Case presentation: A 45-year-old woman presented for evaluation with a 5-day history of progressive bilateral visual loss and orbital pain associated with numbness, tingling, and weakness of lower limbs, as well as urinary retention. Two years before, she was diagnosed with CIDP, considering a history of an insidious symmetric weakness with reduced tendon reflexes and sensory involvement of the four limbs, endorsed by characteristic findings in nerve conduction studies. She had been clinically stable after steroid courses. On examination, she could count fingers at two meters with the right eye, whereas her left eye had only light perception and a relative afferent pupillary defect. She had flaccid paraplegia with abolished reflexes and extensor plantar responses, as well as loss of touch, pain, and vibratory sensation below the level of T4. MRI was noticeable for bilateral optic neuritis involving the optic chiasm and a longitudinally extensive spinal cord lesion involving almost all segments except for the conus medullaris, with no evidence of nerve root involvement. Laboratory exams were normal, including serological, arboviral, and rheumatological tests. A lumbar puncture showed a CSF with 55 cells/mm3 (lymphocytic predominance but with 15% of neutrophils and 4% of eosinophils) and 98 mg/dL of protein, without other biochemical or microbiological findings (including herpesvirus and HTLV tests). Serum aquaporin 4-IgG and anti-myelin oligodendrocyte glycoprotein (MOG) were negative. She received a high-dose course of steroids and intravenous immunoglobulin. She was kept with a maintenance dose of prednisone, with good improvement of visual acuity but little of other symptoms. **Discussion:** To date, we have found only two cases in the literature of CIDP concomitantly with NMOSD. There was evidence of simultaneous central and peripheral inflammatory activity in both, whereas in our case, CIDP preceded optic neuritis and myelitis. Diagnosing NMOSD with a negative anti-AQP4 test requires the presence of at least two clinical syndromes (optic neuritis, acute myelitis, area postrema syndrome, acute brainstem syndrome, acute diencephalic syndrome/symptomatic narcolepsy, or typical symptomatic cerebral syndrome), with at least one of the first three syndromes being present. Besides, there are additional MRI requirements, such as longitudinally extensive lesions on the spinal cord or optic nerve, and the need to exclude alternative diagnoses. In view of that, our patient fulfilled the criteria for NMOSD. **Final comments:** CIDP and NMOSD are inflammatory demyelinating diseases; the former is usually restricted to peripheral nerves and the latter to the central nervous system. However, no previous studies have determined a common underlying pathology to explain both presentations concomitantly. Despite the few cases reported so far, we should point out a possible autoimmune overlap of these two syndromes.

Correspondence: Regina Maria Papais Alvarenga; Email: reginaunirio2016@gmail.com.

Case presentation: A 43-year-old Caucasian woman presented in March 2021 with severe cervical pain and paresthesias affecting her entire body following a COVID-19 infection in February 2021. A neurologist suspected Transverse Myelitis and empirically treated her with oral prednisone. A magnetic resonance imaging (MRI) scan on March 15, 2021, revealed an elongated area of high signal intensity in the spinal cord at the C2 level on the right, and a focus in the left postcentral gyrus, both with contrast enhancement. Neurological examination confirmed altered superficial sensation. In her medical history, the patient reported episodes of eyelid ptosis and fluctuating muscle weakness since age 19 (1997), exacerbated during pregnancy, which remained undiagnosed despite consulting several neurologists. In 2001, after giving birth, her child had neonatal complications but recovered without treatment. Following discharge, she experienced arm weakness and sought another neurologist who suspected Myasthenia Gravis (MG), confirmed by anti-acetylcholine receptor antibody testing. She responded to oral anticholinesterase medication and thymectomy, after which the disease went into remission. Investigation for Transverse Myelitis and MG: Cerebrospinal fluid analysis and blood tests were normal; anti-acetylcholine receptor and anti-MUSK antibodies were negative; anti-aquaporin 4 antibody was positive, and anti-MOG was negative. Treatment with methylprednisolone improved her pain, with residual mild distal hypoesthesia (EDSS = 2.0). Prophylactic treatment with Rituximab was chosen and has been effective and safe. **Discussion:** This represents a rare case of AQP4-positive Transverse Myelitis currently classified as Neuromyelitis Optica Spectrum Disorder (NMOSD), despite not having extensive spinal cord involvement, associated with Myasthenia Gravis occurring 23 years earlier and stabilized post-thymectomy. This case shares similarities with findings in a multicenter study of 16 cases of MG-NMOSD overlap, where most initially presented with MG, and the interval to NMOSD onset varied (1 to 41 years). Thymic hyperplasia was frequent, with 70% undergoing surgery before NMOSD onset, resulting in MG remission for most. Genetic susceptibility studies indicate the DRB1*03:01 allele, associated with NMOSD, is also linked to other autoimmune diseases like Systemic Lupus Erythematosus and Sjogren's syndrome. While MG genetic susceptibility is heterogeneous, recent research suggests early-onset MG may be associated with the DRB1*03:01 allele, potentially linking these rare autoimmune conditions. **Final comments:** We describe the sole AQP4-positive NMOSD spectrum syndrome associated with MG in our cohort of 300 NMOSD cases in Rio de Janeiro.

Neuromyelitis optica spectrum disorder with atypical presentation and evolution

Lucas Vergne Cheade Lins[1], Daniel Lordelo San Martin[1], Julia Cordeiro Braga[1], Adriana Alves Rapp[1], Brenda Francisca Cardoso Brito[1], Victor Xavier da Silva[1], Marcel Leal Ribeiro[1], Karla Oliveira Couto[1], Rubson Soares Rocha[1], Renan Carvalho Castello Branco[1]

[1]Hospital Santa Izabel, Salvador BA, Brazil.

Correspondence: Lucas Vergne Cheade Lins; Email: lucascheade@gmail.com.

Case presentation: Female patient, 45 years-old, white, previous hypothyroidism, reports itching for 45 days in the dorsal region with progression to allodynia up to the anterior thoracic region associated with burning. In a medical evaluation at the time was prescribed oral acyclovir. After a few days, sensory symptoms persisted and the patient developed reduced strength in the left lower limb, numbness in feet and urinary retention. There was clinical worsening requiring hospitalization. On examination, it was noted superficial hypoesthesia at T6 level and grade 4- strength in lower limbs, bilateral support for walking. CSF analysis: 320 cells/mm^3 (82% lymph), 50mg/dL protein and 61g/dL glucose. Magnetic Resonance of the brain and spine showed an inflammatory lesion with T2-T8 enhancing contrast. The initial possibility of infectious myelitis and demyelinating disease was raised, intravenous acyclovir and corticosteroids were started on 2º and 3º day of hospitalization, respectively. VDRL, hepatits viral, HIV serologies, vasculitis tests, and CSF viral panel (PCR for HSV 1/2, VZV, CMV) were negative. Vitamin B12 normal. Anti-AQP4 antibody: 1:10. Diagnosis of Neuromyelitis Optica Spectrum Disorder (NMOSD) was confirmed and it was decided to prescribe plasmapheresis, given little clinical improvement with corticosteroids. At the end of treatment, the patient developed significant improvements in urinary retention, gait and strength and sensory deficits **Discussion:** NMOSD is an inflammatory astrocytopathy of the CNS, common in women (10:1) with a mean age of 36 years. Its clinical course usually occurs lasting up to 30 days, typically with involvement of the optic nerve, extensive myelitis and area postrema syndrome. It's rare for the condition to progress for more than 4 weeks, 1-2% is considered secondary progression and only 1 case has been reported as chronic progressive course from onset. Cellularity in CSF may be > 50 cells/mm^3 in 13-35% and > 100 cells/mm^3 in 6% of cases. Acute treatment must be carried out immediately in order to reduce inflammatory activity. The options are: methylprednisolone, plasmapheresis or Human Immunoglobulin (IVIG). Complete recovery rates with the use of corticosteroids alone are low, studies indicate a percentage of 17%, often requiring associated plasmapheresis or IVIG. **Final comments:** Progressive cases are challenging in NMOSD, with difficult differentiation from other etiologies. The patient presented a prolonged evolution and CSF with significant pleocytosis, leading to the consideration of infectious etiology. However, these levels of pleocytosis and evolution of the clinical picture beyond four weeks may occur in a small proportion of NMOSD. The diagnostic exclusion or treatment of infectious agents favors earlier immunotherapy treatment, aiming for better functional recovery. The suspicion of NMOSD, even in atypical situations, is essential for the institution of early treatment at the first clinical manifestations

Neuromyelitis optica spectrum disorders (NMOSD) with systemic lupus erythematosus and thrombotic thrombocytopenic purpura: an overlapping demyelinating syndrome with systemic disorders in a young male patient uncommon case report

Lucas Wilson Matos Gomes[1], Victor Hugo de Souza Silva Gomes[1], Gabriel Carvalho Alves[1], Gabriel Santos de Castro[1], Danyelle Rute Francisco e Silva[1], Letícia Leão Alvarenga[1], Luany Patrícia Liberato de Oliveira[1], Guilhermes Henrique Cavalcante[1], Denise Sisterolli Diniz[1], Delson José da Silva[1]

[1]Universidade Federal de Goiás, Goiânia GO, Brazil.

Correspondence: Lucas Wilson Matos Gomes; Email: lucaswilson95@hotmail.com.

Case presentation: A 19-year-old male, mixed race, previously healthy, began experiencing left-sided paresthesias accompanied by low-grade nocturnal fever, stiffness, and pelvic girdle arthralgia without signs of arthritis and worsening with movement. Within a month, he developed bilateral amaurosis, initially in the left eye (LE) progressing to the right eye (RE), accompanied by

intractable vomiting, epistaxis, and diffuse petechiae. He was hospitalized for investigation, evolving with symmetrical tetraparesis, a single seizure, and decreased consciousness. Complementary exams revealed pancytopenia, and neuroaxis magnetic resonance imaging (MRI) showed findings suggestive of demyelinating lesions with extensive bilateral optic neuritis up to the optic chiasm, rhombencephalitis, and extensive cervico-dorsal myelitis, with a probable diagnosis of neuromyelitis optica spectrum disorder (NMOSD), confirmed by the presence of anti-aquaporin IV antibody - AQP4-IgG - (1:40 in serum by CBA method). Additionally, he had a high titer of ADAMTS-13 in serum, ANA 1:640 multiple nuclear dot and centromeric pattern, and positive anti-SM, anti-RNP, and anti-RO. Therefore, he has a confirmed diagnosis of thrombotic thrombocytopenic purpura (TTP) secondary to probable Systemic Lupus Erythematosus (SLE) according to the 2019 EULAR/ACR criteria. He was started on pulse therapy with methylprednisolone 1g/day for 7 days, 21 sessions of plasmapheresis, and one cycle of cyclophosphamide 1g, with partial improvement. Rituximab (RTX) was chosen, with an attack dose of 500mg/week for 4 weeks, leading to stabilization and partial recovery of deficits. However, 3 months after the RTX cycle, he experienced a new decline in visual acuity, confirmed as a clinical relapse. New pulse therapy was administered, and a new high-efficacy and on-label disease-modifying therapy for AQP4-IgG-positive NMOSD with Ravulizumab, an anti-complement C5, was chosen, reducing the risk of new relapses by an estimated 98%. **Discussion:** Although rare, the overlapping of NMOSD with other autoimmune diseases, such as SLE and TTP, is relatively common, with an estimated association of 7%. Serum autoantibody positivity can be found in 38 to 45% of NMOSD patients, regardless of AQP4-IgG positivity. Chronic inflammation and immunological activation inherent to SLE can compromise the blood-brain barrier (BBB), facilitating the infiltration of AQP4-IgG into the CNS, precipitating complement activation with membrane attack complex formation and thus demyelinating lesions. Endothelial disturbances observed in TTP can exacerbate BBB permeability, corroborating the pathogenesis of NMOSD. **Final comments:** Currently, Ravulizumab is a new high-efficacy disease-modifying treatment option in cases of overlap between SLE and NMOSD due to the shared complement activation in their pathophysiologies, with this patient being one of the first in Brazil to receive this medication through the public health system (SUS).

Neuromyelitis optica with ANTI-AQP4 antibodies associated with dermatomyositis: a case report

Luís Fernando Fernandes Miranda[1], José Guilherme Pinhatti Carrasco[1], Rodrigo Pernomian Cianca[1], Antonio Paulo Felci Rodrigues Leite[1], Matheus da Silva de Oliveira[1], Felipe Merchan Ferraz Grizzo[1], Juliana Yuri Sekiyama[1], Paulo Roberto Donadio[1], Guilherme Henrique Silva Fogaça[1], Gabriel Bortoli Ramos[1]

[1]Universidade Estadual de Maringá, Maringá PR, Brazil.

Correspondence: Luís Fernando Fernandes Miranda; Email: ra123503@uem.br.

Case presentation: A 20-year-old female,diagnosed with dermatomyositis (DM) and continuously using prednisone and hydroxychloroquine, required four pulse therapies with cyclophosphamide due to nonspecific interstitial pneumonia related to DM. After that, she sought medical care with fever (39°C), asthenia and severe ventilatory-dependent pain in the posterior cervical region. She developed urinary retention and tetraparesis and, on physical examination, had a sensory level at T2. Complementary tests were performed, revealing an erythrocyte sedimentation rate of 100mm, CRP <0.5, creatine kinase of 95 and cerebrospinal fluid analysis with 453 leukocytes/mm^3, hyperproteinorrhachia (718mg/dL), hypoglycorrhachia (23mg/dL) and lactate at 42.7mg/dL (reference <19.8). Bacterioscopy, Cryptococcus and VDRL were negative. Ceftriaxone 2g was administered every 12 hours. The patient was admitted to an intensive care unit due to hypoxemia. The patient's level of consciousness improved, however there was no improvement in the motor and sensory neurological deficit. Therefore, cefepime and vancomycin were started and a neuroaxis magnetic resonance imaging (MRI) was requested with cervical (C2-C7) and thoracic (T7-T11) myelitis was evident, affecting nearly the entire transverse diameter of the spinal cord with gadolinium enhancement. As a result, the patient received pulse therapy with methylprednisolone for seven days and was referred for plasmapheresis, in addition to the collection of Anti-aquaporin-4 (AQP4) and anti-MOG antibodies. The patient showed slight clinical improvement, gaining only one degree of strength in the upper limbs. It was decided to maintain 80mg/day of prednisone. The anti-AQP4 (CBA method) was reactive at a dilution of 1:40, confirming the diagnosis of neuromyelitis optica and the patient is currently awaiting rituximab administration. **Discussion:** NMO is an autoimmune disease that attacks astrocytes. In over 80% of cases, it is caused by IgG autoantibodies anti-AQP4, the most abundant water channel in the central nervous system, predominantly located at the astrocyte end-feet.It should be noted that 10-40% of patients with NMO have associated autoimmune diseases, with the most common being systemic lupus erythematosus, Sjogren's syndrome and thyroiditis. Cases of association between NMO and DM are rare,with only one case report in 2014 and the cause of this association is still unknown. Both diseases are autoimmune mediated by B cells, which suggests a possible role for specific biological therapy, such as the Rituximab. **Final comments:** The possibility of an association between NMO and rheumatological diseases should be considered in patients with neurological symptoms and previous rheumatological conditions. Complementary tests, such as MRI and anti-AQP4 antibodies, can help establish the diagnosis. The collaboration of neurologists and rheumatologists is essential for proper management of patients, optimizing the choice of immunosuppressive therapy.

Case presentation: A 63 years-old female patient presented a six month history of dementia, with prominent memory, visuospatial deficits and executive dysfunction. She was born in Brazil, but her family was from Japan. Four years before the onset of cognitive impairment, she presented with episodes of urinary retention of unexplained etiology. Cerebrospinal fluid analysis revealed a normal initial opening pressure, 2 cells, slightly elevated proteins (48mg/dL) and 57mg/dL of glucose. Her screening for infectious and autoimmune diseases was negative. During the investigation, she developed other episodic neurologic dysfunction, characterized by fever and acute confusional state after vaccination, with complementary investigation unremarkable. The same episode happened a year ago. On her brain MRI, the diffusion sequence revealed hyperintensities in the subcortical white matter of the cerebral hemispheres, predominating in the frontal lobes, without alteration in the ADC map. It was accompanied by signal changes on T2/Flair in both cerebellar hemispheres. These findings were suggestive of neuronal intranuclear inclusion disease (NIID). Suspecting it, a skin biopsy showed eosinophilic hyaline intranuclear inclusions on hematoxylin and eosin, compatible with NIID diagnosis. **Discussion:** NIID is a rare disease, with intranuclear eosinophilic inclusion bodies are the main characteristic pathological changes in the central and peripheral nervous systems and are caused by repeated GGC expansion in the NOTCH2NLC gene, especially in Asiatic patients. The most common feature of NIID is symptom heterogeneity. The clinical phenotypes are broad and include cognitive impairment, movement disorder, episodic events, autonomic dysfunction and neuromuscular disease. The most common in adults is the cognitive impairment subtype. The existence of intranuclear inclusions and symptoms in systemic organs may precede the onset of cognitive symptoms. The median onset of urinary symptoms is 55 years. Hyperintensity in the corticomedullary junction on diffusion-weighted imaging (DWI), focal cortical edema/enhancement, and white matter lesions involving the paravermis, middle cerebellar peduncle, and corpus callosum have been reported to be characteristic imaging for NIID. Currently, there is no treatment to cure or slow down the process of NIID, and the treatment is supportive for improving quality of life. **Final comments:** The high heterogeneity of clinical symptoms and signs of NIID increases the difficulty in the clinical diagnosis of NIID. The prevalence rate of adult-onset NIID may be higher than previously thought, and it may be underdiagnosed in the population. It must be considered during the differential diagnosis of dementia.

Palliative care in neurology is a recent speciality to improve the quality of life of patients with severe neurological diseases. This study aims to determine the frequency of neurological inpatients who had indication of palliative care, and evaluate the symptomatology, demographic profile, the need for supportive measures, advance directives for life and medical history of patients in a tertiary hospital in Brazil. This cross-sectional analytical study evaluated all patients admitted to the neurological semi-intensive care unit (ICU) with neurological conditions from February through August 2022. The Palliative Performance Scale, weight loss greater than 5% associated with body changes and a negative response to the question: "Would you be surprised if the patient died within 1 year?") was used to indicate palliative care. Patients were divided into three groups: patients with palliative care needs (group indication), patients without palliative care needs (group without indication) and patients who received at least one assessment of a palliative care team (group palliative). Demographic data were analysed using the Qui quadrado test for qualitative and Kruskal-Wallis test for quantitative variables. Of the 198 patients included in the study, 115 (58%) had palliative care needs. Only 6.9% received assessment by the palliative care team, and 9.56% had advance directives in their medical records. Patients in group indication had a higher prevalence of symptoms, such as fatigue, depression, shortness of breath and lack of appetite, and required more supportive measures, such as oxygen therapy, enteral/ parenteral nutrition,

admissions at ICU and days in hospital. Despite the high demand for palliative care in neurology, few patients receive this treatment, resulting in decreased quality of care. Therefore, greater integration and discussion of palliative care in neurology are needed.

Background: The V122I variant is typically associated to cardiomyopathy. Polyneuropathy is considered a minor manifestation. **Objective:** To evaluate the presence of neuropathy associated to the V122I variant in Brazilian referral centers and determine its demographic, clinical and neurophysiological characteristics among V122I carriers. **Methods:** A national, multicenter (10 referral centers), observational, retrospective cohort study. All V122I carriers underwent a demographic assessment. For clinical and EMG analysis we excluded: a compound heterozygosity in the TTR gene, the presence of comorbidities or other factors known to predispose a neuropathy, or patients who had not undergone EMG. The homozygous patients were analyzed separately. **Results:** We found 246 V122I carriers from 84 families: 240 heterozygous, 4 homozygous, and 2 compound heterozygous (V30M/V122I and I107V/V122I). Gender distribution was similar. Age:19-89 years, mean 53.4. Race: 26.7% White, 17.3% Black and 56% mixed. Individuals were born in all regions of Brazil, mainly in the states of Pernambuco (32.4%), Bahia (32.0%). Considering the 122 heterozygous submitted to clinical and electrophysiological analysis: 42.6% were symptomatic. Carpal tunnel syndrome (CTS) preceded the onset of polyneuropathy and/or cardiomyopathy in 69.2%. Onset manifestation excluding CTS: cardiomyopathy-52.9%, polyneuropathy-37.3% and mixed-9.8%. Mean age of disease onset: 64.9 years, 2.1 years earlier in homozygous. Follow-up: 14/27 cardiological patients developed polyneuropathy and 8/19 neurological patients developed cardiomyopathy. The mixed phenotype increased to 52.9%. Polyneuropathy: sensory/sensory-motor polyneuropathy-62.2%, small fiber neuropathy-32.4% and isolated dysautonomia-5,4%. Coutinho stage: stage1-92.3%, stage2-7.7%. Sensory symptoms-91.7%, weakness-44.4%, dysautonomia-14.3% to 54.3%, neuropathic pain- 52.8%. EMG was abnormal in 50%. Asymptomatic patients: CTS-20%, Radiculopathy-2.9%. Symptomatic patients: CTS-70.6%, Cubital tunnel syndrome-11.8%, sensory axonal polyneuropathy-13,7%, sensory-motor axonal polyneuropathy-35.3%, CIDP-like-2.0%, multiple mononeuropathy-3.9%, radiculopathy-11,8%. CTS was bilateral in 95.8%. SSR response was absent in 17.6%, never in isolation. **Conclusion:** The V122I variant was found in Blacks, mixed-race (Black/White), and White populations. The Northeast region is an endemic area, particularly Bahia and Pernambuco. Neuropathy is frequent at onset, and the only manifestation in 21·6% after follow-up. Symptoms related to dysautonomia, neuropathic pain and motor impairment were less common. CTS was the most frequent EMG finding, almost always bilateral. Cubital tunnel syndrome should be investigated regularly. An axonal polyneuropathy predominated; atypical patterns were also observed. Sympathetic skin response (SSR): absent in 17·6%, never occurring as an isolated change. CTS associated with an absence of SSR may be suggestive of amyloid neuropathy.

Neurophobia and neuroaffinity: a study among medical students in a Brazilian federal Southeast University

Iuri Sena Melo[1], Roberto Pereira Santos[1], Rita de Cássia Leite Fernandes[1]

[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Iuri Sena Melo; Email: iurisenamelo@gmail.com.

Background: With the increase in population longevity, there is a rise in the prevalence of neurological diseases. However, the training of specialists does not keep pace with the demand, leading to a potential shortage of neurologists. The scientific literature identifies a phenomenon known as neurophobia, characterized by a fear of neurological sciences and clinical Neurology, stemming from the inability to apply basic scientific knowledge to clinical situations. This topic has been evaluated in many countries and at various levels of medical education, prompting proposals for diverse strategies to prevent neurophobia throughout the academic trajectory. **Objective:** To identify the frequency of neurophobia among medical students and its possible causes. **Methods:** Cross-sectional study conducted with medical students divided into three subgroups: pre-clinical knowledge (2ºy of medical school), clinical knowledge (4ºy), and internship (6ºy). A standardized questionnaire was distributed to those who voluntarily agreed to participate, addressing levels of confidence, knowledge, interest, and ease in various medical specialties (scale 1-5). We created the Affinity Index (AI) based on the average values obtained - the lowest AI, the highest aversion to the speciality. We also enquired specifically for fear of Neurology and about possible causes for the negative perception of neuroscience knowledge (scale 1-4). **Results:** From 567 questionnaires sent, 58 responses were received. One was excluded due to inconsistent data. 42.1% reported fear of Neurology and/or neurosciences, but this percentage reached 56% in the last year of medical school. Neurology had the second-lowest value of AI (2.41), surpassed only by Rheumatology (2.07). The "ease in Neurology" had the lowest average value (1.98) compared to the other characteristics evaluated and also compared to the ease of other specialties, including Rheumatology (2.06). "Interest" in Neurology knowledge had the third-highest value (3.16), with only Nephrology (3.17) and Cardiology (3.29) scoring higher. Among the causes of fear of Neurology, the most associated factors were difficulties in neurophysiological knowledge, the complexity of diagnoses, insufficient class hours, and limited exposure to neurological patients. **Conclusion:** There is a high trend of aversion to Neurology, although in this small sample we found it less prevalent than in previous similar studies. Nonetheless, the high interest in Neurology compared to other areas may indicate that neurophobia does not reflect a disregard for its knowledge, being probably more associated with teaching failures. Among the possible causes for neurophobia, difficulty in "neurophysiology" was more prevalent, different from other studies who found it to be "neuroanatomy". In conclusion, this preliminary work points to the need for new medical education policies specifically aimed at teaching neurological sciences.

Neurophysiologic data in a cohort of transthyretin familial amyloidosis patients: understanding where we stand on small fiber evaluation

Isadora Versiani[1], Eduardo Rodrigues Davidovich[1], Ligia Rocha Andrade[1], Salim Lazaro Balassiano[1], Robson Teixeira Vital[1], Clarissa Neves Spitz[1], Larissa Bittencourt de Carvalho Chaffin[1], João Vitor Ribeiro dos Santos[1], Livia de Almeida Afonso Abi-Haila[1], Marcia Rodrigues Jardim[1]

[1]Universidade do Estado do Rio de Janeiro, Hospital Universitário Pedro Ernesto, Rio de Janeiro RJ, Brazil.

Correspondence: Isadora Versiani de Lemos; Email: isadora.versiani@gmail.com.

Background: Transthyretin familial amyloidosis (ATTRv) is a heterogeneous hereditary disease, endemic in our country, that gradually leads to significant disability. Recent advances in genetic research have allowed improvement in disease modifying treatment options. However, currently available therapeutic strategies show benefit when started early in the course of disease. It is therefore necessary to optimize diagnostic workup to ensure early detection. Neurophysiologic studies prove to be allies in managing these patients, and special techniques for evaluation of small nerve fibers are considered as possible tools for early diagnosis, since small fiber neuropathy is a common initial presentation of ATTRv. To contribute to future development of new diagnostic workup algorithms, we find it essential to debate where we stand regarding the use of neurophysiologic tests among these patients. **Objective:** Our goal is to analyze neurophysiologic data from our cohort of ATTRv patients, to learn where we stand and what we need to pursue to compare small fiber neurophysiologic studies, aiming to achieve earliest possible diagnosis. **Methods:** A cohort of 46 adult transthyretin mutation carriers was identified in our university neuromuscular outpatient clinic, from April/2019 to June/2024. Clinical and neurophysiologic data were collected via thorough chart review. Tests were done by our team on the same clinic. **Results:** Out of 46 transthyretin mutation carriers analyzed Val30Met mutations were detected on 18 patients, Val122Ile on 15 patients, Ile127Val and Phe84Leu on 5 patients each, and Glu74Lys on 1 patient. 2 patients had no documentation found of the specific mutation. 31 patients out of all 46 (67,4%) were symptomatic from a neurologic point of view. All symptomatic patients underwent routine nerve conduction studies, as well as 9 asymptomatic patients. Out of those tests, 14 came normal (35%), 20 showed sensorimotor polyneuropathy (50%), 1 showed pure sensory lower limb neuropathy (2,5%), and 5 showed carpal tunnel syndromes of varying degrees (12,5%). Only 6 patients (13%) underwent pain-related somatosensory evoked potentials, 1 with altered results. 17 patients underwent sympathetic skin response testing (42,5%), among which 9 were altered (52,9%). No patients had yet done R-R interval or electromyography silent period testing. **Conclusion:** Early accurate diagnosis defines ATTRv management and prognosis. Neurophysiologic studies focused on evaluation of small fibers may be an accessible, non-invasive and useful tool in this scenario. We found that although most of our mutation carriers underwent nerve conduction studies, only part of them had small fiber tests done. This shows the importance of bringing these tests and the need of standardization to light, and of continuing our search to compare different small fiber tests, aiming to identify whether one of them stands out as a potential standard.

Correspondence: Gabriel Gaspar Bíscaro; Email: g.g.biscaro@gmail.com.

Nerve injuries frequently occur within the spinal canal, affecting the most proximal part of the peripheral nervous system, namely the spinal roots. This results in a longitudinal spinal cord injury, which is characterized by profound alterations in the spinal cord microenvironment. These include motoneuron apoptosis, chronic gliosis and synaptic pruning. Glutamate excitotoxicity, which is mediated by excessive NMDAr and AMPAr stimulation, plays an important role in its pathophysiology. Consequently, the use of NMDAr antagonists has been proposed as a promising treatment for central and peripheral nerve injuries. In this context, the present study aimed to investigate the putative neuroprotective effects of memantine, an NMDAr antagonist, after ventral root crush (VRC) in mice. Therefore, unilateral crushing of the ventral roots of L4, L5, and L6 was conducted in adult C57BL/6J mice, which were divided into four experimental groups: vehicle, and memantine at doses of 30 mg/kg, 45 mg/kg, and 60 mg/kg. The mice were administered memantine or vehicle solution via gavage daily for a period of 14 days following the injury. Twenty-eight days after the lesion, the mice were perfused, and the lumbar intumescences were collected and processed for histological analyses. The number of motoneurons was quantified in both sides of the respective spinal cord segments (following toluidine blue staining) in order to calculate the motoneuron survival rate. Astrogliosis and microglial reaction were assessed by immunohistochemistry for GFAP and Iba-1, respectively. Immunohistochemistry was further applied to synaptophysin and VGLUT-1 to evaluate synaptic pruning and plasticity. The protocol for the use and handling of animals was approved by the local ethical committee (CEUA protocol number 5740-1). The administration of memantine following VRC, at all studied doses, was associated with a significant increase in motoneuron survival. The 45 mg/kg group exhibited the most pronounced effect ($p<0.001$). Memantine also demonstrated the capacity to downregulate microgliosis in the doses of 45mg/kg and 60 mg/kg ($p<0.01$ and $p<0.05$, respectively), and astrogliosis in all treated groups in comparison to the vehicle ($p<0.01$). Moreover, the administration of memantine at a dose of 45mg/kg was found to result in a significant reduction of activated microglia ($p<0.05$ compared to vehicle group), as evidenced by morphological characterization. Memantine treatment was also associated with an increase in motoneuron synaptic coverage, which was observed in all doses ($p<0.001$). However, no statistically significant differences were observed in VGLUT-1 expression among the experimental groups ($p=0.08$). These findings suggest that memantine may have a significant impact on motoneuron survival, gliosis reduction, and inhibition of synaptic pruning, which could have implications for clinical applications.

Neuroprotective effect of therapeutic hypothermia in critically ill patients with traumatic brain injury: a systematic review

Loyslene Maria de Paula Bonifácio[1], Leandro de Souza Cruz[1]

[1]Faculdade de Ciências Médicas e Saúde de Juiz de Fora, Juiz de Fora MG, Brazil.

Correspondence: Loyslene Maria de Paula Bonifácio; Email: loyslene.med@gmail.com.

Background: Therapeutic hypothermia has emerged as the most extensively studied neuroprotective intervention in laboratory settings, demonstrating significant neuroprotective benefits across various neurological disorders. However, its clinical application remains limited due to challenges in routine medical practice and adaptation to specific pathological conditions. In recent years, therapeutic hypothermia has been recommended for traumatic brain injury with the aim of normalizing intracranial pressure while providing neuroprotective effects. Traumatic brain injury is a leading cause of mortality and morbidity globally. Clinical research indicates a negative correlation between elevated body temperature and outcomes in traumatic brain injury patients, suggesting that lowering the body temperature to around 35°C may reduce neurological damage. **Objective:** To evaluate the neuroprotective effect of therapeutic hypothermia on neurological function in critically ill patients with traumatic brain injury in an intensive care unit setting, through a systematic review. **Methods:** Randomized controlled trials published in English over the past decade were analyzed, focusing on adult human subjects (18 years and older). Data sources included the National Library of Medicine (MedLine) and the Brazilian Scientific Electronic Library Online (SciELO). The search utilized terms from the Health Sciences Descriptors (DeCS), specifically: induced hypothermia, traumatic brain injuries, and intensive care. Studies involving critically ill TBI patients treated with therapeutic hypothermia were included, while those with unclear methodologies, available only in abstract form, involving pediatric participants, or where therapeutic hypothermia was used in cardiac arrest were excluded. The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) scale was used to enhance the reporting quality of this review. **Results:** Nine studies were analyzed, encompassing 1304 participants aged 19 years and older with traumatic brain injury. The effects of therapeutic hypothermia on mortality and neurological recovery during intensive care and subsequent months were examined. Statistical tests with a p-value <0.05 were considered significant. Despite the large body of preclinical and clinical research on therapeutic hypothermia, there is no robust evidence supporting its neurological benefits in the short and long term for critically ill traumatic brain injury patients. However, clinical trials indicate a reduction in mortality and neurological damage. **Conclusion:** The best available evidence supports the use of mild to moderate therapeutic hypothermia in traumatic brain injury patients to reduce mortality rates and enhance neurological recovery. Nevertheless, further randomized controlled trials are necessary to consolidate these findings

[2]University of California San Francisco, Memory and Aging Center,

Correspondence: Gabriela Barbosa Rodrigues; Email: g242237@dac.unicamp.br.

Background: Alzheimer's disease (AD) is a neurodegenerative disorder that has become increasingly prevalent around the world and can be characterized in vivo by amyloid-beta peptide and hyperphosphorylated tau protein. Subjective cognitive decline (SCD) and mild cognitive impairment (MCI) are potential previous stages of AD dementia. Behavioral and psychological symptoms are common in SCD and MCI, but their biological basis is still not clarified. **Objective:** To investigate the potential correlations between neuropsychiatric symptoms and AD biomarkers in patients with SCD and MCI. **Methods:** 71 subjects were recruited for a medical and psychological evaluation in the Clinical Research Center of Universidade Estadual de Campinas, Brazil. They were diagnosed according to NIA-AA criteria and underwent neuropsychiatric scales, including the Mild Behavioral Impairment Checklist (MBI-C), a helpful questionnaire to measure behavioral and neuropsychiatric symptoms in the AD continuum. The subjects also underwent CSF collection to measure the biomarkers in the samples using immunoassay kits. We used Pearson correlation for the statistical analyses. **Results:** We found statistically relevant correlations between the MBI-C C domain and the CSF amyloid-beta ($p=0.026$, $r= -0.302$, $n=54$) and a correlation between the MBI-C E domain and the CSF total-tau protein ($p=0.026$, $r= 0.295$, $n=57$). **Conclusion:** The MBI-C C domain approaches symptoms of impulse dyscontrol, and the MBI-C E domain comes with symptoms of abnormal perception or thought content. We found that psychological symptoms imply an association of these symptoms with the neurodegenerative process due to the correlation with total-tau protein, a more specific biomarker.

Case presentation: 34 years old female patient presented, in January 2024, with the symmetric, additive, and inflammatory course of poly arthritis, in symptomatic therapy at the moment without clinical benefit. In February, developed multiple episodes of emesis, asthenia, hyporexia, and mood disorder, with a history of 10 Kg weight loss. In April she developed alopecia, microvascular lesions in the skin, anemia, and worsening mood disorder, being admitted to Dr. João Lúcio Pereira Machado in a post-ictus state, after the first impaired awareness of tonic-clonic seizure event, and submitted to abortive therapy she developed proximal upper and lower limb par during the admissions, compromising her gait. After two days she presented symmetric lower limb paralysis and upper limb paresis, oropharyngeal dysphagia, and dyspnea, being transferred to Fundação Hospital Adriano Jorge for diagnostic investigation. At the time, she presented through a physical exam, psychomotor agitation, associated with disorientation in space and time, depressive affect, horizontal nystagmus, oral ulcers, symmetric +2 lower limb edema, +2 muscle weakness in the upper and lower limb, preserved deep tendon reflexes. She underwent several laboratory testings, highlighting anemia (6 hemoglobin), direct coombs test positive, renal impairment (4,5 creatinine), 24h proteinuria as 753,4 mg/24h (1.395 ml), as well as image exams such

as thoracic computed tomography (CT) scan revealing bilateral pleural infusion, cranial CT scan without signs of ischemia or bleeding, nuclear magnetic resonance without signs of vasculitis, renal ultrasound revealing bilateral nephritis and ascites. Due to central nervous system affection, worsening of agitation, and irritability, it was indicated a lumbar puncture and cerebrospinal fluid analysis to guide the treatment, presented no signs of infection, elevated protein levels, normal glucose, absence of cells, compatible with an inflammatory pattern. Autoantibody testing revealed a 1:640 mixed pattern anti-nuclear antibody, anti-Ro/SSA positive, and anti-LA/SSB negative. **Discussion:** The case presented evidentiate SLE patient, which is a chronic idiopathic autoimmune disease affecting multiple organs, including the central nervous system, presenting with several neurological syndromes such as seizure disorder and psychosis. The recurrent seizure events are a less common manifestation of Neuropsychiatric systemic lupus erythematosus (NPSLE) and psychosis presents rarely in less than 1%, presenting mood disorders and acute confusional state. Due to the presence of nephritis associated, she underwent pulse therapy with cyclophosphamide, followed by mycophenolate mofetil with significant clinical benefit. **Final comments:** Due to the unusual presentation, it is highlighted the importance of relating this case, the patient had severe clinical affection due to generalized disease activity with multiple organ damage associated with NPSLE, such as lupus nephritis.

https://doi.org/10.5327/CBN241194

Neurorehabilitation of a patient with alpha-mannosidosis: a case report

Marcos Matheus da Silva Fonseca[1], Leonardo Honorato Cheng[1]

[1]Irmandade da Santa Casa de Misericórdia de São Paulo, São Paulo SP, Brazil.

Correspondence: Marcos Matheus da Silva Fonseca; Email: marcosmatheus6@gmail.com.

Case presentation: A 44-year-old female patient, daughter of consanguineous parents, was admitted at the neurological rehabilitation clinic with history of delayed neuropsychomotor development, manifested by speaking and walking difficulties (tiptoe gait), frequent falls due to weakness in the lower limbs, poor school performance and hearing problems since childhood, requiring the use of a hearing aid. By the age of 20, she began to show behavioral changes and visual hallucinations, and was diagnosed with schizophrenia, currently stable. About 3 years ago, the patient developed progressively worse weakness in her lower limbs, requiring the use of a 4-point walker for walking at home and a wheelchair for locomotion in the community. On physical examination, she was lively, oriented in time and space, speech was slightly slurred, language was preserved, with no alterations in the cranial pairs; gait with support on a walker, with slowed speed and cadence, with an extensor pattern in the left hip due to a pain limitation, with no signs of imbalance or incoordination; overall motor strength was reduced, but sensitivity was preserved; index-index test with the presence of dysmetria and decomposition, no postural instability on the Romberg test; hypoactive osteotendinous reflexes overall; heel-knee test not performed due to pain in the hip joint, where there was a bilateral osteonecrosis of the femoral head, according to imaging tests. The diagnostic hypothesis of Alpha-mannosidosis was suggested by the patient's family history, who has a sister with the disease, and was confirmed by genetic testing (Alteration C.2696C > A P. (SER899*) in homozygosity in Exon 22 of the MAN2B1 gene). The therapies proposed were neurofunctional physiotherapy, aimed at balance and proprioception training; orthostatism and gait training with aids; global muscle strengthening, with emphasis on the lower limbs and antigravity muscle groups; stretching training; and occupational therapy, aimed at training activities of daily living, posture change, ergonomics and energy conservation training and routine enrichment measures. **Discussion:** Alpha-mannosidosis is a rare, progressive genetic disease caused by a deficiency of enzyme alpha-mannosidase. This deficiency leads to the accumulation of a substance called mannose oligosaccharide in various parts of the body, resulting in progressive damage to organs and tissues. The symptoms can vary in severity and include physical deformities, intellectual impairment, respiratory, skeletal and visual problems. There is no cure for alpha-mannosidosis, and treatment is mainly aimed at relieving symptoms and improving the patient's quality of life. Supportive therapies such as physiotherapy, occupational therapy and speech therapy may be recommended. **Final comments:** due to the complex nature of this condition, it is important that patients are followed up by a multidisciplinary medical team to ensure comprehensive and personalized treatment.

Neurosarcoidosis and metastatic testicular seminoma: case report

José Victor Ribeiro Silva Gomes[1], Ligia Henriques Coronatto[2], Gabrielly Pereira Figueira[3], Kananda Oliveira Garcia Ruiz[1], Rafael Fonseca Drumond[1], Natália Silva Fernandes[2], Bruna Gutierrez Gambirasio[2], Adrialdo José Santos[1]

[1]Universidade Federal de São João do del-Rei, São João del Rei MG, Brazil.
[2]Universidade Federal de São Paulo, São Paulo SP, Brazil.
[3]Universidade São Judas Tadeu, Cubatão SP; Brazil.

Correspondence: José Victor Ribeiro Silva Gomes; Email: josevrsgomes@gmail.com.

Case presentation: A 34-year-old male patient presented with paresthesia and hemiparesis in the right limb. After 2 years, he presented with a progressive loss of fixed muscle strength in the left lower limb. Brain CT revealed a juxtacortical nodular formation in the right perirhinal region, associated with vasogenic edema of the adjacent parenchyma. Under the initial hypothesis of metastatic disease in the Central Nervous System (CNS), oncological screening was carried out and retroperitoneal lymph node enlargement and atrophic changes in the left testicle were found. The cortical lesion, investigated with brain MRI, revealed a "target" appearance, with central peripheral enhancement, and a dramatic response to treatment with dexamethasone. The patient developed severe abdominal pain, with radiological evidence of enlarged retroperitoneal lymph nodes in the periaortic and paracaval chains, with necrotic content. A lymph node biopsy revealed an infiltrative/metastatic connective tissue seminoma, treated with chemotherapy and currently in remission. The patient also developed epitheliopathy in the right eye and trigeminal neuralgia. The patient is still taking dexamethasone, with a sustained response to CNS lesions, and is clinically and neurologically stable. **Discussion:** Sarcoidosis, a chronic systemic granulomatous disease, has an unknown etiology and can affect the nervous system in approximately 5% of cases. In this condition, any part of the central or peripheral nervous system can be affected. In this case report, several corroborative findings support the clinical diagnosis, without confirmation by biopsy, of sarcoidosis: an inflammatory lesion in the CNS, highly responsive to corticotherapy; trigeminal neuralgia, and ocular epitheliopathy. In addition, the patient presented criteria for possible neurosarcoidosis, such as clinical manifestations and images suggestive of granulomatous inflammation, excluding other differentials, without pathological confirmation. Evolutionarily, the oncological picture of a seminomatous tumor supports the diagnostic hypothesis since previous data in the literature has already shown a correlation between this histological subtype and granulomatous disease. In most cases reported, the oncological diagnosis precedes or is simultaneous with the inflammatory diagnosis. From a pathological point of view, it is known that some seminoma-type tumors have granulomatous reactions (local, metastatic, or even in distant sites not affected by the cancer) **Final comments:** The synchronous occurrence of testicular seminoma and neurosarcoidosis is rare, although it has been reported in the literature. More studies are needed to understand the real pathophysiological correlation between the diagnoses presented here.

Neurosensory anacusis after traumatic brain injury: a case report

Hélio Aquaroni Farão Gomes[1], Itamar Meireles Andrade Santos[1], Dominick Esthephanny Monteiro Silva[1], José Eduardo Trentim Longo[1], Caroline de Barros Viegas[1], Eduardo Abrão Spinola Rezk[1], Gabriela Rossini Dantas[1], Marcos Vinicius de Almeida Silva[1], Patrick Emanuell Mesquita Sousa Santos[1], Daniel Fabiano Barbosa dos Santos[1]

[1]Universidade Estadual Paulista, Botucatu SP, Brazil.

Correspondence: Hélio Aquaroni Farão Gomes; Email: heliofarao@hotmail.com.

Case presentation: AFP, 42 years old, with no previous comorbidities, suffered a car rollover accident presenting traumatic subarachnoid hemorrhage without the need for surgical intervention. During hospitalization, bilateral hearing loss was noted, and the patient was evaluated by the otolaryngology team, who performed auditory brainstem response (ABR) testing with normal latency values and interpeak values, normal tympanometry, and transient evoked otoacoustic emissions present in all frequency bands, leading to a referral to Neurology after 7 days due to worsening hearing. On evaluation, the patient reported more difficulty hearing low-pitched sounds, could hear the ringtone of a cellphone but had difficulty hearing people's speech. Additionally, the patient reported visual misalignments without diplopia and taste alterations. Neurological examination revealed no motor or sensory alterations, negative Romberg sign, preserved tandem gait, cerebellar tests showed dysmetria to the right, intact cranial nerves regarding ocular motricity or visual fields, preserved sensory and motor evaluations, Weber test was non-lateralizing, positive Rinne test, preserved taste sensation with glucose and salt, suggestive of a neurosensory disorder. Cerebrospinal fluid analysis showed 0 leukocytes, 62 proteins, lactate 1.2, with no infectious alterations, negative cultures, and MRI displayed hyperintense lesions in bilateral inferior colliculi, more prominent on the right, and increased density in the left vestibular nerve on SPIR and FLAIR sequences. The isolated lesion resulting from traumatic contusion was confirmed, not affecting other brain structures. Rehabilitation measures were indicated, and on a 2-month follow-up, the patient reported partial improvement in hearing, more noticeable on the left, continuing with biannual follow-ups for reassessment and rehabilitation. **Discussion:** Trauma-related neurosensory hearing loss commonly occurs with temporal bone fractures and is often associated with neurological symptoms like facial paralysis or fistulization, which were not present in this case. Traumatic cases usually affect the vestibular portion of the nerve, leading to vertigo or unilateral vestibular dysfunction with nystagmus. **Final comments:** The uniqueness of this case lies in the exclusive and bilateral auditory involvement with lesions in the inferior colliculi, an uncommon presentation in TBI, concussions, or brain contusions, or even for cerebrovascular injuries. The rehabilitation of bilateral anacusis is very complex due to impaired communication, so adaptations are necessary in comprehensive care and clinical improvement measures to allow the use of a hearing amplifier and return to usual activities.

Neurosyphilis associated with uveitis and the many faces of an inflammatory disease: a case report

Danilo Cabral Pentagna[1], Leonardo Luiz Lino[1], Renato Cabral Pentagna[2], Cristiane Marcos Soares Dias Ferreira[3]

[1]FCMS, SUPREMA, Juiz de Fora MG, Brazil.
[2]Hospital Federal dos Servidores do Estado, Rio de Janeiro RJ, Brazil.
[3]Hospital e Maternidade Therezinha de Jesus, Juiz de Fora MG, Brazil.

Correspondence: Leonardo Luiz Lino; Email: leonardolino5@gmail.com.

Case presentation: A 33-year-old woman presented to the emergency department with complaints of blurred vision and scotomas in oculus uterque (OU) for 20 days. Figure 1 illustrates colored retinography, red-free retinography and autofluorescence, and the latter denotes diffuse hypoautofluorescent spots in macular region in OU and superior temporal peripheral laser marks in left eye. Fluorescein angiography reveals bilateral diffuse hyperfluorescent macular spots, without extravasation, suggestive of bilateral acute macular chorioretinitis (Figure 2). These tests, combined with a VDRL titer of 1:64 and a positive treponemal test, corroborate the diagnosis of bilateral uveitis due to syphilis. The patient was hospitalized to receive crystalline penicillin for 14 days with improvement of visual symptoms on D1. Collected cerebrospinal fluid (CSF): clear; LDH 24; glucose: 54; proteins: 27; albumin: 0,7; lymphocytes: 100%; leucocytes: 2; chloride: 124; Cryptococcal antigen: negative; bacterioscopy: negative; FTA-ABS IgG: positive; VDRL: non-reactive. FAN and ANCA (non-reactive); Latex (< 15). On D14, after uneventful hospitalization and complete resolution of symptoms, the patient was discharged subsequent to 2.400.000 IU benzylpenicillin administration. She was advised to return in 3 months to VDRL and CSF (FTA-ABS IgG+) reevaluation, realize ophthalmological follow-up and the need of sexual partner assession. **Discussion:** Ocular syphilis can occur in any stage of syphilis and clinical manifestations include optic disc edema, uveitis, vitreitis, corioretinitis, vasculitis, retinal detachment and acute retinal necrosis, being uveitis the most common. All patients with syphilis presenting ocular symptons should have their cerebral spine fluid (CSF) tested due to co-ocurrence of neurosyphilis and evaluation of human immunodeficiency virus co-infection. A positive CSF-VDRL is the Gold standard for neurosyphilis diagnosis, with sensibility of 50-80% and high specificity. FTA-ABS, such as other treponemal tests present high sensibility but low specificity to diagnose neurosyphilis. Ocular syphilis and neurosyphilis treatment consist of 18-24 million units of intravenous aqueous crystalline penicillin G per day for 10-14 days. **Final comments:** There is a recrudescence of syphilis cases and its complications worldwide according to the Panamerican Health Organization. Uveitis may be the first symptom of the disease, so its promptly investigation is mandatory to provide early diagnosis, treatment and greater prognosis, preventing vision loss and in many cases, completely symptoms resolution.

https://doi.org/10.5327/CBN241198

Neurosyphilis presenting as multiple cranial nerve palsy in an HIV-positive patient: a case report

Amanda Cipriano Torquato[1], Tainara Martins de Oliveira[2], Wanessa Caroline Ferreira[1], Maria Eduarda Oliveira Araújo[2], Paula Ravenna Sampaio Bastos[3], Arthur Pena Ferreira[3], Mariana Sotte da Silva[3], Mateus Nader Cunha[3], Grasielle Xavier[3]

[1]Universidade Vale do Rio Doce, Governador Valadares MG, Brazil.
[2]Universidade Federal de Juiz de Fora, Juiz de Fora MG, Brazil.
[3]Hospital Municipal de Governador Valadares, Serviço de Neurologia, Governador Valadares MG, Brazil.

Correspondence: Amanda Cipriano Torquato; Email: amanda.cipritorquato@gmail.com.

Case presentation: Male patient, 35 years, HIV-seropositive for ten years in treatment (six months ago his viral load was undetectable), comes to the emergency service referred from primary care after one month with right peripheral facial palsy, partial hearing loss with related dizziness and diplopia that improves with closing the right eye. At the examination, the Skew test was positive. He presented an anterior positive rapid syphilis test and received two doses of intramuscular benzathine penicillin. The blood count, coagulogram, renal function and electrolytes were within the patterns; the serum venereal disease research laboratory (VDRL) was 1:32. It was hypothesized the diagnosis of neurosyphilis and the lumbar puncture and cranial magnetic resonance imaging (MRI) was performed. The cerebral spine fluid (CSF) analysis displayed a positive VDRL; glucose 49mg/dl (more than ⅔ of capillary glucose); white blood cell count 1074 cells/µl, 75% of neutrophils. Gram stain and culture were negative. Cranial MRI showed thickening after gadolinium administration in the intracanalicular portion of the VII cranial nerves bilaterally, being slightly evident on the right, probably related to neuritis. There was no evidence of ischemic attacks. The diagnosis was neurosyphilis with multiple cranial nerve palsy and the patient started on intravenous penicilin G. After a fourteen-day course, he exhibited clinical improvement. **Discussion:** Neurosyphilis associated with multiple cranial nerve syndrome is a rare presentation of neurosyphilis, representing an atypical form of the infection that can occur at any stage of tertiary syphilis. This condition is characterized by simultaneous involvement of multiple cranial nerves, which can lead to a variety of neurological symptoms, including facial weakness, hearing loss, diplopia, dysphagia, and facial pain. The pathogenesis involves inflammation and vasculitis of the cranial nerves and their nuclei, resulting in multifocal neurological deficits. Radiologic findings may reveal thickening of the affected cranial nerves. CSF analysis may show pleocytosis, increased protein, and a positive VDRL, although it may be negative in some cases. Contrast-enhanced magnetic resonance imaging may demonstrate enhancement of the cranial nerves. Intravenous penicillin G is the standard treatment, and corticosteroids may be considered to reduce inflammatory processes. **Final comments:** Neurosyphilis associated with multiple cranial nerve syndrome is an important clinical presentation to be considered in patients with multifocal neurological symptoms, especially those with a history of sexually transmitted infections or positive VDRL. Early diagnosis and correct treatment are essential for a good prognosis. In addition, VDRL testing and CSF analysis should be part of the evaluation in suspected patients, allowing a good therapeutic approach.

https://doi.org/10.5327/CBN241199

Neurosyphilis with atypical presentation: case report

Sarah de Souza Chinelato[1], Guilherme Leonel Gomes da Cunha[1], Bruna Santos Silva Guzzardi[1], Rodrigo Batista Irikura[1], Anouar Sacca Colognesi[1], Gustavo Carvalho Viveiros[1], Isabella Brasileiro Quintella Migueis[1], Talles Camin Rajab[1], Fábio de Araujo Pereira[1], Luiz Henrique Soares Santos Stefano[1]

[1]Faculdade de Medicina de Marília, Marília SP, Brazil.

Correspondence: Rodrigo Batista Irikura; Email: rodrigoirikura@gmail.com.

Case presentation: Female patient, 35 years old, from Oscar Bressane - SP, referred for evaluation at the emergency department due to diplopia that started 1 month ago. The patient also complained of changes in ocular motility associated with a pulsatile right-sided hemicranial headache, starting in the periorbital region and radiating to the ipsilateral temporal region. She denied loss of visual acuity or other associated complaints. After ruling out ophthalmological causes, the patient was referred for evaluation by the Neurology team. Neurological examination revealed alterations in extrinsic eye movement, with paralysis of the right superior rectus and oblique muscles, reporting diplopia only when looking vertically upwards. Complementary imaging tests and cerebrospinal fluid analysis showed no significant changes. However, serological testing for syphilis was positive, with reactive treponemal test and VDRL result of 1:8. **Discussion:** The diagnosis of neurosyphilis can pose a challenge in medical practice, as infection of the central nervous system by Treponema pallidum can occur at any stage of the disease, although most patients with this condition have a negative VDRL in cerebrospinal fluid. In cases of atypical ocular presentations, such as in this patient, ophthalmoplegia due to cranial nerve III damage can be included in the differential diagnosis of any ocular inflammation in the context of syphilis infection. Therefore, it is important to include syphilis screening in laboratory tests for patients with these ophthalmological symptoms. **Final comments:** The presence of clinical signs consistent with cranial nerve III palsy associated with positive serological tests for syphilis led to the diagnosis of neurosyphilis. The patient was promptly treated with Crystalline Penicillin for 21 days and subsequently underwent corticosteroid therapy, with a good clinical response. Neurosyphilis occurs in approximately 25 to 35% of patients diagnosed with syphilis, but of these, only 10% present with cranial nerve abnormalities like the patient in this report, making this an atypical presentation of neurosyphilis.

https://doi.org/10.5327/CBN241200

Neurosyphilis with ocular involvement

Jackson Batista da Silva[1], Mayara Romero Canal[1], Mariana Tonon Giovannone[1], Ketimila Aparecida Pereira[1], Fernando Pierini Costa[1], Mauro Gomes Araujo[1], William Thiago Almeida Leite[1], Natasha Cutolo[1], Eduardo de Almeida Guimarães Nogueira[1], Ana Luiza Vilela Sá Fortes[1]

[1]Santa Casa de Santos, Santos SP, Brazil.

Correspondence: Jackson Batista da Silva; Email: jacksonbs1992@gmail.com.

Case presentation: CLS, 54 years old, married, seeks care for asthenia, edema and joint pain associated with episodes of fever that have not been measured for 4 weeks. History of type 2 DM, under investigation for reactive arthritis. On admission, ophthalmology assessed hyperemia bilateral ocular, photophobia and edema and blurring of bilateral optic disc. We opted for hospitalization and investigation with serology for STIs, arboviruses, rheumatological screening, magnetic resonance imaging (MRI) of the brain/orbits and CSF collection. Observed rapid treponemal test FTA-ABS IgM reagents, CRP 5mg/dL; ESR 70mm/h; and CSF with glucose 70 mg/dL, proteins 135 mg/dL, VDRL reagent ¼. The diagnosis of neurosyphilis was made and treatment with crystalline penicillin G was started. **Discussion:** Syphilis is a curable STI, caused by the bacterium Treponema pallidum, transmitted through unprotected sexual intercourse with an infected person, blood transfusion and vertically, with various clinical manifestations and different stages. The diagnosis is challenging. There are increasing cases of ocular involvement caused by Treponema pallidum infection, which is why the diagnosis should be considered in all cases with unexplained neuro-ophthalmic findings, regardless of sexual history. Neurosyphilis is usually a late manifestation, but it can occur in the early stages of the disease, in immunocompromised individuals or in any infected individual.

According to the literature, treponemal neuroinvasion is seen in approximately 30-70% of patients with early syphilis, of which 80% have asymptomatic spontaneous recovery. The others evolve with different clinical syndromes, often with neuropsychiatric symptoms, cognitive disorders, autonomic dysfunctions, paresthetic syndromes, visual disorders, uveitis, neuroretinitis and even dementia when more advanced. Ocular manifestations can occur at any stage of the disease and target practically the entire ocular system (vessels, chambers, optic nerve, pupillomotor pathways and cranial nerves). Diagnosis is made through non-treponemal testing (indicators of disease activity) and confirmatory tests (FTAbs). Once reagents are associated with neurological symptoms or suspected neuroinvasion, CSF collection is performed. If positive, pleocytosis and hyperproteinorrhaquia are observed. Therefore, the case is now treated as neurosyphilis, regardless of whether or not there is positive serology in the sample. In this analysis, treatment with crystalline penicillin G was carried out 4 million units intravenously every 4 hours for 14 days. **Final comments:** Syphilis manifests itself in the body with the most diverse clinical syndromes, which is why it is called the great imitator. Eye involvement has been better and more observed, since for treatment purposes it must be treated as neurosyphilis. Highlighting that the probability of CNS and ocular syphilitic involvement increases in HIV co-infection, which is why screening for STIs is essential.

Background: Due to the widespread abuse of anabolic-androgenic steroids (AAS) among professional athletes and amateur sportspeople and their related health problems, determining the effects of these substances on the nervous system becomes vital for designing efficient preventive and educational measures. **Objective:** To investigate the main neurological effects associated with the abuse of anabolic-androgenic steroids. **Methods:** This systematic review was conducted through comprehensive searches of electronic databases, including PubMed, MedLine, Scopus, and Google Scholar (between 1980 and December 2023, in English), and also from citations in the selected articles. Keywords such as "anabolic-androgenic steroids", "AASs" and "neurological effects" were searched. Randomized clinical trials, prospective or retrospective human studies and experimental studies (in vivo) were included. **Results:** Twenty-one clinical and experimental articles were selected (12 for anabolic-androgenic steroids and 9 for adverse effects). The neurotoxic effects of AAS are associated with both the membrane androgen receptor (AR) and G protein-coupled receptors. Apoptosis plays a crucial role in brain damage, caused by high concentrations of methandienone and 17-a-methyltestosterone. These substances inhibit the maintenance of the neuritic network, leading to cell death by apoptosis and cleavage of protective chaperone proteins, as Hsp90. The apoptosis in brain areas of rats treated with nandrolone has been suggested to be associated with oxidative stress and NF-Kb signaling, affecting the hippocampus, striatum, and frontal cortex. In another study, prolonged oxidative stress due to AAS exposure was also related to lower cognitive functions, such as motor and executive performance. Dysregulation of miRNA may also contribute to AAS-related brain damage, with a significant increase in miR-34 and miR-132 observed in AAS users compared to cocaine abusers and the elderly. Neuroimaging studies have shown a reduction in global gray matter, cortical volume, putamen, cortex, and right amygdala volume, as well as a marked decrease in dACCgln/glu and Scyllo-inositol levels. Additionally, a chronic administration of EAA in high doses is linked to anxiety-like behavior through the corticotrophin-releasing factor, increasing gabaergic inhibitory effects from the central amygdala to the bed nucleus of the stria terminalis. Furthermore, abuse of EAA alters the phosphorylation of the NMDA receptor, with an increase in excitatory neurotransmission, affecting the control of aggression, which is intensified by a reduction observed in the orbitofrontal cortex in these cases. Finally, people who use AAS are more likely to be drug and alcohol abusers. **Conclusion:** The cognitive and neurodegenerative effects associated with EAA abuse have a wide range of mechanisms involving apoptosis, miRNA derangement, oxidative stress, and alterations in neurotransmitters and neurohormones.

Case presentation: A 63-year-old male patient was admitted to the hospital because his wife noticed behavioral and gait changes the previous day. According to her, he appeared distracted, disoriented, and stumbled several times during this period. He has HIV, hypertension, and heart disease as comorbidities, however adheres to his pharmacological treatments. Four days prior, the patient had been hospitalized in another city for acute respiratory failure of an unknown etiology, without the need for orotracheal intubation. During the second hospitalization, he reported a pulsing headache in the right hemicranium, triggered by coughing. Upon clinical examination, no other abnormalities were observed. During hospitalization, he became disoriented in time and space and began to desaturate. Additional examinations of cerebrospinal fluid, mucus, and blood ruled out the presence of acid-fast bacilli, fungi, Epstein-Barr virus, and bacteria; IgG and IgM antibodies for toxoplasmosis were non-reactive; HIV viral load was undetectable. A full blood count showed 15,500 leukocytes/mm^3 and an absence of basophils. Urea, aspartate aminotransferase, and C-reactive protein levels were elevated. The CD4 lymphocyte count was 629.7/μL. An MRI revealed a hemorrhagic lesion in the right temporoparietal corticosubcortical region, associated with vasogenic and cytotoxic edema, not typical of toxoplasmosis. A biopsy of the brain lesion exhibited round structures morphologically suggestive of tachyzoite forms of Toxoplasma sp., confirming the diagnosis through pathology. **Discussion:** Neurotoxoplasmosis typically presents with similar symptoms to other central nervous system infections, including headaches, motor disturbances, mental confusion, and sometimes ocular and pulmonary manifestations. Therefore, the diagnosis relies on clinical, radiological, serological, and histological examinations. Toxoplasma gondii rarely affects the nervous system of individuals with an adequate immune system. In HIV-positive patients, the risk of developing neurotoxoplasmosis is high when CD4 levels are below 100/μL and extremely rare in immunocompetent patients. Consequently, chemoprophylaxis in immunocompromised individuals with a positive IgG for toxoplasmosis is maintained until CD4 levels exceed 200/μL. **Final comments:** The effectiveness of recent treatments for HIV/AIDS has reduced the incidence and severity of opportunistic infections. Despite the correlation of neurotoxoplasmosis with HIV-positive patients, controlling the disease, indicated by an undetectable viral count and a CD4 lymphocyte count above 200/μL, makes the infection unlikely. Therefore, this clinical case shows an exception and underlines the importance of not disregarding neurotoxoplasmosis as an opportunistic infection of the nervous system in HIV-positive patients, even when controlled.

Neurotoxoplasmosis induced by the use of multiple immunosuppressants in a patient with refractory dermatopolimyositis: case report

Maria Eduarda Vieira Fiber[1], Fernanda Kelly Moreira Almeida[1], Ana Paula Guadagnin[1], Bárbara Isabella Wentz Costa[1], Julia Mariana dos Santos Silva[1], Luana Mesquita de Lima Floriano[1]

[1]Faculdade Atenas, Sorriso MT, Brazil.

Correspondence: Maria Eduarda Vieira Fiber; Email: mdudavieira1@hotmail.com.

Case presentation: Female patient, 28 years old, with refractory dermatopolymyositis (DPM) taking prednisone, methotrexate, and azathioprine. She received an intravenous immunoglobulin infusion in August 2022, with paradoxical worsening observed in December 2022, manifested by the accentuation of pain, myasthenia, anasarca, nausea, and lipothymia. In June 2024, the patient presented with Toxoplasma gondii infection, with ocular involvement and bilateral amaurosis. She developed persistent fever, right hemiparesis, and ipsilateral rhyme deviation. The cranial tomography showed a hypodense lesion in the region of the capsular nucleus of the right cerebral hemisphere, midbrain, and medulla oblongata, with a hyperdense focus in between, associated with a mild mass effect, which was poorly absorbing to the contrast medium. There were no abnormalities on physical examination. Given the clinical picture and imaging findings, she was diagnosed with neurotoxoplasmosis. The treatment included sulfadiazine, pyrimethamine, and folinic acid. **Discussion:** DPM is a rare autoimmune disease belonging to the group of inflammatory myopathies. Treatment involves using potent immunosuppressants, such as glucocorticoids used by the patient in the reported case. Prolonged use of these immunosuppressants may predispose patients to the development of serious opportunistic infections, such as toxoplasmosis. Toxoplasma gondii infection in immunosuppressed patients can lead to serious complications, including neurotoxoplasmosis (NTX), which is the main cause of lesions with mass effect on the central nervous system (CNS), responsible for 50 to 70% of these cases. NTX is commonly found in individuals with the human immunodeficiency virus (HIV), unlike the case reported, where the possible cause of the infection was the treatment with multiple immunosuppressants. It progresses with focal brain lesions with mass effect, generating several sequelae that appear depending on the topography and number of brain lesions. Clinically, it presents as headache, fever, motor impairment, and focal neurological deficits. In this case, the patient presented right hemiparesis and lip rhyme deviation, symptoms suggestive of a focal brain lesion. The diagnosis of NTX is suggested by neuroimaging, which shows hypodense or hypointense lesions with ring enhancement after contrast administration, consistent with the patient's presentation. Standard treatment includes sulfadiazine and pyrimethamine, combined with folinic acid to prevent bone marrow

toxicity caused by pyrimethamine. **Final comments:** Opportunistic infections, such as neurotoxoplasmosis, represent serious challenges in immunosuppressed patients. Early diagnosis and appropriate treatment are crucial to improving clinical outcomes. This case highlights the importance of surveillance and integrated management in patients with complex autoimmune diseases and prolonged immunosuppressive therapy.

Neurotuberculosis in a patient treated with rituximab for anti-synthetase syndrome

Geovane Brito Afonso[1], Maria Júlia Tabosa de Carvalho Galvão[1], Vitor Gustavo Leão Souto[1], Túlio Marlus Castro Lucena[2], José Alves da Costa Neto[1], Inah Araujo de Almeida Murta[1], Érika Santos Machado[2], Assis Porfirio Furtado Nogueira[2], Fernando Tenorio Gameleira[1]

[1]Universidade Federal de Alagoas, Hospital Universitário Professor Alberto Antunes, Maceió AL, Brazil.
[2]Hospital Geral do Estado, Secretaria de Estado da Saúde, Maceió AL, Brazil.

Correspondence: Maria Júlia Tabosa de Carvalho Galvão; Email: mariajuliatcgalvao@gmail.com.

Case presentation: A 48-year-old previously healthy woman began experiencing myalgia in 2016, associated with weakness in all four limbs, intermittent dysphagia, and Raynaud's phenomenon. Elevated CPK and aldolase levels, along with positive Anti-Jo1 and Anti-RO antibodies, and electromyography indicating muscle disease, supported the diagnosis of Anti-synthetase Syndrome. In 2019, she started treatment with rituximab for 2 years but subsequently developed interstitial lung disease and pulmonary tuberculosis. After treating tuberculosis, her condition stabilized clinically. In 2020, she developed a confusional syndrome and insidious cognitive deficit over 3 months. Cerebrospinal fluid analysis showed elevated protein levels, but rapid molecular tests and cultures were negative for tuberculosis. Brain MRI revealed right periventricular ring enhancement, suggestive of an abscess or cerebral tuberculoma. She underwent treatment for neurotuberculosis for 12 months, and post-treatment brain MRI showed diffuse brain volume reduction and gliosis with ischemic lacunae in both cerebral hemispheres. A new immunosuppressive regimen was initiated with prednisone 20 mg/day, methotrexate 10 mg/week, and monthly immunoglobulin. In 2024, she experienced generalized tonic-clonic seizures of likely structural origin and physical examination revealed bilateral palatal paresis, global muscle atrophy, abasia, and flaccid tetraparesis. The most recent imaging showed diffuse supratentorial hypoattenuating foci, diffuse brain atrophy, and ex-vacuo hydrocephalus. **Discussion:** Anti-synthetase syndrome is a type of idiopathic inflammatory myopathy that may progress with myositis, interstitial lung disease, arthritis, fever, and Raynaud's phenomenon. Anti-Jo1 is the most prevalent antibody. Treatment involves immunosuppressants, and patients using Anti-TNF-alpha agents like rituximab are at increased risk of developing tuberculosis. Neurotuberculosis, in the absence of other symptoms, can emerge as a rare infection in these patients, accounting for 5-10% of total cases. It progresses rapidly or insidiously and in its most common manifestation, tuberculous meningitis, can lead to complications such as hydrocephalus, stroke, tuberculoma, and cranial nerve involvement. More rarely, as reported in this case, some patients may present with tuberculoma without meningitis and with normal or slightly altered cerebrospinal fluid. Many patients are diagnosed at more advanced stages of the disease due to its paucibacillary nature. **Final comments:** Diagnosing neurotuberculosis in immunosuppressed patients undergoing treatment for Anti-synthetase syndrome is challenging and must be addressed to prevent the development of disabling neurological sequelae or fatal outcomes during the patients' productive years.

Neurotuberculosis in Brazil: an analysis of the epidemiological profile related to the effectiveness of control strategies (2013-2023)

Vinícius Gabriel Nunes de Freitas[1], Juliana Alencar Isacksson Vieira[1], Arthur Andrade da Silva[1], Willian Alves Costa[1], Paulo de Oliveira Neto[1], Eliezer Paulo Ferreira Júnior[1], Thiago da Costa Brito[2]

[1]Universidade Federal do Amapá, Macapá AP, Brazil.
[2]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Juliana Alencar Isacksson Vieira; Email: julianaisacksson17@gmail.com.

Background: Tuberculosis (TB) is one of the oldest and most prevalent infectious díspares in history and primarily affects the lung tissue. However, when it invades the nervous system, it is called neurotuberculosis (NT). Therefore, the disease is a concern for healthcare services, once it has a difficult diagnosis and severe prognosis. Tuberculosis prevention and epidemiologic control are extremely important to public Healthcare system, which has measures against the disease like BCG vaccine and the National Program of Tuberculosis Control. Thus, understanding the epidemiological profile becomes in the context of tuberculosis control strategies. **Objective:** To describe the evolution of epidemiological and evaluate the effectiveness of brazilian neurotuberculosis control strategies in the period of 2013 until 2023. **Methods:** Data available from the Unified Health System Informatics Department and the Hospital Information System from 2013 to 2023 were used to conduct thus cross sectional descriptive study. The following informations were extracted: Mortality rate and absolute deaths specified by age group, sex, region of the country and year of notification. **Results:** Total number of deaths was 340. The Southeast Region was the most affected in absolute numbers, with 50% of the total (n=170) and mortality rate of 12.57. However, the North Region with 11.31 has the second highest mortality rate. Among the states from the region, São Paulo has the highest number of notifications, with 60,6% of the total (n=103). 2022 was the year with highest number of cases with 13,8% (n=47). In addition, the most affected age group was the one of 30-39 years old, with 20.6% of the cases (n=70), the male group has the highest number of cases with 64.4% (n=219) and the highest mortality rate prevail in the female group, with 11.1. The brown population has a higher number of deaths, 41.2% (n=140), in terms of mortality rate, indigenous people have the highest value with 13.33, followed by black people with 12.21. However, the data describing race/color have a large number of patients with no information, 23.5% (n=80). **Conclusion:** The epidemiological profile of neurotuberculosis in the period of time analyzed shows an relative increase in the number of deaths, with the peak in 2022. The Southeast Region is the one with highest absolute numbers, specially the state of São Paulo. Still, the northern region presents the second highest mortality rate despite its small population size. Thus, the data demonstrate the vulnerability of these populations, which are marginalized in healthcare services. The data also show that control strategies have been effective in reducing the incidence of neurotuberculosis cases in recent years, with an urgent need for greater focus on the most affected racial/ethnic groups and regions of the country.

Neurotuberculosis in immunocompetent patients: atypical manifestations of a common disease

Maria Eduarda Slhessarenko Fraife Barreto[1], Gabriela Rodrigues Tomaz[1], Lucas Toshio Uenishi[1], Guilherme Antonio Silva Ribeiro[1], Lara Santos Machado[1], Luiz José Malta Gaia Ferreira Júnior[1], Enedina Maria Lobato de Oliveira[1], Henrique Ballalai Ferraz[1], Carolina Candeias da Silva[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Maria Eduarda Slhessarenko Fraife Barreto; Email: madusfbarreto@gmail.com.

Case presentation: Case 1: A 41-year-old previously healthy man presented with acute behavioral change, mental confusion, and persistent fever during 3 days. He denied cough or weight loss but had a history of a car accident two years prior. On admission, he was inattentive, with right hemiparesis, and nuchal rigidity. Cranial CT revealed acute hydrocephalus and an urgent ventricular drainage was performed. Cerebrospinal fluid (CSF) analysis showed lymphomonocytic pleocytosis, low glucose, and elevated protein. CSF cultures, molecular tests for Mycobacterium tuberculosis and Histoplasma were negative, as were serologies for HIV, syphilis, and hepatitis. Chest CT was unremarkable. Empirical treatment with broad-spectrum antibiotics + tuberculosis regimen (RIPE) was initiated. Brain MRI demonstrated a left frontal heterogeneous hyperintensity lesion with irregular contrast enhancement. Clinically, he exhibited mild, progressive improvement. After 6 weeks, CSF culture confirmed Mycobacterium tuberculosis. He was discharged with a 1-year treatment plan. Case 2: A 28-year-old man developed continuous bilateral eyelid and lip myoclonus during three months. He had a history of adequately treated miliary tuberculosis five years ago. Brain MRI revealed multiple ring-enhancing nodular lesions with surrounding vasogenic edema in various brain regions. Some lesions exhibited a tree-in-bud appearance, with leptomeningeal enhancement. Laboratory investigations were unremarkable for immunodeficiency, and electroencephalogram was normal. Brain biopsy confirmed granuloma with molecular testing positive for Mycobacterium tuberculosis. The patient was discharged under neurotuberculosis treatment, with some radiological reduction in lesions noted, although involuntary movements persisted. **Discussion:** These two cases show atypical manifestations of Neurotuberculosis. Case 1 is remarkable due to an acute history, more compatible with bacterial agents. Case 2 presented with unusual cranial movement disorders. Neurotuberculosis typically presents as subacute/chronic meningitis with cranial nerve involvement, and may progress to hydrocephalus. Movement disorders are an unusual presentation. Usually, it disseminates through hematogeneous or lymphatic routes from another site. CSF often shows lymphomonocytic pleocytosis, decreased glucose, elevated adenosine deaminase (ADA), and specific microbiological tests. Direct bacillus detection is positive in 25-30% of culture-confirmed cases in the literature. Mycobacterial culture has <50% positivity in larger cohorts. Diagnosis can be reasonably made based on clinical data, CSF profile, and evidence of tuberculosis elsewhere, even if culture is negative. **Final comments:** CNS tuberculosis has a broad spectrum of clinical presentations. Definitive diagnosis is challenging and may require biopsy. Early empirical treatment should be started for suspected cases, after other diagnosis have been ruled out, particularly in low income countries, like Brazil.

New generation sequencing in Hyper-CKemia evaluation

Lucas Marenga de Arruda Buarque[1], Nicolas Ruan dos Santos Cavalcante[1], Jose Pedro Soares Baima[1], Ian Felipe Barbosa Souza[1], Felipe Fiorelli Valenzuela[1], Andre Macedo Serafim da Silva[1], Rodrigo de Holanda Mendonça[1], Carlos Otto Heise[1], Cristiane de Araujo Martins Moreno[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Lucas Marenga de Arruda Buarque; Email: l.marengabuarque@gmail.com.

Background: Hyper-CKemia is a common complaint in neuromuscular clinics. Which is the best propaedeutic for its evaluation is still a matter of discussion. **Objective:** We describe the results of using new generation sequencing in patients with hyper-CKemia. **Methods:** All genetics tests made in the neuromuscular disorders division of HCFMUSP were revisited and only those with a history of rhabdomyolysis and hyperCKemia pauci- or asymptomatic were included. We considered hyper-CKemia as a creatine phosphokinase (CPK) level above 1,5 times above reference value. **Results:** Twenty three patients were selected, 21 were submitted to a gene panel for neuromuscular diseases and 2 to exome: 03 with rhabdomyolysis, 06 with asymptomatic hyper-CKemia and 14 with paucisymptomatic hyper-CKemia. Six (26%) were diagnosed by genetic test: 03 ANO5, 01 GPMPPB, 01 PYMG (all of which have paucisymptomatic hiper-CKemia) and 01 RYR1 (rhabdomyolysis). Of those 17 who did not reach a diagnosis, 01 had only one pathogenic variant in ANO5 gene (a recessive condition) and 04 had one or more VUS in genetic tests. The mean maximum CPK levels in the group that reached a diagnosis was 6.977U/L and in the group without genetic diagnosis was 5.851 U/L. **Conclusion:** The new generation sequencing has started a new era in neuromuscular disorders diagnostics. We report a efficacy of 26% of its use in hyper-CKemia evaluation and ANO5 gene was the most prevalent.

https://doi.org/10.5327/CBN241208

New headache in heart transplant patient receiving tacrolimus

Renata Gomes Londero[1]

[1]Hospital de Clínicas de Porto Alegre, Porto Alegre RS, Brazil.

Correspondence: Renata Gomes Londero; Email: renataneuro-abn@yahoo.com.br.

Case presentation: We saw a 51-year-old patient, heart transplant recipient (October 2022), with recurrent headache since the transplant, which changed pattern at the end of September 2023. Patient wakes up at the end of the night or in the morning with a headache that is more intense than the previous one, throbbing, periorbital, with mild phonophobia and photophobia and no nausea. Headache improves spontaneously in the late morning or early afternoon. He also presents episodes of flashes in his vision. A new pattern emerged one week after a 50% increase in the previous dose of tacrolimus. Fundus of eye with bilateral grade 3 papilledema. Skull tomography with angiotomography showed left frontal ischemic sequelae, venous sinuses and patent superficial and deep veins. Brain MRI was unremarkable. Liquor with opening pressure 260mmH20, crystalline appearance, 1 leukocytes, proteins 45.9, glucose 58 (glycemia 110) | viral, bacteriological, bacterioscopic panel, PCR for mycobacterium tuberculosis, Syphilis, negative fungi and Cryptococcus research. He had a normal renal function, BMI of 21 and has not gained weight in the last year. The patient was managed with acetazolamide up to 1.5g and bilateral occipital nerve block (with good headache control). The papilledema was resolved within 1 month of his initial visit. As the patient has a long history of rejection, we did the option to not suspend the tacrolimus until now. But it is still in discussion. **Discussion:** Tacrolimus, a calcineurin inhibitor, is an immunosuppressant used globally to prevent rejection after organ transplantation. Posterior Reversible Encephalopathy syndrome, psychosis, intracranial hemorrhage has already been described as side effects of tacrolimus. We saw in literature one case of idiopathic intracranial hypertension (IIH), in a child submitted to a kidney transplantation and receiving tacrolimus. The elevated intracranial pressure and the response to acetazolamide makes us believe that it's one more case of IIH by tacrolimus. **Final comments:** With the growing number of people receiving transplantation it's very important to know the side effects of the immunosuppressant drugs used to manage those patients. Here we report a case of a 51 years old man, with ischemic cardiomyopathy that received a heart transplant and developed IHH secondary of tacrolimus, with good response to acetazolamide treatment.

https://doi.org/10.5327/CBN241209

New-onset refractory status epilepticus (NORSE) after COVID-19 in a young adult with possible association of steroid-responsive encephalopathy associated with autoimmune thyroiditis (SREAT)

Lorenzo Marinho Morais[1], Emanuel de Assis Bertulino Martins Gomes[2], Chiara Gübel Portugal[1], Antônio Alves Sobreira Neto[1], Samuel Cavalcante Marinho[1], Jose Wagner Leonel Tavares Junior[2], Manoel Alves Sobreira Neto[2], Samir Câmara Magalhães[2]

[1]Universidade Estadual do Ceará, Fortaleza CE, Brazil.
[2]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Lorenzo Marinho Morais; Email: lorenzo.morais@aluno.uece.br.

Case presentation: A 32-year-old previously healthy male patient presented low-grade fever and myalgias for 4 days. These symptoms subsided, but a week later, he presented persistent seizures even after initial drugs (diazepam and phenytoin), requiring the use of midazolam and orotracheal intubation. After sedation, the seizures returned with refractory status epilepticus. He underwent imaging and laboratory tests and lumbar puncture. The investigation only showed a positive test for COVID-19. He was transferred to the intensive care unit and sedated with midazolam and propofol. He underwent electroencephalography (EEG) monitoring, which still showed epileptiform activity. Levetiracetam was started with sedative drugs increased to achieve a suppression pattern. As it was a NORSE case, intravenous immunoglobulin (IVIG) and methylprednisolone (MPIV) were done for 5 days. EEG still disclosed epileptiform activity. A new burst-suppression was attempted for 48 hours, with association of ketamine, midazolam and propofol. The dose of Levetiracetam was increased, with clobazam and topiramate included. 30 days after admission, the patient woke up without seizures, with normal EEG activity and with rapid improvement in the level of consciousness. In the meantime, he received the results of some tests, with anti-tireoperoxidase and anti-thyroglobulin autoantibodies positive, in addition to anti-SSA. The presence of thyroid autoantibodies, in addition to fast clinical response after steroids, led us to raise the hypothesis of SREAT. **Discussion:** Physiopathology of these seizures due to COVID-19 could be the result of neuroinflammation, autoimmune response and viral invasion of the central nervous system (CNS). As far as we know, this is the first report of possible SREAT triggered by Covid-19. This is the first reported case of COVID-19 associated with NORSE in Brazil. Thyroid autoantibodies raised the hypothesis of SREAT. The treatment involves immunotherapy with methylprednisolone and/or immunoglobulin. The association between Covid-19 and SREAT may be due to the autoimmunity triggered by SARS-CoV-2. NORSE treatment involves antiseizure medication and anesthetic drugs. In addition, immunotherapy should always be considered. The present case showed improvement after the addition of ketamine to propofol and midazolam aiming at suppression burst with inter-surge intervals longer than 5 seconds, for 48 hours and after immunotherapy with IVIG and MPIV. This approach was very effective in our present case and the patient was discharged without sequels. **Final comments:** Here we present a case report of a patient who developed NORSE after COVID-19 with a possible SREAT. The patient showed a good therapeutic response to immunotherapy and improved the status epilepticus after burst suppression therapy. The present case serves as a basis for possible future similar cases and demonstrates the importance of correct investigation and early treatment.

Background: hATTR amyloidosis is a rare, progressive, and fatal disease. NfL is a potential biomarker of disease progression and treatment response in patients with hATTR amyloidosis with polyneuropathy. **Objective:** Examine neurofilament light chain (NfL) levels in patients with hereditary transthyretin-mediated (hATTR) amyloidosis with polyneuropathy from the Phase 3 APOLLO and HELIOS-A studies to assess the potential utility of NfL as a biomarker of disease progression. **Methods:** NfL levels were measured using the Quanterix® SimoaTM platform in healthy controls and patients with hATTR amyloidosis with polyneuropathy who participated in the APOLLO or HELIOS-A studies, gave consent, and had sufficient samples. The samples analyzed were from baseline, 21 days, 4 months, and 18 months in APOLLO, and baseline, 43 days, 4 months, 9 months, and 18 months in HELIOS-A. **Results:** At baseline, NfL levels were slightly higher in APOLLO than in HELIOS-A (69.4pg/mL and 58.2pg/mL, respectively) and did not differ significantly between treatment groups within each study. In the APOLLO placebo arm, NfL levels significantly increased vs baseline at 4 months (+19.0pg/mL, p<0.001) and at 18 months (+36.3pg/mL, p<0.001). In the APOLLO patisiran arm, NfL levels decreased significantly at 4 months and 18 months vs baseline (-20.4 pg/mL and -23.2pg/mL respectively; p<0.001 for both). In HELIOS-A, NfL levels in patisiran and vutrisiran groups significantly decreased vs baseline at 4 months (-9.7pg/mL and -11.0pg/mL, respectively; p<0.05 for both) and at 18 months (-16.4pg/mL and -19.9pg/mL, respectively; p<0.001 for both). **Conclusion:** NfL levels significantly decreased from baseline with patisiran and vutrisiran as early as 4 months after treatment initiation and decreased levels were maintained through 18 months. In contrast, NfL levels in untreated patients increased significantly. These results suggest that NfL is potentially useful for monitoring treatment response and disease progression in patients with hATTR amyloidosis with polyneuropathy.

Niemann-Pick type C syndrome, epilepsy and obstructive sleep apnea in a pediatric patient: a case report

Helmut Kennedy Azevedo do Patrocínio[1], Tereza Cristina Batista Dias[1], Tiago Lameque de Sousa e Silva[1], Pedro Henrick Guimarães Carvalho[1], Cláudio de Souza Fernandes Júnior[1], Cláudio de Souza Fernandes[2], Fabricia dos Santos Almeida[1], Lucca Ferdinando Queiroz Fernandes[1], Matheus Araújo de Medeiros[1], Iury Hélder Santos Dantas[1]

[1]Universidade Federal do Rio Grande do Norte, Natal RN, Brazil.
[2]Universidade do Estado do Rio Grande do Norte, Mossoró RN, Brazil.

Correspondence: Helmut Kennedy Azevedo do Patrocinio; Email: hell.kenn@gmail.com.

Female patient, 4 years old, diagnosed with Niemann-Pick type C (NPC), Epilepsy, Severe Mental Retardation and Obstructive Sleep Apnea (OSA). The patient began presenting with splenomegaly at 10 months old. At 1.5 years, neurodevelopmental regression, especially in language and motor skills, was noted, which raised alarms for the investigation of neurodegenerative diseases. At 2 years and 2 months, NPC was diagnosed through the measurement of Chitotriosidase, Lyso-sphingomyelin, and clinical correlation; genetic studies were not performed. Six months later, the patient developed severe dysphagia, generalized hypotonia, inability to sustain head control, and lost her communicative ability, becoming bedridden and fully dependent. Furthermore, the presentation of OSA and epileptic seizures add another layer of complexity to the clinical picture. Despite treatment with anticonvulsant medications, the epileptic seizures persisted, impacting her quality of life. The patient's treatment involves a multidisciplinary approach, including anticonvulsant medications, continuous use of CPAP to correct problems related to OSA, and also Miglustat to reduce the progression of neurological deficits caused by Niemann-Pick disease. Niemann-Pick type C disease is an autosomal recessive disorder, which results in impaired transport of LDL and other macromolecules. It can present from the perinatal period to late adulthood. Clinical manifestations are highly heterogeneous, typically including cerebellar ataxia, vertical gaze palsy, cataplexy, dystonia, dysarthria, dysphagia, epileptic seizures, cognitive impairment, and hepatosplenomegaly. The patient is classified in the early infantile period of NPC. She exhibited isolated splenomegaly for months, associated with neurocognitive and psychomotor impairments classic to the disease, which guided the diagnosis. Additionally, she developed epileptic seizures refractory to standard treatment. Severe epilepsy is associated with a worse prognosis and significantly reduces patients' life expectancy and quality of life. OSA stands out in this patient as a non-motor symptom of NPC. It is believed that OSA associated with NPC results from impaired coordination and reduced tone of the respiratory muscles, despite limited research in this area, it is known to be associated with higher morbidity and mortality, as well as greater cognitive deficits. The patient's treatment is focused on improving her current quality of life and slowing the progression of neurological deficits, as NPC does not have a curative treatment. This case provides important information about NPC, a rare and complex medical condition, in a young patient. Sharing this case is essential to increase understanding about this condition, its symptoms, treatments, and prognoses. It also aims to spark scientific interest for future research related to correlations among the presented diseases to enhance comprehension and treatment of this condition.

NOACs versus antiplatelet agents in ESUS with predictors of atrial fibrillation: a systematic review with meta-analysis

Ocílio de Deus da Rocha Ribeiro Gonçalves[1], Luma Rodrigues da Silva[1], Ana Paula Lima Nascimento[1], Ester Vasconcelos Silva[1], Sabrina Ruthiele Santos de Carvalho[1], Samuel de Castro Campos[1], Lara Beatriz Alves Batista[1], José Henrique de Melo Feitosa[1], Pedro Henrique Ximenes Ramalho Barros[1], Kelson James Almeida[1]

[1]Universidade Federal do Piauí, Teresina PI, Brazil.

Correspondence: Luma Rodrigues da Silva; Email: lumarodrigues@ufpi.edu.br.

Background: Embolic strokes of undetermined source (ESUS) account for approximately 17% of ischemic stroke cases. They are often considered to be caused by occult cardiac embolism from atrial cardiopathy, even without atrial fibrillation (AF). Thus, certain predictors of AF may determine potential advantages of anticoagulation with new oral anticoagulants (NOACs) over antiplatelet therapy. **Objective:** To compare the efficacy of NOACs with antiplatelet agents in relation to clinical outcomes in patients with ESUS and predictors of AF. **Methods:** A search was conducted in PubMed, Embase, and Cochrane Library up to January 2024, including randomized controlled trials (RCTs) and observational studies involving patients with ESUS exhibiting any predictor of AF. The study compared groups treated with anticoagulation versus antiplatelet therapy with aspirin, emphasizing the outcomes of stroke recurrence, major hemorrhagic events, and mortality. Statistical analysis was performed using R Studio 4.3.2 software. Heterogeneity was assessed using the I^2 method. **Results:** Three RCTs and one observational study were included, totaling 8,557 patients. Stroke recurrence showed a tendency to favor NOACs (RR=0.90; 95% CI 0.72 - 1.11, I^2=0%, p=0.32), although without statistical significance. No significant differences in major hemorrhagic events were observed between the groups (RR=1.02; 95% CI 0.33 - 3.14, I^2=0%, p=0.98), nor was there any disparity in mortality (RR=1.02; 95% CI 0.33 - 3.14, I^2=0%, p=0.54). **Conclusion:** Comparing NOACs with antiplatelet agents, NOACs did not demonstrate significant clinical superiority in patients with ESUS and predictors of AF.

Nonconvulsive status epilepticus mimicking acute cerebrovascular syndrome: a case report

Ana Paula de Góes Louly Bustamante[1], Rodrigo Fernandes Cury[1], Regina Maria França Fernandes[1], Amanda Maieski[1], Caroline Darold Vieira[1], Gilberto Bento Magioni Junior[1], Lucas Fernando Chicheto Brancaglião[1], Luciano da Silva Pontes[1], Nadja Layane Gomes Santiago[1]

[1]Universidade de São Paulo, Faculdade de Medicina de Ribeirão Preto, Hospital das Clínicas, Ribeirão Preto SP, Brazil.

Correspondence: Ana Paula de Góes Louly Bustamante; Email: anapaulalouly@hotmail.com.

Case presentation: A.P.O.L., a 35-year-old female inpatient with chronic kidney disease, had cefepime recently introduced to treat a catheter-related bloodstream infection. One day before hemodialysis session, she suddenly presented with left hemiparesis, dysarthria and altered mental status. She was immediately submitted to a contrast-enhanced brain CT and CT angiography, neither of which showed signs of ischemia, hemorrhage or large vessel occlusion. Brain MRI was subsequently performed, and no areas of restricted diffusion were found. An electroencephalogram (EEG) was requested for differential diagnosis and it showed an asymmetric disorganized background with highly prevalent short bursts of lateralized intermittent rhythmic delta activity (LRDA) involving the left frontal region, lasting up to 10 seconds, with a frequency between 2.0 and 2.5 Hz, with superimposed sharp theta waves and no spatiotemporal evolution or time-locked clinical manifestations. Although not strictly falling into the ictal/interictal continuum (IIC) by definition (ref.), we hypothesized it was a case of possible nonconvulsive status epilepticus (NCSE). A therapeutic trial with 10mg/kg intravenous phenytoin was then carried-out, followed by significant clinical and electroencephalographic improvement, with complete recovery from previous neurologic deficits, suppression of the LRDA and appearance of a distinguishable posterior dominant rhythm. **Discussion:** In the context of impaired awareness with clinical/radiological dissociation, the presence of electroencephalographic rhythmic/periodic patterns (RPPs) with a frequency ≥0.5 Hz and up to 2.5 Hz could be considered as a possible NCSE/IIC. The criteria for IIC include: any periodic discharge or sharp wave >1.0 Hz and ≤2.5 Hz over 10 seconds; or any periodic discharge or sharp wave ≥0.5 Hz and ≤1.0 Hz over 10 seconds, with a "plus" modifier or fluctuation; or any LRDA >1.0 Hz over 10 seconds, with a "plus" modifier or fluctuation. Whether or not these criteria are strictly met, but clinical suspicion remains high, as was our case, a trial with intravenous anti-seizure medication (ASM) could be considered. Most cases of NCSE present with impairment of consciousness, and when motor symptoms are present, they are usually positive, such as subtle myoclonus or nystagmus. The hallmark of this case, however, were focal negative symptoms, including hemiparesis, resembling an acute stroke syndrome. **Final comments:** The main objective of this report is to alert clinicians for epilepsy-related etiology within the differential diagnosis of sudden onset neurologic deficits. This should be specially considered when the patient presents with altered mental status in the context of clinical/radiological dissociation. In some selected cases, even when EEG criteria for possible NCSE are not strictly met, a therapeutic trial with ASMs could be considered, depending on clinical suspicion.

Non-epileptic seizures in vertebrobasilar occlusion: a case report

José Eduardo Trentim Longo[1], Ana Flávia Andrade Lemos[1], Gabriel Pinheiro Modolo[1], Rodrigo Bazan[1], Daniel Fabiano Barbosa Santos[1], Pedro Machry Pozzobon[1], Ana Beatriz Marangoni Baston[1]

[1]Universidade Estadual Paulista, Faculdade de Medicina de Botucatu, Botucatu SP, Brazil.

Correspondence: José Eduardo Trentim Longo; Email: jose.longo@unesp.br.

Case presentation: An 81-year-old female patient presented with sphincter release, decreased level of consciousness, left homonymous hemianopsia, and dysmetria, with symptoms persisting for over 24 hours. Brain CT and neck and brain angiography showed hypodensity in the right cerebellum and occipital lobe, and occlusion of the right distal vertebral artery. While in the stroke unit, the patient showed improvement in deficits but then experienced decreased level of consciousness and inexhaustible multidirectional nystagmus. Subsequent imaging showed improved flow in the vertebral artery. The patient maintained only hemianopsia but developed stereotyped limb movements. Repeated imaging identified artery patency. Etiological investigation revealed no epileptiform disturbances on EEG, and brain MRI demonstrated dissection and intramural hematoma in the vertebral artery with preserved flow in the 3D "time-of- flight" technique. Considering the sequence of events and the absence of epilepsy history, we hypothesize that brainstem hypoperfusion related to vertebrobasilar occlusion led to non-epileptic seizures. The interruption of inhibitory projections from the cortex to the medulla or brainstem is one proposed mechanism. Dual antiplatelet therapy was initiated as prophylaxis. **Discussion:** Vertebrobasilar occlusion can present in a manner indistinguishable from an epileptic seizure. If this indeed represents a true seizure, the mechanism may be related to ischemia of the occipital cortex or activation of subcortical epilepsy

generators, necessitating further studies on the pathophysiology. Atypical epilepsy presentations, such as basilar occlusion, represent a potentially fatal condition that can be treated if diagnosed in time. **Final comments:** This case highlights the diagnostic challenges and significant morbidity associated with posterior circulation ischemic strokes. The heterogeneity of signs and symptoms, such as decreased consciousness, cranial nerve abnormalities, tetraplegia, and locked-in syndrome, complicates the diagnosis and contributes to high morbidity and mortality rates. Understanding the nuances and mechanisms of atypical presentations, such as non-epileptic seizures due to vertebrobasilar occlusion, is crucial for timely and effective management.

Non-motor and extracerebellar features in spinocerebellar ataxia type 6

Breno Kazuo Massuyama[1], Marcondes Cavalcante França Junior[2], Orlando Graziani Povoas Barsottini[1], José Luiz Pedroso[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.
[2]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Breno Kazuo Massuyama; Email: breno.massuyama@gmail.com.

Background: Spinocerebellar ataxia type 6 (SCA6) is an autosomal dominant degenerative disease. SCA6 is described as the prototype of pure cerebellar ataxia. However, the calcium receptor subunit affected in SCA6 appears to be ubiquitous in neurons throughout the brain. **Objective:** To access the non-motor symptoms and extra-cerebellar signs of SCA6 patients. **Methods:** Eighteen clinically and molecularly proven SCA6 patients agreed to participate in this study. Our Institutional Ethics Committee approved this study. All patients provided written informed consent. To evaluate ataxia severity, patients were evaluated by the "Scale for the Assessment and Rate of Ataxia" (SARA) and "International Cooperative Ataxia Rating Scale". For evaluation of non-motor and extracerebellar features severity, we applied "Inventory of Non-ataxia symptoms" (INAS), REM Sleep Behavior Screening Questionnaire (RBDSQ), Epworth Sleepiness Scale (ESS), and Fatigue Severity Scale (FSS). INAS Count is a semiquantitative variable of extracerebellar involvement in SCA. RBDSQ is an n-point scale where values greater than five or more questions indicate RBD. ESS is an n-point scale where a cut-off of ten or greater was set for the diagnosis of excessive daytime sleepiness (EDS). FSS is an n-point scale where values greater than twenty-eight are indicators of the presence of fatigue. We performed Spearman's correlation test to calculate the strength of association between CAG repeat length ((CAG)n) and each of the following variables: SARA, ICARS, INAS Count, FSS, RBDSQ, and age at onset of symptoms (AOO). **Results:** Regarding the clinical characteristics of the patients with SCA6, disease duration in years (mean=13; SD=7.33), AOO (mean=53.33; SD=9.14), SARA (mean=13.30; SD=6.71), ICARS (mean=37; SD=17.13), INAS Count (mean=1.77; SD=1.06), FSS (mean-33.52; SD=13.23), RBDSQ (mean=4; SD=1.96), and ESS (mean=5.94; SD=4.00). Restless legs syndrome (RLS) was present in 28.57% (N= 4 out of 14), RBD was present in 23.52% (N= 4 out 17), and EDS was present in 23.52% (N= 4 out of 17). Fatigue was present in 64.70% (N= 11 out of 17). The (CAG)n at the expanded allele was strongly correlated with RBDSQ (cc:-0.609; p=0.046). In addition, (CAG)n was correlated with SARA (cc:0.300; p=0.342), ICARS (cc:0.325; p=0.301), INAS Count (cc:0.267; p=0.401), FSS (cc:-0.386; p=0.240) and AOO (cc:-0.226; p=0.479). We observed a high frequency of non-motor symptoms and other motor manifestation in SCA6 patients beyond cerebellar signs. SCA6 may represent a more widespread condition, affecting other regions of the nervous system besides the cerebellum and spinocerebellar pathways. RBD, RLS and EDS have been reported in SCA2 and SCA3. Considering that we observed comparable results in SCA6, it is feasible that similar pathophysiological mechanisms may also occur in SCA6. **Conclusion:** Our results support the possibility of revising the concept of SCA6 be a pure cerebellar disease.

Non-motor epileptic seizures versus panic attacks: a diagnostic dilemma

Heron Alves Vale[1], Rraissa Josefa Pereira de Moura[1], Ana Caroline Paiva Simeao[1], Nereu Alves Lacerda[1], Ana Carolina Martins Fragoso Carneiro[1], Maria Luisa Roberto Lima Lisboa[1], Natália Nunes Tenório[1], Ana Beatriz Roberto Lima Borba[1], Laura Alícia Morais Lima Oliveira[2], Moema Peisino Pereira[1]

[1]Hospital Pelópidas Silveira, Recife PE, Brazil.
[2]Hospital Universitário Onofre Lopes, Natal RN, Brazil.

Correspondence: Heron Alves Vale; Email: heron_vale@hotmail.com.

Case presentation: A 69-year-old male patient with a prior diagnosis of major depressive disorder was admitted to the neurology emergency department, referred from psychiatry due to reports of transient perceptual behavioral crisis lasting less than 5 minutes over the past 6 months. Phenomenologically, he described these episodes as sudden sensations of "anguish" in the epigastric region, "cold/hot" sensations on his back, and a feeling of "imminent death", associated with sweating, tachycardia, and perioral and extremity tremors. These events progressed in intensity and frequency over three months, occurring up to four times a day. He experienced postictal amnesia and occasionally woke up at night with these symptoms. Concurrently, he demonstrated worsening of his pre-existing depressive symptoms, characterized by, anhedonia, frequent crying, avoidance behavior, and catastrophic thoughts. He sought help from several psychiatrists who considered these manifestations as psychiatric disorders, but treatment, including alprazolam 3mg/day, paroxetine 12.5mg, mirtazapine 45mg, clobazam 10mg, and aripiprazole 10mg, without improvement. On examination, he appeared generally well, conscious, oriented to person, place, and time, with a tearful facial expression consistent with his depressed mood. He had fluent speech, intact comprehension, repetition, and naming abilities. There were no motor or sensory deficits. Brain MRI showed only mild hippocampal rotation, and EEG revealed disorganized baseline activity. Further diagnostic evaluation included a SPECT scan to identify a possible epileptogenic functional lesion, although this had not yet been performed. Nevertheless, given the clinical context, a therapeutic trial with an anti-seizure medication (ASM), valproic acid, was initiated. The patient showed significant improvement with no seizures for weeks at present. **Discussion:** Epileptic seizures are characterized by transient signs and symptoms resulting from excessive and synchronous neuronal activity, with manifestations varying depending on the distribution of the discharges. Seizures originating in the temporal lobe typically present with focal onset and may manifest as sensory, autonomic, emotional, or purely subjective psychic phenomena such as nausea, malaise, fear, depression, anguish, déjà vu, jamais vu, forced thinking, gustatory, olfactory, auditory, somatosensory, and visual hallucinations. These seizure phenomenologies are commonly observed in adults with mesial temporal sclerosis (MTS), characterized by neuronal loss and gliosis primarily involving the hippocampus and amygdala. **Final comments:** Epileptic seizures can manifest in diverse and variable forms, ranging from typical motor presentations like tonic-clonic seizures to non-motor autonomic, sensory, emotional, or cognitive forms. Therefore, a thorough differential diagnosis with psychiatric disorders is essential.

Non-myasthenic fluctuating muscle weakness

Ana Luísa Magalhães de Oliveira[1], Amanda Isabella de Souza[1], Gabriela Carneiro Neves de Carvalho[1], Sofia Silva Olsthoorn[1], Camilla Mannarino Calil[1], Danilo Jorge da Silva[1], Marcelo Maroco Cruzeiro[1]

[1]Universidade Federal de Juiz de Fora, Juiz de Fora MG, Brazil.

Correspondence: Ana Luísa Magalhães de Oliveira; Email: analuisa.magalhaes@estudante.ufjf.br.

Case presentation: A 26-year-old woman with non-consanguineous parents began to experience fatigue and intermittent muscle weakness in her lower limbs (difficulty climbing stairs and standing up), weakness in her cervical region, and weakness in abducting her upper limbs at the age of 15. The weakness intensifies mainly after periods of food abuse, with the ingestion of fatty foods or foods containing milk. There was a progressive decline over 4 months, with a loss of 20 kg in 10 months, diarrhea (4 to 5 times a day), fatigue, dyspnea on medium exertion, pain in the right hypochondrium, progressive weakness, intense myalgia, postprandial fullness, and nausea relieved by vomiting. Grade 4 muscle strength was noted globally, with proximal predominance and global hyporeflexia, except for bilateral Achilles reflex arreflexia. Her brother died of fatty liver metaplasia with the same symptoms. The patient underwent a molecular study, identifying a pathogenic variant of the ETFDH gene. **Discussion:** Glutaric acidurias are part of organic acidurias and may be due to a deficiency of an enzyme in the mitochondria called glutaryl-CoA dehydrogenase (GCDH) (type I); a deficiency of one of the three molecules involved in electron transport in the mitochondria and in the metabolism of acetyl-CoA and glutaric acid: the alpha (ETFA gene) and beta (ETFB gene) subunits of electron transfer flavoprotein and electron transfer flavoprotein dehydrogenase (ETFDH gene) (type II); or glutaryl-CoA oxidase deficiency (type III). The patient has glutaric aciduria type II, also known as multiple acetyl-CoA Dehydrogenase Deficiency (MADD). This inheritance is autosomal recessive, causing impaired riboflavin transport. The genes involved are ETFDH, ETFA, and ETFB. The mutation in the ETFDH gene usually occurs in the late-onset form of the disease and has a myopathic phenotype, rarely causing metabolic acidosis. The most common clinical manifestations are muscle weakness, liver disease, and respiratory disorders. Family history and symptoms are characteristic. It is noteworthy that it occurs more often in men. Early diagnosis can reduce morbidity and mortality by reducing the risk of cardiovascular disease and hepatic steatosis. Treatment includes a low-protein, fatty acid-restricted, high-carbohydrate diet. Meals should be frequent, prolonged fasting should be avoided (this would activate mitochondrial ß-oxidation of fatty acids to obtain energy), and Riboflavin should be administered. **Final comments:** MADD causes impaired mitochondrial metabolism associated with the oxidation of fatty acids of autosomal recessive inheritance, whose diagnosis should be considered in the presence of breathing difficulties, liver problems, kidney and/or heart problems, hypoglycemia, and weakness. Early identification followed by treatment can potentially reduce morbidity and mortality.

Non-oclusive mesenteric ischemia during the management of subarachnoid hemorrhage: case report

Márcio Assis Messias Filho[1] , Ana Flávia Amitti Alvarez[2], Nícolas de Sousa Belonato Terra[2], Raysa Fontes Martins[2], Georgia Piredda Fernandes[2]

[1]Hospital São José do Avaí, Itaperuna RJ, Brazil.
[2]Universidade Iguaçu, Itaperuna RJ, Brazil.

Correspondence: Raysa Fontes Martins; Email: 190062471@aluno.unig.edu.br.

Case presentation: A 32-year-old male patient, with moderate intellectual disability, was admitted to the emergency department in a comatose state for approximately 20 minutes (Hunt-Hess V), with third-party reports of severe headache for 3 days. Non-contrast computed tomography of the skull performed on admission showed hyperdense collections in brain grooves and cisterns, characterizing Subarachnoid Hemorrhage (Fisher IV). After diagnosis, the patient was treated according to SAH management protocols. Cerebral arteriography was performed showing the presence of saccular aneurysmal formation in the topography of the anterior communicating artery, and the aneurysm was embolized. Seven days after the ictus, there was a worsening of the hemodynamic state and shock, accompanied by abdominal distension and gastrointestinal tract failure demonstrated by an increase in gastric residue. Abdominal computed tomography was performed showing the dilated small intestine, with signs of intestinal pneumatosis, intestinal dilation, portal venous gas and aerobilia. Abdominal CT angiography was performed, showing the superior mesenteric artery with preserved caliber, contours and flows, without signs of thrombus that would justify occlusion. The diagnosis of Non-Occlusive Mesenteric Ischemia (NOMI) is then concluded. Over the next few days of hospitalization, the patient continued to show increasing clinical and radiological severity, associated with severe acidosis, shock refractory to treatment with vasoactive amines and volume replacement. He died on the 7th day of hospitalization. **Discussion:** Non-Occlusive Mesenteric Ischemia is associated with vasoconstriction of the mesenteric arteries, without evident occlusion, which causes intestinal hypoperfusion. NOMI as a complication of SAH is secondary to vasospasm, which generally occurs 3 to 14 days after aneurysm rupture. NOMI does not present characteristic symptoms, therefore the diagnosis usually occurs during the progression to a severe stage of the disease, the disease is associated with high mortality rates. The correlation of the diseases in question are barely described in the literature due to the rarity in which they present themselves, however, it has been concluded in previous research that one of the main preponderant factors for their prognostic establishment is how late their diagnostic finding and subsequent installation occur. therapy, with the speed of its execution being essential to minimize the deleterious effects of the disease. **Final comments:** Therefore, it is described how important the need for timely diagnosis of Non-occlusive Mesenteric Ischemia as a complication resulting from Subarachnoid Hemorrhage, not only for Neurosurgeons, but also for Intensive Care physicians, aiming for its identification and subsequent management quickly and effectively, expanding the patient's chances of recovery, as this complication is defined as atypical in current medical-scientific circles.

Not all dropped heads are Parkinson's disease: an atypical manifestation of myasthenia gravis

Paulo Ricardo Sampaio de Melo[1], Brenda Francisca Cardoso Brito[1], Adriana Alves Rapp[1], Julia Cordeiro Braga[1], Camila Maria Barreto Ribeiro[1], Victor Xavier da Silva[1], Lucas Vergne Cheade Lins[1], Marcel Leal Ribeiro[1]

[1]Hospital Santa Izabel, Salvador BA, Brazil.

Correspondence: Brenda Francisca Cardoso Brito; Email: brendaf.cardosob@gmail.com.

Case presentation: Female, 78 years old, from Salvador, Bahia; Medical history: Parkinson disease with 8 years from the diagnosis, using the initial dose of levodopa/benserazide. Relatives described that, 15 days before the admission, the patient presented with a suddenly dropped head, nonspecific generalized discomfort and weakness leading to the inability to walk. At the admission, the patient presented dyspnea and worsening of the malaise, then submitted for orotracheal intubation due to respiratory insufficiency. In the following days, the patient proceeds with failure on the extubation process. Physical examination: cervical, proximal superior and inferior limbs flaccid muscular weakness, however with hyperreflexia, and cervical rigidity. Investigation: Electroneuromyography revealed neuromuscular junction dysfunction in proximal superior limb muscles and bulbar region with decremental pattern. Nonspecific rheumatologic tests, antinuclear antibody (ANA), perinuclear autoantibody (p-ANCA), and thyrotropin receptor antibody (TRAb), were positive. The antibody anti acetylcholine receptor is under analysis until the submission of this report. Diagnosis: probable myasthenia gravis. Treatment: intravenous immunoglobulin for five days, glucocorticoids, and pyridostigmine. Outcome: the patient experienced gradual and significant improvement in muscle strength and was removed from mechanical ventilation after the treatment. **Discussion:** Myasthenia gravis is an antibody mediated autoimmune disease that targets proteins of the postsynaptic membrane of the neuromuscular junction. The diagnosis is challenging, mainly in atypical cases. It is an uncommon condition that occurs in the early second and third decades in females, and in the sixth to eight decades in males. The typical clinical manifestations are ocular with ptosis and diplopia (50%), bulbar with dysarthria dysphagia, and expressionless appearance (15%), proximal limb weakness (<5%), isolated neck (uncommon), isolated respiratory (rare), and distal limb weakness (rare), usually followed by areflexia. Several steps can be performed in order to confirm this condition such as clinical (ice pack and pharmacological testing), serologic (acetylcholine receptor, MuSK, and LRP4 antibodies), and electrophysiologic testing. However, in most scenarios in Brazil, the standard tests are not covered by the public health or insurance services, so the patient must pay individually. These tests are very expensive, which can hamper the diagnosis. Different reports suggest an association of myasthenia gravis and neuromyelitis optica, autoimmune thyroid disease, systemic lupus erythematosus, and rheumatoid arthritis. **Final comments:** Efforts should be applied to disseminate knowledge about the prevalence, epidemiology, and clinical manifestations of myasthenia gravis and to enable the most important tests on the diagnosis, such as electroneuromyography and the autoantibodies involved in the disease.

Correspondence: Guilherme Carvalho de Souza; Email: guicadesouza@gmail.com.

Case presentation: As part of a larger project investigating neurodevelopmental disorders in highly inbred regions of Northeastern Brazil, we evaluated four individuals from the same family (two siblings and their cousins), aged between 11 and 20 years, that presented early onset neuropsychomotor development delay, characterized by progressive spasticity, predominantly in the lower limbs, and lower limb muscle weakness. In addition, they had intellectual disability and speech impairment. We performed the genetic investigation, and the Whole Exome Sequencing (WES) showed a mutation with autosomal recessive inheritance in exon 8 of the ERLIN2 gene: c.47_48delinsAA, identified as the potentially deleterious variant, which was selected for segregation analysis through Sanger Sequencing involving both the affected and unaffected family members. A previously unreported homozygous variant in the ERLIN2 gene, associated with hereditary spastic paraplegia type 18 (SPG18), was identified in all four patients. Furthermore, all patients were diagnosed with childhood cataract, a condition that was not found in any other family member. **Discussion:** Hereditary spastic paraplegias (SPGs) are a group of neurodegenerative diseases with heterogeneous clinical manifestations and genetic etiologies. Mutations in ERLIN2 gene have been associated with SPG18, and its symptoms include contractures, progressive global muscle weakness, muscle atrophy, delayed walking, abnormal gait, spasticity, extensor plantar responses, hyperreflexia, speech impairment, intellectual disability, seizures, scoliosis and kyphosis. To date, all of these patients with different types of SPG18 were from Asia and Europe, and none of them from the American continent. Additionally, childhood cataract were not reported in any other SPG18 patients described in the literature before this study. Here, we present two affected siblings and their two cousins with a novel variant in the ERLIN2 gene. It's important to notice that the children's fathers are brothers and their mothers are cousins to each other, all from an isolated region in the Brazilian northeast. Once the same homozygous variant was found in all four patients, it possibly suggests that they share a common ancestor. Also, all patients displayed childhood cataract, expanding the known clinical spectrum of SPG18. **Final comments:** This research marks the first documented case of SPG18 in the Americas, and the findings highlight a consistent presentation of the complicated form of Hereditary Spastic Paraplegia (HSP) and a notable association with childhood cataracts, suggesting a phenotypic expansion of SPG18. Importantly, it introduces a novel variant in the ERLIN2 gene, contributing to our evolving understanding of the genetic factors underlying SPG18. The approach of combining field investigation in highly inbred regions of Brazil, where clusters of genetic disorders are sought, with advanced molecular techniques has proven to be successful.

Novel homozygous mutation on TRIM32 gene causing autosomal recessive limb-girdle muscular dystrophy 8 (LGMDR8): a case report

Enzo Stinghel Pellacani[1], Alzira Alves de Siqueira Carvalho[1], Ana Marina Dutra Ferreira da Silva Pontes[1], Igor Dias Brockhausen[1], Alessandra Lima Nogueira Tolentino[1], Natalia Merten Athayde[1], Mariah Gomes de Lima[1], Danilo Marinho Pereira[1], Isaías Mendes da Silva Júnior[1]

[1]Faculdade de Medicina do ABC, Santo André SP, Brazil.

Correspondence: Enzo Stinghel Pellacani; Email:

Case presentation: A 50-year-old Brazilian male presents at the neurology department with progressive muscular weakness primarily noticed at 15 years old, when he first

experienced difficulties with running, gradually worsening over time. By 42, he struggled with climbing stairs, initially relying on unilateral support and later evolving to bilateral support. The patient had a medical history of consanguinity (parents were cousins). He had four siblings: two deceased in childhood of unknown causes and two alive and healthy. Neurological examination revealed shoulder girdle muscle atrophy, a waddling gait, symmetrical lower extremities weakness that was worse for hip flexion, hip abduction, hip extension, and knee flexion. The deep tendon reflexes were normal. Laboratory tests showed elevated CPK levels (970U/L; Normal Value: <170U/L). Myography showed a myopathic pattern. Lower limbs MRI revealed fatty infiltration and diffuse atrophy of both thighs and legs, especially afflicting the posterior leg muscles. The echocardiogram was unremarkable, and pulmonary function testing revealed a restrictive pattern. The muscle biopsy revealed a primary dystrophic muscular disorder with protein clusters and cytoplasmic vacuolization. A genetic myopathy panel was performed, identifying a homozygous nonsense variant c.1885C>T (p.Gln629*) in the TRIM32 gene, coding a premature stop codon, leading to a shortened transcript. This variant is currently categorized as of uncertain significance due to the lack of reported data on its clinical impact. Based on clinical and laboratory characteristics, we established the diagnosis of LGMDR8. **Discussion:** TRIM32 acts as an E3 ubiquitin ligase in the ubiquitin-proteasome system and plays multifunctional roles in maintaining skeletal muscle. Pathological homozygotic variants in the TRIM32 gene are known to be associated with protein aggregates and vacuolization in skeletal muscle biopsy. When associated with symptoms of slow progressive limb-girdle weakness (predominantly the posterior compartments of lower limbs), such findings lead to the diagnosis of LGMDR8. To our knowledge, it is the first time this variant is described in association with a phenotypical pattern of LGMDR8. **Final comments:** This report aims to apprise a novel variant associated with LGMDR8. The association between homozigotic variant c.1885C>T (p.Gln629*) in the TRIM32 gene and the muscle biopsy findings safely point toward this diagnosis. Such a variant has not yet been described in the current databases and should be considered as potentially pathogenic.

[3]Hospital Mãe de Deus, Porto Alegre RS, Brazil.

Correspondence: Rhaná Carolina Santos; Email: santoscrhana@gmail.com.

Case presentation: 24 years old female patient, previously healthy. Family members report falls and motor difficulties since the age of 6, worsening in adulthood; no cognitive decline. She denies any family history of similar cases or parental consanguinity. Neurological examination revealed dysarthria, ataxia, and spasticity of all four limbs. No signs of parkinsonism or chorea were detected. MRI showed cerebellar atrophy and iron accumulation in the globus pallidus and substantia nigra. Complete blood count, renal function, electrolytes, liver function tests, serum copper, ceruloplasmin, urinary copper and ferritin were unaltered. Ophthalmologic assessment excluded Kayser-Fleisher rings. Genetic evaluation was carried out through germline exome analysis, identifying two variants in the PLA2G6 gene: c.2032A>G p.(Lys678Glu) and c.1525A>G p.(Lys509Glu), both of undetermined clinical significance. The first has been previously described and the second is absent in the available databases. Based on clinical manifestations, imaging findings and genetic results, PLA2G6-associated neurodegeneration was diagnosed. **Discussion:** PLA2G6-associated neurodegeneration is an autosomal recessive disorder with various phenotypes and distinct clinical features: Infantile Neuroaxonal Dystrophy (INAD), Neuroaxonal Dystrophy (NAD) and PLA2G6-related Dystonia-Parkinsonism. INAD begins between six months and three years of age, characterized by psychomotor delay, hypotonia and progressive spastic tetraparesis, with rapid evolution and high mortality. NAD presents greater phenotypic variability, including gait instability, ataxia or speech delay, as well as neuropsychiatric disorders such as impulsivity, inattention, hyperactivity and emotional lability, which can be stable or progress to encephalopathy. PLA2G6-related Dystonia-Parkinsonism manifests in adulthood with gait disturbances, dystonia, and parkinsonism, possibly accompanied by rapid cognitive decline. There is extensive documentation of phenotypes and genotypes related to PLA2G6, especially in its adult manifestation. The patient's condition suggests an intermediate phenotype, with imaging findings highly suggestive of neurodegeneration with iron accumulation in the globus pallidus and substantia nigra. Exome sequencing confirmed two variants of uncertain significance in the PLA2G6 gene. Segregation study in the parents identified that the two variants are in trans, one on each allele of the PLA2G6 gene, consistent with autosomal recessive inheritance. Possibly, different variants and their combinations are responsible for the wide range of phenotypes associated with PLA2G6-related neurodegeneration. **Final comments:** The case presented is notable as it demonstrates the atypical progression of a rare case with novel germline variants of the PLA2G6 gene.

Background: Cerebral Vascular Accident (CVA) is the main cause of death in adults in Brasil. This neurological syndrome is characterized by the sudden obstruction of the blood flow to the brain, and it is categorized into two types: ischemic stroke and hemorrhagic stroke. Around 40 to 50% of stroke victims die after 6 months, and it is estimated that around 70% of patients that survive don't completely recover, making it a highly disabling illness. **Objective:** To analyze the deaths by CVA in the state of São Paulo, between the years of 2019 to 2023, and comparing them with the timeline from 2014 to 2018. **Methods:** Ecological, retrospective and descriptive study using data from the Hospital Information System (SIH/SUS) through the platform Department of Informatics of the Unified Healthy System (DATASUS). It analyzed the number of deaths in São Paulo between the ages of 20 to 29 years old, comparing 2014 to 2018 with the years of 2019 to 2023. It excluded remaining filters that were not previously mentioned. **Results:** After reviewing data from 2014 to 2018, the number of deaths by CVA between the ages of 20 to 29 years old in the state of São Paulo was 88 in total, being 2016 the highest, with 55 deaths. When analyzing the years of 2019 to 2023, it was noted an increase in deaths, with a total of 124 deaths, of which 31 happened only in 2022. This increase in deaths by CVA in a young population can be related to the increased exposure to risk factors like smoking, emotional conditions, stress, obesity, a sedentary lifestyle and diabetes. **Conclusion:** There was an alarming increase of almost 50% in deaths when comparing both timelines. Following the results, it is important to raise awareness among young adults between the ages of 20 and 29 about the risk factors of Cerebral Vascular Accident and how to cultivate healthy habits such as avoiding alcohol, eating healthier and exercising.

Correspondence: Tiago César Costa da Silva; Email: tiagocesarcs@hotmail.com.

Background: Stroke is the second cause of mortality in the general population, and its incidence tends to increase because of population aging. The blood vessel territory most affected in the stroke is the middle cerebral artery (MCA). A frequent complication of stroke in the right MCA territory is the hemispatial neglect (HN), which can be defined as a disorder characterized by an unconscious attention deficit expressed in the patient's behaviors in relation to the space contralateral to the lesions. The most common presentation is unilateral neglect, related to lesions in the right cerebral hemisphere with deficits in spatial perception on the left. HN correlates with poor prognosis, longer hospitalization and greater acute-phase complications. From clinical practice, some patients who suffered a stroke tend to lie in an oblique decubitus (OD) in the stretcher (diagonal position on the stretcher). **Objective:** Herein, we attempt to relate OD in the stretcher with HN. **Methods:** We performed a clinical prospective cohort study. The sample consisted of 17 individuals and the participants were recruited from the Dom José Maria Pires Hospital Metropolitano, in Paraíba, Brazil. The sample was divided into two groups: case (12) and control (5). The instruments used for data analysis were Star Cancellation Task (SCT), Bcos Apples Cancellation Task (BACT) and Catherine Bergego Scale (CBS) itens 2,5,6,7,9,10 and a Sociodemographic Questionnaire was used to identify the patient's profile. **Results:** 17 individuals were included in the study. Out of 17, 10 (59%) were female, 70% had a right MCA stroke. The average age was 54.8. All participants were right-handed and in the acute phase of the stroke; 29% were in OD; 23% drink; 35.2% smoke; 58% have high blood pressure; 23% have diabetes. The mean NIHSS score was 7; 23% had HN on physical examination and 41% had HN on SCT, of which 28% were in OD. In the BACT 58% presented HN, with 20% in OD. On CBS, 29% presented HN, with 60% found in OD. A correlation was found between right MCA stroke and SCT (p value 0.02) and a positive correlation between CBS items and SCT (p value 0.01). There was no correlation between the other variables. **Conclusion:** Data analysis showed no correlation between OD and HN. However, there was a good result between CBS and SCT, indicating a good choice for testing HN in the acute phase of stroke. Due to the low sample number, further study is needed in the future. This information contributes to neurological semiology when seeking to confirm OD related to HN in patients presented with acute stroke considering that this type of information does not exist in the current literature.

Obstruction of the fourth ventricle decompensated by anabolic steroid use: a case report

Brenno Tavares de Vasconcelos Brandao[1], Ana Carolina Leite[1], Barbara Pina Aiello[1], Marcos Martins da Silva[1]

[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Brenno Tavares de Vasconcelos Brandao; Email: btvbrandao@gmail.com.

A young male, 24 years old, seeks emergency care with a two-week history of progressively worsening headache, associated with visual blurring and photophobia, which worsens when lying down. He was diagnosed with intracranial hypertension. At 10 months old, he had hydrocephalus and required a ventriculoperitoneal shunt (VPS), but he does not know the cause. He had no complaints during childhood or adolescence after the procedure. He reports using thyroid hormone, vasodilator, veterinary beta agonist, and anabolic steroids (both intramuscular and oral) for aesthetic purposes for six months, stopped after the onset of symptoms. During the investigation of intracranial hypertension, fundoscopy showed no abnormalities, but cranial MRI revealed disproportionate tetraventricular hydrocephalus, with the third and fourth ventricles larger than the lateral ventricles. The VPS catheter was in a normal position. Lumbar puncture demonstrated elevated opening pressure (30 cmH20), protein of 129 mg/dL, leukocytes of 8/mm3 (lymphomononuclear), and glucose of 50 mg/dL. There was partial symptom relief after cerebrospinal fluid removal. Treatment with a carbonic anhydrase inhibitor was started but had an unsatisfactory clinical response and caused gastric intolerance, leading to surgical intervention. An endoscopic third ventriculostomy was performed, with postoperative symptom improvement and reduction in the size of the third and fourth ventricles on follow-up imaging. Hydrocephalus can be obstructive or communicating. The obstructive form occurs due to obstructions of the foramen of Monro or the aqueduct of Sylvius. Obstructions of the fourth ventricle outlet, at the foramina of Magendie and Luschka (FVOO), are rare and generally secondary to infections, hemorrhages, or congenital malformations. FVOO is associated with disorders such as Dandy-Walker and Arnold-Chiari malformations in childhood. Other causes include trauma, intracranial hemorrhages, and infections like meningitis or arachnoiditis. However, presentation in adults is rarely described. Obstruction usually manifests in childhood, as in the case of this patient, who remained asymptomatic after VPS insertion. However, there was an acute decompensation of the cerebrospinal fluid drainage system, likely secondary to systemic changes related to anabolic steroid use, with the onset of typical FVOO symptoms such as headache, nausea, and vomiting. Therefore, in cases of hydrocephalus, it is essential to perform imaging evaluation focusing on the foramina of Luschka and Magendie to check for obstructions. This allows for the most appropriate therapeutic proposal, yielding good results in these cases, such as endoscopic third ventriculostomy.

Correspondence: Millene Rodrigues Camilo; Email: millene.camilo@gmail.com.

Background: Obstructive sleep apnea (OSA) is present in more than 70% of stroke patients and has been associated with worse short- and long-term outcomes. Therefore, studies that evaluate the benefit of early OSA treatment in this context are essential. The treatment of choice for OSA is the use of CPAP (continuous positive airway pressure). Previous results regarding the feasibility and safety of using CPAP in post-stroke patients are encouraging. However, efficacy studies are scarce and controversial. Evidence of the benefit of treating OSA in patients with acute stroke will drastically change daily clinical practice. Primary **Objective:** To assess whether early OSA treatment with CPAP in patients with ischemic stroke has a favorable effect on functional recovery. Secondary Objectives - to evaluate whether the use of CPAP will be associated with (1) lower rate of early neurological deterioration; (2) smaller final volume of the cerebral infarction; (3) improvement in cognition and quality of life; (4) lower rate of depressive episodes; (5) reduction of excessive daytime sleepiness and sleep-related complaints; (6) lower serum levels of biomarkers of vascular endothelial injury; and (7) lower rate of recurrence of cardiovascular events and mortality. **Methods:** This is a prospective, multicenter, randomized study, blinded to outcomes (PROBE design), which will include 214 patients diagnosed with ischemic stroke and severe OSA, who will be randomized in a 1:1 ratio (CPAP+ vs. CPAP-). The study will be divided into two stages: (1) Acute Phase: up to 3 months after the ictus and (2) Chronic Phase: from 3 months to 2 years. A multidisciplinary team (nurses, psychologists, physiotherapists, and doctors) will monitor all patients during these stages. **Results:** At the end of this study, we are expected to contribute with answers to gaps in the literature. **Conclusion:** Once the expected benefit is demonstrated, a new perspective will be opened regarding treating OSA in post-stroke patients, enabling a change in daily clinical practice.

Occult neuroendocrine cancer presenting as Isaacs syndrome

Letícia da Silva Alves[1], Wender Rodrigues Teodoro[1], Matheus Cunha Nunes[1], Diogo Fernandes dos Santos[1], Iago Resende Carvalho[1]

[1]Universidade Federal de Uberlândia, Uberlândia MG, Brazil.

Correspondence: Letícia da Silva Alves; Email: draleticiasilvaalves@gmail.com.

Case presentation: A 61-year-old female patient, previously healthy, who presented with sudden onset muscle weakness and ambulation difficulty. Subsequently, she complained muscle cramps and slow relaxation worsened by voluntary muscle contraction. Symptoms progressively worsened, resulting in marked functional impairment and difficulty walking. She also reported distal sensory loss, intense fatigue, and exercise intolerance, in addition to intense sweating, weight loss, and muscle stiffness. On neurological examination, sustained involuntary muscle contractions were noted, with intense difficulty in relaxation. These included abnormal postures on the face, feet, and hands, with a predilection for the distal segments. The stiffness and difficulty in relaxation actually worsened with voluntary muscular activity, confirming the presence of pseudomyotonia. Strength and deep tendon reflexes were normal. An extensive laboratory evaluation was conducted, including metabolic, hormonal, serological, creatinine kinase levels, and inflammatory markers. She underwent electroneuromyography, which showed the presence of afterdischarges in the study of motor conduction and evaluation of F waves, in addition to the presence of high-frequency discharges, affecting the face, paravertebral region, and distal muscles of the limbs, with worsening after voluntary contraction, compatible with neuromyotonic discharges, confirming the diagnosis of a hyperexcitability syndrome. Brain magnetic resonance imaging and cerebrospinal fluid showed no abnormalities. Furthermore, given the possibility of a paraneoplastic condition, a neoplasm investigation was carried out, and a rectal polyp was found on a colonoscopy. Histopathological analysis was compatible with a well-differentiated neuroendocrine tumor. She was treated with Intravenous immunoglobulin (IVIg), presenting a significant improvement in her symptoms. **Discussion:** Isaacs syndrome has been reported in patients with malignancy, suggesting that tumor antigens trigger an autoimmune response and result in antibodies that cross-react with neuronal voltage-gated ion channels. This is consistent with the increased incidence of autoimmune neurological paraneoplastic disorders in patients with Isaacs syndrome. Several neoplasms have already been described in this association, including thymoma, lung cancer, Hodgkin lymphoma, plasmacytoma, lymphoblastic lymphoma, hemangioblastoma, ovarian and bladder cancer. **Final comments:** Our patient demonstrates that Isaacs' syndrome could be the initial and only neuromuscular manifestation of neuroendocrine cancer.

Occurrence of pelvic obliquity and scoliosis in 5q-spinal muscular atrophy

Graziela Jorge Polido[1], Eduardo Vital de Carvalho[1], Rodrigo de Holanda Mendonça[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Departamento de Neurologia, São Paulo SP, Brazil.

Correspondence: Eduardo Vital de Carvalho; Email: duvital1983@gmail.com.

Background: Spinal muscular atrophy linked to chromosome 5 (5q-SMA) is a progressive genetic disease caused by disease-causing variants in the survival motor neuron 1 (SMN1) gene. The modifying therapies have changed the natural history of 5q-SMA, but the scoliosis is still a problem and can present a rapid progression and cause important function impact. **Objective:** To show the frequency of pelvic obliquity in patients with 5q-SMA and occurrence of the scoliosis associated with pelvic obliquity. **Methods:** This retrospective observational study evaluated all patients who developed only pelvic obliquity, pelvic obliquity and scoliosis or only scoliosis. **Results:** 16 patients with 5q-SMA, type 3 (n=3), type 2 (n=6) and type 1 (n=7), were included. All of them were using any disease-modifying therapies. From the type 3 patients, one had pelvic obliquity and was walker. No one had scoliosis. From the six patients with type 2, all had pelvic obliquity, one had spinal surgery and three had unstructured scoliosis. In addition, two had therapeutic walking and one community walking. From the seven patients with type 1, all had pelvic obliquity and five had scoliosis. In addition, all sat without support and four were able to stand with support using upper limbs. **Conclusion:** The pelvic obliquity is an important signal preceding the development of scoliosis and it needs to be treated carefully to avoid the early onset of scoliosis.

Ocular amyloidosis: a rare differential diagnosis of orbital pseudotumor

Monique Evelyn Mendonça do Nascimento[1], Marcelo Ataíde de Lima[1], Mariana Holanda Gameleira[1], Edna Lúcia de Freitas Silva[1], Raiane Raianne Silva Lima[2], Ândrea Virgínia Ferreira Chaves[3], Vanessa de Souza Coutinho[1], Brenda Letícia Lopes Batista[1], Rosevaldo Alves Junior[1], Bárbara Borges de Oliveira[1]

[1]Hospital da Restauração, Recife PE, Brazil.

[2]Fundação Altino Ventura, Recife PE, Brazil.
[3]Hospital Agamenon Magalhães, Recife PE, Brazil.

Correspondence: Monique Evelyn Mendonça do Nascimento; Email: moniqueemnascimento@gmail.com.

Case presentation: A 57-year-old female patient presented with visual loss and proptosis in her right eye. Initial imaging revealed thickening of the extrinsic muscles of the right eye, and subsequent MRI confirmed this, showing thickening and enhancement in the superior rectus muscle and its tendon and insertion. Cerebral angiography ruled out arterial abnormalities. The patient received pulse therapy with methylprednisolone, resulting in partial improvement. Initial hypotheses of orbital pseudotumor, granulomatous diseases (IGG4 disease), and thyroid disease were considered but ultimately ruled out. The patient was discharged on corticosteroid therapy, but two weeks later, she returned with worsening symptoms despite the treatment. She did not experience pain. An ophthalmology re-evaluation was requested, and an ocular biopsy was carried out, with results compatible with ocular amyloidosis (apple-green birefringence to cone-red colouration). **Discussion:** Amyloidosis is a group of diseases caused by the deposition of insoluble fibrils composed of poorly aggregated proteins, which form insoluble protein aggregates. The clinical manifestations and sites affected vary depending on the clinical manifestations and sites. Ocular amyloidosis, or amyloidosis of the ocular appendages, is uncommon and may be related to both the systemic and localized forms of the disease. There is a predominance of females, with an average age of 55 years. In most cases, orbital involvement is asymptomatic and indolent. The differential diagnosis of amyloidosis should include idiopathic orbital pseudotumor, lymphoma, leukaemia, sarcoidosis, and other granulomatous. A biopsy with a finding of birefringence under polarized light after staining with Congo red is the gold standard for a diagnosis. Transthyretin amyloidosis, or ATTR, is one of the subtypes most associated with ocular involvement. Neuropathies, renal and cardiac dysfunction are included in the clinical picture, in addition to ophthalmopathy. The treatment of the ophthalmic manifestations of amyloidosis can be conservative with the use of tafamidis, radiotherapy, or a surgical approach. **Final comments:** Amyloidosis is a heterogeneous spectrum of disease that can affect the eye and the periocular region. The most prevalent ophthalmic manifestations of amyloidosis are proptosis, hyperaemia, and ophthalmoparesis. The gold standard for diagnosis includes optical microscopy after biopsy, with typical features. It is important to consider the disease within the differential diagnoses, as it can mimic many other pathologies. Following the diagnosis, the patient was monitored by the neurophthalmology department and scheduled for radiotherapy.

https://doi.org/10.5327/CBN241230

Ocular dipping in a severe traumatic brain injury patient after being buried: a case presentation

Yves Henrique Ramos Mansano[1], Pamella Francisquini Gardin[1], Rodrigo Pernomian Cianca[1], Ana Letícia Manso Assakawa[1], José Guilherme Pinhatti Carrasco[1], Isabela Kirach Gaio[1], Felipe Bento Michelato[1], Antônio Paulo Felice Rodrigues Leite[1], Antônio Marcos Reissureição Galindo[1], Gabriel Bortoli Ramos[1]

[1]Universidade Estadual de Maringá, Maringá PR, Brazil.
[2]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Yves Henrique Ramos Mansano; Email: ra124955@uem.br.

