-Psiquiatria. **Objective:** To analyze publication trends, authorship patterns, and editorial changes over the first 20 years, highlighting its historical significance. **Methods:** All editions published by the journal in its digital repository from 1943 to 1963 were analyzed, with each article being examined individually. Additionally, all physical editions available in the Professor Jurandir Marães Picanço Health Sciences Library were also scrutinized. Data from both sources were tabulated independently by two blinded, independent researchers. Subsequently, those two individuals cross-verified the collected data. **Results:** Between 1943 and 1963, the journal published 83 issues and 2 supplements in 21 volumes, totaling 923 articles. The annual publication rate was 4 issues, except in 1943, with 3 issues, and in 1954, with 6 publications due to two extra supplements. The study analyzed 479 articles classified as article, case report, update, practical note, and technical note, excluding book reviews, tributes, and non-original articles. A total of 893 authors participated, averaging 1.91 authors per article. The articles were categorized as follows: 325 articles, 109 case reports, 19 practical notes, 13 preliminary notes, 9 updates and 9 in other categories. Horacio Martins Canelas was the most prolific author, contributing with 35 articles, followed by Rolando ngelo Tenuto with 29. Only 3.92% were women, notably Maria Elisa Bierrenbach Khoury, the first woman to co-author an article, Iracy Doyle with 3 main authorships, and Maria I. Valente with 1 authorship and 6 co-authorships. Geographically, 418 articles came from Brazil,

notably São Paulo (352), Rio de Janeiro (21), and Bahia (21), as well as 61 studies from other countries. Oswaldo Lange was the main Editor throughout the entire study period. **Conclusion:** The first 20 years of the Arquivos de Neuro-Psiquiatria established it as a vital platform for disseminating knowledge, with significant contributions from Brazilian researchers. Although female participation was low, the journal took steps toward inclusion. The stability of the editorial board and the involvement of influential authors were crucial for the journal's growth and quality, laying a solid foundation for its continued trajectory of academic excellence and internationalization.

Artificial intelligence algorithms to detect cerebral small vessel disease tomography markers and their association with clinical outcomes in patients with acute ischemic stroke undergone thrombectomy

Thiago Oscar Goulart[1], Rui Kléber Do Vale Martins-Filho[2], Millene Rodrigues Camilo[2], Octávio Marques Pontes-Neto[2]

[1]Harvard, Boston MA, USA.
[2]Universidade de São Paulo, Faculdade de Medicina de Ribeirão Preto, Hospital das Clínicas, Ribeirão Preto SP, Brazil.

Correspondence: Thiago Oscar Goulart; Email: tgoulart@hsph.harvard.edu.

Background: Although mechanical thrombectomy (MT) has expanded its indications over the last years, establishing a robust benefit even for the elderly, some trials have shown neutral effects regarding this subgroup. One possible explanation for these findings is the vulnerability of the patients treated under these trials, which means these populations were frailer and, accordingly, portended a significant burden of cerebral small vessel disease (cSVD), which may work as a surrogate marker for brain frailty. **Objective:** To study the influence of the cSVD markers on the baseline CT scan in the functional outcome and develop Artificial Intelligence (AI) algorythms to detect them. **Methods:** A trained vascular neurologist blinded to clinical details evaluated the CT scans of 351 patients. We focused on markers of cSVD (leukoaraiosis, old lacunes, atrophy), and calculated the Brain Frailty Score (BFS) and modified Small Vessel Disease score (mSVD) (Figures 1 and 2). Then we carried out a multivariable back-stepwise logistic regression and random forest to identify the variables related to disability at 90 days, and other model to analyze the association with Hemorrhagic Transformation. We segmented the images with 3DSlicer and develop an U-Net model to detect leukoaraosis. **Results:** The group with disability at 90 days was older, had higher NIHSS at admission, more prevalence of diabetes mellitus (DM), higher levels of systolic blood pressure and glucose levels at admission, poorer collaterals, lower rate of MT, and higher rates of severe cSVD markers at baseline CT scan. Figure 3 shows the variables associated with poor outcomes in a back-stepwise logistic regression. The model performance was excellent: AUC=0.962 (Figure 3), with no signs of heteroskedasticity (Figure 4). In other models with HT and Symptomatic HT as dependent variables, cSVD markers also were associated with these outcomes. The random forest model determined the variables importance in these models (Figure5). The U-net model had great performance to detect severe leukoariosis (accuracy=100%, macro-precision=100%, AUC of ROC curve=1.00) **Conclusion:** Markers of cSVD on baseline CT scans are related to poorer outcomes, such as disability, mortality and symptomatic Hemorrhagic Transformation in patients with LVO and might be one of the main causes of the lack of benefit of MT in elderly patients, highlighting its importance even in acute LVO context. We also developed a AI software with great performance to detect severe leukoaraiosis.

Artificial intelligence algorithms to differentiate between contrast extravasation and hemorrhagic transformation in tomography of acute ischemic stroke after thrombectomy

Thiago Oscar Goulart[1], Júlio César Nather Júnior[2], Renato Okabayashi Miyaji[3], Danilo Pinheiro Fonseca[4], Octávio Marques Pontes-Neto[4], Millene Rodrigues Camilo[4]

[1]Harvard, Boston MA, USA.
[2]Universidade de São Paulo, Faculdade de Medicina de Ribeirão Preto, Hospital das Clínicas, Ribeirão Preto SP, Brazil.
[3]Universidade de São Paulo, São Paulo SP, Brazil.
[4]Universidade de São Paulo, Ribeirão Preto SP, Brazil.

Correspondence: Thiago Oscar Goulart; Email: tgoulart@hsph.harvard.edu.

Background: Mechanical Thrombectomy (MT) treats Acute Ischemic Stroke (AIS) removing the thrombus, and improves clinical outcome. However, it uses high quantities of contrast, with risk of Contrast Extravasation (CE), but also Hemorrhagic Transformation (HT), both detected by cranial Computed Tomography (CT). However, to differentiate between them, it is necessary to perform a control CT 72 hours after MT (Figure 1). **Objective:** To develop a tool capable of differentiating HT from EC in cranial CT. **Methods:** 398 CTs were classified into four classes: HT, CE, HT with CE, and without HT nor CE. We selected 111 CT performed until 72 hours after angiotomography+MT, segmented the images with 3DSlicer (Figure 2). Then, we had 2 approaches: 1) Three classification models were developed based on phenotypic characteristics: Support Vector Machines (SVM), Random Forest (RF) and Logistic Regression (LR); 2) The U-Net, a Convolutional Neural Networks (CNN) model for biomedical image segmentation. **Results:** SVM and RF had ROC AUC above 92% for the three classes. Cross-validation demonstrated good accuracy (SVM=0.947±0.064; RF=0.893±0.076; LR=0.956±0.048) and macro-precision (SVM=0.947 ± 0.066. RF=0.901±0.075, LR=0.956±0.049). The U-Net also presented good predictive performance after cross-validation: accuracy=0.956±0.072 and macro-precision = 0.965±0.055. Multiclass ROC Curves exhibited AUC ≥ 0.98 for the three classes (Figure 3). **Conclusion:** In this study, we developed a tool with high performance to distinguish between CE and HT with two different approaches, which could help in clinical decision-making, such as introduction of anticoagulants and antiaggregants

https://doi.org/10.5327/CBN240181

Aseptic meningoventriculitis after spinal anesthesia and Epstein Barr finding as a differential diagnosis of rapidly progressive dementia: case report

Luciano Gonçalves do Nascimento Júnior[1], Gilmar Leite Pessoa Filho[1], Felipe Nunes de Araújo[1], Ana Luisa Castelo Branco Gomes[1], Rafael de Souza Andrade[1], Paulo Antonio Farias Lucena[1], Luíza Alves Monteiro Torreão Villarim[1], Alex Tiburtino Meira[1], Matheus Gurgel Saraiva[1], Juliana Magalhães Leite[1]

[1]Hospital Metropolitano Dom José Maria Pires, João Pessoa PB, Brazil.

Correspondence: Gilmar Leite Pessoa Filho; Email: gilmarpessoa@gmail.com.

Case presentation: A 61-year-old female patient from João Pessoa (Paraíba), with a medical history of hypertension and diabetes, underwent uterine polypectomy under spinal anesthesia. Four days post-procedure, she developed an intense headache associated with nausea and vomiting, progressing subacutely to disorientation, recent memory difficulty, disinhibition, incoherent speech, and gait disturbance, and initiated investigation for rapidly progressive dementia. After 40 days, with progressive worsening, she was admitted in a somnolent state, with neck stiffness, bradykinesia in the upper limbs (worse on the right), and left VI paresis. Initial computed tomography revealed cortical sulci effacement with marked supratentorial ventricular dilatation. Contrast-enhanced magnetic resonance imaging demonstrated signs of inflammatory/infectious leptomeningitis affecting cortical gyri and basal cisterns, changes suggesting ventriculitis with moderate supratentorial ventricular dilatation; FIESTA sequence revealed aqueductal stenosis with thin septations. Cerebrospinal fluid analysis revealed limpid fluid with glucose of 69; proteins 111; leukocytes 20 (80% mononuclear); non-reactive VDRL and negative bacterial, fungal cultures, and malignant cells. Viral panel by RT-PCR detected Epstein-Barr Virus (EBV). Serologies for hepatitis C and B, HIV, and VDRL were negative. Initial empiric treatment included vancomycin 2g/day, meropenem 6g/day, and dexamethasone 16 mg/day for 21 days. After aseptic ventriculitis was confirmed, with serial negative CSF cultures, a ventriculoperitoneal shunt was performed. The patient improved cognitively and in his level of consciousness. At 8-month follow-up, she returned to the neurology outpatient clinic with daily activities maintenance and remission of previous symptoms. **Discussion:** Post-spinal anesthesia meningitis is extremely rare (< 0.01%) with potentially severe complications. The reported case suggests DIAM, diagnosed based on a high suspicion level. Aseptic cerebrospinal fluid confirms the diagnosis, facilitating antibiotic withdrawal, shorter hospital stay, and reduced costs. **Final comments:** Serial investigations ruled out infectious causes for the clinical-radiological presentation, suggesting inflammatory process as a cause for aqueductal septations. The presence of EBV in the case is uncertain as to whether it is a concomitant finding or a causative and aggravating agent. The patient had a favorable clinical outcome.

Assesment of the quality of life of elderly individuals attending a senior community center

Natalli Studnicka[1], Tatiana Pizzolotto Bruch[1], Camila Pezente Dal Toe[1], Pedro Mendes Maciel[1], Virgílio Fernandes Bronzatti[1], Gustavo Beltrame[1]

[1]Universidade do Extremo Sul Catarinense, Criciúma SC, Brazil.

Correspondence: Natalli Studnicka; Email: natalli.stu@gmail.com.

A study was conducted to assess the quality of life of elderly attendees of a senior community center in Criciúma. During the first semester of 2023, 286 elderly individuals were interviewed. The questionnaire covered personal data such as gender, age, race/ethnicity, marital status, education level, and socioeconomic status, and included an evaluation of quality of life using the WHOQOL-OLD scale. Results showed an Overall Score of 4.16 for the elderly individuals' quality of life. The highest scoring domain was "Autonomy" (4.24), while the lowest was "Death and Dying" (4.08). Statistical analyses revealed significant differences between genders and between married and separated/divorced individuals in the "Past, Present, and Future Activities" domain. Differences were also found between married and single individuals in the "Social Participation" and "Intimacy" domains. However, no statistically significant differences were found between the variables and the other domains of the WHOQOL-OLD. In conclusion, elderly participants in the senior

community center demonstrated overall good quality of life, particularly in autonomy. Married individuals exhibited better quality of life than singles in domains related to activities, social participation, and intimacy as assessed by the WHOQOL-OLD.

Assessing dysphagia and ventilatory dysfunction in inclusion body myositis: clinical insights and muscle ultrasound findings

Ana Lucila Moreira[1], Bruna Moreira de Souza Proença[1], André Macedo Serafim da Silva[1], Cristiane de Araújo Martins Moreno[1], Eliene Dutra Campos[1], Mariana Cunha Artilheiro[1], Tatiana Ribeiro Fernandes[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas,São Paulo SP, Brazil.

Correspondence: Bruna Moreira de Souza Proença; Email: brunamsproenca@gmail.com.

Background: Inclusion Body Myositis (IBM) is characterized by progressive muscle weakness, with dysphagia affecting 40-80% of patients. Weakness in the pharynx and tongue significantly contributes to dysphagia, which can occur at any disease stage. Patients often adapt to minor swallowing difficulties over time, while asymptomatic respiratory function impairment is also common. Its impact on patients' quality of life is profound, while aspiration pneumonia and respiratory complications are the most common causes of death. Therefore, monitoring for swallowing and respiratory complications is crucial in managing IBM. Imaging techniques, like ultrasound (US), offer potential as non-invasive tools for monitoring muscle changes. The US morphologic study of the tongue and respiratory muscles may provide valuable insights into disease processes. **Objective:** To evaluate dysphagia and respiratory impairment using US in conjunction with clinical analyses. **Methods:** We conducted a cross-sectional study involving ten IBM patients. We analyzed clinical and epidemiological data descriptively to characterize the patient population. Dysphagia assessment used the IBM Functional Rating Scale (IBM-FRS), and we categorized ventilatory restriction based on FVC measurements by spirometry. We examined the patients with B-mode ultrasound, evaluating the diaphragm, intercostals, and tongue muscles (digastrics, geniohyoid, and genioglossus) in the transverse plane. All examinations took place on the right side using a fixed preset. Muscle classification followed the Modified Heckmatt Scale (1=normal, 2=probably abnormal, 3=abnormal). **Results:** The study included ten IBM patients, with 4 males and 6 females, with a median age of 61.5 years and median duration of disease of 9 years. Dysphagia was present in 60% of the patients, who reported occasional choking. US findings of the tongue muscles showed that the genioglossus muscle was altered in all patients and the least altered muscle in the tongue was the geniohyoid. In terms of respiratory function, the FVC of the patients ranged from 25% to 93% of the predicted values, with a median FVC of 67.0%. Ventilatory restriction was observed in the following proportions: 33.3% normal, 11.1% mild, 33.3% moderate, 11.1% severe, and 11.1% very severe. US evaluation of the respiratory muscles revealed that the intercostal muscles and the diaphragm were normal in only 20% of the patients. **Conclusion:** Abnormalities in the genioglossus muscle were frequently observed in patients with dysphagia. Ventilatory restriction was commonly seen in patients with abnormalities in the respiratory muscles. US evaluation of the tongue and respiratory muscles can provide insight into disease processes and guide therapeutic decisions even in patients without complaints of dysphagia or difficulty breathing. This evaluation may serve as an objective assessment of treatment response in the future.

Assessing stroke awareness in Aparecida-SP city: a cross-sectional study from 2023 and 2024

Beatriz Barbosa Nishigima[1], Mariana Rachas Reis[1], Anna Luísa Mennitti[1], Fernanda Yumi Abe[1], Rubens José Gagliardi[1]

[1]Santa Casa de São Paulo, Faculdade de Ciências Médicas, São Paulo SP, Brazil.

Correspondence: Beatriz Barbosa Nishigima; Email: beatriz.nishigima@gmail.com.

Background: Stroke is a leading cause of mortality and disability in Brazil. Despite its severity, it often goes unrecognized, leading to delayed treatment and unfavorable outcomes. This research, conducted as part of a community outreach program, aims to assess the level of stroke awareness among residents of Aparecida-SP city, from 2023 to 2024. By identifying knowledge gaps, it is possible to develop targeted interventions to improve stroke prevention and management, thereby mitigating its impact on communities. **Objective:** To conduct a descriptive analysis of the overall knowledge concerning stroke recognition and prevention in a low-income community in Aparecida (SP), between 2023 and 2024. **Methods:** This is a descriptive cross-sectional study on data from a structured questionnaire available on the REDCAP platform applied in Aparecida-SP city in January 2023 and 2024, during a community outreach program organized by medical, nursing and speech therapy students. The study population was composed of people aged 18 years or older, who were registered for an outpatient appointment and signed the term of consent. In 2024, previous respondents were excluded. They were analyzed demographically and the questions about stroke included definition, symptoms, prevention methods, what to do in case of suspicion and if they knew someone who had a stroke. **Results:** Collecting data in both years resulted in a sample of 534 answers, 258 in 2023 and 276 in 2024. Among all interviewees, 63.8% were women, the most prevalent age group was between 50-59 years (28,3%) and 31.6% of them had incomplete primary education. In the evaluated sample, 71.9% knew someone who had a stroke and 60.7% couldn't define the disease. Considering the total participants, 304 people (57%) know how to identify at least one of the stroke symptoms out of a list. This list included, from the most to least cited: paresthesia in the face, arm or leg (52%), weakness in the face, arm or leg (42.4%), mental confusion, difficulty speaking or understanding (38.5%), severe headache of sudden onset and unknown cause (35.5%), difficulty with movement balance and coordination (34.2%), hemilateral symptoms (30.6%) and vision impairment (15.2%). When asked about preventive measures, 272 (52.8%) knew at list one, being physical activity the most mentioned (69.5%) and dyslipidemia control (17.8%) the least commented in both years. On the occasion of witnessing a stroke, 58.6% would call an emergency service, 0.74% would check the timing and 40.6% wouldn't know what to do. **Conclusion:** Despite the prevalence and mortality of stroke, the population knows little essential information about it. This lack of knowledge contributes to the high incidence of the disease. Therefore, it is important to promote campaigns and healthcare policies to raise awareness of stroke and its prevention.

Assessing the efficacy of donanemab in reducing amyloid plaque levels in Alzheimer's disease: a systematic review and meta-analysis of randomized clinical trials

Victor Hugo Palhares Flávio-Reis[1], Yago Marcos Pessoa-Gonçalves[1], Marlos Aureliano Dias-Sousa[2], Gustavo de Oliveira Almeida[1], Chamberttan Souza Desidério[1], Carlo José Freire Oliveira[1], Wellington Francisco Rodrigues[1]

[1]Universidade Federal do Triângulo Mineiro, Instituto de Ciências Naturais e Biológicas, Laboratório de Imunologia e Bioinformática, Uberaba MG, Brazil. [2]Universidade Federal do Triângulo Mineiro, Hospital de Clínicas, Departamento de Neurologia, Uberaba MG, Brazil.

Correspondence: Yago Marcos Pessoa-Gonçalves; Email: yagompg98@gmail.com.

Background: Alzheimer's disease (AD) is characterized by the accumulation of beta-amyloid (Aβ) peptides plaques in the brain. Donanemab was developed to bind to amyloid plaques and operate through microglial-mediated phagocytosis. In animal studies, this drug has demonstrated efficacy in reducing the number of plaques without causing microhemorrhages. **Objective:** To evaluate the efficacy in humans of Donanemab for the reduction of amyloid plaque levels in AD. **Methods:** This study is a meta-analysis of randomized controlled trials that evaluated the efficacy of Donanemab in reducing amyloid plaque levels of patients with AD. Embase, Pubmed and Cochrane were searched for trials published up to may 2024. Data were extracted from published trials and Cochrane tool for assessing risk of bias was employed. The extracted data were input into Review Manager (RevMan) 5.3 (Nordic Cochrane Centre, Denmark) to calculate the effect size. RevMan calculated as effect measure the mean difference with a 95% confidence interval (CI) using the inverse variance statistical method. **Results:** Regarding the risk of bias in each RCT, three were assessed to have an overall low risk of bias. Only one RCT was found to have some concerns regarding the risk of bias. Out of 528 database results, 146 duplicate articles were excluded. Of the remaining 382 studies, only 4 studies met the inclusion criteria. Four randomized controlled trials comprising 2142 patients were included. Of the participants studied, 1060 (51%) received Donanemab and 1072 (49%) received placebo. Donanemab was associated with a significant reduction of 84.68 amyloid plaque levels (95% CI, -89.77 to -79.58, P<0.00001) when compared to placebo. When conducting subgroup analyses and assessing secondary outcomes, it was observed that Donanemab (95% CI, 1.68 to 4.27, P<0.00001) presented a Integrated Alzheimer's Disease Rating Scale (iADRS - range from 0 to 144, with lower scores indicating greater cognitive deficits) value of 2.97, meaning a significant improvement in patients performing activities of daily living. Regarding the Clinical Dementia Rating Scale-Sum of Boxes (CDR-SB; scores range from 0 to 18, with higher scores indicating greater impairment), no statistically significant difference was observed, with a combined value of -0.29 (95% CI, -1.81 to 1.23, P=0.71). **Conclusion:** This meta-analysis suggests that Donanemab is capable of reducing amyloid plaque levels in patients with AD. Additionally, improvements in the iADRS scale were also noted, although the CDR-SB scale did not show statistical significance. Randomized trials are warranted to further investigate this question.

Assessing the impact of serological profiles on clinical outcomes in suspected paraneoplastic neurological syndromes

Mariana Ribeiro Pereira[1], Ana Flávia Andrade Lemos[1], Amanda Vitória Freire de Oliveira[1], Lucas Gondim Briand Vieira[1], André Cleriston José dos Santos[1], Rodrigo S. S. Frezatti[1], Giuliana França Teixeira Mandia Grossi[1], Vanessa Daccach[1], Pedro José Tomaselli[1], Wilson Marques Junior[1]

[1]Universidade de São Paulo, Faculdade de Medicina de Ribeirão Preto, Hospital das Clínicas, Ribeirão Preto SP, Brazil.

Correspondence: Mariana Ribeiro Pereira; Email: pribeiromariana@gmail.com.

Background: Paraneoplastic neurological syndromes are a rare group of disorders caused by autoimmune responses that are often, but not always, associated with known cancers. Antibodies directed to intracellular neuronal antigens and neuronal cell-surface or synaptic antigens have been described as causative. Among paraneoplastic autoantibodies, anti-Hu, anti-Ma2/Ta, anti-Ma, anti-Ri, and anti-Yo antibodies are known for their association with various neurological manifestations. **Objective:** To analyze patients serological profile and clinical evolution with suspected paraneoplastic neurological syndromes. **Methods:** Clinical and serological data were retrospectively gathered from patient records using a standardized proforma. Data collection included key parameters such as sex, age at disease onset, type of neurological syndrome, cancer type (if present), and clinical outcomes. 274 patients with neurological disorders suspected to be paraneoplastic were included. **Results:** Neuronal autoantibodies were detected in 10/274 (3.78%) of patients. A broad range of neurological symptoms was recorded in patients who tested positive, including cerebellar and sensory ataxia (5), rapidly progressive dementia (2), multiple mononeuritis (1), lower motor neuron syndrome (1), and unresponsible bilateral optic neuritis (1). The most frequently detected autoantibodies were Yo (4/10, 40%), followed by Hu (2/10, 20%) and Ma2/Ta (2/10, 20%). Anti-Ma antibodies were identified in one patient, and anti-Ri antibodies were found in another. Among the 264 patients who tested negative for antibodies, a wide range of diagnoses were observed, with no clear association with specific types of cancer. This group generally exhibited a better prognosis and more favorable responses to symptomatic treatment. Patients positive for paraneoplastic autoantibodies exhibited severe and more rapidly progressive neurological manifestations, regardless of the associated cancer. These findings suggest that the presence of these autoantibodies is a critical factor in managing these patients. However, our cohort shows reduced sensitivity and specificity in detecting a positive diagnosis, possibly suggesting an elevated testing rate. **Conclusion:** The presence of neuronal autoantibodies is associated with more severe neurological manifestations irrespective of association with cancer. In contrast, patients negative for these autoantibodies presented with more varied neurological symptoms and generally better prognosis. Therefore, early identification of autoantibodies remains crucial for patient care, even in the absence of detectable tumors.

Assessment and management of patients with syndromic craniosynostosis associated with hydrocephalus

Letícia Mansano de Souza[1], Sérgio Lourenço Polo Filho[1], João Pedro Leite Pereira[1], Fernando Cendes[1], Enrico Ghizoni[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Sérgio Lourenço Polo Filho; Email: s205772@dac.unicamp.br.

Craniosynostosis is the premature closure of cranial sutures, causing deformities and cranioencephalic disproportion. It can be diagnosed before birth with imaging methods. There are primary types, simple or complex, and secondary types, with complexes being syndromic and non-syndromic. Syndromic forms are linked to genetic conditions such as Apert syndrome. The main treatment is surgery to mitigate complications such as intracranial hypertension and hydrocephalus, focusing on reducing intracranial pressure to preserve cognitive and visual functions. The present study, with a retrospective and non-randomized cohort design, aimed to establish correlations between the presence of hydrocephalus in patients with syndromic craniosynostosis, whether or not undergoing surgical procedures for treatment in a tertiary hospital. The computed tomography images were analyzed in the hospital database using the Horos 4.0.1 for Apple software to determine the size of the anatomical structures of the project patients. A total of 21 patients with syndromic craniosynostosis were included in the research, with a mean age of 5 years (standard deviation of 2.2). In the sample, 43.2% of patients were female. Of the patients evaluated, 71.6% of patients had Apert syndrome, 14.92% had Crouzon, 10.44% had Pfeiffer and 2% had Chotzen. In the neuroimaging exams of the research patients, 61.9% showed early closure of the bilateral coronal sutures, with a brachycephalic skull shape. Anomalous emissary veins were observed in 57% of patients, 76% of patients had hypoplastic jugular foramen. In most of the analyzed cases of Apert, Pfeiffer and Crouzon syndromes, a higher incidence of development of hydrocephalus was observed compared to ventriculomegaly. Hydrocephalus is more common in these patients due to compression of intracranial structures and disturbances in CSF absorption, which can result in changes in cranial anatomy. Surgical approaches were used in the research patients, including posterior decompression (40.4% of the sample), posterior distraction (33.3%) and fronto-orbital advancement (21.4%), also known as FOA, and posterior decompression or distraction plus FOA (4.8%). In post-surgical neuroimaging studies, encephalomalacia was observed, frequently associated with focal epilepsy, suggesting pathophysiology similar to traumatic epilepsy, non-genetic or resulting from brain malformations. Among patients with epilepsy, 61.1% developed the disease after surgery, while 38.8% already had it before the surgical procedure. Craniosynostosis presents a complex challenge that involves early diagnosis, multidisciplinary management and specialized surgical treatment. This study provides valuable information about the association between different genetic syndromes and the development of hydrocephalus. However, there are challenges such as the continued need for research to better understand and personalized treatment of these complex conditions.

Assessment of changes in the sleep/wake cycle of medical students at a private university

Clara Alves Caram[1], Lucas Seri Iijima[1], Mércia Tancredo[1]

[1]Pontifícia Universidade Católica de São Paulo, Sorocaba SP, Brazil.

Correspondence: Clara Alves Caram; Email: claracaram@outlook.com.

Background: Sleep is an essential biological process for humans and has an important role in maintaining homeostasis in the body's environment. It is a complex state of physiological processes with its own behavioral characteristics. Studies show that anxiety disorders and depression affect a high proportion of university students. Among Medicine students, this rate is even higher, due to the high workload and emotional stress faced by students on this course. For this reason, many students use psychotropic drugs, such as antidepressants and anxiolytics, in order to reduce the symptoms of these diseases. Discovered in the 1950s, these medications act on the central nervous system and have a direct impact on the sleep/wake cycle. This, in turn, is essential for the proper functioning of higher brain functions such as memory and learning. **Objective:** To understand changes in the sleep/wake cycle of medical students at a private university. **Methods:** After approval by the Ethics and Research Committee and acceptance of the Free and Informed Consent Form, medical students at a private university responded to a digital form (Google Forms®) developed for this research, on sleep/wake rhythm and the use of psychotropic drugs, with questions based on the Pittsburgh Sleep Quality Index, adapted for Brazil. **Results:** Among 102 students, the majority had good or very good sleep (56.9% and 11.7% respectively), but 24.5% had poor sleep and 6.8% had very poor sleep. In relation to students with very poor or poor sleep, 21.6% of students use antidepressants/anxiolytics and 6.8% do not. Most (68%) have been using psychotropic drugs for more than 2 years. Furthermore, 59.6% use it before starting graduation. When segmenting for clinical indication, the majority (90%) of participants with poor or very poor sleep experience anxiety and/or depression. Furthermore, 68% resorted to therapy and only 3% use sleeping pills. **Conclusion:** The predominant profile of medical students with changes in the sleep/wake cycle is mainly characterized by the diagnosis of anxiety and/or depression, use of antidepressants and/or anxiolytics prior to entering college and for more than 2 years and positively the search for complementary treatment with individual psychotherapy and the non-use of specific sleep medications.

[3]Santa Casa de Misericórdia de São Paulo, Faculdade de Ciências Médicas, São Paulo SP, Brazil.

Correspondence: Marcelle Sanjuan Ganem Prado; Email: cellesanjuan@yahoo.com.br.

Background: Progressive multiple sclerosis (PMS) is a type of MS that leads to a gradual increase in disability without relapses. **Objective:** To evaluate changes in EDSS functions in patients with Progressive Multiple Sclerosis (pwMSP), aiming to define rehabilitation strategies to improve quality of life (QoL). **Methods:** It is a retrospective observational study involving 33 patients diagnosed with pwMSP who were treated at Santa Casa de Misericórdia hospital in São Paulo, Brazil. Medical records were analyzed between the months of December/23 to March/24. The EDSS scale and functional systems analysis were used to collect data. Person's Chi-square test was used for statistical analysis. **Results:** Of the 33 patients evaluated with pwMSP, 6.1% (2) had EDSS less than or equal to 5.0; 54.5% (18) had EDSS between 5.5 and 6.5 and 39.4% (13) had EDSS greater than 7.0. Younger ages were observed in the group with EDSS greater than 7 (48.5 years) compared to those with EDSS < 5.5 and EDSS between 5.5 and 6.5 (56 yo and 58.9 yo respectively). Among the most altered parameters in EDSS have brain stem function (p=0.05), mainly dysarthria, in patients with EDSS greater than 7. As for the complaint of bladder changes, this was more present in EDSS greater than 7.0 (p=0.03), the same did not occur with intestinal functions. Cognitive and coordination changes in the upper limbs were the most frequently observed sequelae in patients with minor EDSS, although without statistical significance. **Conclusion:** Although the sample is small, the findings provide us with information about the main characteristics of pwMSP in the studied group, indicating the needs of pwMS regarding possible interventions to improve QoL.

https://doi.org/10.5327/CBN240190

Assessment of respiratory function in Friedreich's ataxia

Celiana Figueiredo Viana[1], Cristina Saade Jaques[1], Flavio Moura Rezende[1], Orlando Graziani Povoas Barsottini[1], José Luiz Pedroso[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Celiana Figueiredo Viana; Email: celianafigueiredo@hotmail.com.

Background: Friedreich's ataxia (FRDA) is the most common cause of autosomal recessive ataxia. It is caused by expanded guanine-adenine-adenine (GAA) triplet repeats in the first intron of the frataxin gene (FXN), resulting in reduction of mRNA and protein levels of frataxin in different tissues. FRDA can lead to sleep disorders, respiratory complications and dysphagia. The purpose of this study is to evaluate the respiratory function in Friedreich ataxia. **Objective:** To evaluate the lung function of individuals diagnosed with Friedreich's ataxia through respiratory function tests and phrenic nerve conduction when compared to the healthy controls. Furthermore, to correlate respiratory assessment data with demographic data (age, duration of the disease), anthropometric data (weight, height, BMI, cervical and abdominal circumference) SARA and ICARS scales on the Friedreich's group. **Methods:** A total of 15 individuals with FRDA and 20 healthy controls were recruited. The patients and controls underwent, spirometry assessment, inspiratory and expiratory pression test, sniff test and Peak cough flow test. **Results:** Thirty-five participants, with an age of 37.1 years (standard deviation 11.0) were included in the study. Among them, 42.9% (15 participants) were from the Friedreich's group, while 57.1% (20 participants) were healthy controls. There were no differences in sex or age between the groups, but Friedreich's group had significantly lower weight, height, and BMI ($p=0.04$, $p<0.01$ and $p<0.01$, respectively). Friedreich's group had significantly lower values of respiratory parameters (forced vital capacity (FVC), forced expiratory volume in first second (FEV1), PEF, oxygen saturation, respiratory and cardiac frequencies, maximal inspiratory effort in the supine and seated positions, and sniff nasal inspiratory pressure, (all parameters with $p<0.01$), when compared to the control group. There were no differences among the mean and maximum phrenic amplitude's ($p=0.42$ and $p=0.37$, respectively) between groups. For both SARA ($rho=0.70$, $p<0.01$) and ICARS (0.59; $p=0.03$), the Friedreich's group shows a moderate correlation in the duration of disease. There was no statistically significant correlation among SARA or ICARS scale and anthropometric data. **Conclusion:** Evaluating respiratory function in patients with FRDA is crucial for guiding respiratory physiotherapy and preventing life-threatening complications. More studies are necessary to identify respiratory complications in Friedreich ataxia and these findings could be useful when approaching progressive neurological disorders.

https://doi.org/10.5327/CBN240191

Assessment of the accuracy of stroke protocol screening by the emergency medical services

Victoria Cavalcanti de Souza[1], Ester Namie Hanai[1], Alice Volpato Rocha[1], Laura Louise Marques Nobrega Vieira[1], Gabriel Volpato Rocha[1], Viviane de Hiroki Flumignan Zétola[1]

[1]Universidade Federal do Paraná, Curitiba PR, Brazil.

Correspondence: Victoria Cavalcanti de Souza; Email: victoriacavalcantisouza@gmail.com.

Background: Early recognition of Stroke (Cerebrovascular Accident, CVA) within the treatment window directly influences patient outcomes and prognosis. Most patients will access qualified healthcare centers through the ambulance service. However, we have limited data on the challenges in the prehospital period and the screening performed. **Objective:** To evaluate the accuracy of the Stroke Protocol of the Emergency Medical Service (SAMU) in identifying and referring stroke cases. **Methods:** This is an observational retrospective study in which patients directed by the Stroke Protocol via SAMU to a designated hospital in Curitiba from January 2023 to May 2024 were included in the analysis. The evaluated outcome was the final diagnosis upon patient admission, based on medical record review. In cases where the diagnosis was not specified in the patient charts, complementary imaging exams were reviewed with the assistance of a specialist neurologist. Cases that remained without a specific diagnosis were grouped separately. **Results:** Medical records of 297 patients were reviewed. 206 cases (69%) were confirmed with a diagnosis of Stroke (ischemic [176; 85.43%] and hemorrhagic [30; 14.56%]), thus accurately diagnosed by SAMU (accuracy of 69%). Among the main differential diagnoses were seizure (29; 9.76%), stroke mimics (17; 5.72%), syncope (6; 2.02%), headache (6; 2.02%), and subarachnoid hemorrhage (4; 1.35%). 18 patients (6.06%) were grouped into other diagnoses, and 11 (3.70%) did not have a specified diagnosis at the time of hospital discharge. **Conclusion:** The prehospital diagnostic accuracy of the SAMU Stroke Protocol was 69%. Therefore, there is plenty of room for improvement in diagnostic precision. It is important to continue conducting training sessions with the National Institutes of Health Stroke Scale (NIHSS) and to make adjustments and enhancements to ensure the advancement of the Stroke Protocol and provide a better prognosis for those affected by stroke within the appropriate time frame.

Assessment of the pain perception threshold by electrical algometry in migraine and healthy individuals: preliminary study

Renata Michelini Guidi[1], Felipe Franco de Graça[2], Antônio Augusto Fasolo Quevedo[1]

[1]Universidade Estadual de Campinas, Faculdade de Engenharia Elétrica e de Computação, Campinas SP, Brazil.
[2]Universidade Estadual de Campinas, Departamento de Neurologia, Campinas SP, Brazil.

Correspondence: Renata Michelini Guidi; Email: guidirm@gmail.com.

Background: Pain is the brain's interpretation of stimuli captured by nerve structures in the skin, viscera and muscles. Migraine is a type of headache with severe pain symptoms and has a major impact on daily occupational activities and quality of life. Measuring the pain perception threshold plays an important role in evaluating pain improvement throughout treatment. Electrical algometry quantifies the threshold of pain perception and pain tolerance through electrical stimulation of nociceptors present in the skin. **Objective:** To evaluate the pain perception threshold by electrical algometry in migraine and healthy individuals and to establish a protocol for the use of electrical algometry. **Methods:** Observational study was conducted with 14 female individuals, 7 with chronic migraine and 7 healthy. The anatomical points were assessed bilaterally as the temporal, frontal and masseter muscles and the C5/C6 zygapophyseal joint. Measurements were carried out using electrical algometer with two different protocols, the ramp mode and random mode. The difference between the algometry protocols on the sides of the body was evaluated for each anatomical point. Predominant pain side and the contralateral side for migraines, and the dominant and non-dominant side for healthy patients. **Results:** The migraine group (41.4±7 years) had 71% of participants with predominant pain on the right side and 29% with predominant pain on the left side. There was no statistical difference between algometry protocols in the anatomical points evaluated. The only exception was the temporal muscle on the predominant pain side with a significant difference between the algometry protocols, which suggests that there was accommodation of the nociceptor fibers in ramp mode (pain threshold = 7.5 ±1.2 mA), presenting lower pain threshold value (6.4 ±1.2 mA) in random mode. This may be related to greater local sensitivity, which corroborates the participants' reports that the headache is more intense and more present in the temporal region compared to other areas. However, for the healthy group (39±3.5 years), there was significant difference between the algometry protocols on both sides and in all anatomical points, suggesting a probable accommodation of peripheral nociceptor fibers. When comparing groups, the pain thresholds showed significant differences in all anatomical points. The migraine group had lower pain thresholds compared to the healthy group. **Conclusion:** Our study is the first to evaluate pain thresholds in migraine with electrical algometry, showing that pain thresholds are lower in migraine compared to healthy individuals. This may be related to the presence of dysfunctions in pain modulation mechanisms or greater local sensitivity due to the chronic disease. The most appropriate evaluation protocol for electrical algometry seems to be random mode, which is capable of reducing interference from the accommodation of nociceptor fibers in measurements.

Assessment of trigeminal nerve integrity in young adults

Eduardo Rocha Arruda[1], Carlos Ernesto Garrido Salmon[2], Antonio Carlos dos Santos[1]

[1]Universidade de São Paulo, Faculdade de Medicina de Ribeirão Preto, Ribeirão Preto SP, Brazil.
[2]Universidade de São Paulo, Faculdade de Filosofia, Ciências e Letras de Ribeirão Preto, Ribeirão Preto SP, Brazil.

Correspondence: Eduardo Rocha Arruda; Email: duarruda@alumni.usp.br.

Background: Some chronic orofacial pain diseases have a well-defined etiology, such as classic trigeminal nerve (TN) neuralgia. However, in idiopathic trigeminal neuralgia, the individual presents the same symptoms as classic neuralgia, but not the same cause, which suggests a problem directly in the nerve. Diffusion Tensor Imaging (DTI) is the MRI technique that allows the assessment of white matter integrity using diffusion metrics such as fractional anisotropy (FA). Studies on the integrity of the trigeminal nerve in young, healthy adults contribute to defining a standard of normality, but are scarce in the current literature and have a small number of individuals. **Objective:** To evaluate the integrity of the NT of healthy young adults, using the DTI and verify the behavior of the AF values, as well as the bilateral asymmetry of this metric considering the effect of the individuals' age and sex. **Methods:** Structural and diffusion MRI data from 312 healthy individuals, 155 men and 157 women, aged between 22 and 40 years, were obtained from the Human Connectome Project, HCP database and separated into 8 groups considering age and sex. T1w images were used for bilateral marking of the regions of interest (ROIs): NT, root entry zone, middle portion of the cistern and Merckel's cave. The marking of ROIs, the generation of FA maps and the calculation of the average of this metric in the aforementioned regions were done using the MRTrix3 software. With the FA values, bilateral asymmetry was determined in all ROIs according to the expression: A = (FAd - FAe)/(FAd + FAe)*100. The results were analyzed by applying the ANOVA test with a significance threshold of $p<0.05$. **Results:** When comparing the FA values and their asymmetry in the different ROIs, there were no differences between any of the 8 groups when considering the age effect. FA values are higher bilaterally in women in the regions of the NT, root entry zone and in the middle portion of the right cistern (FA women (0.32±0.12); FA men (0.28±0.11); $F(1.898) = 19.78$; $p<0.001$). In the middle portion of the left cistern and Marckel's cave bilaterally, there was no significant difference between the sexes. **Conclusion:** Age does not influence FA values

or laterality asymmetry in any portion of the NT in young adults. However, sex should be considered a confounding factor when evaluating the integrity of the TN, the root entry zone and the middle portion of the right cistern.
Keywords: Trigeminal nerve, DTI, young adult.

Assistive technology for communication accessibility in Machado Joseph disease

Bernardo Caetano Novaes[1], Lara Valentim Vale[1], Igor Dutra Braz[1], Claudia Yamada Utagawa[1]

[1]Centro Universitário de Volta Redonda, Volta Redonda RJ, Brazil.

Correspondence: Bernardo Caetano Novaes; Email: bernardo16.novaes@gmail.com.

Background: Machado Joseph disease (MJD), or spinocerebellar ataxia type 3 (SCA3), is an autosomal dominant neurodegenerative disorder, affecting 1 per 50,000-100,000 individuals. It is the most common hereditary ataxia. The manifestations include dysarthria, lack of motor control, and ophthalmoplegia, creating communication barriers that require assistive technologies to maintain patients´s autonomy, independence, quality of life. **Objective:** This study aims to understand the needs of a 53-year-old patient with MJD through reports from the patient, her family members, and caregiver, and to promote communication accessibility interventions using assistive technologies to optimize her quality of life. **Methods:** Approved by the Ethics Committee (CAAE 163692622.7.0000.5237), a clinical follow-up was performed for one year. Quality of life assessments and semi-structured interviews were conducted with the patient who had been living with the disease for eight years, as well as with family members and the caregiver regarding communication difficulties (verbal, visual/reading, writing, and gestural) and the strategies used to overcome them. Six months after the proposal of assistive technologies, new interviews were conducted, including their perceptions of using these technologies. **Results:** The analysis of the interviews led to the implementation of several assistive technologies, considering the patient's difficulties, disease stage, smartphone access as her preferred communication device. The implemented tools were screen zoom and character enlargement, replacement of typed texts with audio conversations, use of Google Assistant, and Voice Access. The enlargement of characters and screen zoom facilitated the reading of texts and images, mitigating diplopia. Audio communication, despite the patients' slowed speech, made social communication easier. Google Assistant, designed for speech-to-text conversion, had limited use due to slowed speech but it helped convert speech into written messages. Although Voice Access also converted speech to text, the patient preferred not to use it continuously due to its impact on smartphone usability. Other technologies such as SymboTalk, Head Mouse, and TalkBack were proposed but not evaluated due to the current stage of the patient. However, we believe they could be useful as the disease progresses. **Conclusion:** This study proposes interventions with communicational assistive technologies, recommending the use of audio in social networks, screen and character enlargement, and Google Assistant for voice typing in the early stages of the disease. Voice Access did not have good adherence from the patient. The interventions showed a significant positive impact, suggesting that these strategies may benefit other patients with MJD in similar disease stages.

Correspondence: Luísa Dias Moreno Aravena; Email: luisaaravena@ufba.br.

Background: Stroke is still socially considered as a disease that affects only the elderly. There is a lack of awareness about the frequency of stroke in the younger population and less perception of stroke-like symptoms as an emergency. Moreover, premature stroke may represent an evaluation challenge for healthcare professionals, resulting in misdiagnosis and diagnosis delay. Despite lower mortality, younger patients present impaired quality of life, social and economical burden as part of the labour force population. Therefore, early identification is needed to implement correct management and etiology investigation, in order to improve functional outcomes. **Objective:** To evaluate the association between age and ictus-admission time in a stroke unit (SU). **Methods:** This is a cross-sectional study that included patients with confirmed acute stroke in a SU in northeastern Brazil between July 2023 and April 2024. Confirmed acute stroke, age over 18 years and time interval between ictus and study inclusion below 72 hours were the inclusion criteria. Demographic and clinical data were analyzed. Age was dichotomized into elderly (≥60 years) and non-elderly (<60 years), based on the Brazilian Statute of the Elderly. We subtracted the time of admission to the SU from the time of symptom onset to find the ictus-admission time. The Mann-Whitney test was used to evaluate the association between age and time between ictus and admission. **Results:** Two hundred eight patients were enrolled. The majority of patients were female, 108 (51.9%), and the mean age was 65.7 years old (SD=±12.5). The median time between ictus and admission in SU was 7.9 hours (IQR=2.5-8.5). In the dichotomous analysis, <60 years of age were 28.4% of the patients and yours median ictus-admission time was 5 (IQR=3-15), while ≥ 60 years accounted for 71.6% and had a median ictus-admission of 4 (IQR=2.5-6) hours. The Mann-Whitney test showed that age has an effect on the time from ictus to admission (U=3,526; p=0.026). 40.2% of non-elderly patients and 64.4% of those elderly were admitted within the thrombolysis time. The median admission NIHSS for <60 years was 8 (IQR=4-14) and for ≥60 years was 7 (IQR=4-12), but there was no effect of age on patient admission NIHSS (U=3,886; p=0.620). **Conclusion:** Our study indicated that non-elderly patients had a lower ictus-admission gap and thus arrived faster at the healthcare service compared to those elderly. However more studies are needed to understand the factors that influence this time difference.

Association between alpha-1-antitrypsin levels and intracranial aneurysms: a case-control study

João Paulo Mota Telles[1], Jefferson Rosi Junior[1], Julia Leal Bassan[1], Eberval Gadelha Figueiredo[1]

[1]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: João Paulo Mota Telles; Email: joao.telles@fm.usp.br.

Background: Comprehending the mechanisms involved in the formation of intracranial aneurysms can contribute in predicting the risk of its development and provide different types of treatment. **Objective:** This case-control study aimed to compare alpha-1-antitrypsin levels between patients with ruptured and unruptured intracranial aneurysms. **Methods:** We retrospectively analyzed medical records of patients that had collected alpha-1-antitrypsin levels from 2018-2022. A total of 233 patients were identified as having unruptured intracranial aneurysms and 114 were identified as having ruptured intracranial aneurysms. The control sample was formed by 55 patients that had intracranial arteriovenous malformation without aneurysms. **Results:** Alpha-1-antitrypsin mean levels in the unruptured group were 134.9 (±23.3), compared with 132.1 (±20.3) in the ruptured group, which was similar to 132 (±19), the alpha-1-antitrypsin mean level in the control group. Alpha-1-antitrypsin level was not associated with the presence (compared to controls, OR 1.07, 95% CI 0.93-1.25) or rupture (compared to unruptured, OR 0.94, 95% CI 0.84-1.04) of intracranial aneurysms. Alpha-1-antitrypsin levels were not associated with vasospasm (OR 0.94, 95% CI 0.93-1.25) or functional outcomes (mRS ≤ 2, OR 0.77, 95% CI 0.51-1.27). **Conclusion:** alpha-1-antitrypsin levels did not differ between patients with ruptured and unruptured aneurysms. Alpha-1-antitrypsin levels were also not associated with vasospasm or functional outcomes.

Background: As the most widely used drug globally, cannabis has been the subject of numerous studies investigating its health effects. Recent studies have explored the potential link between cannabis use and stroke events, revealing conflicting findings. **Objective:** To determine the real association between cannabis and stroke episodes, contributing to the existing evidence on this topic. **Methods:** We searched PubMed, Scopus, and Web of Science databases for studies investigating the association between cannabis exposure and stroke occurrences. Outcomes of interest included overall stroke incidence and specifically ischemic stroke rates. We computed odds ratios (ORs) for binary endpoints, with 95% confidence intervals (CIs). Heterogeneity was assessed using I^2 statistics. For this meta-analysis, statistical analysis was performed using Review Manager 5.4.5 software. **Results:** A total of 21 studies and 146,873,842 patients were included. Most patients were women (71.60%). The meta-analysis revealed that the ischemic stroke rate was homogeneous between cannabis users and non-users (OR 1.22; 95% CI 1.10-1.35; p = 0.0001; I^2=41%). In contrast, the overall stroke rate was significantly higher in the non-users group (OR 1.85; 95% CI 1.52-2.27; p<0.00001; I^2= 62%). The results showed a significant difference in favor of the control group in terms of increased stroke risk (0.446370% vs 0.273191%; OR 0.72; 95% CI 0.70-0.74; p<0.00001; I^2=99%) or ischemic strokes (0.290268% vs 0.244143%; OR 1.08; 95% CI 1.04-1.12; p<0.0001; I^2=95%) compared with the non-cannabis exposed group. **Conclusion:** While previous studies have produced inconsistent results, this meta-analysis indicates that cannabis use is not significantly associated with higher rates of stroke or ischemic stroke compared to the control group. These findings highlight the importance of continued research to further understand how cannabis use can affect health outcomes.

Association between diffuse glioma and ischemic stroke in a pediatric patient: a case report

Angelo Ponte de Freitas Campos[1], Rodrigo de Paiva Bezerra[1], Marcel Ken Uehara[1], Beatriz Casella[1], Alessandra Milani Prandini de Azambuja[1], Vicente Odone Filho[1], Gisele Sampaio Silva[1]

[1]Hospital Israelita Albert Einstein, São Paulo SP, Brazil.

Correspondence: Angelo Ponte de Freitas Campos; Email: campos_angelo@hotmail.com.

Case presentation: We describe this case of a female patient, 2 years old, previously healthy. At three months she was diagnosed with a diffuse BRAF-KIAA1549 glioma, due to an episode of bilateral nystagmus and drowsiness. MRI revealed a contrast-enhancing expansive lesion in the hypothalamic-chiasmatic region associated with multiple leptomeningeal implants in the cervicodorsal transition without signs of myelopathy. After the introduction of chemotherapy, she was readmitted at 2 years of age due to acute worsening of strabismus with reports of abnormal hand and head movements. A new Cranial MRI showed an extensive area of diffusion restriction and signal alteration in T2/FLAIR in the left frontoinsular cortical area, consistent with a recent ischemic event in the territory of the left superior M2 division of the middle cerebral artery. Increased T2/FLAIR signal in the left cerebellar hemisphere, suggestive of subacute recent ischemic foci. Cerebral angiography revealed moderate stenosis at the origin of the superior division of the M2 segment of the left middle cerebral artery. Further investigation of a cerebrovascular event in a young patient was carried out with TTE showing no microbubble passage and TCD showing no active embolization. Regarding thrombophilia screening, there were no abnormalities justifying the event. **Discussion:** Few studies correlating gliomas and cerebrovascular events are currently available in the literature. Observational studies that have identified the tumor's topography with the highest risk of ischemic events. Cancer represents one of the major causes of ischemic stroke classified as ESUS (Embolic Stroke of Undetermined Source) with an estimated subgroup incidence of 10% of cases. Several mechanisms described in the literature explain the occurrence of ESUS in these patients, among which are paradoxical embolism, non-bacterial thrombotic endocarditis, aortic atheroma, and more rarely, tumor embolism. Regarding treatment, the current literature still diverges on the best therapy to adopt. There is a lack of data on the best treatment regimen for this subgroup of patients with ischemic stroke. In summary, there has been no superiority among anticoagulants as well as an increased risk of bleeding if antithrombotics are chosen. **Final comments:** Oncological patients with acute ischemic stroke should be regarded as a heterogeneous subgroup, thus requiring extensive investigation of the underlying cause of the cerebrovascular event. Patients with the investigation ends in an unknown cause or ESUS, anticoagulation or even antithrombotic therapy still represents a frontier of knowledge available in the literature. In these cases, the decision should be individualized, weighing the risks and benefits of each proposed therapy. Serum D-dimer levels appear to be a useful tool in aiding the early initiation of secondary prophylaxis as well as in monitoring these patients, given its association with increased risk of ischemic stroke.

Correspondence: Caio Fontes do Nascimento; Email: caiofontesdn@hotmail.com.

Background: Stroke is currently one of the leading causes of morbimortality in Brazil and worldwide. Unfortunately, the availability of reperfusion therapies (RT) in Brazil's public health system is limited, and the time window for the effective use of these therapies is relatively short. The development of stroke units (SU) has provided a new perspective for patients admitted to hospitals who are not eligible for RT, showing evidence of better prognoses compared to conventional hospital care settings. **Objective:** To analyze the correlation between the interval from ictus to admission in a stroke unit and functional outcome among patients who did not meet the criteria for RT. **Methods:** This study was a prospective cohort that followed patients who suffered a stroke with a time from ictus to admission to a SU of less than 72 hours between July 2023 and May 2024. All described information was collected from medical records. The functional outcome variable at hospital discharge, at 30 days, and at 90 days was measured using the modified Rankin Scale (mRS). The Mann-Whitney test was used to assess the difference in average time from ictus to admission between the groups, and the Spearman test was utilized to measure the correlation between the variables. **Results:** A total of 114 patients met the inclusion criteria. The mean age was 63.23±12.97, with 21% of all patients showing delirium during hospitalization and a median ictus-admission time of 360 minutes (range: 30 - 3270). When comparing patients with good outcomes (mRS<3) in hospital discharge, 30 days and 90 days and those with bad ones (mRS≥ 3), no difference was found in ictus-admission time ($p<0.05$). Furthermore, there was no statistical significance in correlations between outcomes in hospital discharge (rho = -0.188, p=0.054), 30 days (rho = -0.119, p=0.223) or 90 days (rho = -0.169, p=0.133), and the ictus-admission time, even when analyzing patients with mRS below (rho = -0.153, p=0.216) or above 1 (rho = -0.453, p=0.188), younger (rho = -0.351, p=0.168) or older (rho = -0.050, p = 0.695) than 55 years, and with (rho = -0.004, p=0.989) or without (rho = -0.156, p=0.215) delirium. **Conclusion:** The sample studied exhibited epidemiological data and delirium occurrence frequencies consistent with those reported in current literature. However, no statistically significant correlation was found between the time from ictus to admission in SU and functional outcomes. We attribute this, in part, to the exclusion criterion of a time from ictus to admission greater than 72 hours, which significantly restricted the sample size. Well-established evidence indicates that admission to SU can enhance patients prognosis compared to other hospitalization settings. The results of the study reinforce the importance of RT in improving patient outcomes, however further studies are necessary to determine if early admission can also contribute to better results.

https://doi.org/10.5327/CBN240200

Association between microembolic signals on transcranial doppler and brain atrophy in patients with Chagas disease

Ayla Morais Vitório Guerra[1], Cárita Victória Carvalho de Santana[1], Renan Carvalho Castello Branco[2], Pedro Fernandes Abbade[1], Isabella Reis Vieira[1], Beatriz Malaquias Neves[1], Israela Souza Brito Santos[1], Bruno Felipe Santos de Oliveira[1], Thiago Cerqueira Silva[1], Jamary Oliveira Filho[1]

[1]Universidade Federal da Bahia, Salvador BA, Brazil. [2]Universidade Federal do Recôncavo da Bahia, Cruz das Almas BA, Brazil.

Correspondence: Ayla Morais Vitório Guerra; Email: aylaguerra1@hotmail.com.

Background: Chagas disease (CD) is a neglected chronic disease associated with central nervous system impairment, such as stroke, cognitive dysfunction, microembolic signals (MES) and brain atrophy. However, the relationship between MES and brain atrophy in patients with CD has not been studied. **Objective:** To investigate the association between MES and central nervous system volume in patients with heart failure (HF) of chagasic and non-CD origin. **Methods:** Cross-sectional study conducted between 2002 and 2024 with participants from a cardiology outpatient clinic in Salvador-BA, aged > 18 years, diagnosed with HF by Framingham criteria; CD was confirmed by ELISA or immunofluorescence test, in duplicate. We excluded those with a history of previous stroke, dialysis, chronic parenchymal liver disease, history of malignancy, use of anticoagulants, or metallic prostheses. Eligible participants underwent bilateral transcranial Doppler (TCD) examination of the middle, anterior (ACA), and posterior (ACP) cerebral arteries for one hour to detect signs of MES. Additionally, they underwent cranial magnetic resonance imaging (MRI) to evaluate volume of several brain structures after automated volume assessment using FreeSurfer version 7.4.1 software. We performed univariate tests to assess associations between MES and brain volumes. **Results:** The sample consisted of 336 participants with HF, 45% male, 51% with CD. The mean age among CD participants was 55.5±10.6 years, and the mean ejection fraction was 50.4±17.7%. The presence of MES in TCD was observed in 19 (11%) of CD participants and 11 (7%) non-CD participants. Univariate tests in participants with CD showed that the MES group had a lower mean volume of the ventral diencephalon (3.3±0.7 ml non-MES vs 3.1±0.8 ml MES; p = 0.047). In non-CD participants, the MES group had a lower mean volume of the isthmus of the cingulate gyrus (2.6±0.4 ml non-MES vs 2.4±0.3 ml MES; p = 0.008) and a lower mean volume of the paracentral cortex (3.7±0.5 ml non-MES vs 3.2±0.6 ml MES). No significant differences in the presence of territorial and lacunar infarcts were observed between the groups with and without MES. **Conclusion:** Presence of MES may influence cerebral volume in several anterior circulation structures, highlighting the need for further investigation into its role in the progression of cerebral atrophy in patients with HF, both CD and non-CD patients.

Association between migraine and autism spectrum disorder: a case series of 10 patients

Eduardo Souza Cardoso[1,2,3], Gabriel Eduardo Pereira Cardoso[4], Adileia Santos da Silva[3], Carla Soares Souza[3], Maria da Gloria Canto de Sousa[2], Ana Patricia Pascoal Queiroz de Araujo[2], Grace Patricia Santana Pereira Cardoso[5], Jéssica de Andrade Ribeiro Lima[2], Maiêva Pereira Ribeiro[2]

[1]Universidade Estadual de Feira de Santana, Feira de Santana BA, Brazil.
[2]Universidade do Estado da Bahia, Salvador BA, Brazil.
[3]Clinica IBIS, Salvador BA, Brazil.
[4]Faculdade Zarns, Salvador BA, Brazil.
[5]Hospital Portugues, Salvador BA, Brazil.

Correspondence: Gabriel Eduardo Pereira Cardoso; Email: Gabrielwer204@gmail.com.

Background: Migraine is a common neurological disorder marked by severe headaches, nausea, and sensitivity to light and sound. Autism Spectrum Disorder (ASD) Level 1 support is characterized by difficulties in social interaction, communication, and restricted behaviors,

often accompanied by sensory hypersensitivity and emotional dysregulation. This case series explores the overlap between migraine and ASD Level 1 support in 10 patients, emphasizing sensory hypersensitivity and emotional dysregulation. **Objective:** This study aims to explore the association between migraine and subsequent diagnosis of ASD Level 1 support, with a focus on sensory hypersensitivity and emotional dysregulation observed during clinical follow-ups. **Methods:** We included 10 patients with a confirmed diagnosis of migraine. These patients were followed up regularly and assessed for symptoms indicative of ASD Level 1 support. The focus was on identifying signs of sensory hypersensitivity and emotional dysregulation, which are common in both migraine and ASD. **Results:** The study included 10 patients, with a mean age of 32 years, comprising 7 females and 3 males. Migraine with aura was present in 60% of cases, with an average duration of migraine diagnosis of 5 years. The average time to ASD diagnosis was 2 years after the migraine diagnosis. All patients exhibited heightened sensitivity to light and sound during migraine episodes, and these sensory sensitivities persisted as characteristics of ASD. Additionally, 100% of the patients showed aversion to certain textures, sounds, and lights. Emotional dysregulation, including difficulties in managing emotions, frequent mood swings, and episodes of anxiety and irritability, was reported by 90% of the patients. This emotional instability significantly affected their social interactions and daily functioning. The coexistence of migraine and ASD Level 1 support, with pronounced sensory hypersensitivity and emotional dysregulation, suggests a potential interrelation between these conditions. Understanding the overlap in symptoms can facilitate early identification and comprehensive management, improving patient outcomes. The findings underscore the importance of recognizing sensory and emotional symptoms in patients with migraine, which may indicate an underlying ASD diagnosis. **Conclusion:** Identifying ASD in patients with migraine, particularly considering sensory hypersensitivity and emotional dysregulation, can significantly influence treatment strategies and improve quality of life. Further research is essential to elucidate the mechanisms linking these conditions and develop integrated therapeutic approaches. Early intervention and multidisciplinary care are crucial for managing these overlapping conditions effectively.

Association between risk of obstructive sleep apnea and stroke recurrence: a cohort study

Aurea Maria Lago Novais[1], Juliana Cerqueira Gomes[1], Marina Soledad Benitez Bitencourt[1], Thaise Braga de Oliveira[1], Renan Carvalho Castello Branco[2]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.
[2]Hospital Municipal de Salvador, Salvador BA, Brazil.

Correspondence: Aurea Maria Lago Novais; Email: aureanovais20.1@bahiana.edu.br.

Background: Obstructive sleep apnea (OSA) is a disease of upper airways, diagnosed with polisomnography, that is well associated with stroke through diverse mechanisms. Despite that, it still lacks studies about its role in prognosis of stroke, especially in stroke recurrence. **Objective:** This study aims to elucidate the possible association between stroke recurrence and risk of OSA. **Methods:** We performed a cohort. Patients were evaluated of risk of OSA with STOP-Bang and SOS scores and remotely evaluated with Rankin, Barthel, questioned about stroke recurrence and another hospitalization during 3.6 and 12 months. We performed univariate analysis (T test, Mann-Whitney or chi-square) and a multivariate analysis with logistic regression (considering P < 0.05). **Results:** We obtained 430 patients, 69.1% classified as high risk with STOP-Bang and 50,2% with SOS. 271 finished 3 months of follow-up, 180 finished 6 months and 112 finished 12 months. There was significant difference between groups in hypertension (p<0.001), sex (p<0.001), alcoholism (p=0.01), diabetes (p=0.002), obesity (p=0.01) and previous regular use of medication (p<0.001). In high risk group, Rankin 3 months median 2 (1-4; p=0.03), Rankin 6 months median 1 (1-4), Rankin 12 months median 1(1-4). In low risk group, Rankin 3 months median 2 (1-4), Rankin 6 months median 1 (1-3), Rankin 12 months median 1 (1-3). 15 patients recurred with stroke (71% of high risk; OR 1.2; CI 95% 1-1.4; rs=-0.2; p=0.05). 29 evolved to death (14 of high risk; OR=1.03; CI95% 0.55-1.9; p=0.92). This is the first study to describe association between OSA and stroke recurrence, with a relevant higher rate of recurrence in patients with high risk, denoting the role of OSA in occurrence and prognosis of cerebrovascular disease. Also, patients with high risk tend to have a worst recovery, especially in thirst 3 months,, in comparison to high risk. Higher rates of regular use of medications in high risk appears to reveal the presence of multiple comorbidities, with coexisting mechanisms of impairment. **Conclusion:** In face of this, it is important now to investigate the importance of, not only use risk scores in cerebrovascular disease, but treat obstructive sleep apnea as part of secondary prophylaxis.

Association between stroke etiology and functional outcomes

João Pedro Fernandes Gonçalves[1], Marivaldo Yslan Silveira Leal[1], Luísa Dias Moreno Aravena[1], Gabriel Souza Suzart[1], Lucca Borges Ornelas[1], Vinicius Bessa Mendez[1], Pedro Antonio Pereira de Jesus[1]

[1]Universidade Federal da Bahia, Salvador, BA, Brazil.

Correspondence: Luísa Dias Moreno Aravena; Email: luisaaravena@ufba.br.

Background: The TOAST classification is a widely used and well-described diagnostic approach regarding ischemic stroke etiology. However, the association of different stroke etiologies and functional outcomes is not well established. **Objective:** To assess the effect of different etiologies on functional outcomes of ischemic strokes. **Methods:** We conducted a prospective cohort of patients with a confirmed acute ischemic stroke in a single stroke unit in Brazil. The inclusion criteria were: confirmed acute ischemic stroke, the time interval between ictus and study inclusion below 72 hours and age over 18 years. Exclusion criteria included: RASS scale -4 or -5 at admission, diagnosis of severe bilateral vision or hearing loss and severe sensory aphasia. Stroke etiologies were divided following the Trial of ORG 10172 in Acute Stroke Treatment (TOAST) Classification. Functional outcomes were assessed by the modified Rankin scale (mRs) 90 days post-stroke by telephone interview. The mRs was dichotomized into good functional outcomes (mRs = 0-2) and poor functional outcomes (mRs = 3-6). The chi-square test evaluated the association between stroke etiology and functional outcomes. Anova, Kruskal-Wallis and chi-square tests assessed differences between possible confounding variables. **Results:** In total, 514 patients were included in the final analysis with a mean age of 63.1 (±13.3) years and 54.5% were men. The etiologies investigated and the frequency of poor functional outcomes were: large-artery atherosclerosis (48.6%), cardioembolism (38.9%), small-vessel occlusion (36.7%), incomplete investigation (33.8%), multiple causes (72%) and other defined causes (55.6%). Incomplete investigation was associated with good functional outcomes at 90 days (p<0.05) and multiple causes were related to poor functional outcomes (p<0.05). Relevant differences in age were found: incomplete investigation (61.1) showed a lower mean age when compared to large-artery atherosclerosis (67.6) and multiple causes (70.1), also multiple causes had a higher mean age compared to other causes (50.5). Incomplete investigation had a lower NIHSS median (7.0) compared to cardioembolism (9.0), while multiple causes had a higher NIHSS median (12.0) than small-vessel occlusion (6.0). No differences were found in the thrombolysis frequencies. **Conclusion:** Patients with an incomplete investigation may have better functional outcomes at 90 days, while patients with multiple possible causes may have worse functionality post-stroke. Unfortunately, the associations found may be due to the differences in confounding variables, such as age and NIHSS at admission. Further studies with larger samples and multivariate analysis are needed to help determine the role of stroke etiology in functional outcomes.

Association of neuromyelitis optica and rapidly progressive IgA glomerulonephritis: a case report

João Henrique Reis Duque Estrada[1], Caroline Vianna Costa Pinto[1], Luiza Guimarães Póvoa[1], Victor Waldhelm Cozer[1], Felipe Schmidt[1], Diogo Terrana[1], Sofia Mermelstein[1]

[1]Universidade do Estado do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: João Henrique Reis Duque Estrada; Email: joaohestrada2@gmail.com.

Case presentation: Our case involves a 35-year-old patient admitted for the investigation of sequential bilateral visual acuity loss and ascending paresthesia associated with gait disturbance. The patient reported experiencing a probable area postrema syndrome in March 2023, followed by partial cervical myelitis a few months later, and severe optic neuritis affecting both eyes by September 2023, when admitted to the Neurology ward. The preliminary diagnostic workup for infectious and autoimmune causes was negative, except for a positive anti-AQP4 antibodies detected by cell-based assay. She was then, diagnosed with Neuromyelitis Optica (NMO), with a relapsing course with minimal functional improvement between episodes. Additionally, upon admission, she presented with elevated creatinine levels (3.5 mg/dL or 17 mL/min/1.73 m2), urinary protein/creatinine ratio of 0.63 mg/dL and dysmorphic hematuria on sediment microscopy and denied the use of nephrotoxic medications. Previous tests had shown creatinine levels of 0.9 mg/dL. This led to a concurrent diagnosis of rapidly progressive glomerulonephritis due to IgA nephropathy, confirmed by renal biopsy showing crescents and segmental IgA deposition in the glomerular mesangium. Prompt treatment with pulse therapy and plasma exchange resulted in rapid improvement of neurological symptoms and renal dysfunction. The patient's management included ongoing oral corticosteroids and Rituximab infusion as broad immunosuppressive therapy, targeting both NMO and IgA nephropathy. **Discussion:** To our knowledge, this is the first report describing the association between NMO and rapidly progressive glomerulonephritis due to IgA deposits. The simultaneous involvement of the nervous system and kidneys suggests autoimmune hyperactivity of the humoral immune system, although the mechanisms are not fully understood. One potential link between brain and kidney dysfunction could involve aquaporins. There are at least 10 different isoforms of aquaporins found throughout the human body. AQP4 is located in astrocytic foot processes, in the periventricular regions, the medullary floor of the fourth ventricle, and the area postrema. AQP4 antibodies, known as a diagnostic marker for NMO, can cause significant damage to astrocytes and are considered pathogenic. Interestingly, AQP4 is also present in the medullary collecting tubules of the kidney. Therefore, it's reasonable to hypothesize that antibodies against AQP4 in the serum of an NMO patient could potentially attack the kidney and lead to renal disorders. However, it's important to note that our patient has IgA mediated nephropathy, and the anti-AQ4 is a IgG antibody. **Final comments:** It is of utmost importance to discuss the autoimmune comorbidities of patients with NMO, as they are increasingly being described and contribute to unraveling the pathophysiology of autoimmune mechanisms related to the disease, thereby guiding more effective and eficient treatments.

Background: Huntingtons disease is caused by the expansion of CAG repeats in the HTT gene and exhibits wide variability in age of onset, symptomatology, and disease progression. There is no published data about genetic and clinical aspects of HD in the Brazilian Amazon population. **Objective:** We conducted genetic and clinical assessments in 22 families, with genetic diagnosis in 51 patients with HD in the state of Amazon, Brazil. The main objectives are evaluating demographics, genetic characteristics, and clinical presentations of HD in the Amazonian population. **Methods:** Genetic testing was performed on 51 patients exhibiting HD symptoms. Clinical assessments, including the Unified Huntingtons Disease Rating Scale (UHDRS), were conducted to evaluate motor and cognitive functions. Data on age of onset, illness duration, CAG repeat sizes, and parental transmission were collected and analyzed. **Results:** The study analyzed a cohort of patients with a mean age of 44.9 years, ranging from 11 to 71 years. The average age of onset of the first symptoms was 33.1 years, with a range from 6 to 62 years. The average illness duration was 12.8 years. The average size of CAG expansions was 47.4, with a range between 39 and 84. Paternal transmission was confirmed in 27 patients (52.9%), while maternal transmission was confirmed in 20 patients (39.2%). Patients exhibited a variety of clinical manifestations, including chorea in 37 patients (72.5%), parkinsonism in 36 patients (70.5%), ataxia in 31 patients (60.7%), and dystonia in 30 patients (58.8%). Tics were observed in 8 patients (15.6%).The average score on the Unified Huntington's Disease Rating Scale (UHDRS) was 59.8, assessed in 38 patients, with a range from 7 to 120. These data highlight the diversity of clinical manifestations and genetic variability among patients, underscoring the complexity of diagnosing and managing the disease. **Conclusion:** The study results indicate that HD in the Amazon region manifests predominantly with chorea, parkinsonism, and ataxia, aligning with previously reported clinical profiles in other populations. The observed high prevalence of chorea suggests a significant impact on motor functions, leading to a decreased quality of life for affected individuals. Additionally, the average age of onset in this population is consistent with global trends, although the relatively large CAG repeat sizes may contribute to the severity of symptoms. The more severe forms of ataxia and parkinsonism were significantly related to the size of CAG expansions.

[3]Universidade Federal de Minas Gerais, Belo Horizonte MG, Brazil.

Correspondence: Victor Rebelo Procaci; Email: vrebelop@gmail.com.

Background: ATP1A3 related disorders have a complex clinical presentation and can manifest from childhood to adulthood, presenting as differential diagnosis to several diseases with ataxia, hemiparesis, parkinsonism, dystonia, fever, encephalopathy, epileptic seizures, psychosis, among other features. The description of a clinical spectrum in a cohort of patients is essential for better disease characterization and development of new therapeutic methods. **Objective:** To present a case series of patients diagnosed with mutations in the ATP1A3 gene, through the analysis of medical records from the neurology outpatient clinic of the Universidade Federal de São Paulo and multiple Brazilian universities. **Methods**: This is a retrospective case series that we analyzed medical records from the neurology outpatient clinic of the Universidade Federal de São Paulo, Universidade Federal do Ceará and Universidade Federal de Minas Gerais and included patients with an established diagnosis of ATP1A3 mutation, independent of the phenotype presented. Clinical and genetic data was acquired through medical records analysis. **Results:** We identified 6 cases with a known mutation in ATP1A3, four male and two female. Age of onset varied from less than a year to 17-year-old. We found three main phenotypes: rapid-onset dystonia parkinsonism (2), CAPOS syndrome (2) and alternating hemiplegia of childhood (2). Besides the main phenotype, we identified other neurological features in our cases. Dystonia was present in one patient with AHC and one with CAPOS syndrome. Cognitive impairment was present in four patients. Epilepsy was present only in patients with AHC. AHC patients had positive response to flunarizine therapy. Spasticity, dysarthria, bradykinesia, REM sleep behavior disorder, neuropathy, developmental delay, autism, hypotonia were some of the neurological features that we also identified in our cohort. **Conclusion:** Our cohort highlights the phenotypic heterogeneity of ATP1A3 related disorders, emphasizing the need to consider a combination of neurological symptoms instead of classifying phenotypes in classic separate syndromes. More research is needed to clarify the spectrum of this disorder.

Correspondence: Karina Carvalho Higa; Email: karinacarvalho.fdc@gmail.com.

Case presentation: Patient K.L.L.F, a 37-year-old female, previously healthy presented with tonic-clonic movements followed by a decreased level of consciousness. Brought to the emergency department more than 12 hours after the ictus. On admission, neurological examination revealed a GCS score of 8 (Eye Opening 2; Verbal Response 2; Motor Response 4) and a NIHSS score of 31. MRI and cranial MR angiography showed hyperintense signal on FLAIR with diffusion restriction in the head of the caudate nucleus, lentiform nucleus, anterior limb of the internal capsule, and mesial portions of the left temporal lobe, consistent with an area of acute ischemia; the rest of the brain parenchyma had normal signal intensity of white and gray matter; and thrombosis of the entire length of the left internal carotid artery in its cervical and intracranial segments. The patient underwent mechanical thrombectomy with recanalization of the left carotid artery and left decompressive craniectomy within the first 24 hours of hospitalization. Patient showed good postoperative progress, with a slight left-sided facial droop, but no other abnormalities. In subsequent outpatient consultations, patient began to experience mood disturbances. Initially, with anxiety symptoms, progressing to major depressive disorder and semantic memory impairment on neuropsychological evaluation. Patient continued to have significant mood impairment, with poor response to instituted measures, as well as cognitive impairment. An MRI, two years later, showed changes compatible with atrophy of the left temporal and frontal lobes - a retractable lesion, hyperintense on T2/FLAIR, affecting the left lentiform nucleus and caudate nucleus, causing focal dilation of the left lateral ventricle, and prominence of the cerebral sulci in the left temporal and frontal lobes. **Discussion:** The loss of white matter volume after ischemic events reflects the sensory input from the brainstem as well as the cortical projections of the affected major nuclei. Changes in cortical geometry do not seem to reflect gray matter atrophy but rather the remodeling of the cortical surface due to underlying white matter atrophy. Over time, the reduction in white matter volume appears to result in cortical deformation, but not in gray matter volume loss. Acute unilateral lesions induce central compensation processes by reorganizing sensorimotor networks within the ipsilateral hemisphere and the contralateral hemisphere. The lack of changes in gray matter may reflect the heterogeneous interindividual projection pattern of the affected regions and their connections with various areas of the cerebral cortex. The clinical presentation depends on the affected area and the type of brain tissue involvement. **Final comments:** Strokes lead to a reduction in white matter volume in both the ipsilesional and contralesional hemispheres over time. This reduction in white matter volume is a consequence of cortical remodeling following a stroke.

Attention deficit hyperactivity disorder and autism spectrum disorder in adults

Tatiana Pizzolotto Bruch[1], Camila Pezente Dal Toe[1], Amanda Cardoso da Silva[1], Suélen Galuppo[1]

[1]Universidade do Extremo Sul Catarinense, Criciúma SC, Brazil.

Correspondence: Tatiana Pizzolotto Bruch; Email: tatibruch@yahoo.com.br.

To investigate the presence of symptoms of Attention Deficit Hyperactivity Disorder (ADHD) and Autism Spectrum Disorder (ASD) in university students using validated and translated psychological assessment tools in Brazil. A cross-sectional study was conducted, evaluating 433 students through online questionnaires: the Adult Self-Report Scale (ASRS-18) for ADHD and the Autism Spectrum Quotient - 10 items (AQ-10) for ASD. Analysis of 433 questionnaires identified ADHD symptoms in 62.4% and ASD symptoms in 15.7% of the students. Common ASD symptoms included difficulties in attention to details and communication, while ADHD symptoms primarily involved inattention. Significant associations were also found between ADHD and ASD symptoms and treatment for depression and/or anxiety. Therefore, it was concluded that symptoms of ADHD and ASD significantly impact personal relationships and academic profiles of students, as these psychological disorders are strongly linked to human performance in both social and professional contexts.

Atypical case of HaNDL syndrome: an unusual presentation in a man

Nereu Alves Lacerda[1], Luis Felippe Barros[1], Mayhara Rosany da Silva Santiago[1], Ana Caroline Paiva Simeão[1], Raissa Josefa Pereira de Moura[1], Heloisy Maria Nunes Galvão[1], Felipe Franco da Graça[2], Natália Nunes Tenório[1], Heron Alves Vale[1], Ana Beatriz Roberto Lima Borba[1]

[1]Hospital Pelópidas Silveira, Recife PE, Brazil. [2]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Nereu Alves Lacerda; Email: nereulacerda@gmail.com.

Case presentation: A 23 year-old man, without any comorbidities aside from obesity and history of pain, was hospitalized due to a mild headache in the occipital region, which was not associated to photophobia or phonophobia, did not have a progressive characteristic and did not have improving or worsening factors. Afterwards the pain evolved with a change of pattern, now being a severe holocranial headache associated with an ictal difficult of speech and right hemiplegia. Neurological clinical exam showed motor aphasia, hemiparesis on the right (strength grade 2), ipsilateral hypoesthesia and bilateral papilledema. Notably, soon after admission the patient had complete improvement of the symptoms, but during hospitalization he persisted with sporadic episodes of headache with the mentioned characteristics. Laboratory exams and head CT without contrast had unremarkable results. However, on CSF analysis it was noted increased intracranial pressure (ICP = 52 cmH2o) and a lymphocytic (96%) pleocytosis, but no alterations regarding protein or glucose levels. Serologies with a viral panel were performed for infectious investigation, with all results being negative. We proceeded the investigation with angiotomography, magnetic resonance imaging and arteriography of cervical and intracranial vessels that were within the patterns of normality. Thus the diagnosis of headache with neurological deficits and cerebrospinal fluid lymphocytosis (HaNDL syndrome) associated with idiopathic intracranial hypertension was established. We initiated treatment with acetazolamide, after which a significant clinical improvement along with decrease in opening intracranial pressure on CSF was observed. Henceforth, the patient was discharged with orientation of return for outpatient follow-up. **Discussion:** HaNDL syndrome is a rare, benign and self-limited condition, characterized by headache associated with aphasia and other sensitive or motor deficits, along with CSF lymphocytosis. As in the presented case, opening intracranial pressure of the CSF might be increased, and the investigation of viral etiologies have negative results. In general, the syndrome has a great recovery rate even without long-term treatment, considering its self-limited nature. However, it is relevant to manage acute symptoms and give orientations about possible recurrences. It is important to highlight that the syndrome might initiate with a thunderclap headache, which makes it relevant to consider HaNDL syndrome in patients with this pattern of headache, even though it is an exclusion diagnosis. **Final comments:** HaNDL syndrome is a rare and possibly sub diagnosed condition that might be associated with comorbidities like idiopathic intracranial hypertension and have a thunderclap headache pattern, which makes it difficult to diagnose. Therefore, it is important to be aware of this diagnosis in cases of headache with warning signs.

Atypical cryptococcosis with restricted diffusion mimicking radiological features of ischemic stroke: a case series

Alex Araújo Fernandes[1], Matheus Alves da Silva[1], Matheus Luís Braga Munareto[1], Eduardo Mesquita de Souza[1], Rafael Bragança Rodrigues Matias[1], Ana Luisa Faria Donadon[1], Amanda Miranda de Mendonça[1], Victor Hugo Rocha Marussi[1], Hennan Salzedas Teixeira[1], Alex Machado Baeta[1]

[1]Beneficência Portuguesa de São Paulo, São Paulo SP, Brazil.

Correspondence: Ana Luisa Vieira de Faria; Email: alfaria96@gmail.com.

Case presentation: Case 01 - A 70 year old man with Gilbert Syndrome presented with subacute fever and headache. His neurological examination showed signals of bilateral parkinsonism and appendicular ataxia. The MRI showed multiple foci of restricted diffusion in cerebellum, basal ganglia and cortex associated with leptomeningeal enhancement. The vessel wall imaging sequence showed concentric parietal thickening of middle cerebral arteries, compatible with vasculitis. His lumbar puncture showed normal opening pressure, 15 cells, 31 glucose, 281 proteins, 47 lactate and had a positive testing for Cryptococcus neoformans. He received amphotericin B liposomal and fluconazole. His neurological symptoms completely improved, and he was discharged with Fluconazole treatment. Case 02 - A 66 year old man presented with a one week headache and confusion and new sudden dysarthria onset. He had Budd-Chiari syndrome and cirrhosis. The neurological examination showed mild scandid dysarthria. His initial CT was normal, but MRI showed bilateral cerebellar restricted diffusion. Besides the images of ischemic stroke, his symptoms keep worsening in the hospital, incompatible with a vascular diagnosis. A lumbar puncture was performed, showing a normal opening pressure, 1152 cells with neutrophile predominance, 228 protein, 68 glucose and a positive testing for Cryptococcus neoformans. He received amphotericin B liposomal and fluconazole, with neurological improvement, but evolved with gastrointestinal bleeding and died of hypotensive shock. **Discussion:** Neurocryoptococcosis is an infection of the central nervous system that generally affects immunocompromised patients, but can affect immunocompetent patients and has a high mortality and morbidity. It usually presents with headache and fever; the presence of other symptoms are less common. Central nervous system cryptococcosis produces a wide variety of MRI features. Most common imaging finding in MRI is leptomeningeal and pachymeningeal enhancement, followed by dilatation of perivascular spaces e cryptococcomas. Restricted diffusion is rare, more common as a complication of the disease. While some of the radiographic features may be secondary to vascular injury, like in case one, restricted diffusion may be secondary to intramyelinic edema making the extracellular water restricted in its movement. **Final comments:** These cases presents atypical clinical and radiographic features of neurocryptococcosis. Early diagnosis is critical for successful treatment and avoiding neurological complications from this lethal infection, even in atypical cases.

Correspondence: Mariana Holanda Gameleira; Email: marianagameleira_@hotmail.com.

Background: Epileptic seizures can reproduce from the known generalized tonic-clonic convulsive seizures, to piloerection, episodes of pure apnea, the most several types of pain, speech block, etc. The atypical manifestations of these seizures have not yet been properly defined. Clinical acumen is essential to improve diagnostic accuracy. **Objective:** To describe the prevalence and the clinical features of atypical epileptic seizures in patients with epilepsy, and to know the epidemiological profile of patients presenting atypical manifestations of epileptic seizures. **Methods:** A cross-sectional study was carried out with 1,244 patients from an epilepsy outpatient clinic of an University Hospital between February 2013 and May 2019. The presence of atypical epileptic seizures, and the epidemiological profile of the patients were analyzed. The prevalence of atypical epileptic seizures was determined in patients with epilepsy. For statistical analysis, we performed a case-control study, in which the control population were the patients who presented only typical seizures. We have excluded 305 patients due to uncertain diagnosis of epilepsy, and/or due to cognitive impairment, enough to compromise the reliability of their provided information. **Results:** A prevalence of 5.79% of patients with atypical epileptic seizures was observed, of which 1.85% had exclusively atypical seizures. In this group, female and patients over 50 years hegemony were observed, both with a prevalence of 60.8%. In addition, in atypical epileptic seizures patients, there was an evident predominance of seizures with a focal component, with indeterminate epileptic syndrome, normal neurological examination and with a frequency of more than one seizure per month. **Conclusion:** The prevalence of atypical epileptic seizures in patients with epilepsy is not negligible. The knowledge of these kind of seizures facilitates the early diagnosis of epilepsy, as well as provides an adequate treatment, and improves the patient's quality of life.

Atypical initial manifestations of multiple sclerosis: a case report

Jonh Heberthon de Souza Araújo[1], Andréia Maria dos Santos Carvalho[1], Monique Melo Fortaleza[1], Michelly Bruna Soares de Moura[1], Raimundo Feitosa Neto[2] , Aline Gomes da Costa[1], Janine Midori Figueiredo Watanabe[1]

[1]Universidade Estadual do Piauí, Teresina PI, Brazil. [2]Universidade Federal do Piauí, Hospital Universitário, Teresina PI, Brazil.

Correspondence: Jonh Heberthon de Souza Araújo; Email: johnheberthon@hotmail.com.

Case presentation: A 35-year-old female was admitted to the neurology service on May 14th, 2024 presenting hemilingual ageusia, diplopia, and tinnitus. A month earlier, the patient reported having symptoms including increased fatigue and memory loss, as well as the onset of ageusia. The progression of the clinical condition led to diplopia, tinnitus, vertigo, and a differently patterned headache, which persisted up to the time of consultation. She denied motor symptoms or any other sensory manifestations. Her past medical history included chronic headaches since the age of 15, causing recurrent episodes of dizziness and fibromyalgia. A brain magnetic resonance imaging (MRI) performed on May 21st revealed more than nine lesions including: rounded lesions in the periventricular white matter and bilateral centrum semiovale; a lesion in the right forceps major of the corpus callosum and in the infratentorial compartment of the right posterior portion of the pons; and in the left paramedian region of the pontomedullary junction. Oligoclonal bands were present in the cerebrospinal fluid, confirming the diagnosis of multiple sclerosis. The patient was hospitalized for treatment with methylprednisolone pulse therapy for five

days, leading to clinical recovery. **Discussion:** Multiple sclerosis (MS) is a chronic inflammatory and neurodegenerative disease that affects the central nervous system and results from a demyelination process. It typically manifests between the third and fourth decades of life and can affect various areas, with notable otolaryngological symptoms, especially olfactory and audiovestibular. The tinnitus and vertigo reported in this case are part of the common audiovestibular alterations seen in MS patients due to the central nervous system demyelination. The diplopia reported by the patient results from lesions in the cranial nerves or in the brainstem, and it is among the most common visual complaints. Gustatory alterations, on the other hand, are extremely rare, especially when they occur early. However, they should not be underestimated and need careful investigation as potential indicators of multiple sclerosis, especially in young women. Clinically, it presents as transient ageusia, and on MRI, as demyelinating lesions in the cerebral taste area and pontine lesions, consistent with the patient's examination findings. The combination of symptoms and MRI findings points to brainstem involvement as the initial manifestation of the case, which is atypical and could potentially lead to a delayed diagnosis. **Final comments:** Few reported cases show ageusia, especially associated with diplopia, tinnitus, and vertigo, as initial symptoms of multiple sclerosis, making this an atypical manifestation of the disease. Therefore, a thorough anamnesis and a high degree of clinical suspicion are required for diagnosis in such situations.

Atypical presentation of hypertensive cerebral lobar hemorrhage in a puerperal woman

Thayná Tavares Cutrim Everton[1], Vinicius Gabriel Peneluppi dos Santos[1], Bianca de Araujo Sobral[1], Gustavo Yukihito Anzou de Souza[1], Bruno Barros de Padua Andrade[1], Guilherme Previtale Vitorino[1], Luis Eduadro Belini Soares[1], Rodrigo Ferreira Faria[1], Giovana Santos Rodrigues[1], Luiz Fernando Mohallen Reynaldo[1]

[1]Pontifícia Universidade Católica de Campinas, Campinas SP, Brazil.

Correspondence: Bianca de Araújo Sobral; Email: biancadeasobral@gmail.com.

Case presentation: MB, 41 year old, on the 7th postpartum day, was admitted to the emergency with a sudden onset of thunderclap headache upon waking, along with a sudden focal deficit of right-sided hemiparesis associated with motor aphasia. In the initial evaluation, she presented with hypertension (210/120 mmHg) and a cranial tomography revealed bifrontal hemorrhage with extravasation into the subarachnoid space and ventricles. She was referred to a tertiary care service, where arterial and venous angiographic tomography were performed, excluding cerebral venous thrombosis. Subsequently, she underwent cranial resonance and angiography, also without abnormalities, excluding ruptured aneurysms, arteriovenous malformations, angiomas, and cavernomas. During hospitalization, she experienced hypertension refractory to intravenous drugs, seizure crises, and a decreased level of consciousness, initiating measures for intracranial hypertension, invasive monitoring (ICP), and treatment for Status Epilepticus. After blood pressure control and electroencephalography, she showed awakening with partial remission of motor deficits and aphasia. After discharge, she underwent a post-hemorrhage follow-up exam to exclude structural causes and continues to have motor sequelae, for which she is undergoing rehabilitation. **Discussion:** Non-traumatic intracerebral hemorrhage (ICH) is a public health issue with an annual incidence of 30/100000 people, a mortality rate of 40%, and accounts for 20% of cerebrovascular events. This report describes a case of hypertensive ICH with bifrontal bleeding in a postpartum woman, a rare condition without precedent in the literature. Its most common topographies are basal nuclei (31%), putamen (30%), thalamus (25%), lobes (25%), ventricles (11%), pons (8%), and cerebellum (8%). In the lobar topography, 24% are unilateral and 26% multilobar, with the parietal being the most frequent (31%). The bifrontal finding is rare and generally associated with central thrombosis, which was ruled out by angiography, angiotomography, or angioresonance. The clinical presentations of ICH vary depending on its topography. In this case, there was a sudden focal deficit on the right side that became bilateral, indicating bilateral injury. The incidence of postpartum ICH is 0.05%, with maternal mortality between 60% (12% of maternal deaths). 50% of postpartum ICHs result from the rupture of an aneurysm or arteriovenous malformation, and rarely from the rupture of a carotid-cavernous fistula or cavernous angioma, Moyamoya disease, sickle cell anemia, and disseminated intravascular coagulation. In this case, the hypertensive peak on the postpartum was considered the cause of the bleeding. **Final comments:** This report highlights a rare presentation of hypertensive intracerebral hemorrhage due to its atypical topography and postpartum incidence. Despite its rarity, the diagnosis of such an entity must be prompt due to the high mortality involved with therapeutic delays.

https://doi.org/10.5327/CBN240213

Atypical presentation of Rasmussen's encephalitis as progressive hemispheric atrophy syndrome without epilepsy: an unusual case report and the diagnostic challenge of a rare condition

Lucas Wilson Matos Gomes[1], Victor Hugo de Souza Silva Gomes[1], Gabriel Carvalho Alves[1], Gabriel Santos de Castro[1], Danyelle Rute Francisco e Silva[1], Letícia Leão Alvarenga[1], Guilhermes Henrique Cavalcante[1], Luany Patrícia Liberato de Oliveira[1], Denise Sisterolli Diniz[1], Delson José da Silva[1]

[1]Universidade Federal de Goiás, Goiânia GO, Brazil.

Correspondence: Lucas Wilson Matos Gomes; Email: lucaswilson95@hotmail.com.

Case presentation: A 22-year-old female patient, mixed race, presented five years ago with incomplete and disproportionate spastic hemiparesis predominantly in the right lower limb. She developed complete facial paralysis on the left side and, two years ago, began to experience decreased visual acuity on the left side, executive memory changes, and a decline in phonemic verbal fluency. She reports a febrile epileptic seizure at age 2 during an episode of acute pharyngitis but denies other paroxysmal events. Physical examination revealed complete facial paralysis on the left, lateral rectus muscle ophthalmoplegia with visual acuity of 20/70 (Snellen) in the left eye, and complete hemiparesis on the right with pyramidal release signs. Cranial MRI showed hyperintense areas on T2/FLAIR in the left temporal pole and cingulate gyrus, associated with hemiatrophy of the same hemisphere, accentuation of cerebral sulci and fissures, and hyperintense signals on T1/MTC in the left corticospinal tract from the precentral gyrus to the corona radiata. A biopsy of the left cingulate region showed histomorphological findings of a perivascular inflammatory infiltrate predominantly of CD4 and CD8 T lymphocytes, without identifiable cytotoxic cells, microglial activation with rare microglial nodules, and diffuse gliosis. Testing for Epstein-Barr virus (EBV) antigens was inconclusive, and tests for cytomegalovirus (CMV) and herpes simplex types 1 and 2 were negative. Cerebrospinal fluid (CSF) analysis showed oligoclonal bands with an intrathecal production pattern type 2. Infectious serologies for other agents and tests for autoantibodies anti-AQP4, anti-MOG, anti-NMDA, and anti-GAD were negative. The electroencephalogram was within normal limits and showed no evidence of new clinical or electrographic seizures since the patient's follow-up began. Based on the imaging and histopathological findings, the patient meets the diagnostic criteria for Rasmussen's encephalitis (RE) according to the Bien et al. (2005) criteria. **Discussion:** RE is an immune-mediated syndrome characterized by progressive chronic encephalitis affecting one cerebral hemisphere. It typically results in intractable focal epilepsy, progressive focal neurological deficits, and intellectual decline related to the affected hemisphere, with neuroimaging revealing progressive unilateral cerebral hemiatrophy. This case presents an atypical evolution by not showing one of the main characteristics of the disease: refractory epilepsy. Therefore, it was necessary to proceed with a brain biopsy, which resulted in findings compatible with RE, although not specific. **Final comments:** This is a difficult diagnosis due to the rarity and atypical presentation of the syndrome. Thus, there is a need to review the diagnostic criteria to increase the sensitivity and specificity of diagnoses, as in the case reported above.

https://doi.org/10.5327/CBN240214

Atypical presentation of rhabdomyolysis due to epilepsy in a patient with McArdle disease

Raíssa Josefa Pereira de Moura[1], Cleberson Alberceli Vieira de França[1], Flávio Laurentino de Sousa Júnior[2], Mayhara Rosany da Silva Santiago[1], Ana Caroline Paiva Simeão[1], Nereu Alves Lacerda[1], Renata Amaral Andrade de Mendonça[1], Heron Alves Vale[1], Natália Nunes Tenório[1], Ana Beatriz Roberto Lima Borba[1]

[1]Hospital Pelópidas da Silveira, Recife PE, Brazil. [2]Universidade Federal de Pernambuco, Recife PE, Brazil.

Correspondence: Raíssa Josefa Pereira de Moura; Email: rayssamoura16@gmail.com.

Case presentation: A 45 year-old woman, previously diagnosed with Glycogen Storage Disease Type V (McArdle disease), was hospitalized due to bilateral intense muscle pain in gastrocnemius, knees and triceps that did not respond to medications. Neurological examination revealed proximal tetraparesis, predominantly on lower limbs, and global hyperreflexia. There was no history of physical exertion prior to this clinical condition and no signs or symptoms of infectious diseases were present. Initial laboratory exams showed blood urea nitrogen (BUN) of 28 mg/dL and creatinine 0.84 mg/dL, but had ascending levels of CPK (2289-10.005 U/L). During hospitalization, we also noted mild contractures of short duration on quadriceps, without any facial involvement or impairment of consciousness. However, after one of those contractures, the patient had a tonic-clonic seizure, which was followed by an acute kidney injury (Creatinine 3.1 mg/dL; BUN 57 mg/dL) and progressive increase on CPK levels (CPK = 169.926 U/L). Interictal electroencephalogram showed frequent bilateral frontal-polar epileptiform activity. The patient is still on hemodialysis due to rhabdomyolysis, but after administration of anti-seizure medications the CPK levels started to decrease. **Discussion:** McArdle disease is a genetic metabolic myopathy that occurs due to deficiency of the enzyme myophosphorylase, which causes intolerance to physical exercise. The disorder is mainly characterized by muscle pain, weakness and fatigue after periods of physical activity. Severe muscular damage can occur following intense physical exertion, resulting in acute kidney injury and rhabdomyolysis. Although physical exertion is a known trigger for muscular damage on McArdle disease, the patient in this case had no history of previous physical exertion. Traumas, inflammatory and infectious diseases are also potential etiologies of rhabdomyolysis on those patients, but there was also no clinical or laboratory evidence that pointed to such

causes. Epileptic seizures are not a common occurrence on McArdle disease, but are a possible precipitant factor of rhabdomyolysis that must be actively investigated if clinical and laboratory worsening without a clear factor is identified. There are reports of magnetic resonance spectroscopy questioning a possible accumulation of glycogen on the brain of patients with McArdle disease, which raises the possibility of acute symptomatic seizures of metabolic etiology. **Final comments:** Here we highlight the importance of actively investigating occult epileptic seizures as an etiology for patients with McArdle disease who progress to rhabdomyolysis, especially when there is not a clear cause for the muscular damage.

https://doi.org/10.5327/CBN240215

Atypical presentation of Turner-type X-linked syndromic intellectual developmental disorder: a pediatric case report

João Vítor Moreira Nogueira[1], Oliver Reiks Miyajima[2], Alessandra Marangoni Fante[1], Bruna Barbosa Nobre[1], Enzo Lima Alcântara Parente[1], Marcelo de Almeida Pinheiro[1]

[1]Unichristus, Fortaleza CE, Brazil.
[2]Universidade Estadual do Ceará, Fortaleza CE, Brazil.

Correspondence: João Vítor Moreira Nogueira; Email: jvmnogueira10@gmail.com.

Case presentation: A 5-year-old female patient, daughter of a young non-consanguineous parents with no family history of neurological impairment, was referred by her pediatrician for early stimulation with occupational therapy (OT), physical therapy, and speech therapy at the age of two months due to global delay in neuropsychomotor development, partially reaching the expected milestones for her age. At the age of three, due to persistent delay in language comprehension, low inhibitory control, visual and auditory hypersensitivity, she was evaluated by a neurogeneticist who, upon physical examination, identified apparent intellectual disability, craniofacial dysmorphisms such as broad forehead, ocular hypertelorism, hypoplasia of the ear lobes, dysmorphic upper labial frenulum, thin upper lip and prominent nasal columella, alongside skeletal anomalies in the toes. Following investigation, complete exome sequencing was requested, which revealed a de novo pathogenic variant in heterozygosity in the HUWE1 gene (chrX:53.647.391 G> A), confirming the diagnosis of Turner-type X-linked syndromic intellectual developmental disorder with OMIM nº 309590. Subsequent multidisciplinary evaluation indicated low performance in expressive language, delay in intellectual acquisition and processes, auditory and visual hypersensitivity, fine motor dyspraxia and reduced sustained attention. Currently, the patient undergoes regular multidisciplinary follow-up with psychology, psychomotricity, speech therapy and OT, showing improvements in motor and cognitive development. **Discussion:** Turner-type X-linked syndromic intellectual developmental disorder is a rare neurodevelopmental disorder with a genetic basis caused by pathogenic variants in the HUWE1 gene. This disorder follows an X-linked inheritance pattern, however, in this case, atypically presented due to the de novo mutation, as there is no family history of the disease. The phenotype of this condition is highly variable. Heterozygous females, as in the case in question, may present mild manifestations or be asymptomatic. Affected individuals usually show global developmental delay since childhood, with intellectual impairment of varying intensity. Common dysmorphic features include small palpebral fissures, low-set dysplastic ears, long face, thin upper lip, and mild distal skeletal anomalies, such as brachydactyly. **Final comments:** It is concluded that Turner-type X-linked syndromic intellectual developmental disorder, caused by pathogenic variants in the HUWE1 gene, presents a wide range of phenotypic manifestations, thus highlighting the importance of genetic evaluation of patients with global delay and dysmorphisms, even if minor, in addition to an early multidisciplinary approach to optimize the development of multiple domains compromised by the underlying disease, including language, motor skills, cognition, among others.

[4]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Henrique Alves Bezerra; Email: riq_alves@hotmail.com.

Background: Congenital myasthenic syndromes (CMS) are a group of disorders caused by mutations in genes that encode proteins at the neuromuscular junction. The typical clinical presentation involves congenital or childhood-onset muscle weakness affecting ocular, respiratory, bulbar, and limb muscles, alongside fatigability. However, adult-onset and atypical clinical features have also been reported, depending on the specific gene involved. The MUSK gene, which encodes the muscle-specific kinase (MuSK) protein crucial for neuromuscular synapse formation, is rarely implicated in CMS. The clinical phenotype associated with MUSK mutations is highly variable, ranging from severe neonatal presentations to mild early-childhood limb-girdle weakness often accompanied by early ventilatory insufficiency. **Methods:** Six patients with CMS caused by biallelic variants in the MUSK gene were evaluated at three tertiary centers. They provided informed consent for inclusion of their clinical data in this study. **Results:** We presented the clinical details of six patients with MUSK-CMS. Four males and two females aged 19 to 58 years (mean 36.5 +-12). One patient manifested symptom congenitally and the remaining five in adulthood (mean onset age for adult-onset cases was 21.33 +-6 years). Clinical presentation included mild limb-girdle weakness, respiratory dysfunction, and varied responses to treatments such as salbutamol and pyridostigmine. Our findings underscore the diverse clinical presentations of MUSK-CMS. While childhood-onset cases may not always involve significant respiratory issues, adult-onset presentations can be debilitating, particularly with respiratory involvement. The positive response to salbutamol in all patients suggests its efficacy as a potential treatment. Three patients treated with pyridostigmine showed no worsening of symptoms. Adult-onset forms of MUSK-CMS, uncommon but marked by significant respiratory involvement, differ from the typical congenital or childhood-onset phenotype described in the literature. The varying treatment responses, including pyridostigmine's lack of exacerbation of symptoms, highlight the heterogeneity among individuals with MUSK mutations. **Conclusion:** MUSK-CMS is a rare yet clinically diverse condition that may present in adulthood despite the typical congenital or childhood-onset patterns. Our study emphasizes the importance of recognizing and comprehending the diverse clinical presentations and treatment responses in MUSK-CMS. Tailored management strategies are crucial to optimizing outcomes in this patient population, underscoring the need for further research to elucidate underlying mechanisms and refine therapeutic approaches.

Aura change in migraine: be careful!

Taís Luise Denicol[1,2], André Luiz Girotto[1,2], Carolina Matte Dagostini[1,2], Juan Sebastián Sánchez León[1,2], Pedro Hall Ruschel[1,2], Renato Dumba Monteiro de Castro[1,2], Alexandre Laisson Prado Taschetto[1,2], Fernando Kowacs[1,2], Liselotte Menke Barea[1,2], Paulo Valdeci Worm[1,2]

[1]Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre RS, Brazil.
[2]Irmandade da Santa Casa de Misericórdia de Porto Alegre, Porto Alegre RS, Brazil.

Correspondence: Taís Luise Denicol; Email: taisldenicol@gmail.com.

Case presentation: Female, 49 years old, previously hypertensive and with migraine with aura. Medications: Losartan 50mg SID and atenolol 25mg SID. Denies smoking and other habits. Patient had infrequent episodic migraines with typical visual aura since youth without prophylactic treatment. Positive family history of migraine with aura. The aura was characterized by a fortification spectrum with gradual onset lasting 15-20 minutes followed by a unilateral, pulsatile and periorbital pain associated with nausea, fono/photophobia. However, six months ago, the attacks increased in frequency to 3-4x per week and started with a chronic cough. Two months ago, there was a change in the pattern of the aura, which sometimes became a figure similar to a disco ball. She had 03 episodes of this aura and in the last one followed by a generalized tonic-clonic seizure in which she was referred to a tertiary health service. On physical examination, breath sounds were abolished at the base and decreased at the apex on the left lung. No changes in neurological examination. A chest x-ray was performed with extensive pleural effusion on the left and a head computed tomography showing an intra-axial occipital lesion on the right. It is complemented by a computed tomography of the chest, which reveals a lesion of probable primary neoplastic nature in the left lower lobe. Resection of the extra-axial right occipital brain lesion and continued with the falx and intra-axial lesion with anatomopathological analysis showed metastasis of adenocarcinoma in connective tissue and brain parenchyma. The immunohistochemical study associated with the histopathological findings and clinical data received are compatible with adenocarcinoma metastasis, with a probable primary site in the lung. **Discussion:** Most headaches are a primary disorder, however it is important that during any medical evaluation, alarm signs have been looked for systematically, like the change of pattern of aura, seizures and frequency increase. Red flags have been promoted in the medical literature and it helps the clinician to initiate a workup plan. SNNOOP10 list is a systematic way to screen patients with a new headache and will help to detect a secondary cause. This patient showed pattern change or recent onset of headache that in SNNOOOP10 suggests neoplasms, headaches attributed to vascular, nonvascular intracranial disorders. **Final comments:** The importance of investigating patients with changes in headache and aura patterns that are listed in SNNOOOP10 is reinforced. It is worth noting that even patients with primary headaches disorder can develop secondary headaches disorder and they deserve attention, as in the case of this patient.

https://doi.org/10.5327/CBN240218

Autoimmune necrotizing myopathy associated with 3-hydroxy-3-methylglutaryl-coa reductase (HMGCR) antibody after COVID infection: a case report

Samara Andrea da Costa Fonseca[1], Elberth Henrique Miranda Teixeira[1], Caio Eduardo Rodrigues Falcao[1], Luiziane Maria da Silva Alves[1], Pablo Vinicius Silveira Feitoza[1]

[1]Universidade Federal do Amazonas, Manaus AM, Brazil.

Correspondence: Samara Andrea da Costa Fonseca; Email: samaradacostafonseca@gmail.com.

Case presentation: 64-year-old woman from Manaus, Amazonas. On January 6, 2021, she started suffering from flu-like symptoms and was diagnosed with COVID four days later. Over the following week, she presented with muscle weakness in the lower and upper limbs, with difficulty climbing stairs and walking, including difficulty supporting her neck; associated with dysphagia, myalgia and cramps. On physical examination, the patient was hypotonic, with hypotrophy in the proximal region of the upper and lower limbs; symmetrical tetraparesis with a proximal crural predominance; hyporeflexia in the triceps, biceps and patella bilaterally; preserved superficial and deep sensitivity; eumetrics and eudiadochokinetics; cranial nerves without alterations; myopathic gait requiring bilateral support for walking; absence of skin lesions. Laboratory tests showed hyper-CPKemia of 6,893 U/L. Etiological stratification revealed a histopathological pattern of autoimmune necrotizing myopathy on muscle biopsy and positivity for HMGCR antibody (235, normal <20UA). She is being followed up with methotrexate with a good therapeutic response. **Discussion:** This case of confirmed autoimmune necrotizing inflammatory myopathy associated with HMGCR antibody demonstrates the relevance of SARS-CoV-2 virus infection as a trigger for the development of autoimmune neurological diseases. Autoimmune myopathies represent a set of rare, heterogeneous pathologies and are a major challenge in the medical field when it comes to differential diagnoses. Immune-mediated necrotizing myopathy is a recently described form of idiopathic inflammatory myopathy characterized by a severe clinical picture with rapidly progressive muscle weakness, axial involvement, early muscle atrophy and high CPK titers. Currently, there are two main categories, with anti-signal recognition particle autoantibodies (SRP-IMNM) and anti-3-hydroxy-3-methylglutaryl-coa reductase autoantibodies (HMGCR-IMNM). Serum anti-SRP autoantibodies in IIM were first detected in 1982 and anti-HMGCR autoantibodies were first detected in 2010-2011. **Final comments:** This case study enabled us to make a differential diagnosis between inflammatory myopathies. This report is extremely relevant, as these nosological entities share numerous signs and symptoms, which makes diagnosis challenging, especially considering the correlation with COVID infection.

https://doi.org/10.5327/CBN240219

Autoimmune optic neuritis in a patient with hiv on irregular treatment: case report

Paulo Henrique Martinelli Oliveira[1], Amanda Michelucci dos Santos[1], Rebeca Aranha Barbosa Sousa[1], Larissa Miyashiro[1], Raderi Luiz Cardoso Do Santos[1], Lucas Silva Dias[1], Laiz Helena de Pádua[1], Gustavo Carvalho Costa[1], Alexandre Coelho Marques[1]

[1]Hospital Municipal Dr. José de Carvalho Florence,

Correspondence: Paulo Henrique Martinelli Oliveira; Email: paulohmoliveira96@gmail.com.

Case presentation: Patient E.E.M.F, female, 35 years old, diagnosed with HIV 13 years ago, with irregular treatment (CD4 count: 315, Viral load: 2830 copies). Discontinued antiretroviral therapy in April/2023. In December/2023, developed pain upon movement of the left eye, associated with loss of visual acuity ("counting fingers at 1 meter"), and left optic disc edema was observed without other additional findings. At the time, due to suspicion of Cytomegalovirus infection, intravenous Ganciclovir was initiated with no improvement in symptoms. On the 7th day of antiviral therapy, she underwent Methylprednisolone 1g/day for 5 consecutive days, showing significant improvement in visual acuity (20/70) by the end of pulse therapy. In March/2024, she again presented a similar condition, experiencing a new worsening of visual acuity (20/400) in the left eye. Again treated with Methylprednisolone 1g/day (5 days), with partial recovery after treatment (20/70). Cerebrospinal fluid evaluation showed mild pleocytosis (05 cells/mm^3) and proteinorrhaquia (59 mg/dL), presence of oligoclonal bands, and positive PCR for Epstein-Barr Virus (EBV). Research was negative for other viruses. Magnetic resonance imaging revealed a slight hypersignal on FLAIR/T2 in the right frontal semi-oval center. **Discussion:** Although HIV infection predominantly affects lymphocytic load (CD4) and Multiple Sclerosis (the most prevalent autoimmune disease of the central nervous system) has its pathophysiology intrinsically associated with lymphocytes, recent studies demonstrate a relationship between such pathologies, with viral infection potentially acting as a trigger for a demyelinating outbreak. Furthermore, the positive PCR for EBV in the cerebrospinal fluid may be related to disease activity. **Final comments:** The associations and neuroimmunological triggers related to autoimmune diseases in HIV patients remain largely unknown. Given the high epidemiological focus of HIV in Brazil and its potential concurrence with such autoimmune phenomena, the study and investigation of these pathologies are essential.

Automatic prediction of ASPECTS for patients with posterior circulation infarcts

Aditya Santosh Kondepudi[1], Manuela Yphyn Faria Sung[2], Noam Rotenberg[1], Andreia Vasconcellos Faria[1]

[1]Johns Hopkins University, Baltimore, US. [2]Universidade Estadual do Oeste do Paraná, Cascavel PR, Brazil.

Correspondence: Manuela Yphyn Faria Sung; Email: manuela.yphyn@gmail.com.

Background: The Alberta Stroke Program Early CT Score (ASPECTS) visually assesses the extent and location of ischemic core in Middle Cerebral Artery (MCA) ischemic strokes. Due to its simplicity, ASPECTS gained popularity and was adapted for diffusion-weighted MRIs (DWI). However, variability in human evaluation affects ASPECTS' effectiveness in treatment selection. Automatic classification methods that can replicate expert opinion might add an extra level of reproducibility and aid urgent medical decisions like thrombolysis or prognostic prediction. **Objective:** We previously developed a fully automatic system to calculate MCA-ASPECTS, matching consensus expert readings. This study extends the system to calculate ASPECTS in posterior circulation strokes (PCA-ASPECTS). **Methods:** The study included MRIs of patients admitted to our stroke center with ischemic stroke between 2009 and 2019. This subset of the public "Annotated Clinical MRIs and Linked Metadata of Patients with Acute Stroke" (https://www.icpsr.umich.edu/web/ICPSR/studies/38464). Stroke cores were manually traced. Models identifying ischemic regions were trained on 1,414 MRIs with ischemic evidence in DWI and tested on an independent dataset of 160 patients with posterior circulation infarcts. The models' efficiency was compared to consensus expert evaluations and inter-evaluator comparisons. **Results:** The Random Forest model was the most efficient for classifying stroke locations in the posterior circulation. Balanced accuracy (0-1 scale, with 1 being perfect) was: PCA 0.87; cerebellum 0.92; midbrain 0.84; pons 0.84; thalamus 0.87. This performance rivaled inter-evaluator classification. The model's accuracy in predicting unilateral or bilateral lesions in the PCA, cerebellum, and midbrain averaged 0.9. Accuracy for predicting PCA-ASPECTS was 0.65, and 0.85 for "flexible" ASPECTS (±1 point tolerance). We developed a fully automated system for calculating PCA-ASPECTS with accuracy comparable to inter-evaluator agreement. While accuracy for total score calculation was slightly lower due to multiclass issues, accuracy for predicting individual affected regions and flexible ASPECTS rivaled or exceeded inter-evaluator agreement. This system is part of our Acute Stroke Detection and Segmentation tool, ADS (https://www.nitrc.org/projects/ads), which outputs digital infarct masks, proportions of brain regions injured, automatic radiology reports, and MCA-ASPECTS, all with explanatory features. ADS is public, free, accessible to non-experts, and runs in real time on local CPUs with minimal computational requirements. **Conclusion:** We developed an automated and accessible system to accurately predict PCA-ASPECTS, potentially enhancing acute stroke assessment and supporting urgent medical decisions and reproducible research.

Autosomal recessive spinocerebellar ataxia type 8 and associated non-cerebellar features

Bruno Wendorff Lucci[1], João Carlos Cervelin[1], Fernanda Coan Antunes[1], Pricila Bernardi[1], André Dias de Oliveira[1], Gisele Espíndola[1]

[1]Universidade Federal de Santa Catarina, Florianópolis SC, Brazil.

Correspondence: Bruno Wendorff Lucci; Email: brunowlucci@hotmail.com.

Case presentation: A 58-year-old man presented with lifelong difficulties in running and climbing stairs. He maintained functionality until age 30, when symptoms gradually escalated, including incoordination, imbalance, slurred speech, double vision, hearing loss, and urinary incontinence. Family history revealed consanguineous parents. Neurologic exam findings included an ataxic gait requiring unilateral support, thoracic kyphosis, slurred and nasal speech, hypermetria on saccadic movements with torsional nystagmus on lateral gaze, diffuse hypotonia, normal strength and reflexes without pyramidal signs, bilateral reduction in distal vibratory sensation up to the malleoli, dysmetria, and dysdiadochokinesia. MRI revealed significant volumetric reduction in cerebellar hemispheres, vermis, and cerebellar peduncles. Electroneuromyography indicated moderate to severe sensory-motor peripheral axonal polyneuropathy, predominantly sensory, affecting the distal lower limbs. Audiometry showed bilateral sensorineural hearing loss. Genetic testing identified a homozygous mutation in the SYNE1 gene. **Discussion:** Autosomal recessive spinocerebellar ataxia type 8 (SCAR8), caused by mutations in the SYNE1 gene, is a rare autosomal recessive disorder. This gene, located on chromosome 6q25.2, is one of the largest in the human genome and comprises 146 exons. Onset typically occurs between ages 6 and 42, with classical symptoms including cerebellar ataxia and motor neuron disease. Patients often experience decreased physical activity performance compared to peers and may initially present with ALS-like symptoms. Other manifestations can include cognitive deficit, brainstem dysfunction with oculomotor abnormalities, skeletal anomalies and urinary incontinence. In South America, SYNE1 mutations account for 1.89% of autosomal recessive cerebellar ataxia cases with a known genetic cause. Large cohort studies indicate that 64-81% of SCAR8 patients exhibit ataxia-plus syndromes, characterized by ataxia with additional features. The SYNE1 gene's size and its role in nuclear stability are linked to degenerative conditions, as mutations affect nucleus stability, size, and shape. Truncating mutations near Nesprin-1's N-terminal are associated with late-onset cerebellar phenotypes, while C-terminal mutations cause early-onset, complex presentations. Imaging studies show reduced cortical thickness, volume reduction in subcortical structures, brainstem, and particularly the cerebellum. White

matter disruption is evident in both the brainstem and cerebellum, while spinal cord is typically spared. **Final comments:** This case illustrates the importance of recognizing extra-cerebellar symptoms in SCAR8, which align with findings that most cases of SCAR8 present with ataxia-plus features. Comprehensive genetic testing is crucial for accurate diagnosis and understanding of SCAR8, highlighting the need for further research to elucidate the pathomechanisms and genetic variations of this disorder.

B12 vitamin deficiency and dementia in the elderly

Gabriela de Castro Cavalcante Mendonça[1], Antônio Pinheiro Goes Curvello[1], Italo Francisco Valença da Costa[1], Luisa Villanova Valadares[1], Nathalia Spacassassi Rodrigues[1], Sabrina Gomes de Oliveira[1]

[1]Centro Universitário de Maceió, Maceió AL, Brazil.

Correspondence: Gabriela de Castro Cavalcante Mendonça; Email: gabrieladecastrocm@gmail.com.

Background: Alzheimer's disease is the most common form of dementia, with a prevalence of 70% of cases, with risk factors including advanced age, genetics, low educational level and cardiovascular disease. Vitamin B12 deficiency, linked to cognitive decline, can cause neurological degeneration and affects DNA and myelin synthesis. **Objective:** Evaluate the relationship between vitamin B12 deficiency and dementia. **Methods:** A systematic literature review was realized on the correlation between vitamin B12 deficiency and cognitive decline in dementia. The information was found in articles in the PubMed database between 2012 and 2022. Inclusion criteria involved systematic review and meta-analysis studies, written in English and focused on the cognitive function of vitamin B12. The selection of articles was carried out by 5 reviewers, independently, with differences resolved by consensus. 7 articles that met the criteria were included. **Results:** Vitamins from the B complex, especially vitamin B12, have an immunomodulatory and neurotrophic function in the nervous system. In the meantime, its deficiency is associated with reduced myelination of axons, impairing cognition and the integrity of the brain structure. Studies have shown the prevalence of vitamin B12 deficiency, through elevated serum markers, such as methylmalonic acid and homocysteine, in elderly patients (> 60 years old) with dementia. Thus, it was demonstrated that B12 supplementation, associated with adequate nutrition, has a significant role in improving the Mini Mental State Examination (MMSE) score, a test whose function is the cognitive assessment and tracking of dementia, indicating a reduction of cognitive decline in elderly patients diagnosed with dementia. B12 deficiency, prevalent due to reduced gastrointestinal absorption associated with aging and certain health conditions, is not only linked to cognitive decline and dementia, but may also be a reversible cause of mental deterioration. Some studies indicate that supplementation may be more effective in elderly people with confirmed cognitive impairment, with regular monitoring of B12 levels being part of a preventive approach. Vitamin supplementation in elderly people with cognitive impairment and dementia demonstrated significant improvements, benefiting more than half of test participants. It is important to note that vegetarianism was not related to the worsening of cognitive diseases, indicating that other factors may be more determining for the development of these conditions. **Conclusion:** As it has an immunomodulatory and neurotrophic function in the nervous system, vitamin B12, when deficient, becomes an important factor in the investigation of cases of dementia in the elderly. Furthermore, the studies analyzed demonstrated improved performance on the Mini Mental State Examination (MMSE) among participants who received adequate B12 supplementation.

Bacterial meningitis in the Brazilian public health system: a regional comparison over the last decade

João Lucas Lima Diogo[1], Ana Clara Costa de Siqueira Campos[1], Gabriela Morais de Medeiros Dias Melo[1], Joanna Sousa da Fonsêca Santana[1], Lara Millena Miranda Frota[1], Luísa Lettiery Andrade Santos[1], Maria Antônia Vianna Santos[1], Maria Eduarda Kobayashi Teixeira[1], Ruben Costa Santos Neto[1], Felipe Oliveira Costa[1]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.

Correspondence: João Lucas Lima Diogo; Email: joaodiogo20.2@bahiana.edu.br.

Background: Bacterial meningitis is a global public health issue, with an incidence of 80 cases per 100,000 inhabitants in developing countries. Despite the existence of vaccines against the main pathogens, it remains highly prevalent among children and the elderly. The mortality rate can reach 54%, leading to debilitating neurological sequelae. Therefore, it is crucial to improve healthcare services and implement effective public health policies to reduce the incidence and impact of bacterial meningitis. **Objective:** To analyze the demographic distribution and hospital morbidity of bacterial meningitis in Brazil. **Methods:** This is a descriptive ecological study that analyzes the number of hospitalizations and mortality rates due to bacterial meningitis in the state of Bahia from 2014 to 2023. Data sources included the Hospital Information System (SIH) and Mortality Information System (SIM) provided by DATASUS, as well as data on resident population. Variables considered were number of hospitalizations, deaths, and mortality rate. Mortality rate was calculated as deaths per thousand inhabitants. **Results:** The Southeast region stood out with the highest number of hospitalizations and deaths, totaling 14,572 hospitalizations and 1,590 deaths, respectively. In contrast, the Southern region showed the greatest reduction in the number of deaths, with a decrease of 62 deaths from 2015 to 2016, and the highest percentage reduction in mortality rate, decreasing by 33.23% from 2015 to 2016. The Southeast region had the highest absolute growth in one year, with an increase of 614 hospitalizations from 2014 to 2015, while the North region recorded the highest percentage growth in hospitalizations, increasing by 225.8% from 2014 to 2015. The Northeast region had the highest percentage increase in mortality rate, rising by 58.49% between 2020 and 2021. Regions ranked in descending order of highest mortality rates were: Southeast, North, Northeast, South, and Midwest, with the Southeast region presenting the highest average rate of 10.91 and the Midwest region the lowest at 8.33. **Conclusion:** This study highlights significant regional variations in understanding the epidemiology of bacterial meningitis. The Southeast region had the highest number of hospitalizations and deaths, while the Southern region showed the greatest reduction in mortality. In contrast, the Northeast region experienced a concerning increase in mortality rate between 2020 and 2021, and the North region saw a significant increase in hospitalizations. Study limitations include the inability to establish causality due to the descriptive nature of the data and potential inconsistencies in data quality collected by SIH and SIM. Further studies are recommended to better understand regional factors and develop specific strategies to mitigate the incidence and burden on the healthcare system.

https://doi.org/10.5327/CBN240224

Balint syndrome in the three-territory sign outbreak

Bárbara Luisa Coraspe Gonçalves[1], Maria Luiza Levindo Coelho Martinis[1], Luiz Guilherme Gerhardt Fernandes[1], Bárbara França Amorim[1], Marina Brasileiro Cesar Leitão[1], Osvaldo Pantoja de Oliveira[1], Ana Carolina Andorinho de Freitas Ferreira[1], Cristiane Borges Patroclo[1], Marcelo Cagy[1]

[1]Hospital Federal dos Servidores do Estado, Rio de Janeiro RJ, Brazil.

Correspondence: Bárbara Luisa Coraspe Gonçalves; Email: barbaracoraspeg@gmail.com.

Case presentation: A 71-year-old man, with hypertension, diabetes mellitus, and metastatic prostatic cancer, woke up with left faciobrachial paresis and dysarthria. He arrived at the Hospital Emergency 8 hours after the ictus, when the first head CT showed a right frontal stroke. Just three days later, a neurology consultation was requested. The patient was very inattentive, especially to his left side. Initiation of horizontal saccadic eye movements was impaired bilaterally and it was noticed signs of ocular apraxia and simultagnosia. Although there were superposed findings of left extinction and hemianopsia, there was also a consistent Balint syndrome (BS). A novel CT showed additional biparieto-occipital and right frontal ischemia. **Discussion:** BS is a rare neurologic manifestation of constrained attention and limited spatial orientation in visual processing. It was firstly reported by Reszo Balint in 1909 in a patient also suffering from left neglect. It is described by a triad of simultagnosia, oculomotor apraxia and optic ataxia. This syndrome derives from bilateral parietal lesion, including parietooccipital junction. Etiologies are diverse: cerebrovascular disease (especially watershed infarctions), tumour, trauma, prion disorders, viral infections such as HIV and neurodegenerative conditions, mainly the posterior variant of Alzheimer's disease (Posterior Cortical Atrophy). Simultagnosia is the inability to see multiple stimuli at a time, regardless of visual acuity or field. It can be classified as ventral and dorsal types. In the ventral type, there is involvement of occipitotemporal ("what") pathway. Its dysfunction impairs the visual discrimination of objects without affecting the perception of their position. On the other hand, the "dorsal" or parietal cortical ("where") pathway, participates in motion perception. Its damage compromises spatial-temporal analysis, leads to the inability to judge objects position and size, and flawed visually guided eye and hand control. Hence, this pathway lesion is classically related to the BS, although both pathways might share similar processing mechanisms. Optic ataxia is the difficulty in reaching under visual guidance in the absence of motor or primary visual deficits. Oculomotor apraxia is the inability to voluntarily shift gaze in spite of intact eye rotation. The three-territory sign consists of cerebral infarctions of the bilateral anterior and posterior circulation. It is highly predictive of Trousseau's syndrome, a hypercoagulable state associated with advanced cancer. **Final comments:** BS is the result of higher-level visual processing dysfunction, characterized by the triad of optic ataxia, oculomotor apraxia, and simultagnosia. The current case depicts a rare clinical manifestation caused by multiple vascular territories ischemia, parallel to the condition of metastatic cancer.

https://doi.org/10.5327/CBN240225

Basal ganglia calcification associated with hypocalcemia and hypomagnesemia: a case report of Fahr's disease

Sarah Cardoso Moreira Fagundes[1], João Victor Vieira Giacometti[1], Rodolfo Souza de Faria[1]

[1]Faculdade de Medicina de Itajubá, Itajubá MG, Brazil.

Correspondence: João Victor Vieira Giacometti; Email: joaovgiacometti@hotmail.com.

Case presentation: A 47-year-old male patient underwent thyroidectomy in 2012 due to seven benign nodules, resulting in the partial removal of the parathyroid glands.

Continuous hormone replacement therapy with levothyroxine sodium and calcium citrate malate associated with vitamin D3 was recommended. However, the patient autonomously discontinued the treatment the same year, staying without following medical recommendations for the next 8 years, leading to progressive myasthenia in the limbs and dysarthria. In 2020, then, he experienced eight seizures and weekly episodes of muscle spasms, attributed to severe hypocalcemia and hypomagnesemia, which cause hyperexcitation of the central nervous system. The following year, bilateral brain calcifications in the basal ganglia, thalami, dentate nuclei, and subcortical regions of uncertain origin were detected through computed tomography scans. In 2023, after six months of diligent home follow-up due to the fact that he still did not recognize the importance of his treatment, the patient finally adhered to a daily medication regimen including calcitriol 0.5mg, magnesium chloride 500mg, calcium carbonate 500mg with vitamin D3 400mg, levothyroxine sodium 150mg, clonazepam 2mg, and phenobarbital 100mg, resulting in the cessation of seizures and clinical improvement. However, the patient's speech rigidity progressively worsened. **Discussion:** Fahr's disease affects less than 2% of the global population and typically manifests from the fourth decade of life. Despite its uncertain pathophysiology and etiologies, it is agreed that hypocalcemia and hypomagnesemia, associated with brain calcifications, are hallmark conditions of this pathology. Alongside a probable genetic predisposition, the factors leading to this disease are linked to hyperexcitation of the nervous system, resulting in seizures, spasms, and muscle rigidity. In the discussed case, chronic serum reduction of calcium and magnesium levels, following thyroidectomy and partial parathyroidectomy, was exacerbated by persistent non-adherence to treatment. Additionally, brain imaging emphasizing cerebral calcinosis supported the suspicion of Fahr's disease. Thus, the proposed treatment aimed to alleviate neuromuscular symptoms by normalizing the serum profile. However, the persistent worsening of speech rigidity suggests a possible irreversible involvement of brain areas due to the chronic inadequately treated condition. **Final comments:** This study details a rare case of Fahr's disease, a condition linked to brain calcifications and severe hypocalcemia. The description of this case is crucial for enriching the limited knowledge about this pathology, contributing to the investigation of etiologies and treatments to improve the quality of life of affected patients. The limitations of this research include the scarce scientific literature and the challenging clinical detailing of the case due to the prolonged progression of the disease.

https://doi.org/10.5327/CBN240226

Basal ganglia encephalitis with fulminant Parkinsonian features and dysautonomia in a child: look no further than levodopa

Marciéli Gerhardt[1], Andressa Noschang[1], William Alves Martins[1]

[1]Hospital São Lucas, Porto Alegre RS, Brazil.

Correspondence: Marciéli Gerhardt; Email: marcieligerhardt@yahoo.com.br.