Case presentation: Male, 35 years old, victim of burial beneath a mudslide, was transported to the hospital via air ambulance in trauma protocol. At the time of admission, he had 4 points on the Glasgow Coma Scale and was being ventilated through Guedel and high-flow mask. The patient presented with periorbital ecchymosis, anisocoria and otorrhagia from the right ear. Head computed tomography revealed complex skull fracture, pneumocephalus and discrete intraparenchymal hemorrhagic foci, suggesting traumatic subarachnoid hemorrhage and severe diffuse axonal injury. Neurological examination demonstrated brainstem reflexes present, hyperreflexia in lower limbs and decerebrate posturing in response to painful stimuli. In addition, the patient presented an abnormal spontaneous vertical eye movement with slow phase down, followed by a quick return to the original position. **Discussion:** Ocular dipping consists in cyclical and spontaneous eye movements, which are characterized by a slow deviation of the gaze downward, followed by a delay at the lower extreme of the gaze and a quick return to the intermediate position. Most cases occur in the context of severe anoxic brain injury with associated diffuse cortical and lenticular pathology, but it has also been described in prolonged status epilepticus and Creutzfeldt-Jakob disease. Despite generally being present in severe cases, the movement is not a good prognostic marker, as there are reports in the literature of substantial recovery after an ocular dipping episode. It is assumed that a mechanism for ocular dipping involves dysfunction of cortical/lenticular connectivity - with the centers of vertical gaze located in the rostral portion of the brainstem - and ascending arousal system. The neurological examination is essential for the correct topographic diagnosis and request for complementary exams, especially because there are several ocular movement abnormalities that can be confused with dipping. Reverse ocular dipping is a variant that was described in the context of metabolic encephalopathy or encephalitis, which is characterized by a slow upward deviation with a fast descending phase to the primary position. Ocular bobbing involves quick eye movements downward and a slow return to the intermediate position, usually occurring in cases of pontine lesions. Moreover, dipping and bobbing are differentiated from vertical nystagmus by their irregularity, brief pause between phase changes, and facilitation by harmful stimuli. Prognosis for patients with ocular dipping is variable and, interestingly, a return of consciousness or the use of pentobarbital can abolish the movement. **Final comments:** Neurological examination in critical care patients is crucial for differential diagnosis of brain lesions. Ocular dipping is strongly associated with anoxic brain injuries in critical patients. However, the appearance of ocular dipping cannot be used as a prognostic marker in coma.

https://doi.org/10.5327/CBN241231

Oculomotor nerve paralysis by varicella zoster after dengue fever: case report

Iury Venâncio Pinheiro[1], José Elias Makaron Neto[1], Leonardo de Oliveira Moreno[1], Thire Baggio Machado Marazzi[1]

[1]Universidade de São Paulo, Faculdade de Medicina de Ribeirão Preto, Ribeirão Preto SP, Brazil.

Correspondence: Iury Venâncio Pinheiro; Email: iuryvenancio145@gmail.com.

Case presentation: A previously healthy 47-year-old woman reported myalgia, headache and fever with a diagnosis of dengue confirmed by positive serum NS1. After 5 days, she presented with a new complaint of horizontal diplopia on the lateralization of the gaze to the left, in addition to eyelid ptosis and pain in eye movement. Left eye asymptomatic. On physical examination, she had right eyelid ptosis, mydriatic and bradiareactive right pupil, mild exotropia, restriction of adduction, and infraversion of the right eye gaze. She has no evident skin lesions. Campimetry unchanged. Complementary tests showed thrombocytopenia, increased transaminases, leukopenia, and lymphocytosis. CFS analysis showed no pleocytosis or protein abnormalities, and Dengue DNA PCR was negative. However, a DNA PCR of the varicella-zoster virus (VZV) in CSF was detected. Brain MR showed enhancement in the cisternal path of the right III nerve, suggestive of neuritis, in addition to diffuse thickening of the pachymeninges. The treatment proposed was acyclovir for 10 days. The patient had progressively improved but maintained only mild eyelid ptosis. **Discussion:** Reactivation of VZV classically occurs in situations of immune depletion, with a skin rash respecting the territory of dermatomes and neuralgia. Cranial polyneuritis and ocular inflammatory manifestations induced by reactivation of VZV without rash have been previously described. However, isolated oculomotor nerve palsy, in the absence of skin lesions, is a rare finding and represents a challenging diagnosis in the presence of other viral infections in immunocompetent patients, as in the present case, in which the dengue virus can also cause neurological dysfunctions of self-limited course. Findings of normal CSF biochemistry with dengue negativity reinforce the diagnosis of reactivation and VZV-induced neurological damage. **Final comments:** The reported case is a rare isolated involvement of III nerve by VZV, in the absence of cutaneous lesions, in an immunocompetent patient with dengue. Viral coinfections are uncommon but should be part of the differential diagnosis of cranial neuritis.

https://doi.org/10.5327/CBN241232

Odontogenic cerebral abscess presenting as thunderclap headache and sensory aphasia

Leonardo Villaverde Buback Ferreira[1], Sofia Mônaco Gama[1], Lucas Toshio Uenishi[1], Fernanda Lustosa Cabral Gomez[1], Lara Santos Machado[1], Maria Eduarda Slhessarenko Fraife Barreto[1], Daniel Delgado Seneor[1], Gabriel Lopes da Silva[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Leonardo Villaverde Buback Ferreira; Email: leonardo.buback@gmail.com.

A 28 years-old female was admitted to the emergency department after the sudden onset of a headache described as a pressure feeling, reaching its maximal intensity in a few seconds and associated with "difficulty of speech", all of it starting a few minutes after waking up, 4 days before admission. Her relevant medical history included a diagnosis of Noonan syndrome, and an interatrial communication surgically repaired at 6 years-old. At the moment of the examination, she was afebrile, awake and unable to attend to verbal commands, repeat sentences or name objects, but kept the ability to reproduce gestures and her speech was fluent, thus characterizing a sensory aphasia, without other abnormalities on physical evaluation. Her head CT-scan demonstrated a hypodense lesion in the left temporal lobe, with ring-enhancing aspect after the administration of intravenous contrast, suggesting a cerebral abscess. After the introduction of intravenous antibiotic therapy, using ceftriaxone, metronidazole and linezolid, she was submitted to the surgical evacuation of the lesion which revealed the presence of purulent material, subsequently sent to microbiologic and molecular studies, the latter represented by the metagenomic next-generation sequencing (mNGS) which identified Staphylococcus intermedius. The other microbiological tests (blood and abscess cultures) were all negative, and systemic investigations (transesophageal echocardiogram, thorax and abdomen CT) also. Given the association of this microorganism with odontogenic infections, a facial CT was acquired, demonstrating a dental abscess in the right mandibular region, then submitted to surgical treatment. In the outpatient follow-up 2 months after discharge, she was asymptomatic. The clinical triad of headache, focal deficits and fever is found in about 25% of cases, being fever absent of over 50%. The prevalence of headache reaches

70%, though the most common presentation is a subacute headache, with thunderclap being an uncommon pattern mNGS is a method to directly detect DNA, RNA or transcriptional products in a sample. Its major importance is evident in cases where certain pathogens might not be suspected only by clinical data, and when microbiology tests do not show positive results. In cerebral abscesses, the identification of these rely hugely on cultures, negative in over 63% of cases. The low sensibility can be partially explained by the early introduction of antibiotics and by the delay in culture execution after sample acquisition, which are less important aspects when using mNGS. The present case illustrates an atypical presentation of a common disease, where the molecular identification of the causative agent by mNGS was crucial in the correct investigation and treatment of a primary focus responsible for a cerebral abscess.

Background: Deep brain stimulation in the subthalamic nucleus (STN-DBS) is a common therapeutic intervention for patients with Parkinson's disease (PD), primarily aimed at improving motor symptoms. However, patients with PD often experience non-motor symptoms such as anosmia. Therefore, the impact of STN-DBS on olfaction remains poorly understood. **Objective:** We performed a systematic review and single-arm meta-analysis to evaluate and synthesize the evidence on olfactory changes in Parkinson's patients undergoing STN-DBS. **Methods:** PubMed, Scopus, and Web of Science databases were systematically searched until May 13, 2024. Eligible studies included observational studies with ≥4 patients reporting the effects of STN-DBS on olfactory function in PD patients. A random-effects model was used to calculate the Proportion analysis with 95% confidence intervals (CIs). RStudio version 4.3.2 was used for statistical analysis. **Results:** A total of six studies, encompassing 179 PD patients, were included in our analysis. Of them, 58.6% were men. Six endpoints were evaluated and all presented statistically significant improvements tending towards the post-STN DBS state: Odor discrimination (OD) (mean difference 2.03; 95% CI: 1.25 to 2.82; p<0.000001; I^2=2%), Odor identification (OI) (mean difference 2.38; 95% CI: 1.43 to 3.33; p<0.000001; I^2=16%), Odor thresholds (OT) (mean difference 1.47; 95% CI: -0.36 to 3.30; p<0.000001; I^2=87%), and the TDI (composite score derived from the sum of OD, OI, and OT results) (mean difference 5.46; 95% CI: 3.39 to 7.54; p<0.000001; I^2=0%). In contrast, the Unified Parkinson's Disease Rating Scale part III (UPDRS III) (mean difference -20.67; 95% CI: -34.47 to -6.86; p=0.003340; I^2=93%) and the University of Pennsylvania Smell Identification Test (UPSIT) (mean difference -1.20; 95% CI: -4.23 to 1.83; p=0.438727; I^2=0%) tended towards the pre-DBS state, with UPDRS III being statistically significant and UPSIT not statistically significant. **Conclusion:** In this single-arm meta-analysis, consistent results suggest that STN-DBS is associated with improved olfactory function in PD patients.

One sided chorea associated with lupus anticoagulant with no other abnormalities: case report

Letícia Klabinske Marques Monteiro[1], Eduardo Sousa de Melo[1], Mariana de Almeida Cruz Silva[2], Gabriel Farina Giovani[2], Aimê de Paula Santos[2], Evelliny Gomes da Silva[1], Allefy Beltrão Albano[1], Fabrício Martins Veras[1]

[1]Universidade Federal de Pernambuco, Hospital das Clínicas, Recife PE, Brazil.
[2]Universidade Federal de Pernambuco, Recife PE, Brazil.

Correspondence: Leticia Klabinske Marques Monteiro; Email: leticiaklabinske@gmail.com.

Case presentation: An 80-year-old woman reported symptoms of hyperkinetic and unpredictable involuntary movements in the left side, daytime sleepiness, morning headaches and snoring for 8 months, with worsening of the condition in situations of anxiety. Neurological assessment revealed left hemichorea, with no other alterations. Laboratory screening for chorea was carried out and polysomnography and brain MRI were requested. Negative anti-beta-2 and anticardiolipin antibodies and positive lupus anticoagulant were stated by coagulometric method, but there was no association with Antiphospholipid Syndrome (APS). Brain MRI didn't reveal any findings. She is taking risperidone 2 mg, and is awaiting polysomnography to better elucidate this condition. **Discussion:** Chorea correlated with autoimmune diseases has been reported, as well as in the context of the presence of high plasmatic titers of Anticardiolipin Antibodies, anti-β2-GPI and Lupus Anticoagulant, even in the absence of APS. These recent clinical reports go in contrast to the past belief that this autoimmune chorea occurred only in the setting of fully developed APS. That said, case reports of this condition are uncommon, and the physiopathological subtractes of chorea related to antiphospholipids antibodies (aPL) remain unclear. Two mechanisms have been proposed to clarify the neurological impairment to the Central Nervous System caused by aPL. One of them suggests that the high affinity of aPL to the phospholipids in specific neurons causes damage in the dopaminergic nigrostriatal pathway, which may explain abnormal motor symptoms. The other states that the tropism of aPL for the endothelium of cerebral vessels disturbes its permeability, resulting in a leaked Blood-Brain-Barrier and contributing to thrombosis and hypercoagulation. An older theory used to associate chorea and other movement disorders to the occlusion of lenticule-striate arteries, producing basal ganglia ischemia. **Final comments:** Even though chorea is a recognized but rare manifestation of immune dysfunction related to aPL, the mechanisms of this disturbance are still to be explained, as well as the natural history of the condition. Case reports such as this, in which the clinical presentation of chorea with no other abnormalities besides Lupus Anticoagulant presence are exposed, must be relevant to that discussion.

Oneiric stupor: a clue for immune-mediated encephalopathy?

Carolina Souza Sanchez[1], João Henrique Fregadolli Ferreira[1], Mauricio Elias Nunes[2], Andrey Soares[2], Maira Honorato[2], Lívia Almeida Dutra[1]

[1]Instituto do Cérebro, São Paulo SP, Brazil.
[2]Hospital Israelita Albert Einstein, São Paulo SP, Brazil.

Correspondence: Carolina Souza Sanchez; Email: carol.souza.sanchez@gmail.com.

Case presentation: An 83-year-old man was admitted for investigation after a 7-day history of temporal disorientation, memory complaints, and excessive daytime sleepiness. He was diagnosed with lung carcinoma with brain metastasis in 2018, and underwent chemotherapy and pembrolizumab and continued at 21-day intervals until 2022. He was a prior heavy smoker, had hypertension, and total colectomy in 2011. Neurological examination revealed daytime drowsiness and hypersomnolence. During sleep, he exhibited purposeful, stereotyped masticatory and hand movements, responding to verbal stimuli but sustaining vigilance for less than ten seconds. He was temporally and spatially disoriented, with dysarthric speech. Positive and negative myoclonic jerks in the upper limbs and limb rigidity were also observed. Strength, sensory, cerebellar functions and cranial nerves were normal. Brain MRI showed late post-operative resection in the left frontal lobe with global atrophy. EEG showed mild disorganization. Polysomnography revealed disorganized brain activity, with excess slow waves and lack of N1 and REM stages, with wake-like movements during arousals, increased muscle tone in both limbs, and excessive hand movements consistent with oneiric stupor (OS). CSF analysis revealed < 1 cell/mm^3, protein 32 mg/dL, low beta amyloid 42 mg/dL, with normal pTau and total Tau levels. Cultures and viral panel were negative, as well as antineuronal antibodies for cell surface antigens and high-risk antibodies. PET-CT scan did not show hypermetabolic lesions. He was treated with intravenous immunoglobulin and showed complete improvement. **Discussion:** OS is one of the hallmarks of Agrypnia excitata (AE), an overactivation syndrome with persistent insomnia and autonomic sympathetic activation due to disruption of thalamolimbic circuits that regulates the sleep-wake cycle. AE is classically associated with Fatal Familial Insomnia, Delirium Tremens and Morvan syndrome. However, our patient did not meet diagnostic criteria for any of those diagnosis. The clinical presentation and extensive investigation ruled out autoimmune encephalitis and paraneoplastic syndromes. This report indicates that other conditions may present with OS. Although we could not demonstrate an inflammatory etiology, we believe that it may have an immune-mediated mechanism, due to the prompt response to IVIG and prior use of pembrolizumab. **Final comments:** OS is a rare and complex condition often linked to severe underlying neurological or systemic diseases. This case suggests that OS can occur in other clinical conditions, with a presumed immune-mediated mechanism, emphasizing the need for clinician awareness of OS symptoms and atypical presentations.

On-line speech-language assessment in children with autism spectrum disorder

Camila Pimentel Piemonte[1], Maria Eduarda Godinho Freire[1], Letícia Segeren[1], Fernanda Dreux Miranda Fernandes[1]

[1]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Camila Pimentel Piemonte; Email: camila.piemonte@usp.br.

Background: Autism spectrum disorder (ASD) is characterized by deficits in verbal communication, social interaction, and cognitive flexibility, often resulting in repetitive behaviors. Speech therapy interventions have

shown positive outcomes in improving social communication and adaptive behaviors. Many services, including speech therapy, have transitioned to online delivery. Teletherapy offers several benefits but also presents challenges. **Objective:** Assess the efficacy of an online pragmatic language assessment procedure to determine the social-communication profiles of children with ASD. **Methods:** Fifteen children aged 4 to 13 years undergoing online speech-language pathology intervention at the speech-language research laboratory in ASD at the School of Medicine, University of Sao Paulo, participated in this study. This specialized service for children with ASD provides supervised practice for undergraduate students. Parents were instructed to record their child's behavior during various activities. These videos were analyzed using the «Functional Communication Profile – Checklist» (FCPC), which evaluates communicative functions to determine each child's profile, abilities, and difficulties. **Results:** The video analysis revealed difficulties in asynchronous evaluation by parents. Despite initial recommendations, video durations varied widely (mean 1.32 minutes, range 25 seconds to 10 minutes 24 seconds). Parents often failed to select appropriate behaviors to record. Most videos showed guardian-dominated interactions, which are not typical of face-to-face assessments and may not adequately capture the child's communicative intent. A minority of videos showed challenging situations with predominant children's communication. Frequently observed communicative functions included recognition of the other, exhibition, naming, performative, and exclamatory. Assessment difficulties were due to unclear instructions to parents on what situations to record. With better instructions, parents could provide more focused videos on the communicative functions each child could express, allowing better comparison with face-to-face assessments. Nonetheless, the data obtained about family dynamics and the child's social communication abilities in a natural environment provided valuable insights that could complement therapist evaluations. **Conclusion:** Online speech-language assessments are feasible with clear protocols guiding caregivers on what and how to record. These assessments should ideally be supplemented by face-to-face sessions conducted by speech-language therapists. Home environment videos and caregiver reports can significantly contribute to understanding a child's communication profile in telepractice.

Onset of occipital seizures over 20 years after temporal lobectomy: case report

Márcio Pinheiro Lima[1], Jeana Torres Corso Duarte[1], Adriel Rêgo Barbosa[1], Gabriel Pinheiro Martins de Almeida e Souza[1], João Victor Cabral Correia Férrer[1], André Felipe Candêas Amorim[1], Rafael Tuzino Leite Neves Maffei[1], Ruan Gambardella Rosalina de Azevedo[1], Victor Cardoso de Faria[1], Pedro Henrique Almeida Fraiman[1]

[1]Universidade Federal de São Paulo, Escola Paulista de Medicina, São Paulo SP, Brazil.

Correspondence: Márcio Pinheiro Lima; Email: mplima1997@gmail.com.

Case presentation: A 43-year-old woman was admitted to the emergency department with a complaint of "changes in vision" for four days. She noticed these changes upon waking and they consisted of metamorphopsia (she described objects as being bigger or smaller than they actually were, besides seeing faces as distorted and "monstrous"), difficulty in recognizing objects, and visualizing simple geometric shapes and "stars". These complaints were fluctuating, lasting up to four hours. The patient had a past medical history of a traumatic brain injury at five years old and epilepsy starting at seven years old, with seizures characterized by episodes of behavioural arrest with occasional progression to bilateral tonic-clonic seizures. She was treated with a right temporal lobectomy at 20 years old. After the surgery she had four seizures, similar to those she had previously. At admission, she was using extended-release valproic acid (500 mg/day). Neurological examination revealed left homonymous hemianopia with preserved visual acuity, though she reported she couldn't distinguish details of the examiner's face. General biochemical tests did not show any noteworthy alterations. A 3-tesla magnetic resonance imaging (MRI) of the brain was performed, showing an area of restricted diffusion in the right occipital cortex. An electroencephalogram (EEG) was performed, finding six electroclinical seizures and lateralized delta rhythmic activity (LDRA) in the right temporal and occipital regions. The antiseizure drugs were gradually optimized to valproic acid (1000 mg every 12 hours), clobazam (10 mg every 8 hours), and phenytoin (100 mg every 8 hours), resulting in clinical normalization. **Discussion:** The prevalence of epilepsy is around 1% of the population. Of those, up to 40% have drug-resistant epilepsy. Up to 70% of the patients who undergo surgery for temporal lobe epilepsy achieve a seizure-free outcome. In patients who do not have this outcome, the mechanisms for maintaining seizures are diverse and may involve incomplete resection of the epileptogenic area, mirror foci, other structural brain lesions, or epileptogenic activity in the surgical scar. In these patients, approximately 70% of seizures begin in the hemisphere ipsilateral to the surgical resection. Quantitative evaluations with MRI show cortical changes in the temporal lobe, hemispherical, and bilateral changes postoperatively. In cases of new extratemporal seizures, it is possible that other cortical epileptogenic areas, after the temporal surgical resection, assume the role of generating the seizures. Changes in the propagation pattern of the seizures may also occur. **Final comments:** Epilepsy surgery is an effective procedure for seizure control, but certain patients do not become seizure-free. This may occur due to various mechanisms, and it is necessary to consider the possibility of the appearance of new semiological patterns in these patients.

Ophtalmoparesis with areflexic mydriasis as an atypical presentation of anti-GT1a IgG syndrome

Laura Araújo Paulino[1], Camila Caroso Lobo[1], Kaio Cezar Ferreira[1], Rafael Guimarães Kanda[1], Mayko Nascimento Merscher[1], Luiz Fernando Urzeda[1], Péricles Maranhão Filho[2], Laura Silveira Moriyama[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.
[2]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Laura Araújo Paulino; Email: laurapaulino16.2@bahiana.edu.br.

Case presentation: A 21-year-old male patient with sickle cell anemia developed diplopia and mydriasis 12 days after a gastrointestinal infection. Two days later hematological assessment revealed 60% HbS and two exchange transfusions and transfusion of a packed red blood cell was performed with reported discreet improvement of mydriasis. Two days later he was seen by neurology with ophthalmoplegia characterized by limitation in abduction and adduction bilaterally, worse in the right eye. Additionally, bilateral areflexic mydriasis with a larger pupil diameter on the right, slight ptosis on the left, horizontal nystagmus with rapid phase ipsilateral to lateral gaze, and mild imbalance in tandem gait were noted. Brain magnetic resonance imaging was performed to rule out associated intracranial lesions, revealing subtle enhancement of the III, IV, and V cranial nerves on the right side. Cerebrospinal fluid (CSF) testing was unremarkable including protein electrophoresis and oligoclonal bands. Considering atypical Miller Fisher syndrome (MFS) serum anti-ganglioside testing was performed and detected positive anti-GT1a IgG antibodies (with negative IgM) in the cerebrospinal fluid, without other abnormal findings. Treatment with intravenous human immunoglobulin was administered, resulting in incomplete but significant improvement of both external and internal ophthalmoplegia, as well as improvement in imbalance. **Discussion:** Anti-GT1a IgG antibodies are commonly found in MFS, cases of the pharyngeal-cervical-brachial variant of Guillain-Barré Syndrome (GBS), or in overlaps of GBS spectrum syndromes, whose clinical syndromes commonly involve ophthalmoplegia, weakness in arms and legs, ataxia, and drowsiness. In a retrospective cohort of 140 patients with positive anti-GT1a developed in 2004, 9 has negative anti-GQ1bb and 131 with concomitant positive anti-GQ1b; in the group with activity of anti-GQ1b, external ophthalmoparesis was present in 89 patients; in the group without positive anti-GQ1b, 22 had external ophthalmoplegia; internal opththalmoplegia was only described in those with concomitant anti-GT1a and anti-GT1b IgG detected (40 patients). Among patients with positive anti-GT1a without anti-GQ1b positivity, diarrhea was the most common antecedent, and diplopia was the second most common initial manifestation. Internal ophthalmoplegia is often more described in association with anti-GQ1b antibodies, which is the most common auto-antibodies in Miller Fisher syndrome. **Final comments:** To our knowledge this is the first description of internal opththalmoplegia in atypical MSF with positive anti-GT1a without GT1b.

Opsoclonus-myoclonus-ataxia syndrome associated with dengue virus infection

Nathalye Fernanda Pedroso Dircksen[1], Marcelo Simplicio Carvalho[1], Letícia de Barros Dias[1], Lorena Fernandes Kronbauer[1], Fábio Gonçalves[1], Felipe Leonardo Semensati[1], Mônica Marcos de Souza[1], Damacio Ramon Kaimen Maciel[1]

[1]Irmandade da Santa Casa de Londrina, Londrina PR, Brazil.

Correspondence: Nathalye Fernanda Pedroso Dircksen; Email: n.athalye@hotmail.com.

Case presentation: A 36-year-old woman diagnosed with dengue, on the thirteenth day after the onset of symptoms presented with mental confusion, involuntary eye movements, vertigo and difficulty walking. When evaluated by the neurology team, she appeared confused, with movement eye chaotic, involuntary, multidirectional and hyperkinetic. Non-rhythmic and spontaneous appendicular myoclonic movements, trunk ataxia, consistent with opsoclonus-myoclonus-ataxia syndrome (OMAS). The cerebrospinal fluid showed predominant pleocytosis. Magnetic resonance of the neuroaxis was unremarkable. Dengue serology was reactive and other serology and neoplastic screening tests were normal. During hospitalization, the patient presented a worsening level of consciousness, emotional lability, dysarthria and dysphagia. Due to clinical worsening, it was decide to start pulse therapy with intravenous methylprednisolone at a dose of 1g/d for 5 days, followed by an infusion of immunoglobulin human intravenous 400mg/kg/weight per 5 days. Clonazepam 2 mg every 12 hours was also administered to control symptoms with good response. There was complete improvement after about two weeks. **Discussion:** Dengue is a systemic viral infection, transmitted between humans by the Aedes aegypti mosquito, and can manifest itself in different ways, including neurological involvement like meningitis, encephalitis, transverse myelitis, Guillain-Barré Syndrome, optic neuromyelitis, optic neuritis, and rarely OMAS. Movement disorders as a consequence of dengue virus infection are rare and there are few cases reported in the literature. OMAS was described in 1962 by Marcel Kinsbourne and is also known as "dancing eyes-dancing feet" or "Kinsbourne syndrome". It is associated with ocular, motor, behavioral, sleep and language disorders. In most cases it is a consequence of

neuroblastoma in children and paraneoplastic syndrome in adults. Neurological complications in dengue infection occur through some mechanisms: neurotropism, immune-mediated or antibody-dependent reaction, being more likely the OMAS secondary to encephalitis and post-infectious immunological damage, due to the delay in the onset of symptoms and the response to corticosteroid therapy. Although the pathogenesis from the illness he comes from the dysfunction of pontine neurons, skull MRI does not demonstrate lesions in the parenchyma, whereas CSF with pleocytosis suggests encephalitis. Depending on the patient's clinical condition, expectant treatment or immunotherapy (corticosteroids, intravenous immunoglobulin and/or plasmapheresis) can be chosen. Symptomatic treatment with clonazepam can also be performed. **Final comments:** There are few cases in the literature of OMAS secondary to dengue infection. Therefore, there are no evidence-based guidelines or consensus available to guide treatment, which is carried out empirically. We hope to contribute to the literature by demonstrating the case and outcome after empirical therapy.

Opsoclonus-myoclonus-ataxia syndrome: a case report

Igor Baroni Cardoso[1], Louissa Srama Rosner Cidral[2], Lara Mensato Döring[1], Amanda Yumi Ikematu[3], Ayumi Oya Santos[3], Crislley Mulbauer[3], Johnatan Neuls Pasta[4], Nátali Pimentel da Silva[5], Ana Carolina Andrade[6]

[1]Universidade Federal do Paraná, Curitiba PR, Brazil.
[2]Universidade Positivo, Curitiba PR, Brazil.
[3]Pontifícia Universidade Católica do Paraná, Curitiba PR, Brazil.
[4]Hospital da Cruz Vermelha Brasileira, Curitiba PR, Brazil.
[5]Unifacear, Araucária PR, Brazil.
[6]NeuroDOC, Curitiba PR, Brazil.

Correspondence: Igor Baroni Cardoso; Email: igorbaronic@gmail.com.

Case presentation: A 28-year-old man was admitted to hospital with complaints of involuntary eye movements and motor coordination difficulties. Three weeks prior, the patient had experienced a self-limiting viral febrile episode. Clinical examination revealed bilateral, intrusive saccadic eye movements, exacerbated both during gaze fixation at rest and upon light exposure, consistent with opsoclonus. The patient exhibited mild ataxia in all four limbs, more pronounced on the left side, and truncal ataxia. A subsequent MRI of the neuraxis showed no abnormalities. Cerebrospinal fluid (CSF) analysis revealed a leukocyte count of 40 (98% lymphocytes), protein level of 56 mg/dL, and glucose level of 64 mg/dL. A paraneoplastic screening with a tomography of the chest, abdomen, and skin, along with testicular ultrasound, showed no abnormalities. CSF antibody testing returned negative results for Anti-Hu, Anti-Yo, Anti-Ri, Anti-Amphiphysin, Anti-CV2, Anti-Ma2, Anti-MGT-30, Anti-AGNA, and Anti-Recoverin. Given the syndromic diagnosis of Opsoclonus-Myoclonus-Ataxia, treatment was initiated with methylprednisolone pulse therapy (1g/day) for five days, followed by intravenous human immunoglobulin (2g/kg) for another five days. The patient was discharged from hospital after significant symptom improvement. **Discussion:** Opsoclonus-Myoclonus-Ataxia Syndrome is a rare neurological syndrome, scarcely described in recent literature, requiring precise diagnosis and appropriate therapeutic approach. This case highlights a potential presentation of the syndrome, with intrusive eye movements, significant ataxia, and neuroimaging plus the cerebrospinal fluid studies aided in the exclusion of other possible etiologies. The management of the patient with methylprednisolone followed by intravenous human immunoglobulin, resulting in symptom improvement, suggests a potential therapeutic regimen for Opsoclonus-Myoclonus-Ataxia Syndrome, despite the absence of confirmed autoimmune or paraneoplastic etiology. **Final comments:** The described case illustrates Opsoclonus-Myoclonus-Ataxia syndrome with a positive response to treatment with methylprednisolone and intravenous human immunoglobulin. This underlines the importance of disseminating information about the presentation of this syndrome and its therapeutic possibilities. Furthermore, it exemplifies the significance of considering paraneoplastic and autoimmune hypotheses in the diagnostic and therapeutic approach to this clinical condition. Documenting such cases is crucial for improving the clinical and therapeutic approaches to rare neurological conditions.

https://doi.org/10.5327/CBN241241

Optic neuritis secondary to bartonellosis (cat scratch disease by bartonella quintana): a case report

Luiz Felipe Mota Freitas[1], Iasmim Portela Maifrede[1], Rafael Barbosa Mokdeci Surerus[2], Daniel Sabino de Oliveira[1], Leopoldo Antonio Pires[1], Thiago Cardoso Vale[1]

[1]Universidade Federal de Juiz de Fora, Hospital Universitário, Ebserh, Juiz de Fora MG, Brazil.
[2]Universidade Federal de Juiz de Fora, Juiz de Fora MG, Brazil.

Correspondence: Luiz Felipe Mota Freitas; Email: luizfelipemotafreitas@gmail.com.

Case presentation: A 19-year-old male was admitted in January 2023 due to right optic neuritis without diagnostic elucidation at that time, but treated with methylprednisolone (1g/day for 5 days) with improvement. After discharge, he used prednisone for a month but discontinued on his own, resulting in visual loss in the left eye, which only improved after resuming corticosteroid therapy. In April 2023, he developed focal motor seizures on the left side with secondary bilateral dissemination, requiring intensive support hospitalization. He evolved with moderate, lobulated, exudative pleural effusion with nonspecific inflammatory characteristics, indicating serositis, and also experienced alopecia. Empirical treatment with acyclovir was initiated due to suspected viral encephalitis, even though brain MRI and lumbar puncture investigations showed no changes. During this period, bartonellosis was suspected, and serology showed positive for Bartonella quintana IgG 1:640 and negative IgM. After bartonellosis diagnosis, he was treated with doxycycline for 28 days, showing good progress with the treatment. **Discussion:** Bartonellosis is a vector-borne zoonosis with worldwide distribution, capable of infecting a wide variety of mammals, including humans. The most commonly related species to cat scratch disease (CSD) is Bartonella henselae, with cats as the main reservoir. This case illustrates a less common etiological agent, Bartonella quintana. Clinical presentations of bartonellosis can be self-limiting or severe, such as uveitis, neuroretinitis, and endocarditis. Transmission between animals and humans occurs through flea feces inoculation, scratches, bites, blood transfusions, and needles. Optic neuropathy associated with CSD is relatively rare, often characterized by sudden, painless visual loss, usually unilateral, and associated with macular star formation. Visual complications occur in about 10% of cases, including optic neuritis. The condition is self-limiting with complete or near-complete recovery of visual acuity in immunocompetent patients. Diagnosis is clinical-laboratory based, confirmed by serological testing. The antibiotic therapy used in this case was appropriate for eliminating the infection and shortening the visual recovery time. **Final comments:** Such cases should be reported to clarify the importance of early diagnosis and treatment to reduce complications, especially ocular/visual, in patients with bartonellosis. This case is particularly significant due to the less common etiological agent presented.

https://doi.org/10.5327/CBN241242

Optical coherence tomography in early-onset parkinsonism

Felipe Thomas Braz[1], Max Victor Peter Schramm[1], Larissa Schneider[1], Emanuel Cassou dos Santos[1], Matheus Gomes Ferreira[1], Mario Teruo Sato[1], Naoye Shiokawa[2], Renata Cristine Alves[1], Hélio Afonso Ghizoni Teive[1]

[1]Universidade Federal do Paraná, Curitiba PR, Brazil.
[2]Clínica Retina e Vítreo, Curitiba PR, Brazil.

Correspondence: Renata Cristine Alves; Email: renata_cristinealves@hotmail.com.

Background: Parkinson's disease (PD) is the main etiology of Parkinsonism and was. originally described as a motor disease. However, in recent decades, there has been better understood its non-motor component and its relevance. Among the non-motor signs and symptoms are changes in the visual processing, resulting from the loss of amacrine cells, dopaminergic neurons, in the inner retina. Thus, some studies have been demonstrated a reduction in thickness of the inner layers of the retina, where amacrine cells (dopaminergic neurons) are located. Optical Coherence Tomography (OCT) has been studied as a preclinical diagnostic tool in patients with PD, but there are still no studies on patients with Early-Onset Parkinsonism (EOP). **Objective:** To describe the retinal changes in patients with Early-Onset Parkinsonism (EOP) using Optical Coherence Tomography (OCT), to compare the thickness of retinal layers between the case and control groups, and to evaluate the correlations with disease duration, patient age, and disease severity. **Methods:** Sixteen patients with EOP had retinal layer thickness measured in the macular and peripapillary areas. The inner plexiform layer (IPL), ganglion cell layer (GCL), retinal nerve fiber layer (RNFL), total retina, and minimum rim width (MRW) were all assessed. All patients underwent neurological assessment, and the severity of symptoms classified using Part III of the UPDRS scale. **Results:** There was an increase in RNFL thickness in the Inferior Temporal sector (148.6μm vs. 133.71μm; p<0.001) in the peripapillary retina, while in the macula, there was a significant reduction of IPL in the Nasal (41.4μm vs. 48.5μm; p<0.001) and Temporal sectors (41.8μm vs. 49.9μm; p<0.001), and in the GCL in the Superior (52.7μm vs. 56.9μm; p=0.030), Nasal (52.7μm vs. 58.2μm; p=0.009) and Lower sectors (52μm vs. 58μm; p=0.002). An inverse correlation between the peripapillary MRW in the nasal sector and the severity of symptoms, evaluated by Part III of UPDRS (Spearman correlation = -0.67; p=0.033). **Conclusion:** OCT can detect the neurodegeneration present in EOP by measuring the reduction in thickness of the IPL and GCL in the macula. Furthermore, the value of nasal peripapillary MRW may be related to clinical severity of the disease. However, longitudinal studies with larger samples are necessary to establish macular measurements as diagnostic and disease progression biomarkers.

Optimizing diagnostic pathways for myopathies with exercise intolerance: a random forest model approach

Thales Pardini Fagundes[1], Lucas Gondim Briand Vieira[1], Karolina de Brito Barbosa Trindade[1], Lucas Ravagnani Silva[1], Giuliano Roberto Scarpellini[1], Ana Marina Dutra Ferreira da Silva[1], Eduardo Yukio Nakamura[1], Raissa Gontijo Cabral de Souza[1], Pedro José Tomaselli[1], Cláudia Ferreira da Rosa Sobreira[1]

[1]Universidade de São Paulo, Faculdade de Medicina de Ribeirão Preto, Ribeirão Preto SP, Brazil.

Correspondence: Thales Pardini Fagundes; Email: pardinithales@gmail.com.

Background: Myopathies encompass a heterogeneous group of skeletal muscle diseases with diverse clinical manifestations, including weakness, fatigue, myalgia, atrophy, hypertrophy, contractures, cramps, and myotonia. While some diseases in this group may present with relatively stereotypical clinical pictures, the spectrum of manifestations can include relatively nonspecific phenotypes, especially when fatigue and myalgia predominate. Metabolic myopathies often manifest with exercise intolerance, fatigue, and myalgia related to physical activity, whereas structural myopathies typically lead to muscle weakness. However, a pseudometabolic presentation of muscular dystrophies is well recognized and poses a diagnostic challenge. Despite advances in medical diagnostics, accurately identifying specific myopathies remains challenging, particularly when patients present with oligosymptomatic profiles. **Objective:** To develop a machine learning model to assist in the differential diagnosis of metabolic and structural myopathies in patients with exercise intolerance. **Methods:** The study cohort included 97 patients with myopathies, comprising 58 patients with structural myopathy and 39 with metabolic myopathy. Data were preprocessed, with missing values imputed by the median and features standardized. SMOTE was applied to balance the classes. A Random Forest model was trained on the balanced data and evaluated on the test set. **Results:** The Random Forest model achieved an accuracy of 72%, a precision of 86%, a sensitivity of 73%, and an F1-score of 74% on the test set. The confusion matrix revealed high precision in identifying structural myopathies, while precision was lower for metabolic myopathies. The most important variables for classification were maximum lactate concentrations, minimum creatine phosphokinase (CPK) concentrations, and the initial type of myalgia presented by the patients. The learning curve indicated good model performance and a low risk of overfitting. Analysis of raw data revealed that patients with metabolic myopathies had higher concentrations of lactate and CPK compared to patients with structural myopathies. **Conclusion:** The Random Forest model showed potential in assisting the differential diagnosis of metabolic and structural myopathies. Lactate and CPK concentrations, along with the initial type of myalgia, were the main predictors.

Optimizing epilepsy surgery outcomes: the impact of accurate epileptogenic zone resection on clinical course and survival

Gabriel Chagas Lutfala Paulino[1], Raphael Fernandes Casseb[1], Brunno Machado de Campos[1], Marina Alvim[1], Enrico Ghizoni[1], Clarissa Lin Yasuda[1], Fernando Cendes[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Gabriel Chagas Lutfala Paulino; Email: lutfalagabriel1@gmail.com.

Background: Epilepsy is a debilitating condition characterized by recurrent, unprovoked seizures, affecting 0.5-1% of the world population. Resective surgery of the epileptogenic zone is the treatment of choice in focal epilepsies refractory to antiseizure medications. Nevertheless, the varied rates of good surgery outcomes elicit uncertainties regarding the definition of the target regions to be removed. In this study, we investigated whether cases in which regions with changes identified using EEG-fMRI and which were in fact removed during surgery presented better clinical and survival results over time. **Objective:** To characterize the clinical condition and survival curve of patients undergoing resective surgery throughout time. **Methods:** Thirty-six epilepsy patients (16 women) underwent a 3.0 T MRI scan (Philips Achieva) at Unicamp's Hospital. The anatomical postoperative T1 images were visually inspected for artifacts and then, the resective lacuna was manually segmented using MRIcron (version 1.0.20190902). To assess the correspondence between epileptiform activity and the surgical lacuna, we calculated the distance of the blood-oxygen-level-dependent EEG-fMRI activation clusters to the centroid of the lacuna mask that was segmented manually. In addition, the mean value of the distances was assessed in relation to the Engel score. We divided patients into two groups (Engel I-II and III-IV) and compared their survival curves over time. **Results:** The distances between the EEG-fMRI clusters and lacuna ranged from 27.1mm to 117.2 mm. In the group classified as Engel I-II, patients had significantly ($p<0.05$) smaller mean distances ($\bar{x}$=85.3mm, σ=17.7mm) compared to those classified as Engel III-IV ($\bar{x}$=95.4mm, σ=12.6mm). Furthermore, a cutoff distance of 90 mm revealed that patients with distances ≤90 mm had a higher percentage of Engel I-II (68.75%) than those with distances >90 mm. At 85 mm, this percentage increased to 81.81%, and at 80 mm, it rose to 83.33%. Notably, Engel I-II patients exhibited higher survival rates over 2 years when compared to Engel III-IV patients, with rates of 100% and 83.33%, respectively. **Conclusion:** The enduring correlation between reduced distances from epileptiform activity activation clusters to the surgical lacuna centroid and better Engel scores emphasizes the importance of accurately removing the epileptogenic zone for favorable surgical outcomes. This association also persists when assessing the survival curve over time, with better outcomes in patients with smaller activation-lacuna distances. However, further studies with larger sample sizes are necessary to validate these findings conclusively.

Orthostatic headache as a presentation of jugulotympanic paraganglioma in the cerebellopontine angle: a case report

Luan Yudi Prando Kasuga[1], Melissa Caroline Godoi Prestes[1], Ádria Rodriges da Silva[1], Bruna Beppler[1], Caroline Zapelini[1], Lia Maki Hatisuka Imai[1], Gabriel Rodrigues Espelho Rossi[1], Aline Vitali da Silva[1]

[1]Universidade Estadual de Londrina, Londrina PR, Brazil.

Correspondence: Melissa Caroline Godoi Prestes; Email: melissa.caroline@outlook.com.

Case presentation: An 82-year-old hypertensive female patient presented with a history of progressive orthostatic headache for 3 months, which became incapacitating over the past month. She reported intense, pulsatile left hemicranial headache radiating to the left side of her face, associated with nausea, vomiting, hypoacusis, dysphagia, and decreased visual acuity. The symptoms worsened in the orthostatic position, during movement, or when lying on the left side. The initial cranial computed tomography (CT) scan was performed when the patient experienced a headache and revealed a hypodense nodular formation with contrast enhancement in the left pontocerebellar cistern and jugular foramen, associated with venous dilation of the sigmoid sinus. Due to the progression of symptoms, the patient required hospitalization. A cranial magnetic resonance imaging (MRI) scan was conducted, revealing an infiltrative lesion in the left mastoid and petroclival junction, invading the sigmoid sinus/jugular bulb and the posterior fossa, compressing the left cerebellar hemisphere and involving the left vertebral artery (measuring 4.8x 3.3 x 4.1 cm), suggestive of a Paraganglioma or Glomus Jugulotympanicum. The patient was treated with analgesics, anti-inflammatory drugs, and carbamazepine, initially responding well but later experiencing episodes of delirium and irritability. During her hospitalization, she developed multiple respiratory infections, sepsis, and clinical instability. With surgical intervention being unfeasible, priority was given to comfort measures. Palliative care was initiated, and the patient passed away one month later. **Discussion:** Paragangliomas are rare, well-vascularized, slow-growing neuroendocrine tumors that originate from the chromaffin cells of the paraganglia. These tumors can involve the skull base, commonly affecting the jugular foramen and the paraganglia associated with the tympanic branch of the glossopharyngeal nerve. They are locally invasive and can affect the lower petrous and sigmoid sinuses, the cerebellopontine angle, and the Eustachian tube. The clinical presentation varies depending on the affected region. Involvement of the jugular foramen leads to symptoms such as dysphagia, dysarthria, hypophonia, and weakness of the trapezius and sternocleidomastoid muscles. In contrast, involvement of the tympanic branch results in otalgia, hearing loss, pulsatile tinnitus, and aural fullness. Although headache is not common, it was the primary symptom in this case. The diagnosis involves correlating clinical symptoms with imaging studies: CT allows for the assessment of structural damage to the jugular foramen, while MRI typically demonstrates a "salt and pepper" appearance. **Final comments:** This challenging case of jugulotympanic paraganglioma illustrates the complexity associated with the diagnosis and management of rare and invasive neurological tumors, along with an atypical presentation characterized by secondary headache.

Orthostatic tremor and leukoencephalopathy secondary to chronic toluene poisoning

Brenda Albuquerque de Araújo Marinho[1], Brenda Letícia Lopes Batista[1], Marcelo Ataíde de Lima[1], Mariana Holanda Gameleira[1], Larissa Albuquerque Paes de Araújo[2], Élida Cristina Nascimento do Rêgo[1], Maria Luísa Gonçalves Torres Inácio[1], Bárbara Martins de Carvalho[1], Mateus de Melo Andrade[1], Leandro Correia Gonçalves de Souza[1]

[1]Hospital da Restauração, Recife PE, Brazil. [2]Faculdade de Ciências Médicas da Paraíba, João Pessoa PB, Brazil.

Correspondence: Brenda Albuquerque de Araújo Marinho; Email: brenda.albuquerque65@gmail.com.

A 44-year-old female patient presents with ambulation problems due to tremors over the past three months, accompanied by double vision for the last seven days. Tremors have persisted for over 20 years, but recently, walking difficulties and double vision have worsened. She denies other neurological symptoms, current or past alcoholism, and smoking. She reports long-term use of "glue" (an illicit substance containing toluene) for 30 years. Neurological examination is normal except for tremors in the face and trunk while sitting, appendicular tremors in upright posture, and no tremors when supine. Several complementary tests were conducted, including MRI of the skull revealing diffuse white matter signal alterations in the corona radiata, centrum semiovale, splenium of the corpus callosum, middle cerebellar peduncles, and bilateral dentate nucleus of the cerebellum, with findings of undetermined nature. Given the history of solvent abuse, toluene-related leukoencephalopathy is considered. Electroneuromyography (ENMG) demonstrated postural action tremor with a frequency of approximately 13 Hz in the left tibial muscle, absent in supine and sitting positions. Peripheral nervous system abnormalities were not observed on ENMG. The diagnosis of orthostatic tremor and leukoencephalopathy secondary to chronic toluene poisoning was confirmed. The treatment plan includes discontinuation of "glue" use, psychiatric monitoring, psychotherapy, motor physiotherapy, and pharmacological therapy (Benzodiazepine + Amantadine), with a follow-up in 30 days. Tremor is the most common movement disorder, characterized by rhythmic oscillation due to contractions of antagonistic muscles, typically confirmed by electromyography (EMG). Long-term toluene inhalation can lead to neurological symptoms including cerebellar, cognitive, and pyramidal dysfunctions, as well as optic atrophy, visible on radiological studies. Benzodiazepines have shown efficacy in managing toluene-induced tremors. The main feature of toluene-induced leukoencephalopathy is progressive dementia, correlating with the extent of white matter damage. Additional central nervous

system deficits may include cognitive, cerebellar, and cranial nerve dysfunctions.

Osteitis due to neurosyphilis: a case report

Luiz Felipe Mota Freitas[1], Fernanda Vieira[2], Rafael Barbosa Mokdeci Surerus[3], Daniel Sabino de Oliveira[1], Leopoldo Antonio Pires[1], Thiago Cardoso Vale[1]

[1]Universidade Federal de Juiz de Fora, Hospital Universitário, Ebserh, Juiz de Fora MG, Brazil.
[2]Centro Universitário de Volta Redonda, Volta Redonda RJ, Brazil.
[3]Universidade Federal de Juiz de Fora, Juiz de Fora MG, Brazil.

Correspondence: Luiz Felipe Mota Freitas; Email: luizfelipemotafreitas@gmail.com.

Case presentation: A 21-year-old female patient with a history of chronic tension-type headaches with irregular medical follow-up presented with an elevated and bulging lesion in the frontal region of the skull associated with more intense headache that became refractory to her usual analgesics. She denied any local trauma. Examination revealed a painless, mobile and fibroelastic cervical lymphadenopathy in the posterior chain on the left side. There were no lesions in the oral cavity or skin neither neurological abnormalities or neck stiffness. Brain MRI showed a lesion involving the left frontal bone marrow. Bone scintigraphy revealed a focal increase in osteogenic activity of significant intensity in the frontal region of the skull. CSF analysis showed 6 cells/mm3, with lymphocyte predominance, glucose 51mg/dL (serum: 89mg/dL), proteins 9.53, and a non-reactive VDRL in CSF. Cytopathological examination was normal. Serum tests showed VDRL 1:256 with reactive serology for Treponema pallidum IgM and IgG. Serologies for viral hepatitis and HIV were negative. As CSF showed a slight increase in cells with a lymphomonocytic predominance, we diagnosed an asymptomatic neurosyphilis and treated with intravenous crystalline penicillin for 14 days. There were no complications, maintaining clinical stability throughout hospitalization and the clinical picture improved. Primary bone lesions were ruled out, and the lesion was associated with syphilitic osteitis. Post-treatment tests: serum VDRL 1:2; serology for Treponema pallidum IgM NR, IgG reactive. Post-treatment MRI: near-complete resolution of the permeative lesion involving the left frontal bone marrow. **Discussion:** Treponema pallidum, a gram-negative spirochete bacterium, has an affinity for bone tissue, most commonly affecting long bones and the skull. Neurosyphilis can develop by contiguity from bone lesions of the calvaria and should be ruled out when close to the meninges. Syphilis cases have increased worldwide, with higher incidence among men who have sex with men and HIV patients. Bone involvement is uncommon in primary and secondary syphilis, with a prevalence of 0.15 to 0.23%. The presence of mucocutaneous findings and lymphadenopathy raise suspicion of syphilitic osteitis. There is no consensus on the treatment of secondary syphilis osteitis cases, as they are rare. Symptoms resolve after therapy, but bone lesions may persist for up to 7-11 months. **Final comments:** Syphilitic osteitis is more frequently associated with tertiary or congenital syphilis. It should be considered in the differential diagnosis of bone lesions when accompanied by positive serology for syphilis.

Outcomes in pediatric surgery for drug-resistant epilepsy: a systematic review

Leonardo Portugal Lima[1], Beatriz Caroline Pazzini de Almeida[1], Gabriel Barreto Vinhas Abreu[2]

[1]Universidade de Vassouras, Vassouras RJ, Brazil.
[2]Universidade Federal do Estado do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Leonardo Portugal Lima; Email: leonardo_mali@hotmail.com.

Background: Epilepsy is a chronic nervous system disease characterized by fluctuations between moments of stability and instability within nerve cells, which presents in forms of epileptic seizures. Most cases of epilepsy are controlled by Anti-seizure medication (ASM), but up to 30% can be drug-resistant, posing a higher risk of psychological and neurological impairment in children. In such cases, surgery presents itself as a therapeutic possibility. **Objective:** To conduct a systematic review on current literature of surgical outcomes in epileptic pediatric patients, with focus on efficacy, safety and long-term follow-up. **Methods:** This is a systematic literature review based on articles indexed in the United States National Library of Medicine (PubMed) published between 2019 and 2024. Were used "epilepsy", "surgery" and "pediatric" as a descriptor. Initially, 57 articles were found of which 15 were used after applying an inclusion and exclusion criteria. **Results:** From the articles analyzed, all being systematic review and/or meta-analysis, were mainly composed of long-term follow up of patients as long as 10 years post-operatively, the full-scale intelligent quotient (FSIQ) and neurocognitive academic abilities assessment in pre and post procedure and comparisons with non-surgical groups. **Conclusion:** The review demonstrated that surgical intervention shows significant efficiency in improving quality of life and reducing seizure frequency in pediatric drug resistant epilepsy, with high percentage remaining seizure-free in a long-term follow-up. Among the patients, seizure-freedom was even more strongly correlated with shorter epilepsy duration, highlighting the importance of considering surgery early in those patient's treatment process. Moreover, it was documented that after the procedure, patients mostly surpassed or maintained their neurocognitive functions, with a minority experiencing slight neurologic deficit, most of which were transient. Furthermore, there was no observed decline in core academic skills and in the FSIQ evaluation, and individuals were able to keep their preoperative performances, underscoring the safety implications of the procedure. By consolidating the current literature, it illustrates valuable insights and establishes a solid foundation for the significance of early referral to surgery and a personalized treatment approach in pediatric patients with drug-resistant epilepsy.

Outlining the epileptogenic zone with cortical stimulation in SEEG

William Alves Martins[1], Claude Steriade[2], Imad Najm[3], Juan Bulacio[3]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Hospital São Lucas, Porto Alegre SC, Brazil.
[2]New York University, Langone Health, New York, USA.
[3]Cleveland Clinic, Ohio, USA.

Correspondence: William Alves Martins; Email: walvesm.br@gmail.com.

Background: Mapping of neurological function by cortical stimulation is an essential step in the evaluation of epilepsy patients undergoing invasive EEG for epilepsy surgery. Yet, controversy still exists regarding its role as a tool for delineating epileptogenic cortex. **Objective:** To evaluate the impact of electroclinical patterns of cortico-stimulation induced seizures (CIS) in stereo-electroencephalography (SEEG) and removal of CIS electrodes in seizure freedom. **Methods:** We reviewed all 230 consecutive patients who underwent SEEG and cortical stimulation from 2013 to 2016. CIS were induced in 79 (30.4%) patients, of whom 49 (21.2%) underwent surgical resection and entered the final analysis. Demographic, epilepsy and pathological data were collected. In addition, a detailed analysis of cortical stimulation and Stereo-EEG was performed. For the purpose of our study, we created a simple way to classify CIS based on semiological (complete, partial and atypical patterns), and EEG similarity to spontaneous seizures. Seizure freedom was used to calculate the predictive value of CIS with complete semiology and identical EEG (complete electroclinical picture). **Results:** Seventy-one (45.8%) patients were seizure-free with a mean follow up of 1.42±0.9 years. Twenty-six (52%) patients in the CIS group were seizure-free compared to 45 (42.9%) non-CIS patients (p=0.286). Complete seizure semiology was obtained in 22 (42.9%) patients and resection of electrodes involved in CIS led to seizure freedom in 73.7% compared to 45.9% of the stimulation cohort (p=0.021). Conversely, resection of electrodes involved in partial seizure semiology provided a rate of seizure-freedom of only 20% (p=0.021). Resection of electrodes involved in CIS identical to spontaneous seizures (both semiology and EEG) were significantly associated with seizure-freedom (80% x 42.4%; p=0.006, OR 5.4, 95% CI 1.46-20.0) and largely represented by FCD type 2 (42.9%; Fisher's exact test, p=0.006). Complete electroclinical correlation of CIS displayed sensitivity of 16.9% (95% CI, 9.05-27.66%), specificity of 96.4% (95% CI, 89.8-99.25%) and positive predictive value of 80% (95% CI, 54.03-93.16%) for accurate localization of epileptogenic zone. **Conclusion:** Electroclinical characteristics of CIS are a valuable tool to localize the epileptogenic zone and craft a successful surgical strategy in SEEG. Moreover, it may represent a marker of underlying FCD type II.

Overdiagnosis of normal pressure hydrocephalus: evidence of clinical-radiological dissociation

Ana Carolina Gomes[1], Sephora Sabrina Candido de Almeida[1], Diogo Haddad Santos[1], Yngrid Dieguez Ferreira[1], Alexandre Shoji[1], Isabela Martins de Freitas[1]

[1]Santa Casa de Misericórdia de São Paulo, São Paulo SP, Brazil.

Correspondence: Ana Carolina Gomes; Email: gomesac90@gmail.com.

Background: Normal pressure hydrocephalus (NPH) was described in 1965 by Hakim and Adams and is characterized by the classic triad of cognitive decline, gait apraxia, and urinary incontinence associated with ventriculomegaly on neuroimaging, with normal opening cerebrospinal fluid (CSF) pressure. Its diagnosis is challenging due to its similarity with other neurodegenerative diseases, such as Alzheimer's and vascular dementia. Additionally, there is a noted clinical-radiological dissociation, often leading to the overdiagnosis of the condition. In this context, there has been an increase in the referral of patients with suspected NPH to the Centro de Cognição Paulista (CECOP). **Objective:** This study measures the dissociation between clinical and radiological findings in patients evaluated between January 2022 and December 2023, as well as the overdiagnosis of NPH and the need for revision of diagnostic criteria. **Methods:** A retrospective analysis was conducted on 46 patients referred to CECOP with suspected NPH based on neuroimaging. The presence of imaging findings compatible with NPH, age, gender, clinical symptoms, and final outcome were evaluated. **Results:** Of the 46 patients, 25 had a clinical presentation compatible with NPH (12 men and 13 women, mean age 75 years) but without characteristic neuroimaging. Of these, 14 were diagnosed with Alzheimer's, 5 with vascular dementia, 3 with frontotemporal dementia, and 3 remain under investigation. Only 7 patients (5 men and 2 women, mean age 72 years) had both clinical and imaging findings consistent with NPH and were referred for a tap test. Another 7 patients, despite having clinical

and neuroimaging suggestive of NPH, had more probable other diagnoses. **Conclusion:** The analysis revealed a significant clinical-radiological dissociation, with only 7 patients (15.22%) presenting both clinical and imaging findings compatible with NPH. Of the 25 patients with neuroimaging alterations, 54.3% did not have clinical indications of the condition and received other diagnoses. These findings highlight the complexity of diagnosing NPH and the importance of rigorous criteria. Although the tap test is an important step in evaluation, the latest Japanese consensus considers that patients over 60 years old with compatible clinical and neuroimaging findings can be diagnosed with NPH without the need for a tap test. Furthermore, correlation with CSF biomarkers can help differentiate NPH from other dementias, as NPH typically shows low levels of Aβ42 and pTau in the CSF, contrasting with patients with Alzheimer's. The use of the Radscale Score, which quantifies the severity of neuroradiological changes, can increase diagnostic accuracy of NPH and be an ally in practice. Thus, there is a need for an amplified diagnostic approach: detailed clinical evaluation, CSF biomarkers, and standardized radiological criteria to improve the accuracy of NPH diagnosis and differentiate it from other forms of dementia.

Overdrainage syndrome after idiopatic intracranial hypertension: a case report

Thaís dos Santos Scheid[1], Breno Rampeloti[1], Giuliana Moro[1], Caio de Lima Ferreira[1], Mayara Tszesnioski Maçaneiro[1], Laise Koenig de Lima[2], Natália Cardoso Darabas[2], Thabata Emanuelle Martins Nunes[2], Felipe Ibiapina dos Reis[1]

[1]Universidade da Região de Joinville, Joinville SC, Brazil.
[2]Hospital Municipal São José, Joinville SC, Brazil.

Correspondence: Thais dos Santos Scheid; Email: scheidthais@gmail.com.

Case presentation: A female patient, 47 years old, was admitted to the hospital with progressive right-sided amaurosis and severe visual loss. Physical examination showed a hyperemic optic disc with blurred edges, microhemorrhages and peripapillary exudates associated with macular edema from intraretinal fluid with attenuation of the foveal depression. The neuroimaging showed a partially empty sella and dilated optic nerve membranes, suggestive of idiopathic intracranial hypertension, as well as cerebrospinal fluid (CSF) opening pressure examination in spinal cord above 400mm/H2O. A lumboperitoneal shunt with a high-pressure device was performed 5 days after hospital admission, with significant visual improvement without complications. One month later, the patient was readmitted due to a history of falling from her own height, headache and persistent vomiting for 1 week. The examination revealed drowsiness, dysarthria, paresis of the lower limbs, esotropia in the right eye, papilledema and bilateral retinal detachment. Computed tomography showed erasure of cerebral cisterns, hyperdensity in the subarachnoid space and hypodensity in the bilateral cerebellum and pons. The patient was taken to the operating room, where was found ribbon ventricles, a posterior fossa with tonsillar herniation and a functioning shunt on digital pressure and test puncture. These findings are compatible with probable overdrainage despite the high-pressure shunt and it was decided to close the emergency valve. After the surgical approach, symptoms progressively improved and without loss of vision. **Discussion:** Idiopathic intracranial hypertension is a rare condition and without known cause that mainly affects young obese women. Clinical manifestations include chronic migraine-like headaches, progressive visual deterioration, and pulsatile tinnitus. The diagnosis must meet all five criteria: papilledema; no neurological deficit; no cause shown on imaging; normal cerebrospinal fluid; and elevated lumbar puncture opening pressure (greater than 250 mm/H2O) under proper puncture conditions. Imaging studies can suggest intracranial hypertension, but never used alone for diagnosis. Treatment should be aimed at treating the underlying cause, protecting vision and reducing headache morbidity. Overdrainage is an excessive drainage of cerebrospinal fluid, usually associated with valved shunt systems. In terms of management, replacement or closure of the valve usually resolves the clinical presentation. **Final comments:** The idiopathic intracranial hypertension presented by the patient in this report was well managed clinically and surgically in this case according to recent scientific recommendations and guidelines. The development of overdrainage syndrome, a complication of lumboperitoneal shunting, can occur especially in cases where the surgical approach was an emergency, as in the present report.

https://doi.org/10.5327/CBN241252

Overlap of Guillain-Barré syndrome variants: a case report

Marco Antônio Delazeri[1], Carollina Danezi Felin[1], Guilherme Vanik Pinto[1], Eduarda Rosa Fernandes[1], Carolina Heck Haubrich[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Hospital São Lucas, Porto Alegre RS, Brazil.

Correspondence: Marco Antônio Delazeri; Email: marco.delazeri@outlook.com.

Case presentation: A 63-year-old man, previously diabetic, hypertensive and with coronary artery disease, presents a subacute condition of paresthesias with an ascending and progressive onset, distal to proximal, grossly symmetrical, accompanied by paresis of the same characteristic. Evolving concomitantly with dysphagia, dysarthria and hypogeusia. The neurological examination confirmed the aforementioned condition, also showing facial paralysis with a peripheral pattern on the right, global areflexia and gait ataxia. Normal sensitivity. Computed tomography and magnetic resonance imaging of the brain are normal. Liquor: albuminocytologic dissociation. Electroneuromyographically compatible with demyelinating sensorimotor polyneuropathy in all four limbs, suggestive of Guillain-Barré Syndrome. The patient progresses with partial and spontaneous resolution of the condition, leaving only subsequent paresthesias and facial paresis. **Discussion:** Guillain-Barré syndrome or acute inflammatory polyradiculoneuropathy is a disease of the peripheral nervous system, mostly monophasic and predominantly preceded by vaccination or infectious conditions. Its clinical presentation is vast, however it classically presents as bilateral and symmetrical ascending flaccid paresis, distal to proximal, reaching its symptomatic nadir in two weeks. Considering its clinical variability, variants of the same disease were determined. In the report above we present a curious intersection of variants: acute inflammatory desmyelinating polyneuropathy (AIDP) classic and Miller-Fisher. It has a classic triad: gait ataxia, global arephexia and ophthalmoparesis. In this report, antibodies such as GTA1 and GQ1B could help to differentiate and classify it more precisely. Typically, it is treated with plasma exchange or immunoglobulin. It is important to assess respiratory dysfunction, with the option to use the Erasmus GBS Respiratory Insufficiency Score (EGRIS) to predict the probability of respiratory failure within the first week of admission in patients with the syndrome. **Final comments:** Guillain-Barré syndrome is a disease with a wide clinical presentation and potentially unfavorable outcomes if not promptly recognized and treated. Its variations are not always pure and can intersect with others, which is why we report this case.

https://doi.org/10.5327/CBN241253

Overlap of neuroectodermal syndromes: Sturge-Weber syndrome, Klippel-Trenaunay syndrome, and pigmentary vascular phakomatosis in a pediatric patient - a case report

Lourdes Helena Rabelo Dias[1], Luiz Augusto Fernandes da Silva[1], Cecília Secchin de Jesus[1], João Pedro Cuelhar Rodrigues[1], Marcela Lopes de Almeida[1], Bruno Antunes Contrucci[2], Ursula Thomé[2], Maria Karolina Arantes Assis Castro[1], Igor Mota Andrade[1], Maria Fernanda Alli Ahmad[1]

[1]Centro Universitário Estácio IDOMED, Ribeirão Preto SP, Brazil.
[2]Universidade de São Paulo, Hospital das Clinicas de Ribeirão Preto, Ribeirão Preto SP, Brazil.

Correspondence: Luiz Augusto Fernandes da Silva; Email: fernandeslaugusto@gmail.com.

Case presentation: Female, four years old, non-consanguineous parents, uneventful pregnancy and perinatal period, was referred due the hypothesis of Sturge-Weber syndrome (SWS). Since birth, body spots have been observed, evolving with focal epilepsy starting at five months of age, with daily seizures despite regular use antiepileptic medication (carbamazepine, phenobarbital and lamotrigine). Left hemiface with "port-wine stain" and violet spots scattered in the right frontal region, right hemibody, upper left hemibody, posterior region, genitals, and lower limbs; slight soft tissue enlargement on the right; eyebrow thinning; bilateral congenital glaucoma and developmental delay was presented. Cranial CT scan at 12 months showed right parietal volume increasing suggestive of hematoma. EEG at two years revealed diffuse asymmetric encephalopathy on the left cerebral hemisphere and focal base epilepsy. MRI and angiotomography suggested SWS, with atrophy and probable pial angiomas, cortical-subcortical calcifications on the left, choroid plexus prominent, and bilateral deep venous drainage, especially on the left, diagnostic hypothesis of Pigmentary Vascular Phakomatosis, SWS and Klippel-Trenaunay syndrome (KTS). **Discussion:** The overlap of neuroectodermal syndromes as observed in this case, involves multiple complex anomalies. SWS is the third most common phakomatosis, characterized as neurocutaneous disease with angiomas on the face, choroid, and leptomeninges due to somatic or mosaic mutations in GNAQ gene. Pathophysiology involves deficiency of superficial cortical venous circulation, leading to stasis and ischemic changes. Manifestations include various epileptic seizures, plegias, intellectual disability, glaucoma, and dermal capillary malformations resulting in port-wine stain. KTS is rare congenital mesodermal disease of undefined etiology, characterized by port-wine stain, venous malformations and hypertrophy of bones and soft tissues, usually affecting a single lower limb but can involve trunk and face. The overlap of SWS and KTS increases the phlebitis, bleeding, deep vein thrombosis, pulmonary embolism, hemoperitoneum, hemothorax, and chronic venous insufficiency risks. Hemangiomas and varices are usually presented at birth and become more prominent during adolescence. Venous abnormalities include agenesis, hypoplasia, atresia, valvular incompetence, and deep venous system occlusion due to fibrosis. Pigmentary Vascular Phakomatosis Cesio-Marmorata, vascular malformation with systemic manifestations, affects vision associated with various systemic and cutaneous abnormalities, including Sturge-Weber and Klippel-Trenaunay syndromes. The overlap of these neuroectodermal syndromes highlights the need of deeper studies for better etiological diagnosis and viable therapies. **Final comments:** Our case contributes to scientific knowledge of these rare neurocutaneous diseases, aiding in management and definition.

https://doi.org/10.5327/CBN241254

Overlap of neuromyelitis optica spectrum disorder and systemic lupus erythematosus: a case report

Alexandre Baldissera[1], Marcos Madeira de Lima[1], Eduardo Drews Amorim[1], Alessandro Finkelsztejn[1], Renata Gomes Londero[1]

[1]Hospital de Clínicas de Porto Alegre, Porto Alegre RS, Brazil.

Correspondence: Eduardo Drews Amorim; Email: eduardodrewsamorim@gmail.com.

Case presentation: A 34-year-old woman with a history of Systemic Lupus Erythematosus (SLE) and popliteal vein thrombosis on warfarin presented with paraparesis, hypoesthesia, and urinary incontinence for about a week. One day before arriving at the emergency department, her condition progressed to paraplegia. Cervical and thoracic spine MRI demonstrated longitudinally extensive myelitis from C7 to D11. There was no evidence of infection, and pulse therapy with methylprednisolone 1g was initiated. After two days of pulse therapy, the patient developed a fever spike and productive cough. A lumbar puncture performed two days after pulse therapy (previously contraindicated due to coumarin intoxication) diagnosed probable meningoencephalitis associated with autoimmune myelitis. Antibiotic therapy was initiated for pulmonary and neurological coverage, and pulse therapy was suspended (immunosuppression with methylprednisolone 1mg/kg was maintained). An autoantibody test revealed positive anti-aquaporin-4 (anti-AQP4), diagnosing Neuromyelitis Optica Spectrum Disorder (NMOSD) with positive anti-AQP4. After controlling the infectious condition, plasmapheresis was performed along with the resumption of pulse therapy, resulting in the return of tactile sensation in the lower limbs. The patient continued treatment with Rituximab as an immunomodulatory therapy. She was diagnosed with longitudinally extensive myelitis due to the overlap syndrome of NMOSD and SLE complicated by meningoencephalitis. **Discussion:** The patient presented a complex clinical picture of progressive paraparesis that evolved into paraplegia, associated with active SLE. MRI revealed longitudinally extensive myelitis, a distinctive feature of NMOSD. The presence of anti-AQP4 antibodies was crucial for diagnosing NMOSD, a condition that often overlaps with other autoimmune diseases such as SLE. The overlap syndrome of NMOSD and SLE presents a significant challenge in diagnosis and treatment. The co-occurrence of these diseases can result in atypical clinical presentations and additional complications, such as secondary infections and variable responses to immunosuppressive treatment. The therapeutic approach for patients with this overlap syndrome must be carefully planned to address both autoimmune activity and associated complications. **Final comments:** This case highlights the importance of considering complex differential diagnoses in patients with SLE and severe neurological manifestations. The overlap syndrome of NMOSD and SLE requires a multidisciplinary approach for effective management. Early identification and appropriate treatment, including the use of intensive immunomodulatory therapies and management of infectious complications, are essential to improving the prognosis and quality of life of patients.

https://doi.org/10.5327/CBN241255

Overlap syndrome: systemic lupus erythematosus and dermatopolymyositis

Yasmin de Freitas Santos[1], Luis Fernando Guimarães[1], Marianna Lessa Coelho Vieira de Quadros[2], Rebecca Alves Marinho[2], Esther Alves Marinho[2], Júlia Rodrigues de Senna Mendonça[2], Osvaldo Pantoja de Oliveira[1], Marina Brasileiro Cesar Leitão[1], Luiz Guilherme Gerhardt Fernandes[1], Maria Luiza Levindo Coelho Martinis[1]

[1]Hospital Federal dos Servidores do Estado, Rio de Janeiro RJ, Brazil.
[2]Universidade Estadual de Montes Claros, Montes Claros MG, Brazil.

Correspondence: Luis Fernando Guimarães; Email: luisguimaraesneuro@gmail.com.

Case presentation: A female patient, 14 years old, presented prostration and asthenia, fifty days prior to admission to the hospital . She evolved with night fever (38.3), weight loss of 06 kg, diffuse alopecia,proximal weakness of the upper and lower limbs and hyperemic, non-pruritic papules on the limbs and trunk that have evolved into plaques. These lesions were not influenced by sun exposure. The patient has no previous history of comorbidities or rheumatic diseases in the family. Her neurological examination had the following findings: predominantly proximal tetraparesis in the upper (4/5) and lower (5/5) limbs; arthritis in wrists, ankles and knees; heliotrope bilaterally; erythematous plaques in the trunk region, hypophonetic sounds on cardiac auscultation and mild splenomegaly. Laboratory examination indicated high muscle injury markers, positive antibodies, among others (Table 01); Doppler echocardiogram with signs of pericarditis and an electroneuromyography with a myopathic pattern. The muscle biopsy showed skeletal striated tissue with atrophy, edema, discrete mononuclear infiltrate, and the presence of associated focal necrosis. The diagnosis of SLE Overlap and DPM was considered, and then prednisone, hydroxychloroquine and methotrexate were started, with significant clinical improvement. The patient remains under outpatient rheumatology follow-up. **Discussion:** The overlap syndrome (Overlap) is characterized by the presence of two or more autoimmune diseases in the same patient, following the formal criteria for the individual diagnosis of each one. Overlap in Systemic Lupus Erythematosus (SLE) and Dermatopolymyositis (DPM) is rare, there no data mentioning its incidence in adolescents. Cases reports of patients with SLE and Myositis, regardless of the presence of dermatological alterations are described with an incidence between 4% and 16%, without analyzis of a specific age group. Overlap of SLE and DPM will be reported in a 14-year-old patient. **Final comments:** The Overlap between SLE and DPM is rare and the context of overlapping of juvenile DPM and SLE is even rarer. The importance of electroneuromyography is emphasized as an important complementary test to confirm myopathic impairment with classic findings of the syndrome on examination.

Correspondence: Maria Luiza Leme Camargo; Email: maria.luiza.camargo@uni9.edu.br.

Background: Acute bacterial meningitis is defined as an infectious process affecting the leptomeninges and the subarachnoid space. It is primarily caused by the agent Neisseria meningitidis, transmitted through prolonged and close contact with the patient's nasopharyngeal secretions. In Brazil, this infection presents a 20% mortality rate in confirmed cases. Given its high mortality and morbidity, coupled with childhood vaccination schedules, recognizing symptoms and mapping the epidemiological profile from 0 to 14 years old in the Southeast becomes crucial for better directing prevention efforts and public health policies. **Objective:** Analyzing the epidemiological profile of patients aged 0 to 14 with meningitis in the Southeast. **Methods:** This is a descriptive, retrospective, and quantitative epidemiological study, analyzing the period from 2018 to 2023 in the Southeast region of Brazil. Data were obtained from the Hospital Information System (SIH), accessible through the Department of Informatics of the Unified Health System (DATASUS). The analysis considered variables such as sex, age range from 0 to 14 years, number of hospitalizations, and number of deaths related to meningococcal infection in childhood. Data collection was conducted in April 2024. **Results:** A total of 807 hospitalizations due to meningococcal infection were reported during the analyzed period and location. Hospitalizations showed a decreasing trend from 2018 (211) to 2021 (70), with an increase in 2022 (96) and 2023 (138). Males accounted for 54.52% of notifications. Regarding age group, children aged 1 to 4 years were most affected (290), followed by those under 1 year (249), 5 to 9 years ranked third (170), and the least affected among the age groups analyzed were those aged 10 to 14 years (98). There were 69 deaths from 2018 to 2023 in the 0 to 14 age group, with infants under 1 year being the most affected (24), followed by those aged 1 to 4 years (22). **Conclusion:** A declining trend in hospitalization rates due to meningococcal infection in the 0 to 14 age group was observed until 2021. However, from this point onwards, there was a significant increase in 2022, followed by an even more pronounced increase in 2023. This pattern shift suggests the urgent need for review of prevention and control strategies, especially in the Southeast region. The implementation of effective measures, such as vaccination programs, becomes crucial to reverse this worrying trend and mitigate the impact of meningococcal infection on the population in question.

Overview of bacterial meningitis in brazil: analysis of variables in the last five years

Geovanna Barros Rocha[1], Sávio Roberto Silva Costa[1], Lucas Miquilini de Arruda Farias[1], Douglas Ferreira Pereira[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Geovanna Barros Rocha; Email: geovannaroccha@outlook.com.

Background: Bacterial meningitis is defined as an inflammation of the meninges of infectious origin, commonly caused by respiratory secretions, however, whose access routes to the meninges are hematogenous, due to contiguity or direct access. The etiological agent is linked to factors such as age, vaccination status, site of infection, host susceptibility and other mechanisms, however, Neisseria meningitidis, Haemophilus influenzae and Streptococcus pneumoniae are most commonly found. It is an acute and serious notifiable disease that, despite the lower incidence following advances in immunizations, maintains high rates of morbidity and mortality and motor, sensory and cognitive sequelae. **Objective:** To analyze trends in bacterial meningitis in Brazil and associated factors, from 2019 to 2023, to guide better prevention and treatment strategies. **Methods:** This study adopts an observational, cross-sectional and descriptive approach, using quantitative data obtained from the Diseases and Notifiable Diseases system (SINAN), made available by the Department of Informatics of the Unified Health System (DATASUS). The variables considered include sex, race, age group, region of residence, etiology and clinical evolution. Data analysis was performed using Biostat 5.3 software. **Results:** During the observed period, there were 59,787 confirmed cases of meningitis in Brazil, with the majority of cases occurring in the southeast region, with 52.2%, while the central-west region reported fewer cases (4.3%). Regarding gender, 58.4% were male. In relation to ethnicity, the most affected ethnicity was white, with 47.31% of cases, while the least affected ethnicity was indigenous, with 222 cases. Regarding age, the most affected age group was between 20 and 59 years old, with 36.3%. Regarding the type of meningitis, the majority of registered cases were viral meningitis, with 43.9%, followed by unspecified meningitis, with 18.2%. The vast majority

of cases evolved with the patient's discharge, with 75.6%, while there were around 10% of deaths due to meningitis in the period studied. **Conclusion:** It was observed that, in the last 5 years, the majority of meningitis cases occurred in the southeast region, with males being slightly more affected. The most affected ethnic group is white. Regarding age, the most affected group was between 20 and 59 years old. The majority of cases were viral meningitis, with the vast majority of cases being discharged from hospital. Therefore, it is important that prevalent epidemiological factors are taken into consideration in order to plan strategic and effective actions to reduce the occurrence of meningitis in the country.

Overview of childhood stroke by regions of Brazil in the pre- and post-COVID-19 pandemic periods

Paula Cely da Silva Torres[1], Karollyne de Castro Santos[1], Alexandre David do Nascimento Santos[1], Ester Costa Lima[1], Fabrício Rodrigues Barbosa[1], Victor Alex Purificação de Castro Neves[1], Paulo Vitor Silva Santos[1], Bruna Rafaela Bastos Freite Quixabeira[1], Jéssica de Andrade Ribeiro Lima[1], Lucas Granja Kaupert[1]

[1]Universidade do Estado da Bahia, Salvador BA, Brazil.

Correspondence: Ester Costa Lima; Email: ester.enfe@gmail.com.

Background: Stroke in the pediatric population is a rare neurological disorder, however, it is associated with more severe outcomes, being among the ten main causes of long-term neurological, motor and cognitive impairments, contributing to significant morbidity and mortality. In the context of the COVID-19 pandemic, it has been suggested that coronavirus infection is linked to an increased risk of stroke in childhood, leading to substantial economic costs for society. **Objective:** To evaluate the epidemiological profile and costs of hospitalizations for stroke in children aged 0 to 19 years in Brazil, in the pre- and post-COVID-19 pandemic periods. **Methods:** Ecological study using SIH/DATASUS data on ischemic and hemorrhagic stroke. The period analyzed was from January 2018 to December 2023. Data were collected on the number of hospitalizations, type of care, and total costs according to place of residence. Microsoft Excel® 2016 software was used for data analysis. The variables analyzed were: year of hospitalization, sex, color/race, age group, mortality rate, and regions of the federation. **Results:** During the period analyzed, there were 4621 hospitalizations in Brazil. Among the regions, the Northeast stood out with the highest number of hospitalizations (36.36%), followed by the Southeast (34.75%) and South (13.44%). It was observed that the years with the most cases were 2022 (18.18%) and 2023 (18.03%), while the years 2020 and 2018 obtained the lowest values (13.78% vs. 15.75%), highlighting a considerable variation, probably linked to the post- and pre-pandemic context. Of the services listed, most were emergency (92.21%). There was no significant discrepancy regarding gender, with females being only slightly higher than males (50.36% vs. 49.64%). Regarding color/race and age group, brown individuals (48.17%), between 15 and 19 years old (51.72%) were the ones with the highest number of hospitalizations. The total value of the services provided in the period was R$9,150,002.66. Among the regions of the country, the Southeast was the one with the highest expenses (R$3,569,781.11) and the year with the highest costs was 2023 (R$1,777,286.28). The national mortality rate corresponded to 7.88%, with its peak observed in 2021 (8.63%) and 2022 (8.21%) and the lowest value found in 2018 (7.14%), in the pre-pandemic period, mainly affecting children under 1 year of age (13.31%). **Conclusion:** It is noted that the profile of children hospitalized for stroke in the pre- and post-pandemic period has undergone considerable variations, with an increase in cases registered in the post-pandemic period, especially in the Northeast and Southeast regions, in individuals aged 15-19 years. In addition, there was an increase in costs during the period, and in the mortality rate in the years 2021 and 2022, reflecting the possible increase in notifications and identification of suspected cases, concomitantly with the decline of the pandemic.

https://doi.org/10.5327/CBN241259

Overview of Parkinson's hospitalizations in Brazil from 2019 to 2023

Aline Teixeira[1], Ana Clara Lacerda Freitas[1], Laysa de Souza Maia[2], Andressa Gonçalves Vicente[3], Ana Alice Lemos Lima[4], Gabriela Hernandez Dumani[5], Ana Cristina Carvalho e Silva[3], Estefany Moreno de Souza[6], Geovana Franklim Gomes e Silva[7], Juliana Braga Rodrigies de Castro[8]

[8]Universidade Estadual do Ceará, Fortaleza CE, Brazil.

Correspondence: Laysa de Souza Maia; Email: laysamaia1503@gmail.com.

Background: Parkinson's disease is a neurological disorder of poorly understood and multifactorial etiology, characterized by the degeneration of dopaminergic neurons located in the substantia nigra of the brain. These cells are responsible for the production of the neurotransmitter dopamine, which is essential for the conduction of nerve impulses throughout the body. Deficiency or reduction of dopamine compromises bodily movements, resulting in tremors, bradykinesia, muscle rigidity, imbalance, and changes in speech and writing. **Objective:** To analyze the profile of hospital admissions for the treatment of Parkinson's disease throughout Brazil over the past five years. **Methods:** This is an observational, descriptive, and cross-sectional study using secondary data on Parkinson's disease available from DATASUS - the Hospital Information System of the Brazilian Unified Health System (SUS), covering the period from January 2019 to December 2023. **Results:** Between 2019 and 2023, there were 4,399 hospital admissions for Parkinson's disease. The highest number of cases was recorded in 2023, with 1,099 cases, while the lowest occurrence was in 2021, with 747 cases. In 2020, there was one admission per 100,000 inhabitants, possibly influenced by the COVID-19 pandemic, suggesting potential underreporting. During the study period, 345 people died due to Parkinson's disease. The highest incidence rates were observed in 2023, 2019, and 2022, with 0.47, 0.54, and 0.46 respectively. The highest incidence rates were recorded in the Southeast and South regions of the country. The average incidence rate was 0.43% and the mortality rate was 0.03%. The case fatality rate was 7.87%. The Southeast region recorded the highest incidence rate of 0.98% and mortality rate of 0.07%. The highest case fatality rate was in the Northeast region (9.62%), while the South region had the lowest values. Regarding gender, males were the most affected, accounting for 2,646 admissions (60.15%). The ethnicity with the highest self-reported hospital admissions was White, with 2,273 admissions (51.67%). The majority of hospital admissions were among individuals aged 60 to 69 years, responsible for 2,760 admissions (26.82%), followed by those aged 70 to 79 years, with 2,716 admissions (26.32%). **Conclusion:** Thus, it can be stated that hospital admissions for Parkinson's disease among the male population can be considered a public health issue that requires action from the government and Brazilian society as a whole. In the context of Parkinson's disease, the demand for encouraging studies based on collected data is significant, indicating a high contingency in evaluating data related to deaths due to Parkinson's disease. Therefore, it is pertinent to understand and suggest that new studies addressing this issue should be conducted periodically, to expand data visualization, thereby enhancing the technical-scientific field and the implementation of public policies.

Background: Meningitis is characterized by an inflammation of the leptomeninges (arachnoid and pia mater) and cerebrospinal fluid (CSF) that often occurs due to hematogenous dissemination. It can be caused by viruses, fungi and bacteria, including H. influenzae (Hib), N. meningitidis and S. pneumoniae. The preventive measures implemented by the Unified Health System (SUS) include the administration of the meningococcal C vaccine, targeting serotype C of Neisseria meningitidis, the 10-valent pneumococcal conjugate vaccine (PCV10), which encompasses 10 serotypes of Streptococcus pneumoniae, and the pentavalent vaccine (DTPw-HB/Hib), which combines the diphtheria, tetanus, pertussis (DTPw), hepatitis B (HB), and Haemophilus influenzae type B (Hib) conjugate vaccines, that prevents Hib meningitis. **Objective:** To establish an epidemiological overview of the number of pediatric hospitalizations due to bacterial meningitis in Brazil, relating it to meningococcal C, pneumococcal-10, and pentavalent vaccines coverage in the country between 2013 and 2022. **Methods:** The following research consists of an epidemiological, descriptive and cross-sectional study. Data were obtained from the DATASUS database (TABNET) from 2013 to 2022 in all regions of Brazil. The analysis focused on the number of pediatric hospitalizations in the age groups from 0 to 9 years and bacterial meningitis vaccines available in Basic Health Units (UBS) coverage, in addition to the main causes of the disease over the years in the country. **Results:** According to the data, bacterial etiology was the second leading cause of meningitis in the pediatric population between 2013 and 2022, accounting for 13,6% of cases. In 2013, there were 28 children hospitalized due to bacterial meningitis, a number that grew to 678 the following year. Hospitalizations increased progressively over the years, reaching a peak of 1510 in 2019. There was a decrease in 2020 and 2021, with 877 hospitalizations. However, in the last two years this number has risen again, reaching a record of 1546 in 2022. Simultaneously, the vaccination coverage for meningitis has been decreasing over the years across all regions of the country. The meningococcal C vaccine, which had a coverage of 99.7% in 2013, decreased to 72.17% in 2021 and had a slight increase in 2022 (78,63%). Pneumococcal-10 coverage was 93.57% in 2013 and decreased to 74.84% in 2021, rising again in 2022 (81.51%). On the other hand, the

pentavalent vaccine had a coverage of 95.8% in 2013, which gradually decreased to 70.7% in 2019, and increased in the subsequent years, reaching 77.2% in 2022. **Conclusion:** The period from 2013 to 2022 was marked by an increase in pediatric hospitalizations due to bacterial meningitis, simultaneously with a decrease in vaccination coverage in Brazil, thus highlighting the importance of vaccines in order to eradicate diseases. A decline in hospitalizations was observed in the years 2020 and 2021.

https://doi.org/10.5327/CBN241261

Overview of traumatic brain injury in young adults

Tainá Reis Martins[1], Wívian Maria Pires Figueredo[1], Esther Pinto Veloso Mendes[1], Karina Andrade de Prince[1]

[1]Centro Universitário FIPMoc, Montes Claros MG, Brazil.

Correspondence: Tainá Reis Martins; Email: taina2002@hotmail.com.

Background: Traumatic brain injury (TBI) is defined as an injury due to external biomechanical forces, which generate anatomical or functional brain impairment. TBI is considered the leading cause of disability and death in the population under 45 years of age worldwide. In the Brazilian scenario it represents an important public health issue, due to the high cost of resources for the treatment of its victims. **Objective:** Analyzing the aspects related to traumatic brain injury in young adults in the last 10 years. **Methods:** This is an ecological time series study that used the database of the Health Information System (TABNET), provided by the SUS Department of Informatics (DATASUS). In the SUS Hospital Information System (SIH/SUS), information on TBI in the age group between 20 and 59 was collected from January 2014 to December 2023. Gender, hospital cost, nature of care, average hospitalization rate and deaths were analyzed. **Results:** In the period analyzed, a total of 579,321 hospitalizations with the highest number of cases were reported in 2014 (61,292). There was a decrease of 10.3% (6,342) in hospitalizations between 2014 and 2020 and an increase of 7.9% (4,375) in the period from 2020 to 2023. The region with the most hospitalizations was in the Southeast, with 38.5% (223,162). The highest number of cases occurred in male patients, which represented 82.7% (479,643) of hospitalizations, being the age group most affected by TBI, common to both genders, from 20 to 29 years old, accounting for 29.1% (168,912). In contrast, the mortality rate decreased 11.9% (9.4 to 8.3), in turn the highest mortality rate occurred between 50 and 59 years of age, with an index of 11.2. The region with the highest mortality rate was Northeast, with a rate of 10. In character, 85.5% (495,318) of the visits were emergency. The highest total number of hospitalizations was in 2023 (R$ 145,001,068.62), with an increase from 2014 to 2023 of 46.8% (R$ 46,254,166.74). Male patients comprise 86.6% (R$ 997,181,140.64) of total expenses. The average value of hospitalization increased by 51.7% (R$ 833.09). **Conclusion:** TBI hospitalizations in young adults predominated in men aged 20 to 29, with high mortality between 50 and 59 years of age. The reasons for the increase in the number of hospitalizations in the last 3 years should be analyzed, as well as the justifications for the increase in the necessary financial contribution over the last few years, in order to reduce, respectively, morbidity and mortality and health system workload.

Oxidative stress and mitochondrial dysfunction contributes to postoperative cognitive dysfunction in elderly rats dependent on NLRP3 activation

Edgar Pereira[1], Sandra Bonfantea[1], Lucinéia Gainski Danielskia[1], Nathalya Camila Cruz Guerra Correa[1], Khiany Mathias[1], Solange Stork[1], Richard Simon Machado[1], Naila Maciel Andrade[1], Maria Amélia[1], Fabricia Petronilho[1]

[1]Universidade do Extremo Sul Catarinense, Criciúma SC, Brazil.

Correspondence: Edgar Pereira; Email: roserp8564@gmail.com.

Postoperative cognitive dysfunction (POCD), a complication following procedures such as orthopedic surgery and is associated with a worsened prognosis, especially in the elderly population. Several mechanisms have been proposed for communication between the immune system and the brain after surgery. In an experimental tibial fracture (TF) model, we aimed to understand the role of the NLR family pyrin domain containing 3 (NLRP3) on oxidative stress and mitochondrial dysfunction as mechanisms underlying POCD in aged and adult rats. Adult or aged male Wistar rats were subjected to the TF model and received intracerebroventricular saline or MCC950 (140 ng/kg), a specific small-molecule inhibitor that selectively blocks activation of the NLRP3 inflammasome. We followed the control (sham) and TF groups treated with MCC950 or saline for seven days to determine cognitive function and survival. The prefrontal cortex and hippocampus were isolated for NLRP3 evaluation, cytokine analysis, oxidative stress measurements, myeloperoxidase activity, nitric oxide formation, mitochondrial respiratory chain enzymes, and succinate dehydrogenase (SDH) activity. Seven days after TF induction, NLRP3 levels increased in the hippocampus and prefrontal cortex in both ages, showed an enhancement in aged rats compared to adults, and experienced a reversal with MCC950 administration. The administration of MCC950 restored memory, IL-1β and IL-10 levels, nitrite/nitrate, lipid peroxidation in the hippocampus and prefrontal cortex, and preserved catalase activity in the prefrontal cortex in aged rats. At the same age, the complex I activity alteration in both regions and complex II, IV, and SDH in the prefrontal cortex were reversed. In conclusion, brain oxidative stress and mitochondrial dysfunction after orthopedic surgery led to POCD, which is linked to higher NLRP3 activation, mostly in elderly rats.

https://doi.org/10.5327/CBN241263

P2Y12 inhibitors plus aspirin versus aspirin in patients with stroke or transient ischemic attack: an updated meta-analysis of randomized controlled trials

Ocílio de Deus da Rocha Ribeiro Gonçalves[1], Hilaria Saugo Faria[2], Victor Gonçalves Soares[3], Rian Barreto Arrais Rodrigues de Morais[4], João Lucas de Magalhães Leal Moreira[5], Elísio Bulhões[6], Lucas Cael Azevedo Ramos Bendaham[7], Marianna Leite[8], Márcio Yuri Ferreira[9], Yafell Serulle[9]

Correspondence: Ocílio de Deus da Rocha Ribeiro Gonçalves; Email: ocilio41@gmail.com.

Background: Several randomized controlled trials (RCTs) have shown that combining P2Y12 inhibitors with aspirin may improve National Institutes of Health Stroke Scale (NIHSS) and reduce recurrent strokes. However, their efficacy remains unclear. Therefore, we conducted an updated systematic review and meta-analysis to compare these drugs with aspirin alone. **Methods:** We systematically searched PubMed, Embase, and Cochrane Central for RCTs comparing P2Y12 inhibitors plus aspirin with aspirin alone in patients with stroke or transient ischemic attack (TIA). Primary outcomes were all-cause mortality, major bleeding, and stroke recurrence. We performed a subgroup analysis to stratify patients according to their NIHSS. A random effects model was used to calculate the risk ratios (RRs) with 95% confidence intervals. Statistical analysis was performed using R (version 4.3.2). **Results:** Fifteen studies were included, comprising 51,209 patients, of whom 12,416 (25.3%) received clopidogrel, and 5,523 (11.2%) received ticagrelor. Follow-up ranged from 7 days to 3 years. P2Y12 inhibitors plus aspirin significantly reduced stroke recurrence (RR 0.78; 95% CI = 0.71-0.87; p<0.05; I2=0%), but increased the incidence of all-cause mortality (RR 1.38; 95% CI = 1.11-1.72; p< 0.05; I2=0%) and major bleeding (RR 2.47; 95% CI = 1.21-5.07; p>0.05; I2=0%). There was no difference between groups in all-cause mortality in patients with NIHSS ≤3 (RR 1.27; 95% CI = 0.88-1.82; p>0.05; I2=0%) or NIHSS ≤10 (RR 1.26; 95% CI = 0.91-1.75; p>0.05; I2=0%). **Conclusion:** In patients with stroke or TIA, the use of P2Y12 inhibitors plus aspirin increased the incidence of all-cause mortality and major bleeding. However, the drug combination reduced stroke recurrence. There was no difference between groups in all-cause mortality in patients with mild and moderate NIHSS.

https://doi.org/10.5327/CBN241264

P3 event-related potentials before and after lumbar puncture as auxiliary tool in the diagnosis of idiopathic normal pressure hydrocephalus: preliminary results

Liliane Aparecida Fagundes Silva[1], Lucas Pinto Mielle[1], Nayara Pereira Santos[1], Heloise Cazangi Borges[2], Helena Alessi[3], Fernando Vieira Pereira[3], Renan Barros Domingues[3], Carlos Alberto Salzedas Giafferi[3], Sandro Luíz de Andrade Matas[4], Carla Gentile Matas[1]

[1]Universidade de São Paulo, São Paulo SP, Brazil.
[2]Centro Universitário Nossa Senhora do Patrocínio, Itu SP, Brazil
[3]Laboratório Senne Liquor de São Paulo, São Paulo SP, Brazil.
[4]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Sandro Luiz de Andrade Matas; Email: sandro.matas@gmail.com.

Background: Idiopathic Normal Pressure Hydrocephalus (iNPH) is characterized by an abnormal enlargement of the cerebral ventricles with increased cerebrospinal fluid (CSF) in the elderly population. For the diagnosis, the CSF Tap-test (TT) is indicated, in which a neuropsychological and gait assessment is carried out before and after a CSF lumbar puncture, and the clinical improvement, whether in gait or cognitive performance, indicates a positive predictive result for iNPH. Despite this, CSF TT remains with low clinical sensibility, requiring complementary evaluation methods to improve the diagnosis accuracy. The P3 is a cognitive potential that has emerged as a neurophysiological biomarker in several other pathologies. Thus, it is of scientific and clinical interest to evaluate its applicability as an additional method during CSF TT, minimizing risks to the individual and complementing the diagnosis of iNPH. **Objective:** This study investigates whether patients with a positive predictive value of the CSF TT for iNPH exhibit improved P3 auditory responses after lumbar puncture. **Methods:** Clinical study approved by the Research Projects Appraisal Ethics Committee

institutional, under number 5.964.351. Forty elderly people suspected of iNPH were included in the study, 20 had a negative, and 20 had a positive predictive value of the CSF TT, both sexes, aged between 62 and 86 years old. Besides gait and neuropsychological assessment, auditory P3 responses were recorded with an oddball paradigm before and after lumbar puncture with the removal of 30 to 40 ml of CSF. The changes in P3 auditory responses were compared between the groups by ANOVA test. **Results:** Subjects with a positive predictive value of the CSF TT had a significant decrease in the P3 latency in the right ear, around 27.65 ms, after lumbar puncture compared to subjects with a negative predictive value of the CSF TT. The auditory P3 response is considered a cognitive component and reflects the attentional response to the stimulus, related to the integrity of cognitive functions, providing information on auditory abilities, such as attention and auditory discrimination, and temporal processing. No increase in amplitude was observed in subjects with a positive CSF TT predictive result. **Conclusion:** The decrease in latency of the P3 auditory response after lumbar puncture was associated with the positive predictive value of CSF. Thus, the latency analysis of this component has shown promising for supporting the CSF TT outcome of subjects with suspected iNPH.

https://doi.org/10.5327/CBN241265

Pain and fatigue in amyotrophic lateral sclerosis: a multi-method study

Tatiana Souza Ribeiro[1], Stephano Tomaz da Silva[1], Letícia Maria de Queiroz Aquino[1], Diogo Neres Aires[1], Aline Alves de Souza[1], Luciana Protásio de Melo[1], Lorenna Raquel Dantas de Macedo Borges[1], Ricardo Alexsandro de Medeiros Valentim[1], Ana Raquel Rodrigues Lindquist[1]

[1]Universidade Federal do Rio Grande do Norte, Natal RN, Brazil.

Correspondence: Tatiana Souza Ribeiro; Email: tatiana.ribeiro@ufrn.br.

Background: Pain and fatigue are frequently reported symptoms by individuals with Amyotrophic Lateral Sclerosis (ALS). However, the presentation of these symptoms in populations with the condition remains uncertain. Additionally, the literature is controversial regarding the efficacy of physiotherapy practices in improving these symptoms. **Objective:** To analyze the profile of pain and fatigue symptoms in a Brazilian sample of individuals with ALS, as well as to identify evidence-based physiotherapy practices for treating these symptoms. **Methods:** This is a multi-method study composed of a prospective cross-sectional design and a systematic retrospective design. Individuals with ALS were recruited intentionally, using a non-probabilistic sampling method. Upon agreeing to participate in the research, they were assessed using a specific evaluation form, and data on pain and fatigue levels were collected. The measurement instruments used were the Fatigue Severity Scale, the Visual Analogue Scale, and a body diagram. Data analysis was descriptive, and we also categorized fatigue (presence/absence). The study searches were conducted in four databases: MEDLINE, CENTRAL, EMBASE, and PEDro. The risk of bias and the quality of evidence were assessed using the PEDro scale, the Downs and Black scale, and the Scottish Intercollegiate Guidelines Network, respectively. **Results:** Data were collected from 72 individuals with ALS. The sample had an average of 4.31 points on the Visual Analogue Scale and 37.2 points on the Fatigue Severity Scale, indicating moderate levels of symptoms. The systematic retrospective design, after the searches, yielded 16,747 references. Following the selection process, 13 included studies identified various physiotherapy practices for treating pain and fatigue; however, the evidence analysis pointed to uncertainty regarding the effects. **Conclusion:** The prospective analysis of the pain and fatigue profile in individuals with ALS in Brazil revealed moderate levels of both symptoms. The systematic retrospective analysis, in turn, indicated uncertainty about the effect of physiotherapy on the studied symptoms.

Pain-related evoked potentials uncovers small fiber damage in hereditary transthyretin amyloidosis with polyneuropathy

Renan Flavio de França Nunes[1], Maria Paula Carvalho Azevedo[1], Alberto Rolim Muro Martinez[1], Marcondes Cavalcante França Junior[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Renan Flavio de Franca Nunes; Email: renanunes@uol.com.br.

Background: Pain-related evoked potentials (PrEP) are a valuable neurophysiological tool for screening small fiber neuropathy. They have proven useful in diagnosing various neuropathies; however, no study has yet used PrEP to investigate small fiber damage in ATTRv-PN. **Objective:** To determine the damage pattern using a non-invasive approach. **Methods:** We evaluated 30 genetically confirmed ATTRv-PN patients, dividing them into two groups: 17 symptomatic individuals, identified based on symptoms consistent with the diagnosis, and 13 pre-symptomatic individuals, along with 23 age- and sex-matched controls. The subjects underwent detailed clinical examinations and PrEP evaluations on the sensory nerves of the arms (median) and legs (superficial fibular). Subsequently, we compared PrEP latencies (negative peak) and the frequency of absent PrEP responses in nerves with abnormal sensory function. **Results:** The mean age was 45 years for symptomatic and 45 for pre-symptomatic ans symptomatic patients. The main mutation was V30M (26 out of 30 cases). PrEP N1 latency was significantly prolonged in the symptomatic group compared to the pre-symptomatic group in arms (180.46+/-23.72 vs. 139.83+/-13.6ms, Student's t-test p<0.01) and controls (180.46 +/-23.72 vs. 132.2 +/- 15.79ms, Student's t-test p<0.01). The proportion of absent PrEP responses was also higher in the symptomatic group compared to the pre-symptomatic group in legs (Fisher's p<0.01) and controls (Fisher's p<0.01). The comparison of N1 latencies between pre-symptomatic individuals and controls did not reveal statistically significant differences in either the upper limbs (139.83±13.06ms vs. 127.67±22.7ms, Student's t-test p=0.12) or the lower limbs (166.25±32.82ms vs. 151.45±29.74ms, Student's t-test p=0.27). **Conclusion:** Although preliminary, these results suggest that pain-related evoked potentials (PrEP) may be a valuable tool for assessing small fiber damage in patients with ATTRv-PN. PrEP could potentially offer a non-invasive method to identify and monitor neuropathic changes in these individuals, providing important insights into disease progression and aiding in early diagnosis. However, further studies with larger sample sizes and comprehensive methodologies are necessary to validate these findings and establish standardized protocols for PrEP use in clinical practice.

PAR-2 monoclonal antibody as a treatment for migraine: a systematic review

Ryan Lucas Barbosa Oliveira[1], Mariana Araújo Oliveira Barbosa Rocha[1], Maria Beatriz Cavalcante Brêda[1], Laís Souza da Silva Vitorino[1], Maria Danyelle Farias de Oliveira[1], William Correia da Silva Filho[1], Maryanne Maria Simplício Santos[1], Taíssa Kelly Novais Veiga[1], Valdirene Maria de Barros Barbosa[2]

[1]Universidade Federal de Alagoas, Arapiraca AL, Brazil.
[3]Hospital Santa Marcelina, São Paulo SP, Brazil.

Correspondence: Ryan Lucas Barbosa Oliveira; Email: ryan.oliveira@arapiraca.ufal.br.

Background: Migraine is a highly debilitating pathology capable of causing loss of ability to work and social life. Despite the recent introduction of monoclonal antibodies targeting the calcitonin gene-related peptide for migraine treatment, not all patients respond well to these drugs. Recently, a new class of drugs, the protease-activated receptor 2 (PAR-2) monoclonal antibodies, has emerged as a potential alternative treatment. PAR-2 is based on blocking meningeal nociceptors, which represents a new therapeutic target. **Objective:** To evaluate advances in migraine treatment using monoclonal antibodies targeting PAR-2. **Methods:** This systematic review analyzed studies from Pubmed, Lilacs, BVS, Embase, and Scielo databases, published between 2018 and 2024. The descriptors used were "monoclonal antibodies, migraine disorders, and PAR-2 receptor", using Boolean operators "and" and "or". Systematic reviews, in vitro studies and animal studies on PAR-2 monoclonal antibodies were included. Studies that did not address its use for migraine were excluded. Two authors independently assessed the methodological quality of the studies. **Results:** A total of 314 articles were found, of which 15 were duplicates. 8 articles were eligible for full reading. Among the articles analyzed, a phase 1 study of MEDI0618, a PAR-2 monoclonal antibody, aimed to evaluate its safety and tolerability in healthy volunteers. Initial findings showed it was well-tolerated with no serious adverse effects; common mild side effects were injection site reactions, mild headache, and transient fatigue. No other changes were observed, suggesting a favorable safety profile. Another antibody, PAR650097, demonstrated significant efficacy in inhibiting PAR-2 in human and mouse cells, preventing cutaneous allodynia induced by PAR-2 agonists or CGRP in mice. Selective activation of PAR-2 in the dura mater triggered headache-related responses in normal mice, but not in PAR-2-deficient mice, highlighting its potential as a therapeutic target for migraine. Studies showed that PAR-2 activation in trigeminal neurons and dural fibroblasts could induce nociceptive behaviors, which were attenuated by the antibody C391 and by the sumatriptan. PAR-2 also emerged as a candidate for modulating nitric oxide sensitivity in the meninges by activating its donor, glyceryl trinitrate (GTN). PAR-2 is also a key mediator in chronic inflammatory conditions, including arthritis, asthma, inflammatory bowel disease, pruritus, and pain. In osteoarthritis and rheumatoid arthritis, PAR-2 contributes to several pathological processes, including synovial hyperplasia, cartilage destruction and pain. The involvement of PAR-2 in these conditions highlights its potential. **Conclusion:** PAR-2 antagonism appears to be a promising approach for treating migraines, particularly for patients with comorbid conditions such as asthma and arthritis. Further research is needed to evaluate its efficacy in human migraine treatment.

Correspondence: Matheus Alves da Silva; Email: matheus.alves.123@outlook.com.

Response to levodopa (l-dopa) is characteristic of Parkinson´s disease (PD), but patients often complain of worsening of symptoms after l-dopa intake. Reasons include worsening of non-motor features (dysautonomia, gastrointestinal intolerance, sleepiness, etc) but also motor phenomena. We present the case of a 34 year male patient complaining of paradoxical worsening with l-dopa who

presented with l-dopa induced dystonia on a levodopa challenge test. **Case presentation:** A 34 year male patient living with Parkinson disease for six years presented to clinical evaluation due to a complaint of gait worsening after levodopa usage. He previously worked in an agricultural industry, he had no history of parkinson disease or other neurological disorders in his family, his parents were not consanguineous and were born in different states of Brazil. A broad investigation for secondary parkinsonism was made and his magnetic resonance imaging was normal. He had no genetic testing. He is the middle son of two other healthy male brothers. His cognitive profile was unremarkable, besides a cognitive worsening after a short trial of anticholinergic therapy previously, with improvement after the drug suspension. He was using a total dosage of 800 mg of levodopa divided four times daily. Because of the clinical complaint, we started amantadine 100 mg BID and scheduled a levodopa testing. His UPDRS-III score was 62 before levodopa and he showed a clinical improvement to 30. But presented torsional phasic and tonic spasms in the left lower limb affecting the gait, compatible with dystonia. We then adjusted the dosage of amantadine for clinical improvement. **Discussion:** Levodopa is the mainstay of PD treatment, and in patients with young onset Parkinson disease, like in our case, it is well-known that motor fluctuations and dyskinesias may present earlier in the course of disease and with lower dosages. Besides dyskinesias, other conditions, like worsening of dysautonomia, may be a cause of worsening after levodopa. Paradoxical gait response with dopa worsening dystonia is a previously described phenomenology of levodopa induced dyskinesia, with some author suggesting relation to mutations in the Parkin gene. Amantadine is an anti-dyskinetic drug for PD and could be tried in such cases. **Final comments:** The understanding of young onset parkinson disease brought us previously the knowledge of the premature motor fluctuations and dyskinesias with lower doses of levodopa. Dopa worsening dystonia is one of the phenomenologies recently reintroduced in the literature and we present this case to highlight the importance of recognizing this semiological clue for the adequate management of young patients with parkinson disease.

Paraneoplastic cerebellar degeneration syndrome associated with breast cancer: a case report

Glauco Kody Nagata[1], Paôla Barbosa Schmitt Mendonça[2] , Letícia Bassani Devens[1], Tatiane Morgana da Silva[1], Lucas P. Schilling[1], Cristiano S. Aguzzoli[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.
[2]Universidade Feevale, Novo Hamburgo RS, Brazil.

Correspondence: Glauco Kody Nagata; Email: glauconagata@gmail.com.

Case presentation: We present a female patient of 66 years of age who was admitted to the emergency department with persistent subacute vertigo for 3 weeks, associated with 15kg of weight loss. She had a history of rheumatoid arthritis, type 2 diabetes mellitus, gastroesophageal reflux disease, systemic arterial hypertension, anxiety, and depression, all controlled. She was discharged from the emergency department and was referred to the neurology outpatient clinic. In the 6-month follow-up neurological examination, she presented with opsoclonus, tongue fasciculations, dysmetria with bilateral intentional tremor in the index-nose test, tactile hypoesthesia in the limbs, and significant axial and appendicular ataxia. At this time, she was hospitalized and underwent extensive diagnostic workup. Magnetic resonance imaging revealed mild microangiopathy (Fazekas I) and cerebellar atrophy. Cerebrospinal fluid showed oligoclonal bands and an IgG index of 6,2, but otherwise normal. Pulse therapy with methylprednisolone was performed, but no improvement in symptoms. Chest tomography revealed a left axillary lymph node measuring 1.4 cm x 1.4 cm, and the breast magnetic resonance imaging was classified as BI-RADS 5. A whole-body PET-CT showed hypermetabolic activity in the left lymph node, which supported further pathological investigation. The patient underwent left lymph node biopsy with immunohistochemical study, which showed a positive Automated CK 7 (SP 52); negative CK 20 (Ks 20.8); positive GATA-3 (L50-823); ER (SP1): weakly positive in about 2% of neoplastic cells; negative PR (1E2). C-erbB-2 (4B5): indeterminate (score 2). Ki-67 (30-9): estimated proliferative index of 50% in the neoplasm. The immunohistochemical profile and histopathological aspects of the biopsy confirmed metastasis from primary breast carcinoma. The rapidly progressive cerebellar syndrome associated with a positive pathological study supported the diagnosis of a paraneoplastic syndrome with cerebellar degeneration secondary to breast cancer. **Discussion:** Paraneoplastic neurological syndromes manifest because of autoimmune responses triggered by the presence of a primary tumor or its metastases. Clinical manifestations may appear months or years before or after the diagnosis of the neoplasm. The diagnosis of the disease is based on three pillars: type of clinical phenotype, presence or absence of neuronal antibodies, and presence or absence of cancer. Afterward, a Care Score is established, which is divided into three diagnostic levels: definite, probable, or possible paraneoplastic neurology syndrome. **Final comments:** Early recognition and treatment of paraneoplastic neurological syndromes are crucial not only to alleviate the patient's neurological symptoms but also to identify and effectively address the underlying cancer. Highlighting the importance of carrying out a physical examination and anamnesis, aiming at the differential diagnosis of neurological syndromes.

[2]Hospital São Lucas, Departamento de Neurologia, Ribeirão Preto SP, Brazil.

Correspondence: Mateus dos Santos Renesto; Email: mateusrenesto@hotmail.com.

Case presentation: A 63-year-old woman presented with progressive gait difficulty over a year, abnormal weight loss, hypoesthesia, burning sensation, and paresthesias in her right leg. Physical exam revealed weakness in right foot for extension, inversion, and eversion (MRC grade 2), tactile and painful anesthesia in L5/S1 dermatomes on the right side, absent patellar and Achilles tendon reflexes bilaterally. ENMG showed signs of subacute, chronic and progressively severe denervation from L1 to S1 bilaterally, with acute activity signs. ESR was 91 and CRP was normal, negative serology tests (including herpes and Lyme disease), as well as extensive negative rheumatologic, metabolic, and endocrine screenings. Brain, cervical and thoracic spine MRI were normal, but the lumbar-sacral revealed periradicular thickening with contrast enhancement in nearly all roots and thickening in the cauda equina. Cerebrospinal fluid (CSF) showed 21 leukocytes (98% lymphocytes), protein level of 185, negative cultures and viral PCRs, positive oligoclonal bands, and IgG index of 1.43. Neoplastic screening identified a right renal nodule (Bosniak II) with PET-CT scan showing increased glycolytic hypermetabolism in the right renal nodule with no signs of sarcoidosis. ACE levels, neuronal antibodies, and anti-neuronal surface antibodies were negative (both blood and CSF), except for positive anti-MGT30 in CSF. Partial nephrectomy and pulse therapy were performed, in addition to plasmapheresis; discharged after overwall improvement with oral prednisone, tapered over 2 months (with minimal residual hypoesthesia on the dorsum and lateral aspect of the right foot, with palsy remission after physiotherapy). Pathological examination of the nephrectomy specimen revealed papillary carcinoma without perineural or vascular invasion, confirmed by immunohistochemistry. Months later, there was recurrence after herpes zoster vaccination, managed with new pulse therapy and rituximab (resulting in remission). Subsequent testing for neuronal and surface neuronal antibodies (both blood and CSF) was negative, with normal nerve biopsy and a negative neuropathies genetic panel. **Discussion:** It is an inflammatory polyradiculopathy, related to early diagnosed renal tumor, with an antibody related to thymoma/myasthenia gravis (despite of common ones, such as anti-CV2/CRMP5, amphiphysin and PCA-2). Responsiveness to corticosteroids and the MRI pattern resembled sarcoidosis, which was ruled out by PET and laboratory testing. Recurrence suggested immune dysregulation, with subsequent negative anti-MGT30 testing in the absence of the tumor. **Final comments:** The case illustrates the relationship between inflammatory disorders of the nervous system without obvious etiology and antibodies produced by neoplasms. Further studies are needed to better understand the exact relationship between these conditions, although clinical signs and complementary tests sometimes may guide treatment.

Paraneoplastic subacute cerebellar degeneration associated with invasive ductal breast carcinoma: a case report

Antônio Lourenço Pires Neto[1], Amanda Selvátici dos Santos Dias[1], Humberto Ramos Crispim[1], Lucas do Rego Barros Correa Martins[1], Marcos Matheus da Silva Fonseca[2], Guilherme Vedovato Vilela de Salis[1], Matheus Hisamitsu Facine[1], Amanda Leme da Silva Campinas[1], Fabio de Nazaré Oliveira[1], Andressa Regina de Mello Galego[1]

[1]Fundação Faculdade de Medicina de Rio Preto, São José do Rio Preto SP, Brazil.
[2]Irmandade da Santa Casa de Misericórdia de São Paulo, São Paulo SP, Brazil.

Correspondence: Antonio Lourenco Pires Neto; Email: ntto.cbb@hotmail.com.

Case presentation: A 36-year-old woman presented 6 months before admission a sudden and progressive tremor, gait instability and incoordination. She was first diagnosed with meningitis in another hospital with little improvement on her symptoms after therapy. About 4 months before, she had a new clinical worsening with the same symptoms associated with diplopia and was then referred to a quaternary hospital. Her history included hypothyroidism and cholecystectomy. She denied infectious symptoms, weight loss, and sweating. At the exam, she presented appendicular and axial ataxia, gait incoordination and skew deviation. Her laboratorial exams and serologies were normal. Imaging with Head CT confirmed an arachnoid cyst and subcutaneous nodules of indeterminate etiology on the scalp. The cerebrospinal fluid was normal. We proceed the investigation of a subacute global ataxia syndrome with Magnetic Resonance (MRI) that confirmed the findings of CT exams, with no other alterations. Rheumatologic exams (Anti RO, Anti La, Anti microssomal, Anti GAD, Anti TPO, Antitransglutaminase IGG, IGM, IGA) was normal. The patient was lately full reexamined and was found a nodule on her right breast. The ultrasound confirmed the nodule, and posterior mammography indicated a BIRADS 5 score. She underwent biopsy that confirmed an Invasive ductal breast

cancer (hormonal receptor positive, HER2 Negative, Ki 67 50%). She was diagnosed with subacute cerebellar degeneration secondary to paraneoplastic and was treated with Methylprednisolone 1 gram for 5 days, followed by every other day of plasmapheresis for 5 days. A lumpectomy was also made, and the patient started to improve after the 3rd section of plasmapheresis, with significant improvement in ataxia, walking alone, with no tremors and diplopia after the 5th session. The patient was discharged for follow-up with mastology and oncology to continue staging the disease and was also referred to the genetics clinic. **Discussion:** Cerebellar degeneration secondary to paraneoplastic is a rare but well-known complication of cancer. This case shows a woman with subacute onset, that had a great response and recovery with the corticosteroids and plasmapheresis, reinforcing the needing of fast diagnostic and treatment. **Final comments:** The diagnosis of paraneoplastic syndromes is crucial for the early diagnosis of cancer, as well as it is important to remember the paraneoplastic causes of subacute ataxia in young people, especially those with a positive family history, since early diagnosis has a close influence on the prognosis of the disease.

https://doi.org/10.5327/CBN241272

Paraproteomic polyneuropathy linked to antimyelin antibody: a case report

Eduardo Mendonça Werneck da Silva[1], Caio Gonçalves Gomes[1], Maycon Melo Lopes[1], Jessica Daniele Marques[1]

[1]Hospital das Clinicas Samuel Libaneo, Pouso Alegre MG, Brazil.

Correspondence: Eduardo Mendonça Werneck da Silva; Email: eduardomwerneck@gmail.com.

Case presentation: A 67-year-old male patient with a symmetrical paretic condition that began in 2021 with distal predominance and progressive evolution in the meantime, evolving with hypoaesthesic changes and gait ataxia on an outpatient basis, with an investigation being carried out for the condition with evidence of cytological protein dissociation and electroneuromyographic examination with findings of sensory-motor polyneuropathy with primarily demyelinating motor predominance, presented concomitantly with a monoclonal peak of IGM in protein electrophoresis and urinary immunofixation in follow-up examinations, he evaluated by a hematologist and the hypotheses of POEMS, myeloma and amyloidosis were ruled out at that time. The investigation continued into the case in which the Igm fraction of the antimyelin antibody was present, confirming the diagnosis. **Discussion:** In cases of polyneuropathy, one of the initial screening tests is electrophoresis, given the multiple possible differences linked to antibody clones. The paraproteomic polyneuropathies must Always be considered in such cases, especially if presence of sensory ataxia, demyelinating neuropathy or anti-myelin antibodies. **Final comments:** Due to the wide possibility of diagnosing hupothesis regarding polyneuropathies, one should always search in the anamnesis and physical examination, as well as in routine complementary exams, for cardinal conditions suggestive of specific pathologies, in order to accelerate the diagnosis and thus institute early and effective treatment to reduce disease-related morbidity and mortality.

https://doi.org/10.5327/CBN241273

Parechovirus encephalitis in a Brazilian adult: an extremely rare case report in the world

Yan da Silva Raposo[1], Ilana Werneck Augsten[1], Laryssa Garcia de Almeida[1], Hiago Antunis Silva[1], Patrícia Marques Mendes[1], Igor Pereira Matos de Oliveira[1], Eduardo Mendonça Werneck da Silva[1], Caio Gonçalves Gomes[1], Matheus de Paula Batista[1], Vitor Hugo Machado Silva[1]

[1]Hospital das Clinicas Samuel Libaneo, Pouso Alegre MG, Brazil.

Correspondence: Yan da Silva Raposo; Email: yanraposo@yahoo.com.br.

Case presentation: This case portrays a 50-year-old Brazilian caucasian man, intellectually disabled, chronic alcoholic, epileptic, and history of pellagra who on January 29th, 2024 presented with seizures. He progressed to refractory status epilepticus and required continuous intravenous midazolam. He had been complaining of otalgia for a few days. The computed tomography (CT) scan of the skull showed no significant brain abnormalities, but there was evidence of unilateral mastoiditis. The CT of the chest revealed broncho-aspiration. Ceftriaxone 2 grams twice a day and Clindamycin 600mg four times a day intravenously were started. The cerebrospinal fluid (CSF) showed pleocytosis (13 cells), hyperproteinorraquia (67mg/dL), glucose normal (85mg/dL), and elevated lumbar opening pressure (28cm H2O). Acyclovir 10mg/kg endovenous was empirically associated. The Allplex Meningitis V2 test detected the Parechovirus. It evolved with a mastoid focus and the antimicrobial spectrum was expanded. The second CSF sample was collected on day 7 of treatment and parameters were normal and the meningitis/encephalitis panel PCR CSF was negative. Sedation was gradually reduced and extubation was performed after clinical stability and electroencephalogram without status epilepticus. On March 21st he was awake, alert, and oriented temporally, spatially, and personally, with preserved strength in the upper and lower limbs (MRC scale 5/5) and bilateral patellar (3+/4+) and Achilles (4+/4+) hyperreflexia, and bilateral Babinsky sign. Magnetic resonance imaging of the brain on February 16th revealed a hyperintense lesion on T2-weighted and FLAIR imaging in the right external capsule. **Discussion:** Parechovirus is the Picornaviridae family, comprising 16 genotypes, the most common being HPeV 1, 3, and 6. It presents gastrointestinal, respiratory, and central nervous system tropism (HPeV 3) and transmission is fecal-oral. HPeV is a significant etiological agent of viral meningoencephalitis and sepsis in infants. However, infection in adults is rare, with few cases having been described. **Final comments:** Searching in PubMed, Virtual Health Library, and Cochrane for terms such as meningoencephalitis, encephalitis, and Parechovirus, we found a single report depicting an Australian patient, also a male, chronic alcoholic who began the condition with status epilepticus.

https://doi.org/10.5327/CBN241274

PARK ON - proposal for a computational decision support system for assessing the eligibility of patients with Parkinson's disease for functional neurosurgery, including dbs system implantation and ablative procedures

Renê Vasconcelos Silva[1], Jorge Dornellys da Silva Lapa[1], Myllena Maria Santos Santana[1], Wellington Costa da Silva Filho[1], Gabriel Ribeiro Andrade Neto[1], Helton Benevides Santana de Oliveira[1], Roberto César Pereira Prado[1]

[1]Universidade Federal de Sergipe, Aracaju SE, Brazil.

Correspondence: Helton Benevides Santana de Oliveira; Email: heltonbenevides@vidaampla.com.br.

Parkinson's disease (PD) is the second most prevalent neurodegenerative disease in the world, second only to Alzheimer's disease. Between 1990 and 2015, the number of cases increased by 118%. This implies a growing demand for advanced therapies to manage motor symptoms and preserve the quality of life as the disease progresses. In response to this need, we developed PARK ON, a computational solution aimed at the efficient screening of PD patients for functional neurosurgical treatments, such as deep brain stimulation (DBS) and ablative procedures. The relevance of PARK ON is amplified by the limited availability of specialized PD teams in Brazil, which requires a more accurate selection of patients to be referred, and the lack of similar tools in Portuguese. PARK ON was developed by the Movement Disorders Group of the Neurology Service at the University Hospital of the Federal University of Sergipe using the open-source programming language PHP - Hypertext Preprocessor. PHP is widely used in other computational systems and has low maintenance and hosting costs. The system uses a decision algorithm created by our group based on international standards, including CAPSIT-PD and the Multinational European Delphi Panel. PARK ON is available on a webpage and can be used on any device with a web browser, making it widely accessible. This tool provides non-specialist physicians in movement disorders with a robust initial assessment, optimizing referrals to specialized centers. It is important to emphasize that PARK ON acts as a screening tool and does not replace detailed evaluation by multidisciplinary teams. We hope to optimize patient referrals for the evaluation of neurosurgical therapies, improving clinical outcomes and the quality of life for patients. PARK ON represents a significant advance in the management of PD in Brazil, promoting an accessible and efficient initial approach for selecting potential candidates for advanced surgical therapies. This work paves the way for future improvements and adaptations of the tool, as well as its validation studies, aligned with the specific needs of the Brazilian population and technological advancements in healthcare.

Parkinson's disease in Brazil and its hospital morbidity in 1 decade

Ana Carolina Ribeiro de Araujo e Araujo[1], Aeriberto Carlos Lindoso de Souza[1], Consuelo Penha Castro Marques[1], José Carlos Gomes Patriota Neto[1], Tassya Jordana Coqueiro Batalha[1]

[1]Universidade Federal do Maranhão, Pinheiro MA, Brazil.

Correspondence: Ana Carolina Ribeiro de Araujo e Araujo; Email: anacarolinaraa@hotmail.com.

Background: Parkinson's disease (PD) is a chronic condition, characterized by nigrostriatal degeneration, causing a reduction in dopamine. It is the second most common neurodegenerative disease among the elderly, with age being the most important risk factor. It manifests itself through motor symptoms, such as bradykinesia, tremors (unilateral, resting and asymmetric), rigidity (cogwheel phenomenon) and postural instability; and non-motor, such as hyposmia, psychosis, sleep and mood disorders, considerably impairing the patient's quality of life. The diagnosis is made through a clinical history and detailed physical examination, which can be supported by a good response to pharmacological therapy with levodopa. **Objective:** to study the hospital morbidity profile of patients with Parkinson's Disease in Brazil in the period between 2013 and 2022. **Methods:** This is a descriptive, epidemiological, quantitative study on hospital morbidity due to Parkinson's in Brazil, with secondary data from the System of Hospital Information of the SUS-SIH/SUS, available through the Information Technology Department of the Unified Health System (TABNET/DATASUS), in the period between 2013 and 2022. The variables used were: region, age group, sex and color/race. **Results:** n=9,414 hospitalizations for PD were reported in Brazil between 2013 and 2022, the majority concentrated in the Southeast region, which represented 44.06% of the country, followed by the South region with 27.6%. Furthermore, age groups over 50 years old have a higher incidence of hospital

morbidity, with 89.4% of all hospitalizations due to the disease. Furthermore, over the years, the disease is more prevalent in males, with higher numbers (58.2%) compared to females (41.8%), in addition to affecting mainly individuals of color/ white race (n=4,578), followed by mixed race (n=2,133), highlighting the large amount of hospital morbidity without information regarding color/ race (n=2,321). **Conclusion:** In view of the above, it can be concluded that Parkinson's disease affects, in a potentially serious way, a clinical profile that is based on the male sex, the white race and the age group over 50 years old, highlighting a greater occurrence for this population. of hospital morbidity. That said, clinical monitoring of individuals with this profile must be motivated early, in order to reduce hospitalizations as much as possible, and if so, guarantee improvements in the quality of life of this population. This study has the limitation of being an epidemiological study with secondary data of a descriptive nature and does not allow causality to be inferred, but further studies with primary data must be carried out to better understand this hospital morbidity.

https://doi.org/10.5327/CBN241276

Parkinson's disease: a baseline tremor (electrocardiographic change in Parkinson's disease)

Nadja Layane Gomes Santiago[1], Maria Eduarda Messias Vassoler[2], Ayla Morais Vitório Guerra[2], Gabriel Souza Medrado Nunes[2], Fernanda Garcia Silva Pereira Nascimento[2], Ricardo Jose Menezes Barberino Mendes[1], Luiz Pereira de Magalhães[1], Roberta Borges Gomes Kauark[1]

[2]Universidade Federal da Bahia, Salvador BA, Brazil.

Correspondence: Maria Eduarda Messias Vassoler; Email: maria.vassoler@ufba.br.

Electrocardiogram (EKG) is a simple and non-invasive test that allows clinicians to evaluate heart rhythm. There are some features that can compromise the reliability of the test, such as neurostimulation, psychomotor agitation, fever and, in regards to Parkinson disease (PD), tremor. Such tremors can mimic arrhythmias, thus, if these artifacts are not recognized, they may lead to misdiagnosis. To warn the possibility of misdiagnosis and iatrogenic damage in patients with movement disorders. **Case presenation:** An 80-year-old male patient presented to the neurology department with progressive resting tremor, initially observed in his right arm, and bradykinesia persisting for one year. The patient has a medical history significant for an ischemic stroke affecting the right nucleocapsular region. Neurological examination revealed globally preserved muscle strength, facial hypomimia, parkinsonian gait, bilateral bradykinesia, plastic hypertonia, and resting tremor. The patient was on a regimen of Levodopa/BD 100/25mg, administered four times daily. For secondary cerebrovascular prophylaxis, the patient was advised to continue taking acetylsalicylic acid and a statin, and an EKG was recommended to further investigate cardiovascular status. The subsequent EKG indicated atrial flutter (AFL) with a heart rate of 68 bpm. However, a 24-hour Holter monitor demonstrated a sinus rhythm with an average heart rate of 67 bpm and rare atrial or ventricular extrasystoles. **Discussion:** A multidisciplinary discussion with cardiology and arrhythmology services suggested that the motor artifact, likely baseline tremor, might be responsible for the observed alterations in the electrocardiographic pattern. Approximately one year later, the patient experienced another ischemic event and sought care at a different public health facility, where AFL was again diagnosed. The patient underwent electrical cardioversion and was placed on continuous anticoagulation therapy with Rivaroxaban. Upon returning to our follow-up clinic, both cardiovascular and neurological examinations remained unchanged from the initial assessment. A new EKG showed the same findings as the initial examination. Consequently, anticoagulation therapy was discontinued, and the patient was referred to the arrhythmology service at our hospital for further evaluation. **Final comments:** This case underscores the critical importance of vigilant and comprehensive assessments, particularly in elderly patients presenting with movement disorders. The overlapping symptoms of neurological and cardiovascular conditions, such as tremors potentially mimicking arrhythmias in EKG readings, highlight the necessity for multidisciplinary collaboration, advocating to ensure accurate diagnosis and appropriate management. This case also emphasizes the need for continuous re-evaluation and close monitoring, as initial findings may evolve, necessitating adjustments in therapeutic approaches.

Parkinsonism in bipolar mood disorder: a new look at an old problem

Lorena Dias Resende[1], Leonardo Ferreira Caixeta[1]

[1]Universidade Federal de Goiás, Goiânia GO, Brazil.

Correspondence: Lorena Dias Resende; Email: resende2@discente.ufg.br.

Background: Bipolar Spectrum Disorder is a mood disorder characterized by episodes of depression and mania that usually occur for no apparent reason. When treating Bipolar Disorder with neuroleptics, it is common for patients to be diagnosed with parkinsonism in the medium and long term. This generic term is a movement disorder that presents a blockage of nigrostriatal dopaminergic transmission and its prevalence is increasing. Motor symptoms and functional disorders such as tardive dyskinesia and parkinsonism induced by pharmaceutical agents are commonly found in clinical practice, highlighting the convergence of neuro-psychiatric diseases with the motor system. Most patients with Bipolar Disorder who are treated with antipsychotics develop a degree of facial inexpressiveness, action tremor, rigidity or bradykinesia. **Objective:** Systematic review of studies published in the last 25 years on parkinsonism in Bipolar Disorder. **Methods:** We conducted a systematic review guided by the PRISMA guidelines of prospective studies evaluating the association of Bipolar Disorder with a subsequent diagnosis of idiopathic Parkinson's Disease, with a special focus on motor symptoms and executive dysfunction. 128 original articles indexed between 2000 and 2024 were selected from the Cochrane, Lilacs, Medline, Pubmed, Springerlinks and Psyclnfo databases using the terms Parkinson's Disease, Bipolar Mood Disorder, mania, depression, executive dysfunction, motor alterations and quality of life. The inclusion criteria were impact on the literature and methodological quality. The exclusion criteria were not meeting the inclusion criteria. **Results:** 60 articles were fully evaluated and 35 articles made up the results of this systematic review. The information provided by this study promotes reflection on the association between mood and motor fluctuations, pointing out that tardive dyskinesia and drug-induced parkinsonism are the movement disorders most commonly identified in neuro-psychiatric practice. Motor disorders are relevant symptoms in the assessment of neuro-psychiatric patients, as they are related to variables such as the severity of cognitive and functional impairment, and can contribute to accurate differential diagnoses. **Conclusion:** The causes of parkinsonism in Bipolar Disorder have not yet been fully elucidated, as the combination of medication is a complicating factor for an objective assessment. A variable percentage of patients with drug-induced parkinsonism have previous disorders in the nigrostriatal system, which suggests that in these cases the drug reveals a previous neurodegenerative disease. Parkinsonism has a significant morbidity for patients, so it is important to recognize it at an early stage in order to limit its clinical impact. Further research is needed.

Paroxysmal kinesigenic dyskinesia associated with a pathogenic variant in the PRRT2 gene: a case report

Felipe Thiago Bandeira Serpa[1], Artur Menegaz de Almeida[1], Delcio Francisco Chagas Netto[1], Gabriel Henrique Penha Custódio[1], Ricardo de Oliveira[1], Fernando Augustus de Paula Barreto Garcia[2], Fernando Augustus Bignardi Garcia[1]

[2]Universidade Anhembi Morumbi, São Paulo SP, Brazil.

Correspondence: Artur Menegaz de Almeida; Email: arturomenegaz@gmail.com.

Case presentation: A 16-year-old male presented with a 1-year history of involuntary movement attacks in his right members that last up to 15 seconds and occur 20 to 30 times daily. He denied having loss of sensitivity, sphincter relaxation, or tongue biting during episodes. Pain was not reported, and conscious level remains unaltered. Systems inquiry was unrevealing. He denied a family history of similar symptoms but his mother was diagnosed in adolescence with migraine with aura. The patient had no previous diagnosed pathology, comorbidities, previous surgeries, or is taking any medications. His vaccines were up-to-date. Upon evaluation, he was found to have dystonic findings triggered by sudden muscle movements. MRI of the brain was normal. He was treated with 2mg trihexyphenidyl once daily, after which there was a partial improvement of dystonia, but no change was seen in attack frequency. A karyotype revealed a mutation in the PRRT2 gene, suggesting a diagnosis of paroxysmal kinesigenic dyskinesia. Then, he initiated 200mg carbamazepine once daily, resulting in a complete reduction of attacks and dystonia. **Discussion:** Paroxysmal kinesigenic dyskinesia is a rare movement disorder characterized by sudden involuntary movements affecting one side of the body (unilateral) or both sides (bilateral). Diagnostic criteria require a (1) triggering factor, (2) attacks during less than a minute, (3) unaltered consciousness and no pain during episodes, (4) age of onset of symptoms between 1 and 20 years of age, and (5) clinical response to anticonvulsants. The karyotype was suggested because of PRRT2 heterozygous mutations being associated both with migraine and paroxysmal movement disorders. The identification of the mutation was characterized by a dominant pattern, that is, the allele probably was inherited from the patient's mother, whose partial presence originated the migraine with aura. **Final comments:** This case report contributes to the understanding of the correlation between paroxysmal kinesigenic dyskinesia (PKD) and migraine with aura. The identification of a heterozygous mutation in the PRRT2 gene in the patient, along with the maternal history of migraine with aura, suggests a potential genetic link between these two neurological conditions. These finding underscores the importance of genetic research in the diagnosis and treatment of neurological disorders, enabling a more precise approach and faster diagnosis.

Paroxysmal kinesigenic dystonia: a misdiagnosed condition

Natália da Costa Chiote Pinheiro[1], Luiz Felipe Vasconcellos[1], Bruna Andrade de Oliveira[1], Carolina Rocha da Silveira Brugger Cardoso[1], Gloria Maria Cardoso de Andrade Penque[1]

[1]Universidade Federal do Rio de Janeiro, Instituto de Neurologia Deolindo Couto, Rio de Janeiro RJ, Brazil.

Correspondence: Natália da Costa Chiote Pinheiro; Email: nataliacchiote@hotmail.com.

Case presentation: A 36-year-old man presented with brief attacks of dystonia on his left upper and lower limb triggered by sudden movements from rest, such as starting to walk, with onset in his childhood. The symptoms lasted less than 5 minutes and subsided spontaneously, occurring at least 3 times a week. Despite their short duration, the symptoms had a major impact on the patient's quality of life, interfering with his job and physical activity. The patient has always been in good health and did not take any medications. His family history was negative for involuntary movements. However, his sister presented with absence seizures in her childhood, with complete remission after a few years. Neurological exam and neuroimaging findings were normal. Genetic testing confirmed a PRRT2 mutation in the patient. It was prescribed Carbamazepine (200 mg/day), leading to a significant reduction in the frequency of attacks. **Discussion:** Paroxysmal kinesigenic dyskinesia is a rare movement disorder characterized by episodic and recurrent attacks of uni or bilateral dystonia, chorea, ballistic, and athetoid movement induced by abrupt movement or an increase of speed. Most cases are idiopathic, although familial cases occur and usually have an autosomal dominant inheritance pattern. It can also be secondary to brain lesions, such as multiple sclerosis or stroke. The onset is usually in childhood, and the attack has a short duration without loss of consciousness. The diagnosis is based on history and clinical observation, and in genetic cases, it can be confirmed by genetic testing, showing PRRT2 mutation, the major causative gene for paroxysmal dyskinesia and also related to self-limited familial infantile epilepsy. Neuroimaging is useful for differential diagnosis. The attacks usually have a dramatic response to antiepileptic drugs, being carbamazepine and oxcarbazepine the first-line choices. This case report illustrates a typical presentation of paroxysmal kinesigenic dystonia. Although his sister has not been genetically tested, it is possible that she has the gene due to her history of benign epilepsy in childhood. Despite the typical presentation, it took more than 20 years to get to the correct clinical diagnosis, being confused with epilepsy and psychogenic disorders, showing that this diagnosis is often a challenge. It is important to recognize the presenting features of this condition to facilitate a timely diagnosis and initiate appropriate treatment. **Final comments:** Paroxysmal dyskinesias are a group of rare movement disorders that are underdiagnosed and often misdiagnosed. It is important that physicians are aware of its clinical presentation in order not to dismiss it as a psychosomatic or psychiatric illness, leading to the use of an unnecessary or inappropriate medication. The disease has a good response to antiepileptic drugs and patients should be informed about the benign course and the tendency to have decreased attack frequency with age.

Paroxysmal kinesiogenic dyskinesia: a case report

Bibiana Mayer[1], Chadi Emil Adamo[2]

[1]Universidade de Ribeirão Preto, Ribeirão Preto SP, Brazil.
[2]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Bibiana Mayer; Email: bibiana_mayer@hotmail.com.

C.R.S, 19 years old, male, computer science student. During a neurological consultation, he complained of multifocal involuntary sudden movements since he was 7 years old, with a maximum duration of 20 seconds and starting only at the beginning of a movement, without any signs and symptoms in the interictal periods. The condition was exacerbated in anxious contexts. There was no perception or associated pain. These episodes were not triggered by strenuous physical exercise or caffeine-based foods. There was no exacerbation in a post-viral infectious context. He reported that when getting off the bus, he noticed imbalance as his legs were 'chcrooked' and sometimes he fell, as well as letting objects fall from his hands - according to information collected. He did not present developmental changes, as well as any other changes related to cortical functions and psychiatric morbidities. During his youth, the patient had already been investigated for a series of extrapyramidal diseases, such as Wilson's Disease, Hungtinton's Disease, neurodegenerative diseases related to iron accumulation (NBIA), myopathies, among others. On neurological examination, he showed no changes in his cranial nerves, cerebellar, motor or sensory tests. Deep cutaneous reflexes were largely preserved and there were no extrapyramidal changes. Given the above situation, he was diagnosed with Paroxysmal Kinesiogenic Dyskinesia Not Associated with Exercise. Treatment with carbamazepine 200mg/day was started, showing rapid and satisfactory improvement after 1 week with low doses, as expected for this condition. Attacks of Paroxysmal Kinesiogenic Dyskinesias (PKD) consist of any combination of dystonic postures, chorea, athetosis, and ballismus. They can be unilateral – always on one side or the other – or bilateral. Unilateral episodes may be followed by a bilateral episode. The attacks are brief, usually lasting only seconds, but rarely can last up to 5 minutes. They are precipitated by a sudden movement or a startle, usually after the patient has sat silently for some time. Attacks can be severe enough to cause a fall. There can be up to 100 attacks per day. After an attack, there is usually a short refractory period before another attack can occur. Speech may be affected, with inability to speak due to dystonia, but there is never any change in consciousness. Attacks can sometimes be stopped if the patient stops moving or warms up slowly. Patients often report variable sensations at the onset of paroxysms. These may consist of paresthesias, a feeling of stiffness, crawling sensations, or a feeling of tension. Equivalent to PKD are equally brief bilateral attacks that are not precipitated by sudden movement or fright. Because the duration and therapeutic response are the same as in PKD, they are listed here under the heading PKD and not in a separate category. Seizures respond well to treatment with anticonvulsants such as phenytoin and carbamazepine.

Paroxysmal tonic upward gaze mimicking occipital epilepsy

Lohana Guimarães Souza[1], Samir Andres Ramirez Ojeda[1], William Alves Martins[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Samir Andres Ramirez Ojeda; Email: samir.ramirez@edu.pucrs.br.

Case presentation: A 1-year and 6-month-old boy, born full-term at 39 weeks and 2 days via elective cesarean section, with an Apgar score of 10/10, and appropriate neuropsychomotor development for his age, presented with no family history of epilepsy or other relevant personal and family medical history. At 1 year and 5 months, he began experiencing episodes of upward eye deviation lasting 10 seconds each, occurring more than 100 times per day, followed by a spontaneous return to normal eye movements. During these episodes, his consciousness was preserved, body posture was maintained, and he exhibited downward head movements. After a neurological evaluation, valproic acid was prescribed, showing an initial good response. However, after a few days, the seizures, identical in semiology to the previous ones, resumed. Levetiracetam was then prescribed but discontinued due to side effects of irritability. He was on valproic acid, 2 capsules per day, with adjustments being made to transition to carbamazepine, and clobazam 7.5 mg. A Video-EEG showed an organized baseline rhythm in the posterior regions (theta-alpha 7-9Hz, irregular and symmetrical, with attenuation upon bilateral eye opening) and rare slowing over the left parieto-occipital region. Interictal activity showed rare epileptiform paroxysms in the centrotemporal and left occipital regions. Several episodes of upward eye deviation and slight head drop were recorded with no convening EEG changes. After the VEEG, antiepileptics were gradually discontinued, and the episodes of upward eye deviation persisted for another 3 weeks, completely disappearing afterwards. He remains with no further episodes and with normal development two years later. **Discussion:** The concept of paroxysmal tonic upward gaze (PTU) was proposed by Ouvrier and Billson in 1988. It is a non-epileptic disorder that begins in childhood, characterized by episodes of sustained conjugate upward eye deviation, neck flexion, downward saccadic eye movements to look in that direction, with preserved horizontal eye movements and consciousness. One-third of patients suspected of having seizures suffer from non-epileptic disorders upon VEEG evaluation. Although most patients with non-epileptic events have normal VEEGs, occasional point discharges between attacks can occur. In such cases, non-epileptic events might be mistakenly diagnosed as seizures. The symptoms of PTU are like focal or absence seizures in childhood. Despite being uncommon, epileptiform paroxysms were observed in the present case's VEEG; however, the discharges were interictal. The causes of PTU are unknown, and most patients recover within a year after onset. Additional symptoms, such as developmental delays or ataxia, can predict worse prognoses. **Final comments:** PTU is an important confounder of epilepsy, especially when interictal electroencephalographic discharges are present. Therefore, distinguishing evidence between seizures and non-epileptic events needs to be clarified.

Pathogenic mtDNA variants at low-level heteroplasmy may induce mitochondrial dysfunction and cause exercise intolerance

Margleice Marinho Vieria Rocha[1], Raíssa Gontijo Cabral de Souza[1], Silvia Helena Adrião Escarso[1], Claudia Ferreira da Rosa Sobreira[1]

[1]Universidade de São Paulo, Ribeirão Preto SP, Brazil.

Correspondence: Margleice Marinho Vieira Rocha; Email: margleice@gmail.com.

Background: Exercise intolerance (EI) is an inability to perform a certain level of physical activity expected for that person, accompanied by myalgia and fatigue. **Objective:** To identify the frequency of pathogenic mtDNA variants in patients with IE and to evaluate whether the cumulative effect of pathogenic variants at low levels of heteroplasmy is capable of inducing mitochondrial dysfunction. **Methods:** Medical records, laboratory tests, muscle biopsy and mtDNA sequencing using the NGS technique of 30 patients with IE were retrospectively reviewed. We evaluate the correlation between molecular changes in mtDNA and mitochondrial dysfunction. Mitochondrial dysfunction was defined based on the criteria of Bernier et.al. and the patients were divided into two groups: group A (with dysfunction), group B (without dysfunction), which were compared. **Results:** 30 patients with IE, 1:2 male:female, aged 23 to 69 years, were included. The average age at onset of symptoms was 28.8+10.25 years and on average. Pure IE was observed in 53.3% of patients; and 46,7% showed mild signs of other systems. All the patients presented at least one probably or definitely pathogenic mtDNA variant and 73.3% of patients presented at least one definitely pathogenic variant. The most prevalent variant in this population was m.3271T>C. The percentage of mutants ranged from 1% to 4%, and only one patient showed 100% mutant. The MT-ND6, MT-ND5, MT-ND1 and MT-TL1 genes were hotspots for pathogenic variants. Patients with CIII or CIV deficiency presented a higher number of pathogenic variants and a higher accumulated percentage of mutants, especially those located in genes encoding tRNAs. We demonstrated a correlation between the number of pathogenic mtDNA

variants in low heteroplasmy and the accumulated percentage of mutants with laboratory signs of mitochondrial dysfunction (increased resting lactate and reduced CIV activity). The group A and the group B was composed by 37% and 63% of the patients, respectively. Resting lactate levels and pathogenic variants were higher in group A, but there was no difference between the number of definitively pathogenic variants and CK levels between the two groups. From muscle biopsy findings, group B had more signs of denervation, fibers with subsarcolemmal accumulation of SDH and COX and failures in NADH activity. Group A had a higher prevalence of deficiencies of all complexes. Psychiatric disorders were common in carriers of the m.3394T> C variant in this series. **Conclusion:** Our group of patients with IE have a high prevalence of mtDNA variants with low heteroplasmy in skeletal muscle, significantly higher than the prevalence observed in the general population. The percentage of mutant of our results suggest that, although in low heteroplasmy, those pathogenic variants are contributing to mitochondrial dysfunctions and possibly in IE of ours patients.

Pathological jealousy as an initial symptom of Alzheimer's disease: anatomy clinical study of a case

Paulo Roberto de Brito Marques[1], Janaina Mariana de Araujo Miranda Brito Marques[1], Maria Luiza Vasconcelos Montenegro[1]

[1]Universidade de Pernambuco, Recife PE, Brazil.

Correspondence: Janaina Mariana de Araujo Miranda Brito Marques; Email: marianaaraujo6@gmail.com.

M, 74 years old, higher education. Until the 54-year-old, her husband had never spoken or shown any jealousy that attracted attention. From that age onwards, the patient began to become progressively pathologically jealous of his wife, so that no man could have access to her. Even old employees do housework such as bricklayers, plumbers, electricians, friends, and neighbors. She didn't want to give him money for shopping, avoiding contact with men on the street. His wife consulted a lawyer to initiate separation proceedings, but due to the children, his wife withdrew on the judge's advice. The patient continued to be jealous this time of his youngest son, who denied being his, and when he was shown his identity card the patient said it was easy to put anyone's name there. After 10 years, he progressively stopped being jealous, and not giving much importance to his wife, he lost his language and gradually became dependent and without autonomy for civil activities. MEM=00. Pfeffer=30/30. He lived in bed for 2 years. His maternal grandmother, mother, and 4 cousins died of dementia, and he has 1 demented cousin. Structural and functional imaging studies were carried out. An autopsy confirmed the diagnosis of Alzheimer's disease. Othello syndrome (OS) has already been described in the literature, initially in a theater (Shakespeare, 1596-1598), and a film (The Merchant of Venice, 2004). Its dissemination in the medical literature covers various clinical conditions in psychiatry, neurology, and clinical medicine, including medications like dopaminergic agonists. Psychiatric disorders reach 22%, neurological disorders more than 30%, drug use 19%, etc. However, there is no case in the medical literature of OS whose etiology is Alzheimer's disease with pathological confirmation. We conclude with the statement that Othello Syndrome caused by Alzheimer's disease is a rare entity in neurology.

https://doi.org/10.5327/CBN241284

Pathophysiology of olfactory disorders related to COVID-19 infection

Caroline Lima de Freitas[1], Bruno Augusto Machado Tavares[1], Julia Azevedo Fleury da Fonseca[1], Pedro Lucas de Oliveira Ramos[1], Luis Alexandre Lemos Costa[1]

[1]Universidade Federal do Amapá, Macapá AP, Brazil.

Correspondence: Caroline Lima de Freitas; Email: carolfreitasm7@gmail.com.

Background: The COVID-19 pandemic was declared in March 2020 by the World Health Organization (WHO). The disease is transmitted through close contact with infected respiratory droplets, and symptoms range from cough and fever to severe pneumonia with respiratory failure. Olfactory disorders such as hyposmia, anosmia, and phantosmia are also common. Understanding the pathophysiological mechanisms of these chemosensory alterations is important for formulating effective treatments and for early detection of symptoms and, consequently, the infection itself. **Objective:** To elucidate the pathophysiology of olfactory disorders observed in some cases of COVID-19. **Methods:** This is a systematic literature review, conducted through a PubMed search using the keywords "COVID-19," "Olfactory manifestations," and "Pathophysiology" in October 2023, which yielded 59 results. After applying filters for publication date (2020-2023) and free full-text availability, 53 studies were selected. Titles and abstracts were read, and inclusion and exclusion criteria were applied, resulting in 20 articles that were fully analyzed and used in this study. **Results:** Anosmia was highlighted as a common symptom of COVID-19, and studies revealed it to be a useful neurological marker for early diagnosis. The olfactory epithelium (OE) is composed of various cells that, when infected by SARS-CoV-2, suffer damage, leading to olfactory alterations. The virus's spike protein interacts with the angiotensin-converting enzyme 2 (ACE2), facilitating viral entry into host cells and causing inflammation and cellular damage. Initially, olfactory dysfunction was believed to indicate neuroinvasion, but later studies showed that the virus primarily affects the support cells of olfactory receptor neurons (ORNs), not the neurons themselves. The resulting inflammation can block the olfactory clefts, impeding airflow and olfactory perception. Anosmia resolution varies from an average of 10 days in mild cases to longer periods in some patients. In severe cases, recovery depends on the recruitment of stem cells from the OE. The potential for viral neuroinvasion, which could lead to central nervous system damage, was also explored, but no significant correlation was found between anosmia and other severe neurological manifestations. The spontaneous remission of olfactory dysfunction suggests a localized inflammatory pathogenesis in the olfactory epithelium. **Conclusion:** COVID-19 presented neurological challenges, including olfactory disorders. Studies indicate that SARS-CoV-2 infection of OE support cells via the ACE2 receptor leads to ORN dysregulation and inflammatory alterations, resulting in anosmia. Understanding the mechanisms of how the virus affects chemical senses can aid in developing effective treatments and prophylactic measures.

Patient with hereditary diffuse leukoencephalopathy axonal with spheroids requiring gastrostomy

Bianca Pinheiro Cabral[1], Aléxia de Rezende Gonçalves[1], Uandy Dias Terras[1]

[1]Universidade de Ribeirão Preto, Guarujá SP, Brazil.

Correspondence: Bianca Pinheiro Cabral; Email: biancapinheirocabral@gmail.com.

Case presentation: Diffuse Hereditary Leukoencephalopathy with Axonal Spheroids (HDLS) is a rare, inherited, autosomal dominant neurodegenerative disease first identified in 1984. The initial symptoms manifest around the age of 45, with a variable life expectancy of 6 years. In the pathology, structural brain alterations in the white matter are observed, characterized by demyelination and irregular axonal swellings (spheroids), resulting in motor, cognitive, and personality changes. We present a case report of Diffuse Hereditary Leukoencephalopathy with Axonal Spheroids in a 60-year-old female patient who was admitted with dysphagia, requiring Gastrostomy for nutritional support. She remained hospitalized in the clinic ward for 7 days. **Discussion:** Brazilian female, 60 years old, residing in Santos - São Paulo, presented to the hospital with progressive dysphagia over the past month. Prior to this period, she maintained a diet of liquids and soft foods, but due to worsening dysphagia, this diet has become unfeasible. Gastrostomy is necessary for maintenance of nutritional support. During the anamnesis, it was reported that she was previously diagnosed with Hereditary Diffuse Leukoencephalopathy with Axonal Spheroids (HDLS) since 2016. The diagnostic hypothesis was confirmed by Single Photon Emission Computed Tomography (SPECT) of the brain, which showed moderate decreased perfusion and/or brain activity in the projection of the bilateral frontal lobes, more pronounced on the left side, as well as mild hypoperfusion symmetrically in the temporal lobes. For diagnostic confirmation, Whole Exome Sequencing was utilized, revealing a likely pathogenic heterozygous variant in the CSF1R gene associated with Hereditary Diffuse Leukoencephalopathy with Axonal Spheroids. Following the anamnesis, it was reported that initial symptoms included cognitive impairment (predominantly visuospatial and executive), progressing to bilateral spastic hemiparesis, confining her to bed, anarthria, and dysphagia. Additionally, she presents with pseudobulbar affect and impairment of language and previously learned tasks. During this hospitalization, there has been noted progression of symptoms, with significant dysphagia being the reason for admission.On June 10, 2024, surgery was performed to place a gastrostomy tube for nutritional support, with a good surgical recovery. And on June 12, 2024, she was discharged from the hospital. Currently, the patient is residing in a nursing home for necessary care and treatment in light of the progression of the neurodegenerative symptoms. **Final comments:** Diffuse Hereditary Leukoencephalopathy with Axonal Spheroids (HDLS) is a rare neurodegenerative disease within the group of inherited, autosomal dominant conditions. With a high degree of neurological impairment and clinical repercussions, measures for patient comfort and support are necessary, as presented in this case. With an unfavorable evolution and prognosis.

https://doi.org/10.5327/CBN241286

Patterns of response to antiseizure medication over decades in a cohort of patients with mesial temporal lobe epilepsy with hipocampal sclerosis

Aline de Fátima Dias[1], Pamela Regina Henning[1], William Souza Martins Ferreira[1], Marina Koutsodontis Machado Alvim[1], Luciana Ramalho Pimentel da Silva[1], Clarissa Lin Yasuda[1], Fernando Cendes[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Aline de Fátima Dias; Email: alinedef.dias@yahoo.com.br.

Background: Mesial temporal lobe epilepsy (mTLE) is the most common cause of focal epilepsy in adults and hippocampal sclerosis (HS) is its major cause. Even though the natural history of this type of epilepsy is well studied, little is known about the pattern of seizures and outcomes over decades of follow up. **Objective:** To evaluate outcomes of seizures frequency in patients under pharmacological treatment. **Methods:** We analyzed 275 patients with mTLE-HS under pharmacological treatment

followed at Unicamp. We collected data related to seizures frequency, age of epilepsy onset, duration of epilepsy, dosages, and types of antiseizures medications used during treatment. We divided the patients into 3 groups: pharmacoresponsive (no seizures in the last two years or more of follow-up), fluctuating course (seizure-freedom periods of one year or longer) or pharmacoresistant (never had a seizure-free period of more than one year). Data related to patients who underwent surgery were analyzed up to the year prior to the surgical intervention. **Results:** The mean age was 49.57 years (SD 14.13) and the mean follow-up was 15.27 years (SD 11.2). 50.5% (n=139) had left m-TLE, 38.9% patients (n=107) right m-TLE and 10.5% (n=29) bilateral m-TLE. 60 were pharmacoresponsive (21.84%), 67 had fluctuating course (24.36%) and 148 were pharmacoresistnat (53.8%). Age of onset was lower in the pharmacoresistant group when compared to pharmacoresponsive group (p=0.001). There were no significant differences related to epilepsy duration or family history of epilepsy (p≥0.094). In the pharmacoresponsive group, the mean epilepsy duration before they became seizure-free was 33.7 years (SD 16.64). In 88.3% of these patients it took more than 10 years after the diagnosis of epilepsy until they became seizure free. The number of ASMs used along the follow-up were higher in the fluctuating group when compared to the other groups (p<0.028). The number of ASMs used in the last follow-up appointment were lower in the pharmacoresponsive group when compared to the other groups (p<0.033). There were no differences related to the use of carbamazepine (p=0.306). The most common ASM was carbamazepine. **Conclusion:** Younger age at the epilepsy onset was related to worse seizure control, as demonstrated in other studies. The pattern of response to ASM was not static in our cohort of mTLE-HS, and up to 21% achieved seizure freedom at some point in life; however, this took 10 years or longer for most of them, and in many, more than 30 years. This reinforces that early surgical treatment of mTLE-HS is essential to guarantee better quality of life. As expected, the number of ASMs used was lower in the pharmacoresponsive group. Our study suggests that a subgroup of patients with mTLE-HS begins to experience good seizure control after decades of refractory epilepsy. It is still unclear whether this improvement is linked to older age or other factors.

https://doi.org/10.5327/CBN241287

Pediatric Guillain-Barré syndrome in a 27-year cohort

Mario Emílio Teixeira Dourado Junior[1], Daiane de França Falcão Leal[1], Isadora de Albuquerque Falcão Feitosa[1], Tarcila Fontes Lucena[1], Henrique de Paula Bedaque[1], Selma Maria Bezerra Jerônimo[1]

[1]Universidade Federal do Rio Grande do Norte, Natal RN, Brazil.

Correspondence: Mario Emilio Teixeira Dourado Junior; Email: medourado03@gmail.com.

Background: Guillain-Barré syndrome (GBS) is the most common cause of acute flaccid paralysis (AFP) in childhood after eradication of Polio in many countries. Various clinical variants and divergent pathogenic mechanisms that lead to axonal, demyelinating, or mixed findings of GBS observed on electrodiagnostic studies have been described. However, compared to adults, recognition of GBS is sometimes delayed in young children. **Objective:** To examine epidemiological and clinical characteristics aspects of pediatric GBS over the past 27 years in n the state of Rio Grande do Norte, Brazil **Methods:** Data collected prospectively from a cohort of 132 children (<18 years) with GBS, between June 1995 through December 2022 were assessed. **Results:** median age 8 (1- 17); 22% were under 3 years of age. Antecedent events were found in 71.2% patients (56% respiratory infections; 15.2 % Diarrhea). Clinical variants included: 36.6% motor-sensory, 20.4% pure motor, 7.6% overlap GBS-Miller-Fisher, 3% sensitive pure, 1.5% Miller-Fisher syndrome, 4.6% others. Electrophysiological subtypes were: AIDP in 64.2% and axonal in 30.1% patients. 23.2% needed mechanical ventilation and 5.3% died. Pain was present in 70.5% and meningeal irritation was observed in 48.8% of the patients. The presence of pain was associated with elevated protein in cerebrospinal fluid. At 6 months, 93% recover the walking ability. Pediatric GBS had shorter nadir, more frequently presented pain/meningeal irritation, and had a better prognosis. **Conclusion:** The favorable evolution of the clinical outcome is evident, however, GBS can be severe in some patients, progressing to the need for mechanical ventilation and even death. Therefore, considering the particularities of the clinical picture of the pediatric population it is important to have GBS as differential diagnosis for paralysis and early and appropriate treatment be started timewise.

Case presentation: Strokes occur in the pediatric population, although usually considered an adult's disease. Delayed treatment and misdiagnosis are common due to the unfamiliarity and uncommon occurrence. Moyamoya disease is increasingly diagnosed worldwide and represents a significant cause of childhood stroke in Western countries. Similar angiographic features are common in children with other medical conditions, such as sickle cell disease. In these cases, the term "moyamoya syndrome" is used. A patent foramen ovale (PFO) is the most frequent incidental communication diagnosis between the two atria during echocardiography in otherwise healthy children. No further follow-up or intervention is necessary for most healthy children with an isolated patent foramen ovale. Here, we report a case of a 7-year-old male child with sickle cell anemia (SCA) who was admitted to the hospital with a motor deficit in the left limb, noticed upon waking. The previous day, he had been prostrated and feverish. The blood count suggested significant anemia (Hb:6.7 g/dl). **Discussion:** Empirical antimicrobial treatment for incipient meningitis and blood transfusions were administered. After an etiological investigation, the symptoms were attributed to an ischemic stroke, and two potential disease mechanisms were identified: patent foramen ovale and Moya-Moya syndrome. During hospitalization, the child presented bradycardia, hypertension, and a right axis deviation in the electrocardiogram. He completed antibiotic therapy, ventilatory, and transfusion support and was discharged with a complete improvement based on the Pediatric National Institute of Health Stroke Scale (PEDNIHSS) under a scale of 0. Exchange transfusions due to sickle cell anemia were maintained, and he was referred to outpatient cardiology for patent foramen ovale follow-up. **Final comments:** In the absence of large randomized clinical trials in pediatrics, much of the management of pediatric stroke is adapted from adult guidelines. The challenge and the decision-making process for secondary prevention therapy are critical when a child with stroke has rare diseases simultaneously.

Perception of quality of life and social support of patients with amiotrophic lateral sclerosis followed up at a tertiary outpatient in Fortaleza

Tamires Ferreira Do Carmo Macedo[1], Lara Albuquerque de Brito[1], Cleonísio Leite Rodrigues[1], Hermany Capistrano Freitas[1], Eduardo Braga de Oliveira[1], Monica Maria Costa do Rego Alvares[1]

[1]Hospital Geral de Fortaleza, Fortaleza CE, Brazil.

Correspondence: Tamires Ferreira do Carmo Macedo; Email: tamisfcarmo@gmail.com.

Background: Amyotrophic lateral sclerosis is a neurodegenerative disease that affects upper and lower motor neurons. This neuropathological process is responsible for the clinical presentation, which includes progressive muscle weakness, atrophy, fasciculations, spasticity, dysarthria, dysphagia, among other symptoms. **Objective:** To evaluate the perception of quality of life and satisfaction with social support of patients with amyotrophic lateral sclerosis who are followed up at the neuromuscular diseases outpatient clinic of the General Hospital of Fortaleza. **Methods:** This is a cross-sectional, quantitative, and descriptive study in which interviews were conducted using a sociodemographic and quality of life questionnaire, answered by 26 patients diagnosed with amyotrophic lateral sclerosis according to the revised El Escorial criteria. **Results:** Among the 26 individuals, 10 (38.4%) were female and 16 (61.5%) were male. The average age was 51 years, ranging from 30 to 79 years. Regarding the perception of quality of life, 5 patients reported being very satisfied, 6 satisfied, 5 neither satisfied nor dissatisfied, 7 dissatisfied, and 2 very dissatisfied. Regarding social support, all 26 patients responded that they were satisfied or very satisfied with family support, and 20 patients were satisfied or very satisfied with support from friends. When asked about the importance of family and friends in coping with the disease, 96% of the patients declared that family members were important or very important, and 65% considered friends to be important or very important. **Conclusion:** Among the participants, 42.3% had a good perception of quality of life despite the severity of the disease and its consequent loss of functionality. The social support provided by family and friends was markedly important in coping with the disease and was recognized by the patients.

Performance of a Brazilian population with mild cognitive impairment and Alzheimer's disease in the three words: three shapes (3W3S) test

Carla Karnoski[1], Wellington da Cruz Souza[2], Claudia Lopes Carvalho[2], Ariella Fornachari Ribeiro Belan[2], Orestes Vicente Forlenza[2], Márcia Radanovic[2]

[1]Centro Universitário Fundação Assis Gurgacz, Cascavel PR, Brazil.
[2]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, Departamento e Instituto de Psiquiatria, Laboratório de Neurociências (LIM-27), São Paulo SP, Brazil.

Correspondence: Carla Karnoski; Email: carla.karnoski@hotmail.com.

Background: The three words - three shapes (3W3S) test enables differentiation between aspects of learning and memory, characterizing incidental recall (IR), delayed recall (DR), and recognition (REC), thereby allowing assessment of both verbal and non-verbal memory. The test's simplicity and its form of assessment can be useful in diagnosing amnestic and non-amnestic mild cognitive impairment (a/naMCI), and Alzheimer's disease (AD). **Objective:** To verify the applicability and discriminatory capacity of the 3W3S test in patients with aMCI, naMCI and AD within a Brazilian population. **Methods:** We evaluated 107 elderly individuals divided into four diagnostic groups: normal control; (n=33), aMCI (n=20), naMCI (n=42), and

mild AD (n=12) and their performance throughout different stages of the 3W3S test were compared. **Results:** In the non-verbal task, the AD group exhibited the poorest performance across all stages; in IR, the naMCI group surpassed the AD group; both MCI groups (except by AD) were able to match controls after learning and in recognition memory; the MCI group performed worse than the controls in DR (all p-values <0.001). In the verbal task, the AD group demonstrated the worst performance in all stages; the aMCI group performed better than naMCI in IR (all p-values <0.001). Patients with aMCI and naMCI achieved similar scores in all stages of the tasks (all p-values >0.005). **Conclusion:** The 3W3S test demonstrated effectiveness in clinical diagnosis between AD, MCI, and normal controls, revealing score discrepancies. There was no significant difference in scores between the naMCI and aMCI groups.

Performance of a cost-effective olfactory test to evaluate hyposmia in Parkinson's disease patients

Maria Fernanda de Abreu Rodrigues[1], Josevânia Fulgêncio de Lima Arruda[1], Liene Duarte Silva[1], Rodrigo Tavares Brisson[1], Gabriel de Castro Micheli[1], Ana Lucia Zuma de Rosso[1], Marco Antônio Sales Dantas de Lima[1], Rita de Cássia Leite Fernandes[1]

[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Maria Fernanda de Abreu Rodrigues; Email: maferodriguesufrj@gmail.com.

Background: Parkinson's disease (PD) is a neurodegenerative condition with its main clinical signs being motor. However, hyposmia is evidenced in more than 90% of patients. Olfactory analysis is conducted using tests such as the Sniffin' Sticks test® (SS-12®) and the Connecticut Chemosensory Clinical Research Center (CCCRC), which has recently been validated for olfactory assessment in Brazilians. The CCCRC has not yet been tested in Parkinsonian patients. Objectives To verify the cost and the ease of manufacturing the CCCRC test and to compare its performance with the SS-12® in the evaluation of hyposmia in PD. Methods A cross-sectional case-control study conducted at the outpatient Neurological clinic of a university hospital. The PD group (PDG) consisted of individuals aged up to 85 years with PD diagnosis of at least 2 years and no dementia diagnosis. The control group (CG) comprised volunteers without neurodegenerative conditions, aged between 60 and 85 years. The H&Y and the UPDRS-III were used to evaluate PDG. Cognitive function was evaluated using the MoCA for all participants. Clinical data and complaints of hyposmia were collected. Exclusion criteria included a history of head trauma, symptoms of rhinosinusitis, or previous nasal surgery. The groups underwent olfactory testing using SS-12® and CCCRC. Mann-Whitney test was employed to compare scores obtained in the two olfactory tests. Correlations used Spearman's rank correlation coefficient (rho). Results SS-12® cost US$200.00 with validity of 1 year use; CCCRC cost US$5.00 and could be used for up to 3 months, being easily manufactured. PDG (n=34) and CG (n=38) had similar age, gender and educational level. CG scored higher on MoCA (21.3+4.0 vs 17.1+6.2 points; p=0.003). Most part of PDG was in H&Y stages I to III (85%). CG scored higher in olfactory tests: 7.76±2 hits in SS-12® and 4.63 ±2.1 hits in the CCCRC vs 4.70±2.3 hits and 1.17±1.6 hits for the PDG (p<0.0001). The results of both tests showed a moderate correlation (rho=0.65; p<0.0001) and a non-significant tendency toward a negative correlation with age for both groups together (SS-12® rho=-0.05; CCCRC rho=-0.13). There was a positive correlation between MoCA scores and odor results on both tests. There was no correlation between motor performance or disease duration and olfactory test scores. In CG, 21.5% scored normally in SS-12® and 44.7% in CCCRC. In the PDG, only 2.9% had normal scores in SS-12® and 0% in CCCRC. We found that, among participants classified as having hyposmia, 96.6% in CG and 30.3% in PDG denied it. **Conclusion:** The CCCRC test showed similar good performance to SS-12® in assessing olfaction. The ease of manufacturing and low cost of the CCCRC olfactory test may facilitate its use in neurological practice, particularly in medium to low-income countries in the future.

Performance of a healthcare line stroke and its impact on stroke mortality in the Brazil's central arid Northeast countryside

Alan Alves de Lima Cidrão[1], Deborah Moreira Rangel[2], Mara Cibelly da Silva Piheiro[1], Wesley Soares de Melo[2], Nicole Evelly Andrade Alves[1]

[1]Hospital Regional do Sertão Central, Quixeramobim CE, Brazil.
[2]Hospital Geral de Fortaleza, Fortaleza CE, Brazil.

Correspondence: Alan Alves de Lima Cidrão; Email: alancidrao@hotmail.com.

Background: Stroke is a major national health problem in Brazil and, in 2022, was the main cause of mortality in Brazil. The hospitalization of patients in an organized Stroke Unit Care (SUC) during acute phase improves survival, functional outcomes and decreases length of hospital stay when compared to patients admitted elsewhere. **Objective:** The purpose of this study is to show the performance and describe the impact of SUC on stroke mortality in the Brazil's Central Arid Northeast countryside, during the first five years of the service's operation. **Methods:** Data on consecutive stroke admissions to the SUC were prospectively collected from 31 July 2018 to 31 July 2023. The SUC is composed by multidisciplinary team, has 10 monitorized hospital beds and is reference to 20 near cities. The SUC performance was evaluated by time number of thrombolysis, time door-CT, time door-needle, median days of hospitalization, Rankin modified scale on admission and discharge and NIH scale on admission and discharge. Stroke mortality in SUC was monitored internally and mortality in the macro-region was analyzed according to the DATASUS registry. Continuous variables were presented as mean and standard deviation (SD), or median, and categorical variables as frequency and percentage. SPSS version 21 was used for all analyses. **Results:** There were 2375 cases of ischemic stroke/transient ischemic attack, 313 of hemorrhagic stroke and 25 of cerebral venous thrombosis. 440 intravenous thrombolysis were performed (42 in year 1, 100 in year 2, 114 in year 3, 93 in year 4 and 91 in year 5). These numbers represent, in relation to all cases of ischemic stroke each year, respectively, 10.5% - 19.8% - 24.1% - 19.6% - 17.2%. The median door-CT (min) was, respectively, 14 - 11 - 9.6 - 10 - 8. The median door-needle (min) was, respectively, 39.5 - 22 - 17 - 21 - 21. Hospitalization median was 10.5 days, 9.4, 8.3, 9.1 and 8.6 days on year 1 to 5, respectively. There was also a clear improvement in the NIH and Rankin modified scales at hospital discharge compared to admission. By the end of third year, stroke unit hospital mortality was 9.05%. On the last year, this data went down to 5%. When compared the mortality in local macro-region between years before the stroke unit and after its implantation, we can see a clear and sustained decrease since 2019. The year of 2021 had decrease of 24.5% in relation to 2011. **Conclusion:** The SUC performance was better than worldwide average described previously. As for door-needle time, the unit has 80.2% of thrombolysis until 30 minutes, accordingly with desired by American Heart Association, which goal is 50% until 30 minutes. The numbers of hospital mortality are comparable with developed countries services. The impact on local macro-region mortality rates by the stroke unit implementation is one of the main data of our research, showing the importance of SUC on countryside regions.

Peripheral facial paralysis post-viral dengue infection: a case report

Luiza Rodrigues Simões[1], Evelyn Paradzinski Alves[1], Nina Vieira Russo[1], Gabriel Frota Salbego[1], Juliana Oliveira Freitas Silveira[2], Fernando Von Bock Bolli[3], Kelly de Oliveira Harada[1], Fabio Pascotto de Oliveira[1]

[1]Universidade Franciscana, Santa Maria RS, Brazil.
[2]Hospital Universitário de Santa Maria, Santa Maria RS, Brazil.
[3]Universidade Federal de Santa Maria, Santa Maria RS, Brazil.

Correspondence: Juliana Oliveira Freitas Silveira; Email: julianaofs@yahoo.com.br.

Case presentation: A 48-year-old previously healthy woman presented to the emergency department with myalgia, headache, retroauricular pain and fever for 6 days. Laboratory tests confirmed dengue infection. She was evaluated and discharged with symptomatic treatment. The next day, she returned with a worsening headache associated with right hemiface paresis and paresthesia. Physical examination revealed leftward deviation of the labial commissure and paresis of the right orbicularis oculi muscle, consistent with Bell's sign. Cranial computed tomography (CT) showed no abnormalities. Laboratory tests indicated elevated transaminases and tests for Hepatitis, HIV and syphilis were negative. The patient was admitted, received analgesics, hydration, and started on corticosteroids. She also reported tinnitus, altered taste and hearing acuity. Contrast-enhanced cranial magnetic resonance imaging (MRI) revealed significant enhancement of the canalicular and labyrinthine segments of the right seventh cranial nerve. Partial improvement in facial mimicry was achieved with physiotherapy. Three months later, she developed right hemifacial spasm and was prescribed clonazepam. The patient was referred for botulinum toxin injection. **Discussion:** Bell's palsy is the most common type of spontaneous peripheral facial paralysis. Its etiology remains unknown, but it is suspected to occur due to viral reactivation of herpes simplex type 1 in most cases. Other viruses, such as cytomegalovirus, herpes zoster, and Epstein-Barr, may also be associated with Bell's palsy. Dengue is an arboviral disease caused by one of the dengue viruses, transmitted by Aedes aegypti or Aedes albopictus mosquitoes. There are four serotypes: DENV1, DENV2, DENV3, and DENV4. DENV2 and DENV3 have a bigger affinity for the central nervous system. Dengue progresses through three phases: febrile, critical, and recovery. During the febrile phase, patients experience fever, myalgia, headache, ocular and joint pain, nausea and vomiting, lasting 3 to 7 days. Afterward, most patients advance to the recovery phase without entering the critical phase. Dengue should be suspected in patients with the typical clinical picture and a history of exposure to the virus. Diagnosis can be clinical or confirmed through laboratory testing, including serology with IgM detection. **Final comments:** Dengue is a notifiable arbovirus disease with an increasing number of cases in Rio Grande do Sul, becoming a public health problem. Acute infection rarely causes neurological symptoms. The exact mechanism of the virus's action in the nervous system is unknown, leading to cases of encephalitis (the most common presentation), Guillain-Barré syndrome, vascular lesions, myelitis, and myositis. There are some reports of cranial nerve involvement. However, the epidemiology of the association between dengue and Bell's palsy is not well-established yet, making this case extremely important.

Persistent hypoglossal artery stroke presenting as alternating hemiparesis with fourth nerve palsy, internuclear ophthalmoplegia, and dissociated torsional-vertical nystagmus

Carolina Oldoni[1], Marcelo Somma Tessari[1], Gabriel Paulo Mantovani[1], Ana Leticia Amorim de Albuquerque[1], Arthur Pille[1], Rosane Brondani[1], Sheila Cristina Ouriques Martins[1]

[1]Hospital de Clínicas de Porto Alegre, Porto Alegre RS, Brazil.

Correspondence: Carolina Oldoni; Email: carololdoni15@gmail.com.

Case presentation: An 81-year-old woman presented with the sudden onset of left eye ptosis, binocular diplopia, nausea, and vertigo. The neurologic examination revealed an NIHSS score of 6, which included left eye hypertropia, minor right facial palsy, right arm drift, mild hypoesthesia of the right arm, and mild dysarthria. Additionally, she exhibited internuclear ophthalmoplegia and dissociated torsional-vertical nystagmus. There were no pupil abnormalities. Initially, she had partial ptosis of the left eye, which days later improved. A head CT scan didn't show any new ischemic or hemorrhagic areas. CT angiography revealed a persistent hypoglossal artery arising from the right internal carotid artery (ICA) and passing through the hypoglossal canal to form the basilar artery. The vertebral arteries were hypoplastic. These arteries showed moderate to severe atherosclerosis and an occlusion in the distal right P1 segment with distal recanalization via the anterior circulation. Brain MRI revealed a new ischemic stroke in the medial portion of the left inferior colliculus, left paramedian midbrain, and left posterior thalamus. **Discussion:** This case presents dual rarities in neuroanatomy and clinical presentation. First, the persistent hypoglossal artery (PHA), which is an embryonic carotid-vertebrobasilar artery anastomosis that arises from the ICA, usually between the C1 and C2 vertebral levels, and traverses the hypoglossal canal to join the vertebrobasilar system. It has an estimated angiographic incidence of 0.03-0.09% and represents a failure of regression of the presegmental arteries. Bilateral vertebral arteries can be hypoplastic in these cases, making the PHA the main feeder supplying the vertebrobasilar territory. Second, this patient presented with a rare form of nystagmusdissociated torsional-vertical nystagmus (the left eye exhibited ipsiversive torsional nystagmus and the right eye an upbeat nystagmus, a seesaw pattern). This can be explained by the lesion of the excitatory fibers from the anterior canal. These fibers cross the midline in the lower pons and ascend in the medial longitudinal fasciculus (MLF) to innervate the ipsilateral superior rectus and contralateral inferior oblique muscles. Damage to this pathway in the MLF from the contralateral anterior canal causes a downward deviation of the contralesional eye and intorsion of the ipsilesional eye, resulting in corrective quick phases of nystagmus with upbeating in the contralesional eye and extorsion in the ipsilesional eye. It is worth noting that this presentation is reminiscent of Weber's syndrome; however, in this case, there was a trochlear nerve lesion (intra midbrain trajectory) at the left inferior colliculus and a MLF lesion without involvement of the cerebral peduncle, as first described by Hermann Weber. **Final comments:** In the literature, there are no previous reports combining these two features.

https://doi.org/10.5327/CBN241295

Persistent MRI contrast enhancement in calcified neurocysticercosis and its association with refractory epilepsy: a case report

Rafael Guimarães Kanda[1], Fernando Cendes[1], Felipe Guimarães Kanda[2], Leslie Ortega Hernandez[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.
[2]Universidade de Taubaté, Taubaté SP, Brazil.

Correspondence: Rafael Guimarães Kanda; Email: kanda@unicamp.br.

Case presentation: Neurocysticercosis (NCC), caused by the larval stage of Taenia solium, is a significant cause of seizures in endemic regions. We report the case of a 48-year-old woman with recurrent seizures since age 21. Initial cranial CT in 1999 revealed multiple active NCC lesions, accompanied by papilledema and abnormal cerebrospinal fluid findings. Despite multiple treatments with albendazole (1999, 2000, 2005), praziquantel (2004), and corticosteroids (multiple courses of prednisone), her seizures remained uncontrolled. Four cranial MRIs from 2020 to 2024 showed multiple persistent contrast-enhancing lesions. **Discussion:** This case highlights the dynamic nature of calcified NCC lesions and their potential role in refractory seizure disorders. Previous studies have demonstrated the association between perilesional edema and seizure activity, but these were often based on single-timepoint MRI data. Our longitudinal perspective, showing persistent contrast enhancement over a four-year period, underscores the need for comprehensive surveillance and specialized treatment strategies. Histopathological findings indicate that inflammation and immune response play a crucial role in perilesional edema, suggesting that calcified NCC lesions are not entirely inert. This supports the evidence that targeted anti-inflammatory treatments could be beneficial for managing refractory epilepsy in patients with calcified NCC. **Final comments:** Persistent MRI contrast enhancement in calcified NCC lesions may be linked to severe, difficult-to-control epilepsy. This case emphasizes the need for ongoing monitoring and tailored therapeutic interventions, including potential anti-inflammatory treatments, to manage complex epilepsy cases effectively. By providing a longitudinal perspective on MRI findings and their correlation with seizure activity, our report contributes to a deeper understanding of NCC's pathophysiology and management, potentially leading to improved patient outcomes and quality of life.

Pharmaceutical and non-pharmaceutical treatments for migraine: a systematic review of efficacy and safety

Mônica Bagnara[1], Danielly Machado Iaroszeski[1]

[1]Universidade Comunitária da Região de Chapecó, Chapecó SC, Brazil.

Correspondence: Mônica Bagnara; Email: monica.bagnara.eq@gmail.com.

Backgound: Migraine is a chronic neurological condition marked by episodic attacks of headache, usually unilateral, pulsating in quality, and of moderate to severe intensity. Migraine pathophysiology involves complex interactions between genetic, environmental, and neurological factors. Triptans, acetaminophen, nonsteroidal anti-inflammatory drugs, dihydroergotamine, calcitonin gene-related peptide antagonists, lasmiditan, and certain nonpharmacologic treatments have been associated with improved pain relief and function. However, the evidence for many other interventions, such as opioids, is limited, and adverse side effects from pharmacological treatments cause people with migraine to delay or avoid taking medication. **Objective:** To investigate pharmaceutical and non pharmaceutical treatment for migraine and their efficiency to control the symptoms. **Methods:** A systematic review was conducted in the Pubmed database using expressions such as 'migraine non pharmacological' and 'migraine pharmacological'. The filters used were, '5 years,' 'full text,' 'clinical trial' and 'Meta-analysis.' A total of 277 papers were found related and 161 were chosen to be relevant for the research. **Results:** Migraine medications include triptans, beta-blockers, anticonvulsants, and CGRP inhibitors. Triptans, such as sumatriptan and rizatriptan, are often used to relieve acute migraine attacks but can cause side effects like dizziness, drowsiness, and nausea. Beta-blockers, like propranolol and metoprolol, are commonly prescribed for migraine prevention, though they may lead to fatigue, cold extremities, and weight gain. Anticonvulsants, including topiramate and valproate, help reduce the frequency of migraines but can result in cognitive impairment, weight changes, and hair loss. CGRP inhibitors, such as erenumab and fremanezumab, are a newer class of preventive medications with side effects that may include injection site reactions and constipation. Although non-pharmacological treatments offer benefits without the side effects of medications, some disadvantages can limit their effectiveness and accessibility for some people with migraines. Neuromodulation appears as a promising treatment for migraine, causing moderate pain relief. Other non-pharmaceutical prophylaxis treatments include emiketo diet and cognitive behavioral therapy. Overall, however, non-drug treatments have proven to be moderately effective for treating pain and very effective as a preventive measure. Recent drugs, such as erenumab, are safe and capable of alleviating migraine attacks. **Conclusion:** It is concluded that classic medications used in migraine prophylaxis, such as beta-blockers, anticonvulsants, and triptans, are good, effective, and easily accessible. However, new medications and non-pharmacological interventions should be considered, especially in refractory and difficult-to-control cases.

https://doi.org/10.5327/CBN241297

Phelan-McDermid syndrome, autism spectrum disorder and intellectual disability in a pediatric patient: a case report

Lucas Medeiros Dunga[1], Matheus Procópio Guimarães[1], Tiago Lameque de Sousa e Silva[1], Helmut Kennedy Azevedo do Patrocínio[1], Pedro Henrick Guimarães Carvalho[1], Cláudio de Souza Fernandes Júnior[1], Artur Rebouças de Souza[1], Diógenes Emanuel Dantas da Silva[1], Iury Hélder Santos Dantas[1], Cláudio de Souza Fernandes[2]

[1]Universidade Federal do Rio Grande do Norte, Natal RN, Brazil.
[2]Universidade do Estado do Rio Grande do Norte, Mossoró RN, Brazil

Correspondence: Lucas Medeiros Dunga; Email: lucasdunga2000@gmail.com.

P.G.G.B, 7 years old, is diagnosed with Phelan-McDermid Syndrome (PMS), Autism Spectrum Disorder (ASD), and Intellectual Disability (ID). The initial presentation included strabismus, muscle hypotonia, and deficits in neurodevelopmental. Despite consultations with various pediatricians, no causes for these alterations were found. After contact with pediatric neurologists, a more thorough investigation was conducted, including a cranial MRI that demonstrated anatomical brain alterations, such as thinning of the corpus callosum, a prolonged EEG with normal results and a genetic study revealing alterations in chromosome 22. Currently, the patient presents deficits in social and communicative skills, repetitive patterns and restricted interests, flapping, motor stereotypies, significant delays in speech and language. Based on these characteristics, he is diagnosed not only with the syndrome but also with ASD and intellectual disability. He has a history of three epileptic seizures that were considered febrile by pediatric neurologists. His current treatment involves a multidisciplinary approach with physiotherapist, occupational therapy, speech therapy, psychopedagogy, and the use of risperidone. Phelan-McDermid syndrome is a rare condition of unknown prevalence.. It is a genetic disorder caused by SHANK3 haploinsufficiency due to a 22q13.3 chromosomal deletion. Individuals with PMS present a wide range of systemic and neurodevelopmental manifestations, including global developmental delay/intellectual disability, impaired/limited language, autism spectrum disorder, hypotonia, epilepsy, congenital heart defects, gastrointestinal (GI) disturbances, urogenital malformations, and short stature. The patient initially presented with neonatal hypotonia and strabismus, which should serve as early warning signs for the diagnosis of

the syndrome. Subsequently, he developed neurodevelopmental delay, impaired social and communicative skills, associated with stereotyped, repetitive movements and restricted interests, leading to an additional diagnosis of ASD. The overlap of PMS and ASD symptoms adds complexity to the clinical picture, but the genetic confirmation of the 22q13.3 deletion is decisive for diagnosing PMS. Although there is a history of three febrile seizures and a normal EEG, the occurrence of seizures must be carefully monitored, as it is a common aspect associated with the syndrome. The current therapeutic approach for PMS involves a multidisciplinary treatment plan with interventions tailored to the patient's specific needs, maximizing developmental potential and improving the patient's quality of life. Reports like that of P.G.G.B. contribute to the early identification and treatment of PMS, highlighting early warning signs and the clinical overlap with other conditions, such as ASD. The multidisciplinary therapeutic approach emphasized in the report provides a treatment model that can be adapted and applied to other patients with PMS.

Phenotypes associated with autosomal recessive polg in adults: description of a series of cases

Alessandra Lima Nogueira Tolentino[1], Ana Marina Dutra[1], Igor Dias Brockhausen[1], Pedro Nogueira Fontana[1], Roseli Corazzini[1], Alzira Alves de Siqueira Carvalho[1]

[1]Centro Universitário Faculdade de Medicina do ABC, Santo André SP, Brazil.

Correspondence: Alessandra Lima Nogueira Tolentino; Email: ale.tolentino1994@hotmail.com.

Variants in the DNA polymerase gamma gene (POLG) are the most common cause of autosomal inheritance mitochondrial disease, affecting around 2% of the population. The following is a description of 7 cases. **Case presentation:** Patients 1/2: Two male siblings, 60 and 51 years old, with a history of epilepsy, sensory ataxia, psychiatric symptoms, ptosis, chronic progressive external ophthalmoplegia (CPEO) with 21 and 15 years of evolution respectively. Nerve conduction study and myography (NCSM) revealed sensory neuronopathy and myopathic motor unit potentials (MUP). Muscle biopsy showed ragged red fiber in modified Gomori's Trichrome and COX-negative fibers. Brain MRI indicated cortical atrophy and foci of hypersignal T2/FLAIR in white matter. NGS study showed a homozygotic variant in POLG, c.1399G> A (p. Ala467Thr) in both. Patient 3: A 43-year-old female with a history of epilepsy, ataxia, CPEO initiated in her 30's. Presents family history. NCSM was compatible with sensory neuronopathy. NGS panel showed c.1399G> A (p. Ala467Thr) in homozygosis in the POLG. Patients 4/5: Two brothers, 67 and 59 years old. The first one presents CPEO and sensory ataxia since the age of 30 and, last two years, initiated choreic movements and myoclonus. Brain MRI showed cortical and cerebellar atrophy with hypersignal T2/FLAIR of basal nuclei. The second brother has had CPEO and ataxia since he was 50. NCSM showed sensory neuropathy and myopathic MUP. NGS revealed c.752C> T (p. Thr251Ile) in homozygosis in the POLG in both siblings. Patient 6: 46-year-old male with a history of CPEO since the age of 33, evolving with cognitive dysfunction and Parkinsonism. The muscle biopsy was similar to that of patient 1. Brain MRI revealed diffuse cortical atrophy. NGS panel revealed c.1198G> A (p. Val400Met) in homozygosis in the POLG. Patient 7: 26-year-old female, initiated at 19 recurrent stroke-like episodes and status epilepticus. Brain MRI showed foci of hypersignal T2/FLAIR in white matter. Trio exome sequencing showed a compound heterozygous variant: c.1433+1G> A (her father) / c.1880G> A (p. Arg627Gln) (her mother). **Discussion:** Five patients presented the SANDO phenotype (sensory ataxia, neuropathy, dysarthria, ophthalmoplegia). Two families have the p. Ala467Thr, and another has the p. Thr251Ile. Both variants were described as associated with the SANDO phenotype. One patient presents early-onset Parkinsonism and CPEO associated with the variant p. Val400Met. This variant was cited in a Chinese cohort as a cause of early-onset Parkinsonism. The last patient presented the MELAS phenotype (mitochondrial encephalomyopathy, lactic acidosis, stroke-like episodes), with compound heterozygous variant in the POLG. The p. Arg627Gln variant was reported in a patient with MELAS phenotype; c.1433+1G> A was related to POLG-related disorders. **Final comments:** Autosomal recessive POLG gene variants can manifest in adults with epilepsy, SANDO, early-onset Parkinsonism, and MELAS.

Background: Hereditary spastic paraplegia (SPG) is a heterogeneous group of monogenic conditions sharing lower limb weakness and spasticity as the key features. There are multiple genes and modes of transmission. Biallelic variants in the CAPN1 gene were recently associated to this condition and account for SPG type 76 (SPG76). Little is known about the phenotypic and genotypic spectrum of this condition, particularly in Brazil. **Objective:** Hence, we designed the current study to address this issue. **Methods:** All patients with molecular confirmation of SPG76 under regular follow-up at a tertiary neurogenetics reference center between 2021 and 2024 were enrolled. We collected genotypic data from each individual. Detailed phenotypic information was also recorded, including age, sex, age at onset, neurological manifestations and estimated rate of progression, based on the Spastic paraplegia rating scale. **Results:** There were 12 patients (9 men:3 women). Mean age and age at onset were 49.5±10.4 and 32.5±7.0, respectively. None of them had pediatric onset. Eleven out of 12 patients had a complicated phenotype. Associated manifestations were ataxia (n=9), bulbar symptoms (n=7) and cognitive decline (n=2). One patient had comorbid myotonic dystrophy type 1. The estimated rate of progression was 1.6±2.5 points per year. Parental consanguinity was reported by 8 patients. We found 7 distinct variants in our cohort. 11/12 patients had homozygous CAPN1 variants whereas 1/12 compound heterozygous. The CAPN1 variant c.1176G>A was the most prevalent, found in 10 cases. **Conclusion:** SPG76 is an adult-onset condition that presents most frequently as a slowly progressive spastic paraplegia. The variant CAPN1 c.1176G>A seems to be frequent in Brazilian patients, possibly due to a founder effect.

Background: Leprosy is a chronic infectious disease of significant public health concern in Brazil, primarily affecting individuals in disadvantaged socio-economic conditions. This disease is caused by the bacillus Mycobacterium leprae, which primarily affects epithelial and neural cells, thereby conferring a high potential for disability to the patient. Patients with leprosy are categorized based on skin lesion count, bacterial load, and peripheral nerve involvement. Those without neural impairment are classified as grade 0 for physical disability. Grade 1 disability denotes decreased sensitivity or loss in the eyes, hands, and feet, while grade 2 applies to severe lesions in these areas. **Objective:** To evaluate the epidemiological profile of leprosy patients according to the degree of physical disability from 2002 to 2022 in Brazil. **Methods:** This is a descriptive study, prepared with secondary data obtained from the Notifiable Diseases Information System (SINAN), provided by the Department of Informatics of the Ministry of Health (DATASUS). Notifications of physical disability associated with leprosy were evaluated according to the degree of impairment during the period from 2002 to 2022, in each region of the country. **Results:** During the analyzed period, 254,273 cases of physical disability due to leprosy were reported in the country, with 189,357 cases classified as grade 1 physical disability and 64,916 as grade 2 physical disability. Regarding the number of physical disability cases reported per year, the highest number of notifications was observed in 2007, with 15,899 cases, and the lowest in 2020, with 8,489 cases. In terms of physical disability episodes reported by region, the Northeast region leads with 92,115 cases, of which 68,725 are grade 1 disabilities and 23,390 are grade 2. Next, the Southeast recorded 53,355 cases, including 37,882 grade 1 physical disabilities and 15,473 grade 2 disabilities. The North ranks third with 49,995 notifications, of which 37,671 are grade 1 disabilities and 12,324 are grade 2. The Central-West is fourth with 45,258 cases, including 35,450 grade 1 physical disabilities and 9,808 grade 2 disabilities. The South is fifth with 13,550 cases, including 9,629 grade 1 physical disabilities and 3,921 grade 2. **Conclusion:** There was a high number of notifications of grade 1 physical disabilities due to leprosy in Brazil, with the Northeast region standing out as having the highest number of cases in the country, possibly due to socio-economic conditions, limited access to health services, and climate. Followed by the Southeast, explained by higher population density, social inequality, and greater access to diagnostic methods. To achieve goals aimed at reducing disability levels associated with this disease, it is necessary to improve national health surveillance, access to quality public services, and combat the long-standing stigma associated with leprosy.

Physiotherapeutic treatment with motor imagery and tdcs on essential tremor: a case presentation

Tatiana de Paula Oliveira[1], Ricardo Galhardoni[2]

[1]Glia Fisioterapia, Barueri SP, Brazil.
[2]Universidade Cidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Tatiana de Paula Oliveira; Email: tatidepaula@gmail.com.

Case presentation: MEP, female, 69 years old, essential tremor (ET) for five years. Previous use of pramipexole, levodopa, and cannabidiol without effect. She is currently taking escitalopram oxalate 10mg and medication for hypertension and heart disease. On assessment: bilateral

tremor in the upper limbs at rest, worsening during movement, making it impossible to eat independently, doing bimanual activities, and carrying objects; pain in the neck and shoulders (VAS 6) and difficulty sleeping; 35.8 on the Tremor Rating Scale Fahn Tolosa Marin (FTM); 34 sec on the nine-hole peg test (NHPT) in the dominant hand; 4 on the cup test. A mental training protocol of motor imagery (MI) with biofeedback, using a brain-machine interface (BMI), was carried out with training in the following tasks: holding hands still at rest, handling cutlery, bringing food to the mouth, bringing a glass to the mouth and handling a cell phone, followed by physical practice (PP) of these activities associated with non-invasive neuromodulation (tdcs: cerebellar cathodal; F3 and F4 anodal stimulation,4mA for 25 minutes). The treatment consisted of 5 weeks of intervention: 10 sessions of MI/BMI +PP/tdcs in the first two weeks and six sessions of PP/tdcs for three weeks, plus 30 minutes a day of MI+PP at home throughout the intervention period. After treatment: 19.23 in the FTM; 25 sec in the NHPT; 3 in the cup test, and a perceived improvement of 80% in keeping hands still at rest, 80% when handling cutlery, 80% when bringing food to the mouth, 50% when getting a glass to the mouth and 80% when handling a cell phone. She began to eat independently and sleep through the night, and her pain completely improved. After five months, she was reassessed: 15,38 in FTM, and 25 sec in the NHPT, maintaining functional gains. **Discussion:** Evidence reports the increased activity of the cerebellar cortex and deep cerebellar nuclei in ET patients. The mental training of motor imagery (MI) can lead to plastic changes in the brain and, when associated with BMI can provide real-time feedback on the person's mental attempts and is considered a promising tool in the rehabilitation of movement disorders. Tdcs applied to the cerebellar region has been shown to cause inhibition of the primary motor cortex by regulating dentate-thalamo-cortical synaptic excitability. Some case reports show positive results with cerebellar and prefrontal tdcs of ET. In this case, we combined these resources to promote neuroplasticity while training functional activities affected by ET. **Final comments:** In this case of ET with significant impairment of activities of daily living (ADL) and no response to medication, physiotherapeutic treatment with motor imagery plus biofeedback and neuromodulation during ADL training promoted improvement of the condition, with gains maintained over five months. This report could be instructive for long-term randomized controlled trial protocols with a larger number of patients.

Pisa syndrome induced by brexpiprazole: a case report

Ilana Cwajgenberg[1], Orsini Neves[2], Wanderson Alves Ribeiro[3], Daniel Antunes Pereira[2]

[1]Universidade do Estado do Rio de Janeiro, Hospital Universitário Pedro Ernesto, Rio de Janeiro RJ, Brazil.
[2]Universidade Iguaçu, Itaperuna RJ, Brazil.
[3]Universidade Federal Fluminense, Niterói RJ, Brazil.

Correspondence: Ilana Cwajgenberg; Email: ilanacwajg@gmail.com.

Case presentation: A 58 year old female, with a medical history of high blood pressure and depression, presented dystonic movement of the trunk after initiating Brexpiprazole 2mg per day. The drug dose was reduced until it was interrupted and, after twelve days of drug suspension, the dystonic movements ceased. **Discussion:** Drug induced Pisa syndrome (PS) was initially considered to be a rare acute ou tardive collateral effect of typical antipsychotics. Nowadays, however, it has been linked to various classes of drugs, including atypical antipsychotics. However, Bexpripazole has been described as inducing PS in only one previous report. **Final comments:** PS, a dystonic posture of the trunk, may be idiopathic or drug induced, most frequently associated with typical antipsychotic drugs but has already been linked with the use of atypical antipsychotic drugs and other classes of drugs. This case report describes the second case of Bexpripazole induced PS. To better understand this condition and its real prevalence, further studies are necessary.

https://doi.org/10.5327/CBN241303

Pituitary tumor simulating cluster headache

Amauri Pereira da Silva Filho[1], Danielle Cortellazzi Colonna Romano[2], Gabriela Yumi Nakamura[2], Melissa Fernandes Vilela de Freitas[2], Sabrina Borges Batista[2], Natália Rebeca Karpejany[3], Taianara Sampaio Reis[3]

[1]Hospital de Emergência e Trauma Dom Luiz Gonzaga Fernandes, Campina Grande PB, Brazil.
[2]Universidade Nove de Julho, São Paulo SP, Brazil.
[3]Universidade Federal do Piauí, Teresina PI, Brazil.

Correspondence: Amauri Pereira da Silva Filho; Email: amauri.filho@yahoo.com.br.

Case presentation: Patient, male, 42 years old, with periocular pain radiating to the right temporal region, associated with malaise and vomiting. He had intermittent headaches lasting a few minutes several times a day. These headaches always occur at similar times and partial drooping of the right eyelid and tearing, which have occurred in several previous episodes. After the emergency room (ER), he had partial relief with intravenous dipyrone and nasal oxygen (O2), and a probable diagnosis of cluster headache was made. Due to the high frequency of headaches (7 days per month), a decision was made to initiate prophylactic treatment with verapamil in addition to abortive treatment. Additionally, he presented with a visual field defect (bitemporal hemianopsia). The MRI with and without contrast showed an expansive sellar and suprasellar process with slight extension into the cavernous sinus. The diagnosis was revised to a pituitary macroadenoma, and the patient was referred for surgical treatment. **Discussion:** Pituitary tumors account for approximately 17% of all intracranial neoplasms with the majority being pituitary adenomas. They have unique clinical features that are determined by the secreted hormone gene product. Often, these are found incidentally during a workup for headache, in special the trigeminal autonomic cephalalgias (TACs), a group of primary headache syndromes all marked by unilateral headache and ipsilateral cranial autonomic features. The TACs include cluster headache, paroxysmal hemicrania, short-lasting unilateral neuralgiform headache attacks with conjunctival injection and tearing, and hemicrania continua. Pathophysiology includes the trigeminal pain system, autonomic system, hypothalamus, and more recently an identified role for the vagus nerve. Diagnosis is made after looking at headache frequency, duration, and accompanying symptoms. Each TAC has its own unique treatment, which is discussed in depth. Cluster headache (CH) is a TAC with a prevalence of 0.1-0.2% and it is not caused by any known underlying structural pathology. It is often considered to be one of the most painful conditions known to mankind and can be mimicked by symptomatic causes in a small minority of patients, for example tumours, dissections and infections, but a causal relationship between the underlying lesion and the headache is difficult to determine in many cases. There are several reports in the literature suggesting that CH can be mimicked by pituitary disease. The proper diagnostic evaluation of cluster headache is an issue unresolved. **Final comments:** A pituitary tumor presenting with cluster headache is challenging to diagnose due to the variability of symptoms and the need to accurately identify the headache type. The main challenge is to create a treatment plan that effectively addresses both conditions, minimizes side effects, and improves the patient's quality of life through multidisciplinary care.

Plasma Aβ42/p-Tau ratio predicts csf amyloid status in subjective cognitive decline and mild cognitive impairment

Marcio L. F. Balthazar[1], Isadora Cristina Ribeiro[1], Marjorie Cristina da Rocha Silva[1], Ítalo Karmann Aventurato[1], Liara Rizzi[1], Luis Eduardo da Silva Santos[2], Gustavo Bruniera Peres Fernandes[3], Fernanda Guarino de Felice[4]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.
[2]Instituto D'Or de Pesquisa e Ensino, Rio de Janeiro RJ, Brazil.

[4]Queen's University, Ontario, Canadá.

Correspondence: Marcio L. F. Balthazar; Email: mbalth@unicamp.br.

Background: Detection of amyloid status in the central nervous system, based on a non-invasive blood test, is essential, especially in patients in potentially pre-dementia stages and candidates for receiving new anti-amyloid drugs. **Objective:** To evaluate if plasma measurements of Aβ42/Aβ40, Aβ42/p-Tau181, and Aβ42/T-tau ratios can predict cerebrospinal fluid (CSF) amyloid alteration in patients with Subjective Cognitive Decline (SCD) and Mild Cognitive Impairment (MCI). **Methods:** We evaluated 51 patients (31 women) diagnosed with SCD and MCI (NIA/AA criteria). All participants underwent neuropsychological assessment, magnetic resonance imaging, blood and cerebrospinal fluid tests. Roche's Elecsys immunoassay measured the quantification of CSF Aβ42 peptide (normal > 1000 pg/mL). Plasma biomarkers Aβ42, Aβ40, p-Tau 181, and t-Tau were measured on an automated SIMOA HD-X immunoassay equipment. Logistic regression models considering Aβ42/Aβ40, Aβ42/p-Tau181and Aβ42/t-Tau ratios in plasma, age, and sex were performed, as well as ROC curve analysis to evaluate sensitivity and specificity. **Results:** 29 subjects had altered Aβ42 in the CSF. The full model was significant, $\chi 2$ (5.51) =11.53, p=0.042, R2=0.272. Only Aβ42/p-Tau181 contributed significantly to the model (B=8.09, p=0.022). At the threshold of 0.368, the model achieved a sensitivity of 75.8% and specificity of 54.5%, with an AUC of 66.6%, 95% CI: 0.52-0.79), p = 0.033 **Conclusion:** The plasmatic Aβ42/p-Tau181 ratio could predict CSF amyloid alteration with good sensitivity and low specificity in subjects at high dementia risk. As far as we know, this is the first study in a Brazilian sample to evaluate plasmatic Alzheimer's biomarkers in potential pre-dementia subjects using gold-standard diagnostic methods like Elecsys and SIMOA.

Plasma miRNAs correlate with structural brain and cardiac damage in Friedreich's ataxia

Alexandre Hilário Berenguer de Matos[1], Thiago M. Peluzzo[1], André S. Vieira[2], Cynthia Silveira[1], Mariana Martin[1], Otávio R. C. Filho[1], Thiago J. R. Rezende[1], Alberto R. M. Martinez[1], Marcondes C. França Jr[1]

[1]Universidade Estadual de Campinas, Faculdade de Ciências Médicas, Departamento de Neurologia, Campinas SP, Brazil.
[2]Universidade Estadual de Campinas, Instituto de Biologia, Departamento de Biologia Estrutural e Funcional, Campinas SP, Brazil.

Correspondence: Alexandre Hilário Berenguer de Matos; Email: alexandrehbm@gmail.com.

Friedreich's ataxia (FRDA) is the most common autosomal recessive ataxia worldwide and is caused by biallelic

unstable intronic GAA expansions at FXN. In recent years, miRNAs have emerged as promising biomarkers in various medical fields such as oncology, cardiology, and epilepsy. Cell-free plasmatic miRNAs have potential advantages as biomarkers because of their size, stability against blood RNases, relative ease of obtaining (from peripheral blood), storage (-80°C), and qRT-PCR measurement. However, there is a limited number of studies looking at plasmatic miRNA expression in FRDA. In this study, we attempted to characterize the plasma miRNA signature (using RNA-Seq followed by real time PCR) and its clinical correlates in a cohort of Brazilian patients with FRDA. We found two abnormally expressed miRNAs, the miR-26a-5p overexpressed and the miR-15a-5p underexpressed. The first was correlated with age at onset, cerebellum volume, spinal cord cross-sectional area (C2-CSA) and the left cardiac ventricle mass (LV_Mass). For the miR-15a-5p, significant correlations were found with the cerebellum volume, spinal cord eccentricity and LV_Mass. Although the specific biological pathways these miRNAs act are not yet fully elucidated, both have BDNF as their target and, hypothetically, modulate its expression. The reduced expression of this gene leads to neuronal loss, both in the cerebellum and sensory pathways, explaining the ataxic phenotype and our results reinforce this hypothesis. Both miRs were correlated with the LV_Mass, but the miR-26a-5p was already associated with cardiomyocyte hypertrophy through the increased inflammasome NLRP3 activity, which is indirectly linked with cardiac hypertrophy. Considering that, we propose these miRNAs as possible prognostic biomarkers for FRDA. However, we should consider that this is a cross-sectional study, so, longitudinal studies are still needed to validate the clinical use of these miRNAs.

PLP-1 spectrum disease: two female cases of a X-linked inheritance

Catarina Dantas Corrêa[1], Renata Cristine Alves[1], Luis Eduardo Borges de Macedo Zubko[1], Daniel Fortes Amarante[1], Francisco Manoel Branco Germiniani[1], Max Rainer Rosado Novaes[1], Luiz Eduardo Novis de Farias[1], Helio Afonso Ghizoni Teive[1]

[1]Universidade Federal do Paraná, Hospital de Clínicas, Curitiba PR, Brazil.

Correspondence: Renata Cristine Alves; Email: renata_cristinealves@hotmail.com.

Case presentation: A female patient began experiencing right-hand tremor and dysarthria at age 15. Seven years later, she developed progressive lower limb spasticity and ataxia, leading to frequent falls. By age 38, she presented with urinary incontinence and tonic-clonic seizures. Neurological examination revealed mild dysarthria, dysmetria in the upper limbs with right-hand kinetic tremor, mild lower limb paresis with spastic tonus, global hyperreflexia, and bilateral Hoffmann and Babinski signs. She was born into a family of German descent with no history of consanguinity. Her mother was diagnosed with spastic paraparesis and cognitive decline in her fourth decade. Her brother experienced delayed neuropsychomotor development and frequent falls and died at 29 years old after status epilepticus. Her younger sister began experiencing upper limb polymyoclonus, nystagmus, and cervical and laryngeal dystonia at age 13. Both sisters had brain MRIs showing diffuse white matter increased T2 signal intensity. These patients underwent whole exome sequencing (WES), which revealed the same PLP1gene mutation: heterozygous variant c.449del. This mutation causes a frameshift starting at asparagine 150, resulting in a stop codon 10 amino acids later, confirming the diagnosis of Pelizaeus-Merzbacher disease or Spastic Paraplegia type 2 (SPG2). **Discussion:** Pelizaeus-Merzbacher disease (PMD) is a rare X-linked inherited demyelinating leukodystrophy of the CNS, typically manifesting in early childhood with impaired neuropsychomotor development, nystagmus, and hypotonia, and progressing with spasticity and ataxia. Epilepsy is rare in this condition. PMD results from loss or gain of function mutations in the proteolipid protein 1 (PLP1) gene, located on the long arm of the X chromosome (Xq22), which is crucial for myelin synthesis. These mutations lead to abnormal protein production and toxicity to oligodendrocytes. As an X-linked disease, only 14 cases have been reported in women, who typically presente with later onset and milder symptoms. **Final comments:** As far as we know, this is the first reported case of PMD with epilepsy in a female patient.

https://doi.org/10.5327/CBN241307

Poliomyelitis sequelae in Brazil: an analysis of hospitalizations and deaths according to age groups in the eradication era

Alisson Rafael de Oliveira Pereira[1], Ana Júlia Alves de Oliveira Andrade[1], Lucas Abreu Dias[1], Rodrigo Ferreira de Moura[1]

[1]Universidade Federal de Lavras, Lavras MG, Brazil.

Correspondence: Alisson Rafael de Oliveira Pereira; Email: alissonropereira@gmail.com.

Background: Oral poliomyelitis vaccine (OPV) was introduced in Brazil in 1961, initiating a process of interrupting the circulation of the virus. Officially, the last case of a wild poliovirus infection occurred in 1989. Despite the eradication status of acute poliomyelitis, hospitalization for polio sequelae continued to be recorded, mainly due to three mechanisms: patients whom had contact with poliovirus prior to eradication, and therefore may have developed disease at an earlier age; patients who received the oral attenuated virus vaccine, and due to immunodeficiency, developed a vaccine reaction; and patients who had contact with the wild virus in another country, importing the disease. **Objective:** To evaluate the distribution of hospitalizations and deaths due to poliomyelitis sequelae according to age group and investigate changes in trends between the period 2008-2023. **Methods:** A retrospective study was conducted using data recorded in the SIH available in DATASUS. Groups according to age were evaluated using joinpoint regression analysis and a generalized linear model (GLM). **Results:** Overall, hospitalization rates for polio sequelae decreased (AAPC -8.1; 95%CI: -10.4 to -5.7; p<0.01), with a change in trends. The significant reduction up to 2015 (APC: -15.1; p<0.01) was replaced by a stationary trend with a non-significant decrease (APC: -1.6; p=0.73). Regarding death rates, a non-significant increase was identified (AAPC: 1.4; 95%CI: -3.7 to 6.1; p=0.52) composed of a joinpoint with trend reversal. In 2018, the previous reduction effect (APC: -11.4; p<0.01) was replaced by a significant increase that has been maintained to date (APC: 33.1; p<0.01). Analysis of the subgroups according to age group showed that the overall trend of reduction in hospitalizations was similar between those over 30 years of age who had contact with the wild virus and those who received at least one dose of OPV (AAPCw: -7.9; APCv: -8.5; p<0.01). The GLM showed an important difference between the groups (B= 0.13; 95%CI: 0.08 to 0.16; p<0.001), with the hospitalization rate being 0.13 units higher for those who had contact with the wild virus. Similarly, in absolute numbers, hospitalizations were 3.6 times higher than those in the vaccinated group after eradication. The analysis of death rates showed similar results (B=0.004; 95%CI: 0.003-0.005; p<0.001), with the number of deaths 25.6 times lower in the group after eradication. **Conclusion:** A similar trend of reduction in hospitalizations between groups demonstrates the collective effect of OPV in interrupting the transmission of the virus, while the higher concentration of cases in the >30 years age group indicates that those who were presumed to have had contact with the wild virus before eradication accounted for the majority of hospitalizations for polio sequelae. Further investigations are needed to determine the abrupt upward trend in deaths that began in 2018.

Polyneuropathy and folate deficiency: a case report

Natália Cardoso Darabas[1], Gustavo Cardoso da Silva[2], Caroline Cardoso da Silva[3]

[1]Hospital Municipal São José, Joinville SC, Brazil. [2]Hospital São João Batista, Criciúma SC, Brazil. [3]Universidade do Extremo Sul Catarinense, Criciúma SC, Brazil.

Correspondence: Natália Cardoso Darabas; Email: natiii_cardoso@hotmail.com.

Case presentation: Female patient, 22 years old, underwent bariatric surgery 4 months ago. She began with a deficit in strength and sensitivity in the lower limbs, later progressing to intense shock-like pain. An investigation was carried out with an orthopedist, with spinal resonance showing no changes. Admitted to the neurology service due to severe pain. On physical examination, she presented a subtle strength deficit in the lower limbs and reduced tactile, painful and proprioceptive sensitivity in the lower limbs, worse distally, with abolished deep reflexes. No changes to the upper limb examination. A new neuraxial resonance was performed during hospitalization, with no changes, normal liquor, electroneuromyography with predominantly motor axonal injury, acute denervation in progress. Laboratory tests showed vitamin B12 1.159 pg/mL, vitamin B1 92,5 mcg/L and folic acid 1.4ng/mL. Diagnosed with peripheral polyneuropathy with subacute onset due to folic acid deficiency. The patient began treatment with appropriate replacement and resulted in complete improvement of symptoms. **Discussion:** Peripheral neuropathy is a term given to indicate a disorder of the peripheral nervous system. Characterized by symmetrical sensory symptoms, such as numbness, paraesthesia, pain, and muscle weakness, which usually begins in the hands and feet and may progress to the arms and legs. The most common causes of polyneuropathy are diabetes, excessive alcohol consumption and deficiencies in certain vitamins, but about 25% are considered idiopathic. About the deficiencies, is much more common among patients with vitamin B12 deficiency. The nerve cells may have some ability to accumulate folate, the risk of neuropathy in those with folate deficiency is meant to be much rarer than that of vitamin B12 deficiency. However, patients with folate deficiency can develop peripheral neuropathy, because of the essential role of folate in the methylation of homocysteine to methionine, a precursor to S-adenosyl methionine, which is important for myelination of nerve cells. Importantly, the risk of peripheral neuropathy increased as serum folate decreased. The study carried in 1978 was the first characterization of a pure folate deficiency neuropathy confirmed. Even after several years since it became known that folic acid deficiency can cause polyneuropathy, there are still few studies on the subject. The relationship between folate deficiency and neurological symptoms it's harder, since most patients suffer from nutritional disorders or excessive alcohol intake, resulting in deficiency of nutrients other than folate. **Final comments:** This report demonstrates the importance of research and quantification of folic acid in the investigation of polyneuropathies. Furthermore, in the absence of large randomised controlled trial evidence, the association between serum folate and peripheral neuropathy should be examined in large longitudinal studies.

Polyneuropathy as an initial manifestation of adrenal neoplasia: case report

Bruna Santos Silva Guzzardi[1], Gustavo Carvalho Viveiros[1], Rodrigo Batista Irikura[1], Anouar Sacca Colognesi[1], Isabella Brasileiro Quintella Migueis[1], Sarah de Souza Chinelato[1], Guilherme Leonel Gomes da Cunha[1], Talles Camin Rajab[1]

[1]Faculdade de Medicina de Marília, Marília SP, Brazil.

Correspondence: Gustavo Carvalho Viveiros; Email: gustavocarvalhoviveiros@outlook.com.

Case presentation: A 62-year-old male patient was referred via cross for evaluation by the institution's neurology service. He was admitted to the emergency room on April 4, 2024, with the report that about 15 days ago he began to suffer from pain in his right shoulder, which progressed slightly to paresis, followed by progressive evolution of the paresis to the ipsilateral lower limb, and in less than 5 days the patient already had tetraparesis. As soon as tetraparesis was established, it was associated with excruciating muscle pain of a generalized nature, dysphagia for liquids, psychomotor alterations (with hallucinatory experiences: visual and auditory). CSF was collected and showed xanthochromic CSF, no cells, protein 505 mg/dl, red blood cells 32/mm3, glucose 26mg/dl. As a result of the CSF, human immunoglobulin was started for 5 days, with no response to treatment. Myositis was confirmed with CPK 1445. Magnetic resonance imaging showed infiltrative lesions in the brain and cervical spinal cord, causing ascending edema at the level of the lesion. A CT scan of the abdomen showed a heterogeneous nodule with contrast enhancement and areas suggestive of cystic degeneration/necrosis in the topography of the left adrenal gland, measuring 6.7 x 8.3 x 8.0 cm. Due to the patient's weakness, the neurosurgery and urology specialties decided not to biopsy the lesion and, together with the neurology and oncology teams, a probable diagnosis of malignant neoplasm of the left adrenal gland with brain and spinal cord metastasis was reached. **Discussion:** Paraneoplastic syndromes represent clinical disorders that are often not directly attributed to the physical effects of the primary tumor or metastasis. Paraneoplastic alterations can develop from the production of substances released by tumor cells, as well as being triggered by the depletion of substances commonly present in the body, whose deficit leads to the onset of symptoms, or even as a result of the body's immune response to the tumor. It's important to remember that the patient's symptoms may be synchronous with the onset of the tumor, but they may be a late symptom that appears after the tumor is established or even precede the tumor. **Final comments:** polyneuropathy can manifest as one of the first symptoms of neoplasms, and in this case it was related to malignant adrenal neoplasia. Unfortunately, however, the time of presentation of the tetraparesis did not coincide with the initial appearance of the tumor, as brain and spinal cord metastases had already set in at the time of diagnosis. It is important to note that human immunoglobulin was not effective in resolving the patient's paretic symptoms, despite being the treatment used in polyneuropathies. However, it would be more likely that the symptoms of the paraneoplastic syndrome would be resolved by treating the tumor lesion with chemo and radiotherapy, which in turn was not eligible for this patient.

https://doi.org/10.5327/CBN241310

Polyneuropathy secondary to Rocky Mountain spotted fever: a case report

Sarah de Souza Chinelato[1], Bruna Santos Silva Guzzardi[1], Rodrigo Batista Irikura[1], Anouar Sacca Colognesi[1], Isabella Brasileiro Quintella Migueis[1], Gustavo Carvalho Viveiros[1], Talles Camin Rajab[1], Guilherme Leonel Gomes da Cunha[1], Fábio de Araujo Pereira[1], Luiz Henrique Soares Santos Stefano[1]

[1]Faculdade de Medicina de Marília, Marília SP, Brazil.

Correspondence: Sarah de Souza Chinelato; Email: sarahchinelato@hotmail.com.

Case presentation: Male patient, 47 years old, presented to the emergency room reporting the presence of four ticks on his skin after returning home from a fishing trip. The following week, he developed fever, malaise, myalgia, and headache. He was diagnosed with Rocky Mountain spotted fever based on clinical and epidemiological criteria. Eighteen days after symptom onset, he experienced worsening symptoms, including seizures, progressing to toxemia and sepsis, along with flaccid tetraparesis in the limbs, with overall muscle strength grade II. During hospitalization, cranial and total spine MRI showed no abnormalities, and electromyography of all four limbs diagnosed severe axonal motor polyneuropathy predominantly affecting the lower limbs. Cerebrospinal fluid collected at admission showed 10 cells (67% neutrophils) and 115 proteins; a repeat procedure by the Neurology Team after 16 days showed normalization. Serology for Rocky Mountain spotted fever was positive (02 samples >1/256). Throughout the hospital stay, the patient developed respiratory failure requiring orotracheal intubation and sedation. He received various antibiotics, including doxycycline, and after 40 days showed favorable clinical improvement. **Discussion:** Rocky Mountain spotted fever is an acute febrile infectious disease with variable clinical presentation and severity, potentially lethal. It is caused by the obligate intracellular gram-negative bacteria Rickettsia rickettsii and Rickettsia parkeri, primarily transmitted by the Lone Star tick, Amblyomma americanum. The disease mainly affects men aged 20 to 49 who have been exposed to ticks or frequented areas such as waterfalls, rivers, or forests. Most cases occur between June and November when young tick stages are abundant, with these arachnids remaining infected throughout their lifespan. Initially, the disease may present with nonspecific symptoms such as high fever, myalgia, diarrhea, vomiting, and headache. A maculopapular rash may appear after several days. The clinical course can progress with neurological complications such as encephalitis, polyneuropathy, and meningitis. Polyneuropathy associated with Rocky Mountain spotted fever is characterized by diffuse damage to peripheral nerves, resulting in muscle weakness, pain, and paresthesia. Treatment with doxycycline is recommended as first-line therapy, while chloramphenicol is the second-line therapeutic option, prioritized in severe cases. **Final comments:** This study is relevant due to the low prevalence of reported cases regarding neurological complications of Rocky Mountain spotted fever, particularly polyneuropathies. Clinical and epidemiological detection is essential for early diagnosis and treatment, thereby improving prognosis with reduced mortality and severe complications.

Polyradiculoneuritis due to HSV-2 mimicking miller Fisher syndrome: a case report

Pedro Vinicius Brito Alves[1], Riccardo Casarotti[1], Luiz Gustavo Breinneisen Santos[1], Aida Maria Negrao Esteves[1]

[1]Prevent Senior Brasil, São Paulo, São Paulo SP, Brazil.

Correspondence: Pedro Vinicius Brito Alves; Email: pvbalves@gmail.com.

Case presentation: We report the case of a 75-year-old man who, 4 days before admission, presented with paresthesias in hands and feet associated with postural instability, urinary retention, and pain on radicular stretching maneuvers. Cerebrospinal fluid analysis revealed lymphocytic pleocytosis (7 cells) and elevated protein levels (86mg/dl), with a positive PCR for HSV-2. During hospitalization, despite treatment with intravenous acyclovir for 14 days and pulse therapy with methylprednisolone 1g/day for 5 days, the patient experienced further neurological deficits with loss of axial strength and worsening paresthesia and radicular pain. He also developed areflexia, sensory and cerebellar ataxia, complex ophthalmoparesis and facial diparesis. Given the triad of complex ophthalmoparesis, areflexia and ataxia, immunotherapy was escalated to plasmapheresis for the hypothesis of Miller Fisher Syndrome (MFS). The patient showed subtotal reversal of cranial nerve symptoms and gained independent walking. Good control of neuropathic pain symptoms was achieved with low dose opioids and gabapentinoids. **Discussion:** Herpes Simplex II infection is generally unrecognized, with up to 90% of infections going undiagnosed. When active, it is usually oligosymptomatic and associated with milder neurological conditions, such as aseptic meningitis and Mollaret's meningitis. The patient presented with an acute sensory-motor symptoms, with urinary retention, asymmetrical areflexia and radicular pain, which could represent a HSV-2 associated radiculitis. However as facial diparesis, ophthalmoparesis, sensory and cerebellar ataxia developed, we leaned towards a Miller Fisher syndrome (MFS) clinical picture and approach. HSV-2 infection can affect the entire nervous system, leading to potential necrotizing encephalitis, cranial neuropathies, myelitis, and involvement of roots and peripheral nerves. The recommended treatment consists of intravenous acyclovir for 14 days, with some authors advocating for extending treatment to 21 days based on persistently positive PCR results. Intravenous corticosteroids may hasten recovery in single cases. The clinical progression despite acyclovir and methylprednisolone pulse therapy and improvement with plasmapheresis highlights the anti-body and complement mediated natures of the auto-immune response and aligns with the treatment guidelines for Guillain-Barré syndrome and its variants. **Final comments:** This case highlights heterogeneous clinical spectrum of the HSV-2 infection in the central nervous system, granting it a mimicker fame. Furthermore, touches on the presence of more complex immune-mediated responses to viral infections. Understanding which component of the immunity one wishes to address can help them focus on more effective and tailored therapies, obtaining better functionality outcomes.

Polyradiculoneuropathy and multisystem complications in a Chikungunya-infected patient: a case report

Natalia Rebeca Alves de Araujo Karpejany[1], Taianara Sampaio Reis[1], Vinicius Araujo do Vale[1], Amanda Melo Barradas[2], Maria Clara Andrade Alvim Vieira[2], Priscila de Sousa Barros Lima[2], Danielle Cortellazzi Colonna Romano[3], Melissa Fernandes Vilela de Freitas[3], Sabrina Borges Batista[3], Gabriela Lustosa Said Uchoa[1]

[1]Universidade Estadual do Piauí, Hospital Universitário, Teresina PI, Brazil.
[2]Universidade Estadual do Piauí, Teresina PI, Brazil.
[3]Universidade Nove de Julho, São Paulo SP, Brazil.

Correspondence: Natália Rebeca Alves de Araújo Karpejany; Email: nataliarebeca2607@gmail.com.

Case presentation: A 43-year-old man began experiencing, about 5 months ago, joint pain and muscle weakness in his right lower limb, which progressed to his left lower limb, upper limbs, accompanied by lower back pain. Subsequently, muscle weakness worsens, progressing to inability to walk. Concurrently, he experienced severe, asymmetric, migratory polyarthralgia associated with local heat and edema. He was then referred to the Neurology department of a University Hospital for further investigation. Electroneuromyography showed sensory-motor impairment in the nerves of all limbs, primarily axonal in nature, relatively symmetrical, with diffuse distribution, worse in the lower limbs, and of marked degree, suggesting polyradiculoneuropathy. During hospitalization, he developed sepsis of pulmonary origin, rapidly progressing to respiratory failure, requiring mechanical ventilation in the ICU. After stabilization, he returned to the Internal Medicine ward for further investigation. CT and MRI scans of the CNS showed no abnormalities, but cerebrospinal fluid analysis revealed 88 mg/dl of protein

and 4 cells. Serologies for arboviruses were requested from serum, cerebrospinal fluid, and urine samples, with Chikungunya IgM in the serum sample, confirming the infection. During hospitalization, the patient underwent an echocardiogram which showed an LVEF of 22% associated with diffuse hypokinesia. Given that the patient was previously healthy, myocarditis secondary to arbovirus infection was hypothesized, and treatment with inotropes was initiated. However, to date, the patient is awaiting a cardiac MRI for better etiological definition. At the time of writing this report, the patient is undergoing treatment with Prednisone, Methotrexate, Folic Acid, Gabapentin, and Carvedilol, in addition to physical therapy sessions, showing improvement in motor function, reduction in pain, and better hemodynamic stability. **Discussion:** Chikungunya is caused by an alphavirus transmitted by Aedes aegypti mosquitoes, presenting with acute febrile polyarthralgia, inflammatory arthritis, skin eruptions, and other systemic symptoms. Although rare, severe complications have been reported during chikungunya outbreaks. These include respiratory failure, cardiovascular decompensation, myocarditis, renal failure, hemorrhage, and neurological involvement such as Guillain-Barré syndrome. These complications are more frequently in patients over 65 years old and with underlying comorbidities. This case is unusual due to occurring in a previously healthy 43-year-old male, with respiratory, cardiovascular, and neurological complications. **Final comments:** The case is notable for the numerous severe complications associated with Chikungunya. Early awareness and recognition of these complications are essential for effective management. Continued surveillance and research are needed to comprehensively understand the diverse manifestations and impact of Chikungunya across various patient groups.

Polysomnographic findings in patients with Parkinson's disease

Emillaine Alves Noronha[1], Diego Monteiro de Carvalho[2], Marcus Vinicius Della Coletta[3], Alvaro Siqueira da Silva[2], Raissa Costa Said[1], Marcello Facundo do Valle Filho[2], Agatha Lopes Azedo[1], Mariana Carvalho Ferreira[1], Yenly Gonzalez Perez[2], Carlos Maurício Oliveira de Almeida[2]

[1]Universidade do Estado do Amazonas, Manaus AM, Brazil.
[2]Universidade Federal do Amazonas, Manaus AM, Brazil.
[3]Universidade Federal do Paraná, Curitiba PR, Brazil.

Correspondence: Agatha Lopes Azedo; Email: agathalopesazedo@gmail.com.

Background: Parkinson's disease (PD) is the primary cause of parkinsonism in the elderly, affecting 1-3% of individuals in this age group and about 1% of the global population. PD is associated with poor sleep quality and various sleep disorders such as obstructive sleep apnoea (OSA), insomnia, Restless Legs Syndrome (RLS), and REM Sleep Behaviour Disorder. Polysomnography (PSG) is the gold standard for the objective assessment of sleep disorders. **Objective:** To analyse the polysomnographic findings in patients with Parkinson's Disease. **Methods:** This is a cross-sectional observational study with a duration of 12 months, conducted at a referral hospital in Manaus, Amazonas. The study was approved by the local Ethics Committee under CAAE No. 58684622.2.0000.0007. The sample consisted of patients with PD, diagnosed according to the criteria of the London Brain Bank and classified as stage 1-3 on the Hoehn-Yahr scale. Exclusion criteria included a diagnosis of dementia, atypical parkinsonism, and language disorders. Patients were invited to spend one night in the sleep laboratory. A digital polygraph was used: BW-III, with 45 channels (Neurovirtual, Brazil), including EEG (10-20 system), bilateral oculogram, ECG, tibial, flexor, and mentalis EMG, airflow sensors and cannula, respiratory effort, body position, O2 saturation, and synchronised video (Intelbras, Brazil). Sleep staging was performed according to the criteria of the American Academy of Sleep Medicine (AASM) by trained and blinded physicians. **Results:** After meeting all the study requirements, eighteen patients underwent PSG over 12 months. The total sleep time averaged 447.25 minutes. REM sleep latency had a mean of 234.2 minutes with a standard deviation (SD) of 123.42. Sleep onset latency (N1) had a mean of 13.74 minutes and an SD of 18.77. The mean O2 saturation during total sleep time was 95.33%, while the mean desaturation index (DI) was 10.44. Regarding diagnoses, 7 patients (38.9%) were diagnosed with OSA, 10 patients (55.6%) with primary snoring, and 2 patients (11.1%) with REM Sleep Behaviour Disorder. The mean periodic limb movement index (PLMI) was 1.17 with a standard deviation of 3.51. **Conclusion:** This study evidenced a high prevalence of sleep disorders in patients with PD, with 38.9% diagnosed with OSA and 55.6% with primary snoring. Sleep fragmentation and prolonged REM sleep latency are common, reinforcing the need for polysomnographic evaluation. Proper assessment and treatment of sleep disorders can significantly improve the quality of life for these patients, although further studies are necessary.

Polysomnography and simplified sleep apnea test devices: mixing water and oil in the cup of the new cfm resolution

Karla Carlos[1], Lucas Martins Teixeira[1], Ligia Geminiani[1], Carla de Oliveira Carletti[1], Douglas Sousa Soares[1], Ana Flavia Machado Pitz[1], Letícia Lambert[1], Gilmar Fernandes do Prado[1]

[1]Universidade Federal de São Paulo, Escola Paulista de Medicina, Departamento de Neurologia e Neurocirurgia, São Paulo SP, Brazil.

Correspondence: Karla Carlos; Email: ka.carlos1@hotmail.com.

Background: Simplified sleep apnea test devices (SSATD) can be used to diagnose obstructive sleep apnea (OSA) in patients with a high probability of having the disease. Supposedly valid in contexts of limited resources, they have notable limitations, such as the inability to record EEG and define the sleep state during the test. **Objective:** Assessing how manufacturers ethically address the limitations of these devices in institutional disclosures. **Methods:** We used the SCOPER criteria to assess SSATD registrations with ANVISA, looking at official and fantasy names, descriptions, purposes, official and advertising data, compliance with SCOPER, and adherence to CFM standards. **Results:** We have identified 5 SSATDs, one of which has been discontinued. They have the following technical versus promotional names: Pulse Oximeter (OP) vs Nocturnal Oximetry; Sleep Monitoring System (SMS) vs Home Sleep Test; Sleep Apnea Syndrome Testing Device (DTSAS) vs Sleep Exam & Snoring and Sleep Apnea Diagnosis; Plethysmograph (PG) vs Sleep Exam. One device is a sleep study type III, and 3 type IV, whose SCOPER classifications are: OP- S0C4O1xP0E0R0; SMS- S0C4O1xP0E0R2; DTSAS- S0C4O1xP0E0R0; PG-S3C4O1xP0E0R0). Discussion. Only OP conducts marketing in line with its ANVISA description. Others take advantage of the PSG's established position in diagnosing sleep apnea by referring to their devices as PSGs. The numbering of these devices, such as type IV PSG, may lead people to assume they are a more advanced version. The ads are superlative, exaggerating both the qualities and advantages of SSATD and the disadvantages of PSG. The ads sometimes include doctors endorsing the technology, complicating them in false advertising, and subject to the penalties provided for in CFM resolution 2336/2023 (articles 9 and 11, items II). The official international guidelines specify the naming conventions, limitations, and conditions of use for SSATD. A doctor must evaluate the test result with the patient in the light of clinical data. Justice and morality are at the mercy of poor oversight, impunity, massification, insufficient rational exercise, and deluded consumption of the magical and unprecedented. This new Giges' ring (The Republic, Plato) allows the visible face to show concern about sleep apnea and the invisible one to hide the imperfections of SSATD. Medical power (Foucault: The Birth of the Clinic and The History of Sexuality) is not meant to exploit people (mostly the fragile), making them mere means, depriving them of the Kantian autonomy that we promote to this day as the categorical imperative (Foundations of the Metaphysics of Customs), obstructing their freedom to decide together with the doctor. **Conclusion:** SSATDs can help manage OSAS, but patients and professionals need to be aware of the limitations in diagnostic accuracy and the risks of not detecting a severe disease. They should not be promoted as PSGs to avoid misleading use and ethical issues.

https://doi.org/10.5327/CBN241315

Pompe disease diagnosed in a neurology clinic in the interior of the Amazon: first adult case in the state of Pará

Marcos Manoel Honorato[1], Eliane Batista Silva[1], Lucas Henrique Silva Coelho[1], Gabriel Nascimento Borges[1], Leandro Picanço de Carvalho[1], Kelson Vinicius Dallabrida Padilha[1], Samuel Oliveira de Amorim[1], Matheus da Silva Ferreira[1], Ana Flávia Ribeiro Nascimento[2], Átila Barros Magalhães[1]

[1]Universidade do Estado do Pará, Santarém PA, Brazil.
[2]Santa Casa de Misericórdia de Barretos, Barretos SP, Brazil.

Correspondence: Marcos Manoel Honorato; Email: marcos.honorato.dr@gmail.com.

Case presentation: A 45-year-old female patient visited the neurology clinic complaining of right lower limb weakness and back pain for approximately 10 years. The condition progressed to the left lower limb, accompanied by numbness and warmth in the legs and feet, and later to the upper limbs, with headache and burning sensation in the mouth. Family history: brother with similar symptoms, progressive dyspnea, cardiorespiratory arrest leading to death without established diagnosis. Consanguineous grandparents. Physical examination: atypical gait, tetraparesis with muscle strength 3 in lower limbs. Reduced deep tendon reflexes. Bilateral plantar reflex in flexion, preserved sensitivity. Complementary tests: CPK: 932 U/L and aldolase 11 U/L. Lumbar spine MRI showed spondylodiscoarthrosis of L4 and L5. Electroneuromyography revealed normal sensory and motor conduction. Enzyme screening for Pompe disease showed reduced activity of the acid alpha-glucosidase (GAA) enzyme of 0.42 mmol/L/h, the genetic panel identified a compound heterozygous mutation in the GAA gene, pathogenic variants c.-32-13T>G and c.925G>A, findings consistent with glycogen storage disease type II. The measurement of acid alpha-glucosidase enzyme activity in leukocytes was low (0.25 nmol/mg PTN), confirming the diagnosis. Enzyme replacement therapy through periodic intravenous infusion was indicated. **Discussion:** Pompe disease is a rare autosomal recessive disorder resulting from a mutation in the gene encoding the GAA enzyme. It participates in glycogenolysis, and its deficiency results in glycogen accumulation in various tissues, particularly cardiac and skeletal muscles. The most common presentation occurs in infancy during the first months of life, but in some cases, it can begin in adulthood. The typical clinical pattern of skeletal muscle involvement, exercise intolerance, progressive girdle weakness, and back pain are notable in the patient in question and are characteristic of the late-onset form. The initial hyperCKemia observed in the case, along with muscular complaints, constitutes a substantial finding of the presymptomatic stage of the disease. Elevated serum levels of AST and LDH often accompany CK levels, which can misleadingly suggest liver disease and contribute to

diagnostic delays. **Final comments:** Despite being a rare, difficult-to-diagnose, and lethal disease in cases like the patient's brother, early initiation of enzyme replacement therapy is crucial for better prognosis, as only then is it possible to effectively alter the clinical progression.

Porphyria variegata: a case report

Lucas Gonçalves Coelho[1], Victoria Nunes Alvares[1], Clara Ribeiro Rizzo[1], Isabella Navarro Diaz Horta[1], Maria Eduarda Braz Ferreira Leão Caldas dos Santos[1], Bernardo Leal Cupello[1], Vanessa Conceição Saar Mautone Lima[2], Ricardo Cézare Araújo[2], Deborah Santos Sales[2], Vivian Pinto de Almeida[2]

[1]Universidade Federal do Estado do Rio de Janeiro, Rio de Janeiro RJ, Brazil.
[2]Universidade Federal do Estado do Rio de Janeiro, Hospital Universitário Gafrée e Guinle, Rio de Janeiro RJ, Brazil.

Correspondence: Lucas Gonçalves Coelho; Email: lucasgcoelho@edu.unirio.br.

Case presentation: A 38-year-old female patient presented with a history of hospitalization for urinary tract infection, lower back pain on the right and reddish urine six months prior to arriving at our service. During this hospitalization, she also reported epigastralgia, nausea, generalized paresis and paresthesia. The patient mentioned a similar case of polyradiculoneuropathy 5 years ago, in which the investigation led to the main hypothesis of Guillain-Barré Syndrome. Therefore, she was treated with intravenous IgG, showing partial improvement after six months. Currently, the patient presents distal paresis and atrophy of the upper limbs, global areflexia and proximal changes in sensitivity of the forearms and tights, being restricted to a wheelchair. Laboratory investigation revealed elevated levels of porphobilinogen (PBG), but normal levels of delta-aminolevulinic acid (ALA) in urine samples. Molecular genetic testing for Acute Porphyria was performed and identified a heterozygous pathogenic variant of the PPOX gene in the patient, confirming the diagnosis of Variegate Porphyria. **Discussion:** Porphyrias are a group of rare manifestations caused by enzyme deficiencies in the heme group synthesis pathway. Among the subtypes of this disease is the Variegate Porphyria, which results from a pathogenic variant of the PPOX gene, derived from an autosomal dominant inheritance that leads to decreased activity of the protoporphyrinogen oxidase enzyme. This rare disease has a wide spectrum or non-specific manifestations, ranging from cutaneous symptoms to abdominal and neuropsychiatric acute conditions. In the presented case, the absence of pathognomonic symptoms, associated with the rarity of the disease, hinders both the diagnosis and the beginning of the appropriate treatment. **Final comments:** The inclusion of porphyria as a differential diagnosis of acute neurovisceral cases is essential to ease the early identification of these conditions. Therefore, specific laboratory and molecular genetic testing are essential for the accurate diagnosis. With the proper diagnosis and treatment, it is possible to control the progression of the disease, in addition to significantly improving the quality of life and reducing mortality associated with Porphyria Variegata.

Positive outcome of natalizumab therapy in multiple sclerosis with leptomeningeal lesion: a case report

Gustavo Silva Schafascheck[1], Laísa Fernandes Bonatto[1], Roberto Navarro Rocha Filho[1], Luiza Lima Oliveira[1], Viviane Tavares Carvalho Crelier[1], Gutemberg Augusto Cruz dos Santos[1]

[1]Universidade Federal Fluminense, Niterói RJ, Brazil.

Correspondence: Gustavo Silva Schafascheck; Email: gustavo.med2016@gmail.com.

Case presentation: A 60-year-old patient was diagnosed with Multiple Sclerosis (MS) in September 2022 and started treatment with Copaxone. In January 2023, a new lesion was identified, and by July, a positive test for latent tuberculosis required additional treatment. In November 2023, a subsequent MRI scan revealed an occipitotemporal leptomeningeal lesion, a rare occurrence in MS. Due to the lack of improvement with the initial treatment, the medical team decided to initiate treatment with Natalizumab, an immunomodulator, in November 2023. After two months of Natalizumab therapy, a follow-up MRI showed a substantial reduction in the leptomeningeal lesion, accompanied by significant clinical improvements, including reduced fatigue, improved vision, and enhanced walking stability. **Discussion:** This case underscores the importance of early and personalized intervention in MS, especially in atypical presentations such as occipitotemporal leptomeningeal involvement. Recent literature highlights the association between leptomeningeal involvement and rapid disease progression, reinforcing the need to tailor therapeutic strategies to individual patient profiles. The use of Natalizumab, as demonstrated in this case, offers a promising alternative for challenging cases where conventional treatments may not suffice. The patient's positive response suggests that the choice of targeted immunomodulators can be crucial in managing complex disease activities and improving patients' quality of life. **Final comments:** The response to Natalizumab in this patient with an atypical presentation of MS emphasizes the need to re-evaluate conventional treatments and consider personalized therapeutic options. This case reinforces the importance of individualized strategies, which are crucial for addressing the complexities of MS and achieving better clinical outcomes. Further studies are needed to optimize outcomes in complex MS presentations and to validate the effectiveness of specific therapies in patient subgroups with distinct disease characteristics.

Possible co-occurrence of CNS demyelination and subdural haematoma caused by TNF-alpha inhibitors

Alberto Pereira Firmino Filho[1], Maria Weryca de Souza Belo Silva[1], Rodrigo Alencar e Silva[1], Joanisson Rubens Gomes Diniz[1], Paulo Santiago Morais Brito[1], Heitor Caetano Santos[1], Miguel Inacio Silva Gomes[1], Fatima de Menezes Dantas[1], Felipe Olobardi Freire[1], Nathalia Lindsay Pereira de Queiroz[1]

[1]Universidade Federal do Rio Grande do Norte, Natal RN, Brazil.

Correspondence: Alberto Pereira Firmino Filho; Email: firminofilho.ap@outlook.com.

Case presentation: A 77-year-old man with psoriatic arthritis was treated with adalimumab for twelve months. He presented with a sudden state of confusion, tetraparesis, and urinary and fecal incontinence. Neurological examination revealed mild asymmetric tetraparesis. There was no history of head trauma or laboratory abnormalities. Magnetic ressonance imaging of the brain and cervical spine revealed right spontaneous subdural hematoma and cervical demyelinating event. **Discussion:** Rare side effects associated with TNF-α blocker therapy have been reported in the literature, including cerebrovascular disease and demyelinating disorders. To our knowledge, no simultaneous injuries of a different nature caused by the use of adalimumab have been described. **Final comments:** We must be attentive and maintain close neurological surveillance of patients undergoing treatment with anti-TNF-alpha therapies to be able to suspect and diagnose possible complications arising from their use, even the atypical occurrence of simultaneous side effects.

https://doi.org/10.5327/CBN241319

Post radiculomedullary trauma intracranial hypertension

Mayhara Rosany da Silva Santiago[1], Ana Caroline Paiva Simeão[1], Raissa Josefa Pereira de Moura[1], Nereu Alves Lacerda[1], Maria Luisa Roberto Lima Lisboa[1], Natália Nunes Tenório[1], Ana Beatriz Roberto Lima Borba[1], Ana Carolina Martins Fragoso Carneiro[1], Heloisy Maria Nunes Galvão[1], Bárbara Matos Almeida Queiroz[1]

[1]Hospital Pelópidas Silveira, Recife PE, Brazil.

Correspondence: Mayhara Rosany da Silva Santiago; Email: santiago.mayhara@gmail.com.

Case presentation: A 46 years old man presented with reduced bilateral visual acuity, described as progressive, within a month of initial perception, and worsening of symptoms in the last 3 days preceding the hospital admission, associated with bilateral ear tinnitus. The patient mentioned a fall from about 4 meters high 5 months before the actual admission, and was seen to have a vertebral lesion, in T12, and opted for conservative treatment. On neurologic examination the low visual acuity was confirmed with 20:200 in the right eye and 20:100 in the left eye, in the fundoscopy was seen bilateral papilledema, and in the amsler grade the patient described tunnel vision. Initial evaluation with neuroimage with head CT scan and magnetic resonance had no signs of mechanical obstruction of liquorice flux, and showed indirects signs of intracranial hypertension such as the empty sella sign. The liquorice puncion confirmed the major hypothesis, with an opening pressure of 60 cmH2O. The laboratorial liquorice evaluation was negative to infections and other inflammatory disorders. The investigation progressed with an arteriography that showed a complex dural fistula, with multiple origins, more prominent in the occipital and vertebral arteries, promoting local venous hypertension and secondary intracranial hypertension. The patient was transferred to the neurosurgery sector, where the fistula embolization was programmed through a hemodynamic approach. **Discussion:** Dural arteriovenous fistulas are a vascular abnormality characterized by connections between dural arteries and venous sinus, resulting in intracranial hypertension. Multiple etiology are possible, being the most common, in adults, venous sinus thrombosis, but is also possible as a result of thrombophilias and head trauma. **Final comments:** When confronted with a case of severe refractory cranial hypertension, the active search of past head trauma and investigation of dural fistulas are essential and may be a key factor for the diagnosis and adequate treatment and, consequently, the prognosis.

https://doi.org/10.5327/CBN241320

Post-endoscopy bilateral cortical infarction presenting as a stroke chameleon: a case report

Raíssa Gomes Castro e Souza[1], Luis Felippe Barros e Silva Pereira Ribeiro[1], Marcus Vinícius Buratti Leal[1], Maria Paula Oiticica de Jesus[1], Sabrina Vechini Gouvêa[1], Izabel Crystine Pereira Barbosa[1], Wagner Mauad Avelar[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Raíssa Gomes Castro e Souza; Email: gcsraissa@gmail.com.

Case presentation: A 66 year-old woman presented with a history of sudden onset rightward gaze preference, quadriplegia, spasticity in inferior limbs and right arm as well as global hyperreflexia with Babinski, Trömner and Hoffmann's signs elicited bilaterally. She also displayed myoclonic spasms in both legs and right arm. Vital signs upon arrival consisted of blood pressure of 132/70mmHg, heart rate 100bpm and peripheral oxygen saturation of 95%. The neurological signs had arisen after a routine endoscopy, as soon as the patient roused from anaesthesia, having been under conscious sedation with IV midazolam (3.5mg), fentanil (30mcg) and propofol (70mg). Prior medical history consisted of glaucoma, dyslipidemia, an ex-smoking habit and esophagectomy for esophageal cancer two months before. Urgent head CT scan showed no abnormalities. Further evaluation with diffusion-weighted MRI revealed acute cortical infarct in precentral gyrus regions in both cerebral hemispheres. Relevant laboratory values included haemoglobin of 7.8g/dl (baseline 10.4g/dl two months prior). Poststroke assessment with electrocardiogram, echocardiogram, transcranial doppler ultrasound and computed tomography angiography was normal. Given the fact that additional investigations yielded no unwonted findings, the most likely diagnosis in this patient remained a hypoxic-ischaemic cerebrovascular injury. She was followed in the outpatient setting and experienced gradual improvement on both motor and speech functions. **Discussion:** Cerebrovascular events following endoscopy have been reported as a consequence of the cardiopulmonary effects, which include periods of hypotension, arrhythmias and hypoxemia. Hypoxic-ischaemic injury to the CNS is typically bilateral and symmetrical, and the damage is most prominent in grey matter structures such as cerebral cortex, basal ganglia, thalami and hippocampi. This type of injury is most commonly seen as a result of cardiac arrest, drowning or asphyxiation but can also occur as a complication of invasive procedures, especially in the presence of predisposing features such as older age and anaemia. As to the clinical aspects, this patient displayed an unusual stroke presentation - mainly related to the motor deficits which encompassed all of the four limbs, but also positive signs such as spasticity and myoclonia. For this reason upon admission the hypothesis of a stroke remained questionable, until proven otherwise with the aid of MRI. **Final comments:** This case has been reported in account of its unique clinical features as well as its presumed aetiology. Being aware of atypical stroke presentations is a resourceful perspective in acute clinical settings, for it might lead to prompt evaluation and timely intervention in dubious cases. Furthermore, although rarely reported, hypoxia-induced stroke can occur during procedures, and discussing means to prevent it is advisable.

Posterior reversible encephalopathy syndrome (PRES) in an infant: case report

Rodrigo Ibañez Tiago[1], João Ormond de Miranda[2], Jéssica Feltraco[2], Karina Galli Cardoso Mello Roberto[2], Isabela de Carvalho Florêncio[3], Gabriel Pereira Braga[3], Glauco Almeida[3]

[1]Universidade Federal de Mato Grosso do Sul, Faculdade de Medicina, Campo Grande MS, Brazil. [2]Hospital São Julião, Campo Grande MS, Brazil. [3]Hospital Universitário Maria Aparecida Pedrossian, Campo Grande MS, Brazil.

Correspondence: Rodrigo Ibañez Tiago; Email: rodrigoibaneztiago@gmail.com.

Case presentation: An 8-year-old female with a three-day exacerbation of asthma developed severe headache and projectile vomiting, without fever. Initial laboratory tests were normal, and cranial computed tomography revealed mucosal thickening of the left maxillary sinus without intracranial abnormalities. After 12 days, she experienced a seizure, progressing to right-sided hemiparesis and bilateral visual impairment. Cerebrospinal fluid analysis showed normal cell count and other parameters. Ophthalmological evaluation revealed visual acuity of 20/25 in both eyes, intraocular pressure of 12 mmHg bilaterally, normal anterior segment examination, and blurred optic disc margins on fundoscopy. Visual field examination (24-2) showed diffuse sensitivity loss in the right eye, particularly in the temporal region, and nasal hemifield loss in the left eye. Optical coherence tomography (OCT) demonstrated increased nerve fiber layer thickness and anterior displacement of the RPE-Bruch's membrane complex, suggesting increased intracranial pressure. The autoimmune panel revealed fine speckled pattern ANA 1:128 and weakly reactive anti-cardiolipin IgG. Brain magnetic resonance imaging showed vasogenic edema affecting bilateral frontal, parietal, and occipital lobes, with a pattern consistent with vascular boundary zones and mass effect, with no abnormalities on angiography. Clinical evaluation indicated elevated blood pressure (170/90 mmHg). Captopril was initiated with subsequent improvement in clinical and neurological status. Further rheumatological investigation revealed a nuclear fine speckled pattern ANA 1:160. Follow-up showed resolution of papilledema and significant improvement in visual field defects approaching normal parameters within 4 months, confirming the diagnosis of Posterior Reversible Encephalopathy Syndrome (PRES). **Discussion:** PRES is a clinical and radiological syndrome characterized by acute encephalopathy with vasogenic edema, often associated with elevated blood pressure, preeclampsia, autoimmune, and infectious diseases. The pathophysiology involves cerebral autoregulatory dysfunction and increased blood-brain barrier permeability, leading to cerebral edema. The association with positive autoimmune markers may suggest an underlying autoimmune predisposition, although causality remains unclear. **Final comments:** This case emphasizes the importance of considering PRES in diagnosing children with seizures and acute neurological symptoms. Effective management includes strict blood pressure control. Recovery is generally complete with appropriate intervention, as observed in this patient. Investigating underlying diseases is crucial to prevent recurrence and ensure a favorable prognosis.

Post-irradiation internal carotid artery vasculopathy: a case report

Samia Talise El Horr de Moraes[1], Fernanda Michely Nicoli[1], Bárbara Akemy Barbosa Cruz[1], Juliano André Muzzio[1], Claudia Suemi Kamoi Kay[1]

[1]Universidade Federal do Paraná, Complexo do Hospital de Clínicas, Curitiba PR, Brazil.

Correspondence: Samia Talise El Horr de Moraes; Email: samiatalise1@gmail.com.

Radiotherapy used to treat various neoplasms can result in acute, subacute, and late clinical syndromes. Cranial blood vessels may be affected by radiation, resulting in late structural changes. Knowledge of the clinical picture, the time interval from radiation therapy, and additional tests will assist doctors in diagnosis and treatment. A 17 years-old female patient presented with a changed-pattern headache. She had a previous history of migraine without aura and right ocular rhabdomyosarcoma treated with resection, chemotherapy, and radiotherapy at 4 years-old, using monthly combined injectable contraceptive. Physical and neurological examinations were unremarkable, as well as further investigation with laboratory tests, cerebrospinal fluid, and cranial tomography. However, cerebral angio-MRI showed signs of probable inflammatory process affecting the right internal carotid artery with significant hypoflow of the ipsilateral middle cerebral artery. Also, transcranial Doppler was performed presenting significant decrease in flow velocity and pulsatility index in the right middle cerebral artery, reversal of flow direction in the right anterior cerebral artery, intracranial right internal carotid artery with significant reduction in pulsatility index (15/0.35). These findings were compatible with the diagnosis of internal carotid artery stenosis after radiotherapy, and treatment with cilostazol was initiated. It is important to remind general neurologists that vasculopathy is a possible complication after radiotherapy. The prevalence of carotid stenosis in patients with head and neck neoplasia varies from 10% to 50% after radiotherapy and can lead to TIAs or infarction. Children are more sensitive to vascular injuries and can develop moyamoya syndrome and vascular malformations. The average interval from the end of irradiation to the onset of ischemic symptoms is 5.4 years in children. Post-treatment follow-up of these patients is essential to have an early diagnosis and approach of these kind of complication, minimizing permanent neurological deficits.

Post-pump chorea: a rare and persistent neurological complication of cardiopulmonary bypass

Cândida Driemeyer[1], Renato Dumbá Monteiro de Castro[1], Ana Letícia Amorim de Albuquerque[2], Daniel Teixeira dos Santos[2], Arlete Hilbig[1], Carlos Roberto de Mello Rieder[1]

[1]Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre RS, Brazil. [2]Santa Casa de Porto Alegre, Porto Alegre RS, Brazil.

Correspondence: Cândida Driemeyer; Email: candidaplena@gmail.com.

Case presentation: A 42-year-old woman was referred to the neurology outpatient clinic due to involuntary movements. The symptoms started 1 day after thromboendarterectomy with cardiopulmonary bypass support due to thromboembolism and secondary pulmonary hypertension when she was 34 years old. Before thromboembolism, the patient had no comorbidities. On neurological examination, the patient presented with chorea affecting the face, tongue, neck, trunk and limbs. Hemogram, electrolytes, renal, hepatic and thyroid function were normal. Investigating the procedure, it needed 248 minutes of extracorporeal circulation with aortic clamping and intermittent circulatory interruption. Hypothermia at 18 degrees Celsius was required for 144 minutes. Computed tomography of the skull at the time showed hypodensity with a sequelae appearance of 0.4cm in the lentiform nucleus on the left and investigation by magnetic resonance imaging two months after the opening of the neurological condition showed hyperintensity on the T1 sequence bilaterally in the pale globus, suggestive of metabolic alteration. Initial rheumatological investigation returned normal. The recently performed MRI shows minimal sequelae in the globus pallidus, more evident on the left, without hypersignal and without restriction to diffusion. Currently using haloperidol 1 mg once a day with stability of symptoms, because of low tolerance to the adverse effects of atypical neuroleptics. **Discussion:** Suggested risk factors for neurological sequelae such as chorea after cardiopulmonary bypass are age of onset, latency of onset, underlying disease, response to treatment and surgical characteristics (minimum body temperature, time of total circulatory arrest and control of gaseous microembolism). There are several pathophysiological mechanisms that can explain the emergence of this symptom post extracorporeal circulation, although the exact pathogenesis has not yet been revealed: microembolic events affecting basal ganglia, lactic acidosis induced by hypothermia, increased blood viscosity with resultant thrombi formation and also the circulation of inflammatory agents and hemolysis products that occur in the stages of the circuit. The higher frequency observed in children remains unclear. **Final comments:** The appearance of chorea in an adult patient requires extensive investigation, which includes rheumatological diseases, toxic-metabolic insults, use of continuous medications,

neoplasia, cerebrovascular and autoimmune diseases. In our case, the abrupt appearance of chorea 1 day after pulmonary thromboendarterectomy and the absence of laboratory changes leads us to the probable diagnosis of chorea after cardiopulmonary bypass, or "post pump chorea". The detailed description of the occurrences of neurological sequelae secondary to extracorporeal circulation has an important contribution to clarifying and differentiating the multiple causal factors.

Post-stroke delirium in younger is associated with worse long term functional outcome

Gabriel Souza Suzart[1], Iva Taiuan Fialho Silva[1], Joao Pedro[1], Vinicius Mendez[1], Luiz Paulo Oliveira Martins[1], Marivaldo Yslan Silveira Leal[1], Luísa Dias Moreno Aravena[1], Thais Barbosa de Oliveira[1], Gabriel Souza Medrado Nunes[1], Pedro Antonio Pereira de Jesus[1]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.

Correspondence: Luiz Paulo Oliveira Martins; Email: luizpom2000@gmail.com.

Background: Although post-stroke delirium is a common condition in the elderly, younger patients are less prone to have it and are recognized for favorables outcomes. **Objective:** To assess the impact of delirium on functional outcomes of stroke patients in different age groups. **Methods:** Prospective cohort of stroke patients admitted in a stroke unit from 2017 to 2023. Delirium was diagnosed using the CAM-ICU. Patients with delirium were divided into ≥60 years or <60 years and compared to non-delirium patients. The main outcome was mRs>2 in 90 days post-stroke. **Results:** A total of 585 patients were enrolled. Delirium occurred in 115 patients (19.7%), of which 81 (70.4%) were elderly and 34 (29.6%) were younger. Even though they had lower Charlson Comorbidity Index (median, 3 vs 5 points; p<0.001), younger patients affected by delirium had higher NIHSS scores than elders and no-delirium patients [12 (±5) vs 10 (±6) vs 8 (±5); p<0.001] and lower ASPECTS scores [IQR, 8 (4-9) vs 8.5 (6-10) vs 9 (8-10) points; p<0.001]. Delirium in younger people showed higher odds of long term functional dependence than in elderly (OR [IC95%], 2.4 [1.8-3.1; p<0.001] vs 2.0 [1.6-2.5; p<0.001], compared to no-delirium patients. **Conclusion:** Although delirium is less frequent in younger people, this group may have a poorer prognosis. Delirium in younger patients may be predisposed by larger lesions and higher neurological impairment. This is the first study to investigate the influence of age on post-stroke delirium prognostic value.

Post-traumatic epilepsy: biological and social description

Giulianna Luzia Pereira[1], Livia Nogueira de Godoi[1], Helena Rubini Nogueira[1]

[1]Universidade Municipal de São Caetano do Sul, São Caetano do Sul SP, Brazil.

Correspondence: Giulianna Luzia Pereira; Email: giuliannaluzia2013@gmail.com.

Background: Post-traumatic epilepsy (PTE) refers to recurrent and spontaneous seizures caused by complex and chronic repercussions resulting from traumatic brain injury (TBI). Primary injuries are those that occur seconds to minutes after the trauma, while secondary injuries involve physiological mechanisms and progressive damage, as is the case with PTE. In addition, this epileptic process tends to be resistant to the anticonvulsant drugs in use, with 30% of patients suffering from the disease refractory to treatment. **Objective:** To understand the basic biological process of post-traumatic epileptogenesis and the social consequences of this condition. **Methods:** This is an integrative review made with PUBMED as a database, using the descriptors "Epilepsy" AND "Brain Injuries, Traumatic"; and "Epilepsy, Post-Traumatic". The inclusion criteria were: publication date within the last 5 years and free access to the full text. The exclusion criteria chosen were: not having post-traumatic epilepsy as the main theme, being written in chinese and repeated texts. **Results:** 34 articles were selected, of which 25 explained the pathophysiology and 12 the impact that its occurrence would have on the patient's life. With regard to etiopathogenesis, mechanisms such as the breakdown of the blood-brain barrier, oxidative damage and the release of chemokines are fundamental to epileptogenesis. At the same time, the social impact of Post Traumatic Epilepsy can be seen both for the patients themselves and for life in society, since they can suffer disorders that disable them from executive activities. **Conclusion:** Post-traumatic epilepsy is a highly complex condition that requires specialized care and which repercussions have significant potential for chronicity and incapacity in the patient's activities of daily living. Given the biopsychosocial and economic impact involved in this condition, we highlight the importance of further studies to promote collective policies that specifically address the Brazilian population.

Post-vaccinal dengue encephalitis and dengue shock syndrome: case report

Lucas Oliveira Mourão[1,2], Cíntia Silveira[1], Sônia Maria Dozzi Brucki[2], Fernando de Mendonça Cardoso[1]

[1]Hospital Glória D'or, Rio de Janeiro RJ, Brazil. [2]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Lucas Oliveira Mourão; Email: lucas.omourao@gmail.com.

Case presentation: A 87-years-old male, Rio de Janeiro resident, hypertensive, diabetic, with non-dialytic chronic renal disease, diabetic polyneuropathy, and normal pressure hydrocephalus (NPH), walking with aid, received his first vaccination of a live attenuated dengue tetravalent vaccine (QDenga®) on May 16th 2024. After 6 days (22nd of May) he became wheelchair-dependent. On the 23rd of May he had headache. One day later, he lost consciousness for 10 minutes and was admitted to the Intensive Care Unit for a syncope workup: he was oriented on space and time and didn't present any neurological focal deficit. Brain MRI was unremarkable for acute lesions, displaying ventriculomegaly and a callosal angle of 82 degrees compatible with previous NPH diagnosis. However, the following day he had nausea and progressed to torpor, hemodynamic shock and acute renal failure with need for norepinephrine and continuous hemodialysis. Over the next 24 hours he became comatose with need for orotracheal intubation. On May 27th he underwent lumbar puncture and Dengue virus was identified through PCR on cerebrospinal fluid (CSF). Other CSF findings: initial pressure of 33 cm H2O; 1 cell/mm3 (rare lymphocytes); protein 24 mg/dl; glucose 60 mg/dl. **Discussion:** An elder received the first vaccination of QDenga® (drug TAK-003), a live attenuated dengue tetravalent vaccine licensed for dengue prevention in Brazil, for people up to 60 years of age. Phase 3 double-blind, randomized, placebo-controlled studies assessed QDenga®'s efficacy on 702 children from 4 to 16 years living in endemic areas of Asia and Latin America (DEN-301) and 379 adults from 18 to 60 years living in parts of the United States considered non-endemic for dengue (DEN-304). Open-label, phase 3 study DEN-307: 174 United States adults (18 to 60 years); sepsis was reported 2 days after second dose and wasn't considered drug-related. QDenga® studies reported mild neurological adverse events (headache, somnolence and dizziness), but it is known that vaccines may cause severe neurological adverse events and that dengue can cause a wide range of neurological manifestations: encephalopathy, acute encephalitis, chronic progressive panencephalitis, stroke cranial neuropathies, acute demyelinating encephalomyelitis (ADEM), acute cerebellitis, Guillain-Barré Syndrome, acute transverse myelitis and acute myositis. Dengue encephalitis diagnosis was made due to impaired consciousness and dengue virus PCR detection on CSF. In a dengue-endemic region dengue is the main cause of encephalitis with normal CSF cellularity, as observed. He also had dengue shock syndrome: hemodynamic shock and organ failure (acute kidney injury). **Final comments:** to our knowledge we report the first case of post-vaccinal dengue encephalitis and dengue shock syndrome. Possibly a result of the elder's frail immune system response after receiving a live attenuated dengue tetravalent vaccine. Patient's age group wasn't studied.

Potentials and limitations of genetic testing in autism spectrum disorder

Luisa Maria Resende Morais[1], Gleison Carlos Arantes Filho[1], Clara Oelze Cardoso[1], Gustavo Lucas Viana dos Santos[1], Sanny Kemelly Miquelante Yoshida[1], Leonardo Brandão Barreto[1]

[1]Universidade Federal de Ouro Preto, Ouro Preto MG, Brazil.

Correspondence: Luisa Maria Resende Morais; Email: luisamresendem@gmail.com.

Background: The diagnosis of Autism Spectrum Disorder (ASD) is challenging due to considerable clinical and genetic heterogeneity. However, with the development of molecular technologies, it has been understood that genetic findings such as copy number variations (CNV), single nucleotide variations (SNV), and small insertions/deletions are associated with the disorder, enabling the use of genetic testing for etiological investigation. **Objective:** To systematize the current evidence in the literature on the potentials and limitations of genetic tests in ASD. **Methods:** A systematic review of the databases: PubMed, LILACS, SciELO, and Web of Science using the descriptors: "Autism Spectrum Disorder" and "Genetic Testing". Inclusion criteria were articles published in the last 5 years, and exclusion criteria were systematic review papers or those not addressing the studied proposal. **Results:** A total of 762 studies were found, and after applying the criteria, 21 were selected. For the family, the main reported benefits were providing information for reproductive planning (n= 7 studies) and understanding the disease's etiology, which led both to a change in parents' perceptions of ASD, with a tendency to blame their children and themselves less for the presence of this condition (n=2 studies), and to an improvement in their ability as caregivers (n=1 study). For the patient, early and definitive diagnosis stood out (n= 6 studies), considering that many neurodevelopmental disorders have overlapping clinical presentations, making diagnosis based solely on symptom investigation difficult. Additionally, 5 articles highlighted that genetic tests provide prognostic information, aiding in directing earlier and more personalized interventions, as some genetic variations are associated with specific comorbidities and clinical presentations. However, 2 of these articles emphasized that genetic testing cannot definitively predict prognosis, as the same genetic variation can lead to different phenotypic profiles. Another important limitation is the current low diagnostic yield, such as exome sequencing, with a yield of 17.1% (11%-25%) for ASD, generating many negative results that can be false negatives and do not rule out a genetic cause (n=7 studies). Finally, the difficulty of interpreting results by non-geneticist doctors, in addition to the high

cost for families and the health system, was pointed out (n=2 studies). **Conclusion:** Many medical societies recommend the use of genetic tests, which, despite having several potentials, still have limitations to be overcome. It is expected that, with more studies directed at the genetic architecture of ASD, these tests will become more accurate and advantageous. It is essential that healthcare professionals inform families about these difficulties to align expectations regarding genetic tests.

Precision medicine in the FGF12 gene related to refractory epilepsy responsive to phenytoin: a case report

Joana Laura Aihara Barbosa[1], Lucas Henrique de Moura Rogerio Garcia[1], Matheus Rodrigues Nogueira[1], Ahmad Kassem El Zein[1], Josenice Gomes Trindade Seidel[1], Lucas D'Andrea Pereira Souza[1], Luiz Gustavo Brenneisen dos Santos[1], Paula Fiuza Rodrigues de Medeiros Lacerda[1], Eliana Garzon[1], Luciana Midori Inuzuka[1]

[1]Hospital Sírio-Libanês, São Paulo SP, Brazil.

Correspondence: Joana Laura Aihara Barbosa; Email: joana.lab@gmail.com.

Case presentation: 12-year-old boy, unrelated parents, uncomplicated pregnancy, full term, no relevant family and neonatal history, no dysmorphic features. The first afebrile seizure was at 3 months (hypotonic, cyanotic, hypoventilation, less than a minute), neurological exam, cerebrospinal fluid, brain MRI and electroencephalogram (EEG) were normal. After a week he had recurred focal motor seizures. Carbamazepine was prescribed. Until 3 years old, the seizures remained every 6 months, and an episode of status epilepticus occurred. The patient stayed seizure-free for two years and antiseizure medication (ASM) was withdrawn. After one month seizures had recurred, and levetiracetam, pyridoxine, clobazam, and sodium valproate were administered unsuccessfully. EEG demonstrated normal background and sporadic centrotemporal, frontocentral, bifrontal, central epileptiform discharges. The genetic panel at this time (2017) had no pathogenic variants. In the following two years, although the patient had a normal neuropsychological test and no changes in neurodevelopment, the seizures remained bilateral, tonic-clonic, generalized, and pharmacoresistant. Exome revealed a pathogenic variant of the FGF12 gene, missense, resulting in a substitution of glycine-to-serine [(Chr3: 192.335.441 C>T, p(Gly112Ser ENST 00000454309)]. After this finding we prescribed phenytoin. The patient remains seizure-free to date. **Discussion:** Recent studies have identified mutations in the fibroblast growth factor 12 (FGF12) gene as a potential genetic cause of epilepsy and neurodevelopmental disorders. The gene encodes a cytosolic binding protein that enhances the voltage-dependent fast inactivation of neuronal sodium channels, modifying their excitability. Pathogenic variants in FGF12 have few published case reports, with most other cases with neuropsycomotor development disorder and refractory epilepsy (Developmental and Epileptic Encephalopathy 47). In our patient, neurodevelopment was normal and revealed an expansion of phenotype. Genetic panel had identified no pathogenic variants, at this time FGF12 gene had not yet been related to epilepsy. Due to the persistence of the seizures, an exome was requested and revealed a pathogenic variant of the FGF12 gene. Phenytoin was utilized in other published cases of refractory epilepsy with this gene mutation, owing to its molecular mechanism, which stabilizes neuronal membranes by blocking voltage-gated sodium channels, thereby inhibiting excessive neuronal firing. New generation sequencing is essential in refractory epilepsy guiding ASM strategies for better outcomes. **Final comments:** Genetic causes of epilepsy, particularly FGF12 gene mutations, highlight the relevance of precision medicine strategies for treatment selection.

https://doi.org/10.5327/CBN241329

Predictors of azathioprine therapeutic success in patients with neuromyelitis optica spectrum disorder

Ana Carolina Amaral de Andrade[1], Gabriel de Deus Vieira[1], Mariana Moreira Soares de Sá[1], Alfredo Damasceno[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Ana Carolina Amaral de Andrade; Email: anaca_andrade@yahoo.com.br.

Background: Approximately 44.9% of patients using azathioprine (AZA) for the treatment of Neuromyelitis optica spectrum disorder (NMOSD) have therapeutic failure. **Objective:** To evaluate prognostic factors of treatment failure of AZA in patients with NMOSD. **Methods:** Demographic and clinical aspects of 49 patients with NMOSD, according to fulfilling INPD 2015 diagnostic criteria, were analyzed in regards the therapeutic success of AZA 2 to 3 mg/kg/day for 6 months, 79,6% of these patients, were reagents for serum anti-aquaporin 4 antibodies (AQP4-IgG) using the cell based essay (CBA) methodology. We consider therapeutic failure to be the replacement of AZA due to relapse or adverse effects. Severe relapse were defined as those that progressed without improvement after plasmapheresis; bilateral visual impairment or worse than 20/200; muscle strength less than grade III with gait or sphincter disorder. Univariate and multivariate logistic regression were performed to evaluate factors associated with treatment failure (gender, ethnicity, AQP4-IgG positivity, ages at the first outbreak and at the onset of AZA, severity and type of the first outbreak, number of pre-AZA relapse, and time between the first relapse and the onset of AZA). **Results:** The group of treatment failure with AZA had 90.9% of female subjects, 59.1% non-white, who were between 18 and 40 years old in the first outbreak (63.6%) and at the beginning of AZA (40.9%), positive for AQP4-IgG (77.27%), 27.3% had at least 1 severe pre-AZA relapse, with severe optic neuritis being the most common type of first relapse (40.9%), 81.8% started AZA as their first treatment, 1 to 5 years after the first relapse (45%) and after the occurrence of 2 to 4 relapse (68.2%), with an annualized relapse rate (AAR) pre AZA between 1 and 5 (50%). After 180 days of AZA use, 22.27% of the patients took up to 6 months to present the first therapeutic failure and 50% of them had AAR post-AZA of up to 1. After logistic regression analysis, the factors associated with failure with AZA in the total sample were: white ethnicity (p=0.023; OR=0.183, 95%CI 0.025 - 0.763), age of onset AZA (p=0.017; OR=0.892, 95% CI 0.812 - 0.980) and number of relapses before the onset of AZA (p=0.049; OR=1.675, 95%CI 1.003 - 2.795). Similar results were observed in logistic regression analyses in patients who tested positive for AQP4-IgG: white ethnicity (p=0.037; OR=0.026), age at first relapse (p=0.039; OR=0.809) and number of relapse before AZA (p=0.028; OR=3.606). AZA is considered a first-line therapy for NMOSD in emerging countries, in which monoclonal antibodies are in the process of being incorporated into health services, however, almost 45% of patients using AZA have therapeutic failure in the management of NMOSD. **Conclusion:** Knowledge of predictors of treatment failure with AZA may contribute to determining which patients should start treatment with monoclonal antibodies.

Correspondence: Renan Carvalho Castello Branco; Email: castellorenan@yahoo.com.br.

Obstructive sleep apnea is a disease of upper airways, with great association with stroke through diverse mechanisms. Although, it still lacks in literature tha relation with hemorrhagic subtype. This study aims to stablish the predictors of death in patients with hemorrhagic stroke and high risk of obstructive sleep apnea. We performed a transversal study, part of a cohort of stroke patients. They were evaluated about risk of obstructive sleep apnea with SOS and STOP-Bang scores. Data of previous comorbidities and stroke profile were collected. Comparison between groups was done with T test/chi-schare/Mann-Whitney, considering p< 0.1, and multivariate analysis with logistic regression, considering p< 0.05, to outcome of death during internment. We obtained 81 patients, of which 64.2% were classified as high risk with STOP-Bang (19 hypertensive, 18 traumatic, 6 aneurysmatic) and 52% with SOS (16 hypertensive, 14 traumatic, 4 aneurysmatic). Considering high risk of STOP-Bang, there was higher prevalence of obesity (p=0.02), hypertension (p=0.02) and atrial fibrillation in low risk (p=0.05). Considering high risk of SOS, we obtained obesity (p=0.03) and sleep disorder (p=0.09). Patients with higher risk of OSA evolved more to death (p=0.08). There were no independent factors related to death during internment. The difference in obesity and hypertension was due to their character of comorbidity with obstructive sleep apnea. The stroke profile did not vary between groups, denoting a less preponderant role of obstructive sleep apnea in hemorrhagic stroke, although higher risk evolved more to death, demonstrating subjacent mechanisms of worst outcomes, not necessarily related to stroke. Further studies are needed to achieve a higher sample.

Predictors of fast visual recovery in idiopathic intracranial hypertension: a cohort study

Ana Carolina Montouro Storarri[1], Annelise Akemi Higa Lee[1], Lorrane Campidelli Arthuzo[1], Luis Armando Sawada[1], Beatriz Marques dos Santos[1], Thassia Cavalcante de Oliveira Moraes Marques[1], Bruno Pissolati Mattos Gonzaga[1], Renan Barros Domingues[1]

[1]Santa Casa de Misericórdia de São Paulo, São Paulo SP, Brazil.

Correspondence: Ana Carolina Storarri; Email: anastorarri@gmail.com.

Background: Idiopathic intracranial hypertension (IIH) is characterized by increased intracranial pressure without a discernible cause, often leading to visual impairment and papilledema. Understanding the factors influencing visual outcomes in IIH patients is crucial for improving management strategies. This study aimed to identify predictors of satisfactory visual outcome (SATISF) defined as the resolution of reduced visual acuity and/or disappearance of papilledema. **Objective:** To evaluate the factors associated with satisfactory visual outcomes in female patients with IIH. **Methods:** This retrospective cohort study included female patients diagnosed with IIH. The potential predictors of a satisfactory visual outcome evaluated were age, initial body mass index (BMI), cerebrospinal fluid (CSF) opening pressure (Pi), duration of symptoms, and the need to discontinue acetazolamide. Visual outcomes were categorized as SATISF or non-satisfactory (NAOSATISF). Independent sample t-tests were used for comparing means, and chi-square tests were employed for comparing proportions. The average interval between the first and second visual assessments was

55.4±48.4 days. Results The study involved the following comparative **Results:**

- Age: NAOSATISF 32.2±12 years, SATISF 35.9±18.8 years, P=0.3
- BMI: NAOSATISF 33.4±4.3, SATISF 33.7±4.3, P=0.8
- Pi: NAOSATISF 41.7±12.5 cmH2O, SATISF 39.3±13.2 cmH2O, P=0.5
- Duration of symptoms: NAOSATISF 352.25±566.5 days, SATISF 317.2±815.7 days, P=0.9
- Acetazolamide discontinuation: NAOSATISF 4.7%, SATISF 15.7%, P=0.24

None of the evaluated factors showed a statistically significant association with satisfactory visual outcomes. **Conclusion:** This study did not identify any significant predictors of satisfactory visual outcomes in IIH patients. The results suggest that age, BMI, CSF opening pressure, duration of symptoms, and the need for acetazolamide discontinuation do not significantly impact visual recovery. Further research is needed to better understand the factors contributing to the rapid neuro-ophthalmological recovery in IIH patients.

Correspondence: Renan Carvalho Castello Branco; Email: castellorenan@yahoo.com.br.