Case presentation: A 5-year-old presented to our service with a history of altered mental status, rigidity and tremors. A few days prior, he presented a minor upper respiratory illness, which improved upon receiving azithromycin for 5 days. Six days after, he became confused and developed a slow and monotonous voice tone. At the emergency room, head CT was unremarkable. Lumbar puncture showed 7 cel/mm^3 (100% lymphocytes) with slightly increased protein on CSF, prompting initiation of acyclovir for possible HSV encephalitis. Despite treatment, his condition worsened with supervening spasms, akinetic mutism, worsening conscience and severe dystonic "seizures". MRI showed bilateral striatum and caudate hyperintensities, with minor gadolinium enhancement. At the same time, PCR for HSV and other viruses returned negative, and he was started on methylprednisolone 20mg/kg and IVIG 400mg/kg/day for 5 days each. Acyclovir was weaned off and he was transferred to our hospital. At arrival, he had painful dystonia in which his lower limbs would extend with flexion of his arms, at times with oromandibular spams - so severe he eventually lesioned his lower lips - intermixed with low frequency tremors. After the immunotherapy he could interact, however still exhibited akinetic mutism. Alongside worsening of his parkinsonian features, he developed spiking temperatures (39-40.5°C) and his CPK increased slowly. Due to this, we provided a trial of levodopa/benzerazide up to 20mg/kg/day, which controlled his dystonic seizures and significantly improved his rigidity. A new LP was done and neuronal surface antibodies (CBA method), as well as onconeural antibodies were negative. Subsequently, both IgG and IgM antibodies against Mycoplasma pneumoniae were positive, as well as low serum titers of anti-GAD (1/64). Six weeks after onset he was discharged with a diagnosis of autoimmune/post-infectious basal ganglia encephalitis (BGE), already walking and speaking a few words. A week after discharge, he was completely asymptomatic and began weaning off levodopa. **Discussion:** BGE is a rare autoimmune or post-infectious encephalitis that affects mostly the caudate and putamen. Symptoms include severe Parkinsonism, dystonia and altered consciousness. A few causes have been reported, including direct invasion by M. pneumoniae and other respiratory viruses. This, however, has been challenged for the discovery of anti-DR2 antibodies against the basal ganglia, leading to an autoimmune etiology, perhaps with an infectious trigger. Our case of BGE showed significant improvement after immunotherapy and levodopa. **Final comments:** Due to the rarity of this condition, it is unlikely large studies will give definitive answers over which treatment course to follow. Nonetheless, our case demonstrates high dosages of levodopa could improve parkinsonism and cease dystonic 'seizures' and dysautonomia, while immunotherapy has not fully stopped the autoimmune process.

Behavioral variant frontotemporal dementia and the DYSF gene: causal relationship or coincidence? A case report

Thamires Marx da Silva Santos[1], Paulo Caramelli[1], Leonardo Cruz de Souza[1], Elisa de Paula França Resende[1]

[1]Universidade Federal de Minas Gerais, Hospital das Clínicas, Belo Horizonte MG, Brazil.

Correspondence: Thamires Marx da Silva Santos; Email: marxthamires@gmail.com.

Case presentation: The patient is a 75-year-old woman, daughter of consanguineous parents, with a family history of muscular dystrophy and neurofibromatosis, but no reported familial cases of dementia. She was diagnosed with behavioral variant (bv) frontotemporal dementia (FTD) at the age of 65, presenting symptoms such as forgetfulness, visual hallucinations, lack of empathy, and unmotivated laughter. She did not present clinical features of motor neuron disease. Magnetic resonance imaging studies revealed significant frontotemporal atrophy, without significant white matter hyperintensities (Fazekas scale = 1). A genetic panel was performed, confirming the presence of the DYSF gene mutation in heterozygosity variant c.5979dup (p.Glu1994Argfs*3). Of note, the patient did not present other pathogenic mutations such as GRN, MAPT or TARDBP. **Discussion:** Current literature does not report an association between FTD and mutations in the dysferlin (DYSF) gene, which are associated with specific myopathies. However, there are reports linking this gene to Alzheimer's disease, indicating a possible role in neurodegeneration. **Final comments:** This clinical case raises the question of whether the presence of the DYSF gene mutation constitutes a mere coincidence or if there is a causal relationship with the manifestation of bvFTD. Previous study showing the accumulation of dysferlin intra-neuronal in the brain may suggest a pathological substrate for neurodegenerative disorders. Further investigation with other samples and additional studies may help clarify this relationship and its relevance in understanding the pathogenesis of FTD.

Beneficial nucleosides reposition at TK2d: the first Brazilian cohort of treated patients

Cristiane Araujo Martins Moreno[1], Tatiana Ribeiro Fernandes[1], Gabriel Saboia de Araújo Torres[1], André Macedo Serafim da Silva[1], Mariana Hiromi Manoel Oku[1], Gabriella Corrêa Dousseau[1], Michelle Abdo Paiva[1], Clara Gontijo Camelo[1], Mariana Cunha Artilheiro[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, São Paulo SP, Brazil.

Correspondence: Cristiane Araujo Martins Moreno; Email: cristianeammoreno@gmail.com.

Background: Thymidine kinase 2 (TK2) is the enzyme responsible for the phosphorylation of deoxyribonucleosides deoxythymidine and deoxycytidine to deoxythymidine and deoxycytidine monophosphates, respectively. Both are phosphorylated to generate the deoxynucleosides triphosphates needed for the replication of mtDNA. Biallelic pathogenic variants within the TK2 gene result in TK2 deficiency (TK2d) and lead to DNA maintenance defects and depletion of mitochondrial DNA. This condition typically presents with a progressive and threatening myopathy. A supplementation therapy using monophostate nucleosides to bypass the biochemical defect was developed and showed pronounced clinical benefits at open-label trials, enhancing the importance of an early diagnosis and early treatment to change the lethal natural history of the disease. Here we present the clinical findings and follow up of eight Brazilian patients receiving the nucleosides reposition through compassionate program. **Methods:** Eight patients followed at a large Terciary Center in Brazil were receiving supplementation therapy with deoxynucleosides (D'Thd and dCtd) in a compassionate program by the sponsor, offered orally at a dosage of 400mg/kg/day for each compound. **Results:** Patients were 20(±16) years old, two presented infantile-onset and the others childhood-onset. All of them were severely affected and attended to the requirements for a compassionate program. The protocol was approved by ANVISA in addition to the Clinical Hospital at FM/USP. One patient received the treatment for 15 months and presented an increase of 28 points at Chop-Intend, increased weight, descreased time-on ventilation and regained the ability to swallow. Two patients were on treatment for 6 months, both presented a significantly increased at MFM-32. Five adult patients with severe presentation of the disease were receiving the reposition for one month. Despite not presenting improvement at motor scales, all of them referred subjective improvements. They were more active and feeling less fatigued. **Conclusion:** TK2d is a progressive disease with high mortality rates. However, due to a potential treatment capable of changing the natural history of the diseas, the early recognition of this disease is urgent. We demonstrasted positive from the first patients receiving the treatment in Brazil.

Background: The latest edition of the International Classification of Sleep Disorders (ICSD-3) has redefined narcolepsy terminology, replacing the subdivisions " with" or "without" cataplexy to narcolepsy type 1 (NT1) and type 2 (NT2), based on hypocretin-1 levels in cerebrospinal fluid (CSF). However, this biomarker is not readily available in many countries, including Brazil, and the lumbar puncture required for its measurement may deter patients. Also, hypocretin could be low in other neurological disorders with damage to the blood-brain barrier. Cataplexy and a positive multiple sleep latency test (MSLT) are used to diagnose NT1 without hypocretin data. Nevertheless, these criteria have limitations, as both NT1 and NT2 patients may exhibit atypical or absent cataplexy, and most episodes are not witnessed by the specialist, leading to diagnostic challenges. **Objective:** To compare clinical and genetic variables between NT1 and NT2, focusing beyond cataplexy and hypocretin measurement. **Methods:** Narcolepsy was diagnosed according to ICSD-3 criteria. Classification into NT1 and NT2 were based on CSF hypocretin levels measured by radioimmunoassay. Clinical, neurophysiological, and genetic data were obtained. Univariate and multivariate analyses were performed to compare the two groups using Chi-Square or ANOVA with the aid of Epi Info® and Partial Least Square Discriminant Analysis (PLS-DA), Variance Importance of Projection (VIP score), cross-validation with R2 and Q2 values and Area Under the ROC Curve (AUROC) were generated on MetaboAnalyst 6.0. **Results:** A matrix table encompassing 73 variables and 33 patients (17 NT1 and 16 NT2) was generated. NT1 subjects exhibited higher Body Mass Index (BMI), Epworth Sleep Scale (ESS) scores and frequency of cataplexy, along with lower Sleep Latency (SL), Total Sleep Time (TST) and diagnostic delay compared to NT2 ($p<0.05$). Cataplexy was reported by 15 NT1 (88.3%) and three NT2 (18.7%) subjects. Detailed characterization allowed differentiation between typical and atypical cataplexy. No NT2 patients present typical cataplexy, but atypical cataplexy was present in 17.6% of NT1 cases. The most common features of atypical cataplexy included triggers by negative emotions.HLA-DQB1*06:02 had the highest ranking on the VIP Score. Shorter sleep latency, typical cataplexy, and higher BMI were also significant parameters in differentiating NT1 from NT2 in both univariate and multivariate analyses ($p<0.05$). **Conclusion:** No single test alone is perfect for distinguishing NT1 and NT2. While detailed anamnesis can aid in the interpretation of typical and atypical cataplexy, it remains subjective. Therefore, objective parameters beyond cataplexy, such as HLA-DQB1*06:02, shorter sleep latency, and higher BMI, are essential for a more accurate diagnosis of NT1 and NT2. This differentiation can be helpful since new drugs based on hypocretin function have been developed.

Beyond myelopathy: neuromuscular manifestations of HTLV-1

Andre Vinicio Cruz Mesias[1], Maria Fernanda Hamamoto Leati[1], Camila Rodrigues Nepomuceno[1], Daniel Santos Uchoa[1], Gabriella Corrêa Dousseau[1], Daniel Thomás Pereira Lopes[1], Cristiane de Araújo Martins Moreno[1], Julian Letícia de Freitas[1], Maria Sheila Guimarães Rocha[1]

[1]Hospital Santa Marcelina, São Paulo SP, Brazil.

Correspondence: Maria Fernanda Hamamoto Leati; Email: mfleati@gmail.com.

Case presentation: Patient 1: A 68-year-old woman presented in 2008 with progressive lower limb weakness that progressed to wheelchair dependence in less than 3 years, accompanied by a 30 kg weight loss over 2 years. Motor strength examination revealed proximal (MRC grade 2) and distal (MRC grade 4) weakness in the lower limbs, along with proximal atrophy. In the upper limbs, proximal weakness (MRC grade 4) was observed. Osteotendinous reflexes were preserved, except for the abolished patellar reflex. Plantar cutaneous reflexes showed flexion. Laboratory tests indicated normal CPK and aldolase levels, but serology was positive for HTLV-1. Cerebrospinal fluid (CSF) analysis confirmed HTLV-1 positivity. Electromyography (EMG) demonstrated asymmetric proximal myopathy, more severe in the lower limbs, with early recruitment and small amplitude potentials. A muscle biopsy indicated inclusion body myositis, showing CD8+ cells and macrophages surrounding and invading non-necrotic fibers, rimmed vacuoles, mitochondrial alterations, and protein aggregates. Patient 2: A 59-year-old man reported reduced strength in his lower limbs, particularly the left leg, for several years without knowing the exact onset. Significant limitations became apparent after 2020, when he required unilateral support to walk. Motor strength examination revealed MRC grade 4 weakness in the right lower limb and MRC grade 3 in the left. Atrophy, fasciculations, spasticity in the lower limbs, and signs of pyramidal release were noted in all four limbs. He walked with a scissor gait, more severe on the left side, using unilateral support. HTLV serology was positive. MRI did not indicate myelopathy. Electroneuromyography (ENMG) met the criteria for diffuse lower motor neuron involvement (four segments) with active denervation and chronic reinnervation, classifying this case within the HTLV-ALS spectrum. **Discussion:** There are several clinical and radiological presentations of neuromuscular diseases related to HTLV-1, as seen in our cases. The most frequent complications are tropical spastic paraparesis/myelopathy (HAM/TSP) and adult T-cell leukemia/lymphoma (ATL). Some cases of HAM/TSP mimic ALS (Amyotrophic Lateral Sclerosis), potentially leading to diagnostic confusion, though differing mainly in autonomic and sensory symptoms in addition to the bulbar segment. Inflammatory myositis associated with HTLV-1 has few reported cases despite in vitro evidence of myotoxicity by the virus. So far, there are several case reports of patients with IBM and HTLV-I infection. In addition, we have polyneuropathy also composing other neuromuscular presentations described with HTLV. **Final comments:** Both patients in these cases exhibit rare complications related to chronic HTLV-1 infection, highlighting the importance of clinical reasoning for accurate investigation given the wide range of differential diagnoses.

Bilateral asynchronous lateralized periodic discharge in a patient with intraparenchymal hemorrhage

Marcillio Holanda Bezerra[1], Carlos Alexandre Twardowschy[2]

[1]Universidade Federal do Maranhão, Hospital Universitário, São Luís MA, Brazil.
[2]Pontifícia Universidade Católica do Paraná, Curitiba PR, Brazil.

Correspondence: Marcillio Holanda Bezerra; Email: marcillio.holanda@hotmail.com.

Case presentation: A pregnant, 43 years old, 35 weeks of gestation, was admitted with pre-eclampsia and seizure. On physical examination: the patient presented scale coma Glasgow 14 (A4V4M6) and left hemiparesis. Brain MRI showed: Image with low signal on the SWI, T2 and FLAIR sequences with hypersignal foci on T1, without enhancement after the use of venous contrast in the lentiform nucleus up to the corona radiata on the right, measuring 2.2 x 2.1 x 2.0cm, corresponding to intraparenchymal hemorrhage. An EEG was performed, which showed asynchronous lateralized periodic discharges (LPD) starting in the right temporal region, followed a few milliseconds by LPD in the left temporal region (Bilateral Asynchronous LPD). Patient was discharged after the 12th day of hospitalization, GSG 15 and with left brachiofacial paresis. **Discussion:** One of the changes to the ACNS Standardized Critical Care EEG Terminology in the 2021 version was the addition of the term asynchronous bilateral LPD. Bilateral LPDs are less common than other rhythmic and periodic patterns. It is estimated to occur in less than 1% of ICU patients, but the incidence of bilateral asynchronous LPDs is not known. These are defined as a lateralized periodic pattern that consistently begins in one hemisphere and propagates to the other hemisphere more than 80% of the time. Unlike independent bilateral LPDs, which are associated with acute bilateral brain injury in more than 70% of cases and consequently tend to have a poor prognosis, bilateral asynchronous LPD is associated with unilateral brain injury. We highlight in the present case that the right hemisphere involved with the intraparenchymal hemorrhage was where the bilateral asynchronous LPDs consistently began. **Final comments:** Bilateral asynchronous LPD is a rare pattern, and more studies are needed on its prevalence, pathophysiology, etiologies and prognosis.

Bilateral facial palsy secondary to dengue fever: a case report

Guilherme Rocha Cardoso[1], Gustavo Alves Cangussú[1], Gustavo de Souza Campos[1], Luídi Neves Nascimento[1], Victor Santos Vilares[1], Davi Tanajura Costa[1], Philip George Glass Andrade[1], Emmanuel Santos Trindade[1], Priscila Santos Oliveira[1]

[1]Universidade Estadual do Sudoeste da Bahia, Vitória da Conquista BA, Brazil.

Correspondence: Érica Otoni Pereira Miranda; Email: ericaotoni15@gmail.com.

Case presentation: A 50 year old female patient was referred to the neurology outpatient clinic with complaints of facial palsy for 10 days. She reported hospitalization due to dengue hemorragic fever 30 days ago. Subsequently, she developed a bilateral facial palsy, with difficulty in facial mimicry movements and blinking. She also presented progressive cephalocaudal paresthesias, worsening in the perioral region right hemiface and limbs. There were no reports of headache, fever, or associated visual and auditory impairments. Upon physical examination, it was noticed a bilateral seventh cranial nerve impairment, with ptosis, generalized facial mimicry limitation, reduced strength and inability to completely close the eyelids. In view of the above, a clinical diagnosis of bilateral facial palsy secondary to dengue was made. The therapeutic approach was corticosteroid therapy with prednisone 40 mg/day, facial physiotherapy and ocular protection with ophtalmic lubricating solution and occlusion at night. **Discussion:** Dengue is an acute febrile illness with a systemic and dynamic nature, and it has a highly variable severity spectrum. It is endemic in Brazil, transmitted by the Aedes aegypti mosquitoes, mainly in hot and rainy months. Besides its classic manifestations such as fever, myalgia and circulatory shock in severe cases, dengue can also present with neurologic involvement. The literature describes cases of encephalitis, meningitis, Reye's syndrome, and polyradiculoneuritis, which includes Guillain-Barré syndrome (GBS) and

its variants. This report presents a patient with a typical pattern of polyradiculopathy, characterized by bilateral facial motor impairment, which may indicate bilateral seventh cranial nerve involvement. Additionally, there was sensory impairment, with diffuse paresthesias throughout the body. These findings point to the diagnosis of a GBS variant, characterized exclusively by bilateral facial paralysis and paresthesias. GBS can occur early or late in the disease course and is likely mediated by an immune mechanism in which antibodies (due to cross-reaction) are directed against myelin and/or axon, resulting in increased latency for the transmission of neuronal signals to the innervated regions and a reduced compound muscle action potential, indicating a decrease and/or blockage in impulse conduction velocity. Furthermore, GBS secondary to arbovirus infection presents a faster clinical course compared to GBS from other causes. This is a rare post-infectious manifestation in dengue cases, with few cases described in the literature. **Final comments:** Therefore, it is suggestive that the bilateral facial palsy in this patient is due to GBS variant secondary to arbovirus infection. Despite being a low-incidence clinical presentation, it presents significant implications that must be carefully analyzed for diagnosis, as dengue has various spectrums of nervous system involvement.

Bilateral fusiform internal carotid artery aneurysms: case report and challenges in the approach

Maria Clara Motta Barbosa Valente[1], Filipe Brito Ferraz da Silveira[1], Camila Lopes Figueiredo[1], Rafael Chaves Claudino de Queiroga[1], Letícia Machado Dumont[1], Cícero Rodrigues Veloso[1], Lorenna Castro Di Filice[1], Tomaz Lima Moreira[1], Vivian Dias Baptista Gagliardi[1], Rubens José Gagliardi[1]

[1]Santa Casa de Misericórdia de São Paulo, São Paulo SP, Brazil.

Correspondence: Maria Clara Motta Barbosa Valente; Email: mariaclarambvalente@gmail.com.

Case presentation: A 55-year-old male patient with a history of hypertension and smoking presented with an 8-month history of progressive dysphagia and weight loss. He was initially investigated for gastroesophageal reflux disease. Two months prior to hospital admission, he experienced an episode suggestive of a seizure (without further clinical details). A cranial and cervical CT scan revealed bilateral intracranial expansile lesions of undetermined etiology. He was admitted to the emergency department with left hemiparesis and decreased level of consciousness (Glasgow Coma Scale: 9). Neurological examination revealed left hemiparesis, hyperreflexia and bilateral extensor plantar responses. CT angiography showed fusiform dilatation of the right internal carotid artery (26 x 16.8 mm) and irregularities and dilatation of the left internal carotid artery (maximum diameter of 9.3 mm). There was also displacement of the left posterior cerebral artery, superior cerebellar artery, and basilar artery, suggesting an adjacent mass. Angiography confirmed bilateral aneurysms. The patient's level of consciousness deteriorated and he required endotracheal intubation. A repeat CT scan showed brainstem displacement due to aneurysm compression. A joint discussion with neurosurgery considered endovascular or bypass approaches, but the patient developed loss of brainstem reflexes and brain death before the procedure. **Discussion:** Bilateral fusiform internal carotid artery aneurysms (FCIAs) pose a therapeutic challenge due to their extensive size and the inability to perform techniques such as clipping due to the absence of a neck. We present a case of bilateral FCIA with brainstem compression. In this case, the risks of surgical and non-surgical approaches were high, as the latter would lead to an unfavorable outcome due to compression of vital structures. Two options were considered: open bypass or stress test with occlusion of the right internal carotid artery and assessment of collateral circulation, followed by endovascular intervention for aneurysm exclusion. However, there is no gold standard treatment technique due to the complexity and individuality of each case. **Final comments:** Despite the unfavorable outcome, this case highlights the importance of discussing the approach technique and the therapeutic challenges of FCIAs, especially in the presence of adjacent structure compression. The rarity of these cases limits the evidence for the best treatment, and decision-making regarding the timing of intervention is crucial due to the risk of rupture with aneurysm expansion and adjacent structure compression.

https://doi.org/10.5327/CBN240235

Bilateral optic neuritis and probable MOG-associated demyelinating syndrome in pediatric patient: a case report

Danielli Regina da Silva[1], Renata Cristina Franzon Bonatti[1], Airton Sena Oliveira Sales[1], Laisy Bárbara Souza Silva[1], Guilherme Victor Rocha Pereira[1], Marcos Luiz Belotti de Souza[1], Cairo Cruvinel[1], Lucas Santos Andrade[1], Lorenzo Pereira de Almeida Melo Montes[1], Alex Eduardo da Silva[1]

[1]Universidade Federal do Triângulo Mineiro, Uberaba MG, Brazil.

Correspondence: Danielli Regina da Silva; Email: d202011051@uftm.edu.br.

Case presentation: Male patient, 11 years old, mixed race, presenting with progressive bilateral decreased visual acuity for three days and weight loss of eight kilograms over one week. Denies fever, headache, nausea, vomiting, weakness, speech changes, confusion, ocular trauma, recent infections, or prior comorbidities. Diagnosed with myopia one year ago, corrected with visual aids. Neurological examination revealed bilateral papilledema, midriasis, and absent pupillary light reflexes, without other abnormalities. Cranial computed tomography showed mild elongation and tortuosity of the optic nerves. However, magnetic resonance imaging demonstrated symmetric T2 and diffusion hyperintense areas in the posterior orbital and anterior intracranial portions of the optic nerves and optic chiasm, with anomalous post-contrast enhancement in the proximal intracranial portions of the optic nerves and faint hyperintensity in the Flair sequence in the right thalamic pulvinar. Serological tests were negative for antinuclear antibodies, rheumatoid factor, HLA-B-27 antigen, as well as Cytomegalovirus, VDRL, Treponema pallidum, toxoplasmosis, HBSAg, anti-HBS, HIV, and Herpes simplex virus. Cerebrospinal fluid analysis was normal, with negative results for Cryptococcus neoformans antigen, IgG antibodies against aquaporin 4 (AQP4-IgG), and other serologies. Provisional diagnosis of bilateral optic neuritis and probable MOG-associated central nervous system demyelinating syndrome (MOGAD). Treated with five days of methylprednisolone pulse therapy, resulting in gradual improvement of bilateral visual acuity. Oral corticosteroid initiated for outpatient follow-up. **Discussion:** Optic neuritis in childhood, a rare and severe autoimmune inflammatory demyelinating disorder of the central nervous system, occurs in only 5 to 10% of cases. In cases negative for AQP4-IgG antibodies, like the one described, the presence of antibodies against myelin oligodendrocyte glycoprotein (MOG-IgG) is the leading etiological hypothesis, particularly with bilateral anterior involvement while sparing the optic chiasm. However, due to limitations in resources within the Unified Health System, specific confirmatory testing could not be conducted. Initial treatment with methylprednisolone pulse therapy followed by oral corticosteroids is recommended, as demonstrated in this case. **Final comments:** This case underscores the importance of a meticulous approach to diagnosing neurological disorders in children, including detailed clinical history, thorough neurological examination, and imaging studies. Diagnostic confirmation through specific tests such as AQP4-IgG and MOG-IgG is crucial for guiding appropriate and safe treatment in this age group, where optic neuritis presents unique challenges compared to adults.

Bilateral petrosal apex cephalocele and empty sella turcica - case report

Renan Iegoroff[1], Alvaro Marcelo Huchani Huanca[1]

[1]Afya, IPEMED, São Paulo SP, Brazil.

Correspondence: Renan Iegoroff; Email: renan_iego@outlook.com.

Case presentation: Woman, 42, Caucasian, early childhood education teacher. Has been working with neurology for migraines with aura for approximately ten years, with partial pain control and irregular prophylactic treatment, and for ten months resuming treatment with Topiramate 25mg/day. No history of metabolic endocrine changes, absence of galactorrhea and vision changes, presenting grade 1 obesity as a comorbidity and a previous history of two episodes of pulmonary thromboembolism of unclear cause, on neurological examination, without evidence of focal signs and cephaliatric examination only with finding of painful palpation of the greater occipital nerve on the left, a magnetic resonance imaging examination was performed without contrast (23.12.23) which revealed an empty sella turcica, when carrying out additional tests for differential diagnosis. This was evidenced on the Sela Turcica Magnetic Resonance Imaging with Contrasts (21.01.24) enlargement of the Bilateral Cavum of Meckel at the expense of cystic formations with characteristics of bilateral petrous apex cephalocele; in laboratory tests (01/24/24) resting prolactin, IGF-1, cortisol, aldosterone, fasting insulin, TSH, T4L, FSH were within normal limits. **Discussion:** Cephalocele of the petrous apex is a cystic lesion resulting from the herniation of Meckel's Cavum, and the bilateral condition is a rare phenomenon, described in the literature until 2022 around 21 cases, it is believed that this pathology occurs due to increased intracranial pressure with herniation of the meninges, and must be differentiated by its characteristics from cholesteatomas, mucocele and paragangliomas, which in this case were discarded due to the well-defined characteristics of the image. When reviewing the 21 bilateral cases, 80% of the cases were in women, around 55% of the cases bilateral lesions presented with an empty sella turcica, 32% presented with headache and 0.01% (2 cases) underwent surgical interventions, and always without changes in endocrinological functionality. Management, therefore, is mostly conservative, with management of the symptoms associated with the condition, in the cases reported surgically, one of them had surgery due to the initial diagnosis of cholestoma with lateral gaze paralysis, and the other case had surgery due to bilateral cranial changes with cerebrospinal fluid leaks and recurrent meningitis. **Final comments:** The rarity of the described case and the growing clinical association of presentation with empty sella turcica are evident in the literature, making it necessary for the neurologist to understand the differential diagnosis and recognition of the lesional aspect due to the management being mostly conservative.

Bilateral profound sensorineural hearing loss due to cerebrovascular event

Hélio Aquaroni Farão Gomes[1], Caroline de Barros Viegas[1], Ana Beatriz Marangoni Baston[1], Pedro Machry Pozzobon[1], Gabriel Pinheiro Modolo[1], Renan Macionil Cotrim[1], João Marcio Borgue de Oliveira[1], Luiz Felipe Moraes Schwerz Bonadiman Blanco[1], Itamar Meireles Andrade Santos[1], Dominick Esthephanny Monteiro Silva[1]

[1]Universidade Estadual Paulista, Botucatu SP, Brazil.

Correspondence: Hélio Aquaroni Farão Gomes; Email: heliofarao@hotmail.com.

Case presentation: A 59-year-old patient with a history of diabetes, hypertension, and smoking presented with a sudden onset of vertigo, nausea, and hearing loss in the left ear. The following day, he noticed facial paralysis on the same side and was referred to the hospital 20 hours after the onset of symptoms. Upon admission, the patient complained of horizontal diplopia and hearing loss. Neurological examination revealed dysarthria, altered balance in orthostasis with a tendency to fall backwards, left lateral rectus paresis, and peripheral facial paresis on the left. Additionally, inexhaustible multidirectional nystagmus, bilateral sensorineural hypoacusis, hypoesthesia on the left side, and dyskinesia between the trunk and limbs were observed. A CT scan of the brain showed hypodensity in the bulbopontine transition. Arterial angiography revealed occlusion of the basilar artery. The patient was admitted to the stroke unit. Further investigation with magnetic resonance angiography showed hypoplasia of the right vertebral artery, hypersignal in the left vertebral artery, and occlusion of the basilar artery with reperfusion by communicating arteries near the intracranial source. Brain MRI revealed hypersignal in the pons, middle cerebellar peduncle, dentate nucleus of the left cerebellum, and the right cerebellar hemisphere. This affected region overlaps with the facial and vestibulocochlear nerve nuclei on the left. A transcranial Doppler was also performed, showing subocclusion of the basilar artery from its origin to the middle third. Following the investigation, prophylaxis was started with 300 mg of aspirin (AAS) and 75 mg of clopidogrel for 3 months. Evaluation by the otorhinolaryngology department showed continued anacusis on the left and hypoacusis on the right. Audiometry revealed bilateral profound sensorineural hearing loss, with a voice detection threshold of 80 decibels on the right and over 100 decibels on the left, indicating greater impairment on the left. Electro-oculography was compatible with mixed cochleovestibulopathy. **Discussion:** Posterior circulation strokes can manifest with non-specific symptoms, causing a delay in diagnosis compared to anterior circulation cases. Sensorineural deafness has been described in stroke cases, especially in those involving occlusion of the anteroinferior cerebellar artery, but it usually occurs unilaterally. **Final comments:** In this case, due to the occlusion at the origin of the basilar artery with collateral filling at its uppermost portion, the anteroinferior cerebellar artery, which originates from the initial part of the basilar artery, was bilaterally impaired. Consequently, the bilateral labyrinthine artery was compromised by the pattern of the lesion. Brainstem lesions with a better prognosis are typically microvascular and usually have more unilateral involvement, unlike this case, which involved a large vessel lesion.

Bilateral schwannomas: a case of schwannomatosis

Daniel Mariani Favalessa[1], Ivo Gabriel Ribeiro Carvalho[1], Melissa dos Santos Matos[1], Guilherme Valiate Picoli[1], Guilherme Marques Nunes Mamede[1], Renann Nunes Pirola[1]

[1]Universidade Federal do Espírito Santo, Vitória ES, Brazil.

Correspondence: Daniel Mariani Favalessa; Email: dmfavalessa@gmail.com.

Case presentation: A 55-year-old male reported that at 27 years old, he began experiencing paresthesia followed by loss of strength in his right hand, progressing from distal to proximal, and subsequently involving the rest of the upper limb. After three months, similar symptoms occurred in the left upper limb. At 52 years old, he noticed the appearance of two bilateral supraclavicular cervical nodules. He has no complaints regarding the lower limbs, bulbar, vestibular, or ocular symptoms. He has a history of epilepsy since age six, with seizures starting with facial paresthesia, progressing to impaired consciousness and disjointed speech, without significant postictal symptoms. He denies a similar family history, skin spots, or other neurological diseases. On examination, bilateral interscalene tumors were observed, with no café-au-lait spots, interosseous muscle atrophy more pronounced on the left side, grade IV strength in the upper limbs, except for left shoulder abduction (grade II). Global areflexia, preserved superficial sensation, and distal hypopallesthesia in the lower limbs and left hand were noted. Electroneuromyography indicated severe demyelinating sensorimotor polyneuropathy with signs of activity. A biopsy of the left tumor indicated schwannoma. **Discussion:** Schwannomatosis is a term used by neurologists to describe conditions involving multiple schwannomas, excluding NF1 and NF2. In 2022, its classification was updated to include a spectrum of schwannoma predisposition syndromes, such as those involving SMARCB1 and LZTR1 genes. Among these, the LZTR1 gene has the most significant diagnostic overlap with NF2, making differentiation challenging. However, the absence of bilateral vestibular schwannomas is particularly reliable in ruling out NF2 in patients over 30 years old. In this case, the patient presents with severe demyelinating sensorimotor polyneuropathy associated with bilateral peripheral schwannomas and a history of epileptic seizures since childhood, without skin, eye, or cranial nerve involvement. The biopsy revealed lesions consistent with non-intradermal schwannomas, confirming unspecified schwannomatosis, with genetic testing necessary for specific diagnosis. However, genetic testing is still difficult to access and does not determine prognosis or inform medical treatment, making clinical diagnosis often sufficient. Treatment is mainly symptomatic, focusing on pain management. **Final comments:** Finally, the diagnostic complexity of schwannomatosis and the difficulty in distinguishing it, especially from NF2, are highlighted. This requires a comprehensive approach combining clinical data, laboratory tests, imaging studies, and, when possible, genetic testing. Management is symptomatic, with the primary focus on pain relief.

Correspondence: Caroline Zapelini; Email: zapelinicarol@gmail.com.

Case presentation: A 73-year-old female patient presented with frontal headache, fever, myalgia, and nausea. After six days of progression, the patient was admitted to a tertiary hospital due to bilateral third nerve palsy, complete on the right side and incomplete on the left side. There was no alteration in the level of consciousness or signs of meningeal irritation. Laboratory tests showed mild leukopenia, no thrombocytopenia, normal coagulation profile, and no renal or hepatic dysfunction. Cerebrospinal fluid analysis revealed 432 cells with predominance of lymphocytes, protein level of 141, and glucose level of 81. Bacterial cultures were negative. Empirical acyclovir treatment was initiated and later discontinued after negative herpes PCR. Dengue fever IgM antibodies were detected in the blood. Brain MRI showed an enlarged hypophysis with suprasellar extension, heterogeneous appearance, and contrast enhancement, suggestive of a pituitary macroadenoma with hemorrhagic degeneration. The dimensions were approximately 2.2 x 1.7 x 1.4 cm (estimated volume of 2.74 cm^3). Hormonal tests confirmed hypopituitarism. The patient was diagnosed with pituitary apoplexy and started on dexamethasone, leading to complete resolution of bilateral III cranial nerve palsy in a few days. Follow-up MRI showed reduction of the adenoma, and the patient remained stable without adrenal crisis. She was discharged with outpatient follow-up. **Discussion:** Bilateral third nerve palsy is uncommon and may be associated with lesions in the nucleus or cavernous sinus, such as tumors, hemorrhages, aneurysms, and other etiologies. In the described case, where ophthalmoplegia is due to pituitary apoplexy (PA), there is a sudden increase in content in the sella turcica, raising intrasellar pressure and leading to compression of adjacent structures in the cavernous sinus, such as the oculomotor nerve. Bilateral third nerve palsy in PA is rare. PA is an endocrine emergency resulting from hemorrhage or infarction in a pituitary tumor and must be promptly recognized to avoid possible complications such as acute adrenal insufficiency. In the reported case, besides the atypical presentation, the patient had an ongoing dengue infection, with cerebrospinal fluid (CSF) changes suggesting a differential diagnosis of viral meningoencephalitis. PA usually does not affect CSF, although aseptic meningitis has been described in some cases. Dengue fever has been described as a precipitating factor for PA in patients with pituitary adenoma and has been linked to coagulation abnormalities. Although the patient did not show laboratory abnormalities such as thrombocytopenia, elevated INR, and TTPA, the infectious condition may have contributed to the case's progression. **Final comments:** The case illustrates a rare presentation of AP, with bilateral involvement of the oculomotor nerve, associated with dengue fever

Bilateral vestibulopathy due to aminoglycoside otoxicity in patients with chronic kidney disease: a series of cases

Thaís Laura Almada da Fonseca[1], Isabelly Arruda Cardoso Slavec[1], Yasmin Coelho Patrial[1], Enã Rezende Bispo Do Nascimento[1], Aline Mizuta Kozoroski Kanashiro[1]

[1]Hospital Regional de Mato Grosso do Sul, Campo Grande MS, Brazil.

Correspondence: Thaís Laura Almada da Fonseca; Email: thaisalmada123@gmail.com.

Bilateral vestibulopathy (BVP) is an uncommon disease, with an incidence of approximately 28/100,000 cases per habitant. In around 50% of cases BPV is idiopathic, however it can be secondary to ototoxicity, bilateral Ménière's disease, bilateral infectious/inflammatory vestibular diseases; autoimmune, neoplastic, genetic and other causes. Despite the well-established diagnostic criteria by the Barany society in 2017, recognition of this condition is still not achieved by many doctors in clinical practice. This is the report of a series of 5 cases of BPV treated in 2023, in an outpatient clinic specialized in vestibular disorders. All patients had a previous diagnosis of chronic kidney disease (CKD), among them, 4 were on renal replacement therapy. There was history of previous use of aminoglycoside (gentamicin) in a dose adjusted for renal function, within one month of the onset of symptoms. The otoneurological examination was altered in all 5 cases, with pathological vestibuloocular reflex (VOR) on both sides and imbalance, with fall during the examination on an unstable surface and substantial worsening when closing the eyes. The main symptoms are those of chronic vestibulopathy and are generally reported by the patient as a non-specific imbalance. However, in most cases the patient is not able to spontaneously report the complaints characteristic of this disease. After a guided anamnesis, it is possible to identify the presence of oscillopsia, dizziness and imbalance during gait and head movements, which typically improve when in a static position with

the head still, and worsen in dark environments or on uneven surfaces. The diagnosis is based on the typical clinical history and the presence of bilateral altered VOR, which can be acessed through complementary exams such as the video head impulse test (v-HIT) and caloric test. This case series is a warning regarding the use of aminoglycosides as the first line of infectious treatment in patients with severe renal dysfunction. Furthermore, it is important to highlight the need to identify BPV, given the functional impact on patients' lives.

Bilateral wrist drop revealing symmetric polyradiculoneuropathy and optic neuritis secondary to dengue infection successfully treated with human immunoglobulin - a case report

Matheus Luís Braga Munareto[1], Matheus Alves da Silva[1], Alex Araújo Fernandes[1], Amanda Miranda de Mendonça[1], Ana Luísa Faria Donadon[1], Rafael Bragança Rodrigues Matias[1], Eduardo Mesquita de Souza[1], Karlla Danielle Ferreira Lima[1], Alex Machado Baeta[1], Bruno Shigueo Yonekura Inada[1]

[1]Beneficência Portuguesa, São Paulo SP, Brazil.

Correspondence: Matheus Luís Braga Munareto; Email: matheusbragamunareto@gmail.com.

Case presentation: A 67-year-old male patient with prediabetes presented with a history of fatigue and subfebrile state associated with subacute, bilateral and symmetric wrist drop. He also developed blurred vision. He tested positive for dengue with NS1 exam. His examination showed symmetric strength loss, more evident in wrist and finger extension and thumb abduction. There was no synkinetic wrist extension, his reflexes were diminished in the arm and he had no sensory loss. There was proximal loss of strength in the elbow extension bilaterally. He had a decreased visual acuity of 20/160 in his left eye associated with afferent pupillary defect in this side. In view of these findings, magnetic resonance imaging of the limbs and orbits were performed. His arms MRI demonstrated denervation pattern of the left posterior interosseous nerve (posterior branch of the radial nerve), symmetrical thickening and hyperintensities of the roots and trunks of the brachial plexus. His orbital MRI was suggestive of anterior left optic neuritis. His electroneuromyography showed chronic and bilateral (symmetric) preganglionic motor impairment in the cervical region, of a moderate degree at the level of C7 and a marked degree at the level of C8/T1, with signs of acute denervation, compatible with multiradicular involvement. His CSF was unremarkable. The testing for DENV in the cerebrospinal fluid was unavailable. Due to the important strength and visual impairment, we started immunoglobulin for five days, with complete clinical improvement. **Discussion:** Dengue fever is the most prevalent arbovirus globally. It is an arthropod-borne viral disease caused by the four dengue virus serotypes (DENV 1, 2, 3, 4). DENV infection can be categorized into three stages: the febrile phase, critical phase, and recovery phase. Not all infection cases experience critical phases. Although dengue usually presents as a febrile illness, it can present with neurological symptoms. Besides the high prevalence of dengue infection, the neurological manifestations of DENV are rare, but may affect the central and the peripheral nervous system. The pathogenesis of dengue-associated neurological manifestations is thought to be immune-mediated, and there is some evidence in vitro for neurotropism. Encephalitis is one of the most common neurological manifestations of DENV infection. Optic neuritis and polyradiculoneuropathy are rare clinical manifestations. There is no specific antiviral treatment for dengue infection but corticosteroids and immunoglobulin may be an option for severe neurological manifestations. There is a lack of evidence to guide the treatment in these cases, due to the infrequency of neurological manifestations. **Final comments:** We present a case of a rare manifestation of a very common arbovirus disease. The case highlight the importance of correct follow up of these patients to manage the complications, including the unusual ones.

Biopsy diagnosis of fungal infections affecting the central nervous system

Isabella Queiroz Barbosa[1], Évely Almeida Souza[1], Gabriel Lédo Pereira de Oliveira[1]

[1]Faculdades Santo Agostinho de Vitória da Conquista, Vitória da Conquista BA, Brazil.

Correspondence: Isabella Queiroz Barbosa; Email: qbisabella@hotmail.com.

Background: Fungal infections affecting the central nervous system (CNS) represent a significant challenge in clinical practice due to their complexity and diversity of presentation. These infections generally affect immunocompromised patients. Early and accurate diagnosis is fundamental to defining treatment and improving the patient's prognosis. Analysis of cerebrospinal fluid (CSF) is the method of first choice when there is a suspicion of fungal infection in the CNS, mainly because it is not very invasive and has high sensitivity. However, in more challenging cases, or where CSF analysis is inconclusive or cannot be performed, tissue biopsy is a viable alternative. **Objective:** To analyze data on cases of CNS fungal infection diagnosed by tissue biopsy. The evaluation will be carried out with data from a health service responsible for the pathology service of a local referral hospital, in the years 2022 to 2024. **Methods:** A descriptive analysis of biopsy results was carried out in order to draw up a diagnostic profile for fungal infections that affect the CNS using this method. These tests were provided by a pathology laboratory and comprise all the histological analyses from the neurosurgery department of a local referral hospital. The inclusion criteria were cases in which the patients had a suspected fungal infection of the CNS or in which the infectious diagnosis was incidental. **Results:** Between 2022 and 2024, the laboratory received 139 requests for analysis of neurological biopsies from the hospital. Of this total, around 4% were diagnosed with fungal infections, totaling 5 cases, 2 of which were cryptococci, and of these, 100% had another pathology as their suspected diagnosis. The following prevalence rates were also found: 35% of Gliomas (including glioblastomas), 20% of Meningiomas, 5% of carcinoma metastases, as well as other varied diagnoses such as Medulloblastoma, Hemangioblastoma, Ependymoma and Schwannoma. This distribution corroborates current literature, which indicates neurocryptococcosis as the most common fungal infection in the CNS, with an annual global incidence of 3.9 cases per 100,000 inhabitants. **Conclusion:** Fungal infections in the CNS are rare, but represent a significant diagnostic challenge. Tissue biopsy analysis, although less frequently used than CSF analysis, has proven to be a relevant tool in cases where the diagnosis is unclear or the CSF is inconclusive. This study highlights the need to consider fungal infections, such as neurocryptococcosis, in the differential diagnosis of CNS lesions, especially in immunocompromised patients or when symptoms do not correspond to more common pathologies. Accurate identification of these infections is vital for appropriate treatment and improving the patients prognosis.

Biopsy-proven myosistis and myocarditis due to immune checkpoint inhibitor treatment

Lucas Bruno Rezende[1], Bruna Moreira de Souza Proença[1], Beatriz Gioppo Betini[1], Gustavo Ramos de Lima[1], Augusto Bragança Reis Rosa[1], Ana Carolina Zetehaku[1], Carolina Novaes Perniquelli[1], Antônio Francisco de Araújo Netto[1], Mariana Cavalcanti Costa[1], Rafael Paternò Castello Dias Carneiro[1]

[1]Hospital Nove de Julho, São Paulo SP, Brazil.

Correspondence: Lucas Bruno Rezende; Email: lucasbrunorezende@hotmail.com.

An 83-year-old woman with locally invasive non-metastatic lung adenocarcinoma was admitted to the hospital due to mialgia, weakness and blurry vision. Two weeks earlier, she had received her second cycle of treatment with nivolumab and ipilimumab, anti-PD1 and anti-CTLA-4 immune checkpoint inhibitors respectively. Bilateral semiptosis, multidirectional ophtalmoplegia and proximal muscle weakness grade III predominantly affecting the limb girdles were noted on neurological examination. Bulbar function, cranial nerves and deep tendon reflexes were normal. CK was elevated with levels of 10.970 U/L. Brain MRI was unremarkable. Thigh MRI suggested myositis and disclosed patchy bilateral areas of edema and gadolinium enhancement affecting the quadriceps femoris, adductors, hamstring and gluteal muscles. Shortly after admission, hemodynamic instability due to a 3rd grade atrioventricular block ensued. Cardiologic work-up showcased high troponin levels, but no structural cardiomyopathy on transthoracic echocardiography. Cardiac catheterization was pursued and an 80% stenosis in the anterior descendant artery was treated with a drug-eluting stent, but bradyarrhytmia did not resolve and a transvenous pacemaker was put in place. Neurophysiological studies were unavailable at the time and serum anti-acethylcoline receptor antibodies were negative. Since a concomitant neuromuscular junction disorder could not be completely ruled out, prompt treatment with both pulse-dose steroids and intravenous immunoglobulin was then instituted whilst preparations for muscle biopsy were being undertaken. Left quadriceps femoris biopsy confirmed the diagnosis of immune checkpoint inhibitor-related myositis with findings of multifocal muscle necrosis and mild inflammatory infiltrate constituted mainly by macrophages and CD8-positive lymphocytes. The patient eventually died due to infectious complications of her critical illness.

[3]Hospital do Coração do Mato Grosso do Sul, Campo Grande MS, Brazil.

Correspondence: Isabela de Carvalho Florencio; Email: isabelacflorencio@hotmail.com.

Case presentation: A 56-year-old male with a history of posterior circulation ischemic stroke one month ago, TOAST atherothrombotic, presented with sequelae of left hemifacial paresis and abducens nerve palsy in the left eye. The patient was on acetylsalicylic acid and clopidogrel. He was admitted to the emergency department due to recurrent left hemibody paresthesia, worsening over the past two days. Upon admission, clopidogrel was replaced with ticagrelor. Angiographic study via catheter of the aortic arch, subclavian, vertebral, and carotid arteries revealed an occluded dominant left vertebral artery and sub occlusion in the distal V4 segment,

affecting the posterior inferior cerebellar artery, as well as sub occlusion at the vertebrobasilar junction. Despite the medication switch and prophylactic heparin, the patient continued to experience recurrent focal symptoms of posterior circulation five days post-switch, leading to the indication for endovascular treatment. The right vertebral artery at the V4 segment was treated with percutaneous transluminal angioplasty using an Appolo stent (2.5 x 8 mm - MICROPORT), and angioplasty with a balloon (Treck 1.5 x 6 mm - ABBOT) was performed at the vertebrobasilar junction. Final control demonstrated total regression of the stenoses with the Appolo stent well-adhered to the vessel lumen and no signs of direct procedure-related complications. The patient was discharged while continuing acetylsalicylic acid and ticagrelor. A follow-up cerebral angiography performed six months after the procedure confirmed the stent was well-adhered with no signs of stenosis. **Discussion:** Vertebral artery stenosis is responsible for approximately 20% of ischemic strokes in the posterior circulation, potentially resulting in devastating neurological deficits. This ischemia is related to hemodynamic changes in many patients, due to proximal vertebral artery obstruction. For symptomatic patients who do not respond to dual antiplatelet therapy, endovascular therapy is beneficial, leading to lower rates of symptom recurrence and improved survival. It is known that morphological factors of vertebral artery lesions can affect the outcome of angioplasty therapy. Therefore, even with a promising result, it is necessary to maintain patient follow-up due to the possibility of restenosis, particularly at the vertebrobasilar junction. **Final comments:** We report a case of a patient with previous complete occlusion of the left vertebral artery who had a stroke and transient ischemic attacks while on antiplatelet agents and atorvastatin due to critical stenoses of the right vertebral artery. Angioplasty with stent placement resulted in clinical stabilization and the absence of new ischemic events. This case underscores the importance of endovascular intervention in patients with complex vertebral stenoses and reinforces the need for multidisciplinary management to optimize outcomes.

Bladder pattern profile of children with Zika virus congenital syndrome

Larissa Coutinho de Lucena[1], Vitor dos Santos Rodrigues[2] , Jhulia Thaysa Macena da Costa[1], Amanda Georgia Diniz de Campos[3], Marília da Costa Paiva[1], Amanda da Silva Santos[1], Milena Thaisa Silva de Lima[2], Fernanda Gomes Mourão[1], Gabriel Alves Mendes Vasiljevic[1], Lilian Lira Lisboa[1]

[1]Instituto Santos Dumont, Macaíba RN, Brazil.

[3]Centro Maurício de Nassau, João Pessoa PB, Brazil.

Correspondence: Larissa Coutinho de Lucena; Email: larissa.lucena@isd.org.br.

Background: Congenital Zika virus syndrome (CZS) is characterized by a range of alterations in the anatomy and physiology of the central nervous system (CNS). These changes reverberate through all other body structures as well as neuropsychomotor development. In consensus with the evidence in the literature, a correlation is described between bladder dysfunction and motor functionality, which influences the production capacity in the urinary tract. **Objective:** To characterize the urinary profile of children with urinary sequelae caused by CZS. **Methods:** This is a cross-sectional study, carried out between 2023 and 2024, approved under CAAE 51865521.5.0000.0129 and financed by the CNPq/MCTI/FNDCT-18/202, UNIVERSAL call (403498/2021-0), carried out in patients diagnosed with CZS using the evaluation protocol recommended by the Brazilian Ministry of Health, which included Immunoglobulin G and Immunoglobulin M serological tests. The patients were evaluated using cystometry in the urodynamic study to assess the following variables: detrusor pressure, hyperactivity and maximum cystometric capacity; renal ultrasound examination in search of dimensions, echo textures and contour; and micturition and bowel movement diaries. **Results:** Ten children were enrolled, being eight (80%) female and two (20%) male, with a median age of 7.2 years. Bladder function showed a mean detrusor pressure of 23.3 cmH2O, 95% CI [16.93, 29.67]; mean expected cystometric capacity of 252 ml, 95% CI [240.92, 263.08]; and mean maximum cystometric capacity of 58.7 ml, 95% CI [33.98, 83.42]. It was also noted that 70% of the children had 20% or less of the maximum expected capacity in residual volume. All of the upper urinary tract assessments made by ultrasound showed normal dimensions, echotexture and contour. Urination was not triggered. **Conclusion:** Bladder alterations caused by CZS, over the long term, are indicative of the possible triggering of upper urinary tract lesions as a result of the high pressures generated by these alterations. The findings also suggest the need for interventions that promote an increase in maximum cystometric capacity in accordance with the expected capacity. More extensive and in-depth studies on the subject need to be carried out so that neurogenic bladder and bowel can be monitored and treated, even with low-cost resources such as transcutaneous electrostimulation, with the aim of minimizing future deleterious effects on the upper urinary tract that could limit the rehabilitation and quality of life of these patients.

Body composition in older adults with mild cognitive impairment: effect of 6 months of resistance training

Isadora Cristina Ribeiro[1], Thiago Mattos Frota de Souza[1], Jose Igor Vasconcelos[1], Gabriel Barzon Silva[1], Marco Carlos Uchida[1], Paula Teixeira Fernandes[1], Italo Karmann Aventurato[1], Marjorie Cristina Rocha da Silva[1], Brenda Costa Gonçalves[1], Marcio Luiz Figueredo Balthazar[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Isadora Cristina Ribeiro; Email: isadora.cr@hotmail.com.

Background: Mild cognitive impairment is the diagnosis applied to older adults who present a cognitive loss unnatural to aging, affecting one or more domains of cognition. These individuals maintain their functional independence and are at greater risk of developing dementia, such as Alzheimer's disease, which is related to obesity and a decrease in muscle strength. Investigating the impact of interventions that promote changes in body composition in this population, such as physical exercise, helps to understand how non-pharmacological tools can be effective against risk factors for dementia. **Objective:** This study investigated the influence of resistance exercises practicing for 6 months on body composition in older adults with mild cognitive impairment. **Methods:** older adults (N=22) diagnosed with mild cognitive impairment following the National Institute on Aging and Alzheimer's Association criteria underwent a resistance training protocol twice a week for 6 months. The protocol consisted of large muscle group exercises (3 sets of 10 repetitions at 80% of 1RM). Before and after the intervention, participants were assessed for body composition on a Tanita® BC-108 bioimpedance scale. For measurement, the individual's sex and the "non-athlete" option were selected. The participant removed the handles electrodes from the equipment, keeping their arms away from the torso. The participants' body composition data to be evaluated were body fat percentage, lean mass, fat mass, body water, and basal metabolic rate. Data normality was assessed using the Shapiro-Wilk test. Due to the normal distribution of the data, the paired T-test was used to compare the initial and final moments of the intervention in the IBM SPSS Statistics 22 software. **Results:** Data are presented as mean and standard deviation, and before and after the intervention, respectively: body fat (%): 32.35 (8.68), 32.87 (9.76); lean mass (kg): 52.84 (12.35), 51.94 (11.10); fat mass (kg): 25.60 (9.69), 26.21 (11.50); body water (kg): 38.38 (8.62), 38.51 (7.96); basal metabolic rate (kcal): 1515.40 (332.97), 1503.95 (299.99). As a result of the comparison between the pre and post-intervention moments, no significant changes were found for any of the measures: body fat percentage: p=0.52, lean mass: p=0.37, fat mass: p=0.41, body water: p=0.77, basal metabolic rate: p=0.55. We point out as a limitation that another factors relevant to body composition changes, such as diet, for example, were not evaluated. We suggest further investigations with larger populations and longer durations to contribute to the knowledge of the body composition changes in mild cognitve impairment. **Conclusion:** We highlight that to our knowledge this is the first study to compare bioimpedance parameters in elderly people with mild cognitive impairment after resistance training. Our findings suggest that 24 weeks of resistance training were not enough to change body composition in older adults with mild cognitive impairment.

Botulinum toxin as a therapeutic option in Graves' orbitopathy: a case report

Vinícius Andreata Brandão[1], Lavínia Damacena Perin[1], Jovana Gobbi Marchesi Ciríaco[1]

[1]Universidade Federal do Espírito Santo, Vitória ES, Brazil.

Correspondence: Vinícius Andreata Brandão; Email: viniciusandreatab@gmail.com.

Case presentation: Female, 62 years old, with a significant past pathological history, including systemic arterial hypertension (SAH), mitral valve disease secondary to rheumatic fever corrected with implantation of a metal prosthesis, iron deficiency anemia, actinic colitis after radiotherapy for neoadjuvant treatment of cervical cancer, as well as Graves' disease treated with total thyroidectomy in 2003, presenting postoperatively with refractory bilateral exophthalmos, worse on the right. A therapeutic attempt was made with botulinum toxin administration, with control of ocular proptosis with injections at 4-month intervals since 2015. **Discussion:** Graves' orbitopathy (OG) is the main extrathyroidal manifestation of Graves' disease. It is characterized by inflammation of the extraocular muscles and orbital connective tissue, which becomes progressively larger, leading to ocular proptosis, which can result in damage to the cornea or conjunctiva. In general, exophthalmos does not regress with the treatment of thyroidopathy and surgical intervention is necessary to decompress the orbit and thus allow for better accommodation of the eyeballs. However, in some cases surgery is not appropriate and may be contraindicated, such as in complex patients with a high surgical risk. Therefore, effective and safer alternatives can be chosen, such as the administration of botulinum toxin type A (BTXA) for controlled induction of eyelid ptosis. Botulinum toxin is a potent neurotoxin from the bacterium Clostridium botulinum that selectively inhibits the secretion of acetylcholine vesicles at the neuromuscular junction, resulting in chemical denervation. Its use in the levator palpebrae muscle has been shown to be effective in reducing the symptoms resulting from Graves' orbitopathy, as it allows for better occlusion of the eye, leading to better aesthetics and a reduction in the risk of complications due to conjunctival and corneal exposure. **Final comments:** The use of botulinum toxin A for Graves' orbitopathy is effective, with the potential to substantially improve symptoms, providing a viable alternative for patients at high surgical risk.

Botulinum toxin as an ally in the treatment of belly dancer syndrome: a case report

Leticia Machado Dumont[1], Filipe Brito de Ferraz[1], Rafael Chaves Claudino de Queiroga[1], Camila Lopes Figueiredo[1], Cícero Rodrigues Veloso[1], Maria Clara Motta Barbosa Valente[1]

[1]Irmandade Santa Casa de Misericordia de São Paulo, São Paulo SP, Brazil.

Correspondence: Leticia Machado Dumont; Email: leticiamachadodumont@gmail.com.

Case presentation: This case report describes a female patient, 48 years old, diagnosed with neuromyelitis optica (NMO) in 2010 after presenting an episode of optic neuritis in the right eye. In 2020, the patient presented a new bout of NMO, this time characterized by T8 paraparesis and crural paraparesis. After the attack, the patient began to present painful involuntary movements in the abdominal and dorsal region, radiating to the lumbar region, characterized as contraction of bilateral internal and external oblique muscles. An investigation with Electroneuromyography was carried out in September 2020, the report demonstrated spontaneous discharges of action potentials with arrhythmic activity and variable frequency, suggestive of myokymia at rest in the rectus abdominis muscles and more markedly in the left oblique muscle. Based on the diagnostic hypothesis of belly-dancer syndrome (BDS), an attempt was made at pharmacological therapy with levetiracetam, without satisfactory response, nor when combined with carbamazepine and gabapentin. Due to the failure of pharmacological therapy, the patient underwent application of botulinum toxin to the left rectus abdominis and left external oblique muscles, showing partial improvement in symptoms, with a reduction in the intensity and frequency of muscle spasms. **Discussion:** "Belly-dancer" syndrome is a rare syndrome involving repetitive and involuntary movements of the abdominal wall muscles, also known as diaphragmatic myoclonus. Various etiologies have been associated with the phenomenon, from medications, post-operative abdominal surgery, stroke, metabolic changes, trauma and autoimmune disorders, as is the case with NMO. Such changes lead to abnormal excitation of the phrenic nerve, via the central nervous system or along the nerve. Another proposed mechanism is irritation of the diaphragm muscle itself. Regarding treatment, there are reports of relative success with the use of phenytoin, carbamazepine, as well as clonazepam, fluoxetine, gabapentin, pimozide, valproic acid, among others. Thus, this syndrome becomes a therapeutic challenge, as the response to pharmacological therapy is variable. The use of botulinum toxin is one of the most recent therapies and appears as a promising alternative for treatment, especially in cases refractory to medication. The toxin works by blocking the release of acetylcholine at the neuromuscular junction, which results in temporary paralysis of the affected muscles. In the present case, the application of botulinum toxin provided partial improvement in the patient's symptoms, which corroborates the literature that points to the effectiveness of this therapeutic approach in BDS. **Final comments:** BDS can be a debilitating condition, but with proper treatment, patients' quality of life can be significantly improved. The application of botulinum toxin appears to be a promising alternative for treating the syndrome, especially in cases refractory to pharmacological therapy.

Botulinum toxins on muscular spasticity rehabilitation in a reference center in Northern Brazil

Gustavo Celeira de Sousa[1], Vitor Ferreira Baia[1], Fernando Gabriel dos Santos Santiago[1], Savio Roberto Silva Costa[1], Danusa Neves Somensi[2], Mariângela Moreno Domingues[1], Emanuel de Jesus Soares de Sousa[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.
[2]Universidade Federal do Pará, Belém PA, Brazil.

Correspondence: Gustavo Celeira de Sousa; Email: gustavo.c.sousa0@gmail.com.

Background: Muscle spasticity is the exacerbation of stretch reflex, resulting in continuous muscle contractions and is a common sequel to various neurological disorders, especially those that affect the first motor neuron. In Brazil, epidemiology of spasticity is directly related to the etiology of this condition, which may be secondary to ischemic insult, as in stroke and cerebral palsy; or traumatic brain and spinal cord injury. One of the main treatments for this condition is intramuscular injection of botulinum toxin A (TBA), a neurotoxin that blocks acetylcholine liberation on neuromuscular junction, causing reduction of muscle tonus. **Objective:** Analyzing and monitoring results of TBA treatment in patients with spasticity in a specialized service. **Methods:** This is a cohort study that followed treatment of spasticity in 43 individuals. The location and amount of TBA applied was defined according to the patient's clinical characteristics and current Ministry of Health guidelines. Patients were evaluated monthly using modified Ashworth scale (MAS). In addition, epidemiological and demographic data were collected. Statistical analysis of collected data was performed using GraphPad Prism 9.0 software; simple statistical calculations and p-value calculation were performed using the chi-square test. For this study, a p-value less than 0.05 was considered statistically significant. **Results:** Regarding etiology, about 29% of the patients had cerebral palsy, followed by patients with stroke sequelae. It was observed that spasticity pattern was different amongst between different etiologies for spasticity, of note patients with cerebral palsy-related spasticity had predominance of affection of lower limbs (LL) muscles bilaterally, while patients with stroke-related spasticity had bigger prevalence of unilateral upper limb (UL) and lower limb commitment. The main muscles of the UL affected were brachial biceps, finger flexors, finger flexors, while in LL the most affected were gastrocnemius, hamstrings, and leg adductor. Regarding the patient's age, it was observed that individuals with cerebral palsy usually were under 20 years old; stroke sequelae patients usually were over 30 years old. From start of treatment to deadline it was evidenced substantial reduction in muscle spasticity, mainly in lower limbs muscles, with statistically significant difference, thus having a positive impact in gait and improvement of quality of life. The results related to muscles of UL showed slight improvement of spasticity, but no statistically significant difference. **Conclusion:** This research reinforced the effectiveness of TBA treatment, remarkably in lower limb spasticity, causing an improvement not only in the kinetics of the limbs, but also functionally, by facilitating movement and enabling advances of physical therapy treatment. Thus, it is possible to conclude that use of TBA is associated with positive outcomes and improvement on individuals' quality of life.

Case presentation: A 51-year-old female patient with a history of systemic hypertension, depression, Systemic Lupus Erythematosus, and a previous stroke ten years before was admitted for a neurology evaluation at the Emergency Room due to significant neck pain and paroxysmal vertigo occurring with head rotation to the left. Additionally, she experienced a sudden event of left hemiparesis, lasting less than 24 hours, attributed to a Transient Ischemic Attack (a head CT at the time only described the previous lesion). During the neurological examination, performing cervical rotation to the left by approximately sixty degrees induced vertigo, oscillopsia, and erratic rapid saccadic eye movements. In a motor assessment, she presented a slight deficit in strength on the left side and hypoesthesia. Brain and cervical MRI and MRA showed no current or previous infarction; MRA findings suggested hypoplasia and dissection of the left vertebral artery. Transcranial Doppler revealed a stenotic process in the left vertebral artery, along with spontaneous brain embolic activity during insonation of the left vertebral artery (V4 segment), proximal basilar artery, and right posterior cerebral artery. Further investigation with arteriography showed irregularities and moderate stenosis (around 40%) in the right vertebral artery; at the transition of its V3/V4 segments, this narrowing became critical during a left head rotation maneuver. Additionally, there was occlusion of the left vertebral artery in its V3 segment. Considering the findings-occlusion of the left vertebral artery and compression of the right vertebral artery during head rotation resulting in vertigo and nystagmus, confirmed by angiography - a diagnosis of Bow Hunter's Syndrome or Rotational Vertebrobasilar Insufficiency was made. In this context, platelet anti-aggregation with Clopidogrel was introduced due to the patient's allergy to aspirin. Cardiological changes and thrombophilia were ruled out, and the patient showed good recovery during follow-up visits. **Discussion:** Vertigo is a common complaint in emergency rooms worldwide, including Brazil. Diagnosing its cause is crucial, with benign paroxysmal positional vertigo (BPPV) being the most frequent diagnosis due to its high prevalence and benign nature. However, considering a stroke is essential, even if no other focal neurological signs are present, as vertigo can be a primary symptom of a vertebrobasilar stroke. Early identification and treatment of a stroke are critical to reduce the risk of permanent damage and improve outcomes. **Final comments:** Managing vertigo in the emergency department remains an important challenge. In cases of acute onset and continuous duration, the hypothesis of ischemic posterior circulation stroke must be considered. Additionally, when transient symptoms are associated with cervical and head movements, vertebral artery compression syndrome should be considered, as seen in Bow Hunter's syndrome.

Brachial plexitis: an unusual presentation in dengue virus infection

Caio Vinicius Barroso de Lima[1], Marcelo Annes[1], Vinícius Boaratti Ciarlariello[1], Cristina Gonçalves Massant[1], Anna Maria Andrei[1]

[1]Hospital Israelita Albert Einstein, São Paulo SP, Brazil.

Correspondence: Caio Vinicius Barroso de Lima; Email: caiolimaneurologista@gmail.com.

Case presentation: We report the case of a 61-year-old female patient. She presented in the emergency room with acute weakness of the left upper limb, upon awakening, 3 days before hospitalization. The patient denied pain, fever or other associated symptoms in the last few weeks. She had monoplegia in the left upper limb, hypoesthesia and areflexia with flaccidity of the same limb. Initially

investigated with cranial and cervical angiotomography, excluded cerebral vascular events. In laboratory, only mild thrombocytopenia was relevant. Cranial and cervical MRI were also unremarkable. A brachial plexus MRI demonstrated thickening and enhancement of the left C6, C7 roots, the upper and middle trunks with changes in diffusion. Edema of the left scalene, left teres major and infraspinatus muscles were also seen, related to denervation. Electroneuromyography revealed severe hyperacute involvement of the left brachial plexus. CSF demonstrated slight pleocytosis with lymphomonocyte predominance. Finally, specific research confirmed positive IgG and IgM serology for dengue virus with negative NS1 antigen. **Discussion:** Neurological dengue is classified as a severe form of dengue. Neurological complications are seen in 4.2 - 13% of all DENV. Brachial neuritis is characterized by severe neuropathic pain (95%), sudden weakness (80%), hypoesthesia (78%) and atrophy of the proximal musculature. Most of cases are unilateral. One of the manifestations associated with dengue virus is the immune-mediated neurological complications (IMNC), which include brachial plexus neuritis. Majority of IMNC cases occur in the subacute (7-30 days) latency period. All patients achieved complete clinical recovery after a course of intravenous methylprednisolone (MP) and immunoglobulin (IVIg). Studies hypothesize that post-dengue infection leads to an autoimmune response against the myelin sheath, causing brachial neuritis due to demyelination of the plexus. Unlike most reports, our patient did not demonstrate pain related to brachial plexitis. She also did not present any classic viral symptoms of dengue preceding the neurological condition. Not even fever, which is the symptom most related to the dengue IMNC. Corroborating literature, our case presented in a subacute interval of dengue virus infection (negative NS1 with positive IgM IgG indicates infection between 7 - 29 days). According to recent literature, we treated her as a dengue IMNC case: immunomodulation with 3 days of MP concomitantly with IVIg for 5 days, and a complete response should be assessed within the next 3 months. **Final comments:** Dengue is a viral infection with worldwide distribution, especially in underdeveloped tropical countries. Where diagnostic resources are often limited and access to appropriate treatment is also scarce. Therefore, diagnostic suspicion is crucial for adequate investigation and preservation of resources, as well as aiming the best outcome for the patient.

Brachial plexus axonotmesis after coronary artery bypass surgery: a case report

Natana Rangel da Silva Ribeiro[1], Natália Curcio Fedrizzi[1], Ana Maria Hoppe[2]

[1]Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre RS, Brazil.
[2]Irmandade da Santa Casa de Misericórdia de Porto Alegre, Porto Alegre RS, Brazil.

Correspondence: Natana Rangel da Silva Ribeiro; Email: natanarangel@gmail.com.

Case presentation: A 60-year-old man with a history of coronary artery disease, pre-diabetes, hypertension and smoking, was admitted for a coronary artery bypass surgery. After awakening from sedation, he noticed weakness and numbness in his left hand. On examination, sensation was diminished on the left palmar and dorsal surfaces of fourth and fifth fingers, medial edges of the hand and of the ipsilateral forearm. He had weakness of left interossei and thumb abductors, and of extensor digitorum. Triceps, biceps and brachioradialis reflexes were preserved. Electrodiagnostic studies were realized 1 month later. Nerve conduction studies demonstrated decreased left ulnar compound muscle action potential amplitude, recorded from the first dorsal interosseous and the abductor digiti minimi muscles, and reduced medial cutaneous of the forearm and ulnar sensory nerve action potentials amplitudes. On needle electromyography, evidence of active denervation and also early reinnervation in the left first dorsal interosseus, extensor indicis and flexor pollicis longus was seen, suggesting a Sunderland second-degree axonotmesis injury of the lower trunk of left brachial plexus. **Discussion:** The brachial plexus is formed by the C5, C6, C7, C8 and T1 nerve roots, and is divided into roots, trunks, divisions, and cords. It is responsible for the upper limbs innervation and its injuries can be classified as preganglionic, which are not repairable, or postganglionic, which can be spontaneous or surgically repaired. Through electrodiagnostic studies, nerve injuries can also be classified by the Seddon and Sunderland classification systems as neuropraxia, axonotmesis or neurotmesis. Neuropraxia is a demyelinating injury with no axon loss, and complete recovery within days to weeks. Axonotmesis is a partial loss of axons with intact endoneurim, and complete (Sunderland second-degree axonotmesis) or partial (Sunderland third-degree axonotmesis) recovery. Neurotmesis is a severe damage to axons, myelin sheath and connective tissue elements, with surgical repair being essential for recovery. In all injuries described, physiotherapy plays an important role in rehabilitation and is the best course of action before surgery. After surgery, it can also help restore neurological function. **Final comments:** Patients undergoing open heart surgery must be closely monitored for peripheral nerve injury during the postoperative period, as missed injuries may subsequently lead to delay in recovery, morbidity, and poor functional outcome. The investigation can be done with detailed history and examination, complemented with timely electrophysiological studies.

https://doi.org/10.5327/CBN240253

Brachial plexus injury after breast prosthesis exchange

Sara Pessoa de Oliviera[1], Julia Gasparino de Oliveira[1]

[1]Centro Universitario Integrado, Campo Mourão PR, Brazil.

Correspondence: Julia Gasparino de Oliveira; Email: julia.gasparino@grupointegrado.br.

Female patient who underwent mastopexy surgery and breast implant replacement on Agt 24, 2022. Postoperatively, she developed anesthesia and brachial paraplegia. She was prescribed Etna® and Dexador® and referred for physical therapy. She sought neurological consultation on Sep 1, 2022, reporting hypoesthesia, paresthesia (tingling), and weakness in the upper limbs. Physical examination (upper limbs): arm abduction (strength (S) grade 1 on the right and 3 on the left), flexion and extension of forearms (S grade 2), and hands (S grade 4); upper limb hypoesthesia; globally reduced deep tendon reflexes (DTR) grade 1; absent Hoffman sign. Upper limb nerve conduction studies were requested on Sep 16, 2022, revealing bilateral brachial plexopathy with signs of acute axonal loss. By September 22, 2022, there was partial improvement in upper limb weakness - arm abduction (S 2 on the right and 3 on the left), flexion and extension of forearms (S 4 on the left and 3 on the right), and hands (S 4). Dexador® and Etna® were gradually discontinued, and Millgama® and Pregabalin were prescribed along with continued physical therapy. Cervical spine MRI on Sep 30, 2022, showed a posterior central disc protrusion at C5-C6 level indenting the ventral aspect of the dural sac; brachial plexus MRI showed mild T2 hyperintensity. On Oct 20, 2022, the patient exhibited difficulty maintaining isometry, upper limb hypoesthesia, and paresthesia in the right thumb. Physical examination showed improved upper limb strength (S 4 in hands and forearms; S 3 in arm abduction and shoulder elevation), grade 2 brachioradialis reflex on the right, and grade 1 elsewhere. Medications and physical therapy were continued. At the last visit, the patient reported complete improvement in movements, reducing physical therapy sessions. Nerve conduction studies on Feb 3, 2023, did not reveal significant abnormalities, demonstrating clear improvement in electrophysiological patterns compared to previous studies. Neurological examination showed S 5 in both upper limbs, preserved tone, reflexes grade 2, and intact tactile sensation. The patient was discharged. Disscution Fernandes notes that most peripheral nervous system injuries involve the brachial plexus, mainly from traumas during shoulder manipulation, leading to functional and sensory loss. This case details brachial plexopathy post-breast reconstruction surgery, highlighting varied surgical techniques impacting outcomes. Initial assessment revealed proximal upper limb weakness on the Medical Research Council (MRC) Scale. Electromyography confirmed bilateral plexopathy, aligning with complex diagnostic challenges requiring advanced imaging. Follow-up showed muscle strength improvement and MRI findings suggesting transient plexopathy. Early suspicion and treatment led to full recovery in five months, emphasizing non-surgical intervention benefits. Clinical vigilance and prompt patient response significantly influenced prognosis.

Brain abnormalities in early-onset spinal muscular atrophy with neurodevelopmental disorders

Rodrigo de Holanda Mendonca[1], Raquel Diógenes Alencar Sindeaux[1], Clara Gontijo Camelo[1], Erasmo Barbante Casella[1], Kellen Faria Silva Chillon[1], Antônio José da Rocha[2], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Departamento de Neurologia, São Paulo SP, Brazil.
[2]Alta Medicina Diagnóstica, São Paulo SP, Brazil.

Correspondence: Rodrigo de Holanda Mendonca; Email: rodrigo.holanda@hc.fm.usp.br.

Background: Recent literature has reported the occurrence of neurodevelopmental comorbidities in early-onset spinal muscular atrophy linked to 5q (SMA-5q). Furthermore, previous reports before the advent of disease-modifying therapies (DMT) suggested brain involvement in 5q-SMA. **Methods:** This cross-sectional study of a case series included five patients with early-onset and pre-symptomatic SMA-5q under treatment with DMT and who presented with neurodevelopmental disorders, including four cases with autism. These patients underwent brain MRI with volumetric analysis utilizing Neuroquant® software and tractography using diffusion tensor imaging (DTI). **Results:** Patients with type 1 SMA-5q exhibited a consistent pattern of volumetric reduction in the frontal lobes and reduced representation of association fibers corresponding to the superior longitudinal fasciculus. In contrast, pre-symptomatic patients who received treatment did not show any abnormalities on brain imaging. In an older SMA-5q type 1 patient with advanced disease, used as a control, the spectrum of imaging changes was more severe, presenting marked atrophy in both frontal lobes. **Conclusion:** Brain involvement in early-onset SMA-5q may occur even in patients treated with new DMT, and its correlation with neurodevelopmental disorders remains an open question.

Brain aneurysm neurogenetics: a systematic review

Graziele Gleice da Silva[1], Ana Silvia Suassuna Carneiro Lúcio[2], Alexandre Jorge de Andrade Negri Júnior[2]

[1]Cabedelo.
[2]Faculdade de Ciências Médicas da Paraíba, Cabedelo, PB, Brazil.

Correspondence: Graziele Gleice da Silva; Email: grazielle_gleice@hotmail.com.

Background: Genetic factors are crucial to the formation and clinical evolution of intracranial aneurysms. Several loci have been associated with its pathogenesis, many of which implicate several pathways related to endothelium maintenance and extracellular matrix integrity. Subarachnoid hemorrhage (SAH) and intracranial aneurysm (IA) have a complex origin, entailing the interaction of several genes and environmental factors. The rupture of the extracellular matrix of an arterial wall, which confers strength and elasticity to intracranial arteries, is a probable factor in the pathophysiology of intracranial aneurysms. In this review, the focus lies on genetics association, linkage, and gene expression of SAH and IA. Loci neurogenetics studies include functional structural-protein-codifying genes of extracellular matrix. The elastin and type 1A2 collagen genes are the most promising candidates given their allelic association with IA.**Objective:** To determine whether polymorphism of genes implicated in the maintenance of vascular endothelium may modify the risk of developing IAs. **Methods:** This is a systematic review carried out through the following databases: Medical Literature Analysis and Retrieval System Online (MEDLINE/PubMed), Latin-American and Caribbean Health Sciences Literature (LILACS/Bireme), Science Direct, Web of Science, and Scientific Electronic Library Online (SCIELO). The filters used were title, subject, and type. The terms used in the search for the articles were standardized by the Medical Subject Headings (MeSH) and Health Sciences Descriptors (DeCS). The descriptor "brain aneurysm" was combined using the boolean operator AND with the descriptors: "neurosurgery" and "genetics". The guiding question of the study was: How can the study of the genetic profile of brain aneurysms improve the prevention and diagnosis of this pathology? **Results:** The T allele of the rs1799983 polymorphism of the endothelial nitric oxide synthesis gene (eNOS) is correlated with a decreased risk of developing the disease. Likewise, the G allele of the rs1799983 polymorphism of the eNOS increased the risk of developing intracranial aneurysm. A comprehensive understanding of the genetic basis that governs the risk of developing IA and the resulting aneurysmal subarachnoid hemorrhage may aid in the screening, clinical management, and risk stratification of these patients, and may also allow the identification of putative mechanisms for the further development of medications. **Conclusion:** The association of the rs1799983 polymorphism of the eNOS with an elevated risk of IA reinforces the hypothesis that genetic variants in the eNOS gene may be crucial in its pathogenesis. Future studies need to demonstrate which alleles are related to the origin and incidence of aneurysms, as well as determine the screening for this pathology.

Brain changes in an elderly woman with Hypomelanosis of Ito

Patricia Soares Rodrigues Mello[1], Igor Castro Tavares[1], Rafael Cavalcanti Fernandes Rocha[2], Massanobu Takatani[2], Nise Alessandra de Carvalho Sousa[2], Satiko Andrezza Ferreira Takano[2]

[1]Universidade Nilton Lins, Manaus AM, Brazil. [2]Universidade Federal do Amazonas, Manaus AM, Brazil.

Correspondence: Satiko Andrezza Ferreira Takano; Email: satikotakano.neuro@gmail.com.

Case presentation: A 66-year-old woman with amnestic, visuospatial, executive, and attention deficit complaints, also presenting with peripheral vertigo, headache, and depressive and anxiety disorder. Physical examination revealed hypochromic spots in the abdomen, and upper and lower left limbs, present since childhood. Laboratory tests, including complete blood count, and renal, hepatic, and thyroid function tests, were within normal limits. Magnetic resonance imaging (MRI) of the skull revealed multiple enlarged perivascular spaces in the bilateral periventricular white matter and cavernomas. Skin biopsy showed mild lymphohistiocytic infiltrate in superficial vessels, favoring the diagnosis of Hypomelanosis of Ito. **Discussion:** Hypomelanosis of Ito or Incontinentia pigmenti achromians is a rare, multisystem neurocutaneous disease with hypopigmentation of the skin along the Blaschko lines. The cause is genetic, but not fully known, and chromosomal alterations with somatic mosaicism may occur. The clinical presentation is related to dermatological findings, unilateral or bilateral, and 75% have extracutaneous neurological, musculoskeletal, cardiac, and genitourinary manifestations. Neurological manifestations may include cognitive impairment, epilepsy, spasticity, cerebellar ataxia, and microcephaly. Neuroradiological alterations include lissencephaly, polymicrogyria, laminar heterotopias, cerebellar atrophy, atrophy of the posterior third of the corpus callosum, dilation of the Virchow-Robin spaces, and tumors. Subcortical alterations may aggravate the patient's cognitive symptoms. **Final comments:** Recognition of clinical, dermatological, and brain changes in patients with Hypomelanosis of Ito is necessary for early diagnosis of this disease, allowing for appropriate treatment with a multidisciplinary approach

https://doi.org/10.5327/CBN240257

Brain changes in pediatric multiple sclerosis

Gabriel de Deus Vieira[1], Fernanda Ferrão Antônio[1], Alfredo Damasceno[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Gabriel de Deus Vieira; Email: gabrieldedeusvieira@gmail.com.

Background: Pediatric-onset multiple sclerosis (POMS) comprises about 5% of all multiple sclerosis (MS) patients. It presents similarly to the adult disease, but with a more inflammatory disease. **Objective:** we aimed to evaluate clinical and neuroimaging data in POMS subjects. **Methods:** A total of 10 pediatric MS patients were enrolled (under 18 years of age). For neuroimaging comparisons, 16 controls were selected. Brain volume evaluations were performed on volumetric T1 and 3D-FLAIR images using the Sequence Adaptive Multimodal Segmentation, a FreeSurfer pipeline to segment brain structures. All patients underwent to timed 25-Foot Walk Test, 9-Hole Peg Test, Symbol Digit Modalities Test (SDMT) and Expanded Disability Status Scale. Cortical gray matter volume, deep white and gray matter structures were analyzed. The paramagnetic rim lesions were assessed for each lesion with SWI sequence. Statistical analysis was performed using the SPSS software. To compare data between groups, the General Linear Model and Mann-Whitney U test were used. Correlations were performed using Spearman correlation coefficient. **Results:** The MS group consisted mainly of girls (n=8), with a mean age of 15.3 years old. All patients had a relapsing-remitting clinical, 60% used fingolimod, 20% interferon beta-1a, 10% natalizumab and 10% rituximab. None of them presented severe physical disabilities. There was a higher choroid plexus and lower thalamic volumes in POMS group compared to controls. Regarding PRL, 90% had this type of lesion. The percentage of white matter lesions with a paramagnetic rim lesions was 18.8%. Regarding correlations, the SDMT had a strong correlation with paramagnetic rim lesions percentage ($R=-0.800$, $p<0.01$). **Conclusion:** POMS is characterized by a greater number of relapses compared to adults, having a higher frequency of paramagnetic rim lesions and its correlation with SDMT (a cognitive test, related to information processing speed). In addition, the MS group presented changes in volumetry, with atrophy of the thalamus and enlargement of the choroid plexus.

https://doi.org/10.5327/CBN240258

Brain damage in carriers of DMD pathogenic variants

Mariana Rabelo de Brito[1], Thiago Junqueira Ribeiro de Rezende[1], Stephany da Silva Passos[1], Anamarli Nucci[1], Fernando Cendes[1], Marcondes Cavalcante França Jr.[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Mariana Rabelo de Brito; Email: mariana_rabelo_@hotmail.com.

Background: Duchenne muscular dystrophy (DMD) is typically a male disease, but mounting evidence indicates that females carrying DMD mutations (cDMD) can also be affected. More recently, cognitive impairment has been noticed in women with cDMD. Despite this, no studies have attempted to evaluate brain damage using imaging tools, particularly MRI. **Methods:** Sixty-six women (33 with cDMD and 33 controls) underwent cognitive assessment using the Addenbrooke's Cognitive Examination Revised (ACE-R) and 3T MRI to evaluate gray matter (GM) and white matter (WM). FreeSurfer was used to assess cerebral GM and DTI multi-atlas for cerebral WM. All analyses were corrected for multiple comparisons. **Results:** The average age of women with cDMD was 38.5 years, and their average educational level was 9.4 years of formal education. The mean score on the ACE-R was 73.4±9.6 points, with almost 50% of the patients (n=16) scoring below the expected range, suggesting some degree of deficit. Cortical thinning was observed in the right inferior parietal, bilateral precuneus, and bilateral superior parietal pole. Additionally, a reduction in gyrification index was seen at the bilateral gyrus and sulcus parietal. However, we did not find a correlation with the patients' cognitive deficit. **Conclusion:** Cognitive impairment has been observed in women with cDMD, who are also characterized by structural damage, especially in the temporal lobe and its gyrus and sulcus. Our results shed some light on the pathophysiology underlying the disease.

https://doi.org/10.5327/CBN240259

Brain death after a cardiac arrest: main characteristics of a group

Rafaela dos Santos Braga[1], Gisele Sampaio Silva[1], Maramelia Miranda[1], Ingrid Marques[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Rafaela dos Santos Braga; Email: braga.rafaela@gmail.com.

Background: The occurrence of brain death in patients with hypoxic-ischemic brain injury after resuscitation from cardiac arrest creates opportunities for organ donation. About two-thirds of patients admitted to hospital or an intensive care unit after cardiac arrest die before hospital discharge. Most of these deaths are due to hypoxic-ischemic brain injury. Brain death is an unfavorable outcome for the individual patient; however, it creates opportunities for organ donation. **Objective:** Knowing the epidemiology of brain death after cardiac arrest could help physicians organize a timely screening and identification of potential organ donors after resuscitation. **Methods:** We reported the main characteristics of a group of patients that evaluated to brain death after a cardiac arrest. **Results:** On period of six months, 45 patients were notified as potential donor under the Brazilian criteria of brain death and the cause of death was described as hypoxic-ischemic encephalopathy after a cardiac arrest. Patients from 0 to 78 years old were included, with a median age of 42.66 years old, 3 cases under 2 years old, 7 cases between 2-18 y-o, 24 cases between 18-65 y-o and 11 cases above 65 y-o. The eldest patient was 78 years old. There was 27 female (60%) and 18 men (40%). Mean time of cardiac arrest was 11 minutes, with a minimum of 2 minutes and the maximum of 30 minutes. The number of days since the cardiac arrest included from 3 days to 10 days, with a median of 5.5 days. In patients with primary brain

injury as the cause of cardiac arrest a median of 4.6 was the number of days until brain death was confirmed. Cardiac arrest is a catastrophic event with high mortality. Fortunately, survival has improved over the past several decades; however, mortality rates are still high, and wide variability in survival exists, plus some underreported data. Nowadays, there is an urgent need to improve postcardiac arrest care, and there are multiple knowledge gaps related to patient management and neuro prognostication. The postcardiac arrest syndrome includes varying levels of brain injury, circulatory dysfunction, and multiorgan ischemia/reperfusion injury and dysfunction. The number of days from the cardiac arrest until the confirmed brain death varied from 3 10 days, (median 5.5 days). In some cases, the occurrence of brain death has been reported within 1 day after cardiac arrest. This is common when cardiac arrest is due to neurological causes, most commonly a subarachnoid hemorrhage. When a neurological rather than a cardiac cause of arrest is suspected, a brain computerized tomography immediately after the return of spontaneous circulation is recommended. If brain computerized tomography demonstrates a catastrophic brain injury, an early evaluation for brain death may be considered. **Final comments:** This small study had the intention to bring up the importance of studying the population who suffered a cardiac arrest.

https://doi.org/10.5327/CBN240260

Brain morphometric changes in SAA positive individuals with idiopathic Parkinson's disease

Stella Duarte Pinto[1], Andrei Bieger[2], Daniel Teixeira dos Santos[3], Rafaela Ravazio[1], Christian Mattjie[1], Lara Angi Souza[4], Thomas Hugentobler Schlickmann[4], Rodrigo C. Barros[1], Eduardo R. Zimmer[4], Artur Francisco Schumacher Schuh[3,4]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.
[2]Pontifícia Universidade Católica do Rio Grande do Sul, Hospital São Lucas, Porto Alegre RS, Brazil.
[3]Hospital de Clínicas de Porto Alegre, Porto Alegre RS, Brazil.
[4]Universidade Federal do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Stella Duarte Pinto; Email: stella.pinto@edu.pucrs.br.

Background: Molecular diagnostics are becoming increasingly important for detecting Parkinson's disease (PD) in its early stages. The α-synuclein seed amplification assay (SAA) has shown high sensitivity and specificity in detecting synucleinopathies in the cerebrospinal fluid (CSF). Differences in brain morphometry between PD patients with and without a positive SAA test are still unknown. **Objective:** This study analyzed cortical and subcortical morphometric alterations comparing them with the outcome of the SAA in patients with idiopathic PD. **Methods:** We used T1-weighted 3-dimensional brain MRI images from participants of the Parkinson's Progression Markers Initiative (PPMI) database with idiopathic PD who also underwent CSF collection and SAA analysis. Using Freesurfer's v7.4.1 recon-all pipeline, we extracted volumes of cortical and subcortical regions of interest, according to the Desikan-Killiany-Tourville atlas. Volumes were normalized according to estimated total intracranial volume. Linear models evaluated differences in volumes between positive and negative SAA groups, correcting for age and sex. **Results:** A total of 267 participants (95.5% positive SAA, 63.2% males, mean age 60.6 years, standard deviation 8.1) were included. In patients with idiopathic PD, volume changes in positive SAA were observed in the right parahippocampal (p=0.02), right fusiform (p=0.03), and left posterior cingulate gyri (p=0.04), and in the left frontal pole (p=0.05). Subcortical structures presented changes in volumes of left putamen (p=0.02) and left globus pallidus (p=0.03). Conclusions The results of this study demonstrate a clear association between SAA positivity and specific morphometric changes in the brains of patients with idiopathic PD. These changes include significant reductions in cortical thickness and subcortical volumes in critical regions associated with memory, cognition, and motor control. These findings suggest that SAA may be a valuable biomarker not only for the early detection of PD but also for monitoring disease progression through structural changes in the brain. Identifying specific morphometric changes can help personalize therapeutic strategies and monitor the efficacy of treatments over time. To consolidate these findings, future studies should include larger samples and consider the clinical heterogeneity of PD. Additionally, integrating neuroimaging data with other diagnostic modalities, such as molecular and clinical biomarkers, may provide a more comprehensive view of PD progression and treatment responses. **Conclusion:** This study significantly contributes to understanding the relationship between α-synuclein and structural brain changes in Parkinson's disease. Detecting morphometric changes associated with SAA positivity can enhance the diagnosis and treatment of PD, offering new perspectives for managing this neurodegenerative condition.

https://doi.org/10.5327/CBN240261

Brainstem encephalitis and subacute sensory neuropathy accompanied by colon cancer: is there a possible paraneoplastic association?

Camila Rodrigues Nepomuceno[1], Gustavo Celeira de Sousa[1], Maria Fernanda Hamamoto Leati[1], Heitor Nunes de Oliveira Sento-sé Neto[1], Flavio Vieira Marques Filho[1], Arthur de Medeiros Dias[1], Graziella Aguiar Santos Faria[1], Maria Sheila Guimaraes Rocha[1]

[1]Hospital Santa Marcelina, São Paulo SP, Brazil.

Correspondence: Camila Rodrigues Nepomuceno; Email: camilarnepomuceno@gmail.com.

Case presentation: A 51-year-old woman was transferred to our service due to flaccid areflexic tetraparesis and diffuse nociceptive and neuropathic pain which began seven days before hospitalization. The onset of symptoms occurred four days after the resection of a colonic tubular adenoma. Neurological examination showed preserved consciousness, cognition, memory, language and muscle strength. Important impairment on sensory pathways, mainly on profound system (sensory ataxia, pseudoparesis, pseudoathetosis) was observed. Other relevant clinical finding was multidirectional nystagmus. Laboratory tests did not show significant changes, including anti-SSA and anti-SSB antibodies. CSF analysis evidenced elevated protein levels and light pleocytosis. On MRI, signal hyperintensity in pons paramedian region. Her electroneuromyography also showed pure sensitive polyneuropathy non-length-dependent. The anatomopathology of colon biopsy revealed moderately differentiated adenocarcinoma of the colon. Onconeural antibodies were not available for our patient due to the resource-limited setting. Treatment with methyl-prednisolone pulse therapy was instituted, followed by immunosuppressive therapy with azathioprine and prednisone. On follow-up of less than a year patient had significant control of symptoms and improvement on autonomy. **Discussion:** Subacute sensory neuropathy (SNN) and brainstem encephalitis are included in paraneoplastic neurological syndrome (PNS) and are rarely accompanied by colon cancer. Typically, SNN is associated with small-cell lung cancer (SCLC) and involves Hu, amphiphysin, CRMP5, and PCA2 antibodies, which are present in both central and peripheral syndromes. According to a 10-year retrospective study conducted by the Mayo Clinic, out of 115,081 cancer patients, only 58 (0.05%) were diagnosed with a paraneoplastic neurological syndrome, and among these, five patients had colon cancer. These patients presented with peripheral neuropathy and a cerebellar syndrome, similar to the present case. Given the unknown antigen expression status and a follow-up period of less than two years, our patient was classified as having possible PNS according to the PNS-Care score. **Final comments:** PNS treatment targets underlying malignancies. Early neural destruction can limit clinical improvement despite treatment. Consequently, high-risk neurological phenotypes should prompt an intensive search for malignancy. It is also crucial to consider colon adenocarcinoma, although rare, as a potential cause of PNS.

Background: Carotid web (Web-Ca) is considered an underrecognized cause of stroke. The lack of prospective studies results in a poor understanding of its clinical characteristics, recurrence rate, treatment strategies, and stroke prevention. **Objective:** We present a prospective ongoing Brazilian cohort to describe the epidemiology, treatment outcomes, and long-term prognosis of patients diagnosed with Web-Ca. **Methods:** Patients admitted to our stroke unit or attended in our stroke clinic were systematically evaluated. This involved an in-depth review of neuroimaging data (CT Angiography and/or MR Angiography) at our center, from 2017 to 2023. Two experienced stroke neurologists confirmed the diagnosis. Data on demographics, risk factors, treatment, and patient outcomes were gathered using a standardized questionnaire. **Results:** A total of 42 cases were identified (57.1% male) with a median age of 50.5 (IQR 42.25-58). Most of the patients were identified after an ischemic stroke, and the initial NIHSS median was 11 (IQR 4-15.5). Twenty-two patients (52.4%) were treated with either endarterectomy or angioplasty, and 32 (78%) were considered symptomatic. There were three cases of colorectal neoplasm associated (7.7%). In addition, Web-Ca was identified in two cases of Intracranial hemorrhage, one case of subdural hematoma, and five cases of subarachnoid hemorrhage. **Conclusion:** The ongoing Brazilian cohort study provides valuable insights into epidemiology, treatment outcomes, and long-term prognosis of patients with Web-ca. This study underscores the importance of recognizing Web-Ca in the differential diagnosis of ischemic stroke etiology and also in non-ischemic stroke patients. Suggesting the necessity for further research on its management and prevention.

Brazilian medical students' knowledge and interest in headache and other common pain conditions: a comprehensive survey

Caroline Matielo Ricci[1], Fernanda Firmiano Casarotto[1], Isadora Miarelli Fortuna[1], Lucas da Silva Oliveira[1], Hilton Mariano da Silva Júnior[1]

[1]Pontifícia Universidade Católica de Campinas, Campinas SP, Brazil.

Correspondence: Caroline Matielo Ricci; Email: carol.iccir@gmail.com.

Background: Pain, a pervasive issue in healthcare, necessitates that future doctors are well-versed in various pain syndromes, their origins, diagnoses, and treatments. It also seeks to evaluate their preparedness to manage patients afflicted by diverse pain types in the emergency room and outpatient settings. However, studies that aimed to estimate the knowledge and interest of medical students in primary pain syndromes, particularly headaches, are scant. **Objective:** To assess the knowledge of medical students about the main pain syndromes, to quantify the frequency of pain-related classes in medical school and identify potential gaps in the medical curriculum related to this topic. **Methods:** This is a cross-sectional and descriptive study involving medical students from various Brazilian universities. An online questionnaire was used as the data collection instrument. It included questions about demographic data (age, gender, university, year of graduation, faculty, city, and state), objective questions to assess knowledge about the main pain syndromes and questions about the frequency of pain-related classes during medical school. The questionnaire link was made available to students through the university communication channels, social media, and promotion by student organizations and responses were collected over seven months. Subsequently, the results were analyzed. **Results:** Five hundred twenty responses were obtained from undergraduate medical students from fifty-four medical universities in various states nationwide. From these responses, it is noted that although most students (90%) recognize how frequent headache complaints are in the emergency room, a large portion (56.9%) have not had classes on how to evaluate these patients initially, and about 70.6% have never participated in conferences on this complaint. In contrast, only 33.7% have not had classes in the emergency department to evaluate patients with chest pain. Similarly, only 26.7% have not learned how to approach abdominal pain in the emergency room. These data highlight the negligence of educational institutions regarding the topic of headaches compared to other types of pain frequently encountered in the hospital setting. **Conclusion:** Our results reveal a substantial knowledge gap concerning headaches and other pain syndromes in the medical education curriculum despite the high prevalence of these conditions in clinical practice. This deficiency in medical training leads to patient dissatisfaction with the healthcare system, frequent cases of malpractice, and undertreatment. Your role as future doctors is crucial in addressing this issue. Therefore, medical students must receive comprehensive headache management education, particularly in emergencies. This can be addressed by integrating dedicated classes and events into the academic curriculum to enhance proficiency in pain management in clinical practice and healthcare services.

Breakthrough coma: a severe myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD) case report

Josenice Gomes Trindade Seidel[1], Thiago Gonçalves Guimarães[1], Ahmad Kassem El Zein[1], Lucas Henrique de Moura Rogerio Garcia[1], Matheus Rodrigues Nogueira[1], Joana Laura Aihara Barbosa[1], Luiz Gustavo Brenneisen Santos[1], Tarso Adoni[1], Julia Martins Brunelli[1], Gabriela Almeida Pimentel[1]

[1]Hospital Sírio Libanês, São Paulo SP, Brazil.

Correspondence: Josenice Gomes Trindade Seidel; Email: josegomes15@hotmail.com.

Case presentation: A 40-year-old black woman was admitted to our emergency department due to a 30-day history of progressive headache, unresponsive to analgesics, associated with fever, bilateral visual deficit, bladder dysfunction, and lower limb paresthesia. She deteriorated with tetraparesis and encephalopathy, despite treatment with acyclovir and antibiotics. No previous infections, vaccinations, or neurologic symptoms were reported. Neurological examination revealed somnolence, mental confusion, and flaccid bilateral hemiparesis, ataxia, and light-near dissociation. The patient evolved with coma and required ventilatory support. Brain magnetic resonance imaging (MRI) showed multiple T2/FLAIR-hyperintense tumefactive lesions affecting the supratentorial white matter, cerebral cortex, basal ganglia, brain pedunculi, the whole brainstem, optic nerves, optic chiasma, and optic tracts, with gadolinium enhancement. Cervical MRI showed a mild non-tumefactive lesion in C2. The cerebrospinal fluid analysis revealed increased protein with lymphocytic pleocytosis and normal glucose levels, negative bacterioscopy and cultures. Oligoclonal bands were negative. No infectious agents were detected. Electroencephalogram did not reveal epileptic discharges. A comprehensive molecular panel for infectious meningitis and encephalitis came out negative. Of all rheumatological markers, only rheumatoid factor was positive. The whole-body 18F-FDG PET/CT scan showed no hypermetabolic lesions. Brain biopsy revealed an active chronic inflammatory process with necrosis, cellular debris, and secondary demyelination (predominantly perivascular lymphomononuclear inflammatory infiltrate). A Cell Based Assay (CBA) for anti-MOG was positive. Anti-aquaporin-4 antibody was negative. Acyclovir and antibiotics were discontinued. Plasma exchange and high dose methylprednisolone were initiated. The patient had a dramatic response and close to full recovery from neurological deficits. Three-month follow-up showed regression of MRI lesions. **Discussion:** MOGAD is a recently identified acquired autoimmune central nervous system demyelinating disease. It is typically associated with acute disseminated encephalomyelitis (ADEM), optic neuritis (ON) or transverse myelitis, and is less commonly associated with cerebral cortical encephalitis, brainstem or cerebellar presentations. The MOGAD spectrum is broad and varies according to age, with ADEM being more common in children, and recurrent ON and longitudinally extensive transverse myelitis (LETM) being more common in adults. MOGAD attacks needing ventilatory support are rare. Most attacks respond well to treatment. We report a case of MOGAD with ADEM phenotype in an adult patient, evolving into coma, with need of ventilatory support, an uncommon, life-threatening, complication. **Final comments:** MOGAD should be considered as a cause of coma in adult patients with inflammatory diseases of the central nervous system suggestive of ADEM.

Background: Seasonal humor disorders are prone to have a link with daylight exposure. However, the effect of external light on non-seasonal disorders remains unclear. Evidence is lacking for the validity of Bright Light Therapy (BLT) as an adjunctive treatment for these patients. **Objective:** To assess BLT effectiveness as an adjunctive treatment for non-seasonal depressive disorders. **Methods:** In March 2024, a comprehensive search of publications in MEDLINE, Embase, and Cochrane databases for randomized clinical trials (RCTs) evaluating BLT effects in non-seasonal depressed patients. Truly randomized clinical trials published since 2000 were eligible. Comparisons between BLT and Dim Red Light (DRL) or antidepressant monotherapy alone were considered for inclusion. Using the systematic review approach on randomized controlled trials published from January 1, 2000, through March 25, 2024, differences between patients treated with and without BLT were estimated using the Mantel-Haenszel method; heterogeneity was assessed using I^2 statistics. R Studio, version 4.3.2, was used for statistical analysis. Remission of symptoms, response to treatment rates, and depression scales were assessed. **Results:** In this systematic review and meta-analysis of 11 unique trials with data from 858 patients, statistically significant better remission and response rates were found in the BLT group (40.72% vs. 23.52%; OR 2.42; 95% CI 1.503.91; p=0.0002; I^2=21%; and 60.36% vs. 38.56%; OR 2.34; 95% CI 1.463.75; p=0.0003; I^2=41%, respectively). Subgroup analysis based on follow-up times (<4 weeks; >4 weeks) also showed better remission and response rates with BLT: Remission (<4 weeks; 27.38% vs. 9.21%; OR 3.59; 95% CI 1.458.88; p=0.005; I^2=0%;) and (>4 weeks; 46.59% vs. 29.08%; OR 2.18; 95% CI 1.194.00; p=0.01; I2=47%). Response (<4 weeks; 55.55% vs. 27.35%; OR 3.65; 95% CI 1.817.33; p=0.0002; I2=35%) and (>4 weeks; 63.03% vs. 44.91%; OR 1.79; 95% CI 1.013,17; p=0.04; I2=32%). **Conclusion:** This meta-analysis established BLT as an effective adjunctive treatment for non-seasonal depressive disorders. Additionally, our results suggest that BLT may improve the time to respond to the initial treatment.

BRPF1-associated disease mimicking congenital myasthenic syndrome

Mariana Hiromi Manoel Oku[1], Clara Gontijo Camelo[1], Cristiane de Araujo Martins Moreno[1], Raquel Diogenes Alencar Sindeaux[1], Gabriella Corrêa Dousseau[1], Gabriel Saboia de Araujo Torres[1], Edmar Zanoteli[1]

Correspondence: Mariana Hiromi Manoel Oku; Email: mari.hiromi.mo@gmail.com.

Case presentation: We describe a case of a two-year-old Haitian girl who presented with bilateral ptosis since birth. She is the first child of a non-consanguineous Haitian couple, born via vaginal delivery, at term, with no history of obstetric complications. The parents reported bilateral eyelid ptosis with mild fluctuation and weak crying since her first weeks of life. There was no description of feeding difficulties, choking spells, hypotonia, or respiratory distress. She was diagnosed with cystic fibrosis after neonatal screening and a confirmatory chloride sweat test. Neurological exam at 11-month-old showed mild generalized hypotonia and weakness with axial involvement. There was no social/cognitive delay. In addition, there was bilateral partial ptosis without clear fatigability. Brain MRI was unremarkable and electromyography with repetitive nerve stimulation showed no signs of neuromuscular transmission dysfunction. Creatine phosphokinase levels were normal. Pyridostigmine was prescribed with no neurological improvement. Genetic testing revealed a pathogenic mutation at the BRPF1 gene, confirming the diagnosis of BRPF1-associated intellectual development

disorder with dysmorphic facies and ptosis. **Discussion:** BRPF1 gene mutations and consequent BRPF1 haploinsufficiency have been described to result in decreased H3K23 acetylation which leads to epigenetic deregulation and impaired development. The typical phenotype consists of ptosis, hypotonia/weakness associated with dysmorphic facies, intellectual developmental disorder, and epilepsy. Nevertheless, milder phenotypes with congenital ptosis and normal intellectual development have been reported. Bilateral ptosis and fatigable weakness are typical findings in congenital myasthenic syndrome (CMS). There is a wide clinical variability ranging from mild symptoms such as exercise intolerance or fluctuating ptosis to severe phenotypes with disabling weakness, bulbar symptoms, and respiratory insufficiency. The age of presentation (neonatal, childhood, adult-onset), course of the disease, and response to acetylcholinesterase inhibitors are also variable, which leads to a broad differential diagnosis, especially in childhood-onset forms. We present a case of a rare genetic disease that can mimic CMS and therefore should be included as a differential diagnosis in patients presenting with ptosis and weakness. **Final comments:** BRPF1-associated disease can mimic CMS and should be considered as a differential diagnosis even in children with mild or no intellectual development disorder.

Bulbar hematoma presenting as Wallenberg syndrome due to possible radiotherapy-induced vasculopathy as an atypical etiology: a case report

Alex de Novais Batista[1], João Herculano Lins[1], Maria Clara Arcoverde Santana[1], Virgílio Sátyro da Nóbrega Segundo[1], João Eudes Magalhães[1], Letícia Nunes Campos[1]

[1]Universidade de Pernambuco, Recife PE, Brazil.

Correspondence: Alex de Novais Batista; Email: alexnovaisb@gmail.com.

Case presentation: A 38-year-old woman presented to our outpatient clinic in late 2023 with left-sided limb weakness and numbness. Initially, she presented with hiccups, which lasted for four days and progressed to numbness and weakness in the left upper and lower limbs, visual disturbance in the left eye, and a staggering gait. Because of these symptoms, the patient sought emergency care. However, stroke features were not recognized in the computed tomography scan and no thromboembolic treatment was prescribed. Regarding her medical history, the patient underwent chemotherapy and radiotherapy for nasopharyngeal cancer from 2006 to 2007. As a result, she developed hypothyroidism and hypercholesterolemia, which were adequately treated with levothyroxine and rosuvastatin. The patient also presented a right foot drop due to Hansen's disease, which she was treated for in 1998. Neurological examination revealed left hemifacial hypoesthesia, impaired left corneal reflex, mild left trapezius weakness, and mild tongue deviation to the left. Other findings included incomplete left hemiparesis (grade 4), hemihypoesthesia, decomposing finger-to-nose movement, and hyperreflexia. A brain magnetic resonance imaging (MRI) showed a right-sided, elongated, lobulated hemorrhagic lesion at the bulbomedullary junction extending to the C3 level (2.5 x 1.4 cm). The patient was diagnosed with Wallenberg syndrome due to a bulbar hemorrhagic stroke. In early 2024, the patient demonstrated significant strength improvement (grade 5). Follow-up brain angiography and echocardiogram were unremarkable, while lab tests showed hypercholesterolemia. Although she had atherothrombotic factors, the stroke was attributed to vasculopathy induced by her previous radiotherapy, which probably affected microvessels after a long interval. Six months after the stroke, a new brain MRI showed complete resorption of the hematoma with gliosis. **Discussion:** Wallenberg syndrome results from infarction or hemorrhage in the lateral portion of the medulla oblongata, causing patients to experience vertigo, dysphagia, hoarseness, hiccups, ipsilateral facial hypoesthesia, and contralateral body sensory deficits. Common etiologies for the syndrome include vertebral artery occlusion, posterior inferior cerebellar artery occlusion, and vertebral artery dissection. None of these causes were found in our patient. Radiation-induced vasculopathy is a known but rare complication that can lead to cerebrovascular events years after treatment, often involving large vessels. Furthermore, the presence of a hematoma, as opposed to ischemia, is likely due to vessel wall fragility from an actinic lesion. **Final comments:** In this case, radiation-induced vasculopathy was a possible cause of the bulbar hemorrhagic stroke leading to Wallenberg syndrome. The atypical etiology and stroke nature highlight the importance of considering cerebrovascular disease as a long-term complication of cancer therapy.

CADASIL presenting with Foix-Chavany-Marie syndrome: a case report

Beatriz Pires Paes[1], Bruna da Silva Lima[1], Poliana Lima Campos[1], Beatriz Ballarin Costa[1], Anthony Magalhães Morais Santiago[1], Camilo Carvalho[1], Larissa Lucas Schloicka[1], Andre Gustavo Fonseca Ferreira[1], Pedro Manzke de Carvalho[1], Plínio Rodrigo Máximo Macêdo[1]

[1]Hospital de Base do Distrito Federal, Brasília DF, Brazil.

Correspondence: Beatriz Pires Paes; Email: beatrizpirespaes@gmail.com.

Case presentation: A 49-year-old man, cocaine user, alcoholic, and smoker, presented initially with dengue fever symptoms, with a positive serology. After three days, these symptoms were improving. However, he progressed within 24 hours to bilateral facial palsy, severe dysphagia, sialorrhea, hypophonia, and significant dysarthria. He also developed psychomotor agitation and emotional lability that did not improve with the use of antipsychotics, and persisted during the entire month of hospitalization. Infectious-metabolic causes were ruled out and lumbar puncture was within normal limits. The initial hypothesis was a post-infectious autoimmune response (rhombencephalitis). Therefore, we performed five days of pulse therapy with methylprednisolone, without much improvement. After two weeks, we carried out five plasmapheresis sessions, but the patient evolved with only partial betterment. Magnetic Resonance Imaging (MRI), only available one month after hospitalization, revealed in the T2 sequence multiple confluent hyperintensity foci with involvement of the white matter of the cerebral hemispheres predominantly in temporal lobes, and foci of heterogeneous contrast enhancement in the posterior topography of the left corona radiata, centrum semiovale and right frontal periventricular centers in a perivenular course. Throughout hospitalization, a family history of frequent neurovascular events was evident, with three brothers having previous histories of ischemic stroke, one of which was diagnosed with CADASIL at 60 years old. **Discussion:** Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) is a rare monogenic cerebral small vessel disease (SVD). As with all SVDs, CADASIL manifests on brain MRI with various combinations of white matter hyperintensities, lacunar infarcts, microbleeds, and brain atrophy, predominantly in locations such as anterior temporal poles, the basal ganglia and thalamus, and superior frontal gyri. It usually affects young or middle-aged adults, and it's typically characterized by migraine, subcortical ischaemic events, mood disturbances, and cognitive impairment. This condition can have a myriad of different presentations, and in this case, the anterior operculum was involved bilaterally. The Foix-Chavany-Marie syndrome (FCMS), also known as anterior opercular syndrome, is a rare neurological condition that presents with voluntary facial, pharyngeal, lingual, and masticatory paralysis bilaterally. FCMS can be differentiated from other conditions, such as bulbar paralysis and cranial nerve palsies by intact extraocular movements, preserved brainstem reflexes, and the absence of lower motor neuron signs. **Final comments:** CADASIL remains a diagnostic challenge, especially with atypical manifestations, such as presented in this patient with FCMS. This syndrome was consistent with our patient's presentation since he had central facial palsy, dysphagia, and sialorrhea.

https://doi.org/10.5327/CBN240269

Calcinosis of the cervical spine: a cause of myelopathy in crest syndrome

Natália Contini[1], William Alves Martins[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Natália Contini; Email: nataliacontini4@gmail.com.

Case presentation: A 53-year-old patient with CREST (Calcinosis, Raynaud's phenomenon, Esophagopathy, Sclerodactyly and Telangiectasias) syndrome for the past 30-years presented with slowly progressive weakness in her lower limbs and vesical incontinence. She had been treated with prednisone 20mg/day and azathioprine 150mg/day. Magnetic resonance imaging demonstrated severe compression at cervical spine due to a spinal tumoral calcinosis, with signs of myelopathy. The patient refused surgical intervention due to increased surgical risk. She remains clinically stable two year after diagnosis, without progression of her neurological deficits. **Discussion:** CREST syndrome is an acronym for calcinosis, Raynaud's phenomenon, esophageal dysfunction, sclerodactyly and telangiectasias. Tumoral calcinosis is a classical finding of this syndrome, however, it has only rarely been reported to cause myelopathy. Here, we report a 54-years-old woman with CREST syndrome who presented with slowly progressive spastic paraparesis and urinary incontinence, in whom diagnostic investigation demonstrated spinal tumoral calcinosis of the cervical spine. This diagnosis should be suspected in CREST patients presenting with spinal cord symptoms. Tumoral calcinosis is characterized by focal or multifocal soft tissue calcification, occurring usually in periarticular tissue or justa-articular regions of the extremities. Calcinoses occur in a dystrophic fashion in this disorder, where calcification is promoted in damaged or devitalized tissues in patients with normal calcium levels. It is common in areas that experience recurrent microtrauma. Thus, calcinosis of the spine is being recognized, as the spine is a common place for microtrauma, due to the extensive flexibility and susceptibility of some areas to degenerative disc disease and intervertebral disc herniation. Spinal tumoral calcinosis is defined as tumor-like deposits of calcium usually involving both the vertebral bodies and the posterior elements of the cervical, thoracic, and lumbar spine. It is a rare manifestation of CREST syndrome. Differential diagnosis remains difficult, as it may mimic neoplasms and infections. However, in CREST syndrome presenting with progressive paraparesis and spinal masses, this diagnosis should be primarily considered, especially in the absence of infection. Although patients may be asymptomatic, surgical resection remains the only effective treatment for patients with progressive symptoms. In these cases, surgery can be recommended, as the patient can be symptomatic and/or have extensive destruction of the vertebrae and surrounding structures. **Final comments:** Calcinosis of the spine can cause morbidity in patients with CREST syndrome. When intervention is necessary, surgical resection with spinal cord decompression and fusion can be effective in managing symptoms and preventing further spinal cord injury.

Cannabidiol for acute stroke treatment: cast study

Millene Rodrigues Camilo[1], Jaime Eduardo Cecílio Hallak[1], Priscilla Queiroz de Lima[1], Alline Cristina de Campos[1], Rodrigo Bazan[2], Maurício Yonamine[3], José Alexandre de Souza Crippa[1], Octávio Marques Pontes-Neto[1]

[1]Universidade de São Paulo, Faculdade de Medicina de Ribeirão Preto, Ribeirão Preto SP, Brazil.
[2]Universidade Estadual Paulista, Botucatu SP, Brazil.
[3]Universidade de São Paulo São Paulo SP, Brazil.

Correspondence: Millene Rodrigues Camilo; Email: millene.camilo@gmail.com.

Background: Cannabidiol is a non-psychoactive phytocannabinoid derived from Cannabis sativa. In animal models, it has been demonstrated that cannabidiol is associated with reduced in cerebral infarction volume, increased blood flow, and modulation of neuroinflammatory processes. Although clinical studies have already shown good tolerance and few adverse effects, none have yet been carried out to evaluate the safety and efficacy of cannabidiol in acute stroke patients. Primary **Objective:** To assess the safety of the use of cannabidiol when administered to patients with ischemic stroke within the first 7 days of the onset of symptoms. Secondary objectives (1) evaluate the functionality and severity of the stroke using the modified Rankin scale and the NIHSS 90 days after the stroke; (2) assess anxiety, depression, and drowsiness through specific questionnaires on admission, on the 7th day or hospital discharge and after 90 days; and (3) evaluate the final volume of cerebral ischemia. **Methods:** This is a phase II clinical trial of intervention, double-blind, randomized, multicenter, prospective, placebo-controlled to evaluate the safety and efficacy of oral treatment with cannabidiol in doses of 150mg, 300mg, and 600mg in the first 7 days of evolution of an acute ischemic stroke. Randomization will be stratified by stroke center and severity (NIHSS <10 or >10). A total of 80 participants will be included, 20 in each group: placebo, 150mg, 300mg, and 600mg of cannabidiol. **Results:** The use of cannabidiol in ischemic stroke patients will likely be safe and points to possible neuroprotection, allowing the continuation of a phase III study.

https://doi.org/10.5327/CBN240271

Cannabidiol in the cognitive neurology of aging: current evidence, challenges and future prospects

Tereza Raquel Xavier Viana[1], José Eduardo Martinelli[1]

[1]Faculdade de Medicina de Jundiaí, Jundiaí SP, Brazil.

Correspondence: Tereza Raquel Xavier Viana; Email: espacotr@hotmail.com.

Background: Population aging represents a growing challenge for global health, with a corresponding increase in neurodegenerative diseases affecting cognition. Cannabidiol (CBD), a non-psychoactive component of Cannabis sativa, has emerged as a potential therapeutic agent in the cognitive neurology of ageing, due to its anti-inflammatory, antioxidant and neuroprotective properties. **Objective:** To investigate the current evidence of CBD in the cognitive neurology of aging, identifying potential benefits, methodological challenges and future prospects as a therapeutic intervention to improve cognitive function in the elderly and mitigate the impacts of age-related neurodegenerative diseases. **Methods:** This is an exploratory and descriptive systematic review conducted according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) and PICO (Population, Intervention, Comparison, Outcome) guidelines. Searches were carried out in the PubMed, SciELO, Cochrane Library and BVS databases, using the descriptors: "Cannabidiol" and "Cognitive Impairment" AND "Neurodegenerative Diseases". We included studies published in the last 5 years (2019 - 2024), in English and Portuguese, which investigated the effects of CBD on older people with cognitive impairment, dementia or age-related neurodegenerative diseases. Experimental studies, controlled clinical trials and systematic reviews were considered for inclusion. **Results:** During the initial search, nine articles were identified, of which one was a duplicate. After reviewing the titles, abstracts and conclusions of the remaining eight, five were excluded because they did not meet the inclusion criteria. Three studies were selected for full reading and inclusion in this research. These studies highlight that CBD has the potential to mitigate neuroinflammatory processes, reduce oxidative stress and modulate neuronal plasticity in brain ageing. Pre-clinical evidence indicates benefits in cognitive function and improved quality of life in the elderly. However, variations in methodological quality and the dosage used highlight the need for more robust research and well-controlled clinical trials. **Conclusion:** This study highlights the growing body of evidence supporting the therapeutic potential of CBD in the cognitive neurology of ageing. Although promising, the use of CBD faces significant challenges, including the need for longitudinal studies, standardization of formulations and dosages, and accurate understanding of its mechanisms of action. Future research should focus on filling these knowledge gaps, with a view to translating pre-clinical findings into tangible clinical benefits for an increasingly large and vulnerable ageing population.

https://doi.org/10.5327/CBN240272

Cannabinoid treatment for autism spectrum disorder (ASD): a systematic review with single-arm meta-analysis

Jonas Leite de Souza Filho[1], Ocílio de Deus da Rocha Ribeiro Gonçalves[1], Maria Antônia Oliveira Pereira[2], Victor Gonçalves Soares[3], Celli Veloso Cavalcanti[1], Dário Correia Negreiros[1], Laura Martins Soares Cortez[1], Gielson de Sousa Silva[1], Lara Beatriz Alves Batista[1], Kelson James Almeida[1]

[1]Universidade Federal do Piauí, Teresina PI, Brazil.
[2]Universidade Estadual do Piauí, Teresina PI, Brazil.
[3]Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina MG, Brazil.

Correspondence: Jonas Leite de Souza Filho, Email: jonaslf25@gmail.com.

Background: Autism spectrum disorder (ASD) is a complex neurodevelopmental condition. It can exhibit a range of symptoms, from deficits in communication and social interaction to repetitive disorders and stereotypical behaviors. Currently, despite increased prevalence of this condition, drug therapy is still limited. The use of cannabinoid chemical compounds, derived from the cannabis plant, has shown potential as a therapeutic alternative for individuals with ASD. **Objective:** The present study aims to evaluate the effectiveness of cannabinoid treatment on behavioral symptoms of ASD. **Methods:** We systematically searched PubMed, Embase, and Cochrane for studies reporting. All included studies used plant extracts containing the same concentrations of Cannabidiol and Tetrahydrocannabinol in a 20:1. The outcomes of interest were mean change from baseline for the Autism Parenting Stress Index (APSI), Home Situation Questionnaire-ASD (HSQ), and the prevalence of success regarding anxiety problems and behavioral problems. Mean changes and prevalences were pooled using a random-effects model with 95% confidence intervals (CIs). We used R software version 4.3.2 and the extension package "meta" for all statistical analysis. **Results:** Five studies were included, consisting of one randomized clinical trial, two retrospective, and two prospective, involving a total of 469 patients. The mean change from baseline for the APSI outcome was -0.66 (95%CI -0.85 to -0.47; I^2=0%) and for the HSQ outcome was -1.35 (95% CI -1.78 to -0.92; I^2=0%). The prevalence of success regarding anxiety problems was 37.65% (95%CI 29.73% to 45.56%; I^2=0%). The prevalence of success regarding behavioral problems was 51.13% (95%CI 34.84% to 67.41%; I^2=84%). **Conclusion:** We observed the effects of cannabinoid treatment on behavioral symptoms of ASD, with positive effects on anxiety and parental stress. However, due to the scarcity of blinded clinical trials with control groups, there is still limited evidence to justify its widespread use, making further studies necessary. Furthermore, as the scales used assessed behavioral symptoms, there were no observable positive effects on core ASD symptoms.

Cardiac calcified amorphous tumor-induced ischemic stroke treated with intravenous thrombolysis: a case report

Pedro Almeida Martins Pontes[1], Igor Izoton[1], Richardson da Silva Nogueira[1], Gunnar Willy Pereira Crepaldi[1], Henrique de Moraes Bernal[1], Ingrid Lorena da Silva Gomes[1], Giovanni Caniçali Simões[1], Werley de Almeida Januzzi[1], Marcele Schettini de Almeida[1], Sônia Maria César de Azevedo[1]

[1]Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo SP, Brazil.

Correspondence: Pedro Almeida Martins Pontes; Email: pedroalmeida.pontes@gmail.com.

Case presentation: A 69-year-old woman with a history of smoking, obesity, hypertension, cardiac arrhythmia, and a report of a transient ischemic attack one year ago presented with sudden weakness in her left leg and numbness throughout her entire left side. She was admitted three hours after the onset of symptoms and stroke protocol was initiated. Her neurological examination revealed a National Institutes of Health Stroke Scale (NIHSS) score of five points (4.1, 6A.4), with no movement in the left leg. Brain computed tomography (CT) showed no acute brain lesion, and angio CT did not reveal any major vessel occlusion. The patient underwent intravenous thrombolysis without complications, maintaining the same NIHSS score at its conclusion. Her electrocardiogram revealed a left bundle branch block. A point-of-care ultrasound (POCUS) was also performed. In the apical 4 chamber view, there was an irregular hyperechoic image, on the basal inferolateral wall of the left ventricle, attached to the mitral annulus, adjacent to the posterior mitral leaflet. Due to the suspicion of a cardioembolic stroke mechanism caused by a cardiac mass, further tests were conducted. Transthoracic echocardiogram revealed an amorphous, irregular nodular image, measuring 3.0 x 2.5 cm, suggestive of a calcified tumor with necrotic content inside. Cardiac MRI showed a nodular formation on the basal inferolateral wall, adjacent to the mitral valve, measuring 2.8 x 4.2 x 2.5 cm, showing iso-signal on T1 and T2 and heterogeneous late enhancement. Brain MRI showed diffusion restriction in the right frontal and parietal lobes. At the time of discharge, the patient had grade IV strength in her left leg and no facial paralysis (NIHSS 1 point). In joint management with Cardiology, her surgical risk was considered too high at the moment, therefore a diagnosis of probable Cardiac Calcified Amorphous Tumor (CAT) was made. She was discharged with oral anticoagulation for secondary stroke prophylaxis. **Discussion:** To our knowledge, this is the first case of stroke caused by CAT that was treated with intravenous thrombolysis. Cardiac CAT is a rare type of non-neoplastic cardiac tumor, occasionally associated with cardioembolic stroke. It is suspected that the embolization mechanism of these tumors is related to either a part of the mass itself detaching or a

thrombus attached to the mass causing emboli. Surgical treatment is usually performed, involving excision of the mass. However, there are reports of patients with contraindications to surgery who underwent conservative treatment, with periodic monitoring and anticoagulation, who remained free of recurrence of strokes. **Final comments:** More studies are needed to better establish the risks of stroke in the population with CAT, as well as the appropriate treatment for preventing new cerebrovascular events in this disease.

[1]Universidade Nove de Julho, Bauru SP, Brazil.

Correspondence: Nicoli Lindissey Zuim; Email: nicolind14@gmail.com.

Case presentation: GCR, 25 years old, male, presented to the Emergency Department of the Clinical Neurology Department with a complaint of headache in the nape region, which was more intense on the right side, associated with fainting. Unremarkable general physical examination. Neurological examination revealed upper foveal, hemiplegia, temporal hemianopia, and hypoesthesia, all on the left with a National Institutes of Health Stroke Scale (NIHSS) score of 18 on admission. Further tests were ordered and revealed abnormalities: non-contrast brain computed tomography (CT) with loss of cortico-subcortical differentiation in the putamen, M1, and M2 territories, as well as a cerebral/neck angiogram showing dissection of the right internal carotid artery with subocclusion in M1 on the right. The patient reported previous surgery 45 days ago for a left ankle injury and denied any further comorbidities. He reported a family history of cerebrovascular events. With a presumptive diagnosis of ischemic stroke of large vessels with Tandem occlusion, mechanical thrombectomy intervention was initiated for the patient. In 24 hours, the patient developed intracranial hypertension and delineation of the ischemic area in the territory of the right middle cerebral artery. Consequently a right decompressive craniectomy was performed. To investigate the possible causes of the event, a transesophageal echocardiogram was requested. It revealed a patent foramen ovale (PFO), with passage of macrobubbles between the right and left chambers after Valsalva maneuver. In addition, lower limb venous Doppler confirmed deep vein thrombosis of fibular veins in the middle and proximal third of the left lower limb, providing a potential source of emboli. The findings allowed the etiology of the ischemic stroke to be elucidated. **Discussion:** In the presented case, the complexity of cerebrovascular events is evident, as well as the importance of a multifaceted diagnostic and therapeutic approach during follow-up. The suggestive picture of a significant neurological event was corroborated by the findings on neurological examination, as well as by imaging tests and the NIHSS score of 18, indicating a severe stroke due to the prothrombotic state and a genetic predisposition to vascular events. Therefore, the combination of patent foramen ovale and deep vein thrombosis indicates a paradoxical and fortuitous embolic mechanism, where a venous thrombus passes to the arterial system through the patent communication between the chambers of the heart, resulting in a malignant and complexly evolving ischemic stroke. **Final comments:** In summary, it is important to emphasize the need for a comprehensive approach to the diagnosis of stroke in young patients, especially when they have atypical risk factors or a medical history suggestive of prothrombotic states. Prompt intervention combined with a thorough etiological investigation is crucial for effective management and prevention of future events.

Carotid artery stenosis after 13 years of radiotherapy for head and neck cancer: a case report

João Henrique Reis Duque Estrada[1], Caroline Vianna Costa Pinto[1], Luiza Guimarães Póvoa[1], Victor Waldhelm Cozer[1], Diogo Terrana[1], Felipe Schmidt[1], Sofia Mermelstein[1]

[1]Universidade do Estado do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: João Henrique Reis Duque Estrada; Email: joaohestrada2@gmail.com.

Case presentation: A 58-year-old male patient, hypertensive, with a history of laryngeal cancer treated with ionizing radiotherapy in 2010, presented to the emergency department of his municipality with a right brachio-crural hemiplegia, non-fluent aphasia, and general malaise with symptom onset of approximately 1 hour and 30 minutes. Despite no contraindications, reperfusion therapies were not performed. He was then transferred to a tertiary hospital for etiological investigation, where he underwent magnetic resonance imaging of the head and neck, as well as other complementary exams, which showed severe right carotid artery stenosis, suggestive of actinic involvement. He underwent carotid angioplasty with non-pharmacological stent placement, without complications, and was discharged 24 hours later. In addition to the diagnosis of actinic carotid artery stenosis, the patient started treatment for primary hypothyroidism of probable actinic etiology after initial exams. **Discussion:** Carotid artery stenosis is an important late complication in patients who have undergone head and neck radiotherapy. This complication sometimes presents with ischemic stroke, occurring years after radiotherapy, as seen in the present case. The incidence of cerebrovascular events ten years post-irradiation is prevalent in up to 34% in large studies. With increasing survival rates among patients undergoing radiotherapy for head and neck tumors, actinic carotid artery stenosis has become an important topic for discussion. Actinic carotid stenosis is characterized by vascular obstructions usually distal with diverse pathophysiology, which can be explained by endothelial vascular injury, vasa vasorum injury, and accelerated atherosclerosis, with extensive fibrosis of the media and adjacent tissues, sometimes accompanied by atheromatous plaques, which often confuses the etiological diagnosis. According to the literature, the main therapeutic approach for actinic carotid stenosis is angioplasty with stent rather than surgical endarterectomy proposed for most cases, due to the adherence of the actinic lesion to the muscular planes and adjacent fascia, besides the high prevalence of restenosis after endarterectomy in these patients. Even though there is evidence of associated atheromatous plaques, these are usually disproportionately smaller than the fibrotic component. **Final comments:** The high incidence of actinic carotid stenosis after head and neck radiotherapy is a condition often underdiagnosed due to its atheromatous component. Better understanding of these lesions is necessary to assist in prevention, diagnosis, and choice of the most appropriate therapeutic approach.