Obstructive sleep apnea (OSA) is a disease of Upper airways associated with stroke through diverse mechanisms, but there is no clear association with hemorrhagic transformation. This study's aim is to determine the predictors of hemorrhagic transformation in patients with high risk of OSA. We performed a transversal study, part of a cohort of stroke patients. They were evaluated about risk of obstructive sleep apnea with SOS and STOP-Bang scores. Data of previous comorbidities and stroke profile were collected. Comparison between groups was done with T test/chi-schare/Mann-Whitney, considering p<0.1, and multivariate analysis with logistic regression, considering p<0.05, to outcomes of hemorrhagic transformation and its type (ECASS). We obtained 326 patients, 71% high risk with STOP-Bang and 51% with SOS (27% cardioembolic, 24% atherothrombotic, 11% de small vessels, 6% other causes e 31% undetermined; p=0.068), of which 12% evolved to hemorrhagic transformation. High risk had higher prevalence of male sex, hypertension (p<0.001), diabetes (p<0.001), ASPECTS (p=0.02), also they evolved more to death (p=0.03). Considering SOS, etiology of stroke (OR=1.6; IC=95% 1.1-2.4; p=0.013) and ASPECTS (OR=1.347; IC=95% 1.1-1.7; p=0.006) were independently associated to hemorrhagic transformation. Obesity was independently associated to ECASS I and II (p<0.001). Cardioembolic etiology is a determinant of higher risk of hemorrhagic transformation, due to the mechanism well described in literature of increased risk of hemorrhage in infarcted area with emboli and its inherent friable characteristic. In patients with high risk of obstructive sleep apnea, better admitional ASPECTS can be relevant to further worst outcomes, leading to a improvement of care in patients that appear to have better images.

Predictors of quality of life in patients with myasthenia gravis treated in the unified health system

Antonio Lázaro Santos Soares Junior[1], Luísa Dias Moreno Aravena[1], Marivaldo Yslan Silveira Leal[1], Marcel Leal Ribeiro[2], Bruno Bacellar Pedreira[2], Alice Silva Oliveira[2], Jamary Oliveira Filho[2]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.
[2]Hospital Universitário Professor Edgard Santos, Salvador BA, Brazil.

Correspondence: Antonio Lázaro Santos Soares Junior; Email: antoniolssj@ufba.br.

Background: Myasthenia Gravis (MG) is an autoimmune disease caused by antibodies targeting structures at the neuromuscular junction, leading to skeletal muscle weakness characterized by fatigability and fluctuating strength. These clinical manifestations create various difficulties for sufferers, compromising their quality of life. **Objective:** To evaluate predictors of quality of life in individuals with MG treated by the Unified Health System. **Methods:** This single-center cross-sectional study involved patients over 18 diagnosed with MG at a Unified Health System reference center. Current symptoms and quality of life were assessed using the "MG-Activities of Daily Living" (MG-ADL) and "MG-Quality of Life-15 revised" (MG-QoLr) scales, respectively. Relationships between variables were analyzed using univariate linear regression. Variables with a p-value less than 0.1 were included in the final model to identify factors independently affecting quality of life. The final multivariate analysis was conducted using multiple linear regression, with a significance level of 0.05. **Results:** Fifty-four individuals were recruited, predominantly female (72.2%), brown (46.3%), and high school graduates (35.2%). The average age was 44.7 (±14.5) years, with an onset age of 31.3 (±15.5) years and illness duration of 13.4 (±9.5) years. The predominant clinical form was generalized, affecting 37 (68.5%) participants, and the serological profile was anti-AchR positive in 26 (48.1%). The median MG-ADL score was 3 (1-6.25). Comorbidities were present in 39 (72.2%) participants. The median time to diagnosis was 7 (2-22.25) months, with 18 (33.3%) having a late diagnosis (over 12 months between symptom onset and diagnosis). Azathioprine was used by 51.9% and corticosteroids by 48.1%. At the time of the survey, 45 (83.3%) did not have private health insurance, and 32 (59.3%) reported difficulty accessing the public health network, with a median difficulty perception score of 6 (0-8) on a scale of 0 to 10. Of the total sample, 27 (50%) stopped working and/or studying after diagnosis. The median MG-QoLr score was 10.5 (3.75-15.25). The following variables with a p-value < 0.1 in simple linear regression were included in the multiple linear regression model: MG-ADL, age at disease onset, late diagnosis, use of azathioprine, corticosteroid therapy, interruption of work and/or study activities, and self-perceived difficulty accessing Unified Health System. MG-ADL (B=1.47; CI: 0.95 - 1.99) and late diagnosis (B=3.12; CI: 0.31 - 5.93) correlated with MG-QoLr in the final model, with all p-values < 0.05. No significant correlation was found with other variables. **Conclusion:** Higher MG-ADL scores and late diagnosis are predictors of poorer quality of life in patients with MG.

Correspondence: Rafael Oliveira Vidon; Email: rafaelvidon@hotmail.com.

Background: Hereditary Sensory and Motor Neuropathy (HSMN), also known as Charcot-Marie-Tooth disease (CMT), is part of a heterogeneous group of genetic diseases where the peripheral nerve is primarily affected. CMT affects about 1 in every 2,500 people worldwide. Despite its prevalence, patients with the disease may take many years to have their diagnosis confirmed. More than 90 causative genes have been identified for this neuropathy, with diverse phenotypic manifestations. It can start as early as at birth or as late as the fourth or fifth decade of life. In terms of severity, some patients may need early assistance with walking, while others may have only mild symptoms. Etiological diagnosis of neuropathy avoids unnecessary, sometimes costly and harmful treatments. It allows for genetic counseling, guidance, and anticipation of possible morbidities, as well as identifying potential therapeutic options. **Objective:** The study aims to achieve a better understanding of the clinical and neurophysiological history characteristics in a population treated at Pedro Ernesto University Hospital (HUPE), State University of Rio de Janeiro. **Methods:** The study consists of a retrospective and prospective analysis through a clinical and neurophysiological database of patients with the syndromic diagnosis of sensory-motor polyneuropathy, who are treated at the neuromuscular disease outpatient clinic at HUPE and who have undergone genetic testing to confirm the disease. **Results:** Thirty-four patients with suspected hereditary neuropathy, seen between 2018 and June 2024, are being followed. Results Of the total, 32 patients from 27 families had a diagnosis of CMT, with the genetic mutation confirmed. The most frequent was the duplication of the PMP22 gene (43.7%, 14/32), followed by the MPZ gene (18.7%, 6/32), deletion of PMP22 (12.5%, 4/32), and MFN2 (6.25%, 2/32). The observed pattern was predominantly distal involvement in the lower limbs (96%, 28/29), with a slow and progressive course and initial manifestation of loss of strength (82.7%, 24/29), often associated with foot deformities (80%, 20/25). The age of onset of symptoms ranged from 0 to 53 years, with a median of 14.5 years. Most manifestations occur in the first two decades of life. Patients underwent neurological examination and the scales used to measure the degree of neurological disability were the Neuropathy Impairment Score - Lower Limbs (NIS-LL) and CMT neuropathy score (second version). The electromyography data of 25 patients were analyzed, with analysis of conduction velocities, amplitudes, and morphologies of motor and sensory potentials. In one patient with late onset and predominant sensory symptoms, a mutation in the BAG3 gene, a gene recently associated with axonal polyneuropathy, was identified. **Conclusion:** The study describes phenotypes associated with mutations causing CMT and contributes to expanding the spectrum of diagnostic possibilities in patients with peripheral neuropathy.

Preliminary assessment of the use of the virtual brain in the study of patients with brain gliomas: a descriptive approach

Thalles Olivi de Almeida[1], Jose Reynaldo Walther de Almeida[2], Ana Carolina Campos[1], Brigida S. de Oliveira[1], Marcos Vinicius Calfat Maldaun[1]

[1]Hospital Sirio Libanes, São Paulo SP, Brazil.
[2]Instituto de Neurociências de Araraquara e de Barretos, Araraquara SP, Brazil.

Correspondence: Thalles Olivi de Almeida; Email: almeida.thalles@outlook.com.

Background: Brain gliomas represent a significant challenge for both diagnosis and treatment due to their heterogeneous nature and their ability to alter the functionality of surrounding brain regions and at a distance. Mathematical models can contribute to the prior understanding of

possible postoperative complications. However, effective parceling of MRI images containing gliomas is complicated by the presence of the tumor, which can displace or infiltrate functional areas, making it difficult to accurately identify healthy and affected regions. MRI with Diffusion Tensor Imaging (DTI) and fMRI offer the possibility to study the different structural connectivities both visually and through validated models. The Virtual Brain (TVB) emerges as a potentially powerful tool, enabling the simulation of brain activity and analysis of the impact of gliomas on connectivity and neural function. **Objective:** To preliminarily explore in 3 glioma patients and 3 normals the application and difficulties of TVB in analyzing the influence of gliomas on brain structure and function. **Methods:** We conducted the parceling of T1 and DTI MRI of available images. The process was supervised until the result was in accordance with the neurosurgeon's understanding using the Glasser atlas, which includes 180 cortical regions. We applied the Wong-Wang model and carried out simulations in the TVB environment and the statistics in the R platform, using local and global efficiency, and MPR complexity, in an exploratory search for insights into the organization and efficiency of the brain tumor regions. **Results:** Evaluation of the pipeline - The parceling of MRI images in patients with tumors revealed the complexity of identifying functional areas in brains with gliomas. Regions of necrosis need to be adequately differentiated from tumor areas with functional potential. Evaluation of peritumoral structural connectivities in relation to the total connected areas in both hemispheres - The mean MPR complexity in tumor regions was 0.207 compared to 0.373 in contralateral homologue regions ($p<0.05$). The means of global and local efficiency were also significantly different between tumoral (0.20) and contralateral homologue regions (0.36) ($p<0.05$). In the control group, there were no differences ($p>0.05$). **Conclusion:** The implementation of The Virtual Brain (TVB) in the analysis of gliomas can be an exceptionally valuable tool, offering new perspectives on the structural and functional modifications caused by these tumors in the brain. The ability to identify and differentiate regions affected by necrosis from active tumor tissue, although challenging, highlights the importance of a detailed approach and specialized knowledge in the interpretation of magnetic resonance images.

Background: Current treatment options for early Alzheimer's disease (AD) are limited to recently approved amyloid-lowering monoclonal antibodies, necessitating the exploration of additional therapeutic avenues due to the complexity of AD. Semaglutide, a glucagon-like peptide-1 receptor agonist (GLP-1RA) approved for type 2 diabetes and obesity, is now being investigated for early AD. **Methods:** The ongoing phase 3 evoke (NCT04777396) and evoke+ (NCT04777409) trials are multicenter, randomized, double-blind, placebo-controlled studies being conducted in 40 countries. Enrollment was completed on September 8, 2023. Participants, aged 55-85 years, were amyloid-positive, with mild cognitive impairment due to AD or mild AD dementia. The primary endpoint is the change in CDR-SB score from baseline to week 104. A cerebrospinal fluid (CSF) sub-study is being conducted in 15 countries to explore the effect of semaglutide on CSF biomarkers of AD and neuroinflammation. Baseline characteristics were compiled after enrollment completion and without knowledge of randomization assignments. evoke and evoke+ enrolled 1855 and 1953 participants, respectively. **Results:** Baseline demographics and clinical parameters were similar in the two trials. Additionally, 2.8% of participants in evoke+ exhibited concurrent significant small vessel pathology. The proportion of participants on an AD medication was 59.7% and 56.0% in evoke and evoke+, respectively. Type 2 diabetes was present in 11.8% of participants in evoke and 15.6% in evoke+. **Conclusion:** The evoke and evoke+ trials represent the first large-scale phase 3 investigations into the disease-modifying potential of GLP-1RAs in individuals with early AD. Both trials recruited a very similar population of individuals with early AD. The primary read-out of the trials is expected in the second half of 2025.

Preliminary data on the validation of the comprehensive coordination scale for individuals with Parkinson's disease

Clara Rezende Rocha[1], Maria Eduarda Salum Aveiro[1], Caroline Rodrigues Osawa[1], Pedro Henrique Souza de Andrade[1], Luciane Aparecida Pascucci Sande de Souza[1], Gustavo José Luvizutto[1]

[1]Universidade Federal do Triângulo Mineiro, Uberaba MG, Brazil.

Correspondence: Clara Rezende Rocha; Email: d202010477@uftm.edu.br.

Background: The motor coordination refers to the recruitment and organization of muscles and joints to produce precise movements. The inefficiency of this aspects may reduce the quality of life and daily activities execution. The Parkinson's disease (PD) is a neurodegenerative condition wich symptoms as tremor, badykinesia and muscle stiffness, reduce motor coordination in PD patients. **Objective:** To validate the Comprehensive Coordination Scale (CCS) as a evaluation instrument of motor coordination in PD. **Methods:** It is a cross sectional study with PD patients. Was assess 20 individuals: Parkinson's Group (PG; n=13) and Control Group (CG; n=7), neurological healthy older adults. For the PD evaluation, beside CCS, was applied the Hoehn and Yard Scale disability states scale (H&Y) and the motor evaluation of the Unified Rating Scale of Parkinson's Disease adapted by Movement Disorder Society (MDS-UPDRS). Both groups were evaluated by CCS, a qualitative scale with specifical tests that measure the precision, performance and quality of the movements of each task (finger-to-nose; arm-trunk coordination; finger opposition test; interlimb coordination test - bilateral upper limb movements; lower extremity motor coordination – lower limber coordination; interlimb coordination – bilateral upper and lower limb movements). The scale score is divided in bilateral and unilateral for lower and upper limbs to assess the left and right hemibody, it totalizes 69 point. The evaluation was recorded and assessed by five evaluators. The data comparation of CCS between groups was assessed by the Mann-Whitney test and the correlation between CCS, H&Y and UPDRS was measured by the Spearman correlation test. **Results:** In PG the H&Y mean was of 1.8 which demonstrated a group with more unilateral commitment with or without axial deficit. In the MDS-UPDRS the mean was 29,61 which demonstrated a higher presence of individuals with PD dominant tremor in relation to akinetic ones. In regarding of CCS there was a statistical difference between both groups on the domains: upper limb ($p<0.001$), lower limb ($p=0.006$), bilateral ($p=0.015$) and total ($p<0.001$). There was negative and moderate correlation of the total and subdomains of CCS and MDS-UPDRS, the same happened between CCS and H&Y. **Conclusion:** This study demonstrated that there is a moderate correlation between the subitens of CCS, MDS-UPDRS and H&Y. It is important to highlight that this scales presents different domains which makes necessary the investigation of CCS and other motor coordination tests. Furthermore it is important the modification of some evaluation itens of CCS to make the scale more sensitive to PD symptoms.

Preliminary study evaluating the structures of medial temporal lobe in epilepsy with hippocampal sclerosis using transcranial sonography

Bárbara Pina Aiello[1], Ingrid Pereira Marques[1], Fernando de Oliveira Morais Nacur[1], Sophia Keiko Inuzuka[1], Claudia Cecilia da Silva Rego[1], Valeria Coelho Santa Rita Pereira[1], Soniza Vieira Alves Leon[1], Rita de Cássia Leite Fernandes[1]

[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Bárbara Pina Aiello; Email: drabarbarapina@gmail.com.

Background: Mesial temporal lobe epilepsy (MTLE) has a high prevalence, accounting for 40% of epilepsy cases. In 80% of MTLE, the crisis begins in the hippocampus, with Hippocampal Sclerosis (HE) being the etiology found in 50-70% of patients with MTLE refractory to clinical treatment, with surgical treatment as an option. **Objective:** Considering the prevalence and burden of this morbidity, we aim to evaluate the feasibility of transcranial sonography (TCS), a cost-effective and harmless neuroimaging method in detecting structural changes in ELTM-EH and to compare it to the already validated method, Magnetic Resonance Imaging (MRI), in patients with MTLE-EH. **Methods:** Preliminary prospective cross-sectional study. Patients were recruited from the epilepsy outpatient clinics of a university hospital with a diagnosis of MTLE-EH with MRI performed <1 year ago. The TCS was performed with HD11XE equipment (Phillips, Netherlands) and a 2-4 MHz sector probe positioned in the temporal bone window in axial and coronal planes. The same measurements were obtained by MRI and TCS bilaterally - choroidal fissure (CF), temporal pole of the lateral ventricle (TP) and height of the hippocampus (HIPh). With MRI, images of the hippocampal formations were obtained in T1 sequences in the sagittal plane with 1mm slices, in addition to FLAIR and T2 sequences angled for the hippocampus without the administration of gadolinium. Measurements were taken at the largest vertical diameter of the structure, regardless of its position in relation to the hippocampus. The mesial temporal lobe atrophy index (MTA=CF+TP) was calculated for both methods. **Results:** Four patients were analyzed, 3 men and 1 woman, aged 24 to 50 years and disease duration between 48 and 420 months. The comparison of the measurements taken by the 2 exams showed a good correlation in all patients, especially the

MTA, with an agreement of 74%. The worst measurements were those of TP, with an agreement of 43%. Only 1 patient had no bone window for analysis by TCS on the left side. The definition of the laterality of hippocampal atrophy between the 2 exams was 100%. **Conclusion:** To the best of our knowledge, this is the first study to evaluate patients with MTLE-EH diagnosed by MRI with TCS, a practical, harmless and relatively low-cost method. The structures of the mesial temporal lobe were easily visualized with TCS and, in this preliminary study, the measures obtained showed good agreement with MRI and offered the correct identification of the laterality of hippocampal sclerosis. The disadvantages of the method are its dependency of a permissible bone window, which usually occurs in 85-90% of individuals, and of an experienced operator. Studies with larger participant groups are highly desirable to prove TCS accuracy in clinical neurological practice as a neuroimaging modality in epilepsy patients.

Pre-surgical hippocampus and amygdala volumes do not present relationship with seizure freedom after surgery in temporal lobe epilepsy patients

Marco Tulio Medina[1], Lucas Scárdua-Silva[1], Brunno Machado de Campos[1], Marina Koutsodontis Machado Alvim[1], Fabio Rogerio[1], Enrico Ghizoni[1], Helder Tedeschi[1], Fernando Cendes[1], Clarissa Lin Yasuda[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Lucas Scárdua Silva; Email: scardua@unicamp.br.

Background: Temporal Lobe Epilepsy (TLE) is the most common cause of pharmacoresistant epilepsy in adults, and many neuroimaging studies have presented microstructural alterations in the brains of these patients. However, it is still a research theme if pre-surgical neuroimaging can predict surgical outcomes. **Objective:** To compare bilateral amygdalae and hippocampi volumes (before surgery) of surgical-responsive and surgical-non-responsive TLE patients - as evidence of possible neuroimaging-base prediction. **Methods:** We acquired 3T T1-weighted images (Achieva Phillips) of 86 TLE patients before surgery and divided them into two groups: the surgical-responsive (56 subjects who achieved seizure freedom until the last visit after surgery) and the surgical-non-responsive (30 subjects without seizure freedom until the last visit after surgery). We used MATLAB 2019/SPM12/CAT12 to preprocess and perform a Voxel-Based Morphometry (VBM) calculation. After this, we utilized MATLAB2019 to perform the normality test (Kolmogorov-Smirnov, the samples were statistically normal, p>0.05) and the two sample t-tests. **Results:** The two-sample t-tests yielded negative results, in which the left hippocampus, right hippocampus, left amygdala, and right amygdala volumes did not show a statistical difference in surgical-responsive and surgical-non-responsive patients (p>0.05). Although there was no statistical difference, surgical-responsive patients exhibited bigger volume means and medians in all four structures. **Conclusion:** While our study did not find a statistical difference in the volumes of amygdalae and hippocampi between surgical-responsive and surgical-non-responsive patients, it is noteworthy that the surgical-responsive group exhibited higher means and medians for all four pre-surgical volumes (left hippocampus, right hippocampus, left amygdala, right amygdala). These findings, though not conclusive, could potentially guide future studies in this area.

Prevalence of comorbidities in patients admitted to a stroke care unit in a reference hospital in the state of Pernambuco

Caio Roberto Alexandre Cavalcante dos Santos[1], Ana Dolores Firmino Santos do Nascimento[2], Déborah Emmily de Carvalho[1], Rafael Cabral de Carli[1], Janaina Gomes Pereira de Oliveira[1], Maria Eduarda Moreira Cardoso[2], Ricardo Martins Silva[2], Monique Evelyn Mendonça do Nascimento[2], Noelle Ventura Jordão[2]

[1]Universidade de Pernambuco, Recife PE, Brazil. [2]Hospital da Restauração, Recife PE, Brazil.

Correspondence: Caio Roberto Alexandre Cavalcante dos Santos; Email: caiosantosupe@gmail.com.

Background: Stroke is a focal disorder of vascular origin. Approximately 87% of total stroke cases are ischemic, mainly caused by atherosclerosis of large arteries, occlusion of small vessels, and cardioembolism, often associated with atrial fibrillation. Etiological factors are known to be associated with various comorbidities that increase the risk of stroke and interfere with recovery after the acute event, with some of these being modifiable and others non-modifiable. Among hemorrhagic strokes, hypertension, excessive alcohol consumption, and smoking are known risk factors. **Objective:** To analyze the prevalence of comorbidities as risk factors in patients admitted to the stroke unit of a high-complexity hospital in Northeast Brazil. **Methods:** This is a retrospective, cross-sectional study analyzing medical records of stroke patients from May 2023 to May 2024 at a neurology reference hospital in the state of Pernambuco, including patients with ischemic stroke, hemorrhagic stroke and transient ischemic attack. Statistical analysis was performed using Excel software, with appropriate statistical tests applied to the selected variables. **Results:** A total of 2391 patients were included in the study. Of the total sample, 1228 patients (51.35%) were previously diagnosed with Systemic Arterial Hypertension. Regarding other comorbidities, Diabetes Mellitus was observed in 614 (25.67%) patients, previous stroke in 272 (11.37%), and previous Acute Myocardial Infarction in 77 (3.22%). Among the modifiable risk factors, 143 (5.98%) patients had been active smokers for more than ten years, and 112 (4.68%) had a history of alcohol abuse. **Conclusion:** There is a high prevalence of comorbidities in the studied population. Considering stroke is a rapidly evolving pathology with a high mortality rate, it is essential to track the main risk factors associated with its progression. Therefore, preventing and treating such comorbidities is crucial to reducing the incidence of this neurological vascular condition and improving outcomes.

https://doi.org/10.5327/CBN241341

Prevalence of gastrointestinal symptoms in patients with autism spectrum disorder: a systematic review

Milena Fernandes de Oliveira[1], Sofia Sampaio Paixão[1], Thais Barbosa de Oliveira[1], Cibele Dantas Ferreira Marques[1]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.

Correspondence: Milena Fernandes de Oliveira; Email: milenafer.oliv@gmail.com.

Background: Children with ASD have a higher frequency of concomitant conditions, such as gastrointestinal symptoms, epilepsy, sleep disorders, autoimmune and psychiatric diseases. The presence of gastrointestinal symptoms in children with ASD is associated with worsening repetitive behaviors, worsening sleep habits, difficulty in social reciprocity and increased anxiety. **Objective:** To identify whether there is a higher prevalence of gastrointestinal symptoms in the population of children with ASD compared to the population of neurotypical children. **Methods:** A systematic literature review with meta-analysis was carried out. Cross-sectional case-control observational articles from 2008 onwards, in English, Portuguese and Spanish, were considered eligible. The case group consisted of individuals with ASD, diagnosed by the DSM-V, DSM IV, ICD-10 criteria, or by the ADOS and ADI-R tests, and the control group consisted of children without any developmental disorder, both groups younger than 18 years. The search was carried out in four databases: PubMed, Embase, Lilacs and Scielo. The studies needed to provide information on at least one of the following gastrointestinal symptoms: constipation, diarrhea, vomiting, abdominal pain and excessive flatulence. **Results:** Of the 803 studies, 194 duplicates were deleted. Thus, 609 articles were selected. The selection was carried out by two researchers independently and any disagreements were decided between the two. Of the 609 articles, 9 articles were selected for this study. Afterwards, the risk of bias was assessed using a specific questionnaire for prevalence articles and all studies had acceptable risk to be included in this review. There was a higher risk of constipation (RR 2.62; 95%CI 2.17-3.17; I^2=38%), diarrhea (RR 4.22; 95%CI 2.58-6.91; I^2=59%), abdominal pain (RR 1.90; 95%CI 1.29-2.82 ; I^2=44%), excessive flatulence (RR 3.51; 95%CI 1.84-6.69; I^2=71%) and vomiting (RR 3.09; 95%CI 1.61-5.92; I^2=49%), that is, a higher prevalence of symptoms gastrointestinal disorders in individuals with ASD compared to children without developmental disorders. **Conclusion:** Gastrointestinal symptoms are more present in individuals with ASD and this may be due to greater difficulty in eating due to the restrictive diet pattern or genetic and intestinal microbiota findings.

https://doi.org/10.5327/CBN241342

Prevalence of hypertension and its impact on NIHSS scores in ischemic stroke patients at a tertiary hospital

Maria Eduarda Vieira de Oliveira[1], Maria Thayana Barros Bandeira[2], Noelle Ventura Jordão[3], Maria Eduarda Moreira Cardoso[3], Ana Dolores Firmino Santos do Nascimento[3], Maria Luiza Vasconcelos Montenegro[1], Letícia Gomes Fonseca[4], Lívia Barbosa Cavalcanti[1], Mariana Lucena Loureiro[1]

[1]Universidade de Pernambuco, Recife PE, Brazil. [2]Faculdade de Medicina de Olinda, Olinda PE, Brazil. [3]Hospital da Restauração, Recife PE, Brazil. [4]Faculdade Pernambucana de Saúde, Recife PE, Brazil.

Correspondence: Maria Eduarda Vieira de Oliveira; Email: eduardaoliveira0194@gmail.com.

Background: Ischemic stroke is a leading cause of morbidity and mortality worldwide, with hypertension being a significant risk factor. The National Institutes of Health Stroke Scale (NIHSS) is a critical tool for assessing the severity of stroke and predicting outcomes. Understanding the relationship between hypertension and stroke is crucial for developing targeted interventions to improve patient outcomes. **Objective:** To determine the prevalence of hypertension in patients admitted with ischemic stroke and its impact on NIHSS scores at admission and discharge in a tertiary hospital in Northeastern Brazil, compared with non-hypertensive patients. **Methods:** A retrospective cohort study was conducted in a stroke unit at a tertiary hospital from May 2023 to May 2024. Data were meticulously collected from medical records. Statistical analysis included descriptive statistics to outline patient demographics and health status, and the Student's t-test to assess the association between hypertension and NIHSS scores at discharge. **Results:** The sample consisted of 1100 ischemic stroke patients, 923 (83.91%) of whom had hypertension. The mean NIHSS score at discharge was analyzed for both groups, with and without hypertension. Among hypertensive patients, the mean NIHSS score at discharge was significantly higher compared to non-hypertensive patients, indicating worse neurological outcomes. The Student's t-test showed a statistically significant difference between the two groups at discharge (t=2.178, p=0.030). At admission, however,

the NIHSS scores did not show a statistically significant difference between hypertensive and non-hypertensive patients (t=0.175, p=0.861). The average NIHSS score at discharge for hypertensive patients was 10.57 (SD 8.66), while for non-hypertensive patients it was 7.72 (SD 9.41). Despite the lack of significant difference at admission, the higher NIHSS scores at discharge among hypertensive patients suggest that hypertension may contribute to poorer recovery or greater complications during hospitalization. **Conclusion:** Hypertension is highly prevalent among ischemic stroke patients and is associated with worse neurological outcomes, as indicated by higher NIHSS scores at discharge. The statistically significant difference observed at discharge underscores the importance of effective hypertension management in improving stroke recovery. Further studies with larger samples and more robust methodologies are needed to confirm these findings and develop effective management strategies for hypertension in stroke patients.

Prevalence of incidental findings in the brains of non-sedated nonclinical population of full-term neonates undergoing MRI scans

Larisssa Melo Marques de Sousa[1], Célia Maria de Araújo[1], Gabriel Ronatty Tavares[1], Lucas Pinto Ribeiro[1], Maret Rand[1], Aline Camargo Ramos[1], Ana Carolina Milani[1], Ivaldo Silva[1], Nitamar Abdala[1], Andrea Parolin Jackowski[1]

[1]Pontifícia Universidade Católica de São Paulo, Sorocaba SP, Brazil.
[2]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Larissa Melo Marques de Sousa; Email: marq.lari@gmail.com.

Background: Magnetic resonance imaging (MRI) is considered safe for neonates, but incidental findings (IF) in healthy populations pose a challenge due to limited data. These findings can guide early intervention or monitoring. **Objective:** To investigate the prevalence IFs in a nonclinical population of full-term neonates participating in the Healthy MINDs study. **Methods:** MRI were performed at the Diagnostic Imaging Department of the Federal University of São Paulo in a Siemens 3T (IRB:1200/2017). Before the MRI scan, the neonates were examined by a pediatrician and after having their ears protected and falling asleep naturally, they conducted a brain MRI. Structural analysis included cerebral myelination, anatomical variants or malformations, brain parenchyma lesions, ventricular system changes, and intra- or extracranial hematomas or hemorrhages, always evaluated by the same neuroradiologist. **Results:** Out of 301 neonates (mean age = 32.13 ± 9.018 days; 153 males), 32 (10.63%) had IFs and 77 (25.58%) had anatomical variants like cavum of septum pellucidum (CSP). The IFs included 4 subgaleal hematomas, 1 subdural hematoma, 1 cortical laminar necrosis, 7 arachnoid cysts, 4 ventricular anomalies, 2 vascular anomalies, 3 volumetric reductions of the left cerebral hemisphere, 1 lipoma, 3 cerebellar and intracranial hemorrhagic components, 1 subcortical signal alteration/hemoglobin degradation product, 1 brain parenchyma signal alteration, 2 Virchow-Robin perivascular space increases, 1 benign enlargement of the subarachnoid space, and 1 thickening of the mucous lining of the ethmoidal cells bilaterally. All altered exams were communicated to the mothers, and infants were referred for follow-up as needed. **Conclusion:** The prevalence of IFs was 10.63% and CSP was 25.58%. Arachnoid cysts were present in 21.7% of IFs, higher than previous studies. A 9.3% prevalence of left cerebral hemisphere volumetric reduction was noted, contrasting with other studies. More research is needed on IFs in nonclinical full-term neonates to inform early intervention and follow-up practices.

[5]Universidade Federal de Santa Maria, Santa Maria RS, Brazil.
[6]Universidade Federal do Maranhão, São Luís MA, Brazil

Correspondence: Maria Regina Saddi Guerra; Email: mreginasaddi@gmail.com.

Background: Leprosy is a notifiable disease, with high infectivity and low pathogenicity. Initially, it affects the peripheral nervous system (PNS) and, later, the skin (non-contagious, paucibacillary form). This disease is associated with factors such as social inequality and unfavorable socioeconomic conditions and can cause physical disability, being neglected. Although it has been eliminated in many countries, it persists in developing nations, such as Brazil, especially in the state of Maranhão, which has the highest number of new cases. **Objective:** Analyze the epidemiological profile of Leprosy in the state of Maranhão from 2013 to 2023. **Methods:** This was an ecological study using data of leprosy cases in the Brazilian state of Maranhão, diagnosed between 2013-2023 from the Notifiable Health Conditions Information System (SINAN). The variables investigated were: total frequency of notifications per year, sex, age group, color/race, level of education, operational class, smear microscopy and number of lesions. **Results:** During the period from 2013 to 2023, 40,327 cases of leprosy were reported in the state of Maranhão. The disease predominantly affected men (51.9%), of mixed race (67.4%). The age group with the highest notification was between 30 and 39 years old (17.7%), followed by the age group of 40 to 49 (16.4%) notifications, and in children under 15 years old there was the lowest notification (8.3%). Notifications were predominant in people with low education, with 43% of reported cases not having completed primary education and 14.6% being illiterate. The multibacillary classification was predominant in 80.45%, the paucibacillary in 19.5%. The predominant bacilloscopy was negative (27.3%), however 28.5% had an inconclusive result and in 25.9% the test was not performed. According to the number of injuries, 35.8% had more than 5 injuries, 28.7% between 2 and 5 and 22.3% had single injuries. During the period analyzed, it was noticed that notifications of Maranhão disease are in constant decline, with the highest number of notifications in 2013 (11.9%) and with the lowest number in 2023 (2.27%), this reduction could be attributed to the actions of the Family Health Strategy and its teams in the fight against leprosy. **Conclusion:** The epidemiological profile of leprosy in Maranhão is characterized by a higher prevalence among men of mixed race, with multibacillary classification, aged 30 to 39 years, and who have an education level of up to elementary school. Even with the reduction in cases in the period, public policies are still essential to eradicate them.

Prevalence of meningitis by case evolution in Brazil between the years 2013 and 2023

Luan Victor Silva Ribeiro[1], José Antônio Solano Silva[1], Laisa de Paula da Costa Lobato[1], Hálisson Ferreira Freitas Filho[2], Leandro Gabriel Costa Macedo[1], Bárbara Coutinho Morgado[3], Ricardo Ferreira Silva[1], Bárbara Alessandra Solano Silva[3], Dirceu Jose de Freitas Cardoso[1], Leonardo Kadu Tavares Veloso[1]

Correspondence: José Antônio Solano Silva; Email: jsjosesolano108@gmail.com.

Background: Meningitis is an acute inflammation of the membranes that cover the brain and spinal cord, with significant potential to cause neurological and systemic damage, sometimes irreversible, and is important for notification systems, directly impacting public health. Thus, understanding these data is essential for developing effective public health policies that can reduce incidence and improve outcomes for affected patients. **Objective:** To investigate the epidemiological data related to the evolution of meningitis cases from 2013 to 2023 in Brazil. **Methods:** This is a cross-sectional, descriptive epidemiological study with a temporal trend design and quantitative focus, using secondary data collected from the Notification of Injury Information System (SINAN), provided by the Department of Informatics of the Ministry of Health (DATASUS). Confirmed cases of meningitis were reviewed according to their etiology: Meningococcemia (MCC), Meningococcal Meningitis (MM), Meningococcal Meningitis + Meningococcemia (MM+MCC), Tuberculous Meningitis (MTBC), Bacterial Meningitis (MB), Unspecified Meningitis (UM), Viral Meningitis (VM), Meningitis of other etiology (MOE), Haemophilus Meningitis (HM), Pneumococcal Meningitis (PM), and by their clinical evolution, whether discharge, followed by deaths due to the disease or deaths due to another associated cause, from January 2013 to December 2023, in each region of the country. **Results:** Between 2013 and 2023, there were 149,475 confirmed cases of meningitis, including 3,053 of MCC, 4,425 of MM, 3,022 of MM+MCC, 3,609 of MTBC, 24,496 of MB, 23,129 of UM, 70,003 of VM, 7,035 of MOE, 1,185 of HM, and 9,518 of PM. Thus, a rapid progression of the disease is noted, respectively, in VM (96.24%), MM (84.72%), UM (81.39%), HM (80.50%), MM+MCC (78.25%), MB (76.78%), MTBC (65.41%), PM (64.79%), MOE (60.98%), and MCC (56.66%). On the other hand, mortality from this disease is highest in MCC (39.79%), followed by PM (32.01%), MOE (21.76%), MM+MCC (21.24%), MTBC (20.42%), HM (17.21%), MB (14.68%), MM (14.30%), UM (11.92%), and VM (1.61%). Finally, deaths due to other causes in patients with meningitis follow the order of MOE (17.25%), MTBC (14.15%), MB (8.53%), UM (6.63%), MCC (3.53%), PM (3.19%), HM (2.27%), VM (2.13%), MM (0.97%), and MM+MCC (0.49%). **Conclusion:** The findings presented highlight a high number of VM cases, which accounted for the majority of confirmed cases between 2013 and 2023, followed by MB and UM. VM, followed by MM and UM, were the most prevalent concerning rapid disease progression, with high mortality in cases of MCC, PM, and MOE. Additionally, deaths due to other causes associated with the pathology are also alarming, such as in MOE, MT, and MB, which were the most predominant. In this context, the data emphasize the need for preventive measures and strategies tailored to the specificities of each meningitis etiology, aiming to reduce mortality and disease burden in the country.

Correspondence: Leandro Gabriel Costa Macedo; Email: leandrogabrielzinho11@gmail.com.

Background: For a long time, the possibility of viral infections interfering with pregnancy and causing congenital anomalies in newborns (NB) has been studied. Currently, this interference is well established in the literature, with Zika virus (ZIKV) being a major focus of study in this field. Numerous studies indicate that the presence of ZIKV RNA in amniotic fluid can lead to malformations in NB, such as neonatal microcephaly, a condition where the baby is born with a smaller than expected head, leading to problems in neurological development. **Objective:** To present evidence related to comparative findings between ZIKV infection during pregnancy and the occurrence of microcephaly in NB. **Methods:** This is a descriptive, analytical, and retrospective study with a quantitative approach, using secondary data from the Notification of Injury Information System (SINAN) and the Live Births Information System (SINASC). We evaluated cases of ZIKV among pregnant women, trimester of pregnancy, year of notification, and analyzed the frequency per Live Birth Certificate with microcephaly, by year of birth, from January 2016 to December 2022, in the Northern region of Brazil. **Results:** In 2016, an alarming number of ZIKV cases among pregnant women were observed (3,356), with 920, 1,298, and 1,138 cases in the first, second, and third trimesters of pregnancy, respectively. In 2017, there were 1,304 cases, with 371, 509, and 424 in the first, second, and third trimesters. In 2018, there were 598 cases of ZIKV among pregnant women, with 187, 224, and 187 occurring in the first, second, and third trimesters. In 2019, there were 344 cases, with 97, 129, and 118 in the first, second, and third trimesters. In 2020, 175 cases, divided as follows: 56, 67, and 52 in the first, second, and third trimesters. In 2021, there were 149 cases, with 27, 46, and 45 in the first, second, and third trimesters. As for the numbers of NB with microcephaly from 2016 to 2021, the following values were obtained respectively: 181, 62, 42, 32, 21, and 22 cases. Finally, in 2022, unlike previous years, there was no decrease trend, with 242 cases of ZIKV among pregnant women, including 54, 100, and 76 in the first, second, and third trimesters, and 27 cases of microcephaly in babies. **Conclusion:** In 2016, a ZIKV epidemic spread across Brazil, resulting in a higher number of pregnant women testing positive for ZIKV and more babies born with microcephaly that year. In 2017, there was a significant decline in these cases, possibly due to a combination of acquired immunity in the population, vector control efforts, and reduced virus exposure; a trend that continued in the following years. However, in 2022, there was an increase in ZIKV rates among pregnant women and microcephaly in NB. Thus, measures should be implemented in the country, considering transplacental transmission and the complexity of the pathophysiological mechanisms of Zika Congenital syndrome.

Case presentation: Primary amebic meningoencephalitis (PAM) is a rare, highly lethal infection caused by the free-living amoeba (FLA) Naegleria fowleri. This pathogen penetrates the central nervous system through the cribriform plate following exposure to contaminated water, causing fulminant hemorrhagic brain necrosis. Diagnosing PAM is challenging and there is no widely standardized treatment. This report describes two PAM cases in Northeast Brazil. Case 1: A 34-year-old male with systemic arterial hypertension and hypothyroidism, working in oil refinery maintenance, was admitted with intermittent headache and fever 40 days after cleaning a water tank. He received a clinical diagnosis of meningoencephalitis. Cerebrospinal fluid (CSF) and serological analyses didn't detect the pathogen. A month later, he developed intense occipito-vertebral pain and vomiting, leading to intensive care admission. Treated with antifungals and an extensive combination of antibiotics, he showed slight improvement but then developed neck stiffness, underwent external ventricular drainage (EVD) and suffered a subarachnoid hemorrhage; brain death was declared. Autopsy revealed brain edema, ventriculitis and hemorrhagic necrosis in the right temporal lobe and olfactory tract, with microscopy confirming the diagnosis of PAM associated with fungal infection. Case 2: A 7-year-old male student with no comorbidities experienced vomiting, headache and diplopia within two days of visiting a water park. Fundoscopy revealed papilledema and an expansive brain lesion was detected by neuroimaging. Biopsy ruled out neoplasm. He then had headaches, vomiting and seizures. Increasing intracranial pressure led to a craniectomy and EVD. The patient remained under mechanical ventilation, hemorrhagic CSF was drained and new imaging revealed extensive intraparenchymal hemorrhage. Laboratorial tests did not detect the parasite. Clinical suspicion of PAM led to treatment for FLA, as well as for bacteria and other protozoa, but the patient died 16 days after symptom onset. Autopsy revealed extensive hemorrhagic necrosis of the right temporal lobe and ventral surface of the brain. Microscopy confirmed PAM. **Discussion:** This report reinforces the importance of clinical history in suspecting PAM, as prior contact with potentially contaminated water and fulminant disease progression are characteristic. Lesions in the right temporal lobe were common to both cases and fungal coinfection is noteworthy. Despite initiating treatment for PAM in one of the cases, the outcome was still fatal, consistent with the documented 98% lethality. Both diagnoses were only confirmed post-mortem, as in most cases of PAM, highlighting the need for rapid and widely available diagnostic methods. Underreporting remains significant in Brazil and worldwide. **Final comments:** Although rare, PAM is highly lethal, justifying efforts for its control. Broad access to rapid diagnostic methods and new therapeutic plans are urgent.

Primary central nervous system lymphoma presenting as demyelinating disease

Patrick Emanuell Mesquita Sousa-Santos[1], Pedro Machry Pozzobon[1], Itamar Meireles Andrade Santos[1], Helio Aquaroni Farao Gomes[1], Paula de Almeida Souza Santos da Costa[1], Daniela Cristina dos Santos Souza[1], Laura Cardia Gomes Lopes[1], Fernando Coronetti Gomes da Rocha[1]

[1]Universidade Estadual Paulista, Botucatu SP, Brazil.

Correspondence: Patrick Emanuell Mesquita Sousa Santos; Email: patrickemanuell@gmail.com.

Case presentation: Male, 32-year-old, previously healthy and HIV-negative was diagnosed with COVID-19 in January/2022 and two weeks later present progressive vertigo, gait instability, binocular diplopia and right hemifacial palsy. Only in April he was sent for investigation in our hospital. MRI showed a lesion with FLAIR hypersignal in the pontomesencephalic transition with gadolinium enhancement. Cerebrospinal fluid (CSF) examination showed protein levels of 83mg/dL, 2 leukocytes, glucose of 79mg/dL (serum glucose 115mg/dL), and lactate level of 1.2. Oligoclonal band testing in CSF was negative. CSF cytology did not reveal neoplastic cells. Levels of anti-AQP4 and anti-MOG antibodies were also negative. In this moment, considering the infectious antecedent and MRI characteristics, he has been diagnosed with ADEM and submitted to pulse therapy with methylprednisolone, showing improve of symptoms. In outpatient follow-up he presents with worsening of symptoms. In November he was hospitalized again, MRI show new lesions on medulla and cerebellum. Submitted to pulse therapy followed by plasma exchange, with no improve. In December he had a fall with head trauma and CT show hyperdense lesion on pontomesencephalic transition with perilesional edema. New MRI presents with infiltrative lesion without gadolinium enhancement. CSF analysis show 48 cells (98% lymphocytes), no evidence of neoplastic cells. In this moment the diagnosis was reviewed to Primary CNS Lymphoma (PCNSL), confirmed on biopsy showing atypical lymphoid infiltrate with B-Cells predominance. Initiated chemotherapy, but unfortunately patient die in consequence of neutropenia. **Discussion:** PCNSL is an uncommon neoplasm and rarely affects brainstem. When it occurs the prognosis is poor, nearly half of patients died within 1 year after diagnosis. Glucocorticoids could promote tumor shrinkage. Neuroimaging characteristics could be confounding with infections, demyelinating lesions, and gliomas. **Final comments:** Our case illustrates a patient initially diagnosed with ADEM and submitted to corticotherapy with good response, however he worse in months later and the diagnosed reviewed to PCNSL. This shows the importance of considering atypical PCNSL in differential diagnosis of demyelinating diseases.

Primary presentation of demyelinating polyneuropathy in POEMS syndrome: a case report

Tainá Reis Martins[1], Wívian Maria Pires Figueredo[1], Ana Luisa Colares Ribeiro[1], Érica Guimarães Castro[2]

[1]Centro Universitário FIPMoc, Montes Claros MG, Brazil.
[2]Hospital Santa Casa de Montes Claros, Montes Claros MG, Brazil.

Correspondence: Tainá Reis Martins; Email: taina2002@hotmail.com.

Case presentation: Patient, 42 years, male, referred to neurology due to chronic low back pain for three years, evolving with hypoesthesia and progressive weakness in the lower limbs (LL) after one year. At physical examination, she presented tetraparesis, with chilling, dysesthesia and hypoesthesia of the LL. He performed electromyography with evidence of sensory-motor polyradiculopathy, predominant myelin, chronic. He was referred for hospitalization due to suspicion of chronic demyelinating inflammatory polyneuropathy (CDIP) and performed pulsotherapy for five days, without improvement of the picture. After discharge, he returns with disabling neuropathic pain and dysesthesia, using prednisone and gabapentin, presenting cutaneous rash, flaccid tetraparesis, intense dysesthesia and Raynaud in feet. Requested further investigation for secondary diagnoses of CDIP, as well as prescribed duloxetine and tramadol. It returns with complete improvement of the pains, but the weakness of the LL remains. It presents electrophoresis proteins with presence of monoclonal band in the region of gamma globulins and computed tomography (CT) of

spine and lumbosacral with diffuse sclerotic bone lesions in vertebrae and pelvis. Requested new propaedeutics, in which presented immunofixation in blood and urine with presence of monoclonal protein IGG/lambda. Chest and abdomen CT showed a numerical increase in lymph nodes in several sites, as well as mild bilateral gynecomastia and hepatosplenomegaly. Referred to hematology with suspected POEMS syndrome (PS), after hospitalization myelogram was performed with inconclusive result, and lymph node biopsy that demonstrated chronic lymphadenopathy with Plasmocyte proliferation, suggestive of Castleman's disease (CD). The presence of another criterion defined the PS diagnosis and made it possible to perform treatment with ritoxumab and the patient evolved with exponential improvement of symptoms and mobility. **Discussion:** PS is a paraneoplastic disease and its acronym represents its main manifestations: polyneuropathy; visceromegaly; endocrinopathy; monoclonal gamopathy and dermatological changes. The diagnosis tends to be late because it is a rare syndrome, which is commonly confused with CDIP, due to its symptoms and electrophysiological findings. The diagnosis of PS is made with three of the major criteria, being peripheral neuropathy and monoclonal gamopathy mandatory, and at least one of the minor criteria. The patient presented the mandatory criteria, in addition to the larger criteria of sclerotic bone lesions and CD and smaller ones: visceromegaly, cutaneous rash and gynecomastia. **Final comments:** The PS represents an important differential diagnosis in the face of polyneuropathy, although it represents a great challenge. Therefore, there is an urgent need for early recognition in order to ensure adequate treatment and support measures, consequently improving prognosis and quality of life.

Probable bickerstaff encephalitis due to dengue fever: a case report

Marcelle Janaina Baldez do Amaral[1], Camila Albuquerque Pavão[1], Beatriz Passinho Heinle[1], Myllena Batista Ribeiro[1], Thuane dos Santos Leske[1], Pedro Gil Reis de Sá[2], Luiza Joaquina Botton Reginatto[1], Fabio Pascotto de Oliveira[1], Thiego Teixeira Cavalheiro[1], Juliana Oliveira Freitas Silveira[3]

[1]Universidade Franciscana, Santa Maria RS, Brazil.
[2]Universidade Federal de Santa Maria, Santa Maria RS, Brazil.
[3]Hospital Universitário de Santa Maria, Santa Maria RS, Brazil.

Correspondence: Juliana Oliveira Freitas Silveira; Email: julianaofs@yahoo.com.br.

Case presentation: Woman, 64 years old, hypertensive and diabetic, is admitted to a tertiary hospital due to reduced level of consciousness and ophthalmoplegia. Two days before admission, she started with asthenia, nausea, vomiting and fever. She then developed ataxia, mental confusion and obnubilation. On exam, she presented spontaneous eye opening, with incomprehensible sounds and mobilized the left upper limb to painful stimuli, with bilateral sixth nerve paresis, right hemiparesis (grade IV), bilateral Babinski sign. Ataxia could not be assessed due to disturbance of consciousness. She also presented dysautonomic signs with fluctuations in blood pressure and tachycardia. Laboratory tests showed thrombocytopenia. Serologies for HIV, syphilis and hepatitis B and C were non-reactive. ANA, ANCA and complement levels C3 and C4 were normal. CSF examination showed proteinorrhaquia with proteino-cytological dissociation and there was no growth of microorganisms. Research for Cryptococcus neoformans, herpes types 1, 2 and 6, also negative. Brain MRI showed focal areas of FLAIR hypersignal in the white matter of both hemispheres, in addition to the corpus callosum, mesial region of the thalami, pons and midbrain, suggesting encephalitis. Anti-GQ1b was also negative, but it was only available after 30 days of the onset of symptoms. After the patient's family members started showing symptoms of acute febrile syndrome with positive NS1 antigen, the patient's dengue serology was requested, with positive IgG and IgM, suggesting recent dengue infection. **Discussion:** Bickerstaff brainstem encephalitis (BEE) is a rare neurological condition, a variant of Guillain-Barré syndrome (GBS), as well as Miller-Fisher syndrome (MFS). It is associated with a combination of bilateral symmetric ophthalmoplegia, ataxia, muscle weakness and sensory changes, in addition to brain stem involvement, with pyramidal signs. CSF examination may demonstrate proteino-cytological dissociation. Anti-GQ1b antibodies may be presente but is not necessary for the diagnosis of MFS and BEE. In Brazil, studies point to dengue as the main cause of encephalitis and viral meningitis. Patients with dengue encephalitis may experience decreased consciousness, headache, seizures and behavioral symptoms. GBS has been described in reported cases of patients who manifested a variety of neurological symptoms after being infected with the dengue virus. **Final comments:** Dengue should be considered in the differential diagnosis of acute febrile illnesses with neurological symptoms, especially in endemic regions and in patients with a history of recent travel to such areas. Many neurological manifestations of dengue have been recorded, given the virus's tropism for the nervous system. Dengue encephalitis is a common complication, however, BEE represents a rare neurological syndrome, being an atypical neurological manifestation of dengue, making this report important in the academic and scientific sphere.

Problematic of neurocysticercosis in Angola: a systematic review

Adalberto Cassucussuco[1], Job Monteiro C. Jama António[2]

[1]Universidade José Eduardo dos Santos, HMZ, Luanda, Angola.
[2]Universidade Agostinho Neto, Luanda, Angola.

Correspondence: Adalberto Moisés João Cassucussuco; Email: adalbertomoises017@gmail.com.

Background: Neurocysticercosis is one of the leading preventable causes of epilepsy worldwide. It is estimated to contribute to up to 30% of epilepsy cases in areas where the disease is endemic. The total number of people with symptomatic or asymptomatic neurocysticercosis is estimated to be between 2.56 and 8.30 million, according to available data on the prevalence of epilepsy. However, these numbers may be underestimated due to the limited access of the most at-risk groups to diagnostic tests. **Objective:** To describe neurocysticercosis in Angola, through a systematic review of the literature, to highlight the relevant clinical, epidemiological, and social aspects. **Methods:** Systematic review that searched works and literature articles with available text, published between 2008 and 2023. Through the descriptors: "Neurocysticercosi", "Diseases of the Nervous System" and "Angola". On the following platforms: Angolan Journal of Health Sciences, Science Direct, SciELO, Google Scholar, UFV Repository, and FM-UAN Repository. In addition, studies that did not address the research proposal, as well as repeated or duplicate studies, were excluded. **Results:** A total of 3 studies were reviewed, and the frequency of neurocysticercosis was 3.3%, and the prevalence was considered high, which is 55.0%. Social impact was estimated at 208 years lived with disability. 51.6% were female, and the annual economic impact was estimated at 246.94 USD=106,133.38 Kwanzas, per affected individual. Most of the patients came from urban areas. There was a significant variation in age from 25 to 75 years. The most frequent symptoms were seizures and headache. The diagnosis was made by computerized tomography and magnetic resonance imaging, with calcifications being the most relevant imaging finding. **Conclusion:** Neurocysticercosis is a common disease in Angola, with high prevalence, and high economic and social impact. It mostly affects individuals from urban areas, especially females, with seizures and headaches being the most frequent clinical manifestations.

https://doi.org/10.5327/CBN241352

Professor, how is your mental health?

Ana Beatriz Bataglia Sperandio[1], Eliana Meire Melhado[1], Liara Ruiz Lima[1], Laura Beatriz Maciel Comisso[1], Julia Lucato Fontes[1], André Soares Rodrigues[1], Jadde Inhã Lisboa de Souza[1], Bruno Seabra Queiroz[1]

[1]Centro Universitário Padre Albino, Faculdade de Medicina de Catanduva, Catanduva SP, Brazil.

Correspondence: Ana Beatriz Bataglia Sperandio; Email: anabsperandio@gmail.com.

Background: Quality of life at work consists of the dynamic management of physical, technological and socio-psychological factors that affect culture and renew the organizational climate, reflecting on the well-being of workers. The promotion and protection of mental health at work is an area of growing interest and can be supported through legislation and regulation, organizational strategies, manager training and interventions for workers. With this in mind, the mental health of university professors is an area of growing concern, especially in the academic context of Medicine, since teachers in this area have to reconcile the demand for academic excellence with factors such as financial pressure and working conditions. Thus, this work sought to determine the mental health status and quality of life of university medical professors, along with symptoms related to mental health, using a cross-sectional observational approach. **Objective:** To determine the mental health status and quality of life of university medical professors, in addition to the symptoms presented related to mental health. **Methods:** The present work is a cross-sectional observational study carried out in a single interaction using a form on health and quality of life with a focus on mental health, carried out on Google Forms with 46 responses. **Results:** The results presented demonstrate the analysis of association between different categorical variables using the chi-square test of independence. When comparing mental health with physical health, there is a significant association between the two, with another words, there is an unequal distribution between the categories of mental and physical health, indicating that one influences the other's mental and physical health. A significant association was found between physical health and anxiety classification (χ^2=17.64, p=0.040). The results suggest that anxiety can negatively influence physical health. The analysis revealed a significant association between anxiety classification and depression classification (χ^2=60.78, p<0.001). This indicates that different levels of anxiety are associated with different levels of depression. Statistical analysis revealed that different levels of anxiety and depression are correlated with different mental health states, indicating the complexity of these interactions. **Conclusion:** These results provide solid evidence that mental health is significantly associated with physical health, frequency of perceived lack of money, anxiety rating, and depression rating. This can be crucial for guiding mental health policies and interventions, showing how these factors are interrelated and highlighting the importance of integrated approaches to promoting overall well-being.

https://doi.org/10.5327/CBN241353

Profile and outcome post-rehabilitation of patients with vertigo in a clinic in Southern Santa Catarina

Tatiana Pizzolotto Bruch[1], Camila Pezente Dal Toe[1], Letícia Salvaro Fernandes[1], Emanuela Hannoff Pilon[1], Vitor Benincá Fernandes[1]

[1]Universidade do Extremo Sul Catarinense, Criciúma SC, Brazil.

Correspondence: Tatiana Pizzolotto Bruch; Email: tatibruch@yahoo.com.br.

Vertigo is the sensation of spinning or rotation of the environment. The demand for medical attention due to these complaints has been increasing, making it important to understand the profile of patients presenting with vertigo, its primary causes, comorbidities, associated factors, and their response to rehabilitation. A cross-sectional secondary data analysis examined the epidemiological profile of patients treated for vertigo at a specialized clinic in Southern Santa Catarina, along with the outcomes of physiotherapeutic rehabilitation. A questionnaire developed by the authors was used to evaluate 195 patients, with an average age of 51.18 years and 62.6% being female. Benign Paroxysmal Positional Vertigo (BPPV) was the most common cause (55.9%), often accompanied by symptoms such as tinnitus (30.8%), depression, and/or anxiety (29.2%). The majority of patients responded positively to vestibular rehabilitation, with 58% showing improvement as early as after the first session. Thus, it was identified that vertigo predominantly affects women over 50 years old, with BPPV being the main cause often associated with psychological symptoms. Vestibular rehabilitation proved effective in improving symptoms in a high proportion of patients. The population over 50 years old is most affected by vertigo, predominantly women, with BPPV as the primary cause and associated symptoms such as tinnitus and psychiatric disorders.

https://doi.org/10.5327/CBN241354

Profile of deaths and hospitalizations of elderly patients affected by stroke in Northeastern Brazil: analysis of a 12-year epidemiological overview

Marconny Alexandre Oliveira de Medeiros Cavalcante[1], Thiago Luís Marques Lopes[1], Mateus Dutra Balsells[1], Hildel Freire Leite Filho[1], Matheus Lima de Oliveira[1], Oliver Reiks Miyajima[1], Lorenzo Marinho Morais[1], Daniel Pereira dos Santos[1], Chiara Gübel Portugal[1], Késia Sindy Alves Ferreira Pereira[1]

[1]Universidade Estadual do Ceará, Fortaleza CE, Brazil.

Correspondence: Marconny Alexandre Oliveira de Medeiros Cavalcante; Email: alexandremarc1912@gmail.com.

Background: Stroke is an acute illness caused mainly by an abrupt rupture of the cerebral vasculature or by a blockage of blood vessels (hemorrhagic and ischemic stroke, respectively), leading to tissue damage to this organ. The incidence of stroke and associated mortality increase with age, especially in elderly individuals. As life expectancy increases, the occurrence of strokes is expected to more than double in the next 30 years. Even with its relevance, this topic needs better elucidation, given the lack of publications related to stroke in this age group. Thus, the rationale for this study is to better understand this epidemiological profile in northeastern Brazil. **Objective:** To analyze the relationship between deaths and hospitalizations caused by stroke in the northeastern region of Brazil, using a twelve-year epidemiological overview. **Methods:** As this is an epidemiological study of secondary data, of the observational, descriptive and analytical type, the "TabNet" platform was accessed, where the axis "Epidemiological and Morbidity" and the topic "Hospital Morbidity of the SUS (SIH/SUS)" were chosen. Next, we selected "General, by place of hospitalization - from 2008 onwards" and "Brazil by Region and Federation Unit". Subsequently, in order to obtain the data for this study, the line "Age group 1", the column "Year of processing" the period "Jan/2012-Dec/2023" and the contents "deaths" and "hospitalizations" were adopted. Finally, from the available selections, "Cerebral vascular acid, ische, transit and correl syndrome" and "2 Northeast Region" were chosen in the ICD-10 Region and Morb List, respectively. **Results:** In the period from January 2012 to December 2023, 87,512 deaths from strokes were recorded, of which 67,920 (77.6%) occurred in elderly people. By separating this period into four three-year intervals, it is possible to perceive, comparing the 2012-2014 interval (14,333 deaths) with that of 2021-2023 (18,575 deaths), an increase of more than 25% in the number of deaths of people over 60 years of age. With regard to hospitalizations, during the 12-year period previously defined, 517,599 occurrences were recorded, of which the majority, 373,541 (72.2%), were associated with elderly people. Comparing the last three years (104,857 hospitalizations) with the oldest three-year period under analysis (77,912 hospitalizations), an increase of 34.6% is seen. **Conclusion:** Therefore, it is valid to infer that, along with the increase in the number of elderly individuals due to strokes, there was an increase in the number of deaths due to this type of episode in the population considered. Thus, due to the increasing relevance of this conjuncture, there is a need for more and more studies that evaluate the epidemiological circumstances linked to stroke in the elderly, in order to facilitate the understanding and, consequently, the attenuation of this phenomenon.

Background: The traumatic brain injury (TBI) is a harm that occurs when there was a head impact, resulting in damages to the skull and the brain. In Brazil, occurred, in the last years, 131,014.83 hospitalizations because of TBI, showing up a theme of huge importance due to the high incidence and morbimortality. In the elderly, the TBI could be specifically worrisome due to aging of the central neurologic system and the fragility of the bones, increasing the risk of grave complications and revealing a problem of public health. **Objective:** Describe the profile of hospitalizations by traumatic brain injury in elderly in Brazil from 2014 to 2023. **Methods:** Ecological and descriptive study with the utilization of quantitative data extracted by the Department of Information and Informatics of the Unified Health System, of Hospitals Informations System of the Unified Health System, according to the International Classification of Diseases (CID-10). The hospitalizations analyzed covered the period of 2014 January to 2023 December, with analysis of the variables: hospitalizations per region, year and age group over 60 years. The data search was organized in spreadsheets of Microsoft Excel. **Results:** In the period analyzed, there were registered a total of 258,078 hospitalizations of elderly patients with traumatic brain injury in Brazil. Among the data analyzed, there are a higher incidence in the Southeast region, with 131,189 (50.8%) of the cases; followed by Northeast with 52,295 (20.2%); South with 45,327 (17.6%); Midwest with 17,813 (6.9%); and North with 11,454 (4.4%). In this period, there was an increasing number of hospitalizations, with a minimum in 2014 (20,953 cases) and a peak in 2023 (34,096 cases), in exception of 2020 (25,321), where it was a decrease in relation to 2019 (26,151). **Conclusion:** It was observed that the number of hospitalizations was concentrated in the most developed region of the country (Southeast) while the less developed region (North) presents the lower number of hospitalizations. In addition, there was a progressive increase in the numbers of hospitalizations per year. This study highlights the necessity of public actions aimed at prevention, especially in the elderly.

Profile of hospitalizations for viral encephalitis in children and teenagers under 14 years old in the Southern region of Brazil from 2013 to 2023

Marina Ottmann Boff[1], Alessandro Batista Soares[1], Eloísa Bortolini[1], Eduarda Alexander Hilgert[1], Eduarda Gandolfi Horst[1], Júlia Supptitz[1], Natalie da Silveira Donida[1], Taís Michele Werle[1], Frederico Orlando Friedrich[1], Magda Lahorgue Nunes[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Marina Ottmann Boff; Email: mottmannboff@gmail.com.

Background: Viral encephalitis is a severe and rare condition characterized by inflammation of the brain parenchymal, associated with neurological dysfunction. The incidence of encephalitis in children at the age of two is about 16 per 100,000, and at fifteen years old, it is 1 per 100,000, highlighting its high morbidity rates. Hence, the importance of identifying the profile of children affected by this disease is emphasized, given its severity. **Objective:** Analyze hospitalizations for viral encephalitis in children and teenagers under 14 years old in the Southern Region of Brazil from 2013 to 2023. **Methods:** An ecological study with a quantitative approach was conducted in April 2024, using data from the Hospital Information System of SUS (SIH/SUS), linked to the Department of Informatics of the Unified Health System (DATASUS-TABNET). The study examined variables such as hospitalizations, year of service, Southern Region, state, sex, age group, color/race, deaths, and mortality rate. The study period was from January 2013 to December 2023. The data were organized into Microsoft Excel 365 spreadsheets and analyzed using descriptive statistics. **Results:** During the investigated period, the Southern Region recorded a total of 1,786 hospitalizations due to viral encephalitis. The distribution of hospitalizations was uneven, with the years 2013 and 2014 registering the highest percentages of cases (11.2% and 9.9%, respectively) and the years 2020 and 2021 registering the lowest (5.4% and 6.8%, respectively). From 2013-2015, the frequency of hospitalizations was 30.4%, from 2016-2018 it was 29.5%, and from 2019-2023 it was 40%. Paraná accounted for 51.2% of the cases, Rio Grande do Sul 30%, and Santa Catarina 18.8%. Males were more affected (58.5%) than females (41.5%). Regarding age groups, hospitalizations were distributed as follows: 14.4% in children under one year old, 37.5% in children aged 1 to 4 years, 27.2% in children aged 5 to 9 years, and 20.7% in children aged 10 to 14 years. In terms of color/race, 57.4% were white, 32.4% had no race information, 7.2% were mixed race, 2% were black, 0.7% were Asian, and 0.16% were indigenous. There were a total of 20 deaths from 2013 to 2023, with the year 2014 having the highest number of deaths (5) and the highest mortality rate (2.81/100,000). **Conclusion:** There is a close

relationship between hospitalizations for viral encephalitis in the Southern Region from 2013 to 2023, particularly in children aged 1 to 4 years, males, white children, and those from the state of Paraná, with the most negative outcomes in 2014. Additionally, the lower frequency of hospitalizations between 2020 and 2021 may be correlated with the SARS-CoV-2 pandemic. Therefore, public health measures that reinforce integrated care, especially for the youngest age groups, are essential.

https://doi.org/10.5327/CBN241357

Profile of hospitalizations of patients affected by multiple sclerosis in Northeastern Brazil: a 12-year epidemiological overview

Marconny Alexandre Oliveira de Medeiros Cavalcante[1], Thiago Luís Marques Lopes[1], Mateus Dutra Balsells[1], Hildel Freire Leite Filho[1], Matheus Lima de Oliveira[1], Oliver Reiks Miyajima[1], Lorenzo Marinho Morais[1], Daniel Pereira dos Santos[1], Chiara Gübel Portugal[1], Késia Sindy Alves Ferreira Pereira[1]

[1]Universidade Estadual do Ceará, Fortaleza CE, Brazil.

Correspondence: Marconny Alexandre Oliveira de Medeiros Cavalcante; Email: alexandremarc1912@gmail.com.

Background: Multiple sclerosis (MS) is an idiopathic inflammatory demyelinating disease. One of the main suspicions regarding the etiology of MS is that it is associated with Epstein-Barr virus infections. This disorder is the most common neurodegenerative disease in young adults, affecting the performance of various daily activities of these individuals with the progression of the disorder and, thus, interfering with their quality of life. Despite such relevance, there is a lack of research on the occurrence of this disease in northeastern Brazil. Thus, based on the need for a better understanding of this scenario, the justification of this study is given by the intention to better understand this situation, analyzing its epidemiological profile in the referred region. **Objective:** To analyze the progression of hospitalizations caused by MS in the northeastern region of Brazil, using a twelve-year epidemiological overview. **Methods:** As this is an epidemiological study of secondary data, of the observational, descriptive and analytical type, the "TabNet" platform was accessed, where the axis "Epidemiological and Morbidity" and the topic "Hospital Morbidity of the SUS (SIH/SUS)" were chosen. Next, we selected "General, by place of hospitalization - from 2008 onwards" and "Brazil by Region and Federation Unit". Subsequently, in order to obtain the data for this study, the line "Age group 1", the column "Year of processing", including the period "Jan/2012- Dec/2023" and the content "hospitalizations" were adopted. Finally, in the available selections, "2 Northeast Region" and "Multiple Sclerosis" were chosen in the ICD-10 Region and Morb List, respectively. **Results:** From 2012 to 2023, 3,840 hospitalizations caused by MS were recorded in the Northeast of Brazil. Dividing this time interval into four three-year periods, it is noted that, comparing the 2021-2023 interval (1,813 hospitalizations) with the 2012-2014 interval (553 hospitalizations), there was an increase of more than 227.8% in the number of admissions to health services for this reason. It can also be observed that the majority of hospitalized people, 2811 (73.2%), belong to the age group ranging from 20 to 49 years and that young adults, represented here by individuals aged 20 to 29 years, represent 25.5% of the total hospitalizations in the Northeast, with 978 hospitalized. **Conclusion:** Therefore, it is correct to understand that, according to the literature, there is a very significant occurrence of MS in the young adult population. It can also be inferred that, in the period analyzed, there was a very strong increase in hospitalizations due to this neurodegenerative disorder, confirming the need for more and more studies to be developed to help in a deeper understanding of the epidemiological scenario in question, in order to promote greater precision in the identification of these cases of MS and, thus, improve the quality of life of the affected group.

https://doi.org/10.5327/CBN241358

Profile of hospitalizations, deaths and mortality rate in Brazil due to malignant brain neoplasms from 2008 to 2023

Luís Henrique dos Santos Sousa[1], Vitor Fernando Bordin Miola[2], Maria Fernanda de ávila Reis[3], Rafael Alvarenga de Oliveira Pereira[4], Nicolas Minavia Delgadillo[4]

[1]Universidade de Pernambuco, Serra Talhada PE, Brazil.
[2]Universidade de Marília, Marília SP, Brazil.
[3]Pontifícia Universidade Católica de Campinas, Campinas SP, Brazil.
[4]Universidade Metropolitana de Santos, Santos SP, Brazil.

Correspondence: Rafael Alvarenga de Oliveira Pereira; Email: rafael.oliva192@gmail.com.

Background: Malignant brain neoplasms, although less common than other types of cancer, represent a significant impact on global morbidity and mortality, being responsible for serious clinical outcomes and high costs for health systems. In Brazil, these neoplasms represent a particular challenge due to regional disparities in access to early diagnosis and specialized treatments, in addition to the aging population. Healthcare infrastructure, availability of medical resources, and unequal distribution of services can significantly influence patients' clinical outcomes. Therefore, understanding the profile of hospitalizations, deaths and the mortality rate associated with these conditions is essential to inform public health policies and direct resources effectively. **Objective:** To describe the number of hospitalizations, deaths and mortality rate due to malignant neoplasia of the brain in each region of Brazil, analyzing the period from 2008 to 2023. **Methods:** This is a quantitative, observational and descriptive study based on secondary data from the Department of Informatics of the Unified Health System (DATASUS), of the Ministry of Health, on cases of hospitalizations for malignant neoplasia of the brain in the last 16 years (2008 to 2023). **Results:** In Brazil, during the period observed, there were 215,386 hospitalizations for brain cancer. Of these, 43.6% were from the Southeast region, 23.5% from the South, 20.3% from the Northeast, 8.6% from the Central-West and 4.0% from the North. Of these hospitalizations, 76.5% were urgent, with an average length of stay of 10.7 days, with a mortality rate of 13.66%, which corresponded to 29,411 deaths, 46.5% of which were in the Southeast region, 21.7% from the South and 19.5% from the Northeast. **Conclusion:** A high incidence of brain neoplasms is noted in the Southeast when compared to other regions, representing a significant part of Brazilian health costs. Furthermore, it demonstrates regional disparities in the incidence of pathology or diagnostic capacity. Most hospitalizations occurred urgently and with a significant average length of stay, in addition to a significant mortality rate, which highlights the severity of the condition and the need for improvements to enable early diagnoses. Furthermore, more in-depth studies are needed to understand the causes of hospitalizations and develop strategies to avoid hospitalizations and deaths due to brain neoplasia.

Profile of meningitis mortality in Brazil from 2010 to 2022: an ecological study

Barbara Zorzi Sanfins[1], Lucas Charuri de Andrade Castello Branco[1], Francisca Isabelly Leite de Almeida[2]

[1]Faculdade São Leopoldo Mandic, Campinas SP, Brazil.
[2]Centro Universitário Unifacisa, Campina Grande PB, Brazil.

Correspondence: Barbara Zorzi Sanfins; Email: basanfins@gmail.com.

Background: Meningitis is a disease characterized by inflammation of the meninges, caused mainly by viruses and bacteria. Despite the fact that vaccination is only available for some serogroups of bacterial etiology, 895 deaths from meningitis were reported in 2022, which constitutes a public health problem. To date, there is no literature analyzing the mortality profile in the selected period. **Objective:** To describe the epidemiological profile of meningitis deaths in Brazil between 2010 and 2022. **Methods:** Ecological study with secondary data collection on deaths from meningitis (ICD G03.9) in Brazil between 2010 and 2022. The data was collected from the Mortality Information System (SIM), managed by the Health Surveillance Secretariat in conjunction with the state and municipal health secretariats, available on the website of the SUS Information Technology Department - DATASUS. Descriptive statistics were carried out and the following variables were used: age, gender and region of notification. **Results:** A total of 12,066 deaths from meningitis were recorded in Brazil during the period analyzed. There was a pattern of decreasing deaths from 2010 to 2021, with an increase in 2022 (n=895) compared to the previous year (n=574), representing an increase of 55.92%. Deaths predominated in the 50-59 age group, totaling 15.5% (n=1,871). In addition, men were more affected, accounting for 59.18% (n=7,140) of deaths. The North and Midwest regions showed the lowest number of deaths in the period, despite the increase of 25.64% and 52.5% respectively, comparing 2022 with 2021. Meanwhile, the Southeast showed the highest mortality in all years, with an increase of 86.49% from 2021 to 2022. **Conclusion:** The epidemiological profile of deaths found in the period studied was: men, aged 50-59, with the highest numbers in the Southeast and the lowest in the North and Midwest. The analysis shows that there was an increase in deaths from meningitis from 2021 to 2022 in all regions. Therefore, greater incentive and public policy actions are essential to control and reduce the disease throughout the country, especially in the regions with the most deaths.

Profile of mortality due to viral meningitis in Brazil between 2014 and 2023

Kaike Eduardo da Silva Lobo[1], Felipe Moraes Costa[1], Marcus Paulo Oliveira Lopes[1], Leonardo Bastos Santos[1], João Lucas Lalor Tavares[1], Flavio Lobo Altieri[1], Arthur Moraes dos Santos[1], Arley Nikson Oliveira Barreto[1], Ruan Pablo da Silva Gomes[1], Leonardo Aguiar dos Santos[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Marcus Paulo Oliveira Lopes; Email: marcus.polopes@aluno.uepa.br.

Background: Meningitis is an inflammatory process of the meninges, protective membranes surrounding the brain and spinal cord. Viral Meningitis, usually a self-limited condition with a favorable prognosis, has become more common than bacterial meningitis, which has declined due to successful vaccination efforts. Enteroviruses, herpes simplex virus, varicella-zoster and Epstein-Barr virus account for about 95% of Viral Meningitis cases. Despite its generally good prognosis, Viral Meningitis still contributes to mortality, particularly in vulnerable populations and in cases where timely medical intervention is not received. **Objective:** Evaluate the epidemiological profile of mortality due to Viral Meningitis in Brazil from 2014 to 2023. **Methods:** This is a descriptive ecological study, using secondary data in the public domain, accessed

from the Hospital Information System (SIH-SUS) in the database of the Information Technology Department of the Unified Health System (DATASUS). The variables analyzed were: number of hospitalizations, geographic region, sex, age and race. Descriptive statistics were performed using absolute (n) and relative (%) frequencies. **Results:** During the ten years analyzed, there were 886 deaths due to Viral Meningitis in Brazil, with a decrease from 113 deaths in 2014 to 95 in 2023. The year with the highest number of deaths was 2015 with 118, while 2020 had the lowest number with 61 records. In the distribution by region of the country, it was observed that 40.2% (356) occurred in the Southeast, 23.8% (211) in the Northeast, 21.6% (191) in the South, 8.1% (72) in the North, and 6.3% (56) in the Midwest. In addition, it is possible to note that mortality was higher in males, accounting for 56% (496), while females accounted for 44% (390) of the deaths. The age groups most affected by mortality due to viral meningitis were as follows: those aged 30 to 39 years, comprising 16.2% (144); those aged 40 to 49 years, comprising 14.2% (126); and those aged 50 to 59 years, comprising 12.3% of deaths (109). Furthermore, mortality was higher among individuals of brown race, with 34.6% (307) of the deaths, followed by those of white race, with 33.5% (297). **Conclusion:** Despite a slight reduction in mortality over the ten-year analysis, it remains high, predominantly affecting individuals in the Southeast region, males, those aged 30-39, and those of brown race. These findings underscore the need for targeted public health interventions and improved health management strategies, particularly in the most affected regions and demographic groups, to reduce the burden of Viral Meningitis in Brazil.

Profile of multiple sclerosis in Brazil over the last 12 years in an epidemiological and cost analysis: an underestimated disease ?

Lorenzo Marinho Morais[1], Thiago Luís Marques Lopes[1], Oliver Reiks Miyajima[1], Chiara Gübel Portugal[1], Marconny Alexandre Oliveira de Medeiros Cavalcante[1]

[1]Universidade Estadual do Ceará, Fortaleza CE, Brazil.

Correspondence: Lorenzo Marinho Morais; Email: lorenzo.morais@aluno.uece.br.

Background: Multiple sclerosis (MS) is the leading cause of non-traumatic disabilities around the world, mainly affecting young adults. It is characterized by a relapsing-remitting stage and a possible secondary progressive stage. In Brazil, MS affects approximately 40,000 people. This study becomes relevant due to the increase in hospitalizations in the country over the years, raising questions about possible causes of this raise and how the government has reacted to economically manage it through the Universal Health System (SUS). **Objective:** To analyze hospitalizations and SUS expenses for MS in Brazil over the last 12 years. **Methods:** This is an analytical epidemiological study. The "TabNet" platform was used. Under the section "epidemiological and morbidities", in the topic "Hospital Morbidity of the SUS (SIH/SUS)", the subtopic "General, by place of hospitalization - from 2008" was selected, defining "Brazil by Region and Federation Unit" as the data territory. Then, the cell content "Internment" was selected. The cause "Multiple Sclerosis", the period "2012-2023", and the variables of "age group", "sex" and "region" were analyzed. "Total value" was accessed, in which the annual cost was analyzed before and after monetary correction, through the website of the Central Bank of Brazil. **Results:** From 2012 to 2023, there were 1,806, 1,793, 2,021, 2,078, 3,168, 4,134, 4,963, 4,374, 3,972, 5,456, 7,299 and 6,485 cases, totaling 47,549 hospitalizations and an increase of 259.08% between first and last year. Dividing this period quadrennially, it is inferred that from the first (7,698 cases) to the second (16,639 cases) there was an increase of 116.15% and from the second to the third (23,312 cases) there was an increase of 39.50%. All regions had an increase, with the Northeast having the highest percentage increase, followed by the Southeast, Central-West, North and South. Females had more hospitalizations, with a ratio of 2.3 women to 1 man, and the most affected age group was 20 to 49 years old, representing 74.23% of all cases. As for expenses, R$27,583,582.83 was spent by the SUS. Comparing the values of 2012 (R$1,394,753.77) and 2023 (R$3,649,310.85), there was an increase of 161.14%. After monetary correction, this increase drops to 17.96%. Finally, in 2012, R$1,712.94 was spent per hospitalization, while in 2023 this value was R$562.73. **Conclusion:** Hospitalizations due to MS have increased significantly over the years. However, the amounts spent by the SUS have not increased proportionally. This should worry the government, since the disease mainly affects economically active adults. Therefore, more studies should be conducted to understand the reasons for the increase in hospitalizations, evaluating the impact of new diagnostic methods, as well as to understand why the government has not been able to reduce this increase with the amounts currently expended on hospitalization, evaluating the efficiency of SUS treatments.

Profile of neurological complications in patients treated with CAR-T cell therapy at a Nove de Julho Hospital in são Paulo

Augusto Bragança Reis Rosa[1], Lucas Bruno Rezende[1], Gustavo Ramos de Lima[1], Ana Carolina Zetehaku[1], Antonio Francisco de Araújo Netto[1], Carolina Novaes Perniqueli[1], Giancarlo Fatobene[1], Celso Arrais[1], Vanderson Geraldo Rocha[1], Rafael Paternò Castello Dias Carneiro[1]

[1]Hospital Nove de Julho, São Paulo SP, Brazil.

Correspondence: Augusto Bragança Reis Rosa; Email: augustobraganca@gmail.com.

Chimeric Antigen Receptor (CAR) T cell therapy is an emerging therapeutic modality used in patients with hematopoietic and lymphoproliferative tumors, with the expectation of increased availability in the future, including for the treatment of solid tumors. The most common complications associated with its use include Cytokine Release Syndrome (CRS) and Immune Effector Cell-Associated Neurotoxicity Syndrome (ICANS), which can range in severity from mild to fatal. ICANS, may present with a variety of neuropsychiatric symptoms such as encephalopathy, behavioral changes, visual and auditory hallucinations, linguistic and speech disturbances, headache, fatigue, tremor, dysgraphia, clinical or subclinical seizures, coma with cerebral edema, and death. Onset is usually three to ten days after immunotherapy infusion, more frequently following previous CRS. Daily screening for neurological symptoms along with bedside tools such as the Immune Effector Cell-Associated Encephalopathy (ICE) score, aid in identifying and monitoring symptoms. Additionally, electroencephalogram, cranial MRI, and lumbar puncture help to understand the greater involvement of the central nervous system. Patients at higher risk for ICANS include younger individuals, those with preexisting neurological conditions and medical comorbidities, higher malignancy burden, severe lymphocyte depletion and other cytopenias, and those with severe and early-onset CRS. In our center CAR-T cell therapy has been in use since March, 2023. Six patients have been treated thus far, all males. Median age at treatment was 65 years old (24 - 82), and the most common therapeutic indication was Diffuse Large B-Cell Lymphoma. Therapeutic cells used were axicabtagene ciloleucel (Yescarta®) and tisagenlecleucel (Kymriah®). Herein, we describe the clinical and radiological profile of patients undergoing CAR T cell therapy at Nove de Julho Hospital, as well as the occurrence of complications such as CRS and ICANS associated with this treatment.

Profile of patients affected by movement disorders in subspecialized outpatient clinics of a tertiary hospital in Southern Brazil

Eduardo Drews Amorim[1], Daniel Teixeira dos Santos[1], Thalya Osmilda Alves de Carvalho[2], Patricia Ribeiro Rigo[2], Jullivan Käfer Pasin[2], Isabella Fonseca Benati[2], Manoella Guatimuzim Testa da Silva[2], Gabriela Magalhães Pereira[2], Artur Francisco Schumacher Schuh[1,2]

[1]Hospital de Clínicas de Porto Alegre, Porto Alegre RS, Brazil.
[2]Universidade Federal do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Eduardo Drews Amorim; Email: eduardodrewsamorim@gmail.com.

Background: The distribution of movement disorders in outpatient settings is key to planning and resource allocation, but data is lacking, particularly in southern Brazil. Profile of patients affected by movement disorders in subspecialized outpatient clinics of a tertiary hospital in Southern Brazil **Objective:** To delineate the epidemiological and clinical characteristics of movement disorders (MD) in patients attending subspecialty clinics at a tertiary hospital in Southern Brazil. **Methods:** This cross-sectional study analyzed medical records from patients with MD who consulted in 2023 at specialized outpatient clinics of a public academic hospital. It included patients who had at least one visit that year and used ANOVA, Kruskal-Wallis, and Chi-square tests to examine demographic and clinical differences across MD syndromes. **Results:** Patient distribution across outpatient clinics are as follows: 307 in dystonia, 289 in parkinsonism, 90 in the DBS clinic, and 246 in the other MD clinic. Significant age and sex differences existed across clinics ($p<0.0001$). Comorbidities profiles among clinics are also detailed. Regarding MD syndromes distributed across all clinics, parkinsonism (362 cases), dystonia (330), ataxia (128), and tremor (59) were the most common. Significant age and sex differences were noted ($p<0.0001$). Dystonia was more prevalent in females (69.7%), while tremor and parkinsonism cases were older (mean ages: 68.0±13.2, 65.8±10.2 years). Chorea and ataxia patients showed younger onset ages (13.6±14.4, 32.9±16.2 years). The syndromes with the most diagnostic delay were other movement disorders (paroxysmal dyskinesias, tics and myoclonus), tremor, and ataxia, averaging 16.0±21.0, 6.0±5.3, and 4.7±5.6 years, respectively. The most common etiology for each syndrome are the following: Parkinson's disease (87.8%) in parkinsonism; primary dystonia (85.2%) in dystonia, hereditary ataxia (70.3%) in ataxia, essential tremor (62.7%) in tremor, and Huntington's disease (75%) in chorea. Notably, a considerable number of tremor and ataxia patients (33.9% and 23.4%, respectively) lacked a definitive etiological diagnosis. **Conclusion:** This study at a Southern Brazilian tertiary hospital shows a varied profile of MD, with significant age, sex, age at onset and diagnostic delay differences. The high number of undiagnosed cases indicates limited access to advanced genetic testing in Brazil's public health system.

https://doi.org/10.5327/CBN241364

Profile of patients who underwent intravenous thrombolysis after ischemic stroke at a stroke care unit

Luis Bandeira Alves Neto[1], Maria Eduarda Moreira Cardoso[2], Noelle Ventura Jordão[2], Maria Luiza Vasconcelos Montenegro[1], Isaias Henrique Martins de Vasconcelos Norte Bezerra[1], Lívia Barbosa Cavalcanti[1], Caio Peixoto Parizi[1], Ricardo Martins Silva[2], Monique Evelyn Mendonça do Nascimento[2], Ana Dolores Firmino Santos do Nascimento[2]

[1]Universidade de Pernambuco, Recife PE, Brazil.
[2]Hospital da Restauração, Recife PE, Brazil.

Correspondence: Luis Bandeira Alves Neto; Email: luis.bandeira@upe.br.

Background: Ischemic stroke is associated with high rates of functional disability and, consequently, high health costs, corresponding to a severe global public health problem. This disease accounts for 80% of the cases, and its early diagnosis is essential to the possibility of thrombolytic therapy, which can improve neurological recovery rates and reduce rates of incapability. The analysis of variables in patients undergoing this therapy has the potential to enhance the outcomes in these patients. **Objective:** To study the profile of patients who underwent intravenous thrombolysis with alteplase in a stroke care unit in northeastern Brazil. **Methods:** This retrospective study considers medical records from January 2023 to May 2024. **Results:** In the study population, the mean age was 65 years old, 55% male. The most common comorbidities in patients were hypertension (76%), diabetes mellitus (31%), previous stroke (10.6%) and smoking (6.8%). Atrial Fibrillation (AF) was present in 9.3% of the patients, and 4% of them had a previous heart attack. The mean time from ictus to the hospital was 152 minutes. The mean time from arrival to CT scan was 18.2 minutes, and the mean door-to-needle time was 48.2 minutes. The mean National Institutes of Health Stroke Scale (NIHSS) score was 14.45 (±7.64) at admission and 11 (±12.07) at discharge, with difference between them of 3.45, no statistically significant (95% CI: -1.73, 8.63; p=0.18). All intracranial hemorrhage (including symptomatic and non-symptomatic) was seen in 12.3% of patients. The overall in-hospital mortality was 3%. **Conclusion:** As prevention strategies struggle to reduce stroke incidence, the literature reports outcome enhancement by thrombolysis. Lower ictus-to-hospital, door-to-needle, and ictus-to-needle time have been linked to fewer deficits and higher functionality post-treatment. This study is vital once it can improve the understanding of the patients with acute ischemic stroke, allowing the development of strategies to achieve better outcomes and fewer thrombolytics adverse effects.

Profile of patients with chronic demyelinating polyneuropathy (CIDP) according to the 2021 diagnostic criteria in a reference center: a series of cases

Maria Eduarda Moreira Cardoso[1], Bruno Paulo Teles Chaves[1], Lidiane Alves de Macedo[1], Monique Evelyn Mendonça do Nascimento[1], Maria Íris Morais Machado[1], Vanessa Cristina Fragoso Cassiano Alencar[1], Alvaro José Porto Moreira[1], Marcelo Ataíde de Lima[1], Maria Lúcia Brito Ferreira[1]

[1]Hospital da Restauração, Recife PE, Brazil.

Correspondence: Maria Eduarda Moreira Cardoso; Email: dudacardoso1145@gmail.com.

Background: Chronic inflammatory demyelinating polyneuropathy (CIDP) is an immune-mediated disease whose diagnostic criteria have been updated recently. Identification of the disease, although challenging, is crucial because it can be functionally debilitating if not diagnosed and treated correctly. **Objective:** To describe the socio-demographic, laboratory characteristics, and treatments performed on patients. **Methods:** Retrospective study with information from medical records followed up at a reference center for neuroimmunological diseases, at Hospital da Restauração, from 1999 to 2024. **Results:** The sample consisted of 25 patients, 56% female. The average age at onset of symptoms was 34.79 years (from 2 to 66 years), with a mean time to diagnosis of 31.42 months. There was a high prevalence of pediatric patients, with 32% under 16 years of age, with a mean time to diagnosis of 51.28 months. Regarding ethnicity, we identified that 13% of patients were white, 65.2% were mixed race, and 21.7% did not specify their ethnicity. All individuals underwent electroneuromyography, and 81.81% were compatible with chronic demyelination. The mean cerebrospinal fluid (CSF) cellularity was 6.85 (from 0 to 93), and the mean CSF protein was 111.86 (from 24 to 293). In the study population, 32% did not present comorbidities, and among these, the most common were diabetes mellitus (20%), systemic arterial hypertension (16%) and hypothyroidism (12%). Other less common ones included Chikungunya, Dengue, non-Hodgkin's lymphoma type B, Hashimoto's thyroiditis, papillary thyroid tumor, plasmacytoma, and POEMS syndrome, among others. In 12% of patients, there was a report of recent vaccination. Relative to CIDP subtypes, 26.7% of patients presented the typical form, including 46.7% with an acute initial presentation, mimicking Guillan-Barré Syndrome. Regarding treatment, 77.3% of patients received induction therapy with intravenous immunoglobulin. Additionally, 40.9% received pulse therapy with methylprednisolone, 4.5% received high-dose oral prednisone, and 4.5% underwent plasmapheresis. Two patients received induction treatments with methylprednisolone followed by intravenous immunoglobulin. Concerning maintenance therapy, 56.3% of patients received monthly intravenous immunoglobulin, 18.8% received monthly pulse therapy with methylprednisolone, 12.5% received daily oral corticosteroids, and 12.5% received azathioprine. Of the 17 patients with treatment information available, only 17.6% showed a complete response to treatment. **Conclusion:** Considering CIDP is a rare disease with significant morbidity, with evolving diagnostic and treatment concepts, it is vital to establish a patient profile for differential diagnosis and treatment. In light of discoveries and reclassifications, especially considering autoimmune nodo-paranodophaties, there must be a review of these cases considering red flags for possible nosological review.

https://doi.org/10.5327/CBN241366

Profile of renal function in stroke patients with high risk of obstructive sleep apnea: a transversal study

Aurea Maria Lago Novais Castello Branco[1], Juliana Cerqueira Gomes[1], Marina Soledad Benitez Bitencourt[1], Thaise Braga de Oliveira[1], Renan Carvalho Castello Branco[2]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.

Correspondence: Renan Carvalho Castello Branco; Email: castellorenan@yahoo.com.br.

Renal impairment is known as risk fator to worst outcomes in stroke patients. Recently, stroke has been associated to obstructive sleep apnea (OSA), but the link between OSA-stroke-renal impairment is not yet known, neither the renal function is related. This study objectives to describe renal function of stroke patients with diferente risks of obstructive sleep apnea. We performed a transversal study, part of a cohort of stroke patients. Individuals were evaluted to risk of OSA with STOP-Bang and SOS scores. Renal function (creatinine and urea) at admission,peak,and discharge was assessed, described with dispersion measures and compared between groups with T test/Mann-Whitney, depending on normality (Kolmogorov-Smirnov test). We obtained 430 patients (69% classified as high risk with STOP-Bang and 50% with SOS). In high risk with STOP-Bang: creatinine of admission median 1 (0.89-1.31), peak 1.7 (1.02-1.62), discharge median 1.1 (0.9-1.3) and clearance median 55.5 (39.4-76). Urea of admission mean 35 (27-48), peak mean 49 (36-83) and discharge mean 38 (28-50). In low risk with STOP-Bang: creatinine of admission mean 0.89 (0.74-1.1), peak 1.08 (0.89-1.28), discharge mean 0.97 (0.81-1.13) and clearance median 59.6 (43-80.3). Urea of admission mean 33 (26-38), peak mean 42 (32-58) and discharge mean 32 (25-45). There was significant difference between groups with all the renal measures (p<0.02), considering STOP-Bang. With SOS score, discharge urea was significant (p=0.02). This is the first study to demonstrate significant diferences between renal function in stroke patients with different OSA risks. It can lead us to hypothetise about a connection between OSA, renal impairment and stroke. Patients are admited with similar measures, but the difference is significant, which reafirm the relation between obstructive sleep apnea and kidney impairment. Individuals are admitioned with similar measures (althought significant), but those with higher risk are discharged with worst renal function, suggesting that stroke triggers acute renal injury in patients with high risk of OSA. Further studies are needed to clarify subjacent mechanisms.

https://doi.org/10.5327/CBN241367

Progressive encephalomyelitis with rigidity and myoclonus (PERM) associated with anti-GAD antibodies

Luiz Eduardo Betti Paiva[1], João Henrique Fregadolli Ferreira[1], Lívia Almeida Dutra[1], Caio César Diniz Disserol[2,3,4]

[1]Hospital Israelita Albert Einstein, Instituto do Cérebro, São Paulo SP, Brazil.

[4]Hospital Israelita Albert Einstein, São Paulo SP, Brazil.

Correspondence: Luiz Eduardo Betti Paiva; Email: luizeduardobettipaiva@gmail.com.

Case presentation: A 32-year-old woman presented, in the last month, severe lumbar pain, acute spasms of the abdominal, dorsal, and thoracic musculature lasting minutes to hours and triggered by tactile stimuli, sound, or movement, with significant impact on daily activities. She also developed hyperhidrosis, hypertension, tachycardia and episodes of anxiety when climbing the stairs, bathing, and loud noises. Within two weeks she developed focal seizures evolving to bilateral tonic-clonic seizures. After ten days, she was admitted to a hospital due to decreased level of consciousness and worsening of the spasms and myoclonus. Her physical examination showed a rigid abdomen, which led her to undergo an exploratory laparotomy to rule out abdominal life-threatening causes. She remained in the ICU for 40 days, lost 30kg, and required tracheostomy and gastrostomy. After slight clinical improvement, the patient was discharged without a diagnosis. Two weeks later, neurologic examination revealed hypertonic gait, severe hypertonia of abdominal and lumbar muscles and hyperreflexia. Brain and spinal MRI were normal, antineuronal antibodies were tested in serum and CSF, both of which revealed anti-GAD antibodies, confirming the diagnosis of anti-GAD-associated PERM. The patient was started on IVIg, with partial response, and she was switched to rituximab. **Discussion:** PERM is a clinical syndrome characterized by stiffness, muscle spasms, reflex myoclonus, encephalopathy, symptoms affecting the brainstem and spinal cord, specific-task phobias, and dysautonomia. PERM is mainly associated with anti-GAD and anti-glycine (GlyR) antibodies. Pathophysiology involves autoimmune responses leading to neuroinflammation, which contributes to neuronal damage and loss of inhibitory neurotransmission such as glycinergic and GABAergic signaling, resulting in neuronal hyperexcitability. PERM is considered part of the stiff-person syndrome spectrum and differs from stiff-person itself by the occurrence of encephalopathy, dysautonomia and brain stem involvement. Management involves symptom-alleviating, and combinations of corticosteroids, IVIg, and plasma exchange have shown sustained improvement, with rituximab in refractory cases. **Final comments:** This report aims to alert the medical community regarding PERM, in order to prevent diagnostic delay and consolidate

knowledge about the most associated antibodies and the importance of testing them, as well as to outline the main recommended treatment approaches for this rare and complex autoimmune disorder.

[2]Fundação Faculdade de Medicina de Rio Preto, São José do Rio Preto SP, Brazil.

Correspondence: Caique Alberto Dosualdo; Email: caiquedosualdo100@gmail.com.

Case presentation: A 39-year-old male patient presented with a progressive 3-month history of diplopia, associated with hypoesthesia on the right side of his face, progressing to motor incoordination and imbalance, as well as gait ataxia and unspecified limb weakness during the period. Initially investigated elsewhere, cerebrospinal fluid showed mild pleocytosis with lymphomonocytic predominance and slightly elevated protein levels. Brain MRI revealed hyperintense T2/FLAIR lesions involving the pons, middle cerebellar peduncles, dentate nuclei, and cerebellar white matter, without contrast enhancement. Initially treated with 5 days of pulse therapy for suspected demyelinating disease, the patient was later evaluated in our service with positive HIV serology and CD4 count of 55. Further investigation for listeriosis via CSF culture and PCR, as well as molecular tests for herpes family viruses, yielded negative results. The patient received empirical therapy with acyclovir, ampicillin, and gentamicin. A cerebral PET/CT scan showed diffuse hypermetabolism in the brainstem and bilateral mesial temporal regions. Polyomavirus testing in urine was positive. Despite therapy, the patient clinically deteriorated, prompting a stereotactic brain biopsy in the right cerebellar peduncle region, which histopathological analysis revealed inclusions staining positive for SV-40, confirming the diagnosis of progressive multifocal leukoencephalopathy. **Discussion:** The investigation of rhombencephalitis poses a significant challenge for neurologists and general practitioners, encompassing various etiologies such as autoimmune, infectious, neoplastic, and metabolic causes. Early diagnosis and treatment are crucial for reducing morbidity and mortality. In this case, stereotactic biopsy provided definitive diagnosis confirmation; however, in most cases, this is not feasible, necessitating investigation through CSF profile, imaging patterns, clinical progression, and confirmatory tests in serum or plasma. **Final comments:** Attention to clinical history and results from complementary exams should guide the next steps in the investigation and empirical treatment of rhombencephalitis, aiming to reduce morbidity and mortality.

Correspondence: Maria Clara Motta Barbosa Valente; Email: mariaclarambvalente@gmail.com.

Case presentation: A 42-year-old female presented for the first time to our service with a history of progressive motor weakness starting at the age of 17. The weakness initially affected her lower limbs, predominantly proximally, and gradually progressed over the years. In 2003, she was evaluated by a neurologist and diagnosed with multiple sclerosis (MS), but she did not have any medical records from that time and denied taking any medication. The symptoms continued to progress over the years and eventually involved her upper limbs (also predominantly proximally) and were associated with significant muscle atrophy. The patient was currently wheelchair-bound. She denied any other comorbidities. The patient had two brothers who were also diagnosed with MS and died from the disease in adulthood. She did not know of any other family history and denied consanguinity of her parents. The patient was admitted for further investigation. Initial laboratory tests were within normal limits, with no abnormalities suggestive of muscle disease or other metabolic etiologies. Magnetic resonance imaging (MRI) of the brain, cervical spine, and thoracic spine ruled out lesions in the central nervous system but showed significant liposubstitution in the paraspinal muscles. MRI of the thigh revealed diffuse atrophy and liposubstitution in the pelvic and thigh muscles, as well as edema in the gluteus maximus, suggesting chronic myopathy. Based on the findings of the neurological examination and MRI, myopathy was suspected. However, electroneuromyography (ENMG) showed anterior horn involvement of the spinal cord, without signs of current denervation, suggesting the diagnosis of Spinal Muscular Atrophy (SMA). The definitive diagnosis was confirmed by genetic testing, which identified the p.Ala2Gly variant in the SMN1 gene, in addition to two copies of the SNM2 gene. **Discussion:** The clinical presentation and course of the case are consistent with SMA type III, with onset in adolescence, gradual progression of muscle weakness, and proximal motor involvement in both the upper and lower extremities. The c.5C> G (p.Ala2Gly) variant in the SMN1 gene is located in exon 1 and has been reported in patients with SMA type II and III. In some specific mutations in SMA cases, there is a correlation between clinical phenotype and the number of SMN2 copies, but the c.5C> G variant generally determines a milder phenotype regardless of SMN2 copies. Genetic testing in this context was essential for the confirmation of the diagnosis. **Final comments:** SMA type III is a rare disease, but with proper diagnosis and treatment, disease progression can be slowed and patients' quality of life can be significantly improved. This case highlights the importance of recognizing the symptoms of SMA, especially in the adult population, and emphasizes the importance of genetic testing for definitive diagnosis.

Correspondence: Olívia Gameiro de Souza; Email: gameiroolivia@gmail.com.

Case presentation: Case 1: 89 years old white woman. The condition began 7 years ago with unexplained falls, imbalance, retropulsion when trying to get up, fatigue, and mild cognitive impairment. At that time, the neurological examination was normal; mini-mental = 25/30. Brain MRI showed enlargement of sulci and fissures compatible with the age; mild microangiopathy (FAZEKAS 1); MTA 1 hippocampi; normal spectroscopy, brainstem and basal nuclei unaltered. Current appointment revealed tendency to fall, mainly backwards, dysphagia. Physical examination showed hypomimia, procerus sign, absence of Romberg's sign, positive pull test, base enlargement, imbalance when turning around own axis, axial hypertonia, bilateral dysdiadochokinesia, unchanged sensitivity and reflexes, supranuclear vertical ophthalmoplegia, square waves, applause sign (perseveration in clapping), dysarthria (scanning speech). No symptoms or signs of dysautonomia (no urinary incontinence or postural hypotension). A new MRI of the brain revealed changes in the upper contour and volumetric reduction of the mesencephalon, usually associated with progressive supranuclear palsy; high parkinsonism index: 10.3 (version 1.0) and 2.3 (version 2.0). No signs suggestive of olivopontocerebellar atrophy were found. Case 2: 78 years old white woman. Onset one year ago with dysarthria, cognitive impairment, emotional lability. Followed by mood depressive disorder and imbalance. Neurological examination: bradykinesia, hypomimia, dystonic neck posture, eyelid retraction, procerus sign, reduced automatic arm movements, axial and upper limb rigidity, dysdiadochokinesia, dysarthria (scanning speech), pseudobulbar affect (involuntary crying and laughter), bradyphrenia. Neuropsychological assessment revealed CDR 1. No symptoms or signs of dysautonomia (no postural hypotension, effort urinary incontinence). MRI of the brain showed changes in the upper contour and volumetric reduction of the mesencephalon; parkinsonism index 15.0 (version 1.0) and 5.1 (version 2.0). No signs suggestive of olivopontocerebellar atrophy were found. **Discussion:** Progressive Supranuclear Palsy is a neurodegenerative disease with different phenotypes. The predominantly cerebellar form is rare and can be confused with cerebellar form of Multiple System Atrophy. An important distinction between the two conditions is the absence of dysautonomia in Progressive Supranuclear Palsy, which is, on the other hand, one of the diagnostic criteria for Multiple System Atrophy. Two cases with clinical presentation and imaging findings compatible with Progressive supranuclear palsy with predominant cerebellar ataxia have been reported. **Final comments:** Progressive supranuclear palsy should be considered in the differential diagnosis of late-onset cerebellar ataxia. Detailed medical history, repeated neurological examinations at each appointment, and imaging studies contribute to establishing the diagnosis and differentiation from other neurodegenerative diseases.

[2] Universidade Estácio de Sá, Rio de Janeiro RJ, Brazil.

Correspondence: Isabella Nascimento Guedes;
Email: isabellaguedes21@icloud.com.

Background: Pain is a common non-motor symptom of Parkinson's disease (PD) that disables and significantly compromises patients' quality of life. However, there is little data on the best treatment for this symptom. Although clinical experience and evidence from observational studies suggest a role for additional dopaminergic replacement therapy (DRT) in its treatment, clinical trials are needed to confirm this hypothesis. **Objective:** To evaluate DRT efficacy on nociceptive pain in PD patients. **Methods:** The present study is a randomized, double-blind, placebo-controlled, monocentric clinical trial that is currently ongoing. The data collection is expected to be completed in January 2025, with subsequent data analysis and results disseminated. 90 patients with PD will be selected, aged 18 to 85 years, with nociceptive pain related to PD according to the Parkinson's Disease Pain Classification System (PD-PCS), with pain intensity ≥4 out of 10 on the numeric rating scale (NRS). Participants will be divided into 3 groups of 30 people each (A, B and C). Group A will receive placebo, group B an DRT of 10% of the levodopa equivalent daily dose (LED), and group C an DRT of 20% of the LED. The treatment intervention will last 14 days. The DRT will be performed in all groups with levodopa/benserazide tablets and the placebo will be composed of tablets similar to those of the active medication. During the study, patients will be assessed in person at baseline (D0) and by videoconference at the end of treatment (D14) according to: numeric rating scale (NRS), PD-PCS, Brief Pain Inventory, 8-item Parkinson Disease Questionnaire, Hospital Anxiety and Depression Scale, Global Impression of Change and the third item of the MDS Unified Parkinson's Disease Rating Scale. Efficacy analyzes will be carried out by intention to treat, and the primary outcome will be the variation in pain intensity in NRS between D0 and D14. The level of statistical significance will be $p<0.05$. The number needed to treat (NNT) will be calculated to reduce NRS by ≥30% and ≥50%.

Background: Stroke is one of the main causes of morbidity and mortality in the world. With the advancement of the SARS-CoV-2 pandemic, cases of stroke in patients hospitalized with COVID-19 have accumulated in the scientific literature. **Objective:** To investigate the association between exposure to SARS-CoV-2 and the presence of pro-thrombotic factors in stroke patients treated in public neurology services of the SUS. **Methods:** This is a prospective, hospital-based study. The study is nested within the multicenter case-control titled NeuroCOVID: Association of SARS-CoV-2 with the occurrence, prognosis and pathogenesis of cerebrovascular diseases and other neurological manifestations, funded by the Inova Fiocruz Program (Fundação Oswaldo Cruz - Fundo Emergencial de Combate to COVID-19: VPPCB-005-FIO-20-2-22). **Results:** 148 patients were enrolled for this study at a single center. Among the participants, there was a predominance of female individuals (51.4%, n=76), white ethnicity (29.1%, n=43) and specifically the economically active population (43.9%, n=65). The majority of admitted patients had acute/subacute exposure to SARS-CoV-2 (72.3%, n=107), most of whom were previously vaccinated (80.4%, n=86). Ischemic troke constituted the majority of stroke cases in this study (77%, n=114). The average age was 55.3 years, with a median of 55.5. Fifteen patients (10.1%) showed expression of some prothrombotic antibody (IgM-B2 glycoprotein, IgA-B2 glycoprotein, IgM Anticardiolipin, IgA-Anticardiolipin or Anti-PF4). It is clear that the majority of patients who were positive for any antibody were in the acute/subacute phase of exposure classification. **Conclusion:** This study is one of the pioneers in demonstrating clinical-epidemiological and laboratory characteristics of patients investigated with stroke. The studied sample presents characteristics similar to those described in other clinical studies.

Protocols for analyzing effective connectivity in patients with refractory frontal and temporal lobe epilepsies

Helka Fabbri Broggian Ozelo[1], Benito Pereira Damasceno[2], Fernando Cendes[2], Andréa Alessio[2]

[1]Unviersidade Federal de São Carlos, Araras SP, Brazil.
[2]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Helka Fabbri Broggian Ozelo;
Email: helka@ufscar.br.

A growing literature has corroborated the understanding of focal epilepsy as a network disease, which has led to an increasing interest in neuroimaging techniques that allow for studying in vivo neuronal networks. However, there is still a need for more research investigating the default mode network (DMN) effective connectivity in patients with refractory frontal and temporal lobe epilepsies (FLE and TLE) as compared to normal controls, by means of functional magnetic resonance imaging (fMRI). Therefore, the first step of this study was to develop appropriated protocols for data analysis, having in mind different hypotheses about neuronal connectivity to be quantified in six distinct groups. The sample comprised: 15 normal controls; 23 patients with FLE related to unilateral frontal focal cortical dysplasia (FCD), 10 right- and 13 left-sided; 21 patients with mesial TLE (MTLE) associated with unilateral hippocampal sclerosis (HS), 11 right- and 10 left-sided; and 9 patients with TLE related to unilateral left temporal FCD, in the absence of HS. All subjects underwent structural and fMRI with resting-state (RS) paradigm. The effective connectivity analyses were performed using the spectral dynamic causal modeling (spDCM) and considering four DMN nodes: the ventromedial prefrontal cortex (vMPFC), the right/left inferior parietal cortex (RIPC/LIPC) and the posterior cingulate cortex (PCC). Soon afterwards, group comparisons were made by means of the parametric empirical Bayes (PEB) model. The data analysis of the four nodes revealed positive bidirectional effective connectivity between: (1) LIPC and RIPC in the six groups; and (2) vMPFC and PCC in control, right-FLE, left-FLE, right-MTLE and left-TLE. Positive unidirectional connectivity was found from: (1) LIPC to vMPFC in in all groups; (2) LIPC to PCC in control, right-FLE, left-FLE, right-MTLE and left-MTLE; and (3) PCC to vMPFC only in left-MTLE. A single negative connection was observed from PCC to RIPC in right-MTLE group. In general lines, the protocols developed for data analysis revealed rs-DMN effective connectivity preponderance in left cerebral hemisphere, which is dominant for language in most people, including the four investigated areas listed in the current literature, as well as some relevant modifications in both left-MTLE and left-TLE groups. Based on that, it will be possible not only to add more regions of interest to the basic model but also to apply the same final protocols for analyzing the subsequently acquired cognitive data.

Pseudo-INO in Steinert myotonic dystrophy: a case series

Pedro Lucas Grangeiro de Sá Barreto Lima[1], Antônio Edvan Camelo-Filho[1], Pedro Helder de Oliveira Junior[1], Rebeca Bessa Maurício[2], Mariana Michiles Santos Ramos[1], Jorge Luiz de Brito de Souza[2], Julia Viana de Castro[1], Avelino Missialdes Dutra Junior[1], Pedro Braga-Neto[1], Paulo Ribeiro Nóbrega[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.
[2]Universidade Estadual do Ceará, Fortaleza CE, Brazil.

Correspondence: Pedro Lucas Grangeiro de Sá Barreto Lima; Email: pedro.lucas@alu.ufc.br.

Background: Myotonic Dystrophy Type 1 (Steinert Myotonic Dystrophy or DM1) is the most frequent muscular dystrophy in adults. This disorder is a monoallelic autosomal disorder caused by pathogenic expansion of CTG trinucleotides in DMPK. DM1 is associated with weakness, muscular atrophy and myotonia. These clinical manifestations may vary from mild to severe. The disease often causes ocular impairment, mostly in the form of posterior subcapsular cataracts, ptosis and slow saccades. The current literature supports the hypothesis of relative sparring of the extrinsic ocular musculature in DM1. However, most recently ophthalmoparesis in DM1 has been increasingly reported in the literature. **Objective:** To report a series of patients with DM1 presenting with ocular mobility impairment. **Methods:** This was a retrospective observational study including patients with DM1. Patients were identified through an active search in the medical records of the neurology department of our service. **Results:** Three unrelated patients with previous diagnosis of Myotonic Dystrophy Type 1 (Steinert's disease or DM1) presented with progressive impairment of ocular mobility associated with ptosis. All patients had medical history marked by progressive muscular weakness, diffuse myalgia, frequent falls, postural instability and posterior cataracts compatible with the diagnosis of DM1. They had the genetic confirmation of the diagnosis by the study of were tested for CTG expansion in DMPK Southern Blot analysis. Upon general inspection, the patients had frontal alopecia, "hatchet" facies and bilateral ptosis. Neurological examination revealed diffuse muscular hypotrophy, diffuse muscular weakness, global hyporeflexia and myotonic phenomenon in both hands. No fasciculations or tremors were noticed in these patients. The three patients presented exotropia and bilateral ophthalmoparesis for the 9 cardinal positions of gaze. The ophthalmoparesis was more markedly observed during ocular abduction, impairing the gaze convergence. This specific pattern of ocular paresis resembled an internuclear ophthalmoplegia (INO), with the absence of nystagmus in the abducted eye during the pursuit test. Interestingly, this pattern of impairment suggests a peripherical-muscular cause. We defined this combination of findings as pseudo-INO, as it is similar to an "incomplete" internuclear ophthalmoplegia. This pattern of ophthalmoparesis is a rare manifestation of DM1 and is reported consistently in 3 patients in literature to

the best of our knowledge. Those 3 patients in the literature all had very similar presentations compared to ours. **Conclusion:** We presented a series of three patients with Steinert's disease presenting with an uncommon pattern of ocular impairment. This series provides insights in disease manifestations and may help to identify future DM1 cases. Further studies are necessary to better comprehend the observed phenomenon and to characterize the ocular findings in DM1.

Pseudotumoral lesion mimicking glioblastoma in a patient with multiple sclerosis

Luana Gomes Dias Pimentel[1], Francyane Peixoto Ramos de Abreu[1], Marina Papais Alvarenga[1], Regina Maria Papais Alvarenga[1]

[1]Universidade de Vassouras, Vassouras RJ, Brazil.

Correspondence: Luana Gomes Dias Pimentel; Email: luanagpimentel@hotmail.com.

Case presentation: On December 3rd, 2018, a 62-year-old white female doctor presented with altered sensitivity in her right hand, which progressed to incoordination of the ipsilateral upper and lower limbs due to proprioceptive alteration. She was admitted to a private hospital in Rio de Janeiro, and between December 4th and 6th she underwent serial MRI scans of the skull with spectroscopy, showing a nodular lesion with parietal contrast enhancement, measuring 3.0x2.3x2.4 cm, in the left parietal region, with extensive perilesional edema, suggestive of glioblastoma, and foci of hypersignal in T2 and FLAIR in the left anterior commissure. A CT scan of the chest and abdomen was carried out to rule out another primary site of neoplasia or metastases, which revealed no alterations. On December 7th, she underwent microsurgery with partial resection of the lesion. Post-operatively, she underwent an MRI scan which showed persistence of the foci of hypersignal. She also had weakness in the right dimidium and incomplete Gerstmann's syndrome with right-left confusion and dyscalculia. After discharge, she developed visual clouding and a CSF test was carried out, which was negative for infections and oligoclonal bands. According to the brain biopsy histopathology report, a demyelinating lesion was suggested, and corticosteroid therapy was started. In September, 2019, she went to a neurologist specialized in demyelinating diseases, who indicated prevention with Rituximab. In the week scheduled for the infusion, she experienced vertigo, and the neurological examination confirmed cerebellar dysfunction. A new MRI was requested which showed recent demyelinating lesions in T2 and FLAIR. In November, she underwent pulse therapy with methylprednisolone and the first infusion of Rituximab, showing clinical and radiological improvement. She continued to be treated every six months, and in 2022, switched to Ocrelizumab, and since then she has had no recurrences. **Discussion:** The pseudotumoral lesion is a rare form of presentation of demyelinating diseases, with a prevalence of 1-3 per 1000 cases of multiple sclerosis. It has an acute evolution and is usually solitary, larger than 2 cm, hyperintense, in which the clinical picture and MRI pattern mimic CNS neoplasms. In most cases, the pseudotumoral lesion manifests in patients previously diagnosed with MS. In this case, the tumefactive lesion was the first presentation of the disease. Diagnosis was confirmed by histopathology. The suspicion of MS was raised by the T2 and FLAIR foci identified from the first MRI scans, and concluded after a new neurological outbreak. **Final comments:** In this report, the manifestation of the pseudotumoral demyelinating lesion before the diagnosis of MS, which is rare, and the MRI report suggestive of glioblastoma led to diagnostic confusion, in which unnecessary surgery caused neurological sequelae, thus highlighting the need for further investigation before defining surgery.

Pseudotumoral manifestation of primary central nervous system vasculitis: a case report

Maria Clara Motta Barbosa Valente[1], Camila Lopes Figueiredo[1], Filipe Brito Ferraz da Silveira[1], Cícero Rodrigues Veloso[1], Vitor Colpo Paes[1], Angelo Chelotti Duarte[1], Carmen Lucia Penteado Lancellotti[1], Antonio José da Rocha[1], Vivian Dias Baptista Gagliardi[1], Rubens José Gagliardi[1]

[1]Santa Casa de São Paulo, São Paulo SP, Brazil.

Correspondence: Maria Clara Motta Barbosa Valente; Email: mariaclarambvalente@gmail.com.

Case presentation: A 34-year-old male patient was admitted to the emergency department with recurrent generalized tonic-clonic seizures. The initial neurological examination was unremarkable. A cranial CT scan revealed a frontal right expansive lesion of undetermined etiology, associated with significant vasogenic edema and midline shift. Further investigation with brain MRI showed extensive involvement of the right hemisphere, with focal periventricular lesions with ring enhancement on gadolinium, as well as vasogenic edema. The perivascular enhancement and calcifications favored the diagnosis of an inflammatory vascular process, particularly inflammatory vasculopathy (primary vasculitis) with a pseudotumoral pattern. Laboratory tests were normal and serologies were negative. Lumbar puncture was not performed due to significant midline shift. A biopsy of the lesion was performed, and pathological evaluation revealed extensive necrosis with perivasculitis, no evidence of neoplasia in the material studied was observed. Ziehl-Neelsen (BAAR) and fungal (PAS and GROCOTT) stains were negative. Immunohistochemistry (with antigen testing for toxoplasma, BAAR, BCG, CMV, CD3, and CD68) revealed CD3 immunoexpression, demonstrating perivascular and scattered CD3-positive T-lymphocytes, along with abundant CD68-positive macrophages. Considering the observed inflammatory response, immunocompromise was questioned. Further investigation ruled out other underlying diseases - especially infectious and immune diseases - allowing treatment with steroids. **Discussion:** Primary central nervous system (CNS) vasculitis is a rare inflammatory disease involving small and medium-sized vessels. The reported case demonstrates one of the rare forms of manifestation of CNS vasculitis. The pseudotumoral form presents a diagnostic challenge as it allows for the differential diagnosis of a series of other expansive processes, including neoplastic ones. Early diagnosis is essential for treatment initiation, as early initiation implies better outcomes given the severity of the condition and the progression to death if untreated. In this context, the importance of biopsy and pathological evaluation for definitive diagnosis is emphasized. **Final comments:** Primary central nervous system vasculitis has a variable clinical presentation, and among the imaging findings, the pseudotumoral form presents a diagnostic challenge as it can be interpreted as other expansive lesions, including neoplastic ones. In these cases, biopsy plays an essential role in definitive diagnosis and should be performed to allow for prompt initiation of appropriate treatment.

Correspondence: Ana Luísa Castelo Branco Gomes; Email: analuisa_gomes@hotmail.com.

Case presentation: F.S, 26-year-old female, in late puerperium, with a previous diagnosis of hypertension, presented with disorientation in time-space, weakness in the left hand, psychomotor agitation and recent memory deficit four days prior to the admission. She has a history of ischemic stroke 9 months ago. The neurological examination revealed impaired comprehension and short-term memory loss, along with left hemiparesis. Brain MRI revealed a vascular pattern compatible with Moyamoya disease (MMD), as well as bilateral chronic ischemic lesions in the frontal lobe and temporal lobe on the right. Cerebral angiography revealed bilateral carotid occlusion in its supraclinoid portion, confirming the diagnosis of MMD. Laboratory results for investigation of lupus and antiphospholipid syndrome without abnormalities, as well as electrocardiogram and echocardiogram. Due to the clinical picture of personality disorder, the patient was monitored by psychiatry during hospitalization. She was treated with anticonvulsant, antipsychotics, antiplatelet drugs and was discharged to follow-up in the neurology and psychiatry outpatient clinics. **Discussion:** MMD is a chronic occlusive cerebrovascular disease. It is characterized by endothelial hyperplasia and fibrosis of the intracranial portion of the carotid artery and its branches, leading to progressive stenosis and cerebral hypoperfusion, causing multiple and recurrent ischemic events. The chronic hypoperfusion to the brain induces the formation of collateral vessels that can rupture and cause intracranial hemorrhage. It can occur at any age, but is most common in children aged 5 to 10 and adults aged 25 to 50. The initial manifestations include transient ischemic attack, ischemic stroke, hemorrhage, headache, seizures, cognitive impairment, and movement disorders. The diagnosis relies on both anatomical and functional aspects, with angiography serving as the gold standard for anatomically assessing the disease. The cornerstones of the clinical approach to MMD are prophylactic and generic symptomatic treatment, such as the use of antiplatelet drugs, anticonvulsant drugs, and pain management, Surgical revascularization is the treatment of choice in symptomatic patients. Several studies have linked MMD with psychiatric sequelae; however, no controlled trials have definitively established causality or investigated the effectiveness of specific treatments for managing associated psychiatric symptoms. **Final comments:** In the present case, we report a patient with MMD and psychiatric comorbidity, a condition that might result from the progression of the disease. Therefore, as it is a complication that may have a negative impact on quality of life, disability, and prognosis, a team-based multidisciplinary approach is highly recommended in the MMD, with collaboration between psychiatric and neurology early diagnosis.

Background: Dystonia is defined as a movement disorder characterized by sustained or intermittent muscle contractions, which cause abnormal and often repetitive movements and postures. Despite the definition exclusively related to motor aspects, recent studies show non-motor manifestations in patients diagnosed with dystonia. There has been great emphasis on aspects related to psychiatric disorders, cognitive impairment, pain, sleep and abnormalities in sensory perception and their importance as predictors of quality of life. **Objective:** Investigation of psychiatric symptoms and cognitive impairment in patients with idiopathic cervical dystonia in a tertiary center. **Methods:** Cross-sectional, descriptive and analytical study including 31 patients diagnosed with isolated idiopathic cervical dystonia and 31 healthy control subjects matched by sex, age and education. The sample was evaluated by standardized scales and interviews to obtain data on psychiatric symptoms and cognitive disorders. The instruments used were Mental State Mini Exam, Brief Cognitive Test Battery, Digit symbol substitution test, Hayling Test, Facial Emotion Identification Test, Frontal Evaluation Test Battery, Mini International Neuropsychiatric Interview, Yale Brown Obsessive Compulsive Scale and Toronto Western Spasmodic Torticollis Rating Scale. **Results:** The psychiatric symptoms assessed in this study showed statistically significant differences in the prevalence of current depressive episode (38.7% and p=0.020) and depressive episode with melancholic symptoms (32.3% and p=0.003) among idiopathic cervical dystonia patients compared to the prevalence of 12.7% and 3.2% respectively among control group participants. Regarding cognitive aspects, no statistically significant difference was found in this study for results of tests applied to assess cognitive domains. A statistically significant difference was observed between patients with cervical and idiopathic dystonia and healthy control subjects to identify anger and neutral emotions (p<0.05) on the emotion recognition test. **Conclusion:** Our study showed no difference between cervical dystonia and control subjects in tests of visual and verbal episodic memory, attention, visuo-constructive skills and executive function. However, both the higher prevalence of depression and the facial emotion recognition test were capable of distinguishing patients with cervical dystonia in this study.

Psychiatric-onset multiple sclerosis: case report

Daniel Lacerda da Costa[1], Rafael Augusto Rosalem[1], Gabriela Abrahão Allioni[1], Guilherme Diogo Silva[1], Samira Luisa dos Apostolos Pereira[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Daniel Lacerda da Costa; Email: dlacerdadacosta@gmail.com.

Case presentation: H.V.P, 31 years old, has had a history of epilepsy since he was 4 months old. When he was 4 months old, he began to have afebrile seizures controlled with phenitoin. At age 10, he had his first psychotic break. In 2010, he was diagnosed with bipolar affective disorder and started on lithium and carbamazepine. In 2016, after a suicide attempt with the medications he was already taking, he developed severe apathy, affective dullness, progressive loss of functionality, in addition to worsening gait. He was admitted to our institution in April 2022, after presenting with acute strabismus. On neurological examination Vigilance with impaired attention, executive dysfunction with echolalia and echopraxia. He presented significant rigidity and waxy flexibility, with resting tremors in the upper limbs, in addition to internuclear ophthalmoplegia on the right. On MRI, he presented global atrophy, with a capturing lesion in the territory of the medial longitudinal fasciculus on the right. He was admitted with suspicion of a demyelizing event and catatonia. He underwent treatment with lorazepam, risperidone and electroconvulsive therapy due to refractoriness. We chose to undergo pulse therapy with corticosteroids and natalizumab for hospital discharge. **Discussion:** 95% of people with multiple sclerosis (MS) have some psychiatric comorbidity. These include depression, anxiety and psychosis. Bipolar affective disorder is twice as common as in the population without MS. The prevalence of "psychiatric-onset MS" was initially studied by Lyoo et al, when they assessed MS in a psychiatric population who met criteria for MS by T2 MRI. Other studies have come out and seen an average of 1% of the population with MS. There are reports of up to 9% of cases in study by Skegg of MS with psychiatric onset. Berna et al, evaluated that patients who presented relapses with purely psychiatric symptoms, had a delay in diagnosis of 7 years. Identifying warning signs are important to increase the suspicion of MS in psychiatric patients, such as: onset of the disorder at an atypical age, family history of MS, absence of psychiatric illness in family members, neurological evaluation in search of neurological signs, absence or minimal response to standard therapy and cognitive decline. All of these signs were described in the patient, and the need for imaging is important for diagnosis. Other signs that point to an already chronic condition are the significant atrophy in the patient's image, in addition to the loss of functionality upon arrival at the hospital. **Final comments:** MS with psychiatric onset is a rare entity and difficult to diagnose. It is known that delayed diagnosis of multiple sclerosis leads to a worsening of the prognosis. The recognition of alarm signals and the importance of neurological examination are relevant keys to organic diagnosis in an endogenous context.

Psychosocial impact of narcolepsy on the health-related quality of life of late-diagnosed patients: a systematic literature review of the last 10 years

Nicoli Lindissey Zuim[1], Anna Júlia Silveira Freitas[1], Tamiris Romão Pereira da Costa[1], Anna Beatriz Popi e Souza[1], Clara Molinari Ferraresi Lopes[1], Giovanna do Nascimento[1], Fabrício de Mira Vieira[1], Ana Julia Fragoso Dias Rodrigues[1], Ana Beatriz Melo de Andrade[1], Thais Aiala Silva[1]

[1]Universidade Nove de Julho, Bauru SP, Brazil.

Correspondence: Nicoli Lindissey Zuim; Email: nicolind14@gmail.com.

Background: Narcolepsy is a chronic and rare neurodegenerative disorder characterized by excessive daytime sleepiness and REM sleep dissociation manifestations, such as: cataplexy, sleep paralysis, hypnagogic hallucinations, and early REM sleep. With an incidence of 25-50 patients per 100,000 inhabitants, the disease is commonly associated with psychological and social dysfunctions, leading to considerable damage to daytime life. The impact of this disorder is reflected in the impairment of health-related quality of life, which results in occupational and academic difficulties. **Objective:** To evaluate the impact of late diagnosis of narcolepsy on psychological and social aspects of health-related quality of life. **Methods:** Articles containing the descriptors "Narcolepsy, Quality-Adjusted Life Expectancy, Delayed Diagnosis" were searched through the following databases: PUBMED, LILACS, and GOOGLE SCHOLAR. Inclusion criteria: articles in Portuguese and English, published between 2013 and 2023, addressing the theme proposed for this research, and available in full. After analysis, of the 37 selected articles, 16 were retained for reading and data collection. **Results:** Data analysis revealed the following statements: a) the symptoms type 1 narcolepsy pentad (especially excessive daytime sleepiness, cataplexy, and interrupted nocturnal sleep) have a critical impact on health-related quality of life, both in self-care and in habitual activities; b) the functional impairment of the disease directly implies an increase in pain and discomfort, as well as anxiety and depression; c) health-related quality of life is affected due to the constancy of sleepiness and the unpredictability of symptoms, with greater impairment in underdiagnosed cases; d) patients with late-diagnosed narcolepsy have greater impairment in physical, emotional, cognitive, and social health compared to patients with early diagnosis and follow-up. Data collection included 303 people interviewed. **Conclusion:** The results suggest that there is a substantial impairment of health-related quality of life in patients with narcolepsy, especially those with late diagnosis. Important components of the individual's social life, such as physical and mental well-being, are persistently compromised due to excessive daytime sleepiness, cataplexy, and interrupted nocturnal sleep, characteristics more common to type I narcolepsy. In the meantime, the patient presents greater episodes of pain and discomfort, as well as psychiatric disorders, such as anxiety and depression, due to functional impairment and impact on quality of life. In addition, there is a negative public perception of the disease due to constant sleepiness and the unpredictability of the associated symptoms. Knowing that late diagnosis leads to greater impairment in the individual's physical, emotional, cognitive, and social health, it is essential to make it as skillfully as possible.

Puerperium as a risk factor for immunocompetent patients with neurotuberculosis?

Mariana Tonon Giovannone[1], Fernando Pierini Costa[1], William Thiago Almeida Leite[1], Mauro Gomes de Araújo[1], Evelyn Chevitarese Nastari Saia[1], Simone Pincer[1], Maria Leíza Vinhadelli Ribeiro[1], Jackson Batista da Silva[1], Natasha Cutolo[1], Eduardo Nogueira[1],

[1]Santa Casa de Santos, Santos SP, Brazil.

Correspondence: Mariana Tonon Giovannone; Email: mariana.tonon@yahoo.com.

Case presentation: A 33 year old female patient, postpartum, without comorbidities, started in December 2023 with a 3 week history of weight loss, progressing to encephalopathic syndrome, decreased level of consciousness, and intracranial hypertension syndrome. Initially treated at the Emergency Care Unit, a cranial CT scan was performed, showing areas of nonspecific frontal hypodensity on the left and cerebellar hypodensity on the right, associated with vasogenic edema. During hospitalization, laboratory and imaging tests were performed, including cerebrospinal fluid collection with a positive GeneXpert® result, diagnosed with Neurotuberculosis, in addition to serology collection, all negative. The patient had an unfavorable evolution due to extensive vasogenic edema, requiring EVD due to intracranial hypertension, remaining in the ICU for approximately 30 days. Treatment was initiated with rifampicin, isoniazid, pyrazinamide and ethambutol, corticosteroid therapy and anti-seizure medication, in addition to antibiotic therapy for sepsis due to VAP and hemodynamic control with vasoactive drugs. During clinical stabilization, a cranial MRI was performed, showing nodular leptomeningeal thickening in the frontal and base of the skull and tuberculoma nodules in the right cerebellum and in the left MCA. After starting treatment with the RIPE regimen, the patient's neurological condition improved and he was discharged after 3 months of hospitalization. **Discussion:** Tuberculosis is an infectious disease caused by Mycobacterium tuberculosis and its most severe extrapulmonary form is Neurotuberculosis. Its occurrence increases in patients with the HIV, making it a rare diagnosis in immunocompetent individuals. The infection is acquired by inhalation of bacilli, which produce granulomas in the CNS, which may become inactive;

The decrease in immunity causes its rupture, forming a serofibrinous exudate containing blood vessels and areas of caseous necrosis. The symptoms are not specific and may present with headache, irritability and anorexia. The diagnosis is made through clinical, laboratory and imaging evaluation, with GeneXpert® being one of the most sensitive and specific for diagnosis. Its treatment is based on 2 months of RIPE, which can be extended to 18 months. The puerperium is the period from six to eight weeks after childbirth, when the woman suffers from significant immunological changes; studies show that despite the increase in interleukins, promoting a pro-inflammatory state and decreased immunity, there is no increase in the occurrence of Neurotuberculosis during this period. **Final comments:** The case shows that, although rare, Neurotuberculosis in immunocompetent patients is a disease present in our clinical practice. Early diagnosis helps the patient's progress. Furthermore, there is still no evidence that the postpartum period increases the risk of contamination.

https://doi.org/10.5327/CBN241382

Pulmonary arteriovenous microfistulas as an uncommon cause of stroke in a young adult

Vinícius Canhestro Roedel[1], Maíra Cardoso Aspahan[1], Rachel Laguardia Rego[1], Aretha Miranda Silva[1], Bárbara Cristina Silveira de Oliveira[1], Verônica Moreira Belo[1], Samuel Inácio Oliveira Araújo[1], Larissa Cruvinel Leite[1], Arthur Braga Pereira[1], Paolla Giovanna Rossito de Magalhaes[1]

[1]Hospital Madre Teresa, Belo Horizonte MG, Brazil.

Correspondence: Vinícius Canhestro Roedel; Email: roedelvinicius@gmail.com.

Case presentation: A 24-year-old man with a history of focal epilepsy and mild cognitive impairment due to a childhood traumatic brain injury experienced sudden weakness and numbness in his fourth and fifth fingers of the right hand. Over the following days, he developed right hemibody paresthesia and abnormal movements in his right upper limb, which were challenging to precisely characterize since they weren't seen by the staff. Upon examination, mild weakness was noted in his right upper limb, and a brain computed tomography revealed a new area of hipodensity in the left postcentral gyrus. Considering his history of focal seizures originating in the same limb and the lack of traditional stroke risk factors, focal status epilepticus was suspected. A phenytoin attack was prescribed, with no effect on symptoms. Subsequent electroencephalogram and angiotomography scans were inconclusive. A brain magnetic resonance imaging then indicated restricted water diffusion in the left postcentral gyrus. Transesophageal echocardiogram revealed a right-to-left shunt with microbubbles crossing, though no patent foramen ovale was found. Doppler ultrasound of the lower limbs showed no signs of thrombosis. Cardiac arteriography uncovered a high-flow right-to-left shunt in the left lung, but no correctable fistulas were visualized. A diagnosis of paradoxical embolism due to pulmonary arteriovenous microfistulas was considered. The patient was discharged with instructions to take aspirin and undergo rehabilitation physiotherapy. **Discussion:** Pulmonary arteriovenous fistulas are vascular abnormalities, both congenital and acquired, that can lead to various neurological issues such as strokes, seizures, and migraines. They are frequently linked with hereditary hemorrhagic telangiectasia (Rendu-Osler-Weber disease), which is characterized by recurrent bleeding and paradoxical brain emboli. While most reported cases of symptomatic fistulas involve patients with the syndrome, our patient did not present with it. Some patients may benefit from embolization therapy, a course of action not feasible in this case due to the size of the fistula, which was not large enough to be visualized. As a stroke prophylaxis measure, we opted for the use of single antiplatelet therapy, though more research is needed to determine the optimal antithrombotic treatment in these cases. **Final comments:** Pulmonary arteriovenous fistulas are a rarely considered cause of stroke in young individuals and should be part of the differential diagnosis for neurologists investigating stroke etiology. Right cardiac arteriography remains the gold standard for identifying this condition. Best practices for managing patients with microfistulas are not yet defined, underscoring the need for additional research to establish optimal antithrombotic regimens for secondary prophylaxis

https://doi.org/10.5327/CBN241383

Pure ataxia related to CACNA1A: report of a non-episodic and non-migrainous case

Lucas do Rego Barros Correa Martins[1], Laura A. M. Montouro[1], Maria da Penha Morita[1], Érica Nogueira Coelho[1], Fábio de Nazaré Oliveira[1], Charles Marques Lourenço[1], Humberto Ramos Crispim[1], Matheus Hisamitsu Facine[1], Caique Alberto Dosualdo[1], Eduardo de Paula Estephan[1,2]

[1]Faculdade de Medicina de São José do Rio Preto, São José do Rio Preto SP, Brazil.
[2]Universidade de São Paulo, Faculdade de Medicina, São Paulo SP, Brazil.

Correspondence: Lucas do Rego Barros Correa Martins; Email: lucasrbcmartins@gmail.com.

CACNA1A gene has long been a focus of expert studies due to its clinical relevance. The range of phenotypic changes that emerge from mutations on that gene usually correlates with the abnormal functioning of the voltage-dependent Ca^2+ channels. This entails neurologic syndromes such as epilepsy, migraine and different forms of ataxia. This case presents a rare association between a mutation in CACNA1A and pure congenital non progressive ataxia, reinforcing the vastness of clinical features that can be expressed by mutations in this gene. **Case presentation:** A 37-year-old woman, with persistent motor difficulties since childhood due to notable imbalance, such as the inability to ride a bicycle and climb stairs unaided. Delay in motor development was reported, having delayed ability to crawl and walk. No notable headaches or abrupt worsening of coordination during her life was reported. On physical examination, the patient exhibited dysarthric speech, as well as a difficulty to perform the Tandem Walk test. There were no signs of pyramidal tract lesions and no dysdiadochokinesia. Her daughter and one of her brothers also had a history of symptoms such as incoordination and speech alterations, respectively, suggesting a possible hereditary with autosomal dominat fashion of the disorder. On magnetic resonance imaging cerebellar vermis atrophy was revealed. Genetic panel for movement disorders identified a pathogenic variant on the CACNA1A gene: c.4034G> A (p.Arg1345Gln; chr19:13.262.789 C> T on GRCh38 genome version). **Discussion:** Pathogenic variants in CACNA1A are associated with a range of neurological phenotypes, such as developmental and epileptic encephalopathy, spinocerebellar ataxia (SCA6), episodic ataxia type 2 and familial hemiplegic migraine. More rarely, it has been linked to autosomal dominant nonprogressive congenital ataxia, in which the phenotype of our clinical report fits. Cases of congenital ataxia have been described in patients with CACNA1A missense mutations, but usually associated with migraine or epilepsy. The prognosis of such presentation is usually good, with mild/moderate symptoms throughout life. **Final comments:** This case report highlights the importance of considering CACNA1A among ataxic patients, even in the absence of episodic attacks, migraine and epilepsy. Moreover, it also illustrates the possibility of phenotype variability with the same pathogenic variant.

https://doi.org/10.5327/CBN241384

Pure transverse myelitis secondary to multiple sclerosis: an unusual case

Carolina Flores Welker[1], Larissa Lucas Schloicka[1], Nícolas Philippe Balduíno Nogueira[1]

[1]Instituto Hospital de Base do Distrito Federal, Brasília DF, Brazil

Correspondence: Carolina Flores Welker; Email: carolinafwelker@gmail.com.