Carotid web and ischemic stroke in young adult: a case report

Brenda Leticia Lopes Batista[1], Barbara Borges de Oliveira[1], Daniel Duarte Rolim[1], Victor Souza Torres de Vasconcelos[1], Mariana Holanda Gameleira[1], Igor Santos Sales[1], Ana Dolores Firmino Santos do Nascimento[1], Ubiratan Alves Viturino da Silva[1], Ana Rosa Melo Correa Lima[1]

[1]Hospital da Restauração, Recife PE, Brazil.

Correspondence: Brenda Leticia Lopes Batista; Email: brendalopes.academico@gmail.com.

SLNL, 44 years old, female, massage therapy professional, married, admitted to the neurological emergency department of a tertiary hospital with a history of right-sided hemiparesis, aphasia and combined gaze deviation to the left with a sudden onset lasting 3 hours and 30 minutes. On admission, she underwent a head tomography (CT) scan without acute injuries, with an Alberta Stroke Program Early CT Score (ASPECTS) of 10 points. In the absence of contraindications, as well as within the therapeutic window, chemical thrombolysis was performed with alteplase, with slight gingival bleeding. The patient had an initial NIHSS of 20 points, with a final NIHSS of 9 points, showing partial improvement in strength deficit and aphasia. The patient remained in the stroke unit and underwent control neuroimaging the following day, showing hypodensity in the territory of the left middle cerebral artery. The patient was discharged from the stroke unit for follow-up in the neurology ward, where the etiological investigation continued. Hypertensive patient with recent diagnosis, dyslipidemic, overweight and without other comorbidities. She evolved with significant improvement, presenting some phonemic and semantic paraphasias during hospitalization. During the etiological investigation, she underwent magnetic resonance imaging of the brain that showed diffusion restriction with hypersignal on T2/FLAIR affecting the cingulate gyrus, precuneus, insula and left frontoparietal opercular region without post-contrast enhancement, compatible with recent ischemia. Remaining unchanged. Usg doppler of carotid and vertebral arteries without changes. However, resonance angiography of intracranial vessels showed irregularities in the posterior wall of the origin of the left internal carotid artery, insinuating itself into the lumen, compatible with the same side of the ischemiated territory; suggesting carotid membrane or carotid web. Patient was released home and returned for elective angioplasty with carotid stent to treat carotid web. She was again discharged from hospital with a final NIHSS of 3 points, using dual antiplatelet therapy with acetylsalicylic acid (ASA) and clopidogrel, in addition to a high-potency statin. Carotid web is a rare event, often undiagnosed, representing a risk of recurrence for stroke in the absence of other risk factors. The webs are protrusions into the lumen of the vessel, similar to a shelf, and can be considered a variant of fibromuscular dysplasia. Regarding treatment, there are favorable clinical results with both angioplasty and endartectomy, although there are few reports describing angioplasty with stent. For this reason, there must be a high clinical suspicion in young patients, without defined causes, in cases of cryptogenic stroke, for timely diagnosis and prevention of recurrences and future disabilities.

Carotid web under an ulcerated carotid atherosclerotic plaque: a case report

Pedro Almeida Martins Pontes[1], Giovanni Caniçali Simões[1], Henrique de Moraes Bernal[1], Ingrid Lorena da Silva Gomes[1], Guilherme Lago Miranda[1], Tainá Fátima Ramos Gonçalves[1], Mateus Paquesse Pellegrino[1], Marcele Schettini de Almeida[1], André Luiz de Rezende[1], Sônia Maria César de Azevedo[1]

[1]Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo SP, Brazil.

Correspondence: Pedro Almeida Martins Pontes; Email: pedroalmeida.pontes@gmail.com.

Case presentation: A 49-year-old woman, with a history of hypertension and diabetes, presented with a sudden onset of aphasia. She was admitted to the emergency room with aphasia and dysarthria and a NIHSS score of 9 points. A brain computed tomography (CT) showed a hypodense area in the left frontal region, associated

with regional bleeding. There was a report of a previous event with a similar presentation one month ago, when she was diagnosed with an ischemic stroke of undetermined mechanism, and was prescribed dual antiplatelet therapy (DAPT) and high-potency statins. Angio CT revealed a mild (less than 50%) stenosis in the left carotid bulb region. Digital Angiography confirmed this suspicion, showing an ulcerated plaque in the left carotid bulb with adjacent contrast retention, without significant stenosis. Cardiac and laboratory tests were unremarkable. Based on these findings and CCS stroke analysis, stroke etiology and mechanism were defined as possible large vessel atheroembolism secondary to the aforementioned atherosclerotic plaque. She was again discharged on DAPT and statins. Over the next two months, despite proper adherence to therapies, she experienced three new episodes of sudden neurological deficits, characterized by aphasia and right-sided hemiparesis. All events were confirmed by Brain MRI as new ischemic strokes. A new Angio CT showed an occlusion of the middle cerebral artery in the distal M1 region. Reperfusion therapies were not performed, due to arrival outside of the appropriate time window. Initially, a new angiography was performed with an identical report to the first one. On the third angiography, a carotid web was identified, with an ulcerated atherosclerotic plaque on its surface at the left carotid artery bifurcation. Thus, a diagnosis of ischemic stroke secondary to carotid web associated with an ulcerated atherosclerotic plaque was established. Angioplasty was performed, and DAPT was maintained. The patient has been free from new ischemic events for 16 months, with progressive rehabilitation of previous deficits. **Discussion:** Carotid web is a shelf-like lesion that typically occurs on the inner wall of the carotid bulb and is suspected to be an intimal variant of fibromuscular dysplasia. The protrusion of this lesion into the carotid artery lumen causes blood stasis, increasing the risk of thrombus formation and subsequently the risk of stroke. Retrospective studies show a risk of up to 40% of recurrence of stroke, depending on the choice of drug prophylaxis. The most effective treatment for these lesions is not completely known, but angioplasty appears to be superior to DAPT and to anticoagulation. **Final comments:** Carotid web is a condition that should be investigated as a possible cause of ischemic stroke, especially in young patients without a defined etiology for the event or those who experience recurrence despite optimized clinical treatment.

Carotid web: a rare etiology of ischemic stroke

Ana Luísa dos Santos Carregosa[1], Eduarda Leitzke[1], Carlos Eduardo Marisco Ceretta[1], Robert Luís Kern[1], Pedro Damassini[1], Gustavo Roberto Minetto Wegner[1], Luciana Estacia Ambros[1]

[1]Universidade de Passo Fundo, Passo Fundo RS, Brazil.

Correspondence: Ana Luísa dos Santos Carregosa; Email: carregosaluisa@gmail.com.

Case presentation: A 62-year-old hypertensive female presented to the emergency department with Broca's aphasia, ataxia, and swallowing difficulty, which began upon waking 3 hours prior. She exhibited difficulty following commands and had an NIH Stroke Scale (NIHSS) score of 6 upon arrival. The patient denied smoking and is allergic to azithromycin. Neurological examination revealed preserved cranial nerves with a slight deviation of the labial commissure, intact sensation, and preserved symmetric muscle strength in all four limbs. Cranial computed tomography (CT) revealed a left frontoparietal hypodense area consistent with stroke, along with a hyperdense middle cerebral artery (MCA) sign. As it was a wake-up stroke, cranial magnetic resonance imaging (MRI) was performed, showing no mismatch, rendering the case ineligible for thrombolysis. Subsequent magnetic resonance angiography revealed proximal occlusion of the left middle cerebral artery at the M1-M2 junction. Percutaneous mechanical thrombectomy was performed, along with full heparinization, followed by prophylactic heparin and dual antiplatelet therapy. Follow-up CT scan showed hemorrhagic transformation in the territory of the left MCA extending into the subarachnoid space, which was later reabsorbed without new lesions. Additional examinations demonstrated a small concentric plaque in the left carotid artery, with no other abnormalities. Cervical and intracranial CT angiography revealed a membrane at the transition from the left common carotid artery to the left internal carotid artery, likely representing fibromuscular dysplasia, suggestive of a "carotid web". The patient was discharged with follow-up by speech therapy and physiotherapy, along with instructions regarding signs of severity. **Discussion:** Carotid web is a rare cause of ischemic stroke, defined as an intimal fibromuscular dysplasia found in the carotid bulb or the beginning of the internal carotid artery. Epidemiologically, its incidence in ischemic stroke is approximately 1.2%, more common in men and individuals of African descent, and typically presents unilaterally. Histologically, it lacks calcification and atherosclerosis, with its pathophysiology stemming from disturbed normal laminar flow and increased platelet aggregation. Diagnosis is made through imaging modalities such as digital subtraction angiography, computed tomography angiography, magnetic resonance imaging, and ultrasound. **Final comments:** Despite its rarity, understanding of carotid web is crucial as it constitutes a part of the etiological differential diagnoses of ischemic stroke, especially in patients without atherosclerotic disease or cardiac arrhythmias. Diagnosis through imaging modalities such as angiography is essential for appropriate management and follow-up.

Correspondence: Melissa Fernandes Vilela de Freitas; Email: melissa.fernandesvf1@gmail.com.

Case presentation: A 37-year-old woman presented with a sudden onset of numbness and weakness affecting her left side. She had no history of hypertension, diabetes, dyslipidemia, smoking, cardiomyopathy, or other conditions. Initial non-contrast brain computed tomography (CT) and magnetic resonance imaging (MRI) revealed a non-lacunar acute ischemic stroke in the right anterior circulation. Cardiac evaluation included an electrocardiogram (ECG) to check for arrhythmias and an echocardiogram to assess cardiac function and detect potential sources of emboli; however, no sources of emboli or significant vascular pathology were identified. Given the negative initial work-up, a digital subtraction angiography (DSA) was performed. This detailed imaging revealed a carotid web (CW) in the ipsilateral carotid bulb associated with the stroke. Other cervical arteries, including the left carotid and both vertebral arteries, appeared normal. The patient was started on dual antiplatelet therapy with acetylsalicylic acid and clopidogrel to prevent further strokes and prepared for a future stenting procedure. **Discussion:** A CW is an intimal variant of fibromuscular dysplasia with recently recognized implications in patients with cryptogenic ischemic stroke. Its hallmark is a focal shelf-like intraluminal protrusion in the posterior aspect of the carotid bulb. CW is considered a rare entity and a significant proportion of cases have been associated with recurrent ischemic strokes, most frequently in younger adults who lack other known risk factors. It is best demonstrated and diagnosed on CT angiography (CTA) of the neck because of its ability to resolve calcium and create multiplanar reconstructions. Although they can be readily visualized on CTA, carotid webs may be missed or misinterpreted because they do not typically cause hemodynamically significant stenosis and can mimic arterial dissection, non-calcified atherosclerotic plaque and intraluminal thrombus. Options for management include antiplatelet therapy, carotid endarterectomy and carotid artery stenting. Modern management strategies for cryptogenic stroke include long-term cardiac monitoring, further investigation for structural cardiac disease and a diagnostic workup for arterial hypercoagulability, however, these strategies are not likely to capture the possibility of a carotid web. **Final comments:** This case underscores the importance of considering a CW as a potential cause of cryptogenic ischemic stroke, especially in younger adults without typical risk factors. It highlights the necessity of thorough vascular imaging and the consideration of CW in stroke patients lacking other risk factors. The patient's management with dual antiplatelet therapy illustrates the critical role of tailored treatment strategies in such cases. Comprehensive diagnostic and therapeutic approaches are essential for improving patient outcomes in rare but impactful conditions like CW.

Carotid-cavernous fistula with drainage to the cavernous sinus: a case report and literature review

Carlos Eduardo Marisco Ceretta[1], Ana Luísa dos Santos Carregosa[1], Eduarda Leitzke[1], Tami Zang Crestani[1], Werner Petry Silva[2], Luciana Estacia Ambros[1]

[1]Universidade de Passo Fundo, Passo Fundo RS, Brazil.
[2]Instituto de Neurologia e Neurocirurgia, Passo Fundo RS, Brazil.

Correspondence: Carlos Eduardo Marisco Ceretta; Email: caduceretta@hotmail.com.

Case presentation: Patient A.A.A., 48 years old, male, with no comorbidities and continuous medication, was seen in the emergency department of a tertiary hospital in Rio Grande do Sul (RS) with edema and erythema of the eyelids in the right eye, associated with orbital discomfort, visual clouding and diplopia for 2 days. On physical examination, the right eye showed significant periorbital edema, chemosis, proptosis, and signs of paralysis of multiple cranial nerves on the right (III, IV, and VI). To better elucidate the diagnosis, an angiotomography of the skull and cervical vessels was requested, which showed signs of enlargement of the superior ophthalmic vein, a protruding cavernous sinus with asymmetrical enhancement, suggesting a carotid-cavernous fistula (CCF). The neurosurgical team was asked to evaluate the patient, and cranial arteriography was performed, which confirmed the suspicion of an arteriovenous fistula with multiple afferents, mainly the right external carotid artery draining into the cavernous sinus. Venous embolization was performed, with complete exclusion of the fistula involving the ascending pharyngeal artery and the right inferior petrosal sinus. The patient was discharged from the hospital 2 days after the procedure, with complete improvement of the ocular deficit and signs of cranial nerve palsy. **Discussion:** Carotid-cavernous fistulas are a rare condition involving an abnormal connection between the carotid artery or its branches and the cavernous sinus. CCFs have an incidence of 0.16 to 0.29 per 100,000 adults per year,

mostly due to the rupture of intracavernous aneurysms. The main symptoms are ocular, usually pain, conjunctival injection, and proptosis, with a risk of vision loss. Suspicious clinical findings can be investigated by angiotomography or cranial angiography, which have a sensitivity of 87% and 90% for diagnosing CCF, respectively. The standard approach is endovascular embolization, both arterial and venous. After effective intervention with complete fistula closure, ocular symptoms tend to disappear. **Final comments:** This case clearly illustrates the clinical presentation, diagnostic investigation, and successful therapeutic management of CCFs. It can lead to significant ophthalmic symptoms as a rare and serious condition. Imaging tests play a fundamental role in diagnosis. Venous embolization is a safe and effective therapeutic option, leading to a rapid patient recovery with complete improvement of symptoms.

Carpal tunnel syndrome with Riche-Cannieu anastomosis: an electrophysiological-ultrasound correlation report

Antonio Edvan Camelo Filho[1], Pedro Lucas Grangeiro Sá Barreto Lima[1], Francisco Luciano Honório Barreto Cavalcante[1], Pedro Vitor Ferreira Rodrigues[1], Oliver Reiks Miyajima[2], Paulo Ribeiro Nóbrega[1], Pedro Braga-Neto[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.
[2]Universidade Estadual do Ceará, Fortaleza CE, Brazil.

Correspondence: Antonio Edvan Camelo Filho; Email: edvan.camelo@gmail.com.

Case presentation: A 53-year-old woman who complained of numbness and tingling in both hands was referred for evaluation of possible carpal tunnel syndrome (CTS). There was no atrophy in the thenar muscles, and motor function was preserved during all hand movements. All nerve conduction studies except for median nerve data were bilaterally normal in amplitude, latency, and conduction velocity. Median sensory nerve amplitude potentials (SNAPs) were obtained bilaterally with reduced velocity and normal amplitude values. Right median compound motor amplitude potential (CMAP) had a normal distal latency and markedly reduced amplitude (2mV) without motor block along elbow and axilla stimulations. Left motor median nerve studies were normal. Needle examination was normal, including bilateral abdutor pollicis brevis (APB) muscles, proximal median nerve, and C8T1 territories. These findings supported the diagnosis of a severe right CTS, yet the lack of thenar atrophy and a normal APB myography alerted us to the possibility of an anomalous innervation. We performed muscle and median nerve ultrasounds that confirmed CTS in both hands with a thickened median nerve (R 11 mm2 /L 10 mm2) without abnormalities in the nerve trajectory on both arms. APB muscle echogenicity (Heckmatt 1) and thickness were preserved. The final diagnosis of this patient was the coexistence of a mild bilateral CTS with a Riche-Cannieu anastomosis (RCA) in the right hand. **Discussion:** The Riche-Cannieu anastomosis involves variations in the innervation of intrinsic hand muscles, in which thenar muscles normally supplied by the median nerve are innervated by the ulnar nerve. When complete, this condition is sometimes called the "all ulnar hand". Misinterpretation of RCA may cause several diagnostic problems; for example, in ulnar nerve injury, the presence of signs of denervation in the median-innervated muscles would lead one to suspect the possibility of a C8-Tl or brachial plexus injury. Also, in CTS cases, mild sensory abnormalities may be misclassified as severe CTS and, therefore, indicate surgery. **Final comments:** Electrodiagnosis of peripheral nerves presents challenges due to anatomical anomalies like RCA. This case shows the importance of recognizing anomalous innervations such as the RCA, particularly when interpreting low-amplitude motor responses in the median nerve. Furthermore, integrating neuromuscular ultrasound into clinical practice can significantly enhance diagnostic capabilities. This imaging modality provides real-time visualization of nerves and muscles, offering additional insights into anatomical variations and pathological conditions that may not be fully captured by traditional electrodiagnostic tests alone. By incorporating the awareness of rare anatomical variations like RCA and the use of neuromuscular ultrasound, clinical neurophysiologists can improve accuracy in diagnosis, optimize treatment planning, and ultimately enhance patient care outcomes.

Case of Wernicke's encefalopathy following hyperemesis gravidarum

Pedro Sanches Corrêa[1], Rodrigo da Franca Santos[1], Ilana Cwajgenberg[1], Crissia Pitanga Malta[1], Maria Eduarda Morgado da Silva[1], Sofia Mermelstein[1], Felipe da Rocha Schmidt[1], Diogo Matheus Terrana de Carvalho[1]

[1]Hospital Universitário Pedro Ernesto, Rio de Janeiro RJ, Brazil.

Correspondence: Crissia Pitanga Malta; Email: crissiapitanga@hotmail.com.

Case presentation: 27 year old female, G4P4A0, diagnosed pregnancy at 31 weeks, due to nausea and intense vomiting, associated with weight loss of 20kg between February and March 2024. In April, fetal death was verified and the patient was submitted to a cesarean section. After 3 days, the patient developed progressive ataxic gait and mental confusion and is readmitted in the fourth day of symptoms at the maternity hospital, where Ampicillin and Aciclovir were administered for 14 days, without clinical improvement. She was transferred to a reference service of Neurology on the 24th day after the cesarean section. At admission, the patient presented with inattention, ataxia with dysmetria, dysdiadochokinesia, intention tremor, saccadic eye pursuit, hypotonia of arms and legs, absent patellar tendon reflex, clonus of the lower limbs, spastic dysarthria and Pseudobulbar affect. Due to the clinical history of hyperemesis gravidarum, Wernicke's Encefalopathy was suspected. Brain MRI demonstrated areas of hyperintensity in T2 and FLAIR with restriction to water diffusion diffusely in the cerebellar cortex with reduced sulcus in the cerebellar folia associated with cytotoxic edema, as well as discrete hyperintensity in FLAIR with restriction to water diffusion in the mammillary bodies and hypothalamus. CSF exam had normal opening pressure, glucose of 59mg/dl, proteins of 31 mg/dl and 15 leukocytes/mm3 (100% lymphocytes). High dose thiamine was initiated orally and intravenously, with progressive improvement of the symptoms. After 1 month, a new brain image showed an exuberant cerebellar atrophy. **Discussion:** Wernicke's encephalopathy is an acute neuropsychiatric condition secondary to thiamine deficiency. Common clinical manifestations include nystagmus or other ocular motility disorders, ataxia and altered mental status. Risk factors include mal-nutrition and excessive vomiting, as in hyperemesis gravidarum. When not adequately treated, it may develop to Korsakoff Syndrome, in which confabulations and amnesia are frequent. Diagnosis may be established by dosing serum thiamine levels or erythrocyte transketolase activity, although these tests have low specificity and are not widely available. Hence, clinical and radiological diagnosis are accepted. Usually, CSF examination is normal and brain MRI usually presents with hyperintensities in T2 in the medial thalamus, mammillary bodies, periaqueductal gray matter and cerebellum. **Final comments:** This case report exemplifies a patient with a probable diagnosis of Wernicke's Encefalopathy following hyperemesis gravidarum, which is very underdiagnosed due to a wide range of possible symptoms and because few patients present with the classic triad. This condition has a high morbidity and mortality rate, and may be easily treated if correctly identified, therefore, must be included as differential diagnosis when risk factors are present.

https://doi.org/10.5327/CBN240283

Case report - ELOVL4: cerebellar ataxia with axonal sensory-motor polyneuropathy, epilepsy, psychosis and cognitive decline

Kaliny Oliveira Peixoto[1], João Paulo Barile[1], Renan Brandão Rambaldi Cavalheiro[1], Patrícia Marques Mendes[1], Igor Braga Farias[1], Paulo de Lima Serrano[1], Wladimir Bocca Vieira de Rezende Pinto[1], Paulo Victor Sgobbi de Souza[1], Acary Souza Bulle Oliveira[1]

[1]Universidade Federal de São Paulo, Escola Paulista de Medicina, São Paulo SP, Brazil.

Correspondence: Kaliny Oliveira Peixoto; Email: kalinyop355@gmail.com.

Case presentation: 52-year-old woman, with adequate neuropsychomotor development up to 3 years old, when she presented the first episode of dysperceptive focal epileptic seizure. Since childhood, she had an intellectual deficit. She had seizures with moderate frequency, becoming rarer after the 30 years old, when she began experiencing visual and auditory hallucinations, heteroaggressiveness and persecutory delirium, associated with cognitive decline. After 2 years, she developed an imbalance, with frequent falls, inability to remain in orthostasis with her eyes closed and impaired fine motor coordination. Two years ago, she began to experience dysphagia for solids and liquids and one year ago, she became wheelchair-bound. She currently has chronic constipation and osteoporosis, with previous ankle fractures. She uses medications to control symptoms. Denies consanguinity. On examination, she presents bradypsychism, dysarthria, slowing of saccades, nystagmus in the horizontal conjugate gaze; appendicular hypotonia; areflexia in lower limbs, hyporeflexia in upper limbs; apalesthesia in the lower limbs, tactile and painful hypoesthesia in the lower limbs; abasia/astasia; cerebellar tests with mild dysmetria in the upper limbs and significant dysmetria in the lower limbs; pyramidal tract signs absent. She underwent electroneuromyography, which showed marked axonal sensory-motor polyneuropathy in the lower limbs (predominance of the sensory component) and absence of the cutaneous-sympathetic reflex in the upper and lower limbs (involvement of fine autonomic fibers). Brain resonance showed bilateral hemispheric cerebellar atrophy, without olivary or pontine atrophy. Deltoid muscle biopsy showed subsarcolemmal mitochondrial proliferation. The genetic panel revealed the presence of the variant c.428T> C (p.Val143Ala) in simple heterozygosity in the ELOVL4 gene. **Discussion:** This gene is involved in the biosynthesis of very long chain fatty acids. Autosomal dominant variants cause spinocerebellar ataxia type 34, classically associated with erythrokeratodermia. Most patients present with axial and appendicular ataxia, dysarthria, and nystagmus. Other manifestations include pyramidal tract signs, autonomic disorders, retinitis pigmentosa, and cognitive impairment. Brain resonance usually reveals cerebellar atrophy and may present Hot Cross Bun Sign, typically associated with Type C Multiple System Atrophy. In our patient's case, we can highlight the absence of erythrokeratodermia, significant neuropsychiatric involvement (psychosis and cognitive decline) and epilepsy as a significant neurological manifestation during evolution. **Final comments:** This report therefore contributes to expanding the spectrum of clinical presentations associated with ELOVL4, whose diagnosis must be considered independently of dermatological manifestations and in the differential approach of cognitive and epileptic syndromes.

Correspondence: Renan Brandão Rambaldi Cavalheiro; Email: renan.rambaldi@icloud.com.

Case presentation: A 25-year-old man from São Paulo (SP), with no known medical ou neurological familiar history, born to non-consanguineous parents, presented with a 7-year history (onset at age 18) of symmetric proximal lower limb weakness, with progressive worsening. Approximately 2 years later, he noticed weakness in his upper limbs and worsening weakness in his lower limbs, making it impossible for him to run. He started training at a gym, experiencing significant difficulty with upper and lower body resistance exercises and squats. A non-medical professional at the gym advised him to use testosterone, which he found to have some effect on muscle hypertrophy. Physical examination revealed only muscle weakness, as follows: in the upper limbs, grade 4- for shoulder abduction and elbow flexion and grade 5 for wrist extension; and in the lower limbs, grade 3 for hip flexion and knee extension and grade 4 for dorsiflexion of the feet. Laboratory tests (all in UI/L) revealed: creatine phosphokinase 4,213, aldolase 51.4, alanine aminotransferase 198, aspartate aminotransferase 107, and lactate dehydrogenase 474. Electroneuromyography with sensory and motor conduction studies showed no abnormalities; needle examination showed low-amplitude potentials and a sparse recruitment pattern, indicating a myopathic process. MRI of the thighs showed high signal in the posterior compartments on the T1-weighted sequence, indicating fat substitution, with no abnormalities on the T2 and STIR sequences. Finally, a muscle dystrophy panel revealed a heterozygous variant c.2167A> G in the CAPN3 (calpain 3) gene. Based on the clinical and molecular context, a diagnosis of calpain-associated limb-girdle muscular dystrophy was made. **Discussion:** Limb-girdle muscular dystrophies (LGMD) are a heterogeneous group of genetic disorders characterized by proximal muscle weakness. Dozens of subtypes have been described associated with specific gene loci, with dominant forms being less common than recessive forms, accounting for less than 10% of cases. Calpainopathies, also known as autosomal recessive LGMD type 1 (LGMDR1), are considered the most common autosomal recessive LGMD and are characterized by weakness of the proximal muscles of the shoulder and pelvic girdles, with great clinical heterogeneity. Most pathogenic variants in CAPN3 cause loss of function, resulting in recessive disease. In recent years, this exclusive recessive inheritance has been reconsidered with the publication of independent families with an autosomal dominant inheritance pattern. The patient in this study, with no family history of neurological disorders, has a heterozygous variant in the CAPN3 gene, favoring the possibility of inheritance from an unaffected heterozygous relative, resulting in autosomal dominant LGMD. **Final comments:** This case describes a patient with calpain deficiency-related muscular dystrophy with a heterozygous variant. It expands the variability of known genetic presentations.

Correspondence: Luciane Ramos Perez Silveira; Email: lucianeperez@yahoo.com.br.

Anti-NMDA receptor encephalitis is an autoimmune form of encephalitis often misdiagnosed as viral encephalitis due to varied initial symptoms.. Diagnosis involves EEG, MRI, and lumbar puncture for cerebrospinal fluid analysis. Symptoms include personality changes, autonomic dysfunction, and neurologic deterioration, especially in young females. Treatment includes immunosuppression. We report the case of a51-year-old female patient with a history of bariatric surgery and depression, who was admitted to the emergency room due to acute confusion and seizures. Physical and neurological examination did not reveal any abnormalities. Laboratory tests showed no significant abnormalities. A lumbar puncture that showed WBC of 35, RBC of 20, glucose of 106, and protein of 103; CSF gram was negative. The CSF Herpes virus type 1 PCR was positive, confirming the diagnosis of herpes encephalitis. Brain MRI indicated extensive signal changes affecting cortical and subcortical regions of the mesial temporal lobes, hippocampi, right thalamus, insular regions, anterobasal aspects of the frontal lobes, suggesting viral encephalitis. The ECG was normal. The patient was treated with acyclovir for 21 days. On the 10th day of treatment, she experienced worsening symptoms of headache and fever. A repeat CT scan showed a large intraparenchymal hematoma. Despite this, the patient showed improvement over time, with resolution of seizures. She was discharged on day 41 with a prescription for levetiracetam 1000mg daily. Sixty days after the initial symptoms, the patient returned to the hospital with fever, insomnia, hallucinations, echolalia. Treatment with olanzapine and diazepam was initiated, and the antiepileptic medication was changed to valproic acid. The lumbar puncture revealed WBC of 15, glucose of 56, and protein of 178. A subsequent Brain MRI demonstrated anterior lesions with improved edema and diffusion restriction areas. The patient continued to develop episodes of acute agitation and persistent insomnia. Further investigations, including a transvaginal ultrasound, confirmed the presence of an ovarian teratoma. Finally, CSF results showed testing for anti NMDA receptor antibodies were positive. The patient benefited from intravenous methylprednisolone therapy followed by a cyclophosphamide 1G continued for 9 months. The patient's clinical condition gradually improved. Despite a slow but favorable clinical course with corticosteroid and cyclophosphamide therapy alongside tumor removal, the patient continued to experience some functional deficits at a 10-month follow-up, including episodes of disorganized speech. However, improvements were noted in insomnia and visual hallucinations. **Final comments:** Anti-NMDAR encephalitis typically occurs in young patients with no history of acute psychiatric symptoms. The possibility of this pathology should be considered before diagnosing a patient with a psychiatric illness.

Case report of Creutzfeldt-Jakob disease in a tertiary center: clinical manifestations and findings on complementary exams

Gabriela Rossini Dantas[1], Caroline de Barros Viegas[1], Dominick E. Monteiro Silva[1], Eduardo Abrão Spinola Rezk[1], Hélio Aquaroni Farao Gomes[1], Itamar Meireles Andrade Santos[1], José Eduardo Trentim Longo[1], João Márcio B. de Oliveira[1], Luciano Ribeiro da Silva[1], Pedro Machry Pozzobon[1]

[1]Universidade Estadual Paulista, São Paulo SP, Brazil

Correspondence: Gabriela Rossini Dantas; Email: rossinidantasg@gmail.com.

Case presentation: Report of 3 cases of probable Creutzfeldt-Jakob disease (CJD). A 69-year-old man, hypertensive and diabetic, started a progressive decline in executive, attentional, and memory functions a month ago, along with inverted sleep-wake cycle, apraxic gait, myoclonus and recently, akinetic mutism. Investigations revealed: Brain MRI with cortical hyperintensity in the left temporal lobe and gyral enhancement in the left parietal and frontal cortex on FLAIR; EEG with moderate baseline activity disturbance and generalized periodic activity (GPD); Cerebrospinal fluid (CSF) showing mild hyperproteinorrachia and presence of 14-3-3 protein. A 59-year-old man, hypertensive and dyslipidemic, developed progressive amnestic, dysexecutive, and aphasic symptoms over 2 months, later accompanied by gait ataxia, abnormal limb movements during sleep, myoclonus and physical examination revealed global hyperreflexia, frontal release signs, and upper limb dysmetria. Brain MRI: cortical enhancement in the left hemisphere and left basal nuclei with associated diffusion restriction; EEG: GPD with sharp wave complexes below 2.5 Hz; CSF: hyperproteinorrachia and presence of 14-3-3 protein. A healthy 59-year-old man presented with progressive spatial disorientation, executive dysfunction, gait ataxia, reduced verbal fluency, and behavioral changes over 2 months, progressing to complete dependence in activities of daily living. Physical examination revealed myoclonus and signs of pyramidal release (bilateral hyperreflexia and Babinski sign). Brain MRI: diffusion restriction in bilateral cortical and basal nuclei; EEG: rhythmic GPD at 1 to 1.5 waves per second. The patient died 3 months after symptom onset. **Discussion:** Sporadic CJD is considered the most common prion disease in humans. With long incubation periods and a rapid clinical course, definitive diagnosis is based on spongiform changes and abnormal prion protein accumulation in brain biopsy. Probable CJD is defined by neuropsychiatric disorder with a positive real-time quaking-induced conversion (RT-QuIC) test; or progressive dementia with two or more clinical features (myoclonus; visual or cerebellar disturbances; pyramidal or extrapyramidal dysfunction; akinetic mutism) and one or more supportive findings on tests (EEG with periodic sharp wave complexes; positive 14-3-3 in CSF with clinical duration less than two years; MRI with hyperintensity in caudate nucleus or putamen and/or in at least two cortical regions on DWI or FLAIR). **Final comments:** Although rare, sporadic CJD should be considered in the differential diagnoses of rapidly progressive dementia when typical clinical, electrophysiological, and neuroimaging features are present. The presence of 14-3-3 protein in CSF is not mandatory for diagnosis. The occurrence of three cases within a relatively short period underscores the importance of early clinical suspicion and detailed investigation for appropriate management of these patients.

Case report of familial hemophagocytic lymphohistiocytosis in a 5-year-old child: diagnostic and therapeutic challenges in central nervous system involvement

Tomás Tejerina Sellos Costa Bahia de Almeida[1], Guilherme Marques Nogueira[1], Julia Viana Gil de Castro[1], Filipe de Deus Tozani[1], Maria Eduarda Guimarães Porto[1], Weslley Nunes Teles[1], Ana Beatriz Calmon Nogueira da Gama Pereira[1], Ivana Rocha Raslan[1]

[1]Universidade de Vassouras, Vassouras RJ, Brazil.

Correspondence: Tomás Tejerina Sellos Costa Bahia de Almeida; Email: tejerinatomas@gmail.com.

Case presentation: It is a previously healthy 5-year-old male who was admitted with acute symptoms of imbalance, vomiting, nausea, and headache, that worsened over time. The family history was negative for neurological diseases, except for a brother with an undiagnosed intellectual disability. Physical exam revealed cerebellar ataxia signs, global hyperreflexia with bilateral Babinski and Hoffman signs, and bilateral horizontal nystagmus in all gazes. Brain MRI showed multiple cerebral areas with hyperintense signal on T2 and FLAIR, some with isointense to slightly hypointense signal on T1, with mild contrast enhancement, suggesting with a demyelinating lesion. The patient received pulsotherapy with methylprednisolone with clinical and radiological imaging. Upon tapering the corticosteroid, the patient experienced significant clinical deterioration and was readmitted. After an extensive laboratory investigation, genome test confirmed a PRF1 gene mutation (Het. c.1A> Gp.? and Het.c.529C> Tp.(Arg177Cys) pathogenic variants) associated with Familial Hemophagocytic Lymphohistiocytosis Type 2, with CNS involvement only. The patient underwent chemotherapy with hydrocortisone and intrathecal methotrexate, followed by a bone marrow transplant. The patient has been clinically stable for 2 years, with no signs of disease reactivation. **Discussion:** Hemophagocytic Lymphohistiocytosis (HLH) results from a cytokine storm triggered by various stimuli, causing dysfunction of Natural Killer cells and CD8+ T cells. These cells become overly activated, producing excessive INF-γ and other inflammatory cytokines. HLH can be primary (genetic) or secondary (linked to cancers and infections). Its hallmark is histiocyte build-up in tissues with poor cytotoxic function. Key symptoms include fever, hepatosplenomegaly, and pancytopenia. Neurological symptoms, in 30-73% of patients, include seizures, focal deficits, ataxia, meningismus, and altered consciousness. Diagnosis of HLH involves assessment of clinical presentation, performing tests such as measuring CSF neopterin level, urine B2 microglobulin, liver enzymes, LDH and CPK levels. Nowadays, genetic analysis is an important tool to establish the specific diagnosis. Treatment involves corticosteroids, immunomodulators, intrathecal methotrexate for progressive CNS disease, and hematopoietic stem cell transplantation (HSCT). Despite treatment advances, 25-50% of patients need additional therapies to achieve remission. **Final comments:** Although rare, HLH has high morbidity and mortality, often causing severe neurological damage and death if not promptly diagnosed and treated. Highlighting such cases ensures that physicians consider HLH prior to extensive neurological system involvement, leading to timely intervention and significantly improved patient outcomes.

Case report of hematomyelia due to cervical intramedullary cavernous hemangioma after plastic surgery

Rafael Chaves Claudino de Queiroga[1], Renan Brandão Rambaldi Cavalheiro[2], Camila Lopes Figueiredo[1], Cícero Rodrigues Veloso[1], Filipe Brito de Ferraz[1], Letícia Machado Dumont[1], Maria Clara Motta Barbosa Valente[1], Francisco Tomaz Meneses de Oliveira[1]

[1]Irmandade da Santa Casa de Misericórdia de São Paulo, São Paulo SP, Brazil.
[2]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Camila Lopes Figueiredo; Email: camila04_lopes@hotmail.com.

Case presentation: A 23-year-old woman with a previous medical history of severe scoliosis and bilateral congenital clubfoot developed headache and right hemiparesis shortly after waking up from anesthesia for a reduction mammoplasty. She was discharged from the hospital where the surgery was performed and sought emergency department on the next day. On neurological examination, she had severe scoliosis, Horner's syndrome on the right, ipsilateral hemiparesis, disproportionate, incomplete, predominantly distal and in the upper limb (hand flexion grade 1), with Babinski's sign present, as well as thermal hypoesthesia in the left half of the body. The possibility of spinal cord syndrome was raised, and an magnetic resonance imaging (MRI) of the cervical and thoracic spine was performed, which revealed an extensive cervical intramedullary lesion, located centrally and paramedially to the right, characterized by a heterogeneous signal with hypointensity on T1, hyperintensity on T2/STIR, measuring 2.3 x 0.9 x 0.8 cm, with faint gadolinium impregnation at levels C6 and C7, without restriction to the free diffusion of water molecules in the diffusion sequence images. There were foci of hyperintensity on T1 and hypointensity on T2/STIR, suggestive of hematoma content. Spinal cord edema was associated, characterized by hyperintensity on T2/STIR, extending from C1 to T1. During hospitalization, coagulopathies and systemic neoplasms were ruled out. The patient was referred for outpatient follow-up to undergo rehabilitation (mainly motor physiotherapy) and to investigate family involvement. **Discussion:** Intramedullary cavernous hemangiomas (or cavernomas) are rare vascular malformations, especially when compared to cerebral cavernomas. They can present with progressive and slow neurological decline or with acute impairment that occurs due to a complication of these malformations, which is intraspinal bleeding or hematomyelia. Differential diagnoses include spinal ependymomas, astrocytomas, and spinal arteriovenous malformations. Surgical treatment may be indicated, especially in cases of repetitive hemorrhages to prevent progressive neurological deterioration. The patient in this case presented with a complication of cavernomas in the postoperative period of plastic surgery (reduction mammoplasty) that was performed with general and epidural anesthesia. She presented with lateral spinal cord syndrome, including ipsilateral Horner's syndrome to the lesion. No reports like this were found in the literature. The patient followed up on an outpatient basis and is undergoing rehabilitation, especially with neurofunctional physiotherapy. **Final comments:** Intramedullary cavernomas are rare vascular malformations that can manifest with acute neurological impairment in case of complication (intraspinal hemorrhage). The case in question presents an interesting report of hematomyelia with lateral spinal cord syndrome after plastic surgery.

Case report of late diagnosis of subependymal heterotopia as a cause of refractory epilepsy in a male with normal neuropsychomotor development

Rafael Chaves Claudino de Queiroga[1], Thomás Hagemann Monteiro[1], Maria Clara Motta Barbosa Valente[1], Letícia Machado Dumont[1], Filipe Brito de Ferraz[1], Cícero Rodrigues Veloso[1], Camila Lopes Figueiredo[1], Vanessa Cristina Colares Lessa[1], Fábio Barreto Cabral[1], Cristine Mella Cukiert[1]

[1]Irmandade da Santa Casa de Misericórdia de São Paulo, São Paulo SP, Brazil.

Correspondence: Cristine Mella Cukiert; Email: cmcukiert@uol.com.br.

Case presentation: A 27-year-old man, with no other medical history besides seizures started at 9 years old. His seizures were characterized as impaired awareness with behavior arrest that sometimes evolved to tonic posture of the right upper limb associated with orofacial automatisms. Neuropsychomotor development (NPMD) and neurological physical exam were unremarkable since that time. He began a follow-up with a neurologist with no etiological cause identified at the time and progressed to refractory epilepsy by 16 years old. At 23 years, as seizures remained uncontrolled, he was referred to a specialized center in the treatment of drug resistant epilepsy for investigation. His electroencephalogram (EEG) showed left temporal posterior sharp waves, sometimes with diffusion to nearby and contralateral areas. A brain magnetic resonance imaging (MRI) revealed nodular subependymal heterotopia (SEH) in the lateral ventricles and nodular inter hypothalamic adhesion. Nowadays, he uses 3 anti-seizure medications (carbamazepine 800 mg/d, clobazam 10 mg/d and levetiracetam 500 mg/d) with a better control of his epileptic events. **Discussion:** SEH is a cortical malformation that can be a cause of epilepsy. Females with SEH typically present with focal seizures starting at the second decade of life, with normal NPMD and neurological examination. Males, on the other hand, can have either X-linked or autosomal inheritance. X-linked SEH, caused by mutations in FLN1 gene on chromosome Xq28, is often associated with visceral and central nervous system anomalies, associated with abnormal NPMD. Autosomal SEH has a similar clinical course to symptomatic females. Diagnosis is made by neuroimaging, with MRI being the most sensitive exam. Treatment is focused on the type of seizure and surgery may be indicated in some cases. Our patient developed seizures at the end of the first decade of life, with progressive refractoriness and delay to referral to a treatment specialized center in drug resistant epilepsy. Only around the age of 25, after the MRI and subsequent diagnosis, he achieved good control with three anti-seizure drugs. **Final comments:** SEH is an established cause of epilepsy, however, it is not always diagnosed at the onset of seizures due to access difficulties or limited resources, demonstrating the importance of assessment in a specialized center. Additionally, it is more common in women and, in men, it can lead to impaired NPMD. This case highlights the importance of considering SEH in the differential diagnosis of epilepsy, particularly in males with normal NPMD and refractory epilepsy.

https://doi.org/10.5327/CBN240290

Case report of neuro-behçet and intervention with infliximab

Giovanni Caniçali Simões[1], Aldren Thomazini Falçoni Júnior[1], Sephora Sabrina Candido de Almeida[1], Ingrid Lorena da Silva Gomes[1], Guilherme Lago Miranda[1], Tainá Fátima Ramos Gonçalves[1], Henrique de Moraes Bernal[1], Pedro Almeida Martins Pontes[1], Herval Ribeiro Soares Neto[1], Sônia Maria César de Azevedo[1]

[1]Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo SP, Brazil.

Correspondence: Giovanni Caniçali Simões; Email: gcanicali@gmail.com.

Case presentation: A 44-year-old woman presented with severe headache, nausea, and photophobia of acute onset, treated with simple analgesics, and discharged with total symptom relief. In three days, she experienced recurrence of symptoms, now including vomiting, asthenia, fatigue, and somnolence, difficulty walking, imbalance requiring a wheelchair, diplopia, and facial numbness. Neurological examination revealed exaggerated deep tendon reflexes in the right upper limb, sensory ataxia with stomping gait. Active search showed erythema nodosum on the lower limbs and arthralgia in the wrists and hips and oral ulcers. MRI and angio-MRI showed hyperintensity in T2 and FLAIR at the pontomesencephalic junction with slight expansion and gadolinium enhancement, without vascular abnormalities. CSF analysis revealed 16 leukocytes (42% lymphocytes, 45% neutrophils, 12% monocytes), with normal protein, glucose and lactate levels. Given the likely inflammatory etiology of the rhombencephalitis, the patient received a 5-day course of 1 gram/day methylprednisolone, resulting in significant clinical improvement. The associated findings of oral ulcers, erythema nodosum, and

joint involvement suggested Behçet's disease, supported by positive HLA-B51/52. For maintenance therapy, infliximab was chosen. The patient has remained stable and symptom-free since. **Discussion:** Behçet's disease (BD) is a rare chronic multisystemic inflammatory condition characterized by recurrent oral and genital ulcers and uveitis, with a relapsing-remitting course. Neurological involvement in BD, known as Neuro-Behçet's disease (NBD), typically occurs years after the onset of systemic symptoms, although it is one of the more severe complications. NBD presents in two distinct forms: parenchymal (80%) affecting the brainstem, brain, spinal cord, and optic nerve, and non-parenchymal (20%), primarily cerebral venous thrombosis. HLA-B51 is a marker for NBD development. Monoclonal antibodies, especially anti-TNF, are recommended for severe or refractory disease. Infliximab has proven most effective for NBD, with substantial literature support. Poor prognostic factors include parenchymal CNS involvement, lesion extent, inflammatory CSF changes, relapses, and early disease progression. **Final comments:** This case call attention to the importance of early diagnosis and appropriate management of BD with neurological involvement. The high diagnostic suspicion of NBD in the presence of rhombencephalitis, along with an active anamnesis focusing on systemic manifestations, was essential for diagnostic confirmation. The therapeutic success, maintaining symptom remission, was guaranteed with infliximab, given the minimal risk of recurrence in a patient with severe manifestation and high functional demand.

https://doi.org/10.5327/CBN240291

Case report: a new phenotype of ataxia with oculomotor apraxia type 4 in a young woman

João Carlos Cervelin[1], Bruno Wendorff Lucci[1], Sarah Prech e Souza[1], Fernanda Coan Antunes[1], Pricila Bernardi[1], André Dias de Oliveira[1], Gisele Espindola[1]

[1]Universidade Federal de Santa Catarina, Hospital Universitário, Florianópolis SC, Brazil.

Correspondence: João Carlos Cervelin; Email: joaocarloscervelin@gmail.com.

Case presentation: A 21-year-old female patient developed appendicular and gait ataxia at the age of 7, progressively experiencing lower limb weakness. She exhibited normal neuropsychomotor development and lacked a family history of neurological diseases. On neurological examination, she presented with cerebellar dysarthria, gait ataxia (requiring support for walking), mild bilateral dysmetria, distal weakness, distal hypoesthesia, absent deep tendon reflexes, and no oculomotor apraxia. Electroneuromyography (ENMG) revealed sensory-motor axonal polyneuropathy, while brain magnetic resonance imaging (MRI) displayed cerebellar and brainstem atrophy. Laboratory findings included hypercholesterolemia. Genetic testing identified 100% homozygosity for the PNKP gene, confirming the diagnosis of Ataxia With Oculomotor Apraxia Type 4 (AOA4). **Discussion:** Ataxia with oculomotor apraxia encompasses a heterogeneous group of autosomal recessive cerebellar ataxias characterized by a spectrum of clinical manifestations, including cerebellar ataxia, sensorimotor axonal neuropathy, oculomotor apraxia, and extrapyramidal features. AOA4 is a relatively rare subtype, first described in a Portuguese population in 2015. The pathogenesis of AOA4 involves mutations in the PNKP gene, resulting in defective DNA repair mechanisms, particularly in response to oxidative stress. AOA4 typically presents in childhood or adolescence with progressive cerebellar dysfunction, including dysarthria, gait ataxia, and limb incoordination. Our patient's clinical course aligns with these typical features, as she developed appendicular and gait ataxia at a young age, followed by progressive lower limb weakness. The absence of oculomotor apraxia in our patient is noteworthy, as it is a cardinal feature of AOA but may not manifest in all cases. Neuroimaging studies, such as brain MRI, play a crucial role in the diagnosis of AOA4, often revealing cerebellar and brainstem atrophy, as observed in our patient. Additionally, electrophysiological studies, including ENMG, aid in confirming the diagnosis by demonstrating sensorimotor axonal polyneuropathy, as seen in our patient's. Cognitive impairment is a common feature of AOA, affecting a significant proportion of patients with AOA4. However, our patient demonstrated preserved cognitive function, highlighting the variable expressivity of this condition. The absence of cognitive impairment in our case may suggest potential genotype-phenotype correlations or modifier effects influencing the disease presentation. **Final comments:** We report a case of AOA4 in a young woman characterized by cerebellar ataxia, sensorimotor polyneuropathy, and absence of oculomotor apraxia and cognitive impairment. Our findings underscore the clinical heterogeneity and variable expressivity of AOA4, emphasizing the importance of comprehensive phenotypic characterization and genotype-phenotype correlations in understanding the disease pathogenesis.

Case report: atypical Guillain-Barré syndrome associated with dengue infection

Rafael Bragança Rodrigues Matias[1], Eduardo Mesquita[1], Ana Luisa Vieira de Faria Donadon[1], Amanda Miranda de Mendonça[1], Alex Araujo Fernandes[1], Matheus Luís Braga Munareto[1], Alex Machado Baeta[1], Hennan Salzedas Teixeira[1], Karlla Danielle Ferreira Lima[1]

[1]Beneficência Portuguesa de São Paulo, São Paulo SP, Brazil.

Correspondence: Rafael Bragança Rodrigues Matias; Email: rafaelwaa@gmail.com.

Case presentation: A 20-year-old patient with a history of controlled migraines presented to the emergency room with exacerbation of migraine with photophobia, phonophobia, frontal pain, and associated nausea and vomiting. Neurological examination revealed partial sixth nerve palsy with medial esophoria of the right eye, horizontal diplopia, and weakness while walking. Laboratory tests showed dissociated cerebrospinal fluid (CSF) protein levels (cellularity 3, protein 74), with other laboratory parameters within normal limits. Brain and orbital magnetic resonance imaging demonstrated bilateral optic perineuritis with enhancement of the seventh and eighth cranial nerves, as well as impregnation of the C1 and C2 nerve roots. Additionally, brachial and sacral plexus imaging revealed mild nerve thickening and enhancement. Based on these findings, we hypothesized a variant of GBS, and initiated intravenous immunoglobulin therapy for 5 days. The patient showed satisfactory clinical improvement, including resolution of ophthalmoparesis and ataxia. **Discussion:** Dengue fever is a prevalent mosquito-borne disease affecting millions of people worldwide. While the classic symptoms include high fever, joint pain, and rash, there is growing evidence of neurological involvement in dengue cases. The various neurological manifestations reported include encephalitis, myelitis, Guillain-Barré syndrome (GBS), and myositis. **Final comments:** This case report draws attention to an unusual presentation of a little-recognized neurological syndrome in a context of a dengue epidemic. The syndrome, often overlooked by non-specialists, warrants consideration when encountering patients with neurological symptoms during such outbreaks.

https://doi.org/10.5327/CBN240990

Case report: atypical meningoencephalitis due to cysticercosis

Lorraine Alves de Souza[1], Kesllin Mariane Gomes Valadão[1], Omar El Sayed[1], Rafael Hofmann[1], Eduardo Augusto Borba[1], Jivago Szpoganicz Sabatini[1], Crislaine Freitas Petla Silva[1], Ana Júlia Kounaris Fuziki[1], Gabriela Alves Jupen[1], Mariana Fonseca[1]

[1]Universidade Estadual de Ponta Grossa, Ponta Grossa PR, Brazil.

Correspondence: Lorraine Alves de Souza; Email: lolorrainealves@gmail.com.

Case presentation: Patient E. A. C., female, 23 years old, with headache and vomiting for 4 months; dysarthria, loss of strength and reduced level of consciousness (CNR), 1 week ago. On admission, she presented bilateral papilledema, paresis of the lateral and medial rectus muscles of the left eye and Glasgow 11. Magnetic resonance imaging (MRI) was performed with intracranial hypertension (ICH), meningoencephalitis, diffuse leptomeningeal enhancement, especially in the occipital lobes and cerebellar hemispheres, and optic neuritis on the left. Cerebrospinal fluid (CSF) with opening pressure: >20 mmHg, leukocytes: 20/mm3, mononuclear: 78%, proteins: 75 mg/dL, glucose: <20 mg/dL, corroborating the hypothesis of ICH with meningoencephalitis, acyclovir was started. When investigating the etiology of meningoencephalitis, the following were requested with negative results serologies for tuberculosis, Epstein-Barr, herpes simplex, parvovirus B19, HIV and hepatitis; PCR for herpes in CSF and autoantibodies for vasculitis. Due to the refractoriness of ICH, the hypothesis of meningoencephalitis due to cysticercosis was raised, and empirical treatment was initiated with dexamethasone and albendazole and anti-cysticerci antibodies in CSF and serum were requested, with a positive result. Despite the treatment being implemented, the patient died. **Discussion:** Neurocysticercosis can manifest in different ways - hypertensive: resulting from obstruction of ventricular drainage; epileptic: convulsive manifestations; meningitic: outbreaks of meningitis. CSF obstruction may progress to ICH. This form is associated with an inflammatory reaction, with arachnoiditis, which can manifest as aseptic meningitis. In this case, the patient presented a compatible clinical picture and MRI with ICH and inflammation of the meninges. Cysticercosis in the optic nerve may present as atypical optic neuritis, as evidenced on MRI in this case. CT and MRI are the gold standard in diagnosis, enabling visualization of the parasite and the reactional process of the lesion, however, on CT, the cysticercus is isodense to the CSF and those in the basal subarachnoid cistern are not detected by these techniques, emphasizing the need for research of IgG anti-cysticerci antibodies in CSF and serum. In this case, although no suggestive findings were found on CT or MRI, the diagnosis of meningoencephalitis due to cysticercosis was concluded, with positive anticysticercal antibodies. Even after treatment with anthelmintics and corticosteroids, the patient died, demonstrating the severity of this form of presentation. **Final comments:** In patients with meningoencephalitis of unknown etiology, it is essential to search for parasitic causes. The diagnosis of cysticercosis was challenging in this case, as imaging tests did not make it possible to identify the parasite. It was necessary to test for anti-cysticercus antibodies, which is an important tool to be included in the list of investigation tests.

https://doi.org/10.5327/CBN240293

Case report: blue eyes as an initial indicator in the investigation of waardenburg syndrome in a family

Vanessa Gil Humberto dos Santos[1], Amanda Melo Leite Leão[1], Jorge Luiz Alves[1], Poliana Marcela Silva de Farias[1], Lais Felix Teixeira da Cunha[1], Willian de Souza Santos[1], Lais Borneo Moreira[1]

[1]Unigranrio, Duque de Caxias RJ, Brazil.

Correspondence: Vanessa Gil Humberto dos Santos; Email: vanessaterapia@hotmail.com.

Case presentation: In a family from Duque de Caxias, RJ, consisting of nine siblings, five are carriers of Waardenburg syndrome (WS), a genetic disorder characterized by pigmentation anomalies and sensorineural hearing loss. One of the siblings has blue eyes and white hair since birth but does not have deafness. His 29-year-old son was born deaf, with blue eyes and white hair streaks. Two other siblings were born with partial hearing loss, blue eyes, white hair streaks, mental retardation, and clinodactyly, although the latter is minimally noticeable. The two sisters have profound bilateral deafness, blue eyes, and white hair streaks. The father of the family was identified as a carrier of the syndrome. **Discussion:** WS is an autosomal dominant genetic disorder caused by mutations in genes affecting the migration and development of neural crest cells, such as PAX3, MITF, and SOX10. The phenotypic variability within the same family, as observed in this case, can be attributed to the variable expressivity and incomplete penetrance of the genetic mutation. The main diagnostic criteria includes pigmentation anomalies, such as blue eyes or iris heterochromia, and white hair. Hearing loss is a significant, ranging from profound to partial deafness. Other manifestations can include mental retardation and congenital malformations. The blue eye phenotype is particularly notable and common among WS carriers due to a deficiency in melanin production in the irises, resulting from genetic mutations associated with the syndrome. To diagnose of WS, leads clinicians to rely on distinctive clinical features. Audiological exams are essential to determine the degree of hearing loss. Imaging studies, such as computed tomography or magnetic resonance imaging, can be performed to evaluate and confirm malformations. Genetic testing is used to identify specific mutations in WS-related genes, helping to confirm the diagnosis and provide appropriate genetic counseling. There is no significant prevalence of WS between males and females. However, the expressivity of symptoms can vary considerably, even among individuals of the same sex within the same family, as observed in this case. **Final comments:** This case highlights the phenotypic variability of WS within a family with multiple carriers. Identifying WS carriers and understanding the clinical manifestations are crucial for appropriate management and genetic counseling of affected families. Early detection and continuous monitoring can improve the quality of life of the affected individuals, allowing the proper audiological interventions and educational support. This case report contributes to the understanding of the diverse clinical presentations of WS and emphasizes the importance of multidisciplinary follow-up involving geneticists, otolaryngologists, and hearing rehabilitation specialists.

https://doi.org/10.5327/CBN240294

Case report: cerebellar ataxia of adult onset associated with coenzyme Q10 deficiency

Maria Fernanda Hamamoto Leati[1], Antônio Avelino Mendes Filho[1], Camila Rodrigues Nepomuceno[1], Felipe Cenicio Juliatti[1], João Roberto Ribeiro Pimenta[1], Nayara de Paula Guerreiro[1], Atie Calado Ribeiro[1], Cristiane de Araújo Martins Moreno[1], Julian Letícia de Freitas[1], Maria Sheila Guimarães Rocha[1]

[1]Hospital Santa Marcelina, São Paulo SP, Brazil.

Correspondence: Maria Fernanda Hamamoto Leati; Email: mfleati@gmail.com.

Case presentation: A 52-year-old female patient from Ceará, Brazil, was referred to the General Neurology outpatient clinic for investigation of motor incoordination. She reported the onset of symptoms around age 30, affecting both her lower and upper limbs insidiously. The condition progressively worsened, leading to impaired gait (feeling drunk), frequent stumbling and falls over the years, and difficulty grasping and frequently dropping objects. She denied other symptoms. Family history revealed consanguinity (parents were cousins) and an older sister with similar lifelong symptoms but without a diagnosis. Neurological examination showed square-wave jerks, vertical gaze paresis, broad-based gait, and altered cerebellar tests (dysmetria and dysdiadochokinesia). Brain MRI revealed diffuse cerebellar atrophy without other abnormalities. Laboratory tests were unremarkable. Genetic testing for Friedreich's ataxia was negative. Whole exome sequencing identified a pathogenic variant c.589-3C> G in the COQ8A gene consistent with coenzyme Q10 (COQ10) deficiency. **Discussion:** COQ10 plays a crucial role in the mitochondrial electron transport chain, and diverse enzymes catalyze the formation of coenzyme Q10 and regulate other biosynthetic proteins. Mutations in the genes (COQ1, COQ2, COQ3, COQ4, COQ5, COQ6, COQ7, COQ8A, COQ8B, COQ9) that code for these enzymes lead to coenzyme Q10 deficiency. The main phenotypes related to coenzyme Q10 deficiency include encephalomyopathy, isolated myopathy, cerebellar ataxia, severe infantile multisystemic form, and steroid-resistant nephrotic syndrome. Clinical manifestations vary, but cerebellar ataxia is a hallmark observed in all patients, and pathogenic variants in the COQ8A gene are the most common genetic cause of COQ10 deficiency-related cerebellar ataxia. Although classically described with onset in childhood, there are cases in the literature with late onset. Epilepsy, cognitive impairment, and movement disorders may accompany the condition. Ocular motor abnormalities such as gaze palsy, ophthalmoplegia, or oculomotor apraxia can also occur. MRI findings typically show cerebellar atrophy, sometimes with diffuse cerebral atrophy in severe cases. **Final comments:** This case is noteworthy not only because the patient presented with adult-onset cerebellar ataxia but also due to the rare finding of a splice proximal mutation in COQ10, a variant scarcely reported in the literature. Moreover, the clinical follow-ups that exceeded ten years showed no disease progression during this period.

Case report: chronic optic disc edema, unilateral, secondary to vitreopapillary traction syndrome

Theodora Cristina Cruz de Assis[1], Amanda Jardim Diniz da Gama[1], Raphael Cândido Sepúlveda Coutinho[1], Frederico Castelo Moura[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Theodora Cristina Cruz de Assis; Email: t223442@dac.unicamp.br.

Case presentation: Male patient, 57 years old, referred to the Clinical Hospital of the State University of Campinas (HC-Universidade Estadual de Campinas) due to a complaint of amaurosis fugax in the right eye (OD) that lasted fifteen minutes in 2022. He reports that visual acuity (VA) in OD did not return to what it was after this event and that visual blurring got worse during headache episodes. In May 2023, optic disc edema and peridiscal hemorrhage were observed in the OD in an external service. Denied other complaints or previous comorbidities. In evaluation at Universidade Estadual de Campinas in April 2024, he presented corrected visual acuity (VA) of 20/20 in both eyes (OU). Fundoscopy exam revealed optic disc stained in OD with physiological excavation, edema in the nasal region of the optic disc with presence of a superior shunt. Fundoscopy exam without alterations in the left eye (OS). Performed visual field exam (Humphrey campimetry) on 24-2 protocol within normal limits in OD with slight enlargement of the blind spot and exam in normal conditions in OS with nonspecific findings related to learning effect in visual field testing. Optical coherence tomography (OCT) was performed in OD, which showed nasal sectorial optic disc edema, vitreopapillary traction (VPT) in the nasal region of the optic disc, bulging of the peridiscal Bruch's membrane, and peripapillary nerve fiber layer (RNFL) and ganglion cell layer within normal limits. Cranial and orbital magnetic resonance imaging (MRI) within normal limits. Considering clinical and multimodal analysis, the main diagnostic hypothesis was VPT syndrome in OD. **Discussion:** The VPT syndrome is an uncommon condition characterized by increased traction in adhesion points at the vitreopapillary interface, which can be secondary to incomplete posterior vitreous detachment (PVD) in vitreoretinal adhesion, subsequent to previous detachment of the perifoveal (stage 1) and perimacular (stage 2) regions. The pathophysiology of VPT is related to contraction forces associated with liquefaction of the vitreous body with aging, being a case more prevalent among adults aged 50 or older. The strong adherence of the posterior vitreous to the optic nerve head and to peripapillary membranes can primarily lead to hemorrhages, thinning and stretching of ganglion cell axons, decline of visual function and papillary edema formation. In this clinical case, the presence of nasal sectorial edema in the OD and VPT, evidenced in the OCT, in the nasal region of the optic disc confirmed diagnosis of subclinical unilateral optic disc edema in the OD. One of the differential diagnosis was intracranial hypertension due to headache and optic disc edema, although the unilateral edema, which does not represent a common pattern. **Final comments:** The VPT syndrome should be considered in the diagnostic investigation of patients with chronic optic disc edema.

[2]Centro Universitário Funcesi, Itabira MG, Brazil.

Correspondence: Izac Lage Oliveira; Email: izacoliveira93@hotmail.com.

Case presentation: A 59-year-old female patient sought neurological care with chronic CPK elevation, with values ranging between 200 and 700, with moments of significant elevation associated with metabolic and infectious changes. The patient reported that she had already been evaluated by professionals from different specialties without diagnostic definition (medical clinic, cardiology, endocrinology, rheumatology, neurology and orthopedics). Patient with no known comorbidities, did not use any medication or dietary supplement, her parents are cousins. No neurological changes or deficits were observed, muscle strength and reflexes were preserved. She reported weakness and fatigue since childhood, with difficulty in practicing physical activities. A relevant situation observed during the anamnesis is that she quickly became tired during physical exercise, however, after a brief period of rest, she was able to complete more vigorous activities, compatible with the second wind phenomenon, leading to suspicion due to research into glycogenoses. The genetic study showed variation in the PYGM gene (T> TA) in homozygosity (2 copies). After completing the diagnosis, the patient was advised on non-pharmacological measures, showing good responses. No drug treatment was introduced, genetic guidance was carried out to research the disease in the children. **Discussion:** Myophosphorylase deficiency, historically known as McArdle disease (GDS V), is the most common glycogen storage disease affecting the muscle. In myophosphorylase deficiency, glycogen is not properly broken down in muscle cells, interfering with their function. Myophosphorylase deficiency usually presents in adolescence or early adulthood with exercise intolerance, fatigue, myalgia, cramps, myoglobinuria, poor endurance, muscle swelling, and fixed weakness. However, symptoms

are often seen in childhood and may be misdiagnosed for decades. The disease is suspected on the basis of the history of exercise-induced symptoms. Genetic testing is the most efficient and least invasive means of confirming the diagnosis in patients with clinical findings consistent with the diagnosis. There was no benefit with: D-ribose, glucagon, verapamil, vitamin B6, branched chain amino acids, dantrolene sodium, and high-dose creatine. Minimal subjective benefit was found with low dose creatine and ramipril only for patients with a polymorphism known as the D/D angiotensin converting enzyme phenotype. A carbohydrate-rich diet resulted in better exercise performance compared with a protein-rich diet. Two studies of oral sucrose given at different times and in different amounts before exercise showed an improvement in exercise performance. **Final comments:** Diagnosis of McArdle disease is frequently delayed by many years following the first presentation of symptoms to a health professional. Some simple changes in lifestyle and diet can improve the quality of life of these patients.

Case report: congenital paramyotonia, a mutation in the SCN4A gene

Ellen Kátia dos Santos Pessoa[1], Hellen Júlia Fernandes Alves[1], Nykassia Rodrigues Coelho[1], Dhulyān Severo Soares[1], Ana Beatriz Vieira Pachêco[1], Thiago Parreira Guzzo[2]

[1]Uninassau, Vilhena RO, Brazil.
[2] Academia Brasileira de Neurologia, São Paulo SP, Brazil.

Correspondence: Ana Beatriz Vieira Pachêco; Email: beatrizpachecoana@gmail.com.

Case presentation: Male patient, 56 years old, started with sustained, non-painful muscle tension in childhood that intensified in winter, associated with loss of limb coordination. At the age of 11 he lost coordination of his lower limbs with limited movement for a period of five months, returning without any intervention. Myotonic crises predominated mainly in the limbs, face and neck. At the age of 54, the weakness in the limbs intensified and after performing the electroneuromyography, acute axonal neuropathy was revealed, starting human immunoglobulin and later mestinon 60mg, but without positive effects. With the persistence of symptoms, a molecular study of the CLCN1 and SCN4A genes was requested, identifying alterations c.4343G> A (p.Arg1448His) in heterozygosity in exon 24 of the SCN4A gene, corresponding to congenital paramyotonia and hypokalemic periodic paralysis, both characterized by a pattern of autosomal dominant inheritance. The patient currently uses phenytoin 100 mg and acetazolamide 100 mg, but still suffers from painful myotonic crises daily. One of his children presents similar symptoms, however, the condition is still being investigated. **Discussion:** Paramyotonia congenita is an autosomal dominant neuromuscular disease, with mutation of the SCN4A gene. The first clinical manifestations begin in childhood, with myotonic crises, induced by physical exertion and exposure to low temperatures. During myotonic crises, the patient has greater difficulty promoting muscle relaxation. There is no cure for PMC, however with appropriate management of diet, lifestyle and medication, patients can maintain a normal life. **Final comments:** The main clinical manifestations of congenital paramyotonia include myotonic crises triggered by cold or repetitive activities, causing muscle weakness and stiffness, which are the main complaints of patients. In principle, other causes can be considered, as paramyotonia congenita is much rarer than myotonia congenita or myotonic dystrophy, highlighting the importance of carrying out a molecular study of the SCN4A gene to conclude the diagnosis. However, more studies on paramyotonia congenita are still needed, especially in relation to the diagnosis early and treatment, in order to improve the patient's quality of life, who, even when using medication, still presents symptoms as in the aforementioned case.

Correspondence: Fabrício Weinheimer Lippert; Email: fabriciowlippert@gmail.com.

Case presentation: M.G.C.F, a 57-year-old Caucasian female, was diagnosed with a cerebral aneurysm at the the right posterior inferior cerebellar artery origin during investigation for headaches. The patient had a death family history due to aneurysm rupture. She was admitted for elective embolization. The procedure was performed under general anesthesia via right femoral artery without complications. A 6 French guiding catheter was positioned in the left vertebral artery, and a flow-diverting stent was deployed covering the cerebellar artery origin. Using a microcatheter jailing technique inside the aneurysm, coils were deployed to guide flow. A total of 150 ml of contrast was used during the procedure. Control arteriography and cone-beam CT at the end of the procedure showed no complications. Upon awakening in the intensive care unit, the patient reported bilateral amaurosis. Skull arterial angiography was normal. Subsequent cranial MRI ruled out ischemia, leading to a diagnosis of contrast-induced encephalopathy (CIE). Intravenous corticosteroid therapy was initiated. The patient experienced complete visual deficit improvement over 72 hours. **Discussion:** CIE is an acute neurological disorder, typically reversible, attributed to intra-arterial administration of iodinated contrast medium, occurring in < 1% of procedures. The prognosis is excellent with unique supportive care. However, CIE can potentially cause permanent neurological dysfunction or death, such as persistent visual field defects, retrograde amnesia, and fatal cerebral edema. Under normal circumstances, iodinated contrasts do not cross the blood-brain barrier (BBB). However, they can disrupt the BBB, facilitating their own entry into the brain and causing neurotoxicity. Cortical blindness is characterized by complete loss of visual perception, optokinetic nystagmus with preserved ocular motility, normal pupillary responses, and normal fundoscopic examination. CB is the most common symptom of CIE, likely due to the relatively higher permeability of the BBB in the occipital cortex. Diagnosis of contrast-induced encephalopathy is made by demonstrating typical CT findings such as abnormal cortical enhancement with contrast and cerebral edema, or not, in a symptomatic patient after exclusion of thromboembolic and hemorrhagic complications. Neurological recovery typically occurs within an average of 2.5 days. Treatment of CIE is supportive, usually involving intravenous hydration, systemic corticosteroids, and osmotic diuretics. CIE can recur upon re-exposure to contrast although hydration and low volume of contrast can help in prevention. The risk/benefit ratio of re-exposure to iodinated contrast should be carefully evaluated. **Final comments:** Cortical blindness due to contrast-induced encephalopathy is a rare and potentially serious complication of contrast use, although this case had a favorable outcome.

Case report: Creutzfeld-Jacob disease in young patient

Erick Dupont[1], Leonardo de Andrade da Cruz[1], Marcele Schettini de Almeida[1], Sônia Maria César de Azevedo[1]

[1]Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo SP, Brazil.

Correspondence: Leonardo de Andrade da Cruz; Email: leoandcruz@gmail.com.

Case presentation: A 54-year-old male patient, with no relevant medical history, presents with repeated episodes of behavior arrest, depressive mood, and insomnia. Two months later, with recent memory changes and gait instability, he was hospitalized for investigation. He presented complex visual hallucinations in the hospital and was then diagnosed with Acute Stress Reaction and taken home with Aripiprazole. The condition continued to worsen, especially with severe psychomotor agitation, leading to hospitalization three months after the onset of symptoms. The initial suspicion was autoimmune encephalitis, leading to CSF collection, without relevant changes. Skull Magnetic Resonance Imaging (MRI) demonstrated restriction of the diffusion of water molecules in the thalamus (Hockey stick sign) and cortical regions, especially on the left, a pattern highly suggestive of prion disease. Electroencephalogram (EEG) showed a pattern of short periodic waves, at which time the patient also had myoclonus, especially in the right hemisphere. Patient was discharged with a diagnosis of probable Creutzfeldt-Jacob disease - CJD (sporadic form), using Levetiracetam to control myoclonus, already with severe motor and cognitive impairment. A few weeks after discharge, testing for the 14-3-3 protein and RT-QuiC in the CSF came back positive, further corroborating the diagnosis given. **Discussion:** Prion diseases, such as CJD, when compared to others, are infrequent pathologies in everyday neurology. The disease affects 1 in every 1 million, with a ratio of 1 man to 1 woman. In its pathophysiology, the production of PrPSc (abnormal scrapie prion protein) occurs, which causes cellular changes with consequent neurodegeneration. The most common form is sporadic, which represents 80 to 85% of cases, without identifiable triggers, with the onset age between 55 and 65 years. The genetic form, for 10 to 15% of cases. Symptoms are non-specific, such as: headache, vertigo, fatigue and sleep disturbances. After a period, there is worsening of confusion, disorientation, in addition to symptoms of cooperation. The diagnosis is based on electroencephalographic changes (periodic complexes and triphasic waves), markers in the cerebrospinal fluid, 14-3-3 proteins and RT-QuiC, in addition to changes in imaging tests. Currently, without specific treatment, we prioritize support. The case portrays a patient with behavioral changes who underwent psychiatric and autoimmune diagnoses before prion disease was suspected. Although the definitive diagnosis occurs after a post-mortem biopsy, the sum of the elements presented (history, physical examination, MRI, EEG, and liquid analysis) allows a greater degree of security for these progressive and incurable diseases. **Final comments:** Due to its extremely guarded prognosis, its recognition, especially in cases of not so typical presentation, is essential to offer the best management for the patient and family.

Case report: diarrhea induced by subthalamic nucleus deep brain stimulation

Glauco Kody Nagata[1], Letícia Bassani Devens[1], Marine Warmling[1], Sheila Trentin[1], Bruno Samuel Fraiman de Oliviera[1], Yuri Ferreira Felloni Borges[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Glauco Kody Nagata; Email: glauconagata@gmail.com.

Case presentation: A 62-year-old right-handed woman presented with predominant left-sided rigid-akinetic Parkinson's disease (PD) at the age of 55. Throughout disease progression, she developed medical refractory

motor fluctuations and dyskinesias and gastrointestinal intolerance to higher doses of Levodopa. Her current medication schedule at the age of 60 was Levodopa 600 mg/day (divided in 6 intakes), Amantadine 400 mg/day; Pramipexol ER 1,5 mg/day and Entacapone 200 mg TID. Therefore, she underwent bilateral Subthalamic Nucleus Deep Brain Stimulation (STN-DBS). During the following 14 months post-operatively, her medication was reduced, as Entacapone was discontinued, Amantadine was reduced to 100 mg/day, and her stimulation settings was L STN1 C+ 1- /5.0 mA/50 mcs/60 Hz; L STN2 C+ 8-/1.5 mA/60 mcs/60 Hz; R STN1 C+ 1-/5.3mA/50 mcs/60 Hz; R STN2 2.0 mA/60 mcs/60 Hz with good outcome. She developed motor fluctuations and bilateral tremor, so bilateral dorsal stimulation amplitude was increased to 1.7 mA on the L STN2 and 2.3 mA on the R STN2 with good symptom control. Although, 4 days after the adjustment, she presented profuse recurrent diarrhea and vomit, requiring three emergency department visits within one month that was persistent despite Ondansetrone 4 mg TID and Loperamide 2 mg 2 tablets a day. She underwent gastrointestinal laboratory tests, abdominal Computed Tomography, endoscopy and colonoscopy that were unremarkable. One month later, after direct contact with her attending neurologist, she was advised to revert the stimulator to the previous program. Two days after this adjustment, the patient reported a complete resolution of gastrointestinal symptoms. **Discussion:** In this reported case, a patient without prior complaints of constipation developed diarrhea following STN-DBS dorsal stimulation. Interestingly, this patient also experienced gastrointestinal side effects with Levodopa doses higher than 600 mg/day. Non-motor symptoms are common and play a significant role in the well-being of PD patients. Abnormal gastrointestinal motility is commonly presented in PD even before the motor features and deteriorates with disease progression. Its physiopathology is likely related to extranigral degeneration due to alpha-synuclein deposition, mainly in the peripheral autonomic nervous system. The effects of STN-DBS on gastric motility are not well understood. Stimulation may improve gastrointestinal functioning by activating fibers that project from or to the hypothalamus. Connections between the hypothalamus and the dorsal motor nucleus of the vagus nerve can strengthen this hypothesis. Red nucleus stimulation can also be involved in autonomic side effects, such as nausea, excessive sweating, and dizziness. **Final comments:** To our knowledge, there is no other case of stimulation-induced diarrhea reported. Further studies with larger cohorts are needed to better understand this mechanism.

https://doi.org/10.5327/CBN240301

Case report: Foster-Kennedy syndrome associated with optic nerve sheath meningioma

Gilmar Silveira da Silva[1], Thaise Fellini Dal Moro[1], Luiza Toscan[2], Matheus Felipe Kuhn Urnau[2], Alex Roman[1]

[1]Universidade Federal da Fronteira Sul, Hospital São Vicente de Paulo, Passo Fundo RS, Brazil. [2]Universidade de Passo Fundo, Passo Fundo RS, Brazil

Correspondence: Gilmar Silveira da Silva; Email: silveirasilva.gilmar@gmail.com.

Case presentation: A 17-year-old previously healthy patient sought care due to loss of visual acuity on the right side for months. He denied headache or eye pain. Physical examination revealed amaurosis and mydriasis on the right, without direct photoreaction, and only consensual. Direct and indirect fundoscopy with pharmacological pupillary dilation was performed, which showed atrophy of the optic nerve on the right and papilledema on the left. Regarding the complementary tests requested to elucidate the case, the evoked potential showed a reduction in nerve conduction velocity in the visual pathway bilaterally, with accentuation on the right side. MRI of the skull and orbit showed an expansive tumor lesion in the paramedian sellar tubercle on the right extra-axial side, with dimensions of 10×7mm, with compression of the chiasm and extension to the pre-chiasmatic, intracanalicular, and intraorbital right optic nerve up to the middle third, suggesting an extensive meningioma of the optic nerve sheath. Laboratory test results and liquor analyses were unremarkable. After diagnosis, the patient underwent a microsurgical approach to resect the cranio-orbital tumor on the right side, associated with decompression of the optic nerve. The patient's complaints slowly improved over the days following the surgical procedure. **Discussion:** Foster-Kennedy syndrome is fundamentally characterized by atrophy of the optic nerve unilaterally, ipsilateral to an expansile mass, associated with contralateral papilledema due to increased intracranial pressure. It is estimated that the syndrome occurs in 1-2.5% of cases of intracranial tumors, with risk factors potentially associated with the condition: hereditary, female hormones, and previous radiation exposure. Among the tumors, those most associated with the condition are meningiomas, mainly in the subfrontal regions, olfactory groove, and sphenoid wing. Initial evaluation of these patients is usually performed using fundoscopy. Computed tomography and/or magnetic resonance imaging can be performed, the latter being responsible for images that allow a better assessment of the condition. Treatment varies depending on the case and can be carried out through surgical intervention, chemotherapy, radiotherapy, and/or drug therapy, most often using glucocorticoids to reduce peritumoral edema and intracranial pressure. **Final comments:** The case described demonstrates the importance of thorough evaluation of patients with visual changes, such as amaurosis, through fundoscopy, in addition to neuroimaging if a central etiology is suspected. Due to the lack of information about Foster-Kennedy syndrome and its potential complications, it is essential to conduct studies and disseminate greater knowledge on the subject to better define the management of the condition.

https://doi.org/10.5327/CBN240302

Case report: inflammation related to cerebral amyloid angiopathy

Caroline Dresch Sabadin[1], Emilyane Batalha[1], Luana Lindner Cruz[1], Andressa Luiza Cintra Barbosa[1], Matheus Ramos Pinto[1], Lázaro de Lima[1], Paulo Victor Muller Francescon[1], Paulo Eduardo Mestrinelli Carrilho[1]

[1]Universidade Estadual do Oeste do Paraná, Cascavel PR, Brazil.

Correspondence: Caroline Dresch Sabadin; Email: caroldsabadin@gmail.com.

Case presentation: A 73-year-old female patient was referred to the neurology outpatient clinic of a tertiary hospital due to a headache, emesis, mental confusion and memory loss that began 1 month ago. At that time, the patient developed decreased verbal and motor responses, psychomotor agitation, and agnosia. A cranial computed tomography (CT) scan showed areas of diffuse vasogenic edema. The patient was treated with Phenytoin, Haloperidol, and Risperidone and admitted to the Intensive Care Unit (ICU), with dexamethasone added to the therapeutic regimen. The patient showed clinical improvement, but continued to experience anterograde memory loss. Outpatient follow-up revealed overall improvement, though episodes of mental confusion and memory loss persisted. Angiography revealed a mass effect with multiple foci of sparse subcortical microhemorrhages bilaterally, suggesting inflammatory amyloid angiopathy as one of the main hypotheses. Testing for anti-β-amyloid antibody was not performed due to service unavailability. During outpatient follow-up, ivermectin was initiated along with a plan for pulse therapy with methylprednisolone, followed by an oral taper. Currently, the patient is undergoing the tapering phase without complaints of mental confusion or memory loss. **Discussion:** Cerebral amyloid angiopathy associated with inflammation (CAA-ri) is a rare encephalopathy related to increased cerebrospinal fluid concentrations of autoantibodies directed against the β-amyloid protein deposited in the layers of cortical and leptomeningeal vessels. It primarily affects patients aged 60 to 80 years and is characterized by acute neurological symptoms ranging from cognitive disturbances and headaches to progressive cognitive decline, seizures, altered mental status, and focal neurological deficits. CT findings are characterized by unifocal cortical and subcortical hypodensity. On magnetic resonance imaging (MRI), white matter hyperintensities are observed, indicating vasogenic edema, along with cerebral microhemorrhages. Definitive diagnosis of CAA-ri requires histopathological confirmation. However, recent clinical-radiological criteria and tests for detecting anti-β-amyloid autoantibodies in the cerebrospinal fluid have reduced the need for invasive brain biopsies. Treatment consists of pulse therapy, with or without immunosuppressants. **Final comments:** The atypical case results in a diagnosis of CAA-ri, with initial symptoms of headache, vomiting, mental confusion, and recent memory loss. The final diagnosis was possible only through the clinical-imaging combination. Pulse therapy with methylprednisolone was effective in resolving symptoms. Discussing this case is relevant to broaden the understanding of CAA-ri in similar cases. Demonstrating the clinical-radiological criteria and laboratory testing avoids ineffective investigations, allowing effective treatment. Further research is needed to elucidate the underlying mechanisms of CAA-ri.

https://doi.org/10.5327/CBN240991

Case report: multidisciplinary management and challenges in treating HTLV-1 in a pediatric patient

Laura Lorenzo Serra[1], Ana Clara de Lemos Guimarães[1], Joanna Sousa da Fonseca Santana[1], Amanda Hellen Sousa Leal[1], Daniel Abreu Santos[1]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.

Correspondence: Ana Clara de Lemos Guimarães; Email: anaguimaraes21.1@bahiana.edu.br.

Case presentation: An 11-year-old girl started outpatient treatment for HTLV-1 in 2023. Symptoms began at age 6 with walking difficulties, though developmental milestones were met. Her mother, diagnosed with HTLV-1, died in 2022, while her father has negative serology. She has five siblings, three positive for HTLV-1, one with virus-associated myelopathy. Diagnosed in 2020, she presented with severe urinary issues, including urgency, incontinence, and nocturia, and was diagnosed with neurogenic bladder related to HTLV-1, often linked to tropical spastic paraparesis (HAM/TSP). Psychological challenges included bullying due to her condition. Neurologically, she showed moderate spasticity and scissor gait. Treatment started with oxybutynin for incontinence, pregabalin for pain, and amitriptyline with prednisone for mood and motor symptoms. She experienced partial symptom improvement but continued to suffer frequent urinary infections, managed by infectious disease specialists. Psychological support improved her emotional state and school relationships. By September 2023, there was notable improvement in her depression and bladder function, though she maintained muscle atrophy and spasticity. Medications included amitriptyline 25 mg, prednisone, and oxybutynin 5 mg. A CSF examination for a definitive HAM/TSP diagnosis had not been performed. **Discussion:** Diagnosed at age 11, this case from Bahia – where HTLV-1 is highly prevalent, particularly in Salvador – illustrates the complex nature of this infection. The high transmissibility and severe impact highlighted by her family history underscore the urgency

for effective public health strategies and multidisciplinary approaches to improve life quality and control the spread. **Final comments:** This case emphasizes the importance of a personalized, continuous multidisciplinary approach involving neurology, psychology, infectious diseases, and dermatology to manage HTLV-1 challenges and enhance patient quality of life.

https://doi.org/10.5327/CBN240303

Case report: multifocal acquired demyelinating sensory and motor neuropathy diagnosis after 15 years of evolution

Leonardo de Andrade da Cruz[1], Erick Dupont[1], Sônia Maria César de Azevedo[1], Mateus Paquesse Pelegrino[1], Davi Vargas Freitas Teixeira[1]

[1]Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo SP, Brazil.

Correspondence: Leonardo de Andrade da Cruz; Email: leoandcruz@gmail.com.

Case presentation: A 71-year-old female patient with a previous diagnosis of Multifocal Motor Neuropathy (MMN) 15 years ago sought care for progressive dysphagia and dyspnea 2 months ago. Upon admission, in addition to the symptoms reported, she presented a reduction in strength exclusively in her hands, grade III, which was accompanied by significant atrophy and regional hyporeflexia, without other changes on the neurological examination. The investigation revealed paralysis of the right vocal fold and, in speech therapy evaluation, severe dysphagia, thus proving the involvement of bulbar nerves in the condition. Magnetic resonance imaging (MRI) of skulls, cervical spine and neck without clinically relevant changes, as well as liquor, with parameters within normal limits. The electroneuromyography (ENMG) performed at the service showed that, in addition to the motor impairment with conduction block in the upper limbs (UL), already documented in previous exams, there was now involvement of sensory fibers, with a demyelinating, asymmetric pattern and associated axonal degeneration. With these new discoveries, the patient was diagnosed with Multifocal Acquired Sensory and Motor Demyelinating Neuropathy (MADSAM), being discharged with a proposal to undergo Rituximab, but no longer responded to Human Immunoglobulin (IgH). **Discussion:** Even with technological advances in modern medicine, diagnosing peripheral neuropathies is still a challenge. Patient monitoring is crucial in these cases, as it allows for the correct diagnosis and therapy for the disease. The case exemplifies a patient who presented pure motor impairment for a long period, respecting a pattern compatible with MMN. After 15 years, she presented with asymmetric sensory and bulbar involvement, which fit into a new diagnosis of a rare variant of Chronic Inflammatory Demyelinating Polyneuropathy: MADSAM. The condition is characterized by being an acquired chronic demyelinating disease, with symptoms that appear as asymmetric weakness, mainly in the upper limbs, associated with sensory deficits caused by a demyelinating autoimmune response. It is considered a rare disease and is confused with other diagnoses, such as Carpal Tunnel Syndrome and Guyon Syndrome. Unlike Carpal Tunnel Syndrome, in electrophysiological examinations, MADSAM presents conduction block, in addition to asymmetric demyelination of multiple nerves. Furthermore, the 2 syndromes can be differentiated using ultrasound. Early treatment is recommended, as the disease responds well to intravenous human immunoglobulin and corticosteroid therapy. Based on this fact, we noticed that the patient was diagnosed at an advanced stage of the disease and had fewer responses to the therapies used. **Final comments:** The diagnosis of this condition remains a challenge, as it is a rare disease in clinical practice and it is necessary to know its characteristics, as early treatment presents a better prognosis.

Correspondence: Tiago Camilo Eisemberg de Alvarenga; Email: tiagocea@hotmail.com.

Case presentation: Female patient, 53 years old, reports headache, prostration, inappetence and nausea lasting 5 days, being investigated and diagnosed with dengue (positive NS1 test). Self-limited condition with spontaneous resolution. However, she states that after 4 days of resolution of the initial condition, she began to notice pain in her eyes associated with a progressive worsening of visual acuity over a few days. Ophthalmological evaluation identified bilateral optic disc edema, with visual acuity restricted to visible figures. She underwent magnetic resonance imaging of the orbits which confirmed the clinical suspicion of bilateral optic neuritis, opting for pulse therapy with Methylprednisolone for 5 days. The patient showed improvement in eye pain after 5 sessions with methylprednisolone, followed by progressive improvement in visual acuity over the following days. MRI of orbits 02/24/24 showed hypersignal on STIR associated with possible gadolinium impregnation in the intra-orbital segments of both optic nerves. After 60 days of the condition, the patient reports that he continues to have daily difficulties related to low visual acuity, without other associated neurological deficits. **Discussion:** Dengue viruses have spread rapidly within countries and across regions in the past few decades, resulting in an increased frequency of epidemics and severe dengue disease, of multiple dengue virus serotypes. Dengue is caused by one of four single-stranded, positive-sense RNA viruses of the genus flavivirus. Infectious virus and the virus-encoded NS1 are present in blood during the acute phase, and high-level early viremia and NS1 antigenemia have been associated with more severe clinical presentations. Dengue has a wide spectrum of neurological complications such as encephalitis, myositis, myelitis, Guillain-Barré syndrome and mononeuropathies.The main ocular changes reported in the literature dengue-related hemorrhages include retinal and macular hemorrhages, peridiscal hemorrhage, Roth spots, diffuse retinal edema, cells in the vitreous, blurring of the margin of the optic disc, serous retinal detachment, choroidal effusion and non-specific maculopathy. Optic neuritis is an inflammatory infectious or demyelinating process of the optic nerve that may manifest as retrobulbar neuritis, papillitis, or neuroretinitis.The prognosis is generally good and resolving spontaneously, although some patients may report relative central scotoma that may persist for months. The use of steroids to treat visual changes is controversial. **Final comments:** The severity of ocular involvement varies greatly according to data observed in the literature. The use of corticosteroid therapy, although controversial, should be considered in severe cases, as well as complementary therapy with plasmapheresis. The knowledge of the various neurological complications helps in looking for the warning signs and early diagnosis for better outcomes.

Case report: Parkinsonism-hyperthermia syndrome

Alberto Pereira Firmino Filho[1], Maria Weryca de Souza Belo Silva[1], Rodrigo Alencar e Silva[1], Clecio de Oliveira Godeiro Junior[1], Gabriel Soares Dutra de Souza[1], Felipe Toscano Lins de Menezes[1], Mario Teruo Yanagiura[1], Francisco Gil Sarmento Neto[1], Nathália Lindsay Pereira de Queiroz[1], Fátima de Menezes Dantas[1]

[1]Universidade Federal do Rio Grande do Norte, Natal RN, Brazil.

Correspondence: Alberto Pereira Firmino Filho; Email: firminofilho.ap@outlook.com.

Case presentation: A 62 year-old female with Parkinson's disease underwent Deep Brain Stimulation (DBS) placement in October 2023. The device was turned on after six days from surgery with worsening of dyskinesias leading to withdrawal of antiparkinsonian medications. The patient develops behavioral changes and agitation. There is a new DBS adjustment on the 18th post-operative day (POD) followed by the reintroduction of levodopa in low doses. Fluctuations in the level of consciousness persisted, with the appearance of drowsiness. From the 23rd POD onwards she started tachycardia, hypertensive peaks and hallucinations. Investigation for infectious was negative. The patient develops refractory hyperthermia (41 °C), worsening tremors, reduced level of consciousness, increased creatinine and CK levels (maximum 7,000U/L), and thrombocytopenia (54,000 U/mm^3). The hypothesis of Parkinsonism-hyperthermia syndrome complicated with renal failure due to rhabdomyolysis was raised, medications with dopaminergic blockade were suspended, antiparkinsonian medications were escalated, benzodiazepine was reintroduced, dantrolene was started with good control of tremors and correction of hyperthermia. There was no improvement in the level of consciousness and emergency orotracheal intubation was performed and transfer to the ICU. Over the course of days, the patient was able to walk, eat orally and communicate verbally without cognitive complaints. She was discharged with the DBS system on associated with pharmacological therapy. The patient had been using quetiapine regularly since 2019 due to a psychotic episode. **Discussion:** Parkinsonism-hyperthermia syndrome is a rare and potentially fatal complication that occurs when antiparkinsonian drugs are abruptly discontinued, and may also occur when the DBS system functions suddenly stops working. Other risk factors include dehydration, infections and use of neuroleptics. Symptoms are similar to neuroleptic malignant syndrome, with dysautonomia, hyperthermia, rigidity or tremors, and rhabdomyolysis classically within 7 days of changing the dopaminergic drug. Complications such as sepsis, respiratory and renal failure and seizures have also been described. Thrombocytopenia is rarely described in these cases and can be explained by the modulatory role played by dopamine in the platelet response. It is crucial to return to doses of dopaminergic drugs prior to the onset of the syndrome and reactivate the DBS system. The use of bromocriptine and/or amantadine during acute management, as well as the use of dantrolene as an adjuvant to control tremor and hyperthermia, are valid therapeutic options. **Final comments:** The acute worsening of parkinsonian symptoms associated with signs of dysautonomia should raise the suspicion of parkinsonism-hyperthermia syndrome, which may eventually lead to thrombocytopenia. Treatment is based on intensive clinical support, return of medications to usual doses and correction of risk factors.

Case report: paroxysmal sympathetic hyperactivity syndrome in a patient with fat embolism

Lia Maki Hatisuka Imai[1], Adria Rodrigues da Silva[1], Bruna Beppler[1], Caroline Zapelini[1], Maria Caroline Martins de Araujo[1], Luis Sidonio Teixeira da Silva[1], Lucio Baena de Melo[1], Gabriel Rodrigues Espelho Rossi[1], Juliana Passos de Almeida[1], Luca La Valle Pedrao[1]

[1]Universidade Estadual de Londrina, Londrina PR, Brazil.

Correspondence: Lia Maki Hatisuka Imai; Email: hatisuka.imai@gmail.com.

Case presentation: A 21-year-old male, with no prior medical history, was admitted to a tertiary hospital after a motorcycle accident, presenting with closed fractures of the right lower limb (tibia, fibula, and femur). There were no signs of cranial trauma, and the initial neurological examination was normal. On the first day of admission, skeletal traction was performed. After two days, the patient suddenly became confused and agitated. Vital signs revealed tachycardia and desaturation, necessitating invasive ventilation on the third day of hospitalization. A chest and cranial CT angiography diagnosed pulmonary thromboembolism and raised the suspicion of pulmonary fat embolism; the cranial examination showed no significant findings. During the ICU stay, the patient developed episodes of hypertension, tachycardia, tachypnea, fever, sweating, and dystonic extension posturing. Initially, these episodes were misinterpreted as seizures, but an electroencephalogram ruled out epileptiform activity during the dystonic posturing. The patient remained febrile since ICU admission despite negative cultures. Cerebrospinal fluid analysis excluded central nervous system infections. Due to the recurrence of these episodes, cerebral fat embolism was suspected. Partial improvement was noted with the administration of morphine, gabapentin and baclofen. **Discussion:** Fat embolism is a rare but potentially life-threatening complication commonly associated with long bone fractures. The classic clinical triad of fat embolism includes respiratory distress, neurological impairment, and petechial rash; however, this patient did not present all these symptoms. Instead, he exhibited signs consistent with Paroxysmal Sympathetic Hyperactivity (PSH), characterized by episodes of hypertension, tachycardia, tachypnea, fever, sweating, and dystonic posturing. PSH can arise secondary to neurological injuries and is often misdiagnosed due to its similarity to seizure activity. The management of PSH in this case involved the use of morphine, gabapentin and baclofen, which partially controlled the symptoms. MRI was instrumental in confirming the diagnosis of cerebral fat embolism, showing multiple small hypointense foci in T2 gradient echo in the supratentorial white matter, predominantly in the subcortical region and corpus callosum (characteristic of fat embolism). **Final comments:** This case underscores the necessity of considering fat embolism and PSH in patients with multiple long bone fractures and acute neurological symptoms. Cerebral fat embolism can present atypically, making differential diagnosis critical for proper management. The use of advanced imaging techniques and a comprehensive therapeutic approach were vital in managing this patient. Effective monitoring and management of complications like PSH are essential for improving patient outcomes and quality of life.

Case report: pericallosal artery stroke with multiple executive dysfunctions

Robercon Aves do Carmo[1], André Teixeira de Souza e Castro[1], Fernanda Sousa Lima[1], Larissa Lucas Schloicka[1], Rodrigo Torres Sena Pita[1], Carolina Flores Welker[1], André Gustavo Fonseca Ferreira[1], Wagner Afonso Teixeira[1]

[1]Hospital de Base do Distrito Federal, Brasília DF, Brazil.

Correspondence: Robercon Aves do Carmo; Email: robercon025@gmail.com.

Case presentation: A 47-year-old female patient, previously hypertensive, with chronic dialytic kidney disease caused by crescentic glomerulonephritis, atrial fibrillation, and rheumatic mitral valve disease. Admitted in December 2023 with severe expressive aphasia, central pattern facial paralysis on the right, and complete and proportionate right hemiparesis; due to these findings and being within the therapeutic window with unaltered tomography - aspects 10; she underwent chemical thrombolysis with alteplase. Subsequently evolved with difficult-to-control hypertension, remaining for three days on intravenous nitroprusside. A follow-up examination revealed hyperdense image formation compatible with hemorrhagic transformation (PH1-ECASS3) in the left anterior cingulate gyrus. Since admission, the patient had presented with emotional blunting, laconism, however, after 4 days of evolution, the patient began to show logorrhea, disinhibition, with recurrent mood variations, often incongruent with her current state (pseudobulbar affect), also reporting significant difficulty in recalling recent memories and performing calculations. Evaluated during hospitalization, she showed alterations in cognitive assessments (mini-mental state examination - MMSE) in recall memory, working memory, calculation, and attention. After controlling the hypertensive condition, defining the etiology of the stroke (cardioembolic), and initiating appropriate treatment, the patient continued in the neurology outpatient clinic. **Discussion:** Stroke is becoming increasingly important in public health, ranking among the top 10 most prevalent diseases in Brazil. It is important to have broad knowledge about the mechanisms involved in the pathophysiology of the disease and the wide range of symptoms associated with it. Studies show a significant impact on the lives of affected patients, both in motor and cognitive deficits, highly related to functional disability after the disease. **Final comments:** In this presentation, we describe a patient with a pericallosal artery stroke, showing multiple executive dysfunctions after the ischemic insult.

https://doi.org/10.5327/CBN240308

Case report: progressive encephalopathy associated with BSCL2 gene mutation

Caroline Dresch Sabadin[1], Juliana Dourado Grzesiuk[2], Marta Regina Clivati[3], Matheus Pereira Guarini[1], Amanda Gonçalves Tochettto[1], Camila Fonseca Balcewicz[1], Estela Soares Carniel[1], Gabriel Santos de Almeida[1], Paulo Eduardo Mestrinelli Carrilho[1]

[1]Universidade Estadual do Oeste do Paraná, Cascavel PR, Brazil.
[2]FAG.
[3]Centro Clivati de Neurologia e Desenvolvimento.

Correspondence: Caroline Dresch Sabadin; Email: caroldsabadin@gmail.com.

Case presentation: A 24-year-old female was referred to the neurology clinic at the University Hospital in 2018. She exhibited delayed and regressive neuropsychomotor development – she lost the ability to walk by the age of six and also had an expressive regression on the ability to talk and communicate. At physical examination, she presented with spastic upper and lower limbs with decreased mobility and muscle strength. MRI showed signal changes and signs of volume loss in the cerebral white matter in the fronto-parieto-occipital region and ill-defined signal changes in the deep white matter of the cerebral hemispheres, particularly evident in the periatrial regions and adjacent to the posterior thirds of the lateral ventricles bodies. It also showed global signs of supratentorial and infratentorial brain volume reduction, bilateral and symmetrical, which is early for her age. Fundoscopy revealed slightly pale optic discs in both eyes with good symmetry and sharp borders, and biomicroscopy examination was normal, ruling out late-onset Tay-Sachs disease. Whole exome sequencing detected a heterozygous pathogenic mutation on gene STAC3, which is associated with congenital myopathy 13 when in homozygosity or compound heterozygosity, and also a variant of uncertain significance in the BSCL2 gene which may explain the clinical features of autosomal dominant Silver spastic paraplegia syndrome. The patient remains under outpatient follow-up. **Discussion:** Mutations in the BSCL2 gene, which encodes the seipin protein, can cause various neurological conditions, being 2 recessive: Encephalopathy progressive, with or without lipodystrophy, and Lipodystrophy type 2, and 2 dominant: Neuronopathy, distal hereditary motor, autosomal dominant 13, and Spastic paraplegia type 17 (SPG17), also called Silver spastic paraplegia syndrome. Despite the overlapping phenotypes of the dominant syndromes, Silver's disease causes more spasticity. Seipin is essential for lipid homeostasis; when mutated, it causes endoplasmic reticulum stress, leading to neurodegeneration. In the Silver syndrome, the p.N88S substitution results in cortical white matter anomalies, delayed and regressive neuropsychomotor development, spasticity, and visual and cognitive changes. The condition often manifests in childhood and adolescence with progressive weakness and stiffness of the lower limbs. Management includes physiotherapy and antispastic medications. **Final comments:** The uncertain variant in BSCL2 gene may be related to the spastic tetraparesis presented by the patient, since missense mutations in BSCL2 are associated with autosomal dominant motor neuron diseases and Silver syndrome, causing generalized congenital lipodystrophy, locomotor abnormalities and progressive encephalopathy. Children with Silver syndrome are at increased risk of developing motor, cognitive, speech delays, and learning disabilities. More studies are needed to provide a more accurate prognosis.

Case report: progressive supranuclear palsy like of vascular etiology

Erick Dupont[1], Leonardo de Andrade da Cruz[1], Sônia Maria César de Azevedo[1]

[1]Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo SP, Brazil.

Correspondence: Leonardo de Andrade da Cruz; Email: leoandcruz@gmail.com.

Case presentation: A 71-year-old male patient was hospitalized in 2019 due to a sudden neurological deficit, right hemiparesis, dysarthria, and aphasia. MRI angiography demonstrated intracranial arteries with irregular parietal arteries, mainly in the distal bed. Subsequently, on angiography, these findings were corroborated, leading to a diagnosis of vasculitis involving the central nervous system (CNS). Due to the absence of involvement of other somatic sites, the diagnosis was primary CNS vasculitis. He was discharged with immunosuppressive therapy and returned again in November 2021 with a new deficit after attempting to wean off corticosteroid therapy. On examination, in addition to the sequelae of the previous event, he presented facial hypomimia, rigidity and bradykinesia in the upper limbs, worse on the left, exalted facial axial reflexes and restriction of vertical gaze upwards. New MRI showed several foci of ischemia throughout the brain parenchyma, highlighting an area with restricted diffusion of water molecules in the left cerebellar hemisphere. Furthermore, there was significant midbrain atrophy with numerous lesions with hypersignal on T2/FLAIR, secondary to old ischemic events. In this way, it was concluded that his vasculitis, through ischemia, promoted the intense volumetric reduction of the midbrain, thus demonstrating the clinical syndrome seen in patients with Progressive Supranuclear Palsy (PSP). **Discussion:** As part of tauopathies, PSP is a degenerative clinical syndrome. In these cases, the patient, in addition to the symptoms of a parkinsonian syndrome, also presents restriction of vertical upward gaze and, on imaging tests, intense volumetric reduction of the midbrain, forming the "hummingbird" sign. The case above portrays a patient who presented symptoms and images compatible with the diagnosis of PSP. However, due to his underlying pathology, it was possible to establish that his mesencephalic

atrophy was attributable to an ischemic etiology, and not degenerative, as seen in the classic picture. It is known that PSP of vascular etiology is rare and generally characterized by multiple areas of ischemia in different regions such as the brain stem, basal ganglia, thalamus, frontal lobe, and cerebellum, without presenting anomalous protein deposits, as in tauopathies, with involvement of the cortical-striatum-pallid-nigral-thalamo-cortical pathway, responsible for Parkinsonism. These patients have a high cardiovascular risk and multiple ischemic lesions on imaging tests and do not respond well to high doses of Levodopa. **Final comments:** Even in the face of an apparently classic picture, precise diagnoses cannot be given before the correct investigation of atypical parkinsonian syndromes. The case described, in which a vascular syndrome (vasculitis) mimics a degenerative syndrome (PSP), exemplifies

https://doi.org/10.5327/CBN240310

Case report: reversible cerebral vasoconstriction syndrome in a young patient using thermogenic supplements and hormonal therapy for high-performance exercise

Thamira Espindola[1], Gabriel Martins Rodrigues[2], Pietra Molin Lorenzzoni[1], Lisandra Farias[1]

[1]Universidade do Sul de Santa Catarina, Florianópolis SC, Brazil.
[2]Hospital Governador Celso Ramos, Florianópolis SC, Brazil.

Correspondence: Thamira Espindola; Email: thamiraespindola@gmail.com.

Case presentation: A 28-year-old male was admitted to a tertiary hospital with an intense, persistent headache lasting over 72 hours. The patient reported a history of pressure-like headaches in the biparietal region, associated with photophobia, triggered by physical exertion and sexual activity. He was using Deposteron, Stanozolol, and Oxandrolone, with recent increases in dosages. The patient had a prior diagnosis of secondary syphilis and had completed a three-dose course of benzathine penicillin 30 days, with a treponemal test titer of 1:64. Cranial MRI demonstrated cerebral volumetric reduction and compensatory dilation of the sulci and cisterns, hyperintense areas on FLAIR and T2 sequences in the bilateral supratentorial white matter, suggesting possible microangiopathy, gliosis, or demyelination. There was irregular contour and slight caliber reduction in the left A1 segment and proximal portions of the right and left M1 segments. Cerebrospinal fluid (CSF) analysis was clear and colorless, with 1 leukocyte/mm^3, 2 red blood cells/mm^3, serum glucose 59 mg/dL, protein 64 mg/dL, and a non-reactive VDRL. Given the headache pattern, the patient was admitted for investigation of central nervous system vasculitis (primary or secondary), with the main differential diagnosis being reversible cerebral vasoconstriction syndrome (RCVS). The patient was treatment with crystalline penicillin G and was initiated for 14 days for possible meningovascular syphilis. Nimodipine 60 mg every 4 hours was also administered during hospitalization. A follow-up CT scan showed no stenosis, occlusions, aneurysms, or vascular malformations. The patient was referred for outpatient follow-up with instructions to discontinue the use of thermogenic supplements and hormones and to monitor for new headache episodes. **Discussion:** RCVS is a clinical syndrome characterized by severe, sudden-onset headaches, often described as thunderclap headaches. The pathophysiology suggests a transient disturbance in the regulation of cerebral arterial tone, often linked to the use of vasoactive substances such as alpha-adrenergic agonists. Diagnosis is based on clinical symptoms, neurological examinations, and cerebral imaging studies, which are used to assess cerebral blood flow and detect arterial vasoconstriction. Cerebral angiography is considered the gold standard for diagnosing RCVS, typically showing uniform narrowing of cerebral arteries. Treatment involves blood pressure control and symptom relief. Most patients recover completely from RCVS. **Final comments:** This case presented a differential diagnosis of RCVS and secondary syphilis, with the possibility that the syndromes might overlap. In this case the patient has no evidence of neurosyphilis in the CSF and has no complications in the control CT in conclusion the diagnosis is most likely a case of RCVS.

https://doi.org/10.5327/CBN240311

Case report: rhombencephalitis by varicella-zoster virus (VZV) in an elderly and immunosuppressed patient

Patrícia Fagundes[1], Samia Talise El Horr de Moraes[1], Letícia Dall'agnol[1], Gustavo Figueiredo da Silva[1], Alana Bacelar Limeira Sales[1], Matheus Gomes Ferreira[1], Helio Afonso Ghizoni Teive[1], Luis Alfredo Olbertz[1], Lucas Wagner Gortz[1], Maurício de Carvalho[1]

[1]Universidade Federal do Paraná, Curitiba PR, Brazil.

Correspondence: Alana Bacelar Limeira Sales; Email: alanabls@hotmail.com.

Case presentation: A 68-year-old woman with a history of chronic lymphocytic leukemia, currently undergoing chemotherapy with chlorambucil, diabetes mellitus type 2, hypertension, glaucoma, and recent use of corticosteroids, was admitted for investigation of abdominal pain. Due to a characteristic rash in the dermatome of the right hypochondrium (T7 level), a diagnosis of Herpes Zoster was made. On the fifth day of hospitalization, the first day of acyclovir, she developed a moderate dysarthria, resting and action tremor of moderate amplitude and frequency, negative myoclonus and cerebelar ataxia of the upper limbs. After a syndromic and topographic diagnosis of rhomboencephalitis, further investigation was carried out. Brain MRI showed signs suggestive of microangiopathy, with no other significant changes. EEG showed signs of diffuse cerebral dysfunction; irregular bursts of delta pattern were recorded, as well as a single focal epileptiform activity over the temporal region of the left cerebral hemisphere. Initial CSF analysis showed hypoglycorrhachia and viral PCR with detectable Varicella Zoster Virus (VZV). Other analyses showed no abnormalities. Follow-up CSF on the ninth day of symptoms suggested lymphocytic meningitis: proteins 45 mg/dl, leukocytes 77/mm^3 (90% lymphocytes), glucose 42 mg/dl, and lactic acid: 2.1 mmol/L. Based on these findings, the diagnosis of VZV rhomboencephalitis was confirmed, and IV acyclovir treatment was maintained for 21 days. During hospitalization, the patient showed complete neurological improvement. At the outpatient follow-up after six months, she still had neuropathic pain in the affected dermatome. **Discussion:** Rhomboencephalitis is a clinical syndrome of inflammation of the brainstem and cerebellum, with a mortality rate between 4.3 to 12% depending on the case series and etiology. It can be secondary to infections, autoimmune diseases, and paraneoplastic syndromes, with VZV being a rare cause. Central nervous system infections by VZV have an estimated incidence of 1.02 cases per 100,000 inhabitants, with rhomboencephalitis being an even rarer complication. VZV is neurotropic, with a worse prognosis in immunocompromised patients, due to its ability to reactivate at multiple levels of the dorsal root ganglia and subsequent dissemination. In the above case, we identified several risk factors, such as immunosuppression due to chemotherapy, neoplasia, and corticosteroid use, as well as immunosenescence (40% of VZV reactivation cases occur over 60 years of age). **Final comments:** Rhomboencephalitis secondary to VZV infection is a rare, severe neurological condition with variable semiological presentation. Therefore, in view of the aging population and the development of immunosuppressive therapies, we present this case to highlight the importance of recognizing this condition.

https://doi.org/10.5327/CBN240312

Case report: sensory neuronopathy secondary to paraneoplastic syndrome

Ana Luisa Rufino de Sousa[1], Amanda Soares Pimenta[1], Daniela Aparecida Lima Viana[1], Elisangela Ferraz Pazinato[1], Giovani Zago Borges[1], João Henrique da Matta Clementino[1], Alex Eduardo da Silva[1]

[1]Universidade Federal do Triângulo Mineiro, Uberaba MG, Brazil.

Correspondence: Ana Luisa Rufino de Sousa; Email: analuisardesousa@gmail.com.

Case presentation: Female patient, 49 years old, admitted to the emergency room with a history of weakness in lower limbs, associated with subacute onset global paresthesia. History of alcoholism, smoking, and breast cancer treatment. Neurological examination revealed anisocoric pupils (5mm on the right and 2mm on the left) and photoreactive, globally reduced muscle tone and trophism. Mild tetraparesis, tetraparesthesia with reduced tactile and painful sensitivity in upper limbs, lower limbs, and trunk. Hypopallesthesia and reduced osteotendinous reflexes in all segments. Evident sensory ataxia, with significant gait alteration and positive Romberg's sign. Under the syndromic hypothesis of sensory neuropathy (SN), complementary exams showed: normocytic and normochromic anemia, vitamin B12 deficiency, positive tumor marker dosage (CA 125, CA 19-9, and CEA), negative serologies for HIV, HTLV, toxoplasmosis, cryptococcosis. Cerebrospinal fluid biochemical analysis with 2 cells, 174 proteins, glycorrhachia of 55 mg/dL. Imaging exams included cranial and total abdominal computed tomography scans (CT) with no significant findings, chest CT showing marked irregular pleural thickening at the left lung apex associated with para-aortic lymphadenopathy. Electroneuromyography showing sensory neuronopathy. Thoracic magnetic resonance imaging provided clearer definition of the expansive lesion near the subpleural area of the left lung. The patient subsequently underwent pleural biopsy, which confirmed oat cell carcinoma. She was treated with methylprednisolone 1000 mg for 3 days, without satisfactory response, along with nutritional support and correction of vitamin B12 deficiency. **Discussion:** There are various manifestations of neurological syndromes in paraneoplasias. In patients with SN, 80% of cases originate from oat cell lung carcinoma. The immune-mediated etiopathogenesis can be explained by the presence of anti-neuronal nuclear antibody (ANNA-1) or anti-Hu in most cases, acting on intracellular tumor and neuronal antigens. Immunosuppressive treatment is indicated, but the response is not significant. Early diagnosis and treatment of neoplastic disease may stabilize or even regress the neurological condition. **Final comments:** Face of the syndromic picture of SN, it is necessary to establish the relationship with paraneoplastic syndromes and immediately start screening for the main associated primary neoplasms. Multidisciplinary follow-up and planning of symptomatic treatment of patients from a neurological perspective is important. However, diagnosing and initiating oncological treatment is the main modifying factor in the course of the disease for the patient.

Case report: Takayasu arteritis leading to stroke

Julia Ágata Cardoso Barbosa[1], Samuel Natal Rodrigues[2], Drielle Nogueira Sales[1]

[1]Universidade Federal do Amazonas, Manaus AM, Brazil.
[2]Universidade do Estado do Amazonas, Manaus AM, Brazil.

Correspondence: Julia Ágata Cardoso Barbosa; Email: Juliaa.cardoso12@gmail.com.

Case presentation: A 38-year-old female initially presented with left ankle edema on February 2024 and was evaluated by an orthopedic surgeon, finding no radiological abnormalities. On 03/30/2024, she returned to the hospital with left-sided hemiparesis, nausea, emesis, and facial asymmetry starting 13 hours prior. A cranial CT and CTA on 03/31 showed hypoperfusion in the right posterior cerebral artery territory, occlusion of the right common carotid artery, and critical stenosis of the left common carotid artery. Admitted to the ICU with over 12 hours since symptom onset, she presented left hemiparesis (grade 2 in the left lower limb, grade 1 in the left upper limb), left facial paresis, and mild dysarthria, NIHSS score of 7 indicating moderate neurological deficit. The arteriography revealed brachiocephalic trunk occlusion 2 cm from its aortic origin, severe left common carotid artery reduction, 50% left vertebral artery stenosis, and absent upper third basilar trunk and left subclavian artery visualization. A subsequent brain MRI confirmed right pons ischemia. Positive serum VDRL indicated neurosyphilis investigation. Physical examination revealed upper limb blood pressure discrepancies, stronger left radial, inguinal, and popliteal pulses, with systolic murmurs in the aortic and left subclavian arteries. Symptoms suggested Takayasu arteritis. Primary diagnosis: acute ischemic stroke in the right pons. Secondary diagnoses: critical left common carotid artery stenosis, right common carotid artery occlusion, neurosyphilis, suspected Takayasu arteritis confirmed with 12 points on ACR criteria. Treatment initiated with aspirin 300 mg + clopidogrel 300 mg, followed by aspirin 100 mg and clopidogrel 75 mg daily, corticosteroid therapy for vasculitis control, and penicillin for neurosyphilis. Intensive ICU care monitored ischemic progression, aimed to prevent new occlusions and ischemic events. **Discussion:** Takayasu arteritis, a granulomatous vasculitis affecting aortic and major branches, commonly affecting young women causing vessel stenosis, occlusion, or dilation with varying symptoms, including cerebral ischemia. Clinical and angiographic signs in this case included carotid and vertebral artery stenosis, brachiocephalic trunk occlusion, and absent vertebral and basilar trunk visualization, indicating severe vascular involvement. Neurosyphilis, though not primary, required concurrent treatment due to positive VDRL. **Final comments:** Early diagnosis and multidisciplinary management of Takayasu arteritis are crucial, highlighting improved patient outcomes. Differential diagnoses consideration and coexisting condition management, such as neurosyphilis, are essential for comprehensive care, emphasizing timely identification and treatment to enhance patient prognosis and quality of life.

[3]Hospital Metropolitano de Alagoas, Maceió AL, Brazil.

Correspondence: Túlio Marlus Castro Lucena; Email: tuliomarlus.neuro@gmail.com.

Case presentation: A 22-year-old man presenting with behavioral changes, characterized by apathy and catatonia, for approximately one month, was admitted to the Psychiatric Hospital. He developed seizures and fever and was referred for neurological evaluation. Cranial MRI revealed mild diffuse and symmetrical atrophy with slight gliosis of the bilateral hippocampal formations. A lumbar puncture was performed, and cerebrospinal fluid (CSF) analysis showed high CSF protein levels and normal cell count. The patient developed refractory seizures, progressing to status epilepticus, requiring intensive care unit admission and orotracheal intubation. Due to suspiction of immune-mediated encephalitis, plasmapheresis was performed with only partial response, followed by methylprednisolone pulse therapy, which yielded better results. After clinical stabilization, further investigation with CSF collection for immune-mediated encephalitis panel was conducted, which was positive for anti-NMDA receptor encephalitis. The patient was discharged on immunosuppressive therapy with cyclophosphamide and antiepileptic drugs and is currently under outpatient follow-up. **Discussion:** Anti-NMDA receptor encephalitis is a disorder affecting mainly young adults and children, with a higher prevalence in females, particularly in young adults. Symptoms include seizures, decreased consciousness, language disturbances, sleep disorders, and prominent psychiatric manifestations such as disorganized thinking, psychosis, hallucinations, and behavioral changes. Diagnosis is made through CSF analysis and confirmed by detecting IgG antibodies against the GluN1 (also known as NR1) subunit of the NMDA receptor. There is a demonstrated association with herpes simplex virus (HSV) infections and ovarian teratoma. Treatment involves immunomodulatory therapy with methylprednisolone pulse therapy combined with intravenous immunoglobulin or plasmapheresis, and tumor resection when appropriate. Additionally, some patients may benefit from maintenance immunomodulatory therapy to prevent recurrence. **Final comments:** Anti-NMDA receptor encephalitis should always be considered in cases of psychiatric alterations, as seen in this patient. The attending physician should seek signs and symptoms supporting or excluding this diagnosis and perform appropriate investigations. Early therapy improves patient response and outcomes.

Case presentation: We report the case of a previously healthy 46-year-old woman who was admitted to the emergency department with a 24-hour history of new-onset seizures accompanied by fever and headache. Initial neurological assessment revealed mutism, marked waxy flexibility, catalepsy, and stupor, meeting the DSM-V diagnostic criteria for catatonia. She also exhibited nuchal rigidity and mild confusion, with no other neurological findings. A computed tomography scan was normal, and a lumbar puncture revealed an opening pressure of 20 cm H2O. CSF analysis showed 300 cells/μL and elevated protein levels (52.8 mg/dL). Empirical antibiotic treatment was initiated. A few hours after admission, she developed focal seizures with facial automatisms and status epilepticus. The patient was intubated and later transferred to the ICU. Following the initial analysis, a CSF PCR panel was performed, revealing a Herpes simplex type 1 virus infection. Based on this result, acyclovir was continued and the other antibiotics were discontinued. Brain MRI revealed bilateral cortical and subcortical FLAIR hyperintensities in the temporal and frontal lobes. She was treated with intravenous acyclovir for 14 days, showing marked improvement. The patient was discharged home after 40 days due to multiple respiratory infections associated with mechanical ventilation. She had no further seizure episodes after discharge and no motor disabilities. **Discussion:** Catatonia is a complex and not fully understood clinical syndrome marked by speech, behavior and consciousness alterations. Our patient had hallmarks for the diagnosis, waxy flexibility, mutism, stupor and catalepsy. This disorder presents in many psychiatric and clinical disorders. The neurologic disorder most associated with catatonia is autoimmune encephalitis, followed by metabolic disorders and drug abuse. Herpes encephalitis, whatsoever, unusually presents with catatonia, just 4 cases found in literature, with good response to intravenous antivirals. **Final comments:** This report adds to infectious encephalitis to the differential diagnosis when facing a new onset catatonia in the emergency department.

Correspondence: Francisco Luciano Honório Barreto Cavalcante; Email: francski2304@gmail.com.

Background: Cathepsin A-related arteriopathy with strokes and leukoencephalopathy (CARASAL) is a rare monogenic disease associated with cerebral small vessel disease (cSVD). As a recently described disease, overall knowledge on CARASAL is still lacking in certain areas. Therefore, it is important to assess this disease's characteristics, such as prevalence, pathophysiology, signs and symptoms. **Objective:** This review aims to summarize the current knowledge on CARASAL, describing its genetic, pathophysiological, epidemiological and clinical aspects. **Methods:** We conducted searches in Pubmed and Medline databases with the terms "CARASAL" and "Cathepsin A-related arteriopathy with strokes and leukoencephalopathy". These searches yielded 17 articles. An 18th article was added due to its relevance, as it contained the possible first descriptions of CARASAL. After screening, 6 articles were included and analyzed. **Results:** CARASAL is a cause of stroke with leukoencephalopathy presenting between the third and fifth decades of life, with only 21 cases described in literature. Most patients were European, hailing from the Netherlands, Britain and France. One patient was Chinese, and another was Brazilian. CARASAL is an autosomal dominant disease associated with a c.973C>T; p.Arg325Cys variant in CTSA, located on chromosome 20q13.12. This gene encodes Cathepsin A (CathA), a protective carboxypeptidase that degrades Endothelin-1 (ET-1), which, in turn, is associated with vasoconstriction and inhibition of the maturation of oligodendrocytes. Astrocytes of CARASAL patients were found to be immunoreactive to CathA and ET-1. Their role in CARASAL's pathogenesis is unclear. Clinically, CARASAL patients present with many neurological findings, such as cognitive decline, migraine, stroke and movement disorders. Brainstem symptoms, such as hearing abnormalities, vertigo, dysphagia and facial pain, were also observed. Non-neurological findings were described, such as resistant hypertension, muscle cramps and sicca syndrome. Neuroimaging usually shows T2 hyperintensities in thalami, basal ganglia, brainstem, subcortical and deep white matter. Such lesions tend to be more widespread in older patients. Infarcts and

microbleeds are present, albeit mild in comparison to the leukoencephalopathy. There's no disease-modifying treatment currently available. Prophylaxis for stroke has been used in some patients. **Conclusion:** CARASAL is a rare cause of cSVD and leukoencephalopathy with very few cases reported in the literature. The actual prevalence of this disease is yet to be estimated. Despite its rarity, CARASAL should be considered as a differential diagnosis in middle-aged patients with stroke, otologic and brainstem signs or cognitive decline, in association with typical imaging findings. Further studies are needed to comprehend the disease's pathophysiology, evaluate prognosis and enable potential treatment strategies.

Cauda equina syndrome as an initial manifestation of Burkitt leukemia

Carolina Oldoni[1], Matheus Piccoli Machado Schweitzer Klauberg[1], Cesar Augusto Weschenfelder[2], Lorenzo Ricardo de Medeiros Duso[2], Alessandra Aparecida Paz[1], Artur Francisco Schumacher Schuh[1], Pablo Brea Winckler[1]

[1]Hospital de Clínicas de Porto Alegre, Porto Alegre RS, Brazil.
[2]Universidade Federal do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Carolina Oldoni; Email: carololdoni15@gmail.com.

Case presentation: A 70-year-old male patient with psoriasis under treatment with secukinumab was admitted due to progressive worsening of paresis, which started in the distal left lower limb 1.5 years earlier and slowly progressed to paresis in the right lower limb accompanied by lower back pain, hypoesthesia in the lower limbs (LL) and genital region, constipation, and erectile dysfunction. Weight loss of 10 kg in 2 months following dietary changes was reported. Neurological examination revealed asymmetrical paraparesis, worse distally and bilaterally, hypoesthesia in the L5 and S1 dermatomes, and saddle hypoesthesia. The diagnosis of cauda equina syndrome (CES) was made. Extensive etiological investigation was performed, with initial normal cerebrospinal fluid (CSF) findings. Infections, neoplasms, paraneoplastic, structural causes, rheumatologic diseases, and sarcoidosis were ruled out. There was mild anemia (Hb 11.6), normal total leukocytes but lymphopenia, and an ESR of 80. Hematimetric changes were attributed to 7 monthly doses of SC methotrexate received in another clinic. MRI showed diffuse thickening of the cauda equina roots with focal contrast enhancement. Electroneuromyography was compatible with CES. A second CSF 9 days after the first showed 15 leukocytes (90% lymphocytes), with normal glucose and protein. An immune-mediated CES was considered. The patient was treated with methylprednisolone 1g for 5 days, with slight improvement. Nine months after, with no significant improve, prednisone 60 mg/day was started, which was used for 3 months until rehospitalization due to fever, hypoxemia, worsening of previous neurological deficits, anemia (Hb 9), thrombocytopenia (39,000), acute kidney injury, hyperferritinemia, and hypertriglyceridemia. Bone marrow biopsy diagnosed hemophagocytic lymphohistiocytosis (HLH) secondary to Burkitt leukemia (BL). Etoposide and dexamethasone (HLH-94 protocol) were initiated. After transient clinical improvement, the patient developed septic shock and died. **Discussion:** There are scarce case reports of BL presenting as a cause of CES, with CES occurring after the diagnosis of the neoplasm in those cases. In this case, the diagnosis of the hematological disease occurred afterward. It is inferred that the BL initially presented with CES, but the disease was possibly masked by chronic corticosteroid use. BL is an aggressive form of B-cell lymphoma, accounting for 1-2% of non-Hodgkin lymphoma cases. HLH is also rare, characterized by hyperstimulation of the immune system, leading to inflammation, increased cytokines, and multiple organ failure. HLH usually occurs in association with malignancy (especially lymphoma), immunodeficiency, or autoimmune diseases. **Final comments:** This case aims to report the presentation of Burkitt leukemia with cauda equina syndrome in a patient outside the epidemiological profile for the hematological diseases presented.

CEBALID syndrome: a rare cause of genetic-based intellectual disability

João Vítor Moreira Nogueira[1], Oliver Reiks Miyajima[2], Alessandra Marangoni Fante[1], Bruna Barbosa Nobre[1], Enzo Lima Alcântara Parente[1], Daniela Vieira Cavalcante[1], Marcelo de Almeida Pinheiro[1]

[1]Unichristus, Fortaleza CE, Brazil.
[2]Universidade Estadual do Ceará, Fortaleza CE, Brazil.

Correspondence: João Vítor Moreira Nogueira; Email: jvmnogueira10@gmail.com.

Case presentation: A 7-year-old male patient, with young, non-consanguineous parents and no family history of intellectual disability or other relevant neurological condition, had a follow-up with a pediatric neurologist due to a learning disorder. The physical neurological examination revealed apparent intellectual disability, significant impairment of expressive language, in addition to microcephaly, flat feet and craniofacial dysmorphisms such as macrotia, micrognathia, retrognathia, oblique palpebral fissure, thick eyebrows, large and pointed nose, high-arched palate and thin upper lip. The investigation identified mild bilateral sensorineural hearing loss, marked hyperopia and moderate intellectual disability with Intelligence Quotient (IQ) of 49. Additional investigation with karyotype, CGH-Array, electroencephalogram and magnetic resonance imaging of the brain showed no alterations. The whole exome sequencing identified a heterozygous mutation in the MN1 gene (c.1347_1348dup;p.[Tyr450Leufs*35]) compatible with CEBALID Syndrome with OMIM entry nº 618774, which does not present structural brain involvement in this case. **Discussion:** The MN1 gene is named as such as it was first identified as an oncogene in meningioma and may be associated with the development of this type of tumor. Another correlation of the pathogenic variants of this gene is with CEBALID syndrome, present in this case, with complex developmental disorder characterized by global developmental delay and variable impairment of intellectual development, craniofacial and structural brain abnormalities. The case presented is typical of this rare syndrome, as the patient presents craniofacial dysmorphisms, sensorineural hearing loss, language impairment and moderate intellectual disability, without brain abnormalities. Although the patient presents no family history indicative of an autosomal dominantly inherited disorder and no consanguinity among parents, whole exome sequencing encountered pathogenic MN1 mutation associated with CEBALID, indicating a de novo mutation. **Final comments:** CEBALID syndrome, related to the pathogenic mutation of the MN1 gene, is a rare autosomal dominant genetic condition, with few cases described in literature, presenting with intellectual disability associated with minor craniofacial dysmorphisms and significant impairment of expressive language. CEBALID syndrome, although rare, should be considered as a possible differential diagnosis in patients fitting in description, even without the presence of parental consanguinity or family history.

Cenobamate for refractory epilepsy in a Brazilian private practice setting: a preliminary report

Felipe Couto Amendola[1], Rhuan Pimentel Nogueira[1], Matheus Parra Barcelos de Mendonça[1], Bruno Lucca Bonucci Alves Costa[1], Luiz Henrique Martins Castro[1]

[1]Universidade de São Paulo, Faculdade de Medicina, São Paulo SP, Brazil.

Correspondence: Felipe Couto Amendola; Email: felipe.couto@fm.usp.br.