DAS, 37 years old, male, previously healthy, developed paresis and paresthesia in all four limbs on May 2022, one day after receiving the influenza vaccine. There was a partial improvement in symptoms over the days, but the patient still complained of spasms and paresthesias in the right upper limb, in addition to shocks along the spine during cervical flexion. In June 2022, MRI of the cervical spine without contrast showed centromedullary hypersignal on T2/STIR at C2, with a slight swelling effect. On August 2022, the lesion had larger dimensions and also captured contrast. The other neuraxial MRIs showed no changes and the infectious, neoplastic and rheumatological investigations were normal. The CSF analysis in September 2022 revealed the presence of BOC type 2 and serum levels of Anti – AQP 4 (CBA) and Anti MOG (CBA) were non-reactive on October of the same year. After discussion with the attending physician, the patient received methylprednisolone 1 gram for 5 days on November 2022. He remained asymptomatic for 20 days after the end of corticosteroid therapy and, afterwards, he presented brief episodes (lasting less than 24 hours) of paresthesias in right arm and shocks along the spine. A control imaging examination was performed in May 2023, which showed the same centromedullary lesion at the C1-C2 level, with stable dimensions compared to the examination on June 2022. Considering that the patient met the McDonald 2017 criteria for diagnosis of MS, in August 2023, the attending neurologist decided to start fingolimod and, since then, the patient has remained asymptomatic. During follow-up, a neuraxial MRI was performed on May 2024, which indicated that the centromedullary lesion at the level of C1-C2 captured contrast and that two small left lateral lesions have appeared at the level of C4 and C6, both with slight contrast enhancement. Considering the radiological progression of the lesions, the exchange of fingolimod for natalizumab was indicated. Multiple sclerosis (MS) is an immune-mediated, inflammatory, demyelinating and neurodegenerative disease that involves the white and gray matter of the central nervous system (CNS). Its etiology is not yet well understood and involves genetic and environmental factors that are not yet well defined. It predominantly affects individuals between 20 and 50 years of age; it is twice as common in females and has a lower incidence in the Afro-descendant, oriental and indigenous population. The structures most affected by MS are the optic nerve, brain stem, cerebellum and spinal cord. Transverse myelitis lesions secondary to MS are usually partial, short and eccentric. Sensory symptoms tend to be more exuberant than motor symptoms; the clinical picture is asymmetric and the evolution is usually subacute. The presence of a neurogenic bladder is also common. This report describes a case of MS with pure spinal cord involvement, which is considered uncommon.

Pyridostigmine in the management of dropped head syndrome following botulinum toxin injection: case report

Gabriel Felipe Almeida de Barros[1], Eduardo Sousa de Melo[1], Leticia Klabinske Marques Monteiro[2], Evelliny Gomes da Silva[2], Allefy Beltrão Albano[2], Fabrício Martins Veras[2], Carla Bianca Alves Leite Santos[1], Giovanna da Silva Gamba Dias[1], Aimê de Paula Santos[1]

[1]Universidade Federal de Pernambuco, Recife PE, Brazil
[2]Universidade Federal de Pernambuco, Hospital das Clínicas, Recife PE, Brazil

Correspondence: Leticia Klabinske Marques Monteiro; Email: leticiaklabinske@gmail.com.

Case presentation: A 66-year-old man, diagnosed with Parkinson's disease (PD), presented a significant anteriorization of the cephalic and dorsal regions with contractions and significant pain, in addition to a lateralization of the neck to the right. It was recognized as camptocormia, which has been frequently associated with PD. The medical team opted to administer botulinum toxin in the affected area. However, two days after the application, the patient developed Dropped Head Syndrome, a relatively rare condition. Thus, pyridostigmine was prescribed to enhance symptom management, along with physical therapy sessions. After about a month of use, the treatment proved to be effective. **Discussion:** Dropped head syndrome (DHS) is characterized by severe weakness of the cervical paraspinal muscles, resulting in gradual sagging of the head and usually culminating in the chin-on-chest deformity. It is a relatively rare condition with various differential diagnoses that can be categorized into neurological, neuromuscular, muscular, and other causes. This deformity has significant implications on the quality of life of affected individuals, resulting in considerable restrictions to daily activities. Botulinum toxin injection has been reported to produce measurable weakness at both adjacent and distant sites after injection, by systemic spread and retrograde axonal transport. However, this application can cause adverse effects, such as DHS, as in this clinical report. The management of this symptom can include physical therapy, orthotic devices (including cervical collars), and even, in severe cases, surgical intervention. For cases of DHS caused by myasthenia gravis, pyridostigmine has been used for symptom reversion. This drug is a reverse acetylcholinesterase inhibitor, which works by preventing the breakdown of acetylcholine in the neuromuscular junction. Therefore, given that the mechanism of action of both myasthenia gravis and botulinum toxin are similar, since the two work by reducing the amount of acetylcholine in the synaptic cleft, it was decided to use pyridostigmine to reverse the DHS caused by botox. The acetylcholinesterase inhibitor's mechanism is such that it may reduce the effect of BTX by potentiating neuromuscular transmission, decreasing muscle flaccidity, and thus promoting the resolution of the case. **Final comments:** Although pyridostigmine is not commonly used to reverse the head drop syndrome caused by BTX, its effects are known for DHS treatment in myasthenia gravis. Therefore, considering the similarities in mechanism of action of both myasthenia gravis and botulinum toxin and the safety and efficacy of this medication, pyridostigmine should be considered to treat severe sequelae of botulinum toxin injection in selected patients.

Background: The JAV-Raras study is an initiative integrated in the National Network of Rare Diseases project and aims to measure the Journey of Value (JAV) of patients with rare diseases in Brazil. Among the diseases under analysis, there is Amyotrophic Lateral Sclerosis (ALS). **Objective:** To understand the quality of life of patients diagnosed with ALS and to evaluate their satisfaction with the care and treatment received at a specialized in Rare Diseases service. **Methods:** Data was collected from medical records and clinical and quality-of-life questionnaires were applied. The EUROQOL questionnaire was used to assess quality of life, which consists of the EQ-5D descriptive system and the EQ-VAS scale. The EQ-5D is a multiple-choice questionnaire that assesses health-related quality of life in five dimensions: mobility, self-care, daily activities, pain/discomfort and anxiety/depression. The EQ-VAS uses a visual analog scale ranging from 0 to 100 to measure quality of life. In addition, the Net Promoter Score (NPS) was used as an indicator of patient satisfaction with the care team and treatment received. **Results:** The sample consisted of 30 patients followed up in a specialized service, 40% female and 60% male. The quality of life results assessed by the EQ-5D-3L show that the median score is 0.238, with a minimum score of -0.131 and a maximum score of 0.47. Regarding satisfaction with the care team: 50% of patients rated the team in the "excellent zone", which indicates a high level of satisfaction. However, 26.7% rated the team in the "critical zone" or "improvement zone", suggesting that there are areas where the quality of care can be improved. With regard to satisfaction with the treatment: 60% rated the treatment as excellent, which shows a high level of satisfaction with the effectiveness and quality of the treatment received. **Conclusion:** The median EQ-5D-3L score indicates a low health-related quality of life, suggesting that, in general, these patients have significant problems in the multiple dimensions assessed, such as mobility, personal care, usual activities, pain/discomfort and anxiety/depression. This low score reflects the negative impact that ALS has on the quality of life of these individuals. These results reinforce the necessity for a multidisciplinary approach to the management of the disease, aimed not only at clinical treatment, but also at improving the quality of life of these patients. With regard to the NPS, the results indicate that, in general, patients have a good level of satisfaction with both the care team and the treatment received.

Background: The JAV-Raras study is an initiative integrated in the National Network of Rare Diseases project and aims to measure the Journey of Value (JAV) of patients with rare diseases in Brazil. Among them is the transthyretin-related familial amyloidosis (ATTRv). **Objective:** To measure the quality of life of patients diagnosed with ATTRv amyloidosis and to assess their satisfaction with the care and treatment received in a specialized service. **Methods:** Data was collected from medical records, clinical and quality-of-life questionnaires. The EUROQOL questionnaire was used to assess quality of life. This instrument consists of the EQ-5D descriptive system and the EQ-VAS scale. The EQ-5D is a multiple-choice questionnaire that assesses health-related quality of life in five dimensions: mobility, self-care, activities of daily living, pain/discomfort, and anxiety/depression. The EQ-VAS consists of a visual analog scale with a score from 0 to 100 to assess quality of life. In addition, the Net Promoter Score (NPS) is an indicator of patient satisfaction with the care team and treatment. **Results:** 33 patients were included, 46% female and 54% male. All responded to the Quality-of-Life Questionnaire and the results assessed by the EQ-5D-3L show that the median score is 0.582, with a minimum value of -0.131 and a maximum value of 1. Of this sample, 32 patients responded to the questionnaire assessing satisfaction with the care team: 40.6% rated the team in the "critical zone", meaning a high level of dissatisfaction. Another 40.6% rated the team in the "zone of excellence" indicating satisfaction with the care received. Only 18.8% rated the team in the intermediate zones of "improvement" and "quality". In terms of satisfaction with care, almost all of them (93.7%), rated the care received in the "excellence" zone, indicating a high level of satisfaction with the effectiveness and quality of care. Only 6.7% rated it in the "quality zone", with no negative evaluations. **Conclusion:** The median score of 0.582 on the EQ-5D indicates that the sample's quality of life is significantly reduced compared to the quality of life of those outides of the sample. This is probably due to symptoms, functional limitations, disability and reduced general well-being. This highlights the need to implement care strategies that include more effective therapeutic approaches, psychosocial support and measures to minimize the impact on quality of life. Regarding the NPS, data suggest that there is dissatisfaction with the care team on the part of patients, although the same percentage is very satisfied with the care. This points to the need for improvements in communication, empathy and quality of care provided by the healthcare professionals involved.

Correspondence: Camila Caroso Lobo; Email: camilaloboc@gmail.com.

Background: RFC1-related ataxia is a neurological disorder characterized by progressive impairment of motor coordination, affecting standing balance and gait. Quantitative assessment of ataxia-specific gait impairments using wearable technology holds promise for providing sensitive outcome measures. However, the application of motion sensors to evaluate these impairments in patients with RFC1-related ataxia remains unexplored. **Objective:** This study aimed to identify specific standing balance conditions and digital postural sway measures that differentiate between patients with RFC1-related ataxia patients and healthy controls. Additionally, the study sought to evaluate the correlation between motion sensor parameters and the severity of ataxia. **Methods:** In this study, seventeen patients with RFC1-related ataxia and nine healthy controls were equipped with six inertial sensors to assess parameters, including gait during a 2-minute natural pace walking task, postural sway, turn times, and sit-to-stand times. The severity of ataxia was assessed using the Scale for the Assessment and Rating of Ataxia (SARA), administered consistently by the same

experienced neurologist across all patients. The median values of these parameters were compared between the groups using the Mann-Whitney test. Spearman's correlation coefficient was employed to examine the relationships between these measures and the severity of ataxia. **Results:** Significant differences were observed between RFC1 mutation patients and healthy controls in postural and gait parameters. Mann-Whitney tests showed higher mean postural sway velocity (p=0.030), larger sway area (angles and acceleration, p=0.030), and greater turn angle (p=0.004) in RFC1 patients. Spearman's correlations indicated significant associations between the SARA scale and various parameters: increased double support duration (R=0.634, p=0.015 left, R=0.664, p=0.010 right) and decreased turn velocity (R=-0.633, p=0.009). Strong correlations were also found between postural sway with eyes closed and feet apart, particularly mean velocity (R=0.718, p=0.003), reflecting impaired postural control in RFC1 patients. **Conclusion:** Wearable sensors can effectively differentiate motor impairments in RFC1-related ataxia and correlate well with the severity of the condition. These technologies may offer sensitive measures for clinical assessment and therapeutic strategies in ataxia management in these patients.

Correspondence: Graziella Aguiar Santos Faria; Email: graziasf@hotmail.com.

Background: Cognitive decline is a significant concern in Multiple Sclerosis (MS) and is closely associated with myelin loss. Various neuroimaging methods have been employed to quantify myelin and correlate it with cognitive dysfunctions. Magnetization Transfer Ratio (MTR) and Positron Emission Tomography (PET) with [11C]PIB have yielded promising results in cross-sectional studies; however, longitudinal follow-up investigations remain underexplored. **Objective:** This study aims to measure myelin content using PET and MTR and evaluate their potential in predicting cognitive decline and functional capacity over a one-year follow-up period in patients with MS (pwMS). **Methods:** Fifty-one pwMS underwent clinical and neuropsychological assessments, as well as MTR and [11C]PIB-PET imaging. After one year, 39 of these patients were re-evaluated clinically and neuropsychologically. Myelin content was measured in white matter (WM), normal-appearing white matter (NAWM), and lesions. **Results:** The clinical follow-up evaluations did not show significant differences overall, but when divided by phenotype, the Expanded Disability Status Scale (EDSS) was significantly higher one year later for progressive MS (p=0.025). The cognitive profile remained similar between both assessments. Lower MTR values were associated with lower cognitive z-scores in the follow-up evaluation. Specifically, in NAWM, lower MTR values correlated with lower scores on the Selective Reminding Test (SRT) delayed recall (r^2=0.079, p=0.042), Paced Auditory Serial Addition Test (PASAT) (r^2=0.127, p=0.019), Word List Generation (WLG) (r^2=0.076, p=0.036), and EDSS (r^2=0.792, p=0.020). Similarly, in WM, lower MTR values were associated with lower scores on the SRT delayed recall (r^2=0.088, p=0.035), PASAT (r^2=0.117, p=0.023), WLG (r^2=0.061, p=0.048), Symbol Digit Modalities Test (SDMT) (r^2=0.136, p=0.011), and EDSS (r^2=0.792, p=0.021). Lower [11C]PIB uptake was associated with lower z-scores one year later in NAWM (PASAT r^2=0.071, p=0.050) and WM (PASAT r^2=0.094, p=0.030; SDMT r^2=0.073, p=0.041). There was no significant relationship between MTR and [11C]PIB uptake in lesions and cognitive variables. **Conclusion:** Although there were no significant overall differences in cognitive and disability measures between the initial assessment and the follow-up, lower MTR and [11C]PIB uptake were associated with worse cognitive performance and higher disability scores one year later. This suggests that MTR and [11C]PIB uptake could be valuable in predicting cognitive decline and increased disability in pwMS over time.

Background: Alzheimer's disease (AD) is a neurodegenerative disorder, an irreversible and progressive brain pathology. Etiological hypotheses suggest that genetic risk factors and environmental factors contribute to the onset of AD. It is characterized by the formation of senile plaques and neurofibrillary tangles through amyloid fibrillar deposits and hyperphosphorylation of Tau protein, which cause lesions in brain areas. The incidence of neurodegenerative diseases, including Alzheimer's Disease, increases with age, impairing memory and cognitive functions. Symptoms begin insidiously and progress, with subtle memory losses, motor weakness, and loss of ability to perform tasks, eventually leading to incapacitation. **Objective:** To evaluate the profile of hospital admissions for AD in Brazil between 2019 and 2023. **Methods:** Data collection was carried out using information available from the Hospital Information System of SUS (SIH/SUS) of the Ministry of Health, which is publicly accessible on Tabnet/DATASUS, between January 15 and May 15, 2024. This retrospective, longitudinal study utilized a quantitative, descriptive design. Data were grouped by Brazilian macroregions, type of care, sex, age group, and race/ethnicity. Statistical inference was performed using BioEstat 5.3 software, employing the paired T-test for two related samples to compare groups, with data presented through descriptive statistics, measures of central tendency, and dispersion. **Results:** During the period from 2019 to 2023, there were 7,547 hospital admissions for AD in Brazil. The majority of these admissions occurred among females, accounting for 65.76% (n=4,963) (p<0.0001), and 50.02% (n=3,775) among whites (p<0.0001). The population aged over 80 years was proportionately more affected, comprising 59.36% (n=4,480; p<0.0001) of admissions, primarily concentrated in the Southeast region (n=3,549), representing 47.03% (p=0.0005) of the total, with an average annual cost of R$ 2,634,689.11 for care. Deaths were more frequent in the Southeast, with about 58.01% (n=1,105) of cases (p=0.0006), and the average mortality rate was 50.21 (p=0.0043). The number of admissions peaked in 2023, accounting for 28.10% (n=2,121) of the total, compared to 16.06% (n=1,212) in 2020. Most admissions were classified as urgent, representing 83.32% (n=6,288; p<0.0001) of the cases. **Conclusion:** Hospital admissions for AD are concentrated in the Southeast region of Brazil, with higher proportionality of deaths and care costs during the period. The majority of cases involved females over 80 years old of white race, with urgent care being the most prevalent type of admission.

Racemose neurocysticercosis and cerebral venous thrombosis: case report

Lucas Vieira Pinto[1], Alexandre Motta Mecê[1], Alessa de Andrade Santana[1], Matheus Oliveira Povoa[1], Júlia Domingues Gatti[1], Leonardo Grande de Almeida[1], Rafael Shiniti Yabiku[1], Kevin Yoshimi Nakaie[1], Gabriel Costa dos Reis[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Lucas Vieira Pinto; Email: lucasvip2803@gmail.com.

Case presentation: A 29-year-old female, with no significant past medical history, first presented with an altered level of consciousness preceded by vomiting, and behavioral changes. On first evaluation in her hometown, the patient obtained a computer tomography (CT) scan revealing hydrocephalus with evidence of intracranial hypertension (ICH), being referred to a tertiary service for further evaluation. Upon admission, the patient presented with a Glasgow Coma Scale of 13, being empirically treated for acute meningoencephalitis with vancomycin, acyclovir and ceftriaxone, also presenting spontaneous improvement with orthostatic posture. A magnetic resonance imaging (MRI) scan was performed, revealing signs of ICH and a nodular cystic lesion located in the fourth ventricle, partially obstructing the foramina of Magendie and Luschka bilaterally, suggestive of neurocysticercosis. The MRI also showed indirect signs of cerebral venous thrombosis of the inferior sagittal, transverse and sigmoid sinuses, later confirmed in vascular exams. The patient was anticoagulated with Rivaroxaban for 30 days, with evidence of thrombosis recanalization observed on a follow-up image exam, along with preoperative corticosteroid use. The diagnosis was confirmed through histopathological examination when the patient underwent cystectomy in the fourth ventricle, revealing Cysticercus cellulosae (with scolex and membrane). The patient is currently stable, undergoing outpatient follow-up, corticosteroid tapering, and proposed anticoagulation for 6 months. **Discussion:** Neurocysticercosis can manifest in the parenchymal form (an important cause of epilepsy) and the racemose form (obstructing the ventricular system and causing hydrocephalus), making high clinical suspicion essential. The association with cerebral venous thrombosis is, however, a rare event in the literature. It is believed that the increase in procoagulant factors secondary to the local infectious process, combined with the proximity of the venous sinuses, is primarily responsible for the thrombus formation. We highlight the case reported, as the first one reported in literature, presenting this rare association of events with a remarkable response to anticoagulation treatment, corticosteroid therapy, and surgical approach. **Final comments:** Neurocysticercosis is the most common helminthic infection of the central nervous system, accounting for 30% of epilepsy cases in endemic countries. The racemose form is a severe presentation often causing hydrocephalus and intracranial hypertension. This case report presents a favorable outcome resulting from proper treatment of the disease and its complications, supporting the significance of being vigilant towards the suspect of the disease and the possibility of neurovascular complications, which, although rare, have significant implications for clinical management.

Radiation therapy-induced plexopathy: a case report

Ana Paula de Almeida Campos[1], Ketimila Aparecida Pereira[1], Maria Clara Motta Barbosa Valente[2], Fernando Pierini Costa[1], Mauro Gomes Araujo[1], William Thiago Almeida Leite[1], Ana Luisa Vilela Sá Fortes[1]

[1]Santa Casa de Misericórdia de Santos, Santos SP, Brazil.
[2]Santa Casa de São Paulo, São Paulo SP, Brazil.

Correspondence: Ana Paula de Almeida Campos; Email: anapac187187@gmail.com.

Case presentatio: An 88-year-old woman presented with a one-month history of ascending paresthesia, hypoesthesia, and paresis in all four limbs, more pronounced in the lower limbs. She had a history of breast cancer treated with radiotherapy (RT) and chemotherapy (CT) in 2019 and 2020 for disease recurrence. Physical examination revealed bilateral ulnar nerve hypoesthesia, symmetric weakness in all limbs, and hypoactive reflexes. Magnetic resonance imaging (MRI) of the spine and laboratory tests were normal. Electromyography (EMG) showed axonal peripheral polyneuropathy in all four limbs associated with bilateral lumbosacral plexopathy and signs of current denervation (fibrillation and positive sharp wave) at rest. Considering the clinical findings, EMG, and reported history, a diagnosis of RT-induced plexopathy was raised, although secondary involvement due to CT could not be ruled out, especially since CT is a risk factor for plexopathy. **Discussion:** This case report presents a patient who developed axonal peripheral polyneuropathy in all four limbs associated with bilateral lumbosacral plexopathy after treatment for breast cancer. These electromyographic findings can be seen in both chemotherapy-induced neuropathy and radiation-induced plexopathy, although they are more commonly secondary to radiation therapy. The clinical presentation can be early or late onset, usually more than six months after radiation therapy. The exact mechanism of injury is not well established, but it is known that there is direct damage to axons due to toxic effects, as well as microvascular damage, and that concomitant chemotherapy has a synergistic effect, increasing the risk of plexopathy. Symptoms include sensory and motor changes, as well as neuropathic pain. An important differential diagnosis is tumor recurrence or metastasis. EMG plays an essential role in assessing the severity and prognosis of the disease. Nerve conduction velocities help to detect blockages in the damaged nerve. In severe cases, EMG shows fibrillation and absence of motor unit potentials in the affected muscle group supplied by the plexus. Treatment consists of supportive therapies due to the irreversible nature of the lesion. **Conclusion:** Radiation-induced neuropathy is a rare condition that is an important differential diagnosis for tumor recurrence (depending on the site) or metastatic disease. It is also a differential diagnosis for purely axonal polyneuropathies without plexus involvement. There is no curative treatment, and supportive therapy for symptom control is of paramount importance for patient quality of life.

Correspondence: Gustavo Lopes de Freitas Honorio; Email: gugahonorio@hotmail.com.

Case presentation: A 53-year-old male diagnosed with peripheral non-Hodgkin T lymphoma involving the right frontal, right ethmoid and left maxillary sinuses presented with tonic-clonic seizures and altered mental status. Antiepileptic drugs (phenobarbital 200/day and levetiracetam 1000 mg/day) were started, leading to control of seizures. He was previously treated with one session of gemcitabine-oxaliplatin and one session of dexamethasone, methotrexate, ifosfamide, L-asparaginase and etoposide without response. Two months before the neurological symptoms, he underwent 20Gy local radiotherapy, divided into 10 sessions of 2Gy under intensity-modulated radiotherapy (IMRT). Facial Magnetic Resonance Imaging (MRI) showed an expansive contrast-enhancing lesion in the lower portion of the nose extending to the anterior portion of the maxilla and the palate, while cranial MRI T2/FLAIR revealed hyperintensity on cortico-subcortical in the right frontobasal, insular, medial temporal region and frontobasal left cortex, without contrast enhancement. Initially, lymphoma progression and viral encephalitis was suspected but cerebrospinal fluid analysis findings were normal, including neoplastic cells, HSV-1 and HSV-2 PCR. However, despite any specific treatment, a control brain MRI revealed reductions of the parenchymal lesions, leading to the diagnosis of radiation-induced brain injury. Although in treatment, the patient had systemic progression, being referred to palliative care. **Discussion:** Radiotherapy is widely used in the treatment of neoplasms, generating direct double-stranded DNA breakage and cell death, vasculopathy causing tissue hypoxia, and even inducing increased inflammatory activity with microglial activation. The effect on healthy brain tissue can be long-lasting, remaining for years after initial exposure. Brain injuries associated with radiation can be divided into acute, occurring within two months after radiation therapy; early-delayed, up to 6 months; and delayed, that develops 6 months after the treatment. Acute brain lesions are associated with high total doses, few fractions and high brain volume exposure to radiation. The clinical features can range from altered mental status, seizures and focal signs, as in the presented case. Additionally, when dealing with aggressive systemic lymphomas, it is important to consider progression to the central nervous system as differential diagnosis. In this case, involving an immunosuppressed patient and given the initial imaging pattern with bilateral mesial temporal and insular involvement, it was also necessary to exclude herpetic encephalitis. **Final comments:** As radiotherapy is widely used in medical practice, neurologists must be aware of the entire spectrum of clinical manifestations and the neurological complications that a patient exposed to radiotherapy may have. Moreover, in patients with aggressive cancer, it is important to consider progression of the underlying disease to the nervous system.

Background: Risdiplam (EVRYSDI®) is a centrally and peripherally distributed, oral survival of motor neuron 2 (SMN2) pre mRNA splicing modifier that has been approved in more than 90 countries worldwide. **Methods:** RAINBOWFISH (NCT03779334) is an open-label, single-arm, multicenter study assessing the efficacy, safety and pharmacokinetics/pharmacodynamics (PK/PD) of risdiplam in infants with genetically diagnosed and presymptomatic spinal muscular atrophy (SMA) from birth-6 weeks of age (at first dose), regardless of SMN2 copy number. The primary endpoint is the proportion of infants, with two SMN2 copies and baseline compound muscle action potential (CMAP) amplitude ≥1.5mV, who are able to sit without support for ≥5 seconds (assessed by Item 22 of the Gross Motor Scale of the Bayley Scales of Infant and Toddler Development, third edition). Secondary endpoints include: the development of clinically manifested SMA; survival and permanent ventilation; motor milestone achievement; motor function; growth measures; nutritional status; CMAP; PK/PD; and safety monitoring. **Results:** The median age at first dose was 26.5 days (range: 16-40 days) for the first 18 enrolled infants (data cut-off: 1 July 2021). No treatment-related serious adverse events were reported in infants treated for ≤22.8 months. A preliminary analysis of seven infants treated for ≥12 months demonstrated that most reached near maximum scores on the Children's Hospital of Philadelphia Infant Test of Neuromuscular Disorders scale by 4-5 months of age and achieved motor milestones within World Health Organization windows for healthy children. All seven infants treated for ≥12 months were alive without permanent ventilation, maintained swallowing and feeding abilities, and had not required hospitalization. **Conclusion:** Here we report for the first-time results from the RAINBOWFISH primary analysis conducted at Month 12.

Correspondence: Marcus Vinicius Cristino Albuquerque; Email: drmarcusalbuquerque@gmail.com.

Case presentation: 72-year-old woman presented with depressive symptoms 8 months ago. After 2 months, she experienced memory impairment, language difficulties, perseverative speech, and hypokinesia. After 3 months, presented with acute worsening of speech, psychomotor slowing, drowsiness, and lower limb weakness. She was hospitalized, aphasic for 3 days. She was discharged with a presumptive diagnosis of lacunar ischemic stroke and prescribed dual antiplatelet therapy and high-dose statin. The following month, she was readmitted to another facility for further investigation of rapidly progressive dementia syndrome associated with an ictal event, initially suspected to be encephalopathy. PMH: osteogenesis

imperfecta, hypertension, dyslipidemia. On examination: normal speech and language; grade V muscle strength, normal reflexes; no movement disorders or crisis stigmata; axial facial signs present; no sensory, coordination, or cranial nerve abnormalities. MMSE: 14, MoCA: 6 points. Laboratory tests were normal (complete blood count, sodium, calcium, TSH, free T4, VDRL, vitamin B12, anti-TPO, anti-GAD). MRI showed no ischemic changes. PET scan: moderate glycolytic hypometabolism in the frontal lobes extending to the anterior cingulate, associated with slight hypometabolism of the right striatum. Thoracic CT: normal, abdominal CT: ovarian cyst; CSF: 1 cell, protein 86, no oligoclonal bands; normal EEG. She was readmitted the following month due to worsening ability to retain and recall information and temporal disorientation. MRI displayed FLAIR and DWI hypersignal in the semioval centers in the venous drainage topography. Angiography revealed a fast-flow dural fistula in the torcula region along with signs of chronic venous sinus thrombosis with cortical venous stasis and contralateral venous reflux. She underwent embolization of an extensive dural fistula in the right superior sagittal and transverse-sigmoid sinuses with an 80% reduction of the diseased dural segment. Two months after the procedure, the patient showed cognitive and radiological improvement. MoCA: 10 (previously 6). MMSE: 18 (previously 14). Cranial MRI: improvement of FLAIR hypersignal in semioval centers. **Discussion:** Dural fistulas comprise 10 to 15% of intracranial vascular malformations, with 35% located in the posterior fossa. They are more common in females and in the sixth decade of life. Symptoms are usually benign: bruit, tinnitus, headache, dizziness, conjunctival bruising, and/or orbital congestion. Occasionally, more aggressive manifestations can occur: intracranial hemorrhages, dementia, encephalopathy, epilepsy, cranial nerve deficits, intracranial hypertension, focal/transient deficits. **Final comments:** This pathology should be considered in all cases of rapidly progressive dementia and recurrent ictal events. Chronic venous sinus thrombosis with venous congestion should also be considered whenever FLAIR and DWI hypersignal are present in the semioval centers.

A 35-year-old man with a history of hypertension and gout presented with a one-month history of infantile behavior, memory loss and repetitive speech, followed by sudden left arm weakness and focal seizures. Neurological examination revealed dysarthria, apathy, infantile behavior, slowed speech, temporo-spatial disorientation, executive function decline, left lower limb weakness with hyperreflexia, Babinski sign, and clonus, and hypopalesthesia. A monoparetic gait was observed, with no cranial nerve or meningeal abnormalities. Brain MRI showed extensive cortico-subcortical T2/FLAIR hyperintensities with scattered extensive microhemorrhages and gyriform gadolinium enhancement in the mesial portions of the frontal lobes, left frontal and parietal lobe, right insula, and the temporo-occipital transition, apparently respecting multiple vascular territories. The patient tested positive for HIV, and antiretroviral therapy was initiated (dolutegravir, lamivudine, and tenofovir). CSF analysis showed 4.3 leukocytes/mm^3, glucose 72 mg/dL (serum glucose: 99 mg/dL), protein 111.3 mg/dL, lactate 2.20 mmol/L, and VDRL, viral panel, bacteria and fungi tests were negative. The EEG showed diffuse cerebral dysfunction, worse in the left temporal lobe. Although the viral panel was negative, he was empirically treated with acyclovir. There was no improvement, but neurological stabilization. The patient's condition worsened over some weeks, developing drowsiness, left hemiparesis, and worsened memory, behavior, and seizures. Further MRI and a brain biopsy indicated chronic lymphocytic vasculitis. Treatment included intravenous methylprednisolone and cyclophosphamide monthly for 3 months, followed by an oral taper of prednisone. New brain MRI showed involution of the previous lesions. Despite treatment, the patient remained with severe cognitive and motor impairments. Brain biopsy metagenomics ruled out other pathogens, concluding HIV-associated CNS vasculitis. HIV-related CNS angiitis is rare and usually associated with other pathogens (such CMV, EBV, and others). The differential diagnosis between this condition and primary CNS vasculitis is difficult in this case. Due to the recent unavailability in our service of CSF viral load and genotyping testing, we opted for antiretroviral therapy characteristically with high CNS penetration and, concurrently, started immunosuppressive therapy with pulse therapy with methylprednisolone for 5 days, monthly cyclophosphamide, and prednisone for gradual corticosteroid tapering. With the appropriate stabilization of the condition, prednisone remains in gradual tapering, and cyclophosphamide has already been discontinued. This case report is an important way to remind neurologists about these two rare conditions, and how the appropriate diagnosis can make the difference in the patient's prognosis.

Rapsyn-associated congenital myasthenic syndrome: distinctive phenotype mimicking limb-girdle dystrophy

Gabriella Corrêa Dousseau[1], Mariana Hiromi Oku[1], Gabriel Saboia de Araújo Torres[1], Filipe Tupinambá Di Pace[1], André Macedo Serafim Silva[1], Beatriz Carneiro Godim Silva[1], Antonio Alberto Zambon[1], Eduardo de Paula Estephan[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, São Paulo SP, Brazil.

Correspondence: Gabriella Corrêa Dousseau; Email: gabrielladousseau@gmail.com.

Case presentation: A 51-year-old woman has experienced fatigue after any physical effort since childhood. During her teenage years, she noticed slower movement compared to peers, difficulty running, climbing stairs, and supporting her neck. In adulthood, her condition worsened, resulting in difficulty rising from a chair without support, frequent falls, increased neck weakness, bilateral semiptosis, and episodes of intense shortness of breath, particularly after infections. On a few occasions, she required hospitalization with mechanical ventilation. Her family history revealed no consanguinity between her parents and noted that 2 of her 5 siblings have similar weakness. Physical examination showed eyelid ptosis, proximal limb and girdle weakness, axial neck weakness, and fatigue with sustained muscle effort. General laboratory tests and CK were all normal. Electromyography (ENMG) demonstrated a decrease greater than 10% with repetitive stimulation and a myopathic pattern. Genetic sequencing revealed two pathogenic variants in compound heterozygosity in the RAPSN gene: c.264C> A (p.Asn88Lys) + c.490C> G (p.Arg164Lys). She was gradually put on pyridostigmine, and salbutamol, result in increased independence in walking, greater resistance for daily activities and no more hospitalizations. On periods of intensification of symptoms, low-dose oral ephedrine provided additional benefit. **Discussion:** Congenital myasthenic syndromes (CMS) are a heterogeneous group characterized by abnormal synaptic transmission at the neuromuscular junction. Pathogenic variants in the RAPSN gene result in a deficiency of the end-plate acetylcholine receptor because rapsyn stabilizes this receptor to the postsynaptic membrane and subsynaptic cytoskeleton. Most RAPSN patients exhibit myasthenic symptoms at birth or in childhood, though some present in the second or third decade of life. Common symptoms include eyelid ptosis, but only 25% have ophthalmoparesis. Other manifestations may include facial, cervical, and bulbar weakness. Respiratory infections or febrile illnesses can exacerbate weakness and respiratory distress. Rarely, RAPSN cases may present proximal weakness, as in our patient. Limb-girdle weakness phenotypes are more frequent with other CMS genes, such as DOK7, GFPT1, MUSK, COLQ, GMPPB, and AGRN. The long-term prognosis for RAPSN-related CMS is generally favorable. The clinical course is typically stable, with intermittent weakness triggered by infections or fever. Respiratory crises decrease in frequency and severity and are rare in adulthood. However, exacerbations characterized by cervical weakness, bulbar symptoms, and ptosis may persist throughout adulthood. **Final comments:** Limb and girdle weakness should not preclude suspicion of congenital myasthenic syndrome. In RAPSN cases, patients typically present with mild to moderate myasthenic symptoms and respond favorably to anticholinesterase treatment, with beta-agonists also showing effectiveness.

Rare association between CADASIL and multiple system atrophy: a report of three Brazilian cases and literature review

Vanderson Carvalho Neri[1], Ralph Lettieri[2], Karoline Lobo[2], Saulo Machado[3], Leonardo Vandesteen[2], Cristiane Cardoso[4], Ana Luisa Goes[5]

[4]Hospital Unimed, Campos dos Goytacazes RJ, Brazil.
[5]Universidade Federal do Estado do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Vanderson Carvalho Neri; Email: vandersoncn@yahoo.com.br.

Case presentation: Report of 3 cases of patients with association between CADASIL and MSA-C. Case 1: Woman, 58 years old, symptoms for 18 years, clinical presentation of imbalance, dysarthria and left crural hemiplegia. Progressing to urinary incontinence, short-term memory and language impairment, as well as dysphagia. Severe dependence on daily activities. Case 2: A 75-year-old woman, with pathology for 8 years, has been presenting with imbalance, short-term memory changes, left crural hemiparesis. 1 year ago the condition progressed to cognitive decline (moderate bradypsychism), urinary incontinence and dysphagia. Moderate dependence on daily activities. Case 3: Male, 55 years old. Clinical condition for 5 years, characterized by imbalance, bradykinesia, generalized decrease in muscle strength, bradypsychism and urinary incontinence. Intense paresthesia in the upper limbs and tongue region, denies dysphagia. Independent living. For all cases, secondary causes were ruled out and neuroimaging studies demonstrated typical CADASIL changes, as well as the "sign of the cross" in the pons and atrophy of the cerebellum and peduncles. NOTCH3 mutation gene was found in all cases. **Discussion:** CADASIL (Autosomal

Dominant Cerebral Arteriopathy with Subcortical Infarcts and Leukoencephalopathy) is an autosomal dominant pathology caused by mutations in the NOTCH 3 gene. Multiple System Atrophy - MSA is a group of neurodegenerative syndromes characterized by cerebellar ataxia, parkinsonism and dysautonomia. In this work, 3 cases of association of these 2 chronic pathologies were reported. All individuals were followed up on an outpatient basis according to radiological criteria compatible with the 2 pathologies, CADASIL and MSA-C (cerebellar form). MRIs were performed to assess the progression of structural degeneration and leukoencephalopathy. **Final comments:** This is a very rare association between CADASIL and MSA. Currently, only one post-mortem case has been described in the literature. All three forms had cerebellar involvement (MSA-c). The three cases presented cognitive impairment in several domains, with little response to the proposed medications. The association between CADASIL and MSA may be associated with some types of mutations in the NOTCH3 gene.

Rare early onset CSF-1R-related leukodystrophy

Renata Cristine Alves[1], Luis Eduardo Borges de Macedo Zubko[1], Camila Lorenzini Tessaro[1], Luis Daniel Silva Pilatti[1], Daniel Fortes Amarante[1], Talita Aparecida Conte[1], Caio Cesar Diniz Disserol[1], Francisco Manoel Branco Germiniani[1], Helio Afonso Ghizoni Teive[1]

[1]Universidade Federal do Paraná, Hospital de Clínicas, Curitiba PR, Brazil.

Correspondence: Renata Cristine Alves; Email: renata_cristinealves@hotmail.com.

Case presentation: A 20 years-old man, born to non-consanguineous parents, presented with a history of epilepsy starting at 8 months of age and unilateral amaurosis at 4 years of age, associated with short stature and thoracic disproportion. Conversely, he had normal neuropsychomotor and academic development. He later developed right hemiparesis, initially responsive to corticosteroids, rapidly progressing to spasticity, dysarthria, and dystonia in the right upper limb. He was diagnosed as having multiple sclerosis, but showed inadequate response to therapy. A few months later, he had further significant functional deterioration, with dysphagia leading to multiple hospitalizations for bronchopneumonia and became completely dependent for activities of daily living. He also had a second epileptic seizure, which was adequately controlled with phenobarbital. Additionally, on physical examination there was psychomotor slowing, executive dysfunction, bilateral pyramidal release signs, dystonia, dysarthria, and other signs of appendicular ataxia, as well as reduced visual acuity with unilateral amaurosis and optic nerve papillary atrophy. Cranial MRI showed progressive symmetric subcortical white matter lesions with water diffusion restriction, suggestive of leukodystrophy. Following a comprehensive diagnostic work-up that ruled-out other relevant abnormalities, genetic analysis confirmed a diagnosis of genetic leukodystrophy related to the CSF-1R gene (c.1441C> T variant, p.Gln481Ter). **Discussion:** Leukoencephalopathy with spheroids, a hereditary disease linked to CSF-1R gene mutations on chromosome 5, typically manifests in the fourth decade of life with neuropsychiatric symptoms, cognitive decline, parkinsonism, pyramidal signs, bulbar manifestations, and ataxia. This case reports an unusually early onset, suggesting possible childhood manifestations, which is rather rare, particularly in males. **Final comments:** The possibility of CSF-1R disease with an early presentation should be considered in young patients presenting with the specific phenotype, as a more accurate and earlier diagnosis better correlates with a potential positive response to therapy, especially, bone marrow transplantation.

Rare presentation of giant cell arteritis following COVID-19 infection

Bruna Pereira Correia[1], Thire Baggio Machado Marazzi[1], Ellen Silva de Carvalho[1], Soraia Fábio Ramos Cabette[1], Maria Lúcia Habib Simão[1], Francisco Antonio Coletto[1], Renato Ramon da Cruz[1]

[1]Hospital Unimed, Ribeirão Preto SP, Brazil.

Correspondence: Bruna Pereira Correia; Email: brunapereirac@hotmail.com.

Case presentation: A 75-year-old woman was admitted to a private tertiary hospital with two days of bilateral consecutive visual impairment, headache, and mandibular pain during feeding. She tested for COVID-19 (Elisa method) for 30 days because of cough and rhinorrhea without support from respiratory necessity. Her past medical history included obesity, arterial systemic hypertension, and dyslipidemia. An ophthalmologic exam described an altitudinal inferior defect in the left eye (LE) and perception of hand movement in the right eye (RE). Fundoscopy showed a papilledema and retinal pallor. Retinal angiography suggested central retinal artery occlusion RE. Doppler US of temporal arteritis demonstrated halo signal bilateral-perivascular hypoechogenicity and a severe thickening vessel wall. MR brain was expected, but orbital MR showed an actual diffusion restriction and SWI hypersocial bilateral intrabulbar optic nerve. Hemo Sedimentation velocity was 72 mmol-seg(ref 15), and no alteration was detected in CFS, including viral pain. The diagnosis of GCA was performed. Screening for other infectious diseases (respiratory, urinary, and sexuality) resulted in negative. Five days of corticoids pelotherapy were performed following rituximab. **Discussion:** Recent concerns have arisen regarding GCA post-COVID-19 vaccination and infections, previously perceived as rare with an incidence of less than 1 in 1,000,000 cases. The median duration from initial symptom onset to the presentation was approximately seven days, with a range spanning from 2 to 25 days, signifying the rapid progression of this condition. This underscores the critical need for healthcare practitioners to remain vigilant, particularly post-vaccination or in infectious contexts when assessing elderly patients with similar symptoms. Given the potential for irreversible vision loss, if diagnosis and treatment are delayed, a multidisciplinary team approach involving ophthalmologists, neurologists, and rheumatologists remains paramount in effectively managing cases like these. **Final comments:** The possibility of GCA following COVID-19 infection is rare but consistent in European literature. No other rares were detected in Brazilian reports.

Rare simultaneous bilateral thalamic hemorrhage with the presence of the Austregésilo-Esposel sign: a case report and literature review

Leticia Bragalia Passarella[1], Hilton Mariano da Silva Júnior[2], Pedro Neves Fortunato[3]

[1]Pontifícia Universidade Católica de Campinas, Campinas SP, Brazil.
[2]Pontifícia Universidade Católica de Campinas, Depatamento de Neurologia, Campinas SP, Brazil.
[3]Hospital Mário Gatti, Departamento de Neurologia e Neurocirurgia, Campinas SP, Brazil.

Correspondence: Leticia Bragalia Passarella; Email: leticiabpassarella@gmail.com.

Case presentation: A 46-year-old man was admitted with loss of consciousness, unresponsiveness, and a blood pressure of 220/105 mmHg. He had bilateral hemiplegia and plantar extension after left sole stimulation, indicating a positive Babinski sign on the left. Hallux extension after stimulating the anterior left thigh characterized the Austregésilo-Esposel sign. Brain tomography revealed bilateral thalamic hyperdensity. Findings suggest a rare hemorrhagic stroke, with pyramidal tract involvement. The Austregésilo-Esposel sign, eliciting the same reflex as the Babinski sign, can be used alternatively. However, its literature description is scarce. **Discussion:** Antonio Austregésilo Rodrigues Lima, a Brazilian neurology pioneer, first described the Austregésilo-Esposel sign in 1912. Squeezing the anterior thigh triggers hallux extension. Mentioned in "The Babinski Sign: A Centenary" by Van Gijn in 1996, this rare sign is clinically relevant but underused due to unfamiliarity. Plantar extension reflexes, like the Babinski sign, indicate pyramidal system dysfunctions and help detect lesion levels. Described in 1896, Babinski established the link between this reflex and pyramidal tract injuries. Notable substitutes include Chaddock's, Oppenheim's, and Gordon's signs, which are beneficial when traditional methods are unsuitable, ensuring a complete examination, especially when patients are sensitive to sole stimulation. This case is remarkable not only for the rare Austregésilo-Esposel sign but also for the presentation of simultaneous bilateral intracranial hemorrhage. Typically associated with hypertension, spontaneous intracranial hemorrhages often affect the thalamus and putamen due to artery degeneration from untreated chronic hypertension. The simultaneous occurrence of bilateral hemorrhages is exceptionally rare and scarcely mentioned in the literature. This suggests symmetrically vulnerable vessels, highlighting the need for heightened clinical awareness. Recognizing symmetrically vulnerable vessels can alert clinicians to the risk of such events, prompting vigilant monitoring of patients with hypertension. This case underscores the importance of comprehensive diagnostic evaluations and tailored treatment plans to address these rare but critical conditions effectively. **Final comments:** Neurological semiology evolves continually, and understanding diverse signs is crucial for accurate diagnoses. The Austregésilo-Esposel sign, though scarce, emphasizes the need for knowledge of various neurological assessments. Babinski sign substitutes improve examination accuracy and patient compliance. Recognizing simultaneous bilateral hemorrhage enriches clinical understanding. The medical community must familiarize itself with both conventional and alternative tests to enhance patient assessments, particularly for pyramidal system dysfunctions. This case underscores the complexity and rarity of semiological signs and clinical presentations in medical practice.

Realistic simulation training in stroke care: a systematic review

Maria Clara Motta Barbosa Valente[1], Vivian Dias Baptista Gagliardi[1], Rubens José Gagliardi[1]

[1]Santa Casa de São Paulo, São Paulo SP, Brazil.

Correspondence: Maria Clara Motta Barbosa Valente; Email: mariaclarambvalente@gmail.com.

Background: The safety of patients and improvement in medical care to minimize the occurrence of adverse events is a widely discussed topic. In neurological emergencies, stroke stands out as a major concern. The time from recognition of the event to the initiation of treatment is crucial for outcomes, considering morbidity and mortality. Due to the emergency environment, there is a higher propensity for adverse events. Therefore, continuous education for team training is of utmost importance. For adults, the learning process differs from children, as they need to understand the reasons for their learning, motivated by problem-solving and active involvement in the learning process; in this aspect, realistic simulation becomes relevant. **Objective:** To evaluate the effectiveness of Realistic Simulation as a teaching and training method for stroke care teams. **Methods:** For the conduction of this review,

the methodology proposed by the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) was used. Experimental studies of the type Clinical Trial, Quasi-Experimental, Cohort Studies and Case-Control studies were included; the study population was health professionals and the intervention was the use of Realistic Simulation as a training method in acute stroke care. The databases used were MEDLINE (PubMed), LILACS and Cochrane. The search was carried out in October 2023, by two independent evaluators, using the following search strategy: ("Realistic Simulation" OR "Simulation Training") AND ("Acute Stroke" OR Stroke). **Results:** A total of 159 studies were identified, of which 90 were selected and 17 included. Among the 17 studies evaluated, seven had the primary outcome of Door-to-Needle Time before and after team training through realistic simulation. All studies observed a reduction in Door-to-Needle Time, with some findings being statistically significant. Two studies assessed knowledge on the topic through pre and post-testing, both demonstrating an increase in score on the evaluation after training with Realistic Simulation. Another important concept addressed was Patient Safety, improvement in non-technical skills such as Leadership and Team Communication, which were also proven. Additionally, there was an improvement in personal perception of training capacity, greater learning of the topic, increased confidence in decision-making, and indication for thrombolysis. One of the limitations of this review was that, due to the diversity of study designs and primary outcomes, a meta-analysis was not performed. **Conclusion:** The results obtained through this systematic review allow us to conclude that training through Realistic Simulation for stroke patient care is associated with improved personal learning perception, acquisition of technical and non-technical skills, directly influencing important markers in acute stroke care, such as Door-to-Needle Time and higher thrombolysis rates.

https://doi.org/10.5327/CBN241403

Real-world experience with Fabry disease: case series in a neuromuscular center

Patrícia Marques Mendes[1], Renan Brandão Rambaldi Cavalheiro[1], João Paulo Barile[1], Kaliny Oliveira Peixoto[1], Wladimir Bocca Vieira de Rezende Pinto[1], Paulo Victor Sgobbi de Souza[1], Paulo de Lima Serrano[1], Igor Braga Farias[1], Acary Souza Bulle Oliveira[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Patrícia Marques Mendes; Email: patricia.marques.11@hotmail.com.

Case presentation: In order to investigate the clinical presentations of Fabry disease, 12 medical records were reviewed in a neuromuscular outpatient clinic. Of these, 7 were female, 5 were male and 8 of them had a similar family history. Patients had an average onset of neurological symptoms at 21 years of age with an interval of 17 years until diagnostic definition. The initial neuromuscular manifestations were burning pain (58%), shock pain (16%) and dysesthesia (25%), 66% of which were in the upper and lower limbs and 33% in the lower limbs. The pattern of involvement was mostly small fiber neuropathy (83%), and less than 10% manifested as ganglionopathy or sensorimotor polyneuropathy. The other associated disorders were fatigue (100%), neuropsychiatric disorders (91%), changes in intestinal habit (66%), migraines (66%), sleep changes (58%), abdominal pain (58%), angiokeratomas (51%), structural heart disease (41%), nephropathy (50%), cornea verticillata (50%), arthralgias (50%), anhidrosis or hyperhidrosis (41%), systemic arterial hypertension (33%), urinary incontinence (30 %), gastroparesis (25%), mild sensorineural deafness (25%), arrhythmias (25%), fever (25%), ischemic stroke (16%). Electroneuromyography was normal in the majority, but 25% had axonal sensory-motor polyneuropathy and less than 10% had sensory polyneuropathy. The findings on brain resonance were leukoencephalopathy (41%) and basilar doliectasis (16%). The mutations found in the alpha-galactosidase (GLA) gene were p.Asn34Asp (33%), p.Asp25fs* and p.Arg118Cys (16%), and p.His186Pro (8%). **Discussion:** Fabry disease is an X-linked sphingolipidosis caused by mutations in GLA that manifests predominantly in men from childhood onwards. Its morbidity is generated by the accumulation of ceramide-trihexoside in the walls of nerves and vessels, triggering systemic damage, which can then culminate in vascular diseases in addition to small fiber neuropathy. The diagnostic investigation begins with the measurement of the alpha-galactosidase enzyme in leukocyte cultures, which is reduced and is confirmed by genetic testing, and electroneuromyography may show normal or reduced sensory potentials. **Final comments:** In contrast to the literature, our patient sample consisted mainly of women, and the most prevalent manifestations were non-specific, such as fatigue, neuropsychiatric disorders and small fiber neuropathies, leading to a diagnostic delay of almost two decades. It is noted that specific findings such as angiokeratoma and cornea verticillata were present in only half of the patients. Since enzyme replacement treatment with agalactosidase-beta can offer clinical improvement and reduce morbidities when started early, we must pay attention to atypical presentations and optimize genetic investigation in small fiber neuropathies.

https://doi.org/10.5327/CBN241404

Reasons for ketogenic diet therapy discontinuation in pharmacoresistant adult epilepsy patients

Raque Alencastro Veiga Domingues Carneiro[1], Maiara Cristina de Lima[1], Mariana dos Santos Lunardi[1], Fernando Netto Zanette[1], Rosa Mendes Cardoso[1], Maria Teresa Salvador[1], Leticia Carina Ribeiro da Silva[1], Júlia Dubois Moreira[1], Débora Kurrle Rieger Venske[1], Katia Lin[1]

[1]Universidade Federal de Santa Catarina, Florianópolis SC, Brazil.

Correspondence: Raquel Alencastro Veiga Domingues Carneiro; Email: raquelalencastrov@gmail.com.

Background: Ketogenic diet therapy (KDT) is a well-established and effective nonpharmacologic therapeutic option for adult patients with pharmacoresistant epilepsy. However, this treatment may present challenges to compliance and adherence which need to be better understood to improve KDT protocols and develop new ways to aid patients in KDT. **Objective:** To describe the main reasons adult patients with pharmacoresistant epilepsy discontinued or did not initiate KDT. **Methods:** Adult patients with non-surgical amenable pharmacoresistant epilepsy were offered to initiate KDT protocol between 2018 and 2024 and were followed-up by a multidisciplinary team (Neurologists, Nutritionists, and Psychologists). Patients could discontinue the diet at any time, and the reasons for discontinuation were recorded. Patients who discontinued the diet before two years of completion or failed to initiate it were analyzed. The reasons for discontinuation were categorized into six groups: (1) Implementation (failure to maintain diet due to its restrictive nature and desire to eat forbidden foods); (2) Social (patients felt the diet negatively impacted their social activities); (3). Financial (diet was too costly to maintain); (4). Weight loss (patients were losing weight excessively); (5). Adverse events (ie, increase in cholesterol levels), 6. Unknown reasons (loss of follow-up). **Results:** A total of 21 participants (F = 10, Mean age = 36 years) were analyzed from a pool of 29 patients who were offered to initiate KDT between 2018 to 2024. Among total, only 2 patients (9.5%) did not start KDT and 5 patients (23.8%) interrupted the diet due to loss of follow-up (group 6). Most patients (33.3%) lost adherence due to the diet's restrictive nature (group 1), often reporting the desire to eat carbohydrates in greater amounts, difficulties to match the daily fat intake or the wish to drink alcoholic beverages. Even though the diet was specifically designed for each patient, some (14.3%) experienced excessive weight loss (group 2), and one patient (4.8%) presented a negative impact on cholesterol levels (group 5), raising concerns about his cardiovascular health. As to socio-economic impacts, one (4.8%) patient did not continue KDT because of social limitations (group 4) caused by the diet, especially at work over not being able to participate in collective meals, for example. A total of 3 patients (9.5%) reported the main adversity being financial reasons (group 3), in which the diet became too expensive to maintain. None of the patients discontinued the diet due to lack of effectiveness for seizure control. **Conclusion:** People with pharmacoresistant epilepsy undergoing KDT face challenges in treatment compliance mainly due to the diet's restrictive nature and cost, as well as its impact on social activities and work environments. Understanding these parameters can aid in the development of new strategies and alternatives so patients can better cope with KDT challenges.

https://doi.org/10.5327/CBN241405

Reccurent epilepsy seizures in carriers of a heterozygous variant of the PIGN gene

Lorena Emanuele da Silva Castro Oliveira[1], Sophia Calábria da Silveira[1], Fernanda Franklin Pedroso Moreira[1], Marilena Regina de Oliveira Vaz[1], Daniele Soares Vidal[1], Pietro Soares Motta[1], Iasmin Portela Maifrede[1], Bruno Jhonatan Costa Bordest Lima[2], Marcelo Maroco Cruzeiro[1], Danilo Jorge da Silva[1]

[1]Universidade Federal de Juiz de Fora, Juiz de Fora MG, Brazil.
[2]Universidade Federal do Mato Grosso, Cuiabá MT, Brazil.

Correspondence: Danilo Jorge da Silva; Email: danilomachadosilva@gmail.com.

Case presentation: Male child, born after uncomplicated pregnancy and cesarean section. No consanguinity history in the family. Patient presented with profound developmental delay. Initial symptoms were noticed at 2 weeks old, characterized by global hypotonia, seizures, and dysphagia. Seizure semiology included multiple events per day of head turning and tonic posture. Additionally, physical examination revealed shortened metacarpals, facial dysmorphisms, and horseshoe-shaped epiglottis on videolaryngoscopy. Initial investigation with cranial magnetic resonance imaging (MRI), transfontanelle ultrasound, and screening for inborn errors of metabolism showed no alterations. A variant classified as likely pathogenic in the PIGN gene c.283C> T and two mutations of uncertain significance in the CILK1 and CCSNK2A1 genes, all in heterozygosity, were detected. At his last evaluation, currently at 3 years old, patient had flaccid tetraparesis, significant cognitive impairment, and unmanageable epilepsy. New cranial MRI showed hypoplasia of the cerebellar vermis, hippocampus, and predominantly frontotemporal cerebral hemispheres. The hypothesis of Multiple Congenital Anomalies-Hypotonia-Seizures Syndrome type 1 (MCAHS1) was raised. **Discussion:** MCAHS1 is a rare genetic condition (1: 1,000, 000) associated with mutations in the PIGN gene, involved in glycosylphosphatidylinositol (GPI) anchor biosynthesis. The syndrome manifests with severe hypotonia, uncontrollable epilepsy, developmental delay, and varied congenital anomalies. The clinical extent of the disease depends on the severity of the PIGN mutation, with possible gastrointestinal malformations (including severe gastroesophageal reflux), global cerebral and cerebellar hypoplasia, diverse genitourinary and cardiac malformations, and facial dysmorphisms such as micrognathia and depressed nasal bridge. Diagnosis is confirmed by identifying mutations in the PIGN gene, typically in homozygosity, through genetic testing. However, there are reports in scientific literature of MCAHS1 associated with compound heterozygous mutations, considered of

uncertain significance in some databases but reported as possibly pathogenic in literature. **Final comments:** MCAHS1 is a underdiagnosed cause of epilepsy, which can lead to delayed diagnosis and initiation of appropriate support for affected individuals. It should be considered in cases of hypotonia and multi-organ/system malformations. This case report demonstrates a particularly atypical case with a clinical picture consistent with MCAHS1, extensive investigation excluding other syndromes, yet revealing a heterozygous mutation in the PIGN gene. Despite this unexpected genetic finding, diagnosis should not be dismissed. Presence of deep intronic variants, repetitive elements in the gene of interest, allelic dropout, and imprinting disorders are some examples of mechanisms that could explain the phenotypic manifestation in the absence of a clear molecular diagnosis.

https://doi.org/10.5327/CBN241406

Recurrence of epilepsia partialis continua on the opposite side after hemispherectomy: an uncommon yet severe outcome of focal cortical dysplasia

Samir Andres Ramirez Ojeda[1], William Alves Martins[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Samir Andres Ramirez Ojeda; Email: samir.ramirez@edu.pucrs.br.

Case presentation: At three months old, a girl began experiencing clonic spasms originating in her left hand, spreading to her left arm, face, and leg, sometimes accompanied by eye deviation to the left. Antiseizure drugs failed to control these spasms, which increased in frequency and occasionally progressed to TC seizures. EEG findings initially showed slowing in the right hemisphere, with frequent multifocal discharges evolving into a hemi-hypsarrhythmic pattern. MRI revealed mild hemispheric asymmetry with significant right-sided atrophy. By the age of two, she presented to our epilepsy surgery service with inability to speak and dependence on support for sitting. Physical examination indicated noticeable weakness on the left side. Subsequent MRI revealed multifocal cortical dysplasia and marked atrophy in the right hemisphere. EEG continued to depict intense epileptic activity predominantly in the right hemisphere, confirmed by PET-SCAN findings of reduced metabolism in that area. A decision was made to proceed with right hemispherectomy, initially resulting in partial control of seizure frequency. However, shortly after surgery, seizures recurred in her right arm and face. EEG demonstrated disorganized activity with a slow rhythm on the right and bilateral epileptiform discharges, more frequent in the left hemisphere. Histological examination confirmed focal cortical dysplasia. Despite adjustments in ASDs, her seizures persisted, highlighting ongoing challenges in managing her condition post-hemispherectomy. **Discussion:** Contralateral epilepsia partialis continua following hemispherectomy is a rare and complex clinical phenomenon. Hemispherectomy involves partial or complete removal of one cerebral hemisphere, typically performed for severe, medically refractory epilepsy originating from a single hemisphere. The goal is to eliminate the epileptogenic zone and achieve seizure control. However, in some cases, seizures may reappear in the contralateral hemisphere, presenting as contralateral EPC. This condition poses diagnostic challenges as it may mimic or coexist with residual or new-onset epilepsy following hemispherectomy. Diagnosis relies on comprehensive clinical evaluation, Video-EEG, and neuroimaging to assess post-surgical brain anatomy and identify any residual abnormalities. Long-term outcomes vary widely based on factors such as age at surgery, underlying epilepsy etiology, completeness of resection, and cortical reorganization extent. They range from successful seizure control to persistent epilepsy necessitating ongoing management. **Final comments:** Contralateral EPC following hemispherectomy underscores the complexity of epilepsy surgery and the potential for intricate post-operative seizure patterns. Continued research into mechanisms of contralateral epileptogenesis, along with advancements in surgical techniques and adjunctive therapies, is crucial to optimizing outcomes for patients with refractory epilepsy undergoing hemispherectomy.

Case presentation: A 71-year-old male patient began presenting in 2021 with mental confusion, psychosis, episodic and work-related amnesia, and epileptic seizures with brachiofacial dystonic presentation. He was hospitalized and underwent a lumbar puncture that showed normal cellularity (1 cell/mm3), hyperproteinorrhachia (108 mg/dl), non-reactive VDRL, culture for fungi and bacteria without alterations, negative oligoclonal bands, positive IgG index, and antibody panel with positive LGI1. Brain MRI showed signs of supratentorial microangiopathy. ECG showed diffuse disorganization of the basal activity with the presence of triphasic waves. He underwent pulse therapy with methylprednisolone, presenting partial improvement of symptoms, maintaining episodic amnesia and visuospatial disorientation. Given the incomplete response, it was decided to start pulse therapy with monthly cyclophosphamide for 3 months, with partial response. During hospitalization, neoplastic screening was performed, with no findings. Approximately 1 year after the onset of the first symptoms, the patient began to have nocturnal awakenings accompanied by visuospatial disorientation, mental confusion and epileptic seizures with the same initial pattern. Upon admission, the patient was disoriented in time and space and had high-frequency, low-amplitude distal tremor. During the initial laboratory investigation, hypokalemia was identified, which was corrected by enteral route. A cerebrospinal fluid puncture was performed, the result of which showed hyperproteinorrhachia (139.5 mg/dl), glucose (64 mg/dl) and 5 cells. After ruling out infectious causes, a new cycle of pulse therapy with methylprednisolone for 5 days was chosen, with significant improvement in symptoms. The patient is being monitored on an outpatient basis using immunosuppressive therapy with rituximab, with no recurrence of epileptic seizures, but with cognitive impairment. **Discussion:** Anti-LGI1 encephalitis is an autoimmune condition that usually presents with confusion, amnesia, cognitive decline, brachiofacial dystonia, and seizures with low response to anticonvulsants, with the possibility of progressive symptomatic onset with no signs in the cerebrospinal fluid or imaging. The LGI1 protein acts as a ligand for epileptic proteins such as ADAM22 and ADAM23. When the antibody binds to LGI1, it triggers a state of neuronal hyperexcitability, manifesting symptoms. Therefore, in most patients, immunomodulatory therapy tends to be effective. Approximately one-third of patients present relapses, which are more common in the first six months after therapy, predicting poor outcome. Most patients maintain cognitive deficit despite therapy. **Final comments:** The reported case presents the challenge of identifying and treating recurrent anti-LGI1 encephalitis after approximately 1 year of therapy. In addition, it portrays therapeutic management with improvement of the condition but with maintenance of cognitive dysfunction.

Recurrent encephalopathy with extensive brain lesions associated with mog antibody: a case report

Pedro Ferreira Bastos[1], Rafael Bastos Delgado[1], Regina Maria Papais Alvarenga[1], Marina Papais Alvarenga[1], Camille Freitas de Araujo[1], Gabriel Lisbôa Pereira[1]

[1]Universidade de Vassouras, Vassouras RJ, Brazil.

Correspondence: Pedro Ferreira Bastos; Email: pedroferreirabastos1@gmail.com.

Case presentation: Girl, 11 years old, brown, suddenly started aphasia and distal paresis in the right upper limb in February 2020 without previous neurologic episodes. Magnetic resonance (MRI) of the brain showed hypersignal on FLAIR and T2-weighted images with a digitiform edema pattern in the subcortical white matter of the frontal regions, more to the left, with slight hypersignal diffusion and areas of contrast enhancement with a perivascular/perivenular impregnation pattern. There were also small areas of hypersignal on T2-weighted and FLAIR sequences in the subcortical white matter of the parietal and temporal regions, with no hypersignal diffusion and no contrast enhancement, suggestive of ADEM. CSF unaltered. The patient progressed in 15 days with progressive improvement of aphasia. The examination was repeated after 2 months, demonstrating significant improvement of the lesions. Still, it showed a new lesion on the right parietal surface and a more extensive lesion involving the right temporooccipital subcortical white matter, consistent with new active lesions. Signs of optic neuritis were also observed on the left, with no further contrast uptake, and on MRI of the cervical and thoracic cords, no demyelinating plaques were identified. Pulse therapy (PST) was performed with methylprednisolone in a decreasing regimen (3 days in the first month, 2 days in the second month, and 1 day in the third month) in June, July, and August, with complete remission of symptoms. In 2021, without preventive treatment, she presented a focal seizure, went to the emergency room, and was released without treatment. In February 2022, the patient started a generalized seizure with a postictal state that evolved with somnolence and Brady psychism. After 1 week, she was admitted to three days of treatment with methylprednisolone with total improvement. She was seen for the first time at the referral center in Rio de Janeiro in June 2022, with no new neurological manifestations. She was investigated for the biological markers AQP4 and MOG. The result indicated negative AQP4 and positive MOG. The tests were repeated in December of the same year, confirming the findings. After this period, the patient again presented distal paresis of the right upper limb, alteration of coordination, and dysarthria. In 2023, she showed partial recovery of the deficit, without dysarthria and seizures, but maintained paresis in the right upper limb. **Discussion:** MOG-Ab antibodies were identified in NMO and ADEM negative for AQP4-Ab in 2011. Encephalopathy MOG-AB was described after 2017. In 2023, international criteria for the diagnosis of MOGAD were proposed for the first time, considering that the spectrum of the syndrome was broadening. **Final comments:** The presenting case met the diagnostic criteria for MOGAD. The core syndrome was encephalopathy with polyfocal deficit with an additional criterion of multiple lesions on MRI.

Recurrent hemorrhagic stroke with associated use of lurasidone: a case report

Isabella Beserra Ramos[1], Rebeca Talita de Souza Siqueira[1], Pedro Thiago Simões Ferreira[1], Neila Clediane de Sousa Menezes[1], Raíra Yana Lima Barbosa[2], Rita Di Cássia Oliveira Ângelo[2], Américo Danuzio Pereira de Oliveira[1,2]

[1]Hospital Eduardo Campos, Serra Talhada PE, Brazil. [2]Universidade de Pernambuco, Serra Talhada PE, Brazil.

Correspondence: Isabella Beserra Ramos; Email: isabellabeserramos@gmail.com.

A 45-year-old woman presented to the emergency department with a sudden and severe headache, accompanied by nausea, vomiting and dizziness. Despite the intense pain, she was fully conscious, alert, and showed no signs of neurological impairment. Her previous medical history included generalized anxiety disorder, scleroderma, obstructive sleep apnea syndrome. She was taking Desvenlafaxine and Alprazolam in previous consult. A week earlier before the symptoms it was prescribed Lurasidone because of the worst of the anxiety symptoms. A cranium CT scan revealed a dense area in the right parietal region. AngioCT of the intracranial vases was negative for aneurysm, arterial or venous malformation and thrombosis. She received conservative treatment, and her symptoms improved over a 5-day period, allowing her to reasume her regular medications. Three days after being discharged, she returned with a recurrence of similar headache symptoms and a new dense area on the opposite side, along with evidence of subarachnoid hemorrhage. Magnetic resonance angiography showed narrowing of the bilateral middle cerebral arteries. Analysis of cerebrospinal fluid indicated elevated red blood cells with normal glucose and protein levels. The onset of symptoms coincided with the recent introduction of lurasidone. Treatment with nimodipine provided pain relief, and lurasidone was discontinued upon discharge. Follow-up angioMRI after 60 days showed normal vascular findings. Reversible cerebral vasoconstriction syndrome (RCVS) is characterized by sudden, severe thunderclap headaches and focal narrowing of cerebral arteries. The global epidemiology of RCVS remains uncertain, likely underestimated, and predominantly affects middle-aged women. It can occur spontaneously or secondary to factors such as childbirth and medications affecting vascular tone. While the direct vasoactive effects of lurasidone are not well-established, antipsychotics like lurasidone can potentially influence vascular regulation through modulation of neurotransmitters. Lurasidone primarily antagonizes dopamine and serotonin receptors, with serotonin playing a role in regulating cerebral vascular tone, potentially contributing to vasoconstriction. Diagnosing RCVS requires differentiation from conditions like aneurysmal subarachnoid hemorrhage, necessitating a high index of suspicion. Treatment focuses on managing symptoms and preventing cerebrovascular complications. This case underscores the diagnostic challenges of RCVS and emphasizes the importance of investigating potential triggers, including psychotropic medications. Further studies are needed to fully elucidate any causal association between lurasidone and RCVS, demonstrating the need for a multidisciplinary approach to patients with complex neurological presentations.

Recurrent Takotsubo cardiomyopathy associated with recurrent status epilepticus: a clinical case report

Julia Costa Nacif Santos[1], Luna Lila Fernandes de Faria[1], Mariana Di Paula Rocha Rodrigues[1], Camila Mendes dos Passos[1], Rodolpho Poeys Lima[1], Lucas Vilas Boas Magalhães[1]

[1]Universidade Federal de Viçosa, Viçosa MG, Brazil.

Correspondence: Lucas Vilas Bôas Magalhães; Email: lvbmagalhaes@ufv.br.

Case presentation: A 63-year-old woman, diagnosed with epilepsy in 2002, was admitted to the emergency room (ER) in 2016 with prolonged tonic-clonic status following an episode of significant emotional distress. The patient went into respiratory depression, and an electrocardiogram was performed, showing diffuse ST-segment elevation. She was admitted in the ICU and underwent cardiac catheterization, which was suggestive of Takotsubo Cardiomyopathy. Sequential echocardiograms showed ventricles with normal systolic function and just a grade 1 diastolic dysfunction after 4 months from the episode. Patient's history revealed a similar episode of cardiogenic shock following status epilepticus in 2011. Catheterization performed in this first event showed left ventricle with antero-lateral-apical akinesia and increase in end-systolic and end-diastolic volumes, with no signs of arterial obstruction, which leads us to believe that was, in fact, her first episode of Takotsubo syndrome (TTS). In 2017, a new admission to the ER by TTS following a status epilepticus and emotional distress occurred, although early diagnosis and adequate treatment led to better evolution of the condition. **Discussion:** Takotsubo syndrome consists of an acute transient left-ventricular systolic dysfunction, typically triggered by a physical and/or emotional stressor. According to an International TTS Registry, neurological triggers account for 6.7% of TTS's admissions and seizures have been characterized as the second most common of those. Albeit the incomplete understanding of Takotsubo Cardiomyopathy, the sympathetic nervous system seems to play a pivotal role in its pathophysiology, and catecholamine release after seizures may explain the correlation between these two conditions. TTS occuring after seizures is more frequent in younger and male patients, they suffer less from chest pain, have a more serious course and have higher recurrence than other conditions. Furthermore, recent data from an international cohort on TTS showed an overall recurrence rate of 4.7%. Out of the 1402 patients, only 5 had more than one recurrent episode, and all of these had associated psychiatric and/or neurological conditions. Despite that, we haven't found, in our research, a description of these multiple recurrences or their triggers. This case describes the rare presentation of multiple recurrent episodes of Takotsubo syndrome, all triggered by both emotional and tonic-clonic status epilepticus. **Final comments:** There are very few multiple recurrent episodes of Takotsubo syndrome documented in literature. Neurologic comorbidities might be a predisposing condition for recurrence, and better characterization of neurologic triggers in patients presenting with multiple episodes of TTS might contribute to elucidate this association.

Red flags in dermatomyositis diagnosis: a pilot study

Pedro Nogueira Fontana[1,2], Alessandra Lima Nogueita Tolentino[1], Roseli Corazzini[1], Carolina da Cunha Correia[2], Nathalia Merten[1], Ana Marina Dutra[1], Igor Brockhausen[1], David Feder[1], Alzira Alves de Siqueira Carvalho[1]

[1]Centro Universitário Faculdade de Medicina do ABC, Santo André SP, Brazil.
[2]Hospital Universitário Oswaldo Cruz, Recife PE, Brazil.

Correspondence: Alessandra Lima Nogueira Tolentino; Email: ale.tolentino1994@hotmail.com.

Background: Dermatomyositis (DM) is classically defined as an inflammatory myopathy associated with typical rash, elevated creatine phosphokinase (CK) and characteristic patterns on muscle biopsy, such as inflammatory infiltrate, perifascicular atrophy (PFA) and positive immunohistochemistry (IHC) for myxovirus resistance protein A (MXA). However, some cases may be difficult to diagnose because they may present some atypical characteristics, such as normal CK levels and absence of inflammation or PFA on muscle biopsy. **Objective:** We present a series of cases with atypical morphological findings, in which it was possible to conclude a diagnosis of DM through MXA immunostaining. **Methods:** All cases presented proximal muscle weakness, DM skin lesions and positivity for MXA at IHC. All underwent serum CK measurement. Muscle biopsy was performed using previously described techniques; analysis included IHC for CD4, CD8, CD20, CD68, C5b9 and MXA. Immunostaining for MXA was performed in cases with unspecific findings on muscle biopsy and/or negative immunostaining for CD4, CD8, CD68 and C5b9 and/or normal CK. Typical cases of DM in which MXA was also positive were used as positive controls. **Results:** We identified 6 patients with these redflags, being 3 women, with a mean age of 37±8.85 years old. Median CK was 146.5 IU/L, ranging from 77 to 15.220 IU/L; 5 cases had normal CK. 4 cases were using immunossupressive treatment at biopsy time (mean time: 2.8 months). At muscle biopsy, 2 cases had no PFA, 4 cases had no CD4 and 5 cases had no CD8 inflammatory cells, 2 cases had negative immunostaining for MHC-I, 3 cases had no expression of C5b9. In the comparison group, there were 5 women and 1 men, with a mean age of 51±16 years old. Median CK was 2402, ranging from 390 to 7000 IU/L; all cases were using immunossupressive treatment at biopsy moment (mean time: 5.9 months). At muscle biopsy, 2 cases had no PFA and 1 case had no CD4 inflammatory cell. All cases had MHC-I, CD8 and C5b9 expression. In both groups, all cases were positive for MXA immunostaining. **Conclusion:** We demonstrate that, in the absence of classical pathological criteria and normal CK values, IHC for MXA can be a valuable diagnostic tool due to its high specificity for DM (98-100%), despite a reported sensitivity of around 70%. Imunossupressive treatment does not seem to influence MXA immunostaining. In the absence of such characteristics, MXA immunostaining should be included to confirm DM diagnosis. More studies are necessary to confirm our results.

Refractory chronic inflamatory demyelinating polyneurophaty (CIDP) syndrome in a pregnancy patient: a case report

Pedro Henrique Queiroz de Oliveira[1], Guilherme Menezes Mescolotte[1], Maria Teresa Fernandes Castilho Garcia[1], Ana Caroline Kuniochi[1], Elaine Fernanda Dornelas de Souza[1], Guilherme Eugênio Gil[2], Mayara Zavatini Cansini[1]

[1]Universidade do Oeste Paulista, Presidente Prudente SP, Brazil.
[2]Universidade de Marília, Marília SP, Brazil.

Correspondence: Pedro Henrique Queiroz de Oliveira; Email: pedroqueiroz@unoeste.edu.br.

Case presentation: Female, 22 years old, presented to the Emergency Care Unit in July 2023 with paresthesias and loss of strength in the lower and upper limbs, with caudo cranial evolution, areflexia and frequent falls. No comorbidities were related. She was referred to a tertiary service with normal cranial tomography. Cerebral spinal fluid had 5/mm^3 lymphomononuclear cells, and 140mg/dL of proteins. The hypothesis of Guillain Barré Syndrome was made, she was treated with 2g/kg of immunoglobulin in the Intensive Care Unit, with improvement, and was discharged and returned to outpatient care. She returned in 2 months with sudden tetraparesis and difficulty swallowing and walking. During this hospitalization, electroneuromyography showed an active demyelinating process suggestive of CIDP. Methylprednisolone therapy (1g/day) was carried out for 5 days with improvement, the patient was discharged and prescribed continuous use of prednisone 20mg/day, until her return. In January 2024, she returned with complaints of tetraparesis and difficulty walking. Due to the pregnancy, it was decided with obstetrics to carry out treatment with immunoglobulin, however, it was not released. In two days the patient presented a progressive worsening of motor symptoms, and was decided to start methylprednisolone for 5 days. She improved and received prednisone 60 mg/day orally,

with almost no more symptoms. **Discussion:** CIDP is an autoimmune neuropathy that affects peripheral nerves and nerve roots, with a remitting-recurrent or progressive course of symmetrical weakness of proximal and distal muscles. It is identified by electrodiagnostic and/or pathological features of demyelination. For untreated patients with progressive worsening, treatment with intravenous immunoglobulin (IVIG), plasmapheresis or glucocorticoids is recommended. Glucocorticoids can be administered intravenously or orally and have been shown to be effective, being reduced once clinical stabilization is achieved. However, there is still little data regarding the course of CIDP in pregnant women and how to manage cases during pregnancy. **Final comments:** CIDP is a progressive, rare and sometimes disabling disease which, although it mainly affects men in adulthood, in the case presented, we observed a pregnant woman suffering from the same condition. There is still a lack of evidence as to the best course of action in these cases. This study makes a scientific contribution by presenting a rare and little-reported condition of CIDP during pregnancy, so that health professionals can better guide cases that present in the same way in their daily work.

[7]Universidade de Fortaleza, Fortaleza CE, Brazil.

Correspondence: Oliver Reiks Miyajima; Email: oliver.miyajima@aluno.uece.br.

Case presentation: A 14-year-old female diagnosed with (AML) began treatment with all-trans-retinoic acid (ATRA), presenting with headache and vision loss a few days later. Lumbar puncture revealed a cerebrospinal fluid (CSF) opening pressure of 52 cmH2O and no other abnormalities, confirming the diagnosis of intracranial hypertension . ATRA was stopped and acetazolamide was started. Magnetic resonance imaging (MRI) showed no abnormalities.There was initial improvement in pain intensity, but the patient had severe metabolic acidosis. Acetazolamide was switched to topiramate with reduction of headache intensity. Two weeks later ATRA was reintroduced and headache recurred with increased intensity. She was treated with opioids with little response and repeated LP revealing a persistently increased CSF pressure of 41 cmH2O. Despite very high CSF pressure, fundoscopy did not reveal papilledema. She completed 3 cycles of ATRA and received most of the fourth cycle before the medication was suspended to control the refractory intracranial hypertension syndrome. One month later, the patient reported improvement of headache and CSF opening pressure decreased to 26 cmH2O. She was able to achieve remission of AML. **Discussion:** Idiopathic intracranial hypertension (IIH) is defined as intracranial hypertension without changes in neuroimaging or CSF composition. This patient presented with IIH during treatment with ATRA and acetazolamide was administered in an attempt to control intracranial hypertension, without significant improvement. Only once ATRA was discontinued was IIH controlled. Despite very elevated intracranial pressure, papilledema was not observed. IIH is manageable and early intervention is essential in preventing persistent visual loss and other complications. Acute promyelocytic leukaemia (APL) is an aggressive subtype of acute myeloid leukaemia with the presence of retinoic acid receptors and a high response to ATRA, achieving remission rates of 100%. The pathophysiology of ATRA-induced intracranial hypertension is unclear. ATRA is thought to elevate intracranial pressure by altering choroid plexus and arachnoid villi composition, leading to enhanced CSF production and impaired absorption. In the context of ATRA-induced intracranial hypertension, withdrawal of ATRA therapy and reintroduction at lower dose alongside prophylactic administration of acetazolamide is a useful treatment approach, but this approach was attempted in this case and failed. Using topiramate and low dose ATRA, the patient was able to achieve remission. **Final comments:** Intracranial hypertension is a significant complication in Acute Myeloid Leukaemia patients in treatment with all-trans-retinoic acid. Early treatment can prevent long-term complications, such as persistent visual loss. Risks and benefits must be weighed when deciding whether to continue treatment with all-trans-retinoic acid in patients with intracranial hypertension.

https://doi.org/10.5327/CBN241414

Refractory post-herpetic anti-NMDA receptor autoimmune encephalitis: case report

Ellen Silva de Carvalho[1], Bruna Pereira Correia[1], Thire Baggio Machado Marazzi[1], Renato Ramon da Cruz[1], Soraia Fábio Ramos Cabette[1], Francisco Antonio Coletto[1]

[1]Hospital Unimed, Ribeirão Preto SP, Brazil.

Correspondence: Bruna Pereira Correia; Email: brunapereirac@hotmail.com.

Case presentation: An 18-year-old woman started experiencing irritability, progressing to headache, fever, and language alteration. Herpes Simplex Virus type 1 (HSV1) encephalitis was confirmed, and treatment with acyclovir was initiated in the hospital and continued on an outpatient basis. On the 8th day of treatment, she developed vomiting, focal epileptic seizure, and language alteration, leading to readmission and treatment for left temporal and insular focal structural epilepsy. During the investigation, left middle cerebral artery arteritis was identified, and pulse therapy with methylprednisolone 1g/day for five days was administered. Two weeks later, she was readmitted due to dysautonomia and behavioral and consciousness level changes. Fludrocortisone was started, resulting in improvement. However, she was readmitted a week later with mutism and oromasticatory movements, suspected of post-herpetic autoimmune encephalitis. Cerebrospinal fluid analysis revealed positive anti-NMDA antibodies. Pulse therapy was administered with 1g/day methylprednisolone for five days and human immunoglobulin infusion at 2g/kg over five days. Due to poor clinical response, rituximab 1g was given, repeated in 15 days. At discharge, she followed simple commands, moved all four limbs spontaneously (more on the left), and spoke single words. Ambulatory motor rehabilitation therapy was initiated, resulting in improvement, with fluent and mildly dysarthric speech, active limb movement, and return to previous instrumental activities. **Discussion:** Herpetic encephalitis is uncommon, with an estimated annual incidence of 2-4 cases per million. Clinical deterioration after herpetic encephalitis can occur due to viral invasion and autoimmune mechanisms. Anti-NMDA autoimmune encephalitis, though rare, is the most common autoimmune etiology in these cases, with HSV1 being identified as the primary associated virus. Managing these conditions requires a detailed approach considering both viral and autoimmune aspects, reflecting the evolving trends and diagnostic complexities in neuroinflammatory disorders. First-line treatment includes pulse therapy with methylprednisolone and intravenous human immunoglobulin or plasmapheresis. Second-line treatment with rituximab or cyclophosphamide is indicated for refractory cases. **Final comments:** The case report discusses the rare co-occurrence of HSV1 encephalitis and anti-NMDA receptor encephalitis, presenting a challenging clinical scenario. A positive clinical outcome was achieved through tailored treatment and collaborative interdisciplinary efforts, emphasizing the importance of ongoing surveillance and research in infectious and autoimmune encephalitis. This case underscores the intricate epidemiology and clinical challenges in post-herpetic anti-NMDA receptor autoimmune encephalitis, emphasizing the importance of ongoing research and vigilant management in infectious and autoimmune encephalitis conditions.

https://doi.org/10.5327/CBN241415

Regional epidemiological analysis and costs associated with admissions for headache in the unified Brazilian health system: notifications from 2019 to 2023

Ana Clara Lacerda Freitas[1], Giovanna Edméa Rosário Luthy Carletto[2], Jeová Fernandes Pereira[3], Guilherme de Andrade Ruela[4]

[1]Centro Universitário Funorte, Montes Claros MG, Brazil.
[2]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.
[3]Universidade Estadual do Tocantins, Augustinópolis TO, Brazil.
[4]Universidade Federal de Juiz de Fora, Juiz de Fora MG, Brazil.

Correspondence: Ana Clara Lacerda Freitas; Email: anaclf15@yahoo.com.br.

Background: Primary headaches are one of the most disabling and common neurological conditions around the world. Although general lifestyle factors such as poor diet, excessive stress and bad posture are known causes of headaches, other aspects of modern life such as smartphone use also affect headaches, contributing to the disorder and lack of focus that characterize presenteeism in the workplace. That way, it is important to understand headaches and their associated costs, as well as to define the most affected population profile. **Objective:** To describe the profile and hospital costs of hospitalizations for headache in each region of Brazil from 2019 to 2023. **Methods:** Ecological study carried out using data extracted from the SUS Hospital Information System (SIH/SUS) through the Department of Informatics of the Unified Health System (DATASUS). A descriptive analysis was carried out in Microsoft Excel, covering the variables number of hospitalizations, total cost spent, gender, race and region, from 2019 to 2023. **Results:** The data obtained indicate that 51,257 hospitalizations for headache were recorded in Brazil, with an accumulated cost of R$28,033,387.80. The Northeast Region recorded the highest number of hospitalizations, 30.9% of cases, and the highest volume of costs, R$11,081,078.73 (39.5%). In contrast, the North Region, with 8.3% of cases, had costs of around R$2,864,694.80 (10.2%), not representing the lowest costs despite the smaller number of cases. The Central-West Region had 5.8% of hospitalizations, with a cost of R$777,869.80 (2.8%), presenting the lowest costs and the smallest number of cases. It was observed that women, with 65.5% of hospitalizations, and the mixed race, with 44% of cases, were the most affected. Furthermore, there was a 13.6% reduction in hospitalizations in 2020 compared to 2019, followed by a recovery in subsequent years. Thus, the Northeast Region has the highest prevalence and highest costs associated with hospitalizations for headache. However, there are variations in terms of number of cases and costs between different regions, as well as racial disparities. **Conclusion:** The results obtained

in this study reveal a heterogeneous distribution of hospitalizations for headache in Brazil between the years 2019 and 2023, with a decrease of 13.6% in 2020, possibly due to the restrictions of the COVID-19 pandemic and changes in practices seeking medical care. These data indicate that there are regional differences in the profile of hospitalizations, access and treatment practices. The importance of public health policies that promote effective therapeutic practices and guarantee equitable access to health services is highlighted, with a focus on primary care, which plays a crucial role in preventing hospitalizations and improving quality of life.

Relapse comparison between parenchymal and non-parenchymal forms of Neuro-Behçet

Gabriel Samir Martins de Souza[1], Gabriela Abrahão Allioni[1], Guilherme Diogo Silva[1], Marcia Rubia Rodriges Gonçalves[1], Dagoberto Callegaro[1], Leandro T. Lucato[1], Rafael Alves Cordeiro[1], Gisela Tinone[1], Henrique Ayres Mayrink Giardini[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Gabriela Abrahão Allioni; Email: gabriela.allioni@hc.fm.usp.br.

Background: Neuro-Behçet (NB) refers to neurological manifestations associated with Behest disease, encompassing two main clinical and radiological presentations: parenchymal (e.g., brainstem encephalitis) and non-parenchymal (e.g., cerebral venous thrombosis) forms. Although NB is recognized as either monophasic or recurrent, there is limited data on relapse frequency in Latin-American patients and how distinct clinical and radiological presentations influence this risk. **Objective:** To determine the frequency of relapses in NB and assess whether the initial presentation in parenchymal or non-parenchymal form impacts this outcome. **Methods:** This is a retrospective observational study conducted at the tertiary academic referral outpatient clinic specializing in Behçets disease in São Paulo, Brazil. We reviewed medical records of patients diagnosed with NB from 2010 to 2021, according to the International Consensus of NB criteria. Data on relapse occurrence and clinical-radiological characteristics were collected to classify the initial NB presentation into parenchymal and non-parenchymal forms. Time to relapse was illustrated using Kaplan-Meier curves, and the log-rank test compared time to relapse between non-parenchymal and parenchymal presentations. **Results:** Thirty-one patients were included (48% male; 24 (77%) with parenchymal disease), with 20 (65%) experiencing recurrence during follow-up. All participants with non-parenchymal disease (n=7) had cerebral venous thrombosis. While half of NB patients experienced relapse within the first five years after presentation, the timing varied from one to ten years. Participants with non-parenchymal disease had a median time to relapse of one year compared to a median time to relapse of six years in those with parenchymal disease (p=0.043). **Conclusion:** Recurrence was observed in 65% of NB patients, time to relapse ranged from one to ten years, and occurred earlier in patients with non-parenchymal disease, particularly cerebral venous thrombosis. This study is ongoing.

Relapse frequency and predictors in immune-mediated hypertrophic pachymeningitis

Amanda Angulo Soares[1], Tarso Adoni[2], Guilherme Diogo Silva[2], Luiz Henrique Martins Castro[2]

[1]Universidade de São Paulo, Faculdade de Medicina, São Paulo SP, Brazil.
[2]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Amanda Angulo Soares; Email: anguloamanda@gmail.com.

Background: Immune-mediated hypertrophic pachymeningitis (IHP) is an inflammatory condition characterized by dura mater thickening, headaches, cranial nerve palsies, seizures, and focal deficits. Previous studies showed different recurrence rates of the disease, and little is known about prognostic factors for relapse. A deeper understanding of recurrence is necessary to guide optimal immunosuppressant strategies in IHP. **Objective:** To evaluate the frequency and time to the first relapse, and to identify potential clinical, radiological, and laboratory predictors of relapse in this patient population. **Methods:** This observational retrospective case series was carried out in a dedicated outpatient clinic for IHP in São Paulo, Brazil, followed from 2002 to 2024. We included consecutive patients with radiological or pathological evidence of pachymeningitis due to probable immune-mediated etiology, after excluding infection, neoplasm, and intracranial hypotension. Patients were divided into relapse (R) and non-relapse (NR) groups, according to occurrence of relapse until the last follow-up. We collected clinical, neuroimaging, and laboratory features from the initial or first available clinical presentation. Time to relapse was calculated using Kaplan-Meier curves. Variables that were significantly different between R and NR groups were compared to identify prognostic factors for relapse. **Results:** We included 78 patients, of whom ten (13%) had IgG4-related disease, 15 (19%) probable or definitive neurosarcoidosis, two (3%), systemic vasculitis, and one (1%), amyloidosis. Idiopathic pachymeningitis corresponded to 51 (65%) of cases. Relapse occurred in 43 (55%) patients. Median time to relapse was six years (range 0 to 17 years). Seizures at disease onset and C-reactive protein levels above 10mg/dL in presentation were associated with shorter time to release (p<0.05). **Conclusion:** In this consecutive single center series of IHP relapse was common, and associated with seizures and elevated C-reactive protein levels on initial presentation. Future studies should evaluate immunosuppressant use strategies, especially for those identified as higher relapse risk.

Relapse of neuromyelitis optica with atypical presentation of painful tonic spasms and area postrema syndrome: a case report

Juliana Magalhães Leite[1], Thaís Magalhães Lima Leite[2], Lucas Silva Barbosa Bezerra[2], Lívia Gonçalves Santos Costa[2], Ana Lívia de Andrade Rangel[2], Bianca Etelvina Santos de Oliveira[3], Matheus Saraiva Gurgel[4], Rafael de Sousa Andrade[4]

[1]Faculdade de Medicina Nova Esperança, João Pessoa PB, Brazil.
[2]Centro Universitário de João Pessoa, João Pessoa PB, Brazil.
[3]Fundação Centro Integrado de Apoio à Pessoa com Deficiência, João Pessoa PB, Brazil.
[4]Hospital Metropolitano Dom José Maria Pires, Santa Rita PB, Brazil.

Correspondence: Thaís Magalhães Lima Leite; Email: thaismlleite@gmail.com.

Case presentation: A 37-year-old female patient, diagnosed with anti-aquaporin-4 antibody positive Neuromyelitis Optica Spectrum Disorder (NMOSD) for 4 years, was on prednisone and azathioprine. She had sequelae from previous relapses, including grade IV+ paraparesis of the lower limbs and visual acuity loss in the left eye due to optic neuritis. Ten days prior to hospitalization, she began experiencing recurrent painful contractions in the left upper limb, described as mild internal shoulder rotation, forearm pronation, and wrist flexion lasting a few seconds with spontaneous improvement, without loss of consciousness. Three days later, she developed intractable nausea and vomiting, exacerbated postprandially. A cranial MRI revealed subtle signal alterations affecting the deep white matter of the corona radiata, posterior limbs of the internal capsules, and the periaqueductal region, showing hyperintensity in T2/FLAIR sequences without diffusion restriction or contrast enhancement. Additionally, a localized alteration was noted on the posterior surface of the medulla in the right median/paramedian area corresponding to the area postrema. Extensive cervical hyperintensity in T2/FLAIR sequences extended from C3-C4 to C6-C7, and another lesion with similar characteristics from D4-D5 measuring 2.8 cm without contrast enhancement. The patient underwent immunoglobulin therapy and was started on carbamazepine and antiemetic medications. She showed partial improvement in painful spasms and complete resolution of nausea and vomiting. **Discussion:** The presence of intense pain associated with tonic limb posture characterizes painful tonic spasms (PTS) or paroxysmal dystonia, common in NMOSD patients. Additionally, the area postrema syndrome, presenting with intractable nausea and vomiting, is a clinical syndrome that can occur in NMOSD. However, the onset of a relapse with the acute association of area postrema syndrome and painful spasms is atypical. Thus, recognizing this presentation is crucial for the early treatment of NMOSD relapses, preventing sequelae, and improving the patient's quality of life. **Final comments:** The onset of a relapse with the acute association of area postrema syndrome and painful spasms is atypical and rare. Therefore, recognizing this presentation is essential for the early identification and treatment of NMOSD relapses, preventing sequelae, and enhancing the patient's quality of life.

Relapse rate and associated factors in multiple sclerosis: a Brazilian cross-sectional study

Nara Samara Silva dos Santos[1], Júlia Xavier Oliveira[1], Alex de Cerqueira Silveira Figueiredo[1], Maria Eduarda Messias Vassoler[1], Milena Fernandes de Oliveira[1], Luana Araujo Passos[1], Caio Fontes do Nascimento[1], Marcos Paulo Rodrigues Oliveira[1], Bruno Bacellar Pedreira[2]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.
[2]Hospital Universitário Professor Edgard Santos, Salvador BA, Brazil.

Correspondence: Nara Samara Silva dos Santos; Email: nara.samara@ufba.br.

Background: Multiple sclerosis (MS) relapses are episodic exacerbations of neurological signs and symptoms lasting at least 24 hours in the absence of infection or fever. Although relapses help form part of the diagnostic criteria for MS, their incidence increases the chances of worse outcomes throughout the disease course. Therefore, identifying factors related to the occurrence of more relapses provides an opportunity to enhance disease management and improve functional outcomes. **Objective:** To investigate risk factors associated with relapse incidence in MS patients. **Methods:** This cross-sectional study was conducted on patients primarily diagnosed with RRMS based on the McDonald criteria, carried out from July 2021 to May 2024. Clinical and demographic characteristics were obtained through interviews and medical records review at a reference center in Bahia, Brazil. The relapse rate was stratified based on quartiles in three different groups: individuals experiencing a single relapse (0-50), those with 2 or 3 relapses (50-75), and those with 4 or more relapses (75-100). After checking the prerequisites, ordinal regression was performed to analyze the association

between sex, race, comorbidities, illness duration, visual and sensory symptoms at first relapse, diagnosis delay (>3 months), and the incidence of relapses before and after the MS diagnosis. **Results:** A total of 270 individuals were selected, of whom 87 (32.2%) were female. The median age at admission was 37.50 (29-46.25) and at disease onset was 30 (22-38). Of the patients included in the analysis, 73 (27.0%) had only one relapse, 117 (43.3%) had 2 or 3 relapses and 80 (29.6%) had more than 3 relapses. As for the clinical course, 268 had relapsing-remitting MS (RRMS) and 2 had secondary progressive MS (SPMS). In the ordinal regression, illness duration (OR 1.008 [95% CI 1.005-1.012], p=0.000) and visual symptoms at disease onset (OR 1.946 [95% CI 1.203-3.148], p=0.007) were the factors associated to a higher incidence of relapses, while younger age at onset (OR 0.957 [95% CI 0.935-0.979]) was related to fewer relapses (p=0.000). **Conclusion:** In this study, a longer time of illness was an important risk factor in the incidence of relapses, which is understandable, given the greater exposure to pathological activity. The impact of initial visual symptoms as a factor related to a higher relapse rate may point to optic neuritis as an indicator of a worse disease course, highlighting the importance of not neglecting it in clinical assessments and the need for more targeted studies to better understand this relation.

Relation between childcare centers and neuropsychomotor development: an experience report from the "conviver" project

Amanda Mendes Santos[1], Elzilaine Domingues Mendes[1]

[1]Universidade Federal de Catalão, Catalão GO, Brazil.

Correspondence: Amanda Mendes Santos; Email: amanda.mendes@discente.ufcat.edu.br.

Background: Neuropsychomotor development is the result of various factors, including environmental ones. In this context, childcare centers promote socialization and are a space where children are introduced to language. At daycare, children make significant progress in their cognitive, emotional and motor development, as long as they are properly stimulated. There are, however, restrictions on the presence of health professionals in these spaces, who could help with early detection of risks of developing diseases, such as neurological ones. **Objective:** To report the experiences and observations made in a daycare center and the impact on children's development. **Methods:** In a daycare in a Brazilian municipality, weekly visits were made, lasting 2 to 3 hours during one semester. The classrooms observed were pre-school (children aged 2 to 4), and kindergarten (children aged 4 to 6). The actions belong to the "Conviver" extension project, which aims to detect developmental problems and promote children's health. **Results:** The project allowed the observation and contact with educators and children, in a space where they are far from their guardians. In each classroom, there was a teacher/caregiver and an assistant with incomplete secondary education. However, due to the large number of students, the caregivers were overworked and consequently imposed too many rules and limits, as well as being exclusively concerned with essential biological functions such as hygiene, feeding and sleep. There were no educational activities or games that could stimulate the children at an early age, mainly due to the teachers' working conditions. Children's interaction with their peers was also not encouraged, nor were group activities. In this sense, limitations in locomotion, socialization difficulties and deficits in language acquisition were noted among the children. It is worth noting that in all the classrooms, at least one child needed special care or was suspected of having neurodevelopmental disorders, such as autism spectrum disorder. In addition, another factor that possibly influenced the behavior and hindered the neuropsychomotor development of the children was the constant presence of the television on, exceeding the recommended daily hours for each age group. This meant that the children often stopped interacting and playing in order to watch TV programs. **Conclusion:** There was an excessive use of screens and a lack of stimuli, due to the overload of work by the staff, which leads to difficulties in socialization and neuropsychomotor development. Therefore, it can be concluded that the daycare space is extremely important for the child's development and could be improved, including hiring more teachers, in order to contribute to the child's integral health. The observations made in these places are fundamental for screening for signs and symptoms of possible psychopathologies and deficits in neuropsychomotor development, thus enabling early interventions.

Relationship between anxiety and stroke: experience report from the world stroke campaing

Fernanda Liborio Pereira de Paula[1], Ana Carolina Chagas Alves da Silva[1], Euclair Benedito Cremasco[1], Sinesio Grace Duarte[1], Marina Rodrigues de Oliveira[1]

[1]Universidade de Franca, Franca SP, Brazil.

Correspondence: Fernanda Liborio Pereira de Paula; Email: fer2004fernandafer@hotmail.com.

Background: Stroke occurs when cerebral vessels become obstructed or ruptured, depriving brain tissue of nourishment. This is associated with various risk factors, including atherosclerosis, smoking, and hypertension, which in turn is correlated with generalized anxiety disorder making them related to stroke either directly or indirectly. **Objective:** To draw a parallel between generalized anxiety disorder and stroke in order to deepen research on such prevalent topics in today's world. **Methods:** From 2021 to 2023, in the month of October, stroke prevention campaigns were conducted. During these campaigns, risk factors, blood pressure, and glucose levels were assessed. The data was stored and analyzed to establish correlations. Additionally, searches were conducted in the PubMed, BVS, Elsevier ScienceDirect, and Scielo databases using the terms "high blood pressure and anxiety," "high blood pressure and stroke," and "stroke vs anxiety". **Results:** Anxiety disorder was found to be directly associated with stroke. Articles that relate anxiety to the uncontrolled management of chronic diseases such as hypertension, a factor already proven to be a risk for stroke, were found. Furthermore, during the campaign, blood pressure values were found to be above the reference value, already classified as stage 3 hypertension. **Conclusion:** Anxiety is a factor for the uncontrolled management of blood pressure, which leads to stroke and indirectly is an important risk factor. Moreover, as reviewed in the literature, this factor can directly result in stroke.

https://doi.org/10.5327/CBN241422

Relationship between motor and respiratory function in Duchenne muscular dystrophy patients

Karlla Danielle Ferreira Lima, Leandro Augusto de Almeida[1], Tatiana Ribeiro Fernandes[1], Marco Antônio Veloso Albuquerque[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Karlla Danielle Ferreira Lima; Email: karlla.dfl@gmail.com.

Background: Duchenne muscular dystrophy (DMD) is a genetic disease caused by a mutation in the DMD gene, leading to the inability to produce dystrophin in skeletal muscle. As a result, there is a progressive loss of skeletal muscles, leading to progressive muscle weakness that begins in early childhood in boys, progressing to severe disability and loss of gait in adolescence, progressive cardiomyopathy and respiratory failure. Motor scales are important assessments to monitor the deterioration of motor function in these patients, with the MFM-32 being one of the most used scales. The MFM-32 assesses proximal, distal and axial motor dysfunctions, across the broad spectrum of neuromuscular diseases. The percentage of correct answers on this scale progressively reduces with the loss of motor function and progression of the disease. Respiratory failure, a later manifestation of the disease, is assessed mainly with forced vital capacity (FVC) and progressively reduces as the disease progresses, beginning a decline around 10 years of age. **Methods:** This is a single-center prospective observational study, carried out at the Muscle Clinic of a reference center, from January 2022 to July 2023. Twenty-four DMD patients between 0-18 years of age were evaluated for the correlation between lung function and motor function. All patients underwent spirometry to quantify FVC% and for the application of the MFM-32, that consists of 32 items divided into 3 domains (D1, D2, D3). **Results:** Among 24 evaluated DMD patients, 14 were able to walk. The FVC mean was 95% for the walking patients and 78% for the non-walking. MFM-32 motor scale scores were 28% (± 33.4) on D1, 84.9% (± 19.7) on D2, 86.1% (± 13.2) on D3 and 60.8 % (± 20.4) in total domain. Patients in the non-walking group had lower scores in all domains of the scale, but the age had statistical significance correlation only in domain D1 (p=0.006). When comparing lung function with age, we observed a statistically significant correlation between age and FVC% (p=0.026, r=-0.45), demonstrating that the older the patient, the lower is FVC%. The results of the correlation between the assessment of motor tests using the MFM-32 scale (D1, D2, D3 and total D) with pulmonary function (FVC) showed statistical significance only between the categories D1 (p=0.005), D2 (p=0.031) and total D (p=0.011) with FVC. **Conclusion:** This study shows that the group of non-walking DMD patients had worse results in MFM and FVC%. Only D1, D2 and D total of MFM32 had a significant correlation with FVC. These findings confirm the close relationship between worsening motor function and progression of the ventilatory pattern, which is in line with other studies in the literature.

Relationship between the presence and subtypes of auras and extrahippocampal cortical and subcortical atrophy in patients with temporal lobe epilepsy associated with hippocampal sclerosis

Giovanna Gobbi Obalhe[1], Fernando Cendes[1], Luciana Ramalho Pimentel da Silva[1], Clarissa Lin Yasuda[1], Marina Koutsodontis Machado Alvim[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Giovanna Gobbi Obalhe; Email: g235613@dac.unicamp.br.

Background: Mesial temporal lobe epilepsy (MTLE), the most common form of focal epilepsy in adults, primarily stems from hippocampal sclerosis and affects the amygdala, thalamus, and entorhinal cortex. Seizures can initiate with brief focal perceptual events known as auras. **Objective:** This study explores the relationship between hippocampal and extra-hippocampal structural changes in MTLE patients with and without auras. **Methods:** 129 MTLE patients with unilateral hippocampal atrophy on Magnetic Resonance Imaging (MRI) were categorized into: (G1) exclusively autonomic auras, (G2) other auras (cognitive, emotional, sensory) with or without

autonomic auras, and (G3) no auras. Controls included 205 healthy individuals. MRIs were acquired using a 3T Achieva scanner with high-resolution 3D T1-weighted sequences and processed via Freesurfer 6.0 for subcortical volumes and cortical thickness in temporal regions and insula. We used SPSS Statistics V-26 for statistical analyses. We used the Chi-square test for categorical data and a generalized linear model with the Sidak post hoc test to analyze continuous data. Subcortical volumes included total intracranial volume as a covariate. We included age in the cortical thickness analysis based on the Akaike Information Criterion. **Results:** There were no significant age or sex distribution differences between patients and controls. G3 had 7.96±2.98 more years of epilepsy duration than G2. Subcortical volumetry showed atrophy in the thalamus ipsilateral to the seizure focus on all patients, with G3 showing further reduction than G1 and G2. The contralateral thalamus was reduced in G1 and G2 compared to controls and G3 compared to G2. The ipsilateral hippocampus was reduced in all groups compared to controls, with G3 additionally reduced compared to G1. The ipsilateral amygdala was reduced in G3 vs. controls and G2. The contralateral hippocampus and amygdala did not differ between patients and controls. Cortical thickness revealed ipsilateral middle temporal gyrus reduction in all groups, with G1 also showing contralateral reduction compared to controls. The ipsilateral superior temporal gyrus was reduced in all groups, with G3 also showing contralateral reduction vs. controls. Thickness reductions were observed only in the ipsilateral side: inferior temporal gyrus (G3 vs. controls), parahippocampal gyrus (G3 vs. controls and G1), and insula (G3 vs. controls). **Conclusion:** We identified group-specific structural changes. Only G2 and G3 had atrophy of the ipsilateral amygdala. All groups had atrophy of the ipsilateral hippocampus, thalamus, and the superior and middle temporal gyri, but it was worse in G3. In addition, G3 had more widespread atrophy, including the ipsilateral parahippocampal gyrus, insula, inferior and middle temporal gyri, contralateral thalamus, and superior temporal gyrus. In conclusion, MTLE patients with no auras had more pronounced and extensive extrahippocampal damage than those who reported auras.

Reliability of perfusion measured by non-contrast magnetic resonance imaging (arterial spin labeling) in patients with ischemic stroke: a systematic review and meta-analysis

Jéssica Borges Kroth[1], Suzete Nascimento Farias da Guarda[2,3,4], Adriana Bastos Conforto[5]

[1]Universidade de São Paulo, São Paulo SP, Brazil.
[2]Harvard Medical School, Massachusetts General Hospital, Boston, USA.
[3]D'Or Institute for Research and Education (IDOR).
[4]Universidade Federal da Bahia, Salvador BA, Brazil
[5]Universidade de São Paulo, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Jéssica Borges Kroth; Email: jessicakroth@usp.br.

Background: Magnetic resonance imaging (MRI) with pseudocontinuous arterial spin labeling (PcASL) is a non-invasive technique that quantifies cerebral blood flow (CBF) and other hemodynamic parameters as hypoperfusion volume, diffusion/perfusion mismatch volume and mismatch ratio. It is possible to monitor these parameters in hours or days, without use of radiotracers or contrast, compared to dynamic susceptibility contrast (DSC), computed tomography (CT) perfusion and positron emission tomography (PET-Scan). **Objective:** This systematic review aims to verify the test-retest reliability of the pCASL technique in measuring CBF and to compare hemodynamic parameters measurements with those obtained with PET-Scan, CT perfusion and DSC in patients with ischemic stroke. **Methods:** This study was carrie out according to the PRISMA protocol and registered on PROSPERO platform (CRD42024539509). Three databases were systematically consulted by two independent reviewers and 245 records were accessed. The risk of bias and methodological quality was evaluated by Quality Appraisal for Reliability Studies (QAREL) in test-retest studies and Quality Assessment of Diagnostic Accuracy Studies (QUADAS-2) in studies comparing PcASL and the other imaging tests. **Results:** Test-retest reliability was measured in one study, PcASL was evaluated against DSC in eight studies and PcASL was contrasted with CT perfusion in two articles. Test-retest reliability study was classified as low quality with a high risk of bias. Excellent reliability of CBF was found across all assessed cerebral regions, particularly in white matter. Most studies comparing DSC and PcASL showed low risk of bias and low concerns regarding applicability. A meta-analysis of relative CBF (rCBF) and hypoperfusion volume is ongoing; data synthesis was not possible for other hemodynamic parameters due to insufficient reported values. All articles that compared CT perfusion with PcASL had low risk of bias and low applicability concerns. CBF was the only outcome analyzed in both included studies, but missing data prevented summarization. The other hemodynamic parameters were analyzed in only one study, indicating excellent correlation between CT perfusion and PcASL using rCBF thresholds of less than 35 to 45% for hypoperfusion volume and less than 40% for mismatch volume. **Conclusion:** There was good to excellent test-retest reliability of PcASL technique in measuring CBF in ischemic stroke patients and correlation between PcASL and CT perfusion values for hypoperfusion volume and mismatch volume. However, more studies are needed to confirm this result. Comparison between rCBF and hypoperfusion volume obtained with PcASL and DSC is still under verification through meta-analysis.

https://doi.org/10.5327/CBN241425

REM sleep: definition and relevance

Gabriel Dalves Lauretti Betez[1], Antonio Augusto Faria Castro[1], Eduarda Antunes Giacometti[1], Nidia Ledur Muller[2], Catherine Arcaro Coghi[1], Larissa Rossetti Davanso[1], Isabela Moura de Oliveira[1], Enrico Saccomani Marcondes[1], Gabriela Lara[1], Maria Eduarda Zorer Meneghetti[1]

[1]São Leopoldo Mandic Araras, Araras SP, Brazil.
[2]Universidade de Rio Verde, Luziânia GO, Brazil.

Correspondence: Gabriel Dalves Lauretti Betez; Email: gabriel.betez@icloud.com.

Background: The stage of sleep known as REM is characterized by rapid eye movements, brain activity similar to wakefulness, and hypotonia. Since its discovery, it has been established that this phase is not merely a passive stage but is extremely important for memory consolidation, especially procedural and emotional memory. Moreover, it is strongly associated with emotions and brain development. Therefore, understanding what REM sleep is, its functions, and related areas of the nervous system is extremely important for medical practice to develop greater importance to a significant pillar of health: sleep. **Objective:** To review the evidence on the role of REM sleep in memory consolidation, emotional regulation, and physical health, highlighting the main brain structures involved and the impacts of deprivation of this sleep phase. **Methods:** This study is a narrative review. Research was conducted in the PubMed database, covering the period from 1969 to 2024. Keywords "REM sleep" and "memory" were used. Inclusion criteria involved studies addressing the role of REM sleep in memory consolidation, emotional regulation, and physical health.**Results:** REM sleep, or paradoxical sleep, is a crucial phase of the sleep cycle characterized by rapid eye movements, intense brain activity, and almost complete muscle atonia. Discovered in 1953, REM sleep revolutionized the understanding of sleep, showing it to be an active state with important functions for the brain and body. During this phase, the brain exhibits activity similar to wakefulness, essential for the consolidation of emotional and procedural memories. Deprivation of this phase can impair memory and the ability to learn new skills, increase irritability and anxiety. In the first months of life, REM sleep is predominant and vital for brain development, stimulating growth and plasticity. In adults, it plays an important role in creativity and problem-solving, facilitating the formation of new connections and insights. REM sleep is also associated with cellular recovery and tissue repair, being crucial for physical health. It regulates hormone production (cortisol). Furthermore, during REM sleep, the brain reorganizes information acquired during the day, facilitating learning and adaptation. Structures such as the brainstem, thalamus, and limbic system are activated during REM. Increased activity in various regions of the cerebral cortex during this phase explains vivid dreams and intense mental activity. **Conclusion:** Understanding the relevance of REM sleep is crucial for medical practice. This sleep phase is vital for memory, emotional regulation, brain development, creativity, and physical health. It activates important brain areas, facilitating learning and adaptation, as well as promoting cellular and hormonal recovery, essential for overall well-being.

Remarkable response to capecitabine, trastuzumab, pertuzumabe and radiotherapy in a woman with brain metastasis from breast cancer

Fernanda Lustosa Cabral Gomez[1], Roberto Sobocinski Castro[1], Ligia Henriques Coronatto[1], Natalia Silva Fernandes[1], Carolina Simão Martini[2] , Heloisa Aurora Cavalcante Soares de Melo[1], Adrialdo José Santos[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.
[2]Hospital Santa Paula, São Paulo SP, Brazil.

Correspondence: Fernanda Lustosa Cabral Gomez; Email: fernandalustosacg@gmail.com.

Case presentation: A 48-year-old woman was diagnosed with breast cancer following an investigation of a painful breast nodule. Anatomopathological and immunochemistry revealed an invasive carcinoma grade 3, negative for calponin, progesterone and estrogen receptors; and positive for p63 protein and HER2 expression. Systemic staging was unremarkable at the time of diagnosis. The patient underwent mastectomy and lymphadenectomy, along with adjuvant trastuzumab and paclitaxel therapy. Radiotherapy was not performed due to clinical complications at that time. One year later, systemic restaging revealed multiple metastasis (lungs, liver and brain). Brain MRI revealed multiple contrast enhanced and non-enhanced lesions suggestive of metastatic disease. Whole brain radiotherapy (WBRT) was performed (10 sessions, 3Gy each). Anti-HER2 therapy was started with trastuzumab and pertuzumabe, along with capacitabin. Radiological response two months after WBRT and one month after introduction of target therapy was remarkable. The patient is currently asymptomatic and being followed up to assess maintenance of therapeutic response. **Discussion:** Breast cancer (BC) is the second most common cancer overall and approximately 30% of BC patients will develop brain metastasis (BM). Even though the prognosis and survival are typically lower in patients with BM, specific strategies have brought the possibility of better outcomes in this scenario due to the advent of targeted therapy. Trastuzumab is a monoclonal antibody directed against the extracellular domain of HER2. Usually, it does not cross the blood-brain-barrier (BBB) but, under impaired conditions, such as radiotherapy, trastuzumab levels in cerebrospinal

fluid increase. Preclinical studies also demonstrated the role played by trastuzumab as a radiosensitizer. Pertuzumab is a humanized monoclonal antibody that inhibits the dimerization of HER2 with other HER receptors. Our patient underwent therapy with Trastuzumab, Pertuzumab along with Capacitabin, a tumor-activated fluoropyrimidine carbamate with high activity in metastatic breast cancer. As for local treatment for BM, surgical resection is the standard treatment, but in our case the high number of lesions favored the use of WBRT. Symptomatic improvement with WBRT alone has been documented in 64-83% of patients, and median overall survival also improved. **Final comments:** In our case, we believe this remarkable response was due to radiotherapy increasing levels of trastuzumab and possibly contributing to a better effect of other targeted therapies; altogether with the evidence that trastuzumab enhances the effect of radiotherapy. It is possible that the high number of metastatic lesions also played a role in augmenting drug delivery through dysfunction of BBB. We have yet to observe if this imaging response will translate into more disease-free time, however our case highlights an exciting finding for future studies on combination of WBRT and targeted therapies.

https://doi.org/10.5327/CBN241427

Renal biomarkers in the evaluation of patients with hereditary amyloidosis related to ttr gene mutation

Lara Albuquerque de Brito[1], Cleonisio Leite Rodrigues[2], Hermany Capistrano Freitas[2], Gdayllon Cavalcante Meneses[3], Alexandre Braga Libório[1], Raynrich Kevin Assis Lima[1], Fernanda Martins Maia Carvalho[1]

[1]Universidade de Fortaleza, Fortaleza CE, Brazil. [2]Hospital Geral de Fortaleza, Fortaleza CE, Brazil. [3]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Lara Albuquerque de Brito; Email: laraalb.brito@hotmail.com.

Background: Hereditary amyloidosis is a disease characterized by the accumulation of abnormal proteins called amyloids in body tissues, including the kidneys. Renal biomarkers detectable in blood and urine can provide information about the presence and severity of kidney involvement in various diseases. **Objective:** To evaluate renal biomarkers, such as NGAL, MCP-1, urinary creatinine, and nephrin, and endothelial biomarkers, including VCAM, ANG-2, and syndecan-1, in patients with hereditary amyloidosis associated with the TTR gene. Additionally, to detail the profile of these biomarkers, comparing them with a healthy population. Clinical findings, especially neurological and renal manifestations, will be described to assess the degree of disease involvement. **Methods:** In this cross-sectional study, we evaluated 25 patients with pathogenic mutations in the TTR gene, investigating renal biomarkers that may provide new information about ATTR-related nephropathy. The biomarkers evaluated include NGAL, MCP-1, urinary creatinine, nephrin, VCAM, ANG-2, and syndecan-1. The biomarkers were quantified using the ELISA method. **Results:** Urinary creatinine was observed to be reduced in patients with the TTR gene compared to the control group. Regarding MCP-1, no specific pattern was observed, with similar results found between patients and the control group. Concerning syndecan-1, 48% of patients with the TTR gene had values above 155, whereas in the control group, 26% had values above 100. It was noticed that VCAM values in patients with the TTR gene were below 1300 (84%), whereas in the control group, 100% had values above 1600. **Conclusion:** The study is still ongoing, and some biomarkers have not yet been analyzed. However, with the current data, we can already observe that renal biomarkers are important tools to stage hereditary amyloidosis in association with clinical symptoms. In patients studied with the TTR gene compared to the control group, clearer abnormalities were observed, particularly in the biomarkers urinary creatinine, syndecan-1 and VCAM. We hope that by the end of the research, it will be possible to identify biomarkers associated with the progression and severity of the disease. Furthermore, it is important to emphasize the significance of studies in this area to ensure better care and management for these patients.

Renal predictors of mortality in patients with wake-up stroke

Juliana Cerqueira Gomes[1], Aurea Maria Lago Novais[1], Marina Soledad Benitez Bitencourt[1], Renan Carvalho Castello Branco[1], Thaise Braga de Oliveira[1]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.

Correspondence: Juliana Cerqueira Gomes; Email: juligomesc5@gmail.com.

The literature indicates that renal function increases stroke risk and predisposes to poorer outcomes. Wake-up stroke patients often miss the thrombolysis window, potentially worsening outcomes. The association between renal function and mortality in wake-up stroke patients is not well-established. This cross-sectional cohort study aims to assess the influence of renal function on mortality in wake-up and determined ictus stroke patients. The data collected included prior renal insufficiency, dyslipidemia, diabetes, ASPECTS, atrial fibrillation, sex, obesity, alcohol use, smoking, hypertension, admission, peak, and discharge creatinine and urea levels. The outcome was death during hospitalization. Univariate analysis was performed using T-test/Mann-Whitney/chi-square tests, followed by multivariate logistic regression (p< .05).A total of 451 patients were evaluated, of which 23% were diagnosed with wake-up stroke. Among the wake-up stroke patients, the following pre-existing characteristics were observed: 52% were male, 12.5% had obesity, 19% had a history of alcoholism, 20% were smokers, 65% had hypertension, 30% were diabetic, 2% had renal insufficiency, 3% had atrial fibrillation, and 10% had dyslipidemia.Regarding renal function markers, wake-up stroke patients had a median creatinine level at admission of 1.0 mg/dL (IQR 0.85-1.2), while patients with definite ictus had a median of 1.0 mg/dL (IQR 0.83-1.2). The median peak creatinine was 1.1 mg/dL (IQR 0.9-1.4) in wake-up stroke, compared to 1.2 mg/dL (IQR 0.9-1.5) in definite ictus patients.The median discharge creatinine was 1.06 mg/dL (IQR 0.8-1.2) in wake-up stroke, compared to 1.03 mg/dL (IQR 0.9-1.1) in definite ictus patients.As for urea levels, the admission values had similar medians of 34 mg/dL (IQR 26-47) between the groups, while the peak values had medians of 39 mg/dL (IQR 33-77) for wake-up stroke and 48 mg/dL (IQR 33-72) for definite ictus patients. At discharge, the urea medians were similar between the groups, with 36 mg/dL (IQR 25-48) for wake-up stroke and 36 mg/dL (IQR 27-50) for definite ictus.In univariate analysis, there was a significant difference for previous dyslipidemia (p=0.01) and the ASPECTS score (p=0.04, median 9, IQR 7.5-10). In multivariate analysis, the ASPECTS score (p=0.06; OR=1.2, 95% CI 0.9-1.6) and the discharge urea levels were identified as independently associated with patient mortality (p=0.01; OR=1.01, 95% CI 0.98-1.05).Renal function, particularly discharge urea levels, predicted mortality in wake-up stroke patients. Despite similar median urea values between wake-up stroke and definite stroke groups, discharge urea levels independently correlated with mortality, reasons for which are not fully understood.Additionally, a higher ASPECTS score was associated with a 1.2-fold increased risk of death in wake-up stroke patients.This study underscores the significance of discharge urea levels as a critical prognostic indicator in wake-up stroke patients.

Renal predictors of mortality in stroke patients with risk of obstructive sleep apnea: a transversal study

Juliana Cerqueira Gomes[1], Aurea Maria Lago Novais[1], Marina Soledad Benitez Bitencourt[1], Renan Carvalho Castello Branco[1], Thaise Braga de Oliveira[1]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.

Correspondence: Juliana Cerqueira Gomes; Email: juligomesc5@gmail.com.

Renal factors are central in disease prognosis due to their modifiability. Despite extensive research on the link between stroke and obstructive sleep apnea (OSA), the influence of renal factors on outcomes remains unclear. This cross-sectional cohort study aimed to examine how varying OSA risks affect renal factors in stroke outcomes, including hemorrhagic transformation, delirium, infection, and mortality.Patients' OSA risks were assessed using STOP-BANG and SOS scores, with data collected on prior renal insufficiency and creatinine/urea levels at admission, peak, and discharge. Statistical analyses comprised univariate tests (T-test, Mann-Whitney, chi-square) followed by multivariate logistic regression (p<0.05). We obtained data from 434 patients (69% high risk with STOP-Bang and 50% with SOS).For the STOP-BANG, the median creatinine level at admission was 0.8 mg/dL (IQR 0.71-0.94) for low-risk patients and 0.9 mg/dL (IQR 0.77-1.22) for high-risk. The median creatinine level at discharge was 0.9 mg/dL (IQR 0.6-1.01) for low-risk patients and 1 mg/dL (IQR 0.7-1.4) for high-risk. The median peak creatinine level was 0.9 mg/dL (IQR 0.8-1.1) for low-risk patients and 1.4 mg/dL (IQR 1-2) for high-risk.Regarding urea levels, the median urea level at admission was 32 mg/dL (IQR 28-53) for low-risk patients and 31 mg/dL (IQR 25-53) for high-risk. The median urea level at discharge was 33 mg/dL (IQR 24-55) for low-risk patients and 44 mg/dL (IQR 26-82) for high-risk. The median peak urea level was 55 mg/dL (IQR 31-81) for low-risk patients and 63 mg/dL(IQR 36-113) for high-risk patients.Univariate analysis showed admission, peak and discharge creatinine (p<0.01), as well as urea admission (p=0.05), discharge (p<0.01), and peak (p=0.001) were significant. For SOS score, discharge urea levels differed significantly (p=0.02).Multivariate analysis for STOP-BANG found peak urea levels were significantly associated with mortality (p=0.01;OR=0.9, 95% CI 0.90-0.94) infection (p 0.01;OR=1.0, 95% CI 0.94-0.97) and delirium (p<0.01;OR 0.9 95% CI 0.95-0.98) with admission urea also linked to infection (p=0.04;OR=1.01, 95% CI 1.0-1.03). Also, diabetes was associated with delirium (p=0.03;OR 1.8 95% CI 1-3). For the SOS score, discharge urea was associated with mortality (p=0.02;OR=0.9, 95% CI 0.97-1.05), while admission urea (p=0.04;OR=1.0, 95% CI 1-1.03), peak urea (p<0.01;OR=0.9, 95% CI 0.94-0.97) and diabetes (p=0.03;OR 1.8 95% CI 1-3) were linked to delirium.Hemorrhagic transformation was not significant.High-risk patients exhibited better urea values at admission but worse at discharge, suggesting a physiological mechanism linked to OSA, possibly influenced by hypertension and increased metabolic waste, that may contribute to worse outcomes.The analysis indicates that high urea levels, including discharge levels may act as protective factors against certain complications. Additionally, diabetes is an established risk factor for worse post-stroke outcomes.

Repercussions of the use of oral contraceptives in women with migraine

Maria Eduarda Julião Leite[1], Artur Bruno Silva Gomes[1], Cesário Silva Souza[1], Maria Eduarda Dantas Arruda Silva[1]

[1]Centro Universitário de Maceió - Afya, Maceió AL, Brazil.

Correspondence: Maria Eduarda Julião Leite; Email: duddaleite1@outlook.com.

Background: Migraine is a disabling pain that can be associated with nausea, emesis and photo/phonophobia, lasting between 4 and 72 hours. This condition is three times more prevalent in women than in men, with a peak incidence (24%) occurring during the fourth decade of life. This is due to hormonal influences during the reproductive cycle, related to fluctuations in estrogen levels. **Objective:** To analyze the repercussions of oral contraceptive (OC) use in women with migraine. **Methods:** This is a cross-sectional observational case-control study carried out on a sample (n=25) of females aged between 18 and 60 over a 12-month period at the Doctor José Lages Filho Teaching and Care Unit (UDA) of the Centro Universitário de Maceió, Alagoas. The Migraine Disability Assessment (MIDAS) questionnaire was used to quantify the disability caused by headache over a 3-month period. The results were classified into 4 levels of severity. Level I - minimal or infrequent; level II - medium; level III - moderate and level IV - severe. Inclusion criteria: women with migraine without aura, of childbearing age and in the climacteric period, followed up at the UDA. Exclusion criteria: women using other hormonal contraceptive methods and smokers. It was approved by the Research Ethics Committee, under Certificate of Presentation for Ethical Appraisal: 70105023.2.0000.5641 and opinion: 6.163.274. **Results:** Of the 25 women interviewed, 12 were selected to be part of the sample and 13 were excluded because they had migraine with aura. Of the sample, 66.7% had used OACs at some point in their lives but did not currently use them; 25% had never used them and 8.3% used them continuously. Of the patients evaluated, 44.4% of them reported worsening of their attacks during the period in which they were using OCPs; 62.5% mentioned improvement after stopping the drug and only 25% showed worsening after stopping it. No patient reported an improvement in migraine attacks while taking the OCP. In the assessment of the disability caused by the headache, it was observed according to the MIDAS classification that 33.3% were categorized as grade I and II; 16.7% as grade III and IV, respectively. The study's limitations involved patients after menarche, as the sample only included women over 18 years of age and did not include women in the postpartum period. **Conclusion:** The group investigated showed that women who had never used OCPs or had already used them and had stopped or were post-menopausal had less disabling migraine attacks than patients who were using the drug. Those who were using OCP showed a worsening of their attacks, which indicates that OCP acts as a potentiator of migraine. It was also observed that post-menopausal women had the lowest rates of disability compared to menopausal women.

Report of a series of patients with mosaic trisomy 18: Edwards syndrome

Maria Fernanda Peruci Felippe[1], Viviane Müller[1], Fabiana Dolovitsch de Oliveira[1], Pedro Lorenzo Neves da Silva[1], Roberta Beiser de Medeiros e Albuquerque[1], Aline Deborah de Moraes[1], Maria Eduarda Corrêa Pereira[1], Rafaela Gageiro Luchesi Soares[1], Amanda Vieira Alves[1], Thiago Menezes Cézar[1]

[1]Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre RS, Brazil.

Correspondence: Maria Fernanda Peruci Felippe; Email: maria.felippe@ufcspa.edu.br.

Background: Trisomy 18 (T18) Edwards syndrome is characterized by a broad and variable clinical picture, usually associated with neurological symptoms and a poor prognosis. **Objective:** This abstract aims to describe the clinical findings of a sample of patients with mosaic T18. **Methods:** The clinical and cytogenetic findings of patients with mosaic T18 were evaluated in a Clinical Genetics Service from 1975 to 2008. All cases were diagnosed in the service's laboratory through karyotyping from peripheral blood samples. **Results:** During the study period, 50 patients were diagnosed with T18, 5 of which (10%) had mosaicism. The average number of cells analyzed was 27,8. The percentage of cells in the lineage with T18 ranged from 9 to 87%. Three of the 5 patients (60%) were male. Age at assessment ranged from 14 to 5,926 days (median 93 days). Attention was drawn to the small number of clinical findings described, both in the dysmorphological assessment and through complementary imaging exams. The main changes observed were micrognathia (n=3), low-set (n=2) and retroverted ears (n=3), clenched fists with overlapping fingers (n=2) and congenital clubfoot (n=1). Regarding internal organs, congenital heart disease was reported in 2 cases (40%), including one patient with tetralogy of Fallot. All patients had a history of delayed neuropsychomotor development. The older patient also presented cognitive deficits and seizures. **Conclusion:** The clinical presentation of our patients is consistent with that described in the literature, as they draw attention to the small number of alterations, including major malformations, such as congenital heart disease. However, neuropsychomotor delay and neurological symptoms are considered constant findings. Therefore, pediatricians and neurologists especially should be very aware of this possibility in their clinical practice.

Report of two new cases of the extremely rare Cluster-Tic syndrome

Cassio Mota Freitas da Silva[1], Hilton Mariano da Silva Junior[1]

[1]Pontifícia Universidade Católica de Campinas, Campinas SP, Brazil.

Correspondence: Cassio Mota Freitas da Silva; Email: cassiomotafds@gmail.com.

Case presentation: Case 1: A 72-year-old previously healthymandeveloped episodes of intense, stabbing pain in the right malar region of very short duration, without associated autonomic phenomena, triggered by touching, speaking, and chewing. He experienced pain remission after ten days of using carbamazepine. Soon after, attacks of intense pain began in the right frontotemporal and retro-orbital region, lasting 15 to 40 minutes, associated with tearing, hyaline coryza, eyelid ptosis, and ipsilateral nasal obstruction. The crises were not daily, but up to 3 episodes occurred in 24 hours. He presented significant weight loss and social isolation. A neurological examination during the interictal period and a brain MRI showed no changes. He was associated with verapamil and carbamazepine, progressing to remission of symptoms after three months. He has been followed for one year. Case 2: A 70-year-old woman started 25 years ago with episodes of intense stabbing pain in the right hemiface, lasting around an hour, associated with tearing, hyaline runny nose, and nasal obstruction, which showed a good response to the use of prednisone and verapamil. She remained asymptomatic for six years until the attacks returned and began to alternate with episodes of "shock pain" in the right malar region of strong intensity, without other associated phenomena, and lasting around 60 seconds. The radiological investigation was unremarkable. The patient had a good response to the combination of carbamazepine and verapamil. She has been followed up in our service for four years. **Discussion:** Cluster-Tic syndrome is a rare clinical condition characterized by cluster headaches associated with trigeminal neuralgia, with ipsilateral symptoms. In these cases, the maxillary division of the trigeminal nerve was affected, and there were similar symptoms of trigeminal neuralgia. It is noteworthy that the female patient had shock pain without associated factors, which is unusual in the classification of trigeminal neuralgia and for a much longer period than the male patient. Finally, is observed that the most efficient treatment of this is the combination of the drugs verapamil for cluster headache and carbamazepine for trigeminal neuralgia. **Final comments:** Rare and exceptionally debilitating, the syndrome that combines cluster headache and trigeminal neuralgia represents a profound challenge in the field of neurology. Both conditions are independently recognized as among the most painful disorders known to medicine.The first case suggests that the cluster headache appeared due to unsuccessful treatment of trigeminal neuralgia, given the short time interval between the appearance of symptoms. On the other hand, the second case indicates a lack of interrelationship between them due to the long asymptomatic period and the alternation of symptoms. Thus, our two new cases report shed light on the discussion about the legitimacy of the hypothesis of common pathophysiology in this syndrome.

Background: Mild cognitive impairment (MCI) refers to the diagnosis of individuals between preserved cognition and dementia who have a decline in one or more cognitive domains (memory, attention, executive functions, language, perception, visuospatial skills) and are at risk of developing dementia. Stimulating increased mental activity has been shown to be beneficial in altering the course of disease progression. Therefore, non-pharmacological interventions such as physical exercise have been explored as a tool to promote cognition in older adults with mild cognitive impairment. The increase in muscle strength was correlated with better cognitive performance in elderly people with MCI and decreased risk of developing dementia in elderly with preserved cognition. Resistance training's main **Objective:** To increase muscle strength. Thus, this study aimed to compare the performance of elderly people with mild cognitive impairment on different cognitive tests before and after 24 weeks of resistance training. **Methods:** This investigation includes 22 elderly people aged 65.64±6.15 years old (11 men and 11 women) and with Mild Cognitive Impairment. The diagnosis was based on NIA-AA criteria, which include complaints of cognitive changes, evidence of impairment in one or more cognitive domains, preservation of independence in functional activities, and not meeting the criteria for dementia. The participants practiced 24 weeks of resistance training consisting of 3 sets of 10 repetitions in 10 exercises for a large muscle group twice a week and with an intensity of 80% of one maximum repetition. Participants were assessed for cognitive performance before and after 24 weeks of resistance training using the following tests: RAVLT (List A6 and B1), RAVLT Recognition, Rey Complex Figure (late recall), and Memory Complaint Scale. A neuropsychologist applied the tests, and the paired T-test was used for statistical analysis in the IBM SPSS Statistics 22 software.

Results: The comparison test between the baseline and the end of the intervention showed a significant difference in the RAVLT (List A6): p=0.04 and a tendency towards significance in the RAVLT Recognition: p=0.05. No other cognitive test show significant differences: RAVLT (List B1): p=0.78, Rey Complex Figure (late recall): p=0.82, Memory Complaint Scale: p=0.06. The statistical analysis was performed using the paired T test in the IBM SPSS Statistics 22 software. **Conclusion:** Resistance training favored the learning, recall, and recognition of episodic memory in elderly people with mild cognitive impairment, suggesting that resistance exercise is beneficial for the cognition of these individuals at increased risk of developing dementia.

Restless legs syndrome/Willis-Ekbom disease in Parkinson's disease: a cross-sectional analysis

Agatha Lopes Azedo[1], Diego Monteiro de Carvalho[2], Marcus Vinicius Della[3], Alvaro Siqueira da Silva[2], Marcello Facundo do Valle Filho[2], Raissa Costa Said[1], Emillaine Alves Noronha[1], Mariana Carvalho Ferreira[1], Yenly Gonzalez Perez[2], Carlos Mauricio Oliveira de Almeida[2]

[1]Universidade do Estado do Amazonas, Manaus AM, Brazil.
[2]Universidade Federal do Amazonas, Manaus AM, Brazil.
[3]Universidade Federal do Paraná, Curitiba PR, Brazil.

Correspondence: Agatha Lopes Azedo; Email: agathalopesazedo@gmail.com.

Background: Parkinson's disease (PD) is a neurodegenerative disorder that primarily affects the substantia nigra pars compacta and basal ganglia, leading to the characteristic motor symptoms of the disease: bradykinesia, resting tremor, and muscle rigidity. Sleep disturbances are present in 90% of patients with PD, commonly including excessive daytime sleepiness (EDS) and Restless Legs Syndrome (RLS). These sleep disorders contribute to a deterioration in quality of life, complicate the treatment of PD, and can worsen its prognosis. The validated Parkinson Disease Sleep Scale (PDSS-1) includes questions about sleep complaints in PD, with total scores ranging from 0 to 150, where higher scores indicate better sleep quality. Another widely used tool is the Epworth Sleepiness Scale (ESS), which assesses the presence of EDS through 8 items measuring the propensity for sleep in various daily situations. **Objective:** To analyse the prevalence of Restless Legs Syndrome in patients with Parkinson's Disease and their quality of life using the PDSS and ESS questionnaires. **Methods:** The study was approved by the local Ethics Committee under CAAE nº 58684622.2.0000.0007. This was an observational, cross-sectional study conducted at a referral hospital in Manaus, Amazonas, over a period of 24 months. Patients with Parkinson's Disease aged > 18 years, diagnosed according to the London Brain Bank criteria, were included, while patients with diagnoses of dementia, language disorders (aphasia, dysphasia), or speech articulation disorders (dysarthria, hypophonia) that precluded the application and understanding of the questionnaires were excluded. **Results:** Of the 63 individuals selected, 43 (68.5%) were diagnosed solely with PD and 20 (31.5%) had concurrent RLS. The average PDSS score was 74.8, with a median of 71. The mean PDSS score for patients with only PD was 80.1, while for those with both PD and RLS, it was 62.3. Regarding the presence of excessive daytime sleepiness among the 63 patients, 41 (65.1%) had EDS and 22 (34.9%) did not. Among those with EDS, 13 (31.7%) also had RLS, and 28 (68.3%) had only PD. Among patients without EDS, 7 (31.9%) had both PD and RLS, while 15 (68.1%) had only PD. The sample had a p-value of 0.782. **Conclusion:** There is a high prevalence of Restless Legs Syndrome/Willis-Ekbom Disease in patients with Parkinson's Disease. Overall, there is a decline in the sleep quality of patients, which is more pronounced in those with both diagnoses, as evidenced by the nearly 20-point decrease in PDSS scores between the two populations. Additionally, patients with PD tend to be sleepier, and the coexistence of both conditions further exacerbates this, as shown by the fact that within the PD and RLS group, the number of patients with EDS according to the ESS is nearly double those without EDS.

https://doi.org/10.5327/CBN241435

Rethinking hot cross bun sign: an uncommon finding on spinocerebellar ataxia type 2

Letícia Klabinske Marques Monteiro[1], Paulo Felipe Bezerra Silva dos Santos[1], Bruno Henrique Carneiro Costa Filho[1], Victor de Mores Chagas[1], Evelliny Gomes da Silva[1], Allefy Beltrão Albano[1], Ana Eunice Oliveira Rodrigues[2], Giovanna da Silva Gamba Dias[2], Miriam Carvalho Soares[2], Marcos Eugênio Ramalho Bezerra[1]

[1]Universidade Federal de Pernambuco, Hospital das Clínicas, Recife PE, Brazil.
[2]Universidade Federal de Pernambuco, Recife PE, Brazil.

Correspondence: Leticia Klabinske Marques Monteiro; Email: leticiaklabinske@gmail.com.

The hot cross bun sign is a neuroradiological MRI finding, best visualized in T2W or T2 FLAIR sequences, mostly associated with Multiple System Atrophy Cerebellar type (MSA-C). However, over recent years, various etiologies have been associated with this radiologic finding, including neurodegenerative, genetic, autoimmune, infectious, inflammatory, neoplastic, and vascular causes. Its association with spinocerebellar ataxias (SCA) is uncommon although well documented. **Case presentation:** We present two cases of female patients, sisters, aged 29 and 32 years, with progressive postural instability and imbalance since the ages of 21 and 22, respectively. They had no relevant past medical history, except their family history of five people with a similar disorder, including their mother, maternal grandfather, two uncles, and one cousin, suggesting a genetic disease with an autosomal dominant inheritance. Neurological examination of both patients included bilateral dysmetria, scanned speech, slow saccadic eye movements, postural instability, and broad ataxic gait. No parkinsonism or dysautonomia were reported. Their Scale for the Assessment and Rating of Ataxia (SARA) scores slowly worsened over time, indicating the progressive and degenerative nature of the disease. Brain MRI of both patients revealed the hot cross bun sign, along with cerebellar atrophy. Genetic evaluation of one of the sisters disclosed a CAG trinucleotide expansion in one allele of the ATXN2 gene (41 CAG repetition, with a normal range below 31), confirming spinocerebellar ataxia type 2 (SCA2) diagnosis. **Discussion:** Cerebellar atrophy is the most common radiological finding among SCAs. Other radiological changes in SCA patients may more commonly appear after about five years of the onset. Among SCA patients, the hot cross bun sign was most frequently seen in patients with SCA2 and has already been documented in types 1, 3, 6, 7, 8, and 34. The possible pathophysiological process for this finding is due to the atrophy of the pontine neurons and transverse pontocerebellar fibers, with preservation of the pontine tegmentum and corticospinal tracts. This alteration occurs regardless of the length of the CAG repeat expansion, with age-related atrophy mainly in SCA2 and SCA7, contributing to a higher prevalence in these subtypes. **Final comments:** Despite its close association with MSA-C, the hot cross bun sign is not pathognomonic to this etiology. The association of this sign with SCA2, although uncommon, must be considered in ataxia patients, particularly in cases with a positive history, slow saccades, and absence of parkinsonism or dysautonomia.

https://doi.org/10.5327/CBN241436

Retinal neurodegeneration and brain atrophy in patients with Chagas disease: a cross-sectional study

Catharina Ribeiro Lyra[1], Pedro Fernandes Abbade[1], Débora Nalígia Moraes Luna[2], Ana Beatriz Cazé Cerón[1], Bruno Felipe Santos de Oliveira[1], Graziele Carolina Araújo Soares[1], Bruna Helena Ribeiro Araújo dos Santos[1], Rebeca Souza Borges[1], Thiago Cerqueira-Silva[3], Jamary Oliveira Filho[1]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.
[2]Oftalmodiagnose, Salvador BA, Brazil.
[3]Fundação Oswaldo Cruz, Salvador BA, Brazil.

Correspondence: Catharina Ribeiro Lyra; Email: catharinarlyra@gmail.com.

Background: Chagas disease (CD) is associated with brain atrophy and cognitive impairment. Retinal optical coherence tomography (OCT) may be a noninvasive method to detect both outcomes but has not been previously studied. **Objective:** To investigate the association between retinal thickness and foveal vascular density with volumes of the central nervous system in patients with CD. **Methods:** Cross-sectional study performed in 2020-2024, with adult heart failure patients from a cardiology outpatient clinic in Salvador-Brazil. We excluded those with anticoagulants, metallic prostheses, cancer, chronic liver disease, dialysis, stroke, glaucoma, diabetes, or retinal diseases. CD was defined by a positive ELISA or immunofluorescence test in duplicate. Eligible participants underwent MRI to assess central nervous system (CNS) volumes using FreeSurfer software and manual counting of lacunar and territorial infarcts. Patients underwent OCT to evaluate macular, ganglion cell layer, and retinal nerve fiber layer thickness and the vascular density in the fovea at the superficial and deep plexus. OCT with quality <50% were excluded. We performed multivariate logistic regression between OCT parameters and CNS volumes, controlling for age, sex, CD, left ventricular ejection fraction (LVEF), and intracranial volume. **Results:** We included 36 participants with CD and 29 without CD. The CD group had more females (81% vs 55%) and preserved LVEF (81% vs 30%), but other clinical variables were similar. Foveal macular thickness was lower in patients with CD (230 vs 242 µm, p=0.02). Its reduction was associated with a decrease in the volume of the nucleus accumbens (β=0.62, p<0.01), putamen (β= 3.51, p<0.01), parahippocampal cortex (β=1.01, p<0.01), thalamus (β=3.53, p=0.01), cerebellum (β=17.34, p=0.01), globus pallidus (β=1.35, p<0.01), ventral diencephalon (β=2.1, p=0.01), lateral orbitofrontal cortex (β=1.32, p=0.04), and entorhinal cortex (β= 2.6, p< 0.01). The foveal vascular density in the superficial plexus was lower in patients with CD (13.4 vs 16.9%, p=0.022). Its reduction was associated with an increase in the volume of the posterior cingulate cortex (β=-4.84, p=0.03), and a decrease in the transverse temporal cortex (β=3.26, p=0.01), and the number of territorial infarctions (β=0.06, p=0.03). Foveal vascular density in the deep plexus was lower in patients with CD (26.6 vs 31.1%, p=0.031), and its reduction was related to a decrease in the volumes of the cortex in the following regions: caudal middle frontal (β=8.02, p<0.01), rostral anterior cingulate (β=4.26, p<0.01), superior temporal (β=8.85, p<0.01), lateral orbitofrontal (β=5.97, p<0.01), middle temporal (β=7.13, p=0.02), and superior parietal (β=15.27, p<0.01). **Conclusion:** Retinal thickness and foveal vascular density correlate with CNS volumes in patients with CD. This contributes to the understanding of the effects of CD in the CNS and might be used as an easy, quick and noninvasive marker of brain atrophy.

Retrospective analysis of data from thrombectomies performed from january to march 2024 in a public hospital in João Pessoa/PB

Gilmar Leite Pessoa Filho[1], Ana Luisa Castelo Branco Gomes[1], Felipe Nunes de Araújo[1], Luciano Gonçalves do Nascimento Júnior[1], Rafael de Souza Andrade[1], Juliana Magalhães Leite[1], Matheus Gurgel Saraiva[1], Paulo Antonio Farias Lucena[1], Apolônio Peixoto de Queiroz[1], Rafael Gonçalves Duarte Cunha[1]

[1]Hospital Metropolitano Dom José Maria Pires, João Pessoa PB, Brazil.

Correspondence: Gilmar Leite Pessoa Filho; Email: gilmarpessoa@gmail.com.

Background: Stroke is one of the leading causes of death and morbidity worldwide. Therapeutic advances in the treatment of acute stroke have changed outcomes. Mechanical thrombectomy has emerged as an effective treatment for the acute stroke. Although its benefits and safety have been proven for over 8 years, it was implemented in Brazil's public health system less than 1 year ago. **Objective:** Analyze epidemiological data and variables related to mechanical thrombectomies performed at a quaternary public hospital in João Pessoa/PB, Brazil. **Methods:** This is a cross- sectional, descriptive study based on the retrospective analysis of medical records of 18 patients who underwent mechanical thrombectomy between January and March 2024. The following variables were analyzed: age, sex, chemical thrombolysis, symptom-to-femoral puncture time, puncture-to-recanalization time, TICI, ASPECTS, NIHSS, pre- and 90-day mRS, symptomatic hemorrhage, occluded vessel, time of hospitalization, technique used, and admission-to-puncture time. **Results:** The mean age was 60.1 years (33-79), with a sex ratio of 1:1. Only 2 patients (11.1%) underwent both thrombolysis and thrombectomy. The average time from symptom onset to femoral puncture was 10.8 hours (2h-22.5h), with only 4 patients (22.2%) presenting less than 6 hours. The mean NIHSS was 15.8 (8-31). Only 1 patient had a prior modified Rankin Scale (mRS) score of 1 and another scored 2; all others had a previous mRS zero before admission. The mean mRS at 90 days was 4.2. Six patients (33.3%) died, and only 2 (11.1%) achieved functional independence at 90 days (mRS of 0 to 2). Symptomatic intracranial hemorrhage occurred in 2 cases (11.1%). Regarding the occluded vessel, 8 (44.4%) were in the M1 segment of the middle cerebral artery, 7 (38.8%) in the intracranial internal carotid artery, 3 (16.6%) in the basilar artery. The mean time from hospital admission to femoral puncture was 172.5 minutes (60-280). The average time from femoral puncture to vessel recanalization was 38.8 minutes (5-140). The average length of hospital stay was 21 days (3-52). Regarding procedural technique, stent retriever was used in 7 cases (38.8%), aspiration in 5 (27.7%), and a combination of both in 7 (38.8%). On the reperfusion scale, 11 (61%) achieved TICI 3, 4 (22%) TICI 2b, only 1 (5%) TICI 2a, and another TICI 1. The 90-day outcome showed that only 11% achieved functional independence (mRS 0-2). **Conclusion:** Mechanical thrombectomy has revolutionized the treatment of acute stroke, resulting in improved functional recovery. In the Brazilian Unified Health System (SUS), the availability of this treatment remains limited. Additionally, the indications for the procedure were restricted until recently. It is expected that increased access to this therapy and expanded indications will improve patient clinical outcomes.

Rett's syndrome: a case report

Antonio Marcos Reissureição Galindo[1], Rodrigo Pernomian Cianca[1], Antonio Paulo Felice Rodrigues Leite[1], José Guilherme Pinhatti Carrasco[1], Felipe Bento Michelato[1], Maria Júlia Costa Rocha[1], Giovanna Volpato Segura[1], Emanuel Gomes Ferreira[1], Yves Henrique Ramos Mansano[1], Thiago Honório Dutra da Silva[1]

Case presentation: A Caucasian female patient was born at term at 40 weeks of gestation, cesarean section. The mother made adequate use of ferrous sulfate and folic acid supplementation during pregnancy. After neonatal screening, there were no significant changes in the newborn. The mother reports a perception of the delay in the child's neuropsychomotor development. At the age of seven, the patient was admitted to an Urgency and Emergency Unit complaining of muscle spasms and hypoactivity, with her oxygen saturation at 92%. The patient developed respiratory failure, bronchospasms, and recurrent epileptic seizures with clonic movements lasting more than one minute and postictal period of more than ten minutes. There was the presence of sialorrhea, muscle stiffness in the lower and upper limbs, feet in internal rotation and claw-shaped hands. Also, acquired chest deformity and scoliosis. Also, low body development and aphasia, but with a perception of understanding of what is said to the patient. The patient's diagnosis was made through the sum of the associated clinical signs and confirmed by the sequencing of the Methyl CpG Binding Protein-2 gene present on the X chromosome. **Discussion:** Rett syndrome is a rare genetic pathology related to the dominant X chromosome, resulting in the translation of proteins capable of promoting severe motor destruction. Male individuals with this syndrome die and female individuals carry severe sequelae throughout their lives. Because the evolution of the disease is characteristic, it is possible to divide four stages of this syndrome. The first has a deficiency in body development. The second consists of a rapid psychomotor regression, onset of epileptic seizures, impairment of reflexes, communication and social interaction. In addition, the patient already develops respiratory irregularities. In the third phase, there may be an improvement in communicative ability in contrast to a worsening in ambulation and balance, which is more evident in the presence of scoliosis. In stage four, present at about ten years of age, there is a visible progression of motor delay, poor ability to walk and perform manual actions. Evident signs of peripheral motor neuron injury, body rigidity, malnutrition, and gastrointestinal dysfunction. **Final comments:** Rett's disease, because it is a rare genetic syndrome and its first cases were discovered in Brazil only close to the date of 1990, still causes delays for medical professionals in making an assertive diagnosis to patients with this mutation in their genes. And, because it is a disease with no cure that occurs in multiple disabilities, starting a multidisciplinary care work early to assist in the functional capacity of the patient in question is of great importance. Therefore, popularizing the existence of this syndrome, along with its signs and symptoms, helps in the training of health professionals and reflects positively on the patient's survival.

Case presentation: A 19-year-old woman with no relevant medical history, except for regular use of marijuana and a narcotic based on chloroform and ether, reported an onset of an acute holocranial headache a week earlier. She was found unresponsive and admitted to the hospital following a generalized tonic-clonic seizure. A non-contrast computed tomography (CT) scan of the skull revealed hyperdense foci in the splenium of the corpus callosum and the cingulate gyrus, with no other significant findings. Diagnostic cerebral arteriography showed diffuse narrowing of intracranial arteries, particularly in the P1 and P2 segments of the posterior cerebral arteries. The diagnostic hypothesis was Reversible Cerebral Vasoconstriction Syndrome (RCVS), with marijuana and the narcotic considered as precipitating factors. After 15 days, neurological improvement was observed, and a follow-up angiographic study documented the reversal of arterial narrowing. **Discussion:** RCVS is a condition characterized by arterial involvement of intracranial vessels, manifesting with vasospasm. It primarily affects individuals between 20 and 50 years of age, with a higher prevalence in females. The patient in this case fits within the typical demographic for sex but is at the lower age limit. The hallmark of RCVS is a sudden and severe headache. This can be accompanied by seizures, as seen in this patient, as well as focal neurological deficits. Laboratory tests and cerebrospinal fluid analysis are often nonspecific, typically showing no significant abnormalities, which aligns with the findings in this case. Therefore, imaging studies are crucial for the diagnosis. Non-contrast CT scans of the brain can produce variable results and are sometimes normal. However, an angiographic study is more definitive, often showing the characteristic "string of beads" appearance due to alternating segments of arterial narrowing and dilation. This patient's angiography revealed diffuse narrowing, especially in the posterior cerebral arteries, supporting the RCVS diagnosis. The etiology of RCVS is multifactorial, with precipitating factors identified in approximately 60-80% of cases. These factors include the postpartum period, preeclampsia/eclampsia, and exposure to certain medications such as antidepressants and immunosuppressants. Vasoactive substances, including illicit drugs like marijuana, cocaine, and heroin, are also well-documented triggers. In Brazil, the use of a clandestine narcotic mixture based on chloroform and ether for recreational purposes is a concern. This mixture's vasoactive properties may have contributed to the development of RCVS in this patient. **Final comments:** It is essential to recognize the variety of clinical and imaging patterns of RCVS to quickly identify suspected cases and exclude differential diagnoses. While the link between RCVS and marijuana is documented, this case suggests a potential new association with narcotics containing chloroform and ether.

Reversible posterior encephalopathy syndrome (PRES) after endovenous iron infusion: unusual case in the literature

Carolina Flores Welker[1], Larissa Lucas Schloicka[1]

[1]Hospital de Base do Distrito Federal, Brasília DF, Brazil.

Correspondence: Carolina Flores Welker; Email: carolinafwelker@gmail.com.

M.C.N., female, 37 years old, admitted to a high-complexity hospital on 02/14/2023 after experiencing headache, vomiting, visual disturbances and reduced level of consciousness two days earlier, shortly after intravenous iron infusion. She had a previous diagnosis of uterine myomatosis and iron deficiency anemia. She had already undergone oral iron replacement, but had not yet received parenteral iron replacement. Upon admission to the emergency room, she was drowsy; inattentive, with fluctuation in level of consciousness and multidirectional rotatory nystagmus. There were

no focal neurological deficits evident. Head CT showed vasogenic edema in the left parietal lobe and ischemia in the cerebellar hemispheres, with compression of the fourth ventricle and ectasia of the supratentorial ventricular system. Hours later, the patient developed a lower level of consciousness, requiring OTI and, on the same day, a EVD was inserted . In the following days, there was significant clinical improvement, she remained without neurological deficits and there was resolution of encephalopathy. She was Extubated on 02/25/23 and the EVD was removed on 03/05/23, without complications. On 02/28/23, she was admitted to the neurology ward, alert, oriented; without any motor or sensory deficits; with preserved balance, coordination and gait. She maintained central pattern nystagmus. Skull MRI on 03/13/23 showed sequelae changes in the cerebellar hemispheres suggestive of previous vascular insult. She was discharged on 03/13/2023 with a diagnostic hypothesis of PRES. PRES is a clinical-radiological syndrome, whose clinical picture is characterized by encephalopathy, headache, visual disturbances and seizures. Imaging usually shows vasogenic edema predominantly in the occipital and parietal lobes. The most frequently described associated conditions are high blood pressure, eclampsia and use of immunosuppressants and chemotherapy. Its pathophysiology is not well understood, however, endothelial dysfunction and loss of cerebral autoregulation are the most accepted theories. The prognosis is good and, in most cases, symptoms and imaging findings are reversible. Our patient was retrospectively diagnosed with PRES and the only factor identified was intravenous iron infusion. As yet, we have not found a similar case in the literature. There are reports of PRES after infusion of packed red blood cells, which, as it is rich in iron, may have a pathophysiology similar to that of the case described.

Reversible posterior leukoencephalopathy syndrome after intravenous iron infusion

Robercon Alves do Carmo[1], André Teixeira de Souza e Castro[1], Fernanda Sousa Lima[1], Larissa Lucas Schloicka[1], Rodrigo Torres Sena Pita[1], Carolina Flores Welker[1], André Gustavo Fonseca Ferreira[1], Wagner Afonso Teixeira[1]

[1]Hospital de Base do Distrito Federal, Brasília DF, Brazil.

Correspondence: Robercon Alvesd Carmo; Email: robercon025@gmail.com.

Case presentation: A 37-year-old female patient, previously diagnosed with uterine myomatosis, presented with significant metrorrhagia and iron deficiency anemia as a result. In February 2023, she was referred after experiencing occipital headache and uncontrollable vomiting following intravenous iron infusion (ferripolimaltose). Subsequently, the patient experienced progressive worsening of the headache associated with altered consciousness, alternating between periods of psychomotor agitation and drowsiness. Upon admission, she exhibited active movement of all four limbs but maintained a state of encephalopathy, making it difficult to cooperate with the physical examination. Initially evaluated by the neurosurgery team, a CT scan revealed extensive cerebellar ischemia leading to compression of the fourth ventricle. She underwent external ventricular drainage and was transferred to the intensive care unit, where she remained hospitalized for 10 days. During this period, she underwent conversion to a ventriculoperitoneal shunt and was subsequently referred to neurology for the etiological definition of the ischemic vascular insult that triggered her condition. Following extensive investigation during hospitalization, the patient was diagnosed with mild triglyceride elevation in the context of dyslipidemia. No other common triggering causes were found, although there are only two reported cases in the literature of a similar condition triggered by iron replacement. After identifying intravenous iron infusion as the trigger for the condition, the patient was referred to the vascular neurology clinic for follow-up, currently reporting only dizziness while being able to carry out her work activities without impairment. **Discussion:** Reversible posterior leukoencephalopathy syndrome is a rare cause of cerebral vascular insult, but should always be considered in patients presenting with symptoms suggesting a posterior fossa location. Extensive investigation is necessary for diagnostic confirmation, and whenever possible, the causative agent should be identified to prevent subsequent events. **Final comments:** In this presentation, we described a case of reversible posterior leukoencephalopathy syndrome in a patient, with the etiological agent being a medication that is poorly described in the literature.

Rhino-cerebral mucormycosis presenting with ophthalmoplegia and intracerebral hemorrhage

Fernanda Lustosa Cabral Gomez[1], Lara Santos Machado[1], Maria Eduarda Slhessarenko Fraife Barreto[1], Gabriela Rodrigues Tomaz[1], Leonardo Villaverde Buback Ferreira[1], Larissa Braga Mendes[1], Maria Elisabeth Matta de Rezende Ferraz[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Fernanda Lustosa Cabral Gomez; Email: fernandalustosacg@gmail.com.

Case presentation: A 55-year-old man was admitted to the emergency department with a one-day history of sudden loss of vision of the right eye. He had a previous diagnosis of uncontrolled diabetes. Upon admission, his blood glucose level was 406 mg/dL. Neurological examination revealed no perception of light, mydriasis and complete ophthalmoplegia of the right eye, as well as right facial hypoesthesia. Noncontrast brain CT showed invasive right maxillary-ethmoidal sinusitis and nasofibroscopy revealed necrosis of the lower right turbinate. Brain MRI suggested acute invasive fungal rhinosinusitis. The patient was placed on intravenous amphotericin and ethmoidal sinusectomy was performed. Two days later, he presented with reduced consciousness level and bilateral mydriasis. Emergency brain CT revealed right frontal lobe hemorrhage with midline shift and bilateral subfalcine and uncal herniation. CT Angiography was unremarkable. The patient underwent emergency decompressive surgery but two days later brain death was documented. Nasal biopsy later revealed Rhizopus spp (Mucormycosis). **Discussion:** Mucormycosis is a rare and often fatal opportunistic infection caused by the pathogenic genera Mucor, Absidia, and Rhizopus of the family Mucoraceae. Rhino-cerebral mucormycosis (RCM) is a form of cephalic mucormycosis known to occur in immunocompromised patients. The infection usually begins with symptoms of sinusitis and rhinitis and, as the fungus disseminates to the orbit, it causes involvement of the cranial nerves, such as in the case above, a classic orbital apex syndrome. Mucor fungus has a high affinity for blood vessels, particularly for the elastic membrane. Therefore, RCM may present as a stroke due to a major artery occlusion. However, case reports of intracerebral hemorrhage due to mucormycosis are extremely rare, specially with the genera Rhizopus. Although CT angiography was unremarkable in our case, we believe that it could be due to occlusion of a cortical vein or, less likely, arterial dissection or mycotic aneurysm. **Final comments:** Although rare, mucormycosis should be sought in cases of ophthalmoplegia and intracerebral hemorrhage in immunocompromised patients, such as in uncontrolled diabetics. In RCM we also highlight the importance of urgent otorhinolaryngologic evaluation. Early treatment with intravenous amphotericin B, surgical debridement and control of risk factors are imperative for survival.

Rhino-orbital mucormycosis presenting as orbital apex syndrome: a case report

Pedro Almeida Martins Pontes[1], Filipe Marçal Junqueira[1], Henrique de Moraes Bernal[1], Ingrid Lorena da Silva Gomes[1], Aldren Thomazini Falçoni Júnior[1], Guilherme Lago Miranda[1], Eduardo Takashi Takehara[2], Mateus Paquesse Pellegrino[1], Marcele Schettini de Almeida[1], Sônia Maria César de Azevedo[1]

[1]Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo SP, Brazil.
[2]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Pedro Almeida Martins Pontes; Email: pedroalmeida.pontes@gmail.com.

Case presentation: An 83-year-old man was admitted with myalgia, fever and headache and was diagnosed with dengue. His medical history included diabetes mellitus (HbA1c 10.1%), heart failure with reduced ejection fraction and alcoholism. Throughout the next few days, he showed clinical improvement but had persistent thrombocytopenia. This led to a diagnosis of post-dengue Idiopathic Thrombocytopenic Purpura, and treatment with Prednisone 60 mg was started. On the seventh day of corticosteroid treatment, platelet count progressively improved. Concurrently, he developed acute ptosis, ophthalmoplegia, and reduced visual acuity in the left eye. Upon initial evaluation by Neurology, the patient showed alterations on the left side in the cranial nerve exam: ptosis, proptosis, complete paralysis of cranial nerves III, IV, and VI, absence of the corneal reflex, hypoesthesia in the V1 territory, and visual acuity with no light perception. There were no other abnormalities in the neurological physical exam. This clinical presentation is consistent with Orbital Apex Syndrome. The patient underwent etiological investigation, with main suspicions of vascular or infectious causes. Digital angiography was normal, ruling out vascular causes such as dural fistulas. CSF analysis showed no abnormalities. Brain and orbit MRI showed severe sinus disease in the left frontal sinus, along with infiltrative effects, with the presence of gas in the ipsilateral orbit. Nasofibroscopy revealed necrotic crusts throughout the left nasal cavity, with culture positive for Mucor sp., confirming the diagnosis of Rhino-Orbital Cerebral Mucormycosis. Antimicrobial treatment was started, and the patient underwent extensive surgical debridement. Fourteen days after diagnosis, the patient died from secondary bacterial complications. **Discussion:** Mucormycosis is an invasive fungal disease caused by fungi of the order Mucorales. Although rare, Mucormycosis is known to present with Orbital Apex Syndrome, especially in diabetic patients or those with prior immunosuppression. In a review conducted in India, 73.5% of patients diagnosed with Mucormycosis were diabetic, making it the main isolated risk factor for this condition. In the reported case, the patient had uncontrolled diabetes and was started on corticosteroids, which could have triggered the fungal infection. Even with early diagnosis and appropriate treatment, the mortality of Rhino-Orbital Cerebral Mucormycosis remains high (50 to 100%, depending on the reference). **Final comments:** Diabetic patients or those with general immunosuppression presenting with Orbital Apex Syndrome should be promptly investigated for Mucormycosis. It is a disease with high mortality. Neurologists need to be aware of the topic for high clinical suspicion and early therapeutic intervention to potentially improve prognosis in these high-risk populations.

Rhomboencephalitis as a differential diagnosis of stroke: a case report

Daniele da Costa da Silva[1], Artur Gasparovic Chagas[1], Ana Carolina Grande[1], Ivo Marcos Darella

Lorenzin Fernandes Neto[2], Eduarda Basso Badalotti[2], Angelo Marcelo Wosniacki Filho[2], Gabriel Angelo Garute Zenatti[2], Renato Endler Iachinski[2], Antonio Carlos de Andrade Soares[2]

[1]Centro Universitário Fundação Assis Gurgacz, Cascavel PR, Brazil.
[2]Fundação Hospitalar São Lucas, Cascavel PR, Brazil.

Correspondence: Daniele da Costa da Silva; Email: dani.costadasilva09@gmail.com.

Case presentation: A 54-year-old male was referred from primary care to the Neurology department for further investigation due to a stroke suspicion. The patient reported blurred vision and intermittent loss of strength for a few days, with spontaneous resolution. No past medical history of infections, vaccinations, and negative family history of neurological diseases. On neurological evaluation, presented with a decreased visual acuity, proportionate right hemiparesis, dysplasia, and gait ataxia relapse-remission symptoms. Lesions with hypersignal on T2/Flair sequence in the pons, left cerebellar peduncle, cerebellum, heterogeneous contrast restriction, without obeying vascular territory associated with changes in the left optic nerve suggestive of neural inflammation were described on the MR. No abnormalities on cerebrospinal fluid and no positive serology for Cytomegalovirus, Epstein-Barr, Herpes, and Cryptococci infection. Together, the Neurology and Neuroradiology team defined the condition as Rhomboencephalitis associated with idiopathic Neuritis Optica. After a 5-day methylprednisolone 1g treatment, the patient improved significantly in previous symptoms. **Discussion:** Rhomboencephalitis is defined as an inflammation of the pons, medulla oblongata, and cerebellum. Typically viral or bacterial origin and usually affects immunocompromised people, especially patients under immunosuppressants, paraneoplastic syndromes, and autoimmune conditions such as Behcet disease. The gram-positive bacterium Listeria monocytogenes, with a 9% chance of developing the disease, is the most common pathogen, normally transmitted through contaminated food. Initial clinical findings include flu-like symptoms, progressing with neurological manifestations and diagnosis is made by hematological or cerebral fluid test. **Final comments:** Rhomboencephalitis is an uncommon condition with a high morbidity and mortality rate. Due to its extensive clinical presentation, it is an important differential diagnosis in patients with sudden neurological symptoms to provide the appropriate treatment.

https://doi.org/10.5327/CBN241445

Right peripheral facial paralysis in a 1-day-old neonate: a case report

Taianara Sampaio Reis[1], Amauri Pereira da Silva Filho[2], Melissa Fernandes Vilela de Freitas[3], Danielle Cortellazzi Colonna Romano[3], Gabriela Yumi Nakamura[3], Sabrina Borges Batista[3], Natália Rebeca Karpejany[1]

[1]Universidade Federal do Piauí, Teresina PI, Brazil.
[2]Hospital de Emergência e Trauma Dom Luiz Gonzaga Fernandes, Campina Grande PB, Brazil.
[3]Universidade Nove de Julho, São Paulo SP, Brazil.

Correspondence: Taianara Sampaio Reis; Email: taianarasampaio21@hotmail.com.

Case presentation: A term male neonate, 1 day old (d.o.), born via cesarean section with an Apgar score of 8/8, presented for outpatient evaluation with right-sided facial mimic alteration. The mother reported inadequate prenatal care, without regular check-ups, vaccination, or serological tests. PHYSICAL EXAMINATION: The neonate was in good general condition, 1 d.o., weighing 3 kg, with a normotensive anterior fontanel open to one finger breadth, showing hemifacial alteration with deviation of the buccal rim to the left. Bell's sign was present in the right eye. After examination, the diagnostic hypothesis of right peripheral facial paralysis was raised. Subsequently, tests were requested to investigate the probable cause of the paralysis. Routine examinations of the child were normal, with no history of birth trauma, and no signs or stigmata of syndromic diseases. Therefore, cranial computed tomography (CT) and magnetic resonance imaging (MRI), lumbar puncture, and serological tests were performed to continue the investigation. The test results were: normal cerebrospinal fluid, normal cranial CT with no fractures, normal cranial MRI without clinical abnormalities, negative serology for VDLR, HIV, Hepatitis B and C, Rubella (IgM negative and IgG positive), cytomegalovirus (CMV) (IgM negative and IgG positive), Toxoplasmosis (IgM negative and IgG positive), Herpes 1 and 2 (IgM negative and IgG positive). **Discussion:** Bell's palsy is a neuropathy affecting the seventh cranial nerve, also known as the facial nerve. It can have different etiologies, such as trauma, infections, inflammation, or compressions involving the nerve. Some cases are classified as idiopathic when no probable etiologies can be found. The most common cause of Bell's palsy is the herpes simplex virus, but it can also be caused by other viruses such as Epstein Barr, HIV, and hepatitis B. The presentation of this syndrome in the pediatric population is very rare, with few reports in the literature. This makes early diagnosis and appropriate treatment crucial for better prognosis. **Final comments:** The patient was diagnosed with Bell's palsy and treated with symptomatic medications and physiotherapy. The neonate initially presented with a House-Brackman scale score of 3 and improved to a score of 2 after physiotherapy. Bell's palsy does not have a specific etiology, and it could have been due to previous infections. The patient is IgG positive for rubella, CMV, and herpes 1 and 2. Differential diagnoses considered for this patient included birth trauma, mastoid trauma, syndromic alterations, HIV, hepatitis B, brain tumor, meningitis, and meningoencephalitis. All these diagnostic hypotheses were ruled out after testing, ultimately confirming the diagnosis of Bell's palsy.

Risdiplam treatment for spinal muscular atrophy: real life data from a Brazilian cohort

Cristina Iwabe[1], Felipe Franco da Graça[1], Marcondes Cavalcante França Jr[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Cristina Iwabe; Email: crisiwabe@hotmail.com.

Background: Risdiplam is an oral SMN2 splicing modulator used to treat spinal muscular atrophy (SMA) that became recently available in the Brazilian public health system. Real life data on Risdiplam in the Brazilian population are missing. **Objective:** To describe Ridisplam effects in a mixed SMA cohort from a referral center. **Methods:** This is an 8-month retrospective analysis of subjects taking Ridisplam, who were evaluated with motor scales before and at least 3 months after treatment onset. Motor function was assessed either using the HFMSE or the CHOP-INTEND scales depending on the clinical type of SMA. **Results:** There were 6 men and 6 women. Two patients had SMA1, 6 SMA2 and 4 SMA3. Mean age was 28.9 years (ranging from 6 to 60 years), whereas mean treatment duration was 6 months (ranging from 3 to 8 months). During follow-up, we had the same number of patients with stable (n=6) or improved (n=6) functional scores. In the stable group, there were 3 SMA2 and 3 SMA3; mean age was 36.6 years. Risdiplam use lasted on average 6.1 months. In the improved group, we had 2 SMA1, 3 SMA2 and 1 SMA3. Percentual improvement ranged from 11,10 to 33,30% in this subgroup. Mean disease duration was 21 years. None of the patients reported meaningful side effects during treatment. **Conclusion:** In this mixed Brazilian cohort, Risdiplam led to either motor functional stabilization or improvement. Further studies are needed to identify predictors for better response.

https://doi.org/10.5327/CBN241447

Risk factors and prognosis of myelomeningocele associated with holoprosencephaly: a case report

Lizandra Stefani Barbosa[1], Andressa Girelli Cardoso[1], Gabrielle de Souza Bernardes[1], Jessica Helena Gomes Ferreira[1], Caroline Chaves Bittencourt[1]

[1]Universidade Nove de Julho, Guarulhos SP, Brazil.

Correspondence: Lizandra Stefani Barbosa; Email:

Case presentation: A newborn male, born on 22/03/2024, at term via a difficult cesarean section (11 minutes) due to macrocephaly and myelomeningocele (MMC), with polyhydramnios and meconium-stained amniotic fluid (2+/4+), weighing 5,190g and with a head circumference of 48 cm. He required resuscitation and intubation and was transferred to the neonatal ICU. A cranial CT scan revealed hydrocephalus (HC) and alobar holoprosencephaly (HPE), and a spinal CT scan showed lumbosacral MMC. On physical examination, he presented with macrocephaly, large and communicating fontanelles, suture dehiscence; a ruptured MMC in the sacral region, and bilateral congenital talipes equinovarus (CTEV). On 28/03/2024, he underwent a ventriculoperitoneal shunt (VPS) placement and MMC repair without complications. He was discharged from the hospital on 08/04/2024. **Discussion:** Folic acid deficiency is the main risk factor for neural tube defects, with MMC being the most common. The mortality rate reaches up to 70% within the first 6 months of life if untreated. MMC is a complex condition frequently associated with HC (in up to 80% of cases), Chiari II malformation, and orthopedic malformations (approximately 9% of cases) such as CTEV, with variability in prognosis. Macrocephaly and higher anatomical levels of the spinal defect increase the incidence of complications, which, along with HC, require multidisciplinary treatment, with shunt placement, such as VPS, being necessary in about 83.5% of cases. Shunt dysfunction affects approximately 47.7% of patients and requires frequent surgical revisions. Thus, MMC remains one of the leading causes of chronic disability, maintaining a mortality rate of 7.4% even with treatment. No risk factor has been well established for HPE, but the condition appears to be influenced by genetic, environmental, and multifactorial causes. Genetic etiologies, such as trisomy 13 and 18 and triploidy, account for most cases. Persistent hyperglycemia in pre-existing or insulin-dependent maternal diabetes, as well as salicylate consumption, are associated with a higher risk of HPE. Alobar HPE is the most severe form of this condition and has a poor prognosis, as developmental milestones, such as sitting or speaking, are not achieved even later in life. Additional complications may include dysphagia, gastroesophageal reflux, hypothalamic dysfunction, and endocrine problems. Mortality reaches 50% within the first 5 months of life, with only 30% surviving beyond the age of 1 year. **Final comments:** Despite the severity of the patient's neurological conditions–alobar HPE and MMC–with the interventions performed and the absence of critical clinical findings such as severe facial anomalies and other major dysfunctions, the patient's progress was observed. There is scarce data on the association of HPE and MMC, but it is known that these conditions separately have high mortality rates in the first year of life, and their co-occurrence worsens the prognosis.

https://doi.org/10.5327/CBN241448

Risk stratification for stroke among professionals in a hospital network

Aline Fernanda Alves Ribeiro[1], Mayk Penze Cardoso[2], Andreia Insabralde de Queiroz-Cardoso[1]

[1]Universidade Federal de Mato Grosso do Sul, Campo Grande MS, Brazil.
[2]Hospital Universitário Maria Aparecida Pedrossian, Campo Grande MS, Brazil.

Correspondence: Aline Fernanda Alves Ribeiro;
Email: aline.ribeiro@ufms.br.

Background: Stroke is one of the leading causes of mortality and disability worldwide. It is estimated that more than 15 million strokes occur each year, of which about 6 million are fatal. The increased risk for stroke is multifactorial. Additionally, epidemiological studies have shown that certain work environments and occupations are associated with a higher risk of stroke. **Objective:** To report the development of a stroke risk stratification activity among professionals in a public hospital network. **Methods:** This is an experience report regarding an action carried out in a public hospital in October 2023, aimed at professionals on "World Stroke Day". The professionals were stratified according to the "Stroke Riskometer" software questionnaire, which includes variables related to age, sex, race, anthropometric data, lifestyle habits, family history, and comorbidities. The application provided results on a scale from 0 to 100%, indicating the probability of a stroke within 5 years. Blood pressure measurements, general guidance, and risk factor control were also performed. **Results:** The activity included 35 professionals, most of whom were female (n=19). The occupations included nursing technicians (n=13), nurses (n=6), nursing assistants (n=2), radiology technicians (n=1), doctors (n=2), pharmacist (n=1), pharmacy technicians (n=4), receptionists (n=2), stretcher-bearer (n=1), pantry worker (n=1), and cleaning assistants (n=2). The stroke risk score ranged from 0.5% to 5.5% probability of developing the disease over 5 years. The highest risk scores were among males, with an average risk of 2.07%, while females had an average risk of 1.94%. Notably, in this study, the occupations with the highest indices were, respectively: radiology technicians, receptionists, nursing technicians, doctors, and pharmacy technicians. Furthermore, the main concerns of the professionals were related to risk factors and the identification of comorbidities, such as hypertension and diabetes. Recommendations included regular visits to health units to identify potential problems, regular physical activity, and maintaining a healthy diet. **Conclusion:** Awareness of modifiable stroke risk factors is essential to implement effective preventive measures and highlight the importance of occupational health in preventing this condition. Therefore, it is crucial that organizations adopt measures to promote healthy work environments, with occupational health policies aimed at reducing stroke risk factors, including health promotion programs, encouraging physical activity, and managing stress levels at work.

Rockstar hands: a complex pattern of hand dystonia in Wilson's disease

Luis Eduardo Borges de Macedo Zubko[1], Renata Cristine Alves[1], Francisco Manoel Branco Germiniani[1], Hélio Afonso Ghizoni Teive[1]

[1]Universidade Federal do Paraná, Complexo Hospital de Clínicas, Curitiba PR, Brazil.

Correspondence: Luis Eduardo Borges de Macedo Zubko; Email: luis.zubko@gmail.com.

Case presentation: A 27-year-old man presented with subacute generalized dystonia, low serum ceruloplasmin levels, and increased copper urinary excretion, which were consistent with the diagnosis of Wilson's disease (WD). Following treatment with D-penicillamine, biperiden and baclofen the generalized dystonia improved significantly, but a residual significant hand dystonia persisted. His treatment was afterwards altered to trientine and weaned-off of anticholinergic drugs. The remaining hand dystonia had a complex pattern that resembled the finger and hand positions commonly seen in electric guitar players playing rock songs with major barre chords. The fingers of the left hand exhibit a distinctive pattern, with the left 3rd and 4th fingers flexed, while the 2nd and 5th fingers are extended. The left hand showed an additional severe wrist flexion. The right wrist was flexed with an ulnar deviation, associated with 3rd finger extension, while the 2nd, 4th and 5th fingers were flexed. The hand dystonia was refractory to botulinum toxin therapy and persisted in this fixed position suggesting shortening of tendons. **Discussion:** WD is a hereditary inborn error of copper metabolism caused by a mutation of the ATP7B gene. It usually occurs between the ages of 5 and 35 years and presents with hepatic, neurological and psychiatric symptoms. The most common neurological symptoms are movement disorders, especially, dystonia, parkinsonism, tremor and ataxia. Dystonia in WD frequently presents in either a generalized distribution, or as a focal dystonia in the oromandibular region. Dystonia affecting the hands may have several etiologies and present in various forms, with cases reported as "starfish hand", claw hand, and task-specific dystonias (including musician's dystonia, writer's cramp, hairdresser's dystonia), among others. It is important to accurately identify the pattern and muscles involved for optimal treatment. Final remarks dystonia in young patients warrants prompt investigation to rule out reversible conditions such as WD and other inborn errors of metabolism. Even with disease-modifying treatment, incapacitating dystonia with complex patterns may remain. Recognition of these patterns is important to assist in muscle selection for treatment with botulinum toxin.

Correspondence: Fernanda Valeriano Zamora; Email: dra.fernandavaleriano@gmail.com.

Case presentation: A 44-year-old female patient under neurological care due to cryptogenic epilepsy (absence type), with complex partial seizures since 1998, refractory to all previously used medications, likely due to a 15x14x13mm tumor in the right amygdala, consistent with low-grade glial neoplasia, with no surgical approach proposed. The patient has experienced progressive worsening, nearly daily seizures, significantly impacting quality of life and occupational capacity. The patient has previously tried Phenobarbital 800mg/day, Carbamazepine 800mg/day, Valproic acid 1,500mg/day, Sodium valproate 1,500mg/day, Topiramate 100mg/day, Lamotrigine 200mg/day, Oxcarbazepine, Clobazam, Phenytoin, Clonazepam, Bromazepam, and Levetiracetam, none of which reduced seizure frequency and caused various side effects such as dizziness, memory loss, and fatigue. Cannabidiol (CBD) isolate was initiated at 200mg/ml, 5mg/kg/day, with dose escalation. Seizure frequency improved from daily to approximately 1 seizure per month. Stability was achieved at 15mg/kg/day (660mg/day for a 44kg patient), with reported side effects of diarrhea and nausea. **Discussion:** Patients with drug-resistant epilepsy and no surgical option showed positive outcomes with CBD, improving seizure control and overall well-being, consistent with previous studies demonstrating significant reductions in seizure frequency and improvement in quality of life. Generally, cannabidiol is associated with minor side effects and has a favorable safety profile, offering a good risk/benefit ratio. Furthermore, there is still no consensus on the appropriate dosage for treating seizures, which leaves uncertainties among prescribing professionals and warrants extensive discussion. **Final comments:** CBD therapy presents as a promising adjunctive treatment for drug-resistant epilepsy patients and may complement surgical options. Its potential to reduce seizure frequency and improve quality of life highlights the need for further research into optimizing its use in clinical practice. Continued investigation into dosage, long-term effects, and patient-specific responses will be crucial in fully understanding CBD's role in managing refractory epilepsy.

Role of skin biopsy in the etiological diagnosis of multiple mononeuritis

Samir Andres Ramirez Ojeda[1], Leidys Pedrozo[1], Tais Werle[1], Bruna Klein[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Samir Andres Ramirez Ojeda; Email: samir.ramirez@edu.pucrs.br.

Case presentation: Male patient, 66 years old, pre-diabetic and dyslipidemic, starts with slowly progressive symptoms over the last 2 years of fatigue and loss of strength in the lower limbs associated with muscular atrophy and later neuropathic pain. No paresthesias or autonomic changes. On examination, broad and symmetrical pulses and the presence of livedo reticularis in the lower limbs, positive Romberg, proximal hypopalesthesia and distal apalesthesia in the lower limbs. Strength grade 3 (MRC) at nadir. Severe pain on palpation of the Achilles tendons due to tendinopathy. Electroneuromyography showed a pattern compatible with mononeuritis multiplex. Systemic investigation for infectious, metabolic, neoplastic diseases and negative vitamin deficiencies. Cerebrospinal fluid unchanged. Glycated hemoglobin 6.3%. Antinuclear antibody (ANA) positive 1:640 centromeric pattern, others negative. A skin biopsy of the livedo reticularis area was performed, which demonstrated dermal lymphocytic capillaritis with extravasation of red blood cells (micropurpuric), without evidence of fibrinoid necrosis or thrombosis. He received pulse therapy with methylprednisolone 1gIV/day for 5 days followed by gradual reduction of oral corticosteroids and cyclophosphamide 1g/month with a plan of 4 to 6 doses with significant improvement and progressive functional recovery. **Discussion:** Lymphocytic capillaritis associated with livedo reticularis is a condition of unknown etiology, with possible immunological mechanisms proposed. In our patient, a skin biopsy was essential to rule out livedoid vasculopathy. Furthermore, the presence of tendinitis, reactive ANA in high titers and response to immunotherapy suggest autoimmunity as the cause of mononeuritis multiplex. **Final comments:** Consider skin biopsy as a resource for the etiological differential diagnosis of mononeuritis multiplex.

Background: Neurological endovascular procedures have been performed via transfemoral access (TFA). This procedure has become the standard approach, given its greater ease in mechanical thrombectomy (MTB) for large occlusion stroke treatment. However, TFA can present potential complications. Thus, transradial access (TRA) and transcarotid access (ACT) have been considered viable alternatives, presenting better results and fewer complications. **Objective:** To demonstrate if using alternative vascular access (TRA or TCA) is safer and more effective than TFA in MTB for large occlusion stroke. **Methods:** MEDLINE, Cochrane, and Scopus databases were assessed to gather randomized clinical trials (RCT) and case-control studies (CCS) comparing TRA/TCA interventions versus TFA as a control group in MTB treatment for large occlusion stroke. Any complication related to any access (ACC), successful recanalization (SRC), mortality (MOR), and mean time from arrival to recanalization (ATR) were the outcomes evaluated. Data were examined using the Mentel-Haenszel method and 95% CIs. Heterogeneity was assessed using I^2 statistics. The statistical analysis was based on the R Studio, version 4.3.2. **Results:** A total of 1 RCT and 8 CCS comprising 4023 patients were included, of which 669 (16.63%) underwent MTB either through TRA or TCA and 3354 (83.37%) through TFA. The TRA/TCA group was associated with a reduction in ACC (6% vs 9%, RR 0.6, 95% CI 0.45-0.82, p=0.001, I^2=0%), compared with the TFA group. There was no significant statistical difference in SRC (90% vs 89.94%, OR 1.09; 95% CI 0.79,1.50; p=0.69; I^2=0%), MOR (12% vs 13.51%, RR 1.04; 95% CI 0.79,1.37, p=0.7964; I^2=0%) and ATR (MD -4.92; 95% CI -20.56, 10.71; p=0.5371; I^2=94%). **Conclusion:** This meta-analysis demonstrated that the use of TFA or TRA as alternative vascular accesses in MTB for large occlusion stroke reduced the risk of any type of procedure-related complication by 40% when compared to TFA. In this scenario, new studies, especially RCTs, need to be developed to clarify the effectiveness of these alternative vascular accesses in MTB for large occlusion stroke.

Background: Several neonatal Fc receptor (FcRn) inhibitors represent a possibility in the treatment of generalized Myasthenia Gravis (gMG). However, the precise therapeutic profile and efficacy of batoclimab in this context are not yet fully understood. **Objective:** To evaluate the efficacy and safety of batoclimab for the treatment of generalized Myasthenia Gravis. **Methods:** MEDLINE, Scopus, and Web of Science databases were systematically searched. Data were examined using the DerSimonian Laird method and 95% confidence intervals. Heterogeneity was assessed using I^2 statistics. R, version 4.3.2, was used for statistical analysis. **Results:** A total of 3 randomized control trials and 179 patients were included. Compared with placebo, treatment with batoclimab achieved better reduction of MG-ADL score (MD -2.07; 95% CI -2.06 - -1.49; P ≤0.000001; I^2= 0%); treatment with batoclimab had a better improvement of QMG score (MD -5.47; 95% CI -7.70 - -3.25; P=0.000001; I^2=79%). The rate of treatment-emergent adverse effects and other specific adverse effects such as diarrhea, headache, and upper respiratory tract infection did not reach a statistically significant difference between groups. **Conclusion:** Consistent results suggest that the use of batoclimab is associated with efficacy in the treatment of gMG, reducing MG-ADL and QMG scores. The drug had no significantly relevant adverse events in comparison to placebo. In conclusion, our results support the use of batoclimab for the treatment of gMG.

Background: BRAF V600E mutations are prevalent in childhood cancers and are associated with a diminished response to standard chemotherapy. Recent clinical trials have demonstrated the effectiveness of dabrafenib, both as a monotherapy and in combination with trametinib, in managing refractory mutant gliomas in patients of various ages. However, safety-related outcomes and clinical improvements of this therapeutic approach in the pediatric population remain unclear. **Objective:** Evaluate the efficacy and safety of dabrafenib and trametinib in children with gliomas harboring BRAF V600E mutations. **Methods:** PubMed, Embase and Cochrane databases were searched up to April 2024, following the recommendations in the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement. Included studies were peer-reviewed randomized controlled trials (RCTs) or non-randomized studies comparing the efficacy and safety of dabrafenib in combination with trametinib among pediatric patients (<18years) with BRAF V600E mutated-gliomas. Outcomes included overall response rate (ORR), clinical benefit rate (CBR), stable disease rate, complete response rate, and incidence of adverse events. Meta-analyses were conducted with random-effects models. **Results:** Four studies met the inclusion criteria, consisting of two RCTs and two non-randomized clinical trials, encompassing a total of 326 patients (with 198 receiving dual therapy). Among these, three studies focused on low-grade gliomas (LGG), while one targeted high-grade gliomas (HGG). The pooled ORR was 44.01% (95% confidence interval [CI] 37.12–50.90), accompanied by a CBR of 81.87% (95% CI 75.9187.83), stable disease rate of 50.23% (95% CI 43.29–57.17) and complete response rate of 1.35% (95% CI 0.00–3.31). Grade 1–4 adverse events were reported in 100% of patients, with pyrexia (61.21%, 95% CI 54.46–67.96), dry skin/skin toxicity (43.46%, 95% CI 36.56–50.36), and vomiting (30.7%, 95% CI 23.58–37.82) being the most common. Adverse events necessitating dose reduction or interruption occurred in 73.66% of patients (95% CI 66.86–80.46), while treatment discontinuation due to adverse events was observed in 9.76% (95% CI 5.20–14.32). **Conclusion:** Dabrafenib and trametinib exhibit promising efficacy in pediatric glioma patients with BRAF V600E mutations, as evidenced by favorable response rates. However, the occurrence of adverse events underscores the need for further research to elucidate the long-term safety and efficacy profile of this treatment in the pediatric population.

Correspondence: Mariana Rachas Reis; Email: marianarachas@gmail.com.

Background: Managing low back pain (LBP) presents a significant healthcare challenge. Duloxetine, a selective dual neuronal serotonin and norepinephrine reuptake inhibitor, is believed to have beneficial effects in LBP patients. Despite previous studies testing duloxetine in LBP patients, new trials have been conducted on the subject requiring a more comprehensive analysis to update the body of evidence. **Objective:** To assess the safety and efficacy of duloxetine for treating patients with LBP. **Methods:** MEDLINE, Embase, and Cochrane databases were systematically searched for randomized placebo-controlled trials (RCT) that tested duloxetine in LBP patients. Data were examined using the Mantel-Haenszel method and 95% confidence intervals (CIs). Heterogeneity was assessed using I^2 statistics. This meta-analysis was performed to evaluate average pain intensity (Brief Pain Inventory [BPI]), clinician1s assessment of the overall disease severity (Clinical Global Impressions of Severity [CGI-S]), and safety (Treatment Emergent Adverse Events [TEAEs] and Serious Adverse Events [SAEs]). Statistical analysis was conducted using R, version 4.3.2. **Results:** A total of 4 randomized controlled trials and 1326 patients were included, of whom 659 received duloxetine 60 mg once daily. Compared with placebo treatment, duloxetine-treated patients presented

a statistically significant reduction in all domains of BPI-Severity: worst pain (MD -0.502; 95% CI -0.737, -0.266; P<0.001; I^2=0%); average pain (MD -0.569; 95% CI 0-.779, -0.359; P<0.001; I^2=0%) and least pain (MD -0.550; 95% CI -0.750, -0.350; P<0.001; I^2=0%). There was also a decrease in BPI-Interference (MD -0.509; 95% CI -0.847, -0.170; P=0.003; I^2=63%) and CGI-S (MD -0.255; 95% CI -0.362, -0.148; P<0.001; I^2=0%). Regarding safety, the duloxetine group had higher TEAE rate compared with placebo (40.87% vs 23.15%; risk ratio [RR] 1.984; 95% CI 1.286, 3.063; P=0.002; I^2=83%) and there were no significant differences in the occurrence of SAEs between groups (2.46% vs 1.19%; risk ratio [RR] 1.657; 95% CI 0.635, 4.323; P=0.302; I^2=16%). **Conclusion:** This meta-analysis underscores the effectiveness of duloxetine in improving outcomes in patients with LBP, as evidenced by improvements in CGI-S, BPI-Interference, and all domains of BPI-Severity. In terms of safety, the increased incidence of TEAEs in the duloxetine group, alongside no significant differences in the occurrence of SAEs, emphasize the importance of vigilant monitoring and risk assessment in clinical practice. These findings support duloxetine as a valuable treatment option for LBP, with careful management ensuring its safe and effective use.

Correspondence: Paula Schumaker; Email: paula.schumaker@uol.com.br.

Background: Stellate Ganglion Block (SGB) is widely used to block impaired sympathetic nerve activity, affecting physiologic functions such as heart rate and blood pressure. After a subarachnoid hemorrhage, there is usually an increase in the cerebral blood flow velocity (CBFV), at which SGB may be efficient in controlling cerebral hemodynamics. **Objective:** To assess the effects of SGB on cerebral hemodynamics and functional outcomes in patients with subarachnoid hemorrhage. **Methods:** MEDLINE, Scopus, and Web of Science databases were systematically searched until May 2024. Data was examined using 95% Confidence Intervals (CIs). Heterogeneity was assessed using I2 statistics. Meta-analysis was conducted to evaluate a possible link between the Stellate Ganglion Block and the Middle Cerebral Artery Cerebral Blood Flow Velocity (MCA CBFV) in patients with subarachnoid hemorrhage. RStudio version 4.3.2 was used for statistical analysis. **Results:** Six studies and 212 patients were included. There was a statistically significant difference between groups tending for the intervention regarding Middle Cerebral Artery Cerebral Blood Flow Velocity (MCA CBFV) 24 hours before SGB (MRAW 113.30 cm/sec; 95% CI: 71.48-155.12; P<0.01; I^2=98%). After 24 hours, both the CBFV on the ipsilateral side (MRAW 115.78 cm/sec; 95% CI; 93.17-138.40; P<0.01; I^2=95%) versus CBFV contralateral to the SBG (MRAW 100.79 cm/sec; 95% CI: 85.66-115.92; P<0.01; I^2=84%) showed a statistically significant better response in the intervention group. However, in the ipsilateral method, the CBFV was higher (115.78 cm/sec). Additionally, the Glasgow Outcome Scale (GOS) between I and III after 6 months of SGB showed a proportion of (PROP 0.393; 95% CI: 0.317-0.474; P=0.46; I^2=0%). **Conclusion:** In the present study, SGB showed beneficial outcomes for subarachnoid hemorrhage patients. However, further randomized controlled trials comparing bilateral SBG and its hemodynamic effect are needed to investigate possible outcome differences between each anatomical side for SBG application.

Background: Patients on certain immunosuppressive therapies often fail to develop sufficient immunity after COVID-19 vaccination, making them more susceptible to severe disease outcomes. To address this vulnerability, a monoclonal antibody combination of tixagevimab and cilgavimab has been proposed for pre-exposure prophylaxis (PrEP) against COVID-19. This strategy may be efficient in patients with multiple sclerosis (MS), neuromyelitis optica spectrum disorder (NMOSD), or myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD). However, the PrEP efficacy in reducing the incidence of COVID-19 in this population has not yet been fully elucidated. **Objective:** To assess the safety and efficacy of tixagevimab and cilgavimab pre-exposure prophylaxis against COVID-19 in patients with MS, NMOSD, or MOGAD on sphingosine 1-phosphate receptor modulators or B-cell depleting therapy. **Methods:** MEDLINE, Scopus, and Web of Science databases were systematically searched until May 13, 2024. We included trials that involved patients with MS, NMOSD or MOGAD who underwent Tixagevimab/Cilgavimab dual therapy. Data were analyzed using the Mantel-Haenszel method to calculate risk ratios (RR) and 95% confidence intervals (CI). Heterogeneity was assessed using I^2 statistics. Statistical analysis was performed using R, version 4.3.2. **Results:** We included five studies with a total of 797 participants, of whom 434 (54%) underwent Tixagevimab/Cilgavimab therapy. The primary outcome was COVID-19 infection rate between the groups. The number of COVID-19 infection events recorded in the intervention group was 69, whereas 74 events were recorded in the control group. However, no statistically significant difference was seen between groups (16% vs 20%; risk ratio [RR] 0.87; 95% CI 0.51-1.49; P=0.612661; I^2=42%). **Conclusion:** Our study found no statistically significant difference between groups concerning COVID-19 infection rates in patients treated with Tixagevimab/Cilgavimab or placebo. The potential benefit suggested by the risk ratio requires further investigation with larger studies to confirm safety and efficacy in patients with MS, NMOSD, or MOGAD on immunosuppressive therapies.

Safety and efficacy of topiramate in migraine prophylaxis in younger patients: a meta-analysis

Natália Gabrielli Silva Alves[1], Lais Cabral Almeida[1], Ana Paula Alves Lima[1], Luana Maria da Silva Rodrigues[1], Artur Menegaz de Almeida[2], Ítalo Barros Andrade[3], Giovanna Molitor Perini[1], Michele Kreuz[4]

[1]Centro Universitário de Várzea Grande, Várzea Grande MT, Brazil.
[2]Universidade Federal do Mato Grosso, Sinop MT, Brazil.
[3]Faculdade Santo Agostinho, Vitória da Conquista BA, Brazil.
[4]Universidade Luterana do Brasil, Canoas RS, Brazil.

Correspondence: Natalia Gabrielli Silva Alves; Email: alvesn544@gmail.com.

Background: Prophylactic treatment of migraine using the AMPA (amino-3-hydroxy-5-methyl-4-isoxazolepropionic) receptor-blocking anticonvulsant Topiramate is associated with adverse events and questionable efficacy in youngers. The combination with adjunctive vitamin D3 is discussed to be more efficient and safer in younger patients with migraine. **Objective:** Compare the safety and efficacy of Topiramate alone or in combination with vitamin D3 versus placebo in the prophylaxis of migraine in younger patients. **Methods:** PUBMED, Scopus, and Web of Science for randomized controlled trials assessing the safety and efficacy of topiramate in younger patients for migraine prevention, alone or with vitamin D. Data were analyzed using Mantel-Haenszel statistics with 95% confidence intervals. Patients older than 18 years were excluded. Statistical analysis was performed using R version 4.3.2. **Results:** We included 6 RCTs comprising 653 patients, of which 306 underwent isolated use of Topiramate 100mg and 234 received a placebo. The subgroup analysis of Topiramate (2mg/kg/day) plus adjunctive vitamin D3 (daily dose 5,000 IU daily or 500,000 IU weekly doses) encompassed 57 patients receiving the combination treatment and 56 receiving a placebo. The topiramate therapy in association with vitamin D3 demonstrated a statistically significant difference in reducing migraine frequency (MD -3.66; 95% CI -4.33 to -2.98; P< 0.000001; I^2=0), while topiramate alone did not show any difference in comparison to the placebo group (MD -0.92; 95% CI -2.39 to 0.55; P=0.22; I^2=75%). The overall frequency reduction tended to the intervention group (MD -1.99; 95% CI -3.78 to -0.19; P=0.029; I^2=93%). PEDMIDAS reduction rate was greater with topiramate alone (MD -8.51; 95% CI -16.53 to -0.49; P=0.03; I^2=59%) when compared with the combination with vitamin D (MD -6.24; 95% CI -9.84 to -2.63; P=0.00069; I^2=68%). Concerning the occurrence of adverse effects, our findings showed that patients receiving topiramate associated with vitamin D3 (3,50% vs. 5,35%; 95% CI 0.11 to 3.91; P=0.64; I^2=0%) are at no increased risk for anorexia than those receiving topiramate alone (14,38% vs. 2,91%; 95% CI 2.42 to 11.42; P=0.000027; I^2=0%). The overall risk for anorexia tended in favor of te placebo group (12,57% vs. 3,43%; 95% CI 1.86 to 7.68; P=0.000246; I^2=20%). Paresthesia was reported only in studies comparing topiramate alone versus placebo, which analysis showed an increased risk for the intervention group (35% vs 5%; RR 6.19; 95% CI 2.81-13.62; P=0.000006; I^2=18%), as well as the adverse effect of fatigue (18% vs 10%; RR 1.69; 95% CI 1.06-2.69; P=0.027752; I^2=0%). **Conclusion:** Topiramate as monotherapy showed low safety and efficacy in reducing the frequency of migraines, with side effects such as paresthesia, anorexia, and fatigue. Conversely, the combination with vitamin D3 showed better results in preventing migraines in younger patients, with a lower risk of adverse events.

Background: Magnetic Resonance-guided Focused Ultrasound (MRgFUS) is well-established for the treatment of essential tremor and is emerging as a promising non-invasive treatment for Parkinson's disease (PD). However, the safety of MRgFUS among patients with PD is not well established. **Objective:** To evaluate the incidence of adverse events among medication-refractory patients with PD treated with MRgFUS. **Methods:** PubMed, Embase, Scopus, and Cochrane databases were searched up to December 2023, following the recommendations in the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement. Included studies were peer-reviewed randomized controlled trials (RCTs) comparing MRgFUS to sham-procedure among patients with medication-refractory PD. The Cochrane risk-of-bias tool for randomized trials (RoB 2) was used for quality assessment. **Results:** Three RCTs were included, with a total of 161 patients (MRgFUS, n=115). Dizziness was the most commonly reported procedure-related adverse event (odds ratio [OR] 4.25; 95% confidence interval [CI] 1.23-14.64, p=0.02, I^2=0%). Pin-site complications (OR 0.52, 95% CI 0.23-1.20, p = 0.13, I^2 = 0%) and headache (OR 0.88, 95% CI 0.19-4.16, I^2=48%) were also notable. Given the heterogeneity related to headache, a leave-one-out sensitivity analysis was conducted, resulting in a reduction in the proportion of variance (I^2) to 0% (OR 2.14, 95% CI 0.47-9.67; p = 0.32). The most notable ablation-related adverse events included gait disturbances (OR 4.53, 95% CI 0.79-26.07, p=0.09, I^2=0%), primarily ataxia, and facial disturbances (OR 2.93, 95% CI 0.49-17.51). Most ablation-related adverse events persisted at 3 and 4-month follow-up. While no significant differences were observed between intervention and sham groups for life-threatening adverse events (OR 1.76, 95% CI 0.55-5.65; p=0.35; I^2=0%), severe adverse events included pulmonary embolism, persistent hemiparesis, cholecystitis, and falls. RoB2 analysis indicated a low risk of bias for all included studies. **Conclusion:** MRgFUS demonstrated a reasonable safety profile for the treatment of patients with medication-refractory PD. Statistically significant associations were observed for procedure-related dizziness, while gait disturbances, despite being relevant, were not statistically significant. These findings emphasize the need for further multicenter studies to clarify comprehensively the safety profiles of MRgFUS and its implementation.

Correspondence: Fernanda Firmiano Casarotto; Email: ferfirmiano@hotmail.com.

Background: Subarachnoid hemorrhage (SAH) is a neurosurgical emergency associated with high morbidity and mortality. **Objective:** To prospectively evaluate all cases of SAH attended to by the service during 2023-24, seeking to detail their clinical presentation and the accuracy of complementary diagnostic methods. **Methods:** The sample was 127 patients (82 women - 64.6%), with an average age of 50.4 years (SD of 12.2) presenting with a clinical picture suggestive of SAH confirmed by neuroimaging. All patients were evaluated by a single examiner, who completed a questionnaire developed specifically for this study. **Results:** The most frequent presentation (64 patients - 50.4%) was a sudden headache not preceded by sentinel headache. Sentinel headache was reported by forty patients (31.5%) who sought emergency care for an unusual headache. Thirteen patients (10.2%) presented with a clinical picture suggestive of syncope as the first manifestation of bleeding. On physical examination, the average Glasgow Coma Scale score was 12.8; the average systolic blood pressure was 160 (SD: 33) and the average diastolic blood pressure was (SD: 21). Nuchal rigidity was found in 85 patients (67%), and 49 patients (38.6%) presented with focal, motor and sensory signs. Fifty-three patients (42%) had Hunt-Hess scores between 1 and 3. Cranial CT showed some SAH-related alteration in 103 cases (81%). Cerebral angiography was performed on 124 patients (3 died before the exam): 66 (53%) with aneurysm without vasospasm, 56 (45%) with aneurysm and vasospasm, and 2 (1.6%) showed no abnormalities on the first exam. **Conclusion:** The study demonstrated that a significant portion of patients presented differently from the classic descriptions in the literature of an atraumatic SAH, contributing to diagnostic errors during the initial assessment of a condition with high morbidity and mortality, even when diagnosed early and appropriately.

Correspondence: Cristiane Araujo Martins Moreno; Email: cristianeammoreno@gmail.com.

Background: Chronic progressive external ophthalmoplegia (CPEO) is the most common manifestation of mitochondrial diseases and is characterized by bilateral symmetrical progressive ptosis and reduced ocular motility. CPEO can be isolated or accompanied by a clinical feature of systemic involvement of mitochondrial dysfunction (CPEO plus syndrome). Both mtDNA and nDNA can be affected in mitochondrial diseases. Most common genetic variants that cause PEO are point mutations at mtDNA, large scale deletions at mtDNA or even mutation in nuclear genes interfering at mitochondrial function. The most common method used for the molecular studies in these conditions includes direct mitochondrial from muscle or urine DNA sequencing. Diagnostic rates from CPEO using saliva WES are not well defined in the literature. **Objective:** Here we present a molecular analysis of saliva WES from 28 patients presenting PEO. Patients and **Methods:** Patients had a confirmed diagnosis of mitochondrial myopathy and presented PEO at clinical exam. Whole exome sequencing was performed from saliva DNA. Large Scale deletions were also analyzed from BAM files using custom scripts. **Results:** 28 patients were included in the study. Patients were 46 ±22 years old (6 male e 21 female). 19 patients presented CPEO and nine patients presented CPEO-plus. A conclusive molecular confirmation was obtained for seven patients in the CPEO group: POLG (n=4), MYH2(n=1), DGUOK(n=1), MSTO1(n=1), PNPLA8(n=1) and mt large-scale deletion (n=1); and four patients in CPEO+ group: MT-TK (n=1), SLC24A4 (n=1), TAMM41 (=n1) and TRMT10 (n=1). **Conclusion:** CPEO is a common manifestation among mitochondrial diseases. WES was able to analyze both nuclear DNA and mtDNA and found a definite molecular diagnosis in 36% of CPEO and 44% of CPEO+, oh those, two patients from the CEPO group carried mutations in mtDNA. Large-scale deletion was detected in one single patient. In order to compare both techniques, we'll perform a WES from muscle DNA as the next step.

Background: The hospital length of stay (LOS) after surgical procedures, such as brain tumor resection, tends to be increasingly shorter, as it seems to be associated with lower complication rates, reduced risk of infection, and better cost-benefit. However, the safety of shorter LOS compared to longer stays in patients who underwent those kinds of procedures remains unclear. **Objective:** To assess the safety of same-day discharge compared to postoperative day 1 in patients who underwent brain tumor resection. **Methods:** We searched MEDLINE, Scopus, and Web of Science databases for studies that assessed shorter LOS among patients who underwent brain tumor resection intervention. Data were examined using the Mantel-Haenszel method and 95% confidence intervals (CIs). Heterogeneity was assessed using I^2 statistics. R, version 4.3.2., was used for statistical analysis. **Results:** Five retrospective cohort studies encompassing 1,102 patients with resectable brain tumors were included, of whom 385 (34.94%) underwent early discharge. In comparison with later discharge, same-day discharge showed no statistically significant difference in 30-day readmission rates (OR 0.54; 95% CI 0.28-1.07; p=0.078), with minimal heterogeneity (I^2=0). Similarly, no significant differences were noted in postoperative neurological deficits (RR 0.73; 95% CI 0.35-1.54; p=0.413), wound complications (RR 1.02; 95% CI 0.41-2.52; p=0.968), or mortality (RR 0.36; 95% CI 0.06-2.11; p=0.255). **Conclusion:** In this meta-analysis, no statistically significant differences were seen regarding neurological complications, wound complications, mortality, and readmission 1-30 days postoperatively, which showed SDD and POD1. Further methodologically sound randomized controlled trials are needed to produce a more accurate analysis.

Scar dancing syndrome: a rare presentation of a unique condition

Bruno Henrique Carneiro Costa Filho[1], Vitor Maia Arca[1], Víctor de Moraes Chagas[1], João Pedro Matos de Santana[1], Ana Eunice Oliveira Rodrigues[2], Míriam Carvalho Soares[2], Marcos Eugenio Ramalho Bezerra[1]

Correspondence: Bruno Henrique Carneiro Costa Filho; Email: brunohccosta97@gmail.com.

Case presentation: A 40-year-old man with suffered a thoracic spinal cord trauma, at T8 level, secondary to a car accident. He was treated surgically and did not present at first any weakness or sensory sequelae related to the spinal cord injury. However, he began to complain of pain and involuntary contractions around the surgical scar, starting two months after the event. In this context, it was decided for botulinum toxin (BT) treatment, with 100 units of onabotulinum toxin A applied. It was injected in the greater and lesser rhomboid muscles bilaterally, as well as supraspinatus, latissimus dorsi, teres minor, and paravertebral muscles on the right. After 28 days of applying the toxin, the patient reported a subjective perception of 50% improvement of muscle contractions. Furthermore he reported a pain intensity reduction of 3 points in the visual analog scale (from 7 to 4). **Discussion:** Peripherally induced movement disorders (PIMD) can be defined as abnormal and involuntary movements that occur after a traumatic event involving cranial or peripheral nerves, as well as its roots. The diagnostic criteria requires a clear anatomical and temporal association with the trauma to determine causality. The phenomenology is variable and may present mainly as dystonia, tremors, and myoclonus. Among cases of PIMD, the rare dancing scar syndrome has been described, as characterized by the presence of involuntary movements around the site of a surgical incision. In a previously published systematic review, the average time for symptom onset was 21 days, with 95% of patients starting symptoms in less than a year. The presence of sensory symptoms was present in 42% of patients. The main sensory symptoms are hyperalgesia, hyperesthesia, hypoalgesia, hypoesthesia, or the emergence of a complex regional pain syndrome. In a previous case report series, in patients who received treatment with botulinum toxin, around 50% of cases showed symptomatic improvement after application. A common factor among patients who had better responses was the presence of neuropathic pain. Neuropathic pain was also present in the clinical picture of the patient described in this case report, suggesting a greater benefit of this treatment for this group of patients. **Final comments:** We present a case of scar dancing syndrome, a rare presentation of PIMDs, for which the best therapeutic option is not yet established. Even though BT injection did not cease the abnormal movements completely, it's role in controlling the patient's pain was remarkable.

Correspondence: Maria Weryca de Souza Belo Silva; Email: mariaweryca@hotmail.com.

Case presentation: Male patient, 16 years old, presented with a complaint of sudden, intense pain in his thighs and calves, progressing to paresthesias in the soles of his feet and difficulty walking. He was admitted to a referral hospital, where he developed urinary and fecal retention. Neurological examination revealed flaccid paraplegia, areflexia in the lower limbs, and painful hypoesthesia up to the T12 spinal level. During the investigation, neuroimaging showed a pattern of longitudinally extensive myelitis, suggesting autoimmune/demyelinating diseases of the central nervous system that present with such findings. However, what appeared to be typical extensive myelitis was actually a spinal cord imaging alteration mimicking longitudinally extensive myelitis. After completing the investigative exams, the diagnosis of schistosomal myeloradiculitis was confirmed. **Discussion:** Schistosomiasis is a prevalent disease in tropical regions. This condition can affect the central nervous system, with schistosomal myeloradiculitis being its most common and severe form. In this manifestation, magnetic resonance imaging often reveals alterations such as spinal cord and/or cauda equina root enlargement on T1 sequences; hyperintensity in the affected region on T2 sequences; and contrast enhancement, usually heterogeneous and granular. In the reported case, these findings were visible on neuroimaging; nevertheless, the appearance of longitudinally extensive myelitis initially directed clinical reasoning towards other hypotheses. **Final comments:** The presented case illustrates a relatively common condition, especially in endemic areas. Notably, in addition to the typical neuroimaging alterations found in schistosomal myelopathy, an imaging pattern mimicking longitudinally extensive myelitis was also observed. This led to the consideration of various other hypotheses until the case was resolved through histopathological examination.

Correspondence: Amanda de Jesus Araujo Dias; Email: a291103@dac.unicamp.br.

Spinocerebellar Ataxia 27B (SCA27B) is a recently described autosomal dominant neurodegenerative disease, prevalent in Europe and North America, but not yet properly investigated in Latin America. It is caused by a heterozygous trinucleotide repeat expansion (GAA) >300 in FGF14 gene. Since it is an expansion disorder, diagnosis requires specific molecular techniques. In this scenario, the aim of this study is to screen a large cohort of adults with unsolved ataxias for SCA27B. To date, 108 patients with ataxia were recruited, including patients negative for SCA1,2,3,6,7 and 8. DNA was extracted from peripheral blood and analyzed using different PCR techniques. Initially, long-range PCR (LR-PCR) was used to exclude patients with two alleles within the normal repeat range, 90 patients were negative for FGF14 expansion and eighteen patients showing only one allele in normal size range. Repeat-primed PCR was carried out to identify the expansion and in five out of the 18 analyzed patients the expansion pattern was detected (4.6%). The phenotype was a late-onset slowly progressive ataxia in all cases, with paroxysmal symptoms in 3/5 and pyramidal signs in 1/5. None of them had sensory manifestations. The mean age at onset was 55 years. Our results are consistent with previous publications, which showed that SCA27B ataxia presents initial symptoms at an advanced age and has slow progression. The prevalence of SCA27B we found (4.6%) was much smaller than in French Canadian (61%) and European (18%) cohorts. In conclusion, LR-PCR followed by RP-PCR is a reliable and fast approach to diagnose SCA27B. The phenotype of Brazilian patients with SCA27B is similar to previous reports, however considering that most of the patients included in this study have unsolved ataxia, often with distinct clinical manifestation, the frequency is much smaller. Further studies are needed to understand the genetic epidemiology of this new disease beyond Europe and North America.

Seasonality of fatigue in Parkinson's disease in a high temperature location

Luma Rodrigues da Silva[1], Lara Beatriz Alves Batista[1], Pedro Henrique Ximenes Ramalho Barros[1], Isabel Maria Oliveira Macêdo Lima[1], Sabrina Ruthiele Santos de Carvalho[1], Jonatas Paulino da Cunha Monteiro Ribeiro[1], Samuel de Castro Campos[1], Gustavo Viana Castro[1], José Henrique de Melo Feitosa[1], Kelson James Almeida[1]

[1]Universidade Federal do Piauí, Teresina PI, Brazil.

Correspondence: Luma Rodrigues da Silva; Email: lumarodrigues@ufpi.edu.br.

Background: Fatigue is one of the most common and disabling non-motor symptoms in Parkinson's disease (PD), and its assessment is important to measure the quality of life of these patients. Simultaneously, rising temperatures due to global warming may aggravate conditions such as fatigue. The city of Teresina has a warming scenario that will only become a reality in some regions of the globe in the next decade, making it relevant to analyze the influence of temperature on neurological diseases in this city. **Objective:** To assess the severity of fatigue and quality of life in patients with Idiopathic Parkinson's Disease (IPD) according to seasonal variations in a high temperature location. **Methods:** This is a longitudinal observational study. It included patients with IPD according to the UK Parkinson's Disease Society Brain Bank and Movement Disorders Society criteria, followed at a movement disorder center in Teresina-PI. Assessments took place in the high temperature period (September to December) and the mild temperature period (January to April), using the Unified Parkinson's Disease Rating Scale (UPDRS), Montreal Cognitive Assessment (MoCA), Parkinson's Disease Questionnaire-39 (PDQ-39), and Fatigue Severity Scale (FSS). The R software (R Core Team) was used for statistical data analysis. The normality assumption of the data was verified by the Shapiro-Wilk test. The Wilcoxon test was used to compare the UPDRS scale values in the high and mild temperature periods. The paired t-test was used to compare the levodopa equivalent dose (LED) values and the FSS and PDQ-39 scales in the high temperature period (HTP) and mild temperature period (MTP). The criterion for a statistically significant difference was p-value <0.05. **Results:** A sample of 16 patients with a mean age of 65 years, 75% male, with a mean duration of symptoms of 9.06 years and a mean diagnosis time of 8.12 years, the mean MoCA score was 18.81. The mean UPDRS was 33.18 in HTP and 31.64 in MTP (p=0.9645). The average LED in HTP was 617.31, and in MTP was 667.37 (p=0.1730). The average FSS in HTP was 4.56, while in MTP was 4.53 (p=0.9227). The average PDQ-39 was 46.33 in HTP and 45.36 in MTP (p=0.6906). There were no statistically significant differences between the high and mild temperature periods. **Conclusion:** The severity of fatigue and quality of life in patients with Idiopathic PD did not differ between seasons in a high temperature location. The restricted sample became the current findings limited.

Secondary epileptogenesis in acquired hemispheric lesions: a case of too-little-too-late?

Carolina Heck Haubrich[1], William Alves Martins[1], Rafael Paglioli[1], Thomas More Frigeri[1], Fernanda Schuh[1], Eliseu Paglioli[1], André Palmini[1]

[1]Universidade Católica do Rio Grande do Sul, Hospital São Lucas da Pontifícia, Porto Alegre RS, Brazil.

Correspondence: Carolina Heck Haubrich; Email: carolhhaubrich@gmail.com.

Case presentation: Case 1: An 18-year-old female sustained a traumatic brain injury at age two, resulting in multiple cerebral contusions, hydrocephalus, and subsequent epilepsy with left hemiparesis. Despite normal developmental milestones, she suffered daily seizures characterized by altered consciousness, bilateral automatisms, and occasional tonic extension of both arms. MRI revealed significant atrophy, gliosis, and hyperintensities in the right hemisphere. Scalp EEG localized seizure activity to the right temporal and frontal lobes. Initial multi-lobar resection failed to achieve seizure control. Eight years later, ongoing refractory seizures prompted re-evaluation, revealing only frontoinsular connections between hemispheres and pronounced atrophy in the presumed "healthy" hemisphere. EEG indicated interictal discharges in the left frontotemporal region and ictal activity in the remaining right frontal region. Subsequently, a right hemispherectomy was performed. Initial seizure freedom lasted one month, followed by recurrence characterized by altered consciousness and automatisms. Adjustments in antiepileptic medications reduced seizure frequency to once per week. Case 2: A 15-year-old female presented with seizures from birth, featuring tonic extension of the right arm, dystonic posture of the left arm, and tonic eye and neck deviation to the left. MRI showed a congenital lesion affecting the entire right hemisphere, corroborated by ictal EEG showing hemisphere involvement. She underwent functional hemispherectomy and initially experienced three months of seizure freedom before relapse. Further investigation revealed no residual connections between the diseased hemisphere and healthy brain tissue. MRI exhibited diffuse cortical atrophy, primarily in frontal regions. Co-registered ictal SPECT with MRI (SISCOM) identified contralateral seizure activity, pinpointing it to the pre-motor regions. Despite medication adjustments, she continues to experience weekly seizures. **Discussion:** Epilepsy surgery is typically effective for patients with focal lesions, aiming for positive outcomes through meticulous resection planning, medication optimization, and surgical feasibility. However, the recurrence of seizures in the "healthy" hemisphere in both cases underscores potential challenges and complications. Hidden focal cortical dysplasia may manifest with subtle contralateral disease signs, as seen in Case 1, leading to unexpected contralateral seizure recurrence. Animal studies suggest prolonged severe epileptic activity may induce healthy neurons to synchronize into seizure activity. **Final comments:** Early surgical evaluation is critical as epilepsy surgery offers potential cure for severe cases. Prolonged epilepsy, even with acquired lesions, risks irreversible cortical damage and may predispose healthy neurons to epileptogenic changes, emphasizing the importance of timely intervention and comprehensive post-operative management.

Secondary nummular headache: a case report

Bibiana Mayer[1], Chadi Emil Adamo[2]

[1]Universidade de Ribeirão Preto, Ribeirão Preto SP, Brazil.

[2]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Bibiana Mayer; Email: bibiana_mayer@hotmail.com.

G.V.S., male, 24 years old. One year ago, he used a psychostimulant (lisdexamfetamine 70 mg) for the first time before taking an exam, resulting in body tingling, headache, and diaphoresis, associated with tachycardia of 160 beats per minute. In the emergency room, an electrocardiogram revealed supraventricular tachycardia and a hypertensive peak. Heart rate control and analgesia were administered, leading to remission of the acute episode. Subsequently, he experienced insomnia with difficulty initiating sleep. He then developed a chronic headache localized to the high convexity, well-demarcated, with an area of approximately 3.5x2.5 cm, characterized by dysesthesias, tingling, allodynia, and pressure pain, occurring daily. The patient had previously undergone occipital nerve blocks, radiofrequency, transcranial magnetic stimulation, and prophylactic medication with topiramate, all of which showed minimal efficacy. Magnetic resonance imaging of the brain revealed a small extradural hydrocephalus adjacent to the left superior frontal gyrus and ipsilateral bone thinning. Consequently, a diagnosis of secondary nummular headache was made, secondary to the structural alteration. Beta-blocker therapy with propranolol was initiated, gradually and cautiously increased to 160 mg/day (progressing with satisfactory response), and nortriptyline was introduced, gradually increased to 50 mg/day. Upon reevaluation, the patient reported substantial improvement after three months of treatment. The pain in nummular headache is localized to a round or elliptical focus that is fixed in place, ranging in size from 1 to 6 cm and may be continuous or intermittent. In rare cases, it may be multifocal. Nummular headache is usually continuous with exacerbations, although it can be episodic. There may be focal sensory disturbances, such as allodynia or hypesthesia. The pathophysiology is unknown, although a focal neuropathic disorder has been suggested. In the authors' experience, the presentation is best treated by detailing the entire phenotype and treating the underlying primary headache disorder. Local dermatologic or bony lesions must be excluded by examination and investigation. Treatment includes tricyclics, such as amitriptyline, or anticonvulsants, such as topiramate, valproate, or gabapentin. Additionally, propranolol has been mentioned as a treatment option. In this particular case, reducing the arterial and venous gradient with propranolol was found to be an effective treatment for the patient. The condition is considered difficult to treat, although this is complex in relation to any underlying headache disorder.

Seizure outcome in patients with malformations of cortical development other than focal cortical dysplasia in a tertiary center

Athos Paixão Silva Santos[1], Marina Koutsodontis Machado Alvim[1], Clarissa Lin Yasuda[1], Fernando Cendes[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Athos Paixão Silva Santos; Email: a231744@dac.unicamp.br.

Background: Malformations of cortical development (MCD) comprise a vast and heterogeneous group of disrupted cerebral cortex formation. The MCD may be classified according to the predominant embryological stage compromised: a) abnormal proliferation or increased apoptosis of neurons or glial cells (microcephaly, hemimegalencephaly, focal cortical dysplasia - FCD); b) abnormal neuron migration (heterotopia, lissencephaly-pachygyria); c) abnormal cortical organization (polymicrogyria, schizencephaly). MCDs are the most common cause of refractory focal epilepsy in adults after hippocampal sclerosis and the most frequent in children. **Objective:** To evaluate seizure outcomes in patients with different types of epilepsy caused by MCD other than FCD. **Methods:** The clinical data of 36 patients with MCD (excluding FCD) and epilepsy from tertiary center outpatient clinics were obtained from medical records. **Results:** The mean follow-up was 19.5 years. Two patients had hemimegalencephaly, 14 heterotopia (2 double cortex and 12 nodular heterotopia), 8 polymicrogyria, 7 schizencephaly associated with polymicrogyria, and 5 had schizencephaly associated with polymicrogyria and heterotopia. One patient underwent callosotomy and 4 patients underwent resective surgery: 2 with associated FCD (1 with hemimegalencephaly and 1 with polymicrogyria), and 2 with associated hippocampal sclerosis (1 with nodular heterotopia and 1 with polymicrogyria, schizencephaly and heterotopia combined). Of these, one (25%) was seizure-free after the procedure, one (25%) was classified as Engel IB, one (25%) as class IIA, and one (25%) as class IVA. Only 2 patients were without antiseizure medication (one after surgery and one not operated). The remaining patients were taking 1 to 5 ASM (mean 2.6). Five of the 36 (14%) patients were seizure-free for at least one year: 3 with nodular heterotopia, 2 with polymicrogyria, and one with polymicrogyria, schizencephaly, and heterotopia combined. The mean seizure frequency was 23.5 per month in patients with nodular heterotopia, 15.5 per month in those with double cortex, 38.5 per month in those with polymicrogyria, 2 per month in those with polymicrogyria with schizencephaly, 14 per month in those with polymicrogyria, schizencephaly, and heterotopia combined. Family history of epilepsy was present in 10/36 (28%): 2 patients with nodular heterotopia, one with double cortex, one with polymicrogyria, 4 with polymicrogyria and schizencephaly, and one with polymicrogyria, schizencephaly, and heterotopia combined. **Conclusion:** This tertiary center cohort study characterizes the clinical data from patients with cortical malformation other than FCD. Interestingly, a few patients (14%) were under seizure control with the use of ASM. Among the four patients who underwent surgical treatment, excluding callosotomy, 3 (75%) had significant improvement (Engel IA-IIA).

Seizure outcomes in patients with burned-out hippocampus syndrome operated after noninvasive investigation

Leslie Ortega Hernandez[1], Renata Torres Jaimes[1], Marina Alvim[1], Enrico Ghizoni[1], Clarissa Lin Yasuda[1], Fernando Cendes[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Leslie Yadira Ortega Hernandez; Email: leslie-ortega@hotmail.com.

Background: Temporal lobe epilepsy secondary to hippocampal sclerosis (MTLE-HS) is the most prevalent subtype of refractory epilepsy among adult patients undergoing presurgical evaluation. The definition of the epileptogenic zone requires the concordance of clinical, imaging, and electrophysiological data. However, some patients with severe hippocampal sclerosis have an unusual spread of seizure discharges, leading to a significant discrepancy between MRI findings and scalp ictal EEG recordings, also known as a "burned-out hippocampus syndrome" (BHS), which makes the surgical decision due to suspicion of bilateral disease. Previous reports have shown that the intracranial EEG of these patients localizes the seizure onset in the atrophic hippocampus with a spread to the contralateral temporal neocortex before the ipsilateral side. **Objective:** To evaluate the postoperative outcome of patients with BHS operated with noninvasive investigation. **Methods:** We retrospectively reviewed the medical records of patients with temporal lobe epilepsy who

underwent surgery at the Hospital das Clínicas of Unicamp from 2011 to 2024 with the following criteria: a) unilateral hippocampal sclerosis and b) surface electroencephalogram with onset of the majority of ictal activity in the contralateral side and few or none on the side of hippocampal atrophy. **Results:** Of all patients with MTLE-HS who underwent surgery at this time, 5 met the diagnostic criteria for BHS, four women and one man, with a mean age onset of epilepsy of 21.2 years, mean epilepsy duration of 26.4 years, and mean seizure frequency prior to surgery of 8.9 seizures per month. Four patients had right, and one had left HS. Ictal activity was discordant with hippocampal atrophy in 75% of the records. The unilateral interictal activity was discordant in 28.9% of the records, and bilateral interictal EEG activity was predominantly contralateral to the affected hippocampus in 50% of the cases. FDG-PET/SPECT scans showed hypometabolism or ictal hyperperfusion lateralizing to the side of the hippocampal sclerosis in all patients. The surgical decision was based on all noninvasive investigations, including neuropsychological evaluation. At the last postoperative follow-up (mean 5,8 years) 3 (60%) were classified as Engel Ia, one (20%) as Engel Ib, and one (20%) as Engel IIb. **Conclusion:** In this series of BHS, all patients had excellent postoperative outcomes, becoming seizure-free or almost seizure-free. Some patients with MRI signs of unilateral hippocampal sclerosis have scalp ictal activity that is falsely lateralizing (BHS), which does not contraindicate surgical management when other studies are congruent. These patients may not need intracranial EEG recordings when semiology, neuropsychological investigation, and other noninvasive techniques for localizing the epileptogenic zone, such as FDG-PET and ictal SPECT, lateralize to the side of the HS.

Seizures and myoclonus in systemic lupus erythematosus: an uncommon neurological presentation in a young woman

Carolina Oldoni[1], Alexandre Baldissera[1], Eduardo Drews Amorim[1], Raphael Machado Castilhos[1], Artur Francisco Schumacher Schuh[2], Marino Muxfeldt Bianchin[2]

[1]Hospital de Clínicas de Porto Alegre, Porto Alegre RS, Brazil.
[2]Universidade Federal do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Eduardo Drews Amorim; Email: eduardodrewsamorim@gmail.com.

Case presentation: A 25-year-old previously healthy woman presented to our emergency department with a one-month history of intermittent fever. Two days before arriving at the emergency department, she developed generalized myoclonus. Upon arrival, she experienced a focal seizure in her left upper limb that evolved into bilateral tonic-clonic seizures. Valproic acid and clobazam led to minimal improvement in the myoclonus. Brain MRI was unremarkable. Cerebrospinal fluid (CSF) analysis showed 9 lymphocytes/dL, normal glucose, and protein levels. Extensive testing for infectious pathogens in blood and CSF was negative. The patient had normochromic normocytic anemia, leukopenia, a positive Coombs test, decreased C3 and C4 complement levels, ANA > 1/640 (AC-1), ANA IgG > 1/320, anti-Sm = 135.4 UI/ml, and anti-RNP = 96.5 UI/ml. Anti-Ro (SS-A) and Anti-La (SS-B) were negative. Systemic lupus erythematosus (SLE) was diagnosed. **Discussion:** Neuropsychiatric SLE can initially be characterized into 19 types of neurological manifestations according to the American College of Rheumatology, though it is important to note that it is not limited to these 19 manifestations, despite them being the major subgroups related to the central and peripheral nervous systems. Among these manifestations, in terms of movement disorders, the most frequently reported is chorea. It is commonly known that there is a scarce volume of scientific publications about neuropsychiatric lupus, although there are references that cite that over the course of the disease (SLE), at least 50% of patients will present some neuropsychiatric manifestation. Among this small group of publications, cases with presentations other than chorea are even more rare, making the description of this case an important contribution to the global literature, to be remembered as a differential diagnosis in similar cases. **Final comments:** Despite being a rare clinical presentation, SLE should be considered in all patients presenting with encephalitis and myoclonus. Early identification and appropriate treatment are essential to improve the prognosis and quality of life for patients.

Sensory aphasia as sole manifestation of focal status epilepticus

Bruno Barros de Padua Andrade[1], Rodrigo Ferreira Faria[1], Giovanna Santos Rodrigues[1], Luiz Fernando Mohallem Reynaldo[1], Victoria Lot Avezum Mestriner[1], Matheus Spilari[1], Elizardo Nogueira Junior[1], Gloria Maria Almeida Tedrus[1], João Caetano Coutinho Mariuzzo[1]

[1]Pontifícia Universidade Católica de Campinas, Campinas SP, Brazil.

Correspondence: Bruno Barros de Padua Andrade; Email: brndepadua@gmail.com.

Case presentation: Male, 70 years old, previously epileptic due to structural cause after ischemic stroke in 2017, forwarded to tertiary hospital after two episodes of tonic clonic seizures, with no description of focal seizures preceding both events. In the past, patient had shown a pattern of impaired awareness non motor seizures with short duration and typical post ictal of confusion and drowsiness. At first assessment, patient has shown repetitive speech, descride as possible paralalia, read at first as possible new aphasia or Todd's paralysis. After realization of Magnetic Resonance Imaging (MRI), it was evidenced hyperintensity in DWI at Wernicke's área, characterizing cortical laminar necrosis. At EEG, it was reflected as frequent epileptiform paroxysms, characterized by sharp waves and spicules on frontotemporal at left cerebral hemisphere (possible dominant). Due to focal aspects of seizure, advanced age and comorbidities, it was chosen to optimize anticonvulsant treatment with later remission of language deficit, achieving full recovery during hospitalization. **Discussion:** Speech or language disturbance is frequently present during seizures, although ictal aphasia is infrequent as the sole symptom of epileptic seizures. De Pasquet et al. first reported a case of ASE in 1976. Magnetic Resonance Imaging (MRI) gives more precise information for detection of anatomical lesions associated with epilepsy and plays a key role in the management of epileptic patients when in association of EEG, that can be helpful to precise the location of the epileptiform focus and pattern. The presence of focal status must be always considerate at patients who have previously diagnosis of epilepsy, but a chance from pattern of seizure, should demands inquisition of other diagnosis, such as neurovascular diseases. **Final comments:** The RMI and EEG play a key role in the diagnosis of the structural abnormalities, but should not delay the begin of treatment in order to prevent prolonged seizure activity as cause of neuronal damage and poor outcomes. Once diagnosed, the treatment must be accurate and guided to etiological definition.

Sensory motor axonal polyneuropathy in association with granumatosis with polyangiitis and secondary Sjogren's syndrome: a case report

Georgia Piredda Fernandes[1], Raysa Fontes Martins[1], Fernanda Mendes Carneiro[1], Ana Flávia Amitti Alvarez[1], Nicolas de Sousa Belonato Terra[1], Marcio Assis Messias Filho[1]

[1]Hospital São José do Avaí, Itaperuna RJ, Brazil.

Correspondence: Raysa Fontes Martins; Email: 190062471@aluno.unig.edu.br.

Case presentation: A 67-year-old woman presented with intense pain and distal weakness of the lower limbs, associated with edema and arthralgia with difficulty walking for 2 months. He developed disproportionate and areflexic flaccid tetraparesis, weight loss and urinary retention. On examination, there was distal muscular atrophy of the four segments, disproportionate flaccid tetraparesis with muscle strength scores as follows: distal upper limbs -3 and distal lower limbs -2, according to the Medical Research Council Scale (MRC). Deep reflexes abolished (patellar, achilleus, biccipital and triccipital). Normal cranial nerves. He reported immunization against COVID-19 (Astrazeneca) 4 days before the onset of symptoms, with post-vaccination Guillain-Barré syndrome (GBS) as the diagnostic hypothesis. The electroneurographic study revealed a primarily axonal sensorimotor polyneuropathy, affecting nerves in the upper and lower limbs, compatible with the axonal variant of GBS. Human immunoglobulin 0.4g/kg/day was administered for 5 days, there was a slight improvement in muscle strength with muscle strength scores evolving to: distal upper limbs -4 and distal lower limbs -3 according to the Medical Research Council Scale (MRC). After 6 months, it progresses again insidiously with disabling pain, progressive, asymmetric quadriparesis, worse in the left upper limb and left lower limb, in addition to xerostomia, xerophthalmia, livedo reticularis in the lower limbs, scleritis of the right eye and oral ulcers. For investigation, serology was requested, resulting in positive ANCA, positive anti-Ro, positive anti-MPO, in addition to a ground-glass interstitial lung lesion. An evaluation was carried out in conjunction with rheumatology and ophthalmology, and, based on clinical characteristics and laboratory and imaging findings, she was diagnosed with Granulomatosis with Polyangiitis (GP) and Secondary Sjögren's syndrome (SS), with sensory axonal polyneuropathy as the first symptom. engine. The patient continues to be treated with monthly cyclophosphamide, maintaining severe functional disability. **Discussion:** Early diagnosis of SS and GP remains a challenge given the complexity of clinical manifestations, in addition to the need for comprehensive immunobiological tests. In the case in question, it is worth highlighting that the neurological manifestations preceded the typical symptoms of the pathologies in question. This report allows us to discuss the clinical situation and immunological patterns of this condition and emphasizes the importance of comprehensive immunological testing for patients with GBS variants. **Final comments:** The association between GP and SS brings a high level of complexity to the clinical presentation and represents a challenge diagnosis. The specific temporal relationships and clinical presentation of this overlap syndrome can be difficult, and it is important to suspect this correlation given the early appearance of a polyneuropathy.

The term polyneuropathy refers to a generalized involvement of peripheral nerves, usually involving mainly the distal nerves and, more often, presenting with sensory, motor, and autonomic symptoms and clinical findings. Drug-induced peripheral neuropathy (DIPN) is a persistent condition, most often associated with anticonvulsants, chemotherapy, cardiovascular, psychotropic, and antimicrobial drugs, such as Metronidazole. In this article, we report the case of a patient who developed polyneuropathy secondary to the use of Metronidazole. **Case presentation:** D.D.S.L., a 45-year-old female, previously healthy, presented with abdominal discomfort. Entamoeba histolytica was detected after investigation, and she started a 7-day cycle of 500 mg of Metronidazole three times a day for seven days, without clinical response. A new therapeutic approach was attempted, with three cycles of 2 grams of Secnidazole single dose and Tinidazole for four weeks. However, the patient presented dysesthesia in the distal third of the thighs, followed by allodynia in the four limbs and trunk. After new abdominal discomfort, three months after the first medication cycle, another pharmacological cycle was started. Neurological examination and electroneuromyography (ENM) examination suggested axonal sensorimotor polyneuropathy in all four limbs. **Final comments:** Polyneuropathy can be caused by many factors, including some frequently prescribed drugs such as Metronidazole and other medications in the 5-nitroimidazole group. Therefore, although the relationship between these drugs and polyneuropathy is not fully elucidated, their neurotoxicity is indisputable, even in rare cases, but with significant variability in terms of the dose-dependent potential for this disease.

Infection is a complication after stroke and outcomes vary by sex. Thus, we investigated if sepsis affects brain from ischemic stroke and sex involvement. Male and female Wistar rats, were submitted to middle cerebral artery occlusion (MCAO) and after 7 days sepsis to cecal ligation and perforation (CLP). Infarct size, neuroinflammation, oxidative stress, and mitochondrial activity were quantified 24 hours after CLP in the prefrontal cortex and hippocampus. Survival and neurological score were assessed up to 15 days after MCAO or 8 days after CLP (starting at 2 hours after MCAO) and memory at the end. CLP decreased survival, increased neurological impairments in MCAO females. Early, in male sepsis following MCAO led to increased glial activation in the brain structures, and increased TNF-α and IL-1β in the hippocampus. All groups had higher IL-6 in both tissues, but the hippocampus had lower IL-10. CLP potentiated myeloperoxidase (MPO) in the prefrontal cortex of MCAO male and female. In MCAO+CLP, only male increased MPO and nitrite/nitrate in hippocampus. Males in all groups had protein oxidation in the prefrontal cortex, but only MCAO+CLP in the hippocampus. Catalase decreased in the prefrontal cortex and hippocampus of all males and females, and MCAO+CLP only increased this activity in males. Female MCAO+CLP had higher prefrontal cortex complex activity than males. In MCAO+CLP-induced long-term memory impairment only in females. The parameters evaluated for early sepsis after ischemic stroke show a worse outcome for males, while females are affected during long-term follow-up. Keywords: ischemic stroke, sepsis, sex differences, neuroinflammation, oxidative stress.

Background: Ischemic stroke is characterized by reduced cerebral blood flow, leading to mitochondrial dysfunction, oxidative stress, and cell death, accompanied by an intense neuroinflammatory response. Inflammation is a key mechanism in the progression of ischemic stroke, affecting responses from important structures such as the hypothalamus. **Objective:** To investigate the relationship between ischemic stroke and sepsis in young rats of both sexes, analyzing the levels of cytokines in the hypothalamus. **Methods:** Male Wistar rats aged 60 days were randomized into four experimental groups, namely: sham+sham, sham+CLP, MCAO+sham, and MCAO+CLP, and subjected to the middle cerebral artery occlusion model (MCAO) for 7 days, then to the cecal ligation and perforation (CLP) sepsis model, suffering painless death after 24 hours, and the hypothalamus was removed. **Results:** All groups showed increased levels of TNF-a and IL-1B compared to sham+sham in both males and females, while only males showed increased levels of IL-6. Only the MCAO+CLP group showed a decrease in IL-10 levels in males, while females did not show significant results. **Conclusion:** We conclude that post-stroke sepsis can intensify the reduction in anti-inflammatory cytokines in the hypothalamus in male rats.

Sequential optic neuritis secondary to aspergillosis mimicking Foster Kennedy syndrome: a case report

Luiz José Malta Gaia Ferreira Júnior[1], Larissa Braga Mendes[1], Gabriela Rodrigues Tomaz[1], Lucas Toshio Uenishi[1], Daniel Delgado Seneor[1], Lara Santos Machado[1], Maria Eduarda Slhessarenko Fraife Barreto[1], Leonardo Villaverde Buback Ferreira[1], Orlando Graziani Povoas Barsottini[1], José Luiz Pedroso[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Luiz José Malta Gaia Ferreira Júnior; Email: jr_malta@hotmail.com.

Case presentation: A 60-year-old woman underwent neurological evaluation due to a recent onset of decreased visual acuity in her left eye, which progressively worsened over two weeks before stabilizing a week ago. She also reported mild pain upon eye movement. She denied any fever, weight loss, or other systemic or local symptoms. Similar symptoms had occurred in her right eye three months prior. On neurological examination, she presented with reduced visual acuity in both eyes (20/100 bilaterally), pallor of the right optic disc, and edema with hyperemia of the left optic disc. Laboratory investigations, including tests for syphilis, HIV, toxoplasmosis, rheumatological conditions, anti-MOG, and anti-AQP4 antibodies, were unremarkable. MRI of the brain and orbits revealed hyperintensity on T2/STIR sequences in the left optic nerve, with contrast enhancement noted in the orbital segment of the nerve. Additionally, hypointense signals on both T1 and T2 images were observed, correlating with a concurrent CT scan showing a hyperdense lesion with gas pockets. This finding suggested fungal sinusitis, with apparent bone erosion at the lesion site. Furthermore, it was important to rule out compressive lesions that could be causing Foster Kennedy syndrome. Surgical resection confirmed invasive fungal rhinosinusitis upon histopathological examination, with microbiological analysis of tissue cultures indicating growth of Aspergillus fumigatus complex. Cerebrospinal fluid analysis showed no abnormalities. The patient commenced parenteral antifungal therapy, later transitioning to oral itraconazole for a three-month course. She experienced partial improvement in visual acuity, particularly in the left eye, followed by stabilization of her condition. **Discussion:** The subacute onset of visual acuity decline, coupled with pain exacerbated by eye movement, represents a significant clinical feature of optic neuritis (ON). Most cases are associated with inflammatory demyelinating conditions, particularly multiple sclerosis. However, it is crucial to emphasize that ON can also arise from other autoimmune, granulomatous, infectious, and paraneoplastic disorders. Therefore, a thorough etiological investigation is imperative to accurately select appropriate laboratory tests and complement them with imaging evaluations for precise diagnosis and treatment planning. Among the infectious causes of optic neuropathy, fungal infections are infrequent but warrant investigation, especially in diabetic and immunocompromised patients, as well as those displaying signs of sinus pathology. In our case, the presence of sinus pathology observed on facial sinus CT scans played a critical role in achieving a diagnosis. Prompt and appropriate treatment has shown promise in achieving symptomatic improvement. **Final comments:** Although rare, fungal infections should be considered as a possible cause of optic neuritis. If not treated promptly, they can lead to irreversible visual sequelae.

https://doi.org/10.5327/CBN241478

Serial levels of antiseizure medications and quantitative MRI analysis in mesial temporal lobe epilepsy

Lilian Audi Goulart[1], Yasmim Nadime Jose Frigo[1], Julio Cesar dos Santos Moreira[1], Tarcisio Nunes Alvarenga[1], Maria Beatriz Bravin[1], Lucas Barbosa Napolitano de Moraes[1], Luiz Eduardo Betting[1]

[1]Universidade Estadual Paulista, Botucatu SP, Brazil.

Correspondence: Lilian Audi Goulart; Email: lilian.audi@unesp.br.

Background: In mesial temporal lobe epilepsy (mTLE), seizure control is often not achieved with antiseizure medications (ASMs). The mechanisms behind refractory epilepsy and the effects of ASMs on the brain structure of patients with mTLE are still under investigation. We hypothesized that ASM concentrations may be related to brain structural changes. **Objective:** To investigate whether areas of structural abnormalities are correlated with serial concentrations of ASMs. **Methods:** Twenty-four patients with mTLE and twenty-four control subjects were enrolled.

All subjects underwent 3T MRI scans, with T1 sequences used for anatomical analysis. ASMs were dosed on the same day as the MRI. For each patient, the relative position of the medication was calculated and standardized according to the concentration range, where a score of 0 corresponded to the lower therapeutic limit and 1 to the upper limit. For patients taking more than one medication, an overall ASM ratio was calculated by summing the individual medication scores. Negative scores were not included. Image processing was conducted using SPM12. High-resolution T1 images were automatically segmented, normalized, and smoothed using the DARTEL algorithm. Modulated gray matter maps were used for the analysis. Statistical analysis was performed using a general linear model (GLM). Comparisons between patients and controls and correlations between gray matter volume and the overall ASM ratio were performed. **Results:** Thirteen patients had left mTLE and eleven had right mTLE, with a mean age of 55±12 years. Patients were using an average of two medications, with carbamazepine (n=14) and clobazam (n=12) being the most frequently used medications. The mean serial dose ratio was 0.9±1.1 (range: -0.3 to 5). Extensive areas of gray matter atrophy were detected (135,393 mm^3, p<0.001 FWE), involving the left precuneus, gyrus rectus, thalamus, insula, superior temporal gyrus, and the right planum temporale, middle occipital gyrus, and posterior cingulate. A weak positive correlation with ASM scores was observed (3,368 mm^3, p<0.01 unc), involving the bilateral calcarine cortex, right thalamus, and hippocampus. **Conclusion:** ASM levels were mainly positively correlated with brain structures, particularly in more preserved, non-atrophic areas. This observation may indicate that preserved neural networks, which include these structures, may be responsible for a better response and tolerability to ASMs. Therefore, preserved areas may be critical for the effectiveness of ASMs in patients with mTLE.

Serial nerve ultrasound as a predictor of therapy response in a case of chronic inflammatory demyelinating polyradiculoneuropathy

Maria Fernanda de Abreu Rodrigues[1], Liene Duarte Silva[1], Josevânia Fulgêncio de Lima Arruda[1], Rodrigo Tavares Brisson[1], Marcos Raimundo Gomes de Freitas[1], Rita de Cássia Leite Fernandes[1]

[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Maria Fernanda de Abreu Rodrigues; Email: maferodriguesufrj@gmail.com.

Case presentation: A 60-year-old woman, diagnosed with CIDP had recurrent motor symptoms for the last 35 years and evolved with a progressive limb weakness. The neurological exam revealed tetraparesis with MRC grade 4/5 in proximal limbs and 3/5 in distal limbs, requiring unilateral support for walking. Electrophysiological studies (EMG) showed typical demyelination pattern and cerebrospinal fluid (CSF) analysis revealed high protein levels. In the past years she experienced recurrent disease, and has been receiving monthly Vig to remain asymptomatic. An ultrasonographic examination of her nerves was performed twice with high-resolution ultrasound (HRUS): once soon after an IVIg dose and once close to the next one. We found an enlargement of the ulnar (cross-sectional area [CSA] 50 mm^2) and median (CSA 68 mm^2) nerves in the humerus segment prior to the next dose, correlating with the need to restart treatment. After the IVIg course, the patient reported significant improvement in her motor function and we observed that she no longer needed crutches for walking. HRUS showed CSA of 36 mm^2 and 52 mm^2 in the ulnar and median nerves, respectively. A third measurement taken one month after IVIg, revealed a tendency for the nerves to increase in size again (CSA 48 mm^2 and 52 mm^2 in the ulnar and median nerves). **Discussion:** The diagnosis and management of inflammatory polyneuropathy are often challenging. CIDP, for example, is a potentially incapacitating disease thatrequires appropriate treatment. However, overdiagnosis and inadequate Vig prescription can compromise health systems and cause harmful effects in patients. This case shows that HRUS may contribute to the diagnosis and management of CIDP because, as previous study has already demonstrated, nerve size varies with response to treatment and disease activity over time. **Final comments:** HRUS as an interesting cost-effective tool that may aid neurological practice providing information for diagnosis, therapy decisions and follow-up especially in inflammatory polyneuropathies.

https://doi.org/10.5327/CBN241480

Seronegative limbic encephalitis presenting as new-onset refractory status epilepticus (NORSE): the case for early initiation of ketamine and ketogenic diet

Caroline Schiochet Verza[1], Bruna Klein[1], Glauco Kody Nagata[1], Giuseppe Dick Bonato[1], Letícia Bassani Devens[1], William Alves Martins[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Hospital São Lucas, Porto Alegre RS, Brazil.

Correspondence: Caroline Schiochet Verza; Email: carolinesverza@gmail.com.

A previously healthy 32-year-old male presented with fever, cough, and headache, initially diagnosed with Influenza A and prescribed Oseltamivir with improvement of symptoms. After five days, he developed confusion, disorientation, and severe anterograde amnesia, followed by a bilateral tonic-clonic seizure prompting ICU admission. Influenza test was negative. Initial investigations including brain MRI, CSF and EEG were unremarkable. Later, he experienced temporal lobe seizures and was started on acyclovir at a tertiary center where a lumbar puncture revealed mildly elevated leukocytes. Despite treatment with phenytoin and levetiracetam, seizures worsened, progressing to focal status epilepticus necessitating mechanical ventilation and continuous EEG monitoring, which showed ongoing right and left temporal lobe seizures. Management included antiseizure drugs along with midazolam and propofol until burst-suppression was achieved. Pulsetherapy with methylprednisolone and IVIG was initiated for suspected autoimmune limbic encephalitis. Systemic screening did not reveal any tumors. Seizures persisted upon medication tapering, characterized by dysautonomia and oral automatisms, which were further treated with topiramate, clobazam, and intravenous ketamine 4mg/kg/h alongside ketogenic diet. After three weeks, seizures ceased, and intravenous medications were tapered off, although hepatic dysfunction necessitated diet and medication adjustments. Negative surface and intracellular antibody tests guided ongoing treatment with Levetiracetam, Lacosamide, Gabapentin, Clobazam, and topiramate. Rituximab was used for autoimmune encephalitis maintenance, resulting in no seizure recurrence or cognitive impairment upon discharge.NORSE (New-Onset Refractory Status Epilepticus) and limbic encephalitis are severe neurological conditions characterized by treatment-resistant seizures. NORSE manifests as prolonged seizures in previously healthy individuals without clear triggers, potentially causing significant brain damage and cognitive impairment. Its etiology involves genetic predisposition, immune dysregulation, and possible infections. Treatment includes high-dose antiepileptic drugs, immunotherapy and therapeutic coma induction when necessary to halt seizures. Diagnosis of autoimmune NORSE involves detecting specific antibodies in blood or cerebrospinal fluid, although seronegative cases are common in limbic encephalitis.Management strategies focus on seizure suppression, inflammation reduction, and addressing underlying immune dysfunction, tailored to individual patient characteristics and underlying causes. Ketamine infusion and implementation of the ketogenic diet are therapeutic approaches used in NORSE to manage refractory status epilepticus and improve seizure control. These interventions aim to modulate neuronal excitability and metabolism, potentially offering relief and enhancing the effectiveness of conventional treatments in challenging cases of NORSE.

Severe case of cavernous sinus thrombophlebitis due to pseudomonas ecthyma

Adria Rodrigues da Silva[1], Bruna Beppler[1], Caroline Zapelini[1], Lia Maki Hatisuka Imai[1], Luis Sidônio Teixeira da Silva[1], Lúcio Baena de Melo[1], Maria Caroline Martins de Araújo[1], Jéssica Camila Fizinus[1], Manuel Victor Silva Inácio[1], Natasha Caroline Cardoso de Moraes Sanches[1]

[1]Universidade Estadual de Londrina, Londrina PR, Brazil.

Correspondence: Ádria Rodrigues da Silva; Email: adriarodriguess@hotmail.com.

Case presentation: A 52-year-old female patient, HIV-positive and hypertensive, on Dolutegravir, Darunavir, Ritonavir and Losartan, but with a history of poor adherence to treatment, was admitted to a tertiary hospital due to the sudden appearance two days prior of a blackened crusty papule on the left maxillary and malar region, associated with swelling, pain, fever, and difficulty chewing. Upon examination, there was gingival hypertrophy, palatal ulceration, upper lip edema, and painful cervical lymph nodes. CT scan of the face showed enlargement and infiltration of soft tissues of the left hemiface, mucosal thickening, and diffuse thick secretions in the paranasal sinuses. HIV viral load was 498,000 with a CD4 lymphocyte count of 87. Two days after admission, the patient developed acute respiratory and renal failure, requiring orotracheal intubation and hemodialysis. As the lesions progressed with necrosis, wound debridement was necessary. One month after symptom onset, the patient presented with ptosis, fixed mydriasis, conjunctival chemosis, exophthalmos, edema, and paresis of leftward gaze, indicative of cranial nerves III, IV, and VI palsy on that side. A new CT scan revealed expansive peri-orbital to submental formation in close contact with adjacent bony surfaces, alongside left cavernous sinus enlargement with poor iodinated contrast enhancement, leading to a diagnosis of septic cavernous sinus thrombophlebitis. Biopsy and culture of the lesion indicated Pseudomonas aeruginosa ecthyma, and the patient received polymyxin B, meropenem, amikacin, and moxifloxacin eye drops, remaining in the intensive care unit for 69 days. Gastrointestinal bleeding and facial wounds, along with three debridements, precluded full anticoagulation. Follow-up angiotomography after 46 days showed no evidence of sinus thrombosis. The patient was discharged with symptom improvement, underwent upper lip reconstruction, and continues with rehabilitation and multidisciplinary treatment. **Discussion:** The cavernous sinus is the most frequently infected and thrombosed due to its trabeculae and proximity to the paranasal sinuses. This complication has become rare with the advent of antibiotics, reducing mortality rates from nearly 100% to around 20-30%. Staphylococcus aureus is the primary agent involved, with sinusitis being the most prevalent primary infection. Although facial lesions due to Pseudomonas are reported in some studies, they are less common. Broad-spectrum antimicrobial therapy and surgical intervention, depending on the extent of the lesion, constitute the mainstay of treatment. However, the role of anticoagulation and corticosteroids remains controversial. **Final comments:** This case underscores the importance of early diagnosis and therapy implementation in severe cases associated with Pseudomonas aeruginosa in immunocompromised patients with bleeding and renal failure.

Severe dysautonomia and chagas disease: a case report

Larissa Scarpini de Carvalho[1], Ana Luiza Meneses de Oliveira[1], Emily Godoi Pereira[1], Helen Maia Tavares de Andrade[1], Matheus Spilari[1]

[1]Pontifícia Universidade Católica de Campinas, Campinas SP, Brazil.

Correspondence: Larissa Scarpini de Carvalho; Email: l.scarpinipuc@gmail.com.

Case presentation: A.B.L, a 64-year-old female, reports difficulty standing for the past 6 years, experiencing malaise and episodes of syncope during moderate physical activities and when in an orthostatic position.The condition has progressively worsened, leading to an inability to ambulate, confining her to a wheelchair, and being accompanied by constipation. She has a medical history of Systemic Lupus Erythematosus (SLE) for 26 years, hypothyroidism, and cardiac arrhythmia.The patient was on continuous use of amiodarone. On general physical examination, her seated blood pressure was 80/60 mmHg and heart rate was 50 bpm.Upon standing, she exhibited significant lip cyanosis and pre-syncope; it was necessary for her companion to support her during the orthostatic blood pressure measurement, which was 65/40 mmHg with a heart rate of 64 bpm.There were no abnormalities on neurological physical examination. Initial differential diagnoses considered included Severe Dysautonomia secondary to amiodarone-induced polyneuropathy, hypothyroidism, SLE, or an autoimmune condition. Laboratory tests showed only a positive ANA, without indications of active SLE. Cerebrospinal fluid (CSF) analysis revealed: RBC 145 (90% intact), WBC 1.25, protein 68 (reference < 45), Chloride 124, CSF glucose 48, serum glucose 70, VDRL non-reactive, CSF protein electrophoresis: Total proteins 37.5, albumin 46.6, gamma globulin 14.70% (reference >10-12%), culture negative, bacteria negative. Methylprednisolone 1g/day was administered for 5 days without improvement.Under cardiology guidance, amiodarone was discontinued. Following corticosteroid treatment, serology for Chagas disease returned positive (result: 1/30), leading to the diagnosis of dysautonomia secondary to Chagas Disease (CD) becoming our primary consideration.From the outset, therapeutic management included increased fluid and salt intake, along with the use of compression stockings. **Discussion:** Although far less common than metabolic, inflammatory, and autoimmune disorders, infectious disorders can also affect the autonomic nervous system. Chagas disease is one such infection that can cause diffuse damage to the autonomic nervous system, with proposed mechanisms being primarily denervation due to persistent parasitic infection and immune-mediated injury. Parasympathetic regulation of heart rate becomes impaired, and the tonic inhibitory mechanism exerted by the parasympathetic system fails to respond with tachycardia to rapid transient changes in blood pressure. Our patient, despite severe orthostatic hypotension, does not exhibit compensatory tachycardia. **Final comments:** Dysautonomia is a diagnosis frequently overlooked by healthcare professionals, as evidenced by our patient, who took six years to receive a diagnosis. Determining the etiology can be challenging, necessitating extensive investigation. In Brazil, given the endemic nature of Chagasd, this diagnosis should always be considered.

Background: i The study of dementia and its differences between the sexes is widely investigated, mainly in Alzheimer's disease. However, most studies on dementia were conducted in high-income countries, mostly in White participants. This study examined sex differences in dementia neuropathology and cognitive abilities in a diverse sample. **Methods:** Participants were classified by sex, and neuropathological lesions were assessed using immunohistochemistry according to international criteria. Cognitive abilities were evaluated using the Clinical Dementia Rating Sum of Boxes (CDR-SOB). We used ordinal logistic and linear regressions to explore the associations of sex with neuropathological and cognitive data adjusted for sociodemographic and clinical variables. **Results:** Of the 1,611 cases included, 801 were men and 810 were women, 65% were white. Women were older, had less education, and presented more Alzheimer's disease neuropathological changes, such as higher scores for Braak stages and CERAD (p> 0.001). No differences were found regarding other neurodegenerative and cerebrovascular lesions. Women presented worse cognitive abilities measured by the CDR-SOB than men in multivariate linear regression models adjusted for age and education. The association of sex, neuropathological assessments, and severity of clinical findings showed a tendency for women to present severe symptoms, regardless of the subtype of the neuropathological lesion. For Alzheimer's disease pathology, there was statistical significance with the clinical pathology and continuous staging with prevalence in women, as well as in the presence of TDP-43 pathology and hyaline arteriosclerosis in vascular pathology. **Conclusion:** Sex in the neuropathology of dementia plays an essential role in cognitive symptoms, highlighting the need to consider it in future prevention and treatment strategies.

Background: Alzheimer's disease (AD) is the most frequent dementia and predominantly affects women. Studies have described a possible influence of sociodemographic, biological and pathological characteristics underlying sex differences in AD. Among these, cognitive resilience, lifestyle and genetic factors, and longer life expectancy were reported. **Objective:** To analyze the burden of neurofibrillary tangles (NFT) in a large multiethnic population with AD-type pathology and determine sex differences. Additionally, investigate possible risk factors for developing cognitive impairment. **Methods:** 352 cases with clinical, neuropathological and genetic data from the Biobank for Aging Studies of the University of Sao Paulo were analyzed. Demographic, socioeconomic, and clinical data from a postmortem semi-structured interview were revised. The burden of NFT pathology was evaluated in the following areas of immunostained sections using hyperphosphorylated tau antibody (AT8): entorhinal cortex, CA1 of the hippocampus, and locus coeruleus. Additionally, neuropathological evaluation was performed according to the internationally accepted criteria. **Results:** The mean age of death was 72.1±13.4 years, 57.1% were male, the mean of education was 5.3 ± 4.4 years and 65.6% were Caucasians. Around 51% had middle socioeconomic status (SES). Cognitive impairment was observed in 22.7% (CDR>0). The most frequent neuropathological diagnosis was argyrophilic grain disease. Some degree of neurofibrillary pathology was observed in 90.4%, meanwhile, neuritic plaques were observed only in 31.4%. Only 9.7% of 360 individuals met the criteria for neuropathological AD according to NIA-AA, and only 1.6% had a vascular pathological diagnosis. APOE genotype was available only in 155 individuals (43%) and the most frequent genotype was ε3/ε3. Females were older (p<0.001), and had lower mean of education (p=0.003) and higher CDR sum of boxes (p<0.001) compared to males. Additionally, a higher burden of neurofibrillary pathology was found in women compared to men regardless of the presence of cognitive impairment. **Conclusion:** This study provides an opportunity to identify risk factors associated with sex differences that can help to understand the pathophysiological mechanisms underlying AD pathology.

Sheehan's syndrome: a case report

Lianna da Silva Facco[1], Luidia Giacomini[2], Milena Moraes[1], Matheus Felipe Kuhn Urnau[1], Mauricio Konig Luz[1], Amanda Hedel Koerich[1], Guilherme B. Getelina[1], Júlia Fiorentin[1], Thainá Stolfi[1], Charles André Carazzo[2]

[1]Universidade de Passo Fundo, Passo Fundo RS, Brazil.
[2]Hospital São Vicente de Paulo, Passo Fundo RS, Brazil.

Correspondence: Lianna da Silva Facco; Email: lianna.facco@gmail.com.

Case presentation: Woman, 36 years old, 7th postoperative day of twin cesarean section with a history of bleeding due to placental abruption. She presented weakness, vomiting, insomnia, disorientation, and apathy. Neurology evaluation with a request for a contrasted cranial MRI. The patient developed recurrent episodes of tonic-clonic seizures. Laboratory findings reveal severe hyponatremia (Na 103 mEq/L). A hypertonic saline solution infusion of 250mL was administered. Due to a drop in saturation (80%) and vomiting, sedation and orotracheal intubation (OTI) in the ICU were indicated. Despite the administration of hypertonic saline solution, the patient's hyponatremia worsens, favoring new seizures. MRI shows an enlarged pituitary with a hyperintense lesion, suggestive of pituitary apoplexy, Sheehan's syndrome (SS). After three days of hospitalization, sodium gradually increases (Na 126 mEq/L). Hydrocortisone and levothyroxine are prescribed. Evolution to hemodynamic stability, spontaneous breathing, orientation, and communication. Presentation of diabetes insipidus was treated with desmopressin. After extubation, the patient is maintained on levetiracetam, levothyroxine, and hydrocortisone is replaced by prednisone. A new MRI shows a reduction in pituitary size. Hospital discharge 18 days after admission. **Discussion:** Sheehan's syndrome is characterized by postpartum hypopituitarism secondary to pituitary necrosis caused by shock or hypotension, resulting from massive bleeding during or after childbirth. Considered a rare syndrome, responsible for up to 6% of hypopituitary subjects in developed countries, it does not receive due attention in

textbooks. The pathology is still poorly understood, but it is believed to result from infarction of the pituitary gland, mainly in the anterior lobe, owing to decreased blood flow secondary to vasospasms. In the original clinical description of the disease, Sheehan described the inability to breastfeed, rapid involution of the breast, and menstrual cycle alterations. The symptoms are compatible with different degrees of pituitary hypofunction diagnosed days or years after childbirth. Thus, careful obstetric history is necessary for diagnosis. Management consists of the administration of glucocorticoids, fluids, and, if necessary, thyroid hormone replacement. Importantly, thyroid hormone replacement should not be started before glucocorticoid therapy unless a normal hypothalamic-pituitary-adrenal axis is evidenced in the laboratory to avoid an adrenal crisis. **Final comments:** Although rare, SS requires in-depth investigation for a better understanding of its pathophysiology. It should be considered in patients with obstetric hemorrhage and signs of hypopituitarism. Early diagnosis is essential to prevent complications and improve prognosis.

Siblings report enforces the relationship between the polynucleotide kinase 3′-phosphatase gene (PNKP) and the clinical manifestation of Charcot-Marie-Tooth disease type 2b2

Letícia Jabur Vaz Ribeiro[1], Sarah Camargos[2]

[1]Universidade Federal de Minas Gerais, Faculdade de Medicina, Belo Horizonte MG, Brazil.
[2]Universidade Federal de Minas Gerais, Hospital das Clínicas, Ambulatório de Neurogenética, Belo Horizonte MG, Brazil.

Correspondence: Letícia Jabur Vaz Ribeiro; Email: leticiajaburvribeiro@gmail.com.

Case presentation: QS, a 19-year-old female patient, was born at term with no complications. Her parents were not related. In early childhood, she presented with global developmental delay. At 13 years old, mild imbalance and incoordination were noted by her mother. During the COVID-19 pandemic, at age of 15, she experienced a subacute worsening of her condition, leading to hospitalization for investigation and rehabilitation. Her older brother had a history of hypotonia in infancy developing impairment of gait and coordination, which also worsened rapidly in 2020. On the neurological examination, the patient presented a slurred and scanning speech, optokinetic nystagmus and absence of tendon reflexes with cold and hypotrophic extremities. Strength was reduced in distal muscles of all limbs. She could walk only with bilateral support. Magnetic resonance imaging showed cerebellar atrophy especially in the vermis. Electroneuromyography demonstrated a primarily demyelinating sensorimotor polyneuropathy. Exome sequencing revealed the presence of PNKP variants: PNKP:c.1123G> T;p.Gly375Trp and PNKP:c.1298+19_1299-37del, in trans. The variant PNKP:p.Gly375Trp variant is classified as likely pathogenic and the PNKP:c.1298+19_1299-3 7del variant is classified as uncertain significance. Segregation analysis demonstrated the presence of PNKP:c.1298+19_1299-37del variant in heterozygosity and absence of the PNKP:c.1123G> T;p.Gly375Trp variant in the mother, whereas both variants were present in the affected brother. The father's DNA was not available. Alpha fetoprotein and total cholesterol was elevated only in the affected brother. **Discussion:** The PNKP gene has three described phenotypes: "CHARCOT-MARIE-TOOTH, AXONAL, TYPE 2B2 (CMT2B2)", "ATAXIA-OCULOMOTOR APRAXIA 4" (AOA4), and "MICROCEPHALY, SEIZURES, AND DEVELOPMENTAL DELAY; MCS". The relationship with the CMT2B2 condition (MIM 605589) is provisional and still requires more data to confirm. Our patients exhibit clinical features consistent with Charcot-Marie-Tooth disease type 2B2 (CMT2B2), an axonal sensorimotor polyneuropathy with ataxia. CMT2B2 has been described in Brazil and Costa Rica. The PNKP:p.Gly375Trp variant is described in several Portuguese families with AOA4. Patients in this study show a phenotypic expansion with primarily demyelinating peripheral neuropathy with an intermittent exacerbation. **Final comments:** The relationship between the Charcot-Marie-Tooth disease type 2B2 phenotype and the PNKP gene is still uncertain. The reported siblings reinforce that this relationship may exist. It is important the report of new cases/families to further strengthen this genotype-phenotype relationship.

Simultaneous neurocryptococcosis, neurotuberculosis and invasive aspergillosis in a patient with primary immunodeficiency

Thaís Laura Almada da Fonseca[1], Isabelly de Arruda Cardoso Slavec[1], Yasmin Coelho Patrial[1], Enã Rezende Bispo do Nascimento[1], Aline Mizuta Kozoroski Kanashiro[1]

[1]Hospital Regional de Mato Grosso do Sul, Campo Grande MS, Brazil.

Correspondence: Thaís Laura Almada da Fonseca; Email: thaisalmada123@gmail.com.

Neurosyphilis, neurotuberculosis and invasive aspergillosis are infectious diseases that usually occur in patients with severe immunosuppression, generally in the setting of AIDS or other causes of acquired immunodeficiency. **Case presentation:** P.O.S, 33 years old, from a rural area, previously healthy, working in a poultry farm, she started on 07/12/2023 with an acute headache that gradually worsened to a strong intensity, with twinge, frontal and occipital, associated with phono-photophobia, nausea and fever, being treated at the primary hospital with endovenous analgesy and released with symptomatics. On 07/17/2023, she developed mental confusion and was referred to the neurology service due to suspicion of meningitis. Upon admission, she was disoriented and showed meningeal signs. Normal head CT, cerebrospinal fluid (CSF) with opening pressure 500 mmH2O and closing pressure 320 mmH2O, cloudy, with 389 leukocytes/mm3 (lymphomonuclear 90%; polymorphonuclear 10%); glucose 31mg/dL; protein 82.2 mg/dL; direct mycological examination with presence of Cryptococcus sp; VDRL non-reactive. Serum treponemal test for Syphilis was positive, patient previously treated; positive galactomannan in serum; other non-reactive serologies (including HIV and HTLV). Amphotericin B lipid complex and flucytocin were initiated, with partial improvement of symptoms. After 3 days of CSF collection, TRM-TB was positive, and the COXIP regimen was added to the therapy. During the patient's evolution, she remained symptomatic and had increased CSF pressure levels. A new head CT was performed and communicating hydrocephalus was revealed, with a ventriculoperitoneal shunt performed. CD4 (315 mm3) and CD8 (133 mm3) counts were investigated, both decreased. After therapeutic institution, her symptoms improved completely and now she is under investigation for genetic cause of primary immunosuppression. **Discussion:** Primary immunosuppression results from qualitative and/or quantitative changes in the cellular and/or humoral immune response, which may manifest clinically at birth or in adulthood, as described above. These are genetic alterations, most often linked to the X chromosome, however they can be autosomal recessive. This hypothesis should be considered when there are multiple and recurrent infections by different microorganisms (opportunistic or not) in the absence of an acquired cause. The investigation of these conditions involves measuring T and B cells (through immunoglobulins), in addition to determining malformations, searching for cancer or dysfunctions of other systems. **Final comments:** In the case described, the patient had an infection caused by 3 opportunistic germs and did not fit into any secondary cause, therefore it was necessary to investigate the primary cause.

[3]Universidade Federal do Paraná, Serviço de Neurologia, Curitiba PR, Brazil.

Correspondence: Davi Telécio Firmino; Email: davitelecio@gmail.com.

Background: The surname Sjögren is rare outside Sweden and Finland. Two physicians with this surname became famous for describing four syndromes and one disease. The Swedish Henrik Samuel Konrad Sjögren from the Karolinska Institute and the Swedish Karl Gustaf Torsten Sjögren graduated in Medicine in Stockholm. **Objective:** To approach the five disorders to which the two physicians contributed, analyzing the historical aspects of each one and their contribution. **Methods:** This is a narrative review based on searching articles in main databases (PubMed, LILACS, Research Gate, ScienceDirect, Web of Science, Embase, Google Scholar, and SciELO) using "Sjogren", "Sjögren, "Sjogren Syndrome", "Henrik Samuel Konrad Sjögren", and "Karl Gustaf Torsten Sjögren" as keywords. **Results:** Henrik Sjögren described the sicca syndrome (Sjögren syndrome) in his doctoral thesis in 1935, describing 19 female cases with dry eyes and dry mouth and proposing treatments. Although it had already been described, it was Henrik Sjögren's contribution in correlating xerostomia and polyarthritis that coined the name of the syndrome. Sjögren reticular dystrophy is a rare dystrophy characterized by macular lesions with a reticular pattern. In 1950, Henrik Sjögren was the first to describe it in a family with 8 children. Spielmeyer-Sjögren disease(Batten disease) is a neuronal ceroid lipofuscinosis, a lysosomal storage disease that affects the retina associated with progressive brain degeneration. The first report was made in 1826, but it was only in 1931 that Torsten Sjögren conducted extensive clinical and genetic studies, demonstrating that these disorders had a monohybrid recessive inheritance pattern, which distinguished them genetically from infantile amaurotic idiocy. Marinesco-Sjögren syndrome is a rare genetic disorder that affects multiple body systems, first reported in 1904. It leads to balance problems, congenital cataracts, muscle weakness, learning and growth difficulties, leading to intellectual disability and short stature. In 1947 and 1949/1950, Torsten Sjögren advanced the understanding of the syndrome phenotype, ensuring that his name was coined in the syndrome. Sjögren-Larsson syndrome is an autosomal recessive neurocutaneous disorder caused by mutations in the ALDH3A2 gene leading to the classic triad: spastic diplegia or tetraplegia, mental retardation, and congenital ichthyosis. Torsten Sjögren was the first to describe the syndrome in 1956. Sjogren and Larsson then described 28 patients in their long monograph. **Conclusion:** Henrik and Torsten Sjögren were not the first to describe most of the disorders that bear their surnames. However, their contributions were crucial in gathering, describing, and analyzing the key elements that make up the conditions, providing the basis for more detailed studies that complemented their findings.

Sjogren's syndrome associated with facial palsy: a systematic review

João Gabriel Pacetti Capobianco[1], Júlia Gomes[2], Hadassa Carvalho Victorino[2], Mateus Orlando Belisário[2], Beatriz Teixeira Cardoso[2], Giovanna Amorim Panissi

[1]Instituto Capobianco de Neurologia, Poços de Caldas MG, Brazil.
[i2]Pontifícia Universidade Católica de Minas Gerais, Poços de Caldas MG, Brazil.

Correspondence: João Gabriel Pacetti Capobianco; Email: joao20_03@hotmail.com.

Background: Sjögren's syndrome (SS) is considered a chronic, multisystemic condition, which is characterized by dysfunction and abnormalities of the glands and exocrine organs, one of whose characteristics is lymphocytic infiltration, leading these organs to loss of function and triggering a case of xerostomia and xerophthalmia.It affects around 2.7% of the population and the prevalence is 9 women for every man aged approximately 50 years.The association of this syndrome with facial nerve paralysis is a rare condition.**Objective:** To carry out a systematic review of the literature on the association between Sjögren's syndrome and the clinical manifestation of peripheral facial paralysis. **Methods:** A systematic review was developed based on the PRISMA recommendation.The search was carried out in the databases PubMed, Scielo, Scopus, Portal Biblioteca Virtual em Saúde (VHL) and Cochrane Library. The search strategy used was: (Sjogren's Syndrome OR Sicca Syndrome) AND (Facial Paralysis OR Facial Palsy OR Bell´s Palsy) Inclusion criteria: primary studies, published in English, Portuguese and Spanish,published in the last five years, human patients over 18 years of age.Data analysis was carried out using the qualitative metasynthesis technique. **Results:** After analysis and application of the review criteria, 7 studies were included in the final sample. One was published in 2019, three in 2020, two in 2021 and one in 2022. The studies came from Italy (n=1), France (n=1), Saudi Arabia (n=1), United Kingdom (n=1), Germany (n=1), USA (n=1) and China (n=1). Regarding the study design, (n=3) were case reports with literature review, (n=3) were case reports and (n=1) were case series. The analytical themes identified were: involvement of the central and peripheral nervous system, first manifestation of sjogren's syndrome and treatment/prognosis. **Discussion:** Despite the scarcity of data considering the rarity of this presentation, the sample analyzed followed the recommendations for diagnosis and treatment of SS with systemic characteristics. Serological tests was performed based on specific autoantibodies - anti-SSA/antiSSB and exclusion of Guillain-Barrè syndrome. The treatments carried out in the identified studies were based on the treatment of SS in the acute phase, including: intravenous human immunoglobulin, pulse therapy with methylprednisolone, cyclophosphamide and mycophenolate mofetil. The prognosis varied in the sample analyzed, ranging from clinical improvement between two weeks and two months. **Conclusion:** Peripheral facial paralysis associated with Sjogren's Syndrome is an uncommon pathological condition, rarely reported in the scientific literature. There is no specific consensus for the diagnosis and treatment of this condition, and future studies are needed to determine the prognostic relationships of this condition in relation to other systemic manifestations of Sjogren's syndrome.

https://doi.org/10.5327/CBN241490

Sjögren's syndrome mimicking CIDP: the impact of correct diagnosis on therapeutic choice

Henrique de Moraes Bernal[1], Guilherme Lago Miranda[1], Aldren Falçoni Júnior[1], Pedro Almeida Martins Pontes[1], Ingrid Lorena da Silva Gomes[1], Giovanni Caniçali Simões[1], Tainá Fátima Ramos Gonçalves[1], Mateus Paquesse Pellegrino[1], Herval Ribeiro Soares Neto[1], Sônia Maria César de Azevedo[1]

[1]Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo SP, Brazil.

Correspondence: Henrique de Moraes Bernal; Email: henriquembernal@hotmail.com.