Background: Refractory epilepsy - a failure to achieve seizure freedom after two adequate trials of appropriately chosen, used and tolerated anti-seizure medication (ASM) schedules (ILAE) - affects up to one-third of epilepsy cases. In 2019, a novel drug, cenobamate, was FDA-approved for the treatment of focal seizures. Different studies have shown promising results of the drug in difficult-to-treat epilepsy. Barbieri et al. (2023) report a seizure freedom rate of 11-28% in treatment-resistant cases, notably higher than those of other ASMs. Cenobamate is currently available in Brazil only through importation, at an approximate R$1,100-R$2,200 monthly cost, depending on dose. **Objective:** To evaluate the impact of add-on cenobamate use in refractory epilepsy cases. **Methods:** This retrospective chart review study included consecutive cases of patients receiving cenobamate for refractory epilepsy in a private clinic setting of São Paulo. We excluded patients without follow-up appointments after cenobamate initiation. Primary outcome was the change in mean monthly seizure frequency after cenobamate introduction. Secondary outcomes were new reported side effects, total daily defined dose (DDD), seizure freedom rate and treatment cost. **Results:** We evaluated 9 patients (5 women), of whom 5 had lesional focal epilepsy, 3 non-lesional focal epilepsy and 1 generalized epilepsy. Mean age was 35,6 (28-48) years. Average cenobamate use duration was 15.4 (2.6-27.3) months. Cenobamate dose was 100mg in 1 patient, 200mg in 4, 300mg in 2, and 400mg in 2. Mean monthly seizure frequency was 5.3 before cenobamate use. After cenobamate introduction, seizure frequency dropped to 0.9 (p=0.004). Five (55.5%) patients achieved seizure freedom. Reported adverse symptoms after cenobamate introduction and change in other ASM doses were dizziness, somnolence, diplopia, ataxia, sedation and memory loss. Before cenobamate use, DDD was 5.5 and mean total treatment cost was R$2,560 (3 patients were undergoing vagus nerve stimulation, not included in the cost). After cenobamate introduction, mean DDD was 3.7 (p=0.018), and mean treatment cost, not including cenobamate cost, was R$1,238 (p=0.007) (only 1 patient was still under VNS). Tapering off of other ASM is still ongoing. **Conclusion:** Cenobamate is already being used in Brazilian private practice settings. As indicated in previous studies, our findings corroborate its impressive effectiveness in refractory epilepsy cases, reducing seizure frequency, total DDD, and, possibly, treatment cost. Cenobamate is a promising option in the current landscape of refractory epilepsy treatment. To our knowledge, this is the first study of cenobamate use in Brazil.

Central foot drop: a clinical case of a patient with SPG 83

Diógenes Emanuel Dantas da Silva[1], Helmut Kennedy Azevedo do Patrocínio[1], Lucca Ferdinando Queiroz Fernandes[1], Maria Eduarda Medeiros Martins[1], Matheus Araújo de Medeiros[1], Artur Rebouças de Souza[1], Agábio Diógenes Pessoa Neto[1], Matheus Augusto Araújo Castro[1], Mário Emílio Teixeira Dourado Junior[1], Iury Hélder Santos Dantas[1]

[1]Universidade Federal do Rio Grande do Norte, Natal RN, Brazil.

Correspondence: Diógenes Emanuel Dantas da Silva; Email: diogenes.emanuel28@outlook.com.

Case presentation: Female patient, 17 years old, with a history of consanguinity. In 2022, she began to stumble when walking, which intensified in February 2023, when the patient let her shoes fall off her feet, requiring her to walk barefoot and with difficulty, dragging her leg. She also has cramps, paresthesias and progressive fatigue in her legs when walking. No alterations in the upper limbs. In childhood, she had difficulty jumping, as well as learning and reading difficulties. On physical examination, she had a difficult tandem gait, right-sided sputum and calf hypotrophy, increased patellar and achilles reflexes, bilateral Babinski and exhaustible clonus, cavus feet and preserved tone without spasticity. Laboratory tests, neuroimaging and electroneuromyography were unchanged. Exome sequencing found a probably pathogenic variant of the HPDL gene in homozygosity: NM_032756.4:c.553G> T:p.(Gly185Cys), associated with spastic paraplegia type 83. Treatment with baclofen and rehabilitation with motor physiotherapy was started, with symptom relief. **Discussion:** Hereditary Spastic Paraplegia (HSP) is a condition characterized by progressive degeneration of the corticospinal tract, and consanguinity is a risk factor for autosomal recessive forms. The genetic classification is based on the related gene and the associated inheritance pattern. It is numbered according to the chronological order of discovery as SPG1, SPG2 and so on. It shows genetic and phenotypic diversity, with HSP type 83 HPDL as the associated gene, on chromosome 1p34.1. Under normal conditions it encodes a 371 amino acid protein of unknown function, found in mitochondria, and highly expressed in the central and peripheral nervous system. Its phenotypic spectrum can range from neurological non-formation in the fetus to infantile onset spasticity. Its predominant phenotype is pure, with lower limb involvement, muscle weakness, hypotrophy, spasticity and gait alterations. Thus, foot drop is not one of its typical manifestations, as it is commonly related to lower motor neuron syndrome. The diagnosis is made by genetic analysis, when pathogenic variants in homozygosity or compound heterozygosity are found in the HPDL gene, after excluding differential diagnoses by neuroimaging, cerebrospinal fluid analysis, serologies and electroneuromyography. Current treatment is symptomatic. Future treatment depends on a better understanding of the function of the HPDL gene, with genetic counseling being part of the management. **Final comments:** Clinical presentations of pyramidal release, even with the phenotype that may resemble a superimposed lower motor neuron syndrome, should consider SPG in their differential diagnoses. This is important in cases with a family history of consanguinity, such as ours, in which the possibility of a genetic etiology was considered above all because of this characteristic.

Central pontine myelinolysis not related to rapid sodium correction: a case report

Luiza de Aguiar Lima[1], Catarina Sodré de Castro Prado[1], Izabela Ferreira Pacheco de Oliveira[1], Ana Luisa Utrine Pimentel[1], Johnatan Felipe Ferreira da Conceição[1], Rafael Correa[2], Carolina Bittar Braune[1]

[1]Universidade Federal Fluminense, Hospital Universitário Antônio Pedro, Departamento de Neurologia - EBSERH, Niterói RJ, Brazil. [2]Universidade Federal Fluminense, Hospital Universitário Antônio Pedro, Departamento de Radiologia - EBSERH, Niterói RJ, Brazil.

Correspondence: Luiza de Aguiar Lima; Email: luizadealima@gmail.com.

Case presentation: A 40-year-old male was admitted to the hospital due to a sudden onset binocular visual blurring that had occurred a few days earlier. Furthermore, 3 months ago he began generalized weakness, fatigue, daily fever, anemia, thrombocytopenia and 25kg weight loss. After hospital admission, he evolved with weakness in the lower limbs and left upper limb, resulting in difficulty walking and gripping objects, along with persistent visual blurring and fluctuating consciousness levels. No prior similar medical history was reported, but heavy alcohol and tobacco use were noted. Neurological examination revealed grade 4 paresis in the left upper limb and in lower limbs, symmetric tactile hypoesthesia in legs, bilateral dysmetria in finger-nose and heel-knee tests, worse on the left side, and fluctuating consciousness. The hematology team established the diagnosis of lymphoma based on systemic findings, splenomegaly and bone marrow aspirate. Cerebrospinal fluid analysis showed pleocytosis with predominance of mononuclear cells (83%), mild hyperproteinorrhachia and a positive bacterial culture for Brevebacterium spp., that was regarded as probable contamination. Brain magnetic resonance imaging (MRI) showed a hypointense area on T1 and hyperintense on FLAIR in the central region of the pons, with hyperintensity in DWI sequence, but without restricted diffusion. Considering the clinical picture, brain MRI and CSF without findings suggestive of neuroinfection, the diagnosis of pontine myelinolysis of probable multifactorial etiology was established, including malnutrition, lymphoma and alcoholism. Chemotherapy for B-cell lymphoma was started, and the patient partially improved, being discharged with mild paresis and dysmetria, but clear resolution of level of consciousness. **Discussion:** Central pontine myelinolysis manifests with varied symptoms, mainly consciousness disturbances, cranial nerve dysfunction, and motor deficits. Although classically related to rapid sodium correction, which was not present in our case report, alcoholism, malnutrition, lymphoma and hypoalbuminemia may predispose to the disease. The main differential diagnoses are rhombencephalitis and central nervous system lymphoma, both extremely serious conditions with high mortality rates if not recognized and treated early. Therefore, additional investigation with MRI and cerebrospinal fluid is essential in the workup of these patients, as is follow-up. **Final comments:** This case highlights the importance of considering diverse etiologies beyond rapid sodium correction in pontine lesions. Multidisciplinary management is crucial for improved patient outcomes, despite limited treatment options.

https://doi.org/10.5327/CBN240321

Central retinal artery occlusion in a young woman associated with isolated ophthalmic artery arteritis

Gustavo Freitas Alves de Arruda[1], João Paulo Borges de Melo[1], Mayko Nascimento Merscher[1], Raíssa Habka Cariello[1], Matheus Spilari[1], Camila Caroso Lobo[1], Danilo dos Santos Silva[1], Wagner Mauad Avelar[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Gustavo Freitas Alves de Arruda; Email: garruda@unicamp.br.

Case presentation: A 43-year-old woman with a history of vitiligo presented with episodes of amaurosis fugax in her right eye over the past 20 days. Initially, it had spontaneous resolution within seconds. However, she developed painless persistent visual loss two days before hospital admission. Neurological examination showed reduced right eye visual acuity, limited to hand movements, and ipsilateral nasal hemianopia. Fundoscopy revealed optic disc pallor and edema with a cherry-red spot at the macula, suggesting a diagnosis of central retinal artery occlusion (CRAO). Fluorescein angiography evidenced hyperfluorescence of the optic disc and three additional points nasal to the fovea without areas of capillary dropout or signs of retinal vasculitis. Computed tomography angiography of the head and neck showed no abnormalities. Extensive laboratory workup, with antinuclear antibodies, rheumatoid factor, infectious serologies, and inflammatory markers, returned negative results. However, tests indicated primary hypothyroidism with elevated thyroid peroxidase antibodies. Magnetic resonance angiography revealed mural contrast enhancement of the right ophthalmic artery on post-contrast T1-weighted images, leading to the diagnosis of focal arteritis. She was treated with oral prednisone 60 mg/day. At 1-month follow-up, there was a slight improvement in visual acuity, with finger counting up to 1 meter. **Discussion:** CRAO is defined by a partial or complete interruption of blood flow through the central retinal artery, leading to retinal ischemia with potential cell death within a few hours. There is a paucity of epidemiological data on the disease in Brazil, but it has an estimated occurrence of 1 case for every 100,000 people in the US and it's related to an increased risk of new strokes, with an incidence of 4-15% by 1-year follow-up. Its etiology is usually related to carotid atherosclerosis or cardioembolic disease, though it may also result from systemic vasculitis, hypercoagulable states, or infectious diseases. This case highlights a rare occurrence of CRAO due to isolated arteritis of the ophthalmic artery, without any evidence of carotid or cardiac emboli nor systemic or retinal vasculitis. The ophthalmic artery supplies both the central retinal and ciliary arteries that nourish the choroid and the posterior portion of the optic nerve. This explains why arteritis in such territory can lead to severe visual impairment. Cases of CRAO associated with isolated ophthalmic artery arteritis are exceedingly rare; the authors found only one similar case in the literature. **Final comments:** In this unique case, CRAO was attributed to isolated ophthalmic artery arteritis, independent of typical etiologies such as embolism or systemic vasculitis. The patient's partial visual improvement following oral prednisone may suggest that this intervention could perhaps offer a better chance for more significant visual recovery in similar cases with earlier diagnosis.

Cerebellar ataxia as a presentation of neuro-Behçet: case report

Joyce Tolentino Philippi[1], Paulo Eduardo Mestrinelli Carrilho[1], Luisa Bianca Reis Parode[1], Márcio Augusto Nogueira[1], Ana Paula Adame[1], Gabriela Zimmermann[1], Alvaro Joel Santacruz López[1]

[1]Universidade Estadual do Oeste do Paraná, Hospital Universitário do Oeste do Paraná, Cascavel PR, Brazil.

Correspondence: Joyce Tolentino Philippi; Email: joycephilippi@gmail.com.

Case presentation: A 36-year-old female, who recently received treatment for ocular toxoplasmosis due to visual blurring, sought medical attention due to a condition of ataxia, dysarthria, and global paresthesia. Magnetic resonance imaging identified small cystic images in the brainstem and middle cerebellar peduncles (probable dilatation of perivascular spaces) associated with an enhancement focus, diffuse ischemic areas, as well as cerebellar volume loss. The patient was diagnosed with late-onset cerebellar ataxia and while being followed up by a neurologist for two years until she was referred to a rheumatologist. During the initial consultation with the rheumatologist, in addition to ataxia, recurrent oral and genital ulcers that started two years ago were identified, along with erythematous macules on the upper limbs, erythema nodosum, folliculitis, and pustules on the lower limbs. Furthermore, a new ophthalmological evaluation revealed active posterior uveitis. The combination of signs and symptoms, along with the absence of markers suggestive of other rheumatological diseases, led to the diagnosis of neuro-Behçet. The patient was initially treated with azathioprine 150mg/day as per follow-up, leading to a significant improvement in ulcers and other cutaneous lesions. Ten months after the start of treatment, there was a recurrence of posterior uveitis, necessitating a switch to adalimumab, one 40mg vial every two weeks, which resulted in permanent remission of cutaneous-mucosal lesions and visual symptoms. The patient maintained

ataxia and dysarthria, without worsening after the introduction of therapy. **Discussion:** Behçet's syndrome (BS) is a rare systemic vasculitis, with a prevalence of 0.003% in the Brazilian population, classically characterized by a clinical triad that includes recurrent aphthae, genital ulcers, and posterior uveitis. Approximately 10% of patients develop neurological involvement, named as neuro-Behçet's syndrome (NBS), a condition associated with worse prognosis and high morbidity and mortality. Parenchymal-NBS is seen in up to 75-80% and usually presents with an acute-subacute brainstem syndrome and/or a deep hemispheric involvement. The major symptoms and signs of p-NBS include headache, dysarthria, ataxia, and hemiparesis. And generally clear completely within weeks. However, a third of patients evolve with progressive course characterized by dementia, ataxia and dysarthria. **Final comments:** As a multisystemic condition, BS should be considered an important differential diagnosis in patients with neurological conditions, especially with cerebellar symptoms and brainstem involvement. The timely and appropriate diagnosis and treatment are essential to prevent possible irreversible sequelae and promote a better quality of life.

Cerebellar stroke secondary to bow Hunter's syndrome: a case report

Pedro Cougo Samueli[1], Tauana Caroline Marconato[2], Izadora Celant Miranda da Silva[1], Elora Sampaio Lourenço[1], Ana Carolina de Lima[1], Samara Abdo El Hakim Kadri[1], Emanuel Cassou dos Santos[1], Matheus Kahakura Franco Pedro[1], Caio César Diniz Disserol[1,3,4]

[1]Instituto de Neurologia de Curitiba, Curitiba PR, Brazil.
[2]Universidade Estadual do Centro Oeste,Guarapuava PR, Brazil.
[3]Universidade Federal do Paraná, Hospital de Clínicas, Curitiba PR, Brazil.
[4]Hospital Israelita Albert Einstein, São Paulo SP, Brazil.

Correspondence: Pedro Cougo Samueli; Email: drpedrocougosamueli@gmail.com.

Case presentation: A 46-year-old male with no prior health issues, sought medical attention due to a sudden onset of vertigo, nausea and vomiting, lasting 6 hours. On admission he was asymptomatic and neurological examination was normal. A brain MRI scan revealed an acute stroke in the left cerebellar hemisphere and vermis, and a CT angiography showed an osteophyte at C6 causing stenosis in the V2 segment of the ipsilateral vertebral artery. Initial treatment included a loading dose of dual antiplatelet therapy. Subsequently, a digital subtraction angiography was performed, showing a significant left V2 caliber reduction at C6 level severely exacerbated by left lateral head rotation, confirming an osteophyte-induced stenosis. After stabilization and further evaluation by the neurosurgical team, who opted for a conservative approach, the patient was discharged for outpatient follow-up. **Discussion:** Bow Hunter's syndrome (BHS), also known as rotational vertebral artery occlusion syndrome, is a rare diagnosis with an undetermined true incidence. It represents an uncommon cause of vertebrobasilar insufficiency resulting from dynamic and reversible mechanical compression of the vertebral artery during cervical rotation or extension. Compression occurs due to the presence of abnormal bony structures such as osteophytes, disc herniations, tumors, trauma, or iatrogenic factors. It commonly involves compression of the dominant artery when the contralateral blood supply is limited. Ischemic injury results from blood flow stasis caused by mechanical tension or complete lumen obstruction, leading to endothelial damage and platelet aggregation, culminating in thrombus formation. This can result in transient ischemic attacks and strokes in the posterior circulation. Symptoms include vertigo, nystagmus, syncope, visual disturbances, and infarction in the brainstem and cerebellum. Symptom improvement in the neutral position is considered a pathognomonic sign of BHS. The primary diagnostic methods include CT, MRI and angiography. Currently, dynamic angiography is the diagnostic test of choice, with sensitivity and specificity close to 100%. Treatment with decompression of the affected artery appears to be an option with a low recurrence and complication rate. Other options include arthrodesis or conservative treatment combined with antiplatelet therapy, the latter showing a lower resolution rate. **Final comments:** Although BHS represents an exceptional diagnosis, this syndrome should be considered as a differential in ischemic strokes of the posterior circulation. Emphasis is placed on the importance of thorough investigation to elucidate the etiological factors of mechanical compression

https://doi.org/10.5327/CBN240324

Cerebral amyloid angiopathy-related inflammation (CAARI): a case report and review

Mateus Coltro Dornelles[1], Jamileh Ferreira Chamma[1], Mariana de Oliveira Trintinalha[1], Liamara Petroli[1], Gabriella Maria Martins Favero[1], Letícia Graniska Salanti[1], Anelise Daiane Carpiné[1]

[1]Pontifícia Universidade Católica do Paraná, Hospital Universitário Cajuru, Curitiba PR, Brazil.

Correspondence: Mateus Coltro Dornelles; Email: mateuscdornelles@gmail.com.

Case presentation: A 56-year-old male, with a history of high blood pressure and dyslipidemia, on losartan and ciprofibrate, was referred to our service after a seizure episode associated with suspected intracerebral hemorrhage (ICH). On admission, he presented with lacunar amnesia. During the investigation, cranial magnetic resonance imaging (MRI) showed numerous spots with low signal on SWI, suggesting microhemorrhage in the periphery of the brain parenchyma, associated with vasogenic edema, mainly in parieto-occipital regions, a pattern suggestive of inflammatory cerebral amyloid angiopathy (CAARI), along with mild proteinorrachia (57.3mg/dL). Pulse therapy was administered with Methylprednisolone 1g/day for 5 days, and, at discharge, he was asymptomatic, being prescribed Phenytoin 300 mg/ day for prevention of further episodes. **Discussion:** Cerebral amyloid angiopathy (CAA) is characterized by the deposition of β-amyloid (Aβ) protein in the leptomeningeal and cortical blood vessels of small and medium caliber. Epidemiological studies on the disease are scarce and estimate a prevalence of 0.13/ 100,000 inhabitants. CAA can be divided into hereditary and sporadic, mainly affecting the elderly (average age of 67 years at diagnosis), with its main clinical manifestations being acute symptomatic lobar intracerebral hemorrhage, cognitive decline, transient focal neurological episodes, or behavioral changes caused by inflammation related to CAA (CAARI). CAARI is characterized by acute or subacute onset of cognitive decline or behavioral changes, and its pathophysiology is explained by three theories: coexistence of vascular Aβ and vascular inflammation, inflammation promoting Aβ accumulation in the vascular wall, and the possibility of Aβ deposition triggering the inflammatory response. Corovic A. et al, 2018, demonstrated the occurrence of proteinorrachia in over 80% of patients, with pleocytosis in 44%. To avoid the need for biopsy, diagnostic criteria for probable CAARI were created: acute or subacute onset of symptoms; age greater than or equal to 40 years; presence of at least one of the clinical features: headache, altered consciousness, behavioral changes, or focal neurological signs and seizures; MRI with irregular or confluent lesions weighted on T2/ FLAIR, presence of previous CAA characteristics (multiple cortical/ subcortical hemorrhages or microhemorrhages and/ or lobar intracerebral hemorrhage), and absence of other causes. Our patient met the proposed criteria and the response to pulse therapy reinforces the diagnostic hypothesis. **Final comments:** We report a case of a patient of atypical age with a clinical and imaging profile highly suggestive of CAARI. The importance of discussions on the subject is highlighted given the importance of early diagnosis for the implementation of therapy, which can modify the course of the disease.

Correspondence: Karla Carlos; Email: ka.carlos1@hotmail.com.

Background: The morphology of the intracranial pressure pulse consists of three waves: P1, corresponding to arterial pulsation; P2, corresponding to cerebral compliance; and P3, corresponding to aortic valve closure. Under normal conditions, P1> P2> P3. Reversal of the P2/P1 ratio represents impaired cerebral compliance (CC) and, indirectly, increased intracranial pressure (ICP). **Objective:** To evaluate cerebral compliance during normal sleep. **Methods:** Cerebral compliance analysis was performed using the Brain4care device placed on patients along with type 1 polysomnography. We evaluated CC during the all-night sleep period and analyzed it according to NREM and REM sleep stages. **Results:** We analyzed CC from 3 participants without sleep disorders. The mean age was 33 years (±3 years). Two participants were female. All participants denied comorbidities and medication use. The mean CC recording time was 363 minutes (minimum = 333; maximum = 385), totalizing 1,088 minutes analyzed. Participant 1. With 370 minutes of CC recording, it exhibited 22.5% REM sleep, 77.5% NREM sleep, and SE of 92%. The mean P2/P1 ratio during sleep was 1.28; 1.29 during REM sleep and 1.30 during NREM sleep. Participant 2. With 385 minutes of CC recording, it demonstrated 14.4% REM sleep, 85.6% NREM sleep, and SE of 84%. The mean P2/P1 ratio during sleep was 0.88; 0.84 during REM sleep and 0.87 during NREM sleep. Participant 3. With 333 minutes of CC recording, showed 28.8% REM sleep; 71.2% NREM sleep, and SE of 87%. The mean P2/P1 ratio during sleep was 0.83; 0.77 during REM sleep and 0.91 during NREM sleep. Only one participant showed P2/P1 ratio values above 1.0 during sleep, suggesting reduced cerebral compliance. We are just starting to understand this new technology, and this sort of result can be somehow explainable by variables that we do not are aware of. After conducting studies comparing invasive and non-invasive methods of ICP assessment, it was possible to establish values to stratify the risk of intracranial hypertension: green zone (P2/P1 0.65 to 1.00); yellow zone (P2/P1 1.00 to 1.20); red zone (P2/P1 >1.21). The higher the ratio, the greater the cerebral compliance disturbance. One of the components influencing ICP is cerebral blood flow, which varies according to the brain's metabolic demand, correlates with the dominant frequency of the electroencephalogram, and is higher during wakefulness. During NREM sleep, blood flow decreases by approximately 10 to 20%. This flow increases by 20 to 35% in REM sleep, compared to wakefulness. The main mechanism justifying this variation is the synergy between cortical activity and perfusion, which represents cerebral metabolism, which is decreased or increased during NREM and REM sleep, respectively. Thus, in normal sleep, an increase in compliance is expected during REM sleep and a reduction during NREM sleep. **Conclusion:** Normal sleep maintains cerebral compliance within the bounds of normality.

Cerebral metastasis of lung cancer mimicking multiple sclerosis lesions.

Gabriela Lam Brawerman[1], Angelo Pontes de Freitas Campos[1], Denison Pedrosa[1], Luís Filipe Godoy[1], Gustavo Bruniera[1], Rodrigo B. Thomaz[1], Roberta Castro Linhares[1]

[1]Hospital Israelita Albert Einstein, São Paulo SP, Brazil.

Correspondence: Gabriela Lam Brawerman; Email: brawermangabriela@gmail.com.

Case presentation: A 43-year-old female presented with symptoms of vertical diplopia and paresis in her left lower limb over the past two weeks. She reported no history of tobacco or alcohol use, and her past medical history was significant only for maculopapular lesions on the trunk, arms, and back, which resolved without intervention three weeks before the onset of neurological issues. Neurological examination revealed that she was alert and oriented with fluent language. Her visual acuity and fundi were normal in both eyes. A positive Bielschowsky sign was found on her left side. Based on the Medical Research Council grading, the patient had preserved power in all muscle groups, present deep tendon reflexes in the lower limbs, a positive Hoffman sign in the left upper limb, and bilateral flexor plantar responses. All sensation modalities were normal in all four limbs. Coordination was intact, with no gait disturbance. Meningismus was absent. A contrast-enhanced brain MRI showed a total of 16 lesions distributed in cortical and juxtacortical regions of both hemispheres, the insula, cerebellum, and mesencephalon on T2-FLAIR weighted images, with no oedema observed. Three of these lesions showed a central vein sign. A paramagnetic rim sign was also found. CSF analysis, oligoclonal bands, and kappa light chains were all unremarkable. An orbital MRI showed thickening in the left medial rectus muscle, an atypical finding for MS. A PET scan was performed for neoplastic screening, revealing an abnormal lung nodule and mediastinal lymph nodes. A biopsy confirmed the diagnosis of primary lung adenocarcinoma with ALK fusion. **Discussion:** The McDonald criteria were first introduced for MS diagnosis in 2001, and the latest revision made in 2017 emphasized the risk of misdiagnosis in clinical practice. Although patients could fulfill the criteria of dissemination in time and dissemination in space supported by MRI and oligoclonal bands, it is important to highlight that the MS diagnosis is still clinical, and potential differential diagnoses must be ruled out. Some data indicate that 30% of cases referred for MS Centers are at some point diagnosed with other diseases, and that over 50% of them carried the incorrect diagnosis for at least 3 years. Many different conditions can be confused with MS, such as migraines, cerebral small vessel disease, and neuromyelitis optica spectrum disorder, inflammatory, infectious, and metabolic disorders. Less frequently, breast cancer, colorectal cancer, and lung cancer are also considered in this differential diagnosis. **Final comments:** Although there has been an increase in the sensitivity of the McDonald MS diagnostic criteria over the past years, MS presents with clinical heterogeneity and a lengthy differential diagnosis. An MS misdiagnosis can be associated with serious risks and potential morbidity, and all patients presenting with lesions characteristic of MS must be considered for other potential diagnoses.

Correspondence: Clarissa Lin Yasuda; Email: cyasuda2807@gmail.com.

Background: Although different studies showed structural brain changes after COVID-19, the neurobiological mechanisms are unknown. Perivascular spaces (PVS) form a central part of the proposed glymphatic system, a cerebral analogue to the lymphatic system, responsible for waste clearance in the brain. PVS can be observed on clinical MRI as CSF-isointense vessel-like structures and have been reported to both enlarge and shrink in neurological conditions. We hypothesised patients with LONG-COVID would present with larger volumes of CSF, presenting a potential mechanistic pathway for the neurological and cognitive deficits observed in COVID and long COVID patients. **Objective:** To investigate PVS changes after COVID-19. **Methods:** 392 participants with previous mild COVID-19 and 212 healthy controls with no self-reported symptoms of SARS-COV-2 were scanned on a 3T (patients after 160 days of infection. Perivascular spaces were automatically segmented on the T1w image using an in-house trained nnUNet (a deep learning algorithm). The MNI 152 subject average 1mm T1 template was registered to each patients' T1w image using ANTS symmetric diffeomorphic transformation. The white matter(WM) regions of interest (based on the Harvard Oxford cortical atlases) were used to mask the PVS segmentation masks, and the volume of the WM for each participant calculated. Distinct PVS clusters were counted using a cluster-detection algorithm. To account for total WM volume, counts were divided by the WM total volume to give number of enlarged PVS per mm3 of WM (WM PVS number density: WMPVSd), which was used as the outcome variable. Groups were assessed for differences in outcome variables using a Mann-Whitney U-test. The effect of symptomatic SARS-COV-2 infection on each outcome variable was assessed using a general linear model with PVS as the dependent variable, COVID status as the independent variable of interest, and age and sex as covariates. **Results:** The WMPVSd were 1.61 (1.51-1.71) x 10-4 mm-3 and 1.78 (1.70-1.86) x 10-4 mm-3 in the control and covid group respectively. The COVID group had a significantly higher WMPVSd than the control group in a two-group comparison (U=35846, p=0.005). The general linear model indicated that WMPVSd was not associated with disease group =-8.85e-07 (5.78e-06), t=-0.153, p=0.878, but age was strongly associated with WMPVSd =3.555e-06 (2.166e-07), t=16.408, p<2e-16. A post hoc Mann-Whitney U test of the ages between the control and covid group indicated a significant between group difference (p<0.001). **Conclusion:** Although our data show a significant increase in WM PVS density in COVID patients compared to controls, this association was not significant after regressing out age and sex. These suggest that although the hypothesis of glymphatic involvement in COVID19 is reasonable, PVS as measured on MRI is not a good biomarker in COVID19, and that it is crucial to account for potential confounds such as age when drawing conclusions from PVS .

Cerebral schistosomiasis due to Schistosoma mansoni infection: a rare case presentation in Brazil

Camila Lopes Figueiredo[1], Carolina Rodrigues Dal Bo[2], Maria Clara Motta Barbosa Valente[1], Leticia Machado Dumont[1], Rafael Chaves Claudino de Queiroga[1], Cicero Rodrigues Veloso[1], Filipe Brito Ferraz da Silveira[1], Antonio José da Rocha[1], Augusto Cesar Penalva de Oliveira[1]

[1]Santa Casa de Misericórdia de São Paulo, São Paulo SP, Brazil.
[2]Hospital Israelita Albert Einstein, São Paulo SP, Brazil.

Correspondence: Camila Lopes Figueiredo; Email: camila04_lopes@hotmail.com.

Case presentation: A 16-year-old female patient presented with a 2-week history of right hemicranial headache, nausea, vomiting, and visual field defect. She had no history of fever, chills, or neck stiffness. She was from the interior of Pernambuco and reported a history of swimming in lakes inhabited by freshwater snails. On examination, the patient had a left homonymous hemianopsia. Cranial computed tomography (CT) revealed a right occipital hypodense lesion with contrast enhancement. Brain magnetic resonance imaging (MRI) revealed cortico-subcortical signal alterations in the right cuneus and precuneus, characterized by intense linear and micronodular enhancement, indicative of the typical pattern observed in cerebral neuroschistosomiasis cases. Serological test for Schistosomiasis mansoni was positive. The patient was treated with praziquantel and corticosteroids. She evolved with complete improvement of symptoms after treatment. **Discussion:** Neuroschistosomiasis is a rare and potentially fatal complication of an infection by larval schistosomes. The primary species responsible for the disease are Schistosoma haematobium, Schistosoma mansoni, and Schistosoma japonicum. In Brazil, Schistosoma mansoni is the prevalent species of parasite responsible for schistosomiasis. It occurs due to the migration of Schistosoma eggs into the central nervous system, where they can lodge and cause granulomatous inflammation. S. mansoni typically affects the spinal cord, while Schistosoma japonicum mainly causes encephalic disease. The clinical presentation can vary widely but typically includes headache, focal neurological deficits, and seizures. Paucisymptomatic cerebral schistosomiasis is more common in patients with chronic S. mansoni infection, as indicated by autopsy studies, and can also manifest as tumor-like lesions. **Final comments:** The case underscores the importance of considering cerebral schistosomiasis in patients from endemic regions presenting with neurological symptoms. Early treatment can reduce the likelihood of disease advancement, thus enhancing overall patient outcomes.

Cerebral superficial siderosis: challenges in diagnosis

Guilherme Araujo Natal Francisco[1], Nathalia Novaretti[1]

[1]Universidade de Ribeirão Preto, Ribeirão Preto SP, Brazil.

Correspondence: Guilherme Araujo Natal Francisco; Email: guilhermearaujonf@hotmail.com.

Case presentation: 80 years old woman with history of progressive weakness in lower limbs for 10 years, associated with paresthesia and fecal incontinence. Investigation with extensive thoracic spinal cord injury which was treated empirically as neurotuberculosis (CSF: BP=40cmH2O| 2 leukocytes| 56.3 protein| 60 glucose| 113 chloride| VDRL negative| Cultures all negative| CIE fungi negative; syphilis and HIV serology=negative; PPD=25; chest x-ray=calcium nodule in the upper third of the left lung, with a residual appearance, measuring 4mm). The patient remained stable after treatment, with ongoing control of the thoracic spine and improvement in urinary incontinence after implantation of a sacral neuromodulator. 2 years ago, patient sought care again due to worsening gait associated with cognitive impairment and ringing in the ears. On examination: MMSE=27/30, bilateral hearing loss, decreased strength on the left inferior member with hyperreflexia and Babinski's sign, bilateral hypopalesthesia (D>E), gait ataxia and positive Romberg's sign. Screening tests were unremarkable. MRI of thoracic spine (appendix 1): late post-treatment control of myelitis and arachnoiditis, with stable changes in relation to the examination on 08/13/2021. Brain MRI (appendix

2): changes suggestive of mild microangiopathy, characterized by foci of signal changes in the cerebral white matter; findings compatible with superficial siderosis, to a greater extent in the posterior fossa and characterized by superficial areas of marked SWAN hyposignal; cerebellar volumetric reduction. Arterial MRI angiography: small saccular addition image in the communicating segment of the left internal carotid artery suspicious for a small aneurysm; superficial siderosis predominating in the posterior fossa. Spinal and cervical angiography showed no changes. CSF: PA=6.5cmH2O| 5 cells | 8400 red blood cells | 72.9 proteins | 84 glucose | 131 chlorides | 2.9 lactic acid | negative cultures| negative direct mycological examination | negative VDRL). **Discussion:** Superficial siderosis is a rare neurologic disease with prevalence of 0.21% in those aged 50 to 69 and 1.43% in those older than 69, with males affected more often than females It is defined as hemosiderin deposition due to chronic leakage of small amounts of blood into the cerebrospinal fluid. The disease constitutes linear hemosiderin deposits in the leptomeninges and the superficial layers of the cerebrum and the spinal cord. The clinical manifestation of SS includes of progressive sensorineural hearing loss, cerebellar ataxia, and myelopathy. MRI is an important means of diagnosis. **Final comments:** It's a case of infratentorial cerebral superficial siderosis in an elderly woman secondary to a cerebrospinal fluid leak probably secondary to extensive spinal cord injury treated as neurotuberculosis. The importance of the case is to discuss the difficulty of investigation and treatment possibilities in these cases.

Cerebral tuberculoma as a differential diagnosis for an extra axial lesion in an immunocompetent patient: a case report

Lucca Ferdinando Queiroz Fernandes[1], Matheus Araújo de Medeiros[1], Lúcio Fábio de Assis Arruda Filho[1], Helmut Kennedy Azevedo Do Patrocínio[1], Amanda Lima Sampaio[1], Artur Rebouças de Souza[1], Cláudio de Souza Fernandes Júnior[1], Renner Cassio Nunes de Lucena[1], Hugo Leandro Andrade Paiva[1], Iury Hélder Santos Dantas[1]

[1]Universidade Federal do Rio Grande do Norte, Caicó RN, Brazil.

Correspondence: Lucca Ferdinando Queiroz Fernandes; Email: queirozlucca@gmail.com.

Case presentation: A 26-year-old immunocompetent woman presented with a generalized tonic-clonic seizure. Brain magnetic resonance imaging (MRI) revealed an extra-axial lesion in the right temporal lobe with heterogeneous contrast enhancement, adjacent dural thickening and vasogenic edema. Analysis of the cerebrospinal fluid (CSF) revealed no significant findings. Excisional biopsy of the lesion for pathological analysis identified complete tuberculoid granulomas with central caseous necrosis, suggestive of cerebral tuberculoma. Based on these clinical, laboratory and imaging findings, a diagnosis of cerebral tuberculoma was made. The patient underwent the standard treatment regimen for tuberculosis (RHZE) for one year, with clinical improvement. **Discussion:** Although tuberculosis of the central nervous system is a rare manifestation, especially in immunocompetent patients, it should be considered in the differential diagnosis of expansive intracranial lesions. MRI is a crucial tool in detecting lesions with ring enhancement and perilesional edema, which can easily be mistaken for brain tumors. The diagnosis of cerebral tuberculoma was corroborated by the presence of caseous granulomas in the biopsy. Early treatment with the standard anti-tuberculosis regimen is essential for a good prognosis. **Final comments:** Mycobacterium tuberculosis infection in the central nervous system, manifested as tuberculoma, is rare but significant, especially in areas with a high prevalence of tuberculosis. Diagnosis can be challenging due to the similarity of clinical and radiological signs with other conditions, such as brain neoplasms. The integration of clinical, radiological and anatomopathological data is vital for the identification and effective management of this condition.

[3]UPA Santa Fé do Sul, Santa Fé do Sul SP, Brazil.
[4]AME Fernandopolis, Fernandopolis SP, Brazil.

Correspondence: Rynele Almeida de Fonseca; Email: rynelef_@hotmail.com.

Background: Cerebral Vascular Accident (CVA), commonly known as stroke, is a cerebrovascular disease caused by a sudden focal neurological deficit due to the acute absence of blood supply to the brain. This can be due to an occlusion caused by a thrombus, fatty plaques, or reduced cerebral perfusion from a ruptured vessel. It is one of the leading causes of death and disability worldwide, significantly affecting the quality of life of survivors. Stroke has a high mortality rate among cardiovascular diseases. It can be classified as ischemic or hemorrhagic, with the latter occurring when a vessel ruptures, causing blood to leak into the brain. **Objective:** To evaluate the profile of hospital admissions for stroke in Brazil between 2019 and 2023. **Methods:** Data were collected from the Hospital Information System of SUS (SIH/SUS) of the Ministry of Health, publicly available on Tabnet/DATASUS, from January 15 to May 15, 2024. This retrospective, longitudinal study utilized a quantitative, descriptive design. Data were grouped by Brazilian macroregions, type of care, sex, age group, and race/ethnicity. Statistical inference was performed using BioEstat 5.3 software, employing the paired T-test for two related samples to compare groups, with data presented through descriptive statistics, measures of central tendency, and dispersion. **Results:** Between 2019 and 2023, there were 859,733 hospital admissions for stroke in Brazil. Of these, 52.54% (n=451,666) of admissions were predominantly among males (p<0.0001) and 42.10% (n=361,920) among individuals of mixed race (p=0.0564). The majority of cases occurred in individuals aged 70-79 years, accounting for 26.37% (n=226,672; p<0.0001), with the highest concentration in the Southeast region (n = 363,567), representing 42.29% (p=0.0007) of the total, with an average annual cost of R$ 161,411,755.57 for care. Deaths were most frequent in the Southeast, with 42.77% (n=55,473) of fatalities (p=0.0008) and an average mortality rate of 28.17 (p=0.0008). The number of hospitalizations peaked in 2023, comprising 22.79% (n=195,953) of total admissions, compared to 17.88% (n=153,714) in 2020. Most admissions were classified as urgent, accounting for 96.48% (n=829,465; p<0.0001) of cases. **Conclusion:** Stroke admissions are concentrated in the Southeast region of Brazil, with higher proportions of deaths and healthcare costs during the study period. The predominant profile of cases involved males aged 70-79 years of mixed race, with urgent care being the most common type of admission.

https://doi.org/10.5327/CBN240332

Cerebral vasculitis and pachymeningitis as the first manifestation of rheumatoid arthritis

Gabriel Etienne Brito de Salles[1], Giuliana Gonçalves Moreira Possidente[1], Marcos Martins da Silva[1]

[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Gabriel Etienne Brito de Salles; Email: gabrieletienne2009@hotmail.com.

Case presentation: A 60-year-old woman presented with recurrent rotatory vertigo, recent short-term memory loss, severe ataxia, fecal and urinary incontinence, and mild decline in sensorium starting 2 years prior to admission. One year before, she experienced an acute episode of binocular diplopia, left-sided eyelid ptosis and superior rectus muscle paralysis, followed by spontaneous improvement, and another episode of right hemiparesis. She denied previous joint pain or swelling. Neurological examination revealed ataxic gait, torsional nystagmus on left gaze, right hemiparesis, dysarthria, bilateral hyperreflexia with clonus, and a Mini-Mental State Examination score of 28. Laboratory tests were negative for antinuclear antibodies, ANCA, anti-dsDNA, anticardiolipin antibodies, anti-Ro, anti-La, anti-HIV, syphilis, IgG4, anti-HCV, and HBsAg. However, there were slightly elevated levels of anti-CCP (7.70) and rheumatoid factor IgM (5.9, with normal <5), and an elevated erythrocyte sedimentation rate of 46 mm/hour. Cerebrospinal Fluid Analysis revealed elevated protein levels, lymphocytic pleocytosis, and cerebral MRI indicated pachymeningeal and leptomeningeal enhancement, diffusion restriction in the left corona radiata, and lacunar ischemic infarcts in splenium of the corpus callosum, corona radiata, basal ganglia, thalamus and pons bilaterally. Angio MRI and Black Blood MRI showed no vascular abnormalities. **Discussion:** Rheumatoid arthritis (RA) can manifest in the central nervous system as compressive myelopathy from atlantoaxial dislocation, subdural hematoma, hyperviscosity syndrome, rheumatoid meningeal nodules or choroid plexus infiltration, pachymeningitis, leptomeningitis, and rarely cerebral vasculitis. Neurological signs of pachymeningitis and cerebral vasculitis can include focal deficits, epilepsy, cranial nerve involvement, headaches and altered mental status. CSF analysis in meningeal involvement may reveal mild lymphocytic pleocytosis and elevated protein, along with characteristic MRI findings of leptomeningeal or pachymeningeal enhancement, among 28 reviewed case reports, five described patients initially presenting with pachymeningitis symptoms as the first clinical manifestation of the autoimmune disease. Cerebral vasculitis typically affects those with long-standing, active, and erosive disease, MRI findings often include multiple bilateral ischemic lesions affecting cortical and subcortical regions and Anti-CCP, rarely studied in published case reports, tends to be positive, even at low titers. This case underscores the diagnostic challenge posed by these two rare neurological complications of RA. **Final comments:** Diagnosing cerebral vasculitis or pachymeningitis due to RA is challenging due to their rarity and limited literature. This case highlights their potential as initial presentations of RA, emphasizing the importance of early recognition and appropriate management.

https://doi.org/10.5327/CBN240333

Cerebral venous thrombosis as a cause of subarachnoid hemorrhage and thunderclap headache: a very uncommon presentation

Amauri Pereira da Silva Filho[1], Danielle Cortellazzi Colonna Romano[2], Gabriela Yumi Nakamura[2], Melissa Fernandes Vilela de Freitas[2], Sabrina Borges Batista[2], Taianara Sampaio Reis[3], Natália Rebeca Karpejany[3]

[1]Hospital de Emergência e Trauma Dom Luiz Gonzaga Fernandes, Campina Grande PB, Brazil.
[2]Universidade Nove de Julho, São Paulo SP, Brazil.
[3]Universidade Federal do Piauí, Teresina PI, Brazil.

Correspondence: Amauri Pereira da Silva Filho; Email: amauri.filho@yahoo.com.br.

Case presentation: Patient, female, 34-year-old arrived at the ER with a sudden and severe headache, described as the worst pain of her life, with visual blurring, nausea and vomiting, mental confusion, and disorientation. With fair general condition, with normal respiratory and cardiovascular functions, blood pressure: 150/80, no pathological history, and had been regularly taking oral anticoagulants (OAC) for the past 9 years. She had a Glasgow Coma Scale score of 14, isocoric pupils, photoreactive, without appendicular deficits, slight convergent strabismus, with right VI nerve palsy, and neck stiffness +2/+5. A syndromic diagnosis of headache was made, with subarachnoid hemorrhage (SAH) as the main hypothesis. A non-contrast CT scan showed a spontaneous SAH classified as Fisher 2. Angiography revealed no arterial vascular lesions and/or AVM. Venous study showed a significant filling defect in the superior sagittal sinus at the level of the confluence of sinuses. The diagnosis of cerebral venous thrombosis (CVT) was concluded in a patient initially presenting with SAH. **Discussion:** CVT is a neurovascular disease caused by a thrombotic occlusion of either a dural sinus or cerebral vein, and results in a variety of neurological symptoms. CVT can manifest as a single symptom, most common being headache, or it can present as a syndrome. The non-specific clinical picture makes diagnosing CVT difficult. Although the mortality rate of CVT has been significantly reduced by improvements in treatment and diagnostic techniques. The priority of treatment in the acute phase is to stabilize the patient's condition and to prevent or reverse cerebral herniation, surgical removal of the haemorrhagic infarct, or decompressive hemicraniectomy. Another option is anticoagulation with heparin. However, there is a risk to become a SAH. It is a neurologic emergency due to bleeding into the subarachnoid space and is a severe subtype of hemorrhagic stroke associated with a high risk of mortality (can reach 50%) and disability. The clinical presentation is most often in the form of headache, classically defined as maximal at onset and worst of life. It is uncommon for patients to have thunderclap headache (TCH), known as an excruciating headache that reaches maximal intensity within a minute. The principal etiology is SAH. Thus, patients with TCH must be evaluated urgently to identify the underlying cause and initiate prompt therapy. **Final comments:** CVT associated with SAH and ICH is an atypical pathology that requires early diagnosis and treatment. To reduce mortality, anticoagulation, patient stabilization, and multidisciplinary management alleviate symptoms and improve the severe prognosis. It is crucial to raise awareness among healthcare professionals for early diagnosis, and there is a need for more effective new therapeutic strategies in cases of thunderclap headache.

https://doi.org/10.5327/CBN240334

Cerebral venous thrombosis associated with the use of testosterone implant: a case report

Caroline Zapelini[1], Lia Maki Hatisuka Imai[1], Bruna Beppler[1], Adria Rodrigues da Silva[1], Luis Sidonio Teixeira da Silva[1], Lucio Baena de Melo[1], Gabriel Rodrigues Espelho Rossi[1], Maria Caroline Martins de Araujo[1]

[1]Universidade Estadual de Londrina, Londrina PR, Brazil.

Correspondence: Caroline Zapelini; Email: zapelinicarol@gmail.com.

Case presentation: A 39-year-old female patient presented to a tertiary hospital due to a generalized tonic-clonic seizure lasting seconds, without sphincter release, and post-ictal drowsiness. The seizure was preceded by holocranial headache. The patient was previously healthy and denied any previous episodes. She reported starting testosterone implant therapy a week ago to enhance sports performance. She denied smoking. Neurological examination revealed no abnormalities. Laboratory tests at admission showed no alterations, and serologies were non-reactive. A CT brain revealed thrombosis of the superior sagittal sinus and bilateral fronto-parietal vein thrombosis, confirmed by a cranial CT angiography. Anticoagulation therapy was initiated, along with investigation for thrombophilias. Testing for factor V Leiden, prothrombin gene mutation, protein S and C, antithrombin, lupus anticoagulant, anti-beta2-glycoprotein, anticardiolipin, and homocysteine were negative. However, the testosterone level was 175 - reference value: 56. **Discussion:** Cerebral venous thrombosis (CVT) represents a diagnostic challenge, given its variability in clinical manifestations and low incidence among stroke cases. It occurs more often in women of reproductive age. The most commonly affected venous sinuses are the superior sagittal sinus and the transverse sinus, with the involvement of multiple veins being common. The etiology is related to hypercoagulability and there are various predisposing factors such as pregnancy, oral contraceptive use, postpartum period, thrombophilias, neoplasms, and autoimmune diseases. Additionally, the use of testosterone for aesthetic purposes, in high doses, is associated with an increased risk of CVT, especially in the early months of use, as seen in the reported case. This leads to an increase in red blood cell production, resulting in blood viscosity and hypercoagulability. Due to the vast etiology, other causes should be investigated, such as thrombophilias, which increase the risk of recurrence. In the reported case, a thorough investigation was conducted, ruling out other etiologies. Treatment should involve anticoagulation, with the duration varying between 3 months and one year depending on the transient or chronic nature of the risk factors. **Final comments:** The report presents a case of cerebral venous thrombosis associated with the use of testosterone. In light of this case, it is important to highlight the risks of testosterone supplementation in unindicated contexts and the role of health education in guiding the population.

https://doi.org/10.5327/CBN240335

Cerebral venous thrombosis due to ChadOx1-s vaccine against COVID-19: pitfalls of VITT syndrome and response to factor-X inhibitors

Alexandre Kreling Medeiros[1], Marciéli Gerhardt[1], Fernanda Schuh Martins[1], Gabriela Heiden Telo[1], João Eduardo Tonini Bastianello[1], William Alves Martins[1]

[1]Hospital São Lucas, Porto Alegre RS, Brazil.

Correspondence: Marciéli Gerhardt; Email: marcieligerhardt@yahoo.com.br.

Case presentation: We report a previously healthy 24-year-old female who developed severe headache 5 days after vaccination with ChadOx1 nCOV-19. She had no viral symptoms and her PCR for COVID-19 was negative. At this time, she had severe thrombocytopenia (26.000/mm^3) and high levels of D-dimer. Initial CT and MRI of the head showed no sinus thrombosis. Nevertheless, her headache continued to progress, accompanied now by persistent vomiting. Two days later, she had two generalized tonic-clonic seizures and was transferred to our institution. At admission, she was dysnomic but readily responsive and alert, maintaining headache and recurrent vomiting. Head-CT revealed extensive bleeding in the left posterior temporal lobe. Additional exams showed high levels of D-dimer (30.871) and low fibrinogen levels. The diagnosis of Vaccine-Induced Immune Thrombotic Thrombocytopenia (VITT) was immediately considered. A CT venography scan confirmed extensive venous thrombosis involving the left sigmoid and transverse sinuses extending to the left internal jugular vein. Screening for other thrombophilias turned out negative. After considering the risk of worsening the hemorrhagic infarct with anticoagulation with heparinoids, apixaban 5mg BID was introduced. Treatment with IVIG (0.4g/kg/d for 5 days) was immediately started alongside with prednisone (1mg/kg/d). Nevertheless, on the second day of ICU her consciousness deteriorated, and an urgent CT scan showed an increase in intraparenchymal cerebral hemorrhage with global edema. Mannitol was then associated, with the other therapies being maintained, including anticoagulation. She had a neurological improvement in the ensuing days, being discharged from the ICU 5 days after. Follow-up MRI venography showed complete recanalization of the affected cerebral venous sinuses. **Discussion:** COVID-19 vaccine complications are known for rare cases of thrombocytopenia and thrombosis, mostly in cerebral venous sinus or splanchnic veins. This syndrome is called VITT and encompasses thrombocytopenia, high levels of D-dimer, low fibrinogen titles, and high level of antibodies to PF4–polyanion complexes. It has shown remarkable resemblance with heparin-induced thrombocytopenia, including presence of PF4-antibodies in almost all reported cases. Early and aggressive treatment decision in terms of anticoagulation for treating this condition is critical and deals with an expected increased mortality associated with enlargement of superimposed hemorrhage and ischemic injury. Although up-front treatment remains anticoagulation and IVIG, the effective onset time to treat with IVIG and other alternatives such as plasma exchange, which is suggested for refractory VITT, is still unclear. **Final comments:** Our case report shows that maintaining anticoagulation combined with IVIG therapy despite intraparenchymal hematoma expansion may lead to a favorable neurological outcome in VITT syndrome.

Cerebral venous thrombosis following lumbar puncture: case report and considerations

Adriana Alves Rapp[1], Julia Cordeiro Braga[1], Renan Carvalho Castello Branco[1], Brenda Francisca Cardoso Brito[1], Victor Xavier da Silva[1], Camila Maria Barreto Ribeiro[1], Paulo Ricardo Sampaio de Melo[1], Filipe Nolasco de Souza e Silva[1], Lucas Vergne Cheade Lins[1], Marcel Leal Ribeiro[1]

[1]Hospital Santa Izabel, Salvador BA, Brazil.

Correspondence: Adriana Alves Rapp; Email: adrianarapp15.2@bahiana.edu.br.

Case presentation: A 34-year-old healthy female underwent spinal anesthesia for myoma embolization. Postoperatively, she developed a subacute, moderate headache that worsened when upright. Initially diagnosed with post-puncture headache, she received conservative treatment with partial relief. After two weeks, she returned to the emergency department due to worsening headache (rated 10/10) and vomiting, again worsened by standing. Hospitalized for a blood patch procedure, she experienced mild improvement. However, the headache persisted, now without a postural component. A neurologist consulted, and a brain computed tomography angiography (CTA) revealed extensive cerebral venous thrombosis (CVT) in the superior sagittal sinus. She returned to the emergency department for further investigation and management. She was not taking oral contraceptives and had no family history of thrombotic events, thrombophilias, or cancer. On admission, she was alert, oriented, and had no neurological deficits. Parenteral anticoagulation with enoxaparin was administered for five days, followed by dabigatran. She remained stable and was discharged with good pain control. Tomography and MRI revealed no ischemic areas or intracranial bleeding. **Discussion:** Post-puncture headache affects about 11% of patients after lumbar puncture (LP). While usually benign, cases have shown potential progression to iatrogenic intracranial hypotension with CVT, accounting for up to 2% of CVT cases. This association aligns with the Monroe-Kellie doctrine, where a reduction in cerebrospinal fluid volume leads to compensatory dilation and distortion of venous sinuses due to brain traction, increasing venous

stasis and predisposing to thrombus formation. A transcranial Doppler study showed a 50% reduction in superior sagittal sinus flow velocity post-LP, supporting this theory. Some cases suggest additional risk factors for CVT, questioning the isolated causal role of LP. Literature reviews indicate most individuals present with typical post-puncture headache symptoms, then experience a change in headache pattern, as observed in this patient. **Final comments:** Evidence is insufficient to support LP as an isolated CVT risk factor. However, the growing number of case reports and biological plausibility suggest heightened suspicion for CVT in patients with headache and alarm signs post-LP, particularly with known thrombotic risk factors. Conversely, it is necessary to actively investigate potential pathologies that predispose to CVT in those without risk factors.

Cerebral venous thrombosis secondary to protein s deficiency: a case report

Bibiana Mayer[1], Chadi Emil Adamo[2]

[1]Universidade de Ribeirão Preto, Ribeirão Preto SP, Brazil.
[2]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Chadi Emil Adamo; Email: neurochadi@outlook.com.

L.A, male, 24 years old, anabolic steroid user, presented with a sudden episode of generalized motor dysperceptive crisis one year ago. He underwent a cranial MRI, which showed an extra-axial area of hyperintensity on T2 and hypointensity on T1 in the vicinity of the posterior and bilateral insula, more evident on the left than on the right, with some foci of diffusion restriction. A few days after the episode, hemorrhagic transformation was observed on the left, and he underwent drainage of the extra-axial hematoma. Several months after the episode, a venous phase arteriography was requested, which revealed thrombosis of perisylvian cortical veins bilaterally with partial recanalization. Subsequently, the patient presented with epileptic seizures nosologically categorized as non-dysperceptive and non-motor, focal, with pars opercularis syndrome, characterized by brief motor aphasias lasting seconds. The electroencephalogram indicated an epileptogenic focus with downward reversal in the T5 region. The patient also phonemic paraphasia errors, with increased effort for proper articulation. The following tests were performed: Laboratory tests: Hemoglobin 16.06 | Platelets 199,400 | Beta 2 glycoprotein 1 IgG 1.4 IgM 1.1 | Complement C3 177/ C4 29.0 | Homocysteine 8.91 | Anticardiolipin IgG 2.3 and IgM 9.4 | Lupus Anticoagulant 1.19 and 1.31 | Prothrombin Gene Mutation G2A21A negative | Functional Protein S 36% | Protein C Resistance negative | Factor V Leiden Mutation negative | Coagulation time for extrinsic, intrinsic, and common pathways within normal range. The protein S tests were repeated, as well as the quantitative value, and protein S deficiency was documented. Therefore, apixaban 5mg every 12 hours was chosen, and phenytoin was replaced with lamotrigine 300 mg/day due to memory complaints. The patient showed a satisfactory response. In this context, a diagnosis of cortical venous thrombosis with hemorrhagic complication was admitted. As a sequela, the patient developed language errors and epilepsy secondary to structural alteration. The most probable cause in this context is protein S deficiency. Additionally, the patient has a family history of thrombosis in his mother at the age of 20 and a sister with a previous miscarriage. Cerebral venous thrombosis accounts for 0.5% to 3% of all strokes. The most vulnerable populations include young individuals, women of reproductive age, and patients with a prothrombotic state. Predisposing factors for cerebral venous thrombosis (CVT) include oral contraception and hormonal therapies which can increase CVT risk nearly 8-fold, with obesity possibly adding synergistic effects. Other well-established risk factors are acquired thrombophilias (like antiphospholipid antibody syndrome), malignancies (particularly myeloproliferative disorders), autoimmune diseases and genetic thrombophilias (such as protein C and protein S deficiency, factor V Leiden, and prothrombin G20210A polymorphism).

Cerebrospinal fluid AD biomarkers in patients with suspected normal pressure hydrocephalus

Vinícius Ribeiro Jeunon[1], Isabela Resende Silva[1], Vinícius Tinarelli Silva[1], Stephanny Pinto de Oliveira Lima[1], Jessica Abdo Gonçalves Tosatti[1], Jessica Diniz Pereira[1], Karina Braga Gomes Borges[1], Paulo Caramelli[1], Leonardo Cruz de Souza[1], Elisa de Paula França Resende[1]

[1]Universidade Federal de Minas Gerais, Belo Horizonte MG, Brazil.

Correspondence: Vinícius Ribeiro Jeunon; Email: vjeunon@hotmail.com.

Background: Alzheimer's disease (AD) and idiopathic Normal-Pressure Hydrocephalus (iNPH) are conditions that affect the elderly. AD and iNPH share several clinical features, which makes the differential diagnosis difficult. Additionally, the co-occurrence of neurodegenerative disease is controversial and may compromise the effectiveness of the ventriculoperitoneal shunt response. The detection of AD biomarkers in the cerebrospinal fluid (CSF) may be a possible resource to help distinguish these two conditions. **Objective:** To investigate and describe the profile of CSF AD biomarkers in patients with iNPH in a tertiary neurological service. **Methods:** We included eleven patients from an outpatient neurological service between 2022 and 2024. The inclusion criteria were the presence of at least one clinical manifestation of iNPH and the analysis of AD biomarkers in CSF. The biomarkers assessed were β-amyloid 1-42 (Aβ(1-42)), β-amyloid 1-40 (Aβ(1-40)), phosphorylated tau (p-tau), and total tau. We used the following cut-off values 1,100 pg/mL for β-amyloid 1-42 (Aβ(1-42)), >24 pg/ml for phosphorylated tau (p-tau), and >266 pg/ml for total tau to access the ATN status. We performed a descriptive statistical analysis to describe the main characteristics. The values of age and CSF biomarkers will be presented as mean ± standard deviation. **Results:** The group consisted of 63.6% men, with a mean age of 75.01±6.6 years, and a mean educational level of 11.6±6.0 years. The average time between the symptoms onset and the clinical visit was 5.1±4.6 years. The most frequent symptom was cognitive impairment (100%), followed by urinary incontinence (70.0%), and gait apraxia (63.6%). Only 54.5% of patients manifested all three symptoms simultaneously. Regarding AD biomarkers, the mean level of Aβ(1-42) was 609.2±292.3pg/mL (A-), of p-Tau was 62.6±45.3pg/mL (T+), of total tau was 348.9±45.3pg/mL (N+), and of Aβ(1-40) was 1861.39±3233.0pg/mL. Only 9.1% of patients were Aβ(1-42) positive, whereas 75% were t-tau positive, 77.8% were p-tau positive, and 100% were Aβ(1-42)/Aβ(1-40) positive. **Conclusion:** Patients with suspected iNPH that presents to a tertiary neurological unity have cognitive impairment as the most common symptom, with the classical triad in half of cases. The AD CSF biomarkers profile was overall not consistent with AD (A+) suggesting that the patients had non-AD neuropathological changes (SNAP) and maybe a good chance of responding to ventricular shunt.

Cerebrospinal fluid HIV viral escape

Bruna Andrade de Oliveira[1], Brenno Tavares de Vasconcelos Brandão[1], Filipe Britto de Matos[2], Giuliana Gonçalves Moreira Possidente[2], Marco Antonio Lima[2,3]

[1]Universidade Federal do Rio de Janeiro, Instituto de Neurologia Deolindo Couto,Rio de Janeiro RJ, Brazil.
[2]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.
[3]Fundação Oswaldo Cruz, Rio de Janeiro RJ, Brazil.

Correspondence: Bruna Andrade de Oliveira; Email: brunaado97@gmail.com.

Case presentation: A 53-year-old woman, diagnosed with HIV infection two years ago and pulmonary tuberculosis at the same time and treated properly presented to the infection diseases clinic with memory difficulties and slowness in thinking, that had begun around one year and a half ago and remained despite the antiretroviral treatment for approximately a year. Her last blood HIV load was 30 copies/mL and T cell CD4+ count of 166 cells/mm^3. A brain MRI two months ago showed extensive areas of high signal on T2 and FLAIR diffusely distributed throughout the white matter, notably in the semiovale centrum, corona radiata and non-specific periventricular regions. She was admitted for investigation one month later, when she underwent a new MRI and lumbar puncture. Neurological examination showed cognitive dysfunction without focal deficits, but neuropsychological assessment was not available. Her MRI showed an increase in the areas of high signal on T2 and FLAIR, hippocampi with preserved signal and slightly reduced dimensions (MTA 2), and prominent cortical grooves, fissures and brain cisterns. The cerebrospinal fluid (CSF) results were: glucose 56 mg/dL, protein 50,4 mg/dL, cell count 12 white cells/mm^3 (all mononuclear), VDRL negative, CRAG negative and GeneXpert test for tuberculosis negative. The viral load in CSF was 8.960 copies/mL. The neurological findings associated with the neuroimaging pattern and the CSF HIV load exceeding the plasma HIV load were indicative of CSF viral escape leading to HIV encephalopathy. The antiretroviral drugs were changed to optimize treatment. **Discussion:** Encephalopathy is a common complication of HIV infection and should be suspected in the presence of cognitive dysfunction associated with brain atrophy and bilateral diffuse white matter abnormalities on brain MRI. The treatment consists in prompt administration of antiretroviral therapy in patients who have not yet started or were abandoning treatment or changing the antiretroviral regimen in those who do not have adequate control of the disease. An important issue is the best course of action in patients with cognitive complaints despite low or undetectable plasma viral load in good use of adequate antiretroviral treatment. Patients living with HIV presenting with new onset neurological symptoms and low or undetectable viral load in plasma benefit from the analysis of viral load in cerebrospinal fluid to assess CSF escape. CSF escape is a rare but important phenomenon because the antiretroviral treatment can be optimized based upon drug susceptibility and penetration in the central nervous system, leading to better outcomes. **Final comments:** When HIV encephalopathy is suspected in patients with a low or undetectable plasma viral load, it is imperative to assess the CSF viral load to search for CSF viral escape.

Cerebrospinal fluid hypotension presenting atypically and with different types of headache: a case report

Apolônio Peixoto de Queiroz[1], Alex Tiburtino Meira[1], Rafael de Souza Andrade[1], Gilmar Leite Pessoa Filho[1], Ana Luísa Castelo Branco Gomes[1], Silvia Helena de Sousa Silva[2], Gabrielly Lopes Rodrigues[2], Yan Carlos de Sousa Diniz[2], Maira Monteiro Amorim[2], Joan Ravy Sousa Lacerda[2]

[1]Hospital Metropolitano Dom José Maria Pires, João Pessoa PB, Brazil.
[2]Centro Universitário de Patos, Patos PB, Brazil.

Correspondence: Apolônio Peixoto de Queiroz; Email: apolopxq@gmail.com.

Case presentation: Female patient, 68 years old, hypertensive and without other comorbidities, presented clinical signs of cognitive impairment and headache. The clinical history began with forgetfulness and inattention in the last year. This was followed, months later, by orthostatic thunderclap headache and then mild motor incoordination with gait imbalance. In the last three months the headache pattern has changed, becoming mild, restricted to the occipital region, unrelated to position, described as a pressure-like pain, relieved by simple analgesics and worsening with the Valsalva maneuver. She was seen in an outpatient clinic, where anxiety, mild dysarthria, dysexecution on the clock test and dysmetria in the left leg were noted on neurological examination. Neuraxial magnetic resonance imaging (MRI) revealed typical signs of hypotension in the cerebrospinal fluid (CSF). Caffeine 300mg/day was started, resulting in small improvement. Cisternal scintigraphy did not locate any fistula. Empirical blood patching was performed. After the procedure and in outpatient follow-up appointments, she reported no headaches, with improvement in cognitive symptoms, according to family members. Post-procedure neurological examination showed improvement in gait, appendicular ataxia and cognitive tests. **Discussion:** Hypotension is a disorder of intracranial pressure, often caused by CSF leakage due to a fistula, which may be traumatic, spontaneous, or iatrogenic. The typical clinical presentation is an orthostatic headache. This patient initially presented cognitive symptoms, with a predominance of executive dysfunction, only later rising a typical headache but which changed its pattern, going from initially orthostatic and thunderclap to tension-type headache, unrelated to orthostasis. She denied any mild head trauma. Magnetic resonance imaging (MRI) of the neuraxial and cisternal scintigraphy were performed, which demonstrated classic signs of CSF hypotension: caudal descent of the cerebellar tonsils beyond the margins of the foramen magnum and extra-axial lamellar subdural collections in the convexities of the cerebral hemispheres, but not the possible leak site. After a joint clinical decision between neurology and neurosurgery teams, she underwent empirical blood patching with a clear improvement in all symptoms. **Final comments:** This case emphasizes the presence of different types of headache as a symptom of CSF hypotension, reinforcing the possibility of atypical clinical presentations even in the face of typical imaging findings. Furthermore, the patient's positive evolution highlights the importance of a rapid diagnosis, a multidisciplinary approach and adequate management in cases of CSF hypotension, ensuring a significant improvement in the quality of life of affected patients.

Cerebrotendinous Xanthomatosis: electrophysiological and ultrasonographic characterization in a Brazilian study

Antonio Edvan Camelo Filho[1], Pedro Lucas Grangeiro Sá Barreto Lima[1], Paulo Ribeiro Nóbrega[1], Pedro Braga-Neto[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Antonio Edvan Camelo Filho; Email: edvan.camelo@gmail.com.

Background: Cerebrotendinous Xanthomatosis (CTX) is a rare autosomal recessive lipid-storage disorder related to bile acid biosynthesis pathways with pathogenic variants in CYP27A1. It leads to the increased formation and storage of abnormal lipid content, mainly cholestanol, in several tissues, especially tendons, eye lenses, and peripheral and central nervous systems. CTX has been recently recognized as a considerably underdiagnosed disease, a fact that might be related to a highly heterogeneous clinical presentation with a wide range of symptoms, severity, and age of onset. Peripheral neuropathy is a frequently reported and disabling feature of CTX. Assessing the peripheral nervous system plays a crucial role in the diagnosis and the ongoing monitoring of CTX. Peripheral nerve ultrasound is a valuable tool for diagnosing and monitoring hereditary neuropathies, but little is known regarding CTX. Recently, nerve enlargement was shown in one case report and one case series of 4 patients in CTX. **Objective:** To describe the patterns and extent of peripheral nerve involvement in Brazilian patients with CTX using nerve ultrasound, EMG, clinical manifestations, and laboratory biomarkers. **Methods:** Included in this study were 5 genetically diagnosed patients. The participants have been examined and received electrophysiological work-up, including NCS and nerve ultrasound, accordingly to a published protocol with a high-resolution probe (15 MHz linear probe, GE Logiq). Nerve ultrasound covered peripheral nerves on the right body site (median, ulnar, tibial, fibular, and sural nerve, as well as the C5 and C6 nerve roots and supraclavicular plexus), assessing the cross-sectional area (CSA) of peripheral nerves. **Results:** Of the 5 patients evaluated, the average age was 31.2 years, with an average diagnostic delay of 21.2 years, and a male-to-female ratio of 3:2. Four out of 5 (80%) of the patients presented with xanthomas. All patients had either sensory or motor complaints in the lower limbs, but only 2 of 5 (40%) had a polyneuropathy on EMG. All polyneuropathies were demyelinating (100%). All patients, including those with normal electroneuromyography, showed thickening of at least 1 nerve evaluated, with the supraclavicular plexus and median nerve at the elbow being the most accurate. **Conclusion:** CTX is an important condition to recognize and should be included in the differential diagnosis of any neuropathy of unknown etiology, even in patients without xanthomas. It is a treatable condition with chenodeoxycholic acid (CDCA), which inhibits cholestanol accumulation by reducing bile acid production. Our findings show the presence of proximal nerve enlargement in patients of CTX even before changes in EMG. Nerve ultrasound emerges as a promising biomarker for early disease progression detection and monitoring and establishing standardized endpoints for future clinical trials in CTX and other hereditary neuropathies.

Cerebrovascular diseases by place o death: investigating associated factors and trends in an ecological time series study

Victor Hugo Palhares Flávio-Reis[1], Yago Marcos Pessoa-Gonçalves[1], Chamberttan Souza Desidério[1], Marlos Aureliano Dias-Sousa[2], Carlo José Freire Oliveira[1]

[1]Universidade Federal do Triângulo Mineiro, Instituto de Ciências Biológicas e Naturais, Laboratório de Imunologia e Bioinformática, Uberaba MG, Brazil. [2]Universidade Federal do Triângulo Mineiro, Hospital de Clínicas, Departamento de Neurologia, Uberaba MG, Brazil.

Correspondence: Yago Marcos Pessoa-Gonçalves; Email: yagompg98@gmail.com.

Background: Cerebrovascular diseases (CD) have been described as one of the leading causes of mortality today. An important factor associated with this spectrum of diseases is the location where the patient dies. This outcome is underexplored in the literature and deeply connected to several determinants such as the response time of emergency medical services, sociodemographic factors that influence the pursuit and access to emergency medical care, and disparities in transportation availability between urban and rural areas in accessing healthcare services, among others. **Objective:** To analyze deaths by CD based on the location of patient death and examine the factors and trends associated with this issue. **Methods:** This is an ecological time-series study. Data on the place of death were obtained from the National Mortality Information System, with sociodemographic variables analyzed for the period from 1996 to 2022. Data for determining the number of deaths per 100.000 inhabitants were obtained from the Brazilian Institute of Geography and Statistics. Subsequently, the data were tabulated using Microsoft Excel version 2309 from 2019, and statistical analyses were conducted using GraphPad Prism version 8.0.0 and Joinpoint Trend Analysis Software version 5.2.0. **Results:** A total of 2,565,168 deaths from CD were recorded in Brazil between 1996 and 2022. The majority (44.2%) were caused by stroke. 80.9% took place in hospitals and other health establishments, 16.9% at home and public places represented 0.45%. The analysis showed a statistically significant decreasing trend in the number of deaths in hospitals and other health establishments over the years (Tau = -0.276, p=0.04536). The federative unit with the highest number of hospital deaths per 100,000 inhabitants was Rio de Janeiro, with 57 deaths per 100.000 inhabitants. The state with the highest number of home deaths was Piauí, with 23 deaths per 100.000 inhabitants. Individuals aged 80 years or older presented the highest mortality rates in hospitals (787/100.000 inhabitants), households (32/100.000 inhabitants), and in public roads (2/100.000 inhabitants). Individuals with 9 to 11 years of education represented 0.3% of deaths, while individuals with no education represented 20% of deaths. Finally, regarding race, the Black population showed the highest mortality rate in hospitals (42/100.000 inhabitants), while Asians presented the highest mortality rate at home (8/100.000 inhabitants). **Conclusion:** It is concluded that the majority of deaths occur in hospitals, but a considerable number of deaths occur in other locations, such as at home. Black men aged 80 years or older, with low educational attainment, and residents of states in the southeastern region of Brazil accounted for the majority of deaths due to stroke in hospitals. Therefore, further studies need to be conducted to better elucidate the relationships between deaths and the place of death of patients.

Cervical and dorsal pain are more prevalent in individuals with headache: preliminary data from a Brazilian cohort

Fabíola Dach[1], Heloisa Betiol[1], Viviane Cunha Cardoso[1], Marco Antônio Barbieri[1]

[1]Universidade de São Paulo, Faculdade de Medicina de Ribeirão Preto, Ribeirão Preto SP, Brazil.

Correspondence: Fabíola Dach; Email: fabioladach@usp.br.

Background: Studies show the existence of comorbidity between headaches and other painful conditions. Patients with headaches are twice as likely to report musculoskeletal pain than those without headaches. Another study showed that 83% of headache patients have neck pain, with high frequency and moderate intensity. The factors involved in the comorbidity between painful conditions are obesity, physical inactivity, anxiety, depression, stress, occupational factors, and genetic factors. **Objective:** To verify the prevalence of pain in another topographies in individuals with headache, whether there is an association between pain in other topographies and the presence/frequency (episodic/chronic) of headache, and to check if there is correlation between the frequencies of pain in another topographies and headache. **Methods:** An analytical and descriptive study from a cohort of live births (1978/79) in Ribeirao Preto/SP. The variables of interest were: presence/frequency of headache in the last three months. Pain in another topography and the place of greatest pain considering the last three months. The regions were separated: cervical, dorsal, lumbar, upper limbs, lower limbs, abdomen, thorax and pelvis. **Results:** 1775 individuals attended this interviewed (average age:38.13±0.579, 52.3% female). Sixty three percent reported headache in the last 3 months (16.3% chronic headaches). Among patients with headaches, 51% had pain in another topography. Among patients with headache and pain in another topography, pain in the cervical

region was observed in 12.1%, dorsal region in 8.7%, lumbar region in 37.4%, upper limbs in 8.7%, lower limbs in 24.6%, abdomen in 3.2%, chest in 0.9% and pelvis in 4.4%. There was an association between headache and pain in another topography [X2(1)=21.743, p=0.001], with the cervical (82.9% versus 17.1%) and dorsal (79% versus 21%) regions being more prevalent among individuals with headache [X2(7)=17.778, p=0.013]. There was an association between pain in another topography and chronic headache [X2(1)=5.079, p=0.024]. There was no correlation between the frequencies of headache and pain in another topography (rs=0.165, p<0.001). **Conclusion:** The prevalence of pain in another topography was 51% among individuals with headaches. An association was observed between pain in another topography with headaches and chronic headaches. Pain in the cervical and dorsal regions was significantly more prevalent in individuals with headaches. There was no correlation between the frequencies of pain in another topography and headache.

Cervical compressive myelopathy due to ossification of the posterior longitudinal ligament: a case report

Rayanne Pereira Mendes[1], Saulo Barros Teixeira[1], Marco Túlio Sette dos Santos[1], Atilio Gomes Romani[1]

[1]Faculdade de Medicina do ABC, Santo André SP, Brazil.

Correspondence: Rayanne Pereira Mendes; Email: rayannepmendes@gmail.com.

Case presentation: A 63-year-old female patient presented with a six-month history of progressive motor weakness and sensory alteration in all four limbs, worse on the left side. She was admitted to the hospital following a fall from standing height, which worsened her pre-existing symptoms. On admission, she was alert and oriented in time and space, with mildly asymmetric spastic tetraparesis: motor strength was grade 3 in the left upper limb, grade 2 in the left lower limb, and grade 4 in the right side, with no other neurological abnormalities. Cervical spine MRI showed extensive calcification of the posterior longitudinal ligament, causing cervical canal stenosis from C2 to C6, extending over 5.5 cm, most notably at C4-C5 with over 50% stenosis, and associated with a signal alteration in the spinal cord at C4-C5. The diagnosis was Cervical Compressive Myelopathy due to Ossification of the Posterior Longitudinal Ligament. The patient underwent C3-C4-C5-C6 laminoplasty with immediate postoperative improvement in motor potentials and long-term segmental strength improvement. **Discussion:** Ossification of the posterior longitudinal ligament occurs as heterotopic bone forms in the posterior longitudinal ligament, resulting in neural compression, myelopathy, and radiculopathy, most commonly in the cervical spine. It is more frequent in East Asian populations, with prevalence rates of 1.9% to 4.3% reported in Japan, and is rare in other populations, with prevalence ranging from 0.1% to 1.7%. Patients with neurological symptoms may require surgical decompression. Cervical laminoplasty and laminectomy are two surgical approaches used to treat spinal cord compression often caused by spinal stenosis, herniated discs, or other degenerative pathologies. Cervical laminoplasty involves reconstructing the lamina, a bony part of the spine, to widen the spinal canal and relieve pressure on the spinal cord and nerves, preserving vertebral structure and stability, being less invasive, and potentially offering faster recovery and lower long-term deformity risk. It is more suitable for patients needing multisegmental decompression. Laminectomy may be preferred when complete removal of the lamina is necessary to relieve symptoms. **Final comments:** In cases of progressive spastic tetraparesis, cervical spine MRI is crucial for diagnosis and treatment planning, with Ossification of the Posterior Longitudinal Ligament being a condition to consider, especially in extensive longitudinal lesions. Proper surgical technique can provide a good prognosis.

Cervical dural arteriovenous fistula presenting as acute extensive longitudinal transverse myelopathy: a case report

Camila Lorenzini Tessaro[1], Catarina Dantas Corrêa[1], Gustavo Figueiredo da Silva[1], Henrique Lacerda Lage Lopes de Oliveira[1], Maria Cláudia Hahn Ferrucio[1], Luana Antunes Maranha Gatto[1], Paulo José Lorenzoni[1], Caio César Diniz Disserol[1], Marcos Christiano Lange[1]

[1]Universidade Federal do Paraná, Curitiba PR, Brazil.

Correspondence: Catarina Dantas Corrêa; Email: catarinadcorrea@gmail.com.

Case presentation: A 20-years-old female with no known comorbidities presented with ascending paresthesias in the lower limbs associated with progressive gait impairment, evolving into wheelchair-bound over 45 days. She was admitted to another hospital and discharged without specific investigation or treatments, with the hypothesis of Guillain-Barré syndrome, because she partially improved and regained the ability to walk with support. After five days the patient experienced acute tetraplegia, T2 sensory level, dysphonia, dysphagia, and urinary incontinence. She was admitted at our hospital for investigation. Due to bulbar symptoms and signs of respiratory failure, the patient was intubated and transferred to the Intensive Care Unit. Brain CT revealed hypoattenuation of the cervical spinal cord, and cranial and cervical CT angiography revealed sigmoid sinus thrombosis associated with venous engorgement in the posterior fossa and around the cervical spinal cord. Spinal cord MRI showed extensive longitudinal transverse myelopathy from the medulla to T1 level, and prominent flow voids along the cervical and thoracic spinal cord segments. Serum and CSF analysis were normal. Anti-aquaporin 4 antibodies were negative. Digital angiography diagnosed and treated a dural arteriovenous fistula supplied by the middle meningeal, occipital, and pharyngeal arteries, draining into the sigmoid sinus. The fistula was successfully embolized without complications. The patient remains under intensive care with partial improvement. **Discussion:** Spinal dural arteriovenous fistulas (SDAVFs) are the most common type of vascular malformation affecting the spinal cord. They usually occur spontaneously but can be secondary to cerebral venous thrombosis. Due to venous congestion and edema a progressive myelopathy may occur, which can mimic polyneuropathy/radiculopathy due to the ascending motor and sensory symptoms. This case is peculiar because acute presentations are quite rare and because the most common location for SDAVFs is the thoracic spine, while cervical locations are extremely rare. Commentary The authors report a rare case of extensive longitudinal myelopathy secondary to a dural arteriovenous fistula at the bulbocervical junction, treated by endovascular embolization.

Case presentation: Child, 11 years old, male, born in Machado - MG, in routine examinations with a pediatrician in 2022, an increase in transaminases was observed. During follow-up, laboratory changes persisted. Associate had elevated creatine phosphokinase and decreased alpha-glucosidase dosage. Genetic testing was requested, which revealed a heterozygous pathogenic variant in the GAA gene. Young man, 15 years old, male, born in Jundiaí- SP, was undergoing regular routine monitoring when he observed increased creatine phosphokinase in three consecutive doses, associated with an increase in alanine aminotransferase, aspartate aminotransferase and lactate dehydrogenase. Asymptomatic patient. A broad panel of neuromuscular diseases was carried out with the following result: two heterozygous variants in the GAA gene. **Discussion:** Pompe disease, a metabolic myopathy, is caused by mutations in the gene that codes for acid alpha-glucosidase (GAA), the enzyme that breaks down glycogen. There are two types of involvement - based on the onset of symptoms and the presence or absence of cardiomyopathy. If the disease occurs early in life, the disease manifests itself with more severe symptoms, known as classic infantile-onset Pompe disease. It is characterized by a clinical condition that begins before 12 months of life, with hypertrophic cardiomyopathy, respiratory distress, muscle weakness and left ventricular outflow obstruction. Another group of patients may have late-onset Pompe disease, which manifests itself after 12 months of life, and may have cardiac involvement, with milder consequences. The progression of symptoms is generally slower, with a poor outcome. For the treatment of the disease, enzyme replacement therapy is available - human recombinant alpha-glucosidase acid. Indicated in the first months of life for cases with early onset and in late cases but with symptoms present. **Final comments:** Currently, there are promising drug therapies capable of preventing the progression of the neurodegenerative condition when used in the early stages of the condition. It is important to highlight that treatment must be individualized as the severity of the disease varies. The progressive nature of the disease that affects the cardiac and skeletal muscles, resulting in death from respiratory insult, must be considered. It is known that starting early treatment in symptomatic patients helps preserve motor function and slow the progression of the disease. In asymptomatic carriers, the indication of drug treatment should be considered. There is still a lack of data to prove better long-term results compared to starting treatment after symptoms appear. Factors such as age, patient wishes and family must be taken into consideration. An obvious harm with early diagnosis is the psychological consequence. Knowing about the disease years before it appears can be devastating. The beginning of psychological therapy should be considered in these patients.

Case presentation: A 53-year-old female patient presented with a six-years history of progressive dysphagia, including an episode of bronchoaspiration pneumonia requiring intensive care unit admission. Slowly after the onset and progression of dysphagia, she noted an evolution of muscle weakness, with cervical involvement, distal involvement of the upper limbs and facial paresis. She was unaware of her family history because she had been adopted. Neurological examination showed grade

4 strength for cervical flexion and shoulder abduction, asymmetric grade 4 (worse on the right) for flexion of only the index fingers and hip flexion (also worse on the right); grade 1 deep tendon reflexes, with abolished achilles; paresis of orbicularis oculi and mouth, characterizing facial diparesis. Additional tests showed elevated creatine phosphokinase, myoglobin and lactate dehydrogenase. Electroneuromyography showed fibrillations and positive sharp waves in all muscles evaluated, an increased number of myopathic potentials and the presence of some repetitive complex discharges. Previous esophagography revealed digitiform narrowing in the upper third of the esophagus secondary to hypertrophy of the cricopharyngeal muscle. Considering the hypothesis of atypical presentation of inclusion body myositis, a left medial thigh muscle biopsy was requested and revealed slight endomysial fibrosis in sections stained with Gomori's trichrome, presence of degenerative fibers with influx of macrophages, fibers undergoing regeneration and endomysial lymphocyte influx, all findings compatible with the diagnosis of an inflammatory myopathy, often described in polymyositis and inclusion body myositis. **Discussion:** Inclusion body myositis (IBM) is the most frequent myopathy affecting adults older than 45 years, being more common in men. The typical clinical presentation is asymmetric and slowly progressive muscle weakness, characteristically affecting knee extensors and deep finger flexors. However, atypical forms with varying patterns of muscle weakness are recognized, including axial weakness, foot drop, isolated dysphagia, facial diplegia and proximal limb weakness. The patient presented in our case was a woman and exhibited an atypical pattern of muscle weakness. In 2024 the diagnostic criteria for IBM were revised, in order to make the diagnosis simpler and inclusive. According to the new criteria, and considering our patient, the diagnosis of IBM would be confirmed if, in addition to the atypical presentation and the mandatory biopsy finding, there were additional supporting criteria (positive anti-cN1a antibody, typical imaging pattern), both of which are limited resources in our setting. **Final comments:** IBM should always be considered as an etiology in adult-onset myopathies. Despite the premise of simplification and inclusiveness of the new criteria, there are still difficulties in confirming the diagnosis of atypical forms in our country.

Challenges in differential diagnosis of demyelinating diseases: a clinical and laboratory review and comparison of four cases

Victor Hugo de Souza Silva Gomes[1], Helen Luiza Silvestrini[2], Leticia Lage Silva[2], Albérico Rocha Lima Neto[1], Beatriz Fulador Maciel[1], Rafaella Resplande Xavier[1], Heloise Helena Siqueira Borges[1], Rhaymysom Jasmy Gomes Abreu[1]

[1]Hospital Geral de Cuiabá, Cuiabá MT, Brazil. [2]Universidade de Cuiabá, Cuiabá MT, Brazil.

Correspondence: Helen Luiza Silvestrini; Email: helensilvest@gmail.com.

Background: Demyelinating diseases are characterized by inflammation and immune-mediated attacks on components of the central nervous system (CNS), with an autoimmune, progressive, and chronic nature. The main representatives are multiple sclerosis (MS) and neuromyelitis optica spectrum disorder (NMOSD). MS is characterized by chronic demyelination with loss of oligodendrocytes and axonal damage, leading to sensory-motor deficits with variable recovery during relapse and remission phases. In contrast, NMOSD is based on the presence of AQP4-IgG autoantibodies targeting astrocytes, manifesting with severe acute episodes of optic neuritis and longitudinally extensive transverse myelitis (LETM), as well as area postrema syndrome. Due to the broad spectrum of symptoms that can mimic other conditions, differential diagnoses such as Susac Syndrome and CLIPPERS must be considered. Additionally, there is an association with systemic autoimmune comorbidities such as Systemic Lupus Erythematosus (SLE) and Sjogren's syndrome (SjS). **Objective:** To analyze the profile of patients who manifested symptoms suggestive of demyelinating diseases like MS or NMOSD and were later diagnosed with other conditions that have a similar course. **Methods:** This is an observational and descriptive study of 4 patients followed in the Neuroimmunology Outpatient Clinic. Data were obtained through medical record review and literature review, information collection, and delivery of the Informed Consent Form (ICF). **Results:** All patients were female, with an average age of 26 years, and presented clinical and neuroimaging findings compatible with the diagnostic hypothesis (DH) of CNS demyelinating diseases. All underwent pulse therapy with variable responses. Case 1 presented LETM; however, after positive ANA 1:640, Anti-SSb, and Anti-SSa antibodies, a diagnosis of Sjogren's was established. Case 2 began with headaches, hemiparesis, and decreased auditory and visual acuity, with MRI indicating callosal and pericallosal lesions, compatible with Susac Syndrome. Case 3 began with headaches, vertigo, diplopia, strabismus, and MRI showing right nucleocapsular, midbrain, pons, and cerebellum alterations, with complete remission after corticosteroids, suggestive of CLIPPERS. Case 4, already diagnosed with SLE, presented with right optic neuritis and LETM. After pulse therapy, significant recovery was noted, with AQP4-IgG negative, suggestive of neurological involvement by SLE. **Conclusion:** It is possible to verify the importance of anamnesis, neurological examination, and complementary tests, given the difficulty in establishing a diagnosis when dealing with autoimmune diseases. The difficulty patients face in accessing the required tests, which must be regular and may present false-negative results, is also highlighted. Despite the challenges, proper management of these conditions directly influences the quality of life and correct long-term treatment direction.

Challenges in managing acute hepatic porphyrias with comorbid conditions: a case series

Daniel Delgado Seneor[1], Paulo de Lima Serrano[1], João Paulo Barile[1], Kaliny Oliveira Peixoto[1], Patrícia Marques Mendes[1], Renan Brandão Rambaldi Cavalheiro[1], Igor Braga Farias[1], Wladimir Bocca V. R. Pinto[1], Acary Souza Bulle Oliveira[1], Paulo Victor Sgobbi de Souza[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Daniel Delgado Seneor; Email: danielseneor30@gmail.com.

Acute hepatic porphyrias (AHP) are rare metabolic disorders characterized by deficiencies in enzymes of the heme biosynthesis pathway, leading to the accumulation of toxic precursors. In spite of showing some chronic manifestations, these disorders typically present with acute neuropathic symptoms, exacerbated by triggers such as emotional stress, fasting, hormonal fluctuations, recreational drugs and unsafe medications. **Case presentation:** Patient 1: A 65-year-old female with hereditary coproporphyria, diagnosed at age 34. She has a history of chronic neuropathic pain and multiple comorbidities, including Tropical Spastic Paraparesis (HTLV-I) an nephrolithiasis. The patient uses tizanidine (safety profile not yet classified) and nitrofurantoin (porphyrinogenic), which may trigger porphyria attacks. Patient 2: A 58-year-old male with variegate porphyria, diagnosed at age 30. He has a history of Charcot-Marie-Tooth disease type 2P (CMT2P - LRSAM1), chronic alcohol abuse and other comorbidities. He experienced an acute porphyria exacerbation triggered by alcohol. Patient 3: A 55-year-old female with variegate porphyria, diagnosed at age 33, who is also HIV-positive. She uses lamivudine, zidovudine (both probably not porphyrinogenic, but may trigger attacks due to inappetence and nausea), and atazanavir (probably porphyrinogenic) as antiretroviral therapy. **Discussion:** Each patient's case illustrates the complexity of managing patients with AHP and superimposed conditions. Patient 1's case highlights the need to consider safety profile when choosing antimicrobial and antispastic medications. Patient 2's case shows that alcohol is an important trigger for porphyria attacks and that a concurrent unrelated cause of neuropathy may interfere with diagnosis and management of AHP. Patient 3's case demonstrates the complexities of managing such condition in HIV-positive patients, since antiretroviral medications must be chosen cautiously. Managing patients with acute hepatic porphyrias is particularly intricate when they have addiction disorders or concurrent conditions requiring pharmacological treatments, as these can exacerbate the disease. Additionally, in patients with comorbidities that cause peripheral nerve damage, distinguishing whether worsening neuropathy stems from porphyria or the coexisting condition poses a significant challenge, complicating their care. **Final comments:** This case series illustrates the multifaceted challenges presented by patients with AHP, including addiction disorders, superimposed diseases, and the use of potentially unsafe medications. Individualized patient management and thoughtful medication selection are of utmost importance for minimizing the risk of attacks, while maintaining an acceptable treatment efficacy. Continued education and awareness can improve the quality of care for these complex patients.

Challenges in the immunocompromised patient: a case of ureaplasma meningoencephalitis

Jackeline Neves Pereira[1], Clara Moreira Gonzaga[1], Luccas Almeida de Andrade[1], Guilherme Antonio Silva Ribeiro[1], Raphael Gusmao Barreto[1], João Vitor Gerdulli Tamanini[1], Gabriel Augusto Wandekoken[1], Fernanda Ferreira de Abreu[1], José Luiz Pedroso[1], Fabiano Moulin de Moraes[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Jackeline Neves Pereira; Email: jac.nevesp@gmail.com.

Case presentation: A 61-year-old male has been regularly treating HIV since 2009, with an undetectable viral load since 2010, and a T CD4+ cell count of 267/mL. He presented an acute headache, vertigo, diplopia, and ataxia, reaching the Hospital two days after the onset of the symptoms, admitted with a blood pressure of 200x120mmHg. A brain computerized tomography (CT) scan revealed a hemorrhagic stroke in the right cerebellar hemisphere. On the following day, due to obstructive hydrocephalus, brain surgery was performed for blood drainage and external ventricular shunt. The patient had a poor recovery, needed invasive ventilatory support, had fever, and a new CT revealed an ischemic area in the left occipital lobe. Cerebrospinal fluid (CSF) had a high Neutrophils and protein count, and low glucose; cultures, GRAM staining, and molecular tuberculosis testing were all negative. A brain magnetic resonance (MR) demonstrated several ischemic lesions, with true diffusion restriction, particularly along vascular border zones. The patient was empirically treated with Vancomycin, Meropenem, and later Polimixin B, without improvement. Metagenomic analysis of the CSF was positive for Ureaplasma urealyticum (UU), confirmed through Polymerase Chain Reaction (PCR). Before the final results, the patient had worsened systemic and neurological parameters and was declared dead. **Discussion:** UU is a bacteria part of the genito-urinary tract microbiota, more commonly associated with newborn central nervous system infections, with scarce literature in adults. In this case report, the patient first

had a hemorrhagic stroke, with subsequent ischemic lesions. It was extremely challenging to reason whether the hemorrhage was the first manifestation of an infectious vasculitis or a separated event from an infectious vasculitis secondary to a surgical wound complication. The patient did not respond to empirical antibiotic therapy, and the pathogen was only identified through molecular testing. All the other infectious tests, including CSF, blood, and cerebellar tissue culture, were negative. Meningitis due to UU was reported in a patient with adult-onset immune deficiency known as Good's syndrome, the diagnosis was made by Next-Generation Sequencing. In another case, a brain abscess related to UU mastoiditis in a hypogammaglobulinemia patient following Rituximab use was also reported, routine culture was negative, and the diagnosis was through 16S rRNA gene PCR. The same method was used to diagnose the first reported case of UU meningitis in an adult, a complication after a kidney transplant, published in 2008. **Final comments:** All taken together, Ureaplasma urealyticum seems to be of particular importance as a cause of encephalomeningitis in immunocompromised adults who do not respond to empirical antibiotics. It is noticeable that molecular methods, which are not ubiquitously available, play a central role in the correct diagnosis, meaning that this condition might be more frequent.

Challenging visual acuity measurement in a child with MOGAD syndrome: a case report

Jonas Leite de Souza Filho[1], Jonatas Paulino da Cunha Monteiro Ribeiro[1], Ocílio de Deus da Rocha Ribeiro Gonçalves[1], Luma Rodrigues da Silva[1], José Henrique de Melo Feitosa[1], Pedro Henrique Ximenes Ramalho Barros[1], Sabrina Ruthiele Santos de Carvalho[1], Tiago José Do Nascimento Teixeira Leite[1], Kelson James Almeida[1]

[1]Universidade Federal do Piauí, Teresina PI, Brazil.

Correspondence: Jonas Leite de Souza Filho; Email: jonaslf25@gmail.com.

Case presentation: Female, 5 years old, admitted due to frequent falls associated with visual impairment and trouble identifying colors. The patient complained of worsening her visual acuity and bilateral blurriness. This symptom begun 14 months ago. Previous comorbidities and continuous medication use were denied. After an ophthalmological evaluation, bilateral vision loss was diagnosed. On physical examination, she presented isochoric and photoreactive pupils. Because the patient did not cooperate in measuring visual acuity, a subjective assessment was conducted. She was tasked with identifying toys, games, pictures on a monitor, and colors. The patient struggled to identify the items, suggesting a reduction in peripheral vision bilaterally. Muscle strength was preserved (grade V), without pathological plantar reflex. No alterations in balance, sensitivity, and coordination were diagnosed. Brain MRI disclosed gadolinium enhancement, without expansive characteristics, affecting the intracanalicular segment of the optic nerves and the intraorbital segment of the right optic nerve, suggesting bilateral optic neuritis (ON). Retinography showed bilateral papilledema. Thus, hospitalization was recommended to perform pulse therapy with Methylprednisolone (20 mg/kg/day for 5 days). Since then, she has been scheduled for Albendazole and pulse therapy, and tests were requested for anti-MOG (positive) and anti-aquaporin IV (non-reactive). After 10 days of hospital treatment, the patients visual acuity was reassessed, showing an improvement in her condition, except for color identification ability. She is followed up by neurology and undergoing rehabilitation for better color visualization. She is on Azathioprine and Prednisolone, as well as Paracetamol for intense headaches. She had unremarkable signs for autoimmune diseases. **Discussion:** We presented a case of a child with MOGAD, a recently recognized inflammatory demyelinating disorder of the central nervous system. The most common findings of MOGAD attacks are severe impairment on visual acuity with a good recovery after an early management. In this case, the patient presented with isolated bilateral ON, with almost complete improvement of visual impairments, despite challenging measurement of visual acuity. We used alternative visual skills to measure the visual acuity in a child with MOGAD optic neuritis. **Final comments:** The diagnosis of MOGAD is necessary for appropriate management to be established. However, the difficulty of clinically assessing visual acuity can hinder this early diagnosis.

Changing the natural course of hereditary transthyretin amyloidosis: the importance of early diagnosis

Ligia Rocha Andrade[1], Ana Siquara[2], Clarissa Neves Spitz[1,2], Eduardo Davidovich[1], Marcelo Imbroinise Bittencourt[1], Salim Lázaro Balassiano[1], Larissa Bittencourt de Carvalho[1,2], Robson Teixeira Vital[1], Rafael Oliveira Vidon[1], Marcia Rodrigues Jardim[1,2]

[1]Universidade do Estado do Rio de Janeiro, Hospital Universitário Pedro Ernesto, Rio de Janeiro RJ, Brazil.
[2]Fundação Oswaldo Cruz, Rio de Janeiro RJ, Brazil.

Correspondence: Ligia Rocha Andrade; Email: ligiaandradee@gmail.com.

Background: Hereditary transthyretin amyloidosis (ATTRv) has a heterogeneous clinical presentation, and the symptoms are mainly neuropathic, including autonomic, sensory, and motor impairment. In addition, it may be associated with gastrointestinal, cardiac, renal, and ocular involvement. Diagnosis in the early stages is essential to allow appropriate treatment and to prevent or slow the progression of the disease. **Objective:** Early detection of the disease in asymptomatic ATTRv carriers. **Methods:** A cross-sectional study of asymptomatic individuals with ATTRv was conducted at the neuromuscular diseases outpatient clinic of Hospital Pedro Ernesto in Rio de Janeiro from April 2019 to November 2023. **Results:** 4 out of 16 individuals (25%) were diagnosed with the disease through salivary gland biopsy, after presenting alterations in at least two complementary tests related to the evaluation of small-fiber neuropathy, even if those individuals remained completely asymptomatic. **Conclusion:** Small-fiber neuropathy was the earliest sign of disease onset, occurring in all four individuals diagnosed and the tests that proved to be more sensitive were sympathetic skin response (SSR) and quantative sensory testing (QST)

https://doi.org/10.5327/CBN240353

Charcot-Marie-Tooth disease in a patient with long-chain 3-hydroxyacyl-coa dehydrogenase (LCHAD) deficiency

Maria Rodrigues Lima de Souza Pessoa[1], Ariele Amaral Alves[1], Marilaine Menezes de Matos Ferreira[1], Marcela Camara Machado Costa[1]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.

Correspondence: Maria Rodrigues Lima de Souza Pessoa; Email: mariapessoa20.1@bahiana.edu.br.

Case presentation: A 9-year-old male patient, with brown skin color, natural childbirth at term without further pregnancy information, started follow-up at the center on June 8, 2022, with a history of motor delay. This was recognized due to a lack of gait, by his parents at 12 months old. The parents were unable to recognise other motor milestones. He developed distal atrophy of the upper and lower limbs, muscle weakness, retraction of the fingers and toes, and bilateral cavus feets, as well as eyelid ptosis, which worsened in multiple episodes of rhabdomyolysis secondary to infections, requiring hospitalization. He had previously been observed at another center where a clinical diagnosis of Charcot-Marie-Tooth disease was made at 22 months of age. His father was observed to have cavus foot and calf atrophy, as well as electroneuromyography with evidence of axial sensory-motor polyneuropathy. Physical examination revealed distal atrophy and retraction of the calcaneus and toes, scoliosis, level 4 limbs strength, global level 1 osteotendinous reflexes, no gait but able to stand. Sensitivity was preserved. At that time, he was using 5 milligrams of baclofen twice a day and was not followed by a multidisciplinary team. The main suspect at the time was long-chain 3-hydroxyacyl-CoA dehydrogenase (LCHAD) deficiency and a genetic panel was conducted, confirming the diagnosis. He was followed at the center and began nutritional support and physical therapy. The neurological status remained unchanged, with no ophthalmic or cardiac changes to date, but with new episodes of rhabdomyolysis associated with the occurrence of infections. **Discussion:** Given the clinical presentation, the progressive, muscle weakness with atrophy and limbs dysmorphism associated with a compatible family history stands out. These factors favor the diagnosis of Charcot-Marie-Tooth disease, considering the clinical features and the frequency of the hereditary nature of the neuropathy. In view of rhabdomyolysis secondary to infection and associated muscular neuropathy, especially in the lower limbs, there is support for a LCHAD case, considering the onset in early childhood. **Final comments:** The patient presents two rare diseases in which the overlapping of the pathologies may have significantly worsened the clinical manifestations, especially those motor in nature.

https://doi.org/10.5327/CBN240354

CHD8 and autism spectrum disorder: genomic advances and clinical implications for neurological practice

Tereza Raquel Xavier Viana[1], José Eduardo Martinelli[1]

[1]Faculdade de Medicina de Jundiaí, Jundiaí SP, Brazil.

Correspondence: Tereza Raquel Xavier Viana; Email: espacotr@hotmail.com.

Background: Autism Spectrum Disorder (ASD) is a complex neurodevelopmental condition characterized by deficits in social communication and repetitive behaviors. Recent advances in genomics have revealed the CHD8 gene as an important factor in the etiology of ASD, with loss-of-function mutations often associated with variable clinical manifestations of the condition. Understanding the specific role of CHD8 in ASD is crucial to developing more accurate diagnostic strategies and targeted therapies. **Objective:** To analyze recent studies on the CHD8 gene and its implications in ASD in order to provide a comprehensive overview of the latest genomic findings and discuss their clinical implications in neurological practice. **Methods:** This is an exploratory and descriptive systematic review conducted according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) and PICO (Population, Intervention, Comparison, Outcome) guidelines. Searches were carried out in the PubMed, SciELO, Cochrane Library and BVS databases, using the descriptors: "CHD8" AND "Genomics" AND "Autism Spectrum Disorder". We included studies published in the last 5 years (2019 - 2024), in English and Portuguese, which investigated the associations between the CHD8 gene and ASD, exploring genomic advances and their clinical implications in neurological practice. Experimental

studies, controlled clinical trials and systematic reviews were considered for inclusion in the analysis. **Results:** During the initial search, 26 articles were identified. After reviewing the titles, abstracts and conclusions, 21 were excluded because they did not meet the inclusion criteria. Five studies were selected for full reading and inclusion in this research. These studies offer significant advances in the understanding of CHD8 in ASD, highlighting its robust association with the pathogenesis of this condition and its influence on specific clinical phenotypes. The research reviewed reveals that mutations in CHD8 are frequently found in individuals with ASD, contributing significantly to the phenotypic variability observed in the condition. In addition, they elucidate the molecular mechanisms by which CHD8 affects synaptic function, gene expression and chromatin compaction, providing important insights for molecular diagnosis and the potential development of personalized gene-based therapies. **Conclusion:** This study underlines the importance of the CHD8 gene in the etiology of ASD and highlights recent genomic advances that are shaping the understanding of the condition. Integrating these findings into neurological practice may offer new opportunities for early diagnosis, more effective clinical management and the development of targeted therapeutic interventions. Future studies should continue to explore the functional and clinical implications of CHD8, aiming to improve outcomes for individuals affected by ASD related to mutations in this specific gene.

https://doi.org/10.5327/CBN240355

Chediak-Higashi syndrome presenting as pure juvenile Parkinsonism

Matheus Gomes Ferreira[1], Renata Cristine Alves[1], Luis Eduardo Borges de Macedo Zubko[1], Christelle Thesson[2], Thomas Courtin[2], Alexis Brice[2], Francisco Manoel Branco Germiniani[1], Helio Afonso Ghizoni Teive[1]

[1]Universidade Federal do Paraná, Hospital de Clínicas, Curitiba PR, Brazil.
[2]Sorbonne Université, Paris Brain Institute, Institut du Cerveau et de la Moelle épinière, Paris, France.

Correspondence: Renata Cristine Alves; Email: renata_cristinealves@hotmail.com.

Case presentation: Here we present a Brazilian patient with juvenile parkinsonism as the sole manifestation of a new LYST mutation. His parents were consanguineous and he had a sister with clinical diagnosis of Chediak-Higashi syndrome based on bleeding diathesis, immunodeficiency and inclusion bodies in peripheral blood leukocytes. He began with asymmetrical parkinsonism when he was 15 years old characterized by bradykinesia, rigidity and resting tremor. By that time, he began treatment with levodopa with a good clinical response. During follow-up the patient developed motor fluctuations, an important impulse control disorder and cognitive decline. His current clinical evaluation had an UPDRS-III score of 64 and a 11/30 on the MoCA test. He was submitted to whole-exome sequencing, with the finding of a homozygous missense mutation p.R3107H in the LYST gene. **Discussion:** Chédiak-Higashi syndrome is a lysosomal storage disorder caused by mutations in the LYST gene with an autosomal recessive inheritance. It is characterized by the disruption of transport and fusion of lysosomes, leading to a myriad of clinical signs and symptoms. Clinically patients manifest variable degrees of partial oculocutaneous albinism, bleeding diathesis and immunodeficiency. Depending on the age of symptoms onset, cases manifesting during childhood have mainly hematological symptoms, while the ones who present in adolescence/early-adulthood usually display neurological symptoms. The latter may include parkinsonism, cerebellar ataxia, dystonia, dementia, neuropathy and epilepsy, with a prolonged clinical course and slow deterioration. **Final comments:** As far as we know, this is the first reported case of homozygous missense mutation p.R3107H in the LYST gene, with an atypical presentation characterized by early-onset parkinsonism without associated hematological disease.

https://doi.org/10.5327/CBN240356

Chorioretinitis, bilateral optic neuritis and pachymeningitis as manifestation paraneoplastic probable of esophageal squamous cell carcinoma

Renan Macionil Cotrim[1], Itamar Meireles Andrade Santos[1], João Márcio Borgue de Oliveira[1], Bianca Latance da Cruz[1], Pedro Enrico Cyprestes Sant Anna[1], Gabriela Rossini Dantas[1], Eduardo Abrão Spinola Rezk[1], Helio Aquaroni Farao Gomes[1], Ana Beatriz Marangoni Baston[1], Laura Cardia Gomes Lopes[1]

[1]Universidade Estadual Paulista, Botucatu SP, Brazil.

Correspondence: Renan Macionil Cotrim; Email: renan.cotrim@unesp.br.

Case presentation: Man, 61 years old, smoker, started in February 2024 progressive visual impairment of the left eye and holocranial headache in "pressure". Evolutionarily, he presented a left clavicle fracture. On physical examination, the patient didn't have neurological deficits, except for the left eye with visual acuity 0.3 and fundoscopy with optical disc edema. Bone scintigraphy detected diffuse radiopharmaceutical uptake, including the skullcap, left clavicle, and costal arches, and the neuroimaging study showed hypersignal on T2/FLAIR sequences, and contrast uptake in the retina, optic nerve on the left, and meningeal enhancement at the base of the brainstem, and anterior cranial fossa. The visual evoked potential test demonstrated bilateral optic neuropathy, worse on the left, and rachicentesis, pleocytosis with lymphomonocytic predominance and hyperproteinorrachia, latex for bacterial or fungal agents, and culture negative. Neoplastic cells on cytopathological examination absent, serology for HTLV, HIV, CMV, HBV , HCV and syphilis negative. Pulse therapy was performed with methylprednisolone 1 g/day for 5 days, with improvement in the condition. Esophagogastroduodenoscopy with histopathology positive for esophagogastric transitional squamous cell carcinoma, palliative chemotherapy with carboplatin and paclitaxel is initiated. Later, the worsening conditions, associated with aggressiveness and convulsive crises of focal onset, the new cytopathological examination of cerebrospinal fluid detects atypical cells, suggesting meningeal carcinomatosis. Admitted to a palliative care ward, he developed a headache that was refractory to optimized analgesia and worsened his behavioral condition, resulting in death. **Discussion:** Paraneoplastic neurological syndromes represent 1 in every 300 cancer patients, and result from the production of antibodies with target organ dysfunction. The diagnosis is based on the understanding of clinical, oncological, and immunological heterogeneity, with the need to exclude other causes, such as meningeal carcinomatosis or brain metastasis, but its treatment is still uncertain. The diagnostic criteria are supported by a panel called PNS-Care that includes high-risk phenotypes, such as limbic encephalitis, and intermediate-risk phenotypes, when the onset is rapidly progressive, with inflammatory findings on cerebrospinal fluid or neuroimaging. Although uncommon in tumors of the gastrointestinal tract, a literature review carried out between 1970 and 2021 about esophageal cancer described phenotypes for neurological paraneoplastic syndromes. **Final comments:** Paraneoplastic neurological manifestations are heterogeneous, we report a case of choreoretinitis, bilateral optic neuritis and pachymeningitis as the initial manifestation of esophageal squamous cell carcinoma, signaling it for further studies, and alerting clinical reasoning in the face of similar conditions that occur in others centers.

https://doi.org/10.5327/CBN240357

Chronic Chagas heart disease presented as comma-shaped stroke

Ana Carolina Leite Ribeiro[1], Brenno Tavares de Vasconcelos Brandão[1], Bárbara Pina Aiello[1], Giuliana Gonçalves Moreira Possidente[1], Marcos Martins da Silva[1], Carolina Rouanet de Albuquerque[1]

[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Ana Carolina Leite Ribeiro; Email: anacarolinaneuro@gmail.com.

A previously healthy 52-year-old woman from Minas Gerais was admitted with subacute left-sided motor and sensory hemiparesis and dysarthria. A head computed tomography scan revealed a large infarct in the right lenticulostriate artery territory. Intracranial and cervical vessel studies showed occlusion of the left MCA segment M1 with preserved cortical vascularization. Brain magnetic resonance imaging revealed similar findings. An electrocardiogram identified atrial fibrillation and right bundle branch block. A 24-hour Holter monitor detected nonsustained ventricular tachycardia. Transthoracic echocardiogram revealed dilated cardiomyopathy with diffuse hypokinesis and an ejection fraction of 36%. The thrombophilia screen was negative. Given the dilated cardiomyopathy in the absence of cardiovascular risk factors or a history of alcoholism, Chagas disease was suspected and confirmed by two serological tests. Large deep striatocapsular infarctions account for 1-6% of ischemic strokes. The basal ganglia and parts of the caudate nucleus, internal capsule, putamen, and globus pallidus are supplied by the lenticulostriate arteries, the artery of Heubner, and the anterior choroidal artery. Large striatocapsular infarctions, previously termed giant or super lacunae, occur due to MCA trunk occlusion affecting all lenticulostriate arteries, typically caused by cardioembolism or atheroembolism. The cortex is often spared due to collateral artery formation, resulting in comma-shaped infarctions. Clinical manifestations include motor and/or sensory hemiparesis and may include dystonia, involuntary movements, aphasia, and hemineglect. Bladin and Verkovic described two mechanisms for preserving cortical perfusion: thrombotic occlusion at the carotid T-junction with cortical blood supply via anastomoses, and embolism at the carotid T-junction obstructing lateral striate arteries while allowing some cortical perfusion. The patient presented with this unusual form of stroke, likely due to chronic Chagas cardiomyopathy, previously asymptomatic. Full anticoagulation and heart rate control were initiated as secondary prophylaxis. Electrical cardioversion was considered after resolving contraindications. The possibility of etiological treatment for Chagas disease was discussed, which is reserved for the chronic indeterminate form in adults under 50 years old. Identifying stroke etiology and understanding the involved pathophysiology, especially in rare presentations, is crucial for establishing secondary prophylaxis and treating the underlying disease. Advanced vessel imaging studies were particularly useful for understanding the pathophysiological and anatomical mechanisms.

Chronic dengue virus encephalitis diagnosed by metagenomic analysis: a case study

Gabriela Abrahão Allioni[1], Gabriel Samir Martins de Souza[1], Julia Haddad Labello[1], Gabriel Saboia de Araújo Torres[1], Yuri Reis Casal[1], Amaro Nunes Duarte Neto[1], Luiz Henrique Martins Castro[1], Gustavo Bruniera Peres Fernandes[2], João Renato Rebello Pinho[2], Bruno Fukelmann Guedes[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

[2]Hospital Israelita Albert Einstein, São Paulo SP, Brazil.

Correspondence: Gabriela Abrahão Allioni; Email: gabriela.allioni@hc.fm.usp.br.

Background: The dengue virus (denV) can lead to acute encephalitis during the initial infection. Chronic encephalitis with progressive dementia is rarely documented. **Methods:** We present a novel case of chronic encephalitis causing rapidly progressive dementia, in which a probable denV brain infection was identified through metagenomic next-generation sequencing of brain tissue. Brain pathology and molecular diagnosis are detailed. **Results:** A 20-year-old male from São Paulo began experiencing symptoms of rapidly progressive dementia, including speech apraxia and apathy, starting in June 2022. Initial cognitive testing in January 2023 revealed severe impairment across multiple domains, with a score of 18 points on the Mini-Mental State Examination. A brain MRI performed six months after symptom onset showed white matter abnormalities and brain atrophy. Cerebrospinal fluid (CSF) analysis indicated elevated white blood cells, increased proteins, and the presence of oligoclonal bands. An extensive diagnostic work-up ruled out common infectious and autoimmune causes of encephalitis. Over a six-month period, the patient's condition continued to deteriorate, resulting in progressive impairment of executive functions and language, accompanied by the onset of tremors and myoclonus. In August 2023, the patient was readmitted for further diagnostic investigation, revealing reactive denV IgG and non-reactive IgM in an arboviruses immunology panel, prompting additional investigation. Due to the lack of an etiological diagnosis and the severity of the case, a brain biopsy was performed. Histopathological examination of the brain biopsy suggested a chronic infectious etiology unrelated to bacteria, supported by the frequent presence of CD8+ T lymphocytes, plasma cells, and glioneuronal alterations. Next-generation sequencing and phylogenetic analysis of brain tissue identified DENV-1 genotype V, with the recovered sequence clustering within a clade of Brazilian sequences from 2000 to 2022. # **Conclusion:** This case highlights the importance of unbiased techniques like metagenomics in diagnosing encephalitis of unknown etiology, providing a potential etiological explanation for the patient's chronic encephalitis. While dengue virus is occasionally described as a cause of acute encephalitis/encephalopathy, this case broadens the clinical spectrum of the infection, demonstrating that it may also cause chronic encephalitis.

Chronic inglammatory demyelinating polyneuropathy (CIDP): a case series from a tertiary center

Mariane Panka[1], Paulo José Lorenzoni[1], Renata Dalprá Ducci[1], Otto Hernandes Fustes[1], Paula Raquel Rodrigues[1], Rosana Herminia Scola[1], Cláudia Suemi Kamoi Kay[1]

[1]Universidade Federal do Paraná, Hospital de Clínicas, Curitiba PR, Brazil.

Correspondence: Mariane Panka; Email: mari_panka@hotmail.com.

Background: Chronic inflammatory demyelinating polyneuropathy (CIDP) represents a spectrum of treatable chronic immune-mediated disorders affecting peripheral nerves and nerve roots. CIDP typically presents with symmetric motor deficits, including proximal and distal weakness and areflexia. Sensory symptoms such as paresthesia and hypoesthesia are often more pronounced than pain and temperature alterations. The disease course can be progressive or marked by remitting-relapsing patterns. Treatment generally involves immunosuppressants or immunomodulators such as glucocorticoids, intravenous immunoglobulin, or plasma exchange. Diagnosis relies on electrodiagnostic evidence of peripheral demyelination, supplemented by laboratory tests, cerebrospinal fluid analysis, neuroimaging, and occasionally nerve biopsy. Distinguishing CIDP from other chronic demyelinating neuropathies is critical due to differing treatment approaches that significantly impact patient outcomes. **Objective:** To assess clinical features, electroneuromyographic findings, cerebrospinal fluid analysis, and imaging results in patients undergoing follow-up at our institution. **Methods:** A retrospective review of medical records, electroneuromyography, laboratory tests, and imaging studies was conducted. **Results:** Seventeen patients meeting CIDP diagnostic criteria were identified from our neuromuscular diseases out patient clinic. Coexisting conditions included well-controlled diabetes mellitus in two patients, Waldenströmma croglobulinemia in one, neurofibromatosis in another, and exacerbation post-influenza vaccination in one case. Cerebrospinal fluid analysis indicated elevated protein levels in all but one patient, averaging 326.37mg/dL (median: 345mg/dL, range: 36 – 964.3mg/dL). Electroneuromyography demonstrated demyelinating and axonal polyneuropathy in 11 patients, with demyelinating patterns in five and axonal patterns in one. Magnetic resonance imaging revealed root thickening in three out of tem patients tested. Genetic testing for hereditary neuropathies or the TTR gene panel was negative in all seven patients screened. Three patients showed poor response to treatment, including one with CIDP associated with Waldenström macroglobulinemia. **Conclusion:** This case series confirms the presence of CIDP in all patients based on diagnostic criteria and consistent electroneuromyographic findings. Most patients exhibited elevated cerebrospinal fluid protein levels, and imaging studies were crucial in diagnosing and managing uncertain cases. Treatment out comes were generally favorable, underscoring the efficacy of current therapeutic modalities.

Chronic inflammatory demyelinating polyradiculoneuropathy related to neurofascin-155 IgG4 with response to rituximab: case report

Luma Elem Soares Batista[1], Patrícia Pereira Nunes[1], Gabriela de Castro Cavalcante Mendonça[1], Amanda de Araújo Cravo[1], Carla Fernanda Veiga Pimentel[1], Marianna Kelly de Araújo Souza Barbosa[1], Gabriel Barroso Cunha[2], Mikaella de Lima Pereira Moraes[1], Paula Raphaella da Silva Melo[1]

[1]Centro Universitário de Maceió, Maceió AL, Brazil.
[2]Universidade Estadual de Ciências da Saúde de Alagoas, Maceió AL, Brazil.

Correspondence: Gabriel Barroso Cunha; Email: gabrielbarrosocunha@gmail.com.

Case presentation: Male, 35 years old, with paresthesia in the hands and feet associated with difficulty walking and progressive neuropathic pain in the lower limbs, for approximately 6 months. He underwent intravenous immunoglobulin (IgEv), showing partial improvement in complaints. Physical examination revealed facial diparesis, vibratory hypoesthesia in the malleoli (left better than right). Grade 4 strength in finger flexion and thumb opposition, in addition to plantar flexion and dorsiflexion (4+ in L and 4 in R). Positive Romberg, heel gait with wide base. Electroneuromyography indicating chronic, slightly asymmetric acquired demyelinating peripheral sensory-motor polyradiculoneuropathy, magnetic resonance imaging of the lumbar spine with contrast compatible with inflammatory radiculitis, cerebrospinal fluid with normal cellularity and hyperproteinorrhaquia with a positive Anti-NF-155 test (1/8100 - predominant IgG4 subclass). He underwent two more cycles of IgEv with improvement in pain and sensitivity (improving MIE hypoesthesia and facial weakness), but maintaining ataxia. We chose to undergo three cycles of intravenous corticosteroid therapy and oral immunosuppressant (azathioprine), with partial improvement of all symptoms, with the exception of ataxia. One month later, the patient returned, maintaining previous changes and then underwent 8 plasmapheresis sessions, also with a slight improvement in symptoms. Rituximab was started, on a schedule of 4 weekly infusions of 500 mg, progressing with significant improvement in neurological examination, as well as in functionality. Patient continues to be monitored for discussion of medication dose progression. **Discussion:** Chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) is an immune-mediated disease that affects roots and peripheral nerves, with a decrease or absence in motor and sensory amplitudes. Around 10% of patients have autoantibodies (mainly IgG4) against nodal and paranodal proteins (NF-155). Because this group of patients with specific antibodies share clinical characteristics and response to treatment different from those of typical CIDP, this disease is included in the recent diagnostic category of autoimmune nodopathy, therefore being a distinct classification from CIDP. In these cases, there is greater distal than proximal muscle weakness, positive sensory symptoms and gait ataxia. Compared to other node-paranodopathies, they have higher recurrence, morbidity and younger age of onset. It is refractory to IgEv, with a favorable response to second-line (Rituximab) and third-line immunosuppressants, and a prolonged time until clinical improvement, up to two years. **Final comments:** Autoimmune node diseases have a broad clinical spectrum, which makes establishing an effective treatment challenging. Thus, serology for specific autoantibodies makes it possible to use treatment based on the most recent evidence, providing an individualized and effective therapeutic plan.

Chronic lymphocytic inflammation with pontine perivascular enhancement responsive to steroids (CLIPPERS): case presentation

Ana Luísa Castelo Branco Gomes[1], Davi Telécio Firmino[2], Gilmar Leite Pessoa Filho[1], Luciano Gonçalves Do Nascimento Júnior[1], Felipe Nunes de Araújo[1], Rafael de Souza Andrade[1], Luíza Alves Monteiro Torreão Villarim[1], Bianca Etelvina Santos de Oliveira[3], Juliana Magalhães Leite[1], Alex Tiburtino Meira[1]

[1]Hospital Metropolitano Dom José Maria Pires, João Pessoa PB, Brazil.
[2]Universidade Federal da Paraíba, João Pessoa PB, Brazil.
[3]Conselho Regional de Medicina da Paraíba, João Pessoa PB, Brazil.

Correspondence: Ana Luísa Castelo Branco Gomes; Email: analuisa_gomes@hotmail.com.

Case presentation: 52-year-old female patient, previously healthy, presented to the ataxia outpatient clinic with a history of progressive imbalance for 8 years. She developed paresthesia in her extremities in the past 4 months, and dysphagia for liquids and solids in the last 2 months. The physical examination revealed dysarthria, Parinaud's syndrome, Collier's sign, global cerebellar ataxia, hyperreflexia in the lower limbs and bradykinesia at alternating movements. Magnetic Resonance Imaging (MRI) revealed a punctate and curvilinear T2/FLAIR hyperintensity on the central portion of the pons and extending to the midbrain with gadolinium enhancement. Cerebrospinal fluid analysis, electroneuromyography and electroencephalography showed no abnormalities. Due to the clinical and laboratory findings, the diagnosis of Chronic Lymphocytic Inflammation with Pontine Perivascular Enhancement Responsive to Steroids (CLIPPERS) was suggested. The patient was treated with methylprednisolone 1g/day for 5 days, progressing with moderate improvement of

the imbalance, dysarthria and dysphagia. **Discussion:** CLIPPERS is a rare chronic inflammatory disorder of the central nervous system (CNS). The disease can occur in all age groups, and both men and women can be affected. Its etiology and pathogenesis remain unknown and most patients have no specific triggering factors. Diagnosis is based on clinical, radiological and pathological criteria. Clinical findings include subacute pontocerebellar dysfunction such as ataxia, diplopia and facial paresthesia, as well as clinical responsiveness to corticosteroid therapy. MRI of the pons shows punctate images with a "salt and pepper" appearance with contrast enhancement. Biopsy, when performed, shows infiltration of the perivascular spaces by T cells. The cornerstone of the treatment is a corticosteroids pulsotherapy, which typically leads to significant improvement in symptoms. No study has shown that CLIPPERS can be cured, so, long-term steroid maintenance therapy is necessary to prevent recurrence of the disease. **Final comments:** Clinical, radiological and pathological findings of CLIPPERS are non-specific and occur in several corticosteroid-sensitive neurological diseases and there is still a lack of specific biomarkers for its diagnosis. Therefore, diagnosis of CLIPPERS is challenging and is a disease yet to be explored due to its rarity. This diagnosis should be kept in mid in patients with subacute or chronic history of cerebellar ataxia.

Chronic meningitis neurobrucellosis: case report

Ahmad Kassem El Zein[1], Lucas Henrique de Moura Rogerio Garcia[1], Matheus Rodrigues Nogueira[1], Joana Laura Aihara Barbosa[1], Josenice Gomes Trindade Seidel[1], Julia Martins Brunelli[1], Gabriela Almeida Pimentel[1], Thiago Gonçalves Guimarães[1], Lucas D'Andrea Pereira Sousa[1], Bruno Fukelmann Guedes[1]

[1]Hospital Sírio-Libanês, São Paulo SP, Brazil.

Correspondence: Ahmad Kassem El Zein; Email: ahd-95@hotmail.com.

Case presentation: A 46-year-old man presented with a 4-month history of headache and fatigue, a 10-kilogram weight loss over the previous 3 months, low-grade fever, night sweats, and blurred vision. He had recently traveled to Lebanon, where he consumed unpasteurized dairy and raw meat. Upon examination, the patient was alert but confused, exhibiting bilateral papilledema without other neurological deficits. Brain magnetic resonance imaging revealed gadolinium enhancement in the leptomeningeal compartment, particularly pronounced in the basal cisterns, accompanied by hydrocephalus and signs of CSF transudation. Cerebrospinal fluid analysis showed an opening pressure of 31 cm H2O, 149 white cells/mm3 (70% lymphocytes), low glucose (24mg/dl), high lactate (30mg/dl), and elevated total protein (160mg/dl). A comprehensive diagnostic workup, including metagenomic next-generation sequencing of CSF, was negative for syphilis, sarcoidosis, tuberculosis and other infectious and autoimmune etiologies. The patient was started on empirical anti-tuberculosis treatment, prednisone, and acetazolamide. Brucella agglutination tests were positivein the CSF (titer, 1:20) and serum (1:40). Tuberculostatics were discontinued, and replaced with an empirical anti-brucella treatment with ceftriaxone, doxycycline, and rifampicin. The patient's symptoms improved steadily over the 3-week course of antibiotics, which paralleled improvement of CSF parameters. The patient was discharged with a good clinical recovery **Discussion:** Brucellosis is a bacterial infection caused by Brucella spp, the neurological presentation is varied and may include meningitis, encephalitis, cranial neuropathies, radiculitis, and peripheral neuropathy. The clinical presentation can be very similar to tuberculous meningitis. The main route of transmission is through the consumption of unpasteurized or contaminated dairy products. The diagnosis of neurobrucellosis is based on suggestive symptoms, positive cultures of cerebrospinal fluid for Brucella spp., or positive IgG agglutination titers for Brucella in the blood or CSF, presence of lymphocytic pleocytosis and increased protein levels in cerebrospinal fluid, and positive response to specific antibiotics. Radiological aspects and cerebrospinal characteristics can aid in diagnosis, but should be differentiated from other conditions causing similar symptoms, presentations of neurobrucellosis can also be diverse, with 45% of cases showing meningeal inflammation with post-contrast enhancement. The treatment of neurobrucellosis typically involves prolonged antibiotic therapy with Ceftriaxone, rifampicin and doxycycline. The duration of therapy may be extended to 4 to 6 months, and other regimens are available. **Final comments:** Given the atypical clinical presentation of neurobrucellosis, diagnosis can be challenging, and clinical suspicion is essential in patients presenting with chronic meningitis and a history of exposure in endemic regions.

Chronic pelvic inflammatory context leading to migraine exacerbation: a case report

Jovana Gobbi Marchesi Ciriaco[1], Lucas Grobério Moulim de Moraes[1], Laissa Fiorotti Albertino[1], Bianca Garcia Sardi[1], Brenda Comper[1], Breno Sousa Paiva[1], Beatriz Gomes da Fonseca[1], Carlos Eduardo de Nadai[1], Amanda Reis Flores[1], Ana Luíza dos Santos Machado Costa[1]

[1]Universidade Federal do Espírito Santo, Hospital Universitário Cassiano Antonio Moraes, Vitória ES, Brazil.

Correspondence: Lucas Grobério Moulim de Moraes; Email: lucasgromoulimdm@hotmail.com.