Case presentation: A 75-year-old woman with hypothyroidism and dyslipidemia was hospitalized with urinary sepsis due to a right kidney staghorn calculus. During a prolonged hospital stay, it was noticed lower limb weakness, initially attributed to immobility. Despite initial recovery with rehabilitation at home, she experienced a biphasic evolution, with progressive worsening in lower limb strength and loss of fine motor skill in her upper limbs, along with distal hypoesthesia. She sought medical care 4 months after symptoms onset. Her neurological exam revealed significant muscle weakness (proximal and distal in all limbs), areflexia, trunk instability, and predominantly distal sensory impairment. Electrophysiological studies confirmed subacute, symmetrical, sensory-motor demyelinating polyradiculoneuropathy. Systemic workup revealed elevated erythrocyte sedimentation rate (140 mm/h), positive anti-Ro (37.6 UI/mL), and antinuclear antibody (1/640). Due to the positive anti-Ro result, despite no clinical complaints of dry eyes or mouth, she underwent Schirmer's test, which confirmed dry eyes bilaterally. Salivary gland scintigraphy showed global hypofunction. Imaging ruled out neoplasms. She received immunoglobulin and methylprednisolone pulse therapy with poor response, escalated to plasmapheresis with partial recovery. Maintenance therapy with rituximab and prednisone led to significant neurological improvement on follow up. **Discussion:** Chronic Inflammatory Demyelinating Polyradiculoneuropathy (CIDP) typically presents with symmetrical sensory-motor symptoms, areflexia, and a course longer than two months. Delaland et al. reported a 24% incidence of retrospective SS diagnosis in CIDP patients, proposing the term "NeuroSjögren" for such cases. First-line treatments for CIDP include immunoglobulin, corticosteroids, and plasmapheresis, with second-line treatments including azathioprine, mycophenolate mofetil, and cyclosporine. For refractory cases, cyclophosphamide and rituximab are options. In this case, first-line treatments provided initial response, and rituximab, an anti-CD20 monoclonal antibody, was chosen based on the consensus of the European League Against Rheumatism (EULAR), which advocates for its use in patients with NeuroSjogren who are refractory to first-line treatment. **Final comments:** The significant improvement observed with rituximab highlights the importance of recognizing NeuroSjögren as a potential diagnosis in patients with a CIDP presentation, particularly when autoimmune markers are present. Systematic screening for SS in such patients can lead to earlier diagnosis and more targeted treatments, improving patient outcomes. The successful use of rituximab in this case aligns with EULAR recommendations and highlights its role in managing severe or refractory SS. The establishment of specific diagnostic criteria for NeuroSjögren is essential in guiding clinical practice and optimizing treatment strategies.

Skeletal muscle channelopathies: a case series and literature review

Frederico de Sousa Marinho Mendes Filho[1], Luiziane Maria da Silva Alves[1], Paulo Hermes de Lima Amaral[1], Leonardo Rodrigues Leopoldo de Menezes[1], Andreia Lira de Oliveira[1], Maria Esther Lima Rios Evangelista[1], Paulo Roberto Moss Lopes[1], Pablo Vinícius Silveira Feitoza[1]

[1]Universidade Federal do Amazonas, Manaus AM, Brazil.

Correspondence: Frederico de Sousa Marinho Mendes Filho; Email: frederico.smmf@gmail.com.

Background: Skeletal muscle channelopathies are rare genetic neuromuscular disorders involving sarcolemmal ion channel dysfunction, affecting muscle membrane electrochemical function. Clinically, they present as muscle weakness or myotonia and are linked to mutations in ion channels such as calcium (CACNA1S), sodium (SCN4A), chloride (CLCN1), and potassium (KCNJ2 and KCNJ18), leading to periodic paralysis, non-dystrophic myotonia, and ryanodinopathy (RYR1). In European cohorts, their prevalence is up to 2.38/100,000 in the Netherlands and 1.12/100,000 in England. **Objective:** To describe these diseases' clinical features and conduct a literature review. **Methods:** This retrospective study involves five patients treated at the neuromuscular clinic in the Araújo Lima outpatient clinic, Manaus, Amazonas, Brazil. Data were collected from medical records and analyzed by age, sex, clinical characteristics, diagnostic methods, time from symptom onset to diagnosis, and management. **Results:** Patient A: A 24-year-old female presented at 14 with acute generalized weakness, dysarthria, dysphagia, and cramps lasting 2-3 hours. She had neonatal hypotonia and feeding difficulties. Examination showed deltoid hypertrophy but no myotonia. Genetic testing revealed a heterozygous SCN4A mutation (Chr17:63,957,427 G> 4 variant). Patient B: A 45-year-old male presented at 32 with muscle weakness in the four limbs associated with myalgia and no facial involvement or triggering factors. Episodes recurred every 11-12 months, lasting 3-4 days with spontaneous relief. Physical examination showed micrognathia and short stature. Genetic testing revealed a KCNJ2 mutation (Chr17:70.175.283 C> T variant), consistent with Andersen-Tawil syndrome. Patient C: A 12-year-old male developed weakness in both legs and myalgia after a second COVID-19 vaccine shot, worsening over a week to the point of being unable to walk. Hospitalized and treated with immunoglobulin for 4 days, he improved in motor functions. Genetic testing showed a CLCN1 mutation, indicating congenital myotonia. Patient D: A 4-year-old male experienced trismus and ventilatory dysfunction after anesthesia with sevoflurane and succinylcholine for postectomy, leading to its suspension. Genetic testing identified a RyR1 mutation, indicating susceptibility to malignant hyperthermia. Patient E: A 54-year-old female reported recurrent episodes of generalized weakness lasting 3 hours, with myalgia, cramps, and fatigue. A physical exam revealed calf muscle hypertrophy. Genetic testing showed an SCN4A mutation, indicating hyperkalemic periodic paralysis. **Conclusion:** We reported five cases of rare genetic neuromuscular diseases in the Amazon region, each with distinct clinical features. These conditions are underdiagnosed, highlighting the need to explore the pathologies further.

Skin wrinkling test in healthy adults: standardization study

Michelle Zonkowski Ribas[1], Renata Dal-Prá Ducci[2], Cláudia Suemi Kamoi Kay[2], Paulo José Lorenzoni[2], Paula Raquel do Vale Pascoal Rodrigues[2], Rosana Herminia Scola[2], Otto Jesus Hernández Fustes[2]

[1]Universidade Federal do Paraná, Curitiba PR, Brazil.
[2]Universidade Federal do Paraná, Complexo Hospital de Clínicas, Curitiba PR, Brazil.

Correspondence: Michelle Zonkowski Ribas; Email: michelle.z.ribas@gmail.com.

Background: Skin wrinkling is a natural phenomenon that occurs on the palms of the hands resulting from vasoconstriction influenced by sympathetic vasomotor function. This phenomenon can be evaluated using the skin wrinkling test (SWT) after water immersion. The absence or reduction of wrinkling can be linked to conditions affecting the dense network of sympathetic nerves in these areas, such as small fiber neuropathy, particularly

in areas where biopsy is unavailable. Despite being quick, inexpensive, and readily accessible, it is not widely used because it lacks clear reference values. **Objective:** To establish SWT's characteristics and normal reference values in healthy individuals. Materials and **Methods:** A cross-sectional study was conducted involving 30 apparently healthy individuals over 18 years old. The participants underwent SWT by immersion in warm water at 40°C for 30 minutes. Wrinkling was assessed by two independent examiners using two grading scales: Clark et al. (1984) and Datema et al. (2012). In the first scale, each finger could be graded from 0 to 4 - (0) absence of wrinkling; (1) very slight, wrinkling that was just present so that the fingertip was not completely smooth; (2) slight, obvious wrinkling with 2 or fewer lines of wrinkling on the fingertip; (3) moderate, obvious wrinkling with 3 or more lines of wrinkling on the fingertip; (4) wrinkling completely distorting the pulp of the fingertip - with a maximum score of 20 for each hand. On this scale, a score of 0 to 2 was considered abnormal. The Datema scale graded wrinkling as follows: 0.0 for no wrinkling, 0.5 for minimal wrinkling, and 1.0 for clear wrinkling, based on comparison to pre-test photos. Absent wrinkling was deemed abnormal, whereas minimal and clear wrinkling was considered normal. The study received approval from the Research Ethics Committee under number: 5.546.162. **Results:** Fifteen men and 15 women, with an average age of 37 years and no history of neurological diseases or diabetes mellitus, participated in the study, with approximately one-third being students (11). The test was conducted on the right hand in all 30 individuals, and additionally on the left hand in 17 of them, with no significant differences in test scores between them. According to the Clark scale, 23 individuals exhibited normal results, while five showed slight wrinkling, and only two showed very light wrinkling. Conversely, using the Datema scale, all individuals displayed some degree of wrinkling, with 2 showing minimal and 28 showing clear wrinkling. **Conclusion:** SWT was normal in 93% of the individuals studied. The data obtained provides a reference point for future research and enables the utilization of this easily accessible and low-cost test in clinical settings. SWT is a clinical tool for assessing the integrity of sympathetic autonomic fibers during neurological examinations.

Sleep and cognition in individuals with mild cognitive impairment and subjective cognitive decline

Elias Ramos Hurtado[1], Tania Aparecida Marchiori[1], Liara Rizzi[1], Isadora Cristina Ribeiro[1], Ítalo Karmann Aventurato[1], Marjorie Cristina Rocha da Silva[1], Brenda Costa Gonçalves[1], Emanuel Rodrigues Guimarães[1], Marcio Luiz Figueiredo Balthazar[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Elias Ramos Hurtado; Email: eliasrhurtado@outlook.com.

Background: Sleep and circadian rhythm disorders are potential markers of neurodegenerative diseases, especially for Alzheimer's disease (AD). Poor sleep is known to have a significant impact on cognitive function, and frequency and severity of sleep disturbance appear to follow the evolution of cognitive impairment. Few studies have addressed the relations of sleep quality and daytime sleepiness problems with cognitive functions in patients with milder stages of cognitive impairment. **Objective:** Investigate the possible association of sleep quality and daytime sleepiness with cognitive performance in individuals with Mild Cognitive Impairment (MCI) and Subjective Cognitive Decline (SCD), potential stages of Alzheimer's continuum. Materials and **Methods:** This is a quantitative observational cross-sectional study, part of a broader project already approved by the ethics committee. Sixty-five individuals (42 women, mean age 65.8 ±6.4) with clinical diagnosis of MCI and SCD (NIA-AA criteria) were included in this investigation. To evaluate the sleep, we used the scores in quality assessment questionnaires of sleep quality and daytime sleepiness: Pittsburgh Sleep Quality Index (PSQI) and Epworth Sleepiness Scale (ESS), respectively. We also used the score in the following neuropsychological tests: Montreal Cognitive Assessment, Clock Drawing Test, Rey Auditory-Verbal Learning Test, Rey-Osterrieth Complex Figure Test (copy, immediate recall and delayed recall), Trail Making Test (TMT-A and TMT-B), Verbal Fluency Test and Boston Naming Test. For statistical analysis, we used a partial correlation test, controlled for age and education. The significance was considered in p< 0.05. **Results:** We found a negative and weak correlation between PSQI and ROCF copy (r=-0.379; p=0.002), PSQI and ROCF immediate recall (r=-0.271; p=0.031), PSQI and ROCF delayed recall (r=-0.31; p=0.014), and a weak and positive correlation between PSQI and TMT-A (r=0.38; p=0.002), all controlled for age and education. There were no other significant correlations. **Conclusion:** These results suggest a role for sleep in cognitive performance for patients with MCI and SCD. Higher PSQI score, indicating worse sleep quality, was associated with lower ROCF score in copy, immediate recall and delayed recall, representing poor performance in constructive praxis, visuospatial abilities and visual memory. Also, it was associated with higher time in TMT-A, indication of worse sustained attention. We conclude that poor sleep quality is correlated with cognitive dysfunction, and especially executive visual episodic memory and visuospatial functions in our sample. Future research, with a longitudinal design and objective sleep metrics may better investigate this bidirectional association between sleep and AD.

Sleep disorders in preschoolers, fundamental motor skills, and manual dexterity

Carla de Oliveira Carletti[1], Karla Carlos[1], Gilmar Fernandes do Prado[1]

[1]Universidade Federal de São Paulo, Escola Paulista de Medicina, Departamento de Neurologia e Neurocirurgia, São Paulo SP, Brazil.

Correspondence: Karla Carlos; Email: ka.carlos1@hotmail.com.

Background: The performance of many daily tasks in childhood, school activities, and play requires mastery of fundamental motor skills such as locomotion, stabilization, and manipulation, and sleep plays an important role in acquiring these skills. **Objective:** To evaluate the association between sleep disorders, fundamental motor skills, and manual dexterity in preschool children. **Methods:** We assessed fundamental motor skills (long jump, throwing, and kicking a ball) based on fundamental movement patterns at the initial, elementary, and mature stages, and manual dexterity using the Nine Hole Peg Test (9-HPT). Poor performance was defined as children classified at the initial stage in motor skills and with an average time above 30 and 34 seconds for the dominant and non-dominant hands, respectively, on the 9-HPT. Sleep assessment was conducted using the Children's Sleep Habits Questionnaire (CSHQ), consisting of 26 items divided into 6 subscales with independent scores and the following cut-offs: Sleep-Disordered Breathing (SDB) >7, Disorders of Initiating and Maintaining Sleep (DIMS) >22, Night Wakings (NW) > 12, Sleep-Wake Transition Disorders (SWTD) >24, Excessive Daytime Sleepiness (EDS) >20, and Sleep Hyperhidrosis (SH) >8. We compared the results obtained in the group of children with and without sleep disorders. **Results:** We included 43 preschool children with an average age of 5.23 ± 0.42 years, of which 32 were boys (74.41%). The average time with the dominant and non-dominant hands to complete the entire task on the 9-HPT was 27.04s ± (4.06) and 32.68s (±5.49), respectively. For the long jump, 53.4% remained at the initial stage, 37.80% at the elementary stage, and only 9.30% at the mature stage. For overhand throwing: 51.16% at the initial stage, 34.88% at the elementary stage, and 13.95% at the mature stage. For kicking a ball: 18.60% were classified at the initial stage, 60.46% at the elementary stage, and 20.93% at the mature stage. Twelve (27.9%) children (10 boys) scored high on the SDB, SH, and DIMS subscales. There was no association between sleep disorders and fundamental motor skills or manual dexterity assessed by the 9-HPT. Discussion. SDB was one of the most prevalent issues presented in our study, with snoring and obstructive sleep apnea syndrome (OSAS) being common. SDB affects school performance, quality of life, and motor control. However, in our study, there was no association between sleep disorders and fundamental motor skills or manual dexterity. Nevertheless, for our sample of children, the expected stage for motor skills was the elementary stage, and we observed that for the skills of long jump and throwing, more than half of the children showed developmental delays. **Conclusion:** The children evaluated showed sleep impairments, with SDB, DIMS, and SH being the most prevalent. There was no association between sleep disorders, fundamental motor skills, and manual dexterity in preschool children.

Sleep in multiple sclerosis and neuromyelitis optica spectrum disorder

Andreia Lira de Oliveira[1], Nise Alessandra de Carvalho Sousa[1], João Victor de Chagas Rossin[1], Carlos Maurício Oliveira de Almeida[1], Satiko Andrezza Ferreira Takano[1], Siane Prado Lima de Souza[1], Ronaldo Marques Pontes Rabelo[1]

[1]Universidade Federal do Amazonas, Manaus AM, Brazil.

Correspondence: Andreia Lira de Oliveira; Email: andreialira.med@gmail.com.

Background: Multiple sclerosis (MS) and Neuromyelitis Optica Spectrum Disorder (NMOSD) are inflammatory demyelinating diseases. They manifest with gait disturbances, spinal cord signs, motor and sensory deficits, cognitive impairment, cranial nerve dysfunction, fatigue, and sleep disturbances. In some studies, sleep and fatigue are considered disabling symptoms, occurring in > 50% of individuals affected by MS. **Objective:** Evaluate sleep disorders such as hypersomnia, fatigue, risk of sleep apnea and presence of restless legs syndrome / Willis-Ekbom disease (RLS/WED) in patients with MS and NMOSD; assess the sleep quality of these patients and correlate these findings with clinical data and imaging. **Methods:** Cross-sectional study conducted in the demyelinating diseases service of the neurology department at HUGV-UFAM, Manaus, Brazil, from January 2017 to December 2020. **Results:** The study consisted of 60 patients, 41 with MS and 19 with NMOSD. They exhibited poor sleep quality (65%) and hypersomnia (53% MS; 47% NMOSD), but low risk of sleep apnea according to the STOP-BANG score. The frequency of restless legs syndrome / Willis-Ekbom disease (RLS/WED) was 14% in MS and 5% in NMOSD. There was no correlation between sleep quality, number of relapses, and Expanded Disability Status Scale (EDSS) scores. **Conclusion:** Patients with MS and NMOSD experience poor sleep quality, hypersomnia, and low risk of obstructive sleep apnea (OSA), but the frequency of restless legs syndrome / Willis-Ekbom disease (RLS/WED) is similar to that of the general population. There does not appear to be a significant difference in sleep disorders between these demyelinating diseases.

Sleep profile in cerebrotendinous xanthomatosis patients: a pilot study

Pedro Lucas Grangeiro de Sá Barreto Lima[1], Liandra Rayanne de Sousa Barbosa[1], Alissa Elen Formiga Moura[1], Antônio Edvan Camelo-Filho[1], Pedro Helder de Oliveira Junior[1], Mariana Michiles Santos Ramos[1], Livio Leite Barros[1], Pedro Braga-Neto[1], Manoel Alves Sobreira Neto[1], Paulo Ribeiro Nóbrega[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Pedro Lucas Grangeiro de Sá Barreto Lima; Email: pedro.lucas@alu.ufc.br.

Background: Cerebrotendinous Xanthomatosis (CTX) is a rare autosomal recessive lipid-storage disorder caused by variant in CYP27A1. The classical neurological phenotype presents with neuropsychiatric symptoms related to the brain, cerebellum, and/or brainstem with various typical systemic manifestations. There is increasing literature reporting sleep disorders in lipid-storage disorders. However, to the date of this research, there are no published studies on sleep assessment in patients with CTX, nor description of most prevalent sleep patterns reported by these patients. **Objective:** To clinically characterize sleep patterns and sleep disorders in CTX. **Methods:** This was a retrospective observational study including patients with CTX. General clinical data was collected through chart review. Scales used for sleep disorders assessment (Epworth Sleepiness Scale, Morningness-eveningness Questionnaire and screening for restless legs syndrome) and results of wrist actigraphy and polysomnography performed in their medical care were collected to characterize the sleep profile of these patients. **Results:** We included four patients with CTX from our center. All of them had diagnoses confirmed by genetic testing and high plasma cholestanol levels. The patients had clinical history compatible with classical form of CTX. Four patients related sleep disturbances. Two patients related daytime sleepiness and two complained of intense snoring. Insomnia was reported by two patients. Two patients performed polysomnography. Both had reduced latency for sleep, reduced amount of REM sleep and increased amount of N2 and/or N1 sleep for age and gender. One of these patients had evidence of moderate obstructive sleep apnea (OSA). One patient performed actigraphy, showing a circadian rhythm of 24 hours, good sleep consolidation pattern with median sleep efficiency of 91% but a median of five awakenings every night. Sleep patterns or even animal models for sleep disturbances in CTX are still to be described. Hence, there is little literature hypothesizing about how sleep disorders develop in this population. The presence of leukoencephalopathy and cerebellum impairment may be two possible reasons for the presentation of sleep disorders in CTX observed in our patients. The cerebellum is an important region in regulation of sleep, modulating function in the genesis of sleep and regulatory function on body movements during sleep. Leukodystrophies are reported to present with sleep symptoms such as hypersomnolence, insomnia and sleep-related breath disorders loke OSA. **Conclusion:** Our study shows that CTX patients may suffer from impairment in the physiological process of sleep. It highlights that the sleep assessment of these patients should be part of medical practice. Our study had several limitations due to the small sample size. More controlled studies are still needed to evaluate and intervene in the sleep of these patients.

Sleep quality and mood disorders impact in quality of life of patients with hemifacial spasm of a public tertiary center

João Augusto de Macedo Cavalcanti de Albuquerque[1], Míriam Carvalho Soares[2], Mariana de Almeida Cruz Silva[1], Clélia Maria Ribeiro Franco[2], Pedro Augusto Sampaio Rocha Filho[1]

[1]Universidade Federal de Pernambuco, Centro de Ciências Médicas, Recife PE, Brazil.

[2]Universidade Federal de Pernambuco, Hospital das Clínicas, Serviço de Neurologia, Recife PE, Brazil.

Correspondence: Mariana de Almeida Cruz Silva; Email: mariana.almeida20021@gmail.com.

Background: Hemifacial spasm (HFS) is a condition defined by involuntary facial contractions, usually being unilateral. The literature reports that HFS is more common in women, close to 40-60 years of age. Previous studies indicate that patients with HFS are more prone to insomnia than the general population. Regarding mood disorders, although controversial, a higher frequency of depression has also been demonstrated. In recent years Botulinum Toxin (BoNT) became the most used therapy for HFS, being able to reduce the symptoms with low side effects. Even though HFS is a non-life-threatening condition, patients in this situation may experience social embarrassment, psychological illness and sleep disorders. It is essential to investigate the frequency and impact of sleep and mental disorders in HFS patients' quality of life. **Objective:** Define insomnia, depression and anxiety disorders frequency in an HFS population. Establish the correlation of the impact of insomnia and mood disorders with the quality of life of HFS patients. **Methods:** Cross-sectional observational study involving 56 HFS patients of a public tertiary hospital along 6 month. Patients with cognitive impairment, use of BoNT in the last three months and other movement disorders were excluded. Data were obtained using the following instruments: sociodemographic questionnaire, hospital anxiety and depression scale (HADS), HFS score (subjective part, for quality of life scores), insomnia severity index (ISI) and Pittsburgh sleep quality index (PSQI). The cutoff points used in this study were based on the original studies described for each scale. For HADS, a score ≥ 9 points in the anxiety and depression subscales was used to define mood disorders. For ISI, scores ≥ 14 points characterized clinically significant insomnia. A cutoff of 5 was used for PSQI defined significant sleep disturbances. Statistical analyses were conducted using the Epi Info software. **Results:** Among the 56 patients, 36 (64.2%) were female. The mean age was 66 years (SD 13.1). The average time since diagnosis was 15.4 years (SD 8.6) and the most common spasm side was left, occuring in 33 patients (58.9%). Anxiety was identified in 19 patients (33.9%) and depression in 21 individuals (37.5%). Significant sleep disturbances was identified in 39 individuals (69.6%) and clinically significant insomnia was verified in 9 patients (16%). When compared to quality of life scores (measured by subjective part of HFS score), no statistical significance was verified between anxiety (student's t-test p: 0.102), depression (student's t-test p: 0.396), PSQI (student's t-test p: 0.571) and ISI scores (student's t-test p: 0.603). **Conclusion:** This study showed a considerable frequency of mood and sleep disorders in HFS patientes of a tertiary care center. However, mood and sleep disorders did not demonstrate a significant impact on the quality of life of HFS patients. Further studies are necessary to better analyze these correlations.

Sleep scales and motor assessment in patients with Parkinson's disease: possible associations?

Carlota Assayag Mendes[1], Diego Monteiro de Carvalho[2], Marcus Vinicius Della Coletta[3], Alvaro Siqueira da Silva[2], Marcello Facundo do Valle Filho[2], Raissa Costa Said[4], Agatha Lopes Azedo[4], Anelisa Campana Itinose[4], Yenly Gonzalez Perez[2], Carlos Mauricio Oliveira de Almeida[2]

[1]Faculdade Metropolitana, Manaus AM, Brazil.
[2]Universidade Federal do Amazonas, Manaus AM, Brazil.
[3]Universidade Federal do Paraná, Curitiba PR, Brazil.
[4]Universidade do Estado do Amazonas, Manaus AM, Brazil.

Correspondence: Agatha Lopes Azedo; Email: agathalopesazedo@gmail.com.

Background: The Unified Parkinson's Disease Rating Scale (UPDRS) is globally recognised and utilised for its capability to capture various aspects of Parkinson's disease, making it a reference standard for disease assessment. The significant and ongoing development of therapies for Parkinson's disease (PD) necessitates outcome measurement strategies focused on disease progression. Hence, this project examined the disease from the perspective of the PDSS, TCSR, Friedman scales, and their comparison with the UPDRS. **Objective:** To analyse the association between the UPDRS and the PDSS (Parkinson's Disease Sleep Scale), TCSR (REM Sleep Behaviour Disorder), and Friedman scales. **Methods:** The study was approved by the local Ethics Committee under CAAE n° 58684622.2.0000.0007. This was an observational, cross-sectional study conducted over 12 months with patients diagnosed with PD. For statistical analysis, Spearman's non-parametric correlation coefficient was used. **Results:** Out of the 33 selected individuals, results indicated that non-motor UPDRS and daily life scores shared the same coefficient of variation and 95% confidence interval range, at 8% and 16.2 - 21.9%, respectively, with mean values of 17.8 and 19.1. The motor scores had a variation of 19.4%, a 95% confidence interval of 39.1 - 53%, and a mean of 46. The overall mean UPDRS score was 89.6 with a variation of 33.2% and an interval between 77.8 - 101.4%. An association analysis was performed between the sum of the UPDRS scores and the final results of the PDSS, TCSR, and Friedman scales. The results in terms of Spearman's correlation coefficient (r) and p-values were as follows: PDSS sum with UPDRS, r=-0.411, p=0.017; TCSR, r=0.76, p=0.674; Friedman, r=0.81, p = 0.654. **Conclusion:** There is no correlation between the sum and final scores of the TCSR (r=0.08, p=0.67) and a significant negative correlation between the sum and final scores of the PDSS (r=-0.41, p=0.02), indicating that as the values of one variable increase, the values of the other tend to decrease (negative correlation). Further studies with larger sample sizes are required to evaluate the associations and specific outcomes of the applied questionnaires.

Slowly progressive als in a patient with TBK1 variant

Rodrigo Fagundes da Rosa[1], José Marcelino Aragão Fernandes[1], Francisco de Assis Aquino Gondim[1], Kauane Emilly Ribeiro Aureliano[1], Leonardo José Rodrigues de Araújo Melo[1], Francisco Duque de Paiva Giudice Junior[1], Leonardo Elias Araujo dos Santos[1], Mariana Alcântara Tavares[1], Alan Duarte Braz[1], Emanuela Freire Caetano Davi[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Rodrigo Fagundes da Rosa; Email: rodrigofdarosa@gmail.com.

Case presentation: A 67 year-old man began experiencing decreased strength in the lower limbs (LL), more pronounced on the left side, in late 2003. The condition progressed to the upper limbs (UL), right more than the left, and was associated with dysphonia. Neurological examination in 2004 revealed Hoffman and Babinski signs bilaterally, hyperreflexia, and reduced strength in both UL and LL. Also in 2004, he was started on Riluzole 50 mg BID. Brain MRI showed bilateral signal changes along the corticospinal tract, and the first EMG was reported as normal. By 2016, he exhibited spastic tetraparesis, diffuse muscle atrophy, fasciculations, dysphonia, dysphagia, emotional incontinence, and global hyperreflexia. Mild parkinsonism was also evidenced (decreased spontaneous blink and hypomimia). Motor evoked potentials in 2017 reported dysfunction of the corticospinal pathway to both upper and lower limbs. Thereafter, repeated EMG testing disclosed lower motor neuron involvement. He underwent gastrostomy in the second half of 2021 after reporting weight loss. Genetic testing in 2021 showed TBK1

c.1612C> T (p.His538Tyr) mutation in heterozygosity and LRRK2 c.3643G> A (p.Ala1215Thr) in heterozygosity. His motor impairment progressed in 2022, and since 2024 has been walking with difficulty and occasionally needs to use a wheelchair. He receives multidisciplinary care and home care. He has no significant respiratory involvement to date. Currently, he is clinically stable with a slowly progressive condition and preserved cognitive functions. **Discussion:** Recent genetic studies have identified a link between mutations in the TANK-binding kinase 1 (TBK1) gene, and Frontotemporal Dementia and ALS. TBK1, a member of the IKK-kinase family, plays a crucial role in innate immunity signaling and autophagy. Specifically, TBK1 is involved in the induction of type-1 interferons and the phosphorylation of autophagy adaptors, essential for autophagy and mitophagy processes. The impairment of autophagy due to TBK1 mutations may lead to the accumulation of protein aggregates. Our patient, carrying this variant, exhibits a slowly progressive condition that has been stable for over two decades with little clinical variation over the years. **Final comments:** Although we were not able to conduct additional genetic testing in other relatives to segregate the variant and establish causality, this study raises the possibility of the association with this variant and slowly progressive ALS without frontotemporal dementia. In addition to contributing to the relationship between TBK1 mutation and ALS, the case may contribute to a better understanding of progression patterns associated with this variant.

https://doi.org/10.5327/CBN241500

Slowly progressive amyotrophic lateral sclerosis associated with SOD1 mutation

Pedro Lucas Grangeiro de Sá Barreto Lima[1], Eugênia Machado Couto[1], Pedro Vitor Ferreira Rodrigues[1], Leonardo José Rodrigues de Araújo Melo[1], Francisco Luciano Honório Barreto Cavalcante[1], Ítalo Ramon de Araújo[1], Brendow Martin Freitas Gadelha[1], Richardson Fernandes de Castro e Silva[1], Anderson Rodrigues Brandão de Paiva[1], Paulo Ribeiro Nóbrega[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Pedro Lucas Grangeiro de Sá Barreto Lima; Email: pedro.lucas@alu.ufc.br.

Case presentation: A 56-year-old woman presents with a history of slowly progressive muscular weakness, frequent falls and gait impairment. She was born from consanguineous parents and had 5 healthy siblings. She had normal motor development. By the age of 34, the patient perceived an impairment on ambulation, associated with proximal weakness in the legs. The deficit slowly progressed over the next 2 decades before the first neurological consultation in our center. At 50-year-old she started using one-arm support as walking aid. No dyspnea or dysphagia was perceived. Neurological examination revealed diffuse muscular weakness, atrophy, fasciculations and hyperreflexia. Electromyography (EMG) revealed a pattern of diffuse lower motor neuron impairment. She started use of riluzole by the age of 50 upon the hypothesis of motor neuron disease. Further evaluation with next-generation sequencing exome revealed a likely pathogenic heterozygous variant (p.Val120Leu; c.358G > C) in SOD1, reported to cause familial amyotrophic lateral sclerosis. Thirty-one years after the initial disease presentation, the patient presents independent ambulation with support, no significant dysphagia and a Forced Vital Capacity (FVC) of 56% of predicted values. **Discussion:** Amyotrophic lateral sclerosis (ALS) is the prototypical motor neuron disease in adults. Patients with ALS experience muscular weakness and fasciculations that progress with atrophy, spasticity and loss of functionality. There is no curative therapy and patients tend to have a mean life expectancy of 3-5 years after the diagnosis. Although it is not typical, ALS may manifest predominantly with features of lower motor neuron (LMN). Pathogenic variants in SOD1 gene are well-reported to cause ALS. Variants in this gene produce a wide spectrum of clinical presentations and prognostics. Interestingly, the distribution of SOD1 mutations differs markedly even among similar populations. Treatment with the antisense oligonucleotide drug, Tofersen, is a possibility for ALS-SOD1 patients and has shown to decelerate the decline of clinical function. The variant p.Val120Leu (c.358G > C) in SOD1 is reported to cause ALS with predominantly LMN signs in Brazilian families. Patients reported with this variant tend to have a better prognosis than classical ALS, even without target therapy. Our patient presentation is compatible with the current literature for ALS-SOD1. **Final comments:** We reported a case of a Brazilian woman with ALS due to SOD1 variants that experienced a slow progression of the disease, keeping independent clinical and respiratory function 22 years since the initial presentation. The present report adds to the literature by reinforcing the milder phenotype associated with the presence of this variant in a monoallelic state. Further studies are needed to assess the frequency of ALS due to this variant in northeast Brazil.

Background: Although mechanical thrombectomy (MT) has been expanding its indications over the last years, establishing a robust benefit even for the elderly, the RESILIENT trial has shown neutral effects regarding this subgroup. One possible explanation for these findings is the vulnerability of the patients treated under these trials, which means these populations were frailer and, accordingly, portended a significant burden of cerebral small vessel disease (cSVD), which may work as a surrogate marker for brain frailty and even Vascular Cognitive Impairment (VCI). **Objective:** Based on this hypothesis, we studied the influence of the cSVD markers on the baseline CT scan in the functional outcome of the patients randomized in the RESILIENT trial. **Methods:** A trained vascular neurologist blinded to clinical details and randomization allocation evaluated the CT scans of the patients in the study focusing on markers of cSVD (leukoaraiosis, old lacunes, atrophy) and its overall burden. We chose 15 points in MoCA test as the cut-off for severe VCI. Then we carried out a multivariable logistic regression to identify the variables related to disability at 90 days. Finally, the effect of MT was evaluated between subgroups defined by its cSVD imaging markers. We also evaluated the data with an artificial intelligence technique called XGBoost. **Results:** The group with disability at 90 days was older, had a higher NIHSS at admission, had more prevalence of diabetes mellitus (DM), higher percentage of smokers, higher levels of systolic blood pressure and glucose levels at admission, poorer collaterals, lower rate of MT, and higher rates of severe cSVD markers at baseline CT scan. Only NIHSS; randomization for the control group; cSVD score; and glucose levels at arrival were associated with a poor outcome. In the subgroup analyses, the allocation group (standard treatment) influenced the functional outcome just for patients with severe leukoaraiosis and old lacunes. As for VCI, glycemia at admission, systolic blood pressure , NIHSS and cSVD markers were associated with a MoCA test ≤ 15 points. **Conclusion:** Markers of cSVD on baseline CT scans are related to disability, mortality and VCI in patients with LVO and might be one of the main causes of the lack of benefit of MT in older patients observed in the RESILIENT trial.

Smart syndrome identification and successful treatment

Thais Lins Gemir[1] , Silvana Sobreira Santos[1], Barbara Matos Almeida Queiroz[1], Alberico Carvalho Oliveira Bernardo[1], Denise Carvalho de Albuquerque[1], Natalia Saraiva Ramos e Cruz[1], Mauricea Novaes Costa Pereira[1]

[1]Rede D'Or.

Correspondence: Thaís Lins Gemir; Email: tatalg_30@hotmail.com.

Case presentation: A 62-year-old woman with hypertension, dyslipidaemia, hypothyroidism (secondary to Hashimoto thyroiditis) was admitted in 2024 to the emergency room (ER) with acute onset of global aphasia, lethargy and a left hemicranial headache. The patient had a brain tumor and was successfully treated in 2004 with chemotherapy, local radiotherapy. When the patient first arrived at the ER, she was afebrile with normal blood pressure. During the neurological examination, she was alert but exhibited impaired attention and global aphasia. She had no meningeal signs. Cerebral tomography (CT) revealed ischaemic/radiation leucoenfalopathy with no acute lesions. The cerebrospinal fluid analysis (including cytology) had 33 cels ahd 75 of protein. The following day, the patient underwent an electroencephalogram (EEG) that showed left temporoparietal cortical dysfunction, without evidence of epileptiform activity. A cerebral magnetic resonance was performed, revealing no evidence of stroke or abnormal enhancement on post-contrast sequences. However, an abnormal signal in the left parieto-occipital cortical in the T2 fluid-attenuated inversion recovery (FLAIR) sequence was observed. These revealed that the patient's antithyroid and anti-Peroxidase antibodies were positive. Seven days after admission, the patient started a 5-day regimen of methylprednisolone 1 g EV for the hypothesis of autoimmune disease and the possible diagnosis of SMART syndrome. The patient gradually improved his level of consciousness and recovered from aphasia and gait instability without new seizures or neuropsychiatric symptoms. Follow-up brain magnetic resonance imaging showed resolution of the typical findings **Discussion:** Stroke-like migraine attacks after radiation (SMART) syndrome is a delayed complication of brain irradiation characterised by recurrent neurological symptoms with episodes of complicated migraine symptoms and neurological deficits, including aphasia, hemiparesis and sensory disturbances and seizures. SMART syndrome's pathogenesis is still unknown; the vast majority of cases described in the extant literature suggest a transient syndrome, with full recovery. The clinical case discussed herein, however, is, to the best of our knowledge, unique. No treatment proved effective; nor did the patient's condition improve over time-in fact, quite the opposite occurred. These factors combined to make this case a significant diagnostic and therapeutic challenge. There is no clear consensus regarding effective treatment for SMART.9 Corticosteroids, antiplatelet agents, propranolol and verapamil have all been used without clear benefit. **Final comments:** This case displays a successful clinical evolution of a patient treated for SMART syndrome in which identification of previous radiation treatment, exclusion of other etiologies, and

prompt treatment institution were key for effectively tackling this disease.

Correspondence: Marília de Paula Ferreira; Email: 19ferreiramarip@gmail.com.

Case presentation: A 21-year-old female patient who had been monitored since birth for various clinical signs characteristic of Smith-Lemli-Opitz Syndrome (SLO), a rare genetic disorder caused by 7-dehydrocholesterol reductase deficiency. Characteristics include retrognathism, microcephaly, protruding teeth and epilepsy of undetermined onset. Complementary tests such as electroencephalogram (EEG) and brain magnetic resonance imaging (MRI) indicated abnormal patterns compatible with diffuse encephalopathy and generalized epileptogenesis. From the beginning of his life, the patient faced health complications, including meconium aspiration syndrome and feeding difficulties. Over time, various malformations and developmental problems were identified, such as ambiguous genitalia, bilateral clinodactyly and syndactyly of the feet. At the age of 3 years and 8 months, SLO was confirmed biochemically and, at the age of 7, a gastrostomy was necessary due to persistent feeding difficulties. Therapeutic treatment included the use of Risperidone, Sodium Valproate (VPA), Clonazepam (CNZ) and a cholesterol-rich diet to control symptoms and improve quality of life. She developed aggressive behavior and absence status epilepticus at the age of 18. **Discussion:** SLO is caused by a deficiency in the enzyme 7-dehydrocholesterol reductase, caused by a recessive pathogenic variant in the DHCR7 gene, which is essential for cholesterol synthesis, resulting in a wide range of clinical manifestations such as congenital malformations and developmental delay. The patient had typical features of SLO, such as retrognathia, microcephaly and protruding teeth, along with epilepsy, which can be attributed to neurochemical dysfunctions due to cholesterol deficiency. Treatment included a combination of antiepileptic drugs (in this case VPA, CNZ and Lamotrigine) and antipsychotics (in this case Olanzapine) for symptom control. EEG and MRI brain scans revealed abnormal patterns, corroborating the neurological symptoms and helping to guide treatment. Although medical control is crucial, there is no definitive cure for SLO. The therapeutic approach's main objective is to attenuate the symptoms and optimize the patient's functionality. This case illustrates the complexity of this syndrome and the importance of its recognition and subsequent follow-up throughout adulthood. **Final comments:** Smith-Lemli-Opitz Syndrome (SLO) is a rare genetic disorder characterized by multiple anomalies and cognitive impairment due to 7- dehydrocholesterol reductase deficiency. Its management requires the collaboration of various specialties, especially Neurology, in order to control symptoms and improve the patient's quality of life.

Snake eye myelopathy: a misdiagnosis entity

Yasmin Ramalho Mandarino[1], Natália Cardoso Darabas[2], Hannah Bang[2], Pietra Cani Linzmeier[2], Thábata Emanuelle Martins Nunes[2], Maria Eduarda Angelo Mendonça Fileti[2], Carla Heloísa Cabral Moro[2], Alexandre Luiz Longo[2]

[1]Universidade da Região de Joinville, Joinville SC, Brazil.
[2]Hospital Municipal São José, Joinville SC, Brazil.

Correspondence: Yasmin Ramalho Mandarino; Email: yasminramalhoo@gmail.com.

Case presentation: A 54-year-old male with history of neck trauma due to a motorcycle accident 10 years ago presented to the neurology service with complaints of strength loss in the upper limbs, worse in the left side, accompanied by myofasciculations. These symptoms started two years ago and have progressed with paresis in the lower limbs in recent months. Patient denies sphincter changes or bulbar symptoms. Physical examination revealed muscle atrophy, fasciculation in the upper limbs, grade IV strength and areflexia in left upper limb and hyporeflexia in the left lower limb. No signs of upper motor neuron involvement were found. Electroneuromyography showed chronic and asymmetric denervation with multisegmental innervation in the cervical region, most pronounced at C5-C7. An cervical spine MRI was crucial for the diagnosis, with hypersignal in the anterior horns of the C2-C5 gray matter, indicative of probable sequelae. The patient has been followed for 11 years without worsening of the condition. **Discussion:** "Snake eyes" myelopathy represents a rare form of myelopathy. Snake-eyes appearance (SEA) is a unique radiological finding characterized as bilateral hyperintense symmetric, circular or ovoid foci on T2-weighted axial magnetic resonance imaging sequences in the anterior horn cells of the spinal cord, and it's called like this because of the similarity to the face of a snake. There is no clear data on the exact prevalence and incidence, as there has been no systematic analysis of the full spectrum of clinical patterns associated with snake-eyes in larger cohorts. It's considered as an anterior horn disorder resulting from local ischemia, triggered by arterial compression from an anterior with shifting of the posterior cervical dura upon neck flexion. Trigger factors such as intensive physical exercise, trauma or carrying heavy loads are common. This "snake-eyes" appearance is not specific to any particular disease and can be seen in a variety of conditions such as spinal artery ischemia, chronic compressive myelopathy, degenerative cervical myelopathy, Hirayama disease or monomelic amyotrophy of the upper limb, amyotrophic lateral sclerosis, and spinal muscular atrophy. Therefore, clinical examination, extensive laboratory tests, nerve conduction studies, and genetic tests may be required to diagnose the underlying condition. **Final comments:** This case underscores the importance of recognizing the "snake-eyes" myelopathy as it is a disease that affects the lower motor neuron that can have a benign prognosis. This serves as a crucial differential diagnosis for amyotrophic lateral sclerosis. The "snake-eyes signal" is an often-under-recognized radiological clue, leading to frequent misdiagnosis of patients with this clinical-radiological entity. Additionally, the case highlights the significance of performing neuroimaging in the diagnostic evaluation of patients with motor neuron disease.

Sneddon syndrome: a rare cause of stroke

Nathalye Fernanda Pedroso Dircksen[1], Marcelo Simplicio Carvalho[1], Letícia de Barros Dias[1], Lorena Fernandes Kronbauer[1], Fábio Gonçalves[1], Felipe Leonardo Semensati[1], Damacio Ramon Kaimen Maciel[1]

[1]Irmandade da Santa Casa de Londrina, Londrina PR, Brazil.

Correspondence: Nathalye Fernanda Pedroso Dircksen; Email: n.athalye@hotmail.com.

Case presentation: A 41-year-old woman with mitral insufficiency treated with valve replacement 20 years ago, was admitted due to recurrent ischemic strokes. She presented paresthesia of the left upper limb and vertigo, She was confused (Glasgow scale 14), mini mental state examination loss of attention, memory and language (score of 25) and livedo reticularis was observed in the limbs and trunk. Magnetic resonance imaging (MRI) of the skull showed multiple hyperintense lesions affecting the frontal, occipital and right parietal lobes, suggesting a subacute/chronic vascular insult, in addition to diffuse volumetric reduction of the brain that was not expected for the age. Skull arterial angiography showed no changes. The echocardiogram transthoracic examination showed significant enlargement of the left atrium and mild mitral reflux - metallic valve. The VHS was 38, with no other changes in rheumatological or hematological screening. Started using warfarin with INR (International Normalized Ratio) target between 2.5-3.5 due to valve prosthesis, antihypertensives and statins. **Discussion:** Sneddon Syndrome (SS) is a rare and slowly progressive neurocutaneous disease that affects small and medium-sized arteries and is characterized by generalized livedo reticularis and recurrent cerebrovascular events. Approximately 80% of patients are women with a mean age at diagnosis of 40 years, as in the case presented. The etiology is unknown, some cases have been associated with an autosomal dominant inherited pattern. Arterio-occlusive pathogenesis is due to 2 proposed mechanisms: autoimmune/inflammatory disease and thrombotic disease. There is no specific biological marker for the diagnosis of SS, however it can be classified as antiphospholipid (APL) positive or negative, depending on the presence of any of these 3 antibodies: anticardiolipin, lupus anticoagulant and anti-beta 2-glycoprotein. Less than half are APL positive, with a higher risk of thrombocytopenia, seizures and chorea. Neurological manifestations generally occur in 3 phases. The first with prodromal symptoms (headache, dizziness and vertigo), the second with ischemic and rarely hemorrhagic strokes (rupture of collateral vessels secondary to occlusion of primary cerebral arteries) and the third with cognitive decline and early-onset dementia. The most common cardiac pathology in SS is thickening of the heart valves and/or libman-sacks endocarditis. Treatment requires control of modifiable risk factors and use of antiplatelet agents or antithrombotics (high-dose warfarin with INR > 3, preferable in APL positive patients). **Final comments:** The absence of specific exams and consensus makes the diagnosis and treatment of the disease more challenging. Currently, SS is a diagnosis of exclusion and is often forgotten. Therefore, attention should be paid to its possibility, as failure to adequately treat it can increase the morbidity and mortality of its sufferers.

Social and occupational functioning in adult patients with epilepsy

Gloria M. A. S. Tedrus[1], Danilo Wingeter Ramalho[1]

[1]Pontifícia Universidade Católica de Campinas, Campinas SP, Brazil.

Correspondence: Gloria M. A. S. Tedrus; Email: gmtedrus@uol.com.br.

Background: Adult patients with epilepsy (PWE) often face greater difficulties in employment and social activities, tending to have lower educational levels. **Objective:** To assess social and occupational functioning in PWE and examine its correlation with clinical aspects. **Methods:** Scores on the Social and Occupational Functioning Scale for Epilepsy (SOFSE) were correlated with demographic and clinical data from 65 PWE, with a significance level of $p < 0.05$. **Results:** The PWE had a mean age of 47.2 years, while their mean age at first seizure was 22.1 years, with an average epilepsy duration of 25.3 years. 40 of them were males and 33 females, 53 (72.6%) patients were employed/retired, and 20 patients were unemployed.

The total score on the SOFSE scale was 66.3±15.6. In the comparison between employed and unemployed individuals, higher scores were observed in the "employed with a salary" facet (T-test, 8.0 ± 6.7 vs 3.7 ± 5.9; p=0.011) and "instrumental activities of daily living" (19.6 ± 7.1 vs 22.8 ± 4.8, p 0.038) in employed individuals. Women and unmarried patients, as well as the occurrence of focal seizures, use of a single antiseizure medication, and epilepsy type were associated with higher scores on the SOFSE scale (facets and/or total score). The total SOFSE scores correlated with age (Pearson correlation, -0.384, p=0.001), education (0.336, p=0.004), and age at the first seizure (-0.231, p=0.049). **Conclusion:** Demographic and clinical factors are associated with impairment in functional and occupational status in epilepsy. Younger patients with higher educational levels and later onset of epilepsy present better occupational and functional adjustment.

Sociodemographic and clinical factors affecting migraine treatment outcomes in the emergency department

Carla Bianca Alves Leite Santos[1], Artur de Oliveira Macena Lôbo[1], Claudia Cristina de Lira Santana[1], Bruno Felipe Novaes de Souza[1], Juliana Ramos de Andrade[1], Marcelo Moraes Valença[1]

[1]Universidade Federal de Pernambuco, Recife PE, Brazil.

Correspondence: Carla Bianca Alves Leite Santos; Email: carla.biancaleite@ufpe.br.

Background: Migraine is the most prevalent neurological disease, currently considered the second leading cause of global disability, the first when it comes to women aged 50 or younger. **Objective:** To analyze the efficiency of the emergency service in treating patients with primary headache, based on the effectiveness of the treatment, taking into account the level of pain reported before and after the medical assistance, and the return rate. All correlating with the sociodemographic, economic, and clinical profile of the patients. **Methods:** An observational, cross-sectional study was designed in the emergency room of a tertiary hospital. The data was collected through interviews and surveys of all International Classification of Diseases (ICD) using the patient's electronic record. The study population comprises adult patients with ICDs for headache, migraine, and their variables, approached before and after care. For evaluation of pain, a Visual Analogue Scale was used (in which 0 indicated absence of pain and 10 represented unbearable pain). The exclusion criteria were: a) patients with a change in diagnosis during their stay in the hospital; b) patients who evaded the service before medical discharge; c) patients who progressed to hospitalization. **Results:** We evaluated a total of 102 patients, with a mean age of 36.9±12.7 years, of whom 83 (81.4%) were female. Concerning the patients' referred pain level when they arrived at the service, we found out that women reported significantly higher initial pain levels (7.48±1.95) compared to men (6.22±2.39) (p=0.009) and that the same applied to patients already under medical follow-up for migraine (8.46±1.45) compared to those without follow-up (7.08±2.11) (p=0.014). Regarding the patient's referred pain level after treatment in the service, we observed that those who had a higher frequency of migraine-related visits to the emergency service in the last year also reported higher levels of pain after treatment (p=0.017). Furthermore, it was observed that patients already under medical follow-up and those with higher purchasing power had a higher frequency of visits to the emergency service due to migraines in the last year (p<0.001 and p=0.028, in this order). No significant association was found between pain in any stage of the medical assistance or frequency of migraine-related medical appointments and the patients' workload, educational level, and use of opioids before coming to the emergency service (all p> 0,05). **Conclusion:** This study highlights potential factors that affect migraine treatment outcomes in the emergency room. While women and those under medical follow-up for migraine reported higher initial pain, those with frequent emergency room visits had higher post-treatment pain levels. These findings suggest the need for a more individualized approach to migraine care in the emergency department, potentially considering alternative treatment pathways for specific patient profiles.

Socioeconomic burden of multiple sclerosis in Brazil: an overview of the last 10 years

João Lucas Lima Diogo[1], Ana Clara Costa de Siqueira Campos[1], Gabriela Morais de Medeiros Dias Melo[1], Joanna Sousa da Fonsêca Santana[1], Lara Millena Miranda Frota[1], Luísa Lettiery Andrade Santos[1], Maria Antônia Vianna Santos[1], Maria Eduarda Kobayashi Teixeira[1], Ruben Costa Santos Neto[1], Felipe Oliveira Costa[1]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.

Correspondence: João Lucas Lima Diogo; Email: joaodiogo20.2@bahiana.edu.br.

Background: Multiple sclerosis (MS) is an autoimmune and chronic neurological disease, resulting from the demyelination of neurons in the white and gray matter of the central nervous system, with a prevalence of 8.69 cases per 100,000 inhabitants in Brazil. This condition is the second most prevalent cause of permanent neurological disability before the age of 50 in the country. Therefore, the scarcity of socioeconomic analyzes on this disease highlights the importance of this study for health policies and resource allocation, ensuring an equitable treatment for all patients. **Objective:** To analyze the socioeconomic burden and demographic distribution of MS in-hospital environment in the Brazilian Unified Health System (SUS). **Methods:** Descriptive ecological study involving the number of hospitalizations for MS in Brazil, between the years 2014 and 2023. All hospitalizations were listed based on access to data from the SUS Hospital Information System (SIH/SUS) using the TABNET tabulator. **Results:** When analyzing data for costs of hospitalizations due to MS in the SUS from 2014 to 2023, we found that the total national amount spent in this period was R$24.797.196,40. The region with the highest average cost of hospitalization was the North Region (R$1.448,50). The region with the highest annual growth in investments was the Central-West Region (18%) from 2015 to 2016. The Central-West Region had the greatest reduction in absolute and relative values, with a decrease of R$214.605,81 (74,62%) between 2018 and 2019. Finally, the highest annual average cost of hospitalization was observed in the Southeast Region (R$1.530.645,38). Regarding the number of hospitalizations, the region with the highest number of hospitalizations during those years was the Southeast Region (31.006 hospitalizations) and the region with the lowest was the North Region (730 hospitalizations). The Southeast Region had an increase of 1.340 hospitalizations from 2021 to 2022 and the Central-West Region showed a reduction of 748 hospitalizations from 2018 to 2019. **Conclusion:** The study reveals a significant regional divergence between costs of hospitalization for MS. The Southeast Region stands out both in terms of expenditure and the number of hospitalizations, denoting a possible greater access to specialized health services. The North Region, despite having the lowest total number of hospitalizations, had the highest average value per hospitalization, suggesting that the cases treated may have greater complexity or higher individual costs. The results suggest the need for a more equitable distribution of health resources and strategic planning to improve access and quality of MS treatment. The limitations of this study include its dependence on SIH data and the lack of data on the quality of care provided. Future studies shall investigate explanations for resource allocation and the inclusion of qualitative data on the impact of treatments.

Somatosensory evoked potentials in neuromyelitis optica spectrum disorders

Otto Jesus Hernandez Fustes[1], Cláudia Suemi Kamoi Kay[1], Paulo José Lorenzoni[1], Renata Dal-Prá Ducci[1], Paula Raquel do Vale Pascoal Rodrigues[1], Rosana Herminia Scola[1]

[1]Universidade Federal do Paraná, Curitiba PR, Brazil.

Correspondence: Otto Jesus Hernandez Fustes; Email: otto.fustes@hc.ufpr.br.

Background: Neuromyelitis optica spectrum disorders (NMOSD) are antibody-mediated disorders of the central nervous system with a predilection for the spinal cord and optic nerves. NMOSD was previously thought to be a variant of multiple sclerosis (MS), but the identification of aquaporin 4–immunoglobulin G (AQP4-IgG), has led to an appreciation of these diseases as distinct entities. The clinical utility of evoked potential recordings (EPs) has already been established for MS, in which EPs can detect clinically silent lesions in visual, auditory, sensory, and motor pathways. In addition, several studies have suggested a prognostic value for EPs in MS and an association between EP abnormality and the level of clinical disability. On the other hand, there have been few reports on EPs in patients with NMO. At the NMO, recent studies are beginning to reveal the role of EPs and their possible value as a diagnostic tool. **Objective:** Determine the characteristics of somatosensory evoked potentials (SSEP) in patients with NMOSD. **Methods:** The SSEP in the upper and lower extremities was prospectively performed in patients with NMOSD according to the International Panel for NMO Diagnosis criteria, recruited from the outpatient clinic of a university neurology center. Recorded as recommended by the IFCN, using the Nihon-Kohden Neuropack software. The latency was measured at the peak amplitude, and the amplitude was measured between the peak and the end of the potential. The interpretation was based on our laboratory standards using the same technique and apparatus. For each latency variable (N20, P40), patients were categorized as "Normal" or "Abnormal". Then the variables of age, gender, AQP4-Ab, and latencies were compared between the two groups (Abnormal vs. Normal). The study was approved by the Local Ethics Committee for Human Research with a number 4.340.521. All studies were conducted following ethical principles after obtaining patient informed consent. **Results:** We evaluated 12 females with a mean age of 42 years old and one man of 25 years old. When categorized concerning the variable SSEP (Normal vs. Abnormal), there was a statistical difference in N20, N21, and P40 latencies. 76.9% of our patients had AQP4-IgG positive. No significant differences in age at onset were observed between anti-AQP4 antibody-positive and --negative patients. Normal patients had an average N20 latency of their limbs of 18.69 ± 1.6 and Abnormal patients had an average of 25.21±10.09 (p=0.016 two-tailed hypothesis). **Conclusion:** SSEP showed a significant increase in N20 and P40 latencies. SSEP is a non-invasive, painless, fast, and low-cost exam that provides neurophysiological data for diagnosis of NMOSD.

Spastic paraplegia type 3: case report

Laura Altomare Fonseca Campos[1], Jéssica Cristina Silveira Damasceno[1], Marcelo Sobrinho Mendonça[1], Thiago Cardoso Vale[1]

[1]Hospital e Maternidade Therezinha de Jesus, Juiz de Fora MG, Brazil.

Correspondence: Laura Altomare Fonseca Campos; Email: lauraaltomare8@gmail.com.

Case presentation: A 66-year-old hypertensive male patient is evaluated with a history of childhood onset of slowly progressive gait impairment. Family history included a father, a paternal uncle and a brother with a similar clinical condition. On physical examination, there was a slight reduction in the distal strength of the lower limbs, associated with significant spasticity, worse in the right lower limb, with scissoring gait. Imaging and laboratory tests were unrevealing, what led us to request a genetic panel, that revealed a mutation in the ATL1 gene. Spastic paraplegia Type 3 (OMIM 182600, variant c.1483 C > T p.(Arg 495Trp) was diagnosed. **Discussion:** Type 3 spastic paraplegia is part of the Hereditary Spastic Paraplegias (HSP) group and is, therefore, a disease with a genetic inheritance pattern, which can be autosomal (recessive or dominant) or X-linked. Despite the genetically diverse forms, it is known that the disease evolves with progressive degeneration of the axons of the corticospinal tract, which typically manifests with spasticity and weakness predominantly in the lower limbs, in addition to other findings that may be systemic or neurological. The phenotype of HSP varies according to the gene involved and can present with the typical clinical features mentioned above, as well as other neurological alterations such as seizures, dementia, extrapyramidal disorders, peripheral neuropathy, amyotrophy, ataxia and hydrocephalus. Some forms may also present with cognitive alterations, which can be observed from the onset of symptoms. Type 3 spastic paraplegia occurs in around 4 to 6% of autosomal dominant HSP, and is usually a pure form, without other neurological involvement, and with onset in childhood, as in the patient reported. **Final comments:** Correct diagnosis is important because the differentials include motor neuron diseases, structural impairments of the spinal cord, leukodystrophies, dystonia, metabolic or infectious disorders, and hereditary ataxias. Although there is no disease-modifying treatment, it is possible to carry out genetic counseling and to provide symptoms relieve through medication, physiotherapy, rehabilitation, and botulinum toxin.

https://doi.org/10.5327/CBN241511

Spatial distribution of incidence and mortality by malignant tumors of the central nervous system in the Southern region of Brazil

Pamella Fracisquini Gardin[1], Rodrigo Penomian Cianca[1], Yves Henrique Ramos Mansano[1], João Marcelo de Souza Baptista[1], Matheus Henrique Arruda Beltrame[1], Miyoko Massago[1], Luciano de Andrade[1]

[1]Universidade Estadual de Maringá, Maringá PR, Brazil.

Correspondence: Pamella Francisquini Gardin; Email: pamfgardin@gmail.com.

Background: Malignant neoplasms of the central nervous system (CNS) have increased in recent years around the world, including Brazil, where this group ranks 11th among the most frequent neoplasms, showing higher incidence and mortality in the Southern region of the country. **Objective:** To analyze geographical disparities in incidence and mortality by CNS neoplasms in the Southern region of Brazil, between the years of 2017 and 2021 **Methods:** This is a cross-sectional ecological study using secondary data obtained from the Oncology Panel, DATASUS Mortality Information System and Brazilian Institute of Geography and Statistics. Data on incidences and deaths from malignant CNS tumor (C70, C71, C72), in individuals aged 20 to 64 years, were filtered. Crude incidence and mortality rates were calculated by the ratio between the number of cases and the resident population adjusted by age. These rates were smoothed by the empirical Bayesian estimator method, being named smoothed incidence and mortality rates. Subsequently, the Global Moran's Index and the Local Indicator of Spatial Association (LISA) were applied to detect spatial autocorrelation at global and local levels of incidence and mortality rates. **Results:** During the study period, there were 4,666 cases and 3,042 deaths by malignant CNS tumor, with 1,922 cases in Paraná, 1,107 in Santa Catarina and 1,637 in Rio Grande do Sul, and a mortality of 100, 998, and 1,944 deaths in the respective states. Analyzing only incidence rates yielded a Global Moran's Index of 0.546 ($p<0.001$). There were 151 municipalities identified with high-high clusters (incidence rate from 5.3 to 17.6 cases per 100,000 inhabitants), that is, municipalities with high incidence rates surrounded by municipalities with high rates, in the northeast, southwest, central and southeast regions of Paraná, west-central Santa Catarina and north Rio Grande do Sul. Regarding mortality, a Global Moran's Index of 0.593 ($p<0.001$) was obtained. Mortality rates varied from 0 to 16.6 deaths per 100,000 inhabitants, with 150 municipalities showing high-high clusters predominantly distributed in the states of Santa Catarina and Rio Grande do Sul, especially on their border, as well as clusters in the extreme south of Rio Grande do Sul, western Santa Catarina and scattered municipalities in Paraná. **Conclusion:** The highest mortality rates were concentrated in Rio Grande do Sul and Santa Catarina, and although the state of Paraná showed high incidence rates of malignant CNS tumors, it corresponds to the lowest mortality rates when compared to the others. Such divergence may be due to variables such as accessibility and quality of reference services. However, more in-depth studies are necessary to elucidate this hypothesis.

Spectrum of ataxic neuropathy in a young woman: case study of POLG gene mutation

Iago César Lopes Tenório de Cerqueira[1], Caio Roberto Alexandre Cavalcante dos Santos[1], Isaías Henrique Martins de Vasconcelos Norte Bezerra[1], Maria Eduarda Vieira de Oliveira[1], Déborah Emmily de Carvalho[1], Lívia Barbosa Cavalcanti[1], Leticia Gomes Fonseca[1]

[1]Universidade de Pernambuco, Recife PE, Brazil.

Correspondence: Iago César Lopes Tenório de Cerqueira; Email: iagocesartenorio@gmail.com.

Case presentation: A 29-year-old woman with no significant prior clinical history developed gait ataxia 16 years ago, beginning with frequent falls and ankle sprains, progressing to independent walking difficulty and clumsy speech. Examination revealed cerebellar ataxia with Romberg sign, wide-based gait, global areflexia, mild proximal tetraparesis, auditory hypersensitivity, spastic dysarthria, and limited upward gaze. General laboratory tests were unremarkable. ENG indicated purely sensory distal peripheral axonal polyneuropathy in the lower limbs. Brain MRI showed cerebellar atrophy and T2 hyperintense lesions in bilateral cerebellar deep white matter, thalami, and inferior olivary nucleus. Genetic analysis confirmed a homozygous pathogenic variant, c.2243G> C, diagnosing a POLG-related disorder with SANDO phenotype. **Discussion:** The Ataxia Neuropathy Spectrum (ANS) is a rare genetic condition, one of six major syndromes associated with POLG gene mutations, affecting a small fraction of the population. These mutations are the most prevalent cause of mitochondrial disease across all ages, accounting for 10% of adult cases. The POLG gene encodes the catalytic subunit of DNA polymerase gamma, essential for mitochondrial DNA replication and repair. This mitochondrial disease primarily affects the nervous system, causing neurological and systemic manifestations, such as auditory neuropathy indicated by auditory hypersensitivity and unilateral hearing loss. Additionally, this dysfunction may present with chronic headaches and osteopenia due to altered bone metabolism. The patient exhibited progressive cerebellar ataxia, dysarthria, and sensory ataxic polyneuropathy with ophthalmoplegia, common characteristics of POLG mutations, with the latter being significant. MRI findings, such as cerebellar atrophy and T2/FLAIR hyperintensities in white matter and deep brain structures, are typical of mitochondrial disorders, supporting the ANS diagnosis. Electroneuromyography corroborates the patient's peripheral neuropathy, also associated with ANS. **Final comments:** The findings described corroborate the complexity of the syndromes caused by mutations in the POLG gene. Due to the rarity of the condition highlighted in this case, it tends to be underdiagnosed, resulting in a poor quality of life for affected patients. To enable early diagnosis and effective management, further studies on ANS are needed, aiming to provide better outcomes for affected individuals.

https://doi.org/10.5327/CBN241513

SPG related to the spast gene (SPG4): case report of a novel variant

João Felipe Pissolito[1], Wilson Falco Neto[1], Gustave Rocha Rodrigues[1], Eliana Meire Melhado[1], Natália Prando[1], Renan Cenize Guardia[1], Laura Alonso Matheus Montouro[1,2]

[1]Centro Universitário Padre Albino, Faculdade de Medicina de Catanduva, Catanduva SP, Brazil. [2]Faculdade de Medicina de São José do Rio Preto, São José do Rio Preto SP, Brazil.

Correspondence: João Felipe Pissolito; Email: felipe.pissolito@gmail.com.

Case presentation: Female patient, 65 years old, non-consanguineous parents, weakness and stiffness in the lower limbs 25 years ago in a progressive evolution. She denies abnormalities in sensitivity, dysphagia or cognitive complaints. Father, two brothers, a sister and four nieces with a similar condition. On physical examination: preserved cognition, significant spasticity tone in the lower limbs (Grade IV - Ashworth Scale), positive Hoffmann and Babinski signs bilaterally, grade 5 strength in the upper limbs and grade 3 strength in the lower limbs (MRC Scale), preserved coordination and exteroceptive/proprioceptive sensitivity. She underwent brain MRI, which showed signs of corpus callosum atrophy and mild diffuse brain volumetric reduction. Commercial genetic panel for hereditary spastic paraparesis revealed a heterozygous mutation: c.886_887del:p.Asn296*, in exon 6 of the SPAST gene. Baclofen 10 mg/day prescription, indicated motor physiotherapy and genetic counseling. **Discussion:** Our proband presents the pure phenotype of hereditary spastic paraparesis (HSP) as progressive weakness of the lower extremities and spasticity without other signs. This variant is a frameshift deletion mutation that results in the deletion of two nucleotides from position c.886 to c.887, resulting in an earlier stop codon compared to the wild-type protein. This leads to the truncation of the synthesis of the coding protein, thus losing its normal function. This new variant was predicted as probably pathogenic by the American College of Medical Genetics and Genomics, absent from gnomAD and ClinVar and scientific literature. Corpus callosum thinning and mild diffuse brain volumetric reduction, it's unusual but can occur in SPG4 and other HSP, although it is most frequently associated with SPG11. Therefore, given the compatible clinical condition, neuroimage, autosomal dominant inheritance pattern and probable pathogenic variant, in heterozygosity, in the SPAST gene, the diagnosis of SPG4 was confirmed by a new genetic variant. **Final comments:** Epidemiological studies and further case reports of HSP in Brazil are necessary to characterize genotype and phenotype of the disease. Performing genetic study to diagnose and classify the disorder is essential in the control and targeted treatment of the disease and genetic counseling.

Sphenoidal sinusitis with neurological complications: a case report

Ricardo Kendy Nishiuchi de Paiva[1], Breno Gonçalves Medeiros[1], Matheus Hisamitsu Facine[1], Lucas Do Rego Barros Correa Martins[1], Humberto Ramos Crispim[1], Maria Izabella Grigoli Passarello Afonso[1], Maria Antunes Villa[1], Leticia Akemi Rama Yamamoto[1], Gabriela Rodrigues Sousa[1], Nasser Faiçal Abou Zeenni Nfa Zeenni[1]

[1]Hospital de Base de São José do Rio Preto, São José do Rio Preto SP, Brazil.

Correspondence: Ricardo Kendy Nishiuchi de Paiva; Email: ricaknpaiva@gmail.com.

Sphenoidal sinusitis is the rarest type and can cause severe damage, mainly ophthalmological. Involvement of the II, III or IV cranial nerves can lead to permanent deficits or, in severe cases, fatalities. Analysis of the clinical evolution of a patient with optical impairment due to sinusitis. **Case presentation:** A 78- year old female presented with a 45-day history of pain in the left cheek and a left frontal parietal headache, which initially improved with over-the-counter analgesics. Two weeks prior to seeking medical attention, the headache returned and she experienced a sudden decrease in visual acuity in the left eye, accompanied by proptosis and ophthalmoparesis with difficulty on left eye adduction. Brain MRI revealed presence of a T2-hyperintense signal suggesting secretion accumulation in the right maxillary sinus, sphenoid sinus and left ethmoidal cells. Comparison with a previous MRI showed a bone dehiscence on the left lateral wall of the sphenoid sinus and the left posterior wall of the ethmoid, resulting in a communication with the left orbital fissure. This extension of the affected area with secretion has impacted the left orbit and, mainly, the III and IV cranial pairs. The patient underwent sinus surgery. Fluid-cultures revealedPseudomonas aeruginosas growth. Empiric treatment with piperacillin-tazobactam was followed by antibiotic de-escalation to levofloxacin, prescribed for two weeks. No improvement of the cranial nerves affected was observed on follow-up. **Final comments::** Although optical impairment is a rare complication of sinusitis, the patient had severe sequelae due to the delay in diagnosing the infection, which resulted in permanent deficits.

https://doi.org/10.5327/CBN241515

Sphenopalatine ganglion block in refractory cluster headache: a case report

Luis Armando Sawada[1], Annelise Akemi Higa Lee[1], Ana Carolina Montouro Storarri[1], Beatriz Marques dos Santos[1], Bruno Pissolati Mattos Gonzaga[1], Lorrane Campidelli Arthuzo[1], Renan Barros Domingues[1]

[1]Irmandade da Santa Casa de Misericórdia de São Paulo, São Paulo SP, Brazil.

Correspondence: Annelise Akemi Higa Lee; Email: a.higalee@gmail.com.

Case presentation: A 58-year-old woman presented with intense, right-sided orbital pain, with 60-minute duration attacks occurring 1-2 times a day, mostly at night. These were associated with right-sided ptosis, conjunctival hyperemia, lacrimation, and rhinorrhea. The patient had previously tried prophylactic treatment with verapamil 320 mg/day, achieving only partial reduction in attacks. Valproic acid and lithium were added at different times to optimize treatment but were discontinued due to adverse reactions. Initially, the cluster headache responded to prednisone 1 mg/kg; however, due to long-term effects, the medication was tapered off, leading to a return of attacks shortly after. Acute treatment with sumatriptan (oral and subcutaneous) resulted in poor responses, providing only mild relief. In most cases, complete relief was achieved only with oxygen therapy in the emergency department. Due to the refractory nature of the condition, bilateral occipital nerve block with lidocaine and dexamethasone was performed while maintaining verapamil at 320 mg/day. However, the patient still experienced severe headaches, responsive only to oxygen therapy. Finally, an alternative approach using a sphenopalatine ganglion block was performed. The patient showed significant improvement on the same day of the procedure, with complete resolution of attacks and no need for any medications. This improvement was maintained in the subsequent days, allowing her to return to normal daily activities. **Discussion:** Cluster headache is a severe and debilitating trigeminal-autonomic headache. It is often underdiagnosed, has few therapeutic options, and in 10-20% of cases, patients can be refractory to acute and prophylactic medications. This case highlights the complexity of cluster headaches management and underscores the importance of an individualized approach in treatment. Although occipital nerve block is evidenced to be effective for many patients, therapeutic response can vary. In this case, the sphenopalatine ganglion block proved to be a safe and effective alternative, providing complete symptom relief. **Final comments:** Thus, it is crucial to consider individual characteristics when choosing treatment, recognizing that the sphenopalatine ganglion block can be a viable and highly effective option for patients with refractory cluster headaches.

Correspondence: Cássia Caroline Aguiar da Ponte; Email: cassiacaroline0311@gmail.com.

Case presentation: A 40-year-old woman presented in 2016 with imbalance and shuffling gait due to hydrocephalus, necessitating a ventriculoperitoneal shunt that moderately improved her symptoms. However, four months later, she developed progressive weakness in her left arm and leg, followed by dysphagia and inability to walk. Spinal cord magnetic resonance imaging (MRI) revealed extensive pachymeningitis with associated cysts causing spinal cord compression. A meningeal biopsy showed nonspecific inflammatory changes. Despite normal laboratory tests, serum and cerebrospinal fluid ELISA for Cysticercus cellulosae were positive, leading to a diagnosis of pachymeningitis associated with cysticercosis. Treatment with albendazole, praziquantel and intravenous methylprednisolone resulted in partial improvement. In September 2017, she was admitted to a neurology ward with dysphagia, dysphonia and tetraparesis. Subsequently, in October 2017, she underwent posterior fossa decompression and cervical laminectomy with dural excision. Histopathological examination of the dural samples indicated significant IgG4-positive plasma cells and storiform fibrosis, showing no signs of cysticercosis and leading to a diagnosis of IgG4-associated pachymeningitis with no evidence of other organ involvement. Treatment included IV methylprednisolone followed by cyclophosphamide and rituximab. Following treatment, the patient experienced improved motor functions and was able to walk with unilateral assistance. However, in 2019, she experienced recurrent dysphagia and dysarthria. In April 2022, she was diagnosed with advanced invasive ductal carcinoma of the breast and she died of sepsis and multiple organ failure. **Discussion:** IgG4 related disease (IgG4-RD) is a multisystemic disease that is characterized by storiform fibrosis associated with fibrogenic cytokines and IgG4 tissue deposition. The condition usually presents with tumor-mimicking lesions, more often affecting lacrimal glands, orbits, pancreas and pachymeninges. Previous studies reported that up to 35% of patients with IgG4-RD present with pachymeningitis, a rare inflammatory process affecting the dura mater that requires a comprehensive diagnostic approach due to its association with various underlying conditions, such as cysticercosis. In our case, the atypical presentation of cystic pachymeningitis and the positivity of serum and cerebrospinal fluid ELISA for Cysticercus cellulosae resulted in a misdiagnosis of neurocysticercosis. **Final comments:** We described a case of cystic IgG4-RD spinal pachymeningitis causing cervical spinal cord compression initially misdiagnosed as neurocysticercosis, delaying immunotherapy. Diagnosis of IgG4-RD remains challenging, as clinical, laboratory, and imaging findings can mimic other conditions. Early identification is crucial since spinal IgG4-RD pachymeningitis responds well to corticosteroids and anti-CD20 agents, thus averting further neurological disability.

Spinal cord damage progression in hereditary spastic paraplegia SPG4

Carelis Gonzalez-Salazar[1], Thiago Junqueira R. Rezende[1], Luciana Ramalho[1], Marcondes Cavalcante França Jr[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Marcondes Cavalcante França Jr; Email: mcfrancajr@uol.com.br.

Background: Hereditary Spastic Paraplegia is a neurodegenerative disease characterized by length-dependent degeneration of the spinal corticospinal tracts. SPG4 is the most frequent subtype worldwide. Spinal cord (SC) atrophy is the neuroimaging hallmark of SPG4, but so far little is known about its progression over time. **Objective:** To characterize SC structural damage progression in symptomatic patients with SPG4 and to identify potential genotypic-phenotypic correlates. **Methods:** We performed a cross-sectional as well as longitudinal study of upper SC (C1-C4) cross-sectional area (CSA) and eccentricity in subjects with SPG4 and matched controls. Images were acquired on a 3T scanner Paired clinical evaluations were also obtained - the severity of the disease was quantified with the Spastic Paraplegia Rating Scale (SPRS-BR). **Results:** There were 42 patients (% male) and 44 controls (% male) in the first evaluation; 31 patients (% male)/ 32 controls (% male) for the second evaluation and 16 patients and 14 controls for the third evaluation, with 3.6- and 3.1-years interval between base-line and second evaluation for patients and controls respectively and 5.7- and 5.9- years interval between base-line and third evaluation for patients and control group respectively. Patients with SPG4 had significantly reduced CSA at all spinal cord level at the 3 cross-sectional analyses (base line, second and third scan). At C2 and C3, progressive atrophy was noticed in the interval between first and second evaluation ($p<0.01$) whereas at C3, progression was noticed between 2nd and 3rd visits. We did not find significant differences in the eccentricity (cross-sectional or longitudinal). **Conclusion:** Quantitative SC MRI is able to capture disease progression in SPG4 and should be explored in further studies.

[2]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Pedro Almeida Martins Pontes; Email: pedroalmeida.pontes@gmail.com.

Case presentation: A 73-year-old man presented with sudden chest pain radiating to the back. Initial exams included a positive troponin curve and a normal electrocardiogram. Therefore, a non-ST-segment elevation myocardial infarction was suspected. A coronary angiography showed a 90% proximal stenosis of the circumflex artery and a 70% middle stenosis of the left anterior descending artery. Suddenly after the procedure, he developed chest pain radiating to the back, followed by loss of pain and temperature sensation and weakness in the lower limbs, as well as distal weakness in the upper limbs. On neurological examination, there was paraplegia and distal paraparesis of the upper limbs. Also, there was loss of sensation at the sensory level of the seventh thoracic spinal segment and absent deep tendon reflexes in the lower limbs. Urgent brain computed tomography (CT) and angio CT of the head, neck, and thoracic aorta were performed. Brain CT showed a hyperdense area in the subarachnoid space of the upper cervical spinal cord and medulla, suggestive of hemorrhage. Angio CT was notable for ulceration, a 14 cm fusiform aneurysm and a mural thrombus in the descending portion of the thoracic aorta. Spinal cord MRI showed a hyperintense signal in the spinal cord at the C4 level, "snake eyes" sign indicating spinal ischemia at the T8-T9 level and intramedullary blood in cervical, thoracic, and lumbosacral regions. Thus, the diagnosis of spinal cord infarction and spinal subarachnoid hemorrhage secondary to thoracic aortic dissection was made. During the next few days, the patient showed substantial improvement of neurological symptoms, fully recovering strength and sensation in the upper and lower limbs. Due to this improvement we opted for expectant management without surgical treatment. He was discharged one month following the event, with plans to reassess the possibility of thoracic aortic surgery later. **Discussion:** Aortic dissection is a potentially fatal condition that presents with neurological symptoms in up to one-third of cases. Spinal cord infarction is one of the less common presentations, being even rarer when associated with subarachnoid hemorrhage. The proposed mechanism for this condition is extension of arterial dissection from the aorta to the vessels supplying the spinal cord, leading to bleeding into the subarachnoid space and secondary spinal cord ischemia. Treatment options include conventional or endovascular surgery to correct the aortic dissection, along with cerebrospinal fluid drainage for cases associated with spinal cord infarction. However, up to half of the patients treated conservatively show significant improvement, as it happened in this case. **Final comments:** Aortic dissection can rarely present with subarachnoid hemorrhage and spinal cord infarction, and early diagnosis and intervention may be related to better clinical outcomes.

Spinal cord ischemia after endovascular aneurysm repair of abdominal aortic aneurysms: a case study

Ana Francisca de Barros Coelho Brandalise[1], Alexandre Luiz Siano[1], Matheus Zago[1], Ivo Marcos Darella Lorenzin Fernandes Neto[2], Eduarda Basso Badalotti[2], Angelo Marcelo Wosniacki Filho[2], Gabriel Angelo Garute Zenatti[2], Renato Endler Iachinski[2], Antonio Carlos de Andrade Soares[2]

[1]Centro Universitário Fundação Assis Gurgacz, Cascavel PR, Brazil.
[2]Fundação Hospitalar São Lucas, Cascavel PR, Brazil.

Correspondence: Ana Francisca de Barros Coelho Brandalise; Email: anafbrandalise@gmail.com.

Case presentation: Female, 57 years, underwent repair of a pararenal aneurysm of the abdominal aorta, using an endoprosthesis. She was admitted to the ICU for the post-operative period and, 2 hours after the procedure, she developed sudden, symmetrical paraplegia in her lower limbs, associated with tactile and painful hypoesthesia in both lower limbs. In the neurological physical examination, he presented motor strength grade 0 in the lower limbs and grade 5 in the upper limbs, tactile and painful hypoesthesia referred to in the legs, and digital rectal examination with absence of sphincter control / absent bulbo-cavernous reflex. A computed tomography of the skull was requested, which showed no acute changes. During hospitalization, laboratory tests were performed (which did not show significant changes) and MRI of the thoracolumbar region, which demonstrated acute myelopathy, probably of a vascular nature, and a fracture due to probable insufficiency of the L1 vertebral body with slight retreat of the posterior wall. During the period, the patient showed improvement in sensitivity on physical examination, with tactile sensitivity with asymmetry between the hemibodies (right - T9 and left - T10), but maintained paraplegia in the lower limbs, rectal examination with lack of sphincter control and bulbo- cavernous absent. He remained clinically stable, with the possibility of being discharged for outpatient follow-up. **Discussion:** The diagnosis of spinal cord infarction is an infrequent entity that represents around 1% of all ischemia. Iatrogenic spinal cord ischemia is a rare and debilitating complication of some open or endovascular surgical procedures, including the repair of thoraco-abdominal aortic aneurysms, resulting from the interruption of blood flow in the aortic branches that supply the spinal cord. In these cases, treatment is still controversial and there is no evidence necessary for an optimal protocol to adequately treat iatrogenic ischemic injury. Some studies support the use of lumbar drainage in patients with spinal infarction after an aortic surgical procedure. In the remaining patients, it is recommended to control vascular risk factors and initiate antiplatelet or anticoagulant medications when clinically appropriate, a strategy used in our case due to the already established ischemic injury. **Final comments:** Spinal cord ischemia is an uncommon pathology, therefore the number of clinical cases reported is low. Therefore, cases like this need to be discussed so that situations like this can be prevented and managed. There is still no literary consensus on what would be the best method adopted to treat this adversity once it has occurred, but it is known that it is necessary to increasingly carry out prevention measures, especially in surgical procedures in which there is a risk of spinal cord ischemia in order to avoid further harm to patients.

Spinal muscular atrophy and home care: the relevance of an accurate follow-up in clinical care

Fabrício Loffredo D'ottaviano[1], Luis Fernando Grossklauss[1], Acary Souza Bulle Oliveira[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Fabricio Loffredo D'Ottaviano; Email: fabriciodotta@gmail.com.

Background: Among the neuromuscular disorders, the hereditary proximal 5q spinal muscular atrophy (SMA) is a severe disease that causes progressive muscle weakness, mainly with infantile and childhood onset. SMA is caused by the lack of the survivor motor neuron (SMN), due to the deletion of the SMN1 gene. A less active gene, the SMN2, acts as a severity modifier. The number of SMN2 copies is inversely related to the clinical severity. **Methods:** Our study aims to describe the clinical features and the scope of home care in treating children with SMA. This is a retrospective review of records of pediatric neurology patients with SMA 1 or 2, over a 10-year period. **Results:** 12 SMA1 and 5 SMA2 patients (N=17) were discharged from the hospital and attended in home health care, provided by a multidisciplinary team. All SMA1 patients had nursing supervision 24 hours a day, whereas SMA2 had at most 12 hours daily. Concerning the use of ventilatory support, 5 patients used invasive ventilation and 12 used non-invasive ventilation. All SMA2 children used non-invasive mechanical ventilation only during night sleep, but most of SMA1 were ventilated for more than 20 hours a day (N=10, or 58% relative to N=17). In terms of monitoring colonization and guiding the rational use of antibiotics, 5 children had + Pseudomonas aeruginosa in quantitative cultures of endotracheal aspiration (all SMA1). Every patient underwent gene therapy such as Nusinersen (N=11), Risdiplam (N=2), Onasemnogene Abeparvovec plus Nusinersen (N=2), or Onasemnogene with Risdiplam (N=1). Six patients with Type 1 underwent a tracheostomy, 5 of them before their first birthday. Among these patients, one SMA1 infant had a positive therapeutic response; he was tracheostomized when 3 months old, started Nusinersen when 5 months old, took Onasemnogene at 7 months, and achieved decannulation (removal of tracheostomy tube) when he was 1 year and 9 months old. Unfortunately, one patient passed away when her tracheostomy tube was pulled out accidentally, while she was being transferred from wheelchair to bed. **Conclusion:** Considering SMA as a disease of the motor neuron associated with weakness and progressive motor impairment, gene therapy has shown to be an effective treatment. No functional loss was demonstrated in our patients, and substantial improvement in motor milestones has been observed in some of the children under treatment. In the overall follow-up, developing home care plans and preparing professionals to work with neuromuscular disorders (NMD) with continuous care, optimized by the clinical aspects of each patient, seems fundamental in the therapeutic process. This accurate follow-up in clinical care contributes to early diagnosis and assertive interventions and has led to great results in the patients' daily lives, including the possibility of attending formal school education for some of them.

Spinal muscular atrophy (SMA) is a rare genetic disease characterized by progressive loss of motor neurons located in the anterior horn of the spinal cord and brainstem, leading to progressive muscle atrophy and weakness. The most common form of SMA (5q-SMA) is classified into subtypes according to the age of onset and the maximum motor function achieved. This study is an international multicenter clinical Registry for SMA diseases (LATAM RegistrAme study NCT05475691) that includes patients with 5q-SMA types 1, 2, 3, and 4 of all ages and both sexes, treated at reference centers in six Latin American countries (Argentina, Brazil, Chile, Colombia, Mexico, and Uruguay). This study aims to describe the clinical characteristics of the participants, as well as the time to start disease-modifying treatment in patients who are using some disease-modifying therapy. Currently, the study already has 361 patients included (Argentina: 63; Brazil: 180; Chile: 35; Colombia: 54; Mexico: 20, and Uruguay: 7). The results show that subtype 2 (158 participants; 43.8%) constitutes most of the participants in this study, followed by subtypes 3 (114 participants; 31.5%) and 1 (86 participants; 23.8%). The average age of the included participants is 12.8 years old (SD 10.9 years), regarding sex at birth, 177 female (49.0%), 184 male (51.0%), regarding declared race, 214 (59.4%) white, 15 (4.2%) black, 3 (0.8%) indigenous and 116 participants (32.2 %) declare themselves or present the breed classification registered in their medical records, as others, and 12 (3.3%) as unknown. Symptom onset period 90.6% postnatal (2 weeks of age or older), at birth (up to 2 weeks) 4.2%, asymptomatic 2.8% and unknown 2,5%. Homozygous deletion of exon 7 of SMN1 is present in 323 included participants, heterozygous (deletion of exon 7 of SMN1) in 18 participants, heterozygous for two substitutions in SMN1 (point mutation) in 1 participant, and 19 participants present genetic reports where only the description "mutation compatible with 5q-SMA". Regarding the need for ventilatory support, 315 (87.3%) have never used invasive ventilation, 25 (6.9%) currently use invasive ventilation, and 114 (31.6%) currently use non-invasive ventilation. To date, 245 (67.9%) use or have had access to disease-modifying therapy, and 116 (32.1%) have never had access to therapies. Knowing the reality of patients' journeys is relevant for greater assertiveness in the clinical management of the disease and management of access to treatments that modify the course of the disease.

Spinocerebellar ataxia type 19: an early-stage onset disease

Isabela de Carvalho Florêncio[1], Thiago Dias Fernandes[1], Victória Almeida Villamil[2], Artur Marques Ferreira[2], Guilherme Ribeiro Correa Garcia[2], Pedro Henrique Andreotti Arakaki[2], Mariana dos Santos Zanelato[2], Vinícius de Lima Montello Jardim[2], Nathan Cândido Teixeira[2], Michelle Fonseca Acosta[2]

[1]Universidade Federal de Mato Grosso do Sul, Hospital Universitário Maria Aparecida Pedrossian, Campo Grande MS, Brazil.
[2]Universidade Federal de Mato Grosso do Sul, Campo Grande MS, Brazil.

Correspondence: Vinícius de Lima Montello Jardim; Email: vmontello1@gmail.com.

Case presentation: Female, 28 years old, daughter of non-consanguineous parents, with no family history of neurological or psychiatric diseases, with a history of delayed neuropsychomotor development and gait ataxia even after starting to walk. The patient's motor skills worsened at the age of 18, with a loss of autonomy for the activities she was capable of performing, as well as behavioral changes (hallucinations and aggression). On examination, she presented with cognitive deficit, ataxic gait, slurred speech, head tremor, difficulty fixing her gaze, dystonic hand posture, bradykinesia and symmetrical appendicular ataxia. Magnetic resonance imaging of the skull showed marked cerebellar atrophy and the exome showed a point mutation (alanine for valine at codon 336) in the KCND3 gene compatible with autosomal dominant spinocerebellar ataxia 19 (SCA19). The patient was referred for multidisciplinary follow-up, with partial improvement in her psychiatric symptoms and, to date, slow progression of her neurological condition. **Discussion:** Spinocerebellar ataxia type 19 is a rare autosomal dominant neurodegenerative disease secondary to a pathogenic mutation in the KCND3 gene, which codes for the Kv4.3 potassium channel proteins present in neurons in the cerebellum and other areas of the central nervous system. The mutation leads to neuronal dysfunction, which is expressed in a slowly progressive cerebellar syndrome. It manifests as cerebellar syndrome, bradykinesia, dystonia, myoclonus, frontal lobe executive dysfunction and epileptic seizures. The age of onset of symptoms is variable and can occur from 2 years to young adulthood. There is no specific treatment. **Final comments:** Although spinocerebellar ataxias mostly manifest after the second decade of life, neurologists should be on the lookout for cases that start early, even in childhood.

https://doi.org/10.5327/CBN241523

Spinocerebellar ataxia type 23 (SCA23): a case report of a rare cause of ataxia

Bruna Andrade de Oliveira[1], Natália da Costa Chiote Pinheiro[1], Carolina Rocha da Silveira Brugger Cardoso[1], Lucas Leroux de Ricchezza[1], Luiz Felipe Vasconcellos[1]

[1]Universidade Federal do Rio de Janeiro, Instituto de Neurologia Deolindo Couto, Rio de Janeiro RJ, Brazil.

Correspondence: Bruna Andrade de Oliveira; Email: brunaado97@gmail.com.

Case presentation: A 19-year-old woman presented a progressive dysarthria associated with bilateral resting and kinetic tremor that worsened when she was anxious. At the time she was submitted to a frenectomy without improvement. When she was 21, she began to present difficulty walking with frequent falls. At the age of 23, she started to present dysphagia, worse for liquids. All the symptoms continue to worsen over the years. Physical examination at the time she was 25 revealed gait ataxia, upbeat nystagmus, dysarthria, dysdiadochokinesia worse in the right upper limb, dysmetria worse in the right upper and lower limbs and no pyramidal signs. The patient had no relevant family history, has always been in good health and did not take any regular medications. At five years of disease progression she was submitted to a brain MRI that showed cerebellar atrophy, with atrophy of the middle and superior cerebellar peduncles with faint hypersignal on T2/Flair, which extends to the cerebellar cortex, apparent atrophy of the pons and the Hot Cross Bun sign. She was submitted to extensive investigation and the genetic testing identified a pathogenic variant in PDYN c.414G> T (p.Arg138Ser), so she was diagnosed with Spinocerebellar Ataxia type 23 (SCA23). She was referred to phonoaudiology, physiotherapy and occupational therapy and received genetic counseling. **Discussion:** SCA 23 is an autosomal dominant spinocerebellar ataxia that is characterized by mutant prodynorphin (PDYN) gene. The prevalence of SCA 23 is estimated to be less than 1:1.000.000 people. The clinical features, brain magnetic resonance imaging (MRI), and neuropathological findings are indistinguishable from other SCA subtypes, so the diagnosis is only made by genetic testing. The inheritance is autosomal dominant and the symptoms begin in adulthood. The treatment consists in genetic counseling and complementary therapies. Disease progression can be slow within wheelchair bound ocurring in more than 20 years after symptomatic disease onset. **Final comments:** SCA 23 is a very rare cause of adult-onset hereditary ataxia. It's important that physicians are aware of this condition because not all genetic panel for hereditary ataxia are able to identify the mutation that causes SCA 23. The diagnosis is important for genetic counseling and to bring awareness to this condition.

Spinocerebellar ataxia type 8: case report and literature review

Bruno Wendorff Lucci[1], João Carlos Cervelin[1], Fernanda Coan Antunes[1], Pricila Bernardi[1], André Dias de Oliveira[1], Gisele Espíndola[1]

[1]Universidade Federal de Santa Catarina, Florianópolis SC, Brazil.

Correspondence: Bruno Wendorff Lucci; Email: brunowlucci@hotmail.com.

Case presentation: A 22-year-old male with non-consanguineous parents and two healthy siblings presented with no relevant family history. Motor and cognitive development were normal in early childhood. At age 9, he began experiencing uncoordinated movements, progressing to gait instability and falls. Symptoms included muscle spasms, orofacial and cervical dystonia, moderate dysarthria, mild dysphagia, malnutrition, and low weight. Medical history: Sleep apnea syndrome; recurrent febrile seizures in childhood; focal motor dysperceptive seizures (ceased at age 16); sensorineural hearing loss; ADHD and major depressive disorder. Neurological Exam: Bilateral winged scapula; pectus carinatum; orofacial and cervical dystonia; scandent speech; preserved eye movement with mild nystagmus; global hypotonia with diffuse muscle atrophy; upper limb hyporeflexia; bilateral patellar hyperreflexia with pendular reflexes; bilateral Achilles hyperreflexia with clonus; hypermetria and dysdiadochokinesia; bilateral intention tremor; broad-based gait with difficulty in tandem walking. Initial tests, including electroneuromyography, ataxia and epilepsy panels, array-CGH, Friedreich's ataxia, and exome sequencing, were normal or inconclusive. Whole genome sequencing showed one allele with 183 CTG*CTA repeats in the 3'UTR region of the ATXN8OS gene and one allele within the normal range (22 repeats). Cranial MRI showed bilateral cerebellar volume reduction. A trial with L-dopa and regular botulinum toxin applications to the neck showed a good response. **Discussion:** Spinocerebellar Ataxia Type 8 (SCA8) is a rare autosomal dominant disease characterized by CAG and CTA/CTG repeat expansions in the ATXN8 and ATXN8OS genes. Symptoms include scandent speech, dysarthria, swallowing disturbances, slowly progressive cerebellar ataxia, oculomotor disturbances, pyramidal syndrome, cognitive and motor disturbances, and sensory neuropathy. Atypical cases can present with epilepsy. The ATXN8 gene encodes a polyglutamine expansion protein, while the ATXN8OS gene expresses a noncoding RNA. SCA8 expansions involve toxic mechanisms at both protein and RNA levels. Polyglutamine toxicity correlates with repeat sizes, showing an inverse correlation between age at onset and repeat size. Typical SCA8 repeat sizes range from 91 to 200. Patients with ≥200 repeats may exhibit reduced toxicity. Pure CTG expansions are more pathogenic and correlate with earlier onset. This bidirectional expression parallels other triplet expansion disorders. **Final comments:** SCA8 mutations have been identified in isolated cases in Brazil, with higher prevalence in Nordic countries. The frequency of SCA8 in Brazilian ataxia patients highlights the importance of comprehensive genetic testing, including whole genome sequencing, for accurate diagnosis. The exclusion of SCA8 from standard ataxia panels may lead to underdiagnosis. Further research is necessary to understand the pathomechanisms and genetic variations of SCA8.

Split-hand-like syndrome in X-linked form of Charcot-Marie-Tooth disease (CMTX) caused by GJB1 mutation: a comparative study of electrophysiological features

Ricardo Vergara Gianvechio[1], Wilson Marques Junior[1], Pedro José Tomaselli[1], Brenda Cristina Navas[2], Gabriela Rodrigues Ramos[2], Lucas Gondim Briand Vieira[1]

[1]Universidade de São Paulo, Faculdade de Medicina de Ribeirão Preto, Hospital das Clínicas, Ribeirão Preto SP, Brazil.
[2]Universidade de São Paulo, Faculdade de Medicina de Ribeirão Preto, Ribeirão Preto SP, Brazil.

Correspondence: Ricardo Vergara Gianvechio; Email: ricardo.gianvechio@alumni.usp.br.

Background: The X-linked form of Charcot-Marie-Tooth disease (CMT1X) is a common form of inherited neuropathy. It's caused by mutations in the GJB1 gene. Some reports in the literature suggest that a "split hand syndrome-like" condition can be found in patients with CMT1X, characterized by more prominent atrophy in the abductor pollicis brevis (APB) than in the abductor digiti minimi (ADM). Nonetheless, we found no studies numerically describing this possible predilection by means of neurophysiologic parameters. **Objective:** This retrospective study was conducted to objectively evaluate the possible predilection of involvement of the APB (in detriment of ADM) in CMT1X, comparing them to CMT1A patients and to control patients without evidence of peripheral neuropathy and with normal nerve conduction studies (NCS). **Methods:** We analyzed the data from electroneuromyography of 59 patients (21 patients with GJB1 mutations, 26 patients with PMP22 duplication - CMT1A group, and 12 patients without peripheral neuropathy and with normal values of NCS). The epidemiological and clinical baseline characteristics were also collected for comparison. The mean age of the patients undergoing electroneuromyography was 36.1 years in the CMT1X group and 35.5 years in the CMT1A group. The ratio APB/ADM (the ratio between the CMAPs in the APB and in the ADM, respectively) was calculated in each patient. In patients where it was possible to calculate the ratio from both arms, we conventionally used the smaller ratio. We then compared the results from the three groups using a two-tailed Student's t-test. **Results:** The mean APB/ADM in the CMT1X group was 0.646 with a standard deviation of 0.444, while in the CMT1A group, the mean APB/ADM was 1.286 with a standard deviation of 0.578. The mean APB/ADM ratio was significantly lower in patients in the CMT1X group compared to patients in the CMT1A group (p=0.0001) and to patients in the control group (p=0.04). There was no statistical difference between the CMT1A group and the control group (p=0.06). **Conclusion:** Although this is a preliminary study, the results suggest a significant predilection for more pronounced atrophy in the APB compared to the abductor digiti minimi ADM in patients with CMT1X. This finding was quantitatively supported by the significantly lower APB/ADM ratios in the CMT1X group compared to both the CMT1A and control groups. The absence of a significant difference between the CMT1A and control groups suggests that this phenomenon is specific to CMT1X. This could be useful to generate hypotheses surrounding the pathophysiology of the disease. Further prospective and/or longitudinal studies should be conducted to evaluate the reproducibility of these results in larger samples and to determine the predictive values of the clinical and neurophysiological findings of "split hand-like syndrome," and the APB/ADM ratio in patients with suspected inherited neuropathies.

Spontaneous intracranial hypotension with atypical presentation: a case report

Rodrigo Fernandes Nitsch[1], Julyana Leoni do Prado[1], Mateus Coltro Dornelles[1], Patrícia Áurea Andreucci Martins Bonilha[1]

[1]Pontifícia Universidade Católica do Paraná, Hospital Universitário Cajuru, Curitiba PR, Brazil.

Correspondence: Mateus Coltro Dornelles; Email: mateuscdornelles@gmail.com.

Case presentation: C.A.P, female, 70 years old with a history of depressive and anxiety disorders and obstructive sleep apnea and hypopnea presented to a Neurology outpatient clinic with a 1 year history of cognitive decline and postural instability, that began with sudden, severe holocranial headache, that resolved spontaneously after one week. There was no history of head and spinal trauma, nor previous surgeries Later, she developed an anterograde episodic amnestic symptoms associated with brief, self-limited confusional states, and, in one year, she has lost independence in instrumental and some basic activities of daily living. As time passed, her cognitive symptoms worsened while new ones manifested: liquid dysphasia, dysarthria, and ataxic gait disorder with recurrent falls. Initial laboratory evaluation was normal and polysomnography evidenced enhanced initial and REM sleep latency and reduced sleep efficacy; her brain magnetic resonance (MRI) revealed meningeal enhancement, Obliteration of perimesencephalic cisterns, straightening of the distance between mamillary bodies and pons, Inferior herniation of cerebellar compatible with Saggy brain Syndrome and intracranial hypotension diffuse volumetric reduction and numerous signs of Intracranial Hypotension, while her spinal MRI enlarged epidural space. Treatment with caffeine 200mg daily was initiated. After initial improvement, the Caffeine dosage was adjusted to 300mg a day with an almost complete clinical resolution. **Discussion:** Spontaneous Intracranial Hypotension is a clinical-radiological syndrome usually caused by dural tear, leaking meningeal diverticulum or venous-CSF fistula with unestablished national epidemiology. It is known to be a rare cause (but treatable and important differential diagnosis) of new-onset headaches with an approximate incidence of 1-3.8/100.000 habitants per year, being an orthostatic headache its most common (approximately 98%) symptom. It is known to mimic a myriad of neurological syndromes, such as motor, cranial nerve, ataxic and cognitive decline. Its diagnosis is made with clinical and imaging investigation, and etiologic diagnosis is important for invasive treatment (such as targeted blood patches or surgical interventions) which, coupled with intensive hydration and caffeine supplementation, help prevent catastrophic complications and potentially reverse severe debilitating symptoms. **Final comments:** We present a case of a patient with atypical presentation, facing limiting symptoms, impairing daily life activities, due to delayed diagnosis. This is a rare, though treatable central nervous system disease with satisfying response to clinical and surgical treatments, highlighting the importance of including Spontaneous Intracranial Hypotension as a differential diagnosis of rapidly progressive dementia on clinical practice.

Sporadic Creutzfeldt-Jakob disease and MRI use: a case report

Áurea Maria Salomão Simão[1], Murilo Caldas Bellotto[1], Beatriz Hog Jorge Silva[1], Davi Legora[1], Diogo Haddad Santos[1]

[1]Santa Casa de São Paulo, Faculdade de Ciências Médicas, São Paulo SP, Brazil.

Correspondence: Beatriz Hog Jorge Silva; Email: beatrizhog@gmail.com.

Case presentation: A 68-year-old woman, with a high school degree, came to Santa Casa de São Paulo's neurology clinic in July 2022 due to memory loss. Her symptoms started in December 2021 and worsened ever since. In those seven months, she also started presenting personality and behavioral changes and an unstable gait. Her family history is positive for Alzheimer's disease in two first-degree relatives. During this first visit she was still able to perform Basic Activities of Daily Living (BADL), and her laboratory and neurological exams were unremarkable, except for a Mini Mental State Examination (MMSE) score of 19/30. In August 2022, she reported sleep pattern alterations and repetitive speech, while maintaining her previous symptoms. The neurological exam showed bradykinesia and a worsening MMSE score of 14/30. She was then submitted to a Magnetic Resonance Imaging (MRI), which showed both the cortical ribbon and the hockey stick signs, the classic imaging presentation of Creutzfeldt-Jakob Disease (CJD). The cortical ribbon sign refers to a curvilinear hyperintense signal involving the cerebral cortex of parietal and occipital lobes on DWI images. The hockey stick sign is described as a hyperintense signal involving the pulvinar and dorsomedial thalamic nuclei bilaterally on the FLAIR view. Once the hypothesis was made, we communicated it to the family, who refused to follow up with the investigation, denying the electroencephalogram (EEG) and cerebrospinal fluid (CSF) exams. One month later, she developed urinary and fecal incontinence and had lost the ability to feed herself. Being the MRI the only exam available in this patient's case, we would like to bring light to the importance of recognizing the typical imaging signs of Creutzfeldt-Jakob disease (CJD). **Discussion:** CJD is a rapidly progressive dementia associated with neurodegeneration and the most common prion disease in humans. Its diagnosis still depends on neuropathological confirmation through biopsy, but the use of other tools such as imaging (MRI), along with the clinical presentation, EEG and CSF analysis for the 14-3-3 protein have shown to be enough for managing the patient. Before assuming it is a CJD case, we must first exclude reversible causes of dementia through imaging and blood tests. We should also first consider more prevalent etiologies such as Alzheimer's disease. In this context, the MRI is considered by the literature as a fundamental tool to detect early signs of neurodegeneration, with a high sensitivity (91%) and a high specificity (97%). Approximately 80% of the patients with CJD had alterations in the MRI, and 60% of them exhibited the classical signs. **Final comments:** In conclusion, CJD is an irreversible dementia with a 100% mortality rate. The fact that 85% of its presentation is idiopathic does assure us the importance of laboratory tests and imaging, especially the MRI in indicating the diagnosis and, therefore, granting the best care for the patient.

Case presentation: From the review of medical records, we found the case of a patient who evolved for six months with progressive gait ataxia and motor incoordination, associated with postural instability and symptom of depression and apathy. Patient presented several hospitalizations due to confusional episodes, associated with progressive cognitive dysfunction, mainly short-term memory, spacial disorientation and executive dysfunction. After this period, the patient became bedridden and developed generalized myoclonus, associated with akinetic mutism. Diagnostic approach was performed with cerebrospinal fluid, without alterations and with negative 14-3-3 protein, but with evidence of an hypersignal basal

ganglia bilaterally and parashagitais region of frontal lobes in brain resonance. Electroencephalogram showed frequent generalized epileptiform discharges in periodic pattern. Patient evolved with death in the same hospitalization after infectious complications. **Discussion:** Sporadic Creutzfeldt-Jakob disease is one of the most dramatic causes of rapidly progressive dementia, and it is characterized by neuropsychiatric symptoms such as depression, apathy, and cognitive changes, especially in memory, social cognition, and executive functions within a period of less than one year. It is often accompanied by complaints of cerebellar ataxia, signs of pyramidal syndrome, and myoclonias and other movement disorders. This pathology represents more than 90% of the sporadic diseases caused by prions. **Final comments:** Rapidly progressive dementias have been considered medical emergencies due to the need of quick diagnosis, since some of the possible etiologies can be reversible.

Bacterial meningitis is a severe infection caused mainly by Streptococcus pneumoniae in adults, inducing brain dysfunction with microglial activation and release of inflammatory mediators. This pathology is a medical emergency, and the neuroinflammation triggered can lead to a generalized lesion of the meninges and brain tissue. The central nervous system relies on the glymphatic system to remove debris and agents in an infection. This system is highly dependent on aquaporin-4 (AQP4) water channels, and its dysfunction may contribute to the worsening of neuroinflammation caused by meningitis. This study aimed to evaluate the glymphatic system activity, β-amyloid (βA) peptide deposition, and behavioral parameters in adult Wistar rats 30 days after induction of pneumococcal meningitis. At 60 days of age, rats Wistar were subjected to anesthesia with intraperitoneal administration of ketamine and xylazine. Then, the animals received, via the cisterna magna, 10 μL of S. pneumoniae suspension (group meningitis) or with artificial cerebrospinal fluid (sham group). The animals were treated with ceftriaxone (100 mg/kg) twice daily for seven days. Thirty days after meningitis induction, animals were subjected to behavioral tests. Immediately after the behavioral tests, 25 μL of albumin and Evans blue (EBA) were injected into the cisterna magna to evaluate the activity of the glymphatic system. Other animals were used for cerebral evaluation of the βA peptide. The animals in the group with meningitis presented impairment of habituation memory and a reduced ability to recognize memory. Furthermore, this study demonstrated an increase in positive cells for βA expression in the prefrontal cortex and hippocampus of animals in the meningitis group when compared to the sham group and lower concentrations of EBA in the serum of the meningitis group about the sham group, indicating impairment of glymphatic system activity due to retention of the EBA in the brain. Our results showed that during pneumococcal meningitis, there were losses in the drainage of βA due to the malfunction of the glymphatic system, leading to cognitive impairment. Loss of function of the glymphatic system may, therefore, be one of the causes of sequelae neurological disorders after pneumococcal meningitis.

Stability of control of epileptic drop attacks with selective posterior callosotomy: do good results persist over the years?

André Palmini[1], Eliseu Paglioli[1], Thomas Frigeri[1], Natalie Donida[1], Bibiana Thome[1], William Martins[1], Fernanda Schuh Martins[1], Rafael Paglioli[1], André Gus[1], Rhana Santos[2]

Epileptic drop attacks are perhaps the most malignant type of seizures, often leading to recurrent trauma and demanding constant supervision while patients are standing and walking. The underlying etiology is usually associated with severe diffuse brain dysfunction and these seizures are virtually always refractory to medications. Corpus callosotomy has been the cornerstone of the surgical treatment, based upon the premise that bilateral hypersynchronization of epileptiform activity is the starting point of a very fast multisynaptic cascade leading to falls. Moreover, several studies suggested that complete callosal sections were the more effective strategy, compared to partial disconnections. However, because new data showed that fibers originating from epileptic premotor and motor cortex - ie, the most relevant fibers for tonic and atonic seizures - cross through the posterior body and isthmus of the callosum, we proposed 8 years ago a novel surgical strategy to control drop attacks, in which the posterior half of the corpus callosum is sectioned, preserving prefrontal interhemispheric connectivity. Results were very good and comparable to those reported with complete sections. Here we report on the stability of those results between and x 8 years later in 41 patients. We hypothesized that should selective posterior callosotomy truly section the relevant fibers for drop attacks, results would remain stable, despite preservation fo the anterior callosum. Forty-one patients operated until 2008, and who had a minimum follow up of 8 years when results were reported in 2016, were re-evaluated in 2024 through outpatient consultations or structured telephone interview. Frequency of drop attacks in the last 2 years was classified as daily, weekly, monthly, yearly or absent (ie, complete control). An estimate of the absolute number of falls per month was also obtained. Seizure frequency at 3 time points - before surgery (t0), at least 8 years later (t1), and 8 years following th previous follow-up (ie, at least 16 years after surgery; t2) were compared according to the Jonckheere-Terpstra test. Mean median frequency of drop attacks at the 3 timepoints was 180 ([Q1 90 - Q3 540]), 0 ([Q1 0 - Q3 25.5]) and 0 ([Q1 0 - Q3 30]) at t0, t1 e t2, respectively (p=0.000). These results suggest that the degree of control of drop attacks with selective posterior callosotomy is stable over large periods of time, giving credence to the hypothesis that the most relevant fibers leading to these seizures are sectioned with this procedure, and that anterior callosal fibers do not need to be sectioned to obtain very good seizure control.

https://doi.org/10.5327/CBN241531

Stability of functionality for activities of daily living following section of the posterior half of the corpus callosum to control epileptic drop attacks

André Palmini[1], Eliseu Paglioli[1], Frederico Orlando Friedrich[1], Bibiana Thome[1], Natalie Donida[1], William Martins[1], Fernanda Schuh Martins[1], Rafael Paglioli[1], Rhana Santos[2], André Gus[3]

Epileptic drop attacks are severe and disabling, usually medically refractory, seizures often presented by children and adolescents with diffuse encephalopathies. Most have no or limited schooling and variable degrees of dependence for activities of daily living. We have shown that selective section of the posterior half of the corpus callosum (selective posterior callosotomy) brings forth dramatic control of the falls, comparable to that seen with complete callosotomy, with preservation of the prefrontal interconnectivity. Because traditional neurology regards preservation of the posterior callosum as relevant to avoid what has been known as posterior disconnection syndrome (ie, symptomatology related to lack of functional integration between the posterior areas of the hemispheres in real time), selective posterior callosotomy has been seen with some suspicion as bound to provoke clinically relevant disconnection syndrome. We hypothesize, however, that because the anterior callosal fibers are preserved, section of the posterior callosum would not lead to interference with tasks related to activities of daily living. M: 41 patients operated until 2008, and who had a minimum follow up of 8 years when results were reported in 2016, were re-evaluated in 2024 through outpatient consultations or structured telephone interview. Relatives were interviewed to assess level of dependence in activities of daily living (ADL) - feeding, dressing, toilet hygiene and sphincter control. Neurological examination focused on axial tonus, gait and word articulation. Gait could be independent or needing assistance and word articulation could be fluent, comprehensible or incomprehensible. Autonomy to eat, dress and go to the toilet, normal axial and jaw tonus, sphincter control, praxis to button and use a spoon, and ability to read scored 1 point each. Fluent speech and independent gait scored 2 each (barely comprehensible, dysarthric speech and walking with assistance scored 1 each, while inability to speak or walk scored 0). From these neurological and functional data we generated a composite functional score ranging from 0 to 13. Functionality scores were then obtained at 3 time points medians and interquartile ranges - before surgery (t0), at least 8 years later (t1), and 8 years following the previous follow-up (ie, at least 16 years after surgery (t2) using the Jonckheere-Terpstra test. RC: The trend analyses of the functional scoring showed significant variation between pre- and both post-operative time points. Medians were 7 ([Q1 4 - Q3 9]) at t0, 8 ([Q1 6 - Q3 10]) at t1 e 9 ([Q1 6 - Q3 10]) em t2 (p=0.041), suggesting a tendency of functional improvement over the years with then stabilization between t1 and t2. These results confirm the hypothesis that disconnection in patients udergoing selective posterior callosotomy does not worsen, but rather improve functionality in patients with severe epilepsies and intellectual deficiency.

Statin-induced myopathy: a case report

Bruno Barreto de Oliveira[1] , Eustaquio Claret dos Santos[1]

[1]Hospital Socor , Belo Horizonte MG, Brazil.

Correspondence: Bruno Barreto de Oliveira; Email: brunobarreto2014@yahoo.com.br.

Case presentation: Female patient, 71 years old, with comorbidities (chronic CAD, dialysis CKD due to polycytic kidneys, previous TIA in January/24), was using AAS 100 mg/day, Ticagrelor 90 mg/day, Concor 5 mg/day, and Rosuvastatin / Ezetimibe - 20mg/10mg - began use 2 weeks before admission. Admitted due to UTI - treated with Ceftriaxone. It started suddenly with proximal paresis of the MSD and lower limbs, progressing rapidly. MSD paresis attributed to AVF. A brain MRI was performed which showed chronic ischemic microvascular changes and volumetric reduction of the brain parenchyma. Cervical MRI showed degenerative changes and reduced amplitude of the spinal canal, without signs of compressive myelopathy. Initial CK dosage on 03/12/24: 6278 U/L . The decision was made to suspend the statin, intensify physiotherapy and perform ENMG. It evolved with a progressive reduction in CK (4150 / 3020 / 231). ENMG of the lower limbs performed on 03/18/24 showed changes suggestive of a myopathic process with the presence of pseudomyotonic discharges - polyphasic of low amplitude and short duration. Pulse therapy was performed with methylprednisolone 1g/day for 5 days. The patient developed a slow and progressive improvement in proximal strength in the lower limbs. He was discharged with instructions to maintain Prednisone 60mg/day in addition to home physiotherapy. **Discussion:** Statin-associated muscle symptoms (SAMS) range in severity from mild-to-moderate muscle pain, weakness, or fatigue to potentially life-threatening rhabdomyolysis. The mechanisms causing SAMS are not defined, but probably result from decreased production of noncholesterol endpoints of the mevalonate pathway. Muscle symptoms, with or without elevation of creatin kinase are one of the main adverse effects of statin therapy, a fact that sometimes limits their use . Statin-related myotoxicity is a common, probably underdiagnosed problem in clinical practice. **Final comments:** Periodic monitoring of patients using statins, knowledge of the pathophysiology of statin-induced myopathy, in addition to the correct management of adverse events, tends to minimize situations of discontinuity in the use of the drug, maintaining the benefits that statins provide to patients at risk. high cardiovascular.

Background: Recent evidence indicates that statins have anti-inflammatory and antioxidant effects, leading to several investigations of whether statins have a neuroprotective effect and may benefit patients with Parkinson's disease (PD). However, the potential mechanisms of this class of medications as modifiers of the course of PD in already diagnosed patients is still unclear. **Objective:** To assess the effectiveness of statins as modifiers of established PD. **Methods:** Two investigators systematically searched for randomized clinical trials and observational studies comparing PD patients treated with statins versus those treated without statins. The search was conducted in PubMed, Embase, Cochrane, and Web of Science. The outcome of interest was the change in the MDS-UPDRS III (Movement Disorder society- Unified Parkinson's Disease Rating Scale Part III) score from baseline. Statistical analysis was performed using R Studio 4.3.2. **Results:** Four studies, totaling 472 patients, were included. The mean difference for the MDS-UPDRS Part III scale between statin and non-statin groups was-0.98 points (95% CI-3.40 to 1.45; p=0.09; I^2=54%). Meta-regression results showed that follow-up time accounted for 77.37% of heterogeneity among studies and 69% of the mean difference. The test for residual heterogeneity was not significant (p=0.283). The regression graph intercept was-6.5714 points, and the coefficient for follow-up time was 0.2913 points, although it did not result in a significant increase in the MDS-UPDRS Part III score over time (p=0.094). **Conclusion:** There was no statistical significance for the potential clinical benefit statins as modifiers of the disease course in PD patients.

Background: Multiple sclerosis (MS) is an autoimmune disease of the central nervous system that affects about 15 out of every 100,000 Brazilians. It is characterized by an inflammatory response against oligodendrocytes and neuronal dysfunction. Its clinical manifestation is extremely variable and complex due to the various sites of inflammation. Treatment is divided into acute phase therapies and disease-modifying therapies (DMTs), which aim to minimize relapses and the progression of disability by suppressing inflammation. These therapies include low/medium efficacy options such as dimethyl fumarate and fingolimod, and high efficacy options such as monoclonal antibodies and cladribine. **Objective:** To analyze the different disease-modifying therapies for Multiple Sclerosis in a neuroimmunology outpatient clinic and the profile of patients undergoing treatment, as well as to evaluate the use of high-efficacy therapies implemented. **Methods:** This is a cross-sectional study observing DMTs in 31 patients diagnosed with MS. Data were obtained from medical records, covering variables such as sex, age, race/color, Expanded Disability Status Scale (EDSS), clinical form, and current medication. Informed consent was obtained from participants and the study was submitted to the hospital's Ethics Committee. **Results:** The sample consisted of 31 patients diagnosed with MS, with a female to male ratio of 2.4:1. The average age was 37 years, ranging from 16 to 65 years. Regarding ethnic distribution, 55% (n=17) of patients were mixed-race. The average EDSS score was 3 among the studied forms. The most prevalent clinical form in this hospital service was relapsing-remitting MS, identified in 27 patients. It was observed that 61% (n=19) of patients use high-efficacy medications, such as natalizumab (16) and ocrelizumab (3), while 39% (n=12) use low-efficacy DMTs like beta interferon (3), dimethyl fumarate (4), and teriflunomide (5). **Conclusion:** The analysis of different disease-modifying therapies revealed a preference for high-efficacy agents like natalizumab and ocrelizumab over less effective immunomodulators. This study highlights the importance of continuous personalized therapeutic adaptation to minimize relapses and disability progression caused by MS, aiming to preserve the quality of life of affected patients. As consolidated in various global references, this service opts to employ a high-efficacy strategy across different types of MS over a stepwise therapy approach to minimize disease progression.

Correspondence: Michelle Abdo Paiva; Email: michelle.abdop@gmail.com.

Background: Myasthenia gravis (MG) is an autoimmune disorder that can significantly impact functionality and quality of life. Approximately 10% of patients remain refractory to treatment. Stem cell transplant (HSCT) has been reported as an option, although no clinical trials are available yet. To our knowledge, HSCT for MG was not previously reported in Brazil. **Objective:** To report the first brazilian case of autologous HSCT (aHSCT) for MG and to review reported cases in literature, presenting all results compiled. **Methods:** We prospectively followed medical records and assessed response to treatment from our patient who underwent aHSCT. We also systematically searched in Pubmed and Google Scholar "stem cell transplant" and "myasthenia gravis". We identified 10 articles and one book chapter reporting MG patients that underwent HSCT. **Results:** Female patient diagnosed with MG anti-acetylcholine receptor antibody (ACh-R) positive at the age of 46 after presenting global weakness and dyspnea. Over a period of more than 3 years, she failed to respond to various therapies including pyridostigmine, ambenonium, prednisone, azathioprine, tacrolimus, cyclosporine, rituximab, eculizumab, ravulizumab, intravenous cyclophosphamide, thymectomy and plasma exchange. Due to the severity of her symptoms and recurrent symptoms, she received intravenous immunoglobulin (IVIG) every 15 days during the last three years and monthly cyclophosphamide over the last year, which significantly affected her quality of life. After conjoint decision, she underwent aHSCT. Before HSCT the patient scored 15 points on the MG-ADL and 34 points on the MGC. Early post-transplant complications included bloodstream infection and pseudomembranous colitis. Neutrophil engraftment occurred on D+10.The patient experienced improvement of symptoms on D+12. Her MG-ADL and MGC scored 0 points at discharge which was maintained until the last follow-up at 3 months. In total, 26 cases were identified in the literature (27, after including ours). Of the total, 17 patients were female, 5 males and 5 had no report on sex. Mean age at the time of HSCT was 44 years-old. Twenty cases were positive for ACh-R antibody and five for anti-muscle specific kinase. MGFA status previous to HSCT ranged from III-V. All patients had already tried multiple treatments, ranging from four to 11 different drugs and 59% had undergone thymectomy. Allogeneic HSCT was reported in two cases and the remaining were aHSCT. Most complications during HSCT were transplant-expected, such as febrile neutropenia and herpes family virus reactivation. MGFA status post-HSCT showed remission or improvement for 25 patients (92%). One death was reported during HSCT and one had no outcome reported. **Conclusion:** HSCT has been described as an option to treat many auto-immune disorders, such as multiple sclerosis. For MG, according to our data, HSCT appears to be relatively safe and effective and may be an option to treat refractory MG patients.

Background: The treatment landscape for brain metastases has significantly evolved in recent decades, driven by advances in radiotherapy techniques. Two primary approaches have been extensively studied: stereotactic radiosurgery (SRS) and whole brain radiotherapy (WBRT). SRS offers millimeter-precision in radiation delivery, limiting exposure to surrounding healthy tissues, whereas WBRT traditionally aims to treat diffuse brain micrometastases more broadly. Choosing between these modalities remains a subject of ongoing debate in clinical practice, focusing on maximizing local disease control, preserving cognitive function, and improving patients' quality of life. In this meta-analysis, we explore the outcomes of randomized controlled trials directly comparing SRS and WBRT in patients with brain metastases. **Objective:** Comparison of stereotactic radiosurgery versus whole brain radiotherapy, analyzing control of intracranial tumor (ITC), overall survival (OS) and quality of life (QOL). **Methods:** We performed a systematic review and meta-analysis assessing the effect of stereotactic radiosurgery in comparison with whole-brain radiotherapy in patients with brain metastatic cancer. We searched PubMed, MEDLINE, Scopus, and Web of Science for eligible trials. A random-effects model was used to calculate the odds ratio with 95% confidence intervals (CIs). Statistical analyses were performed using RStudio version 4.3.2. **Results:** Fifteen trials were included in this study, with all patients with a history of brain tumors. The choice foi stereotactic radiosurgery did not have significant differences over whole brain radiotherapy in the control of intracranial tumor (OR 2.05; 95% CI 0.58-7.19; p=0.61). There were also no significant differences between groups for overall survival (OR 1.14; 95% CI 0.83-1.58; p=0.61) and quality of life (OR 2.02; 95% CI 0.75-5.42; p=0.62). **Conclusion:** The results did not show a benefit of stereotactic radiosurgery over whole brain radiotherapy in all three parameters analyzed, revealing no difference between them about performance for control of intracranial tumors, providing a better quality of life, and overall survival. Therefore, we need more studies for better avaliation of these therapies.

[2]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Isabella Nascimento Guedes; Email: isabellaguedes21@icloud.com.

Case presentation: A 48-year-old female reported intense pain in the lumbar region and hips for 4 months. The case was initially managed as a low back pain, but the diagnosis was later on switched to radiculopathy. The patient progressed with worsening of pain, gait impairment and lower limb tremors, which led her to falls. Clinical examination revealed painful spasms, increase in muscle tonus and presence of rigidity when extending lower limbs. It was also observed resistance in passive and active flexion, particularly on the left lower extremity. Imaging exams performed were: brain CT with no significant findings and spine MRI with lumbar discopathy but no myeloradicular conflict. Laboratories findings were normal. EMG revealed mild axonal distal neuropathy of left limb deep fibular nerve. Anti-GAD assay: results greater than, 2000U/mL suggesting SPS. In this case, the patient was treated with baclofen and clonazepam. Although the patient had a good overall response, she sustained a tonic posture on the left lower limb. However, there were no new episodes of painful spasms. The increased muscle tonus was managed with drug dosage adjustment. **Discussion:** Stiff Person Syndrome (SPS) is a rare neurological autoimmune disease affecting 1 in 1 million people. It is more predominant between 20 and 50 years, and it has a higher incidence in women population. It is characterized by painful spasms and progressive rigidity of axial and proximal limb muscles, mostly. Muscle stiffness can be triggered by noise, tactile stimuli, variations of temperature or psychological stress. Moreover, the disease can progress to gait impairment and recurrent falls. The pathophysiology resides in the production of autoantibodies against glutamic acid decarboxylase (GAD), which leads to a decreased GABA production in the presynaptic neuron and also intense muscle contractions. Treatment consists in using drugs that increase GABAergic tone such as benzodiazepines, and immunotherapy to be further used to reduce neurological 2 / 2 symptoms. Finally, the diagnosis is challenging and often reached by the exclusion of other diseases. SPS's prognosis is reserved, and its progressive course can potentially lead to disability and fatality. **Final comments:** SPS is a rare disease and the literature regarding this pathology is very limited. Thus, cases are often underdiagnosed. This report aims to contribute to the medical literature and improve diagnostic accuracy, therefore reducing morbimortality.

Stiff person syndrome with anti-glycine receptor antibody: a case report

Pedro Maia Nobre Rocha Saffi[1], Leonardo Jadyr Silva Rodrigues Alves[1], Andresa do Rêgo Barros Vieira Santos[1], Talita Novak Thomezyk[1], Lucas Ferreira Alves[1], Ana Carolina Araujo[1], Maria Cecília Mendes Resende[1], Felipe Von Glehn Silva[1], Márcia Silva Santos Neiva[1], Pedro Renato de Paula Brandão[1]

[1]Hospital Universitário de Brasília, Brasília DF, Brazil.

Correspondence: Pedro Maia Nobre Rocha Saffi; Email: pedromaiabsb@gmail.com.

Case presentation: A 33-year-old female patient attended her first consultation in March 2024, reporting hip pain associated with the femoral head rotation, which began in June 2023. Over time, she developed pain extending from the thoracic to the sacral region and rigidity predominantly in the right lower limb (RLL), with difficulty walking due to inversion and plantar flexion of the right foot. She stated that her left foot was starting to show similar symptoms. She denied having any complaints regarding her upper limbs. During the consultation, she also reported urinary urge incontinence, bowel urgency, and a burning sensation in both feet. Physical examination revealed global hyperreflexia, 3+/4+ in the upper limbs (UL) and 4+/4+ in the lower limbs (LL), with an increased reflexogenic area. Muscle strength was grade III in the RLL for right foot dorsiflexion and right thigh extension and grade IV for leg flexion and extension, thigh flexion, and right foot plantar flexion, with hypertonia in the RLL (2+/4+). Muscle strength was grade V in the left lower limb (LLL). Bilateral extensor plantar reflex and positive bilateral Hoffmann's sign were observed. Anti-GAD65 was requested and came back negative. At the following consultation, she reported worsening pain in the LL, arthralgia in the knees and ankles bilaterally, and progression of rigidity in the abdomen and LL. She experienced two episodes of falls during this period. A lumbar puncture was performed, revealing oligoclonal bands restricted to the cerebrospinal fluid. Other tests, such as mammography and contrasted CT scans of the abdomen, pelvis, and chest, showed no abnormalities. During the same consultation, she presented weak positive results for anti-glycine receptor antibodies, and hospitalization for immunoglobulin therapy was requested. **Discussion:** Stiff Person Syndrome (SPS) is characterized by dysfunction in the GABAergic inhibitory pathway, presenting symptoms such as rigidity and painful muscle spasms, primarily in axial and proximal limb muscles. It is associated with high levels of anti-glutamic acid decarboxylase (anti-GAD) antibodies, with other antibodies such as anti-glycine receptor antibodies (anti-GlyR) also described. The classic form of the disease has an estimated prevalence of 1 to 2 cases per million, affecting more women than men. Diagnosis is based on recognizing the symptoms and is corroborated by serologies, response to diazepam, and electromyography (EMG) studies results, which show continuous motor unit activity. Symptomatic treatment involves the use of GABA-stimulating medications, such as benzodiazepines and baclofen, to reduce rigidity and painful muscle spasms. Immunotherapy aims to reduce or remove the antibodies, usually through intravenous immunoglobulin. **Final comments:** SPS me is progressive and generally ensues varying levels of disability. Early diagnosis and treatment initiation significantly impact the patient's prognosis.

Stiff person syndrome: case report of an atypical presentation of the classic form of the disease

Pâmela Ritzmann de Lima[1], Laís Cristina Marques Moura[1], Renan Augusto Campos Manoera[1], Fabio de Paula Conforto de Oliveira[1], Brenda Jahn Henning[1], Patrícia de Morais Della Justina[1], Isabella Flach Antonioli[2], Renan Pires Carneiro da Cunha[1], Chelin Auswaldt Steclan[3], Iuri Pereira dos Santos[1]

[1]Universidade do Contestado, Mafra SC, Brazil.

[3]Universidade Federal de Santa Catarina, Florianópolis SC, Brazil.

Correspondence: Pâmela Ritzmann de Lima; Email: pamelaritzmann@gmail.com.

Case presentation: Female, white patient, started with loss of muscle strength in the lower limbs and recurrent falls at 48 years of age. Over time, the symptoms progressively worsened, with difficulty walking, imbalance, paresthesias and painful muscle spasms in the lower limbs. At the age of 55, he sought medical help for the first time, due to a marked impairment in his quality of life. He consulted with several specialists, having normal brain imaging and electroneuromyography exams, and underwent countless symptomatic treatments with analgesics and anti-inflammatories and even with anxiolytics and

antidepressants, for associated anxiety symptoms, without getting a response. The diagnosis was only confirmed at the age of 56, in the face of an intense symptomatic crisis, after referral to a neurology service and extensive investigation, with normal imaging tests and positive anti-glutamic acid decarboxylase (anti-GAD) serum (> 2,000 IU/ml). Partial improvement was achieved with symptomatological treatment, using neuromodulators (carbamazepine, bacoflene, pregabalin and diazepam) and immunotherapy (IV immunoglobulin), although they were ineffective in controlling clinical worsening and preventing crises. Therefore, at the age of 63, the patient also started to present paresthesia in the thoracolumbar spine and upper limbs. **Discussion:** Stiff-person syndrome (SPS) is a rare autoimmune disease that affects one to two people in every million, causing muscle stiffness, spasms and chronic pain. The pathophysiology is not yet defined, but it is known that it is related to the production of anti-GAD against the synthesis of gamma-aminobutyric acid (GABA), resulting in disturbance of the inhibitory pathways. This case is classified as classic SPS, in which there is positive anti-GAD in the serum. However, this is a classic atypical presentation, as the tendency is for symptoms to begin in the trunk and, later, spread to proximal and distal limbs, and the opposite occurred here. In addition to this and the fact that SPS is a rare disease, constituting a diagnosis of exclusion, the patient also had associated psychiatric symptoms that served as confusing factors, resulting in a late diagnosis. As for treatment, immunotherapies were not enough to reverse the symptomatology. The clinical worsening continued, culminating in the patient's neurocognitive impairment and immobility. **Final comments:** This case discusses an atypical evolution of SPS, which made diagnosis even more difficult, and the ineffectiveness of the therapies adopted, reinforcing that early diagnosis is one of the biggest challenges of this condition, as well as controlling crises and disease progression through available treatments.

Stroke and hemogram: warning signs in blood tests

Santhiago Calvelo Graça[1], Tainá Mosca[1], Vivian Dias Baptista Gagliardi[2], Wilma Carvalho Neves Forte[1], Rubens José Gagliardi[2]

[1]Santa Casa de São Paulo, Faculdade de Ciências Médicas, São Paulo SP, Brazil.
[2]Irmandade da Santa Casa de Misericórdia de São Paulo, São Paulo SP, Brazil.

Correspondence: Santhiago Calvelo Graça; Email: santhiagocalvelo@hotmail.com.

Background: Stroke is a significant cause of death and disability worldwide, with its prognosis closely tied to the severity of this acute condition. This condition is linked to an inflammatory process in the central nervous system, involving various types of cells such as monocytes, lymphocytes, and neutrophils. The inflammatory process can be reflected in peripheral blood through the hemogram, test frequently used in urgent situations such as this vascular disease. Research indicates that relationships derived from the peripheral blood cell count can serve as valuable markers of various inflammatory processes. **Objective:** To investigate the relationship between the severity of stroke and inflammatory markers derived from the peripheral blood cell count. **Methods:** It is a retrospective study based on medical records of patients aged over 18 years, who had ischemic stroke between 2017 and 2022. The clinical data includes the severity of the ischemic stroke (according to the National Institutes of Health Stroke Scale (NIHSS)) and the peripheral blood cells values from the patients' medical records. Based on these last values, the following relationships were established: systemic immune inflammation (SII) index (neutrophils multiplied by platelets and divided by lymphocytes), neutrophil-lymphocyte ratio (NLR), monocyte-lymphocyte ratio (MLR) and platelets-lymphocyte ratio (PLR). NIHSS scores were categorized into the following ranges: ≤ 5, 6-10, 11-15, and > 15. **Results:** Data from 194 stroke patients were collected. It was observed that patients with more severe conditions, as measured by the NIHSS scale, exhibited higher SII, NLR, MLR, and PLR values within the first 72 hours post-stroke ($p \leq 0,05$). There was a statistically significant difference between all groups across all ratios (≤5, 6-10, 11-15 and > 15), apart from the comparison between the 11-15 and > 15 groups. **Conclusion:** Stroke patients manifest an inflammatory process within the CNS, which can be evidenced through peripheral blood markers such as SII, NLR, MLR, and PLR. These relationships are correlated with the severity of the condition according to the NIHSS. Given the complexity of the SII ratio and the fact that all ratios convey similar information, it is advisable to utilize only one of the other three ratios, preferably the one that is the easiest to calculate for the patient in question, thereby obviating the need to determine all others.

Stroke due to neurosarcoidosis: a case report

Roberto Pereira Santos[1], Cícero Cunha Lima[1], Filipi Brito[1], Ingrid Pereira Marques[1], Matheus Jorand Cecatto[1], Celmir Vilaça[1], Carolina Rouanet[1], Gustavo Honório[1], Marcos Martins da Silva[1], Marco Antonio Sales Dantas de Lima[1]

[1]Universidade Federal do Rio de Janeiro, Faculdade de Medicina, Hospital Universitário Clementino Fraga Filho, Serviço de Neurologia, Rio de Janeiro RJ, Brazil.

Correspondence: Roberto Pereira Santos; Email: r.santos.ufrj@gmail.com.

Neurosarcoidosis represents a rare systemic inflammatory condition characterized by the formation of non-caseating granulomas in various organs, including the central nervous system (CNS). Its clinical presentation spans a spectrum of neurological disturbances, posing diagnostic challenges due to its heterogeneous manifestations. Among its phenotypic variants, vascular neurosarcoidosis stands as an uncommon form, fraught with the potential for severe ischemic complications, notably stroke. Herein, we report a case of vascular neurosarcoidosis complicating with ischemic stroke, underscoring the diagnostic conundrums and the imperative of early recognition for the judicious management of these patients. **Case presentation:** A 72-year-old woman with a history of dyslipidemia and hypertension presented to the emergency department of Clementino Fraga Filho University Hospital with a 2-week history of left upper limb paresis and sudden dysarthria onset 2 days prior. Clinical and imaging evaluations unveiled suggestive signs of vascular neurosarcoidosis, encompassing pre-nuclear facial paresis, horizontal gaze nystagmus, positive Romberg sign, and magnetic resonance imaging (MRI) findings consistent with multifocal cerebral ischemia. The patient also bore antecedents of prior acute neurological episodes, aligning with the recurrent course of the disease. Further investigation confirmed perivascular contrast enhancement on dark blood imaging, corroborating the diagnosis of inflammatory vasculopathy concomitant with neurosarcoidosis. **Discussion:** This case epitomizes the diagnostic intricacies inherent to vascular neurosarcoidosis, particularly when manifesting as acute ischemic events. The presence of clinically suggestive signs such as pre-nuclear facial paresis and nystagmus, coupled with typical imaging findings, proved pivotal in the differential diagnosis between inflammatory and atheromatous etiologies of stroke. Perivascular contrast enhancement on dark blood imaging furnished additional evidence, fortifying the hypothesis of inflammatory vasculopathy. This case underscores the imperative of multidisciplinary assessment and consideration of uncommon systemic maladies in patients presenting with atypical neurological phenotypes. **Final comments:** Vascular neurosarcoidosis represents a rare yet potentially grave complication culminating in acute cerebral ischemic events. This case report accentuates the significance of early clinical suspicion and meticulous differential diagnosis to ensure optimal management of such patients. The identification of distinctive clinical and radiological features, coupled with validation through advanced imaging modalities like perivascular contrast enhancement on dark blood imaging, is indispensable in directing therapy and optimizing clinical outcomes.