Case presentation: Woman, 48 years old, infertile, with dysmenorrhea, episodic headache since the age of 35 with weekly attacks and worsening related to the menstrual cycle. In 2020, she developed a sudden onset of dyspnea and chest pain, during menstruation which progressed to pneumothorax. A biopsy of the right upper lung lobe identified subpleural emphysema which, associated with the clinical picture of intense dysmenorrhea and magnetic resonance imaging of the pelvis, was presumptively diagnosed as a pulmonary focus of endometriosis. The patient has been menopausal since 2023 with worsening of migraine symptoms. In gynecological investigation, signs of hypoestrogenism were noted, vulvar atrophy associated with fissures in the vestibule after physical examination, cervix posterior and lateralized to the left, hypotrophic vaginal walls, shortening of the left parametrium painful upon mobilization, thickening of the endopelvic fascia and intense dysmenorrhea. After the pneumothorax, the dysmenorrhea maintained the same pattern with the headache becoming daily, located in the right temporo-occipital region, intense and pulsatile, radiating to the right hemiface with intra and extracranial allodynia, followed by progressive course, accompanied by aura with nausea, blurred vision, scotomas, photophobia and phonophobia. In the post-crisis period, there is a change in mood and hyporexia. **Discussion:** Endometriosis is a chronic gynecological condition characterized by the presence of endometrial tissue outside the uterus resulting in chronic pelvic pain and infertility. Endometriosis affects 60% of women and adolescents with pelvic pain and up to 50% of women with infertility. Migraine is a common neurological disorder characterized by recurrent attacks of intense headache often accompanied by nausea, vomiting and photophobia. The highest incidence occurs among women of reproductive age. A population-based study indicated that migraines are 1.7 times more common in women with endometriosis than in those without the disease, in addition to demonstrating that endometriosis is an independent predictor of migraines. One of the factors described in the literature on the pathophysiological pathways of endometriosis that may explain its apparent relationship with migraine is the activation of sensory fibers in ectopic endometrial tissue that can lead to neuronal hyperactivity throughout the central nervous system (CNS). Pulmonary manifestation demonstrates a possible exacerbation of neuronal activity in the CNS causing worsening of migraine. The scientific literature lacks prevalence rates of pulmonary endometriosis and migraines. **Final comments:** The role of female sex hormones in the pathogenesis of migraine is well established. The prevalence of migraine in patients with endometriosis is high and healthcare professionals need to think about both diagnostic hypotheses when caring for a patient with dysmenorrhea.

Clinical acute manifestations in the multiple sclerosis onset associated with worse functional outcomes

Felipe Asaf Borges Millard[1], João Pedro Gonçalves[1], Gabriel Nunes Medrado[1], Marivaldo Yslan Silveira Leal[1], Luísa Dias Moreno Aravena[1], Gabriel Souza Suzart[1], Pedro Antonio Pereira de Jesus[1,2], Bruno Bacellar Pedreira[2], Thiago Gonçalves Fukuda[2]

[1]Universidade Federal da Bahia, Salvador BA, Brazil. [2]Hospital Universitário Professor Edgard Santos, Salvador BA, Brazilo.

Correspondence: Felipe Asaf Borges Millard; Email: felipemillard@ufba.br.

Background: Multiple sclerosis (MS) is a chronic autoimmune disease with a wide variability of neurological manifestations in the first acute episode. Some symptoms may be associated with long term neurological dysfunction and functional dependence in the patient's daily activities. The Expanded Disability Status Scale (EDSS) and the Multiple Sclerosis Functional Composite (MSFC) are complementary and aim to quantify the degree of disability of patients with MS. In this sense, data regarding the incidence and liability implications of the first acute manifestation are still lacking. This knowledge may help re-evaluate therapeutic protocols in MS. **Objective:** To identify the clinical syndromes in MS onset that are associated with worse functional outcomes. **Methods:** This study is a cross-sectional design with patients diagnosed with MS, according to the McDonald 2017 criteria, who were followed up at a neuroimmunology reference center in Bahia, from January 2019 to May 2024. This study is part of an ongoing cohort study that evaluates the clinical features of patients followed in this reference center. The clinical manifestations of the first acute episode were collected through a clinical interview and compiled into seven major syndromes: visual, motor, sensory, ataxic, postrema area, cranial nerves and autonomic. Functional outcomes were assessed using the EDSS (assessed by neurologists and/or neurology residents) and the MSFC (assessed by trained researchers).Patients with MS and a relapse in the last three months were excluded. The Mann-Whitney test was used to assess the association of the first clinical syndrome and worse functional outcomes. Linear regression was performed to address the effect of each clinical syndrome in both functional scales, considering only syndromes that were associated in univariate analysis with worse functional outcome. **Results:** A total of 274 patients were included in the study, of whom the majority were female (71.5%), non-white (71.9%) and complete secondary education (79.6%). Our sample's mean age was 42 (SD±13) with a median length of disease of 8 years (4-13), a median EDSS of 2 (0-4.5), a global MSFC of -0,6 (-1.6 to 0.0), and relapsing-remitting clinical form as the most common (87.6%). Worse EDSS and global MSFC scores were identified in those patients who presented motor ($p< 0.01$), ataxic ($p<0.01$), and autonomic syndrome ($p<0.01$) in the first acute episode.In multivariate analysis considering EDSS as the dependent variable, motor and autonomic syndrome remained associated with worse functional outcome ($p<0.001$, B=0.373;

p0,05, B=0.163, respectively). Regarding MSFC, we found that motor, ataxic, and autonomic syndromes remained associated (p<0.05, B=-0.206; p<0.05, B=-0.188; p<0.05, B=-0.156). **Conclusion:** Among the possible symptoms in the first acute episodes of patients with Multiple Sclerosis, motor, ataxia and dysautonomic symptoms may be associated with worse functional status.

Clinical and electroneuromyographic assessment in lepromatous leprosy: the confirmation of an asymmetrical and non-length-dependent pattern.

Lucas Kenzo Ozera[1], Caio Luiz Nazar Cunha[1], Ana Clara Nogueira Cezar[1], Ariane Aparecida Correa de Miranda[1], Laura Caroline Felipe de Freitas[1], Eduardo William Farinha Carvalho[1], Isabella Sabião Borges[1], Douglas Eulálio Antunes[1], Isabela Maria Bernardes Goulart[1], Diogo Fernandes dos Santos[1]

[1]Universidade Federal de Uberlândia, Uberlândia MG, Brazil.

Correspondence: Lucas Kenzo Ozera; Email: lucaskenzoozera@gmail.com.

Background: Electroneuromyography (ENMG) is the gold standard test for evaluating neural impairment in leprosy. However, as it is a spectral disease and especially in advanced cases, the neurophysiological pattern is variable. It can be confused with numerous etiologies presenting a symmetrical polyneuropathy pattern. **Objective:** To describe electroneuromyographic findings in patients with lepromatous leprosy (LL). **Methods:** The study is a retrospective observational analysis of leprosy patients undergoing ENMG at a National Reference Center in Brazil. **Results:** 57 patients with LL underwent ENMG at diagnosis. On physical examination, all patients presented an asymmetrical distribution pattern of sensory symptoms, compatible with truncal and intradermal involvement in all cases. 89.5% had neural thickening, and 64.9% had motor symptoms. Concerning the ENMG findings, 417 altered nerves were identified, with an average of 7.9 (±4.2). 100% showed abnormalities in at least one sensory nerve, with an average of 5.5 (±2.3), and 89.0% in at least one motor nerve, with an average of 2.4 (±1.3). 3.6% had mononeuropathy, and 96.4% had multiple mononeuropathy, with asymmetry present in all cases. 100% presented sensory axonal impairment and 40.0% motor axonal impairment. 70.9% showed signs of demyelinating. The most commonly observed electroneuromyographic pattern was an axonal sensory-motor neuropathy, predominantly sensory, with focal myelin impairment in 61.9%. No patient presented a symmetrical neurophysiological pattern compatible with the diagnosis of polyneuropathy. **Conclusion:** The term polyneuropathy defines a diffuse, length-dependent, symmetrical involvement with distal predominance. Therefore, although confluent, the term polyneuropathy should not be used in this disease that presents an essentially asymmetrical involvement, even in LL.

https://doi.org/10.5327/CBN240366

Clinical and epidemiological aspects of patients attended at a reference center for movement disorders

Caio Fontes d Nascimento[1], Maria Eduarda Messias Vassoler[1], Gabriel Souza Medrado Nunes[1], Ayla Morais Vitório Guerra[1], Fernanda Garcia Silva Pereira Nascimento[1], Gabriel Teles de Oliveira Piñeiro[1], Roberta Borges Gomes Kauark[2]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.
[2]Hospital Universitário Professor Edgard Santos, Salvador BA, Brazil.

Correspondence: Caio Fontes do Nascimento; Email: caiofontesdn@hotmail.com.

Background: Movement disorders are neurological conditions characterized by involuntary movements that significantly impact patients' quality of life. These disorders are commonly divided into hyperkinetic and hypokinetic categories. Hyperkinetic disorders include a variety of uncontrollable movements such as dystonias, tremors, myoclonus, and athetosis. Hypokinetic disorders are primarily characterized by parkinsonian syndromes, with Parkinson's disease (PD) being the most prominent and the second most common neurodegenerative disease. The prevalence of movement disorders in the general population is low and specific data on the Brazilian population are scarce, so studies exploring the characteristics of affected populations are crucial for developing better therapeutic strategies. **Objective:** To describe the frequencies of the different diagnoses among patients at the movement disorders clinic and their clinical manifestations, as well as their epidemiological data. **Methods:** This is a retrospective descriptive epidemiological study that analyzed medical records of patients seen at a referral movement disorders outpatient clinic from January 2019 to May 2024. **Results:** Among the 279 patients followed during the period, 57.6% were male, with a mean age of 65.1 years (±14.4). The most frequent diagnosis was PD (48.7%), followed by other forms of parkinsonism (11%), essential tremor (3.6%), Huntington's disease (2.2%), cervical dystonia (1.8%), Segawa's disease (1.1%), Wilson's disease (1.1%), and other diagnoses (9.3%). Additionally, 59 patients (21.2%) remained under investigation. Of the PD patients (136), 94.1% had bradykinesia, 91.1% were rigid, 73.5% had rest tremor and 29.4% had gait block. Regarding non-motor symptoms: 35.2% of patients had REM sleep behavior disorder, 28.6% had insomnia, 33% had constipation and 16% had orthostatic hypotension. Tremor was reported as the first symptom by 53 of these patients (38.9%). The mean Levodopa Equivalent Daily Dose (LEDD) was 638 mg (±677), with 64.3% of patients using levodopa-benserazide. **Conclusion:** The gender distribution and average age of the sample are in line with known epidemiological trends for PD, which suggests an accurate representation of the patient population. The predominance of PD among the diagnoses reflects its high prevalence. The high proportion of undiagnosed cases indicates the challenges of diagnosing movement disorders and scarce resources. Tremor was the most frequently reported initial symptom, which highlights its importance in early diagnosis and patient management. The frequencies of rigidity, bradykinesia, postural instability, insomnia, and REM sleep behavior disorder indicate a relevant prevalence of conditions that can potentially affect patients' quality of life. The average LEDD reflects typical therapeutic practices, and its variability suggests different stages of the disease, necessitating personalized therapeutic approaches.

https://doi.org/10.5327/CBN240367

Clinical and epidemiological aspects of patients with myasthenia gravis in a tertiary center

Beatriz Carneiro Gondim Silva[1], Eduardo de Paula Estephan[1], Ana Flávia Pincerno Pouza[1], André Macedo Serafim da Silva[1], Antonio Alberto Zambom[1], Edmar Zanoteli[1], Sara Caixeta de Souza[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Beatriz Carneiro Gondim Silva; Email: beatrizcgondim@gmail.com.

Background: Myasthenia gravis (MG) is a rare autoimmune disease with variable incidence depending on the geography and over the years. In the literature, there are few studies describing the incidence of MG in centers specializing in neuromuscular diseases and neuromuscular junction disorders, as well as the epidemiological and clinical profile of the population evaluated for this condition. **Objective:** To describe clinical and epidemiological aspects of patients diagnosed with MG at the neuromuscular diseases in a large tertiary service. **Methods:** A retrospective analysis was carried out of medical records of patients admitted and diagnosed with MG between the period 2020 and 2024. Data were collected regarding age, sex, ethnicity, onset of symptoms, severity, presence of antibodies, thymectomy, time since thymectomy and response afterwards, number of myasthenic crises, need to use intravenous immunoglobulin and/or plasmapheresis, in addition to associated comorbidities. **Results:** 217 patients were studied, of whom 152 were females (70%) and 65 were male (30%), with an average age of 51.4 years, ranging from 11 to 90 years. Age of onset of the first symptoms varied from 3 - 69 years (average of 31.7). Generalized myasthenia gravis was the most common clinical presentation, with MGFA IIA, IIIA and IIIB being the most common in the early pre-treatment phase. From those tested for anti-acetylcholine receptor (AChR) and anti-Musk antibodies 88% were AChR positive and almost 6% anti-MuSK. Thymectomy was performed in 107 patients (49%), with an average time to perform thymectomy of 4.3 years and pathology demonstrating thymoma in 16%, with the type B2 being the most common. After thymectomy, 23 patients presented myasthenic crisis requiring immunoglobulin and/or plasmapheresis. Concomitant comorbidities evaluated, most patients had high blood pressure and diabetes. In addition, 4 patients were found with associated rheumatoid arthritis, 1 with multiple sclerosis and 1 with Parkinson's disease. **Conclusion:** In this single center study, the data analyzed are similar with other studies in the literature, but with a higher percentage of thymectomized patients. However, comparing to another Brazilian cohort reported, from a different region of the country, the antibodies profile is quite different, and main reflect regional influences (genetic and/or environmental) on immunopathogenesis of MG.

https://doi.org/10.5327/CBN240368

Clinical and epidemiological characteristics of patients with Parkinson's disease being investigated for obstructive sleep apnoea: an observational analysis in the Brazilian Amazon

Marcello Facundo do Valle Filho[1], Diego Monteiro de Carvalho[1], Carlos Maurício Oliveira de Almeida[1], Marcus Vinicius Della Coletta[1], Alvaro Siqueira da Silva[1], Raíssa Costa Said[1], Carlota Assayag Mendes[2], Yenly Gonzalez Perez[1], Luma Santos Arruda[2], Ana Carolina Freire Nogueira[2]

[1]Universidade Federal do Amazonas, Manaus AM, Brazil.
[2]Faculdade Metropolitana, Manaus AM, Brazil.

Correspondence: Marcello Facundo do Valle Filho; Email: marcello_valle@outlook.com.

Background: Parkinson's disease (PD) is the second most common neurodegenerative disease in the elderly, representing about 1% of the population over 60 years old. Literature data demonstrate that in PD, sleep disorders are observed in up to 90% of patients. Obstructive sleep apnoea (OSA) is diagnosed in more than 50% of these patients, and its presence in PD can impact the quality of life by increasing daytime sleepiness, thereby negatively influencing both motor and non-motor symptoms of the disease. Understanding the clinical and epidemiological characteristics of PD patients being investigated for OSA is essential to improve the diagnosis and management of these concomitant conditions. **Objective:** To analyse the clinical and epidemiological characteristics of

PD patients being investigated for OSA. **Methods:** This is a cross-sectional observational study, with a sample composed of PD patients from the neurology clinic at the Adriano Jorge Hospital Foundation (FHAJ), Manaus-AM. The study was approved by the local Ethics Committee under Certificate of Presentation of Ethical Consideration No. 58684622.2.0000.0007. Patients underwent otorhinolaryngological and neurological evaluations, had their physical data and vital signs collected, and their clinical and epidemiological data were gathered after signing the Informed Consent Form. Patients were also subjected to the Mini-Mental State Examination (MMSE) for cognitive screening. **Results:** Of the 33 patients, the minimum and maximum ages were 31 and 88 years, respectively, with a minimum disease duration of 1 year and a maximum of 33 years, with an average disease duration of 8.1 years, a coefficient of variation of 79.8%, and a 95% confidence interval (CI) of 5.7%-10.3%. Regarding neck circumference, the average was 34.5cm, with a minimum of 20cm and a maximum of 44cm, a coefficient of variation of 5.2%, and a 95% CI of 5.7-10.3%. The majority were male (57.6%-19 patients) and 42.5% (14 patients) were female. Most individuals were married (66.7%), 21.2% were single, 9.1% divorced, and 3% widowed. Considering the body mass index, 48.5% of the patients were overweight and 12.1% had grade 1 obesity, while the remaining 39.4% were eutrophic. Only 3% of the patients had postgraduate education, 24.2% had completed higher education, 57.6% had completed secondary education, and 15.2% had only primary education. **Conclusion:** The majority of PD patients in this study are male, with an average age of 62 years, married, overweight, and with an average disease duration of 8 years. There was no association with low education levels. This information is crucial for a better understanding of the characteristics of PD, thereby contributing to the identification of risk factors, improving diagnosis, and developing more effective management strategies for this population.

Clinical and epidemiological characterization of myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD) in a tertiary center in Amazonas

Andreia Lira de Oliveira[1], Nise Alessandra de Carvalho Sousa[1], João Victor de Chagas Rossin[1]

[1]Universidade Federal do Amazonas, Manaus AM, Brazil.

Correspondence: Andreia Lira de Oliveira; Email: andreialira.med@gmail.com.

Background: Myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD) is the most recently characterized inflammatory disorder of the central nervous system (CNS). It is a demyelinating disease in which an inflammatory response targets this glycoprotein, which is uniquely present on the surface of CNS myelin sheaths. Clinical presentation is diverse and includes optic neuritis, myelitis, brainstem syndrome, acute disseminated encephalomyelitis (ADEM), and FLAIR-hyperintense lesions in anti-mog associated encephalitis with seizures (FLAMES). Diagnosis is made based on compatible clinical and radiological findings, along with the presence of anti-MOG IgG in serum or cerebrospinal fluid. **Objective:** To characterize cases diagnosed with MOGAD managed at the Getúlio Vargas University Hospital of the Federal University of Amazonas (HUGV/Universidade Federal do Amazonas). **Methods:** A retrospective study was conducted by reviewing the medical records of patients diagnosed with MOGAD between 2019 and 2024. **Results:** 6 cases of MOGAD managed by the service were identified during the study period, with 4 cases presenting initially after the age of 20 years. One case occurred in a 7-year-old child. There was no gender difference in the distribution of cases. The most common presentations were optic neuritis, myelitis, and optic neuritis associated with myelitis, with only 1 case of ADEM. Only 1 patient had a preceding infection before symptom onset, and none had been vaccinated in the days preceding the onset. None of the patients had associated autoimmune diseases. All patients showed hyperintense lesions on T2-weighted MRI, and all received acute phase treatment, albeit delayed, as well as ongoing chronic immunosuppression. Five cases experienced symptom recurrence, with myelitis being the most common recurrent clinical presentation. **Conclusion:** Given the recent recognition of MOGAD as a distinct clinical entity, it is crucial to characterize identified cases in different populations. In our study population, a notable finding was that recurrence predominantly manifested as myelitis, contrasting with current literature that mentions optic neuritis as the primary recurrent presentation. Further studies are needed to confirm this characteristic.

Clinical and epidemiological characterization of patients with Guillain-Barré syndrome (gbs) attended at a university hospital, 2014-2018

Lilian Yatiyo Nakagawa Dittmar[1], Isabela de Carvalho Florencio[1], Thiago Dias Fernandes[1], Rodrigo Ibañez Tiago[2], Dalton Santos Pinheiro[1], Rodolfo Antonio Corona[1]

[1]Hospital Universitário Maria Aparecida Pedrossian, Campo Grande MS, Brazil.
[2]Universidade Federal de Mato Grosso do Sul, Faculdade de Medicina, Campo Grande MS, Brazil.

Correspondence: Isabela de Carvalho Florencio; Email: isabelacflorencio@hotmail.com.

Background: Guillain-Barré syndrome (GBS) is an inflammatory polyradiculopathy characterized by acute or subacute symmetrical weakness, areflexia, with mild sensitive symptoms and autonomic manifestations. The diagnosis is essentially clinical, although further examinations are useful for differential diagnosis. Early diagnosis and treatment can modify the disease's natural progression. **Objective:** Tto describe clinical and epidemiological aspects of GBS in a university public hospital of Mato Grosso do Sul state, Brazil. **Methods:** Cross-sectional descriptive study of GBS patients admitted to a university hospital, in Campo Grande/MS from January 2014 to December 2018. **Results:** Between January 2014 and December 2018, 29 patients were admitted with GBS. The incidence was 0.2/100,000 inhabitants per year. The men/women ratio was 1.6 with no statistical significance (p=0.1). Eighteen patients were admitted in the summer-spring period and 11 in the winter-autumn (p=0.1). Twenty-nine patients (93.1%) presented the classic subtype. Sixteen patients presented facial involvement (58.6%), and of these, six (37.5%) needed orotracheal intubation (p=0.1). Autonomic manifestations such as heart rate and blood pressure changes, intestinal constipation, and urinary retention were present in 62.1%. Albumin-cytological dissociation of cerebrospinal fluid (CSF) was observed in eighteen patients with a mean protein value of 103.4 mg/dL. The average duration of hospitalization was 19,7 days and 34.5% needed intensive care. Full recovery occurred in 52.4% of patients, evaluated 60 days after discharge. **Conclusion:** The data obtained are in accordance with the literature. This is the first study for understanding the profile of GBS patients assisted in Mato Grosso do Sul state of Brazil.

Clinical and epidemiological evaluation of sleep disorders in chronic kidney patients at a dialysis center in Amazonas, Brazil

Ana Carolina Souza Galvão[1], Eduarda Kei-lan Tavares Pierre[1], Mariane Marques Queiroz[1], Lucas de Souza Ribeiro[1], Gabrielle Logatto Ignacio de Souza[1], Virgínia Souza Galvão[1], Gabriel Vinicius Silva de Carvalho[1], Ana Matilde Schramm[1], Carlos Maurício Oliveira de Almeida[1]

[1]Universidade do Estado do Amazonas, Manaus AM, Brazil.

Correspondence: Eduarda Kei-lan Tavares Pierre; Email: ektp.med20@uea.edu.br.

Background: Sleep disorders range from simple insomnia to more severe conditions, affecting overall bodily function. In Brazil, about 20 million people report some form of sleep disorders. Studies show a strong relationship between sleeping shorter or longer than normal with the prevalence and severity of chronic diseases such as hypertension, diabetes and cardiovascular diseases. Among patients with chronic kidney disease (CKD), up to 80% prevalence of sleep disorders can occur, which occurs both in patients in the early stages and in patients on maintenance dialysis. Therefore, it becomes relevant to gather clinical and epidemiological data from patients with CKD undergoing dialysis and correlate them with sleep disorders to assess whether there is evidence of a worse prognosis in these patients. **Objective:** Investigate the main sleep disorders in chronic kidney patients at a reference center for kidney diseases in Amazonas. **Methods:** The proposed study is a cross-sectional observational type and will be conducted at the Amazonas Kidney Disease Center, in Manaus, from December 2023 to March 2024. The sample will include CKD patients from the clinic, selected after approval by the Ethics Committee and signing of the Informed Consent Form. Patients underwent extensive data collection, including medical information, completion of sleep questionnaires such as Mini Sleep Questionnaire, Epworth Scale, Stop bang questionnaire and the diagnosis of Restless Legs Syndrome (RLS) that followed clinical criteria. **Results:** 100 CKD patients were evaluated, 63 (63.0%) of whom were male, 51 (51%) aged between 50-69 years, and 43 (43%) in the overweight range. Considering the MSQ, 60 (60%) have highly altered sleep; 43 (43%) have abnormal daytime sleepiness according to the Epworth scale; and, according to the Stop-Bang questionnaire, 41 (41%) are at high risk of developing sleep apnea. According to a previous assessment, of the 100 patients, seven (7%) were diagnosed with RLS. Of the seven patients, one (14.3%) had a mild degree, one (14.3%) had a moderate degree, four (57.1%) had a severe degree, and one (14.3%) had a very severe degree of RLS. There was no statistically significant evidence that sleep quality is related to the presence of RLS in chronic kidney disease patients (p> 0.05), considering the 5% level of significance. **Conclusion:** In this study, 60% of CKD patients through MSQ had alterations in sleep patterns, suggesting complexity in sleep conditions, with a variety of challenges ranging from daytime sleepiness to potential risks of sleep apnea. These findings underscore the importance of a holistic approach in managing the sleep of these patients, necessitating further studies for deeper exploration of this topic.

Clinical and epidemiological profile of hospital admissions due to cerebral venous thrombosis in a reference hospital

Joanna Sousa da Fonseca Santana[1], Amanda Hellen Sousa Leal[1], Ana Clara de Lemos Guimarães[1], Catarina Cavalcanti da Silva[1], Katarina Brito Gama[1], Brena Lima Cunha[1], Lucas Paulo Andrade Borges[1], Maria Clara Bastos de Sá[1], Felipe Oliveira Costa[1]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.

Correspondence: Joanna Sousa da Fonseca Santana; Email: joannasantana20.2@bahiana.edu.br.

Background: Cerebral venous thrombosis (CVT) is a condition where a clot causes occlusion of the cerebral sinus or vein, affecting cerebral blood drainage. About 15% of cases result in death or permanent disability, with the most common occlusion sites being the transverse sinus, superior sagittal sinus, and sigmoid sinus. Given its prevalence and impact on healthcare, understanding the sociodemographic profile of CVT patients is crucial in brazilian reality. **Objective:** To describe the clinical and epidemiological profile of hospital admissions due to cerebral venous thrombosis. **Methods:** This descriptive observational study uses preliminary data from a sample of 75 patients and was conducted based on medical records from a reference hospital in Bahia from January 2015 to August 2023. The sample is a non-probabilistic convenience sample. Inclusion criteria: all patients diagnosed with CVT in a reference hospital in Bahia between January 2015 and December 2023 were included. Patients without demographic, clinical, and pathological data available for the study were excluded. Variables of interest were analyzed using SPSS (Statistical Package for the Social Sciences). The study was approved by the Research Ethics Committee. **Results:** Data from 39 admissions were analyzed, with 3 (7.6%) deaths. The mean age was 35 years, ranging from 20 to 42 years. Of the patients, 30 (76.9%) were female. Imaging reports from 38 patients revealed that the most affected vessels were the transverse sinus (32), sigmoid sinus (29), and superior sagittal sinus (28). The number of affected vessels per patient varied: 4 vessels (12 cases, 30.7%), 3 vessels (11), 2 vessels (8), 1 vessel (5), 5 vessels (3), and 6 vessels (1). Among the 30 women, 17 (56.6%) used oral contraceptives. Additionally, 14 (35.9%) had pre-existing risk conditions: 5 with thrombophilias, 4 with previous CVT, 2 with recent surgeries, 1 during pregnancy/puerperium, 1 with hyperhomocysteinemia, and 1 with a family history of CVT. The most common symptom was headache (85%, 33 cases), followed by visual changes (38%, 15), motor symptoms (28%, 11), sensory symptoms (21%, 8), and cognitive symptoms (13%, 5). Focal deficits were present in 31% of cases. No patient was admitted during a seizure, but 6 (15.4%) had seizures during hospitalization. Laboratory data showed an average MAP of 98.6 mmHg, with maximum value of 133.3 mmHg. Regarding interventions, 33 (84.6%) patients required anticoagulation during hospitalization. **Conclusion:** The study's findings align with existing literature regarding the patient profile and emphasize the significant impact on neurological care, including the risks of intracranial hypertension and seizure development. Effective preventative strategies and early interventions targeting high-risk groups are essential to improve outcomes for CVT patients. By focusing on these areas, healthcare providers can better manage and reduce the incidence and impact of CVT.

Clinical and functional profile of patients with ischemic stroke secondary to arterial dissections

Lealdo Rodrigues de Andrade Filho[1], Yasmin Gabrielle Pereira Pacheco Cavalcanti de Albuquerque[2], Rayane Barbosa Do Amaral[2], Arthur Cavalcanti Pereira da Silva[2], Elizabeth Costa Ferreira de Sousa[2], Ana Beatriz Leite Amando[2], Sara Raquel Ataíde de Oliveira[2], Nicole Maria dos Santos Silva[2], Marcelo Ataíde de Lima[1]

[1]Hospital da Restauração, Recife PE, Brazil.
[2]Centro Universitário Maurício de Nassau, Recife PE, Brazil.

Correspondence: Lealdo Rodrigues de Andrade Filho; Email: leroanfilho@gmail.com.

Background: Cervicocephalic arterial dissection is the loss of integrity of the arterial wall. It is the main cause of stroke in young people identified in industrialized countries, being responsible for approximately 2% of all strokes and 20% in the age group under 45 years, being an important condition to incapacity for adjusted life years. **Objective:** To describe clinical-epidemiological characteristics, in addition to exploring the functional outcome after 90 days of patients diagnosed with cervicocephalic arterial dissection. **Methods:** Observational, descriptive study, based on the review of patient records from the reference tertiary hospital in the State of Pernambuco and referenced health regions, Brazil, between January 2013 and January 2023. **Results:** In this retrospective collection of 10 years in reference hospital, the total number of patients was 73. The average age is 47.6±14.1 years. The absence of comorbidities was present in 40% of patients. There was greater trauma exposure in younger people when compared to patients without associated trauma (40.3±15.4 vs 49.9±11.9 years, p=0.035). There was a significant predominance of patients with a favorable functional outcome after 90 days with posterior circulation involvement compared to an unfavorable outcome (91% vs 42.9%, p=0.003). It was also observed that patients with unfavorable scores were admitted with lower Glasgow Coma Scale scores, more bleeding, as well as longer hospital stays, but all variables were not statistically significant. **Conclusion:** Younger patients were associated with a precipitating factor when compared to older patients, being a critical condition for greater loss of years of life due to disability. Posterior circulation strokes have an apparent better outcome compared to anterior circulation, questioning the choice of tool to assess functionality.

Background: Limb-girdle muscular dystrophy type 2G/R7 (LGMD2G/R7) is an ultra-rare condition caused by bi-allelic pathogenic variants in the TCAP gene that was initially identified within the Brazilian population. **Objective:** We aimed to expand clinical and genetic information about this disease, including its worldwide distribution. **Methods:** A multicenter historical cohort study was performed at 13 centers in Brazil from Middle west, South and Southeast in which data from index cases and their affected relatives from consecutive families with LGMD2G/R7 were reviewed from July 2017 to August 2023. Additionally, a systematic literature review was conducted to identify case reports and series of the disease worldwide. **Results:** Forty-one LGMD2G/R7 cases were described in the Brazilian cohort, being all subjects homozygous for the c.157C> T/(p.Gln53*) variant in TCAP. Survival curves showed that the median disease duration before individuals required walking aids was 21 years. Notably, women exhibited a slower disease progression, requiring walking aids 13 years later than men. LGMD2G/R7 was frequently reported not only in Brazil but also in China and Bulgaria, with 119 cases identified globally, with possible founder effects in the Brazilian, Eastern European, and Asian populations. **Conclusion:** These findings are pivotal in raising awareness of LGMD2G/R7, understanding its progression, and identifying potential modifiers. This can significantly contribute to the development of future natural history studies and clinical trials for this disease.

Clinical and genetic profile of patients with chanalopathies in a reference center for neuromuscular diseases: retrospective observational study

Izadora Vieira Bolzani Lopes Lima[1], Felipe Franco da Graça[1], Anamarli Nucci[1], Marcondes Cavalcante França Junior[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Izadora Vieira Bolzani Lopes Lima; Email: izadoralima7@gmail.com.

Background: Channelopathies are rare muscle disorders caused by mutations in genes that encode ion channels. The most common phenotypes are congenital myotonia, paramyotonia and periodic dyskalemic paralysis. The definitive diagnosis is based on genetic tests and patients can take years to have a defined diagnosis, often undergoing unnecessary and high-cost interventions. The relative low availability of clinical studies on this topic in Brazil brings the need for research in order to establish standards and make possible future efforts to find pharmacological treatments that help in symptomatic control. **Objective:** To describe clinical, genetic and electrophysiological characteristics in patients with muscle channelopathies diagnosed by next sequencing generation tests in a specialized outpatient clinic of a high-complexity hospital based on an observational, retrospective study and to describe the diagnostic journey of these patients. The study was approved by the local Ethics Committee. **Methods:** Data were collected from the medical records of 29 patients who presented with signs and symptoms of channelopathy. We excluded 5 patients with genetic mutation in the RYR1 gene without compatible clinical findings and also 9 patients who had a suggestive phenotype without genetic proof. We compared clinical features between patients according to genetic variations using non-parametric tests, given the sample size. The Mann-Whitney test for continuous variables and Fisher's exact test for categorical ones. **Results:** Fifteen patients met inclusion criteria and had diagnostic confirmation through an NGS panel for pathogenic variants related to channelopathies. We identified 22 variants in 3 different genes: SCN4A (6 cases, 40%), CLCN1 (8 cases, 53.3%) and KCNJ2 (1 case, 6.66%). Of these patients, ten (66.6%) presented an AD inheritance pattern. Missense mutations in all positive panels accounted for 72.7% of mutations. It was noted greater difficulty in establishing a diagnosis in sodium channelopathies, with the highest percentage of misdiagnosis in these cases (83.3% versus 37.5%). We

also observed the long journey until diagnostic definition (median 34.5 years). The presence of warm up phenomenon was present in all patients with chloride CLCN1 and paramyotonia was present in most patients with SCN4A, indicating the role of the active search for these phenomena in the differentiation between conditions (p=0.015). Weakness on physical examination, hypertrophy, presence of cramps, periodic paralysis, seizures, increased CK and diet have not shown statistical significance between the groups. We have found a new variant for the CLCN1 mutation (c.2284+1G> A) and for the KCNJ2 (c.788t> G - p.Leu263Arg) not previously described in literature. **Conclusion:** NGS panel has proven to be a relevant diagnostic tool in the assessment of channelopathies and the knowledge of clinical variables linked to these diagnoses enables better clinical practice.

Clinical and genetic spectrum of the ZFYVE26 gene: an analysis of 7 patients

Renan Brandão Rambaldi Cavalheiro[1], Kaliny Oliveira Peixoto[1], João Paulo Barile[1], Patrícia Marques Mendes[1], Igor Braga Farias[1], Paulo de Lima Serrano[1], Wladimir Bocca Vieira de Rezende Pinto[1], Paulo Victor Sgobbi de Souza[1], Acary Souza Bulle Oliveira[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Renan Brandão Rambaldi Cavalheiro; Email: renan.rambaldi@icloud.com.

Background: The hereditary spastic paraplegias (HSPs) are a heterogeneous group of monogenic diseases characterized by length-dependent corticospinal tract degeneration that manifests as bilateral lower limb spasticity, hyperreflexia and extensor plantar responses. They can be further divided into pure and complex, based on additional clinical features, such as epilepsy or cognitive decline. Their genetic classification uses the designation spastic paraplegia gene (SPG). SPG15/Kjellin syndrome, caused by biallelic pathogenic variants in the ZFYVE26 gene, is the second most common autosomal recessive HSP. While a complex HSP phenotype is described, the clinical spectrum of the ZFYVE26 has expanded over the years, with movement disorders and motor neuron disease being reported as possible clinical features. **Objective:** Describe the clinical characteristics of 7 patients with genetically proven SPG15/jALS. **Results:** The average age at onset of symptoms was 16.4 years (range: 9-24 years) and the average age at diagnosis was 27.6 years (range: 14-45 years). Consanguinity was observed on 4 patiens. Two main phenotypes were observed: 3 patients had a clinical presentation compatible with juvenile amyotrophic lateral sclerosis (jALS), while the other 4 patients were diagnosed with a HSP phenotype. Distinguishing features between the two groups were the presence of cerebellar ataxia (75% in the HSP group, none in the jALS group), muscle fasciculations (66% in the jALS group, absent in the HSP group) magnetic resonance imaging (corpus callosum thinning was observed in all patients; the classic "ears of the lynx" sign present in 100% of the HSP patients, more diffuse cortical atrophy and white matter changes in the jALS group). Retinal "yellowish flecks" were observed on two patients (one on each group). Cognitive decline was observed on five patients, ranging from moderate dysexecutive changes on 3 patients in the HSP to dementia resembling frontotemporal lobar degeneration (1 patient in each group). Dystonia was observed as the sole movement disorder in two patients, while a combination of dystonia and parkinsonism was observed in one patient. **Conclusion:** The ZFYVE26 spectrum ranges from a complex HSP to a disorder resembling FTD-ALS; additional clinical features include dystonia, parkinsonism and cerebellar ataxia. MRI remains an useful diagnostic tool to distinguish between ZFYVE26 HSP/ ALS from other genetic o acquired disorders.

https://doi.org/10.5327/CBN240377

Clinical and genotypic characteristics of patients with Nonaka distal myopathy at a specialized clinic in Salvador, BA

Ananda Vieira de Lima Almeida[1], Rafael Amaral de Matos Albuquerque[1], Maria Carolina Freitas Ferreira[1], Laís Brandão Mota[1], Guiniver Couto Almeida[1], Marcela Câmara Machado Costa[1], Marilaine Matos de Menezes Ferreira[1]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.

Correspondence: Rafael Amaral de Matos Albuquerque; Email: rafaelalbqq@outlook.com.

Case presentation: Distal myopathy of the Nonaka type is a rare genetic disorder, with an estimated prevalence of 1 in 1,000,000. It is progressive and inherited autosomally recessively, caused by mutations in the GNE gene. This gene encodes the enzyme UDP-N-acetylglucosamine 2-epimerase/N-acetylmannosamine kinase, vital for sialic acid biosynthesis. The disease typically manifests in the third decade of life with predominant distal muscle weakness. We describe five patients from four distinct families diagnosed with GNE myopathy at a specialized clinic in Salvador, BA. The group comprises three women and two men, averaging 38.6 years old. All had distal lower limb muscle weakness starting at around 25 years old, yet the average time to genetic diagnosis was 9.6 years. All five patients showed foot drop as a primary clinical feature from anterior leg compartment weakness. Two patients had consanguineous parents. One initially presented with dropped head syndrome, an atypical late manifestation, currently using a cervical collar. This patient is the only one in this series with respiratory involvement, experiencing respiratory effort and dyspnea. Genetic analysis revealed the following GNE mutations: c.829C> T (p.Arg277Trp) in homozygosity, c.766G> A (p.Asp256Asn) in heterozygosity, and G> A in homozygosity. The c.829C> T variant is present in three patients and is one of the most common pathogenic variants associated with this disease. The c.766G> A (p.Asp256Asn) variant, present in one patient, is documented in the literature and considered probably pathogenic. Muscle biopsies from four patients showed autophagic vacuoles and cytoplasmic inclusions consistent with the disease. Three patients use wheelchairs, with a mean onset of 5.6 years after molecular diagnosis. All patients are currently receiving multidisciplinary outpatient care following their confirmed diagnosis. **Discussion:** This case series is crucial for advancing scientific understanding of the genotype-phenotype correlation of this disease. One case presents atypically with the onset of dropped head syndrome, a manifestation typically seen only in advanced stages due to the progressive distal-to-proximal muscle involvement affecting the neck flexors. The usual clinical presentation is distal leg weakness, evident as foot drop, followed by slow progression to upper musculature. Respiratory involvement, rare in literature, occurs in advanced stages. All identified mutations have been previously documented. Most mutations are seen across multiple families or within a single family with several cases, impacting symptom onset, presentation, severity, and disease progression. **Final comments:** Understanding clinical-genotypic aspects of Nonaka distal myopathy is crucial for comprehending disease behavior. As a rare condition with limited global research, this series can enhance knowledge through investigating genotypic and phenotypic characteristics.

Correspondence: Marcela Maria Cabral Ribeiro; Email: mmcabralribeiro@gmail.com.

Background: Primary progressive aphasia (PPA) is a rare neurodegenerative disorder, with estimated prevalence of 3-4 per 100.000 population, characterized by predominant language impairment, alongside prejudice to daily activities and without equivalent disturbance on behavior and episodic memory during symptoms emerge. While PPA is the prototype of a language-predominant dementia syndrome, aphasia could be the presenting symptom of other conditions such as Corticobasal Syndrome, defined as a combination of cortical and subcortical signs usually affecting the parietal lobes asymmetrically. **Objective:** Describe five PPA cases of patients followed at a cognitive neurology reference center in Recife. **Methods:** Case series with thorough revision of health-records, imaging and laboratory tests of all patients classified with language-predominant dementia syndromes between 2019-2023 in a tertiary center. **Results:** Five female patients were described, with ages from 56 to 65 years (average 60.5 years). Language impairment was the first isolated manifestation observed in 80% of cases. Associated symptoms were difficulty in lexical access during speech (n=3), paraphasia (n=3), echolalia (n=2), writing deficits (n=2), apraxia of speech (n=1), dysexecutive (n=1) and stuttering (n=1). Two patients (40%) referred preference for low nutritional foods and one patient (20%) evolved with mutism. Atypical parkinsonism is present in 40% of the cases, raising the possibility of PPA secondary to corticobasal syndrome. Magnetic resonance imaging (MRI) revealed a more pronounced volumetric reduction in the parietal (60% of cases) and frontotemporal (40% of cases) lobes, with a predominance on the left. Metabolic positron-emission tomography (FDG-PET) showed glycolytic hypometabolism compatible with metabolic pattern of frontotemporal dementia (n=3), corticobasal degeneration (n=1), and Alzheimer's disease (n=1). The hypothesized variants were semantic (n=3), nonfluent (n=1), and logopenic (n=1). Multidisciplinary intervention with speech therapy had great adherence in 80% of cases, and selective serotonin reuptake inhibitors (SSRIs) were prescribed for symptoms in 80% of cases. **Conclusion:** PPA is a diagnosis to be considered in middle adulthood and elderly patients with language impairment. The differential diagnosis among other cognitive disorders is subtle and may request imaging. Owing to PPA's insidious nature, the outcome is progressive cognitive decline with language predominance in all cases, associated with movement disorders in 40% and with mutual predominance of behavior disorders in another 40% of cases. These patients' identification allows the early institution of a multidisciplinary therapeutic plan, which aims to retard the progression of dementia and to improve patients' and caregivers' quality of life.

Background: Spinal muscular atrophy linked to chromosome 5 (SMA-5q) is a progressive genetic disease caused by deletions or disease-causing variants in the survival motor neuron 1 (SMN1) gene. Onasemnogene abeparvovec is the first gene replacement therapy (GT) approved to treat SMA-5q. SMN1 gene transfer therapy through AAV9 aims to restore normal levels of functional SMN protein. More recently, new safety concerns have arisen, such as hepatotoxicity, thrombotic microangiopathy (TMA), and prolonged use of corticosteroids, underscoring the importance of continuous post-marketing drug safety monitoring. **Objective:** This study aimed to show the frequency of TMA in patients with SMA-5q treated with onasemnogene abeparvovec in a large multicenter Brazilian cohort and to describe the clinical and laboratory profile. **Methods:** This retrospective multicenter observational study evaluated all patients who developed TMA following treatment with onasemnogene abeparvovec for SMA-5q across Brazil from October 2020 to January 2024. Data were collected from medical records and from results presented at conferences (OPHELIA study). **Results:** Among 150 patients with SMA-5q treated in Brazil from October 2020 to January 2024, seven developed TMA. Six patients were type 1 SMA-5q, and one type 2 SMA-5q. The average age at the time of gene therapy administration was 20.8 months (range: 12 - 37 months), with an average weight of 11.4kg (range: 8.0 - 16.7kg). Notably, only one patient had a documented infection before gene therapy. No patient had received a vaccine within one month before treatment. All patients had antibody titers ≤1:50 before infusion. Patients exhibited the first symptoms of TMA between the first and second week post-infusion (mean 7.8 - range: 6-10 days). Thrombocytopenia in all patients was severe, with values below 50,000 (mean 17,000 - range: 5,000 to 31,000). Six patients exhibited both proteinuria and hypertension, and three experienced oliguria. Additionally, six patients showed increased creatinine levels, indicating signs of acute kidney injury. Five patients required treatment for TMA; two underwent plasmapheresis, and three patients had an increase in the corticosteroid dose to 2mg/kg/day. One patient treated with plasmapheresis developed hematuria, kidney and liver failure, and died. All other patients recovered after TMA. The occurrence of TMA was associated with prolonged corticosteroid use (mean 194 days - range: 70-390). No patient received Eculizumab or any other immunomodulator. **Conclusion:** TMA is a severe life-threatening side effect. Early identification and appropriate treatment are essential for a positive outcome.

Clinical and molecular profile of Duchenne muscular dystrophy in a single center in Brazil

Karlla Danielle Ferreira Lima[1], Marco Antônio Veloso Albuquerque[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Karlla Danielle Ferreira Lima; Email: karlla.dfl@gmail.com.

Background: Duchenne muscular dystrophy (DMD), a disease with X-linked recessive inheritance pattern, is one of the most severe forms of inherited muscular dystrophies, caused by mutation in DMD gene and leading to progressive muscle fiber degeneration and weakness. Progressive weakness results in loss of ambulation early, and death from respiratory impairment or cardiac dysfunction. **Objective:** To evaluate the clinical profile of patients with DMD, followed from 2000 to 2024. **Methods:** This is a cross-sectional and retrospective study carried out at the Muscle Section of a reference center in Brazil. **Results:** The medical records of 143 patients were reviewed. Patients had a mean age of 11 years old (2-23 years old). The average age at onset of signs/symptoms was 3 years of age (ranging from 6 months to 9 years). Patients had their diagnosis confirmed at an average of 6 years of age (ranging from 6-16 years). The mean first baseline serum CPK was 12,936. The main signs/symptoms of initial manifestation were: falls (40%), motor developmental delays (15%) and change in gait (10%). 3% had language developmental delay as first symptoms and 5% had serum enzymes elevation as first manifestation even without symptoms. Regarding the molecular profile, 62% had deletion of 1 or more exons, 14% duplication of 1 or more exons, 10% nonsense variant, 10% frameshift and 4% at the splice site. Regarding corticosteroids, the average starting age was 6.9 years old; 70% were using deflazacort while 25% were using prednisolone/prednisone, and 5% were not using it or did not have data in the medical record. 33% of patients had already lost the ability to walk, with an average age of loss of ambulation of 9.6 years old. 39% of patients had neurodevelopmental disorder: 49 (32%) patients had some degree of intellectual disability, 21 (13%) had Attention Deficit Hyperactivity Disorder (ADHD), 10 (6%) autism spectrum disorder (ASD), 4 (2%) oppositional defiant disorder (ODD). 13% had more than one neurodevelopment disorder. Only two patients had epilepsy, one of which was associated with another genetic variant. **Conclusion:** The study demonstrated a profile of young patients, with 76% of patients presenting deletion or duplication of one or more exons, a molecular profile similar to that described in the literature. The average age of diagnosis was late compared to other studies, and the period between the onset of symptoms and molecular diagnosis was relatively long, reflecting the difficulty for physicians in recognizing the condition in its earliest stages. Finally, there was a higher prevalence of cognitive/neurodevelopmental disorders in this cohort.

Background: Biallelic pathogenic variants at TK2 lead to a severe and progressive myopathy (TK2d). For a scenario with unspecific clinical findings, added to the possibility of supplementation therapy that changes the natural history of the disease, highlighting clinical features that increase suspicion and accelerate diagnosis is essential. **Methods:** Clinical (N=32) and genetic findings (N=36) of patients with TK2d from several centers across Brazil were identified and presented in this work. Genotype-phenotype correlation was performed for recurrent and novel variants. Motor and respiratory assessments were systematically performed in 10 patients. **Results:** Nine patients with the infantile form, 19 with childhood form and 5 with late-onset form were described. Extramuscular features were present in 30% of the cohort. Neuropathy and encephalopathy were clinically predominant for some patients. Four variants were recurrent, and one was novel, allowing genotype-phenotype correlations. T108M patients presented a milder presentation and slower progression when compared to the H121N group. R183T might be associated with peripheral nerve involvement and c.536_538+8del with encephalomyopathic involvement. A two-year follow-up of three patients showed decreased motor, bulbar, and respiratory function, compared to a dramatic improvement in treated patients. **Conclusion:** TK2d is a very debilitating disease. Early diagnosis is essential because a potential treatment can change the natural history of the disease. High diagnostic suspicion is imperative, and extramuscular involvement might play an important role for diagnostic strategies, starting with the inclusion of the TK2d in the differential diagnosis for neuropathies and epilepsy

Clinical and motor functional evaluation of patients with bi-allelic disease-causing variants in SMN1 gene and two copies of SMN2 treated in the pre-symptomatic stage

Raquel Diógenes Alencar Sindeaux[1], Rodrigo de Holanda Mendonça[1], Joemir Jabson da Conceição Brito[1], José Pedro Baima[1], Graziela Jorge Polido[1], Eduardo Vital de Carvalho[1], Leandro Augusto de Almeida[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Departamento de Neurologia, São Paulo SP, Brazil.

Correspondence: Eduardo Vital de Carvalho; Email: duvital1983@gmail.com.

Background: Spinal Muscular Atrophy linked to chromosome 5 (SMA-5q) is a rare genetic disorder that leads to progressive muscle weakness and atrophy. Patients with SMA-5q can be diagnosed in a pre-symptomatic phase through newborn screening or when there is a sibling with SMA-5q. Early diagnosis enables prompt intervention and improves patient outcomes. **Objective:** To describe the experience of a specialized neuromuscular center in the treatment of pre-symptomatic SMA-5 patients and to analyze the clinical aspects during a follow-up period up to 57 months (range 1-57; average 16.3 months). **Methods:** Six SMA-5q patients started treatment in a pre-symptomatic phase and have been monitored in a neuromuscular center specialized in motor neuron diseases, from August 2019 to May 2024. Neurological examination, motor scale and respiratory assessments have been performed by a multidisciplinary team at the diagnosis, every 3 months during the first year of follow-up and every 6 months thereafter. Information on adverse effects have also been collected. **Results:** All six pre-symptomatic patients had homozygous deletion in SMN1 gene and 2 copies of SMN2. Four patients were diagnosed by newborn screening and have been followed from 1 to 10 months old (mean 5.75 months). They started risdiplam between 25 and 29 days of age (mean 26.75 days). One of them started risdiplam recently and remains asymptomatic at 2 months old, but still does not have a comparative motor scale. The other three risdiplam-treated patients achieved maximum score on Children's Hospital of Philadelphia Infant Test of Neuromuscular Disorders (CHOP INTEND) at 4 months old. All risdiplam-treated patients have adequate development for their age, but two of them switched treatment to zolgensma at 6 and 9 months old because it is a single dose therapy. Two patients were younger siblings of SMA-5q patients and had an intrauterine diagnosis. They started nusinersen between 2 and 7 days old (mean

4.5 days) and have been followed from 18 to 57 months (mean 37.5 months). They both changed treatment to zolgensma because they were experiencing weakness in their limbs. One of them received zolgensma at 5 months old, reached maximum CHOP INTEND score at 6 months old and started walking at 1 year and 4 months old. The other patient received zolgensma at 1 year and 6 months old, reached maximum CHOP INTEND score at 1 year old and started walking at 1 year and 10 months old. None of the patients presented dysphagia or need for ventilatory support. Patients who received zolgensma reported these adverse effects: one had fever and vomiting, one thrombocytopenia and two elevated hepatic transaminases. One patient who received risdiplam had anemia. **Conclusion:** The positive outcomes observed in our cohort underscore the importance of early diagnosis and intervention. By demonstrating consistency with clinical trials, our findings further support the efficacy of current treatment approaches for SMA-5q.

Clinical and neuroimaging features of corticobasal degeneration

Carolina Rocha da Silveira Brügger Cardoso[1], Bruna Andrade de Oliveira[1], Natália da Costa Chiote Pinheiro[1], Luiz Felipe Vasconcellos[1]

[1]Universidade Federal do Rio de Janeiro, Instituto de Neurologia Deolindo Couto, Rio de Janeiro RJ, Brazil.

Correspondence: Carolina Rocha da Silveira Brügger Cardoso; Email: carolinarbrugger@gmail.com.

Case presentation: Case 1: 81-year-old man started 3 years ago with rigidity in right lower limb leading to progressive impairment of walking with falls within 6 months and wheelchair bound in 1 year. Later he also presented rigidity of right upper limb. Concomitantly, he presented cognitive impairment and bradyphrenia. Neurological exam: right side bradykinesia, global rigidity, slow velocity of vertical saccades and involuntary elevation of the right arm (alien limb phenomenon). MRI: bilateral hippocampal atrophy. Case 2: 59-year-old woman started at the age of 54 memory impairment, executive dysfunction and motor apraxia. Physical exam: gait apraxia, global rigidity, hyperreflexia with Babinski and Hoffman signs in the right side, resting tremor in the right upper limb, polyminimyoclonus, severely cognitive impairment with global aphasia, slow velocity of vertical saccades and right alien limb phenomenon. MRI: asymmetric frontoparietal atrophy, well-marked on the left. Case 3: 58-year-old woman started with dyscalculia at 54 years, evolving with progressive aphasia, cognitive impairment and gait apraxia. Neurological exam: gait apraxia, global rigidity, myoclonus, dystonic posture of the trunk and upper limbs and severe cognitive impairment. MRI: asymmetric frontoparietal and hippocampal atrophy. Case 4: 68-year-old woman presented with gait impairment and postural instability. The symptoms started at the age of 65 with dystonic movement of the right hand evolving to ipsilateral tremor and motor apraxia. Physical exam: parkinsonian gait, myoclonus, motor apraxia, global aphasia, dysphagia, right alien limb phenomenon. MRI: global parenchymal atrophy, worse on left frontoparietal cortex. **Discussion:** Corticobasal degeneration (DCB) is a rare cause of atypical parkinsonism (1). The terms "corticobasal syndrome" (CBS) and "corticobasal degeneration" (CBD) represent distinct conditions. The former denotes the clinical phenotype, whereas CBD can only be confirmed by postmortem anatomopathological analysis (2). Classically, motor symptoms occur asymmetrically and include akinetic-rigid parkinsonism, dystonia, myoclonus and the alien limb phenomenon. Cognitive symptoms include apraxia, aphasia, cortical sensory deficits (2). In neuroimaging, magnetic resonance imaging typically reveals asymmetric cortical atrophy, predominating on the posterior frontal and parietal cortex (3). However, this pattern is observed around 50% of cases, depending mainly on disease stage. **Final comments:** In this report, we present four cases of CBS/CBD, through its clinical evolution with motor and cognitive findings, describing aspects of neuroimaging. The definition of CBD is only possible by pathological analysis, but neuroimaging could be a useful tool for differential diagnosis.

Clinical and neurophysiological characterization of patients with ganglionopathies: case series

Andreia Lira de Oliveira[1], Pablo Vinícius Silveira Feitoza[1], Luiziane Maria da Silva Alves[1], Tiago Breno de Farias Brito[1], João Victor de Chagas Rossin[1]

[1]Universidade Federal do Amazonas, Manaus AM, Brazil.

Correspondence: Andreia Lira de Oliveira; Email: andreialira.med@gmail.com.

Background: Neuronopathies or ganglionopathies constitute a group of relatively rare sensory neuropathies, resulting from involvement of the dorsal root ganglion. This condition was first described in 1948 and has a distinct clinical presentation from other sensory neuropathies, mostly affecting deep sensitivity with a non-length-dependent pattern. It typically manifests with sensory ataxia and areflexia. **Objective:** To characterize clinically, epidemiologically and neurophisiologically the cases of ganglionopathies observed in our service. **Methods:** A retrospective study was conducted by reviewing the medical records of ganglionopathy cases treated between 2018 and 2024. **Results:** 10 diagnosed cases were identified with ganglionopathy during the study period. The average age of the patients was 59.8 years, with a predominance among women (60%) and symptom onset within 5 years in 70%. Disease presentation was chronic in 90% of cases, initially affecting lower limbs in 70% of cases, although with disease progression, 90% of patients eventually presented involvement of both upper and lower limbs. Half of the patients reported paresthesia as the initial symptom, while others reported ataxia (30%) and pain (20%). Only 30% of patients had pure deep sensitivity impairment, even though all of them predominantly exhibited this type of sensory deficit. Two patients presented with associated cerebellar involvement, 90% of cases presented with hyporeflexia or areflexia, mainly in the lower limbs. Etiologically, half of the cases remained idiopathic, while 2 cases were associated with Sjogren's syndrome, 2 cases with Paraneoplastic syndrome and 1 case with vitamin B12 deficiency. The majority of cases (90%) were treated with immunosuppressive therapy or vitamin b12 supplementation, but only 5 patients reported symptom improvement after treatment, mostly ataxia improvement. Among the 5 cases that showed symptom improvement, 4 patients (80%) received pulse therapy with methylprednisolone. Regarding electroneuromyography, there was a predominance of asymmetric and severe axonal impairment of nerves, with 60% of cases characterized as sensory axonal neuropathy and 20% as sensory-motor axonal neuropathy. **Conclusion:** Our aim is to contribute to the characterization of this relatively rare and understudied condition, encouraging further research in this area, especially its etiology with the identification of autoantibodies potentially associated with this condition, as well as uncertainties regarding appropriate therapeutic choices.

https://doi.org/10.5327/CBN240385

Clinical and neurophysiological epidemiology of brain death

Tarcísio Nunes Alvarenga[1], José Eduardo Trentim Longo[1], Júlio César Moreira[1], Marina Carvalho Acosta Cleto[1], Thalita Luiza Madoglio[1], Laércio Martins de Stefano[1], Lilian Audi Goulart[1], Rebeca Aranha Barbosa Sousa[1], Yasmim Nadime José Frigo[1], Luiz Eduardo Gomes Garcia Betting[1]

[1]Universidade Estadual Paulista, São Paulo SP, Brazil

Correspondence: Tarcisio Nunes Alvarenga; Email: tarcisionalvarenga@gmail.com.

Background: Brain death (BD) is the complete and irreversible loss of brain functions. EEG is a diagnostic test that is low-cost and relatively accessible. In Brazil, the estimated rate of BD is 90-100 cases per million people per year. **Objective:** This study is an epidemiological survey and neurophysiological results of individuals with suspected BD in the region of the Regional Health Department (DRS-VI). **Methods:** Retrospective study reviewing EEG reports of all BD protocols opened in DRS-VI over a 1-year period. This region comprises 68 municipalities with approximately 1.8 million people. All tests are performed by the OPO team at the Hospital das Clínicas, Faculty of Medicine of Botucatu - UNESP. After a compatible clinical analysis, the complementary test of choice is the EEG. This test is performed according to SBNC recommendations derived from ACNS. Basically, tests are performed with video-EEG recordings, electrode placement according to the international 10-20 system, and lasting 30 minutes including 2 painful stimuli. **Results:** 107 BD protocols were opened. The estimated incidence was 57 cases per million people. The individuals had a mean age of 48±18 years (min=10 – max=86, 46 women). Regarding etiology: 61% had stroke (n=8 ischemic stroke, n=48 hemorrhagic stroke, and n=9 unspecified), 22% traumatic brain injury, 7% ischemic encephalopathies, 5% neoplasms, 4% neuroinfections, and 2% others. The EEG was compatible with the diagnosis in 90% of cases. In 11 individuals, the test needed to be repeated. In these cases, it was confirmatory in 8 cases, remained inconclusive in 2, and in only 1 patient presented cerebral electrical activity. **Conclusion:** The incidence of BD in the region is lower than the estimated national rate. EEG helped to rule out one case in 107 and was inconclusive in 2. These findings confirm its importance in the protocol currently used in the country.

https://doi.org/10.5327/CBN240386

Clinical and polysomnographic characteristics associated to excessive daytime sleepiness in obstructive sleep apnea

Eder Leandro da Silva Dantas[1], Eduardo Cordeiro Vitor Martins[1], Fernando Gustavo Stelzer[1], Alan Luiz Eckeli[1]

[1]Faculdade de Medicina de Ribeirão Preto, Hospital das Clínicas, Ribeirão Preto SP, Brazil.

Correspondence: Eder Leandro da Silva Dantas; Email: ederleandro.sdantas@gmail.com.

Background: Obstructive sleep apnea (OSA) is characterized by recurrent episodes of reduction or cessation of upper airway airflow during sleep. One of the most frequent symptoms related to OSA is excessive daytime sleepiness (EDS), with prevalence ranging from 35 to 87%. EDS has elevated morbidity, being related, for example, to increased risk of motor vehicle and work-related accidents and impaired cognitive and work performance. However, there are few studies evaluating epidemiology and polysomnographic characteristics of EDS among individuals with OSA. **Objective:** To evaluate prevalence of EDS and to assess the association of clinical and polysomnographic characteristics of EDS among adult patients with OSA. **Methods:** This was a cross-sectional study, including adult individuals referred for diagnostic polysomnography (PSG) between March, 2014 and

March, 2015. The main inclusion criteria were confirmed OSA diagnosis and age ≥18 years old. Exclusion criteria were participation refusal, age <18 years old, moderate to severe depression symptoms, chronic use of sedative-hypnotic drugs, and cognitive impairment. All participants provided written informed consent forms. EDS was assessed by Epworth Sleepiness Scale (ESS) and defined as a score >10. Depressive and anxious symptoms were evaluated through Beck Depression Inventory and Beck Anxiety Inventory, respectively. All participants were submitted to full-night polysomnography. **Results:** Data from 392 participants was analyzed. EDS prevalence was 45.7%, being more prevalent in men and in the economically active group. There was a positive correlation between body mass index and ESS score and there was a negative correlation between ESS score and age. Prevalence of depressive and anxious symptoms was higher in the EDS-group. EDS was more prevalent in severe OSA. Regarding polysomnographic findings, EDS was associated with shorter sleep duration and REM sleep latency and greater apnea-hypopnea index (AHI), sleep efficiency, sleep fragmentation, and total sleep time in comparison to non-EDS ones. EDS was not associated to oxygen saturation parameters. **Conclusion:** Prevalence of EDS in OSA patients was within mid-range from previous studies. There is a higher prevalence of EDS between economically active young men. Besides, our findings suggest that sleep fragmentation due to respiratory events in OSA might play a role in EDS pathophysiology.

https://doi.org/10.5327/CBN240387

Clinical and radiological improvement of oligodendrocyte myelin syndrome with combined treatment of rituximab and plasmapheresis

Maria Luiza Levindo Coelho Martinis[1], Bárbara Luisa Coraspe Gonçalves[1], Luiz Guilherme Gerhardt Fernandes[1], Marina Brasileiro Cesar Leitão[1], Bárbara França Amorim[1], Osvaldo Pantoja de Oliveira[1], Luiz Fernando Guimarães[1], Ana Carolina Andorinho de Freitas Ferreira[1], Cristiane Borges Patroclo[1], Marcelo Cagy[1]

[1]Hospital Federal dos Servidores do Estado, Rio de Janeiro RJ, Brazil.

Correspondence: Maria Luiza Levindo Coelho Martinis; Email: mlevindocoelho@gmail.com.

Case presentation: Female patient, 22 years old, started in 2015 with paresthesia in the left lower limb. At time she didn't have her symptoms evaluated by a neurologist. Her symptoms were considered to be of psychogenic origin, and she was treated with an anxiolytic drug. In 2019, the patient developed bilateral optic neuritis (ON) and was referred to a neurology service. She underwent magnetic resonance imaging (MRI) which showed several demyelinating lesions, as well as a positive oligoclonal band. Her optical coherence tomography showed bilateral changes. She underwent intravenous methylprednisolone 1000mg per day for five days, with slight clinical improvement, repeating the treatment after a month. The patient was initially diagnosed with multiple sclerosis (MS). Interferon was started and, despite this, progressed to recurrent optic neuritis outbreaks and sensory and motor symptoms. The new MRI shows disseminated demyelinating lesions in the spinal cord. Antibody - aquaporin-4 (anti-aqp4) and myelin oligodendrocyte glycoprotein andibody (anti-MOG) research was performed (cell base assay method) and showed a negative anti-aqp4 antibody and positive anti-MOG. The patient, while using interferon, developed tetraparesis, spasticity in the lower limbs, worsening gait, requiring a wheelchair. After confirming the positivity of the anti-MOG, the patient underwent plasmapheresis (twice a year) and the use of rituximab, showing significant improvement in his gait (walking more than 100 m with a walker) and reducing spasticity after one year of treatment. **Discussion:** Myelin oligodendrocyte glycoprotein (MOG) is present on the surface of oligodendrocytes and the myelin sheath of the nervous system and the MOG antibody-associated disease (MOGAD) is the most recently studied inflammatory demyelinating disease of the central nervous system. The presence of MOG antibodies was found in a small portion of a group of patients with multiple sclerosis, with a more severe disease course, with higher rates of recurrence and no therapeutic response to disease-modifying therapies. Typical symptoms of MOGAD include ON and myelitis, which overlap with MS and neuromyelitis optica (NMO). In profile of the patient, MOGAD has less sex or age predilection than MS or NMO. The above patient presented reduced clinical and radiological activity with concomitant treatment with rituximab and plasmapheresis **Final comments:** The case presented in this article shows a female patient that had the MS diagnosis but the latest investigation showed anti-mog positive. Thus, the anti-MOG research shows it importance in cases of MS with non responsive treatment. In Brazil we have limited access to this type of exam, making diagnostic confirmation difficult. There is no specific medication to treat this disease. Treatment with rituximab and plasmapheresis for the patient resulted in clinical and radiological improvement.

https://doi.org/10.5327/CBN240388

Clinical and ultrasonographic evaluation of dysphagia in patients with LAMA2-CMD

Clara Gontijo Camelo[1], Pedro Henrique Marte de Arruda Sampaio[1], Ana Lucila Moreira[1], Cristiane de Araujo Martins Moreno[1], Mariana Cunha Artilheiro[1], André Macedo Serafim da Silva[1], Umbertina Conti Reed[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Clara Gontijo Camelo; Email: claragc@gmail.com.

Background: LAMA2-CMD is a rare autosomal recessive disease characterized by hypotonia, muscle weakness, and the inability to achieve independent gait. It imposes a considerable disease burden, including difficulty in weight gain and dysphagia. **Objective:** However, this disease burden has not been thoroughly assessed in the medical literature, and this study aims to address this gap. **Methods:** Patients with genetically confirmed LAMA2-CMD were cross-sectionally evaluated. Clinical assessments included analysis of dysphagia, NdSss scale, weight measurement, and the necessity of gastrostomy. Patients received ultrasound evaluations of tongue muscles, and the muscle abnormalities were classified using the modified Heckmatt scale. The ultrasound M mode assessed the hyoid elevation movement during swallowing. Qualitative analysis of ultrasound findings and correlations with clinical presentations were conducted. **Results:** 20 patients with LAMA2-CMD were evaluated, ranging from 3-27 years old (mean 7.7). 8/20 patients (40%) weighted below the 3rd percentile. All patients experienced some degree of dysphagia, with a maximum score of 7 on the NdSss scale. 17/20 patients (85%) reported taking over 30 minutes to finish a meal. 4/20 patients (20%) had gastrostomy tubes. The geniohyoid muscle was the most affected among the three tongue muscles evaluated. 14/ 20 patients had markedly hyperechoic muscle. The genioglossus muscle was the second most affected, with 9/20 patients having markedly hyperechoic muscle. None of the patients had normal geniohyoid or genioglossus muscles. Lastly, the least affected muscle was the digastric, with 7/20 patients having markedly hyperechoic muscle. 16/20 patients required an increased number of hyoid elevation movements and had low amplitude movements during swallowing. A correlation was observed between the patient's age and the severity of ultrasound abnormalities. The genioglossus and geniohyoid muscles appeared more preserved in patients under 5 years old than older patients (p=0.005 and p=0.017, respectively). Similarly, there was a correlation between extremely low weight (p<3) and markedly hyperechoic genioglossus muscle (p=0.0176). **Conclusion:** Patients with LAMA2-CMD experience greater difficulty in weight gain and exhibit some degree of dysphagia. Assessing tongue muscles via ultrasound is a valuable tool for comprehending functional abnormalities in these patients, aiding in clinical management, and potentially serving as a marker for disease progression

https://doi.org/10.5327/CBN240389

Clinical challenges and multidisciplinary management in Takayasu's arteritis: a case report

Rhanice Soares Huguenin Câmara[1], Bruno Castelo Branco Rodrigues[1], Iuri Sena Melo[1], Júlio César Iaia[1], Tatiane Thaís Santos Silva[1], Sophia Keiko Inuzuka[1], Maria Fernanda de Abreu Rodrigues[1], Roberto Pereira Santos[1], Ana Lucia Zuma de Rosso[1], Rita de Cássia Leite Fernandes[1]

[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Rhanice Soares Huguenin Câmara; Email: rhaniceshcamara@gmail.com.

Case presentation: A 43-year-old female patient presented with an ischemic stroke (CVA) in September 2020, resulting in right hemiplegia and aphasia. CT angiography revealed severe bilateral carotid lesions, unusual in extent given hypertension as the only comorbidity. Suspecting Takayasu's arteritis, we requested ESR, which was elevated, confirming the diagnosis. After starting corticosteroid treatment, ESR levels reduced to 6 mm and are now at 3 mm. The patient is on continuous treatment with prednisone (5mg/day), azathioprine (100mg/day), aspirin (100mg/day), and phenytoin (100mg every 8hours). She reports anxiety and anhedonia. Recent lab results show platelets at 199,000, hemoglobin at 14.9g/dL, LDL at 95mg/dL, and ESR at 3mm. Clinically, she presents with hypertension (BP 137/105mmHg), tachycardia (HR 112bpm), hemiplegic gait, grade 4 paresis, mild spasticity in the right upper limb, hyperreflexia, right-sided hypoesthesia, positive Hoffman sign on the right, and central paralysis of the right seventh cranial nerve. **Discussion:** This clinical case highlights the complexity of managing a patient with Takayasu's arteritis, a rare disease affecting large arteries and potentially leading to severe complications like ischemic stroke. The reduction in ESR levels after starting corticosteroids indicates inflammatory control. However, significant stroke sequelae persist, including hemiplegia, aphasia, and neurological signs (hyperreflexia, hypoesthesia, and Hoffman sign), while hypertension and tachycardia require careful management to prevent further complications. Treatment includes prednisone and azathioprine as immunosuppressants, aspirin for thromboembolic event prevention, and phenytoin for seizure prevention. Anxiety and anhedonia underscore the importance of psychological support, making a multidisciplinary approach essential. **Final comments:** This case underscores the complexity of Takayasu's arteritis. The multidisciplinary therapeutic approach has proven effective in reducing inflammatory markers and stabilizing the patient clinically. However, neurological sequelae persist, impacting the patient's quality of life and functional capacity, highlighting the importance of early diagnosis. Thus, it is crucial to identify the disease before complications arise and to conduct longitudinal studies on the progression of Takayasu's arteritis in patients treated with different therapeutic regimens to determine long-term efficacy and side effects. Sharing this clinical experience aims to enhance the understanding of Takayasu's arteritis and serve as a tool for students and healthcare professionals.

Clinical characteristics of patients with positive genetic testing for peripheral neuropathies at a tertiary Brazilian neuromuscular outpatient clinic in an university hospital

Carolina Braga Moura[1], Ana Luiza Morgado Costa[1], Gabriel Thomaz Candido[1], Camila Castelo Branco Pupe[1], Osvaldo Jose Moreira Do Nascimento[1]

[1]Universidade Federal Fluminense, Niterói RJ, Brazil.

Correspondence: Ana Luiza Morgado Costa; Email: anamorgado@id.uff.br.

Objective: To determine prevalent clinical and epidemiological characteristics among patients with positive genetic testing for peripheral neuropathies. Background: Diagnosing peripheral neuropathies frequently necessitates genetic testing. Yet, there is no established protocol to guide neurologists in discerning the appropriate circumstances for requesting genetic testing in a brazilian population. **Methods:** Seventy-one patients were tested at an outpatient clinic for neuromuscular diseases in Brazil. Only patients with positive genetic tests were included. The prevalence of mutations was registered. Clinical characteristics were retrieved from electronic records (i.e., symptoms, physical exam, and nerve conduction study). Descriptive analyses were conducted. **Results:** Thirty patients had a positive genetic test. All patients had a Charcot-Marie-Tooth (CMT) disease phenotype. The mean age of diagnosis was 46 years old. Most patients had a mutation in the PMP22 (9/30, 30%), ALMS1 (4/30, 13%), and SH3TC2 (3/30, 10%) genes. Of the nine patients with PMP22 mutation, six (66%) presented numbness, six (66%) had imbalance, and five (55%) presented weakness. Pes cavus and distal atrophy were each reported by two patients (2/9, 22%). **Conclusion:** Our study highlights key clinical characteristics among patients with positive genetic testing for hereditary neuropathies. We found CMT phenotype was the most prevalent among study participants, with numbness, imbalance, and weakness being recurrent clinical manifestations. Notably, most patients only disclosed diagnosis later in adulthood. This result emphasizes the need to rapidly identify prevalent mutations, symptoms, and associated conditions to order genetic testing for hereditary neuropathies.

Clinical evaluation of dysphagia as a prognosis factor in stroke patients: preliminary results

Victor Vale da Silva[1], Joanna Sousa da Fonseca Santana[1] , Amanda Hellen Sousa Leal[1], Ana Clara de Lemos Guimarães[1], Carla Loureiro Alvarez[1], Catarina Cavalcanti da Silva[1], Brena Lima Cunha[1], Felipe Oliveira Costa, Júlia Ribeiro Oliveira Campos[2]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.
[2]Afya Faculdade de Ciências Médicas de Itabuna, Itabuna BA, Brazil.

Correspondence: Victor Vale da Silva; Email: vitor.futebolclube@hotmail.com.

Background: Dysphagia is a complication of stroke that frequently affects patients, with diagnosis occurring in 40-70% of cases within the first 3 days. This condition can prolong hospitalization, increase the risk of mortality and increase healthcare costs. Furthermore, some patients will experience prolonged dysphagia, which increases risks such as pneumonia, dehydration and reduces quality of life. Therefore, it is essential to clinically evaluate dysphagia as a prognostic factor in stroke patients, considering the severity of dysphagia, in order to improve medical care for these patients. **Objective:** To analyze dysphagia as a prognostic factor in patients who have suffered a stroke. **Methods:** This work is an observational and retrospective cohort study, descriptive and was based on the partial collection of secondary data from electronic medical records of patients previously admitted to a reference hospital in the city of Salvador, Bahia. The study population consists of patients diagnosed with stroke, aged 18 years or older, who were admitted to the hospital between January 2021 and December 2022. Variables of interest include: sex, age, date of admission, infection, length of hospital stay, complications and mortality. Excel and SPSS software were used for data analysis. The study was approved by the Research Ethics Committee. **Results:** To date, the study sample size is 178 patients and, among them, 86 (48.3%) patients presented dysphagia. Of the total number of patients, 128 were aged >60 years (median 75 years), with 68 (53.1%) having dysphagia (43 women [63.2%] and 25 men [36.8%]). Regarding the number of patients who cont racted infection during hospitalization: 7 (25%) of patients with severe dysphagia developed infection, 5 (18.5%) of patients with moderate dysphagia developed infection and 7 (22.6%) of patients with mild dysphagia developed infection. And in relation to length of stay, patients with dysphagia had an average of 20.4 days of hospitalization (standard deviation 21.4) and a maximum length of stay of 150 days. Patients without dysphagia had an average of 11.5 days (standard deviation of 11.9) and a maximum hospitalization of 66 days. **Conclusion:** It is clear that dysphagia is a prevalent and significant condition in patients who have suffered a stroke, considerably impacting the prognosis of these individuals. The majority of stroke patients evaluated had some degree of dysphagia, significantly increasing hospitalization time, with more severe cases being associated with a higher incidence of infections during hospitalization. Therefore, early identification and appropriate treatment of dysphagia are essential to optimize healthcare and clinical outcomes for these patients.

Clinical factors associated with constipation in patients with Parkinson's disease: a Brazilian cross-sectional study in Bahia

Gabriel Teles de Oliveira Piñeiro[1], Maria Eduarda Messias Vassoler[1], Ayla Morais Vitório Guerra[1], Gabriel Souza Medrado Nunes[1], Fernanda Garcia Silva Pereira Nascimento[1], Caio Fontes do Nascimento[1], Roberta Borges Gomes Kauark[2]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.
[2]Hospital Universitário Professor Edgard Santos, Salvador BA, Brazil.

Correspondence: Ayla Morais Vitório Guerra; Email: aylaguerra1@hotmail.com.

Background: Constipation is a well-known non-motor symptom that can occur during Parkinson's disease (PD). However, there is still a lack of studies exploring the associations between constipation and other commonly observed characteristics of PD patients. **Objective:** Investigate clinical characteristics of Parkinson's disease patients and their association with constipation at a reference center for movement disorders. **Methods:** Cross-sectional study carried out between 2023-2024, patients who reported defecating less than three times per week were classified as constipated. Clinical, social, and epidemiological data were collected, in addition to the application of the following scales: Unified Parkinsons Disease Rating Scale-Part III (UPDRS-III) for severity of motor symptoms, Beck Depression Inventory (BDI) for depression assessment, and the Hoehn and Yahr scale (HY) for functional disability. PD subtypes used were Tremor Dominant (TD), Akinetic-Rigid (AR), and Mixed, calculated using the UPDRS. Kolmogorov-Smirnov was performed to assess the normality of the data, Chi-square, Mann-Whitney, and T-test for correlation. **Results:** The study included 70 PD patients, of whom 67.1% were men, with a mean age of 65.45 (±9.28) years. Regarding clinical status, the mean disease duration was 9.60 (±5.16) years, and the severity of motor symptoms, as assessed by UPDRS III, had a mean score of 43.46 (±16.12). The median BDI score and Levodopa Equivalent Daily Dose (LEDD) were 13 (IQR: 4-20.75) and 1000 (IQR: 600-1460), respectively. Among all patients, 69 (98.6%) were using Levodopa and only 4 (5.7%) were using anticholinergics. The most frequent subtype was AR (45.7%), followed by TD (18.6%) and Mixed (8.6%). Constipation was identified in 19 (27.1%) patients, with a mean age of 66.9 (±8.5) years, and its presence was significantly associated with higher UPDRS III (p=0.026). Furthermore, the Mixed subtype was more associated with constipation than AR, while a negative association between TD and constipation was observed (p=0.001). There were no associations between constipation and disease duration LEDD, HY, or BDI (p>0.05). **Conclusion:** Constipation was found to be associated with more severe motor symptoms and Parkinson's subtypes, particularly with the Mixed form, but no correlations were observed with other clinical factors. However, further studies are necessary to better understand this relationship.

https://doi.org/10.5327/CBN240393

Clinical features and quality of life of patients with amyotrophic lateral sclerosis at a specialized care service in Salvador-BA

Marie Lidio dos Santos Galvão Ribeiro[1], Maria Rodrigues Lima de Souza Pessoa[1], Maria Luiza Pereira Falconery[1], Stefania Zingone Andrade Carvalho[1], Marilaine Matos de Menezes Ferreira[1], Marcela Câmara Machado-Costa[1], Têmis Maria Félix[2], Lorena Alves dos Santos Pereira[1], Luana Souza Vasconcelos[1]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.
[2]Hospital de Clínicas de Porto Alegre, Porto Alegre RS, Brazil.

Correspondence: Marie Lidio dos Santos Galvão Ribeiro; Email: marielidiogr@gmail.com.

Background: Amyotrophic lateral sclerosis (ALS) is a rare and progressive neurodegenerative disease that affects motor neurons in the spinal cord, brainstem, and motor cortex. Often misdiagnosed or undiagnosed until its later stages, there are only palliative treatments, leading to a fatal prognosis. Consequently, it is a condition that burdens healthcare systems worldwide, causing loss of productivity and quality of life for patients and their caregivers. In Brazil, there is a lack of research on its clinical profile and epidemiology, which makes it challenging to analyze the disease in the country. **Objective:** To describe the clinical features and quality of life of ALS patients treated at a specialized care service in Salvador, Bahia. **Methods:** This was a cross-sectional observational study involving primary data collection. Patients with a diagnosis of definite ALS (by El Escorial criteria) followed up at the service from February 1, 2022, to July 31, 2023, were included. The following data was collected: gender, age, race, city of residence, disease stage (by Kings College staging), clinical phenotype, onset symptom location, main clinical signs, and complications. Furthermore, a series of questionnaires were applied, including the ALSFRS-R, EQ-5D, and WPAI-GH. The variables were summarized and subjected to descriptive statistical analysis. **Results:** A total of 28 patients were included in the study, with a mean age (SD) of 57 years (12). Most patients were male (64.29%) and brown (64.29%). Salvador represents the primary city of residence for 46.43% of patients. Spinal ALS was present in 78.57% of patients, with initial symptoms occurring more frequently in the upper limbs (60.71%). The most frequently reported symptoms were pain (64.29%), fasciculations (57.14%), and dysphagia (57.14%). Although 57.14% of the population was at stage 4, 75% of the patients

did not use any feeding device, and only 35.71% used non-invasive ventilation. Moreover, only 25% of patients underwent gastrostomy, while 3.57% underwent tracheostomy. The functionality score (ALSFR-R), utility value (EQ-5D), and productivity score (WPAI-GH) had a mean value (SD) of 20.39 (9.85), 0.178 (0.211) and 93.21 (14.92), respectively. **Conclusion:** The ALS profile observed in this study is consistent with that reported in the scientific literature: it shows a male predominance, with greater involvement from the 5th decade of life onwards and an urban setting. Spinal ALS is the main clinical phenotype, and the ethnic profile differed from that presented in the literature due to miscegenation. The population exhibits advanced ALS progression, with significant functional impairment, a wide range of associated symptoms, and a greater dependence on caregivers and family members. Quality of life declines as the disease progresses, but anxiety and depression are the least reported symptoms, suggesting effective psychological coping mechanisms to manage the diseases progression.

Clinical features on Friedreich's ataxia patients in São Paulo, Brazil

Daiana Suelen Machado[1], Marcondes Cavalcante França Junior[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Daiana Suelen Machado; Email: daianamachado@gmail.com.

Background: There are few reports characterizing Friedreich´s Ataxia (FRDA) phenotype beyond Europe and USA. **Objective:** Herein, we describe the clinical profile of a representative FRDA cohort from São Paulo, Brazil. **Methods:** Patients were invited to answer an online survey comprising 24 to 32 questions, which was sent by physicians and the Brazilian Association of Acquired and Hereditary Ataxias via email and releases. We collected data on sex, current age, age at diagnosis, affected relatives, parental consanguinity, ability to walk, the need of ambulatory assistive device or wheelchair and presence of diabetes, cardiomyopathy, and scoliosis. Descriptive statistics was used to report the results - means, proportions, and Standard Deviations (SD). Age at loss of ambulation (LOA) was assessed both for classical and late-onset (LOFA) groups using Kaplan-Meier curves. **Results:** We gathered 104 answers from FRDA patients or legal guardians, being 79 (75.9%) patients with classical FRDA and 25 (24%) with late-onset (LOFA) . There were 64 (61.5%) women and 40 (38.5%) men. Mean age and age at diagnosis were 37.3±13.8 and 24.1±11.5 years, respectively. Parental consanguinity and familial disease recurrence were seen in 24 (23%) and 50 (48.7%) of the patients, respectively. Fifty five out of 104 patients lost ambulation at the mean age of 29.4±11.5 years. Those who are still ambulatory but need assistive devices, first required them at a mean age of 27.1±13.1 years. As expected, patients with classical FRDA had LOA earlier than LOFA (25.5±7.7 vs 47.8±10.2 years). The frequency of diabetes, cardiomyopathy, hearing impairment and scoliosis in this cohort was 36±10.9, 23.6±14.2, 32.5±8.8 and 18.5±9.1, respectively. **Conclusion:** The overall phenotype of FRDA in Brazil is similar to previous European and US reports, but age at LOA was slightly higher. Further studies are needed to better understand such difference.

Clinical outcomes and safety of repetitive transcranial magnetic stimulation in the treatment of Alzheimer's disease: a scoping review

Jéssica Yumi Lago Matsuda[1], Liria Matsuzawa Figueiredo[1], Thelma Yuri Lago Matsuda[1]

[1]Faculdades Pequeno Príncipe, Curitiba PR, Brazil.

Correspondence: Jéssica Yumi Lago Matsuda; Email: jlagomatsuda@gmail.com.

Background: Alzheimer's disease (AD) is a chronic, progressive neurodegenerative disorder and accounts for half to 75% of all dementia cases. Considering that current treatments using pharmacotherapies, such as acetylcholinesterase inhibitors, still present limitations in improving cognitive performance, the investigation of alternate therapeutic methods is needed. In this context, repetitive Transcranial Magnetic Stimulation (rTMS) is emerging as a non-invasive promising therapy for AD. It uses electromagnetic induction to generate a pulsed magnetic field, which can stimulate the brain and modulate cortical excitability and neural activity. **Objective:** To identify in the literature about the clinical outcomes and safety of repetitive transcranial magnetic stimulation in the treatment of patients with AD. **Methods:** A scoping review was conducted based on the Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews (PRISMA-ScR) statement and was duly registered on the Open Science Framework, via the link: https://osf.io/8y6r3/. Searches were selected from PubMed, ScienceDirect and Biblioteca Virtual em Saúde (BVS) databases and the descriptors "Alzheimer's disease" and "repetitive transcranial magnetic stimulation" were used. Inclusion criteria involved: studies published in the last 5 years, studies involving humans and written in english. **Results:** In total, 406 studies were identified, of which 17 were included in the review. 14 studies were randomized controlled trials involving a total of 550 patients who were randomly divided into two groups to either receive real rTMS of the dorsolateral prefrontal cortex (DLPFC) or sham stimulation. The protocols varied in the duration of treatment, from 2 to 24 weeks and the frequency of stimulation, from 10 Hz to 20 Hz. The outcomes were evaluated by score changes in the Alzheimer's Disease Assessment Scale (ADAS-cog) and Mini-Mental State Examination (MMSE). The results indicated that, compared to the sham group, the patients who received rTMS scored significantly higher on the MMSE and showed notably better performances on the ADAS-cog measures. Moreover, a recent meta-analysis analyzed the clinical advantages and safety of rTMS treatment over current pharmacotherapy. 15, 548 individuals with AD in 57 randomized clinical trials were included in the study. Compared with multiple pharmacological interventions, rTMS was more effective in improving global cognition, had the highest likelihood to improve MMSE score and showed notably fewer adverse effects. **Conclusion:** Studies demonstrated that rTMS can improve global cognitive function and may be safely used in patients with Alzheimer's disease. Furthermore, fewer adverse events were observed when compared with the current clinical drug therapy, showing broad prospects in treating AD. However, the long-term effectiveness of rTMS in AD is still little known and should be explored in future studies.

Clinical spectrum of the PLA2G6 gene

Renan Brandão Rambaldi Cavalheiro[1], Kaliny Oliveira Peixoto[1], João Paulo Barile[1], Patrícia Marques Mendes[1], Igor Braga Farias[1], Paulo de Lima Serrano[1], Wladimir Bocca Vieira de Rezende Pinto[1], Paulo Victor Sgobbi de Souza[1], Acary Souza Bulle Oliveira[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Renan Brandão Rambaldi Cavalheiro; Email: renan.rambaldi@icloud.com.

Background: The PLA2G6 gene encodes the enzyme A2-Phospholipase, responsible for phospholipid metabolism. This process is vital for the maintenance of the cell membrane. Disruption of this process leads to accumulation of cell products and development of spheroid bodies in the axons. This, in turn, leads to axonal loss and neuronal death. Pathogenic variants in the PLA2G6 can produce at least 3 distinct clinical entities: Infantile neuroaxonal dystrophy (NAD), atypical neuroaxonal dystrophy (aNAD), and the adult-onset PLA2G6-related dystonia-parkinsonism. These conditions are grouped under the term PLA2G6 associated neurodegeneration (PLAN), one type of NBIA (neurodegeneration with brain iron accumulation) syndromes. The NBIAs are a group of ultra-rare (less than 1 per million people) disease; their recognition is utmost importance in order to provide patients and caregivers adequate support and treatment. **Objective:** To describe the clinical spectrum of 4 cases PLA2G6-associated neurodegeneration in a neuromuscular center results of the 4 patients included in this study, 2 patients had a phenotype of PLA2G6- dystonia-parkinsonism. In addition to dystonia and parkinsonism, these patients presented with negative myoclonus and facial-faucial- finger myoclonus. The other 2 patients presented with a motor-neuron presentation. All patients had myoclonus and 3 of 4 patients had generalized epilepsy. Characteristic brain magnetic resonance imaging findings of low signal on T2/Flair weighted-imaging was observed in only one patient (the other 3 patients had cortical atrophy as the only imaging abnormality). None of the patients had attention deifficts or a dysexecutive syndrome. Genetically, all patients were compound heterozygous for the condition. **Conclusion:** Pathogenic variants in the PLA2G6 can cause a devastating disease with varied clinical presentations and an unmet need of disease-modifying treatments. The present work aims to alert clinicians to these clinical features in order to provide prompt diagnosis and support to the patients and their caregivers.

Clinical study of patients with familial amyloidotic polyneuropathy at Pedro Ernesto University Hospital

Marcia Maria Jardim Rodrigues[1,2], Ligia Andrade[1], Larissa Bittencourt de Carvalho[1], Julia Chaves[1], Camila Tales[1], Felipe Cerqueira Matheus[1], Clarissa Spitz[1], Marcelo Imbroinise Bittencourt[1]

[1]Hospital Universitário Pedro Ernesto, Rio de Janeiro RJ, Brazil.
[2]Fundação Oswaldo Cruz, Rio de Janeiro RJ, Brazil.

Correspondence: Marcia Maria Jardim Rodrigues; Email: jardim.mm@gmail.com.

Background: Hereditary transthyretin amyloidosis (ATTRv) is a rare autosomal dominant disease associated with mutations in the transthyretin gene. Patients present with various symptoms related to sensory, motor and autonomic neuropathy, as well as gastrointestinal, ocular, cardiac, renal and orthopedic symptoms, resulting from the deposition of transthyretin amyloid fibrils in multiple organs. The progressive nature of ATTRv amyloidosis requires pre- and post-onset monitoring of the disease. It is a rare genetic disease considered endemic in some countries. There is phenotypic variability, making it a rare and very heterogeneous disease. **Method:** This is a retrospective study, through the analysis of the database of the Peripheral Neuropathy outpatient clinic of the Pedro Ernesto University Hospital that has ATTR gene mutation. Data from symptomatic and asymptomatic patients followed at the service who underwent genetic testing for the ATTR gene mutation between June 2012 and June 2024 were included. All patients underwent clinical evaluation, including neurological examination, disability score (Polyneuropathy disability score, PND), clinical cardiological Evolution, and neurophysiological and imaging studies. **Results:** A total of 60 individuals, over 18 years of age, with the ATTR gene mutation were

included. Forty individuals (66.6%) were female, mean age 49 years (18-77 years). Forty-four (73.3%) individuals were symptomatic, of which 4 (6.5%) had already died at the time of analysis. The most frequent mutation was val30met (38.3%) followed by val122ile (26.6%), ile 127val (13.3%), Phe84leu (8.3%). Eight individuals (13.3%) had a history of consanguinity. Patients registered at the outpatient clinic. Twenty-three patients (52.2%) had a mixed phenotype. PND 0 36.9%, PND I 32.6%, PND II 7.4% and PND III 19.5%. The first symptoms were neurological (76.9%), with 20.5% presenting paresthesia in the upper limbs, 55.8% paresthesia in the lower limbs, neuropathic pain in 26.4%, cardiac pain occurred in 13% of cases, dysautonomia in 6.5% and weight loss in 5.8%. ATTRv has a heterogeneous clinical presentation, varying between individuals and geographic locations. Brazil is a country with a large number of ATTRv cases. Still, there are no epidemiological studies that could help in public policies to improve early diagnosis and indicate high-cost treatments. Currently, we can conduct research through genetic studies more easily. We have demonstrated the presence of mutations that seem to be more frequent than previously determined. **Conclusion:** The description of epidemiological data from centers monitoring patients with ATTRv is extremely important to understand the nature of this rare disease in Brazil.

Clinical variant of Nasu-Hakola disease associated with frontotemporal dementia and absence of osteodysplasia: case report

Isabelly de Arruda Cardoso Slavec[1], Thais Laura Almada da Fonseca[1], Yasmin Coelho Patrial[1], Aline Mizuta Kozoroski Kanashiro[1], Elder Yanaze Oda[1], Eña Rezende Bispo do Nascimento[1]

[1]Hospital Regional de Mato Grosso do Sul, Campo Grande MS, Brazil.

Correspondence: Isabelly de Arruda Cardoso Slavec; Email: isa_mhta@hotmail.com.

Case presentation: Patient L.S., female, 46 years old, healthy until the age of 43, housewife. In 2020, a slow and gradual progression of cognitive decline began, characterized by memory loss, impairment of executive function, spatial disorientation, as well as inability to judge, disinhibition, inattention and mood swings. It evolved into behavioral changes with infantilization, psychosis, and episodes of tonic-clonic epileptic seizures began. The patient started to neglect her own hygiene, besides loss of autonomy for functional activities and sphincter continence. No reports of movement disorders. Positive family history, with 5 brothers with a similar condition, absence of family consanguinity, and genetic investigation for Huntington's disease was negative. Exome examination revealed the presence of a homozygous variant in the TREM2 gene, an autosomal recessive inheritance condition. In the last outpatient consultation, the patient presented with significant cognitive worsening, with temporo-spatial disorientation, severe speech impairment, with anarthria, dysphagia and need for a gastrostomy for feeding. In addition, she had an apraxic gait, inexhaustible glabellar reflex, palmar grip and graping were present. On magnetic resonance imaging of the skull, significant global volumetric reduction, thinning of the corpus callosum, periventricular, semi-oval and cerebral hemispheres hypersignal on T2/FLAIR, preserved CSF flow. **Discussion:** This condition is rarely reported in the medical literature, with only 8 case reports found in Pubmed, it occurs due to the presence of a pathogenic variant in the TREM2 gene, associated with Nasu-Hakola disease or type 2 sclerosing leukoencephalopathy, which primarily causes changes and bone deformities, with late neurological manifestation, in the case described this last change was of greater severity. **Final comments:** According to the scarce literature on the subject and the age at which symptoms began, it is of great relevance to consider this pathology as a differential diagnosis of early-onset dementia.

https://doi.org/10.5327/CBN240399

Clinical, epidemiological, and genetic profile of late onset Pompe disease in a tertiary hospital in the Northeast of Brazil

Caio Viana Botelho[1], Guilherme Mota Passos[1], Matheus Rolim Mendes de Alencar[1], Natália Merten Athayde[1], Antônio Edvan Camelo Filho[1], Hermany Capistrano Freitas[1], Lara Albuquerque de Brito[1], Keyla Rejane Frutuoso de Morais[1], Eduardo Braga de Oliveira[1], Cleonisio Leite Rodrigues[1]

[1]Hospital Geral de Fortaleza, Serviço de Neuromuscular, Fortaleza CE, Brazil.

Correspondence: Caio Viana Botelho; Email: caiobotelhoneurologia@gmail.com.

Background: Late-onset Pompe disease (LOPD) is a genetically inherited autosomal recessive metabolic myopathy associated with a deficiency of the enzyme acid alpha-glucosidase. It presents with symptoms of proximal appendicular, axial, and respiratory muscle weakness. Although rare, it is a treatable condition, where the early introduction of enzyme replacement therapy (ERT) in symptomatic individuals is crucial to reduce morbidity and mortality. **Objective:** To describe the clinical, epidemiological, and laboratory profile of patients diagnosed with LOPD and medically monitored at a reference center in the state of Ceará, Brazil. **Methods:** A descriptive cross-sectional analysis was performed on 11 patients with LOPD at the neuromuscular diseases outpatient clinic of Hospital Geral de Fortaleza-CE. Data recorded included sex, origin, age of symptom onset, genotype, phenotype, CPK levels, acid alpha-glucosidase enzyme activity, neurophysiological pattern in electromyography, and therapy employed. **Results:** Between 2016 and 2024, 11 patients (from 4 families) were identified with a clinical and molecular diagnosis of late-onset Pompe disease, corresponding to about 31.4% of the patients monitored for genetically determined myopathy in the outpatient clinic (excluding patients with Steinert myotonic dystrophy). There was an equivalent prevalence regarding sex (about 1:1). The average age of symptom onset was around 28 years. The most frequent variant was c.-32-13T>G, present in all patients, and often associated with other pathogenic mutations (compound heterozygosity). The most common phenotype was proximal weakness, occurring in 9 patients. CPK levels were altered in 10 patients (90.9%), with an average diagnostic value of 612 U/L and a maximum of 1457 U/L. Neurophysiological studies showed findings consistent with chronic myopathy in all patients, with the presence of myotonic discharges in 8 of them (72%). Acid alpha-glucosidase enzyme activity was measured in 9 patients and was considered low in all, with an average value of 0.45µmol/L/h (reference value: above 2.1µmol/L/h). Almost all of them (9 out of 11) were on ERT with alglucosidase alfa. For clinical follow-up evaluation, strength grading scales (MRC), grip strength measurement with a dynamometer, 10-meter walk test, and inspiratory and expiratory maximum pressure measurement with a manovacuometer were used. **Conclusion:** To our knowledge, this is the largest series of LOPD cases described from a single neuromuscular disease reference center in our country. The most frequent pathogenic variant was the intronic c.-32-13T> G, along with the phenotypic pattern of proximal weakness and EMG showing proximal myopathy with electrical myotonia. The vast majority of patients are receiving ERT and are being monitored with functional motor exams, respiratory parameters, and 10-meter walk tests.

Clinical, epidemiological, serological, and neurophysiological data of patients with myasthenia gravis from a reference center in Northeast of Brazil

Natália Merten Athayde[1], Matheus Rolim Mendes de Alencar[1], Caio Viana Botelho[1], Hermany Capistrano Freitas[1], Lara Albuquerque de Brito[1], Eduardo Braga de Oliveira[1], Cleonisio Leite Rodrigues[1]

[1]Hospital Geral de Fortaleza, Serviço de Neuromuscular, Fortaleza CE, Brazil.

Correspondence: Caio Viana Botelho; Email: caiobotelhoneurologia@gmail.com.

Background: Myasthenia gravis (MG) is the most common autoimmune disease of the neuromuscular junction. Its hallmark is the fluctuating muscle weakness affecting ocular, bulbar, facial, limb, and/or respiratory muscles. Clinical manifestations of MG can vary from mild, focal weakness in some patients to severe tetraparesis with respiratory failure. It is a treatable condition in most cases but can result in significant morbidity and even mortality. **Objective:** To describe the main epidemiological, clinical, and neurophysiological characteristics of MG patients and their serological correlation in a reference service for neuromuscular diseases in the Northeast. **Methods:** A cross-sectional and retrospective study was conducted by reviewing the medical records of MG patients followed at the Neuromuscular Diseases Outpatient Clinic of Hospital Geral de Fortaleza (HGF). The diagnosis of MG was based on clinical characteristics, positive serology, neurophysiological findings (repetitive nerve stimulation test - RNS, and jitter study), and treatment response. **Results:** A total of 154 patients were included, 93 (60.6%) female and 61 (39.3%) male, aged 17 to 84 years. The vast majority of patients had the generalized form (90.2%), while the pure ocular form was the minority (9.74%). Of the total analyzed patients, 18.18% experienced myasthenic crisis, with the great majority occurring in the first 18 months of disease evolution. All of them were treated with plasmaferesis or IV immunoglobulin. Regarding antibody levels, patients were categorized as positive for anti-acetylcholine receptor antibodies (anti-AChR) (63.63%), positive for anti-muscle-specific tyrosine kinase antibodies (anti-MuSK) (5.19%), double seronegative (21.42%), and with pending results (9.74%). The double seronegative patients had typical clinical presentation, abnormal RNS or jitter analysis and good treatment response. Some of them had negative genetic molecular screening. It was observed that the majority of patients who experienced myasthenic crisis were anti-ACh positive (71.4%). Of the 154 patients analyzed, 151 underwent RNS testing, of which 84.7% had abnormal results. Among patients with normal RNS who underwent jitter analysis (N=17), 100% had abnormalities in this method. Regarding drug treatment, approximately 80.5% of patients showed clinical improvement with first-line treatment, but with high scores on quality of life questionnaires though. **Conclusion:** This study provides a comprehensive overview of the clinical, epidemiological, serological, and neurophysiological findings of 154 patients with MG. The results are generally consistent with those described in the literature, highlighting the percentage of patients who experienced a myasthenic crisis, which, compared to some references, was higher than expected. This finding may be attributed to possible delays in diagnosis and difficulties in accessing healthcare services during the diagnostic phase of the disease.

https://doi.org/10.5327/CBN240401

Clinical-epidemiological aspects of patients with myasthenia gravis in an outpatient of the public health system in northeast of brazil

Marivaldo Yslan Silveira Leal[1], Luisa Dias Moreno Aravena[1], Antonio Lázaro Santos Soares Júnior[1], Marcel Leal Ribeiro[2], Bruno Bacellar Pedreira[2], Alice Silva Oliveira[2], Jamary Oliveira Filho[2]

[1]Universidade Federal da Bahia, Salvador BA, Brazil. [2]Hospital Universitário Professor Edgard Santos, Salvador BA, Brazil.

Correspondence: Luísa Dias Moreno Aravena; Email: luisaaravena@ufba.br.

Background: Myasthenia Gravis (MG) is an autoimmune disease that affects the neuromuscular junction, resulting in muscle weakness with fatigability and fluctuating pattern. The study of clinical and epidemiological aspects in MG is essential to enhance therapy, especially in the context of the public healthy system, in which the majority of users have low income and education, in addition to less accessibility to comprehensive medical care. **Objective:** To describe the clinical and epidemiological factors in patients with MG treated at a reference outpatient clinic of the public health system in Salvador (Bahia). **Methods:** Descriptive and analytical, single-center study, with patients over 18 years diagnosed with MG. Collection was conducted using oral questionnaires and consultation of medical records. **Results:** 60 patients participated in the study. The majority of whom were female (73.3%), more specifically black women (61.7%). The average age of symptom onset was 28.5 (SD±11.98) years. 46.7% of patients presented with the generalized form, 35% with the ocular form and 18.3% with the bulbar form. 7 out of 10 did not have access to a neurologist in the first month. For diagnostic tests, 92.9% of patients underwent the anti-rACh antibody test, which was reactive in 66.7%, and 22.4% the anti-MUSK test, which was reactive in 30% of cases. 96.4% were able to undergo at least one electroneuromyography. The average number of crisis after the initial manifestation was 2.42 (SD±1.60) and half of the participants had a myasthenic crisis. On admission, the generalized form was the most prevalent (68.3%), followed by ocular (20%) and bulbar (11.7%). The median MGADL was 3 (IQ 1 - 6.75) and the median MGQoL was 9 (IQ 4.25 - 15). Anticholinesterase is the medication most used by 96.7%, while 46.7% corticosteroids and 50% azathioprine. 48.3% underwent thymectomy. 58.3% patients have some associated comorbidity, with 30% of these having high blood pressure, 21.7% diabetes mellitus and 20% dyslipidemia. 70% are overweight or obese and only 26.7% practice physical activity. 1 in 5 patients has another autoimmune disease, with Graves' disease (8.3%) and Hashimoto's thyroiditis (6.7%) being the main ones. 86.4% were studying or working before the onset of symptoms and only 36.7% continued to work or study after the diagnosis of MG. 6 out of 10 participants did not complete high school. 61.7% live on a family income of less than 2 minimum wages and 52.2% receive some form of social assistance. 62.7% of public health system users reported difficulty in accessing the public network, especially when it came to making appointments and taking tests. **Conclusion:** The analysis of clinical and epidemiological characteristics is necessary to conduct diagnostic and therapeutic approaches in patients with Myasthenia Gravis in the context of the health system. Thus, it may help guiding the applicability of public health policies in order to minimize treatment delay.

Clinical-epidemiological profile and correlations with arboviruses of inpatients with Guillain-Barré syndrome at a hospital in the Northeast of Brazil

Matheus Rolim Mendes de Alencar[1], Fernanda Martins Maia Carvalho[1], Hermany Capistrano Freitas[1], Eduardo Braga de Oliveira[1], Lara Albuquerque de Brito[1], André Borges Ferreira Gomes[1], Paula Camila Alves[1], Gláuber de Menezes Ferreira[1], Déborath Lúcia de Oliveira Diniz[1], Cleonísio Leite Rodrigues[1]

[1]Hospital Geral de Fortaleza, Fortaleza CE, Brazil.

Correspondence: Matheus Rolim Mendes de Alencar; Email: matheus_alencar_1@hotmail.com.

Background: Guillain-Barré syndrome (GBS) is an acute polyradiculoneuropathy characterized by weakness, sensory deficits and sometimes cranial neuropathy, autonomic dysfunction and respiratory insufficiency. Diagnosis is usually based on clinical features, electrodiagnostic studies and laboratory findings. Timely diagnosis is crucial to stablish the correct treatment and try to avoid disability. **Objective:** To describe the clinical-epidemiological profile of patients with GBS and their correlation with arboviruses infections treated at a public tertiary hospital in the last 3 years. **Methods:** This is a retrospective cohort study of patients with acute polyradiculoneuropathy, who were evaluated for GBS at the time of hospitalization in a reference hospital in Northeast Brazil, between January 2022 and May 2024. Data such as age, gender, functional status, and other clinical and epidemiological information were analyzed from medical records. The test used for arbovirus evaluation was PCR from serum and cerebrospinal fluid, which was not widely available for all patients. **Results:** A total of 64 suspected patients were evaluated. Of these, 57 inpatients were diagnosed with GBS, while 7 had others diagnoses. At the time of hospitalization, patients ranged in age from 18 to 82 years (mean of 46.7 years). Most patients were male (68.4%), and the mean time from symptom onset to hospital admission was 8.22 days (SD 9.11 days). A history of infectious diseases or vaccinations was present in 70% of patients. Arbovirus assays were available for 37 patients (65%), of which 16% tested positive for arboviruses, notably dengue and chikungunya virus; no tests for Zika virus were positive. The main clinical pattern of GBS was classic sensorimotor (79%), but other variants such as Miller-Fisher Syndrome (7%), Bickerstaff brainstem encephalitis (3.5%), paraparetic (3.50%), and bilateral facial palsy with paraesthesias (1.75%) were also present. Albumino-cytological dissociation was present in 74% of patients, and the main electrodiagnostic patterns observed were AIDP (54%) and AMSAN (30%), with sural sparing in 37% and H reflex abnormalities in 98% of the sample. Regarding severity and functional status, 37% of inpatients required assisted ventilation in an intensive care unit. The mean Hughes scale score at hospital admission was 3.61 (SD 0.87), and the Polyneuropathy Disability Scale at hospital discharge was IV (28%) and IIIa (19%). Intravenous immunoglobulin (33%) and plasma exchange (56%) were the chosen treatments; other patients may not have needed treatment either due to loss of the therapeutic window or good functional status. **Conclusion:** The classic AIDP pattern of GBS was the most common in our sample. Arbovirus infections continue to play a significant role as triggers for GBS in our region. Preventive measures to control these infections are crucial, as they could reduce the incidence of future cases of GBS.

Clinical-radiological mismatch in patient with moyamoya syndrome and seronegative rheumatoid arthritis

Vitor Gustavo Leão Souto[1], Bruna Acioly Leão[2], Nayra Roberta Sales Salvador[2], Juliana Oliveira de Almeida[2], Patrícia Pereira Nunes Ribeiro[2], Túlio Marlus Castro Lucena[2], Assis Porfirio Furtado Nogueira[2], Maria Júlia Tabosa de Carvalho Galvão[1], Geovane Brito Affonso[1], Letícia Januzi de Almeida Rocha[1]

[1]Universidade Federal de Alagoas, Maceió AL, Brazil. [2]Hospital Geral do Estado, Maceió AL, Brazil.

Correspondence: Vitor Gustavo Leão Souto; Email: gustavosoutoo11@gmail.com.

Case presentation: A 70 year old female with seronegative rheumatoid arthritis (RA), hypertensive, dyslipidemic and coronary heart disease presented in 2016 with a sudden onset of weakness and headache. In the investigation there was clinical and radiological inconsistency due to complete obstruction of the internal carotid artery in non-symptomatic territory. Between 2016 and 2024, it evolved with improved functionality and motor deficits, but there was progression of intracranial stenosis and the emergence of the moyamoya pattern. There are complete occlusion of the ACID, ACMD M1, ACME M1, ACAD, stenosis less than 50% in several vascular territories and small cerebral aneurysms, with no previous or current history of rupture. Despite the extensive vasculopathy, the skull resonance only showed an ischemic gap in the left internal capsule. **Discussion:** Moyamoya disease is a primary vasculopathy of the brain that causes chronic and progressive steno-occlusion of the internal carotid arteries, forming an abnormal collateral vascular network at the base of the brain known as "moyamoya vessels". When secondary, it is called Moyamoya syndrome (MMS). SMM is associated with atherosclerosis, brain tumor, meningitis, sickle cell disease, thyrotoxicosis and autoimmune diseases. The clinical manifestations of MMS may be related to recurrent stroke, of the ischemic or hemorrhagic type, occurring in up to 25% of patients. Female sex is an independent factor for disease progression, and inflammatory diseases such as RA can contribute to the progression of atherosclerosis. Compared to other autoimmune conditions such as Lupus and Sjögren's syndrome, the association between MMS and RA is less well described. The literature highlights progression to cognitive deficits, visual changes, intracranial hemorrhage, generalized seizures and other neurological manifestations, but in this case only headache and minimal motor deficit without functional impairment have been found so far. **Final comments:** Given the significant risk of morbidity, this case demonstrates the importance of managing comorbid autoimmune conditions that may predispose to the development of MMS. The pathophysiology of this association still remains uncertain. It is believed that the immune system is responsible for amplifying the inflammatory cascade, triggering chain vessel stenosis, but more studies are needed so that secondary prophylaxis for these patients is truly effective.

Correspondence: Ana Letícia Amorim de Albuquerque; Email: analeticia.neurologia@gmail.com.

Background: Spinal muscular atrophy (SMA) is an autosomal recessive neurodegenerative disease characterized by progressive proximal muscle atrophy and weakness. **Objective:** This study addresses the scarcity of research on novel disease-modifying therapies for SMA in Latin America by reporting a real-world experience in Southern Brazil. **Methods:** This is a single-center historical cohort that included all patients diagnosed with spinal muscular atrophy at a Regional Reference Service for rare diseases. **Results:** Eighty-one patients were included, of whom 7 died during follow-up. Of the remaining 74 patients, 5.4% were identified as pre-symptomatic, 24.3% with SMA type 1, 28.4% with type 2, 36.5% with type 3, and 5.4% with type 4. Approximately 42% of these patients received specific disease-modifying therapy, of these, 96.8% received Nusinersen, with 19.35% transitioning to gene therapy using Onasemnogene Abeparvovec, and 6.4% starting Risdiplam. Most patients with SMA type

1 were on disease-modifying treatment, whereas only slightly over a third of patients with type 2 and about 10% of those with type 3 were receiving such treatments. Among treated patients, 80% demonstrated improvement in motor performance during the follow-up, with a lesser therapeutic response being associated with late initiation of treatment and low motor function scores at baseline. **Conclusion:** This real-world study reinforces the effectiveness of disease-modifying therapies for SMA in Brazil within the context of low- and middle-income countries, which is greater the earlier and the better the patient's functional status.

CLIPPERS syndrome: case report

José Víctor Filho de Oliveira[1], Stephania Neves Scapim[1], Iasmim Portela Maifrede[1], Leopoldo Antonio Pires[1], Thiago Cardoso Vale[1]

[1]Universidade Federal de Juiz de Fora, Hospital Universitário, Juiz de Fora MG, Brazil.

Correspondence: José Víctor Filho de Oliveira; Email: victorr_oliveira@hotmail.com.

Case presentation: A 74-year-old man, with a benign prostatic hyperplasia, presents with significant unintentional weight loss combined with progressive tetraparesis over a one-year period, leading to confinement to a wheelchair. The physical examination revealed pseudobulbar affect, mild dysarthria, tetraparesis with distal predominance in the upper limbs and proximal predominance in the lower limbs with signs of upper motor neuron involvement. In addition, there was significant bilateral appendicular and truncal ataxia, intentional tremor and hyperreflexia of axial facial reflexes. A brain magnetic resonance imaging (MRI) revealed multiple areas of heterogeneous enhancement with predominantly perivenular pattern in the white matter of the centrum semiovale, periventricular regions, nucleocapsular areas, brainstem, with predominance in the lower part of the pons and medulla, and midbrain cerebral peduncles. There was also enhancement along the ependymal surface of the lateral ventricles, especially near the atrium, posterior and temporal horns. High signal areas on T2 and FLAIR sequences were associated with no apparent diffusion restriction in the centrum semiovale and confluent periventricular white matter of both cerebral hemispheres, mainly adjacent to the occipital horns of the lateral ventricles. Cervical and thoracic MRI demonstrated signs of cervical myelitis, with scattered areas of irregular enhancement on contrast imaging. Initial hypotheses were autoimmune disorders , lymphoproliferative disease, and chronic lymphocytic inflammation with pontine perivascular enhancement responsive to steroids (CLIPPERS). Cerebrospinal fluid (CSF) analysis revealed elevated protein levels and mild lymphocytosis without other positive infectious markers, and oligoclonal bands of pattern 3. Tests for autoimmune, inflammatory, and systemic granulomatous diseases were negative. Pulse therapy with methylprednisolone was prescribed, with improvement of symptoms. **Discussion:** CLIPPERS is a rare central nervous system condition centered in the pons. Its pathophysiology involves T cells and shows a good response to glucocorticoids. Patients typically present with subacute symptoms such as gait ataxia, diplopia, and dysarthria. MRI reveals a distinctive pattern of punctate and curvilinear perivascular gadolinium enhancement in the pons and adjacent regions. Pathogenesis remains unknown but an immune-mediated process against a perivascular antigen is a possible explanation. Diagnosis is based on clinical findings, radiological features, and response to GCS. The diagnosis is by exclusion. MRI findings show a characteristic pattern of lesions, which include the possibility of extending into the cervicothoracal spinal cord. **Final comments:** Neurologists should recognize the typical conditions and presentations, as prompt and appropriate treatment with GCS shows significant improvement. Maintenance with immunosuppressive agents is often necessary to prevent relapses.

Correspondence: Ítalo Karmann Aventurato; Email: italo.kar.av@gmail.com.

Background: while cognitive dysfunction in post-COVID-19 patients has been documented, a comprehensive exploration of neuropsychological subgroups is yet to be undertaken. **Objective:** This study, however, takes a novel approach, aiming to delineate the neuropsychological profile of various subgroups using a data-centric hierarchical clustering method. **Methods:** we analyzed the data from the NeuroCovid cohort, comprising different neuropsychological tests (covering multiple cognitive domains) and neuropsychiatric scales. Subjects were recruited through online forms and on-campus ads. After outlier removal, a factor analysis was performed to derive the latent cognitive factors in the data. Factor-transformed data was renormalized according to the expected population mean and standard deviation and used in hierarchical analysis with Ward's method. The number of clusters was chosen by Monte-Carlo simulations using a multivariate Gaussian distribution with the same covariance as the sample. Subjects were compared between clusters regarding demographics, illness severity, depression and anxiety scores. **Results:** among more than 5000 subjects screened, 569 were evaluated in person, and complete neuropsychological data was obtained from 265. Sixteen subjects were identified as outliers using the Isolation Forest algorithm. We applied factor analysis to neuropsychological data from the remaining 249 subjects. Data was deemed proper for factor analysis (Kayser-Meyerz-Olkin statistic 0.63), and the number of factors was determined to be six by parallel analysis. Factors regarding memory, executive functions (EF), automatic processes (AP), motor, visuospatial construction (VSP) and visuospatial construction speed were identified and showed congruence with current cognitive theory. One of the six clusters identified was excluded due to insufficient subjects (n=2). The remaining clusters were (A) unimpaired (n=86), (B) visuospatial impaired (n=18), (C) memory impaired (n=83), (D) AP impairment (n=24), and (E) EF impairment (n=36). Cluster C comprised older subjects, whereas subjects were younger in Cluster E. Depression scores (Beck's Depression Inventory-II) were increased in clusters C and E. Remaining demographic and neuropsychiatric scales did not show statistically significant differences. **Conclusion:** our data shows that the individuals with persistent symptoms after mild COVID present a heterogeneous neuropsychological profile with subgroups showing impairments in different cognitive domains. The findings align with recent publications showing that post-COVID subjects in different age ranges and disease severity presented distinct cognitive profiles. An increased score in depressive symptoms is also consistent with previous reports of neuropsychiatric illness in those previously infected by SARS-Cov-2.

Correspondence: Rodrigo Siqueira Soares Frezatti; Email: frezattirodrigo@hotmail.com.

Background: Spinal muscular atrophy (SMA) is mainly linked to biallelic loss-of-function variants in the SMN1 gene located on 5q13. In recent years, with the advance in next-generation sequencing (NGS), several genes outside of chromosome 5 have been recognized. This subgroup, known as non-5q SMA, in linked to a wide phenotypic variability and, albeit a growing list of potentially causative genes, there is a low diagnostic yield amongst them. There is an unmet need to better characterize and molecularly approach these patients. **Objective:** We sought to characterize a Brazilian cohort of non 5q SMA patients through clinical and paraclinical analysis and evaluate NGS performance in two main groups: pure and complex. **Methods:** Cases with non-length dependent neurogenic weakness were included. Patients were categorized regarding a pure lower motor neuron involvement or within a complex phenotype. Molecular analysis was conducted considering initial assessment and included single gene test (ATXN2, VWA1, AR, VAPB), WES or WGS in whom initial analysis was negative. **Results:** The cohort was predominantly composed by sporadic cases (54%). Mean age of onset was 15 years old. So far, sixty-seven probands were tested, most of them with WES (58/67) and in some cases with bespoken single gene test (6/67). Muscle MRI was performed upon structured approach for cases with confirmed molecular diagnosis. Overall, thirty-two patients (49%) had an initial positive result and nineteen different genes have been identified: AR (n=1), AARS1 (n=1), COL6A2 (n=1), COL6A3 (n=1), TK2 (n=2), SIGMAR1 (n=1), VRK1 (n=5), BICD2 (n=2), DYNC1H1 (n=1), FBX038 (n=1), HEXA (n=2), VAPB (n=5), TBCK (n=1), FUS (n=2), SLC52A (n=1), MME (n=1), PRPS1 (n=3), COQ7 (n=2), MYH7 (1).Complex phenotype patients achieved a higher diagnostic yield (60% x 22%) and dysautonomia is, so far, the most predictive feature to positive diagnosis as it was present in 80% of our VAPB cases and not in any other patient. **Conclusion:** This is an ongoing work with still incomplete molecular assessment and muscle MRI analysis. Nevertheless, so far, we highlight the highest diagnostic yield in complex phenotype, the importance of muscle MRI in the deep phenotyping effort, the diversity of encountered genes and the unexpected frequent relation with "myopathic" genes: MYH7,COL6A3, COL6A2, SGCA and TK2. Overall, a comprehensive and clustered phenotyping, using muscle MRI muscle fatty infiltration pattern identification seems to positively influence diagnostic outcome.

Cluster tic syndrome: the duel of two excruciating headaches

Sofia Mônaco Gama[1], Luccas Almeida Andrade[1], Gabriel Pinheiro Martins de Almeida e Souza[1], João Vitor Gerdulli Tamanini[1], Guilherme Antonio Silva Ribeiro[1], Flávio Moura de Rezende Filho[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Sofia Mônaco Gama; Email: smonacogama@gmail.com.

A 50-years-old woman presented with a 3 year-history of severe facial pain that was characterized by paroxysmal episodes of shock-like pain in the right maxillary and mandibular regions, lasting seconds and triggered by a

breeze or light touch in the face. Further investigation with brain magnetic resonance imaging (MRI) demonstrated neurovascular conflict on the right side of the trigeminal nerve. The diagnosis of classical trigeminal neuralgia was made, and treatment with carbamazepine was initiated, resulting in a good response. However, the patient developed a cutaneous allergic reaction and the treatment was replaced with gabapentinoids. Two years ago, the patient began experiencing a new pattern of severe unilateral headache in the right retro-orbital and hemicranial regions, lasting 10 to 40 minutes with a significant sense of restlessness. Concurrently, there was a worsening of the previous facial pain, frequently occurring before this new headache. Additional investigations were unremarkable and optimizing gabapentinoid treatment did not result in improvement. One year ago, both types of pain worsened. Therefore, neurovascular decompression surgery was performed, resulting in improvement of the shock-like pain in the subsequent weeks. Nevertheless, the patient developed a new exacerbation of the right headache, occurring up to 8 times per day. The diagnosis of cluster tic syndrome was made. Treatment with verapamil was initiated, as well as oxygen during crises, resulting in significant improvement of the symptoms. Cluster tic syndrome is a rare neurological condition that combines features of both cluster headaches and trigeminal neuralgia. The first description was in 1978 and since then only approximately 40 patients have been reported. The headache initially presents as trigeminal neuralgia or as cluster headache separately or as a combination of both. The pain is unilateral and severe. In cluster headache episodes, the pain is localized in the periorbital or temporal region, associated with autonomic symptoms. In trigeminal neuralgia, the pain is localized in territories innervated by the trigeminal nerve and characterized by paroxysm sharp, shock-like pain triggered by facial or intraoral stimuli. Treatment of the acute phase is with oxygen therapy, triptans and prednisone in cluster headache attacks. In exacerbations of trigeminal neuralgia, management is with triptans, intravenous phenytoin, lidocaine or local procedures. Maintenance treatment is based on oral medications used for both types of headache, such as verapamil, lithium, carbamazepine, lamotrigine and gabapentin. Surgical decompression of trigeminal nerve is indicated for refractory cases.

- Cluster tic syndrome is characterized by trigeminal neuralgia and cluster headache simultaneously.
- This condition is important to be recognized because both must be treated for the patient to become headache free.

c-NORSE score identifies patients with cryptogenic NORSE in a Brazilian cohort

João Henrique Fregadolli Ferreira[1], Anna Maria Gomes[1], Ana Carolina Zetehaku[1], Taíssa Ferrari Marinho[1], Fabio Fieni Toso[1], Caio César Diniz Disserol[1], Luís Otavio Caboclo[1], Livia Almeida Dutra[1]

[1]Hospital Israelita Albert Einstein, Instituto do Cérebro, São Paulo SP, Brazil.

Correspondence: João Henrique Fregadolli Ferreira; Email: jhfregadolli@gmail.com.

Background: New-Onset Refractory Status Epilepticus (NORSE) is a severe condition requiring extensive investigation and long hospital stays. Most cases remain without a cause, termed cryptogenic (c-NORSE). Data with inconsistent antineuronal antibody testing showed that autoimmune encephalitis (AE) is the most common identifiable cause of NORSE in adults. Second-line treatment for AE and c-NORSE differs, with drugs targeting innate immune pathways, such as anti-IL1 and anti-IL6, recommended for c-NORSE. Recently, a score based on clinical findings and complementary investigation helped identify c-NORSE at early stages. **Objective:** To describe a cohort of Brazilian NORSE patients and evaluate the applicability of c-NORSE score. **Methods:** We retrospectively evaluated patients with Status Epilepticus (SE) or RSE included in the Brazilian Autoimmune Encephalitis Network from January 2017 to November 2023. Patients were investigated with brain MRI, CSF analysis and herpes virus PCR, followed by testing for antineuronal antibodies using TBAs, CBAs, and immunoblots in serum and CSF. Patients were allocated into two groups according to C-NORSE score: high score (≥5) or low score (<5). Groups were compared using Mann-Whitney, Fisher's exact test or chi-square test. p-value<0.05 was considered significant. Sensitivity and specificity were calculated using contingency table analysis. **Results:** Of 81 SE or RSE patients, 40 met NORSE criteria and were selected. Eighteen (40%) were children ≤13y and 52% were female. Based on c-NORSE score, 11/40 (27%) patients were in the high score (HS) group and 29/40 (73%) were in the low score group (LS). HS group had more bilateral and symmetric MRI findings (HS 100% x LS 35%, p=0.003), and fewer memory or behavioral symptoms (HS 27% x LS 83%, p=0.002). No difference was observed in gender, prodromic fever, or dyskinesia. LS group had alternative diagnosis: seropositive AE (n=7), MOGAD (n=2),c-NORSE (n=8), HSV encephalitis (n=4), seronegative AE (n=1), encephalomyelitis (n=1), and other causes (n=5). All patients from the HS group remained as c-NORSE. The sensitivity of the c-NORSE score was 58%, and the specificity was 100%. About 22% NORSE patients had AE, and 47% were cryptogenic. c-NORSE score had lower sensitivity than previously reported, and high specificity. Thus, at bed side, patients with ≥5 points probably present c-NORSE, and treatment decision may favor IL-6 or 1L-1 blocking drugs. Our findings differ from prior reports mostly because (1) we did not consider patients with Graus criteria for probable AE as a final diagnostic category, (2) samples were tested with two different techniques (TBAs and CBAs), and only antibodies with well stablished clinical pathogenicity were considered. Our data confirms that AE can manifest as NORSE, but other findings suggestive of AE other than seizures must be actively searched. **Conclusion:** c-NORSE score is a valuable tool in identifying cryptogenic cases in our population.

Coexisting anti-NMDAR and MOG antibody-associated encephalitis: case report

Santhiago Calvelo Graça[1], Maria Clara Motta Barbosa Valente[2], Cícero Rodrigues Veloso[2], Rachel Leirner Argelazi[1], Mauro Gualano da Costa Abreu[1], Mariana Akemi Takegawa Miyahara[1], Rafael Chaves Claudino de Queiroga[2], Annelise Akemi Higa Lee[2], Keila Narimatsu[2], Francisco Tomaz Meneses de Oliveira[2]

[1]Santa Casa de São Paulo, Faculdade de Ciências Médicas, São Paulo SP, Brazil.
[2]Irmandade da Santa Casa de Misericórdia de São Paulo, São Paulo SP, Brazil.

Correspondence: Santhiago Calvelo Graça; Email: santhiagocalvelo@hotmail.com.

Case presentation: A 29-year-old patient presented to the emergency with a history of epileptic seizure associated with headache, paresthesia and paralysis of the right upper limb. In the previous week, the patient had experienced their first seizure, characterized by sudden appearance of scotomas in the central field of vision of the right eye, associated with abduction of the right eyeball, disperception and progressing to a tonic-clonic seizure. On the days following the initial event, the patient reported episodes of headache after transient episodes of paresis and paresthesia of the right arm and the trunk, alongside motor aphasia. These episodes persisting despite the use of 50 mg/day of lacosamide. Neurological examination revealed slurred speech and atypical gait, without other abnormalities. The patient had previous results from magnetic resonance imaging (MRI) performed on another service, that showed focal lesions suggestive of central nervous system infection and involvement of the leptomeninges. An electroencephalogram revealed right centroparietal epileptic paroxysms. The initial treatment included: acyclovir, dexamethasone, and maintenance of lacosamide. During investigation, a molecular panel for meningitis/encephalitis (FilmArray) was negative for various agents, including varicella-zoster and other herpes viruses. The cerebrospinal fluid was clear with lymphocytic pleocytosis (56 cells with 96% lymphocytes), negative for bacteria and fungi and the autoantibodies test indicated positive anti-NMDA. Given the neuroimaging findings and clinical presentation, the possibility of an overlap with MOGAD was considered. Therefore, anti-MOG antibodies were requested, and the result was positive, confirming the clinical-radiological hypothesis and aiding in the management and delineation of the prognosis. During follow-up, the patient showed improvement in seizures. A new MRI showed improvement of the initial lesions. In this context, the patient was diagnosed with coexisting anti-NMDAR and MOG Antibody-Associated Encephalitis and immunotherapy was introduced. **Discussion:** The presence of antibodies against both NMDA receptor and MOG represents a recently described entity: overlapping autoimmune encephalitis (OAE). This condition can manifest with a distinct clinical phenotype compared to single-antibody encephalitis. In our case, following the positive anti-NMDAR antibody test, the possibility of co-existing anti-MOG antibodies arose based on neuroimaging findings. OAE should be suspected in atypical cases differing from classic anti-NMDAR or MOGAD presentations. Fortunately, after the treatment the patient has maintained a stable clinical course with no relapse. **Final comments:** This case highlights the importance of investigating autoantibodies in patients with encephalitis of probable autoimmune etiology, especially when the clinical is atypical. Early diagnosis and initiation of appropriate immunotherapy are crucial for improving prognosis.

[2]Universidade Federal de Pernambuco, Recife PE, Brazil.

Correspondence: Pedro Igor Lustosa Roriz; Email: pedroilroriz@gmail.com.

Background: Patients with systemic arterial hypertension (SAH) are at higher risk of developing a more severe course of SARS-CoV-2 viral infection, in addition to potentially developing lasting cognitive sequelae. Current literature provides evidence that the mechanism underlying the worse outcome of COVID-19 and the emergence of cognitive impairments in hypertensive individuals is endothelial dysfunction. Flow-mediated dilation (FMD) is a technique that has been used for several decades to assess endothelial function. **Objective:** To evaluate the effect of exposure to mild forms of COVID-19 on the cognitive status and endothelial function of patients with SAH. **Methods:** A cross-sectional study compared cognitive status, assessed through neuropsychological tests, and endothelial function, assessed through FMD, in 52 patients diagnosed with SAH who were previously exposed or not to mild forms of COVID-19. Patients were allocated into two groups: SAH with COVID-19 exposure (SAHEXP_COVID) and SAH without COVID-19 (SAH). Assessment was documented between six months and eighteen months post-infection. **Results:** No difference in FMD% was observed between the studied groups (p=0.69): for the SAH group, FMD% was 6.7 (IQR 6.1) and

for the SAHEXP_COVID group, FMD% was 5.4 (IQR 7.6). No differences in cognitive performance were observed when comparing the groups, nor was there a relationship between cognition and endothelial function. **Conclusion:** Although the study did not show differences between the groups, this finding may provide evidence that many lesions caused by the SARS-CoV-2 virus, in cognitive and endothelial impairment, may be self-limited in nature, especially in cases of mild infection.

Cognitive and neuropsychiatric analysis of patients with myotonic dystrophy type I

Daniel Delgado Seneor[1], Vitor Dias Gomes Barrios Marin[1], Carlos Alberto Castro Teixeira Júnior[1], Fernanda Lustosa Cabral Gomez[1], Lucas Toshio Uenishi[1], Lara Santos Machado[1], Igor Braga Farias[1], Wladimir Bocca Vieira de Rezende Pinto[1], Paulo Victor Sgobbi de Souza[1], Acary Souza Bulle Oliveira[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Daniel Delgado Seneor; Email: danielseneor30@gmail.com.

Background: Myotonic dystrophy type 1 (DM1) is a genetic disorder that affects multiple systems, including the central nervous system. While motor impairments in DM1 are well-documented, the neuropsychiatric profile of these patients, particularly in the Latin American context, is still being delineated. **Objective:** This study aims to evaluate the cognitive and neuropsychiatric profile adult DM1 patients and correlate clinical data with neuropsychiatric test outcomes. **Methods:** Fifty adult patients diagnosed with DM1 were recruited from the Myopathy Unit, Division of Neuromuscular Diseases at Universidade Federal de São Paulo. They were submitted to a comprehensive neuropsychological battery comprising 17 tests that assess emotional status and multiple cognitive domains, including attention, language, executive function, and memory. The patients' performance was systematically compared with that reported in previously conducted population studies documented in the medical literature. Furthermore, correlative statistical analyses were performed to determine whether there is association between performance in each test and the degree of motor impairment in the same individual (quantified by the Medical Research Council Scale for Muscle Strength). **Results:** Cognitive assessments revealed impairments across various domains, notably in the clock-drawing test and the cube drawing test (three-dimensional visuoconstructive praxis). Interestingly, patients did not show difficulties in copying two-dimensional images such as a rhombus, circle, and Rey's semi-complex figure. Despite such alterations in visuoconstructive praxis, executive functions remained unaffected. However, abstract reasoning exhibited apparent difficulty. Additionally, domains such as attention, working memory, and episodic memory appeared largely preserved. Correlation analyses did not reveal a clear association between cognitive impairments and motor function. **Conclusion:** This study highlights the intricate neuropsychiatric manifestations observed in adult DM1 patients, emphasizing visuoconstructive praxis as the most affected cognitive domain. Importantly, the study findings show that cognitive impairment in DM1 does not correlate with motor impairment. These findings reinforce the concept of DM1 as a systemic disease with complex central nervous system manifestations, which seem to be independent of the motor aspect of the disease.

Correspondence: Danilo Jorge da Silva; Email: danilomachadosilva@gmail.com.

Background: Amyotrophic lateral sclerosis (ALS) is a rare neurological disease that leads to impairment of both lower and upper motor neurons, resulting in progressive weakness, muscle atrophy and respiratory and swallowing dysfunction. Despite well-documented motor symptoms, non-motor manifestations remain underexplored. **Objective:** To investigate the cognitive function in individuals with ALS in both sporadic and familial forms and its relationship with disease progression. **Methods:** Observational, cross-sectional, controlled study based on primary data of ALS patients over 18 years old, without a prior diagnosis of dementia. Functionality and neuropsychological assessment battery were measured by the following instruments: ALS Functional Rating Scale Revised (ALS-FRS-R), ALS Cognitive Behavioral Screen (ALSCBS), semantic verbal fluency test, phonemic verbal fluency test, digit span subtest from the Wais III scale, Hopkins Verbal Learning Test-Revised (HVLT-R), five-point test, and Mini-Mental State Examination (MMSE). We also applied the social cognition/theory of mind tests of Faux Pas and Theory of Mind – 15 (ToM-15). **Results:** Twenty-two ALS patients and 24 healthy controls were recruited. Among the patients, nine (40.9%) had the sporadic form and 13 (59.1%) had the familial form. Significant differences were observed in MMSE and ALSCBS scores between the ALS and control groups, with worse scores associated with the ALS group, and these differences were more evident among those with the familial form when compared to controls. Digit span, HVLT-R (total recall), five-point test, and ALSCBS were inversely related to ALS-FRS-R scores suggesting worse cognitive impairment in individuals with greater functional impairment related to ALS. Significant differences were also observed between the ALS and control groups in the performance of social cognition tasks measured by the Faux-Pas intention, comprehension, false beliefs, empathy, and total score. The ALS group (more evidently the familial ALS patients) had worse performance in social cognition tasks. This same pattern was also observed in the ability to detect false beliefs using the ToM-15 test with no evidence of significant relationship between ALS-FRS-R and social cognition impairment, suggesting a possible early compromise of theory of mind abilities. **Conclusion:** Individuals with ALS tend to show alterations in multiple cognitive domains, not all of them directly related to functional decline. Cognitive impairment was more pronounced in individuals with the familial form compared to the sporadic form, and there is evidence that social cognition impairment may occur early in the disease in this population.

Cerebellar cognitive-affective syndrome proposes that patients with cerebellar lesions present not only ataxic symptoms, but also important deficits in cognition, affect, and behavior. Cognitive, behavioral, and affective deficits, found in cerebellar cognitive-affective syndrome, may occur due to a process of diaschesis. Spinocerebellar ataxia type 6 (SCA6) is described as the prototype of a pure cerebellar ataxia. The present study aims to provide data on the contribution of corticocerebellar functional connections to clinical manifestations in a population of subjects with SCA6. It is a qualitative-quantitative, observational and cross-sectional research. 20 subjects (10 with ataxia and 10 controls) will be evaluated. All of those evaluated had an IQ greater than 70. Subjects will be matched by age group and education. This work is ongoing, therefore, 6 individuals from the control group and 6 individuals with a confirmed diagnosis were selected. In terms of intelligence quotient, 5 of the 6 patients evaluated with a diagnosis of type 6 ataxia obtained results below those of the control group. On average, there was a difference of 18.8 points. Regarding selective attention, worse results were obtained in the group of diagnosed, the differences ranged from 1 second to 7.63 seconds, with a mean value of 3.38 seconds. The evaluation of inhibitory control indicated a longer response time in the group of diagnosed, with a mean difference of 105.48 seconds versus 45.69 seconds, respectively. On average, patients diagnosed with ataxia had a difference of 8.16 raw points versus 12.33 in verbal long-term memory. When obtaining the average result, in relation to logical reasoning ability, there were higher results among the control group, in which they obtained an average of 13.3 points versus a result of 11.3 compared to the group of diagnosed patients. Regarding perception, the control group also obtained results higher than those obtained by the diagnosed group, which were 18.83 points versus 14.83 points, respectively. In relation to visuoconstructive ability, there were higher scores in the control group, in which they obtained an average of 45 raw points versus 30.6. In terms of cognitive flexibility, there was a score of 6.22 mean points versus 4 points between the diagnosed group and the control group. Regarding image naming, the control group obtained 56 points and the ataxia group 52.66 points. There was a difference in relation to the pertinent result to the working memory ability of the visual sphere. The control group achieved an average score of 8.66, compared to an average score of 7.33 points in relation to the diagnosed group. The presented data suggest cognitive affective syndrome of the cerebellum in type 6 ataxia. Which leads to the question of whether type 6 ataxia is in fact entirely pure, since it underscores a variety of cognitive changes in different areas.

https://doi.org/10.5327/CBN240415

Cognitive changes in patients with concentric Baló sclerosis: a systematic review

Regina Maria Papais Alvarenga[1], Diana Góes de Souza[1]

[1]Universidade Federal do Estado do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Diana Góes de Souza; Email: dianagoes.cortex@gmail.com.

Background: Baló's concentric sclerosis (BCS) is a rare subtype of idiopathic inflammatory demyelinating disease of the central nervous system, characterized by a pattern of alternating and concentric layers of white matter preservation and demyelination, shaped like "onion rings". The disease affects young individuals, preferably women and has radiological and clinical presentations close to those of multiple sclerosis (MS). Since the emergence of magnetic resonance imaging (MRI), an increasing number of BCS cases have been diagnosed at an early stage and it has become possible to quickly identify the disease, with effective treatments using corticosteroids, which prolonged the survival of patients with BCS. **Objective:** To integrate the findings of a systematic literature review and describe clinical characteristics of BCS cases with

cognitive impairments. **Methods:** An electronic search was carried out in the PubMed database with the terms "Balo Concentric Sclerosis or concentric sclerosis or Balo's disease and Magnetic Resonance" between the years 1989 and 2024, written in English, French, Italian and Spanish, in article format original or case study, with humans. 217 articles were initially identified in the search and 34 were sellected. **Results:** What is generally described in case studies with BCS patients are the clinical symptoms, the age at onset of the disease, the monophasic or recurrent course, drug treatments performed and the MRI findings. Among the different symptomatological presentations of the disease is cognitive impairment. 19 patients were identified with cognitive decline among 65 BCS case reports reviewed (29%), which mainly presented language impairments, memory deficits and attentional changes. An SPSS analysis indicated that man predominated (n=11; 58%) and the mean age of onset was 34.47 years, ranging from 10 to 54 years. The recurrent clinical course was identified in 5 cases (26.3%) and 14 were monophasic (73.7%). Clinical treatment with corticosteroids was administered in 15 cases (79%) and 4 patients did not take any medicine (21%). Regarding the outcome, 13 cases improved (68.4%), 5 had sequels after the events (26.3%) and 1 had no information about the evolution of the symptoms. Among the cases reviewed with cognitive decline, language impairments occurred in 13 cases (68.4%), memory deficits in 4 (21%) and attentional changes in 2 (10%). **Conclusion:** This research achieved the main objective since all 19 cases reviewed that presented with cognitive declines could be identified per type (language, memory and attention), which reinforces the importance of future studies investigating phenotypes of cognitive changes in patients with BCS. It was observed that, differing from socio demographic research with BCS patients, in this systematic review male cases predominated and it could be investigated if cognitive impairment occurs more in man.

Cognitive decline in patients with Chagas and non-Chagas etiology heart failure: a prospective cohort study

Israela Souza Brito Santos[1], Lucy Rodrigues Ribeiro[1], Cárita Victória Carvalho de Santana[1], Bruna Helena Ribeiro Araújo dos Santos[1], Janaina Brito de Pinho[1], Júlia Barreto de Farias[1], Bruna Guilherme Martendal[1], Beatriz Malaquias Neves[1], Graziele Carolina Araújo Soares[1], Jamary Oliveira Filho[1]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.

Correspondence: Israela Souza Brito Santos; Email: israela.souza@ufba.br.

Background: Cognitive impairment in Chagas disease (CD) remains understudied. Patients with chronic CD may exhibit varying levels of cognitive dysfunction; however, the longitudinal evolution of this dysfunction over time is not well understood. **Objective:** To investigate the association between CD and cognitive dysfunction in patients with heart failure (HF), and to assess cognitive decline over time. **Methods:** Prospective cohort study involving adult individuals with heart failure from 2021 to 2024. Exclusion criteria included history of cancer (except skin), stroke, end-stage renal or hepatic disease, and other neurodegenerative conditions. Cognitive assessment tools included: Mini-Mental State Examination, Brief Cognitive Screening Battery, Luria's test of motor sequence, Rey Complex Figure Test, and Digit Sequencing Task, grouped into four cognitive domains (Z-scores): memory, visuospatial, executive, and global. A repeat cognitive assessment identical to the first was conducted at least 2 years later. Z-scores ≤1.5 indicated cognitive dysfunction in each domain. Logistic regression adjusted for age, sex, and education level compared the proportion of cognitive dysfunction between individuals with and without CD. **Results:** A total of 86 participants were included, with 54 having Chagas etiology HF and 32 having other etiologies. Compared to participants without CD, those with CD were predominantly older (53.2±12.7 without CD vs. 57.1±7.6 with CD), female (15 [48%] without CD vs. 39 [84.7%] with CD), and had incomplete primary education (14 [45%] without CD vs. 31 [67.3%] with CD). Cognitive dysfunction was predominantly observed in Chagas patients (vs. non-Chagas) in the executive function domain, present in 37.0% vs. 15.6%, respectively, p=0.034. After a mean follow-up of 6.4 (±3.1) years, executive function domain dysfunction persisted in 29.6% vs. 12.5% of these patients, respectively. **Conclusion:** Patients with Chagas etiology HF exhibit greater cognitive deficits, predominantly in the executive function domain, compared to patients with other cardiomyopathies. However, the degree of cognitive dysfunction appears to remain stable over time.

Case presentation: A 67-year-old woman was admitted to the hospital after episodes of epileptic seizures and mental confusion. She reported anxiety, disorientation, and headaches for the past 15 days. On initial examination, she was confused, drowsy, with signs of meningeal irritation. The cranial nerves were preserved. No alteration in strength or reflexes were found. Glasgow score was 13. A cranial MRI revealed extensive areas of T2/FLAIR hypersignal, severe microangiopathy, and pial enhancement by contrast in the right temporo-parieto-occipital region, in addition to positive Ig M serology for leptospirosis. She was treated with ampicillin and sulbactam. On the 3rd day of admission, there was a worsening of consciousness level, recurrent epileptic seizures, hyponatremia, and worsening renal function, leading to orotracheal intubation and mechanical ventilation for status epilepticus treatment. After 30 days hospitalized, she showed clinical and neurological improvement and was discharged with phenytoin and levetiracetam medication. Prior to hospitalization, she used lithium and sertraline to treat her bipolar affective disorder (BAD) diagnosed in her youth. After discharge, she began to presente cognitive complaints. During the neurologist consultation, the Montreal Cognitive Assessment (MoCA) test was 18 out of 30 points. The diagnostic hypothesis was multifactorial cognitive impairment secondary to deterioration of BAD associated with sequelae of leptospirosis encephalitis and vascular lesions. **Discussion:** Encephalitis is an acute inflammation of the central nervous system (CNS), specifically of the brain parenchyma, often caused by viruses such as influenza, herpes simplex, arboviruses, and in endemic areas like Brazil, dengue, Zika and Chikungunya viruses can also be pathogenic agents. Less commonly, bacterial pathogens such as Leptospira species can lead to this clinical manifestation. Leptospirosis is a zoonosis of significant global concern, prevalent in tropical climates and associated with lower economic levels. The disease is transmitted through contact of an open wound with the urine of the transmitting animal and can manifest in various clinical forms, although neurological presentation is uncommon (about 10-15% of Leptospirosis cases). The CNS can be affected by this zoonosis either through direct infection of the brain parenchyma or secondarily through hepatorenal involvement. This CNS involvement may manifest as meningitis or encephalitis. **Final comments:** Therefore, due to encephalitis being a medical emergency and this manifestation of Leptospirosis being considered rare, many physicians may not consider this possibility and may mismanage the patient or even miss the appropriate time to start treatment to prevent more severe sequelae. It is essential that, especially in the most prevalent areas of this significant zoonosis, this clinical manifestation must be adequately investigated and treated promptly.

Cognitive impairment: clinical presentation of an immunocompetent patient with neurosyphilis

Paulo Henrique Martinelli Oliveira[1], Amanda Michelucci dos Santos[1], Larissa Miyashiro[1], Raderi Luiz Cardoso Do Santos[1], Lucas Silva Dias[1], Laiz Helena de Pádua[1], Gustavo Carvalho Costa[1], Rebeca Aranha Barbosa Sousa[1]

[1]Hospital Municipal Dr. José de Carvalho Florence, São José dos Campos SP, Brazil.

Correspondence: Paulo Henrique Martinelli Oliveira; Email: paulohmoliveira96@gmail.com.

Case presentation: Patient R.P.S, male, 47 years old, previously diagnosed with depression. About two years ago, sought care with a headache, temporal and spatial disorientation, and cognitive impairment, evolving with inability to accomplish activities of daily living without assistance. The patient was diagnosed with syphilis (serologic VDRL 1/64) and received treatment for late latent stage, with benzathine penicillin G intramuscularly in 3 weekly doses. After treatment, the patient persisted with cognitive impairment and infatilized behavior. On May, 2024, was brought to the emergency care unit after first epileptic seizure with secondary generalization. There was no recurrence of seizure since admission. Montreal Cognitive Assessment (MoCA) was performed, with score 15/30. The initial brain computerized tomography was normal. The laboratory revealed syphilis rapid diagnostic test positive, serologic VDRL 1/32, anti-HIV negative, and reactive VDRL in cerebrospinal fluid. The patient underwent treatment with intravenous crystalline penicillin for 21 days. After therapy, his MOCA score was 19/30. He was discharged and referred to the Cognitive Neurology clinic. **Discussion:** Neurosyphilis can occur at any stage of syphilis. Clinical manifestation range from asymptomatic, meningeal, meningovascular, to tabes dorsalis and general syphilitic paresis. Recognizing the neurological manifestations is important, as the treatment differs from that of syphilis without neurological involvement. Failure to diagnose and inadequately treat neurosyphilis can cause severe and permanent damage to the patient. Without proper treatment, the infection can progress, resulting in severe neurological symptoms such as headaches, confusion, loss of vision, hearing, and motor control. The patient may develop dementia, paralysis, personality changes, and psychiatric problems. These complications can lead to a significant reduction in quality of life, inability to work, and increased dependence on medical care and social support. In extreme cases, untreated neurosyphilis can be fatal. **Final comments:** Neurosyphilis can be a diagnostic challenge due to its variety in clinical presentation, and it should be considered as a differential diagnosis in patients with cognitive impairment.

https://doi.org/10.5327/CBN240419

Cognitive multisensory rehabilitation (cmr perfetti): improving motor function in chronic stroke patients

Rafael Correa Fantato[1], Julian Pablo Gorosito[1], Mauro Cracchiolo[1], Mara Cristina Santos Melo[1], Fernanda Devecchi Prado[1], Patricia Simone Lopes de Souza[1], Ivana Brito[2]

[1]Instituto Avencer
[2]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Rafael Correa Fantato; Email: tnc@institutoavencer.org.

Motor recovery following a stroke is a multifactorial and dynamic process influenced by various factors including age, ethnicity, socioeconomic factors, genetic traits, initial injury severity, and time since the stroke occurred. Neurorehabilitation strategies play a pivotal role in facilitating recovery but must account for the considerable variability among patients, making a standardized intervention protocol challenging to develop. Therefore, it is essential that rehabilitative reasoning prevails to guide individualized approaches to rehabilitation. Advancements in our understanding of neural plasticity have transformed the prognosis for post-stroke patients, emphasizing continuous improvement. Cognitive multisensory rehabilitation (CMR), also known as the Perfetti method, is a motor learning model that emphasizes high-level cognitive function and occurs through the integration of perception-cognition-emotional processes, such as motor regulation. Activation of the brain's cognitive process, which represents perception, memory, attention, language, and decision-making, is the core of the training. **Case presentation:** Case 1: A 37-year-old woman, previously healthy, developed spastic hemiplegia on the right following an ischemic stroke caused by dissection of the left internal carotid artery in June 2015. She received conventional physiotherapy treatments until February 2018, after which she underwent CMR Perfetti treatment until July 2023. Case 2: Man, 51 years old, with congenital visual impairment, presents with ataxic tetraparesis with brachial and left predominance, due to hemorrhagic cerebellar stroke in January 2015. He was followed up with conventional physiotherapy treatments until November 2020, when he began treatment with CMR Perfetti. For Case 1: There was a notable 22.2% improvement in MESUPES-hand and a 5% improvement in MESUPES-arm scores, indicating enhanced quality of movement in the paretic upper limb. Tardieu scale showed increased range of motion was observed in shoulder flexors, extensors, adductors, and medial rotators, as well as elbow flexors and extensors. Thumb opponency improved by 2cm. For Case 2: There was a significant 22.5% improvement in MESUPES-arm score, reflecting enhanced quality of movement in the affected arm. Range of motion gains exceeded 50% for shoulder adductors, wrist extensors, and index finger flexors (Tardieu). Physical domain of quality of life (WHOQOL) improved by 10%. **Discussion:** These improvements highlight the effectiveness of CMR Perfetti treatment in enhancing motor function, range of motion and quality of life in both cases, despite their distinct initial conditions and challenges. **Final comments:** Advancements in our understanding of neural plasticity, along with the recognition of the importance of consciously constructing the necessary information for action, have transformed the prognosis for post-stroke patients, emphasizing continuous improvement.

Cognitive symptoms in long COVID patients: clinical and epidemiological analysis

Emanuel de Assis Bertulino Martins Gomes[1], Antônio Alves Sobreira Neto[2], Chiara Gübel Portugal[2], Lorenzo Marinho Morais[2], Samuel Cavalcante Marinho[2], Álissa Elen Formiga Moura[1], Thaís de Maria Frota Vasconcelos[1], Marcello Holanda de Andrade[1], José Wagner Leonel Tavares Júnior[1], Pedro Braga Neto[1]

[1]Universidade Federal do Ceará, Complexo Hospitalar, Fortaleza CE, Brazil.
[2]Universidade Estadual do Ceará, Fortaleza CE, Brazil.

Correspondence: Emanuel de Assis Bertulino Martins Gomes; Email: emanueldeassis@alu.ufc.br.

Background: During the COVID-19 pandemic, some patients presented neurological symptoms in the acute phase of the disease, such as dizziness and headaches. Subsequently, many patients reported long-term cognitive effects of SARS-CoV-2, a phase known as "Long Covid", with mild to severe effects on quality of life. **Objective:** To describe and compare clinical and epidemiological data from patients who developed long-term cognitive complaints after COVID-19. **Methods:** This is a prospective, cross-sectional study of patients previously diagnosed with COVID-19. We used data from the project "Rede Nordeste de Neurocovid Longo", a cohort investigating neurological alterations in "Long Covid". All patients signed an informed consent form to take part in this research. The participants were evaluated at a university hospital complex in Fortaleza city by a neurologist, using scales for cognitive and functional assessment, such as the Mini-mental state examination and the Pfeffer scale. In addition, blood samples were taken to analyze APOE gene and neurodegeneration markers. Data analysis was conducted using Jamovi software. Mann-Whitney U and Kruskal-Wallis tests were used for comparative analysis. **Results:** From March 2023 to April 2024, 136 patients were assessed, with a mean age of 42.79 years (±13.21) and a predominance of women (77.2%). Cognitive complaints were reported by 128 (94.11%) participants, who presented an average age of 42.93 years (±13.26) and 78.12% female patients. In the cognitive assessment, 5.88% of the patients showed no alterations, 86.76% had subjective cognitive decline (SCD), 5.14% had mild cognitive impairment (MCI) and 2.20% had dementia. Regarding related symptoms, cognitive complaints were mainly associated with sleep disorders (76.56%), anxiety (61.71%) and headaches (37.50%). In relation to total patients, 40 (29.41%) had more than one SARS-CoV-2 infection and 22 (16.17%) were hospitalized for COVID-19, of which 16 (11.76%) were admitted to the Intensive Care Unit (ICU). A comparative analysis was carried out between the information described and the clinical cognitive assessment, in which patients were described ordinally as "Unaltered", "SCD", "MCI" or "Dementia". A significant association was seen in comparison with the variables Hospitalization (p=0.022), ICU admission (p=0.007) and Anxiety (p=0.023). **Conclusion:** The epidemiological profile of patients with "Long Covid and cognitive complaints consisted mainly of women and presented a mean" age of 42.93 years. In this group, the majority of participants had Subjective Cognitive Decline according to the clinical assessment. In addition, cognitive symptoms were mainly accompanied by sleep disorders and anxiety. Finally, comparative analyses showed an association between cognitive decline and hospitalization, ICU admission and anxiety.

Cognitive training associated with transcranial direct current stimulation in the treatment of age-related mild cognitive impairment: a systematic review of randomized clinical trials

Felipe Miranda Camboim[1], Daniel Macedo de Oliveira[1], Flávia Blank[1], João Guilherme Gomes Pedrosa[1], João Vitor Andrade Fernandes[1], Rebeca Oliveira da Silva[1], Isabella Araujo Mota Fernandes[2]

[1]Universidade Federal da Paraíba, João Pessoa PB, Brazil.
[2]Hospital Universitário Lauro Wanderley, João Pessoa PB, Brazil.

Correspondence: Felipe Miranda Camboim; Email: felipemirandacamboim@gmail.com.

Background: Cognitive training (CT) is an established therapy for cognitive decline in ,ild cognitive impairment (MCI), however, there are other non-pharmacological alternatives, such as transcranial direct current stimulation (tDCS). A novel approach suggests combining both CT and tDCS, in an attempt to augment its effects on patient cognitive performance. **Objective:** To synthesize evidence on the efficacy of combined cognitive training and transcranial direct current stimulation treatment of age-related mild cognitive impairment. **Methods:** A systematic review was conducted using the following databases: Medline, Embase, Cochrane, Web of Science, and BVS. The search terms utilized included "Transcranial Direct Current Stimulation," "Mild Cognitive Impairment," and "Adult," as well as their entry terms, combined with Boolean operators OR and AND. Only randomized controlled trials (RCTs) were included in the review. No language or date filters were applied during the search. The studies were independently analyzed by two reviewers according to eligibility criteria. The articles were screened using a computerized review software and the data obtained was organized in an online spreadsheet. The inclusion criteria were randomized controlled trials that compared the use of tDCS combined with CT versus sham-tDCS in adult patients with age-related MCI. The intervention group in the selected studies involved the use of tDCS with electrodes positioned in the left dorsolateral prefrontal cortex with a direct current of 2mA, on average, combined with computerized cognitive training. **Results:** A total of 381 articles were found, of which 12 studies were included, according to eligibility criteria, for analysis, totaling 440 patients. None of the studies included were conducted in South America. Overall, the tDCS + CT group obtained a greater improvement in the parameters analyzed (everyday memory, executive functions, working memory) compared to the sham tDCS group. However, most of the studies did not find statistically significant differences between the groups analyzed. **Conclusion:** Although tDCS combined with cognitive training was able to improve patient's overall cognitive performance, these results were not statistically significant in comparison to controls. However, study methods diverged substantially, especially regarding the protocol for application of active and sham tDCS.

Coinfection of neurotuberculosis and neurocryptococcosis in an immunocompetent patient: a case report

Lucca Ferdinando Queiroz Fernandes[1], Maria Eduarda Medeiros Martins[1], Diógenes Emanuel Dantas da Silva[1], Matheus Araújo de Medeiros[1], Artur Rebouças de Souza[1], Tiago Lameque de Sousa e Silva[1], Helmut Kennedy Azevedo Do Patrocínio[1], Lucas Medeiros Dunga[1], Iury Hélder Santos Dantas[1], Fernanda Gurgel de Oliveira[1]

[1]Universidade Federal do Rio Grande do Norte, Caicó RN, Brazil.

Correspondence: Lucca Ferdinando Queiroz Fernandes; Email: queirozlucca@gmail.com.

Case presentation: A 52-year-old woman with no comorbidities, presented with asthenia and weight loss, accompanied by paresis in the right lower limb, initially diagnosed as depressive disorder. After 3 months, developed tetraparesis, gait ataxia, dysarthria, fever and psychomotor slowing. Nuclear magnetic resonance (NMR) with contrast showed leptomeningeal enhancement in the basal cisterns, Sylvius and interhemispheric fissure, brainstem and cerebellar sulci, with extension to the spinal cord and some roots of the cauda equina. Diffusion restriction in T2/FLAIR was observed in the pontine region on the left and the nucleocapsular region on the right. Findings suggestive of neurotuberculosis with ischemic events due to associated vasculitis. The cerebrospinal fluid (CSF) showed mild pleocytosis with a lymphomononuclear

predominance, hyperproteinorrachia and hypoglycorrachia. Fungoscopy, bacilloscopy, TRM-TB in the CSF were negative. A chest CT revealed a calcified granuloma in the middle lobe, with no signs of active pulmonary tuberculosis (TB). Treatment for TB with RHZE and corticotherapy was started, with clinical improvement and discharge after 2 months. One week after discharge, she was readmitted with worsening motor skills, dysarthria, fever and headache. A new MRI showed increased leptomeningeal enhancement. Serial lumbar punctures revealed increased opening pressure, mild lymphomononuclear pleocytosis, hyperproteinorrachia, hypoglycorrachia, negative bacilloscopy and TRM-TB, but positive fungoscopy. A Lateral Flow Assay for cryptococcal antigen (LF-CrAg) was carried out and the serum and CSF were reactive. Liposomal amphotericin B and flucytosine were started, as well as daily CSF punctures for relief, with a good response. Control MRI showed a slight reduction in leptomeningeal enhancement and no new ischemic events. Serologies for HIV and HTLV during hospitalization were non-reactive, with an undetectable HIV viral load. She continues to be followed up as an outpatient, clinically stable, under treatment with RH, fluconazole and weaning off corticosteroids. **Discussion:** Although both neurotuberculosis and neurocryptococcosis are diseases with a high incidence in HIV-AIDS patients, coinfection is rare. Even rarer in immunocompetent patients. This case reports the coinfection of these two infections in a patient with no known immunosuppression. The clinical-laboratory presentation and imaging findings were initially suggestive of TB, a diagnosis reinforced by the initial response to treatment with RHZE and corticotherapy. The subsequent clinical worsening, however, raised the suspicion of a second infection, confirmed by positive fungoscopy and a reactive LF-CrAg test. **Final comments:** Coinfection of neurotuberculosis and neurocryptococcosis is rare, especially in immunocompetent patients. Both infections can share similar epidemiological and clinical characteristics, requiring high clinical suspicion for the diagnosis of coinfection.

Collet-sicard syndrome: a clue to occult malignancy in an elderly female - a case presentation

Guilherme Lago Miranda[1], Erick Dupont[1], Ingrid Lorena da Silva Gomes[1], Henrique de Moraes Bernal[1], Giovanni Caniçali Simões[1], Pedro Almeida Martins Pontes[1], Tainá Fátima Ramos Gonçalves[1], Matheus Reis Rosa[1], Marcele Schettini de Almeida[1], Sonia Maria Cesar de Azevedo Silva Moura Magalhães Gomes[1]

[1]Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo SP, Brazil.

Correspondence: Guilherme Lago Miranda; Email: lagomiranda.g@gmail.com.

Case presentation: A 69-year-old female patient with no previous relevant diseases was admitted to the emergency room of a tertiary hospital complaining of twinging neck pain that had been ongoing for 2 days. She also mentioned dysphagia, and noticed slurred speech and hoarseness. On neurological examination, she had dysphonia and dysarthria that were worse for palatal sounds; the palate was asymmetrical, with a dropped velum on the right and reduced gag reflex on the same side (cranial nerves - CN IX and X); the sternocleidomastoid and trapezius on the right had IV+ strength grade, and contralateral strength was preserved (XI CN); at rest, her tongue was deviated to the left, with deviation to the right on protrusion (XII CN). The rest of the exam was unremarkable. A brain MRI revealed a lesion involving the bones of the right skull base (occipital and small adjacent inferior temporal area), with an erosive nodular image with heterogeneous enhancement by the contrast that measured 2.5 x 2.0 cm. Her head CT revealed a 28 mm paramediastinal nodule in the upper lobe of the right lung associated with a subpleural 14 mm nodule. Hilar and mediastinal lymph node enlargements and osteolytic lesions in bilateral costal arches were also seen, as well as right hemilaryngeal paralysis. **Discussion:** With the data above, the involvement of CN IX, X, XI and XII on the right side was established, which is consistent with the diagnosis of Collet-Sicard syndrome. It is a rare neurological condition resulting from skull base lesions that affect the posterior lateral condylar space, injuring the bulbar cranial nerves. It can be linked to neoplastic, infections, trauma and vascular causes. In this case, the lung nodulation was biopsied and found to be a carcinoma with neuroendocrine differentiation, and the occipital lesion was considered a probable site of metastasis. The patient had no known history of oncological diseases, and the syndrome described above was the manifestation that led her to seek the health service, allowing the diagnosis of the underlying disease and the beginning of treatment. **Final coments:** This case presentation demonstrates the value of considering Collet-Sicard syndrome in patients presenting with the characteristic combination of cranial nerve palsies. Even more importantly, the syndrome's role in unveiling an occult malignancy is further emphasized.

Communication problems are not associated with cognitive decline in people with Parkinson's disease

Camila Pimentel Piemonte[1], Katia Cirilo Costa Nobrega[1], Isaíra Almeida P. S. Nascimento[1], Natalia Cardoso Penha[1], Clara Greif Cerveira de Paula[1], Maria Elisa Pimentel Piemonte[1]

[1]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Camila Pimentel Piemonte; Email: camila.piemonte@usp.br.

Background: Parkinson's disease (PD) is the second neurodegenerative disorder more prevalent globally, typically presenting around age 60. The progressive neurodegeneration process in basal ganglia leads to motor and non-motor symptoms responsible for decreased quality of life. Due to the degenerative process, people with PD present progressive communication difficulty associated with motor symptoms, such as hypokinetic dysarthria and voice variation. Besides the voice dysfunction, cognitive alterations and depression have also been associated with communication impairments. Aim: The present study aims to investigate the association between communication function and motor symptoms severity and mental alterations in people with PD. **Methods:** A cross-sectional study with a convenience sample of 423 (201 women) people with idiopathic PD, mean age 57.98±10.9, in early to advanced disease stages (I-IV stages according to H&Y rating scale) and 4.21±0.96 years of schooling. All participants were evaluated in individual sections by trained researchers. The self-reported communication problems were assessed by the Communication Domain of the Parkinson's Disease Questionnaire (PDQ-39); the global cognitive capacity by Montreal Cognitive Assessment (MoCA), depression by Geriatric Depression Scale (GDS), and motor symptoms severity by Unified Parkinson's Disease Rating Scale (UPDRS III). **Results:** There was a significant difference in self-reported communication problems between people with PD in advanced (H&Y IV) and moderate and early disease stages (H&Y I-III). The self-reported communication problems were correlated with UPDRS III but not age, gender, MoCA, and GDS. **Conclusion:** The communication impairments increase in advanced stages of PDD and are associated with the severity of motor symptoms but not with cognitive decline and depression. Interventions to improve communication skills in people with PD should focus on motor alterations associated with the phonatory process.

Companion's knowledge on stroke and symptoms-to-door time in reference hospital

Bárbara Nascimento Moutinho[1], Mário Luciano de Mélo Silva Júnior[1], João Pedro Wanderley Soares[1], Mariana Leandro Silva[2], Karyne de Souza Nobre[3], Renata Maria de Melo Moraes[3], Teresa Virgínia Macedo de Aquino[3], Yasmin Gabrielle Pereira Pacheco Cavalcanti de Albuquerque[3], Ilo de Vasconcelos Ximenes Júnior[1], Bárbara Francisca Do Nascimento[3]

[1]Universidade Federal de Pernambuco, Recife PE, Brazil.
[2]Faculdade de Medicina de Olinda, Olinda PE, Brazil.
[3]Centro Universitário Maurício de Nassau, Recife PE, Brazil.

Correspondence: Bárbara Nascimento Moutinho; Email: barbara.moutinho@ufpe.br.

Background: Cerebrovascular diseases were responsible for over 107,000 deaths in Brazil in 2022, according to DATASUS data. Rapid recognition of a stroke can increase the likelihood of reaching medical services within a narrow therapeutic window for effective treatment. Previous studies indicate that patients' prior knowledge of stroke was not a predictor of faster arrival at the emergency department, however, studies examining the relationship between companions' prior knowledge of stroke and the time taken for patients to reach reference services after stroke symptoms are scarce. **Objective:** To evaluate previous knowledge and clinical-epidemiological characteristics of companions of patients with ischemic or hemorrhagic stroke and its relation with the symptoms-to-door time. **Methods:** Cross-sectional study involving companions of patients diagnosed with ischemic or hemorrhagic stroke, admitted in a tertiary care center. Data collection was performed using an electronic form developed by our team and applied to the patients' companions, with objective questions about sociodemographic data, personal history, knowledge of warning signs, risk factors for stroke, Mobile Emergency Service (SAMU) telephone number, and we also collected the symptom-to-door time. We considered an optimal symptom-to-door time when patients arrived in up to 270 minutes. **Results:** The sample consisted of 129 companions of patients with acute stroke [98 women, 76%; median age = 45 (IQR=32.5-54) years, with 12 (IQR=7-12) years of formal education, and 24 (18.6%) had health insurance]. About 2/3 (88/129, 68.2%) were the patients' children or partners. Regarding knowledge of stroke, 59 (45.7%) knew the organ involved in a stroke; 74 (57.4%) knew the SAMU hotline number; and 69 (53.3%) knew at least one risk factor for stroke. Thirty-nine (30.2%) patients/companions arrived in optimal time. We did not find any difference between arriving in or out the optimal time regarding sex, having health insurance, education level, having previously cared for someone with a stroke, knowing the organ damaged in a stroke, the SAMU number, or warning signs for stroke; there was also no difference in the NIHSS or Glasgow scores at admission, nor in the perception of disease severity. Knowing at least one risk factor was more frequent in the optimal time group of companions (71.8% vs 45.6%, p=0.007), and this group was older (median 48 vs 42 years, p=0.025). **Conclusion:** Knowledge of risk factors and older age of the companions are associated with a shorter arrival time of patients with acute stroke. Other knowledge about stroke (damaged organ, SAMU number, and warning signs) was not related to arrival time.

Correspondence: Maria Vitória do Nascimento Silva; Email: vitoria.nsilva@upe.br.

Background: Stroke is a medical emergency associated with significant morbidity and mortality, considered the second leading cause of death and disability worldwide. Given the urgency of stroke care, several protocols have been established. In Brazil, the Ministry of Health recommends the use of guidelines from the Brazilian Society of Cerebrovascular Diseases (SBDCV) for emergency stroke care. **Objective:** To describe the emergency care provided to stroke cases at an emergency service in Serra Talhada, PE, and to conduct a comparative analysis with SBDCV guidelines. **Methods:** Cross-sectional descriptive study, including stroke cases admitted at a state public health hospital, a reference in Serra Talhada, PE. Data collection utilized individual registration forms and self-reported health condition questionnaires from the Unified Health System (SUS), as well as an evaluation form developed according to the acute stroke emergency protocol recommended by SBDCV. **Results:** The sample of 194 patients, predominantly male (n=106; 54.6%), Black race/ethnicity (n=140; 72.2%), aged between 61-80 years (n=99; 51%), farmers (n=91; 46.9%), and retirees/pensioners (n=138; 71.1%). Regarding comorbidities and lifestyle habits, the majority were hypertensive (n=158; 81.4%), diabetic (n=97; 50.0%), sedentary (n=170; 87.0%), and did not follow a balanced diet (n=153; 78.9%). Approximately 36% (n=70) reported a previous stroke. The clinical parameters assessed during initial care, the majority had their blood pressure measured (n=180; 92.8%); however, capillary blood glucose (n=72; 37.1%), oxygen saturation (n=70; 36.1%), and temperature (n=103; 53.1%) were not consistently evaluated. Among laboratory tests, complete blood count was requested for 88.6% (n=168), but creatinine (n=51; 26.3%), electrolytes (n=54; 27.8%), fasting blood glucose (n=131; 67.5%), and coagulation studies (n=173; 89.2%) were often omitted. Regarding etiological investigation, electrocardiograms were requested in 68.6% (n=133) of cases. However, trans-thoracic echocardiograms were not assessed in 83.0% (n=88) and carotid Doppler ultrasound in 74.7% (n=84). In terms of treatment, the majority used statins (n=136; 70.6%) and antihypertensive drugs (n=130; 67.0%). Antiplatelet therapy was administered using acetylsalicylic acid (n=131; 68.0%) and clopidogrel (n=16; 8.2%). A minority required anticoagulation; when administered, warfarin was used in only 1 case (0.5%) and new oral anticoagulants in 6 (3.1%). No patients underwent reperfusion therapy as the service is not equipped for it. **Conclusion:** Emergency stroke treatment has advanced significantly, but unevenly across Brazilian territory. In the interior of Pernambuco, the analyzed healthcare service facility deviates from the majority of SBDCV guidelines recommendations and require adjustment.

Comparative analysis of prognosis between patients with wake-up stroke and patients with acute ischemic stroke with defined onset time

Gracchо Cardoso da Silva Neto[1], Joanna Sousa da Fonseca Santana[1], Ana Clara de Lemos Guimarães[1], Amanda Hellen Sousa Leal[1], Maria Clara Bastos de Sá[1], João Lucas Lima Diogo[1], Victor Vale da Silva[1], Brena Lima Cunha[1], Gabriela Morais de Medeiros Dias Melo[1], Felipe Oliveira Costa[1]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.

Correspondence: Gracchо Cardoso da Silva Neto; Email: gracchoneto@icloud.com.

Background: The wake-up stroke is characterized by being a stroke that occurs without a precise onset time, as symptoms manifest upon awakening, representing 25% of ischemic stroke cases. Based on this, it's necessary to analyze the prognosis of these patients and compare it with patients with ischemic stroke with a defined ICTUS time, in order to reduce hospitalization costs with more appropriate treatments, to develop better diagnostic plans and reintegration into society. **Objective:** To analyze the differences in the prognosis of patients with wake-up stroke and patients with ischemic stroke with defined ictus times beyond the thrombolysis window. **Methods:** It's a retrospective and descriptive cohort study with 6,993 patients. The study was conducted based on secondary data extraction from electronic medical records of patients previously admitted to a public state hospital with focus on emergency services in Salvador, BA. The study population comprises patients diagnosed with stroke who were admitted between January 2022 and December 2022. The included variables were: age, sex, length of hospital stay, NIHSS at admission and discharge. We received approval from the Ethics Committee. The analysis was performed using SPSS and Excel, in a descriptive manner. This is a partial result of the STRIVE (Stroke Treatment and Recovery Investigation with Vascular Evaluation) research. **Results:** A total of 72 patients were analyzed, with 62 (86.1%) diagnosed with ischemic stroke beyond the window (iSBW) and 10 (13.9%) with ischemic stroke with unknown onset (Wake-Up). Regarding the primary outcome analysis, 9 patients in the iSBW (14.5%) and 2 in the wake-up group (20%) died. Concerning the length of hospital stay, patients in the iSBW group had a median stay of 9 days (minimum of 1 day and maximum of 150 days), while patients in the wake-up group had a median stay of 12.5 days (minimum of 3 days and maximum of 51 days). Regarding the NIHSS, patients were stratified as follows: minor stroke (MI; ≤4); moderate stroke (MO; >4 - ≤15); moderate severe stroke (MOS; ≥16 - <21); and severe stroke (S; >21). In the iSBW, there were 24 MI patients (38.71%), 11 MO (17.74%), 4 MOS (6.45%), and 4 S (6.45%). In the wake-up stroke group, there were 3 MI patients (30%), 4 MO (40%), 1 MOS (10%), and no MS patients. **Conclusion:** In our limited sample, patients with wake-up stroke had a higher mortality rate and a longer median hospital stay compared to patients in the iSBW group. Therefore, it is important to recognize the specific characteristics of wake-up stroke and develop tailored protocols to improve clinical outcomes and management of these patients. These findings are consistent with those observed in other studies, which also highlight the unique challenges and poorer prognoses associated with wake-up stroke. Further research is needed to better stratify these two groups of patients.

Comparative analysis of the clinical and epidemiological profile of patients with ischemic stroke according to age in a referral hospital in Bahia

Amanda Hellen Sousa Leal[1], Joanna Sousa da Fonseca Santana[1], Ana Clara de Lemos Guimarães[1], Katarina Brito Gama[1], Gabriela Morais de Medeiros Dias Melo[1], Carla Loureiro Alvarez[1], Paula Beatriz Azevedo Marques[1], Bruno de Brito Guimarães[1], Larissa Nunes Almeida dos Santos[1], Felipe Oliveira Costa[1]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.

Correspondence: Joanna Sousa da Fonseca Santana; Email: joannasantana20.2@bahiana.edu.br.

Background: Stroke is a leading cause of disability globally and the second leading cause of death in people over 60. Although it predominantly affects the elderly, the incidence among younger adults is increasing. Approximately 15% of strokes occur in adults under 45 years, termed early-onset stroke. This study aims to compare the clinical profiles of young and elderly stroke patients in Brazil to improve understanding and management of this condition. **Objective:** To compare the clinical profiles of stroke patients younger than 45 years with those aged 45 and older. **Methods:** This is a retrospective cohort. Data were collected from electronic medical records of patients previously admitted to a reference hospital in Salvador, Bahia, with a diagnosis of stroke between April 2015 and August 2023. The study included all patients diagnosed with ischemic stroke by a neurologist with available data. The variables of interest collected and analyzed using the software SPSS (Statistical Package for the Social Science). The study was approved by the Research Ethics Committee. **Results:** Among the patients aged 45 and older, there were 646 individuals, of which 47% were male and 52% female, with a median age of 69 years and a maximum age of 106 years. The average hospital stay for this group was 11.9 days. The most commonly affected arteries were the middle cerebral artery (19%), anterior cerebral artery (16%), and posterior cerebral artery (5%). Thrombolysis was performed in 9% of cases. The most common etiologies were undetermined causes (61%), followed by cardioembolic (18%), small artery occlusion (9%), large artery atherosclerosis (8%), and other etiologies (2.7%). Hypertension was prevalent in 83% of patients, diabetes mellitus in 45%, heart disease in 15.6%, and 19% had a history of previous stroke. For group under 45 years, there were 130 individuals with ages ranging from 14 to 45 years, with a median age of 40 years. This group consisted of 56.2% males and 43.8% females. The middle cerebral artery was most commonly affected (35%), followed by the anterior cerebral artery (3%) and posterior cerebral artery (4%). In terms of comorbidities, 33.1% of young patients had none, 50% had hypertension, 12% had diabetes mellitus, 3.1% had heart disease, and 6.9% had a history of previous stroke. **Conclusion:** The study reveals significant differences and similarities between young and elderly stroke patients. In young patients, stroke onset occurs between 14 and 45 years, with a median age of 40, and the middle cerebral artery being the most commonly affected. The prevalence of hypertension was high in both groups, while diabetes mellitus was more common among older patients, and the absent of comorbities more comun among the younger group. These findings underscore the necessity of tailored stroke management strategies that consider age-specific clinical profiles and risk factors to improve patient outcomes.

https://doi.org/10.5327/CBN240429

Comparative analysis of the management and prognosis of ischemic cerebral stroke patients according to age in a referral hospital in Bahia

Joanna Sousa da Fonseca Santana[1], Amanda Hellen Sousa Leal[1], Ana Clara de Lemos Guimarães[1], Katarina Brito Gama[1], Gabriela Morais de Medeiros Dias Melo[1], Carla Loureiro Alvarez[1], Paula Beatriz Azevedo Marques[1], Larissa Nunes Almeida dos Santos[1], Felipe Oliveira Costa[1]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.

Correspondence: Joanna Sousa da Fonseca Santana; Email: joannasantana20.2@bahiana.edu.br.

Background: Stroke remains a major health concern globally, especially affecting the elderly, yet the incidence in younger populations is rising. Early-onset stroke, defined as occurring in individuals under 45 years, presents unique challenges in terms of management and prognosis. However, the literature still lacks of enough

information about this condition. **Objective:** To compare the prognostic factors and management outcomes of stroke patients younger than 45 years with those aged 45 and older. **Methods:** This is a retrospective cohort study, derived from a larger stroke study. Data were collected from electronic medical records of patients previously admitted to a reference hospital in Salvador, Bahia, with a diagnosis of stroke between April 2015 and August 2023. The variables of interest collected were: sex, age, mortality, NIHSS score at admission, hospitalization time, stroke etiology and dysphagia. Data were analyzed using the software SPSS. The study was approved by the Research Ethics Committee. **Results:** In the elderly group (45 years and older), the sample included 646 patients with 47% males and 52% females. The median age was 69 years, with a maximum age of 106. Mortality was reported at 16%. Dysphagia data were incomplete for 20% of patients; 21% had mild, 17% moderate, and 13% severe dysphagia. The average hospital stay was 11.9 days. Stroke etiology was undetermined in 61% of patients, cardioembolic in 18%, small artery occlusion in 9%, large artery atherosclerosis in 8%, and other causes in 2.7%. Stroke severity was classified as minor in 18.8%, moderate in 38.5%, moderate to severe in 4.7%, and severe in 8.2%. Thrombolysis was performed 9% of cases. Among the under 45 years group, there were 130 individuals, predominantly male (56.2%), with ages ranging from 14 to 45 years and a median age of 40. The mortality rate was 10.8%. Hospital stays averaged 10.8 days. Dysphagia assessment was missing in 13.8%, absent in 52%, mild in 17.7%, moderate in 10.8%, and severe in 5.4%. Thrombolysis was performed in 13% of cases, and craniectomy in 8%. The primary stroke etiologies were undetermined (60.8%), cardioembolic (17%), large artery atherosclerosis (7%), and small artery occlusion and other causes (each 6.9%). Stroke severity was classified as minor in 23.1%, moderate in 42.3%, moderate to severe in 4.6%, and severe in 7.7%. Thrombolysis was performed 13% of cases. **Conclusion:** Younger patients exhibited a lower mortality rate and shorter hospital stays. Dysphagia was less prevalent in the younger group, with a significant number showing no signs of it. The severity of strokes was predominantly moderate in both age groups. Thrombolysis were more possible among the younger group. These findings highlight the importance of age-specific management strategies and the need for further research to better understand the prognostic factors affecting different age groups, ultimately improving stroke care and patient outcomes.

https://doi.org/10.5327/CBN240430

Comparative analysis of the spatio-temporal distribution of acute ischemic stroke treatment with thrombolytic therapy in Brazil from 2019 to 2023

Paola Carolina Santos Foinkinos[1], Karolliny Amador Kzam , Matheus Prado dos Santos[1], Bruno Kauê Rodrigues Vilhena[1], Vinícius Adriano Coelho Amaral[1], Luan Nascimento Pereira de Amorim[1], Fernando Gabriel Rodrigues Baia[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.
[2]Centro Universitário Metropolitano da Amazônia, Belém PA, Brazil.

Correspondence: Paola Carolina Santos Foinkinos; Email: paola.csfoinkinos@aluno.uepa.br.

Background: The treatment of acute ischemic stroke with the use of thrombolytic therapy is a therapeutic approach that aims to dissolve the blood clot responsible for the obstruction of cerebral vessels, using recombinant tissue plasminogen activator (rt-PA). It is crucial that the stroke is diagnosed quickly to confirm that it is an ischemic stroke and not hemorrhagic, as thrombolytic therapy is contraindicated in cases of cerebral hemorrhage. By restoring blood flow, thrombolytics can reduce the extent of damage to brain tissue, improving the chances of functional recovery. Patients treated with thrombolytics within the appropriate time window have better results in terms of neurological and functional recovery. The main risk associated with the use of thrombolytics is bleeding, including intracerebral hemorrhage and, although rare, allergic reaction to the drug. **Objective:** To comparatively analyze the spatial distribution of thrombolytic treatment for ischemic stroke in Brazil between 2019 and 2023. **Methods:** This is a descriptive, cross-sectional and quantitative study in which secondary data was collected from the Department of Informatics of the Unified Health System (DATASUS) from 2019 to 2023. The following variables were analyzed: deaths per procedure, approvals per hospital admission and total amount spent. **Results:** From 2019 to 2023, with regard to the variable deaths per procedure, there were a total of 2,320 deaths in the treatment of acute ischemic stroke with the use of thrombolytic therapy, with an increasing number of deaths. In terms of the country's regions, the North had the fewest deaths, with only 2, 1 in 2020 and 1 in 2023. Regarding the region with the highest number of deaths, the Southeast region stands out, with 800 cases, with the state of São Paulo having the highest number, 485 cases. As for the variable approvals for hospital admissions, there were a total of 22,056 admissions, with the Northeast region standing out with 7,872 admissions. In addition, in terms of the total amount spent on the procedure, there was a total of R$67,024,999.05, with the region that spent the most being the Southeast with R$25,198,904.56. **Conclusion:** It can therefore be seen that there is a considerable discrepancy in the distribution of stroke treatment with thrombolytics in Brazil, with the Southeast receiving the largest share of cases, while the less developed regions (North) still need effective investment in this therapy to avoid stroke complications. The same can be seen with regard to the costs of this therapeutic practice by region of the country, with the Southeast concentrating almost 40% of the total expenditure during the study period. As it represents a good prognosis in the treatment of strokes, the use of thrombolytics should be disseminated so that it can be effectively applied nationwide.

[7]DPIC, São Paulo SP, Brazil.

Correspondence: Artur Menegaz de Almeida; Email: arturomenegaz@gmail.com.

Background: Muscular dystrophies (MDs) are rare neuromuscular disorders that lead to progressive muscle degeneration and early death. MDs like Duchenne have a poor prognosis associated with an unclear preferred treatment. Despite several new agents being assessed in clinical trials, no network meta-analysis (NMA) has been conducted to date evaluating different treatment options for MDs. **Methods:** MEDLINE, EMBASE, and Cochrane databases were searched for randomized and non-randomized clinical trials testing different agents in patients with any type of MD. The NMA was performed under a Frequentist framework using RStudio software version 4.3.2 and extension packages "netmeta" and "dmetar" for all statistical analysis. Our primary outcome was the improvement in 6-minute walk distance (6MWD) and the change in time to run/walk 10 m (TTRW). The NMA pooled all the direct and indirect evidence and simultaneously compared several treatments using the network relationship through a model for continuous outcomes. **Results:** 17 studies and 1,905 patients were included, of whom 1,802 (94.59%) were diagnosed with Duchenne muscular dystrophy. Among the included studies, 11 different drugs were evaluated for their efficacy in improving disease progression. Ataluren and drisapersen significantly increased the 6-minute walk distance in comparison with placebo: (SMD -21.08; 95% CI -23.08 to -19.08) and (SMD -12.91; 95% CI -15.32 to -10.51), respectively. Additionally, no benefit was shown with the administration of tamoxifen or recombinant human insulin-like growth (rhIGF), while the placebo group was favored in comparison with tadalafil treatment. Concerning the change in TTRW, ataluren (SMD 1.07; 95% CI 0.91 to 1.22) and drisapersen (SMD 1.73; 95% CI 1.54 to 1.92) also showed a statistically significant benefit, in addition to viltolarsen (SMD 0.97; 95% CI 0.32 to 1.62) and vamorolone (SMD 0.08; 95% CI 0.03 to 0.13), which showed a slight improvement in the score. **Conclusion:** Our findings suggest that ataluren and drisapersen are both associated with a significant improvement in disease progression, possibly reducing muscle deterioration as seen in the 6MWD and TTRW. Additionally, viltolarsen and vamorolone were also associated with benefits in patients with MDs.

Comparative spatial analysis of leprosy cases in the North and Southeast regions

Fernando Gabriel dos Santos Santiago[1], Rafael Hendrick Freitas de Paula[1], Douglas Ferreira Pereira[1], Savio Roberto Silva Costa[1], Danusa Neves Somensi[1], Mariangela Moreno Domingues[1], Emanuel de Jesus Soares de Souza[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Fernando Gabriel dos Santos Santiago; Email: fernando_gsantiago@outlook.com.

Background: Leprosy represents a significant obstacle for Brazil, which is the second country in the number of leprosy cases in the world. In the meantime, the northern and southeastern regions of the country show significant differences in socioeconomic indices and access to health services, which are determining factors for the disparity in the spread of infection in these regions. Therefore, understanding the epidemiological differences between the regions, aiming to identify distribution patterns, is essential for the development of prevention and control strategies. **Objective:** To compare the epidemiological profile and clinical variables of leprosy between the North and Southeast regions of Brazil. **Methods:** This is an epidemiological and cross-sectional study, with data collected from the Notifiable Diseases Information System, referring to notifications of leprosy cases in the North and Southeast regions of Brazil, from 2014 to 2023. The variables analyzed included: sex, race, education, age, operational class, clinical form, and reactional episode. **Results:** The data analysis revealed a higher predominance of cases in the North region with 181,542 and 118,636 cases in the Southeast. The average incidence rate per 100,000 inhabitants was 100.64 in the North region and 13.58 in the Southeast.The prevalence of males was higher in both regions. The brown race was predominant in the North, corresponding to 72.3. However, in the Southeast region, there was a slight predominance of the white race over the brown, with 40.8% and 40.1% respectively. Leprosy was more prevalent in patients with elementary education, portraying 48.3%-52.11% of cases. The prevalent age group was above 15 years in both regions, corresponding

to about 90.3%. The most found operational class was multibacillary in both regions, being 76,5-77.2%. The most present clinical form was dimorphic, with 53.4% of cases in the North, followed by virchowiana with 16%. In the Southeast, the percentages were 41.8% and 27.8% respectively. In both cases the main reactional form was type 1, corresponding to 10,7-11.1% of cases. **Conclusion:** The significant regional disparities in terms of incidence rate, which may be related to different socioeconomic levels among the regions. The epidemiological profile showed similar in the studied regions, being male, elementary education with age over 15 years, except for the greater predominance of brown color in the northern region, which is related to the larger population quantity of brown race in this region compared to the Southeast. There were no significant differences between the reactional forms among the regions. The greater predominance of the multibacillary operational classification indicates delay in disease identification, so it is necessary to emphasize the importance of public policies aimed at early identification, especially in the North region due to higher incidence of cases.

Comparison between conventional physiotherapy rehabilitation and virtual reality in Parkinson's disease: a systematic review

Maria Eduarda Scheffer Valverde[1], Tacio Rafael Santos Batista[1], Thais Oliveira Bellavinha Martins[1], Virgílio Andrade dos Santos Maciel[1], Paula de Sousa Silva[1], Rafael Henrique Neves Gomes[2]

[1]Faculdade de Ciências Médicas e da Saúde de Juiz de Fora, Juiz de Fora MG, Brazil.
[2]Universidade Federal de Juiz de Fora, Hospital Universitário, Juiz de Fora MG, Brazil.

Correspondence: Maria Eduarda Scheffer Valverde; Email: mariascheffer1418@gmail.com.

Background: Virtual reality (VR) has become a useful tool in physiotherapeutic rehabilitation for patients with Parkinson's disease (PD), particularly in alleviating balance deficits and gait impairments. **Objective:** To compare conventional physiotherapy with VR-based rehabilitation in PD through a systematic review. **Methods:** A search was conducted on PubMed in May 2024 using the keywords "Virtual reality" and "Parkinson Disease," along with their MeSH variations, and filters including "Humans," "Randomized Controlled Trial", "Clinical Trial", "Multicenter Study" and "5 years." Among the 20 studies found, the three most relevant were selected for this review. The PRISMA scale was used to improve reporting quality. **Results:** A total of 111 patients were analyzed across the studies. Inclusion criteria encompassed scales assessing PD progression (UPDRS), motor dysfunctions (POMA, DASH, TUGT), balance impairments (BSS, FGA, DGI), dementia (CDR, MCS) and psychosocial impacts (PIADS). Treatment durations varied among studies, ranging from 5 weeks (Maranesi et al.) to 12 weeks (Feng et al.). Various VR programs were utilized, such as the Tymo system (Maranesi et al.), featuring exergames and motion analysis equipment, and the NIRVANA system (Pazzaglia et al.), employing markerless infrared optoelectronic devices for immersive sensory and audiovisual exercises. All studies demonstrated superior improvements in balance among patients undergoing VR rehabilitation compared to control groups ($p<0.05$). Pazzaglia et al. and Maranesi et al. also noted enhancements in mental health status, while Feng et al. highlighted improvements over conventional methods in UPDRS scores, which assess tremor, rigidity, speech, posture, and gait, indicating broader benefits of VR rehabilitation beyond motor dysfunctions. **Conclusion:** VR proves effective in enhancing functional parameters for PD patients and could serve as a valuable alternative in physiotherapeutic rehabilitation protocols. However, further studies are needed to optimize treatment duration and session frequency for optimal outcomes.

Comparison of disability level between early and late onset Parkinson's disease using WHODAS-2

Isaíra Almeida Pereira da Silva Nascimento[1], Kátia Cirilo Costa Nóbrega[1], Maria Elisa Pimentel Piemonte[1], Isabela Carneiro Barone[1], Giovanna Checchio[1], Vitória Pereira Ponciano[1], Clara Greif Cerveira de Paula[1], Arieni Nunes Possani[1], Natália Cardoso Penha[1], Bruno Rafael Antunes de Souza[2]

[1]Universidade de São Paulo, Faculdade de Medicina, São Paulo SP, Brazil.
[2]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Kátia Cirilo Costa Nóbrega; Email: katiacirilo@usp.com.

Background: Parkinson's disease (PD) is a degenerative neurological disorder that usually affects people over the age of 60. However, 10% – 20 % of patients have an early onset of PD (EOPD). **Objective:** To compare disability levels according to the World Health Organization Disability Assessment Schedule 2.0 (WHODAS-2) between people with EOPD and those with late-onset PD (LOPD). **Methods:** We conducted a cross-sectional study with 95 EOPD patients (mean-age 44.51±4.63, H&Y 1.93±0.93) and 255 LOPD patients (mean-age 63.01±7.99, H&Y 2.02±0.95). Demographic information, clinical characteristics, cognitive evaluation by Telephone-Montreal-Cognitive-Assessment (T-MoCA), functionality self-evaluation by WHODAS-2 and the Unified-Parkinson's-Disease-Rating-Scale (MDS-UPDRS), parts I and II, were documented for each patient by an individual remote interview. **Results:** Analysis showed a statistically significant difference between EOPD and LOPD in two domains of WHODAS-2 only: cognition (Z-adjusted = 2.60; p-value adjusted <0.009) and activities of daily living related to work/school (Z-adjusted = 2.34; p-value adjusted <0.01). T-MoCA scores confirmed more impaired cognition capacity in LOPD (Z-adjusted = 2.42; p-value adjusted <0.01). The two groups had no significant differences in levodopa daily dosage, Hoehn and Yahr (H&Y) stages, disease time duration, and MDS-UPDRS I and II scores. **Conclusion:** People living with EOPD face similar disability levels as those with LOPD, except for cognition, where LOPD patients exhibited higher levels of disability than EOPD and for work activities where the EOPD exhibited higher levels of disability than LODP. These results highlight the challenges faced by people with EOPD in interacting with society and living with the disease for a longer time. The WHODAS-2 can be a useful tool to assess disability and tailor interventions for people with PD of different age groups.

Comparison of electrochemical skin conductance and skin biopsies tests for detection of neuropathy in patients with hereditary transthyretin amyloidosis-polyneuropathy (ATTRv-PN)

Mateus Gustavo Favaro[1], Carolina Lavigne Moreira[1], Marcus Vinicius Simoes[1], Pedro Manoel Marques Garibaldi[1], Pedro Jose Tomaselli[1], Gustavo Maximiano Alves[1], Wilson Marques Junior[1], Manoella Guerra de Albuquerque Bueno[1], Matheus Compart Hemerly[1]

[1]Universidade de São Paulo, Ribeirão Preto SP, Brazil.

Correspondence: Mateus Gustavo Favaro; Email: mateusgustavofavaro@gmail.com.

Background: The diagnosis of neuropathy, especially small fiber type, has been a challenge in ATTRv-PN. Many methods were described, but the gold standard remains the skin biopsy. However, they are invasive and scarcely available in poor countries. The evaluation of the sudomotor function, measured by the electrochemical skin conductance in the palms of the hands and soles of the feet, is a non-invasive method aimed at identifying peripheral nerve involvement. However, Its use in ATTRv-PN has not been properly investigated. In this project we compared the efficacy of the electrochemical skin conductance test against the results of the intraepidermal nerve fiber density (IENFD). **Objective:** To compare the efficacy of the electrochemical skin conductance on the feet of patients with ATTRv-PN with the IENFD of the distal leg. **Methods:** We studied 28 patients ATTRv-PN patients with positive genetic test.. Skin biopsies were performed on the lower limb, and the intraepidermal nerve fiber density (IENFD) was calculated based on normal values published bty the European Federation of Neurology (2010). Electrochemical skin conductance was evakluated with SDOSCAN, a commercial machine. Results of the conductance test were divided into normal or abnormal (categorical variables). Analysis were carried with the Concordance test (Kappa test) and the association test (Chi-squared). Also, the absolute numbers (quantitative variable) from the conductance study were compared using the Wilcoxon/Mann-Whitney non-parametric test. Later, the ROC curve was calculated. SPSS 22.0 was used for statistical tests, and REDCap for data storage. **Results:** We studied 28 patients There is a weak concordance (Kappa=0.25; I.C. 95 [0.0 - 0.56], p=0.13) and no association (Chi-squared p=0.22; Mann-Whitney p=0.42) between the electrochemical skin conductance of the lower limb with IEFND in patients with ATTRv-PN in our center. Also, the skin conductance test has low accuracy 59.1% I.C.95% (37.5%-80.7). **Conclusion:** In this study we did not find a good correlation between nerve fiber density and the electrochemical skin conductance. A possible explanation is that skin biopsy does not distinguish any specific type while the electrochemical skin conductance just measure the pos-synaptic sympathetic fibers. In addition, nerve biopsy identify the fibers, but not their their functional integrity. This result indicates that the diagnosis of small fiber neuropathy must be sought through varied approaches, until the identification of a gold standard method.

Comparison of Kappa index and oligoclonal bands detection positivity in cerebrospinal fluid samples of patients with suspected multiple sclerosis (MS)

Renan Domingues[1], Irineu Massaia[1], Myrna Monteiro[1], Marcio Vega[1], Camila Spinelli[1], Lais Guerra[1], Daiane Salomão[1], Carlos Senne[1]

[1]Senne Liquor Diagnóstico, São Paulo SP, Brazil.

Correspondence: Renan Barros Domingues; Email: contato@renandomingues.med.br.

Background: The evaluation of the intrathecal production of IgG is useful in the evaluation of MS suspected cases. The qualitative detection of oligoclonal bands (OCBs) in cerebrospinal fluid (CSF) and serum and the Kappa Index are currently the best methods to detect intrathecal production of IgG. Besides their diagnostic value it is possible that OCBs and Kappa Index have also prognostic value. **Objective:** To evaluate the results of the Kappa Index and the oligoclonal bands (BOCs) in samples from patients with suspected multiple sclerosis (MS). We also evaluated if patients with 8 or more OCBs have higher Kappa index values. **Methods:** Patients with suspected MS underwent cerebrospinal fluid (CSF) analysis. CSF samples were submitted to the detection of BOCs and kappa index. These comparisons were carried out with Chi Square test. The number of OCBs was classified as 2-7 and ≥8. The comparison of the median Kappa Index between these two groups were carried out with Mann-Whitney test. **Results:** Two eighty-five serum and CSF

samples were included, 115 of them had positive CSF BOCs and 138 were positive with Kappa index. Overall, 148 patients had positive results with at least one of the methods and Kappa index was more sensitive than BOC (93.2% x 77.7%, P<0.0001). 37 patients had 2-7 OCBs and 72 had ≥8 OCBs. The median Kappa index values were: 2-7 OCBs group = 18.23 (range 3.02 to 457.9) and ≥8 OCBs group = 92.49 (range 12.1 to 1117) (P<0.0001). **Conclusion:** The Kappa index showed to increase the sensitivity for detecting intrathecal IgG detection. However, there were cases in which BOC was the only positive method for the detection of intrathecal IgG production. Thus, it remains important to perform both methods to increase the CSF diagnostic performance in MS suspected cases. Patients more OCBs had higher Kappa index values, suggesting that Kappa Index may be a prognostic MS marker. Future studies including clinical data should address this question.

Comparison of mortality rate and length of stay between intracranial aneurysm treatment by endovascular surgery vs. microsurgery in Northeastern Brazil over the past 5 years

Rosa Carolina Santos de Oliveira[1], Felipe de Jesus Gois[2], Christian Wallace Santos Meneses[2], Clayton de Jesus Barbosa[1], Eduarda Tavares da Silva[2], André Luiz Borges Silva[2], Gabriel Valentim dos Santos Menezes Siqueira[2], Helton Benevides Santana de Oliveira[2]

[1]Universidade Tiradentes, Aracaju SE, Brazil.
[2]Universidade Federal de Sergipe, Aracaju SE, Brazil.

Correspondence: Rosa Carolina Santos de Oliveira; Email: rosa.oliveira@souunit.com.br.

Background: This study analyzes the mortality rate and average hospital stay of patients with intracranial aneurysms treated by endovascular surgery versus microsurgery under Brazil's public health system (SUS) in Northeastern Brazil over the last five years. Comparing these approaches is crucial for understanding their specific efficacies, providing relevant data for healthcare optimization and aiding decision-making. **Objective:** To compare the mortality rate and average hospital stay of intracranial aneurysm treatments performed in Northeastern Brazil over the last 5 years by endovascular surgery versus microsurgery. **Methods:** The study utilized DATASUS data to analyze mortality rate and hospital stay averages between endovascular and microsurgery treatments for intracranial aneurysms. Analysis covered the general population and segmented results by Brazilian regions from 2019 to 2023. Data was analyzed using Excel, presenting values in both absolute and percentage terms. **Results:** Temporal analysis of DATASUS data from 2019 to 2023 revealed the following findings: The average hospital stay for microsurgery was 16.2 days in 2019, 14.7 days in 2020, 15.6 days in 2021, 15.4 days in 2022, and 12.8 days in 2023, resulting in an overall average of 15.1 days. The mortality rate associated with microsurgery per 100,000 inhabitants was 12 in 2019, 13.64 in 2020, 9.02 in 2021, 14.18 in 2022, and 9.2 in 2023, with a total average of 11.76. For embolization procedures, the average hospital stay was 10.2 days in 2019, 9.3 days in 2020, 9.7 days in 2021, 10.4 days in 2022, and 10.1 days in 2023, totaling an average of 10 days. The mortality rate per 100,000 inhabitants associated with embolization was 5.6 in 2019, 6.7 in 2020, 8.31 in 2021, 5.75 in 2022, and 5.02 in 2023, resulting in an average of 6.28. Comparing data from 2019 to 2023, a 21% reduction in average hospital stay for microsurgery and a 1% reduction for embolization were observed. Regarding mortality rate, there was a 23.33% decrease in overall mortality for microsurgery and a 10.3% decrease in mortality associated with embolization. **Conclusion:** Both mortality rate and hospital stay duration are lower in patients undergoing intracranial aneurysm treatment via endovascular surgery compared to conventional microsurgery. However, both techniques remain necessary and are not mutually exclusive, requiring individual assessment based on patient and aneurysm characteristics when choosing the method. Furthermore, this study underscores the need for long-term comparative studies, cohorts, and randomized clinical trials to establish the real benefits and indications of each procedure.

Comparison of open-loop and closed-loop transcutaneous auricular vagus nerve stimulation on autonomic control in healthy individuals: new directions for epilepsy treatment

Kevin Gustavo dos Santos Silva[1], Gabriella Maria de Faria[2], Viviane Fajardo Filgueiras[2], Henrique Amorim[2], Lívia Bruni de Souza[2], Fabiana Gomes Ferreira[2], Nádia Bertoncello[2], Karina Rabello Casali[2], Tatiana Sousa Cunha[2]

[1]Universidade Anhembi Morumbi, São José dos Campos SP, Brazil.
[2]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Kevin Gustavo dos Santos Silva; Email: kevingustavo30@gmail.com.

Background: Non-invasive transcutaneous auricular vagus nerve stimulation (taVNS) can activate autonomic control and elicit therapeutic effects on various pathological conditions, especially epilepsy. The significant clinical interest in using such devices has opened the way for new variations seeking to optimize the effects evoked on vagal modulation and expand possibilities in the treatment of patients with epilepsy unresponsive to conventional therapies. In this sense, studies have shown that stimulation applied in synchronization with respiration can enhance the neuromodulation effect of taVNS. Our research group has developed a closed-loop taVNS prototype that aligns stimulation parameters with respiratory rhythms. **Objective:** This study aims to compare the effects of vagus stimulation on the autonomic control of healthy individuals using a commercial open-loop taVNS device (Vitos) and our closed-loop taVNS prototype. **Methods:** A total of 6 healthy volunteers of both sexes (22-48 years old) were included in this blinded controlled study and randomized into two groups: open-loop device (OL; n=4) and closed-loop prototype (CL; n=2), both at 25Hz. Cardiac data was collected at three points: at rest, during intervention (20 minutes of use of OL or CL taVNS), and after intervention, using a continuous and non-invasive heart rate monitor (Polar V800 heart rate monitor). The autonomic nervous system was assessed by quantifying sympathetic (SM) and vagal (VM) modulations, estimated through spectral analysis applied to tachograms. The study was approved by the Research Ethics Committee. **Results:** The results revealed that taVNS, in both protocols, caused a significant increase in VM compared to baseline, in normalized units (nu) (OL_basal = 13.1±5.9; OL_during = 24.9±7.9; OL_post = 25.9±12.8; CL_basal = 13.6±0.8; CL_during = 46.7±3.5; CL_post = 25.1±2.9, p=0.001). CL taVNS produced a substantially greater increase in vagal activity during the maneuver compared to the OL device (p=0.006). In conclusion, both vagus nerve stimulation through OL and CL taVNS resulted in a significant increase in vagal activity during the session, demonstrating the effectiveness of the developed prototype. Additionally, CL had a more pronounced effect on immediate autonomic nervous system activation, reinforcing existing literature that suggests optimization and enhancement of vagal modulation effects. **Conclusion:** The prototype showed a significant effect on vagal modulation, indicating potential for clinical validation and market application. A randomized clinical trial will be conducted for proper certifications involving healthy subjects and patients with epilepsy.

https://doi.org/10.5327/CBN240439

Comparison of quality indicators in a stroke unit during and after the COVID-19 pandemic

Laiza Milena de Araújo[1], Nicole Rampani Franzoni[1], Luana Miyahira Makita[1], Gustavo de Oliveira Morais[1], Ana Carolina Pelek[1], Amanda Paixão Peron[1], Paola Cristine Ramos Santos[1], Luiz Felipe Fontana Triches[1], Renata Dal-Prá Ducci[1], Marcos C. Lange[1]

[1]Universidade Federal do Paraná, Curitiba PR, Brazil.

Correspondence: Luiz Felipe Fontana Triches; Email: luizfelipefontri@gmail.com.

Background: Health quality indicators are essential for monitoring the quality of care provided by healthcare services. In this regard, there are numerous indicators available to measure the quality of care in stroke management. However, during the COVID-19 pandemic, healthcare services faced significant challenges, further highlighting the importance of these indicators. **Objective:** To assess, through quality indicators, whether there have been changes in the care provided to stroke patients during and after the COVID-19 pandemic. **Methods:** This is a cross-sectional, retrospective observational study using data analysis from electronic medical records. The study sample comprised patients admitted to the Stroke Unit of the Clinical Hospital of the Federal University of Paraná for ischemic stroke between November 2020 and May 2024, divided into groups during and after the COVID-19 pandemic. The criterion for dividing the periods was the date of the end of the global emergency proposed by the WHO, on 05/05/2023. A total of 554 patients were studied according to variables such as sex, age, door-to-needle time, imaging exams performed, treatment, evaluation by the multidisciplinary team (physiotherapy, speech therapy, and occupational therapy), and length of hospital stay. **Results:** Overall, 554 individuals diagnosed with ischemic stroke were admitted to the Stroke Unit of the Clinical Hospital during (n=408) and after (n=146) the pandemic. The mean age, percentage of men, and therapeutic strategy were similar (p>0.05) at both time points. The mean door-to-needle time was 43.7±40.8 and 47.4±39.9 minutes in patients admitted intra and post-Covid-19, respectively. Although the data suggest an increase in the number of patients with door-to-image time <30 minutes after the pandemic, a large percentage of patients have unknown data (47.9%). Hence, making concrete statements on the matter becomes unfeasible. Regarding prescription for secondary prevention, there was an increase in the prescription of anticoagulants (25% vs 32.2%, p<0.001) and antiplatelet agents (55.1% vs 57.5%, p<0.001) following the pandemic. Although, there are also many patients with unknown data in this category. Multidisciplinary care, including physiotherapy (84.1% vs 74%, p<0.05) and occupational therapy (82.6% vs 53.4%, p<0.05) were more frequent during the pandemic. Mean hospital stays were similar between intra and post-pandemic individuals (11.8±4.4 days vs 11.1±4.7 days, p>0.05). **Conclusion:** Therefore, although COVID-19 impacted healthcare services, there is no evidence to suggest a worsening of health indicators. Additionally, there is a reduction in the availability of occupational therapy and physiotherapy services. This is due to the reallocation of professionals and an increasing demand for services at the hospital. Indicators are valuable tools for advocating improvements in care. Thus, it is important to accurately record information to reflect reality reliably.

https://doi.org/10.5327/CBN240440

Comparison of stroke awareness between Aparecida (SP) and São Paulo (SP): a cross-sectional study from 2023 and 2024

Beatriz Barbosa Nishigima[1], Mariana Rachas Reis[1], Anna Luísa Mennitti[1], Fernanda Yumi Abe[1], Rubens José Gagliardi[1]

[1]Santa Casa de São Paulo, Faculdade de Ciências Médicas, São Paulo SP, Brazil.

Correspondence: Beatriz Barbosa Nishigima; Email: beatriz.nishigima@gmail.com.

Background: Stroke poses substantial health risks globally, emphasizing the critical importance of early symptom recognition for improving outcomes. Disparities in stroke awareness between metropolitan and smaller urban areas warrant investigation. This study compares stroke knowledge between Aparecida/SP and São Paulo/SP, highlighting regional differences and underscoring the need for target educational efforts. **Objective:** To assess and compare stroke awareness between the population of Aparecida/SP, located in a semi-urban setting, and São Paulo/SP, situated in a metropolitan area. **Methods:** This is a descriptive and comparative cross-sectional study utilizing data from a structured questionnaire available on the REDCap platform. It was administered to participants in two distinct settings: firstly, to random passers-by at subway stations in the city of São Paulo in October 2023; and secondly, to patients of a community outreach program in Aparecida/SP, a semi-urban city of São Paulo, in January 2024 . The study sample included individuals aged 18 years or older who signed the term of consent. Participants in the Aparecida/SP group were also required to be registered for outpatient appointments. The questionnaire collected demographic data and included inquiries about stroke, such as its definition, symptoms, prevention methods, appropriate actions upon suspicion and acquaintance with someone who had experienced a stroke. **Results:** The sample evaluated in Aparecida/SP consisted of 276 individuals, while in São Paulo/SP it comprised 370, totaling 646 answers. Among the interviewees in Aparecida, 62.7% were women, and the most prevalent age group ranged from 60 to 69 years (28.6%), with 31.8% of them having incomplete primary education. In the São Paulo sample, 57.3% were women, the most prevalent age group was also 60 to 69 years (26%) and 28.6% had completed secondary education. In the sem-urban sample, 69.9%% knew someone who had a stroke and 59.8%% couldn't define the disease. Comparatively, in the capital, these numbers were 77.3% and 60%. Regarding symptoms, the most mentioned one in both Aparecida and São Paulo samples was paresthesia in the face, arm or leg (54.6% and 49.2% respectively), while the least cited one was vision impairment (14.3% and 11% respectively). The most frequently cited preventive measure in the small town was physical activity (69.2%), whereas in the big city it was healthy eating (64.3%). In terms of response to witnessing a stroke, in Aparecida, 62.7% would call an emergency service and 0.72% would check the time, and in São Paulo these percentages were 95.7%% and 10.5%. **Conclusion:** This study underscores significant disparities in stroke awareness between Aparecida/SP and São Paulo/SP. Despite varying levels of awareness, both regions exhibit gaps in knowledge about the subject. Targeted educational efforts are essential to enhance public awareness and mitigate the impact of stroke across diverse urban settings.

https://doi.org/10.5327/CBN240441

Comparison of the efficacy of monotherapy with bevacizumab versus combined therapies or monotherapies with other drug classes in the treatment of recurrent glioblastoma

Isabela Lara Marcondes[1], Evelyn de Castilho Brandt[1], Stefany Vitória Schneider[1], Laura Cristina Lazzari[1], Kennyel Andre Veloso[1], Paola Patrícia Dias de Farias[1], Gabriela Tartarotti Godoy[1], Gustavo Colombo Dal-Pont[1]

[1]Universidade Alto Vale do Rio do Peixe, Caçador SC, Brazil.

Correspondence: Isabela Lara Marcondes; Email: belinhamarc@hotmail.com.

Background: Glioblastoma (GBM) is an aggressive type of primary brain tumor that has a mean overall survival (OS) of less than 2 years. GMB causes mutations in Vascular Endothelial Growth Factor (VEGF), leading to exacerbated angiogenesis and tumor malignancy. The standard treatment for newly diagnosed GMB is resection of the tumor, followed by radiotherapy and chemotherapy with temozolomide. However, the tumor almost always reappears after an average of 8 months. Bevacizumab (BEV) is a VEGF antagonist Monoclonal Antibody (MaB) and was approved in 2009 for use in recurrent glioblastoma (rGBM) by the Food and Drug Administration, after studies demonstrated that its use improves progression-free survival (PFS) within 6 months. **Objective:** To compare the use of BEV as monotherapy versus combination therapies or monotherapy with other drug classes for the treatment of rGBM. **Methods:** This is a systematic review of the literature, carried out using the PRISMA method, in the PubMed database in search of clinical trials, controlled and randomized tests from the last 10 years (2014-2024), in the English language. The works included were articles that exclusively analyzed rGBM and the pharmacological treatment with Mabs in combination or as monotherapy. The articles were analyzed blindly by the authors, using Rayyan® software. **Results:** With the search strategy, 117 studies were found, of which 9 met the inclusion criteria. The association of BEV with vorinostat, lomustine, RO5323441, VB-111 or other MaBs, such as pembrolizumab and dasatinib, did not demonstrate benefits in PFS compared to the drug alone in patients with rGMB. On the other hand, new radiotherapy sessions, associated with the use of BEV, proved to be interesting in a randomized phase II study, further increasing PFS. In comparative analyzes of the use of different drugs alone, there is no statistical relevance in the mortality rate with the use of nivolumab versus BEV. In contrast, a phase II study comparing BEV with fotemustine demonstrated the superiority of BEV in objective response rate, showing it to be an effective option for reducing tumor size. However, fotemustine showed a trend towards greater OS, increasing life expectancy by approximately 6 months after the start of treatment, in 62% of patients treated with BEV and 73% of those treated with fotemustine. **Conclusion:** Limiting factors such as death or progression of GMB in patients are a challenge in the search for effective therapies for the treatment of rGMB. Currently, there are studies that show an improvement in PFS in the combined use of BEV with re-irradiation. Although, the use of BEV alone remains the main therapy used. However, fotemustine presents itself as a promising drug, increasing OS compared to BEV. Nevertheless, more research is needed to better understand these mechanisms.

https://doi.org/10.5327/CBN240442

Comparison of the incidence and mortality of intracranial trauma in children under 1 year old in the Southeast region of Brazil during 2020 and 2021

Aline Marques Barreto Scalioni[1], Thiago Luvizon Mollo[2], Karen Paes Mello[3], Polyany Batista de Moura Lemos[4], Guilherme de Andrade Ruela[5]

[1]Universidade Nove de Julho, Guarulhos SP, Brazil.
[2]Universidade Nove de Julho, Bauru SP, Brazil.
[3]Universidade Brasil, Fernandópolis SP, Brazil.
[4]Faculdade CET, Teresina PI, Brazil.
[5]Universidade Federal de Minas Gerais, Belo Horizonte MG, Brazil.

Correspondence: Aline Marques Barreto Scalioni; Email: alinemscalioni@gmail.com.

Background: Traumatic brain injury (TBI) is one of the main causes of pediatric emergencies, responsible for a high incidence of hospital admissions with alarming mortality and morbidity rates. This type of trauma is characterized by any traumatic injury that results in anatomical damage, such as cranial fractures or scalp injuries, or functional impairment of the meninges, brain, or its vessels. Pediatric TBI is considered a public health problem. **Objective:** To analyze and compare the incidence and deaths resulting from Traumatic Brain Injury in patients under 1 year old in the southeastern region of Brazil in 2020 and 2021. **Methods:** This was an ecological, retrospective, descriptive, and quantitative study using data from the Department of Informatics of the Unified Health System (DATASUS). The study analyzed the number of hospitalizations and deaths, as well as the mortality rate, due to intracranial trauma in 2020 and 2021 in the southeastern region of Brazil, including the age group "under 1 year". Any other categories not specified were excluded. **Results:** According to the data collected, there were 2,387 hospitalizations for pediatric TBI in the age group of 0-1 year in the southeastern region of Brazil between 2020 and 2022. There were 30 deaths, representing a mortality rate of approximately 2.51%. The year with the highest incidence of TBI among children under 1 year old was 2021, with 1,173 hospitalizations (and 17 deaths). The state with the highest rate was São Paulo, with 1,467 hospitalizations and 19 deaths. In contrast, Espírito Santo had the highest mortality rate among the states in the region in both years (2.70% and 3.23% in 2020 and 2021, respectively). Despite the increase in hospital admissions, there was no substantial increase in deaths during the analyzed years, keeping the mortality rate low. It is worth noting that there are indications of underreporting and incorrect filling out of Hospitalization Authorizations (AIH) and Death Certificates (DO), which may result in the creation of false epidemiological profiles due to deaths from undefined causes, making it difficult to develop a strategic plan to prevent these deaths. **Conclusion:** The data collected demonstrate the importance of preventive measures and awareness regarding the severity of TBI and its prognostics, due to its potential to cause severe consequences and permanent side effects. Findings from the present study showed high numbers of hospitalizations in this vulnerable age group, which can result in severe outcomes if the patient is not managed correctly by a multidisciplinary team. This highlights the importance of legal guardians taking measures to protect children and ensure their safety at various levels.

Comparison of the prevalence of hospitalizations due to Alzheimer's disease in the federal regions of Brazil and the mortality rate

Guilherme Galardino Santos[1], Bernardo Caetano Novaes[1], Samuel José Feres Ozava[1], Myllene Rodrigues Silva[1], Victor Bruno dos Santos Teixeira[1], Davi Melo de Hollanda Cordeiro[1]

[1]Centro Universitário de Volta Redonda, Volta Redonda RJ, Brazil.

Correspondence: Guilherme Galardino Santos; Email: guilhermegalardino@gmail.com.

Background: Alzheimer's disease (AD) is a neurodegenerative disease that primarily affects older adults. It is considered the most common cause of dementia and one of the leading sources of dependency, disability, and morbidity and mortality in the elderly population. Estimates suggest that currently, 44 million people worldwide live with this dementia, and projections for the year 2050 indicate that these numbers will triple. The main neuropathological features of AD are the accumulation of diffuse and neuritic plaques, marked by the extracellular deposition of beta-amyloid, which induces the spread of neurofibrillary tangles of hyperphosphorylated tau protein in the brain tissue. Although its pathogenesis remains uncertain, the most essential and frequently encountered clinical manifestation of AD is the selective impairment of memory and cognition. While there are treatments that can improve some symptoms of the disease, there is no cure, and the disease progresses

inevitably in all patients. **Objective:** To determine the frequency of hospitalizations due to AD in the different federal regions of Brazil and compare this frequency with the mortality rates in the same regions over the past five years. **Methods:** In this study, the Hospital Information System (HIS) was used to collect data from January 2019 to December 2023, while population data from the 2022 IBGE census were used to calculate prevalence. Mortality rates were extracted from the HIS for the period from January 2019 to December 2023. **Results:** During the study period, there were 7866 hospitalizations due to AD in Brazil. The federal region with the highest prevalence (per 100,000 inhabitants) was the South (6.72), followed by the Southeast (4.33), Central-West (3.17), Northeast (2.56), and North (1.57). Despite the higher prevalence of cases in the South, the annual total processing mortality rate was highest in the Southeast (30.07), followed by the Central-West (27.96), South (19.36), Northeast (16.24), and North (15.07). **Conclusion:** Based on the data, the South region (6.72) recorded the highest number of hospitalizations for AD, followed by the Southeast (4.33), Central-West (3.17), Northeast (2.56), and North (1.57). However, the annual total processing mortality rate was highest in the Southeast (30.07). These regional discrepancies suggest the need for a more in-depth analysis of the factors contributing to the prevalence and outcomes of AD in different areas of the country. Furthermore, the importance of early diagnosis and management strategies for AD across the national territory is highlighted. Equally crucial is ensuring equitable access to quality healthcare in all regions of the federation.

Comparison of the prevalence of hospitalizations due to Parkinson's disease in the federal regions of Brazil and the mortality rate

Samuel José Feres Ozava[1], Guilherme Galardino Santos[1], Bernardo Caetano Novaes[1], Victor Bruno dos Santos Teixeira[1], Davi Melo de Hollanda Cordeiro[1], Myllene Rodrigues Silva[1]

[1]Centro Universitário de Volta Redonda, Volta Redonda RJ, Brazil.

Correspondence: Guilherme Galardino Santos; Email: guilhermegalardino@gmail.com.

Background: Parkinson's disease (PD) is the most common progressive neurodegenerative movement disorder, characterized by numerous motor, non-motor, and neuropsychiatric symptoms that can impact an individual's life to varying degrees. It is caused by the progressive degeneration of dopamine-producing neurons in the substantia nigra of the midbrain. PD is considered a syndrome that manifests with resting tremor, bradykinesia, rigidity, and loss of postural reflexes, which are regarded as the cardinal signs of the disease, thereby impairing the patient's function and quality of life. **Objective:** To determine the frequency of hospitalizations due to PD in the different federal regions of Brazil and compare this frequency with the mortality rates in the same regions over the past five years. **Methods:** In this study, the Hospital Information System (HIS) was used to collect data from January 2019 to December 2023, while population data from the 2022 IBGE census were used to calculate prevalence. Mortality rates were extracted from the HIS for the period from January 2019 to December 2023. **Results:** During the study period, there were 7866 hospitalizations due to PD in Brazil. The federal region with the highest prevalence (per 100,000 inhabitants) was the South (4.32), followed by the Southeast (2.37), Central-West (1.58), Northeast (1.21), and North (1.09). Despite the higher prevalence of cases in the South, the annual total processing mortality rate was highest in the North (9.52), followed by the Northeast (9.60), Central-West (9.34), Southeast (7.58) and South (6.81). **Conclusion:** Based on the data, the South region (4.32) recorded the highest number of hospitalizations for PD, followed by the Southeast (2.37), Central-West (3.17), Northeast (2.56), and North (1.57). However, the annual total processing mortality rate was highest in the North (9.52). These regional discrepancies suggest the need for a more in-depth analysis of the factors contributing to the prevalence and outcomes of PD in different areas of the country. Furthermore, the importance of early diagnosis and management strategies for PD across the national territory is highlighted. Equally crucial is ensuring equitable access to quality healthcare in all regions of the federation.

[3]Centro Universitário Metropolitano da Amazônia, Belém PA, Brazil.

Correspondence: Luan Victor Silva Ribeiro; Email: luanvictorsilvaribeiro21@gmail.com.

Background: Ischemic stroke occurs when there is arterial obstruction, causing paralysis of brain areas, which prevents the passage of oxygen due to the lack of blood circulation. It is one of the main causes of death worldwide, increasing early mortality in several countries with different realities, such as Brazil and Canada. **Objective:** To compare the rate of years of life lost (YLLs) due to ischemic stroke between two countries with public health systems over five years, identifying differences and trends in early mortality, providing data to guide public health policies and prevention strategies. **Methods:** This is an observational, descriptive epidemiological study in which data on years of life lost (YLLs) due to stroke from 2017 to 2021 were obtained from the Institute for Health Metrics and Evaluation (IHME) platform, in the Global Burden of Disease (GBD) section. Information on cerebrovascular disease was selected and data on annual ischemic strokes was filtered out. The YLLs were calculated by multiplying the difference between the country's life expectancy and the age at death by the number of people who died from the disease in question. In order to make the appropriate correlation with the years of the fourth decade of life and calculate the rate (per 100,000 inhabitants), the age groups of both sexes, 30 to 34 years and 35 to 39 years, classified as age group 1 and age group 2, respectively, were selected. **Results:** In both countries, age group 2 had the highest rates in all the years analyzed. In the first year, 2017, men in Canada had a rate of 6.86 and women 7.6. In Brazil, in the same year, the male rate was 37.09 and the female rate was 31.34. In 2018, the second year of analysis, the male rate in Canada was 11.23 and the female rate was 8.77. In Brazil, the rate for men was 40.63 and for women 35.69. In 2019 in Canada, the male rate was 12.02 and the female rate was 9.70. In Brazil, the male rate was 40.99, and the female rate was 38.19. In the penultimate year, 2020, in Canada, the male rate was 12.38, and the female rate was 9.56. This year in Brazil, the male rate remained at 40.99, and the female rate increased slightly to 38.42. Last year, for 2021, in Canada, the male rate was 11.96, and the female rate was 9.10. In Brazil, the male rate was 42.98 and the female rate was 40.16. **Conclusion:** It was concluded that age group 2 had the highest rates in all the years analyzed in both Canada and Brazil. There was a general increase in rates in both countries over the period analyzed, with an increase of 74.3% in Canadian men, 19.7% in Canadian women, 15.8% in Brazilian men and 28.1% in Brazilian women in 2021 compared to 2017, with Brazil showing significantly higher rates than Canada.

Compensated idiopathic intracranial hypertension due to traumatic cerebrospinal fluid fistula: a case report

Apolônio Peixoto de Queiroz[1], Breno Bezerra Arruda Câmara[1], Yan Carlos de Sousa Diniz[2], Ana Clara Melo de Medeiros[2], Joan Ravy Sousa Lacerda[2], Maira Monteiro Amorim[2], Ana Karoline Alves de Brito Marques[2], Rhawana Lorrana Oton Guimarães[2], Maria de Fátima Trigueiro Silva[2], Regina Dayana de Morais Santos[2]

[1]Hospital Metropolitano Dom José Maria Pires, João Pessoa PB, Brazil.
[2]Centro Universitário de Patos, Patos PB, Brazil.

Correspondence: Apolônio Peixoto de Queiroz; Email: apolopxq@gmail.com.

Case presentation: A 33-year-old obese female was followed in an outpatient headache clinic. In 2018, she presented with progressive holocranial headache, worsening with dorsal decubitus, and transient visual darkening. She was diagnosed with idiopathic intracranial hypertension (IIH) after cerebrospinal fluid (CSF) collection and exclusion of other causes. She was treated with topiramate and made lifestyle changes, including regular physical activity, dietary adjustments, and weight loss, leading to significant symptom improvement for several years. In January 2023, she suffered a mild traumatic brain injury (TBI) after hitting her head on a cabinet. Days later, she experienced intense, almost daily headaches different from her previous ones. The new headaches worsened or appeared when upright and were accompanied by clear, colorless, odorless, constant rhinorrhea in the right nostril, ear fullness, nausea, and occasional vomiting. She stopped her medication, resulting in partial symptom improvement. During a follow-up appointment, she reported these new symptoms. An MRI with cerebrospinal fluid flow study revealed a frontoethmoidal meningoencephalocele through a bone defect in the cribriform plate. After consulting with the Neurosurgery team, the decision was made to proceed with a ventriculoperitoneal shunt instead of correcting the fistula. Post-procedure, she showed significant improvement and was discharged without symptoms. **Discussion:** Disorders of intracranial pressure, such as intracranial hypertension (IH) and cerebrospinal fluid hypotension (CSFH), cause headaches and can significantly impair quality of life. These conditions often present with transient visual loss, tinnitus, and gait and balance disturbances, with positional headache being the main symptom. This patient was initially diagnosed with IIH, which was well-managed with medical treatment and lifestyle changes for several years. However, the mild TBI in 2023 caused a notable change in her headache pattern and additional symptoms, including rhinorrhea and orthostatic headache, indicative of a cerebrospinal fluid leak. MRI findings confirmed a frontoethmoidal meningoencephalocele, a rare complication post-head trauma leading to cerebrospinal fluid fistula. **Final comments:** This case demonstrates a secondary headache due to IIH that was well-controlled for years but exacerbated by a mild TBI, leading to a new headache pattern and additional symptoms. The diagnosis of cerebrospinal fluid fistula and meningoencephalocele was confirmed through imaging studies. Opting for a ventriculoperitoneal shunt instead of surgical fistula correction was effective, providing significant symptom relief. In conclusion, this case highlights the importance of thorough evaluation and appropriate management in patients with changes in headache patterns following head trauma.

Complex case of trismus, ischemic stroke and neuromuscular disorder: a diagnostic challenge

Larissa da Cruz Cardoso[1], Isadora Ribeiro Doria[1], Beatriz Palladino Ferreira[1], Augusto Costa Ataides[1], Sandy Karoline Carnaúba dos Santos[1], Matheus Henrique Fonseca Melo[2], Agnaldo Queiroz Plaster[3], Maria Luísa Ribeiro Lima[4], Evellyn Fatima Rasia[1], Mireli Martins Montijo[1]

[1]Universidade do Estado de Mato Grosso, Cáceres MT, Brazil.
[2]Faculdade de Ciências Médicas, Itabuna BA, Brazil.
[3]Universidade Federal de Mato Grosso do Sul, Campo Grande MS, Brazil.
[4]Centro Universitário Governador Ozanam Coelho, Ubá MG, Brazil.

Correspondence: Larissa da Cruz Cardoso; Email: lari_osodrac@hotmail.com.

Case presentation: The patient, MGSB, is a 58-year-old female with no known allergies to medications. She denies smoking or drinking alcohol. She sought hospital care after experiencing multiple ischemic strokes, trismus for 3 days, and tongue protrusion in a lateral frontal bite. Upon physical examination, she was in good general condition, alert, and hydrated. The neurological examination revealed a Glasgow Coma Scale score of 15, with reduced strength in the right upper limb, changes in motor coordination, aphasia, and photoreactive pupils. The diagnosis evolved with a new episode of subacute ischemic stroke, bronchoaspiration, and severe oropharyngeal dysphagia. A cerebrospinal fluid examination was performed, which was clear and colorless, with no significant changes. A head CT scan showed gliosis in the left temporoparietooccipital region and the right precentral gyrus, as well as intracranial atheromatosis. MRI revealed areas of encephalomalacia bordered by gliosis in the left fronto-parietal transition and the left occipital lobe. To investigate the hypotheses of trismus and other neuromuscular changes, laboratory tests were conducted to probe metabolic, infectious, and structural etiologies. However, the test results did not provide reasonable evidence, making the case an important scientific concern. The tests obtained were: non-reactive ANA, negative Anticardiolipin IgM and IgG, and non-reactive Factor V Leiden. The only notable change observed was an elevated Antithrombin III level at 132%. **Discussion:** The clinical picture presents a heterogeneous neurological syndrome, making the case difficult to classify. The result of the lupus anticoagulant was weakly positive and will need to be repeated after six months, indicating Systemic Lupus Erythematosus as a diagnostic possibility. Clostridium research was also conducted to search for botulism, along with diagnostic tests for myasthenia gravis and cephalic tetanus, all of which were negative. The current diagnostic hypothesis centers around autoimmune encephalitis. To justify this diagnosis, analysis of CSF and anti-GAD serum was requested. This research is based on the patient's clinical condition, which includes signs of cerebellar ataxia, epilepsy, and the neuromuscular disorder trismus. As a therapeutic test, immunoglobulin will be used to observe the clinical condition and to determine if there is an association with autoimmune encephalitis. **Final comments:** The patient's clinical condition points to a variety of possibilities that are not supported by the test results obtained. The difficulty in establishing a reliable diagnosis prevents therapeutic decisions from being made, resulting in longer hospital stays and clinical worsening of the patient. This challenge hinders early identification and appropriate management, which are essential to reduce the morbidity and mortality associated with the clinical picture.

Complex dementia case: overlapping symptoms of vascular, Alzheimer's, and frontotemporal dementia with adult leukoencephalopathy

Lucas de Andrade Saraiva[1], Paulo Caramelli[1], Elisa de Paula França Resende[1], Leonardo Cruz de Souza[1]

[1]Universidade Federal de Minas Gerais, Belo Horizonte MG, Brazil.

Correspondence: Lucas de Andrade Saraiva; Email: lucasdeandradesaraiva@gmail.com.

Case presentation: Mr JAS, 73, married, from Betim, 4 years of schooling, a baggage handler, admitted to the neurology clinic on 09/23. Since the pandemic, the patient has been experiencing severe irritability, which escalated to self-harm by hitting himself in the head. His behaviour deteriorated further, displaying uninhibited behaviour such as disclosing sensitive information about a past relationship with a prostitute to his family, heightened verbal aggression, and paranoid jealousy toward his wife. The patient's wife reported that he had a history of learning difficulties and displayed long-term uninhibited behaviour, including verbal aggression, racism, inappropriate jokes; and delusional jealousy towards his wife. Despite these behaviours, he was able to work as a baggage handler at the bus station and use public transport independently. The patient reported obsessive thoughts about buying a coffin, as well as exhibiting compulsive behaviour related to ordering. The wife also mentioned discreet social apathy and mild dysarthria in the last 2 months. Comorbidities: history of cardiac arrhythmia. Family history: His mother had epilepsy, Alzheimer's disease (AD) at age 75, and multiple strokes. His father had AD at age 70. Physical examination findings: reduced visual fields in both eyes, cogwheel joint stiffness, and mild heightened reflexes in the lower limbs. Head CT: showed diffuse atrophy, mild bilateral frontal and temporal predominance and white matter lesions (Fazekas 3). Brain MRI: showed extensive multifocal lesions, with hypersignal on T2/FLAIR and hyposignal on T1. Hippocampi showed moderate atrophy (MTA 3). Brief Cognitive Screening Battery (BCSB): poor performance in naming, learning memory, and delayed memory. **Discussion:** The patient exhibits characteristics indicative of behavioral variant frontotemporal dementia (bvFTD), including behavioral disinhibition, compulsive behavior, and apathy, supported by CT scan findings of consistent atrophy patterns. While bvFTD is likely, AD cannot be ruled out due to episodic memory impairment and moderated hippocampal atrophy (MTA 3). Recent onset of dysarthria, coupled with cardiac arrhythmia and white matter lesions (Fazekas 3), suggest a mixed dementia presentation with bvFTD/AD and cerebrovascular disease, warranting consideration. The latest MRI findings indicate atrophy patterns consistent with adult Leukoencephalopathy, a condition marked by movement disturbances, vision impairments, balance issues, memory loss, behavioural alterations, and attention deficits, some of which the patient displays. In certain instances, this condition may advance to dementia. **Final comments:** In summary, Mr. LFC's case presents a diagnostic challenge due to symptoms suggestive of multiple dementia etiologies. Further assessments are needed to accurately identify the underlying pathology and guide management strategies for his cognitive decline.

Complex neurological manifestations in a case study of narcolepsy and autosomal dominant ataxia

Jonathas Taumaturgo Soares[1], Danilo Lemes Reis[1], Diogo Rabelo de Lima[1], Victor Hugo Soares dos Santos[1], Carlos Maurício Oliveira de Almeida[1], Marcus Vinicius Della Colletta[1]

[1]Universidade do Estado do Amazonas, Manaus AM, Brazil.

Correspondence: Jonathas Taumaturgo Soares; Email: soaresjonathas2004@gmail.com.

Case presentation: A 54-year-old female patient of Italian descent was referred for neurological evaluation due to tremors. At the age of 40, she began experiencing tremors in her left upper limb, which progressed to her right upper limb within a month, accompanied by difficulty in writing. At 44, she noticed progressive hearing loss, and by 46, she had difficulty walking. She also reported episodes of inappropriate daytime naps since the age of 25, agitated sleep with nocturnal vocalizations, and excessive movements during sleep. She described episodes of falls initiated by trunk and lower limb weakness without loss of consciousness and episodic in nature. Upon physical examination, mild bradykinesia, bilateral resting and postural tremor, ataxic gait, and slight dysmetria were noted. Epworth Sleepiness Scale: 13/24. RBDSQ-Br Questionnaire: 5/13. Pittsburgh Sleep Quality Index (PSQI): 8. Audiometry: Bilateral hearing loss. Brain MRI: Hypo signal in T2 in bilateral globus pallidus and midbrain. PANK2 negative. Polysomnography with Multiple Sleep Latency Test (MSLT): AHI 14/hour, PLMI 52/hour; Sleep efficiency 96%, presence of REM without atonia, average latency of 4.64 minutes, and presence of 3 SOREMPs. EEG: Normal; CSF: Normal; Molecular Test: p570 Ala-Val mutation in Exon 21 of the DNMT1 gene. **Discussion:** Narcolepsy is an autoimmune and genetic disorder and is the most common cause of central hypersomnia (ICSD-3). Narcolepsy is caused by the selective loss of orexinergic/hypocretinergic neurons in the lateral hypothalamus, which promote wakefulness. There are two described forms: Narcolepsy type I (with cataplexy) and type II (without cataplexy), and its diagnosis requires PSG with MSLT demonstrating a mean sleep latency of less than 8 minutes and 2 or more SOREMPs, or reduced hypocretin levels in CSF for Narcolepsy type I. The DNMT-1 gene is crucial for DNA methylation and is located on chromosome 19. Three phenotypes have been described for DNMT-1 mutation, all with an autosomal dominant pattern: Hereditary Sensory Neuropathy with Dementia and Hearing Loss (Exon 20), Ataxia, Deafness, and Narcolepsy (Exon 21), and the third with overlapping manifestations. The initially described cases were observed in Italian immigrants, like our patient. The described case represents one of these phenotypes. **Final comments:** Narcolepsy can be one of the manifestations of the DNMT-1 gene mutation. In this case, the presence of deafness and ataxia, in addition to narcolepsy, represents one of the recently described phenotypes.

Complication of herpetic encephalitis: Klüver-Bucy syndrome: clinical case

Daniele da Costa da Silva[1], Carolina Bonifácio Gomes[1], Ana Carolina Grande[1], Ivo Marcos Darella Lorenzin Fernandes Neto[2], Eduarda Basso Badalotti[2], Angelo Marcelo Wosniacki Filho[2], Gabriel Angelo Garute Zenatti[2], Renato Endler Iachinski[2], João Luis Corso Bandeira[2], Antonio Carlos de Andrade Soares[2]

[1]Centro Universitário Fundação Assis Gurgacz, Cascavel PR, Brazil.
[2]Fundação Hospitalar São Lucas, Cascavel PR, Brazil.

Correspondence: Daniele da Costa da Silva; Email: dani.costadasilva09@gmail.com.

Case presentation: A 51-year-old female patient was admitted with progressive confusional status that started one day ago. On arrival, the patient presented on postictal status after two convulsive episodes and no other neurological abnormalities on clinical examination. On further investigation, a CSF and a magnetic resonance with spectroscopy were performed showing an area of signal alteration affecting part of the left cerebral hemisphere, with restriction to the diffusion and with slight leptomeningeal enhancement in the temporal pole. During the exam, a lowering of the level of consciousness was observed and the patient was transferred to the ICU after intubation. Suspected of herpetic encephalitis and started IV Acyclovir. During hospitalization, she developed visual agnosia, placidity, apathy to external stimuli, and

amnesia, leading to a diagnosis of partial Kluver-Bucy syndrome. Discharged after twenty-eight days, presenting with expressive and receptive aphasia and showing partial improvement of mental confusion. **Discussion:** Nervous system infections' clinical manifestations vary according to the pathogen involved, the severity, and the location of the lesion. Initially, fever, changes in the level of consciousness, and convulsions can be acute or subacute. Diagnosis is carried out through lumbar puncture. Imaging exams and electroencephalogram can be performed. Herpes simplex encephalitis generally affects the temporal lobes and adjacent limbic systems, being a common change to meningeal congestion. Behavioral syndromes, such as Klüver-Bucy syndrome, amnesia, and hypomania, may be associated. Treatment is carried out with acyclovir, which is the only medication recommended for this viral condition. Furthermore, KBS is associated with temporal lobe lesions and is characterized by hyperorality, hypersexuality, eating disorders, placidity, visual agnosia, and amnesia. The diagnosis is clinical, and the progression of the syndrome varies in each patient, with treatment focusing on symptom management. **Final comments:** Herpes simplex encephalitis is considered a neurological emergency that must be investigated and treated due to its high morbidity and mortality rate. Lumbar puncture and initiation of treatment with intravenous acyclovir must occur early to ensure a better prognosis. Additionally, continuous monitoring of patients and their families is essential to assist in the rehabilitation phase after treatment.

Comprehensive analysis of the clinical and genetic features of RYR1-related myopathies

Alulin Tácio Quadros Santos Monteiro Fonseca[1], Clara Gontijo Camelo[1], André Macedo Serafim da Silva[1], Cristiane de Araújo Martins Moreno[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, São Paulo SP, Brazil.

Correspondence: Alulin Tácio Quadros Santos Monteiro Fonseca; Email: alulin.fonseca@gmail.com.

Background: The RYR1 gene encodes the skeletal muscle ryanodine receptor, an ion channel responsible for regulating the release of calcium stored in the sarcoplasmic reticulum. Variants in the RYR1 gene are responsible for a wide variety of phenotypes in myopathies, with autosomal dominant (AD) and autosomal recessive (AR) inheritance patterns. **Objective:** We present the clinical and genetic data of 24 patients (from 23 families) with RYR1-related myopathies with either AD or AR inheritance patterns, aged between 1 and 61 years (mean age 16.3 years). **Methods:** Clinical, histological, and molecular data were collected. Clinical information from patients was gathered cross-sectionally between November 2022 and June 2024. Muscle biopsy data were evaluated retrospectively. The RYR1 gene was analyzed using next-generation sequencing. **Results:** An AR inheritance pattern was observed in 13 patients (54%). All variants with AD inheritance patterns were missense. In the AD group, two variants (p.Arg4861His and p.Ile4898Thr) were observed in two patients each. Among the 12 AR families, 50% had truncating variants (splice site or frameshift) associated with a missense variant. Except for one patient who began experiencing weakness in adulthood, all others had a congenital myopathy diagnosis. Eight patients (33%) had reduced intrauterine movement. One patient had bilateral congenital hip dislocation. The mean age at gait acquisition was 1 year and 11 months, with three patients aged between 6 and 19 years never acquiring gait. The oldest age for gait acquisition was 5 years. Eyelid ptosis was observed in 54% of patients. Ophthalmoparesis was seen in 46% of AR cases and in none of the AD cases. Facial weakness was present in 45% of cases, and 70% had a high-arched palate. Trophic changes of the tongue were observed in 69% of patients. Scapular winging was present in 6% of cases. Muscle weakness of the cervical flexors and rectus abdominis was noted in most cases. Joint contractures were more prominent in AR patients, particularly affecting the Achilles tendon. Spinal deformities and rib cage deformities were seen in 45% and 58% of patients, respectively. Two patients required a g-tube, and three were on ventilatory support. Prominent dynamic symptoms (fatigue, myalgia, and cramps) were reported in 37.5% of patients. No patient had a history of rhabdomyolysis or malignant hyperthermia. CPK levels ranged from 32 to 2396 IU/L. Muscle biopsy was performed in 16 patients (66%). A central core pattern was observed in the AD group. In AR patients, the most prominent histological findings were nuclear centralization, mild dystrophic changes, and uneven oxidative staining. **Conclusion:** RYR1-related myopathies are a heterogeneous group of diseases, mostly presenting congenitally. AR forms exhibit more prominent ophthalmoparesis, trophic tongue changes, and joint contractures. Histological changes are more diverse in the AR group.

Comprehensive step-by-step clinical assessment for managing action-induced focal dystonia after bilateral gpi deep brain stimulation for Parkinson's disease

Flávia de Paiva Santos Rolim[1], Verônica Tavares Aragão[2], Joanisson Rubens Gomes Diniz[2], Ana Silvia Sobreira Lima Verde[2], André Borges Ferreira Gomes[2], Fernanda Martins Maia Carvalho[1]

[1]Universidade de Fortaleza, Fortaleza CE, Brazil.
[2]Hospital Geral de Fortaleza, Fortaleza CE, Brazil.

Correspondence: Flávia de Paiva Santos Rolim; Email: flaviarolim@unifor.br.

Case presentation: We report a case of a PD male patient diagnosed at 32 years-old, who underwent bilateral Globus Pallidus internus (GPi) DBS at 43 years-old due to severe motor complications. Despite excellent response to levodopa, he experienced incapacitating ON dyskinesias. Post-DBS, he achieved complete remission of dyskinesias. However, levodopa dosage optimization was necessary to manage wearing off phenomena, despite DBS adjustments. Few weeks after a regular programming session, he reported unpredictable involuntary muscle contractions during right biceps activation, which impaired functionality but disappeared at rest. Movement phenomenology resembled focal dystonia, triggered solely by flexion and extension of the elbow during tasks such as brushing teeth, eating, writing, or other activities requiring biceps activation. This initially led us to hypothesize that the symptom might be related to stimulation, so we opted to progressively reduce stimulation in the left GPi. However, this resulted in worsening of parkinsonism. We also attempted to change the stimulated contacts based on previous monopolar review. A trial of amantadine was started in an attempt to cover a possible peak dyskinesia, but with no improvement after reaching a dose of 300mg. Despite different approaches and adjustments, the involuntary movement persisted. A structured troubleshooting process was initiated to differentiate between potential causes: 1) OFF Medication, ON Stimulation: Baseline assessment conducted 12 hours without dopaminergic medication. 2) OFF Medication, OFF Stimulation: Assessment without pharmacological or DBS influence. 3) ON Medication, OFF Stimulation: Evaluating the isolated effect of levodopa. 4) ON Medication, ON Stimulation: full therapeutic state assessment. During the third phase (ON Medication, OFF Stimulation), the previously unobserved action-induced dystonic movement emerged. This indicated that the dystonic movement was likely related to medication (levodopa-induced). We then decided to reduce the total daily levodopa dose, with partial clinical improvement, in parallel with image reconstruction and neuroimaging-based DBS programming. **Discussion:** This case highlights the need for meticulous clinical evaluations for PD patients with DBS. Understanding medication and stimulation interactions is decisive for managing complex motor symptoms. GPi's somatotopic organization places the face and arm posteriorly and ventrally, and the leg more centrally and dorsally. Deviating from the targeted stimulation area could led to adverse effects, such as the focal dystonia seen in our patient. **Final comments:** This case underscores the intricate balance required in managing advanced PD with DBS. Step-by-step evaluation and neuroimaging-based troubleshooting process provides a comprehensive framework for distinguishing between medication-induced and stimulation-induced movement disorders, ensuring precise and effective therapeutic strategies.

Correspondence: Helena França Alcaraz Ferreira; Email: helena.faf33@gmail.com.

Background: The COVID-19 pandemics has left some consequences in the way we understand host-antigen interactions, despite the great advances during the period, there is still much to be understood about the extension of this disease's impacts on the human body. The cytokine storm resulting from the host's exacerbated response to the virus, as well as its innate ability to infect tissues beyond its point of entry, gives the disease inflammatory and systemic properties. **Objective:** To investigate the concomitant association between the interleukins 6,10 (IL-6, IL-10) and the neurofilament light chain (NfL) level with the death outcome. **Methods:** Peripheral blood had been collected in order to investigate the relationship between the protein biomarker of neurological damage and the anti-inflammatory cytokines. Statistical analysis using the Kruskal Wallis and Mann-Whitney U test with a cohort of 32 critical COVID-19 patients were made. The court was divided between the outcome Deceased and Survivor, and Presence (PNS) or Absence (ANS) of Neurological Symptoms. Each of these groups was compared with its homologous biomarker from a healthy control group. The data evaluation was performed using the SIMOA platform for the NfL, and LUMINEX 200 system for the cytokines analysis. **Results:** The results showed there was a significant difference between the deceased and control patients for both IL-6 and IL-10 expression (p=0.01022) when comparing deceased to the survivor group (p=0.02036). Of the cohort of 32 patients, 9 were classified as PNS, of which 6 were also part of the Decease group with high NfL rates compared to Survivor and control groups (NfL Decease = 805.6±2,696pg/mL; NfL Survivor = 109.9±192.3pg/mL; NfL Heath control = 12.49±5,210pg/mL). **Conclusion:** It is already established from previous studies that an exacerbated immune response may be related to the worsening of the condition, as well as the increase in NfL which has been associated with the death outcome. These variations, combined with the clinical features of the patients, may be an indication of the relevance of these biomarkers for the monitoring of COVID-19 evolution, as well as the important role of inflammatory response in COVID-19 severity.

Congenital insensitivity to pain due to SCN9A gene mutation: a case report

Josiane de Souza[1], Daniel Almeida do Valle[1], Jaqueline Souza Chaves Taniguchi Leite[2], João Pedro Tejerina Bader Maluf[2], Julianna Rodrigues Beltrão[2], Lucas Schiavon[2], Maria Valentina Denardini[2], Marina Faria Negrão[2]

[1]Faculdade Pequeno Príncipe, Curitiba PR, Brazil.
[2]Pontifícia Universidade Católica do Paraná, Curitiba PR, Brazil.

Correspondence: Marina Faria Negrão; Email: mfnegrao@outlook.com.

Case presentation: The patient is a male, the only child of a non-consanguineous couple, with no significant changes related to gestation and appropriate neuropsychomotor development throughout childhood. The investigation of the patient's clinical condition began at 7 months of age and continued for the following 6 years after multiple hospitalizations due to episodes of self-aggressiveness, mutilation, fractures, and recurrent osteomyelitis. The guardians reported episodes of biting and abrasions on multiple parts of the body, resulting in deep wounds with heavy bleeding, as well as occurrences such as direct contact of the skin with fire or motorcycle exhaust. In none of the described events did the patient show signs of pain, crying, reflex, or discomfort. During the years of the patient's follow-up, possible diagnoses such as storage disease, rheumatic diseases, and immunodeficiencies were investigated, without success in defining the etiology. The diagnosis of congenital insensitivity to pain was made at the age of 7, after performing a whole genome sequencing test revealing the pathogenic variant c.2723G> A, p.(Trp908Ter) in exon 16 of the SCN9A gene in homozygosity. This alteration is responsible for generating a premature stop codon and consequently a truncated protein. In the medical record documented at the age of 7 years and 3 months, the patient had good school performance with preserved intellect, which is consistent with the phenotype of the SCN9A variant presented by the patient. **Discussion:** Congenital insensitivity to pain is a rare autosomal recessive neuropathy characterized by damage to small-caliber sensory C fibers and/or A-delta fibers of the peripheral nerves. This alteration results in impaired perception of nociceptive, mechanical, and thermal stimuli. Although pain insensitivity is a universal symptom, each pathogenic variant presents specific peculiarities related to the affected gene, resulting in multiple phenotypes of the disease. Consequently, children with this condition lose an essential defense mechanism, potentially leading to self-mutilation habits and recurrent injuries. Furthermore, this condition results in significant psychological challenges, such as the need for continuous monitoring of the patient, affecting the child's self-esteem and social interactions. Lastly, it is important to highlight the relevance of genetic counseling in this case, which aims to clarify the risks of recurrence of the mutation, enabling the family to make informed decisions regarding future pregnancies. **Final comments:** The reported case involves a patient with a rare mutation in the SCN9A gene, suspected and identified through episodes of self-mutilation and hospitalizations for recurrent fractures. Understanding the molecular, clinical, and genetic characteristics not only provides a comprehensive view of the disease but also contributes to new diagnostic and therapeutic strategies.

[2]Universidade de São Paulo, Hospital das Clínicas, Ribeirão Preto SP, Brazil.
[3]Max Planck University Center, Berlim, Germany.

Correspondence: Ana Beatriz Landim Ribeiro; Email: ablr2016@icloud.com.

Case presentation: Male patient, currently 3 years old, with a history of fetal exposure to alcohol and cocaine, without complications during delivery. At two months of age, he presented with generalized hypotonia and dysphagia. Developmentally, delays in neuro psychomotor milestones were noted, particularly delayed acquisition of walking. Upon physical examination, a prominent forehead, apparent brachycephaly, anteverted nares, bilateral knee flexion contractures, and elbow region contractures were observed, with more prominent appendicular hypotonia in the upper limbs. In 2020, a brain MRI revealed diffuse T2 hyperintensity in white matter, confluent, affecting fibers, pronounced T1 hypointensity, and spectroscopy indicating reduced neuronal viability, findings suggestive of metachromatic leukodystrophy at the time. Additionally, he has a normal ECG and an absence of pathogenic variants in the spinal muscular atrophy (SMA) gene. Therefore, complete exome sequencing was performed, revealing compound heterozygous variants in the intronic region following exon 36 of the LAMA2 gene. The patient continues to be followed up, with appropriate screenings up to date. **Discussion:** Congenital muscular dystrophy type 1A (MDC1A) is an autosomal recessive inherited myopathy, typically characterized by peripheral hypotonia, respiratory insufficiency, loss of muscle mass, and spontaneous movement, all symptoms observed in the case. It may also be associated with gastroesophageal reflux and recurrent thoracic infections. MDC1A manifests from birth or early childhood, with an estimated prevalence of 1 in 30,000 individuals. The pathophysiology of the disease results from pathogenic variants in the LAMA2 gene, which encodes the alpha-2 chain of laminin. Diagnosis can be made through a muscle biopsy, where a deficiency of merosin in muscle and skin can be detected. In this case, the patient exhibits feeding difficulties with neuro psychomotor causes. This can be explained as the disease progresses, weakness of facial muscles, temporomandibular joint contractures, and macroglossia can impair feeding and speech. **Final comments:** Mutations in the LAMA2 gene affect the production of the α2 subunit of laminin-211 (= merosin) and result in either partial or complete laminin-211 deficiency. Complete merosin deficiency, as seen in our patient, is typically associated with a more severe congenital muscular dystrophy (CMD), clinically manifested by hypotonia and weakness at birth, the development of contractures of large joints, and progressive respiratory involvement. So, the diagnosis of this condition should be remembered in cases like ours, primarily when severe muscle weakness, hypotonia, and white matter abnormalities in brain imaging are presented.

Congenital miopathy presenting as mitocondrial miopathy: the relevance of genetic testing and semiological findings in chronic progressive external ophtalmoplegia

Yasmin Ramalho Mandarino[1], Luana Cristina Stefanes[1], Pedro Vitor Fortunato Silveira[1], Hannah Bang[2], Natália Cardoso Darabas[2], Pietra Cani Linzmeier[2], Thábata Emanuelle Martins Nunes[2], Maria Eduarda Angelo de Mendonça Fileti[2], Carla Heloísa Cabral Moro[2], Alexandre Luiz Longo[2]

[1]Universidade da Região de Joinville, Joinville SC, Brazil.
[2]Hospital Municipal São José, Joinville SC, Brazil.

Correspondence: Yasmin Ramalho Mandarino; Email: yasminramalhoo@gmail.com.

Case presentation: A 56-year-old female presented with progressive weakness in her lower and upper limbs since childhood, with description of neonatal hypotonia. She also reported dysphagia and dyspnea on exertion. Her medical history included hemochromatosis, type 2 diabetes, fibromyalgia, and a history of lumbar fracture. Neurological examination revealed grade IV muscle strength in the proximal lower limbs, limited bilateral eye abduction, and impaired upward gaze. Deep tendon reflexes were hypoactive. Electromyography and nerve conduction studies showed borderline myopathic findings. MRI indicated severe liposubstitution of the gluteus maximus and tensor fasciae latae muscles bilaterally. A genetic panel revealed a variant of uncertain significance in the ANO5 gene and a pseudodeficiency allele in the GAA gene. Genetic testing confirmed proximal myopathy and ophthalmoplegia associated with the MYH2 gene. Initially, mitochondrial myopathy was suspected due to the presence of external ophthalmoplegia, however, genetic test results were negative for this condition. **Discussion:** Congenital myopathies constitute a heterogeneous group of diseases in terms of clinical manifestations and genetic mechanisms, characteristic findings can be observed in muscle biopsy. The prevalence of congenital myopathy in the general population is 1.50 per 100,000. Hypotonia and weakness are common clinical findings in congenital myopathy typically observed in the first year of life, accompanied by hip dysplasia, hypomimia, and motor development delays. The presence of specific histopathological changes in muscle biopsy distinguishes these conditions from other neuromuscular disorders. The pathophysiology is complex, but the genes commonly involved affect calcium ion homeostasis, muscle contraction mechanisms, and thin and thick filament structures. More than 30 genes have been associated with congenital myopathies. The diagnosis is made through muscle biopsy, muscle MR and genetic tests. The disease is incurable, and treatment primarily focuses on providing supportive care. A possible differential diagnosis in this case would be progressive external ophthalmoplegia. However, unlike the patient described above, in this condition, patients always have ptosis. In cases of congenital myopathy with ophthalmoplegia, patients do not have associated ptosis. **Final comments:** Congenital myopathies constitute a heterogeneous group of diseases in terms of clinical manifestations and genetic mechanisms. Prognosis and severity vary according to the type of mutation involved, resulting in either a stable or progressive disease course. The absence of specific clinical symptoms and genetic diversity can make molecular diagnosis so complex that even specialist physicians often face difficulties in reaching an accurate diagnosis. The use of new molecular genetic sequencing techniques is essential for the development of future therapies.

Congenital myasthenia gravis: a case report from the perspective of neurology

Camila Yukari Yokota Barbosa[1], Maria Eduarda Barbosa Stecca[1], Maria Luiza Azambuja Locatelli[1], Luiz Felipe Azambuja Locatelli[1]

[1]Centro Universitário Mauricio de Nassau, Cacoal RO, Brazil.

Correspondence: Camila Yukari Yokota Barbosa; Email: camilayukari2005@gmail.com.

Case presentation: A 3-year-old male patient, went to the doctor's office on 04/12/2023, with his grandmother, who reported eyelid ptosis and lower limb asthenia. After the consult, an anti-acetylcholine receptor antibody and a genetic test were solicited, due to suspicion of myasthenic gravis syndrome (MGS). The presence of anti-acetylcholine receptor antibodies was confirmed, reinforcing the diagnostic hypothesis of congenital myasthenia gravis. New muscle exams and genetic testing were required. fluoxetine hydrochloride was initiated. 15 days post-treatment, the exams did not suggest muscle

disease, maintaining fluoxetine hydrochloride for two months and then starting salbutamol sulfate (2.5 ml, 3x/day). On the last consult, genetic tests were negative, and a chest tomography showed no signs of thymoma. The patient was referred to a geneticist, but the consult did not occur due to geographic and socioeconomic issues. This report was approved by the CEP, opinion 6.902.166. **Discussion:** The patient presents typical signs and symptoms of congenital myasthenic syndrome (CMS), such as muscle weakness, eyelid ptosis that worsens throughout the day, and early age onset. As it is an uncommon disorder, diagnosis is usually late, leading to a worsening of clinical aspects. This case is considered rare because the diagnosis was established in early childhood. CMS is a rare disease involving the neuromuscular junction, characterized by Ach receptor defects, which can occur due to autosomal dominant, recessive, or sporadic mutations. For the diagnosis, it is necessary to assess the age at which symptoms appear, delay in psychomotor development, weakening muscle, paralysis or asthenia in eye muscles, skeletal deformities, inefficiency of immunosuppressive therapy, fatigable weakness, and ptosis. According to Abicht (2003), the most common characteristic of CMS is fluctuating muscle weakness, which worsens by use and improves at rest, as seen in this case. Hence, for an accurate diagnosis, it is crucial to rely on physical examination, laboratory findings, repetitive pharmacological stimulation tests, tests that demonstrate the presence of antibodies, response to anticholinesterase therapy, family history, and genetic testing. **Final comments:** In this report, the exams revealed anti-acetylcholine receptor antibodies, indicating MGS. Although the genetic consult had not occurred, clinical symptoms and laboratory findings strongly suggested the condition. The diagnostic complexity and the need for multifaceted therapeutic approaches highlight the uniqueness of this case and the importance of careful and personalized management for patients with CMS in pediatrics. Thus, the exclusion of MGS was necessary based on negative results of genetic and general exams, requiring better follow-up with a geneticist. Identification of genetic defects that lead to CMS is crucial for adequate treatment as they can occur in different locations of the neuromuscular junction.

Correspondence: Jéssica Cristina Silveira Damasceno; Email: drajessicadamasceno@gmail.com.

Case presentation: A 22-year-old man, previously asthmatic, with a history of delayed motor development, having only started walking at the age of 2, noticed proximal weakness in all 4 limbs at the age of 7. At 17 years old, he began experiencing episodes of short-term blurred vision and diplopia that resolved spontaneously. At 20 years old, he developed frequent episodes of liquid dysphagia and dyspnea on medium exertion, when he sought medical assistance due to the greater functional impairment. His family history was that his mother and sister have undiagnosed proximal weakness in the lower limbs. Laboratory investigation, including creatine phosphokinase, was normal. Electroneuromyography demonstrated signs of global myopathy with proximal predominance with (brief) myotonic bursts. Due to the suspicion of congenital myopathy, a broad DNA panel for neuromuscular diseases was carried out in July 2022 with the presence of heterozygosity for the actin alpha 1 (ACTA 1) gene, suggesting a diagnostic hypothesis of nemaline myopathy (NM). The patient was last seen at the end of 2022, when he remained with a grade 4 strength in the limbs without facial weakness and did not require ventilatory assistance. Until that time, no muscle biopsy had been performed. **Discussion:** Mutations in the ACTA1 gene most frequently cause NM, but they can cause other forms of congenital myopathy less frequently. Among these, the main differential diagnosis from NM is myopathy due to disproportion of muscle fibers. Myopathy due to disproportion of muscle fibers occurs due to a selective atrophy of type 1 fibers, which are up to 80% smaller than type 2 fibers, presenting a clinical picture of significant proximal, ocular, facial and cervical weakness that begins at birth. NM, on the other hand, has great clinical heterogeneity, ranging from conditions with the onset of severe hypotonia at birth and even forms with a later onset and mild muscle weakness. However, in most cases of NM, forms with moderate and mild symptoms predominate. In NM biopsy, there are nemaline bodies or rods in the sarcoplasm of the muscle fibers, although fiber disproportion may also occur. Moreover, if the fibers are very small, it may be difficult to detect nemaline bodies. Given that the diagnosis of forms of congenital myopathy requires a muscle biopsy, in the present case it was not possible to determine the patient's histopathological diagnosis. **Final comments:** In short, the patient presents mild proximal appendicular weakness, absence of ophthalmoparesis, facial and bulbar weakness detected on neurological examination, despite reports of diplopia and dysphagia. All of these elements make the diagnosis of fiber disproportion myopathy less likely than the diagnosis of nemaline myopathy. However, due to the lack of histopathological confirmation, the patient remains classified as having congenital myopathy due to a mutation in the ACTA1 gene.

Contrast-induced encephalopathy: a mimicker in the ICU

Gabriel Pinheiro Martins de Almeida e Souza[1], Maria Eduarda Slhessarenko Fraife Barreto[1], Lara Santos Machado[1], Daniel Delgado Seneor[1], Marcio Pinheiro Lima[1], João Victor Cabral Correia Ferrer[1], Victor Cardoso de Faria[1], Ruan Gambardella Rosalina de Azevedo[1], Andre Felipe Candêas Amorim[1], João Brainer Clares de Andrade[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Gabriel Pinheiro Martins de Almeida e Souza; Email: gabrielpinheiromas@gmail.com.

Case presentation: A 57-year-old woman presented with speech disturbance and right-sided weakness during an elective arteriography for a cerebral aneurysm located at the M1-M2 bifurcation of the right middle cerebral artery. She did not report experiencing headaches, nausea, or vomiting. The patient presented lethargy, mild confusion, motor aphasia, gaze deviation to the left, and right hemiparesis. Computed tomography revealed spontaneous hyperdensity in the subarachnoid space of the left hemisphere and mild cerebral edema. She received intravenous hydration and was admitted to the intensive care unit for monitoring. After several hours, she experienced a seizure and was treated with intravenous phenytoin. The patient fully recovered after 48 hours, with resolution of symptoms and imaging findings. **Discussion:** Contrast-induced encephalopathy (CIE) is a rare neurological complication associated with the administration of contrast agents. The incidence of CIE ranges between 0.3% and 2%, depending on the patient characteristics (older age, hypertension diabetes mellitus, impaired renal function, cardiovascular disease) and type of contrast agent (larger volume, hyperosmolarity, higher concentration, and ionic contrast agents). The pathophysiological mechanism is not fully understood but it is thought to involve a direct neurotoxic effect of the contrast agent, leaked in the brain parenchyma and subarachnoid space due to blood-brain barrier disruption and endothelial dysfunction. Clinical manifestations usually develop shortly after administration of the contrast agent and are typically transient. Symptoms include altered mental status, agitation, seizures, headache, visual disturbances, nausea and vomiting. The diagnosis is suspected in cases of clinical deterioration during or shortly after procedures using contrast agents that cannot be explained by the original ischemic area, reperfusion injury, recurrent stroke, or hemorrhagic transformation. Neuroimaging findings can support the diagnosis, such as cerebral edema beyond the infarct core and contrast staining in the brain parenchyma or subarachnoid space. The treatment of this condition is uncertain due to the small number of cases described. Management is symptomatic and individualized. Although there is no consensus, the systematic review by Mariajoseph et al. (2024) showed that intravenous hydration and glucocorticoids were the most used therapies in practice. The clinical course of CIE is usually favorable with full recovery in most patients within 48-72 hour. **Final comments:** Post-contrast encephalopathy is a differential diagnosis to be considered in cases of clinical worsening during or immediately after procedures that used contrast. Recognition of this condition avoids unnecessary additional contrast studies such as CT angiography or perfusion and inadequate treatment.

Background: Brazil has the second-highest number of leprosy cases in the world, with around 25,000 cases reported in 2022 alone. There are specialized centers in the country for the diagnosis, treatment, and monitoring of leprosy. **Objective:** To describe the experience of nerve biopsies at an outpatient clinic specializing in leprosy. **Methods:** We performed a retrospective analysis of the nerve biopsies database spanning 26 years, from 1997 to 2023. Each tissue sample was preserved in glutaraldehyde, 10% formalin, and frozen in liquid nitrogen. For those embedded in paraffin, the sections were stained with hematoxylin and eosin, Wade, and Gomori's trichrome. Semi-thin sections were stained with Toluidine Blue. A total of 31 histopathological parameters were studied. **Results:** The ratio of male to female biopsies was 1.7 to 1. The patients' ages ranged from 11 to 89 years, with an equal mean and median age of 51 years. The most commonly biopsied age group was 50-59 years. Out of 850 nerve biopsy records, 31 biopsies did not contain peripheral nerve material (3.7%). Of the remaining 819 cases, 332 (40.5%) were diagnosed as leprosy. For more than 50 patients with a suspected pure neural form of leprosy (without dermatological lesions), the disease was confirmed. Other diagnoses included vasculitis (5.4%), diabetic neuropathy (3.7%), compression neuropathy (2.4%), amyloidosis (2%), CIDP (0.7%), alcoholic neuropathy (0.4%), MADSAM (0.2%), among others. About 277 cases (33.8%) had no definitive diagnosis, only histopathological description. The diagnosis rate using nerve

biopsy, other complementary tests, and clinical sessions was 66.2%. The most biopsied nerves were the cutaneous branch of the ulnar nerve, the sural nerve, and the superficial peroneal nerve. At the initial evaluation, 68.4% of patients were already symptomatic, and predominant symptoms included sensitivity disturbance (85.7%), paresthesia (70.3%), and decreased muscle strength (59.4%). Pain was reported by 30.5% of the patients. The most frequent findings in ENMG were multiple mononeuropathy (in 84,2% of sensory nerves and 42,7% of motor nerves); motor nerves with mononeuropathy (28,1%); and normal exam (22% of motor nerves and 6,6% of sensitive nerves). **Conclusion:** Nerve biopsy was found to be useful for detecting leprosy, especially in the pure neural form, and it remains a valuable tool for reaching a diagnosis, ruling out differential diagnoses, and guiding treatment in uncertain cases. The clinical-pathological correlation was essential for the final diagnosis of the patients. To optimize its utility, we recommend considering the exam in cases with extensive clinical investigation, asymmetric clinical presentation, and progressive deterioration. Our main indication for performing a nerve biopsy was in a patient with multiple mononeuropathy, as the clinical condition was not sufficient to make the diagnosis of pure neural leprosy.

Correspondence: Gabriel Eduardo Pereira Cardoso; Email: gabrielwer204@gmail.com.

Background: Multiple sclerosis (MS) and autism spectrum disorder (ASD) are distinct neurological conditions that rarely coexist. This study presents a series of 9 patients initially diagnosed with MS, in whom level 1 ASD was observed during follow-up. **Objective:** To document the co-occurrence of MS and level 1 ASD in a series of cases, describe the clinical features observed in these patients, and discuss the diagnostic challenges and management strategies for this combination of conditions. **Methods:** A retrospective review was conducted on the medical records of 9 patients diagnosed with clinically defined MS. During neurological follow-up, characteristics of level 1 ASD were identified in these patients. The diagnosis of ASD was based on detailed clinical assessments using DSM-5 criteria and standardized screening tools. **Results:** The study included 9 patients, consisting of 7 females and 2 males, with a mean age of 34 years. All patients initially presented with typical MS symptoms, including demyelinating lesions visible on MRI, recurrent neurological relapses, and various neurological deficits. During follow-up, signs suggestive of ASD, such as difficulties in social communication, restrictive and repetitive behaviors, and specific interests, were observed. Subsequent evaluations confirmed the diagnosis of level 1 ASD in each case. The patients received multidisciplinary management, which included neurological treatment for MS and specialized support for ASD. The co-occurrence of MS and ASD presents significant diagnostic challenges as symptoms can overlap and affect clinical presentation. Early detection of ASD in patients with MS is crucial for implementing appropriate and personalized interventions. This study highlights the need for a collaborative approach between neurologists and ASD specialists to effectively manage these conditions. The identification of ASD in patients with MS requires vigilance and a comprehensive assessment strategy to ensure both conditions are adequately addressed. **Conclusion:** The co-occurrence of MS and level 1 ASD, although rare, requires special attention to ensure integrated and optimized management. Early identification and combined treatment can significantly improve the quality of life for these patients. The findings of this case series underline the importance of awareness and interdisciplinary collaboration in managing patients with complex neurological conditions.

Co-occurrence of nmo spectrum disorder (nmosd) anti- AQP-4positive and a history of low-grade glioma in childhood: a case report

Letícia da Silva Alves[1], Arthur Costa Nascimento[1], Rogério de Rizo Morales[1]

[1]Universidade Federal de Uberlândia, Uberlândia MG, Brazil.

Correspondence: Letícia da Silva Alves; Email: draleticiasilvaalves@gmail.com.

We present the case of a 17-year-old patient, male, who had a history of low-grade glioma in childhood at the medullary level of C3-T1, which was partially treated with surgery in 2012, with the interruption of adjuvant therapy at the family's option in February 2013. The patient developed paresis of the lower limbs and plegia of the upper limbs when, in 2016, he was hospitalized with pneumonia, experienced cardiorespiratory arrest after hypoxemic acute respiratory failure, and was discharged from the hospital with a tracheostomy and invasive mechanical ventilation. In August 2022, he had the first episode of bilateral optic neuritis with a good response to pulse therapy with corticosteroids. An etiological investigation then confirmed the diagnostic criteria of NMOSD with the presence of anti-aquaporin-4 (AQP-4) antibodies, and treatment with azathioprine was initiated. In October 2024, he presented with further worsening of visual acuity and underwent new pulse therapy with methylprednisolone in December 2022, but experienced a headache followed by a seizure during administration on the fourth day of metilprednisolone. The patient received high-dose corticosteroids to manage acute NMOSD exacerbations and plasmapheresis (PLEX) was scheduled, but suspended after 1 session due to clinical complications and patient choice. Treatment was escalated to biannual rituximab, with good tolerance and no new evidence of disease activity. The patient did not show significant improvement in visual function, but did not experience recurrence of disease attacks. During imaging monitoring, there were no signs of tumor recurrence. Given the concern for immunosuppression, close monitoring of the neoplasm recurrence was maintained. In a literature review, there are few case reports involving NMOSD with the presence of anti-aquaporin-4 (AQP-4) antibodies associated with neoplasms. The coexistence of NMOSD and a history of low-grade glioma in a pediatric patient is rare, and the exact relationship between these two conditions remains unclear; potential mechanisms may involve shared immune dysregulation pathways. Further research is warranted to explore the potential interplay between autoimmune disorders and prior malignancies.

Correspondence: Eduarda Leitzke; Email: leitzkeeduarda@gmail.com.

Background: Guillain-Barré syndrome (GBS) is a clinical condition characterized by immune system disruption and subsequent dysregulation. It can be triggered by antigen exposure through infections or even vaccinations. **Objective:** To analyze the possible correlation between the development of GBS and exposure to the COVID-19 virus through infection or vaccination in patients undergoing therapeutic plasmapheresis at the hemotherapy service of a tertiary hospital. **Methods:** Cross-sectional study with a retrospective approach of patients reported with GBS from March 2020 to March 2022, who underwent the therapeutic plasmapheresis procedure. **Results:** A total of eleven patients were diagnosed with GBS. The average age was 49 years, with six males and five females. Among these, only one patient developed COVID-19 infection, while ten patients did not contract the infection. Additionally, out of the eleven patients, only eight had been vaccinated against COVID-19. **Conclusion:** The relationship between the development of GBS and infection or vaccine against COVID-19 is rare. However, an association is possible, as contact with the virus can trigger an exaggerated and unregulated immune response, contributing to the development of GBS.

https://doi.org/10.5327/CBN240464

Correlation between median motor latency and complementary sensory tests on the 1st and 4th fingers for early diagnosis of carpal tunnel syndrome

Juliana Calvet Kallenbach Aurencao[1], Mariana Quintanilha Deslandes[2], Claudia Cristina Ferreira Vasconcelos[3]

[1]Hospital Federal dos Servidores do Estado Rio de Janeiro, Rio de Janeiro RJ, Brazil.
[2]Neurologia e Neurofisiologia do Rio de Janeiro.
[3]Universidade Federal do Estado do Rio de Janeiro, Hospital Gaffree e Guinle, Rio de Janeiro RJ, Brazil.

Correspondence: Juliana Calvet Kallenbach Aurencao; Email: julianacka@hotmail.com.

Background: Carpal tunnel syndrome (CTS) was first described in 1854 and is characterized by pain, paresthesia and tingling in the hands, and in advanced cases, weakness with atrophy of the thenar region, being a frequent cause of disability and absence from work activities. Electroneuromyography is an accurate tool for diagnosis, making it possible to identify cases in the early stages. **Objective:** To detect patients in the early stages of the disease, through the correlation between the distal motor latency of the median nerve and complementary sensory tests of latency difference of the median nerve in the 1st and 4th fingers. **Methods:** Data from 159 exams were collected, with different indications. Motor neuroconduction of the median and ulnar nerves, and sensory neuroconduction of median, radial and ulnar nerves were performed. Exams with diagnosis of polyneuropathy were excluded. The SPSS program was used for statistical analysis. ROC curves and accuracy tests for diagnostic were performed. **Results:** The shortest motor latency of the median nerve found, with an accuracy of 81%, in the analysis of both the 4th and 1st fingers, was 3.3ms. On the 2nd finger, with an accuracy of 74%, it was

3.5ms. There is a large number of diseases that can simulate the symptomps of CTS, and several other illnesses can be associated with this disease. The electroneuromyography examination routinely begins with the motor neuroconduction of the median nerve, which is then, the first parameter of the examination to be analyzed. Then, followed by examination of the median sensory nerve in the 2nd finger. Complementary sensory tests are usually performed only in patients with high suspicion or indication for the diagnosis of CTS. The results above demonstrate that, when performing stimulation of the median motor nerve, latencies of 3.3ms demonstrated high specificity and sensitivity for detecting positivity in the latency difference tests between median and radial and ulnar nerves in the 1st and 4th fingers respectively. In the 2nd finger, the shortest motor latency for diagnosis was 3.5ms, being then affected later than in the other two tests above. **Conclusion:** When identifying a motor latency in the Median nerve of 3.3ms, complementary comparative tests must be performed, with the aim of identify cases of mild CTS, thus enabling early diagnosis and, consequently, early intervention.

Correlation between meningitis vaccination and mortality rates in Brazil: a retrospective analysis

Antonia Cardoso Silva[1], Júlio César Soares Barros[1], Larissa da Silva Almeida[1], Guilherme Carvalho de Souza[1], Raissa Nogueira de Souza[2], Mariana Reis Prado[1]

[1]Universidade Federal de Alagoas, Maceió AL, Brazil.
[2]Centro Universitário UniFTC, Salvador BA, Brazil.

Correspondence: Antonia Cardoso Silva; Email: antonia.silva@famed.ufal.br.

Background: Meningitis is an inflammation of the meninges, the membranes that surround the brain and spinal cord. The disease can be caused by viruses, bacteria, fungi, or parasites, posing a significant public health challenge due to high mortality rates and neurological complications. Vaccination, available in both public and private healthcare systems, is the most efficient way to prevent meningitis. However, the incidence of meningitis cases remains high. **Objective:** To evaluate the correlation of meningitis mortality with vaccination by region against serotypes A, C, W, Y, and 135 available in the public health system in Brazil from 2020 to 2022. **Methods:** The analysis was conducted through a cross-sectional, retrospective, and descriptive epidemiological study using data from the Mortality Information System (SIM/DATASUS) from 2020 to 2022. The assessment of meningitis mortality was performed by analyzing the variables "Region," "Outcome," "Immunobiologicals," and "Serogroup." **Results:** Between 2007 and 2009, the years prior to the implementation of meningitis vaccines in the vaccination schedule of the Unified Health System (SUS), there were 7,541 meningitis-related deaths in the country. In contrast, from 2020 to 2022, the same period after the implementation of the Meningococcal Conjugate - C and Meningococcal ACWY135 vaccines, the number of deaths was 2,861, a 62.06% overall decrease: 50% in the North, 64.97% in the Northeast, 63.94% in the Southeast, 55.26% in the South, and 66.60% in the Center-West, demonstrating the effectiveness of vaccination. The Center-West region had the highest proportional reduction, followed by the Northeast and Southeast, with variations possibly influenced by factors such as vaccination coverage, access to healthcare services, and socioeconomic conditions. Despite the undeniable effectiveness of vaccination, a notable finding was the linear increase in the number of deaths from 2020 to 2022, with 723 deaths in 2020, 785 in 2021, and 1,308 in 2022. This trend was associated with significant declines in vaccination rates (9,748,789 in 2020, 8,124,523 in 2021, and 8,681,157 in 2022), highlighting the need to strengthen vaccination campaigns. Additionally, there remains a considerable number of deaths associated with serogroups for which no vaccination is available in SUS, particularly serogroup B, responsible for 35 deaths from 2020 to 2022. Although these numbers are substantially lower compared to those covered by vaccination, they still represent an area of concern. **Conclusion:** This study evaluates the effectiveness of meningitis vaccination campaigns in reducing mortality, highlighting the significant reduction in deaths. It reinforces the importance of maintaining and expanding vaccination programs to cover additional serogroups in the vaccination schedule and strengthening efforts in surveillance, education and public health infrastructure in the fight against meningitis.

Correlation between microvascular changes in the retina and choroid with disease duration, severity, and cognitive deficits in migraine with and without aura

Luiz Felipe Mota Freitas[1], Leonardo Provetti Cunha[2], Mauro Eduardo Jurno[3], Márcio Alves da Cruz Júnior[1], Thiago Cardoso Vale[1], Lígia Barros de Oliveira[3]

[1]Universidade Federal de Juiz de Fora, Hospital Universitário, Juiz de Fora MG, Brazil.
[2]Universidade Federal de Juiz de Fora, Juiz de Fora MG, Brazil.
[3]Fundação Hospitalar do Estado de Minas Gerais, Belo Horizonte MG, Brazil.

Correspondence: Luiz Felipe Mota Freitas; Email: luizfelipemotafreitas@gmail.com.

Background: The thickness of the retina and choroid, as measured by optical coherence tomography (OCT), may reflect neurovascular changes in migraine patients. **Objective:** To evaluate the relationships between the changes identified by OCT and optical coherence tomography angiography (OCTA) in patients with migraine with aura (MA) or migraine without aura (MWA) and the duration and severity of the disease using the Headache Impact Test-6 (HIT-6) questionnaire and cognitive assessment through the Montreal Cognitive Assessment (MoCA). **Methods:** In this cross-sectional study, 16 patients with MA and 15 patients with MWA were compared with 16 healthy age-matched controls. **Results:** Foveal choroidal thickness was lower in individuals with migraine than in individuals in the control group ($p<0.05$). Statistically significant negative correlations were found between disease duration and total macular thickness ($p=0.037$; compared with the average thickness of the MWA group), ganglion cell complex (GCC) thickness ($p=0.017$; compared with the average thickness of the MWA group) and choroidal thickness ($p=0.039$; compared with the average thickness of the MWA group), as well as the HIT-6 score and the peripapillary retinal nerve fiber layer (pRNFL) thickness ($p=0.027$; compared with the mean thickness of the MWA group). **Conclusion:** Compared with controls, individuals with migraine showed a significant reduction in choroidal thickness. Our results showed that the longer the disease duration was, the thinner the total macula, GCC and choroidal thickness were. Additionally, the thickness of the pRNFL layer showed an inverse correlation with the disability caused by migraine.

Correlation between motor development and cognitive development in children with cerebral palsy

Môyra Aloia Romero[1], Jordan Paes de Almeida[1], Julia Mirella de Souza Monteiro Silva[1], Nicole Fernanda Bernardino[1]

[1]Centro Universitário UniMetrocamp Wyden, Campinas SP, Brazil.

Correspondence: Jordan Paes de Almeida; Email: almeidapjordan@gmail.com.

Cognitive capacity is closely linked to learning and adaptability in humans, serving as a fundamental component for the survival and evolution of the species. It provides full access to mental functions, which, in turn, enable adaptation to the environment through the monitoring and shaping of behaviors, conduct, and interactions. According to Vygotsky, cognitive development is directly related to social interactions and mental functions. Therefore, an individual does not socialize due to their cognitive development; rather, cognitive development occurs through socialization. Consequently, it is impossible to separate cognitive development from social interactions. Considering that motor development influences cognitive development through curiosity, feedback, reactions, and interactions with the environment, many authors advocate the correlation between the ability to learn and the ability to perform. Children with cerebral palsy (CP), also known as non-progressive chronic encephalopathy of childhood, are inserted in this context. Children with CP who have severe motor impairments (levels III to V on the GMFCS) are often pre-judged as intellectually disabled due to their motor disability. The lack of cognitive assessment methods for children with severe motor disabilities, especially those with significant language deficits, can lead to misinterpretations of their true cognitive abilities. This raises the question of what the actual cognitive development of children with CP might be. Knowing that learning is influenced by a stimulating environment, we must consider the cognitive stimuli present in their surroundings. Given this scenario, this research aims to propose the creation of two instruments to measure the intellectual capacity of children with CP: 1. An environmental analysis tool for school-aged children with CP to assess the daily cognitive stimulation affordances provided; 2. Assessment tools for evaluating the cognitive performance of children with CP. Children with CP can have normal or even above-normal intelligence, or they may have intellectual delays, not only due to brain lesions but also primarily because of a lack of experience and interaction with their environment. The delay in psychomotor development among disadvantaged children is largely attributed to growing up in environments lacking facilitative stimuli. In schools, there is often confusion between motor and cognitive deficits. In the inclusion process, educators may attribute learning difficulties to motor challenges as if they also indicate cognitive issues. Therefore, it is crucial to improve access to and understanding of the cognition of this group, promoting adequate interaction with the environment to positively impact the development and learning of these children.

Correlation between motor, non-motor, and cognitive functions with optical coherence tomography (OCT) in Parkinson's disease

Víctor de Oliveira Costa[1], Daniel de Oliveira Araujo[1], Leonardo Provetti Cunha[1], Thiago Cardoso Vale[1]

[1]Universidade Federal de Juiz de Fora, Hospital Universitário, Juiz de Fora MG, Brazil.

Correspondence: Victor de Oliveira Costa; Email: victordeoliveiracosta82@gmail.com.

Background: Patients with Parkinson's disease (PD) exhibit a wide range of visual disturbances throughout the course of the disease. Many of these visual deficits in PD patients occur due to mechanisms involving changes in retinal cells and layers. Optical coherence tomography (OCT) can non-invasively study different retinal layers and their thicknesses, showing a correlation with PD. **Objective:** To assess the total macular thickness and the

inner and outer retinal layers' thickness in patients with PD and to verify the correlation between these parameters with motor symptoms and cognitive function. **Methods:** Forty-six eyes of 23 PD patients and 40 eyes of 20 healthy controls (HC) were included. Cognitive, functional, and non-motor symptoms were assessed on all participants using the Katz Index of Independence and Pfeffer's of Activities for Daily Living (ADLs), Mini-Mental State Exam (MMSE), the Frontal Assessment Battery (FAB), Schwab & England (S&E) staging scales, and the Movement Disorders Society Nonmotor Symptoms Scale (MDS-NMS). Total, inner and outer OCT macular thickness measurements were recorded. We assessed the correlation between OCT parameters and cognitive, functional, and non-motor symptoms. **Results:** The values of the Katz, Pfeffer's ADL, and MMSE tests were significantly lower in PD than in HC. Total macular measurement was thicker in PD patients. The temporal and inferior outer sectors were significantly greater for the GCC thickness in patients. There was a significant correlation between total macular thickness and MDS-UPDRS-III values. Conversely, there was a negative correlation between outer macular thickness parameters and MDS-UPDRS-III values. There was a significant correlation between the total macular thickness and GCC thickness with MMSE, S&E, FAB, Katz's, and Pfeffer's ADL scores. In addition, the S&E scale correlates with outer macular thickness measurements. **Conclusion:** The total and inner macular thickness measurements at temporal and inferior outer sectors were higher in PD patients when compared to the control group. These findings suggest that macular measurements may be thicker in PD, especially when associated with mild motor symptoms. Additionally, we demonstrated a significant correlation between many total, inner, and outer OCT parameters with motor and non-motor symptoms and cognitive function impairment.

Correlation between postural control and sleep quality in patients with parkinson's disease: a cross-sectional study

Samuel Lidione da Silva[1], Alessandra Cattaneo Estrada Melanda[2], Rogério José de Souza[2], Amanda Lima Nogueira dos Anjos[2], Hayslenne Andressa Gonçalves de Oliveira Araújo[2], Milena Marie Matias Martins[1], Heloísa Freiria Tsukamoto[1], Suhaila Mahmoud Smaili[2]

[1]Centro Universitário Filadélfia, Londrina PR, Brazil. [2]Universidade Estadual de Londrina, Londrina PR, Brazil.

Correspondence: Samuel Lidione da Silva; Email: lidione67@gmail.com.

Background: Postural instability is an integral part of the characteristic motor tetrad of Parkinson's disease (PD) and significantly compromises the functional capacity, independence, and autonomy in this population. Among the various non-motor symptoms, sleep disturbances are very common, difficult to manage, and can also negatively impact physical, cognitive, and social domains. However, little is known about the relationship between postural control and sleep quality in individuals with PD. **Objective:** To correlate postural control and sleep quality in individuals with PD. **Methods:** This is a cross-sectional study, comprising of 42 individuals of both sexes, with mild to moderate disease staging, as assessed by using the modified Hoehn & Yahr scale. For the assessment of signs and symptoms, the Movement Disorder Society Unified Parkinson's Disease Rating Scale (MDS-UPDRS) was applied, and the cognitive status was assessed using the Mini-Mental State Examination. Postural control assessment was performed using the Mini Balance Evaluations Systems Test (MiniBESTest), and sleep quality as well as daytime sleepiness were evaluated using the following instruments: the Parkinson's Disease Sleep Scale (PDSS-2), the Pittsburgh Sleep Quality Index (PSQI), and the Epworth Sleepiness Scale (ESS). Pearson and Spearman correlation analyses were performed, according to data normality, considering a significance level of 5%. This study was approved by the Research Ethics Committee (CAAE: 45459521.6.1001.5188). **Results:** Participants had a mean age of 64.10±9.75 years, H&Y stage of 2.0 [2.0-2.5], and MDS-UPDRS II and III of 41.81±15.39, indicating mild to moderate severity. The final scores of postural control and sleep quality variables were: MiniBESTest = 22.62±2.47 - indicating good postural control (the maximum score is 28 points), PDSS-2 = 15.5 [7.8-22.5] - indicating good sleep quality (the maximum score is 60, and higher scores indicate poorer sleep quality), PSQI = 7.24±3.74 - indicating poor sleep quality (score >5 points), and ESS = 10.67±4.61, indicating excessive daytime sleepiness (score ≥10 points). Additionally, no statistically significant correlations were found between postural control and sleep quality. **Conclusion:** The study did not find any correlation between postural control and sleep quality. Although the PSQI suggested poor sleep quality, the PDSS-2, designed specifically for assessing sleep in PD individuals, did not indicate significant sleep impairment among the participants in this study. Similarly, no significant impairment in postural control was detected. Thus, an investigation into individuals in the mild to moderate phase of PD did not uncover any links between these outcomes. Further research is warranted in individuals in more advanced PD stages and utilizing objective sleep quality and postural control measures, to deepen our understanding of the relationship between sleep and postural control in individuals with PD.

Correlation between severity of ischemic stroke and levels of disability and functional dependence: a cohort study

Jéssica dos Santos Coelho[1], Maria Vitória Do Nascimento Silva[1], Maria Laura Lima da Silva[1], Joan Lins Serafim[1], Thiago Bezerra dos Anjos[1], Ana Luiza Sampaio Lopes[1], Américo Danúzio Pereira de Oliveira[1], Rita Di Cassia Oliveira Angelo[2]

[1]Universidade de Pernambuco, Serra Talhada PE, Brazil. [2]Universidade de Pernambuco, Garanhuns PE, Brazil.

Correspondence: Maria Vitória do Nascimento Silva; Email: vitoria.nsilva@upe.br.

Background: Stroke is the second leading cause of death globally and the third leading cause of loss of disability-adjusted life years. In Brazil, it is estimated that more than 2 million people are affected by stroke, of which nearly a quarter will be left with severe disability. The degree of functional disability may be associated with several factors, including the severity of the cerebrovascular event in the first 24 hours post-stroke. Therefore, prompt recognition of the magnitude of neurological damage and rapid therapeutic interventions can help modify the functional course of the disease. **Objective:** To analyze the relationship between the level of severity of ischemic stroke at hospital admission up to 24 hours post-stroke, and the course of functional capacity in three months, in patients at an emergency service in the city of Serra Talhada-PE . **Methods:** Cohort study, carried out between 2021 and 2023, which included patients diagnosed with stroke admitted to a public hospital in Serra Talhada-PE. Assessments took place at three stages: admission, discharge and after three months. The instruments used were the SUS individual registration form and the assessment scales NIHSS, TOAST, Modified Rankin Scale (ERm) and the Modified Barthel Index (IBM). **Results:** The sample consisted of 157 patients, predominantly male (n=89; 56.7%), aged between 61-80 years (n=86; 54.8%) and hypertensive (n=130; 82 .8%). Of these, 10.2% had moderate to severe disability (ERm≥3) and 11% had severe neurological deficit (NIHSS>22) on admission. The comparative analysis of the levels of disability and functional dependence between the moments of discharge and after three months, showed significant maintenance (p<0.001) of the moderate to severe level of disability and the moderate level of functional dependence, with a median IBM equal to 28 [10-45] in both evaluations. There were strong and significant correlations (p<0.001) between the level of stroke severity at admission and the degrees of functional dependence at discharge (p=0.77) and after three months of follow-up (p=0.61). It should be noted that none of the patients received reperfusion therapy or thrombectomy. **Conclusion:** There is a bidirectional and proportional relationship between the level of stroke severity at admission and the degree of functional dependence and post-stroke disability at three months of follow-up. Patients undergoing reperfusion therapy with thrombolytics or mechanical thrombectomy have a greater chance of a favorable outcome, both in the NIHSS at discharge and in the Rankin scale score after three months. The establishment of a specialized stroke unit can be a useful tool in the effective and efficient in-hospital treatment of stroke, reducing the morbidity and mortality of this event. Such results demonstrate the importance of implementing strategies to reduce the impact of this event on the lives of affected patients.

Correlation between sleep and kinematic gait parameters in people with parkinson's disease

Nathalia de Oliveira Franco[1], Alessandra Cattaneo Estrada Melanda[1], Andressa Leticia Miri[1], Amanda Lima Nogueira dos Anjos[1], Amanda dos Santos Siqueira[1], Denise Bolonhezi Ribeiro[1], Suhaila Mahmoud Smaili[1], Rogério José de Souza[1]

[1]Universidade Estadual de Londrina, Londrina PR, Brazil.

Correspondence: Nathalia De Oliveira Franco; Email: nnatfrancos@outlook.com.

Background: Sleep disorders are highly prevalent in individuals who have Parkinson's disease and negatively impact their quality of life in addition to various other symptoms such as gait freezing, cognitive disorders, mood disorders, and fatigue. However, little is known about the relationship between sleep quality and objective gait parameters. **Objective:** To correlate sleep disorders with the gait of individuals with Parkinson's disease. **Methods:** This is a cross-sectional study that included 24 individuals with a confirmed diagnosis of idiopathic Parkinson's disease according to the London Brain Bank criteria, in mild to moderate staging, and without cognitive deficits. The kinematic gait evaluation was conducted using the Optitrack system under simple gait and cognitive dual-task conditions. The gait parameters analyzed were step length, step width, cadence, maximum ankle angle, vertical center of mass displacement, and gait speed. Sleep quality was assessed using the Parkinson 's Disease Sleep Scale-2 (PDSS-2), Pittsburgh Sleep Quality Index (PSQI), and the Epworth Sleepiness Scale (ESE). The study was approved by the ethics and research committee (CAAE: 72474923.3.0000.5231). The significance level adopted was 5%. **Results:** Regarding simple gait, moderate correlations were found between the following variables: step width with the disturbed sleep domain of the PDSS-2 (r=-0.42; p=0.04); vertical center of mass displacement with the total PDSS-2 score (r=-0.51; p=0.01); and gait speed with the sleep duration domain of the PSQI (r=-0.57; p<0.01). For dual-task gait, moderate correlations were observed between the following variables: maximum ankle angle and the total PDSS-2 score (r=-0.45; p=0.02); vertical center of mass displacement with the total PDSS-2 score (r=-0.46; p=0.02); step width with the daytime dysfunction domain of the PSQI (r=-0.43; p=0.03); gait speed and the sleep duration domain of the PSQI (r=-0.55; p<0.01); and gait speed and the total PSQI score (r=-0.42; p=0.03). No correlation was found between daytime sleepiness, as

assessed by the ESE, and gait parameters. **Conclusion:** Individuals with Parkinson's disease who have poorer sleep quality exhibited worse parameters in both simple and dual-task gait, such as reduced step width, speed, and vertical center of mass displacement. Thus, further studies are needed to investigate the relationship between gait and sleep, especially longitudinal cohort studies. The importance of adequate investigation of sleep disorders in this population for effective treatment is emphasized.

[3]Universidade Federal do Mato Grosso, Cuiabá MT, Brazil.
[4]Faculdade Santo Agostinho de Vitória da Conquista, Vitória da Conquista BA, Brazil.
[5]Universidade Luterana do Brasil.

Correspondence: Lucas Drummond Savassi Stehling; Email: lucasstehling0541@gmail.com.

Background: Depression is the most common psychiatric repercussion in patients after a stroke. **Objective:** To analyze the relationship between serum vitamin D levels and post-stroke depression (PSD), which is not yet fully understood. **Methods:** MEDLINE, Scopus and Web of Science databases were systematically searched until august 02, 2023. Data were examined using the Mantel-Haenszel method and 95% CIs. Heterogeneity was assessed using I2 statistics. Meta regression analysis was conducted to evaluate a possible link between vitamin D deficiency and post-stroke depression. R, version 4.3.2, was used for the statistical analysis. **Results:** Nine studies and 637 patients were included in this meta-analysis. In the Hamilton Rating Scale for Depression (HAMD-17) vitamin D deficiency was statistically correlated with post-stroke depression (MD = -7.62 [-13.02; -2.23]; p<0.01; I2 = 83%). Conversely, in the general analysis with Beck's Depression Inventory (BDI-II), Montgomery Asberg Depression Rating Scale (MADRS), Patient Health Questionnaire (PHQ-9) and HAMD-17 there was no significant correlation between vitamin D deficiency and post-stroke depression (MD = -3.12 [-6.74; 0.49]; p=0.090421; I2 = 89%). **Conclusion:** In this updated meta-analysis, no significant correlation between vitamin D deficiency and post-stroke depression was found. Nevertheless, the sub-group HAMD-17 analysis showed a correlation between these two groups. Consequently, further studies are necessary to solve this controversy regarding different depression scales in order to identify the real role played by vitamin D in post-stroke depression.

Correspondence: Emanuel Rodrigues Guimarães; Email: emanuelrg.inst@gmail.com.

Background: Alzheimer's disease (AD) pathophysiology is complex and not completely known. Emerging new biomarkers that evaluate synaptic function (VILIP-1, neurogranin), co-pathology (alpha-synuclein), and neurodegeneration (NFL) are potential candidates to be incorporated into the early AD diagnosis. **Objective:** To better understand the relevance of these biomarkers, we evaluated the correlations between their CSF concentrations with whole-brain grey matter volumes in SCD and MCI, according to their amyloid status (A- or A+). **Methods:** 75 participants diagnosed with SCD or MCI were included, 30 A- and 45 A+. They all underwent comprehensive neuropsychological assessment, CSF analyses (Roche Elecsys), and volumetric 3T MRI (Philips Achieva). Voxel-based morphometry was used to quantify brain volumes through CAT12 running on MATLAB 2019b. Partial correlation analysis between CSF biomarkers and cortical volumes was performed with SPSS 22, adjusting for age and sex. **Results:** Significant correlations were found in the A- but not in the A+ group. NFL and hippocampus (r=0.40, p=0.028); VILIP-1 and superior temporal gyrus (r=-0.38, p=0.035), and superior frontal gyrus (r=-0.40, p=0.025); alpha-synuclein and hippocampus (r=-0.39, p=0.036), middle frontal gyrus (r=-0.375, p=0.049), and superior temporal gyrus (r=-0.478, p=0.01). **Conclusion:** We found different patterns of correlations between brain anatomy and emerging biomarkers, according to amyloid status, in the very early stage of the neurodegenerative process. Interestingly, these correlations were found only in the amyloid-negative group, which might suggest that different pathological processes involving synaptic function, neurodegeneration, and co-pathology occur in suspected non-Alzheimer pathophysiology cases.

Correspondence: Diogo Rabelo de Lima; Email: diogo.rabelodelima@gmail.com.

Case presentation: E.S.M., a 66-year-old male with a history of diabetes, hypertension, and chronic kidney disease, was admitted on May 21, 2023, presenting with advanced peripheral arterial disease and sepsis due to secondary bacterial infection in the left foot. He developed acute kidney injury and hypotension, requiring high doses of noradrenaline due to inadequate blood pressure improvement. On June 10, 2023, he was transferred to the ICU following a seizure episode. A cranial CT scan revealed bilateral cortical lesions with gyral distribution in the frontoparietal region, characteristic of cortical laminar necrosis (CLN). **Discussion:** Cortical laminar necrosis involves neuronal destruction due to decreased oxygen and glucose supply to the nervous tissue, typically occurring in conditions such as cardiac arrest, generalized hypoxia, hypoglycemia, hematologic disorders, and status epilepticus. Cortical neurons are particularly vulnerable due to their high metabolic activity compared to glial cells and adjacent white matter, with the third layer of the cortex composed of pyramidal cells being especially susceptible to metabolic stress. It is important to differentiate CLN from other conditions such as cortical hyperintensities in T1-weighted MRI or cortical calcifications following ischemic stroke, as CLN exclusively affects the cortex without involvement of subcortical white matter. On CT imaging, CLN appears days after the event as a hyperdensity following the gyri of the cerebral cortex in a linear pattern, devoid of hemorrhage or calcification. In MRI, T1 hyperintensity is characteristic due to denatured proteins and lipid-laden macrophages, distinguishing it from other pathologies. T2/FLAIR sequences typically show isointensity to hyperintensity. **Final comments:** The cerebral cortex integrates sensory inputs and initiates voluntary motor responses, underscoring its pivotal and intricate role. Therefore, understanding the pathophysiology and neuroimaging characteristics of cortical laminar necrosis is crucial. This knowledge facilitates accurate differential diagnosis in cases with similar clinical and radiological features, particularly in emergency and intensive care settings where cerebral energy depletion is common. Identification of CLN serves as a prognostic indicator for neurological outcomes, highlighting its significant implications in patient management.

Correspondence: Laís Brandão Mota; Email: bmota.lais@gmail.com.

Background: The Clinical Protocol and Therapeutic Guidelines (PCDT) is a technical guide that establishes criteria based on scientific evidence for the diagnosis, treatment, and monitoring of specific diseases and health conditions. This work was part of the Journey of Value for Patients with Rare Diseases (JAV-RARAS) project. The JAV-RARAS study presents an innovative approach to understanding the real costs of rare disease care in Brazil. **Objective:** To map the care journeys of patients with Amyotrophic Lateral Sclerosis (ALS) in a specialized healthcare facility and compare them with the PCDT recommendations established by the Ministry of Health. For this, the Time-Driven Activity-Based Costing (TDABC) methodology was used. **Methods:** JAV-RARAS employs the TDABC methodology to assess the costs associated with the management of rare diseases. Through interviews and process analyses, the actual annual costs of managing patients with ALS in the specialized service were identified. The costs defined by the PCDT were compared to the current clinical practice observed in the service. This made it possible to evaluate the adherence of real costs to the standards established in the PCDT and identify opportunities to optimize ALS management. **Results:** Preliminary results showed that the actual annual cost at the institution was $7,506.20 per patient per year, while the estimated cost according to the PCDT was $8,054.67. Furthermore, the estimated cost of treatment by the PCDT ($7,262.04) is also close to the actual cost charged by the institution ($7,238.15). Regarding the source of

the resources, it was found that 98.3% were funded by the Unified Health System (SUS), 0.80% by the patient, and 0.88% by the institution itself. These results indicate an alignment between the costs estimated in the PCDT and those observed in clinical practice. **Conclusion:** The average annual cost per ALS patient in the specialized service was close to the value reported in the study, but with differences in the composition of these costs. This is mainly due to variations in the use of drug therapies and the need to refer certain surgical procedures to other centers, which can generate additional costs not accounted for locally. The TDABC methodology demonstrates its potential to support the review of policies and protocols, aiming in the efficient allocation of resources in the care of rare diseases such as ALS.

Costs of hospitalizations for the treatment of acute ischemic and hemorrhagic stroke in the state of São Paulo between 2019 and 2023

Background: Stroke, whether ischemic or hemorrhagic, is one of the leading causes of morbidity and mortality worldwide. Despite the identification of modifiable risk factors such as hypertension, smoking, and obesity, stroke continues to pose a significant challenge for healthcare systems, especially in terms of resource management and economic impact. In the state of São Paulo, the most populous region in Brazil, the high incidence of stroke necessitates a thorough understanding and analysis of hospitalizations and associated treatment costs, highlighting the importance of an organized and efficient care system for successful treatment outcomes. **Objective:** To analyze healthcare costs related to stroke in the state of São Paulo between 2019 and 2023. **Methods:** This ecological study utilized data obtained from the Hospital Information System of the Brazilian Unified Health System (SIH/SUS) through the Department of Informatics of the Brazilian Unified Health System (DATASUS). Data acquisition, organization, and tabulation were performed using Google Sheets, encompassing the number of cases, duration of hospitalizations due to stroke in São Paulo, average cost per hospitalization, total cost, and mortality rate from 2019 to 2023. **Results:** The analysis included a total of 208,190 hospitalizations, with an average hospital stay of 8 days, irrespective of ward or ICU admission, resulting in an average cost of R$ 1,769.63 per hospitalization. Consequently, direct costs alone amounted to R$ 368,419,830.80 for the state. Additionally, 35,162 patients died, with a mortality rate of 16.89%. There was a 3.2% reduction in the number of cases in 2020 (38,616 cases) compared to 2019 (39,907 cases). However, costs increased from R$ 58,015,826 in 2019 to R$ 60,886,962.95 in 2020, representing a 4.95% increase. This cost increase continued despite the minimal increase in the number of cases, reaching R$ 94,721,716.99 in 2023, with 45,651 cases, the year with the highest number of hospitalizations. **Conclusion:** The study revealed a discrepancy between the number of stroke cases and the associated treatment costs in the state of São Paulo between 2019 and 2023. Despite the reduction in the number of cases in 2020 compared to 2019, there was a consistent increase in direct costs, possibly due to the increased complexity of cases, inflation in medical supply prices, and changes in hospital management practices in response to the COVID-19 pandemic. The high mortality rate underscores the severity of stroke, emphasizing the importance of effective public policies for prevention, focusing on risk factors to reduce hospitalizations. Moreover, it is imperative that health policies be adjusted to optimize the cost-effectiveness of stroke treatment, ensuring the sustainability of the healthcare system and improving patients' quality of life.

Could coinfection accelerate htlv-1-associated myelopathy/tropical spastic paraparesis (HAM/TSP) onset?

Ana Flávia Novaes[1], Davi Tanajura Costa[1], Fernanda Khouri Barreto[1], Qesya Rodrigues Ferreira[1], Jéssica Oliveira de Souza Nascimento[1], Carolina Souza Santana[1], Ariana Leal Borges da Cruz[1], Rebeca Leão Amorim[1], Alice Palmeira Nascimento Cerqueira[1], Felipe de Oliveira Andrade[1]

[1]Universidade Federal da Bahia, Vitória da Conquista BA, Brazil.

Correspondence: Ana Flávia Novaes; Email: anaflavia635@gmail.com.

The human T-cell lymphotropic virus type 1 (HTLV-1) is a retrovirus that infects human cells and causes severe diseases. It is estimated that more than 5 to 10 million people worldwide are infected with this virus. This viral infection can affect the central nervous system, leading to HTLV-1-associated myelopathy/tropical spastic paraparesis (HAM/TSP). Additionally, as a sexually transmitted infection, there is a prevalence of coinfections with other viruses. However, the relationship between coinfections and neurological clinical outcomes has not yet been well studied. This quantitative cross-sectional study was carried out with people living with HTLV-1 and with another infection (HIV, HBV, HCV, or syphilis), monitored in a Sexually Transmitted Infections Reference Center in Bahia, Brazil, from March 2023 to May 2024. Data were obtained by analyzing medical records and during neurological examination. The statistical significance analyses were performed using Fisher's exact test with SPSS software v. 27. A total of 110 patients were evaluated, with 82 (74.5%) classified as non-HAM/TSP and 28 (25.4%) as HAM/TSP. The mean age of the non-HAM/TSP patients was 48.66±16.78 years, with 65 (80%) female. The mean age of the HAM/TSP patients was 56.46±19.75 years, with 21 (75%) being female. From this sample, 32 (29%) patients were coinfected. Half of the HAM/TSP patients (14, or 50%) exhibited coinfection, with a statistically significant difference between groups ($p<0.0001$). Syphilis was the most prevalent co-infection in the HAM/TSP group (25%), followed by HBV (18%), tuberculosis (14%), HIV (10%). HCV and HTLV-2 (3%). with a statistically significant difference noted between groups ($p<0.01$) in those co-infected with syphilis, HBV, and tuberculosis. The presence of diabetes was observed in 1 (3%), hypertension in 7 (25%), memory impairment in 6 (21%). and muscular pain in 7 (25%), all of which were proportionally higher in the myelopathy group, with statistical significance noted in the pain category ($p<0.01$). The role of each co-infection in HAM/TSP outcome is not yet completely clarified. Diseases caused by different pathogens, including HTLV-1, may involve an exacerbated immune response. Studies have shown that syphilis is an independent risk factor for HTLV-1 infection in males and females. In a Brazilian study, tuberculosis was associated with an increased risk of HAM/TSP development, maybe because of the change in immunological response. Some studies suggested that patients with HTLV-1 or HTLV-2 and HIV coinfection have worse clinical outcomes compared to other coinfections, in addition to having a higher mortality rate, also increasing the likelihood of developing neurological manifestations such as HAM/TSP. This study sheds light on the potential role of coinfections in amplifying the risk of HAM/TSP development. Data regarding co-infections' impact on HTLV-1 outcome is extremely limited and more studies are needed.

COVID-19 and vascular complications: case analysis of ischemic stroke in the artery of percheron

Melissa Caroline Godoi Prestes[1], Luan Yudi Prando Kasuga[1], Bruna Beppler[1], Ádria Rodriges da Silva[1], Lia Maki Hatisuka Imai[1], Caroline Zapelini[1], Gabriel Rodrigues Espelho Rossi[1]

[1]Universidade Estadual de Londrina, Londrina PR, Brazil.

Correspondence: Melissa Caroline Godoi Prestes; Email: melissa.caroline@outlook.com.

Case presentation: An 83-year-old woman with a history of hypertension presented with mild diarrhea, rhinorrhea, cough, asthenia, and decreased functionality for three days. She was brought to a tertiary care center by emergency medical services due to a decreased level of consciousness. Family members reported that the patient fell asleep in the afternoon and did not wake up. On physical examination, she scored 3 on the Glasgow Coma Scale, exhibited global hyporeflexia, and had bilateral lung crackles. She was diagnosed with Covid-19 following a positive rapid antigen test. Chest computed tomography (CT) revealed bilateral consolidative foci. Cranial CT indicated a bilateral thalamic ischemic stroke, with well-defined hypodense areas in the medial thalami and the rostral midbrain, suggestive of recent ischemic lesions. The patient developed bilateral convergent strabismus, right hemiparesis, fluctuating consciousness levels, episodes of anisocoria and static gaze, dysphagia, productive cough, and progressively worsening lung crackles. She underwent a prolonged hospital stay, requiring intensive care, and experienced significant clinical deterioration, leading to a decision to limit support, resulting in death after approximately three months of hospitalization. **Discussion:** The artery of Percheron is a rare anatomical variation where a single artery supplies the paramedian thalamus and the majority of the rostral midbrain bilaterally. Occlusion of this artery results in bilateral thalamic ischemic stroke, characterized by severe symptoms. In Covid-19 patients, acute cerebrovascular diseases are relatively common, especially in individuals with pre-existing vascular risk factors, such as hypertension. Ischemic strokes are most frequently associated with Covid-19 due to pathophysiological mechanisms that include hypercoagulable states, vasculitis, and cardiomyopathy. **Final comments:** Ischemic stroke of the artery of Percheron is rare in the general population and poorly documented in Covid-19 patients. Considering the influences of Covid-19 infection, it is a significant risk factor for thrombotic events. Therefore, this case underscores the importance of recognizing extrapulmonary symptoms in patients with severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2).

COVID-19 pandemic and sleep quality in medical students at university of Ribeirão Preto

Lara Helena Graña Uzun[1], Luisa Hasimyan Ferreira[1], Nathália Novaretti[1]

[1]Universidade de Ribeirão Preto, Ribeirão Preto SP, Brazil.

Correspondence: Lara Helena Graña Uzun; Email: anauzun@gmail.com.

Background: Among young adults, medical students have a special place in the populations with the highest risk factors for worse mental health, sleep deprivation, and sleep disorders. In this context, the impact of social isolation and the magnitude of the COVID-19 pandemic may have deteriorated pre-existing mental disorders and the physical health of these young people. However, there are still few Brazilian studies about the impact of the pandemic on this population. **Objective:** Evaluate the impacts of the pandemic on sleep quality and its related factors among medical students. **Methods:** Analytical cross-sectional study, in a single center. Information was collected from a questionnaire created using Google Forms and applied to medical students at the University of Ribeirão Preto between June and August 2021. **Results:** We collected 212 responses. The vast majority of students reported a drop in academic performance (76.4%) and mental health (82.5%), while 71.7% correlated this last topic to a drop in quality of life and/or academic performance. It is identified that the decrease in academic performance was mainly due to difficulty concentrating in front of computer screens (51.8%), lack of motivation (36.9%), external interference during classes (10.1%) and others (1.2%). 9.4% of the students also brought as challenges the difficulty in not picking up the cell phone during classes, workloads at night, lack of perspective in the world, fear and insecurity and a demotivating environment. Among the future doctors, only 39.2% continued to practice physical activities during the pandemic. Among those interviewed, 65.5% reported worsening of previous sleep disorders, diagnosed or not, with insomnia being the most prevalent. Regarding sleep hygiene, only 41.5% didn't know the method, while 59.1% performed it when they were unable to sleep. 58.9% confirmed the use of stimulants to stay awake. There was also evidence of a worsening in mental health (82.5%) during the period of social isolation and, despite this, 66.1% did not receive psychological counseling. It is also believed that the worsening of mental health is closely linked to the worsening of quality of life and/or academic performance during the isolation period (71.7%). **Conclusion:** The consequences of the pandemic on the quality of sleep and health of medical students are evident, and are bidirectionally associated with the physical and mental health of students. Therefore, not only their academic performance was affected, but the quality of our future professionals is at risk, making this a public health problem. New studies will be needed to assess whether this change was temporary or not, so that support and guidance measures should be applied in medical schools.

Case presentation: A 43-year-old white man presented with diplopia in July 2021 while looking in multiple directions. The patient was diagnosed with paralysis of the VI nerve on the right, and the ophthalmologist indicated treatment with orthoptics without resolution of the diplopia. She went to a neurologist and performed cerebrospinal fluid (CSF) analysis and magnetic resonance imaging (MRI). CSF examination on 30/07/2021 detected oligoclonal IgG band with excluded infections. An MRI scan in August 2021 showed a lesion with hypersignal on T2/FLAIR sequences in the integment of the pons in the topography of the nucleus of the VI cranial nerve on the right. As a result, he sought a specialist in demyelinating diseases with the suspicion of Multiple Sclerosis. Neurological examination showed recovery of ocular motility, and a deviation of the labial commissure was observed on the left, resulting in facial nerve involvement. Given the atypical location of the lesion, the biomarkers anti-aquaporin 4 (AQP4-AB) and anti-oligodendrocyte myelin glycoprotein (MOG-AB), positive for MOG-AB, were requested. On 15/01/2022, a new MRI showed an elongated hypersignal plaque with enhancement located in the middle of the cervical cord at the level of C5-C6, extending longitudinally for 8.5mm. In November, she presented a new outbreak with myelitis, with paresthesia and hypoesthesia in the right lower limb ascending to the abdomen. A new MRI was performed, which showed an increase in the cervical plaque and dorsal lesion at the level of D7. The patient underwent corticosteroid therapy with complete remission of spinal cord symptoms. In 2024, he started preventive treatment with Azathioprine 100mg/day. At the last follow-up on this occasion, the neurological examination was normal. **Discussion:** This study aims to report a case of MOG-AB positive disease (MOGAD) with rare brainstem (pons) involvement associated with myelitis in a context of differential diagnosis with multiple sclerosis. MOGAD is a recently described disease in patients with neuromyelitis optica and high-risk syndromes (transverse myelitis and optic neuritis) that are AQP4-AB negative but MOG-positive. It is a rare disease with an estimated annual incidence of 1.6 to 3.4/million people worldwide. The clinical manifestation presented in this case report is a rare presentation of MOGAD that is present in only 8-10% of reported cases. An article published in 2019 presented 3 case reports with cranial nerve syndrome in Mog-IgG positive patients, among them an association of the sixth and seventh cranial nerves with pons involvement in the nucleus region of the respective pairs. **Final comments:** Because it is a rare disease, it is extremely important to recognize atypical symptoms such as cranial nerve involvement associated with unilateral myelitis in cases of MOGAD. In the case reported here, we presented a patient with MOGAD initially characterized by cranial nerve injury with recurrent course and myelitis.

Cranial nerves palsy due to pneumococcal meningitis: a case report

Yan Victor Araújo Rodrigues[1], Leandro Alves Mendes[1], Juliana Gaigher Gonçalves[1], Eliaquim Ribeiro de Oliveira[1], Beatriz Borba Casella[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Yan Victor Araujo Rodrigues; Email: yanvictorped@gmail.com.

A previously healthy 1 year and 2 months-old male child presents with fever and phlegm cough. He is taken to a pediatric visit on the fourth day of symptoms, when a macrolide and an antipyretic are prescribed, under the hypothesis of bacterial tonsillitis. On the sixth day of illness, he is again evaluated by a pediatrician, due to persistence of fever, and a restriction in the abduction of the left shoulder. Through an ultrasonography, an infectious arthritis was ruled out. The following day, the infant is once again taken to medical evaluation, for repeated vomiting, being once more discharged, this turn with antiemetics. After less than 24 hours, the patient develops fluctuation between drowsiness and irritability, neck stiffness and altered eye movement, which carries out hospitalization due to the hypothesis of acute meningoencephalitis. The initial neurological assessment exhibited wakefulness and behavior oscillations, mydriasis, divergent strabismus and right-sided ptosis. Furthermore, there was an infranuclear facial paralysis on the right side and a left hemiparesis with crural predominance, with an ipsilateral Babinski sign. In addition, behavior arrest seizure types are witnessed, requiring intravenous benzodiazepines Prior to initiating broad coverage for acute infectious meningoencephalitis (ceftriaxone, vancomycin and acyclovir), cerebrospinal fluid was collected, with results compatible with bacterial meningitis: pleocytosis of 2,240 cells/mm^3 (61% being neutrophils), high protein level (184mg/dL) and low glucose count (<5mg/dL). The bacterioscopic examination of the CSF showed gram-positive diplococci and, in spite of negative culture testing, the real-time polymerase chain reaction (RT-PCR) detected Streptococcus pneumoniae. Brain and cervico-thoraco-lumbar magnetic resonance imaging, performed when the patient already was on the twelfth day of antibiotics, showed dilation of the supratentorial ventricular system, with bilateral pyogenic ventriculitis. The electroencephalogram was normal. With regards to previous medical history, the child had 2 doses of 10-valent pneumococcal conjugate vaccine, at 2 and 4 months of age. However, he had not yet received the third (booster) dose scheduled for 12 months-old. During the subsequent days after initiation of antibacterial therapy, the child first improved mydriasis, divergent strabismus and peripheral facial paralysis. Thenceforth, the infant showed resolution of right hemiparesis. Upon being discharged from the hospital, after completing 14 days of ceftriaxone and vancomycin, however, a discreet eyelid ptosis on the right side remained.

Creation of a university EEG study group to collaborate with medical education in electroencephalography with the democratic Republic of Congo, Africa

Maria Emilia Cosenza Andraus[1,2], Prince Kazadi[3], Augusto Cesar Marques Santiago[2], Ange-quentin Bedel Togbe[2], Candy Mbuyamba[2], Möise Lubendo[3], Daniel Tshiyuk[3], Nazaire Kimponto[3], Cesar Fantezia Andraus[1,2], Arjune Sen[4,5]

[1]Universidade Federal do Rio de Janeiro, Instituto de Neurologia Deolindo Couto, Rio de Janeiro RJ, Brazil.
[2]Universidade Federal do Rio de Janeiro, Centro de Ciências da Saúde, Faculdade de Medicina, Rio de Janeiro RJ, Brazil.
[3]Epilepsy Awareness Foundation, Democratic Republic of Congo.
[4]University of Oxford, Oxford Epilepsy Research Group, Nuffield Department of Clinical Neurosciences, Oxford, United Kingdom.
[5]University of Oxford, Wolfson College, The Centre for Global Epilepsy, Oxford, United Kingdom.

Correspondence: Maria Emilia Cosenza Andraus; Email: cosenzaandraus@yahoo.com.

Background: The Democratic Republic of Congo (DRC), a large country located in Central Africa, has a population of around 105 million people. It is the 14th most populous country in the world and it is estimated that more than a million Congolese people have epilepsy. According to data from the Epilepsy Awareness Foundation for the DRC (ASLEK), the country has only ten neurologists, who concentrate their work mainly in large cities. There is a marked lack of equipment, such as electroencephalograms (EEGs), to aid the diagnosis of epilepsy. Previously, there were only five EEG machines to serve the entire population. In addition, there was a lack of local training and continuing education related to performing and interpreting EEG, making it necessary for clinicians to seek this from outside the country. **Objective:** To collaborate with continuing Medical Education in EEG with the DRC through the creation of a University Study Group. **Methods:** From May to July 2023, after contact from a group of doctors from the DRC requesting collaboration in training on performing and interpreting EEG, a University Extension Action was carried out under the title "Extension Course on Electroencephalography

and Video-Electroencephalographic Correlation of the Main Epileptic Syndromes in Adults and Children". The Action, registered with the Pro-Rectory of Extension of the Federal University of Rio de Janeiro (PR-5/UFRJ), Brazil, was delivered remotely to overcome barriers relating to travel and other costs. Training was directed to this group of doctors, who serve people with epilepsy in rural and poor setting areas and who already had basic working knowledge relating to EEG. **Results:** A Study Group was created, enlisting three undergraduate medical students already enrolled at our Faculty of Medicine in Brazil - one from the DRC, one from Benin (both French-speaking African countries) and one from Brazil. The final group was coordinated by a professor of clinical neurophysiology (MA) and included three professors (from the areas of neurology, clinical neurophysiology and neurosurgery), three undergraduate medical students and four doctors from the DRC (neurology and general medicine). The course was taught in English and the medical students helped in facilitating communication between MA and the French-speaking participants when this was necessary. Two-hour remote theoretical classes covered topics from the neurophysiological bases of EEG to its applications and clinical interpretation. The total time spent delivering the course was 24 hours. Also, through this Action, a Brazilian EEG company donated an EEG equipment to the DRC and a virtual workshop to use this equipment was held. **Conclusion:** The Extension Action has allowed the creation of a University Study Group that has been collaborating effectively with doctors in the DRC to deliver sustainable Medical Education in EEG.

Creutzfeldt-Jakob disease (CJD): two-cases report

Elisangela Ferraz Pazinato[1], Alex Eduardo da Silva[1], Ana Luisa Rufino de Sousa[1], Giovani Zago Borges[1], Luiza Barbosa de Oliveira[1], Amanda Soares Pimenta[1], Daniela Aparecida Lima Viana[1], João Henrique da Matta Clementino[1]

[1]Universidade Federal do Triângulo Mineiro, Hospital de Clínicas, Uberaba MG, Brazil.

Correspondence: Elisangela Ferraz Pazinato; Email: elisangelapazinato@gmail.com.

Case presentation: Case 1: Female, 57 years old, 3 months before inpatient admission, presented progressive drowsiness, mental confusion, gait ataxia, myoclonus, tremors of the extremities and dysarthria. Magnetic resonance imaging (MRI) of the skull showed areas with restricted diffusion in the thalamus, putamen, caudate and globus pallidus bilaterally, as well as in the frontal neocortex. The electroencephalogram (EEG) showed a rapid temporal rhythm on the right hemisphere, sometimes bilateral, and diffuse disorganization of the tracing. Cerebrospinal fluid (CSF) analysis was positive for search of 14-3-3 protein. Case 2: Male, 77 years old, 18 days before admission, began with blurred vision associated with memory changes followed by slowed speech, difficulty walking and involuntary movements of the right upper limb with progression to the left upper limb. Skull MRI performed at an external service was reported without changes. The 14-3-3 protein was positive in CSF analysis. **Discussion:** Creutzfeldt-Jakob disease (CJD) is a rare, incurable neurodegenerative pathology with a poor prognosis and one of the causes of rapidly progressive dementia. In addition to cognitive impairment, patients with CJD may present with cerebellar, pyramidal and extrapyramidal motor, visual, and psychiatric symptoms. The sporadic form is the most common. Complementary exams such as cranial MRI, EEG and CSF analysis for the 14-3-3 protein are useful in investigating possible and probable CJD, but the definitive diagnosis is obtained from histopathological analysis of the central nervous system. **Final comments:** Although CJD is rare, it should always be considered as a differential diagnosis when suspected of rapidly progressive dementia.

Creutzfeldt-Jakob disease Heidenhain variant: case report with progressive cognitive decline recorded by videos

Rafael Santalena Brambilla[1], Rosana Carandina-Maffeis[2], Hilton Mariano da Silva Júnior[1], Caroline Moraes Tapajós Bolzani[2], Pedro Neves Fortunato[2]

[1]Pontifícia Universidade Católica de Campinas, Campinas SP, Brazil.
[2]Hospital Municipal Dr. Mário Gatti, Campinas SP, Brazil.

Correspondence: Rafael Santalena Brambilla; Email: rafael.bramba@gmail.com.

Case presentation: A 67 year old woman was admitted to the emergency room with a report of "seizures and dementia for 1 month". The condition started, in August 2020, with a decrease in visual acuity. Her son recorded the evolution of the disease in videos on his mobile phone. The patient got worse with inability to reach and to identify objects, optical apraxia, psychomotor slowing, abnormal repetition of acts and impairment of judgment. The first nuclear magnetic resonance (MRI) of the brain was normal and the electroencephalogram (EEG) was performed, with diffuse slowing of the baseline activity. She progressed with intermittent myoclonus and abulia. Extensive investigation for encephalitis was normal. Treatment with acyclovir and pulsetherapy with methylprednisolone were performed. A new brain nuclear magnetic resonance showed restricted area in the diffusion and T2 / FLAIR hypersignal exclusively cortical involving both hemispheres. Also new electroencephalogram showed generalized periodic discharges. The 14-3-3 protein was detected in her cerebrospinal fluid (CSF). The patient died 4 months after the onset of the condition due to infectious complications. **Discussion:** Creutzfeldt-Jakob disease (CJD) is a rapidly progressive neurodegenerative disorder. Heidenhain's variant has isolated visual symptoms that persist even without any cognitive decline for a few weeks. The video recording of the patient allows a detailed analysis of the clinical evolution and becomes an important complementary diagnostic tool. **Final comments:** The Heidenhain variant of CJD should be considered a differential diagnosis in all patients who have isolated visual complaints, especially if associated with cognitive complaints.

https://doi.org/10.5327/CBN240485

Creutzfeldt-Jakob disease in Brazil: a review of its profile and notification mechanisms

Vinícius Bacelar Ferreira[1], Érica Giovanna de Souza Biváqua[1], Felipe Alves de Paiva[1], Pietra Amorim Cerquinho Oliveira[1], Riesly de Oliveira Vasconcelos[1], Ronilson Ferreira Freitas[1]

[1]Universidade Federal do Amazonas, Manaus AM, Brazil.

Correspondence: Vinícius Bacelar Ferreira; Email: viniciusbacelarferreira@gmail.com.

Creutzfeldt-Jakob disease (CJD) is a rare and fatal neurodegenerative condition, characterized by a rapidly progressive dementia. CJD is on compulsory notification list of diseases by the Health Ministry in Brazil and, even though it appears as a potential health risk, it lacks specific data about the disease in Brazil. This project analyzed the CJD profile in Brazil, with the objective to broaden the knowledge of its epidemiological pattern in the country and its distinct characteristics, utilizing as search engine PubMED e SciELO to search for case reports in the country, while the incidence of the disease in Brazil was analyzed based in data accessible through the "Sistema de Informação de Mortalidade" from DATASUS, using the mortality rates of CID A81 that englobes Creutzfeldt-Jakob Disease and other 4 types of neurological diseases, meaning that those data are just an approximation. In the research: initially 35 articles were selected to analyze, from which only 15 filled out the criteria established with 18 cases total. The DATASUS results revealed that CJD affects predominantly white females with greater incidence in the age range of 60 to 69 years, while in global reports the while males are more affected. The southeast region of Brazil is the most affected, principally the states of São Paulo, Rio de Janeiro e Minas Gerais. Meanwhile the case reports in Brazil reveal a younger profile with most case is white males, showing a divergence between what can be found in the databases and what it's been reported by physicians. Furthermore, it was possible to established that feature the disease as compulsory notification has been beneficial to raise notification, as has been show by the raise in numbers after 2018, when it was considered compulsory notification, even though there still are some divergences in the national protocol, if compared with the international standard, as consequence from Brazil's lack of specialized centers and professionals in the area, those divergence may impact and harden this disease's diagnosis. With all the data gathered, it is possible to affirm that Brazil may have a different epidemiological profile that the international one, also the protocols and data access related to CJD are still not optimized, in DATASUS it is impossible to access it specifically, meanwhile the Brazilian notification protocol are unspecific and not well defined, with a lack of specialized centers and personal, the diagnosis in Brazil are even harder than already is. Ultimately, a better notification and data access mechanism must be developed, as more specialized centers are needed.

Creutzfeldt-Jakob disease, a series of cases in a public hospital in Paraíba, Brazil

Gilmar Leite Pessoa Filho[1], Ana Luisa Castelo Branco Gomes[1], Juliana Magalhães Leite[1], Tiago César Costa da Silva[2], Rafael de Souza Andrade[1], Matheus Gurgel Saraiva[1], Luciano Gonçalves do Nascimento Júnior[1], Felipe Nunes de Araújo[1], Rafael Gonçalves Duarte Cunha[1], Alex Tiburtino Meira[1]

[1]Hospital Metropolitano Dom José Maria Pires, João Pessoa PB, Brazil.
[2]Universidade Federal da Paraíba, João Pessoa PB, Brazil.

Correspondence: Gilmar Leite Pessoa Filho; Email: gilmarpessoa@gmail.com.

Background: Creutzfeldt-Jakob disease (CJD) is a rare, transmissible and fatal neurodegenerative disease, caused by abnormally folded prion protein accumulation. Typically, patients present as a rapidly progressive dementia, associated to visual symptoms, movement disorders, cerebellar and pyramidal signs. The global incidence of CJD is unclear, although literature reports to be around 1-2 cases per million per year. Between 2005 and 2021, 10 suspected cases of CJD were reported in Paraíba, Brazil, four of them were confirmed. **Objective:** Herein we report a high incidence of CJD cases in a short period of time from a neurology quaternary hospital in Paraíba, Brazil. **Methods:** We report a series of 5 cases of patients with rapidly progressive dementia syndrome associated with other clinical and imaging signs that meet criteria for probable CJD, between 2022 and 2023 in a public hospital in Paraíba, Brazil. **Results:** Five cases of a rapidly progressive dementia suspected to be CJD related were referred to our service from April 2022 to September 2023. The average age was 63 years (ranging from 46 years old to 75 years old). Two (40%) of them were male. Four (80%) of these patients lived in the metropolitan area of João Pessoa, and only one lived in the rural area. All the cases were sporadic. All of them exhibited

dystonia, myoclonus, appendicular ataxia, rigidity, and global hyperreflexia. Seizures and akinetic mutism were observed in 4 (80%) of them. Magnetic Resonance Images findings were typical in all cases: bilateral and symmetrical hyperintensity in the basal ganglia and diffuse and asymmetrical hyperintensity in cortex, on DWI and T2/FLAIR, with no Gadolinium enhancement. Three patients (60%) showed the hockey stick sign. Three patients undergone Electroencephalogram, all of which showed triphasic waves. Four cases were confirmed by cerebrospinal fluid (CSF) real-time quaking-induced conversion (RT-QUIC), but CSF RT-QUIC of one of the cases was unavailable. Four individuals progressed to death, within less than 4 months of onset and only 1 for 10 months. **Conclusion:** Between April 2022 and September 2023, 5 suspected cases were recorded in just one neurology service, four of which were confirmed by RT-QUIC. Interestingly, 80% of these new patients resided in the same metropolitan region, although no association was found among them. The observed incidence appears to be higher than that described in the global literature, becoming a serious public health problem.

Creutzfeldt-Jakob disease: a case report

Marina de Assis Brasil Mendes Monteiro[1], Carollyna Scherer Brum[1], Gabriel Bess Geier[1], Kelly de Oliveira Harada[1], Juliana Oliveira Freitas Silveira[2], Fernando Von Bock Bolli[3]

[1]Universidade Franciscana, Santa Maria RS, Brazil.
[2]Hospital Universitário de Santa Maria, Santa Maria RS, Brazil.
[3]Universidade Federal de Santa Maria, Santa Maria RS, Brazil.

Correspondence: Fernando Von Bock Bolli; Email: fernandobolli@hotmail.com.

Case presentation: A 71-year-old man presents with a 6-month history of progressive cognitive impairment, disrupting his activities of daily living. He has been under treatment for heart disease and depression. Medications include desvenlafaxine, metoprolol and rivaroxaban. He denies any neurological disorder in his family. A Mini-Mental State Examination (MMSE) was performed during this evaluation, scoring 10 out of 30. Blood tests for measurement of lipid panel, vitamin B12, HbA1c, glucose, blood count and VDRL were normal, apart from TSH levels sligthly increased (6.22mUI/L). The MRI scan showed restriction to diffusion on frontal, temporal, parietal and occipital córtex. The patient was told about his guarded prognosis and lack of a specific therapy for his condition. **Discussion:** Creutzfeldt-Jakob disease (CJD) is a fatal spongiform encephalopathy caused by the transmission of prions, which are misfolded proteinaceous infectious particles. The concentration of prions in CJD is elevated in the retina, optic nerve and central nervous system, resulting in visual symptoms, cerebellar ataxia, extrapyramidal signs, cognitive impairment and myoclonus. CJD accounts for 60% of the main causes of rapidly progressive dementia and there are three major forms that human prion diseases can be manifested: sporadic (accounting for 85% to 90% of CJD cases), genetic (caused by mutations in the prion protein gene PRNP, with a prevalence of 10-15%) or acquired. Pathologically, CJD is characterized by spongiform degeneration of subcortical and cortical gray matter structures, nerve cell loss and gliosis. Definitive diagnosis requires the presence of scrapie associated fibrils in histopathological analysis by brain biopsy ou identification of the protease-resistant PrPSc with immunohistochemistry or Western blot methods. Clinical diagnostic criteria are based on evidence of rapidly progressive dementia with at least two typical features (myoclonus, visual symptoms, or cerebellar and extrapyramidal signs), compatible findings on MRI (diffusion restriction on basal ganglia, or at least two of temporal, parietal, and occipital cortical regions), sharp-wave complexes on EEG or dosage of 14-3-3 protein in the liquor. **Final comments:** The presented case reveals a challenging scenario of progressive cognitive decline in an elderly patient, whose symptoms lead to suspicion of CJD, a rare and fatal neurodegenerative condition. The diagnosis was based on the rapid progression of cognitive complaints associated, especially, with characteristic changes on MRI. Early recognition of these cases is crucial for guiding appropriate clinical management, despite the lack of specific therapies available, allowing for the implementation of supportive measures and palliative care aimed at improving the patient's quality of life and providing support to family members facing a reserved prognosis.

Creutzfeldt-Jakob disease: a case report

Tairine Luiza Esteves da Costa Silva[1], Gabriela Flor Nimer[1], Caroline Bittar Moreira da Silva Amaral[1], Rafael Correia[1]

[1]Universidade Federal Fluminense , Niterói RJ, Brazil.

Correspondence: Gabriela Flor Nimer; Email: gfnmed1@gmail.com.

A 61-year-old male patient began experiencing difficulty naming words and forgetting passwords. Simultaneously, family members reported a slight alteration in his gait, with frequent stumbles. About 2 months later, he started experiencing spatial disorientation and emotional lability, becoming aggressive towards family members. He began experiencing visual and auditory hallucinations and also developed gait difficulty and falls. Approximately 6 months after the onset of symptoms, falls became frequent, and he developed dysphagia for solids and myoclonus. Due to injuries from a fall, the patient was hospitalized, and an investigation was initiated. Cranial MRI revealed hypersignal in T2 and FLAIR in the caudate nucleus, lentiform nucleus, thalamus, as well as involvement of the cerebral cortex including the cingulate gyrus bilaterally; also in the brainstem, insula, and higher portion of the superior frontal gyri, and left temporo-parietal region. Cerebrospinal fluid: positive for 14-3-3 protein. After discharge, he began outpatient follow-up at a tertiary hospital. On examination, he presented with myoclonus, mutism, and lack of cooperation with the examiner. He had spasticity and hyperreflexia, worse in the lower limbs. Levetiracetam was initiated during the consultation, and the indication for gastrostomy was discussed. Two months later, there was partial improvement in myoclonus, and the family accepted the placement of a gastrostomy tube. Creutzfeldt-Jakob disease is very rare, approximately one to two new cases occur per 1,000,000 in worldwide distribution. Clinical findings can be heterogeneous, but must be considered in case of rapidly progressive dementia. For the investigation, complementary exams are available that allow differentiation from other dementias, autoimmune or iatrogenic discordes. The patient presents clinical, radiological, and laboratory evidence confirming the diagnosis of Creutzfeldt-Jakob disease. This case illustrates the diagnostic approach and follow-up of a rare pathology and in addition, it presents high mortality. After diagnosis, it is important supportive and symptomatic treatment and a discussion about palliative care.

Correspondence: Mayara Zavatini Cansini; Email: mayazavatini@gmail.com.

Case presentation: We present a 64-year-old man, referred from a private clinic with a history of ataxia, diplopia, right upper eyelid ptosis, and sporadic episodes of mental confusion. Miller-Fisher syndrome, demyelinating syndrome, and encephalitis were considered initial diagnostic hypotheses. After further examination, he started with ocular apraxia, with moments when he reported not being able to open his eyes, and needed to use his hands to open it. He was diagnosed with prion disease with positive 14-3-3 protein in the cerebrospinal fluid (CSF) and radiological findings such as high signal intensities in the cerebral cortex and basal ganglia.From the onset of symptoms until diagnosis, there was a progressive worsening of the clinical picture leading him to be admitted to the ICU where he died due to complications of a pulmonary thromboembolism after 2 months of hospitalization. **Discussion:** Progressive neurological signs are common in SCJD, but ocular motor apraxia is not frequently reported and it is named Heidenhain variant Creutzfeldt-Jakob.A definite diagnosis requires the identification of the cardinal neuropathological features of sCJD (spongiform change, neuronal loss, and astrocytic gliosis) at postmortem or rarely brain biopsy. RT-QuIC and 14-3-3 protein in CSF can help in diagnosis. The most common findings of sCDJ on neurological examination include rapidly progressive dementia, visual disturbances and cerebellar ataxia, which are non-specific symptoms and can be present in a variety of neurological diseases.However, in the Heidenhain variant, the classic manifestation is cortical blindness resulting from impairment of the parieto-occipital cortex, and myoclonus and progressive dementia may be present. **Final comments:** Although sCJD is incurable and there is no generally accepted treatment currently available, it is important to make an early and accurate diagnosis because the early notice can help the family and the patient to prepare for the expected course of the condition and consider a better palliative treatment. In this case, visual changes were of utmost importance for clinical diagnosis, since their rarity helps to identify the condition and variant

Crossed cerebellar diaschisis: a report of presentation with tardive ataxia and diagnosis with PET-CT and tractography

Evelliny Gomes da Silva[1], Eduardo Souza Melo[1], Luziany Carvalho Araújo[1], Arthur Cesário de Holanda[1], Bruno Henrique Carneiro Costa Filho[1], Allefy Beltrão Albano[1], Fabrício Martins Veras[1], Letícia Klabinske Marques Monteiro[1], Marcelo Palmares Oliveira e Silva[1], Maiza de Oliveira Tenório[1]

[1]Universidade Federal de Pernambuco, Hospital das Clínicas, Recife PE, Brazil.

Correspondence: Evelliny Gomes da Silva; Email: evellinygomes1@hotmail.com.

Case presentation: Female, 76 years old, monitored at the Neurology outpatient clinic of the Hospital das Clínicas of the Federal University of Pernambuco, due to a history of a stroke in 2014, began to develop, in 2021, with global cerebellar ataxia (with an appendicular component more evident at the left), of a progressive nature, characterized by dysmetria in the index-nose and heel-knee maneuvers on the left, slurred speech, nystagmus, limb-trunk dyssynergia, tendon dance and drunken gait, in addition to mild motor sequelae in the right side of a previous stroke. She underwent extensive investigation

for sporadic cerebellar ataxia and received the diagnosis of crossed cerebellar diaschisis after excluding other etiologies of ataxias and undergoing confirmatory positron emission tomography (PET-CT) and magnetic resonance tractography. The patient's PET/CT showed an area of occipital, temporal and parietal hypometabolism on the right, compatible with an area of previous stroke and a cerebellum with hypouptake on the left, compatible with a diagnosis of CCD, and tractography confirmed the absence of the right-left corticopontocerebellar tract. **Discussion:** Crossed cerebellar diaschisis (CCD) is a rare phenomenon, initially described by Constantin von Monakow in 1914, and is characterized by reduced hemispheric cerebellar blood flow and metabolism that can occur contralateral to the supratentorial lesion. It is believed that the mechanism of CCD is due to the interruption of corticopontocerebellar tracts, and may be observed in patients with cerebral infarction, supratentorial tumors, epilepsy or encephalitis. Thus, it is noteworthy that only some patients with CCD may present functional or structural impairment. However, CCD can occur with hemiataxis and it is suggested that it results not only from the interruption of the corticopontocerebellar pathway, but also the dentatorubrothalamic pathway, justifying the patient's clinical description. It has also been shown that functional CCD leads to crossed cerebellar atrophy, that is, structural CCD, over time. This phenomenon was not seen in this case and can be justified by the fact that CCD cerebellar atrophy was more associated with younger patients. The classic diagnosis and finding on PET is, in fact, described as contralateral cerebellar and supratentorial hemispheric hypometabolism. **Final comments:** Indeed, this case illustrates clinical and imaging manifestations of an uncommon but important neurological clinical entity. Therefore, it is important to consider the importance of considering crossed cerebellar diaschisis in the differential diagnosis of ataxias, especially in older patients with previous structural brain damage, especially when secondary to a vascular accident.

Crucial role of the ApoE4 variant in the pathogenesis of Alzheimer's disease in homozygous patients: a systematic review

Luiz Eduardo Ferreira Mazzanti[1], Nicolly Borges Costa Silva[2], Laís de Souza Rodrigues[1]

[1]Universidade de Vassouras, Vassouras RJ, Brazil. [2]Centro Universitário de Valença, Valença RJ, Brazil.

Correspondence: Luiz Eduardo Ferreira Mazzanti; Email: dudumazzanti4@gmail.com.

Alzheimer's disease (AD) is a progressive neurodegenerative condition that mainly affects patients' memory, thinking and behavior. It is one of the most common forms of dementia and accounts for the majority of cases in the elderly, placing a huge burden on the health system and families. In this context, it has been noted that individuals who inherit a copy of the apoE allele, a protein involved in the transportation and metabolism of lipids in the body, have an increased risk of developing Alzheimer's. The aim of this research was to analyze through a systematic review, the relevance of the ApoE4 allele in the development of AD and the consequences that can be caused in carriers of this allele. In this way, the PubMed databases and the regional portal of the virtual health library were taken into account with the descriptors "apoE4", "alzheimer" and "homozygous adults", using the Boolean operator "AND". In this context, the search reported 26 studies. The inclusion criteria were articles available in English and Portuguese, published between 2019 and 2024. The criteria for exclusion were articles that were not pertinent to the subject or duplicated. After using the exclusion and inclusion criteria, a total of 19 articles were selected for this systematic review. All of the articles were unanimous regarding the presence of the ApoE4 allele in homozygous patients with AD, because the presence of this apolipoprotein is associated with a greater accumulation of beta-amyloid protein plaques, which is the first step towards the onset of Alzheimer's. However, some studies have shown that the presence of this allele only has an impact on cognitive performance and does not influence cognitive performance. Nevertheless, some research has shown that the presence of the allele only has an impact on cognitive performance and has no impact on motor performance. It is also important to note that AD is multifactorial and is influenced by a combination of genetic and environmental factors, so not all individuals affected by the pathogenesis who have the ApoE4 allele will develop the disease.

Cryptococcal meningoencephalitis in an immunocompetent patient: case report

Airton Sena Oliveira Sales[1], Danielli Regina da Silva[1], Laisy Bárbara Souza Silva[1], Larissa Batista Xavier[1], Lorenzo Pereira de Almeida Melo Montes[1], Guilherme Victor Rocha Pereira[1], Gabriel Vinícius de Andrade Rodrigues[1], João Pedro Lopes Geraldi[1], Emerson Oliveira Milhorin[1], Luís Carlos Oliveira Resende[1]

[1]Universidade Federal do Triângulo Mineiro, Uberaba MG, Brazil.

Correspondence: Airton Sena Oliveira Sales; Email: d202120376@uftm.edu.br.

Case presentation: A 64-year-old immunocompetent male with a medical history of diabetes, hypertension, and an unspecified pulmonary mass presented with neuropsychiatric symptoms for approximately one month. These symptoms included mood changes (irritability and emotional lability), cognitive dysfunction (memory impairment), and behavioral changes. Due to the progressive worsening of these symptoms, he was admitted to the hospital for further investigation. In addition to the presenting symptoms, he reported intermittent positive visual scotomas (red light flashes), bilateral frontotemporal headache refractory to common analgesics, and unquantified weight loss. During the investigation, cranial magnetic resonance imaging (MRI) revealed eight nodular lesions of uncertain etiology with adjacent hemorrhage, located near the cerebellar vermis, left occipital lobe, and right frontotemporal region. Initial differential diagnoses included primary or metastatic neoplasia and neuroinfection, leading to the decision to perform a biopsy of the lesions. The diagnosis of neuroinfection due to Cryptococcus gattii was confirmed, and treatment with Amphotericin B was initiated. The patient was discharged but returned to the emergency department eight weeks later with refractory septic shock and subsequently died. **Discussion:** Cryptococcus gattii meningoencephalitis predominantly affects immunocompetent individuals and can be associated with pulmonary involvement. Inflammatory lesions of the meninges and brain can impair cranial nerves (causing visual changes), cognition, and consciousness levels. Physical examination frequently reveals signs of meningeal irritation, focal neurological deficits, as well as nausea and vomiting.Diagnosis should be based on compatible clinical and epidemiological history supported by complementary exams such as MRI, cerebrospinal fluid (CSF) analysis, fungal cultures, and biopsy of lesions. The recommended treatment consists of intravenous administration of Amphotericin B combined with Fluconazole. **Final comments:** Fungal meningoencephalitis is rare in immunocompetent individuals but can cause severe manifestations. The clinical presentation and MRI findings are nonspecific and can be easily confused with other conditions, such as neoplasms and metastases, especially in the elderly. Therefore, it is important to consider the epidemiology of infections in tropical regions, which can provide valuable clues for accurate and early diagnosis.

CSF1R-related leukoencephalopathy: case report

Luciane Ramos Perez Silveira[1], Paula de Oliveira Pinto[2] , Pedro Henrique Gargioni de Andrade[3]

[1]Universidade Federal de Pelotas, Pelotas RS, Brazil. [2]Universidade Federal da Fronteira Sul, Passo Fundo RS, Brazil. [3]Universidade Estadual de Maringá, Maringá PR, Brazil.

Correspondence: Luciane Ramos Perez Silveira; Email: lucianeperez@yahoo.com.br.

Hereditary diffuse leukoencephalopathy with spheroids (HDLS) is a rare autosomal dominant disorder characterized by giant neuroaxonal spheroids in the cerebral white matter (WM). Symptoms are variable and may encompass cognitive, psychiatric, and motor dysfunctions. **Case presentation:** Female patient, 28 years old, was admitted to the hospital emergency department with a progressive gait disturbance over the past three months, associated with behavioral changes, movement disorders, and episodes of urinary incontinence. She initially developed avolition and blunted affect at approximately 27 years of age, managed for depression with sertraline by the psychiatric team without improvement. Prior to symptom onset, she lived independently, worked without difficulty, and cared for her child. **Discussion:** There is no reported history of neurodevelopmental abnormalities or delays in the family. Family history includes non-consanguineous parents, a deceased brother at 9 years old from unknown causes, and a father who died at 30 years old in a car accident. On physical examination, she presented with a dysmorphic face, bradykinetic but oriented. Generalized preserved strength, choreoathetoid movements predominantly on the left side, hyperreflexia, and limb rigidity were noted. No skeletal abnormalities were observed. Laboratory tests were unremarkable. Cerebrospinal fluid analysis revealed 10 cells, 60 erythrocytes, glucose 59, protein 29, gram-negative staining. Brain MRI showed extensive signal abnormalities predominantly affecting periventricular white matter in both hemispheres, characterized by T1 hypointensity and T2/FLAIR hyperintensity, with scattered hemorrhagic foci suggesting leukoencephalopathy, vasculitis, inflammatory, or infectious processes. Treatment with methylprednisolone 1g/day was initiated without improvement. Comprehensive investigations including CT angiography of cerebral vessels, chest, abdominal, and pelvic CT scans revealed no significant findings. Further extensive screening for hematologic, infectious, or rheumatologic disorders was negative. Genetic testing for leukodystrophy revealed heterozygosity in the CSF1R (colony stimulating factor 1 receptor) gene. Over an 18-month follow-up period, the patient's condition progressed to cognitive and motor dysfunction, currently requiring a wheelchair, showing disengagement from others, speech and fluency disturbances, spasticity, hyperactive tendon reflexes, pathological reflexes, and recently developing dysphagia. **Final comments:** Accurate disease knowledge is crucial for correct diagnosis. Further studies are needed to elucidate disease classification and potential future treatments.

https://doi.org/10.5327/CBN240494

Cutaneous anaplastic large cell lymphoma in a multiple sclerosis patient receiving natalizumab

Letícia da Silva Alves[1], Arthur Costa Nascimento[1], Rogério de Rizo Morales[1]

[1]Universidade Federal de Uberlândia, Uberlândia MG, Brazil.

Correspondence: Letícia da Silva Alves; Email: draleticiasilvaalves@gmail.com.

A 23-year-old patient, who in 2021 presented with bilateral optic neuritis, which improved after pulse therapy with methylprednisolone. He met McDonald's 2017 diagnostic criteria and was diagnosed with relapsing-remitting multiple sclerosis (MS) in April 2021. Glatiramer was initiated until the release of high-potency medication, and he was switched to natalizumab in February 2022. However, due to high titers for the JC virus, therapy was changed to ocrelizumab in July 2023. In 2023, during outpatient follow-ups, lymph node enlargement was noticed in the cervical region, with slow and progressive growth. A biopsy performed in June 2023 revealed cutaneous anaplastic large cell lymphoma, with positive CD30 and negative ALK, and he was subsequently referred for oncological treatment. Ocrelizumab was suspended after the first dose for the treatment of lymphoma. Anaplastic cell lymphoma is a rare subtype of non-Hodgkin lymphoma. In the literature, there is a case report of a patient with multiple sclerosis using fingolimod, with a similar diagnosis. There is also an association of this type of non-Hodgkin's lymphoma with the use of glatiramer (GA). There are no reports in the literature of similar neoplasms in patients using natalizumab. GA has a mechanism of action that is not yet fully understood, but which involves activation of both the innate and adaptive immune systems, upregulation of anti-inflammatory M2 monocytes, Th2 cells and T regulatory cells (Tregs). The shift to Th2 immunity is potentially tumorigenic. Natalizumab acts as a barrier drug preventing the transmigration of lymphocytes by blocking cell adhesion through alpha4beta1 integrin. Several types of neoplasms have been reported with the use of natalizumab, including diffuse large B-cell lymphoma, with a probable mechanism associated with reduced migration of T cells to tumor sites, due to the blockade of alpha4 integrin that interferes with the activation of antigen-specific T cells. The discussion surrounding disease modifying therapies (DMTs) in MS is extensive. There is a consensus that immunosuppressive therapies with some drugs can increase the risk of neoplasia in patients with MS. However, the most commonly used DMTs have data indicating both their efficacy as anti-cancer medications and post-marketing reports of neoplasias, which do not confirm, but raise hypotheses regarding the nature of the association between them. Case reports involving neoplasms and patients undergoing treatment for autoimmune diseases are important in understanding the possible long-term effects of immunomodulatory treatments, as well as the risk-benefit ratio, and to aid in therapeutic decision-making and patient management, such as extra surveillance in relation to neoplasms, especially but not only in those with acquired or non-modifiable risk factors.

Cyclic stereotypic catatonia revealing anti-nmda encephalitis

Victor Alfonso Garcia Ortiz[1], Manuella Edler Zandona, Lucas Spanemberg, William Alves Martins

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Victor Alfonso Garcia Ortiz; Email: victorgarcia.or@gmail.com.

Case presentation: The case involves a 42-year-old man with a three-month history of psychosis, stereotyped movements, and confusion, complicated by past drug abuse and moderate cranioencephalic trauma. Initially admitted for evaluation of seizures and psychiatric symptoms, he presented with agitation, delusions regarding harm from his girlfriend, and a history of recent cannabis and cocaine use cessation. His symptoms included auditory and visual hallucinations, leading to a bipolar disorder diagnosis despite treatment with multiple antipsychotics. After discharge against medical advice, his behavior deteriorated, exhibiting bizarre actions like rolling around lights and neglecting self-care. Neurological examination revealed frontal dysfunction, supported by MRI findings of encephalomalacia in the left pars opercularis. Treatment with various antiepileptic drugs for suspected seizures and psychosis showed no improvement. Upon admission to Hospital São Lucas, he displayed frontal dysfunction signs, including echolalia and delusions, despite treatment with olanzapine, carbamazepine, clobazam, and valproic acid. A 'washing out' phase of medication exacerbated his agitation and stereotypies, with catatonic episodes responding to lorazepam. Diagnostic tests revealed no new MRI findings but indicated suspicion of autoimmune encephalitis due to atypical progression and CSF abnormalities, including leukocytosis and elevated protein levels. Confirmation came from CSF testing showing anti-NMDA antibodies. Despite initial mental status improvement, he developed dysarthria, left arm dystonia, and parkinsonian features, partially alleviated by levodopa but complicated by bilateral convulsive seizures requiring diazepam. Treatment escalated to rituximab and cyclophosphamide, resulting in gradual recovery. Discharged on carbamazepine and levodopa, he continues rituximab infusions every six months. **Discussion:** Anti-NMDA receptor encephalitis involves autoantibodies targeting NMDA glutamate receptors, causing receptor dysfunction and severe neurological symptoms such as psychosis, hallucinations, seizures, and movement disorders. Frequently misdiagnosed initially as psychiatric illness, particularly in young adults, timely recognition is crucial to prevent severe morbidity and mortality. **Final comments:** This case underscores the challenges and complexities of diagnosing and managing autoimmune encephalitis, emphasizing the importance of comprehensive neurological evaluation and targeted immunotherapy for optimal patient outcomes. Cyclic catatonia may represent one of the many faces of anti-NMDA encephalitis and should prompt neurological assessment.

https://doi.org/10.5327/CBN240496

Cytotoxic lesions of the corpus callosum (CLOCC): a neurological complication of dengue fever

Amanda Monteiro Viagi[1], Renato Pierre Lima[1], Rodrigo Meirelles Massaud[1]

[1]Hospital Israelita Albert Einstein, São Paulo SP, Brazil.

Correspondence: Amanda Monteiro Viagi; Email: amandavalec@gmail.com.

Case presentation: A 25-year-old man presented with acute slurred speech and imbalance. He reported flu-like symptoms, including cough and diarrhea, starting six days prior, without fever. Three days before admission, he began azithromycin for respiratory symptoms. His history includes bipolar disorder and dyslexia, with regular use of lithium carbonate and divalproex sodium, without recent dose adjustments or misuse. During the neurological examination, he was awake, oriented, with slurred speech. Muscle strength was preserved, and cranial nerve examination was normal. Sensitivity was intact, but cerebellar testing revealed axial and bilateral appendicular ataxia, worse on the left, with dysmetria and dysdiadochokinesia. The NIH Stroke Scale score was 3, indicating ataxia and dysarthria. Immediate neuroimaging revealed a partially well-circumscribed lesion in the splenium of the corpus callosum on cranial MRI. The lesion appeared hyperintense on T2-weighted images and FLAIR sequences, with patchy DWI lesions, suggestive of cytotoxic lesions of the corpus callosum (CLOCC). The DWI lesion was extensive and larger than the lesion visible on FLAIR and T2-weighted sequences. The lesion did not enhance with gadolinium contrast. The TOF sequence in MRI did not demonstrate occlusion of major arterial trunks. Further investigation, including serum lithium levels, serological analyses, cerebrospinal fluid examination, PET-MRI with FDG imaging, electroencephalogram, chest and abdominal CT scans, and a respiratory panel with PCR for viruses and bacteria, revealed normal findings, except for a positive dengue IgM, with non-reactive NS1 antigen and IgG. During hospitalization, the patient's neurological deficits worsened, including severe dysphagia and dysarthria, tetraparesis and bilateral Babinski sign. Treatment with human immunoglobulin for 5 days followed by pulse therapy with 1000 mg of methylprednisolone for 5 days resulted in partial improvement. Follow-up MRI showed a reduction in lesion size and intensity in the splenium of the corpus callosum, with new multiple small foci of microbleeds, despite a normal platelet count. **Discussion:** We present a case of CLOCC secondary to dengue fever in an oligosymptomatic and afebrile patient at the onset of neurological signs. This condition can result from severe viral or bacterial infections and may also be associated with drug withdrawal, toxins, vascular conditions, metabolic disorders, drug toxicity, and seizures. A notable aspect of this case was the clinical manifestation of appendicular ataxia and pyramidal symptoms, along with dysphagia, dissociated from the cytotoxic lesions observed in the corpus callosum on MRI. PET MRI with FDG revealed normal findings, suggesting no metabolic alterations in other areas. **Final comments:** This case highlights several atypical features of CLOCCS secondary to dengue, including the patient's presentation and radiological progression, which are uncommon in CLOCCS.

Dabigatran reduced the length of hospital stay for cerebral venous thrombosis

Camila Carneiro[1], Matheus Kahakura Franco Pedro[1], Vanessa Rizelio[1], Caroliny Trevisan Teixeira[1], Zuly Mary Briceno Moreno[1]

[1]Instituto de Neurologia de Curitiba, Curitiba PR, Brazil.

Correspondence: Camila Carneiro Ferreira; Email: camilasilcarneiro@gmail.com.

Background: From the current available evidence, it is reasonable to transition to direct oral anticoagulants or warfarin after a period of lead-in parenteral anticoagulation in the treatment of cerebral venous thrombosis (CVT). But whether 5 to 15 days to do the transition to oral anticoagulants is a safer or more effective strategy than shorter periods is not known. **Objective:** In this study we demonstrate the safety and effectiveness of the transition carried out over an average period of 3,6 days. **Methods:** A retrospective, single-center, longitudinal study evaluating data from the electronic medical records of patients of both sexes hospitalized for CVT from 2014 to 2019 (Warfarin group) and from 2019 to 2023 (Dabigatran group). Statistical analyses were carried out using SPSS (Statistical Package for the Social Sciences) software. **Results:** A total of 137 patients were included: 73 in the warfarin group (WG) and 64 in the dabigatran group (DG). In both groups, patients received 3 days of low molecular weight heparin. After this phase, WG received 10 mg of warfarin until they reached an INR of 2 to 3, and the DG started on 150 mg of dabigatran twice a day and could be discharged. In the warfarin group, there were 57 women (78%), the mean age (SD) of the patients was 36.7 (±10.7). 38 (52%) were using some hormonal therapy, and 16 (22%) were found to have thrombophilia. On admission, 7 (9.6%) had already been with venous infarction, and 13 (17.8%) had refractory symptoms of intracranial hypertension. Of the 73 patients, only 58 (79.5%) were followed up for more than 3 months after hospitalization. None of these patients experienced anticoagulant-related bleeding, 5 (8.6%) had a recurrence of CVT (over 5 years of follow-up), and all achieved recanalization during follow-up. In the dabigatran group, there were 41 women (64%). The mean age (SD) of the patients was 38.6 (±11.8). Twenty-five (39%) were using some hormonal therapy, and 11 (17%) were found to have thrombophilia. On admission, 11 (17%) had already been with venous infarction, and 19 (30%)

had refractory symptoms of intracranial hypertension. Of the 64 patients, 42 (65%) were followed up for more than 3 months after hospitalization. None of these patients experienced anticoagulant-related bleeding, 1 (2.3%) had a recurrence of CVT (over 2 years of follow-up), and all achieved recanalization during follow-up. The mean (SD) length of hospital stay in the WG was 5.42 days (±2.2), and in the DG it was 3.69 days (±1.2). The difference between the means was 1.73 days, which was statistically significant (T= 5.76; p< 0.001) using the Student's t-test. **Conclusion:** The transition from heparin to oral anticoagulants within 5 days was safe and effective in this coorte. Dabigatran can reduce the length of hospital stay even further, as it does not require dose adjustments according to the international standard of 2 to 3, which is necessary with warfarin.

https://doi.org/10.5327/CBN240498

DBS of the Meynert basal nucleus for patients with Lewy body dementia: a meta-analysis of randomized clinical trials

Jonatas Paulino da Cunha Monteiro Ribeiro[1], Ocílio de Deus da Rocha Ribeiro Gonçalves[1], Dário Correia Negreiros[1], Márcio ítalo Santos de Oliveira[1], Társis Vinícius Cronemberger de Carvalho Moura Mendes[1], Guilherme Victor Antas Cronemberger[1], Thaís de Negreiros Neves[1], Luciano Barbosa de Sousa Santos Filho[1], João Luís Reis Freitas[2], Kelson James Almeida[1]

[1]Universidade Federal do Piauí, Teresina PI, Brazil.
[2]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Jonatas Paulino da Cunha Monteiro Ribeiro; Email: jonatas.ribeiro@ufpi.edu.br.

Background: Lewy body dementia (LBD) is a neurodegenerative disease clinically characterized by motor and cognitive symptoms. Its pathophysiology is based on the development of abnormal clusters of defective proteins called alpha-synuclein, which settle in neurons and interneuronal spaces. Currently, LBD has no disease-modifying therapy, with drug treatment offering only moderate improvement in symptoms. Deep brain stimulation (DBS) of the nucleus basalis of Meynert (NBM) is not used therapeutically in these cases, however, considering the impact of this disease and the limitation of pharmacological therapy, it is important to evaluate the effects of procedures such as this in the cognition of patients with LBD. **Objective:** To evaluate the cognitive and neuropsychiatric impact of DBS of the nucleus basalis of Meynert in patients with LBD. **Methods:** Two investigators systematically searched Embase, Cochrane and PubMed for Randomized Controlled Trials (RCTs), with no publication year limit, that compared DBS of the basal nucleus of Meynert with "sham" procedures in patients with LBD. Outcomes of interest included were the change in the Mini-Mental State Examination (MMSE) and Neuropsychiatric inventory (NPI) scales after the intervention. Statistical analysis was performed using the R Studio 4.3.2 software. Heterogeneity was calculated based on the I2 statistic. **Results:** Three RCTs were included in the statistical analyses, it was observed that the NPI and MMSE variables are reported as secondary outcomes. A total of 18 patients, all males aged between 35 and 80 years, 6 patients from each study and 9 for each arm (DBS or sham procedure). For the MMSE measure, there was no statistical significance, with a mean of -0.658 [-3.670, 2.353]. For the NPI measure, there was no statistical significance, with a mean of -6.37 [-16.16, 3.42]. The results are the same for fixed and variable effect methods, and this is due to the fact that there are few studies. Thus, the estimate for tau squared is not reliable. **Conclusion:** Evaluating the cognitive and neuropsychiatric impact of DBS of the basal nucleus of Meynert in patients with LBD, there was no statistical significance for the clinical improvement in the cognitive segment, based on the change in the MMSE and NPI scales.

[2]Universidade Estadual do Centro Oeste, Guarapuava PR, Brazil.

Correspondence: Izabelly Constantinov Lemos; Email: med-izabellylemos@camporeal.edu.br.

Background: Epileptic seizures are abnormal brain states caused by a period of uncontrolled synchronous excitation. The ion channels of the Central Nervous System, involved in communication through the release of neurotransmitters, appear unbalanced in the pathophysiological process of the disease. Studies mention that epileptic channelopathies are derived from genetic mutations, acting on voltage-sensitive channels such as Na+, K+, Ca2+, and Cl-, as well as the nicotinic acetylcholine receptor and GABAA. The high morbidity and mortality rate of the epileptic state is characterized by recurrent seizures, lasting for at least 5 minutes without return to normal physiological characteristics. Considering all this information, the need for investigative research on the epidemiological characteristics of mortality from epilepsy in Brazil becomes clear, especially the comparison between sex and age group, covering the period from 2018 to 2022. **Objective:** To determine the number of deaths (n) from epilepsy in Brazil, associating and comparing the most affected age group and sex between 2018 and 2022. **Methods:** Observational epidemiological study of a descriptive nature based on data extracted from the Department of Epidemiological Analysis and Surveillance of Non-Communicable Diseases (DAENT) referring to the number of deaths from epilepsy in Brazil in the period from 2018 to 2022. The constants used were: place of occurrence, coverage, deaths by residence, notification of deaths, without restriction of race/color. And as variables: sex and age group (0 to ages above 80 years). The ignored category was included in the total number of deaths, since it has little impact on the study results. The indicator used was G40.9 epilepsy, not specified. Subsequently, an analysis was carried out to identify which age groups and sex are most affected. **Results:** Of the total number of deaths (n=14,379), male patients (n=9,322) had the highest number of deaths from epilepsy between 2018 and 2022, accounting for 64.8% of deaths. In comparison, female patients had a significant number of deaths, totaling 5,054 individuals during this period. In addition, the most affected age group was 50 to 59 years old, with 18% (n=2,592) of the total analyzed. **Conclusion:** The number of deaths increased in the period from 2018 to 2022, mainly among men in the age group of 50 to 59 years old. Consequently, it is noted that more research is essential to understand the development of epilepsy in the affected age group and sex, with the aim of ensuring an accurate epidemiological perception and promoting appropriate multidisciplinary care for the profiles presented.

Deciphering the TBK1 mutation: a key to unlocking the mysteries of frontotemporal dementia and als in Brazilian families

Rachel Leirner Argelazi[1], Santhiago Calvelo Graça[1], Pedro Vilaça Thomazoni[1], Yngrid Dieguez Ferreira[2], Diogo Haddad Santos[2]

[1]Santa Casa de São Paulo, Faculdade de Ciências Médicas, São Paulo SP, Brazil.
[2]Irmandade da Santa Casa de Misericórdia de São Paulo, São Paulo SP, Brazil.

Correspondence: Rachel Leirner Argelazi; Email: racheleirner@gmail.com.

Case presentation: In April 2021, two brothers, JLS1, 43 years, and GLS, 45 years, presented at the neurology outpatient clinic with a significant history of cognitive decline starting in their early twenties. Both brothers exhibited progressive symptoms leading to dependence on daily life activities. JLS1 began to show behavioral changes at 36, leading to job loss and increasing social isolation. His condition worsened over time, with symptoms including refusal of personal care, aggression, tremors, dysarthria, and cognitive decline. By 2018, JLS1 was admitted to Dom Pedro Hospital at São Paulo, where he remained socially isolated, experiencing psychomotor agitation and aggression. MRI scans revealed diffuse brain volume reduction, particularly in the caudate nuclei, suggesting a neurodegenerative disorder such as Huntington's disease. GLS, also from São Paulo, had a similar trajectory. He experienced depressive episodes and behavioral changes that intensified after losing his job in 2014, leading to a suicide attempt. Over the years, his symptoms included psychosis, cognitive decline, hallucinations, and severe motor deficits. Despite testing negative for Huntington's disease, MRI scans showed significant brain atrophy and signs of encephalomalacia/gliosis. The brothers' condition reflected a troubling pattern within their family. The youngest brother, JLS2, at 36, exhibited early symptoms and lived in poor conditions. The family history included similar symptoms in their father, uncle, grandmother, and a cousin, starting around age 20 and leading to severe cognitive and motor deficits by their 40s. In May 2022, genetic testing of GLS identified a variant in the TBK1 gene (c.965A> T), linked to frontotemporal dementia (FTD) and amyotrophic lateral sclerosis (ALS). This suggested a genetic basis for the family's symptoms, though the variant's pathogenicity remains uncertain. Both GLS and JLS1 passed away, while the status of JLS2 and other family members remains unknown. **Discussion:** Mutations in the TBK1 gene have been linked to an increased risk of developing both FTD and ALS. The phenotype is diverse, including behavioral variant FTD, primary progressive aphasia, and pure ALS. Studies have found a higher prevalence of TBK1 mutations in European patients compared to Asian patients. In Brazil, only one case report was published on the gene and clinical manifestation. **Final comments:** Despite its rarity, frontotemporal dementia accompanied by motor deficits is significant for neurologists due to the guarded prognosis and potential familial impact on the patient's descendants. In this study, we aim to write a case report on this rare, hereditary neurodegenerative disease that results in rapid neurodegeneration. Our goal is to contribute to the scientific understanding of frontotemporal dementia.

Deep learning for neuroimage classification in Alzheimer's disease: barriers to clinical relevance

Caio Hussid de Góes[1], Diogo Haddad Santos[2]

[1]Santa Casa de São Paulo, Faculdade de Ciências Médicas, São Paulo SP, Brazil.
[2]Hospital Alemão Oswaldo Cruz, São Paulo SP, Brazil.

Correspondence: Caio Hussid de Góes; Email: caio.goes@aluno.fcmsantacasasp.edu.br.

Background: As new pharmacological treatment options emerge for Alzheimer's disease (AD), reliable early diagnosis escalate in importance. In the clinical setting, neuroimaging methods in AD face problems related to the diversity of brain degeneration patterns, as well as overlapping of Alzheimer's characteristics with other dementias.

A possible approach is the development of image classification algorithms through Deep Learning models, a subtype of Machine Learning. Thus, study's **Objective:** was to carry out a literature review to clarify the barriers for clinical use of Deep Learning models capable of identifying patients who will undergo conversion from Mild Cognitive Impairment (MCI) to Alzheimer's. **Methods:** The methodology was organized according to the PRISMA guideline of 2020. Article search was conducted in Pubmed, between 2007 and 2023, while the MeSH terms were chosen based on the pertinent topics for the study: clinical presentations, Deep Learning models, and Neuroimages. After the search, articles were sorted for inclusion based on abstract. Then, the full text of the articles was analyzed, followed by data extraction. Articles that only mentioned Deep Learning, articles that did not predict the conversion of MCI into Alzheimer's and that used neuroimaging sample amplification methods were excluded, as were articles not available in English and studies without access to the full text. **Results:** The initial search resulted in N=178 articles. Of these, 128 were excluded, and of the remaining 50, n=34 fit the inclusion criteria. The most frequent model used was a 3D Convolutional Neural Network (17), followed by Deep Belief Network combined with Support Vector Machine (2), and the remaining 15 models being used by a single article. All articles used the Alzheimer's Disease Neuroimaging Initiative dataset for models, with other 4 much smaller dataset used in 4 different articles. A total of 9 different categories of additional input data were used alongside neuroimages across 14 articles, and 6 articles performed model cross validation. Analyzing different Deep Learning architectures proved to be complex. Inconsistent reporting of important steps in the model's construction was found in the pre-processing protocols for input data, the different processes for obtaining model hyperparameters, and a tendency of association of different architectures to obtain robust models, hurting the study's reproducibility and validation. Moreover, the results reveal a lack of diversity in datasets used for model training, limiting the applicability of the models in real world scenarios despite the relatively high performance reported in most models, which is made worse by the lack of model cross validation. **Conclusion:** Ultimately, it can be concluded that the applicability of Deep Learning models for neuroimaging classification is still in its infancy, and while it shows potential, more studies with robust methodology reports are needed for effective real-world usage.

Background: Hereditary amyloidosis is a multisystemic and heterogeneous disease whose clinical presentation and prognosis varying according to the genotype. The I107V is a rare variant that has been more frequently described in Brazil. However, its precise phenotypic characterization is still incipient, which hinders both its early recognition and optimal clinical management. **Objective:** To conduct an in-depth phenotyping of the I107V variant (ATTRI107V). **Methods:** This is an observational, retrospective, multicenter study that included carriers of ATTR I107V treated in four centers in Brazil between 2020 and 2023. Asymptomatic individuals and those with additional causes for neuropathy were excluded. Demographic and clinical data were analyzed. Quantitative data were described as means and standard deviations, while categorical variables were expressed as frequencies. **Results:** A total of 88 individuals with the I107V variant were identified, of whom 51 were excluded due to additional causes of neuropathy or incomplete evaluation. Thirty-seven individuals were included, 59% of whom were female. The average age of symptom onset was 55±12 years (range: 22-70). The most frequent initial presentation was small fiber neuropathy (SFN) (38%), followed by SFN associated with sensorimotor and autonomic neuropathy (24%). Isolated autonomic neuropathy occurred in 5% of cases, and cardiac onset in 3%. During the disease, 76% presented with dysautonomia, with orthostatic hypotension being the most frequent symptom (50%). Muscle weakness occurred in 59% of patients, with an average onset time of 2.43±1.25 years. The interval between symptom onset and bed restriction was 4.7±1.5 years. Cranial nerve involvement was observed in 64% of patients, with the most frequent manifestations being dysgeusia (47%), followed by tongue atrophy (36%) and dysphonia (33%). Carpal tunnel syndrome (STC) was identified in 82% of cases and preceded polyneuropathy by about 3.4±4.5 years (0.5-24). Electroneuromyography demonstrated axonal polyneuropathy in 62%, mixed in 4%, demyelinating in 4%, and was normal in 8%. Tafamidis was the indicated treatment for most individuals (73%). Only 23% exhibited cardiac symptoms; however, 86% had ECG or Holter alterations, and 43% had cardiopathy on echocardiogram. Cataracts were identified in 15% and dry eyes in 13% of cases. No individual presented with renal impairment. The mortality rate was 16%, and the average survival was 9.3±2.3 years (7-13). **Conclusion:** The ATTRI107V presented a mixed phenotype, with a predominantly neurological initial manifestation, late disease onset, and rapid progression. Dysautonomia and STC were frequent and may serve as warning symptoms for early diagnosis. Cranial nerve involvement is prevalent and should be recognized in these individuals. Cardiac involvement is frequent and can be asymptomatic, underscoring the importance of systematic cardiac investigation and multidisciplinary follow-up.

Delirium phenotype in acute stroke

Gabriel Souza Suzart[1], Luiz Paulo Oliveira Martins[1], João Pedro Fernandes Gonçalves[1], Marivaldo Yslan Silveira Leal[1], Luísa Dias Moreno Aravena[1], Thais Barbosa de Oliveira[1], Vinícius Bessa Mendez[1], Alex de Cerqueira Silveira Figueiredo[1], Gabriel Souza Medrado Nunes[1], Milena Fernandes de Oliveira[1]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.

Correspondence: Luiz Paulo Oliveira Martins; Email: luizpom2000@gmail.com.

Background: Delirium is a common complication in acute stroke. The literature is scarce in studies evaluating underlying delirium phenotype in this setting. **Objective:** Determining the prevalence of delirium phenotypes and its association with long term functional outcome. **Methods:** Prospective cohort of stroke patients admitted to a brazilian reference stroke unit. Subjects included were older than 18 years admitted to the stroke unit within 72 hours of symptoms onset. Delirium was assessed during hospitalization by the Confusion Assessment Method for the Intensive Care Unit. Delirium phenotypes were septic, hypoxic, sedative-related, metabolic, multiple causes or undetermined. The main outcome was functional dependence or death in 90 days after stroke, determined by the modified Rankin Scale >2 points. **Results:** A total of 213 patients were included. Our sample's mean age was 66 (±13) years, with a majority of first ever stroke (74.3%) and ischemic subtype (93.9%). Delirium occurred in 47 (22.1%) patients, from which its phenotype was determined in 15 (31.9%) cases. The septic delirium was the most common phenotype (14.9%), followed by sedative-related (6.4%), multiple causes (6.4%), metabolic (2.1%) and hypoxemic (2.1%), being undetermined in the remaining episodes (68.1%). Delirium patients had a higher rate of poor outcome (odds ratio, 2.2 [IC 95%, 1.6-2.9; p<0.001). Worse outcomes were less frequent in sedative-related and undetermined delirium compared to other phenotypes (0% vs 80% vs 100%). **Conclusion:** Delirium is a clinical predictor of poor prognosis in acute stroke settings. Septic, metabolic and hypoxic delirium phenotypes might have worse effect over functional outcome compared to sedative-related and undetermined causes. To our knowledge, this is the first study to explore delirium phenotypes in acute stroke. Higher sample size is needed to confirm our findings.

Delirium post-stroke: does the cognitive phenotype impact the patient's functional outcome?

Milena Fernandes de Oliveira[1], Nara Samara Silva dos Santos[1], Gabriel Souza Medrado Nunes[1], Thais Barbosa de Oliveira[1], Maria Eduarda Messias Vassoler[1], Luiz Paulo Oliveira Martins[1], Alex de Cerqueira Silveira Figueiredo[1], Antonio Lázaro Santos Soares Junior[1], Marivaldo Yslan Silveira Leal[1], Pedro Antônio Pereira de Jesus[1]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.

Correspondence: Milena Fernandes de Oliveira; Email: milenafer.oliv@gmail.com.

Background: Delirium, an acute cognitive disorder with attention fluctuations, can lead to worse outcomes in post-stroke patients. As for its phenotypes, it is traditionally classified according to the presented level of agitation-sedation, using the Richmond Agitation Sedation Scale (RASS), however, some patients only show fluctuations of inattention and disorganized thoughts, without alteration in the level of consciousness. Therefore, it is important to investigate whether these presentations have a different impact on the functional outcome. **Objective:** To identify if altered levels of consciousness in delirium lead to worse functional outcomes in post-stroke patients. **Methods:** Prospective cohort study with patients over 17 years old admitted to a semi-intensive care unit, from July/2023 to March/2024, in a reference center in Bahia, Brazil. We collected clinical and demographic data through bedside interviews. The level of altered consciousness was classified according to RASS and the presence of disturbances in the content of consciousness was assessed according to the Confusion Assessment Method for the ICU (CAM-ICU) every 48 hours of hospitalization. As for the functional outcome, patients were classified according to the Modified Rankin Scale (mRS) using a bedside approach or through calls to family members after 30 days of the stroke episode. We considered mRS 0-2 as a favorable outcome and mRS 3-6 as a poor outcome. The chi-square test was used for the statistical analysis. **Results:** A total of 213 patients were admitted, of whom 46 suffered from delirium during their hospitalization. Of these 46, 3 were excluded from the analysis due to mRS missing data. Of the patients included in the study, 51.2% were female, as for ethnicity, 30.2% were white, 67.4% were African descent, and 2.3% were Asian descent. Regarding age, the average was 68.9 (±1.96). As for the delirium phenotype, 29 patients had at least one episode of RASS other than 0 concomitant with attention disturbance; 7 (24%) had

favorable outcomes and 22 (66%) had poor outcomes. Regarding the other 14 individuals who presented delirium with only attention disturbance, 4 (28.5%) had favorable outcomes, and 10 (71.5%) had poor outcomes. In the statistical analysis, there was no difference between the proportions of bad outcomes in patients with RASS other than 0 and those with 0 (p=1.000). **Conclusion:** In the studied sample, altered consciousness in delirium did not significantly impact functional outcomes. These results emphasize the importance of addressing delirium in patients without altered consciousness, highlighting the need for prevention, treatment, and further studies with larger samples to better understand these cases, considering that delirium is often underreported in the ICU, particularly in patients without significant changes in consciousness.

https://doi.org/10.5327/CBN240505

Dementia in public health in Brazil: epidemiological analysis regarding hospitalizations and mortality between 2012 and 2022

Ana Laura Capel Sanchez[1], Thiago Oscar Goulart[2], Nathália Novaretti[1]

[1]Universidade de Ribeirão Preto, Ribeirão Preto SP, Brazil.
[2]Harvard University, MA, USA.

Correspondence: Ana Laura Capel Sanchez; Email: analauracapelsanchez@gmail.com.

Background: Dementia is characterized as the association of cognitive and functional impairment. Alzheimer's disease (AD) and vascular dementia (VD) are the main etiologies. Their prevalence has increased worldwide due to aging and demographic changes. Thus, analyzing its epidemiology and its socioeconomic impact is of utmost importance. **Objective:** To perform an epidemiological analysis of dementia syndrome and its burden on the Brazilian public health system. **Methods:** We collected data from DATASUS, a public and open database, searching for the ICD-10 related to Dementias (F00 - F03). Then, we did the statistical analysis with Excel and RStudio regarding the number of hospitalizations and deaths due to dementia syndromes. **Results:** Between 2012 and 2022, Vascular Dementia (F01) exhibited fluctuating death tolls, with 252 deaths reported in 2013 and 461 in 2022. Unspecified Dementia (F03) emerged as the leading cause of death, surpassing other categories and accumulating 29,168 deaths over the decade. However, the data, sourced from death certificates that record only the underlying cause, may underestimate the full impact of dementia-related fatalities. The G30 category experienced a surge in deaths from 13,142 in 2012 to 29,429 in 2022, totaling 221,004 deaths. Altogether, there were 286,524 dementia-related deaths from 2012 to 2022. Mortality rates in the F03 category varied regionally, notably showing a consistent rise in the Southeast region, especially in 2021. In contrast, mortality rates in the F01 category fluctuated across regions, with the Southeast exhibiting higher and relatively stable rates, peaking in 2019. Dementia hospitalization trends over the decade reflected distinct patterns among regions, where the Southeast recorded the highest number of hospitalizations (17,889), while the North Region reported the lowest hospital admission count (512), indicating regional disparities in healthcare utilization for dementia cases. **Conclusion:** Overall, the analysis reveals significant variations in dementia-related deaths and hospitalizations over the past decade, highlighting the notable impact of Vascular Dementia (F01) and Unspecified Dementia (F03) in mortality rates. The data underscore the regional disparities in mortality trends, with the Southeast region demonstrating higher rates and consistent increases. These findings emphasize the importance of targeted interventions and regional healthcare strategies to address the varying burden of dementia across different areas.

Dementia syndrome in multiple sclerosis

Andreia Costa Rabelo[1], Denise Sisterolli Diniz[1], Kamylla Camilo Araujo de Oliveira Diniz[1], Amanda Rabelo Mendonça[2], Leonardo Ferreira Caixeta[1]

[1]Universidade Federal de Goiás, Goiânia GO, Brazil.
[2]Escola Superior de Ciências da Saúde, Brasília DF, Brazil.

Correspondence: Amanda Rabelo Mendonça; Email: amandarm.13@gmail.com.

Background: Dementia syndrome is a clinical condition that results in cognitive decline and impairs patient activities. Cognitive impairment (CI) in Multiple Sclerosis (MS) is a prevalent and disabiliting symptom. Memory, attention and information processing speed are the most common affected cognitive domains, followed by spatial vision, executive functions and verbal fluency. The spectrum of cognitive symptoms in MS may vary in intensity from mild cognitive impairment (MCI) to installed dementia syndrome. **Objective:** To describe finds of dementia syndrome in people with MS (PwMS) in a reference center. **Methods:** The sample included 117 participants with MS randomly selected. All patients were diagnosed and followed up by a neurologist with expertise in MS. Inclusion criteria: patients with MS, <18 years old, vision acuity at least 0.5 in both eyes with or without lens correction, depression only if treated and EDSS <6.5. Exclusion criteria was presence of motor or visual deficit that interferes in tests response. The neuropsychological and behavioral assessment occurred all in a day conducted by a single neuropsychologist using the following instruments in order of application: Brief Repeatable Battery of Neuropsychological Tests (BRB-N), Beck Depression Inventory-2ª edition and Beck Anxiety Inventory. A neuropsychiatrist specialized in cognitive disorder and behavioral changes diagnosed them according to DSM-5 criteria to dementia syndrome. The study was approved by a local Ethics Committee. **Results:** The sample was 80.3% female, 70.1% had ≥10 years of schooling and mean age 42 years old (SD= ±13.3). Regarding clinical profile, 83% presented RRMS, 59.8% was diagnosed >6 years, disease time 7,85 years (SD±5.47) and EDSS <3.0. Were found 20 PwMS that met dementia syndrome's criteria, 7 males and 17 females, 50% with <9 years education, only 25% with EDSS >6, 70% of them 49 year old or younger and 50% presented Bipolar Disorder. The dementia cases divided into fenotypes: 60% like Frontotemporal lobar degeneration (50% apathetic and 50% uninhibited), 20% Alzheimer's disease and 20% none specific. Cognitively, language, semantic memory and executive functions, sensitive to temporal and frontal lobe dysfunctions, was the most impaired performance, following by evocation of visual memory and processing speed. Patients with dementia syndrome's performance was lower and indicate severe clinical deficits: 13 of them had 5 compromised domains and the other 7, 3 or 4 domains. **Conclusion:** MS causes CI in most patients and may increase the possibility of dementia syndrome. Motor severity, age, EDSS and disease time are risk factors for cognitive worsening and for possible dementia syndrome. Emphasis in the find of half the patients diagnosed with dementia were also diagnosed with bipolar disorder.

Dementia syndrome secondary to postherpetic encephalitis: a sequelae lesion

Geovanna Barros Rocha[1], Fredson Lucas de Almeida Soares[1], Denis Antonio Nascimento da Costa[1], Matheus Prado dos Santos[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Geovanna Barros Rocha; Email: geovannarocha@outlook.com.

Case presentation: M.R.S, female, 65 years old, mixed race, retired teacher, completed higher education, is hypertensive, has type 2 diabetes mellitus, using Metformin 850 mg, Losartan 50 mg, Escitalopram 10 mg. The patient reports that around 1 year ago she began to experience frequent forgetfulness, difficulty remembering recent events and changes in behavior, including episodes of irritability and social disinhibition. These symptoms began approximately 6 months ago, after being diagnosed with herpetic encephalitis treated with Acyclovir. She presents cognitive and behavioral symptoms: difficulty forming new memories and remembering recent past events; Episodes of disorientation in time and space; Difficulty finding words and understanding language; Personality changes with irritability, social disinhibition and inappropriate behavior. On physical examination, she appeared in a regular general condition, conscious, but with episodes of confusion, oriented in person, but disoriented in time and space. Cognitive Tests: Minimental 12/30; Verbal fluency 7; Clock test: correct circle drawing, numbers in incorrect position, does not include the 12 numbers and hands in wrong positions. **Discussion:** This is a unique case of dementia secondary to herpetic encephalitis, given the rarity of herpetic encephalitis and its high mortality (70%). The clinical picture of an adult with this dementia syndrome is quite variable, which includes a combination of neurological, cognitive and behavioral symptoms. Herpetic encephalitis, caused by HSV-1, can result in significant damage to the central nervous system, especially the temporal lobe and hippocampus, areas critical for memory and cognition. As a consequence, the patient usually presents with an acute onset of neurological symptoms followed by a gradual development of cognitive and behavioral impairments. **Final comments:** The patient presented serious behavioral changes, which may be the result of the damage resulting from herpetic infection in the brain. The case represented a diagnostic challenge, due to the absence of changes in imaging studies and due to the rarity and complexity of the syndrome, as well as the lack of support in the literature. The patient remains under outpatient follow-up, with progressive cognitive and behavioral improvement. It is important that more studies are carried out in order to provide greater access to information about this syndrome, as well as elucidate the diagnosis and appropriate management of affected patients.

https://doi.org/10.5327/CBN240508

Demographic, genetic and clinical profile of patients with hereditary transthyretin amyloidosis from a reference center in Brazil

Caroline Bittar Braune[1], Fábio de Souza[2], Cibele Franz[2], Kelma Macedo Pohlmann Simões[3], Yuri Vianna Fernandes da Silva[2], Ana Clara Farias de Negri[2], Regina Maria Papais Alvarenga[2,4]

[1]Universidade Federal do Estado do Rio de Janeiro, Hospital Gaffrée e Guinle, Departamento de Neurologia, Rio de Janeiro RJ, Brazil.
[2]Universidade Federal do Estado do Rio de Janeiro, Faculdade de Medicina, Rio de Janeiro RJ, Brazil.
[3]Universidade Federal do Estado do Rio de Janeiro, Hospital Gaffrée e Guinle, Departamento de Oftalmologia, Rio de Janeiro RJ, Brazil.
[4]Universidade de Vassouras, Vassouras RJ, Brazil.

Correspondence: Caroline Bittar Braune; Email: caroline.bittar@gmail.com.

Background: Hereditary transthyretin amyloidosis (ATTRv) is a rare, progressive, and fatal disease caused by pathogenic variants in the transthyretin (TTR) gene. TTR is a protein mainly produced in the liver that circulates as a stable tetramer involved in the transport of vitamin A and thyroxine. Pathogenic TTR variants dissociate into unstable monomers, that misfold to form amyloid deposits, which ultimately accumulate and damage multiple

tissues, including nerves, heart, gastrointestinal tract, and musculoskeletal structures. ATTRv amyloidosis is thus a multisystem disease with phenotypic heterogeneity depending on factors such as geographic location, underlying mutation, age of onset of symptoms, among others. Until recently, liver transplantation was the only therapeutic option, but in the last decades there has been a notable increase in the range of disease-modifying treatment strategies. **Objective:** Brazil is an endemic country for ATTRv amyloidosis, but data on the disease are limited to a few reference centers. The present study aims to describe the demographic, genetic and clinical characteristics of patients with ATTRv amyloidosis followed at a reference center in the southeastern region. **Methods:** This was a cross-sectional evaluation, with descriptive analysis, including patients with pathogenic variants in the TTR gene. All patients were evaluated by a neurologist and cardiologist. Data regarding demographic aspects, genotype and phenotype were collected from medical records. **Results:** A total of 78 patients were evaluated, 33 (42%) of whom were male, with a median age of 56 years (IQR 45-66). Genotypes Val30Met, Val122Ile and Ala39Asp occurred in 50 (64%), 26 (33%), and 2 (3%), respectively. 54% of patients were symptomatic, with a median age at symptom onset of 50 years (IQR 37-62). 29% had undergone liver transplantation, 20 (48%) had pure neurological phenotype, 1 (2%) had pure cardiac phenotype, and 20 (48%) had a mixed phenotype. Neuropathic impairment score (NIS) was available in 39 patients, with a median score of 34 (IQR 8-63). 90% of patients had dysautonomia, and the genotypes without dysautonomia (n=4) were 3 Val122Ile and 1 Ala39Asp. 78% of symptomatic patients were in Coutinho stage I, and 22% were in stages II (17%) or III (5%). **Conclusion:** In the present study, we present a large cohort of patients with ATTRv amyloidosis. Val30Met was the predominant mutation, consistent with that described in Brazil, and a rare mutation (Ala39Asp) also occurred. Most patients exhibit a mixed phenotype of polyneuropathy and cardiomyopathy, including Val122Ile patients, and NIS demonstrated relevant neuropathy in symptomatic patients. 90% of patients had dysautonomia, a known red flag for this disease, and most were in Coutinho stage I. Despite this, 22% were in stages II and III, indicating that we need to increase awareness about the disease even in our endemic country, since many patients still present in more advanced stages.

Background: Leprosy neuropathy (LN) is a chronic condition that starts as an infection of the Schwann cells by the bacilli Mycobacterium leprae, that may evolve into a demyelinating neuropathy that worsens during leprosy reactions (LR), with patterns not being clear, as both demyelination and axonal degeneration are common. Type-1 LR (T1LR) occurs in patients with active cell-mediated immune response against M. leprae and Type-2 LR (T2LR) occurs in multibacillary cases. Chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) is an acquired immune-mediated neuropathy, which can be typical or present as atypical variants, such as multifocal acquired demyelinating sensory and motor neuropathy (MADSAM). In some situations, although the patients fill the neurophysiological and clinical criteria for CIDP, the differential diagnosis of LN should be considered. **Objective:** This study aimed to describe how to interpret the demyelinating impairment in LN and verify if those patients fulfilled the criteria for CIDP. **Methods:** Retrospective observational analysis of patients with leprosy in a National Reference Center in Brazil between 2014-2023. 117 patients underwent neurophysiological examinations that showed a demyelinating pattern defined by prolonged distal motor latency, reduction in motor conduction velocity, and presence of conduction block (CB) and/or temporal dispersion (TD). All cases were analyzed according to the European Academy of Neurology/Peripheral Nerve Society (EAN/PNS) to establish a differential diagnosis of CIDP with neurophysiological and clinical criteria. **Results:** 82.0% had CB and 96.6% TD. 78.6% had both. 46.1% had T1LR and 17.9% T2LR. 81.3% of the patients with LR and 83.3% without LR had CB (p=0.78). 96.0% of LR group and 97.6% in the group without LR had TD (p=0.64). 83.3% of T1LR and 76,2% of T2LR had CB (p=0.47), and 94.4% of T1R and 100.0% of T2LR had TD (p=0.27). 92.3% (108/117) of patients had NCS compatible with CIDP, but none met the criteria for clinical CIDP, as none had proximal muscle weakness of limbs, nor absent or reduced tendon reflexes. On the other hand, 46.3% (50/108) of the patients with compatible NCS met clinical criteria for atypical CIDP, notably MADSAM. **Conclusion:** Leprosy is a spectral disease that may present different patterns of demyelination and axonal damage. The patterns observed in ENMG observed in the LN patients of our study are also observed in other inflammatory neuropathies, especially typical and atypical forms of CIDP. Therefore, an isolated analysis of ENMG does not allow for a correct differential between both conditions. This shows that the diagnosis of LN might be delayed with an incorrect diagnosis of CIDP, especially in developed countries. Hence, a careful clinical evaluation and detailed neurological exam are essential to establish the diagnosis of diseases with similar neurophysiological patterns.

Dengue encephalitis and the differential diagnosis of bilateral thalamic lesions

João Márcio Borgue de Oliveira[1], Itamar Meireles Andrade Santos[1], Caroline de Barros Viegas[1], Jerônimo Moda[1], Renan Macionil Cotrim[1], Camila Bonfanti Baima[1]

[1]Universidade Estadual Paulista, Faculdade de Medicina de Botucatu, Hospital das Clínicas, Botucatu SP, da Brazil.

Correspondence: João Márcio Borgue de Oliveira; Email: jmarcio.bo.md@gmail.com.

Case presentation: Woman, 20 years old, with attention-deficit/hyperactivity disorder, hospitalized due to encephalopathy, with fever, headache, asthenia, and myalgia that started 3 days ago. She appeared drowsy, disoriented, with reduced verbal fluency, partially understanding commands, with dysarthria, dysphagia, incomplete and disproportionate hemiparesis with brachial predominance on the left, Babinsk sign on the left, bilateral palmomental reflex, absent meningeal signs, and normal fundoscopy. Acyclovir was started due to the possibility of herpetic encephalitis. The serum NS1 antigen test was positive. Computed tomography (CT) of the brain with bilateral hypodensity in the thalamus and posterior arm of the internal capsule on the right. Arterial and venous CT angiography without occlusions, stenoses, or other signs of vasculopathy. Cerebrospinal fluid (CSF) with hyperproteinorrachia (68mg/dL) was maintained during evolution (60mg/dL). Electroencephalogram with baseline activity level disturbance. Magnetic resonance imaging of the brain with hyposignal on T1 and hypersignal on T2/FLAIR in the thalamus, posterior arm of the internal capsule, and clear globe on the right, without restriction to diffusion with heterogeneous gadolinium impregnation and intervening microhemorrhages. Acyclovir was suspended after findings not suggestive of herpetic encephalitis, with a negative viral panel in CSF for HSV-1, HSV-2, EBV, VZV, and CMV and a negative IgM for dengue. Throughout hospitalization, the patient progressed with improvement of encephalopathy, dysarthria, and dysphagia, being discharged after 14 days, maintaining temporal disorientation, and partial improvement in hemiparesis. **Discussion:** Patient with dengue in the acute phase, with criteria for probable encephalitis (change in mental status, fever, new focal sign, and parenchymal changes on imaging examination), with neuroimaging findings suggestive of arbovirus encephalitis, with other causes of viral encephalitis being excluded, and although the absence of IgM for dengue in the liquor has low sensitivity for diagnosis, Given the acute evolution and bilateral thalamic involvement, it is important to consider the following differential diagnoses: Stroke due to occlusion of Percheron's arterie–bilateral paramedian thalamic infarction with or without involvement of the midbrain and anterior thalamus; deep cerebral vein thrombosis (CVT); acute disseminated encephalomyelitis (ADEM) – generally start after remission of the febrile period with predominantly white matter involvement. **Final comments:** The diagnosis of dengue encephalitis is based on criteria for encephalitis, suspicion of dengue, laboratory confirmation of systemic infection, neuroimaging changes with or without CSF changes, and the exclusion of other etiological agents for the encephalitis. Furthermore, the presence of bilateral thalamic lesions and acute evolution makes it necessary to exclude stroke, CVT, and ADEM.

Dengue encephalitis: a reality in an endemic country

André Luiz Pereira Martins[1], Olga Cassol Silva[1], Joana Laurindo da Silva[1], Mariana Costa Borges[1], Maria Eduarda Andreatta[1], Carolina Aparecida Donofrio Santos Costa[1], Gabriela da Silva Cremonese[1], Cristine Koehler[1], Rafael Marques Mendes[1], Gladys Lentz Martins[1]

[1]Hospital Governador Celso Ramos, Florianópolis SC, Brazil.

Correspondence: André Luiz Pereira Martins; Email: martinsandrelp@gmail.com.

Case presentation: A eighty year-old woman was transferred to the emergency room in a tertiary hospital at Florianópolis (Santa Catarina, Brazil), due to the report that she woke up with tonic bilateral arms flexion and global aphasia. She had no neurological deficits the night before. As comorbidities, only hypertension and diabetes (either well controlled) and no limitations on daily activities (modified Rankin scale of zero). In the last three days, the patient presented general malaise, myalgia, fever and retro-orbital headache. Evaluated by a neurologist in the emergency, presence of mental confusion and aphasia, without focal neurological deficits. Entry laboratory tests showed leukopenia and thrombocytopenia, without other changes. An imaging investigation was performed with tomography and angiotomography of the skull and neck, with no changes. The patient evolved with lowering of the sensorium. CSF examination showed mild proteinorrhaquia, low cellularity, normal glucose; HSV and CMV investigation, bacterioscopy and bacterial culture were negative. MRI of the skull was unremarkable. Because of the dengue endemic, associated with clinic symptoms, leukopenia and thrombocytopenia, NS1 for dengue was requested; and an electroencephalogram (EEG) investigation was carried out due the altered mental status plus neurological symptoms. Laboratory of NS1 was positive; EEG showed basic activity with severe disorganization and periodic lateralized discharges with greater right fronto-temporal projection - these findings are associated with non-specific diffuse encephalopathies and non-convulsive status epilepticus; furthermore, periodic lateralized

discharge may be associated with encephalitis of infectious etiology, such as viral. A loading and maintenance dose of levetiracetam was administered. The patient progresses with gradual improvement and is discharged with her neurological status recovered. **Discussion:** According to data from the Ministry of Health's Arbovirus Panel, Brazil recorded, in the first half of this year, an unprecedented number of more than 5 million cases (confirmed and probable) of dengue. The endemic - and epidemic - situation is constant in our territory. Neurological manifestations are increasingly diagnosed in patients with dengue infection. In an Asian study, neurological complications occurred in 0.5% – 5.4% of confirmed dengue cases; in other studies, up to 20% of encephalitis cases presented in hospitals were diagnosed with dengue fever. **Final comments:** Dengue infection emerges every year in Brazil, as well as mortality and serious illnesses caused by the disease. Therefore, it is necessary to share experiences of the different forms of neurological presentations of dengue infection, given the current lack of defined diagnostic criteria. Consequently, attention will be given to assessing patients in a holistic manner, correlating clinical and epidemiology data, obtaining the best care for neurological patients.

Dengue fever and neurological complications: a report of acute disseminated encephalomyelitis (ADEM) with good response to plasmapheresis

Bruna Beppler[1], Adria Rodrigues da Silva[1], Caroline Zapelini[1], Lia Maki Hatisuka Imai[1], Luis Sidônio Teixeira da Silva[1], Lúcio Baena de Melo[1], Priscila Audibert Nader[1], Maria Caroline Martins de Araújo[1], Jéssica Camila Fizinus[1], Lívia Souza Primo[1]

[1]Universidade Estadual de Londrina, Londrina PR, Brazil.

Correspondence: Bruna Beppler; Email: brunabeppler@hotmail.com.

Case presentation: A 19-year-old previously healthy male was admitted to a tertiary hospital due to symptoms that began 10 days prior with fever, myalgia, and loss of appetite. Subsequently, he developed decreased level of consciousness, spastic tetraparesis, paresthesia of the lower limbs, and urinary retention. On neurological examination, the patient was lethargic and minimally responsive, with grade 0 muscle strength in the lower limbs, grade III in the upper limbs, normal global reflexes, and no cranial nerve abnormalities. Dengue IgM serology was positive. Cerebrospinal fluid (CSF) analysis showed 1013 cells (56% lymphocytes), glucose level of 56, and protein level of 223. Oligoclonal bands were absent. Viral panel in CSF was negative. The anti-aquaporin (AQP4) serum test was non-reactive Neuroaxis magnetic resonance imaging revealed bilateral and symmetrical T2 hyperintensity in the corticospinal tracts, splenium of the corpus callosum, brainstem, cerebellar peduncles, and dentate nuclei. The spinal cord was continuously affected from the cervical to T11 levels. Intravenous methylprednisolone 1g/day was initiated on admission and continued for 5 days. Due to lack of clinical response to intravenous methylprednisolone, plasmapheresis was performed. After 5 sessions, the patient was discharged with complete improvement of tetraparesis and consciousness level, although still experiencing urinary retention requiring intermittent catheterization. Follow-up showed no neurological progression or new lesions on neuroimaging. **Discussion:** Dengue fever is the most common arboviral disease affecting humans. Neurological manifestations, although rare, are mostly severe. Acute disseminated encephalomyelitis (ADEM) is one of the described complications, characterized by a rare, monophasic, inflammatory-demyelinating condition affecting the central nervous system. Typically triggered by an infection or prior immunization, clinical features may include fever, headache, altered consciousness, optic neuritis, and focal neurological deficits. Neuroimaging in the acute phase reveals diffuse, extensive lesions primarily involving white matter. Differential diagnosis from Multiple Sclerosis can be challenging initially. Treatment options include high-dose corticosteroids, Human Immunoglobulin, and in certain cases, plasmapheresis. **Final comments:** This case illustrates a severe presentation of ADEM following dengue fever, with favorable outcomes following plasmapheresis after inadequate response to intravenous methylprednisolone. It highlights the importance of aggressive treatment in a potentially disabling and life-threatening condition.

Dengue meningoencephalitis: a case of neurological manifestations and diagnostic challenges in pediatrics

Sandra Souza Meirelles[1], Luiza de Azevedo Freitas Giles[2], Thalita Freitas Machado[1], Thiely Guedes Giles[1]

[1]Centro Universitário do Espírito Santo, Colatina ES, Brazil.
[2]Universidade Federal de Juiz de Fora, Juiz de Fora MG, Brazil.

Correspondence: Luiza de Azevedo Freitas Giles; Email: luiza.azevedo.freitas@gmail.com.

Case presentation: A 12-year-old female patient presented to the emergency department with a one-day history of fever and myalgia, which had progressed to incoherent speech and disorientation and retrograde amnesia. On physical examination: fair general condition, alternating between lucidity and espatiotemporal disorientation, afebrile, and without meningeal signs. Considering the hypothesis of meningoencephalitis, she was admitted to the pediatric ward and treated with acyclovir and ceftriaxone. Blood tests showed thrombocytopenia and leukopenia, leading to a positive NS1 test for dengue virus. Cranial computed tomography (CT) showed no abnormalities, and cerebrospinal fluid (CSF) was clear, with 2 leukocytes, 40 mg/dL glucose, 48 mg/dL proteins, and a non-reactive VDRL. Blood cultures were negative, and ceftriaxone was discontinued. During the course of hospitalization, the patient exhibited psychotic episodes, febrile responses, cutaneous rash, nausea, and headache. By the 5th day, cranial MRI showed bilateral and symmetrical hypersignal in the anteromedial portions of the thalami. CSF analysis confirmed Dengue via RT-PCR (serotype DEN-1) by the 10th day, with no additional microbial evidence. The clinical symptoms improved slightly by the 5th day, and she was considered fit for discharge on the 10th day, with outpatient follow-up with a pediatric neurologist. Post-discharge, the patient reported a satisfactory condition with no significant impacts, although family members noted headaches and impulsivity as potential sequelae following dengue meningoencephalitis. **Discussion:** Dengue virus, a Flaviviridae family arbovirus, is generally considered non-neurotropic. However, in recent years, the incidence of neurological manifestations in severe forms of the disease has increased, occurring in 0.5 to 21% of cases. In dengue meningoencephalitis CT may reveal hyperdense parenchymal foci and hypodensities in the thalamus and basal ganglia, while MRI is more accurate, showing hypersignal on T2-weighted images. In this case, cranial CT was unremarkable, but MRI showed thalamic hypersignal. There is still no specific treatment for dengue meningoencephalitis, supportive care is standard. Corticosteroids, antibiotics, and antivirals lack proven efficacy but are often used empirically, as in this case. **Final comments:** This case highlights the complexity and severity of dengue's neurological manifestations. A comprehensive diagnostic approach is crucial for early and accurate clinical management. MRI proved superior to CT, emphasizing its role in evaluating suspected neurological complications of dengue virus. The patient's gradual improvement suggests a favorable prognosis, but neurological sequelae indicates the need for long-term follow-up. This case emphasizes the importance of recognizing neurological manifestations of dengue virus, even if rare, and conducting thorough investigations to ensure accurate diagnosis and appropriate treatment.

Dengue virus-induced encephalitis leading to new-onset refractory status epilepticus

Valmir Vicente Filho[1], Caroline Link[1], Isabelle Pastor Bandeira[1], Camila Emi Fujiwara Murakami[1], Marlon Wycliff Caeira, Helio Afonso Ghizoni Teive[1], Cláudia Suemi Kamoi Kay[1]

[1]Universidade Federal do Paraná, Curitiba PR, Brazil.

Correspondence: Valmir Vicente Filho; Email: valmirvicentef@gmail.com.

Male, 74 years, with functional status, previous hypertension, hypothyroidism, ex-smoker. The initial symptoms were anorexia, diarrhea, vomiting, headache, and fever. Three days post onset, the patient experienced a decline in consciousness level, right lower limb contraction, and subsequent bilateral tonic-clonic seizures. At the Emergency Care Unit, a positive NS1 serum test confirmed dengue virus infection. The patient was transferred to a reference hospital for advanced management due to the necessity of ventilatory support for airway protection caused by altered consciousness. Serial electroencephalography (EEG) studies in the intensive care unit (ICU) revealed severe diffuse cerebral dysfunction, predominantly in the left temporal region, leading to refractory status epilepticus unresponsive to initial phenytoin infusion. The condition required loading doses of phenobarbital and ketamine for seizure control. Magnetic resonance imaging (MRI) of the brain did not show acute changes, aside from mild diffuse cortical atrophy. Cerebrospinal fluid (CSF) analysis showed normal cellularity but elevated protein levels. Type 3 oligoclonal bands were identified. RT-PCR for dengue virus in the CSF was negative, but dengue IgM antigen was confirmed at serum. The patient received a 5-day course of methylprednisolone and intravenous human immunoglobulin. His level of consciousness improved. During hospitalization, he developed ventilator-associated pneumonia and Clostridioides difficile diarrhea. With motor and speech rehabilitation, the patient was discharged with a patent airway, no stomas, ambulatory without assistance, and without cognitive sequelae. Dengue encephalitis can manifest as altered levels of consciousness or personality, seizures, focal neurological signs, reactive IgM dengue antibody, NS1 antigen, or positive dengue PCR in serum and/or CSF, and the exclusion of other causes of viral encephalitis or encephalopathy. This case exemplifies new-onset refractory status epilepticus (NORSE) associated with dengue encephalitis.

Correspondence: Vanderson Carvalho Neri; Email: vandersoncn@yahoo.com.br.

Background: Baló Concentric Sclerosis(BCS) is a rare demyelinating disease of the central nervous system characterized pathologically by large alternating lamellae of demyelinated and myelinated white matter arranged in a concentric pattern. BCS is considered an unusual variant of multiple sclerosis (MS) by some authors. **Objective:** To describe the clinical and neuroimaging characteristics of patients in the State of Rio de Janeiro/Brazil. Define the pattern of neurological involvement that matches differential diagnoses with other demyelinating diseases, cerebrovascular diseases, and brain tumors. **Methods:** A case series with an anti-mortem diagnosis of BCS performed by magnetic resonance imaging between 1985 and 2023 was selected from the base date of a public hospital (Hospital Federal da Lagoa), a University hospital (Gaffrée-Guinle/Universidade Federal do Estado do Rio de Janeiro), and a private clinic (NeuroRio). **Results:** Twenty cases of BCS were selected from a sample of 1,500 patients diagnosed with the inflammatory demyelinating disease. 14 women and 6 men were evaluated; the Average age: was 32.05. 6 cases (30%) had a monophasic course, 14 (70%) had a recurrent course 5 cases (20%) had manifestations during childhood. Monophasic cases: 100% presented symptoms acutely - symptoms: hemiparesis/hemiparesthesia: 6 (100%), dysarthria: 2 (33.3%), language disorder: 2 (33.3%), hemianopsia: 1 (16.7%); 3 patients (50%) showed complete improvement, 3 (50%) maintained neurological sequelae. Recurrent cases: 13 (92.9%) with acute manifestation, 1 (7.1%) progressive symptoms. Outbreaks: mean 3 (min.2, max. 17); Symptoms: hemiparesis/hemiparesthesia: 7 (50%), dysarthria: 1 (7.1%), language disorder: 1(7.1%), hemianopsia: 1 (7.1%); optic neuritis: 1 (7.1%), seizure: 1 (7.1%), 1 (7.1%) chorea/athetosis. 11 (78.6%) cases showed complete improvement, 2 (14.2%) maintained sequelae, and 1 (7.1%) died. One case of NMO-like with AQP4+ and two pseudotumoral/ADEM-like has been described. Neuroimaging: 20 (100%) had a characteristic lesion of BCS in the periventricular white matter, 5 (25%) had a lesion also outside the brain: 5 cases had a lesion in the brainstem, and one case in spinal cord. **Conclusion:** Characteristic lesions were predominant in the periventricular white matter. Symptoms related to long pathways, ascending and descending, were the predominant symptoms. 70% of cases had a recurrence of symptoms. 78% of recurrent cases and 50% of monophasic cases had complete recovery of symptoms, with no neurological sequelae. Therefore, it can be said that BCS is not a variant of MS.

https://doi.org/10.5327/CBN240516

Description of prevalence of hospitalizations for brain neoplasms and the mortality among Brazilian federative regions

Guilherme Galardino Santos[1], Bernardo Caetano Novaes[1], Victor Bruno dos Santos Teixeira[1], Samuel José Feres Ozava[1], Heloisa Magda Resende[1]

[1]Centro Universitário de Volta Redonda, Volta Redonda RJ, Brazil.

Correspondence: Guilherme Galardino Santos; Email: guilhermegalardino@gmail.com.

Background: Brain tumors are neoplasms originating from various cells of the central nervous system (CNS) or from metastases of other primary cancers. The global incidence is low, around 3 cases per 100,000 people, with 11,000 new cases annually in Brazil. Although rare, they are highly incapacitating and have high morbidity and mortality, with a 5-year survival rate of 37%. **Objective:** To calculate the prevalence of hospitalizations due to brain neoplasms (primary and metastatic lesions) in the federative regions of Brazil and to compare these prevalences with the mortality rates in these regions over the last 5 years. **Methods:** The methodology of this study involved data collection from the Hospital Information System (SIH) from January 2019 to December 2023. To calculate prevalence, we used population data from the 2022 census by IBGE. Mortality rates were also obtained from the SIH for the same period. All data were based on the place of residence and year of service. **Results:** From 2019 to 2023, there were 75,799 hospitalizations due to brain neoplasms in Brazil. The federative region with the highest hospitalization prevalence (per 100,000 inhabitants) was the South (58.68), followed by the Central-West (40.09), Southeast (37.5), Northeast (29.66), and North (21.22) regions. Although the highest prevalence of cases was concentrated in the South, the highest annual mortality rate was in the North (15.32), followed by the Southeast (14.82), Northeast (12.88), South (12.25), and Central-West (12.11). The average mortality rate for hospitalizations due to brain neoplasms in Brazil was 13.60. **Conclusion:** Brain tumors, while rare, represent a significant public health challenge in Brazil due to their high morbidity and mortality. Between 2019 and 2023, there were 75,799 hospitalizations for brain neoplasms, with the South region having the highest prevalence (58.68 per 100,000 inhabitants) and the North region the lowest (21.22 per 100,000 inhabitants). However, the highest mortality rate was observed in the North (15.32). The national average mortality rate was 13.60, highlighting the need for interventions to improve the diagnosis and treatment of brain tumors, especially in regions with higher mortality, in addition to enhancing healthcare infrastructure.

https://doi.org/10.5327/CBN240517

Description of the prevalence of epilepsy hospitalizations in the federative regions of Brazil and the mortality rate

Bernardo Caetano Novaes[1], Huyla Pereira de Almeida Lima[1], Lara Valentim Vale[1], Fabiana Aparecida Eller[1], Elder Machado Sarmento[1]

[1]Centro Universitário de Volta Redonda, Volta Redonda RJ, Brazil.

Correspondence: Bernardo Caetano Novaes; Email: bernardo16.novaes@gmail.com

Background: Epilepsy is a neurological disorder characterized by recurrent seizures caused by abnormal neuronal discharges in the brain. The global prevalence is estimated at 621.5 cases per 100,000 inhabitants, including primary and secondary cases. Although treatable, many patients achieve remission. However, epilepsy can have an unfavorable prognosis, leading to death, especially in middle- and low-income countries. **Objective:** To calculate the prevalence of epilepsy hospitalizations in the federative regions of Brazil and to compare the prevalence rates with the mortality rate in these regions over the last 5 years. **Methods:** The methodology employed in this study involved data collection from the Hospital Information System (SIH) from January 2019 to December 2023, and population data from the 2022 Brazilian Institute of Geography and Statistics (IBGE) census were used to calculate the prevalence. Mortality rates were also obtained from the Hospital Information System in the same study period. **Results:** During the studied period, there were 285,241 hospitalizations for epilepsy in Brazil. The federative region with the highest prevalence (per 100,000 inhabitants) was the South (191.1), followed by the Central-West (150.65), Southeast (134.86), Northeast (133.52), and North (92.76). Despite the higher prevalence of cases in the South, the total annual processing mortality rate was highest in the Southeast (3.12), followed by the Northeast (2.88), North (2.35), Central-West (1.96), and South (1.88). **Conclusion:** Based on the data, the South region (191.1) recorded the highest number of epilepsy hospitalizations, followed by the Central-West (150.65), Southeast (134.86), Northeast (133.52), and North (92.76). However, the total annual processing mortality rate was highest in the Southeast (3.12). These regional discrepancies suggest the need for a more in-depth analysis of the factors contributing to the prevalence and outcomes of epilepsy in different areas of the country. Additionally, they highlight the importance of prevention strategies, early diagnosis, and management of epilepsy nationwide. Equally crucial is ensuring equitable access to quality healthcare across all regions.

https://doi.org/10.5327/CBN240518

Description of the prevalence of migraines and other pain syndromes hospitalizations in the federative regions of brazil and the mortality rate

Bernardo Caetano Novaes[1], Davi Melo de Hollanda Cordeiro[1], Victor Bruno dos Santos Teixeira[1], Guilherme Galardino Santos[1], Samuel José Feres Ozava[1], Myllene Rodrigues Silva[1]

[1]Centro Universitário de Volta Redonda, Volta Redonda RJ, Brazil.

Correspondence: Bernardo Caetano Novaes; Email: bernardo16.novaes@gmail.com.

Background: Migraines and other pain syndromes are neurological disorders characterized by recurrent episodes of intense, debilitating pain. Syndromes such as tension-type headache, cluster headache, and neuropathic pain also contribute to the global burden of chronic pain. Although effective treatments exist, their efficacy varies, and many patients suffer from uncontrolled chronic pain. These syndromes and their socioeconomic implications are acute in low- and middle-income countries, where access to specialized care is limited. Studies using the International Headache Society (IHS) criteria indicate that 15-18% of women and 6% of men are affected by migraines, primarily between ages 25 and 55. Migraine varies in severity and disability and is underdiagnosed worldwide. **Objective:** To investigate the prevalence of hospitalizations for migraine and headache syndromes in different regions of Brazil and to correlate these prevalences with regional mortality rates over the past five years. **Methods:** This study was based on data collected from the Hospital Information System (SIH) between January 2019 and December 2023. Population data from the 2022 IBGE census were used to calculate prevalences. Mortality rates for the same period were obtained from the SIH. **Results:** During the period from January 2019 to December 2023, there were 51,269 hospitalizations for migraine and other headache syndromes in Brazil. The highest prevalence was observed in the South region, with 44.23 cases per 100,000 inhabitants, followed by the Northeast (28.98), North (24.52), Central-West (18.21), and Southeast (17.65). The highest mortality rate was recorded in the North region (2.89), followed by the Northeast (1.61), Southeast (0.4), Central-West and South (0.28). The average mortality rate in Brazil is approximately 1.12. **Conclusion:** Headaches are among the most common medical complaints, significantly impacting people's professional lives. This study investigated the prevalence of hospitalizations for migraine and headache syndromes in Brazil, correlating these with regional mortality rates over the past five years. From 2019 to 2023, there were 51,269 hospitalizations. The South region had the highest prevalence (44.23 cases per 100,000 inhabitants) and the lowest mortality rate (0.28 per 100,000). In contrast, the North and Northeast regions had significantly higher mortality rates (2.89 and 1.61 per 100,000, respectively). Although the overall mortality rate is relatively low, it is crucial to investigate the factors contributing to these regional disparities, both to understand the high mortality in the North and Northeast and to explore why the South region, with the highest prevalence, has the lowest mortality rate.

Descriptive analysis of cerebrovascular disease patients at a public hospital in São Paulo - Ipiranga Hospital

Vitória Karoline Justino dos Santos[1], Gabriela Simões Noel da Silva[1], Isabella Guimarães Silva Alípio[1], Rafael Alves Banzati Viana[1], Eduardo Lengruber Oliveira[1], Levy Werneck de Almeida Menezes[1], Vitor Henrique Justino dos Santos[2], Beatriz Azevedo Godke Veiga[1]

[1]Hospital Ipiranga, São Paulo SP, Brazil.
[2]Universidade Anhembi Morumbi, São Jose dos Campos SP, Brazil.

Correspondence: Vitória Karoline Justino dos Santos; Email: vitoriakj25@gmail.com.

Background: Cerebrovascular Disease (CVD) patients have a high prevalence of hypertension (70-80%) and diabetes (30%), particularly in ischemic stroke. Mortality is higher in hemorrhagic stroke (40%) due to the severity of cerebral hemorrhages. Infections such as pneumonia occur in about 30% of cases, complicating the clinical outcome and increasing patient mortality and morbidity. **Objective:** This study aims to evaluate CVD patients' epidemiology at Ipiranga Hospital. **Methods:** We selected 290 CVD patients treated at one center from January 1, 2022 to March 1, 2024. Data collected included gender, age, CVD type, comorbidities such as prior stroke, myocardial infarction, hypertension, diabetes, and whether they were alcoholics or smokers. We collected data on mortality and additional diseases during hospitalization. We described continuous variables in medians (±interquartile range) and categorical variables in percentages. We used the Mann-Whitney test for continuous variables and the chi-square test for categorical variables. The p-value considered statistically significant was <0.05. **Results:** The sample consisted of 290 patients, with 50.3% being men. Of these, 12.17% had a hemorrhagic CVD (CVDh), and 87.2% had an ischemic CVD (CVDi). The median (±IQR) age of the study group was 68 years (±17). The comorbidities frequencies were 71.38% systemic arterial hypertension (SAH), 28,61% diabetes mellitus (DM), 20% previous CVD (CVDp), and 7.23% previous myocardial infarction (MIp). The infection and mortality rates were 11.8% and 12.5%, respectively. The average National Institutes of Health Stroke Scale (NIHSS) score at admission was 6; at discharge, it was about 3 (±7 for both). **Conclusion:** This study suggests CVD patients treated at Ipiranga Hospital have a predominance of comorbidities such as hypertension and diabetes, which is consistent with the existing literature. Therefore, it is imperative to focus on stabilizing these primary conditions through primary and secondary prevention measures to reduce the incidence of such events.

Descriptive analysis of ischemic stroke patients undergoing thrombolysis in a São Paulo metropolitan public hospital

Gabriela Simões Noel da Silva[1], Vitória Karoline Justino dos Santos[1], Isabella Guimarães Silva Alípio[1], Rafael Alves Banzati Viana[1], Eduardo Lengruber Oliveira[1], Levy Werneck de Almeida Menezes[1], Vitor Henrique Justino dos Santos[2], Beatriz Azevedo Godke Veiga[1]

[1]Hospital Ipiranga, São Paulo SP, Brazil.
[2]Universidade Anhembi Morumbi, São José dos Campos SP, Brazil.

Correspondence: Gabriela Simões Noel da Silva; Email: gabisnoel@gmail.com.

Background: Cerebrovascular disease (CVD) is the second leading cause of death in Brazil, with a mortality rate of 51.3%. Currently, in ischemic stroke cases, venous thrombolysis is an effective acute-phase treatment option that reduces mortality and is widely available through the Brazilian public health system. **Objective:** This study evaluates the epidemiological profile of CVD patients who underwent intravenous thrombolysis at a public hospital in São Paulo, and compares the prevalence of this treatment with rates from previous studies. **Methods:** Retrospective analysis of medical records from 267 CVD patients between January 2022 and March 2024. Logistic regression was used to assess factors influencing the likelihood of undergoing intravenous thrombolysis. **Results:** Among 267 ischemic CVD, 30 underwent intravenous thrombolysis (11%), one patient was excluded due to insufficient data in the medical record. Of these, 62.1% were male, with a median age of 64,5 years (±30.5). High blood pressure was present in 50%, and diabetes mellitus in 14.3%. Additionally, 68.9% reported prior exposure to smoking, of which 34.5% were active smokers; 17.2% reported alcoholism. Only one patient (1.8%) with a history of prior stroke underwent thrombolysis. Regarding etiological investigation, the majority of events had an undetermined cause (44.8%), followed by cardioembolism (27.6%), atherosclerosis (24.1%) and lacunar stroke (3.4%). Logistic regression analysis demonstrated that cardioembolic etiology was associated with a 4.3 times higher risk of undergoing thrombolysis compared to atherosclerotic etiology. The anterior circulation was affected in 72% of cases. The mean National Institutes of Health Stroke Scale (NIHSS) on admission was 13.2 (±11) and 6.56 (±9) at discharge. Each point increase in NIHSS on admission correlated with a 22% increase in the likelihood of undergoing thrombolytic therapy. Among the patients who underwent this procedure, 20% died. **Conclusion:** The profile of patients with ischemic stroke who underwent thrombolysis was predominantly composed of men in their seventh decade of life, with multiple comorbidities and a high rate of involvement of the anterior cerebral artery territory. Data analysis indicated a lower occurrence in patients with reduced NIHSS, stroke of atherosclerotic cause, or those with a history of previous stroke. Although the prevalence of thrombolysis was similar to that in some developed countries (11% of patients), such as the United States (8.8%), it is still far from the rates observed in countries like Austria (16.8%) and the Czech Republic (23.8%). Given these data, it is essential to identify potentially reversible factors, such as delays in seeking early medical care and failures in the intra-hospital process, to facilitate access to this therapeutic modality.

Background: Desmopressin is an antidiuretic hormone used to treat central diabetes insipidus (CDI), nocturnal enuresis and bleeding disorders, enhancing platelet adherence and aggregation on the vascular endothelium. Patients on antiplatelet therapy are at an increased risk of intracranial haemorrhage. Therefore, desmopressin administration in patients with intracranial haemorrhage secondary to antiplatelet therapy is often considered. **Objective:** We aimed to perform an updated systematic review and meta-analysis assessing desmopressin safety and efficacy in treating intracranial haemorrhage in patients under antiplatelet therapy. **Methods:** MEDLINE, Scopus, and Web of Science databases were systematically searched until 17 May 2024. We considered the risk ratio and odds ratio for dichotomous outcomes and the mean difference for continuous outcomes. Data were examined using the Mantel-Haenszel method and 95% CIs. Heterogeneity was assessed using I^2 statistics. R, version 4.3.2, was used for statistical analysis. **Results:** A total of 10 studies and 7017 patients were included, of whom 882 (12%) received desmopressin and 6135 (88%) received a placebo. Only the length of hospital stay showed significant statistical results comparing both analysed groups (RR 0.56; 95% CI 0.09-1.03; p=0.019534; I^2=6%). No statistically significant difference between groups was seen regarding levels of haematoma expansion 20% (RR 0.96; 95% CI 0.44-2.13; p=0.929678; I^2=77%) and 33% (RR 0.90; 95% CI 0.48-1.71; p=0.756357; I^2=71%) and thrombotic events incidence (RR 0.66; 95% CI 0.33-1.30; p=0.227244; I^2=0%). **Conclusion:** In this updated meta-analysis, our results suggest that desmopressin administration was not associated with more beneficial outcomes in patients with intracranial haemorrhage undergoing anti-platelet treatments, as only one of the seven outcomes analysed presented a statistically significant difference tending for desmopressin administration.

Background: Intracranial hemorrhage (ICH) is a severe condition that presents high levels of morbidity and mortality in patients who are either traumatized or suffer from poorly controlled hypertension. Its severity is notable, affecting various brain regions and requiring prompt interventions to halt its progression and prevent additional complications. However, the treatment of ICH, especially in patients on antiplatelet therapy, poses significant challenges. In this context, the hypothesis emerged that desmopressin (DDAVP), a synthetic analog of vasopressin, might have some beneficial effect on hematoma expansion (HE) in these patients. **Objective:** In light of this scenario, the present study aimed to qualitatively and quantitatively evaluate, through a systematic review and meta-analysis, the effects of desmopressin on important clinical outcomes such as HE and length of hospital stay, two variables that can significantly affect patient prognosis. **Methods:** This study was a systematic review and

meta-analysis registered via PROSPERO (registration number CRD42024525639) and conducted and presented according to the Preferred Reporting Items for Systematic Review and Meta-analysis (PRISMA) guidelines, which govern all scientific productions of this type. **Results:** Five outcomes were analyzed with the use of desmopressin, of which two showed a slight reduction with desmopressin use (HE and thromboembolic events), and three favored the control group (mortality, unfavorable neurological outcome, and length of hospital stay). However, none of these data reached significance, with p-values >0.05. Hematoma expansion: OR=0.85, CI: 0.51 to 1.42, I^2=69%; Mortality: OR=1.05, CI 0.68 to 1.60; Thromboembolic events: OR = 0.62, CI 0.29 to 1.29; Unfavorable neurological outcome: The combined OR of 1.73 (CI 0.99-3.03) suggests a trend towards increased risk of unfavorable neurological outcomes with desmopressin, but the CI is very close to not including 1, indicating this result is on the borderline of statistical significance. Heterogeneity of I^2=14%, indicating low heterogeneity among the studies. Length of hospital stay: The overall mean difference was 0.49 days in favor of the control (CI [-0.20 to 1.17]; p=0.17). Subgroup analysis among patients with ICH of traumatic or spontaneous etiology showed no difference in HE. Additionally, the epidemiological profile of ICH patients was outlined, with men being the most affected and the mean age among studies ranging from 56.5 to 77 years. **Conclusion:** The present study does not support the standardized use of desmopressin for all patients with intracranial hemorrhage. Its use should be critically evaluated based on the clinical context to determine which individuals may benefit the most from this pharmacological strategy.

Detailed neurological examination in people living with HTLV-1

Qesya Rodrigues Ferreira[1], Ana Flávia Novaes[1], Ariana Leal Borges da Cruz[1], Carolina Souza Santana[1], Larissa Alves Fernandes[1], Jéssica Oliveira de Souza Nascimento[1], Alice Palmeira Nascimento Cerqueira[1], Luiz Guilherme Alves Pinheiro Faria[1], Fernanda Khouri Barreto[1], Davi Tanajura Costa[1]

[1]Universidade Federal da Bahia, Instituto Multidisciplinar em Saúde, Vitória da Conquista BA, Brazil.

Correspondence: Qesya Rodrigues Ferreira; Email: rodriguesqesya@gmail.com.

Background: The Human T-lymphotropic Virus Type 1 (HTLV-1) was the first retrovirus identified and it is estimated that 5 to 10 million people in the world live with the virus. HTLV-1 is the etiological agent of pathologies including HTLV-1 Associated Myelopathy/ Tropical Spastic Paraparesis (HAM/TSP), characterized as an immune-mediated disease of the nervous system. In HAM/TSP, the hip flexor and adductor muscles are particularly affected by spasticity and paresis, causing difficulties in locomotion and a reduction in quality of life. **Objective:** To characterize the neurological examination in patients living with HTLV-1 in the Brazilian hinterland, based on clinical diagnosis. **Methods:** This is an observational study that evaluated patients treated at an HTLV-1 reference center in Bahia, Brazil, between February 2023 and May 2024. Data were obtained by analyzing medical records and neurological consultations. Analyses of statistical significance were carried out with Fisher's exact test using the SPSS v. 27 program. **Results:** 110 participants were included, 82 classified as non-HAM/TSP and 28 as HAM/TSP. The mean age and standard deviation were 50.1±17.9 years, and 86 (78.2%) of the patients were female. Regarding to the neurological physical examination, 1 (1%) of patients classified as non-HAM/TSP and 11(40%) of those classified as HAM/TSP showed weakness in the upper limbs (p<0.001), while 9 (11%) of non-HAM/TSP patients and 24 (86%) of HAM/TSP patients showed weakness in the lower limbs (p<0.001). Analysis of deep tendon reflexes in the upper limbs showed a higher prevalence of exalted reflexes in the HAM/TSP group in relation to the bicipital and brachioradialis reflexes (p<0.05). Regarding the reflexes seen in the lower limbs, 21 (25.6%) patients classified as non-HAM/TSP and 18 (64.28%) classified as HAM/TSP had an adductor reflex (p=0.007). There was also a higher prevalence of exaggerated patellar and ankle jerk reflexes in the HAM/TSP group (p<0.05). As for pathological reflexes, 6 (7.31%) non-HAM/TSP patients had Babinski's sign and 6 (7.31%) had Hoffman's sign, while in the HAM/TSP group, the prevalence of such reflexes was 16 (58%) and 11 (39%)respectively (p<0.01). As for sensitivity, there was a higher prevalence of decreased vibration and pain sensitivity in the HAM/TSP group (p<0.05). There was no difference in the coordination tests performed by the two groups (p=0.159). **Conclusion:** Given the data observed, we conclude that HTLV-1 is a multisystemic virus with heterogeneous clinical manifestations. Despite the physical examination showing more significant findings in HAM/TSP patients, we observed important neurological changes in patients not classified with the disease, which could be related to an incomplete presentation or other neurological conditions. The presence of the adductor reflex appeared to be a good predictor of HAM/TSP in this study.

Detection of latent tuberculosis infection in patients at a reference center for demyelinating diseases in Recife-PE

Bruno Paulo Teles Chaves[1], Vanessa Cristina Fragoso Cassiano Alencar[1], Marcilio Oliveira Filho[1], Nathalia Saraiva Ramos e Cruz[1], Mauricéa Novaes Costa Pereira[1], Lidiane Alves de Macedo Souza[1], Maria Iris Moraes Machado[1], Maria Lucia Brito Ferreira[1]

[1]Hospital da Restauração, Recife PE, Brazil.

Correspondence: Bruno Paulo Teles Chaves; Email: brunopaulo.c@gmail.com.

Background: Latent tuberculosis infection (LTBI) is a persistent immune response triggered by Mycobacterium tuberculosis antigens without evidence of clinical manifestations of active tuberculosis. In recent decades, it is estimated that approximately 5-10% of infected patients develop the active form of the disease within the first five years after infection. Patients with multiple sclerosis (MS) and other neuroimmunological diseases who undergo treatments with immunosuppressants can develop active tuberculosis, making it necessary to carry out tests to detect LTBI before starting such treatments. **Objective:** To establish the prevalence of LTBI in a group of patients with multiple sclerosis and other neuroimmunological diseases undergoing immunosuppressive therapy at the reference center for demyelinating diseases at Hospital da Restauração. **Methods:** 139 medical records of patients who underwent a tuberculin skin test (PPD), defined as reactor when ≥5mm and non-reactor <5mm, and IGRA (interferon-gamma release assay), defined as positive or negative, were analyzed. **Results:** Of the 139 patients, 102 were female (73.4%). The average age was 46 years (range 17 and 74 years). One hundred fourteen were RRMS (82%), 17 SPMS (12.2%), 1 PPMS (2.2%), and 5 Neuromyelitis Optica Spectrum Disorder (3.6%). PPD was performed in 132 patients (95%), and 7 underwent IGRA (5%). Of those who underwent PPD, 37 were classified as reactor (26.6%) and 95 non-reactor (68.3%); of those who underwent IGRA, three were positive (2.2%) and four negative (2.9%). One patient had active tuberculosis. The prevalence of LTBI in this sample was 28,8%. **Conclusion:** We consider essential to perform LTBI detection tests in groups of patients at high risk for developing active tuberculosis. It was possible to observe a high incidence of LTBI in the initial sampling of this study, making it imperative to systematically carry out tests to detect LTBI in order to reduce morbidity and mortality in patients undergoing immunosuppressive therapies.

Development of an instrument for the assessment of compensatory strategies in individuals with stroke

Pedro Henrique Sousa de Andrade[1], Caroline Rodrigues Osawa[1], Luciane Aparecida Pascucci Sande de Souza[1], Gustavo José Luvizutto[1]

[1]Universidade Federal do Triângulo Mineiro, Uberaba MG, Brazil.

Correspondence: Pedro Henrique Sousa de Andrade; Email: pedrohsandradeft@gmail.com.

Background: Essential motor components are lost due to the impairments caused from stroke, leading individuals to acquire new strategies to produce movement, to compensate the lack of the motor components. Since stroke is considered the main cause of chronic disability in adults, the evaluation of their compensatory strategies, mainly during the performance of daily activities (core tasks), is essential to outline a full assessment and treatment plan after stroke. **Objective:** To develop a new biomechanical analysis tool for individuals with stroke, based on the Glittre-ADL test: the Glittre - Assessment of Biomechanical Strategies (Glittre-ABS), with a scoring system that will provide an index for the evaluation of movement quality for each core task. **Methods:** This is a cross-sectional study and literature review. A literature search was performed in the main databases with terms related to sit to stand, stand to sit, gait, stair climbing, 180º turn, postural balance, adaptive strategies and stroke and their synonyms in addition to a compilation and evaluation of patient videos and expert opinions in the field of stroke rehabilitation, to produce a preliminary version of the instrument with the most common compensatory strategies used after stroke. Content validation was performed by a panel of experts to calculate the content validity coefficient (CVC), which was considered acceptable if its value was ≥0.8. **Results:** Thirty-eight studies were selected through a literature search, videos of 5 stroke patients performing the Glittre-ADL test were analyzed and opinions from 10 physiotherapists with experience in the stroke rehabilitation were collected. One table was assembled with the possible compensatory strategies adopted by stroke individuals gathered from these 3 sources of information. These strategies were sent to a panel of 10 specialists for scoring and a CVC of 0.83 for relevance and 0.75 for clarity was obtained for the sit to stand domain, 0.82 and 0.78 for the gait domain, 0.84 and 0.78 for the step up stairs domain, 0.82 and 0.80 for the step down stairs domain, 0.82 and 0.76 for the dynamic balance while standing domain, 0.81 and 0.75 for the 180º turn domain and 0.85 and 0.79 for the stand to sit domain, respectively. **Conclusion:** This data suggest that the strategies defined to compose the instrument are relevant, but their clarity are still uncertain, except for the step down stairs domain.

Diabetes insipidus associated with infundibuloneurohypophysitis: case report

Gilmar Silveira da Silva[1], Thaise Fellini Dal Moro[1], Ana Cláudia Martins Ferreira[1], Marlon Costa Ferreira[1], Luiza Toscan[2], Matheus Felipe Kuhn Urnau[2], Wesley Alfredo Gawlinski de Arruda[1], Victor Emanuel Angeliero[1], Jéssica Vieira[1], Jéssica Maldaner Lui[1]

[1]Universidade Federal da Fronteira Sul, Hospital São Vicente de Paulo, Passo Fundo RS, Brazil. [2]Universidade de Passo Fundo, Passo Fundo RS, Brazil.

Correspondence: Gilmar Silveira da Silva; Email: silveirasilva.gilmar@gmail.com.

Case presentation: A 23-year-old patient, 30 days prior, started experiencing polydipsia, drinking approximately 20 L/day of water, in addition to nausea, vomiting, and weight loss of 17 kg. Smoker (3 pack-years) had anxiety disorder and depression as comorbidities. On physical examination, the patient presented with muscle weakness due to hypokalemia. A tomography of the skull was performed, demonstrating calcification located in the fourth ventricle, measuring 0.4 x 0.3 cm, in addition to a rounded supraclinoid lesion. MRI of the skull and sella turcica demonstrated neurohypophysis without hypersignal on T1, suggesting a relationship with diabetes insipidus, thickening of the pituitary stalk (approximately 5 mm), homogeneous contrast enhancement in the pituitary stalk and pituitary gland, suggesting infundibuloneurohypophysitis, and mild hypersignal in the corpus callosum, probably due to cytotoxic edema, suggesting CLOCS (secondary to hydroelectrolyte disorders). Laboratory tests revealed suppressed TSH (<0.1), hypernatremia (160), and hypokalemia (2.0). After correction of the hydroelectrolyte disorder, the patient recovered muscle strength. The patient was discharged from the hospital after the condition stabilized with endocrinological monitoring. **Discussion:** Infundibuloneurohypophysitis is an autoimmune and inflammatory condition caused by lymphocytic infiltration that selectively affects the neurohypophysis and pituitary infundibulum. In most cases, it manifests as osmotic symptoms, such as polyuria and polydipsia, associated with central diabetes insipidus, in the absence of signs of involvement of the anterior pituitary gland. In addition to confirming the presence of hydroelectrolyte disorders and diabetes insipidus, diagnostic investigations must include complementary tests capable of identifying commonly associated causes, such as granulomatous, xanthomatous, systemic diseases related to immunoglobulin G4, and neoplastic and autoimmune diseases. The neuroimaging of choice is magnetic resonance imaging, with typical findings being the loss of the "bright spot" in the posterior pituitary gland, associated with thickening of the infundibulum (>4 mm). The gold standard for diagnosis is transsphenoidal biopsy with an immunohistological study. Most studies suggest that spontaneous remission occurs, and the management of the condition is controversial, with no benefits demonstrated with glucocorticoids. Long-term follow-up is mandatory through serial neuroimaging examinations and hormonal assessments. Even after radiological remission of the disease, most patients remain with central diabetes insipidus, requiring prolonged desmopressin use for its management. **Final comments:** The case description above highlights the importance of additional investigation of diabetes insipidus, as it has numerous possible etiologies, with infundibuloneurohypophysitis being a commonly associated, but possibly underdiagnosed condition.

https://doi.org/10.5327/CBN240527

Diagnoses of overlapping cases of neuromuscular junction disorders: myasthenia gravis and Lambert Eaton syndrome

Beatriz Carneiro Gondim Silva[1], Filipe Tupinambá Di Pace[1], Nícolas Ruan dos Santos Cavalcante[1], Eduardo de Paula Estephan[1], André Macedo Serafim da Silva[1], Rodrigo de Holanda Mendonça[1], Antonio Alberto Zambon[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Beatriz Carneiro Gondim Silva; Email: beatrizcgondim@gmail.com.

Background: Myasthenia gravis (MG) and Lambert Eaton myasthenic syndrome (LEMS) are autoimmune disorders of the neuromuscular junction. In MG the acetylcholine receptor (AChR) and the postsynaptic membrane are the targets, while in LEMS the epitope is located on the voltage-gated calcium channels, constituting a presynaptic disorder. The coexistence of LEMS-MG seems to be very rare and remains controversial. **Objective:** Aims to describe 4 cases of LEMS-MG overlap focusing on pitfalls in the workup diagnosis. **Results:** Case 1: 47-year-old woman with positive AChR antibody classic MG diagnosed in 2019 evolved with clinical remission after two years of onset. In 2022 she presented with weakness in the lower limbs and areflexia. The neurophysiological study (NPS) showed maintance of pathological decrement (> 10%) in low-frequency repetitive stimulation (already present on earlier study) and an increment greater than 100% after maximum voluntary contraction. The antibody test for voltage-gated calcium channels (anti-VGCC) was positive. She was put on prednisone and pyridostigmine, reaching minimal manifestation status. Case 2: 63-year-old man presented with a history of bulbar and upper limbs weakness, global areflexia with facilitation phenomenon. NPS showed a pathological decrement (> 10%) at low-frequency and a pathological increment (163%) at high-frequency repetitive stimulation. He had positive antibodies to AChR and anti-VGCC, compatible with LEMS-MG overlap. Case 3: 41-year-old woman with no medical history, was admitted with ventilatory insufficiency, ptosis, dysphagia, and global weakness. The investigation demonstrated a pathological increment on NPS only in repetitive stimulation at 50Hz and positive anti-VGCC, the AChR antibody was negative, leading to the diagnosis of LEMS with respiratory crisis, mimicking a myasthenic crisis. Case 4: 90-year-old woman with proximal tetraparesis, worse in the lower limbs, areflexia, hypopalesthesia, and axial ataxia. A first NPS demonstrated an axonal and demyelinating sensorimotor neuropathy and the diagnosis of chronic inflammatory demyelinating polyradiculoneuropathy was made. A second NPS was performed demonstrating low CMAP amplitudes and an increment of more than 400% in high-frequency repetitive stimulation, and a diagnosis of LEMS was subsequently made. Anti-VGCC is not yet defined. She had a good response to intravenous human immunoglobulin and prednisone. **Conclusion:** LEMS-MG association may be an underrecognized condition in clinical practice. It must be suspected not only if signs of both disorders appear simultaneously, but also if they are added to an already established disorder or if the clinical features change.

https://doi.org/10.5327/CBN240528

Diagnosis and treatment of a case of functional (conversion) disorder: the importance of neurology-psychiatry collaboration

Roberto Pereira Santos[1], Bruno Miceli Gonzalez Nogueira[1], Carmem Zapata[2], Soniza Vieira Alves-leon[1], Nathalia Borges Carmo[1], Leonardo Siqueira de Araújo Pinto[1], Adriana Fiszman[1]

[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.
[2]Universidade Federal do Estado do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Roberto Pereira Santos; Email: r.santos.ufrj@gmail.com.

Case presentation: A 60-year-old woman complained of stiffness, pain, and weakness in her lower limbs. She also reported imbalance and difficulty finding words. Neurological examination revealed instability during standing and walking, with the patient falling in a point and support test (incongruence), but not falling with distraction (inconsistency). The shoulder tap test, highly specific for conversive postural instability, was positive (incongruence). Expressive aphasia and phonemic substitutions disappeared when the patient expressed sadness (inconsistency). The patient assumed a posture of thigh extension and painful leg with bilateral plantar flexion (dystonia). A suggestion technique called torpillage was applied: a vibrating tuning fork was placed on the patient's painful points, suggesting that the vibration "penetrated her muscles and led to their relaxation". The painful/dystonic episode was completely reversed by torpillage. **Discussion:** We present a case of functional (conversive) disorder to emphasize the importance of a multidisciplinary approach, particularly involving neurology and psychiatry. The neurologist is pivotal in making the diagnosis, as highlighted by Jon Stone, who underscores the importance of explaining incongruences and inconsistencies leading to the diagnosis. For him, explaining the diagnosis is one of the most critical aspects of treatment. Neurologists should also employ suggestion techniques both to confirm and treat conversive symptoms, particularly in acute cases. Torpillage maneuver is commonly used for these purposes. According to DSM-5 criteria, the patient presented with mixed symptoms of conversion disorder and persistent depressive disorder with obsessive-compulsive symptoms. Pharmacological treatment included paroxetine 80 mg/day alongside psychotherapy based on psychoanalytic principles. **Final comments:** Psychiatric evaluation is crucial to identify diagnoses beyond conversion disorder. It has been demonstrated that for many patients, conversion symptoms are clinical expressions of underlying psychiatric diagnoses. This appeared to be the case for the patient presented here, who received a psychiatric diagnosis of persistent depressive disorder with obsessive-compulsive symptoms. Treatment not only improved this diagnosis but also addressed the conversion symptoms effectively. This case illustrates that an integrated neurological and psychiatric approach is highly effective for diagnosing and treating conversion disorders. Specialized multidisciplinary centers are essential for managing these patients effectively.

https://doi.org/10.5327/CBN240529

Diagnosis and treatment of anaplastic supratentorial cortical ependymoma in an adult patient: a case report

José Nilo Ribeiro Neto[1], Yuri Victor Barbosa Silva[1], Carolina Diniz Furtado[1], Márcio Luís Soares Ferreira[2], Sanzylly Soares França Ferreira[3], Roseliny de Morais Martins Batista[4], João Guilherme de Brito Rodrigues[1], Lael Mendonça Moraes[1], Pedro Marcelo Azevedo Barroso[1]

[2]Universidade Federal do Maranhão, São Luís MA, Brazil.
[3]Universidade Estadual do Maranhão, São Luís MA, Brazil.
[4]Universidade Ceuma, São Luís MA, Brazil.

Correspondence: José Nilo Ribeiro Neto; Email: josenilo999@gmail.com.

Case presentation: G.A.J., 54 years old, male, of mixed ethnicity, originally from and residing in the city of São Paulo (Brazil). Chief Complaint: "Fatigue in the left arm and leg" for the past 10 days. History of Present Illness: The patient reported a progressive onset of weakness 10 days prior to admission at the Primary Health Care Unit, accompanied by paresthesias in the left hemibody. This condition progressed to memory loss for recent events, behavioral changes, and mental confusion. Initially, the patient sought care at a Primary Health Care Unit and was subsequently transferred to a public hospital in São Paulo, where a cranial Computed Tomography scan was performed, revealing an intracranial expansile lesion. The patient denies weight loss, changes in bowel habits, seizures, and headaches. Physical Examination: The patient was in good general condition, eupneic, anicteric, acyanotic and normal-colored. Diagnosis: After topographic and microscopic investigation, the patient was diagnosed with anaplastic supratentorial cortical ependymoma. Treatment: As treatment, the patient underwent tumor resection. **Discussion:** Ependymomas are rare central nervous system tumors that originate from ependymal cells lining the ventricles of the brain and the central canal of the spinal cord. These tumors can occur in both children

and adults, being more common in the brain in children and in the spinal cord in adults (Rudà et al, 2022). These tumors arise from ependymal cells that line the ventricular system, the choroid plexus, the central canal of the spinal cord, and the filum terminale. However, ependymomas can also be found along the neural axis, even outside the boundaries of the ventricular system. Such entities are known as supratentorial extraventricular ependymomas, which exhibit a low incidence and an unclear etiopathogenesis (Cuoco et al, 2022). The treatment of anaplastic supratentorial cortical ependymoma involves complete surgical resection of the tumor as the primary approach. This procedure is essential to improve the patient's prognosis and minimize the chance of recurrence, followed by detailed postoperative evaluation to determine the need for additional therapies, such as radiotherapy or chemotherapy, based on the tumor's molecular characteristics and initial response to treatment (Lin et al, 2022). **Final comments:** Given the studies presented, it is evident that anaplastic supratentorial cortical ependymoma in adult patients is extremely rare. The recommended primary surgical approach is complete tumor resection, which is crucial for improving prognosis and reducing the chance of recurrence. Additionally, radiotherapy has proven effective as an adjuvant therapy, while chemotherapy, though less effective in recent diagnoses, still plays a significant role in the substantial clinical improvement of patients under 3 years of age. These combined treatments are fundamental for the safe management and recovery of patients.

Diagnosis and treatment of myasthenia gravis in a pregnant patient with suspected head and neck tumor: case report

Matheus Jorand Cecatto[1], Roberto Pereira Santos[1], Rita de Cássia Leite Fernandes[1], Liene Duarte Silva[1], Tatiane Thais Santos Silva[1], Marco Antonio Sales Dantas de Lima[1]

[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Matheus Jorand Cecatto; Email: matheuscecatto@gmail.com.

Case presentation: A 23-year-old Black female patient presented with a progressive onset of dysphonia, dysphagia, and significant weight loss, leading to suspicion of a head and neck tumor. Further investigation at the time was inconclusive. Two years later, she developed sudden dyspnea. She underwent tracheostomy and was transferred to Hospital Universitário Clementino Fraga Filho for further investigation. Upon examination, the patient exhibited dysphonia, hypomimia, asymmetric bilateral ptosis with a positive ice pack test, Cogan's sign, curtain sign, ocular paresis on supraversion, and proximal weakness of the upper limbs. Electroneuromyography showed a decremental pattern with repetitive nerve stimulation, and Acetylcholine Receptor (AChR) antibodies were detected in the serum, confirming the diagnosis of myasthenia gravis (MG). Treatment with prednisone, pyridostigmine, and intravenous human immunoglobulin was initiated. To identify and stage a possible thymic tumor, a chest and abdomen computed tomography (CT) was requested. The patient denied any possibility of pregnancy, even if unintended. However, an intrauterine gestational sac was identified on the CT scan, and a 6-week pregnancy was confirmed by transvaginal ultrasonography. The patient showed partial improvement of symptoms after 5 days of immunoglobulin. She was discharged with outpatient follow-up by neurology and referred to high-risk prenatal care. **Discussion:** MG is an autoimmune neurological disease that affects the postsynaptic structures of the neuromuscular junction of skeletal muscles, causing weakness and fatigue in ocular, facial, bulbar, axial, and appendicular muscles. The global incidence rate of MG is 5.3 per million person-years. The most common onset age for MG in women is between 20 and 39 years, coinciding with childbearing age. The concomitant occurrence of pregnancy not only modifies the prognostic factors but also the therapeutic options, given the risk profile of adverse effects on the fetus. Up to 41% of pregnant women will experience exacerbation. There is still no consensus regarding indiscriminate pregnancy screening. **Final comments:** This case demonstrates how predominantly bulbar onset MG can mimic other conditions, delaying the diagnosis and timely treatment of the disease. It is noteworthy to consider the possible benefit of laboratory pregnancy screening in hospitalized female patients who are sexually active and of childbearing age.

Diagnosis journey of Brazilian Friedreich's ataxia patients

Daiana Suelen Machado[1], Marcondes Cavalcante França Junior[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Daiana Suelen Machado; Email: daianamachado@gmail.com.

Background: Friedreich´s Ataxia (FRDA) is the most common recessive ataxia worldwide, but its diagnosis is often delayed for multiple reasons. This impacts the timely introduction of therapeutic interventions and therefore, prognosis. **Objective:** Herein, we sought to characterize the diagnostic journey of FRDA in São Paulo, the most populous state in Brazil. **Methods:** Patients were invited to answer an online survey comprising 24 to 32 questions, which was sent by physicians and the Brazilian Association of Acquired and Hereditary Ataxias via email and releases. We recorded information on age at first symptoms, age at diagnosis, first symptom observed, time since first symptoms to diagnosis, medical specialty first sought, number of physicians visited up to the diagnosis and misdiagnoses. Descriptive statistics was used to report the results - means, proportions, and standard deviations (SD). Comparison between classical (onset <25yo) and late-onset - LOFA (onset >25yo) diagnostic journey was accomplished using parametric tests. **Results:** One-hundred four FRDA patients or legal guardians answered the survey. There were 79 (75.9%) classical and 25 (24%) LOFA FRDA. Mean age at first symptoms was 17.6±9.2 years, whereas mean age at diagnosis was 24.1±11.5 years. Overall, diagnostic delay was around 7.8±6.7 years, for the whole group. There was no difference between classical and LOFA subgroups (7.6±6.8 vs 7.6±6.4 years, p=0.978). Unsteadiness was the most frequent heralding symptom (50%). Neurologists (35.8%) closely followed by orthopedical surgeons (30.8%) were the most frequent medical specialties first sought. On average, 6 different physicians were visited until diagnosis was reached. Misdiagnoses were reported by 38 (46.3%) of patients. **Conclusion:** In Brazil, FRDA is characterized by impressive diagnostic delay and frequent misdiagnoses, with no relevant differences between classical and LOFA patients.

Diagnosis of Chediak-Higashi syndrome in the neurology ward

Crissia Pitanga Malta[1], Pedro Sanches Corrêa[1], Rodrigo da Franca Santos[1], George da Silva Divério Junior[1], Maria Eduarda Morgado da Silva[1], Diogo Matheus Terrana de Carvalho[1], Sofia Mermelstein[1], Felipe da Rocha Schmidt[1]

[1]Hospital Universitário Pedro Ernesto, Rio de Janeiro RJ, Brazil.

Correspondence: Crissia Pitanga Malta; Email: crissiapitanga@hotmail.com.

Case presentation: This is a 35-year-old man, born in Rio de Janeiro, Brasil. His maternal grandparents were first cousins, and there was no known history of neurological disease in the family. Since childhood, he attracted attention due to his grayish hair color and hypopigmented skin. He also had a learning disability, leaving school in fourth grade. When he was around 20 years old, he started presenting recurrent skin infections, accompanied with progressive paresis, global areflexia, trunk and limb ataxia and visual acuity deficit. He has a 30-year-old sister, with a similar condition of skin hypopigmentation, grayish hair, recurrent bacterial lung infections, cerebellar ataxia, areflexia and amaurosis. On physical examination, what stood out was the presence of paraparesis of the lower limbs, requiring assistance from a wheelchair for mobility, bilateral amaurosis, bilateral internuclear ophthalmoplegia, global ataxia, areflexia and hypopalesthesia also in lower limbs. Magnetic resonance imaging of the skull revealed cortical atrophy, and electroneuromyography showed severe sensorimotor polyneuropathy. Presence of giant cytoplasmic granules in leukocytes was seen in a peripheral blood smear. Evaluation by ophthalmology exhibited a pale optic disc and dermatology observed diffuse hypopigmentation and grayish facial hair and capillaries. Genetic testing was carried out, disclosing a LYST gene mutation. Family screening was carried out and the 30-year-old sister, with amaurosis and ataxia, also had giant cytoplasmic inclusions. **Discussion:** This case report concerns a patient admitted to the Neurology ward of a teaching hospital in Rio de Janeiro, diagnosed with Chediak-Higashi syndrome, a rare genetic entity, with less than 500 cases reported worldwide. It is an autosomal recessive condition, which occurs due to mutations in LYST gene. The presence of giant cytoplasmic granules in leukocytes and platelets in a peripheral smear are considered pathognomonic of the disease. Clinical manifestations can range from oculocutaneous albinism, immunodeficiency with recurrent bacterial infections, coagulation defects and hemophagocytic syndrome to progressive neurological dysfunction. Regarding neurological symptoms, they often present cognitive and degenerative alterations. In childhood, they may present learning difficulties. During late infancy other symptoms appear, such as worsening of cognitive impairment, cerebellar dysfunction, weakness, neuropathy and neuronopathy, areflexia and parkinsonian signs. In imaging studies, neurodegenerative findings stand out. **Final comments:** This is a case of Chediak-Higashi syndrome diagnosed in the neurology ward, due to the patient's severe cognitive and motor impairment. Rare, difficult-to-diagnose genetic condition that presents a wide range of varied and non-specific neurological characteristics.

Diagnosis of exclusion in progressive idiopathic ganglionopathy: a case report

Lucas Ferreira Alves[1], Ana Carolina Araujo de Oliveira[1], Leonardo Jadyr Silva Rodrigues Alves[2], Pedro Maia Nobre Rocha Saffi[2], Lorena Oliveira Carneiro[2], Ana Beatriz de Matos Berg Abrantes[2], Maria Cecília Mendes Resende[1], Ingrid Faber de Vasconcellos[2], Keila Rejane Ferreira Galvão[2], Luciano Talma Ferreira[2]

[1]Universidade de Brasília, Brasília DF, Brazil. [2]Hospital Universitário de Brasília, Brasília DF, Brazil.

Correspondence: Ana Carolina Araujo de Oliveira; Email: anacarolinaestudos08@gmail.com.

Case presentation: A 54-year-old female presented with hypoesthesia and paresthesia in the lower limbs seven months ago. Three months ago, she experienced

worsening paresthesia and hypoesthesia in the lower limbs, in addition to muscle tension, which altered her gait. She also reported pain in right thigh for the past month that appears late at night, worsens with right lateral decubitus, and subsides spontaneously after a few hours. Physical examination revealed hypoesthesia and loss of vibration sense in the lower limbs, predominantly in the left lower limb, with abolished Achilles reflex and diminished left patellar reflex. She had a high-stepping gait with a positive Romberg sign. Consequently, magnetic resonance imaging (MRI) of the cervical, thoracic, and lumbosacral spine was requested and showed no signs of compressive myelopathy. Peripheral blood tests showed negative inflammatory markers. Electroneuromyography (ENMG) of the upper and lower limbs showed sensory axonal neuropathy, with amplitudes decreased by 80% in the radial nerves, 85% in the superficial fibular nerves, 20% in the median and ulnar nerves, and the sural nerves were non-excitable. A lumbar puncture was performed, with normal cerebrospinal fluid (CSF) results. The patient was diagnosed with progressive idiopathic ganglionopathy. Three sessions of corticosteroid pulse therapy were prescribed due to the symptoms, followed by Duloxetine, Gabapentin and Citoneurin. **Discussion:** Progressive idiopathic ganglionopathy is a rare sensory neuropathy characterized by primary degeneration of the dorsal root ganglia without an identified cause. The incidence of progressive idiopathic ganglionopathies in the general population ranges from 0.2 to 0.9%, increasing to 2% in the elderly. The most common initial clinical manifestations are hypoesthesia, paresthesia, ataxia, and pain. The disease manifests slowly and gradually, which makes early diagnosis crucial for a good prognosis. The diagnosis consists in exclusion, eliminating other possible causes, such as Guillain-Barré syndrome, sarcoidosis, diabetes, or infections, and involves ENMG and quantitative sensory autonomic testing to assess the patient's thermal and electrical sensitivity. The pathophysiology of the disease involves disruption and demyelination of nerve fibers, primarily Aβ and Aδ fibers. Treatment for progressive idiopathic ganglionopathy includes corticosteroids to prevent autoimmune attacks on the myelin sheath, intravenous immunoglobulin injections, and methotrexate. **Final comments:** The prognosis varies depending on the severity of symptoms, the patient's age, and the response to treatment. Thus, the prognosis can be quite positive when symptoms are adequately controlled and remyelination is effective, or it can result in irreparable sensory losses depending on the level of nerve damage involved.

Diagnostic and treatment pathways for adult patients with brain cancer in bahia: a comparative analysis in 2013 and 2023

Thiago Costa Oliveira[1], Antônio Felipe Rocha Brandão[1], Bruna Rios Beserra[1], Bruno Levy de Souza Amaral Maia[2], Cauã Araujo de Carvalho[2], Clara Carvalho Dantas Muniz[1], Ellen Santos Barreto[2], Fernanda Almeida da Silva de Sá Oliveira[1], Maria Clara Moysés de Siqueira[1], Cleydson Santos[3,4]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.
[2]Universidade Federal da Bahia, Salvador BA, Brazil.
[3]Hospital Mater Dei Salvador, Salvador BA, Brazil.
[4]Obras Sociais de Irmã Dulce.

Correspondence: Thiago Costa Oliveira; Email: thiagocoliveira23.1@bahiana.edu.br.

Background: Primary malignant brain neoplasms are the 10th most common type of cancer in Brazil. The brain is the most frequent location, accounting for 88% of cases. Despite their low incidence, the mortality rate is high, with 84% of individuals succumbing to the disease, necessitating prompt and efficient care as mandated by the "60-Day Law," which stipulates a maximum of 60 days for treatment initiation following diagnosis. This process often requires patients to travel to cities with High Complexity Oncology Care Units (UNACON) or High Complexity Oncology Care Centers (CACON), which provide the necessary diagnosis and treatment. Bahia has 11 hospitals providing such care, with seven located in Salvador and the others in Feira de Santana, Vitória da Conquista, Ilhéus, and Itabuna, thus facilitating the treatment flow for patients within the state. **Objective:** To analyze and quantitatively compare the diagnosis and treatment flows of adult patients (aged 20 and above) diagnosed with primary malignant brain neoplasms in municipalities of Bahia in the years 2013 and 2023. **Methods:** This retrospective study was conducted using the PAINEL - Oncologia platform available on DATASUS, considering secondary data of patients diagnosed with malignant brain neoplasms residing in the state of Bahia in the years 2013 and 2023. **Results:** In 2013, there were 62 cases of this pathology recorded in 26 municipalities in Bahia, with 35 (56.45%) in Salvador and 25 (40.32%) in other regions. Regarding treatment, most occurred where the disease was confirmed: 36 (58.00%) in Salvador, 11 (17.74%) in Itabuna, 8 (12.9%) in Feira de Santana, 5 (8.00%) in Vitória da Conquista, and 1 (1.61%) each in Aracaju and Petrolina. In 2023, for the same age group, there were 196 cases of primary brain cancer recorded in 102 municipalities, with 132 (67.35%) in Salvador and 64 (32.65%) in other locations. Concerning treatment, of the 125 recorded cases, 65 (52.00%) were treated in Salvador, 25 (20.00%) in Feira de Santana, 10 (8.00%) in Itabuna, 9 (7.20%) in Vitória da Conquista, 4 (3.20%) in Porto Seguro, 4 (3.20%) in Santo Antônio de Jesus, 1 (0.80%) in Teixeira de Freitas, and 5 (4.00%) in other states. **Conclusion:** Given the high diagnostic and therapeutic complexity of primary malignant brain neoplasms, which require neurosurgical, oncological, and radiotherapeutic care, along with hospital support from a skilled multidisciplinary team and intensive care units, many patients still need to travel to reference centers, most of which are in the capital and major cities. The referral and counter-referral process can be slow, contradicting the "60-Day Law" and negatively impacting clinical outcomes, including resectability potential and overall and progression-free survival. Decentralizing and expanding specialized services to the interior could improve access, optimize clinical outcomes, and reduce the economic, physical, and psychological burden of traveling to major centers.

Diagnostic and treatment pathways for pediatric patients with brain cancer in Bahia: a comparative analysis in 2013 and 2023

Thiago Costa Oliveira[1], Antônio Felipe Rocha Brandão[1], Bruna Rios Beserra[1], Bruno Levy de Souza Amaral Maia[2], Cauã Araujo de Carvalho[2], Clara Carvalho Dantas Muniz[1], Ellen Santos Barreto[2], Fernanda Almeida da Silva de Sá Oliveira[1], Maria Clara Moysés de Siqueira[1], Cleydson Santos[3,4]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.
[2]Universidade Federal da Bahia, Salvador BA, Brazil.
[3]Hospital Mater Dei Salvador, Salvador BA, Brazil.
[4]Obras Sociais de Irmã Dulce.

Correspondence: Thiago Costa Oliveira; Email: thiagocoliveira23.1@bahiana.edu.br.

Background: Worldwide, primary malignant brain neoplasms are the fourth most common type of cancer and have the highest mortality rate among individuals up to 19 years of age. In Brazil, it is the most common solid tumor in children and adolescents. In this population, therapeutic modalities and their impact on quality of life and long-term consequences are particularly relevant. According to Law 14.238/21, which mandates special attention for children, their transportation to High Complexity Oncology Care Units (CACON) and High Complexity Oncology Care Centers (UNACON) should be optimized. Bahia has 11 referenced hospitals, seven of which are in Salvador, the only municipality with a UNACON that serves pediatric patients. The remaining four units, located in Vitória da Conquista, Itabuna, Ilhéus, and Feira de Santana, are restricted to adult patients. **Objective:** To analyze and quantitatively compare the diagnostic and treatment flows of pediatric patients (0-19 years) diagnosed with brain cancer in the municipalities of Bahia in the years 2013 and 2023. **Methods:** This retrospective study was conducted using the PAINEL - Oncology platform available on DATASUS, considering secondary data of patients diagnosed with malignant brain neoplasms residing in the state of Bahia in the years 2013 and 2023. **Results:** In 2013, 35 cases of primary malignant brain neoplasms were recorded in pediatric patients across 23 municipalities in Bahia: 31 (88.57%) in Salvador, 2 (5.71%) in Feira de Santana, and 2 (5.71%) diagnosed in Recife (PE) and Barretos (SP). Additionally, 31 patients had treatment records, with 29 (93.55%) treated in Salvador and 1 (3.23%) each in Recife and Barretos. By 2023, 31 cases were recorded in 22 municipalities: 19 (61.29%) diagnosed in the capital, 7 (22.58%) in Feira de Santana, 3 (9.68%) in Barretos, and 1 (3.23%) in Recife. Of the 28 patients treated, 20 (71.42%) were treated in Salvador, 6 (21.43%) in Feira de Santana, and 2 (7.14%) in Barretos. **Conclusion:** The data highlights the significant role of the capital city, Salvador, in diagnosing and treating pediatric patients with primary malignant central nervous system neoplasms in the state. Given the overall low incidence, it is expected that patients are directed to specialized high-complexity services with substantial expertise in managing these cases, leading to better clinical outcomes, including overall survival. Optimizing diagnosis and access to excellent services within or outside the state is crucial for achieving better results. Additionally, the decentralization of specialized care services can reduce the physical, psychological, and economic burden of patient and caregiver travel to major centers. This study contributes to a better understanding of the dynamics and challenges faced by this specific group and underscores the need for improved policies and medical training to enable rapid diagnosis and more effective treatment.

Diagnostic challenge in neuromyelitis optica in the pediatric population: case report

Paulo Henrique Martinelli Oliveira[1], Rebeca Aranha Barbosa Sousa[1], Amanda Michelucci dos Santos[1], Larissa Miyashiro[1], Raderi Luiz Cardoso do Santos[1], Lucas Silva Dias[1], Laiz Helena de Pádua[1], Gustavo Carvalho Costa[1], Alexandre Coelho Marques[1]

[1]Hospital Municipal Dr. José de Carvalho Florence, São José dos Campos SP, Brazil.

Correspondence: Paulo Henrique Martinelli Oliveira; Email: paulohmoliveira96@gmail.com.

Case presentation: Patient F.A.P.R, 12 years old, previously healthy. Approximately 20 days after vaccination for SARS-Cov-2 (Pfizer), she developed flaccid, areflexic and asymmetric crural paraparesis (worse on the left). Over the following week, she developed tetraparesis, dysarthria, dysphagia and bilateral appendicular ataxia (worse on the left). Upon hospital admission, the hypothesis of acute polyradiculoneuritis (Guillain-Barré syndrome? Miller-Fisher syndrome?) was suggested, with intravenous immunoglobulin being administered for 5 consecutive days, without improvement in the condition. During hospitalization, the patient developed signs of pyramidal signs, with central nervous system involvement being suggested. After receiving 5 days of intravenous methylprednisolone, she showed partial improvement in symptoms. CSF assessment without significant changes. Electroneuromyography found signs of polyradiculoneuritis in a hyperacute phase, being

unable to define the classification as myelinic or axonal. Cranioencephalic resonance imaging revealed multiple areas of signal alteration compromising the calloseptal interface on the left side, bilateral thalamus, mesial aspect of the temporal lobes, hippocampi, cerebral peduncles, pons and medulla oblongata (images with the appearance of an inflammatory/demyelinating substrate). Serum evaluation revealed a reactive Anti-Aquaporin 4 IgG antibody. At the time of hospital discharge, the patient maintained tetraparesis with a predominantly spastic component, with signs of pyramidal release, being able to walk without support, in addition to oral food intake. **Discussion:** Neuromyelitis optica spectrum disorder (NMOSD) cases in the pediatric population make up approximately 3-5% of all NMOSD records. The median age range is around 14 years (7-17 years) and there is a significant female predominance (around 80% of cases). In addition to the diagnostic difficulty, excluding differential diagnoses of NMOSD is also arduous. Among the main differences are metabolic etiologies (such as late-onset biotinidase deficiency), as well as inflammatory, post-infectious and systemic nosologies (such as MOG antibody disease, sarcoidosis, flaccid myelitis and systemic lupus erythematosus). **Final comments:** Although it is a rare condition, the number of NMOSD cases in the pediatric age group has increased significantly. This finding is mainly due to the evolution and availability of diagnostic imaging methods, in addition to the possibility of serum assessment of the Anti-Aquaporin 4 antibody. However, due to the wide spectrum of clinical presentations, early diagnosis in the face of an acute evolution continues to be a great challenge.

https://doi.org/10.5327/CBN240537

Diagnostic challenges in Behçet's disease: a case report with multisystemic manifestations

Vanessa Gil Humberto dos Santos[1], Amanda Melo Leite Leão[1], Laís Borneo Moreira[1], Jorge Luiz Alves[1], Pollyana Marcela Silva de Farias[1], Lais Felix Teixeira da Cunha[1]

[1]Universidade Unigranrio Afya, Duque de Caxias RJ, Brazil.

Correspondence: Vanessa Gil Humberto dos Santos; Email: vanessaterapia@hotmail.com.

Case presentation: A 29-year-old female patient from Duque de Caxias presented with two months of amenorrhea, urinary incontinence and retention, mild redness eye, oral ulcers, episcleritis, and hypotension. She denied dermatological issues, genital ulcers, pathergy, thrombosis, and cirrhosis, though she had arthritis. In 2017, she reported sudden visual loss, dysphagia, difficulty walking, and dysarthria. At the time, the patient was advised to undergo clinical follow-up with neurology. In 2014, she iniciate experiencing bilateral tremors, more prevalent at the right side, exacerbated by fine motor tasks. When asked about past history she previously presented with pleural effusion and four episodes of pneumonia at the age of 3. She was admitted for screening, including serologies and two MRIs. Initially was suspected by Wilson's disease, after that she was diagnosed with Behçet's disease. Upon receiving the diagnosis, she began treatment with three days of pulse therapy evolving with cervical hypotonia and sialorrhea with improvement of symptoms after second day of treatment. She was discharged with MRI showing a 70% reduction in inflammatory activity, for clinical follow-up discharge with prescription of azatioprine. During the pandemic, she stopped treatment for four years, recently returning the follow-up with physiotherapy and adjunctive therapies and medicine. She's presenting significant clinical improvements, such as motor skills, dysphagia, dysarthria, and tremor. **Discussion:** Behçet's disease is clinically diagnosed based on the criteria of the International Study Group for Behçet's Disease (ISGBD), requiring recurrent oral ulcers and at least two of the following: recurrent genital ulcers, ocular lesions (anterior/posterior uveitis, cells in the vitreous humor, retinal vasculitis), skin lesions (erythema nodosum, pseudofolliculitis, acneiform eruptions), and a positive pathergy test (formation of a papule or pustule after a sterile needle prick).Steps for diagnosis include a detailed clinical history investigating symptoms. Behçet's disease is a rare systemic vasculitis that requires a multidisciplinary approach due to its wide range of clinical manifestations. The diagnosis is based on specific clinical criteria and the exclusion of other pathologies. Early and accurate diagnosis is essential for effective management and improving patients' quality of life.The treatment requires a multidisciplinary approach. Pulse therapy reduced acute inflammation, and azathioprine maintained long-term symptom control. **Final comments:** This case illustrates the diagnostic and therapeutic complexity of Behçet's disease, highlighting the need for a multidisciplinary approach and regular follow-up. It contributes to the understanding and management of rare and complex conditions, emphasizing the importance of health policies that ensure continuous treatment and adequate support, promoting better prognosis and quality of life.

Diagnostic challenges of longitudinally extensive transverse myelitis: unveiling an uncommon culprit

Johnatan Felipe Ferreira da Conceição[1], Olivia Gameiro de Souza[1], Ana Luísa Utrine Pimentel[1], Luiza de Aguiar Lima[1], Caroline Bittar Braune[1]

[1]Universidade Federal Fluminense, Niterói RJ, Brazil.

Correspondence: Johnatan Felipe Ferreira da Conceição; Email: johnatanfelipe@id.uff.br.

Case presentation: A 43-year-old male was admitted with a history of insidious onset of ascending paresthesia and hypoesthesia, starting in the feet. After 1 month, he noticed urinary and fecal retention, as well as difficulty walking due to weakness, along with worsening of sensory symptoms. An orthopedic evaluation established the diagnosis of a herniated disc and intramuscular corticosteroids were prescribed. He showed a significant worsening of symptoms after the administration of this medication, progressing with escalation of sensory symptoms and tetraparesis with rapid progression. He was admitted to the emergency department of an outside hospital and neuraxis magnetic resonance imaging showed a longitudinally extensive transverse myelitis between C1-C7. Cerebrospinal fluid analysis and laboratory analysis were normal. The diagnosis of probable inflammatory myelitis was established, a 5-day pulse therapy regimen with methylprednisolone was defined, resulting in new neurological deterioration, and then the patient was transferred to our university hospital and evaluated by neurology team. Upon admission, neurologic examination showed grade 3 paresis in the upper limbs and grade 1 in the lower limbs, global hyperreflexia with bilateral Babinski sign and achilles clonus, hypertonia in the lower limbs and tactile, thermal and painful hypoesthesia. Considering the etiology of vascular myelopathy, the investigation was continued with an arteriography, which showed a dural arteriovenous fistula at the bulbar-cervical junction. A successful occlusion procedure was performed on the fistula, but the patient showed little functional gain. **Discussion:** Arteriovenous fistula (AVF) is a vascular malformation characterized by anomalous communications between meningeal arteries and dural or subarachnoid veins. It can occur in intracranial or spinal cord topographies, making it the most common spinal vascular malformation. It usually affects individuals in their fifth and sixth decades of life, with a higher frequency of occurrence in the mid-thoracic and lumbar spinal cord. The pathophysiological process consists of congestion and spinal venous hypertension, leading to edema and progressive ischemia in the affected spinal cord levels. Our case illustrates the diagnostic challenge of the approach to longitudinally extensive myelitis. A diagnostic clue was the worsening with corticosteroid therapy, a classic finding described in AVF. Furthermore, the patient was not in the typical age range, as well as the unusual topography of the fistula, all possible confounding factors for diagnosis which may then have contributed to the unfavorable prognosis. **Final comments:** Our case highlights the importance of clinical reasoning and diagnostic clues in the diagnostic approach of longitudinally extensive myelitis. Although AVF is an infrequent etiology, its early recognition can lead to specific therapeutic interventions, with potential impact on prognosis.

Diagnostic imaging of spontaneous intracranial hypotension: a case series

Samara Abdo El Hakim Kadri[1], Camila Carneiro Ferreira[1], Mohamad Ali Hussein[1], Pedro André Kowacs[1], Bernardo Correa de Almeida Teixeira[1], João Victor de Oliveira Souza[1], Lucas Bernardi Garcia[1], Eduarda Nakoula[1], Ana Júlia Caetano Ferreira[1], Gabriella Mara Arcie[1]

[1]Instituto de Neurologia de Curitiba, Curitiba PR, Brazil.

Correspondence: Samara Abdo El Hakim Kadri; Email: samara.kadri@hotmail.com.

Background: Imaging plays a central role in the initial diagnosis of spontaneous intracranial hypotension (SIH) and in its subsequent investigation and management. **Objective:** In this paper, we describe the main findings of brain MRI scans of patients admitted due to SIH at a neurology reference center. **Methods:** A retrospective, single-center, longitudinal study evaluating data from the electronic medical records of patients of both sexes hospitalized for SIH from 2019 to 2024. Statistical analyses were carried out using SPSS (Statistical Package for the Social Sciences) software. **Results:** A total of 16 patients were included, of whom 7 (44%) were female and 9 (56%) were male. The average age of the patients was 48 years (SD ±17.5). The youngest patient was 17 years old, and the oldest was 79 years old. Among the imaging findings, the most prevalent was pachymeningeal enhancement, and the least prevalent was epidural collection. A total of 12 (75%) patients had pachymeningeal enhancement, 9 (56%) had an engorged pituitary gland, 7 (44%) had engorged dural sinuses, 8 (50%) had a reduced nipple-point angle, 9 (56%) had cerebellar herniation, 7 (44%) had thinning of the ventricles, 6 (37%) had subdural collections, none (0%) had epidural collections, 4 (25%) had enlarged venous plexuses, and 1 (6%) had superficial siderosis. **Conclusion:** In this cohort, as previous literature has already shown, pachymeningeal enhancement was the most common imaging finding among SIH patients, while spinal findings were less prevalent.

Diagnostic pathway of Noonan-like syndrome with loose anagen hair 1: case report

Matheus Sathler de Souza, Ivana Rocha Raslan[1], Ana Beatriz Calmon Nogueira da Gama Pereira[1], Ynnaê Côrtes da Silva Neri[1], Clarissa Laurindo de Oliveira[1], Raquel Mendes Moreira[1]

[1]Universidade de Vassouras, Vassouras RJ, Brazil.

Correspondence: Matheus Sathler de Souza; Email: usoaternos@gmail.com.

This report describes a male patient (BSV) aged 8 years, followed since the age of 6 months due to global developmental delay. Parents were not consanguineous and pregnancy and birth were uneventful. Motor development milestones were delayed. Walking was achieved at the age of 3, with nonfunctional speech, cognitive deficits and epilepsy. The disease is typically nonprogressive and nonfluctuating. Dysmorphic features, capillary abnormalities, convergent strabismus, hypotonia and ataxic gait are the major clinical findings. The etiology could not be established despite comprehensive investigation (serum lactate, copper and ceruloplasmin measurement, analysis of biotinidase activity, amino acid chromatography, acylcarnitine profile analysis, chromatographic analysis of glycosaminoglycans and urinary oligosaccharides and hexosaminidase A testing). Cardiovascular and ophthalmological examination, auditory evoked potentials and abdominal ultrasound were unremarkable. Ventricular dilation was detected on brain MRI. G-banded karyotyping failed to detect aneuploidies. Microarray (CGH) analysis revealed a deletion on chromosome 8, p22p21.3, region 18483764_19418072, a variant of uncertain significance. Exome sequencing identified a monoallelic pathogenic variant in the SHOC2 gene NM_007373.5 (SHOC2):c.44A>G;p.(Ser2Gly). Hence, Noonan-like syndrome with loose anagen hair 1 (OMIM: #607721) was diagnosed. Noonan syndrome is a clinically and genetically heterogeneous, autosomal dominant rasopathy characterized by short stature, congenital heart defects and facial dysmorphism. It is caused by mutations in components of the RAS-MAPK signaling pathway and affects 1:1,000 to 1:2,500 live births. Rasopathies are genetic diseases caused by germline mutations in multiple genes of the ERK1/2 pathway. Loose anagen hair (NS/LAH; OMIM 607721) is a variation of the Nooan syndrome, with a single DNA nitrogenous base mutation in the scaffold protein SHOC2. Affected individuals are typically short and have comparatively more severe cognitive deficits, distinct behavior and easily pluckable, sparse, thin and slow-growing anagen hair lacking inner and outer root sheaths. Genetic counseling is advised given the autosomal dominant nature of the disease and probability of transmission. Patients should be monitored on a regular basis due to complications inherent to the syndrome, such as growth hormone deficiency, heart disease (especially pulmonary valve dysplasia and septal defects) and cognitive deficits.

Background: Pure neural leprosy (PNL) is described as a clinical neurological lesion in the absence of cutaneous lesions, with an atypical presentation. Sensory cutaneous impairment, numbness, paresthesia, nerve pain, and nerve thickening are the most common symptoms and signs of PNL. Some authors claim that a definitive diagnosis of PNL can only be achieved by performing a biopsy of the periphery nerve. However, confirmation is still difficult, which encourages the search for the availability of other diagnostic methods. **Objective:** Correlate neurological clinical findings, nerve conduction studies (NCS) and peripheral nerve ultrasound (US) with peripheral nerve biopsy for the diagnosis of the PNL. **Methods:** Twenty-ninepatients were evaluated over a period of 18 months and were selected of possible PNL diagnosis. All of them had already been seen by dermatology and there were no suspicious lesionand negative bacilloscopy. In neurological assessment, patients were asked about the time of onset of symptoms, neural pain and triggering factors, sensory and/or motor symptoms, as well as neurological examination and detecting thickening neural, sensory-motor changes. NCS was performed to topography sensory and/or motor lesios and the type of impairment: axonal or demyelinating. Finally, US to evaluated neural thickening, morphological changes and fasciular echogenicity, flow on Power Doppler or muscular morphostructural changes. Thus, a peripheral nerve biopsy was performed and histopathologically analyzed for the presence of acid-fast bacilli (AFB) as well as the PCR technique. **Results:** Sixty percent of patients were male, median age of 56 years. The most frequently affected nerve was the ulnar and the average time of presentation was 2.5 years. In the clinical evaluation, none of the signs and symptoms were statistically significant. Regarding the NCS, all showed an abnormality in the sensory response and 25 also in the motor; the most common pattern of involvement was mixed (17), followed by axonal (7) and demyelinating (5) - all with conduction block. US: neural thickening in 72% of patients, hypoechogenicity and/or changes in fascicular morphology in 52%. The homogeneous fascicular pattern was the most frequently seen (20 patients). Neither the US nor the NCS method showed statistical significance. Of the 29 cases, 11 had the PNL form confirmed by biopsy, with p<0.05, for AFB and PCR technique. Of the 18 unconfirmed cases, all are still being followed up, with 2 diagnosed with familial amyloid polyneuropathy and 2 with autoimmune neuropathy. **Conclusion:** NLP is still a very common cause of neuropathy in many countries, such as Brazil, but it is still poorly recognized and understood. This work highlights that although we are looking for patterns of disease presentation and characteristics of complementary exams, peripheral nerve biopsy continues to be the exam capable of confirming PNL.

Correspondence: Mateus Gustavo Favaro; Email: mateusgustavofavaro@gmail.com.

Background: Hereditary transthyretin amyloidosis (ATTRv) is an autosomal dominant genetic disease that can lead to severe polyneuropathy and death. Many types of peripheral nerve involvement were described, including sensory-motor, sensory, motor, upper-limb onset, CIDP-like, radiculopathy, and small-fiber neuropathy. Identification of disease onset in pre-symptomatic carriers is a crucial step in order to identify disease onset and initiate early treatment. However, the best instrument to identify disease onset is still a point of debate. This project aims to determine the diagnostic value of intraepidermal nerve fiber density (IENFD) in lower limb skin biopsies in a Brazilian center. **Objective:** Identify sensitivity and specificity of intraepidermal nerve fiber density (IENFD) in lower limb skin biopsies of patients with Hereditary Transthyretin Amyloidosis-Polyneuropathy (ATTRv-PN) in a Brazilian center. **Methods:** 28 patients with pathogenic TTR variants followed at the the Amyloidosis Centre-HC-FMRP-USP were analyzed. These patients were pre-symptomatic carriers that that presented questionable complakints and/or abnormalities on neurological examination. Skin biopsies were performed on the lower limb, 10 cm above the lateral malleolus according to the European Federation of Neurological Societies/Peripheral Nerve Society Guidelines and established normal values (2010) Statistical analysis was performed at SPSS 22.0, and data was stored on REDCap. **Results:** Among this small Brazilian cohort of ATTRv-PN, the test's sensitivity was 69%, with a 100% specificity, a positive predictive value of 100%, and a negative predictive value of 41%. **Conclusion:** The sensitivity of IENFD for the identification of overt polyneuropathy in a Brazilian ATTRv population was lower than previously reported in American and European populations. These results can be related to the standardized values of IENFD, which could be different between populations around the globe, as a lower than expected sensitivity of this biomarker was also reported in a Chinese population

Diagnostic value of voxel-based morphometry in MRI negative epilepsies and focal cortical dysplasia: correlation with electrocorticography and surgical results

William Alves Martins[1], Eliseu Paglioli[1], Ricardo Paganin[1], Thomas More Frigeri[1], Rafael Paglioli[1], Ricardo Bernardi Soder[1], Natalie da Silveira Donida[1], Tais Michele Werle[1], Bibiana Liberman Thomé[1], Andre Palmini[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Hospital São Lucas, Porto Alegre RS, Brazil.

Correspondence: William Alves Martins; Email: walvesm.br@gmail.com.

Background: Epilepsy surgery is still the only hope of achieving seizure freedom for a significant number of patients with epilepsy. However, a visible MRI epileptogenic lesion, the best predictor of surgical success, is not found in a substantial portion of patients. Voxel-based morphometry (VBM) is an emerging method that may help identify and determine the extent of cortical abnormalities unseen in conventional imaging. **Objective:** To evaluate the diagnostic value for seizure control of VBM-based technique (Morphometric analysis program [MAP]) in patients with normal MRI or focal cortical dysplasia (FCD) undergoing epilepsy surgery. **Methods:** In this single center retrospective study, all patients submitted to epilepsy surgery between 2006 and 2020 at the Porto Alegre Epilepsy Surgery Program were screened . We included patients >2 years of age in which MRI was either normal or positive for FCD. Concordance of the extent of VBM-MAP+ lesions with electroclinical hypothesis and electrocorticography (ECoG) was evaluated, and completeness of resection of such lesions was correlated with surgical outcome using Engel classification. **Results:** Of the 141 patients included, 62 had a nonlesional MRI and 79 had a lesional MRI. MAP was positive in 93 (65.9%) patients, 66 lesional and 27 nonlesional. Resection of MAP+ regions was associated with seizure freedom in both in the whole cohort (76.6% x 26.1%; P=0.001) and in nonlesional patients (72.7% x 25%; p=0.02). In addition, resection of ECoG/MAP concordant regions led to a higher rate of seizure-freedom (75.8% x 16.6%, p=0.001). For non-lesional patients, MAP showed a sensitivity of 40% (CI 95% 19-64) and a specificity of 93% (CI 95% 80-98), with accuracy of 76% (CI 95% 63-86) for localizing the epileptogenic zone. **Conclusion:** VBM-MAP provides useful information in planning epilepsy surgery even in the absence of invasive extra-operative investigations. Combining a strong electroclinical hypothesis with ECoG guided resection of MAP+ regions may be a feasible strategy in low resource settings.

Correspondence: Thiago Yoshinaga Tonholo Silva; Email: thiago.yoshinaga@gmail.com.

Objective: To evaluate the diagnostic yield of whole exome sequencing (WES) in identifying autosomal dominant cerebellar ataxias (ADCA) caused by point mutations. Preamble: Currently, there are over 50 different subtypes of ADCA, mainly comprising spinocerebellar ataxias (SCA). The most frequent ADCAs are caused by nucleotide repeat expansions; however, most can be attributed to point mutations. Preliminary studies have demonstrated the utility of WES in the etiological identification of undetermined genetic ataxias. Therefore, WES has potential in the etiological diagnosis of undetermined ADCA after excluding repeat expansions. **Methods:** WES was performed on 130 patients with undetermined ataxia. A subset of the sample, comprising 12 cases, consisted of undetermined SCAs (ataxia with autosomal dominant inheritance and negative tests for the most common repeat expansions: SCA 1, 2, 3, 6, 7, 10, 12, 17, DRPLA). The remaining 118 cases were sporadic adult-onset undetermined ataxia without relevant family history. **Results:** Twenty-four patients were identified with ADCA related to point mutations: 3 patients with SCA28 (AFG3L2), 3 patients with SCA14 (PRKCG), 3 patients with SCA5 (SPTBN2), 1 patient with SCA15 and 2 patients with SCA28 (ITPR1), 2 patients with SCA45 (FAT2), 2 patients with SCA42 (CACNA1G), 2 patients with SCA19 (KCND3), 1 patient with SCA23 (PDYN), 1 patient with SCA26 (EEF2), 1 patient with SCA48 (STUB1), 1 patient with SCA25 (PNPT1), 1 patient with Alexander disease (GFAP), 1 patient with dominant ataxia related to CACNA1A, and 1 patient with SCA21 (TMEM240). **Conclusion:** WES was diagnostic in 18.46% (24 out of 130) of the cases in the Brazilian cohort of undetermined ataxia, identifying ADCA caused by point mutations. The most common point mutation SCAs in the series were SCA5, SCA14, SCA15/29, SCA19, SCA23, SCA28, SCA42, SCA45, and SCA48. These results may have implications for diagnosis, genetic counseling, and potentially treatment.

Diagnostic yield of distinct next generation sequencing approaches in adult patients with suspected genetic myopathy

Alexandre Motta Mecê[1], Alberto Rolim Muro Martinez[1], Anamarli Nucci[1], Marcondes Cavalcante França Júnior[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Alexandre Motta Mece; Email: amottamece@gmail.com.

Background: Myopathies in adults have diverse causes, but a substantial number of cases stem from genetic variations in over 200 identified genes. Whole-exome sequencing (WES), whole-genome sequencing (WGS), and genetic panels (GP) have been utilized as diagnostic tools in this context, showing varying rates of success. Variables such as age, ethnic background, and phenotypic characterization of patients appear to impact the precision in diagnosing myopathies. In this study, we examined the diagnostic yield of WES, WGS, and GP in a heterogeneous group of Brazilian patients with suspected myopathy. **Objective:** To determine the accuracy of WES, WGS and commercial GP in a population of patients from a reference neuromuscular center with suspected genetic myopathy. **Methods:** A total of 161 patients visiting a specialized neuromuscular center were enrolled. Despite physical examinations, muscle biopsies, electrophysiology, and laboratory tests, a definitive diagnosis remained elusive. WES was conducted according to established protocols for 30 patients, while GP was undertaken for 121 patients, and genome sequencing for 10 patients. Variants classified as pathogenic or likely pathogenic were identified following ACMG guidelines. Subsequently, the diagnostic efficacy of WES and GP was assessed across the entire cohort and within subgroups defined by major phenotypic characteristics. **Results:** A definitive genetic diagnosis was established in 12 out of 30 patients in the WES group (40% diagnostic accuracy), 53 out of 121 in the genetic panel group (43%), and 3 out of 10 in the genome sequencing group (30%), resulting in an overall diagnostic yield of 42% in this cohort. Pathogenic variants were identified in genes including SCN4A, ACADS, COL6A2, SGCB, CAPN3, POLG, TWNK, RYR1, TRIM32, TTN, EMD, SLC25A4, TPM3, DOK7, DMD, GAA, SGCB, PYGM, LAMA2, ANO5, CHRNE, GAA, ADSSL1, CLCN1, PABPN1, PYGM, PNPLA, HACD1, NEB, DPAGT1, MYH7, FKTN, and TRAPPC11. **Conclusion:** WES, WGS and GP are valuable diagnostic tools for adult patients presenting with undiagnosed myopathy. In this cohort, the diagnostic yield reached 42%, uncovering variants across multiple genes. Our findings indicate that the diagnostic yield of WGS is not different than that of WES in this population.

Did Thomas Willis describe narcolepsy?

Fernanda Lustosa Cabral Gomez[1], Karla Carlos[1], Lucas Martins Teixeira[1], Letícia Lambert[1], Fernando Morgadinho Santos Coelho[1], Afonso Carlos Neves[1], Gilmar Fernandes do Prado[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Fernanda Lustosa Cabral Gomez; Email: fernandalustosacg@gmail.com.

Background: Narcolepsy is a disorder characterized by chronic daytime sleepiness, sudden sleep attacks and cataplexy. Westphal is often credited for first describing narcolepsy in 1877 and Gélineau for naming it in 1880. However, descriptions by Thomas Willis in the 17th century suggest that the disorder might have been recognized two centuries before. In this article, we explore the possibility of Willis (1621-1675), known as the founder of clinical neuroscience, having described narcolepsy in his works. **Objective:** Analyze Willis' descriptions and identify any indications that he described narcolepsy. Compare Willis' observations with modern understanding of narcolepsy. **Methods:** A group of sleep medicine specialists performed a review of Willis' publications, especially the English translation of "De Anima Brutorum" by Samuel Pordage. We compared Willi's descriptions with the current definition of narcolepsy, altogether with a review of interpretations of Willis' work by later scholars, such as Lennox. **Results:** In one of his most influential works, "De Anima Brutorum," Willis describes a condition he named "continual somnolence" where patients presented with uncontrollable sleep episodes during activities such as talking, walking or eating. Willis described these individuals maintained normal functions between these episodes, aligning with narcolepsy's intermittent sleep attacks . However, Willis did not mention symptoms suggestive of cataplexy, sleep paralysis, or hypnagogic hallucinations, raising the question if, indeed, he was describing the disease. He followed the description of his work with a case report of a man: "(...) afterwards growing aged, being given to idleness and drunkenness, became dull and stupid, and also Dropsical, with a great paunch, and his thighs and legs swelled (...) at length, though he was freed from the Dropsie, he was oppressed with so heavy a sleepiness, and that almost perpetually, that in what place soever he was, or what ever he was doing he would sleep". Despite Willis' descriptions being aligned with the current understanding of narcolepsy, his case report includes clinical signs that suggest the patient might have had other diagnoses. These alternative diagnoses include hepatic encephalopathy and cardiac insufficiency, which could explain "dropsie" (a term historically used to describe edema or swelling), obstructive and/or central sleep apnea syndrome. These conditions could present symptoms like those described by Willis, such as excessive daytime sleepiness, although with the rare occurrence of the "sleep attacks" described. **Conclusion:** It is possible that some of Willis' patients might have had narcolepsy; however, among some of the patients that inspired his descriptions, alternative diagnoses were probably present. These could include systemic diseases and other causes of hypersomnia, especially given the absence of detailed descriptions of cataplexy, sleep paralysis, and hypnagogic hallucinations.

Differences between triggers of migraine and tension-type headache in southern brazilian patients.

Luiz Carlos Porcello Marrone[1], Emanuela da Silva Foletto[1], Cassiana Konig de Lima[1], Rafaela Giulia Zatt[1], Andrei Leonardo Schuster[1], Marina Macedo dos Santos[1], Cássia Elisa Marin Dapper[2], William Alves Martins[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.
[2]Universidade de Caxias do Sul, Caxias do Sul RS, Brazil.

Correspondence: Cássia Elisa Marin Dapper; Email: cassiaemarin@gmail.com.

Background: Headache is a very common neurological condition in clinical practice. Identifying triggering factors is part of the treatment strategy for patients with migraine and tension-type headache (TTH). **Objective:** To evaluate the frequency and association of triggering factors for migraine and tension-type headache in a population from Southern Brazil. **Methods:** We selected 309 patients seen at the Neurology Department of Hospital São Lucas da Pontifícia Universidade Católica do Rio Grande do Sul between January 2010 and December 2013. Patients were diagnosed with either migraine or tension-type headache according to the criteria of the International Classification of Headache Disorders-2 (ICHD-2). The presence of the following triggering factors was assessed: 1) chocolate; 2) cheese; 3) caffeine; 4) wine; 5) other alcoholic beverages; 6) aspartame; 7) processed foods; 8) unpleasant odors; 9) sleep deprivation; 10) menstrual period; and 11) stress. Statistical analysis was conducted using SPSS software, and the chi-square test was used for variable analysis. **Results:** Most patients (218 [70.6%]) were female, and 215 (69.6%) had a diagnosis of migraine. Among headache-triggering foods, there was a statistically significant difference in the presence of chocolate, 21.9% in migraine patients vs. 10.6% in TTH group (p=0.019), and in relation to cheese, 12.6% vs. 4.3%, respectively (p=0.025). Stress was also more common in migraine (54.9% vs. 41.5%; p=0.036). The only trigger more associated with TTH was sleep deprivation, although without statistical significance (29.8% vs. 20.5%; p=0.075). **Conclusion:** Our cohort in southern Brazil showed similar headache triggers compared to other countries. Headache triggers may be identified in 50-75% of migraine patients. These precipitants are diverse, and different studies have found varying results when comparing migraine and TTH patients. Geographical distribution, genetic, and cultural factors

may contribute to these differences. In our population, stress was the most common trigger for both headaches, followed by the menstrual period, sleep deprivation, alcoholic beverages, chocolate, and caffeine. Stress, a major factor in chronic pain, was more commonly associated with migraines than TTH. Other studies have found conflicting results. Both migraine and TTH may share a dysfunction of pain modulation, more likely to appear in stressful situations and making this trigger difficult to evaluate in individual patients. Female gender, chocolate, and cheese were more significantly associated with migraines. In summary, we found that migraine and TTH share many headache triggers, potentially facilitating internal pain modulation. Stress, chocolate, and cheese were significantly more common in migraineurs. Whether these differences are clinically significant is still debated, but awareness of potential triggers and avoidance strategies remain important for educating and supporting patients in their headache management.

Differential diagnoses of inflammatory myopathies with positive biopsy for dysferlin

Ana Luísa Vilela Sá Fortes[1], Maria Clara Motta Barbosa Valente[1], Fernando Pierini Costa[2], Mariana Tonon Giovannone[2], Vanessa Moraes Rossette[2], Ana Paula de Almeida Campos[2], Edmar Zanoteli[3], André Macedo[3]

[1]Santa Casa de Misericórdia de São Paulo, São Paulo SP, Brazil.
[2]Santa Casa de Santos, Santos SP, Brazil.
[3]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Ana Luisa Vilela Sá Fortes; Email: dranaluisa@outlook.com.

Case presentation: A 24-year-old male presented with a four-year history of progressive proximal lower limb weakness and gait difficulty. He had previously been active and engaged in high-impact exercise, but he had discontinued exercise and gained weight over the past four years. His gait became increasingly impaired, and he reported worsening limb weakness Laboratory tests revealed elevated muscle enzymes, including CPK (16,907), aldolase (141), and DHL (878). EMG showed a myopathic pattern in all four limbs, with evidence of membrane instability in the paraspinal and proximal lower limb muscles. Magnetic resonance imaging of the thigh revealed mild fatty replacement of the posterior and medial compartments. Based on the clinical presentation, laboratory findings, and EMG results, a diagnosis of inflammatory myopathy was suspected. The patient was treated with a pulse of corticosteroids and immunoglobulin, but his symptoms did not improve significantly. Other immunosuppressive therapies were initiated, without any improvement in the condition. Due to the progressive worsening of his symptoms, the patient underwent a muscle biopsy which revealed a marked reduction in dysferlin staining, suggesting dysferlinopathy. There was no CD8 staining, moderate CD68 staining, and mild MHC-I staining in some fibers. The histologic pattern was myopathic with rare necrosis and dysferlin deficiency. The features of the biopsy suggest the diagnosis of dysferlinopathy. Patient maintains clinical stability and is being weaned off immunosuppressive drugs. **Discussion:** Dysferlinopathies are autosomal recessive neuromuscular disorders caused by mutations in the DYSF gene, which encodes the dysferlin protein. The dysferlin protein is involved in muscle membrane repair, and mutations in the DYSF gene lead to a spectrum of phenotypes, including Miyoshi myopathy and limb-girdle muscular dystrophy type 2B (LGMD2B). Inflammatory myopathies are a group of autoimmune disorders that also cause muscle weakness and inflammation. Both diseases can share many clinical features, including muscle weakness, elevated muscle enzymes, and a myopathic EMG pattern. However, there are also some key differences. In inflammatory myopathies, there is typically an inflammatory infiltrate present in the muscle biopsy. In dysferlinopathies, there is no inflammatory infiltrate, but there is a deficiency of the dysferlin protein. The initial diagnostic hypothesis in the reported case was inflammatory myopathy, however the lack of response to immunosuppression raised suspicion of an alternative diagnosis, with muscle biopsy being of extreme importance for diagnostic guidance. **Final comments:** This case highlights the importance of careful differential diagnosis in patients with myopathy. The combination of clinical history, laboratory findings, EMG results, muscle biopsy findings, and response to therapy can help to distinguish between inflammatory myopathies and other disorders, such as dysferlinopathies.

Differential diagnosis between ischemic stroke and mitochondrial myopathy, encephalopathy with lactic acidosis and stroke-like episodes (MELAS): a case report

Lucas Antonissen Lima Verde[1], Jamine Yslailla Vasconcelos Rodrigues[1], Thiago Moita Fernandes[1], André Felipe Oliveira Fernandes[1], Francisco Jazon de Araújo Neto[1], Espartaco Moraes Lima Ribeiro[1], Marcondes Pimentel Cruz[1], Paulo Roberto Lacerda Leal[1], Jose Elmano Silva[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Jamine Yslailla Vasconcelos Rodrigues; Email: jamineysl@gmail.com.

Case presentation: A 26-year-old woman presented with a generalized tonic clonic seizure lasting one minute, sialorrhea and no sphincter loss. The patient developed right hemispasticity and her companion reported the occurrence of a similar episode a year ago, without medical supervision. A cranial magnetic resonance imaging (MRI) was performed showing multiple focal areas of diffusion restriction, with hypersignal on T2/FLAIR weightings, diffusely arranged in the cortex of the frontal, parietal, temporal, occipital and insula lobes, compatible with acute ischemic insult. Therefore, a craniocervical angiography was requested, which showed no signs of stenoses or vasculitis, being within the normal range. As a result, the patient was transferred to the hospital's subacute stroke unit, in order to conduct the etiological investigation of the condition, and a spectroscopy resonance was performed in order to evaluate the lactate peak, with MELAS being the main diagnostic hypothesis. The patient progressed well over the days, with an improvement in her previous condition, but, upon neurological examination, she had difficulty understanding more complex commands and lactic acidosis was observed on blood gas analysis. L-carnitine, coenzyme Q10 and citrulline were started with MELAS in mind. Eight days after hospitalization, the patient was discharge from hospital, the diagnosis of MELAS remained as the main hypothesis and instructions were given on outpatient return and treatment. **Discussion:** MELAS is a rare mitochondrial disease involving the central nervous system and its diagnosis is a challenge for neurologists and radiologists. The diagnostic criteria for this disease involve three main points: the presence of encephalopathy (often with dementia and seizure), stroke-like episodes in young people and biochemical evidence of mitochondrial dysfunction, as well as lactic acidosis on muscle biopsy. However, the clinical presentation of these criteria can be difficult to differentiate from cerebrovascular disorders. Technological advances in neuroimaging made it possible to differentiate between stroke and MELAS. MRI with spectroscopy is a non-invasive method used to acquire information about metabolic disorders in brain tissue, which can be used to clarify the diagnosis and monitor the patient's disease. Furthermore, cerebral angiography is used to differentiate stroke-like episodes in MELAS from an ischemic stroke caused by a vascular occlusion. The treatment of this disease is not specific, as is the case with other mitochondrial diseases, and there is still no option to delay the progression of the disease, focusing on options that reduce the symptoms, such as the medications used in the patient. **Final comments:** Although it is very rare, patients living with MELAS have a significant loss in their quality of life. Advances in imaging exams help diagnose MELAS. Treatment depends on the patient's symptoms.

Differential diagnosis for sudden visual deficits: a case series and literature review on Anton-Babinski syndrome

Sephora Sabrina Candido de Almeida[1], Ana Luísa Rosas Sarmento[1], Sonia Maria Cesar de Azevedo Silva Mourão Magalhães Gomes[1]

[1]Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo SP, Brazil.

Correspondence: Sephora Sabrina Candido de Almeida; Email: sephora_sabrina@yahoo.com.br.

Case presentation: Case 1 Female, 76 years old, admitted with a 7-day history of sudden visual deficit, initially partial, progressing 6 days after admission to complete bilateral visual deficit - noticed by family members as the patient frequently stumbled in addition to trauma against objects. The patient did not look at the examiner, responded incorrectly when questioned objectively, including compromising her perception of light, and denied any visual changes. Computed tomography of the skull with initial arterial computed tomography angiography of the skull and neck demonstrated: Right occipital corticosubcortical hypoattenuating area, suggestive of a subacute ischemic event. Areas of gliosis occipital and temporal encephalomalacia on the left and in the left centrum semiovale determining an atrophic effect with compensatory dilation of the corresponding lateral ventricle. Case 2 Female, 75 years old, admitted with a history of lipothymia witnessed by her family when she arrived at the emergency room in the morning. After admission, the patient presents difficulty in locating himself in the environment, apparently with bilateral visual deficits. The patient previously did not present any visual deficit. Upon neurological examination, the patient remained discreetly inattentive but collaborative. No somatic examination deficits. He actively denied any visual changes, but the patient did not keep his gaze fixed on the examiner, responded randomly during confrontation perimetry and responded incorrectly when questioned objectively. Skull tomography demonstrated: a small hemorrhagic focus with adjacent edema in the left occipital lobe, determining the effacement of local sulci. Hypoattenuating area affecting the corticosubcortical region of the right occipital lobe, causing erasure of local sulci, which may correspond to recent ischemia. **Discussion:** Anton-Babinski syndrome is characterized by blindness, which is the syndromic core, without critical deficit. Anterior visual tracts are intact and the lesion is located in the posterior cerebral cortex. In addition to visual deficit, confabulation is an important part of the syndrome. Its main characteristics are visual agnosia, anosognosia and confabulation. It is one of the most striking examples of anosognosia described in medicine. It is important to remember that for the diagnosis of the syndrome there must be no pre- existing memory impairment , such as dementia. This differentiates it from Dide-Botcazo syndrome, which is also known to include the presence of cortical blindness with visual anosognosia, but occurs involving the memory circuitry.The clinical diagnosis of Anton-Babinski syndrome is based on: absence of response to visual stimulation (blinking), preservation of pupillary reflexes, fundoscopy without changes and preserved extraocular movements (absence of damage to anterior visual pathways) and absence of cognitive deficit.

Differential diagnosis of cluster headache: a systematic review

Gabriela Goveia de Sousa Castilho de Lima[1], Felipe Araújo Andrade de Oliveira[1], Ana Beatriz Alves[1], Sarah Ellen Alves Soares[1], Maria Kaylanne Pinheiro de Araújo[1], Luan Santana Martins da Costa[1], Daniel Rodrigues Lemos Neto[1], Filipe Alves da Costa Dias[1], Mariana Leandro Silva[1], Érycle Guilherme da Silva[1]

[1]Faculdade de Medicina de Olinda, Olinda PE, Brazil.

Correspondence: Gabriela Goveia de Sousa Castilho de Lima; Email: gabrielagscl@outlook.com.

Background: Cluster Headache belongs to the group of T rigeminal Autonomic Cephalalgias. It is a subtype of primary headache with an as-yet undetermined cause. It primarily affects men aged between 20 and 40 years, manifesting as intense, unilateral pain crises located in the cutaneous distribution territory of the trigeminal nerve in the orbital and periorbital region, associated with symptoms of autonomic dysfunction ipsilateral to the pain, with a characteristic temporal profile. **Objective:** To describe possible differential diagnoses of Cluster Headache. **Methods:** This is a systematic review, referencing scientific articles from MEDLINE, PubMed, and Scielo, a study of literature review from the 3rd Edition of the International Classification of Headaches, using articles from the last ten years in English and Portuguese. The following descriptors were used in the searches: "Cluster Headache", "Differential diagnosis of cluster headache" in English, and "Cefaleia em Salvas", "Diagnósticos Diferenciais da Cefaleia em Salvas" and "Cefaleias Primárias" in Portuguese. **Results:** Differential diagnosis is one of the most challenging aspects in headache cases, based on the duration, intensity, and topography of signs and symptoms. Several conditions can present as unilateral pain in the periorbital location. A literature review evaluated 63 cases that were compatible with the clinical presentation of cluster headaches. Among the differential diagnoses found in the study, two main pathologies stand out: closure-angle glaucoma and spontaneous or post-traumatic carotid dissection. Closure-angle glaucoma can present with intense, intermittent ocular pain and conjunctival hyperemia. Spontaneous or post-traumatic carotid dissection can lead to hemicranial headache with cervical radiation, accompanied by ipsilateral Horner's syndrome due to the involvement of sympathetic nerve fibers. Symptoms similar to a Cerebrovascular Accident (CVA) facilitate the diagnosis, as does a family history of dissection, connective tissue disorders, and trauma. **Conclusion:** A careful and precise evaluation of the signs and symptoms of cluster headache is needed, observing the diagnostic criteria of the International Classification of Headaches and concurrently maintaining vigilance for the aforementioned differential diagnoses to avoid diagnostic errors and consequent therapeutic errors.

Case presentation: A 2 years old patient, started at the age of 4 months with episodes of loss of consciousness associated with crying. She was referred to a video-electroencephalography (VEEG) in order to investigate breath-holding spells or epilepsy suspicion, as she was taking valproate with no response. This child had normal neuropsychomotor development and unknown comorbidities, but in her family record it was possible to identify a member with epilepsy. VEEG documented episodes that whenever the child was crying after some form of upset, it was followed by collapse with loss of consciousness associated with generalized hypertonia, upward gaze, lip cyanosis and pale skin. Electrocardiographic recording demonstrated bradycardia, followed by asystole lasting 10 seconds, heartbeat returned with irregular rhythm. Ictal EEG demonstrated hypersynchronous, high-amplitude slowing followed by flattening and later generalized spike-wave discharges. With this new diagnosis, the patient was referred for cardiac surgery at a reference center and she had a pacemaker fitted, progressing without recurrence of seizures without using any anticonvulsant drugs since then. **Discussion:** Epileptic seizures are paroxysmal events that must be distinguished from other disorders, specially those that mimic seizures. It is not always a simple task, because clinical presentation of paroxysmal spells attributable to cardiac diseases, syncope and functional seizure may resemble epileptic seizures. Anoxic seizures may present with decerebrate posturing with extensor stiffening that can mimic a tonic seizure and be followed by irregular tonic-clonic movements. In this case, the child presented an anoxic seizure as a consequence of cardiac etiology. When it is difficult to obtain clinical information that corroborates to a diagnosis, complementary exams such as VEEG are extremely important. **Final comments:** The VEEG is an important tool to investigate several differential diagnoses such as anoxic seizure. As we can see, the correct diagnosis allows us to treat our patient correctly. In this dramatic case, it was necessary surgical treatment based on findings on VEEG. This changed the life of the child, avoiding her to remain incorrectly diagnosed, taking inappropriate medications and live with a cardiomyopathy life threatening undiscovered.

A 12-year-old girl presented with severe vomiting, weight loss, ataxia, and nystagmus. MRI revealed a hyperdense lesion at the cervicomedullary junction, initially suspected to be a tumor. She began dexamethasone and was referred to our service. In April 2024, Anti-Aquaporin 4 IgG antibodies confirmed neuromyelitis optica spectrum disorder (NMOSD) with early-area postrema syndrome. Dexamethasone was discontinued, and prednisone at 1 mg/kg/day was initiated. She improved significantly, and Rituximab treatment is planned. Differentiating neuromyelitis optica (NMO) from brainstem gliomas is crucial due to different therapies and prognoses. NMO is marked by Anti-Aquaporin 4 IgG antibodies and responds to immunosuppressants. NMO lesions are extensive in the spinal cord and area postrema, typically non-infiltrative on MRI. Both conditions can present with cranial nerve palsies, ataxia, and long tract signs. Demyelination often has an acute onset, unlike tumors. MRI characteristics of demyelination include hyperintensity on T2-weighted and FLAIR images, with ill-defined margins and variable gadolinium enhancement. In contrast, brainstem gliomas exhibit more mass effect, heterogeneous appearance with necrosis or cystic changes, and pronounced, irregular enhancement patterns. In this case, the hyperdense lesion at the cervicomedullary junction initially suggested a tumor, leading to the administration of dexamethasone. However, the confirmation of Anti-Aquaporin 4 IgG antibodies redirected the diagnosis to NMOSD, highlighting the importance of specific biomarkers in differentiating these conditions. Advanced neuroimaging techniques, such as Amide Proton Transfer-weighted (APTw) imaging and 23Na MRI, can further aid in distinguishing these conditions by providing detailed tissue characterization. These techniques, although not used in this case, represent a valuable tool for future similar diagnostic challenges, potentially offering more precise differentiation between demyelinating lesions and neoplasms. Accurate differentiation between NMO and gliomas is essential for management and prognosis. Anti-Aquaporin 4 IgG antibodies, immunosuppressive response, and imaging are key. This case avoided invasive procedures and ensured effective treatment through precise diagnosis.

Case presentation: AGJ, 27 years old, with a history of epilepsy characterized by tonic-clonic seizures since 7 months of age, underwent surgery for the removal of a brain tumor and for Ventriculoperitoneal Shunting at the age of 24, after which he began experiencing dysperceptive seizures. During the preoperative period for tumor excision, a cranial magnetic resonance imaging (MRI) was performed, revealing a heterogeneous expansive lesion with a solid-cystic component, slight non-homogeneous enhancement with venous contrast, and signs of diffusion restriction within the solid areas. The lesion was located in the midline, occupying the body of the lateral ventricles and involving part of the 3rd ventricle, as well as causing ectasia of the supratentorial ventricular system, notably on the right side. Surgery was performed to remove the mass, which was classified by biopsy as originating from germ cells, extending into the right fronto-parietal lobe, and also included the excision of part of the corpus callosum followed by Ventriculoperitoneal Shunting. A postoperative cranial MRI detected the possibility of residual lesion amid the excision of the tumor, with gliosis in the right fronto-parietal region extending to the 3rd ventricle, enlargement of the cerebrospinal fluid space in the posterior fossa, and asymmetric atrophy in the right hippocampus. **Discussion:** Germ cell tumors (GCT) of the central nervous system (CNS) are rare and primarily occur in the medial structures of the brain due to remnant germ cell lineage cells that have migrated to these locations. With rapid progression, these lesions can cause obstruction in the ventricular system due to their proximity, and patients often present with ventricular ectasia due to the obstruction of cerebrospinal fluid (CSF) flow. Dysperceptive seizures are frequently associated with hippocampal atrophy, the structure most affected in temporal lobe epilepsy, and show greater resistance to pharmacological treatment. Furthermore, since the hippocampus is associated with memory processes, memory deficit is the most significant alteration in patients with hippocampal atrophy.

Final comments: This is a rare case in which surgical intervention for tumor removal and Ventriculoperitoneal Shunting were important for managing hydrocephalus. However, postoperative examinations detected a residual lesion amid the excision, which, combined with right hippocampal atrophy, significantly contributed to complications such as dysperceptive seizures shortly after the shunting, and also proved to be a debilitating factor for memory processes. So, close monitoring is crucial to detect and manage complications early, emphasizing seizure control and reducing long-term cognitive and functional decline. This case highlights the difficulty in managing epilepsy in patients with double brain lesions who have already undergone surgery, due to the risk of a new interventional approach associated with resistance to drug therapy.