Background: Despite advances in the treatment and prevention of strokes, the condition still has a high morbidity and mortality rate and is a major public health problem. Understanding the incidence and mortality of this condition is fundamental for public health. **Objective:** Our study therefore assessed trends in the distribution, demographics and evolution of strokes in Brazil. **Methods:** This is an ecological study. The data on hospitalizations was extracted from the DATASUS platform, with the period selected being 2010-2019 and the origin of the patients accounted for according to their place of origin. Only hospitalizations related to the ICD codes "Transient Stroke" and "Stroke of unidentified cause". Population data was obtained according to the IBGE census. Since the census does not take place every year, a projection based on the 2010 census was used. Geospatial analysis was carried out using geoda software in order to obtain the spatial autocorrelation coefficient and inferential statistics were carried out using R studio software. The age groups were transformed into numbers (1-16) and a simple linear regression was carried out, with confidence intervals for the coefficient obtained using bootstrap. Furthermore, simple linear regressions were also performed to observe the annual evolution of hospitalizations, deaths and mortalities. **Results:** A total of 1,644,590 hospitalizations occurred during the period, with an average hospitalization time of 7.4 days, a total cost of R$1,977,622,972.08, an average cost of 1,202.50 per hospitalization and a total of 250,196 deaths, giving a mortality rate of 15.21. Regarding the epidemiological profile, there were more men (51.81%) than women (48.18%). The main age group was 80+ years (20.87%) and the main race was white (48.52%). A simple linear regression analysis was carried out to investigate the extent to which the age group explained the number of hospitalizations. A statistically significant influence was found ($F(1.16)=88.43$, $p<0.001$; adjusted $R2=0.83$). The regression coefficient B (B=18102.73 , 95% [CI=14165.69 - 24222.12]) indicated that, on average, there was an increase of 18102 hospitalizations for each age group. Spatial autocorrelation was observed when analyzing the incidence of deaths ($I^2=0.439$; $p<0.01$) and hospitalizations ($I^2=0.363$; $p<0.01$). The evolution of hospitalizations showed a linear pattern (($F(1.8)=105.5$, $p<0.001$; adjusted $R2=0.92$), where there was an increase of 3457.921 each year (B=3457.921, 95% [CI=271.903 - 4089.415]). **Conclusion:** Our study observed a growing trend in the number of deaths and hospitalizations, which is in line with that observed in other countries, but differs in terms of epidemiological profile. Investments in structure and training for strokes care are essential for public health.

https://doi.org/10.5327/CBN241543

Stroke in a young transgender patient using estrogen therapy: a case report

Andressa Camilo Oliveira[1], Lucas Blanco Insaurralde da Luz Silva[1], Amanda Boutrik[1], Anny Gabriela Marçal de Carvalho[1], Isabela de Carvalho Florêncio[2], Renata Gratão Rezende[2], Rodolfo Antonio Corona[2], Lucas Luiz Fitipaldi Ferreira[3], Maria Luiza Ferri Cury[2], Gabriel Pereira Braga[2]

[1]Universidade Federal de Mato Grosso do Sul, Campo Grande MS, Brazil.
[2]Hospital Universitário Maria Aparecida Pedrossian, Campo Grande MS, Brazil.
[3]Santa Casa de Misericórdia de Campo Grande, Campo Grande MS, Brazil.

Correspondence: Lucas Blanco Insaurralde; Email: lucasblancoms@gmail.com.

Case presentation: A 30-year-old transgender woman, using estrogen hormone therapy without medical guidance since the age of 17 (cyproterone 2mg + ethinylestradiol 0.035mg 1/day), HIV positive (viral load on December 4, 2023, of 413, and CD4 count on October 3, 2023, of 413) with irregular treatment, and previously treated for syphilis. One day before hospitalization, patient presented with a moderate intensity holocranial headache. In the next day, she woke up with sudden-onset right-sided hemiparesis and associated homonymous hemianopsia. In the admission, her vital signs were blood pressure 130/80 mmHg, heart rate 104 BPM, and oxygen saturation 99%. She underwent an infectious screening and cerebrospinal fluid analysis, which excluded opportunistic neuroinfections. The initial computed tomography scan showed no abnormalities, but magnetic resonance imaging revealed signs of ischemia in the left posterior cerebral artery territory. An etiological investigation for stroke was conducted with transthoracic and transesophageal echocardiograms, carotid and vertebral Doppler ultrasound, electrocardiogram, Holter monitoring, arteriography, rheumatological tests, and thrombophilia workup, all of which were unremarkable. Therefore, the final etiological diagnosis was concluded as TOAST classification other causes due to improper estrogen therapy. After diagnosis, she was discharged on antiplatelet therapy with aspirin 100mg daily, simvastatin 20mg daily, and fluoxetine 20mg daily, with hormone supplementation suspended, and referred to a transgender care clinic and vascular neurology outpatient services. **Discussion:** Ischemic stroke in young adults comprises approximately 10% to 12% of all stroke cases. Among young adults, etiologies such as infections, drug abuse, heart diseases, genetic conditions, and autoimmune diseases must be considered. In the present case, the patient had been on irregular estrogen therapy without medical supervision, and other possible etiologies were excluded. The use of estrogen therapy has been discussed in the scientific community, with evidence indicating increased cardiovascular risk at various levels. This is manifested by increased cases of venous thromboembolism, elevated blood pressure, and acute myocardial infarction. Therefore, the potential for hormone therapy to also cause cerebrovascular diseases is noted, especially after prolonged exposure, which likely led to the pathology presented in this case. The magnitude of this effect in transgender individuals undergoing hormone supplementation remains uncertain. **Final comments:** This case highlights the increased risk of cerebrovascular events in the transgender population with inadequate hormone therapy. Therefore, with the diffusion of services aimed at the transgender population and access to hormone therapy, it has become essential to expand studies on the risk and prevention of cerebrovascular diseases associated with hormone therapy use.

https://doi.org/10.5327/CBN241544

Stroke in young adults in Brazil: analysis of hospital morbidity in the SUS in the pre and post COVID-19 pandemic periods

Henrique Chiarini Batistella[1], Heloísa Chiarini[2], Natalia Alini Haubenthal[2], Gisandra de Fátima Stangherlin[2], Luiza de Gregori Dutra[2], Clândio Timm Marques[2], Lucas Henrique Picur Tavares da Silva[2], Natalia Lançanova da Silveira[2], Kelly de Oliveira Harada[2]

Correspondence: Henrique Chiarini Batistella; Email: hcbatistella@gmail.com.

Background: Stroke stands as the second leading cause of death and the biggest cause of permanent disability in the world and can affect individuals at any age, being uncommon before the age of 40. Studies have shown an increase in the incidence of stroke following the COVID-19 pandemic. **Objective:** To analyze selected aspects of hospital morbidity due to stroke from January 2014 to December 2023. **Methods:** retrospective, cross-sectional ecological study. Data was obtained from the Information Technology Department of the Unified Health System. The population consisted of patients aged between 20 and 49, hospitalized with a diagnosis of stroke (ICD-10 I61, I63, I64, I67 and G45), from January 2014 to December 2023. We considered the period 2014-2019 as pre-pandemic COVID-19 and the period 2020-2023 as post-pandemic. The variables of interest: age group, gender, hospitalization period, ICD-10 and number of deaths. The normality of the variables to be studied was verified using the Shapiro-Wilk test and the t-test for independent data. Differences were significant when $p<0.05$. IBM SPSS Version 25 software was used for statistical analysis. **Results:** The study revealed a total of 350,161 hospitalizations for stroke among individuals aged 20 to 49 years from 2014 to 2023, with 21.8% (76,303) classified as CID-10 I61, 8.3% (29,078) as I63, 53.5% (187,152) as I64, 9.1% (32,018) as I67, and 7.3% (25,610) as G45. Regarding age groups, 11.7% (40,864) were aged 20-29 years, 26% (91,081) were aged 30-39 years, and 62.3% (218,216) were aged 40-49 years. When analyzing the total number of stroke hospitalizations in the pre- and post-pandemic periods, a significant difference ($p=0.023$) was observed among young adults (20 to 49 years) comparing before (33569 ± 1234.3) and after (36452.5 ± 2060.2) the pandemic; the 40-49 years age group showed a significant increase ($p=0.012$) comparing 2014-2019 (20761.3 ± 824.4) to 2020-2023 (22948 ± 1332.6). Concerning sex, a significant increase in the number of stroke hospitalizations was noted in men ($p=0.012$) post-pandemic, particularly in the 30-39 years ($p=0.024$) and 40-49 years ($p=0.007$) age groups comparing pre (4140.2 ± 78.5 and 9873.7 ± 453.4, respectively) and post (4451.7 ± 264.2 and 11125.2 ± 728.2, respectively) pandemic periods. In women, a significant increase ($p=0.025$) was observed only in the 40-49 years age group comparing pre (10888.2 ± 458.6) and post (11822.5 ± 619.9) pandemic periods. Furthermore, a significant difference was found in the number of deaths in stroke hospitalizations in the 40-49 years age group ($p=0.019$). **Conclusion:** Despite the limitations of this study, such as the inability to correlate with risk factors, define the type of cerebrovascular disease and SARS-CoV-2 infection, the results demonstrate an increase in hospital morbidity due to stroke among young adults in the post-pandemic period, particularly in males and the 40 to 49 years age group.

Correspondence: Bárbara Nascimento Moutinho; Email: barbara.moutinho@ufpe.br.

Background: Ischemic stroke is among the leading causes of death and disability around the globe. Early therapeutic intervention for reperfusion is the keystone to enhancing prognosis, but it is time-sensitive. Although guidelines have expanded the time window for intravenous thrombolysis, data suggest that the number of patients with acute ischemic stroke who undergo intravenous thrombolysis remains low, especially in underdeveloped regions. Then, improving comprehension of the factors contributing to undergoing intravenous thrombolysis is crucial. **Objective:** To evaluate the relation between clinical-epidemiological aspects of patients with acute ischemic stroke, prior knowledge about this disease, and receiving intravenous thrombolysis. **Methods:** Cross-sectional study enrolling patients with acute ischemic stroke admitted in a tertiary care center. Data collection was performed using an electronic form developed by our team and administered directly to the patients. The form consisted of objective questions regarding sociodemographic data, personal history, comorbidities, presguenting symptoms, time of symptom onset, time taken to reach the hospital, awareness of stroke warning signs and risk factors, and knowledge about the Mobile Emergency Service (SAMU) telephone number. We also obtained the status of intravenous thrombolysis. **Results:** The sample consisted of 245 patients with acute ischemic stroke, with a median age of 66 (IQR 57-74) years, with 53% being women. Of the total, 48 (19.5%) patients underwent intravenous thrombolysis. Regarding the time taken to reach the referral service, in minutes, the median in the thrombolysis group was 177.5 (IQR 120-210) vs. 240 (IQR 160-507) minutes among controls ($p<0.001$). Regarding the NIHSS, the median was 9 (IQR 6-12) in the intravenous thrombolysis group vs. 3 (IQR 1-8) points in patients who did not undergo it ($p=0.012$). As for patient characteristics, we have for the intravenous thrombolysis group and the control group, respectively: systemic arterial hypertension 71.4% vs. 84.9% ($p=0.069$); diabetes 25.6% vs. 44.7% ($p=0.031$); dyslipidemia 20.6% vs. 38.9% ($p=0.050$); coronary artery disease 2.8% vs. 15.1% ($p=0.053$); health insurance coverage 8.5% vs. 3.6% ($p=0.232$); symptom onset at work 11.4% vs. 3.5% ($p=0.070$); wake-up stroke 13.3% vs. 26% ($p=0.081$). Finally, the variables years of formal education, knowing the SAMU number, knowing at least one stroke risk factor, knowing the affected organ in stroke, and knowing at least one stroke sign or symptom did not differ between the groups. **Conclusion:** The absence of diabetes and dyslipidemia, initial NIHSS score, and a shorter time between symptom onset and hospital arrival were the factors associated with undergoing intravenous thrombolysis. General knowledge about stroke and other variables, however, did not show statistical significance.

Correspondence: Filipe Nolasco de Souza e Silva; Email: filipe.nolasco95@gmail.com.

Background: Stroke mimics are non-vascular disorders that clinically resemble acute stroke. Despite numerous studies in the literature about this topic, there remains limited information about this condition in Brazil. **Objective:** To describe the clinical and epidemiological profile of patients diagnosed with stroke mimics. Secondary objectives were to identify the most prevalent etiologies, management practices recommended by the neurology team, and to determine the outcomes of these patients. **Methods:** This was an observational, descriptive, retrospective study consisting of a case series of patients classified as stroke mimics at a tertiary hospital from August 2020 to August 2023. **Results:** A total of 441 patients were admitted, with 152 (34%) classified as stroke mimics. Among these, 99 were women with a mean age of 61.7 years and a median National Institute of Health Stroke Scale of 4 on admission. Of the patients, 110 (72.4%) had at least one risk factor, including hypertension in 100 patients, diabetes mellitus in 57, prior stroke in 24, coronary artery disease in 11, and atrial fibrillation in 9. The most prevalent etiology for stroke mimics was epileptic events, accounting for 29.6%. None of the stroke mimic patients underwent thrombolysis or thrombectomy, but 25 received single antiplatelet therapy and 30 received dual antiplatelet therapy upon admission. The median modified Rankin Scale at discharge was 0, with a mortality rate of 7.2%. **Conclusion:** Stroke mimics constitute a significant proportion of patients admitted with suspected stroke, with a prevalence higher than the average reported in the literature. Epileptic events were identified as the most prevalent etiology.

Stroke mimics: assessing the most common differential diagnoses of stroke in the emergency department

Luiz Carlos Porcello Marrone, Victor Garcia Ortiz[1], João Pedro Farina Brunelli, William Alves Martins, Luciano Passamani Diogo, Laura Fuchs Bahlis, Leonardo Pisani, Matheus Bom Fraga, Antônio Carlos Huf Marrone

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Victor Alfonso Garcia Ortiz; Email: victorgarcia.or@gmail.com.

Background: Sudden onset of focal neurological deficits in a vascular distribution, such as hemiparesis, facial weakness, and aphasia, typically suggests a stroke. However, other disorders can mimic these clinical manifestations. “Stroke mimics” describe non-vascular disorders that present similarly to stroke, such as multiple sclerosis and facial palsy. Previous studies have found varying frequencies of stroke mimics among patients suspected of acute ischemic stroke, with younger patients and those with fewer stroke risk factors being more likely to have a stroke mimic diagnosis. **Objective:** To evaluate the prevalence and characteristics of stroke mimics in a neurologic emergency department at Hospital São Lucas in Porto Alegre. **Methods:** Over two years and six months, data were collected from 330 patients diagnosed with stroke mimics after being admitted to the emergency room. These patients were initially diagnosed with stroke but later excluded by a neurologist who confirmed other diagnoses. Our study evaluated sex, age, symptom onset, and final diagnosis. Two main groups were analyzed: those arriving within 4.5 hours of symptom onset and those arriving after 4.5 hours. Stroke mimics were categorized into 14 subtypes, including functional disorders, delirium, seizures, migraine, among others. **Results:** Of the 330 patients included, 50.3% were male, with a mean age of 67.1 years. Functional disorders (14.2%) and hydroelectrolytic imbalances (14.2%) were most found, followed by delirium (12.7%). Among patients admitted within 4.5 hours of symptom onset, 73.6% were older than 60, compared to 62.3% of those who arrived later. In the early presentation group, hydroelectrolytic imbalances and seizures were most common, while in the late presentation group, delirium and psychiatric disturbances were more frequent. **Conclusion:** Our study highlighted a variety of disorders presenting similarly to stroke, posing a risk of thrombolysis overtreatment by unprepared professionals. Although symptomatic intracranial hemorrhage in stroke mimics is rare, the correct use of thrombolysis is economically significant due to the high cost of these drugs. Misdiagnosis can also delay appropriate treatment for conditions like seizures and metabolic disorders. Our findings underscore the importance of recognizing stroke mimics in emergency settings. The most common stroke mimics differ between patients eligible for thrombolysis and those who are not, emphasizing the need for careful triage. This knowledge can guide clinicians in accurately diagnosing and treating stroke mimics, ultimately improving patient outcomes. In summary, awareness of the most common stroke mimics is crucial for emergency department clinicians, with functional disorders and hydroelectrolytic imbalances being the most frequent in this study.

Stroke palliative care protocol implementation in a reference hospital for stroke treatment in Joinville, Santa Catarina

Maria Eduarda Angelo de Mendonça Fileti[1], Patrícia Vera[1], Lila Jerusa Nascimento Pereira Abreu[1], Marta Gabriele Pires da Rosa Schmen[1], Camilla Ramos Mohr[1], Jane Rossi[1], Brenner Henrique de Oliveira Marques da Silva[1], Joselma Siqueira de Aquino[1], Carla Heloísa Cabral Moro[1]

[1]Hospital Municipal São José, Joinville SC, Brazil.

Correspondence: Maria Eduarda Angelo de Mendonça Fileti; Email: neuro.mef@gmail.com.

The concept of palliative care has awakened a new vision about the integrality of a person, with its physical, psychological, social and spiritual dimensions. This approach consists of assistance provided by a multidisciplinary team that aims to provide greater comfort to patients and their families and reduce expenses with measures that are disproportionate to the patient’s condition. Studies show difficulties in symptom management, communication, support family and decision-making in patients who present with acute stroke in hospital care. They also identified high case fatality after severe stroke, numerous long-term physical problems, substantial emotional distress, prognostic uncertainty, and a sense of abandonment after hospital discharge. Our experience in a reference center for stroke treatment has shown the need of Post-Stroke Palliative Care Protocol establishment. In 2019 a Protocol for Post-stroke Palliative Care was written, based on NIHSS, Hemphill, Fischer, Palliative Performance, Modified Rankin, Barthel and NECPAL scales. Patients who match the following criteria are eligible for the Protocol: NIHSS > or = 18 one week after the event; Palliative Performance Scale ≤ 30%; mRankin ≥ 4; and NECPAL CCOMS-ICO indicating Palliative Care. Because of the COVID-19 pandemics in 2020, we had difficulties in setting down the Protocol. So in 2023, we were finally able to put it into practice. We created a multidisciplinary committee composed by a neurologist, nurses, psychologist, social worker, occupational therapist, physiotherapist, nutritionist and speech therapist. Bedside visits are taken twice a week, for control and management of symptoms and treatment and multidimensional care planning. Family conferences for effective communication between the patient, health professionals, family members and caregivers are routine, so are conducting lectures for caregivers and family members about care. Promotion of continuous education to update the team’s knowledge is also a concern of ours. From June 2023 to June 2024, 81 patients were followed by our team. Concomitantly with the implementation of the palliative care protocol, a reduction in the need for prolonged hospitalizations was noticed, resulting in fewer emergency visits and readmissions, due to the information offered to family members and the patient himself about the real health condition and its perspectives; in addition to greater awareness among professionals involved in care and a complete demystification related to Palliative Care - avoiding aggressive interventions and unnecessary invasive procedures.

Stroke presenting as bilateral hearing loss: a case report

Guilherme Bitencourt Barbosa[1], Renato Morais Bueno[1], Victor Ezaki Alves Silva[1], Rayanne Pereira Mendes[1], Yasmin Pagano Monteiro[1], Evelyn de Paula Pacheco[1], Miriam Eva Koch[1], Ruda Alessi[1], Eduardo Macedo de Souza Tieppo[1]

[1]Faculdade de Medicina do ABC, Santo André SP, Brazil.

Correspondence: Guilherme Bitencourt Barbosa; Email: guibtencourt@gmail.com.

A 63-years-old male patient, with hypertension, admitted to the Emergency Room due to sudden bilateral hearing loss associated with occipital headache for one day. The patient was referred to an external hospital for evaluation with an otolaryngologist and imaging investigation. Despite brain magnetic resonance imaging (MRI) having no alterations (DWI was not included), MR Angiography of the brain revealed a basilar artery subocclusion in the middle segment. The patient refused hospital admission, but hours later sought a Neurology Emergency Department due to persistent hearing loss for 3 days. His physical examination was remarkable for right facial hypoesthesia, absent right vestibulo-ocular reflex (VOR), hypoacusis, broad-based gait, unable to tolerate Tandem, and a positive Romberg sign with a tendency to fall to the right. A brain CT on admission showed no abnormalities. A new brain MRI was requested due to posterior fossa stroke hypothesis, but his level of consciousness deteriorated rapidly, showing signs of decerebration and Cheyne-Stokes pattern hyperventilation. On the new physical examination, the patient showed no response in both VOR, absent bilateral corneal reflex, and absence of horizontal and vertical gaze. Due to instability to perform MRI, a new brain CT was done instead, showing hypodensity in the cerebellum and right cerebellar peduncle, territory of the anterior inferior cerebellar artery. The patient died due to stroke complications. Commonly, vertebrobasilar territory stroke manifests with prodromal symptoms, with the most characteristic being vertigo and headache. There are less common symptoms including hearing loss, as in the case. These symptoms can start days to weeks before the vascular event and pose a significant challenge for stroke diagnosis, as they are non-characteristic stroke symptoms and are present in other pathologies. Finally, with obstruction of the basilar artery, various signs and symptoms of basilar syndromes can occur, ranging from cortical blindness to decreased level of consciousness and altered breathing patterns. It is a serious and potentially fatal condition, as observed in the reported case. Although rare, hearing loss can be a symptom of a stroke, and should be considered, especially when there are simultaneous focal deficits and a sudden onset. Posterior fossa ischemia is hardly visualized on a brain CT - which is the first and sometimes only available exam in several Brazilian centers. Symptoms of posterior circulation involvement tend to be overlooked, either due to low specificity, absence of typical stroke manifestations, slower progressions and lower CT sensitivity. A detailed neurologic examination by a skilled professional can differentiate the early basilar artery symptoms from a peripheric disease and initiate a precocious treatment to prevent a poor prognosis.

Stroke prevention by combining medical education in the context of primary health care and social media: an extension project

Lorenzo Marinho Morais[1], Chiara Gübel Portugal[1], Gabriel Macedo Cavalcante[1], Júlia Lima Vasconcelos[1], Matheus Lima de Oliveira[1], Gustavo Paes de Andrade Saraiva[1]

[1]Universidade Estadual do Ceará, Fortaleza CE, Brazil.

Correspondence: Lorenzo Marinho Morais; Email: lorenzo.morais@aluno.uece.br.

Background: Stroke is the second leading cause of death worldwide and a major cause of disabilities. Today, it is known that five risk factors account for more than 80% of the global risk for developing a stroke, whether ischemic or intracerebral hemorrhage: hypertension, smoking, obesity, sedentary lifestyle, and diet. Despite this, multicenter studies have shown that most people cannot define what a stroke is, nor can they recognize and respond to a probable episode. In light of this, the Neurology and Neurosurgery League of the State University of Ceará (Neuruece) created an extension project aimed at educating the population about strokes by visiting a primary health care unit to provide valuable information on the subject and also using social media. **Objective:** To educate the general population about the various characteristics of stroke, from understanding the risk factors to recognizing a probable episode. **Methods:** Educational activities were carried out by six medical students at a Primary Health Care Unit in Fortaleza. The unit was chosen due to the high number of users with stroke risk factors. Three actions were conducted throughout the year, using informative materials and a small questionnaire to assess people's level of knowledge on the subject. Regarding social media, several educational posts were made throughout the year on the Neuruece Instagram account. **Results:** The actions reached hundreds of people at the health unit throughout the year. The main topics taught to the population were: definition and types, differentiating ischemic and hemorrhagic stroke; risk factors; main symptoms; and the Brazilian mnemonic SAMU ("Sorriso", "Abraço", "Música" and "Urgência"), a quick and easy method to identify a probable stroke and how to act. Regarding social media, twelve posts were made throughout the year, covering topics from basic to more technical specifics, expanding the project's reach to medical students seeking relevant and evidence-based information. A total of 4669 accounts were reached, averaging 389.1 accounts reached per post. **Conclusion:** The project's relevance was evident, as it proved the lack of knowledge among most users involved regarding basic stroke topics. By disseminating this information, new stroke cases can be prevented, as the vast majority are triggered by modifiable risk factors. This type of project highlights to health authorities the positive impact that medical education can bring to the population, influencing the creation of public policies.

Stroke profile of patients with high risk of obstructive sleep apnea: a transversal study

Aurea Maria Lago Novais Castello Branco[1], Juliana Cerqueira Gomes[1], Marina Soledad Benitez Bitencourt[1], Thaise Braga de Oliveira[1], Renan Carvalho Castello Branco[2]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.
[2]Hospital Municipal de Salvador, Salvador BA, Brazil.

Correspondence: Renan Carvalho Castello Branco; Email: castellorenan@yahoo.com.br.

Obstructive sleep apnea (OSA) is a disease of upper airways, diagnosed with polisomnography, that is well associated with stroke throught diverse mechanisms. Despite that, it still lacks studies about stroke profile in patients with high risk of OSA. This study aims to describe the diferences between stroke in patients with high and low risk of OSA. We performed a transversal study, part of a cohort of stroke patients. Patients were evaluated of risk of OSA with STOP-Bang and SOS scores; also, data of wake-up stroke, stroke type and etiology, transient ischemic attack (TIA), thrombolysis, circulation evolved, ASPECTS (Alberta stroke program early computed tomography score), PC-ASPECTS (posterior circulation - acute stroke prognosis early computed tomography score), hemorragic transformation and its type (ECASS), ABCD2, National Institute of Health Stroke Scale (NIHSS) and death during internment were colectted. We obtained 430 patients, 50.5% female. 69% were classified as high risk with STOP-Bang, median 3 (interquartile range 2-4) and 50% with SOS score, median 10 (interquartile range 7-16). Considering STOP-Bang, there were significant diferences with previous stroke - most prevalent in high risk - (p=0.01) and admitional dyastolic pressure (p<0.001). Considering SOS, we obtained admitional capillary blood glucose (p=0.005), admitional dyastolic pressure (p=0.03). ASPECTS > 7 (p=0.02). In both scores, high risk patients evolved more to death during internment (p=0.04 and p=0.01, respectively). In baseline characteristics of STOP-Bang, there was a higher prevalence in high risk group of male sex (p<0.001), alcoholism (p=0.01), obesity (p=0.01), hypertension (p<0.001) and diabetes (p=0.002); of SOS score, female sex (p=0.007), obesity (p<0.001), hypertension (p=0.001) and diabetes (p=0.001). The stroke profile of patients with high risk of obstructive sleep apnea appears to follow the pattern of stroke in general: a higher prevalence of ischemic type and similar rates of hemorragic transformation. Otherwise, high risk of OSA patients have more recurrence of cerebrovascular event and tend to be admitted with higher measures of capillary blood glucose, dyastolic pressure and worst images, which is concordant with the information of higher prevalence of hypertension and diabetes. This phenomenon also can be explained due to metabolic pattern of this diasease, in addition to vasoreactivity impairment, which is demonstrated most with dyastolic measures.

There is limited information about stroke rehabilitation in low- and middle-income countries. This multicenter study investigated the access to rehabilitation for post-stroke patients in the first 6 months after discharge from public hospitals in Brazil and compared these outcomes between regions stratified by Human Development Indexes (HDI). Sixteen centers in 11 Brazilian states were grouped in Group HDIHigher (>0.750, n=225, South and Southeastern regions) and Group HDILower (≤0.750, n=248, Western and Northeastern regions). A survey regarding referrals to, assessment and treatment by rehabilitation professionals (physiotherapist-PT, speech therapist-ST, occupational therapist-OT, physiatrist) was answered by patients/caregivers. The primary outcome was the percentage of patients who were assessed at least once by a PT within the first six months post-discharge from acute care. Comparisons between groups were performed with Student´s t, Mann-Whitney, Chi-square or Fisher´s exact tests. Multivariate stepwise logistic regression models were planned, with assessment at least once by a PT as the dependent variable. Participants were recruited from January 2020, until October 2023. Participants in Group HDILower were significantly younger (p=0.018), had more hemorrhagic events (p<0.001), and higher NIH Stroke Scale (NIHSS) scores (p<0.001) than patients in Group HDIHigher. Referrals to at least one professional upon discharge from the acute stroke care facility were restricted to 54.5% patients. Referrals for PT were significantly more frequent in Group HDILower (p=0.001) than in Group HDIHigher. The participants referred to PT (p<0.001), ST (p<0.001), OT (p<0.001), were more likely to be assessed at least once, than patients not referred. Only 54.1% of the patients were assessed at least once by a PT, and less than 25%, by other rehabilitation professionals, with no significant between-group differences. The overall rate of PT treatment was higher (42.5%) than rates of treatments by other professionals (range, 1.5% to 17%), with no significant between-group difference. Only 5.1% were assessed by PT, ST, and OT, with no significant between-group difference. Age, gender and timing of data collection were not significantly associated with PT assessment and were removed from the regression model. Education ≤4 years was independently associated (p=0.001 CI 1.29-2.90), while higher NIHSS scores were inversely associated (p<0.001; CI 0.82-0.90) with lack of PT assessment. The AReA study provides objective, novel data about the gaps in stroke rehabilitation in Brazil, to guide effective public policies. AReA study group: Cesar Minelli, Luciane Souza, Luana Miranda, Luana Amaral, Gisela Tinone, Beatriz Neves, Renata Jucá, Maria Elisa Piemonte, Tatiana Ribeiro, Ana Paula Fontana, Lenise Valler, Octávio Pontes-Neto, Millene Camilo, Marco Tulio Pedatella, Isabel Lima.

Stroke secondary to thyrotoxic crisis: case report

Rachel Leirner Argelazi[1], Maria Clara Motta Barbosa Valente[2], Santhiago Calvelo Graça[1], Filipe Brito Ferraz da Silveira[2], Camila Lopes Figueiredo[2], Rafael Chaves Claudino de Queiroga[2], Letícia Machado Dumont[2], Cícero Rodrigues Veloso[2], Vivian Dias Baptista Gagliardi[2], Rubens Jose Gagliardi[2]

[1]Santa Casa de São Paulo, Faculdade de Ciências Médicas, São Paulo SP, Brazil.
[2]Irmandade da Santa Casa de Misericórdia de São Paulo, São Paulo SP, Brazil./

Correspondence: Rachel Leirner Argelazi; Email: racheleirner@gmail.com.

Case presentation: A 44-year-old female patient presented to the emergency department with a history of left hemiparesis and hypoesthesia for the past 10 days. She denied any comorbidities and upon admission was disoriented in time and space, fluctuating between agitation and lethargy. She was tachycardic, hypertensive, and hyperthermic, with exophthalmos. Admission cranial computed tomography (CT) revealed hypodensity in the right occipital and frontal regions. Further investigations

showed free T4 >12 (reference range) and TSH < 0.0008 (reference range). Electrocardiogram showed evidence of sinus tachycardia, and the Burch Wartofsky index was 50 points, defining the diagnosis of thyrotoxic crisis. Despite clinical measures for thyrotoxic crisis, the patient deteriorated with decreased level of consciousness and required orotracheal intubation. A repeat CT scan revealed multiple acute/subacute hypodense areas, as well as central venous thrombosis of the right transverse and sigmoid sinuses. Atrial fibrillation was incidentally detected during the course of intensive care unit (ICU) admission. Despite this, imaging findings suggested venous infarction secondary to thrombosis, and anticoagulation was continued in this context. Despite optimized medical therapy, the patient died on the eleventh day of hospitalization. **Discussion:** Several mechanisms are related to vascular events in the context of hyperthyroidism, including both cardioembolic events precipitated by atrial fibrillation and an increased risk of thrombotic events due to alterations in coagulation factors, such as increased factor VIII and the risk of antiphospholipid antibody syndrome. The patient in the reported case experienced venous infarction secondary to sagittal sinus thrombosis, which was the cause of the stroke. **Final comments:** Systemic conditions should be considered as risk factors for cerebrovascular events; early recognition and rapid intervention significantly influence outcomes. Furthermore, there is a need for better elucidation of thromboembolic and cardioembolic aspects related to hyperthyroidism, as well as the use of anticoagulation as secondary prophylaxis for stroke in this patient group.

https://doi.org/10.5327/CBN241554

Structural integrity analysis of temporal lobe components and the thalamus in juvenile myoclonic epilepsy through T2 relaxometry

Carlos Dibbern[1], Ingrid Carolina da Silva Cardoso[1], Brunno Machado de Campos[1], Marina K. Alvim[1], Clarissa L. Yasuda[1], Fernando Cendes[1]

[1]Universidade Estadual de Campinas, Faculdade de Ciências Médicas, Campinas SP, Brazil.

Correspondence: Carlos Dibbern; Email: c222428@dac.unicamp.br.

Juvenile myoclonic epilepsy is the most common type of generalized epilepsy. A few studies have investigated functional and structural abnormalities of the brain in this form of epilepsy, indicating a possible role of temporal lobe structures and the thalamus on the onset and activity of juvenile myoclonic epilepsy; however, their structural integrity remains unclear. For that reason, here we assessed the structural integrity of the hippocampus, amygdala, temporal lobe pole, and thalamus in patients with juvenile myoclonic epilepsy through T2 relaxometry, a technique capable of detecting T2 signal irregularities (that correlate to tissue abnormalities) undetectable by conventional visual analysis based on MRI. We included 38 healthy controls and 40 patients diagnosed with juvenile myoclonic epilepsy without other neurological comorbidities, followed by the Epilepsy Service of Universidade Estadual de Campinas. All had a multi-echo T2 weighted magnetic resonance imaging with 3mm thickness acquired in a 3 Tesla Philips Achieva® MRI Scanner. We measured the T2 signal of the four structures in both groups through the software "Relaxo LNI" by manually drawing the regions of interest over the T2 relaxometry map in multiple slices to fully represent the components. We performed the statistical analysis using a bicaudate Student's t-test. At first, we compared the T2 signal of the structures between both brain hemispheres: the only structure that presented a significant asymmetry was the thalamus in the group of patients ($p<0.001$; 95% CI [-1.53; -0.53]). The control group and the other structures in the group of patients presented no T2 signal significant difference between hemispheres. In a second step, we compared the T2 signals between groups, which demonstrated an increased T2 signal of the right hippocampus ($p<0.001$; 95% CI [1.84; 4.35]), the left hippocampus ($p=0.009$; 95% CI [0.38; 2.63]) and the right amygdala ($p=0.001$; 95% CI [1.08; 4.57]) in the group of patients. We found no T2 signal differences in the other structures. We conclude that there is a microstructural integrity alteration detectable by T2 relaxometry in the hippocampus, amygdala, and thalamus in patients with juvenile myoclonic epilepsy, which may be relevant for the pathophysiology of this form of epilepsy and reinforces previous studies. However, the cause-effect relationships of these alterations with seizures or medications are unknown and require further investigation.

Study of chronic meningitis at Clementino Fraga Filho University Hospital - UFRJ

Amanda Carvalho de Oliveira[1], Marco Antonio Sales Dantas de Lima[1]

[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Amanda Carvalho de Oliveira; Email: amanda-c16@hotmail.com.

Background: Chronic meningitis is defined as one where the duration of symptoms exceeds four weeks. Typically, patients present with symptoms such as headache, vomiting, and slowly progressive fever. Due to its extensive differential diagnoses and the need for careful analysis of complementary tests, the diagnostic and therapeutic management of chronic meningitis remains poorly explored, with limited studies in the literature. A better understanding of the epidemiology of chronic meningitis can aid in early diagnosis, optimizing treatments, and thereby reducing morbidity and mortality. **Objective:** Through an epidemiological analysis, we aim to create a database providing insights into the most prevalent etiologies, associated conditions, responses to different proposed treatments, and outcomes of cases. Our goal is to contribute to the literature, aiming to enhance protocols for diagnostic investigation and treatment. **Methods:** This is a retrospective observational study of chronic meningitis cases over the past decades at the Clementino Fraga Filho University Hospital, covering the period from 2001 to 2023. Data collection is guided by a questionnaire established by researchers, converted into a table format to accommodate information in a numerical list. Upon completion of data collection, statistical analysis will be performed, presenting descriptive data in numbers, percentages, means, and standard deviations. **Results:** We obtained a total of 1581 medical records, of which 524 have been evaluated, and 92 patients met the inclusion criteria for the study. Among the 92 evaluated patients, 64% of cases encompass the most frequent etiologies: Cryptococcosis and Tuberculosis, with approximately 76% associated with immunosuppressive conditions. Additionally, neoplastic conditions significantly contributed to the number of cases, representing about a quarter of the total. Meningeal syndrome was the initial manifestation in 70% of cases, and hydrocephalus and/or meningeal enhancement were the most common findings on imaging. Interestingly, the diagnosis of chronic meningitis was confirmed even in the absence of such data. Hospitalization duration varied with diverse outcomes. Using the modified Rankin scale at discharge, approximately 70% of patients left the hospital with sequelae, and around 20% of cases resulted in death. **Conclusion:** The study confirms the diverse etiology and clinical/radiological manifestations of chronic meningitis. Despite over two decades, treatment protocols have seen minimal changes. With the establishment of a comprehensive and meticulous database, we aim to identify crucial areas for modification in chronic meningitis protocols, ultimately improving outcomes for future patients.

Study of neuropsychiatric symptoms as post-acute sequelae of COVID-19 during pregnancy

Leonardo José Rodrigues de Araújo Melo[1], Danielle Mesquita Torres[1], Luíza Madureira Silva[1], Marylane da Silva Viana[1], Danielle Macêdo Gaspar[1], Manoel Alves Sobreira Neto[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Leonardo José Rodrigues de Araújo Melo; Email: lleonardomello98@alu.ufc.br.

Background: The SARS-CoV-2 pandemic has had severe impacts on global mental health. In the acute phase of COVID-19, 36% of patients exhibit Neuropsychiatric Symptoms(NS) such as mood changes due to factors like systemic toxemia and metabolic alterations. NS are also common in the Post-Acute Sequelae of SARS-CoV-2 infection (PASC), such cognitive impairment, fatigue, and depression lasting more than six months, regardless of the infection severity. Studies show a higher prevalence of PASC in women, including pregnant women, who already experience cognitive and immunological impairment during pregnancy, known as "pregnancy brain fog", which is exacerbated by viral infections and psychological stress. **Objective:** To evaluate NS due PASC in women exposed to the SARS-CoV-2 virus during pregnancy. **Methods:** The research was conducted through a 12-month follow-up of women at the Maternity School Assis Chateaubriand (MEAC), in Fortaleza/CE, who contracted COVID-19 during pregnancy with long COVID symptoms (PASC-G). COVID-19 is confirmed by serological testing for the detection of anti-SARS-CoV-2 antibodies and/or a nasopharyngeal swab test. Participants underwent neuropsychological and sleep evaluation. Neurophysiological assessments of sleep was made by polysomnography. Neuropsychological evaluation included Mini-Mental State Examination (MMSE), Addenbrooke's Cognitive Examination (ACE), Beck Anxiety and Depression Inventories, Pittsburgh Sleep Quality Index and Epworth Sleepiness Scale. **Results:** Data were collected from 8 PASC-G patients, with an average age of 29.9 years (±5.54). Among these patients, only 2 had neuropsychiatric symptoms (insomnia) before COVID-19. Only one patient experienced severe COVID-19 symptoms, requiring hospitalization. 75% of the patients reported some symptom associated with anxiety disorder. MMSE the average score was 27.3 (±1.91), with only one patient scoring below the expected level for her education. Regarding the ACE, the average score was 81.9 (±8.64), with 4 patients scoring below 84 points, indicating cognitive disability. The average Pittsburgh Sleep Quality Index score was 15 (±4.28), with all participants showing poor sleep quality. The average Epworth Sleepiness Scale score was 6.75 (±3.01), with only one patient showing excessive sleepiness. The average scores for the Beck Anxiety Inventory and Beck Depression Inventory were 15.6 (±4.37) and 24.9 (±12.1), respectively, with significant anxiety symptoms in 4 patients.Two polysomnographies were performed, showing reduced sleep latency and changes in N2, N3, and REM sleep stages. **Conclusion:** It was found that neuropsychiatric symptoms are common in PASC-G patients. Therefore, especialized evaluation of these patients should be considered. The study is still ongoing and, due to the small number of patients, more research is needed to validate the hypothesis.

[1]Universidade Federal do Paraná, Curitiba PR, Brazil.

Correspondence: Otto Jesus Hernandez Fustes; Email: otto.fustes@hc.ufpr.br.

Background: Amyotrophic Lateral Sclerosis (ALS) is the most common form of Motor Neuron Disease. However, although the motor component changes in ALS are widely known, new research also indicates sensory impairment in this disease. As Weis et al. noted in 2011, 79% of patients with ALS diagnosed in their study had a reduction in the number of fine sensory fibers. In this sense, as a disease with sensory impairment, there are methods that can investigate this characteristic of ALS, of which the Skin Wrinkling Test (SWT) stands out. This can provide foundations to understand more deeply how the sensory component is related to ALS and allow substrate for new clinical correlations. **Objective:** To evaluate small sympathetic fibers using the SWT in patients with ALS. **Methods:** We performed a cross-sectional study on 22 individuals over 18 years old, diagnosed with ALS being monitored in a specialized outpatient clinic, who underwent SWT by immersion in warm water at 40°C (104°F) for 30 minutes. Currently, the parameters for evaluating wrinkling are based on the location and quantification of wrinkles produced by the test, which are evaluated on all fingers except the thumb, due to the difficulty of photographing it, so there are 3 possible classifications using the DATEMA scale: 0.0 = not wrinkled, 0.5 = minimally wrinkled and 1.0 = obviously wrinkled. Scores of 0.5 and 1.0 are considered as positive wrinkling, while 0.0 is considered negative. **Results:** 13 men and 9 women were evaluated, with a mean age of 58 and 63 years, respectively. 19 with sporadic ALS and 3 with the P56S mutation linked to ALS of the VAPB genetic type. The scale used for evaluation was DATEMA. Compared to a group of 30 patients without comorbidities, in which 6.4% of the sample tested negative (no visible wrinkles), 31.8% of the population with ALS tested negative, which revealed a statistically significant association between the negative test and the presence of a diagnosis of ALS by Fisher's exact test (p=0.027). **Conclusion:** small fibers controls skin wrinkling, which is present in the majority of the population. The absence of wrinkling may demonstrate abnormalities in the fine fibers. The fact that SWT has significantly more negative results in the population diagnosed with ALS demonstrates that this disease, historically known for its motor impairment, may also have sensory impairment involved in its pathophysiology. Further studies are needed to confirm these findings and to investigate the potential clinical implications of skin wrinkling assessment in ALS.

Background: Amyotrophic lateral sclerosis (ALS) is characterized by the progressive and inexorable neurodegeneration of upper and lower motoneurons. The study of ALS cases in a reference institution, such as a university hospital in the city of Rio de Janeiro, can enable the identification of epidemiological patterns in this population and support improvements in care. **Objective:** To characterize the clinical-epidemiological profile of patients with ALS treated at a university hospital in the city of Rio de Janeiro. **Methods:** The study was designed as an ambispective cohort. In the retrospective segment, data was collected from patients diagnosed with ALS from 12/13/2002 to 06/28/2023. In the prospective segment, new cases were incorporated into the final series between 06/29/2023 and 04/08/2024. The data comprised demographic, clinical and neurophysiological factors, which were statistically analyzed and compared to data published in other studies, nationally and internationally. **Results:** 84 cases of ALS were gathered, of which male patients predominated (57.1%), with an average age of first symptoms in the sixth decade of life (54.3 years), with the main initial motor symptom being impairment of one or both lower limbs (58.4%), with idiopathic etiology (91.7%), clinical phenotype of classic ALS (71.4%), systemic arterial hypertension as the main comorbidity (28.6%) and category El Escorial of defined ALS (48.8%). The time required to establish the diagnosis from the first symptom had a median of 19 months. Specific treatment with riluzole was performed in 59.5% of cases. Forty-five percent of patients had died by the end of the study, among whom an average interval between the first symptom of the disease and death was observed to be 35 months. **Conclusion:** All this compiled data is in line with data published in national and international bibliographic reviews on the disease to date.

Background: The severe acute respiratory syndrome coronavirus type 2 (SARS-CoV-2) has had effects on the central nervous system in cases of acute neurological manifestations (ANM). Although cytokines, chemokines and immunoglobulins were investigated in patients with acute brain syndromes and SARS-CoV-2 infection, data on the integrity of the blood-brain barrier (BBB) and intrathecal production of these biomarkers in these patients are still scarce. **Objective:** To investigate whether patients with acute brain syndromes after exposure to SARS-CoV-2 have inflammatory BBB dysfunction. **Methods:** Experimental study, part of the NeuroCOVID study, funded by Fiocruz (nº VPPCB-005-FIO-20-2-22). Samples from 39 patients admitted in the neurology service of Hospital da Restauração, in Recife, were analyzed. The case series was selected according to three comparison groups: Exposed cases (acute central neurological syndrome and exposure to SARS-CoV-2), exposed controls (peripheral neurological syndrome and with exposure to SARS-CoV-2) and unexposed controls (without neurological syndrome and without exposure). Exposure was defined as positivity in the molecular test for SARS-CoV-2 in swab or serology (IgG or IgA anti-SARS-CoV-2) in serum or CSF. The neurological syndromes comprised acute brain manifestations and were confirmed by clinical-radiological evaluation by neurologists at the service. Inflammatory cytokines and chemokines were measured using CBA in a flow cytometer. The evaluation of the BBB function was evaluated through the protein profile by gel electrophoresis, with calculation of the CSF:serum coefficients and the reibergrams. Clinical and laboratory data were processed by GraphPad, R and CSF Software Tool software. **Results:** Of the 39 patients, 16 exposed cases (mean 59 years; 33-82), 17 exposed controls (mean 49 years; 26-68), and 7 unexposed controls (mean 37 years; 28-53) were included. When compared with controls exposed and not exposed to SARS-CoV-2, patients with acute neurological syndromes exposed to the virus had significantly ($p<0.05$) higher values of IL-6, CCL2, IL-8 and CXCL9 in both serum and CSF; also showed values of CXCL10 only in serum and CXCL5 in CSF. In the BBB integrity study, there were no significant differences in the values of total proteins and fractions (albumin and IgG) of exposed cases when compared with the other groups. The "reibergrams" indicated the absence of total intrathecal IgG production in the three groups. **Conclusion:** Patients with ANM associated with subclinical SARS-CoV-2 infections did not show signs of BBB breakdown or intrathecal production of immunoglobulins. Despite not presenting systemic manifestations of COVID-19, these patients presented increased values in both serum and CSF of some cytokines involved in the systemic inflammatory response. In turn, the highest CXCL5 values only in the CSF suggest that it may have a role in the neurological manifestations in our sample.

Case presentation: A 42-year-old male, with a history of alcohol abuse and bedridden status, was admitted to the emergency department due to a two-month history of temporospatial disorientation with disorganized speech, which had worsened in the past 48 hours. The patient also exhibited anorexia and paraparesis, which had begun a year prior and progressively worsened over the past four months, eventually leading to an inability to walk. Physical examination revealed pale mucous membranes, afebrile status, spastic paraparesis, tactile and pain hypoesthesia in a "glove" distribution, and reduced vibratory sensation in the lower limbs. Initial supportive measures were provided, and laboratory tests showed pancytopenia associated with vitamin B12 deficiency (104.7 pg/mL). Cranial magnetic resonance imaging (MRI) revealed T2/FLAIR hyperintensity in the corticospinal tracts, while thoracic spinal MRI showed T2/FLAIR hyperintensity in the posterior columns of the spinal cord (inverted "V" sign). No abnormal gadolinium enhancement was observed.

Discussion: Subacute combined degeneration of the spinal cord is a neurological complication that affects neuronal myelin integrity due to vitamin B12 (cobalamin) deficiency, either from nutritional deficiency or inefficient absorption. While this condition is more prevalent in the elderly and often associated with pernicious anemia due to cobalamin malabsorption, it's crucial to consider it in alcoholic patients. Clinical manifestations include sensory deficits, paresthesia, weakness, and gait disturbances, which can progress to paraplegia. Laboratory analysis may reveal anemia, macrocytosis, leukopenia, and thrombocytopenia. Additionally, methylmalonic acidemia and homocysteine levels should be measured when characteristic findings are present but vitamin B12 levels are normal or borderline. Imaging studies should also be conducted to rule out other neurological causes; however, in patients with this condition, thoracic spinal MRI may reveal bilateral paired regions of hyperintensity in the dorsal portions of the spinal cord, forming the inverted "V" sign, and in critical cases, there's an increased likelihood of involvement of the lateral columns. Treatment involves cobalamin supplementation via intramuscular injections followed by an oral maintenance protocol. **Final comments:** Subacute combined degeneration is a rare condition typically associated with macrocytic anemia. However, it can also present with pancytopenia, an even rarer association, making it imperative to consider vitamin B12 deficiency in patients with hematologic abnormalities. Prognostic factors indicating a more favorable outcome include age under 50 years, a brief disease course, and the absence of sensory deficits. Moreover, prompt initiation of treatment can arrest disease progression and significantly reduce the risk of permanent neurological damage.

Subacute paraneoplastic cerebellar ataxia syndrome in Hodgkin's lymphoma: a case report

Larissa Canela Ruiz Evangelista[1], Ana Beatriz Esteves Pires[1], Sarah de Souza Chinelato[1], Luiz Henrique Soares Santos Stefano[1]

[1]Faculdade de Medicina de Marília, Marília SP, Brazil.

Correspondence: Larissa Canela Ruiz Evangelista; Email: larissacanelaruiz30@gmail.com.

Case presentation: We report the case of a 47-year-old male patient diagnosed with Hodgkin lymphoma during evaluation and treatment of subacute cerebellar ataxia syndrome. In July 2021, the patient presented with vertigo, frequent headaches, bilateral visual blurring, slurred speech, dysphagia, and difficulty walking, rapidly evolved to oromandibular dystonia. Six months after that, he sought neurological care, with appendicular ataxia, inability to walk, dysdiadochokinesia, diplopia, photophobia, visual scotomas, and scanning speech. Laboratory and neuroimaging exams revealed signs of gliosis and cerebellar atrophy, suggesting a previous ischemic event. Cerebrospinal fluid analysis showed no significant alterations. The patient received human immunoglobulin, exhibiting partial symptom improvement, yet maintained significant ataxia associated with orthostatic incapacity. Three months after hospitalization, he developed painful cervical nodules, nocturnal fever and weight loss, which led to a diagnosis of advanced-stage classical Hodgkin's lymphoma, with enlarged cervical and axillary lymph nodes and lytic bone lesions in the spine. The palliative treatment was recommended due to the unfavorable prognosis and the impossibility of an emergency chemotherapy. **Discussion:** Paraneoplastic syndromes are rare complications of neoplasms outside the central nervous system, frequently preceding tumor detection. Subacute paraneoplastic cerebellar ataxia syndrome (SPCA) is characterized by cerebellar dysfunction, such as appendicular ataxia, vertigo, visual abnormalities, nystagmus, dysarthria, and scanning speech, with subacute onset and rapid progression to severe ataxia within less than a month. This condition is immunologically mediated, resulting in partial destruction of Purkinje cells, astrogliosis and cerebellar demyelination and the neoplasms associated with SPCA include ovarian, breast, lung carcinomas, and lymphomas. The diagnosis of SPCA involves excluding metastases and other neoplasms through laboratory exams, neuroimaging and identification of onconeural antibodies. The magnetic resonance imaging provides superior visualization of the cerebellum, and the laboratory tests include complete blood count, glucose, liver function tests, and cerebrospinal fluid analysis to rule out metabolic disorders and infections. Neurological complications in neoplasms may occur through direct or indirect immune-mediated mechanisms. Therefore, early identification and treatment of the primary neoplasm can reduce neuroimmunological symptoms; furthermore, aggressive immunotherapy, intravenous immunoglobulin, plasmapheresis, corticosteroids, and immunosuppressants are considered therapeutic options with variable response. **Final comments:** In this reported case, immunotherapy resulted in partial improvement of symptoms and, due to the advanced stage of Hodgkin's lymphoma, a palliative approach was adopted, preceding any investigation of onconeural antibody panels.

Subacute spinal cord degeneration due to vitamin B12 deficiency in an alcoholic patient

Marcelo Simplicio Carvalho[1], Nathalye Fernanda Pedroso Dircksen[1], Felipe Leonardo Semensati[1], Fábio Gonçalves[1], Letícia de Barros Dias[1], Lorena Fernandes Kronbauer[1], Mônica Meneguette Silveira[1], Barbara Okabaiasse Luizeti[1], Damacio Ramon Kaimen Maciel[1], Mônica Marcos de Souza[1]

[1]Santa Casa de Londrina, Londrina PR, Brazil.

Correspondence: Marcelo Simplicio Carvalho; Email: marcelo.neurolog@gmail.com.

Case presentation: Male patient, 42 year old, heavy drinker, was admitted to the emergency room, complaining of difficulty walking started 10 days ago, followed by paresis of the flexor muscles of the hands and paresthesia on the back of the feet, on neurological examination: areflexia of deep reflexes, sensitive ataxia, diffuse hypopalestesia. The patient denied fever, allergies and infectious prodromes. On admission, skull tomography, chest radiography and electrocardiogram tests showed no changes. Performed analysis of cerebrospinal fluid (CSF) revealed leukocytes 1, glucose 49, lactate 2.2, proteins 25.7, and absent fungi. Serological and laboratory tests showed no significant reactivity, except for herpes simplex IgG reagent and Epstein-Barr IgG positive. CBC and liver function were normal, with blood glucose and lipid profile within the expected limits. Vitamin B12 was in 213 pg/ML elevated homocysteine (33.90 µmol/L). MRI scans of the dorsal and cervical spine revealed diffuse prominence in the pachimeninge region and venous vascular structures of the cervical spinal canal, changes in the posterior aspect of the spinal cord compatible with subacute combined degeneration due to vitamin B12 deficiency. Patient was treated with Vitamin B12 replacement, evolving with neurological gains. **Discussion:** The patient presents a picture of subacute combined degeneration of the spinal cord due to vitamin B12 deficiency, associated with toxic-metabolic polyneuropathy, exacerbated by excessive alcohol consumption. Clinical and radiological findings are compatible with a subacute myelopathy, often related to vitamin B12 deficiency, which can lead to degeneration of the dorsal and lateral columns of the spinal cord, resulting in severe neurological symptoms such as paresthesia, paresis and loss of proprioception. Vitamin B12 deficiency is commonly associated with pernicious anemia and can be precipitated or exacerbated by chronic alcohol consumption, which interferes with the absorption of essential nutrients. Low vitamin B12 (213 pg/ML) and elevated homocysteine (33.90 µmol/L) reinforce the diagnosis. The absence of significant changes in other laboratory and imaging tests suggests that the main etiology of the patient's symptoms is related to vitamin B12 deficit. **Final comments:** The case highlights the importance of considering nutritional and toxic-metabolic causes in patients with progressive neurological symptoms and a history of substance abuse. Early identification and proper treatment of vitamin B12 deficiency is crucial to prevent permanent neurological damage. In this patient, vitamin B12 supplementation and cessation of alcohol consumption were essential for neurological recovery.

Background: Subarachnoid hemorrhage (SAH) is bleeding into the subarachnoid space of the brain, frequently caused by ruptured aneurysms, and may present with severe headache, neck stiffness, and loss of consciousness. SAH is a medical emergency that reflects social and economic inequalities, affecting different groups in disparate ways. Effective treatment depends on rapid diagnosis and a comprehensive understanding of the social determinants of health. **Objective:** To investigate the correlation between SAH mortality and socioeconomic indicators (SI) in Brazil from 2016 to 2021. **Methods:** This is a retrospective study with a quantitative approach, utilizing data from the Mortality Information System (SIM) of DATASUS, according to the International Classification of Diseases (ICD-10), and the Human Development Atlas (HDA) in Brazil, for the years 2016 and 2021. The average SAH mortality rate for each federative unit was calculated from the annual mortality rates (deaths due to SAH / resident population * 100,000). The human development index (HDI) and its sub-indices (education, longevity, and income) were analyzed. Through simple linear regression with a 95% confidence interval, the Pearson correlation coefficient (r) was obtained for the correlation between average mortality and socioeconomic indicators. **Results:** Statistically significant ($p<0.05$) and positive correlations ($r>0$) were observed between SAH mortality and the overall HDI (r=0.56), HDI-education (r=0.53), and HDI-longevity (r=0.42). However, the HDI-income index did not demonstrate a significant correlation. The state of São Paulo reported the highest average SAH mortality rate (3.42), whereas Acre exhibited the lowest average (1.19). These regional disparities highlight notable differences in SAH mortality rates across the states. **Conclusion:** As the level of human development increases, measured by access to healthcare, education, and income distribution, so does the impact of SAH on total deaths. This relationship is attributed to factors associated with regions with high human development, such as a large geriatric population, availability of diagnostic equipment, early screening, access to primary care, strict reporting practices, and conditions inherent to industrialization, as well as occupational exposure to carcinogenic agents, which may contribute to these findings.

Subarachnoid hemorrhage with anterior wall ST segment depression (1-V4): a rare electrocardiographic change in acute brain disease

Amauri Pereira da Silva Filho[1], Danielle Cortellazzi Colonna Romano[2], Gabriela Yumi Nakamura[2], Melissa Fernandes Vilela de Freitas[2], Natália Rebeca Karpejany[3], Sabrina Borges Batista[2], Taianara Sampaio Reis[3]

[1]Hospital de Emergência e Trauma Dom Luiz Gonzaga Fernandes, Campina Grande PB, Brazil.
[2]Universidade Nove de Julho, São Paulo, São Paulo SP, Brazil.
[3]Universidade Federal do Piauí

Correspondence: Amauri Pereira da Silva Filho; Email: amauri.filho@yahoo.com.br.

Case presentation: A 45-year-old patient arrived at the emergency department with a sudden, severe headache, described as the worst of their life, accompanied by nausea, vomiting, and significant chest discomfort. Vital signs showed hypertension with a blood pressure of 190/120 mmHg and a heart rate of 130 bpm; the respiratory examination was normal. Neurological examination yielded a Glasgow Coma Scale of 15, isocoric and reactive pupils, no appendicular deficits, and mild nuchal rigidity (+1/+5). The patient underwent an immediate non-contrast CT scan which returned normal results. An ECG indicated ST-segment depression from V1 to V4, while routine laboratory tests were normal. Given the suspicion of subarachnoid hemorrhage and acute coronary syndrome, further investigations included a lumbar puncture and ultra-sensitive troponin measurement. The cerebrospinal fluid appeared xanthochromic with numerous red blood cells, and troponin levels were at the upper limit of normal. Following clinical stabilization, cerebral arteriography identified a 3mm aneurysm at the right posterior communicating artery, and cardiac catheterization showed no ischemic heart disease. The ECG changes were attributed to acute pain and a significant rise in blood pressure, mimicking acute coronary syndrome. **Discussion:** Subarachnoid hemorrhage (SAH) with ST-segment depression in anterior leads (V1-V4) is a rare but significant electrocardiographic finding in acute cerebral disorders. SAH, often caused by aneurysm rupture or trauma, can lead to neurological and cardiac manifestations due to the brain-heart interaction. ST-segment depression, typically associated with cardiac ischemia, often indicates neurogenic stunned myocardium rather than coronary artery disease in this context. This results from a surge in catecholamines due to acute brain injury, causing transient myocardial dysfunction. Recognizing these patterns as indicative of SAH's secondary cardiac effects is crucial for appropriate management and improved outcomes. **Final comments:** This case highlights the complexity of the correlation between cardiac manifestations and acute neurological events like SAH. Identifying electrocardiographic changes, specifically ST-segment depression, underscores the importance of integrated management of neurological and cardiac conditions. These findings emphasize the need to consider neurogenic stunned myocardium in SAH patients, recognizing that ECG changes may be neurally mediated rather than due to primary coronary disease. Ongoing investigation and treatment algorithms addressing both neurological and cardiac complications are essential for improving outcomes and patient quality of life.

Subdural empiema due to contiguity of sinusopathy

Lorena Fernandes Kronbauer[1], Letícia de Barros Dias[1], Fábio Gonçalves[1], Felipe Leonardo Semensati[1], Nathalye Fernanda Pedroso Dircksen[1], Marcelo Simplicio Carvalho[1], Bárbara Okabaiasse Luizeti[1], Mônica Meneguette Silveira[1], Damacio Ramon Kaimen Maciel[1], Monica Matos de Souza[1]

[1]Irmandade Santa Casa de Londrina, Londrina PR, Brazil.

Correspondence: Lorena Fernandes Kronbauer; Email: lorenafkronbauer@gmail.com.

Case presentation: DMS, 65 years old, holocranial headache with frontal predominance for 15 days, mental confusion, edema in the left orbital and periorbital region, and presented congestion of the left maxillary sinus and hypodensity in the left frontal. Lumbar puncture: leukocytes 213 - predominance of lymphocytes, glucose 68, protein 186, with negative fungal analysis or culture.. She underwent therapy with ceftriaxone and vancomycin. After 5 days, course with right hemiparesis and clear appearance of left frontal subdural empyema adjacent to the frontal hypodensity; There was a decrease in the level of consciousness, with worsening hypodensity e now with left subdural empyema. Subjected to drainage, without clinical response. Metronidazole, amphotericin and polymyxin added. The exams did not demonstrate cavernous sinus thrombosis or any other finding that could explain the ocular edema. Cerebrospinal fluid culture, culture of secretion drained from the empyema and brain biopsy were performed, with negative results. Patient died. **Discussion:** The most affected are young male adults. There is difficulty in relating cause and effect between meningitis and sinusitis because, un like abscesses, it mostly originates from chronic sinusitis. The clinical picture includes fever, headache that increases in intensity, neck stiffness, irritability and delirium. There are two routes of infection from the paranasal sinuses to the intracranial cavity: Retrograde thrombophlebitis through diploic veins of the skull and ethmoid bone or communicating veins (Breschet's diploic veins) - by continuity; and by direct extension of sinus infection through congenital or traumatic dehiscences, erosion of the sinus wall, that is osteomyelitis, and existing foramina (e.g. olfactory nerves) - contiguity. Complications: meningitis, epidural abscess, subdural empyema, venous sinus thrombophlebitis and brain abscess. The frontal sinus is the most commonly associated with intracranial infection. In subdural empyema, only large collections cause a mass effect, leading to the appearance of an evident clinical picture. Anaerobic germs represent 29% of endocranial complications. Non-betahemolytic streptococcus are the most commonly found. Staphylococcus is isolated in subdural empyemas and brain abscesses, as well as in cavernous sinus thrombophlebitis and osteomyelitis. Pneumococcus and Haemophilus influenzae are more commonly found in meningitis of upper respiratory tract etiology. Anaerobes may occur in up to 50% of non-traumatic brain abscesses. Negative cultures occur in 21% of cases. **Final comments:** A CNS infection resulting from infectious sinusopathy is serious, includes disabling sequelae and is difficult to diagnose due to the chronicity of the symptoms and the exclusive attribution of the symptoms to sinusopathy, as in the case of our patient. CSF and empyema cultures have high rates of false negatives.

https://doi.org/10.5327/CBN241566

Subsyndromal delirium as a predictor of death, loss of independence and functionality in post-stroke patients in the semi-intensive care unit

Thaís Barbosa de Oliveira[1], Gabriel Souza Medrado Nunes[1], João Pedro Fernandes Gonçalves[1], Alex de Cerqueira Silveira Figueiredo[1], Antonio Lázaro Santos Soares Junior[1], Felipe Asaf Borges Millard[1], Júlia Xavier Oliveira[1], Pedro Antônio Pereira de Jesus[1]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.

Correspondence: Thaís Barbosa de Oliveira; Email: thaisbo@ufba.br.

Background: Delirium is an acute, fluctuating confusional state defined by attention disturbances, associated with altered consciousness and/or disorganized thinking. It is common in semi-ICU settings and often underdiagnosed, leading to clinical deterioration, increased mortality, and functional decline. Previous studies also suggest that intermediate stages between normal cognition and delirium can hinder recovery. Patients with acute cognitive dysfunction, not meeting full delirium criteria–subsyndromal delirium (SSD)–may benefit from interventions due to their poorer prognosis compared to those without cognitive symptoms. This is especially relevant for post-stroke patients, as stroke-related brain injury lowers the threshold for cognitive impairment. **Objective:** This study investigates the association between SSD and functional loss in post-stroke patients, and whether SSD differs significantly from asymptomatic conditions. **Methods:** This prospective cohort study was conducted in a semi-ICU for stroke at a hospital in Bahia, Brazil, from 2023 to 2024. Eligible patients had a confirmed stroke diagnosis within 72 hours of symptom onset, excluding those under age of 18, unresponsive at admission, or diagnosed with blindness, complete hearing loss, severe aphasia, and/or dysarthria. Patients were screened for delirium using the Confusion Assessment Method for the ICU (CAM-ICU) every 2 days for up to 30 days. They were classified into 3 groups: non-delirium (4 negative criteria in all assessments), SSD (at least one altered criterion without fulfilling delirium diagnosis), and delirium (positive CAM-ICU test in at least one assessment). The main outcome was independence, functionality, or death, assessed by the Modified Rankin Scale (mRS) ninety days after stroke onset. **Results:** Two hundred sixty-two patients were enrolled, mostly women [138 (52.7%)], brown and hispanic individuals [131 (50%)], with a mean age of 65.34 (±12.4) years-old. The most common highest educational level was primary education [125 (47.7%)]. The mean for Short IQ-Code score was 3.13 (±0.82), 108 (41.2%) participants had a Charlson Comorbidity Index > 5 and most were independent and fully functional before the stroke (mRS < 2) [220 (84.0%)]. The median NIHSS at admission was 7.0 [IQR 4-13], with most cases being ischemic stroke [245 (93.5%)], and 109 (41.6%) were thrombolyzed. Univariate analyses showed a significant difference between non-delirium and SSD groups for mRS-90 < 2 [OR=2.60, 95% CI 1.32-5.09], though smaller than between non-delirium and delirium groups [OR = 10.8, 95% CI 3.67-31.80]. Multivariate analysis confirmed SSD as an independent predictor for mRS-90 <2 (p<0.001), compared to non-delirium. NIHSS at admission (p=0.011) and hospitalization duration (p<0.001) were also independent predictors for mRS-90 <2. **Conclusion:** Subsyndromal delirium predicts loss of functionality, dependency, or death within 90 days after stroke onset in a semi-ICU setting.

Successful use of immunoglobulin as a treatment for post-infectious cerebellitis related to dengue fever refractory to steroids

João Vitor Assumpção Silva[1], Henrique de Moraes Bernal[1], Pedro Almeida Martins Pontes[1], Ingrid Lorena da Silva Gomes[1], Herval Ribeiro Soares Neto[1], Sônia Maria César Azevedo[1]

[1]Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo SP, Brazil.

Correspondence: João Vitor Assumpção Silva; Email: joaosilva7890@hotmail.com.

Case presentation: A 17-year-old boy presented with difficulty standing and walking, along with a sense of imbalance, slurred speech, severe drowsiness, and vertigo. Additionally, he experienced uncontrollable nausea and vomiting refractory to symptomatic medications. The patient's medical history included only atopic dermatitis. Dengue, confirmed by NS1 test, was diagnosed 7 days prior to the onset of neurological symptoms. On examination, the patient was drowsy but responsive to commands, with slurred and scanning speech. Notable findings included bilateral ptosis, opsoclonus, hypermetric saccades,

saccadic pursuit, and significant axial and appendicular ataxia. He was unable to stand or walk without assistance, displaying a wide-based gait. When administering the MoCA test, the patient scored 20 points. Cerebrospinal fluid (CSF) analysis and brain MRI revealed no abnormalities. Serum tests for viral infections, including EBV, Varicella, HIV, Hepatitis, and Herpes Virus, were negative. Treatment with intravenous methylprednisolone (1g/day for 5 days) was initiated, followed by intravenous human immunoglobulin (IVIG) (0.4mg/kg/day for 5 days). After treatment, the patient achieved independent ambulation, and cerebellar symptoms markedly improved. At the conclusion of the treatment, the patient scored 24 points at MoCA. **Discussion:** Acute cerebellar ataxia is characterized by the acute onset of appendicular and axial ataxia associated with symptoms such as nystagmus, hypotonia, dysarthria, and gait disturbances. Causes are divided according to the nosology. This is the tenth reported case of post-infectious cerebellitis related to dengue worldwide. Initially reported in 2012, this condition was first associated with EBV before being observed in isolated cases of dengue infection. Currently, the disease mechanism is believed to involve both viral invasion of the central nervous system and an immune-mediated response. The prevailing hypothesis posits that dengue triggers a 'cytokine storm,' leading to endothelial injury, blood-brain barrier disruption, fluid leakage, and subsequent brain damage. Cerebellar involvement may occur during the acute phase but typically manifests 1 to 3 weeks after the onset of dengue symptoms. Neuroimaging abnormalities are rare, and cases currently described in the literature haven't demonstrated abnormal CSF analysis. Some cases are self-limiting and may not require therapy. When treatment is necessary, corticosteroids are the initial option. In this case, the decision to administer IVIG was based on the lack of response to high-dose corticosteroid therapy and supported by literature for its use in refractory post-viral cerebellitis. **Final comments:** Post-infectious acute cerebellar ataxia must be promptly recognized and investigated as it is a treatable condition with a generally favorable outcome. IVIG should be considered in patients who do not respond adequately to steroids.

Sudden unexpected death in epilepsy (SUDEP): a retrospective longitudinal study of the Brazilian population over the last 10 years

Elvis Lucas Rabelo Shintay Chan[1]

[1]Universidade Federal de Ouro Preto, Ouro Preto MG, Brazil.

Correspondence: Elvis Lucas Rabelo Shintay Chan; Email: elvislucaschan2011@hotmail.com.

Background: Sudden Unexpected Death in Epilepsy (SUDEP) still has an etiology that is not yet fully known, and it is suggested that death occurs in the context of a seizure, which usually occurs at night, during sleep. Cardiogenic, pulmonary and neurogenic causes have been suggested. However, this event is not always witnessed and the diagnosis is not always possible. Although relatively uncommon, SUDEP represents between 2 and 18% of all deaths in patients with epilepsy, thus having a significant impact on the survival. **Objective:** This study sought to evaluate the epidemiology of SUDEP in relation to the Brazilian population, with a view to identifying risk factors or confirming what has already been observed in the population of other countries. METHOD: Epidemiological data on SUDEP between 2013 and 2022 were extracted from the Department of Informatics of the Unified Health System (DATASUS), from the Brazilian Ministry of Health. The outcomes analyzed were incidence by year, incidence by sex, incidence by skin color and mortality by age group, considering 10-year-old intervals. Descriptive and inferential statistical analysis was used to compare variables. **Results:** There were 31959 cases, with a statistically significant increase from 2020 onwards (p=0.004905401). There were more male deaths, in a ratio of 1.85:1 and with a significant difference between the groups (p=0.000210717). The highest incidences occurred in white people and pardo people, but without significant difference (p=0.4307446). There was a significant difference between the incidence between white and black individuals (p=0.00001572). Asian and indigenous populations could not be compared due to the small sample size. Regarding the age group, those who accounted for the majority of cases were between 40 and 49 years old (16,5%), 50 and 59 years old (16,68%), 60 and 69 years old (12,9%), 70 to 79 years old (10,15%) and 80 years old or more (10,3%). CONCLUSIONS: The increase in the incidence of SUDEP raises a warning about the need for careful monitoring of these patients, since one of the main risk factors is the lack of supervision. This implies less medical monitoring and risk of new crises. In fact, the increase observed occurred in 2020, when many individuals lost close contact with family members and health services during the Covid-19 pandemic. The greater occurrence of events in male patients follows the international literature. The differences observed in the incidence by skin color can be explained by genetic factors, since an association with genes related to sodium channelopathies, congenital heart diseases and some syndromes has already been identified. The prevalence of these mutations in the Brazilian population is, however, unknown. Finally, this work showed a higher proportion of cases occurring in people over 40 years of age, which contradicts other authors, who despite this already mention in their works the possibility of underreporting in this age group.

SUNCT: a challenging diagnosis

Márcio Alves da Cruz Júnior[1], Iasmim Portela Maifrede[1], Carlos Eduardo Reis Silva[1], Maria Paula Cezar de Castro[1], Luiz Paulo Bastos Vasconcelos[1]

[1]Universidade Federal de Juiz de Fora, Juiz de Fora MG, Brazil.

Correspondence: Márcio Alves da Cruz Júnior; Email: marcio.jr14@yahoo.com.br.

Case presentation: Case 1: JARL, a 54 years-old male patient, diagnosed with bipolar affective disorder, reported a new headache in 2016, characterized by shock pain in the right temporal/retro-orbital region, of severe intensity, lasting 60 seconds and associated with ipsilateral tearing and ocular hyperemia. The pain was triggered by chewing and tactile stimulation in the supra-orbital region of the right eye and had a frequency of 15 to 20 episodes per day. Initially, he was diagnosed with trigeminal neuralgia (TN). He used carbamazepine and gabapentin in optimized doses, without success. After confirming the diagnosis of SUNCT by ICHD-3 criteria, lamotrigine was started. After 6 months of follow-up, the patient had complete pain resolution at a dosage of 200mg/day. Case 2: FCR, a 71 years-old male patient, previously healthy, started experiencing headaches in 2016, characterized by excruciating shock/stabbing pain in the left orbital and parietal regions, with dozens of daily episodes, associated with tearing and ipsilateral conjunctival hyperemia . His condition worsened in 2018, after starting to use a dental prosthesis in the upper arch. Initially, he was diagnosed with TN and later with cluster headache (CH). He used carbamazepine and gabapentin for neuralgia, without success. The use of verapamil 240mg/day for CH resulted in little relief in the intensity of the attacks. The diagnosis of SUNCT by ICHD-3 criteria was performed and lamotrigine was prescribed. After 1 year of follow-up, the patient had complete control of the condition at a dosage of 300 mg/day. **Discussion:** The short-lasting unilateral neuralgiform headache attacks with conjunctival injection and tearing (SUNCT) are included in the trigemino-autonomic headaches (TCAs) group, listed in ICHD-3. In both patients presented, the initial diagnosis was attributed to other types of facial pain, such as CH and TN, given their semiological similarities. SUNCT and CH are listed in the TCAs group and share clinical characteristics such as the same pain territory and the presence of autonomic symptoms. The differential diagnosis between them is based mainly on the frequency and duration of pain attacks. Regarding NT, the similarities with SUNCT include pain in the trigeminal territory, the presence of pain trigger zones upon touch and stabbing/shock pain. The differential diagnosis is mostly based on the manifestation of autonomic symptoms in SUNCT and on the preferential involvement of the V2 territory of the trigeminal nerve in TN. **Final comments:** SUNCT is rare and may lead to severe functional disability. Both clinical cases presented here illustrate how its diagnosis is challenging. The objective of this report is to reinforce the importance of a detailed cephaliatric assessment to differentiate the types of CTAs. Furthermore, it is important to highlight that facial shock pain is not defining of TN, as it also occurs in SUNCT and other facial neuralgias.

SUNHA case report: exceptional response to lacosamide treatment

Verena Miranda de Souza[1], Felipe Franco da Graça[1], Hiago Antunes Silva[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Verena Miranda de Souza; Email: vemirandasouza@gmail.com.

Case presentation: A 90-year-old individual presented with a new-onset headache described as a severe stabbing pain in the right supraorbital region, lasting for seconds to minutes, associated with photophobia, ipsilateral rhinorrhea and bilateral lacrimation. The pain was triggered by any local tactile stimulus, followed by a period of pain relief, without suspending it. Neurological examination did not reveal any noteworthy abnormalities. Therapies with carbamazepine and gabapentin were initiated with improvement in the frequency and intensity of pain. However, the patient continued to require rescue analgesic therapies. After two weeks, carbamazepine was discontinued due to major-like drug-induced erythema multiforme. The following month, a headache exacerbation led to another hospitalization. Therapeutic attempts were made but failed to significantly released the pain: levetiracetam, valproic acid, chlorpromazine, dexamethasone and anesthetic blocks. Subsequently, lacosamide was initiated at a dose of 100 mg intravenously every 12 hours leading to significant improvement in headache, allowing hospital discharge with maintenance of oral medications and suspension of corticosteroids and chlorpromazine. Due to effective pain management, the dosages of valproic acid and gabapentin were gradually reduced on an outpatient basis without pain recurrence. The patient is currently on lacosamide 100mg/day and gabapentin 600mg/day, maintaining complete headache control. **Discussion:** Short-lasting unilateral neuralgiform headache attacks (SUNHA) are similar to V1 trigeminal neuralgia, with autonomic features and no refractory period to cutaneous triggering. Classified in two subtypes: Short-lasting unilateral neuralgiform headache attacks with conjunctival injection and tearing (SUNCT) and Short lasting unilateral neuralgiform headache attacks with cranial autonomic symptoms (SUNA). Since attacks are short, medical therapy is primarily preventive. Lamotrigine is the treatment of choice for SUNCT and SUNA, with a clear dose-response relationship. As a second line there are an assortment of therapies used for trigeminal neuralgia and other syndromes: oxcarbazepine, duloxetine, topiramate, carbamazepine, gabapentin and pregabalin. In a prospective, open and non-randomized, single-center study of the six patients who tried lacosamide two reported improvement in headache (33%). Both of these patients were considered responders but required a dose higher than the recommended 300 mg daily to achieve a beneficial effect. This report describes a case of SUNHA

refractory to several medications but showing an excellent response to low-dose lacosamide, offering another treatment option for this condition. **Final comments:** So far, there is no consistent evidence for the use of lacosamide in the treatment of SUNHA. Further studies with larger sample sizes are needed to evaluate the true efficacy of lacosamide in this condition.

Sunken eyes as a peculiar finding in neuronal ceroid lipofuscionoses

Raphael Pinheiro Camurugy da Hora[1], Victor Rebelo Procaci[1], Thiago Yoshinaga Tonholo Silva[1], Flávio Moura de Rezende Filho[1], José Luiz Pedroso[1], Orlando Graziani Povoas Barsottini[1], Manuela Magalhães Dardenne Tenório[1], João Victor Cabral Correia Férrer[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Raphael Pinheiro Camurugy da Hora; Email: raphaeldahora@hotmail.com.

Background: Neuronal ceroid lipofuscinoses (NCLs) are lysosomal storage disorders characterized by progressive neurodegeneration and the accumulation of autofluorescent lysosomal storage material called lipofuscin. These disorders result from genetic mutations causing enzymatic dysfunction, with certain types associated with lysosomal enzyme deficiencies and others with mutations in genes encoding transmembrane proteins, ATPase, and potassium channels. Sunken eyes are characterized by deeply recessed eyes within the orbits, resulting in a hollowed appearance, often associated with prominent, bushy brows, narrow palpebral apertures, hooded eyelids, and prominent noses. This facial abnormality is hardly ever described in patients with NCLs, such as in a Turkish series, and could be more frequent than previously though **Objective:** This study aims to report a unique clinical finding of sunken eyes in a Brazilian family with NCL type 2, suggesting it may be a previously under-recognized feature of the disorder. **Methods:** A case series approach was used to document the clinical presentation, genetic testing, and neurological assessments of three siblings with NCL type 2. **Results:** Case 1: A 41-year-old man presented with progressive ataxia, generalized seizures, severe imbalance, dysarthria, dysphagia, and was restricted to a wheelchair. Neurological examination revealed sunken eyes, and brain MRI showed olivopontocerebellar atrophy. Genetic testing identified a pathogenic variant in the TPP1 gene. Case 2: A 42-year-old woman exhibited unsteady gait, motor incoordination, emotional lability, and aggressive behavior, leading to wheelchair dependency by age 14. Similar neurological features and olivopontocerebellar atrophy were observed, with sunken eyes noted upon examination. Genetic testing supported a diagnosis of NCL type 2. Case 3: A 37-year-old woman experienced seizures from age 3, progressing to gait imbalance and slurred speech. Her examination also showed sunken eyes and other neurological symptoms, with brain MRI revealing olivopontocerebellar atrophy. A presumptive diagnosis of NCL type 2 was made based on familial genetic results. **Conclusion:** This case series highlights sunken eyes as a notable clinical feature in patients with NCL type 2. This finding, potentially linked to malnutrition and disease severity, suggests that sunken eyes could be an indicator of the progression of NCLs. Further research is warranted to explore this association and its implications for clinical practice.

Superficial siderosis of the central nervous system: cause of sensorineural deafness and cerebellar ataxia - case report

Mário Natalício de Gasperi[1], Claudio Henrique do Amaral[1], Paulo Roberto Wille[1]

[1]Universidade da Região de Joinville, Joinville SC, Brazil.

Correspondence: Mário Natalício de Gasperi; Email: mario.natalicio2@gmail.com.

Superficial siderosis of the central nervous system is a clinical entity discovered in 1908 by Hamill with the classic symptoms of progressive bilateral sensorineural deafness, cerebellar ataxia, imbalance and sometimes myelopathy. Its clinical findings are very rare in the population, with around 300 cases reported in the literature around the world. **Case presentation:** M.B.R, 73 years old, male, started 3 years ago with progressive bilateral hearing loss and imbalance when walking. He denied dizziness. History: severe head trauma 15 years before the first symptoms, systemic arterial hypertension, atrial fibrillation, benign prostatic hyperplasia and no history of surgery. Family history, nothing noteworthy. Former smoker and reports social alcohol consumption until the age of 62. Currently using Fluoxetine, doxazosin, simvastatin, losartan and apixaban. In the neurological examination, he is conscious, oriented, with preserved speech, severe bilateral hearing loss, other cranial nerves preserved, motor strength and sensitivity preserved, symmetrical reflexes, mild bilateral dysmetria, without didiadokinesia, Romberg test with mild instability, Tanden without conditions to perform and ataxic gait. Skull MRI in ferromagnetic susceptibility sequences reveals areas of signal void characterizing hemosiderin deposits involving the cortical and sylvian sulci bilaterally in a marked way, the cisterns on the cerebellar folia and perimesencephalic cisterns as well as ambiens and pentagonal and the ependymal cerebrospinal fluid space characterizing superficial hemosiderosis. Fazekas grade 3 leukoaraiosis, signs of volumetric involution of the cerebral and cerebellar hemispheres. **Discussion:** Superficial siderosis of the central nervous system is a rare clinical entity whose main cause of pathophysiology is the leakage of blood into the cerebrospinal fluid, which degrades into free iron, ferritin and hemosiderin, which are deposited in the superficial layers of the central nervous system (CNS) and lead to cellular changes such as reactive gliosis, demyelization, neuronal loss. Among the possible causes of hemorrhage in the subarachnoid space is a previous clinical history of surgical procedures in the posterior fossa, trauma, intradural surgery, spinal tumors or vascular malformations of the CNS; Such bleeding is low in volume, chronic and recurrent and may take decades until the first symptoms of superficial siderosis appear. The classic symptoms are associated with areas of susceptibility of the central nervous system to hemosiderin. **Final comments:** The symptom of bilateral progressive sensorineural deafness and ataxia makes a differential diagnosis with neurosyphilis, multiple sclerosis and other autoimmune causes. The rarity of the incidence of superficial siderosis of the central nervous system makes imaging findings on magnetic resonance imaging an ally in the diagnosis in the face of clinical suspicion.

Surgical outcome in patients with mesial temporal lobe epilepsy and unilateral hippocampal sclerosis associated with calcified neurocysticercosis

Karen Karol Vásquez Quicaño[1], Marina K. Alvim[1], Fabio Rogerio[1], Enrico Ghizoni[1], Clarissa Lin Yasuda[1], Fernando Cendes[1]

[1]Universidade Estadual de Campinas Campinas, São Paulo SP, Brazil.

Correspondence: Karen Karol Vásquez Quicaño; Email: karenvasquez1807@gmail.com.

Background: Calcified neurocysticercosis (cNCC) is considered a frequent etiology of epilepsy in developing countries. In Brazil, cysticercosis is an endemic disease, and seizures are the most frequent symptoms, occurring in up to 92% of patients. **Objective:** This study aimed to analyze postsurgical outcomes of patients with mesial temporal lobe epilepsy with unilateral hippocampal sclerosis (MTLE-HS), with and without cNCC, who underwent surgical treatment. **Methods:** A retrospective cross-sectional study was conducted on 82 patients with MTLE-HS who underwent anterior temporal resection plus amygdalohippocampectomy between January 1997 and December 2020 at the epilepsy center of the University of Campinas Universidade Estadual de Campinas. All patients had ictal semiology indicating MTLE and EEG findings concordant with the side of HS diagnosed with high-resolution 3T MRI epilepsy protocol. The presence of cNCC was determined with CT scans or SWI MRIs. We collected clinical data and neuroimaging information. The postoperative results were analyzed using bivariate analysis according to the Engel classification. Differences in proportions were analyzed using Fisher's exact test. **Results:** The median age was 42.15 years, and 54.87% were women. Thirty-three (40.2%) had multiple cNCC lesions in addition to HS, and 49 (59.8%) did not. Fewer patients with cNCC reported a history of febrile seizures compared to the group without cNCC (2 [6.1%] vs. 7 [14.3%]), but without statistical significance (p=0.3). The mean postoperative follow-up was 12.5 years for those with cNCC and 5.5 years for those without. Overall, 58/82 (70.72%) achieved Engel IA. At the last follow-up, 27/33 patients (81.8%) with cNCC were categorized as Engel IA compared to 31/49 (63.3%) in those without cNCC; however, this difference was not significant (p=0.086). **Conclusion:** Our results confirm previous studies showing that in patients with refractory unilateral MTLE-HS with concordant ictal semiology and EEG findings, cNCC does not change the probability of excellent postoperative seizure control and does not contraindicate surgery. These findings also indicate that the real cause of ongoing seizures in these patients who became seizure-free after surgery was not the cNCC but the HS. Therefore, the finding of cNCC on CT or MRI does not necessarily indicate the etiology of epilepsy, and perhaps neurocysticercosis acts as a precipitating insult in some patients with MTLE-HS.

Surgical outcome in patients with severe epilepsies, intellectual disability and bilateral structural lesions: comparison of the Engel's and the pasis (Porto Alegre seizure impact scale)

André Palmini[1], Eliseu Paglioli[1], Rafael Paglioli[1], Francine Hehn[1], William Martins[1], Vicenzo Zarpellon[1], Thomas Frigeri[1], André Gus[1], Natalie Donida[1], Bibiana Thome[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Andre Luis Fernandes Palmini; Email: alpalmini@gmail.com.

IO: The link between surgery and seizure freedom narrows the spectrum of epilepsy surgery candidacy to people with well localized epileptogenic zones, often with visible lesions. However, many children and adolescents with severe epilepsies, do not "fit" the link, ie, may have surgically remediable epilepsies but without a reasonable expectation of seizure freedom. In many Centers, patients with severe epilepsies, intellectual disability and bilateral structural lesions are not considered suitable for surgery. A recurrent argument is that these patients fall in the unfavorable classes (III, IV) of the Engel's outcome scale. However, moving from a dramatic to a manageable situation honors the ultimate goal of epilepsy surgery, ie, to significantly improve the life of patients and families. Many have a potential surgical target, and although

seizure freedom is not likely, the prospect of shorter and milder seizures, eliminating the need to frequent visits to the emergency room and preventing developmental regression is a much desirable outcome. Such post-operative gains beyond complete seizure freedom are seldom captured by the Engel outcome scale. We designed the Porto Alegre Seizure Impact Scale (PASIS), quantifying and integrating objective and subjective data following epilepsy surgery, considering changes in frequency, severity, duration and circadian distribution of seizures and post-ictal abnormalities. Here, we present a comparison between the Engel and the PASIS outcome scales in patients with severe epilepsies, intellectual disability and bilateral structural lesions. M: 31 patients with daily focal onset and generalized seizures and bilateral lesions underwent presurgical evaluation followed by resective surgery. All had a history of delayed psychomotor development associated with bilateral structural lesions. Surgical outcome was classified according to both scales. R: Eleven patients had tuberous sclerosis and the other 20 included: 6 with diffuse atrophy due to perinatal hypoxia , 4 with bilateral MCDs, 4 with bilateral cortico-subcortical encephalomalacia due to severe prematurity, 3 with bilateral cortico-subcortical abnormalities due to meningitis/encephalitis; and one each with diffuse MRI atrophy due to chromosomal translocation or CDKL5 mutation. Mean pre-operative PASIS score was 11 (range: 9 - 12) and 4.3 (- 4 to + 16) after operation. 24/31 (77%) patients were on PASIS 1, 5/31 (16%) on PASIS 2 and the other two on (7%). In comparison, only 7/31 (23%) were in Engel class I, and the other 24 (77%) in classes III and IV. C: Pragmatic assessment of the impact of surgery in the daily life of patients with severe epilepsies and their families demand an outcome scale that integrates objective and subjective observations. Within this framework, many patients with diffuse brain dysfunction and bilateral structural lesions will be candidates for presurgical evaluation and attain a very significant positive impact with surgery.

Survival analysis in patients with myasthenia gravis in a city in the countryside of the Brazilian Amazon

Marcos Manoel Honorato[1], Abraão Luiz Colares Gualberto[1], Jean Augusto de Sousa Tavares[1], Cleizimara Cavalcante Nunes[1], Ilga Milla Chaves Silva[1], Samuel Oliveira de Amorim[1], Ana Flávia Ribeiro Nascimento[2], Matheus da Silva Ferreira[1], Kelson Vinicius Dallabrida Padilha[1], Átila Barros Magalhães[1]

[1]Universidade do Estado do Pará, Santarém PA, Brazil.
[2]Santa Casa de Misericórdia de Barretos, Barretos SP, Brazil.

Correspondence: Marcos Manoel Honorato; Email: marcos.honorato.dr@gmail.com.

Background: Myasthenia gravis is an autoimmune disease characterized by weakness and rapid fatigue of voluntary muscles. This occurs due to a disruption in communication between nerves and muscles, caused by antibodies that block or destroy acetylcholine receptors at the neuromuscular junction. The survival of patients with myasthenia gravis has significantly improved due to advances in treatments and clinical management of the disease. However, variability in access to treatments and socioeconomic conditions can influence these outcomes, especially in specific regions such as the interior of the Brazilian Amazon. **Objective:** To evaluate the profile and survival of patients diagnosed with Myasthenia Gravis in a city in the interior of the Brazilian Amazon between 2005 and 2020. **Methods:** Historical cohort, observational, and retrospective study. Survival analysis methods were used to identify prognostic factors for disease remission during the 36-month observation period. The correlation between variables and the outcome of death was performed using the chi-square test. **Results:** A total of 36 participants were included in the study. The majority of the patients were female (66.6%) and had the generalized form of the disease (86.1%). The most prevalent symptoms were: ophthalmoparesis (97.2%), fatigue (75%), and dysphagia (72.2%). Among the complications, 19.4% experienced a myasthenic crisis. The dosage of anti-acetylcholine receptor antibody (AChR) was positive in 58.3% of the patients, and 69.4% underwent electroneuromyography, with 72% of these showing an electro-decrement. Most patients responded to the standard stepped treatment and achieved remission (83.3%), while 16.6% died. As some patients did not have complete control, it was necessary to introduce adjuvant therapy with corticosteroids (69.4%), in addition to azathioprine (33.3%) or cyclosporine (25%) in patients resistant to corticosteroid therapy. A portion required thymectomy (19.5%) and 33.5% required hospitalization due to disease exacerbation. Survival analysis using Kaplan-Meier curves and Log-rank test showed that the variables related to poor control were male gender (p=0.01), thymic disease (p=0.01), and the use of cyclosporine (p=0.02). **Conclusion:** The study showed that the progression of individuals with Myasthenia Gravis and our patients had a similar progression to those described in the literature.

https://doi.org/10.5327/CBN241576

Survival analysis of risk factors for the West syndrome's refractoriness in Brazilian Amazon's children

Marcos Manoel Honorato[1], Jonas Wesley Pinto de Lima[1], Kariny Facioni Scalabrin[2] , Jaqueline da Rocha Calvo[1], Marissol Rabelo de Almeida[1], Arthur Severiano dos Santos Pontes[1], Clara Sofia da Silva Oliveira[1], Norma Vitória da Silva Fialho[1], Kelson Vinicius Dallabrida Padilha[1], Samuel Oliveira de Amorim[1]

[1]Universidade do Estado do Pará, Santarém PA, Brazil.
[2]Hospital Adventista de Manaus, Manaus AM, Brazil.

Correspondence: Marcos Manoel Honorato; Email: marcos.honorato.dr@gmail.com.

Background: West syndrome is a severe epileptic encephalopathy characterized by infantile spasms, electroencephalographic pattern with hypsarrhythmia and delay in neuropsychomotor development. It presents a poor prognosis and high morbidity, with direct implications for quality of life. **Objective:** To perform a survival analysis related to the control of seizures in patients with West syndrome, as well as estimate the response to treatment, evaluate the clinical and electroencephalographic evolution and identify the main outcomes and prognostic factors. **Methods:** A retrospective observational study was carried out, analyzing the medical records of 34 patients diagnosed with West syndrome treated between 2005 and 2020 in two specialized services in a city in the interior of the Brazilian Amazon. The research was approved by the Ethics Committee of the Baixo Amazonas Regional Hospital, following international bioethical standards. We calculated the proportions of categorical variables, and then performed a survival analysis with an observation time of 6 months from the first consultation, obtaining Kaplan-Meier survival curves. The Log Rank statistical test was used and the risk rate was calculated. **Results:** The average age at first crisis was 4.9 months. Complications during pregnancy and childbirth were observed in 50% and 47%, respectively, perinatal hypoxia was also reported in 47%. The majority of patients (70%) presented changes in the neuroimaging examination. All patients presented changes in the initial neurological examination, predominantly spasticity (64%) and motor deficit. Among the medications, vigabatrin had the highest frequency of use (51%). Only 41.2% of patients achieved complete control of spasms. The median time to control was 4.5 months. The majority progressed to non-evolutionary chronic encephalopathy or intellectual disability. There was converseion to Lennox-Gastaut Syndrome, progressing to focal epilepsy or other epilepsies, in 58.8%. Only 19% progressed to normal neurodevelopment. The most significant factors for poor seizure control over time were non-use of vigabatrin (p= 0.049, relative risk= 2.73), low birth weight (p=0.05, relative risk= 2.64) and spasticity (p=0.05, relative risk=1.99). **Conclusion:** West syndrome has a variable evolution, but the patients in the study had worse control and outcome percentage, compared to those reported in the most recent literature, which increased the risk of cognitive and motor sequelae. This was possibly due to poor access to specialized medical care in the interior of the Amazon and the low availability of high-cost medications in the initial years of the study. Furthermore, among the therapies most used in treatment, vigabatrin was the only one that proved to be relevant for controlling spasms.

Susac syndrome accompanied by Wernicke: a rare presentation

Márcio Alves da Cruz Júnior[1], Luiz Felipe Mota Freitas[1], Leopoldo Antonio Pires[1], Ana Laura Maciel Almeida[1], Daniel Sabino de Oliveira[1], Thiago Cardoso Vale[1]

[1]Universidade Federal de Juiz de Fora, Juiz de Fora MG, Brazil.

Correspondence: Márcio Alves da Cruz Júnior; Email: marcio.jr14@yahoo.com.br.

Case presentation: A 22-year-old woman, with 9 years of schooling, with a history of chronic alcoholism, use of electronic cigarettes and illicit drugs (LSD, MDMA and cocaine), began experiencing apathy, hyporexia and headache that progressed over a period of one week with weakness of lower limbs and difficulty walking and after two weeks with dizziness, mental confusion and imbalance. On neurological examination, she presented spastic asymmetric tetraparesis with hyperreflexia, anarthria, ataxia, fluctuating consciousness and right hearing loss. Brain MRI demonstrated numerous hyperintense foci on T2/FLAIR throughout the supra and infratentorial white matter, with numerous small foci of diffuse enhancement with a non-perivascular miliary pattern, in addition to signs of supra and infratentorial leptomeningeal enhancement. The presence of high signal foci on T2/FLAIR in the corpus callosum accompanied by headache with hearing loss raised a strong suspicion for Susac syndrome. Cerebrospinal fluid (CSF) identified proteinocytological dissociation, increased CSF IgG and albumin, and absence of oligoclonal bands. Serology was negative for rheumatological analysis and infectious diseases. Given the history of long-term alcoholism combined with mental confusion and ataxia, with the presence of hyperintense lesions in the supra and infratentorial white matter, Wernicke's syndrome hypothesis was made, and the patient underwent vitamin B1 replacement, achieving substantial motor and confusional improvement. However, the patient developed marked cognitive impairment (Montreal Cognitive Assessment - MoCA 15 points out of 30), and upon reassessment in an imaging exam 9 months later, the lesions in the corpus callosum persisted, what led us to suspect of Susac syndrome. **Discussion:** Susac syndrome is a rare disease characterized by the triad of encephalopathy, retinal artery occlusions and hearing loss, with an undefined pathogenesis. We report here a case of leukoencephalopathy with a radiological pattern typical of Susac syndrome, with rapid progression of cognitive decline. The syndrome is marked by presumably autoimmune retinocochleocerebral microangiopathy. The toxic-metabolic and infectious relationships are not well established, however the literature has already shown an association between cocaine use and leukoencephalopathy. CSF examination shows mild lymphocytic pleocytosis and hyperproteinorrhachia, and MRI typically shows lesions involving midline areas of the corpus callosum. Wernicke syndrome can typically present with edematous lesions that can be reversed with the use of

thiamine. **Final comments:** This case shows an association of Wernicke's syndrome with significant clinical and radiological improvement with the use of thiamine, and Susac syndrome with cognitive impairment and hearing loss associated with typical lesions in the corpus callosum.

Correspondence: Luis Fernando Guimarães; Email: luisguimaraesneuro@gmail.com.

Case presentation: A 64-year-old man has progressively developed ataxic gait for approximately 10 years. He was referred to the demyelinating diseases clinic due to lesions in the corpus callosum and other white matter, although with a vascular appearance. Approximately 5 years ago, acute bilateral hearing loss of central etiology (sensorineural hearing loss) began through audiometry (Figure 1). In the last 3 years, he has presented dementia symptoms, behavioral changes, loss of anterograde amnesia, aggressiveness, executive dysfunction and prosopognosia. The magnetic resonance imaging of the brain shows lesions in the corpus callosum and white matter of a vascular nature, volumetric reduction of the hippocampal gyri and cortical atrophy (Figure 2 e 3). His optical coherence tomography shows a reduction in the thickness of nerve fibers in the temporal sector of the right eye and a reduction in the thickness of fires in the foveal region of the left eye (Figure 4). His ocular angiography showed prolonged circulatory time and an increase in the foveal avascular zone in both eyes. In analysis of the clinical findings and complementary exams, the patient was diagnosed with Susac Syndrome and started on immunosuppressants. **Discussion:** Susac syndrome is a rare occlusive microangiopathy (vasculitis) of unknown etiology and mechanism involving retinal arteries, cochlea and brain. Ophthalmological signs and symptoms are the first to be noticed in 50% of cases, encephalopathy affects up to two thirds of patients and is expressed by cognitive changes, headache, personality or behavioral changes. Magnetic resonance imaging shows involvement of the corpus callosum with typical multifocal snowball-shaped lesions on T2. Hearing loss is usually acute and bilateral. The typical age of onset of the disease is between 20 and 40 years of age, but the age range is from 2.5 to 72. It predominantly affects women with an estimated male/female ratio of about 1:3. Treatment generally involves corticosteroids and other immunosuppressants such as mycophenolate mofetil, azathioprine, rituximab and infliximab or cyclosporine. Plasmapheresis and the use of immunoglobulins also constitute treatment for the disease. **Conclusion:** The reported case is diagnosed with Susac Syndrome. The patient presents the classic clinical triad of the disease, manifested by visual disturbances, due to occlusion of a branch of the retinal artery, hearing loss and encephalopathy. The exact prevalence is unknown, but to date, just over 300 cases have been published worldwide.

Case presentation: A 23-year-old male office assistant with no significant medical history presented in April 2023 with hand paresthesia and tinnitus, which resolved spontaneously. In May 2023, he experienced a self-limited episode of headache. In June 2023, he developed diplopia and scotoma, seeking care at the emergency room of the Clinics Hospital at the Federal University of Triângulo Mineiro. Upon admission, there was a reduction in vision in the lower field of the left eye; fluorescein angiography revealed branch retinal artery occlusion (BRAO). Laboratory-serological investigation, electrocardiogram, carotid and vertebral artery Doppler ultrasound, and echocardiogram showed no abnormalities. In July 2023, brain MRI revealed numerous hyperintense lesions distributed in the corpus callosum in a "snowball" pattern and throughout the cortex and white matter of both cerebral hemispheres. Suspecting Susac's Syndrome (SuS), audiometry and lumbar puncture were performed, both without abnormalities. In August 2023, there was a catastrophic worsening, with increased visual loss, right hemi-hypoesthesia, and hearing loss. A new audiometry revealed sensorineural hearing loss in the left ear, confirming the diagnosis of SuS according to the European Susac Consortium. The patient was hospitalized and treated with human immunoglobulin and methylprednisolone for five days, with cyclophosphamide on the fifth day. **Discussion:** SuS is characterized by the triad of visual deficit (BRAO), hearing loss, and encephalopathy. Studies show that CD8+ T cells anchor to the endothelium, release granzymes and perforins, cause microvascular bleeding, activate the coagulation cascade, and promote vascular occlusion. It is a rare condition, with fewer than 700 cases reported in the literature, potentially progressing to blindness and deafness without adequate treatment. **Conclusion:** SuS should be considered as a differential diagnosis in diseases with components of its triad for appropriate investigation and treatment.

Case presentation: E.F.V.M, 7 years and 10 months old, woman, with no complications during pregnancy or childbirth. The mother reports using unknown medication for arthrosis in the first trimester of pregnancy and a family history of mood and neurodevelopmental disorders. The patient has a history of congenital heart disease, atopic dermatitis, asthma, obesity and astigmatism. She was referred to the pediatric neurology clinic due to global neuropsychomotor developmental delay. Physical examination revealed prominent ears with low implantation, appendicular hypotonia and reduced muscle strength. CGH array, a genetic test, showed a rare deletion of a 6.5Mb interstitial segment of the long arm of chromosome 8 (8q21.13). During clinical evaluation, the patient presented a pattern of global hypotonia, speech articulation delay, dependence in activities of daily living, delay in personal-social and school development. She is currently being treated with risperidone 0.2 mg, melatonin 9 mg and asthma medication, without any follow-up from the multidisciplinary support team. However, she was referred for multidisciplinary therapeutic follow-up to ensure a better prognosis and quality of life. **Discussion:** Chromosome 8 band deletion is considered rare, with only 18 reported cases in literature. The diagnosis is complex, observed during the postnatal period in individuals with multiple anomalies and developmental delay that do not characterize known genetic syndromes. In this patient, a deletion of the 6.5 Mb interstitial segment of the long arm of chromosome 8 (8q21.13) was identified by chromosomal microarray analysis. The deleted segment of the genome is responsible for approximately 48 genes, 15 of which encode proteins and 4 of which are associated with comorbidities, such as heart disease. The genetic investigation was carried out due to the characteristic phenotype of chromosomal alterations, such as facial dysmorphism, global hypotonia, gait instability and delayed neuropsychomotor development, which could be explained by the syndrome. Given her pathological history, she had atrial septal defect at birth, which was surgically resolved at the age of 4. This comorbidity may be related to the chromosomal alteration presented by the patient. However, the detection of genetic alterations allows for multidisciplinary monitoring, prognosis assessment and genetic counseling. **Final comments:** This shows that genetic tests are fundamental for differentiating cases of global developmental delay, a frequent issue in practice, but with various possible clinical manifestations. Genetic research in this case provided prognostic information regarding clinical evolution and treatment. Therefore, multidisciplinary therapy is also crucial for the development of impaired skills, despite the challenges of access in the Unified Health System and high costs in the health private network.

Correspondence: Loyslene Maria de Paula Bonifácio; Email: loyslene.med@gmail.com.

Case presentation: A 49-year-old right-handed male truck driver, with a history of hypertension, diabetes, dilated cardiomyopathy, and a previous ischemic stroke (with residual left central facial paralysis), presented with a history of fronto-ocular trauma due to his truck's load had fallen over his face two days prior to admission. Since the event, he reported localized pain, malaise, subjective vertigo, moderate left-side headache, and elevated blood pressure. Neurological examination revealed dysarthric speech, right peripheral facial paralysis, horizontal diplopia with conjugate gaze paralysis when attempting to look at right, with left eye adduction paralysis, right eye adduction and abduction paralysis. Only his left eye abduction was preserved. Vertical and convergence eye movements were intact. Additionally, there was decreased tactile, thermal, and pain sensation on his left side of the

body. Cranial computed tomography (CT scan) showed no significant acute abnormalities. Due to the trauma, vertebral artery dissection was hypothesized, but cervical and cranial CT angiography were also normal. However, brain magnetic resonance imaging (MRI) revealed focal diffusion restriction in the mid-dorsal tegmentum of the pons extending dorsally to the right medulla, consistent with an acute vascular insult, confirming a medial pontine infarct as the underlying cause of symptoms. Based on his presentation and neuroimaging, a diagnosis of syndrome of nine (one-and-a-half syndrome - horizontal conjugate gaze palsy with internuclear ophthalmoplegia - plus ipsilateral fascicular seventh nerve palsy and contralateral hemianesthesia due to medial lemniscus involvement in the pons) was made. The patient was admitted to the ischemic stroke unit and treated with antithrombotic therapy, including enoxaparin and clopidogrel, along with supportive measures such as blood pressure control and motor rehabilitation with a speech therapy team. **Discussion:** Syndrome of nine is a rare neurological condition that combines one-and-a-half syndrome with ipsilateral facial paralysis and contralateral hemianesthesia. It is characterized by the presence of internuclear ophthalmoplegia and horizontal conjugate gaze paralysis, along with ipsilateral facial nerve palsy and contralateral hemianesthesia or hemiparesis due to involvement of the medial lemniscus or corticospinal tract, respectively. The syndrome of nine is associated with pontine lesions, predominantly of vascular origin (infarct or hemorrhage). This case report aligns with the literature, where most described cases involve more medial pontine lesions. **Final comments:** This case of syndrome of nine underscores the need for thorough neurological examination, rapid diagnosis, and appropriate treatment to minimize neurological sequelae. Early identification and targeted therapy are crucial for improving the prognosis of patients with this rare syndrome.

Chiari malformation (CM) is an anomaly that can cause various neurological deficits. We describe a patient with MC type I and cervical syringomyelia (CS) accompanied by bilateral vocal cord paralysis. **Case presentation:** Patient F.D.S., male, 59 years old, living in Crato-Ce, 14 years ago began progressive and rapid onset of hoarseness, progressing to complete aphonia in three days, associated with dysphagia, followed by due to dyspnea, having been admitted to the ICU on the same day due to acute respiratory failure, and an emergency tracheostomy was performed. Exams carried out during hospitalization showed a normal chest X-ray, serum tests (blood count, serum electrolytes, CPK, lactic acid, creatinine and blood glucose), cervical ultrasound, electroneuromyography of the four limbs and skull tomography were normal. Laryngoscopy revealed bilateral paralysis of the vocal folds, with minimal opening of the glottis during inspiration. MRI of the skull and cervical spine showed tapered cerebellar tonsils, migrated 1.5 cm below the foramen magnum, compatible with MC type 1, and SC. The patient received a permanent tracheostomy after one month, and over the next 3 months he gradually developed paresis of the right upper limb. The patient was evaluated by a neurologist in March 2021, finding paresis and muscular atrophy in the right upper limb, predominantly distal, and paresis for elevation of the palate, with the presence of nausea reflex, dysphagia and using a metal tracheal cannula, and the patient underwent a surgical approach to treat CS associated with MC. **Discussion:** CM consists of the caudal displacement of the cerebellum and brainstem through the foramen magnum, which may be accompanied by compression of the brainstem and spinal cord, and syringobulbomyelia. Initial symptoms include recurrent headaches, neck pain, progressive ataxia and dysphagia. CS commonly occurs in patients with CM, and consists of a cystic cavity in the spinal cord, which can cause sensory loss and brachial amyotrophy. Its association with bilateral vocal cord paralysis or dyspnea is uncommon but well recognized, but is rarely seen in adults. When the corticobulbar fibers are affected, which culminate in the caudal portion of the nucleus ambiguus, laryngeal nerve cells can be affected, and a lesion below the decussation of the pyramids favors vocal cord paralysis. CS treatment is based on reducing cavity pressure and improving CSF flow, with shunt implantation (SI), lysis of adhesions or cyst fenestration. We describe a patient with type I CM and CS accompanied by acute bilateral paralysis of the vocal folds, treated by SI, and who evolved with no functional recovery, and it should be noted that the presence of long-lasting gliosis limits the surgical benefit. **Final comments:** We highlight the importance of early diagnostic recognition of MC and CS, including through bulbar muscle paresis, as well as rapid treatment, in order to obtain a better prognosis for symptomatic patients.

Syringomyelia associated with xanthomatous plaques in dermis: a case report

Jonnathan Camara da Silva Vianna[1], Eduardo Martiniano de Lima[1], Moisés Vasco de Freitas[1], Gabriel Belo Cavalcante Linhares[1], Yasmin Luíse Lucena e Silva[1], Emanuela Maria de Aguiar Azevedo[1], Samila Marissa Pinheiro Gomes[1], Aglagilson Fernandes das Chagas[1]

[1]Universidade Federal Rural do Semi-Árido, Mossoró RN, Brazil.

Correspondence: Jonnathan Camara da Silva Vianna; Email: jonnathanvianna@gmail.com.

Case report: A 37-year-old woman, the only child of non-consanguineous parents, with two siblings who died as infants due to malformations. She has had scoliosis since childhood. She was referred to the neurology clinic due to a neurological condition of proximal tetraparesis. In 2024, magnetic resonance imaging (MRI) revealed extensive syringomyelia, extending from the cervical region to the T11-T12 level, along with moderate diffuse reduction in medullary caliber. On examination, she exhibited grade IV strength in bilateral deltoids and iliopsoas, impaired deep artresthesia sensitivity in the lower limbs, and abolished vibratory sensation up to the iliac crest. Additionally, she presented Hoffmann's sign in the left hand and Romberg's sign with tendon dancing. Dermatological examinations revealed thick-textured skin with dark spots and increased elasticity. In 2018, histopathological study of the lesions indicated fragmented elastic fibers in the reticular dermis region, with calcium deposition, suggesting pseudoxanthoma elasticum (PXE). A genetic test was requested for diagnostic confirmation. **Discussion:** Syringomyelia is characterized by the formation of a cavity within the spinal canal, commonly associated with central nervous system malformation. Additionally, the MRI showed signs of vertebrobasilar invagination and platybasia, configuring communicating syringomyelia type I. Symptoms vary according to the level and extent of involvement, and in this patient, muscle weakness, progressive scoliosis, ataxia, and reduced superficial abdominal sensitivity were observed. Furthermore, PXE is a rare genetic disorder, inherited in an autosomal dominant or recessive manner, caused by mutations in the ABCC6 gene, leading to abnormal calcium deposition in elastic fibers of the skin, eyes, and blood vessels, resulting in leather-like skin lesions and increased cardiovascular risk. For diagnostic confirmation, ocular changes such as angioid streaks and confirmation of ABCC6 gene mutations by genetic testing are necessary. PXE is progressive and requires serial evaluations by an ophthalmologist and a cardiologist due to the risk of atherosclerosis, reduced walking capacity, and serious complications such as thromboembolic events and ophthalmological changes like drusen and pattern dystrophy. Moreover, even rarer cases of PXE harbor pathogenic variants in the ENPP1 gene, causing generalized arterial calcification of infancy (GACI), inherited in an autosomal recessive manner, and resulting in infant death by the first year of life, which may explain the cause of death of the patient's siblings as infants. **Final comments:** This report illustrates the rare association between PXE and extensive symptomatic syringomyelia. It highlights the importance of careful differential diagnosis and interdisciplinary approach. Early detection and treatment of complications from both conditions can significantly improve quality of life.

Systematic review and meta-analysis of mortality in neuromyelitis optica spectrum disorder (NMOSD)

Leonardo José Rodrigues de Araújo Melo[1], Francisco Luciano Honório Barreto Cavalcante[1], Leonardo Elias Araujo dos Santos[1], Emanuela Freire Caetano Davi[1], Rodrigo Fagundes da Rosa[1], Yasmim Alves de Maria Nunes[2], João Pedro de Oliveira Gouveia Marcotti[1], Alan Duarte Braz[1], Wagner Patrik Sousa Silva[1], João Marcelo Albuquerque Beserra de Sousa[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.
[2]Universidade de Fortaleza, Fortaleza CE, Brazil.

Correspondence: Leonardo José Rodrigues de Araújo Melo; Email: lleonardomello98@alu.ufc.br.

Background: Neuromyelitis Optica Spectrum Disorder (NMOSD) is an autoimmune disease of the central nervous system, characterized by the production of autoantibodies against astrocytic aquaporin-4(AQP4), leading to demyelination and neuronal damage, which causes serious clinical complications such as optic neuritis and longitudinally extensive transverse myelitis. As a result, NMO is a severely disabling disease with insufficiently known mortality rates. **Objective:** To estimate the mortality rate (MR) in NMOSD and identify clinical factors associated with it. **Methods:** A systematic literature search was conducted on PubMed and Web of Science platforms, using DeCS/MeSH descriptors "Neuromyelitis Optica Spectrum Disorder" or "NMOSD" and "Mortality" or "Survival rate". The inclusion criteria were cohorts or observational studies published in English that cites MR. Reviews, case reports or clinical trials were excluded. Articles were analyzed by two blind observers using the Rayyan AI platform, with divergences analyzed by a third independent individual. Data and statistical analysis were processed using jamovi software. Initially, 67 papers on the subject were obtained. **Results:** Thirteen articles met the inclusion criteria, including 12 cohort studies and 1 observational study, from 10 different countries, totaling 29.534 patients of which more than 80% were women, with an average follow-up of 11.8 years (ranging from 2 to 27 years). The total number of deaths among NMOSD patients was 748, with an average age of death of 58.5 years (ranging from 54 to 66 years). The MR was 7.35% (95% CI: 5-10%, $p< 0.01$) and the mean Expanded Disability Status Scale (EDSS) of the deceased patients was 6.35, estimated by 7 articles that presented EDSS data.Standardized mortality ratio (SMR)variables from 2,54% to 3,52%, higher than the general population.The mean EDSS is high in group deceased patients compared to survivors group at

the follow-up time.A later onset of symptoms, especially after the age of 50, was associated with a higher risk of death. Delayed treatment and the number of attacks per year were other conditions associated with high mortality in NMOSD patients. The main causes of death related to NMOSD were infections due immunotherapy, mainly of the respiratory tract, and respiratory failure due to extensive cervical myelitis. **Conclusion:** Patients with NMOSD have a high mortality rate and a reduced life expectancy compared to the general population. High mortality in NMOSD was associated with high EDSS values and a later onset of symptoms. Study limitations include the lack of EDSS data in some papers and the lack of articles investigating risk factors associated with mortality and comparing them with control groups. Further studies with more standardized methodologies are needed to more accurately evaluate MR in NMOSD and risk factors associated with it.

Systemic lupus erythematosus associated with posterior reversible encephalopathy syndrome: a case report

Mariana Costa Borges[1], Jessica Vargas Lopes[2], Caroline Dresch Sabadin[3], Maria Júlia Todero[3], Carolina Aparecida Donofrio Santos Costa[1], André Luiz Pereira Martins[1], Diego Antonio Fagundes[4], Olga Cassol Silva[1], Maria Eduarda Andreatta[5]

[1]Universidade do Sul de Santa Catarina, Palhoça SC, Brazil.
[2]Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre RS, Brazil.
[3]Universidade Estadual do Oeste do Paraná, Cascavel PR, Brazil
[4]Universidade do Extremo Sul de Santa Catarina, Criciúma SC, Brazil.
[5]Universidade Federal de Santa Catarina, Florianópolis SC, Brazil.

Correspondence: Mariana Costa Borges; Email: maricostaborges@hotmail.com.

Case presentation: A 16-year-old male patient initially presented with bacterial tonsillitis, progressing to lower limb swelling, dyspnea and headache. He sought hospital care which revealed hematuria and pleural effusion, and was treated for pneumonia with levofloxacin. After 10 days, he developed two episodes of seizures lasting 10 minutes each, with tonic-clonic tremors, and came to our service. On admission, he had hypertension 160/90mmHg, a positive Brudzinski sign and new seizure episodes. Pulse therapy of 1mg/kg methylprednisolone was carried out in the suspicion of autoimmune encephalitis and the patient showed clinical improvement. The electroencephalogram showed moderately disorganized baseline activity with an excess of slow rhythms in the delta band superimposed by faster rhythms in the alpha band, as well as intermittent rhythmic delta activity in the fronto-temporal regions and a slow sharp wave epileptiform discharge with greater electronegativity in C3P3. Laboratory tests revealed: C3 consumed (< 11), CH 50 consumed, C4 normal, FAN positive (AC-4) (AC-8) 1:320, ASLO positive (349.9), proteinuria of 3.8g. Partial urine test with leukocyturia and hematuria. Magnetic Resonance Imaging (MRI) of the skull showed hypointense signals in T1, hyperintense in T2/ FLAIR, without diffusion restriction and gadolinium impregnation, indicating PRES. Treatment for SLE was started in conjunction with rheumatology. Control MRI of the skull identified a significant reduction in the lesions. The patient is currently taking cyclophosphamide and is stable.The condition, characterized by acute diffuse glomerulonephritis, serositis and laboratory tests, indicates a case of reversible posterior encephalopathy triggered by systemic lupus erythematosus. **Discussion:** Posterior reversible encephalopathy syndrome (PRES) is a rare but serious neurological condition often associated with systemic lupus erythematosus (SLE). The patient's initial presentation of headache followed by seizures and MRI alterations indicates PRES. Characterized by rapid onset symptoms such as seizures, headache, and visual disturbances, PRES involves reversible brain edema primarily in the posterior regions. Treatment with corticosteroids and cyclophosphamide,targeting SLE activity and hypertension control, resulted in clinical and imaging improvement. **Final comments:** Investigating the underlying causes of PRES and initiating early treatment are critical to prevent sequelae associated with delayed management of autoimmune diseases, particularly those involving the central nervous system. Early diagnosis and proper management can prevent irreversible neurological damage and improve patient prognosis.

https://doi.org/10.5327/CBN241586

Task-specific stroke program: developing an extension program to increase exercise intensity

Maria Eduarda Salum Aveiro Henrique[1], Clara Rezende Rocha[1], Danilo Santana Gonsalves[1], Marco Túlio Almeida Lenza[1], Jayne Siqueira Cagliari[1], Pedro Henrique Sousa de Andrade[1], Caroline Rodrigues Osawa[1], Luciane Aparecida Pascucci Sande de Souza[1], Gustavo José Luvizutto[1]

[1]Universidade Federal do Triângulo Mineiro, Uberaba MG, Brazil.

Correspondence: Maria Eduarda Salum Aveiro Henrique; Email: aveiromariaeduarda@gmail.com.

Background: Stroke is a leading cause of death and disability among adults worldwide. Following a stroke, individuals may experience motor, sensory, and/or cognitive impairments that diminish independence and hinder the performance of core tasks such as sitting, standing, walking, stepping up/down, and reaching/grasping/manipulating objects. Despite numerous studies on post-stroke rehabilitation, the literature lacks an exercise protocol specifically based on the essential biomechanical components of these core tasks. **Objective:** To develop an exercise protocol tailored to tasks relevant to post-stroke rehabilitation within an extension university project. **Methods:** The protocol was designed with exercises focused on essential activities involved in executing core tasks, emphasizing gains in muscle strength and range of motion specific to each task phase. The biomechanical components of each task were defined based on existing literature. The protocol's efficacy was assessed using scales measuring improvements in patient structure and function, activity, and participation. **Results:** Exercises for each task were based on Task-Oriented Training (TOT), known for effectively enhancing upper limb function, mobility, and walking post-stroke. Each core task was segmented by its essential biomechanical components, resulting in a protocol comprising 50 exercises - one for each component with two ways to increase difficulty and two to simplify, facilitating protocol customization based on patient needs. Exercises incorporated external focus techniques to optimize muscular recruitment during execution, using readily available materials to ensure reproducibility across different environments. Dual-task exercises were integrated for cases requiring cognitive rehabilitation alongside motor training. Exercises were documented with photographs and organized into a flowchart indicating activities adaptable to patient-specific restrictions. **Conclusion:** Post-stroke individuals often face challenges that impact independence in essential daily activities. This study developed a neurofunctional rehabilitation protocol based on TOT, aiming to restore autonomy in performing core tasks. Exercises consist of straightforward activities using common objects as external focal points, enabling replication in diverse settings. Efficacy will be evaluated based on improvements in function and structure, activity, and participation using validated stroke assessment scales and questionnaires.

Teaching tool in neoplasms of the central nervous system: seeking integration between theory and practice

Ana Caroline Siquara de Sousa[1], Bruna dos Santos Serra de Alencar[1], Rafael de Oliveira Telles[1], Stella Coelho Rodrigues[1]

[1]Instituto de Educação Médica, Rio de Janeiro RJ, Brazil.

Correspondence: Ana Caroline Siquara de Sousa; Email: anasiquara@gmail.com.

Background: Central nervous system (CNS) neoplasms are one of the most challenging diseases in various fields of medicine. The national incidence is around 11 thousand cases annually for the three years from 2023 to 2025. This number makes this group of neoplasms the 11th most common in the country, excluding cases of metastases. The study of these neoplasms during graduation is an opportunity to reinforce general pathology concepts and learn about such a specific diagnosis and its classification. Our research group then proposed to create a tool for the histopathological study of CNS tumors, to help undergraduate students become familiar with these diseases. **Objective:** The objectives of the tool are: to promote integration between theoretical concepts of pathology and the practice of the pathologist, with the observation of microscopy images; and to encourage the use of clinical cases in the diagnostic approach of these neoplasms. **Results:** In the first stage, a histopathological review was carried out on the main types of CNS neoplasms, studying clinical and epidemiological aspects and providing microscopy images of these tumors. Subsequently, a brochure was created with other microscopy images and clinical cases, and a board game (trial type) with 40 questions about these neoplasms. The board game must have the participation of at least two players. The theoretical material, then, was used as guidance for the student to prepare for performance in the match. In the next stage of the research, the game will be promoted among Medicine students by members of the research group themselves. This is a topic that students generally have little contact with during the course, despite its importance mainly for understanding the early signs and symptoms of most CNS tumors. Among the reasons that explain the importance of knowledge about these diseases, the following stand out: their high morbidity and mortality; incidence in all age groups, being common in children; and complexity of histopathological and biomolecular aspects. The study of these neoplasms during graduation was an opportunity to reinforce general pathology concepts learn about such a specific diagnosis and its classification, and stimulate reasoning through the study using clinical cases. Furthermore, there was integration with other subjects in the curriculum, such as Human Anatomy, Oncology, and Neurology. **Conclusion:** There are several ways to diversify teaching-learning formats, such as creating conceptual maps, anatomic-clinical case seminars, creating games such as "escape rooms", etc. These strategies may represent new ways of approaching case studies or problem-based learning, bringing new discussion tools to the classroom.

Tegumentary assessment as a diagnostic clue in demyelinating neuropathies: don't underestimate the tendons!

Támara Larissa Silva Barbosa[1], Isis Maria Lima Cruz[1], André Luis Dias de Figueiredo[1], Vinícius Araújo do Vale[1], Pedro Victor Pinheiro Bezerra Melo[1], Gabryel Felipe Alves de Sousa[1], Rafael Fontes de Carvalho Amorim[1], Ademir Aragão Moura[2]

[1]Universidade Federal do Piauí, Teresina PI, Brazil.
[2]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Isis Maria Lima Cruz; Email: isismarialc@gmail.com.

Case presentation: A 47-year-old male patient sought medical care presenting with episodes of psychomotor agitation, hallucinations, and incoherent speech for the past three months. Family members reported intellectual disability and dysphagia since childhood. Treatment with risperidone 3mg/day and bromazepam 6mg/day was initiated by the psychiatry team. The patient then developed dysarthria, sialorrhea, quadriparesis, weight loss, vomiting, drowsiness, and worsening dysphagia, leading to the discontinuation of medications and neurological evaluation. Upon examination, the patient presented with dysarthria, bilateral Achilles tendon thickening, moderate generalized hypotrophy, bilateral pes cavus, hypoalgesia in the upper and lower limbs, and abolished patellar and Achilles reflexes bilaterally. Subsequently, the following tests were requested: Electroneuromyography (ENMG) of the four limbs, which evidenced mild to moderate, symmetrical, mixed sensorimotor polyneuropathy; cranial magnetic resonance imaging (MRI), which showed hyperintense foci in the periventricular white matter; MRI of the lower limbs, which showed thickening and diffuse signal alteration of the bilateral Achilles tendons with intratendinous deposits suggestive of xanthomas. Genetic testing confirmed the diagnosis by identifying a pathogenic heterozygous variant in the CYP27A gene. **Discussion:** Cerebrotendinous xanthomatosis is an autosomal recessive disease caused by mutations in the CYP27A1 gene, resulting in lipid accumulation in tissues. The reported patient did not present early non-neurological symptoms typical of the disease, such as juvenile cataracts and premature osteoporosis. In line with the literature, psychiatric symptoms usually appear in childhood or adolescence, manifesting as behavioral disorders and learning difficulties, while in the advanced stage of the disease, it progresses with dementia or complex neuropsychiatric syndromes. Neurological examination findings, such as quadriparesis, Achilles tendon thickening, pes cavus, and abolished reflexes, were commonly described in previous studies. As for the test results, the ENMG showed the expected result, as polyneuropathy is a characteristic finding of this disease, which progresses with demyelination; the literature describes characteristic MRI with bilateral lesions in the dentate nucleus, cerebellum, and mild white matter lesions; MRI of the lower limbs usually shows fusiform thickening and heterogeneous signals of the Achilles tendons. In Brazil, there is no drug therapy for the disease. The primary therapeutic approach to delay disease progression is multidisciplinary follow-up. **Final comments:** Progressive and irreversible neurological involvement is the primary manifestation of the disease. To delay disease progression, the main therapeutic option is multidisciplinary follow-up. Early diagnosis is essential for the patient's quality of life.

Teleconsultations specialized in difficult diagnoses: Whipple's disease

Lizandra Lavinia Santos de Albuquerque Menezes[1], Carlos Eduardo Aliatti Mantese[2,3], Rhaná Carolina Santos[3], Aline Oliveira dos Santos Meneses[3]

[1]Serviço Médico Odontológico, Capim Grosso BA, Brazil.
[2]Hospital Sírio Libanês
[3]Universidade do Vale do Rio dos Sinos, São Leopoldo RS, Brazil.

Correspondence: Lizandra Lavinia Santos de Albuquerque Menezes; Email: lizandramenezes18.2@bahiana.edu.br.

Case presentation: A 48-year-old man, of mixed race, residing in the countryside of Bahia, without comorbidities, attended a consultation at the basic health unit in June 2023 with cervical dystonia, dysphonia, slowed gait, and unquantified, progressive weight loss over the past 5 months. The dystonia presented as involuntary contraction of the bilateral platysma muscle, more pronounced on the left, associated with jaw clenching, worsening during stress. He reported depressed mood, insomnia, and, on physical examination, absence of horizontal eye movement in abduction, no pupillary changes, and difficulty keeping eyes closed. He had additive polyarthralgia and poorly characterized diarrhea, which improved spontaneously 10 months earlier, investigated in tertiary care but lost follow- up. Laboratory tests revealed hypochromic, microcytic anemia with plateletosis, albumin/ globulin inversion, and slightly elevated transaminases. A cranial MRI showed gliosis and compensatory ventricular system ectasia. Among the previous tests, which he lost follow-up on, included a chest and abdomen CT scan from August 2022 showing mediastinal, mesenteric, and retroperitoneal lymph node conglomerates suggestive of lymphoproliferative disease. There was also a biopsy of a sentinel lymph node showing reactive inflammatory histiocytosis. **Discussion:** Due to multisystemic alterations, dystonia was considered a guiding symptom, and teleconsultations with neurology have been conducted since September 2023, raising the hypotheses of Wilson's disease, Whipple's disease, and paraneoplastic syndrome. Wilson's disease was an important differential diagnosis, as changes in pigment were observed in the descemet membranes during the slit-lamp examination, consistent with corneal pigment deposits, suggestive of Kayser-Fleischer ring (K-F). Among the differentials for the ring, there is the pseudo-K-F ring, present in hepatobiliary diseases, cholestasis, and exposure to metals. The patient in question has a work history involving aluminum, likely the source of the pigment deposit. By correlating the case with the reactive histiocytosis in lymph node clusters, the absence of alteration in serum/urinary copper and ceruloplasmin, despite the ophthalmological finding, led to the hypothesis of Wilson's disease being ruled out, with Whipple's disease being a possibility to consider. As the condition progressed, the patient was referred to Salvador via the state central regulation system, where gastric and duodenal biopsies in October 2023 were positive for Tropheryma whipplei. Antibiotic therapy was initiated with favorable evolution. **Final comments:** Whipple's disease, although rare, should be remembered in differential diagnoses as it can be a lethal infection if not treated properly. Currently, the patient continues to be under basic and tertiary care, showing improvement in symptoms, with persistent cervical dystonia and resolution of laboratory abnormalities.

Correspondence: Sávio Roberto Silva Costa; Email: saviorsc20@gmail.com.

Background: Stroke is a neurological condition resulting from the interruption of blood flow to the brain, which causes cell damage and brain dysfunction. This condition is one of the leading causes of morbidity and mortality in Brazil and worldwide, resulting in motor, sensory and intellectual deficits that significantly affect patients' quality of life and generate substantial economic costs for healthcare systems. **Objective:** To compare variables related to stroke and analyze their possible changes in two time series. **Methods:** This is a cross-sectional, observational study with a quantitative approach whose data were collected from the Department of Information and Informatics of the Unified Health System (DATASUS), in the hospital morbidity section (SIH/SUS). Variables related to region, age, sex and race were analyzed in two different time series (TS), TS1 (2004-2013) and TS2 (2014-2023). Bioestat 5.3 software was used to statistically analyze and validate the data. A p-value of less than 0.05 was considered statistically significant for this study. **Results:** It was observed that morbidity due to stroke in these two STs showed an increase of 33.62%. As for the regional aspects, all regions showed a significant increase, with the Southeast region having the highest absolute number of morbidities in TS2 with n = 676,247, but showing the lowest increase between the two TSs (21.48%). In addition, the Northeast region showed the largest increase between the two series (54.99%). In terms of age group, all categories showed an increase, especially the under 9 age group, with an increase of 72.19%. In addition, the elderly group (60 years old or more) showed an increase of 35.59% in relation to TS1, with the 60 to 69 age group standing out, which recorded a significant increase of 42.39%. Analyzing gender among the TS, there was an increase in both sexes, 35.69% in males and 31.42% in females, and the predominance of males increased from 6.16% in TS1 to 9.61% in TS2. Finally, with regard to race, in ST2 there was a predominance of brown people with 602,680 cases, followed by white people with 530,523 cases. There was no data on race in ST1. **Conclusion:** Overall, the data indicates a significant increase in stroke morbidity in Brazil between the time series studied, with an increase in variables related to region, age group and gender. This highlights the need to develop more effective public health strategies to identify and mitigate risk factors in the populations most vulnerable to stroke.

Background: Tuberculosis, caused by the bacterium Mycobacterium tuberculosis, is a disease that can affect the lungs and other sites in the body and is the second leading cause of death globally. It is characterized by a subacute or chronic inflammation of the meninges due to the dissemination of *M. tuberculosis* into the subarachnoid space. This form of tuberculosis typically results from a complication of pulmonary tuberculosis and usually manifests within the first six months after an individual is infected. The diagnosis of tuberculous meningitis is often delayed due to the limited efficacy or availability of laboratory techniques, and the treatment is based on protocols for pulmonary tuberculosis. **Objective:** To evaluate the profile of hospitalizations due to tuberculous meningitis in Brazil between the years 2019 and 2023. **Methods:** Data collection was performed using a retrospective longitudinal study design with a quantitative descriptive approach. Data were grouped by Brazilian regions, type of care, sex, age group, and race/ethnicity. Statistical inferences were conducted using BioEstat 5.3 software, employing the paired T-test for related samples to compare groups. Descriptive statistics, measures of central tendency, and dispersion were used to present the data. **Results:** Between 2019 and 2023, there were 1,629 hospitalizations for tuberculous meningitis in Brazil. A majority, 65.56% (n=1,068), were male (p<0.0017), and 46.35% (n=755) were of mixed race (p=0.0371). The age group most affected was 30-39 years, accounting for 20.38% (n=332; p<0.0001) of the cases. The Southeast region had

the highest concentration of cases (n=770), corresponding to 47.27% (p=0.0011), with an average annual treatment cost of R$ 721,076.02. Mortality was also highest in the Southeast, with 53.89% (n=104) of deaths (p=0.0024) and a mortality rate of 24.50 (p=0.1933). The number of hospitalizations peaked in 2023, accounting for 24% (n=391) of the total, compared to only 17.37% (n=283) in 2021. Most hospitalizations, 87.78% (n=1,430; p<0.0001), were classified as urgent. **Conclusion:** Hospitalizations due to tuberculous meningitis are predominantly concentrated in the Southeast region of Brazil, with higher mortality rates and associated treatment costs. Most cases occur in males aged 30-39 years of mixed race, with most hospitalizations requiring urgent care.

Temporal trend of CNS neoplasms mortality rate in Brazil between 2001 and 2022

Victor Santos Vilares[1], Érica Otoni Pereira Miranda[1], Guilherme Rocha Cardoso[1], Lukas Santos Freire[1], Maria Fernanda Aragão Andrade[1], Rebeca Gabrielle Almeida Maciel[2], Priscila Santos Oliveira[1], Emmanuel Santos Trindade[1], Davi Tanajura Costa[1], Philip George Glass Andrade[1]

[1]Universidade Estadual do Sudoeste da Bahia, Vitória da Conquista BA, Brazil.
[2]Universidade Federal da Bahia, Salvador BA, Brazil.

Correspondence: Priscila Santos Oliveira; Email: priscilaoliveira35001@gmail.com.

Background: Central Nervous System (CNS) tumors are a heterogeneous group of neoplasms. Although some types have a high mortality rate, prognosis and evolution depend on their cellular origin, time of diagnosis and location. The most prevalent are gliomas, meningiomas and neurinomas. **Objective:** To analyze the temporal trend of CNS neoplasms mortality rate in Brazil between 2001 and 2022. **Methods:** Death data was collected from the Mortality Information System (SIM) through DATASUS, including those from malignant neoplasm of meninges (C70), brain (C71), spinal cord, cranial nerves and other parts of central nervous system (C72), stratified by sex, ethnicity and age group. A joinpoint regression model was used for the temporal analysis. **Results:** From 2001 to 2022, the average annual mortality rate (MR) from CNS neoplasms was 3.59/100,000 inhabitants in the general population, with higher rates in males (3.82/100,000 inhabitants), in line with the literature regarding the higher prevalence and worse prognosis in males. The white ethnicity was the one with the highest MR (4.78/100,000 inhabitants), in compliance with studies showing a higher prevalence of glioblastoma, one of the most aggressive CNS neoplasms, among whites. In regard to age groups, those aged 60 or over had the highest MR (14.95/100,000 inhabitants), which reinforces the literature, since glioblastoma is more incident from the 5th decade of life onwards. In the general population there was an increasing trend in MR between 2001 and 2022 (AAPC: 1.80 [1.50; 2.10]; p<0.001), with a more pronounced increasing trend from 2001 to 2013 (APC: 2.58 [2,21; 2.95]; p<0.001) than from 2013 to 2022 (APC: 0.78 [0.22; 1.34]; p:0.009). A similar trend was identified in both sex. In addition, whites and browns had the highest MR in 2022, with 5.72 and 2.99, respectively. Between 2001 and 2022, whites (AAPC: 2.19 [1.71; 2.66]; p<0.001) and browns (AAPC: 4.17 [3.70; 4.64]; p<0.001) showed an increasing trend in MR; blacks, however, had a stationary trend (AAPC: 1.78 [-1.32; 4.98]; p:0.26). Those aged 60 or over presented an increasing trend in MR (AAPC: 0.92 [0.39; 1.45; p<0.001) from 2001 to 2022, with a initial increasing trend from 2001 to 2015 (APC: 2.06 [1.56; 2.56]; p<0.001) followed by a stationary trend (APC: -1.32 [-2.68; 0.06]; p:0.06). Those aged between 50 and 59 years showed a stationary trend (AAPC: 0.19 [-0.20; 0.57]; p: 0.32). The other age groups presented decreasing trends in MR. **Conclusion:** Two epidemiological patterns in CNS neoplasms mortality rate were identified from 2001 to 2022: an increasing trend between 2001 and 2013, followed by a stationary trend, which could be partly explained by the improvement in the notification system and diagnosis. Besides, it was noticed a decreasing trend in mortality rate in younger individuals, which could be related to better diagnosis and treatment in those patients.

Tenecteplase versus alteplase in thrombolysis for ischemic stroke

Luiz Mateus Alves de Góis[1], Edla de Andrade Alves da Silva[1], Marcela Carvalho do Nascimento[1], Felipe Hermes Amorim da Silva[1], Thayna Costa Tenório Ribeiro Neves[1], Vinicius Rodrigues Ramos[1], Giovana Gonçalves de Souza[1], Ana Beatriz Benassi de Oliveira[1], Tainá Torres Pedro[1], Analuiza Silva Tenório Luna Sarmento[1]

[1]Universidade Federal de Alagoas, Maceió AL, Brazil.

Correspondence: Luiz Mateus Alves de Góis; Email: luiz.gois@famed.ufal.br.

Background: Stroke is the second leading cause of global mortality, with 84.4% being of ischemic origin (IS). Currently, alteplase is considered the first-line treatment for patients within the therapeutic window for thrombolysis. However, recent studies have raised the possibility of using a modified variant of alteplase (rtPA), tenecteplase (TNK), citing advantages such as a rapid onset of action. **Objective:** To analyze the efficacy and safety profiles of tenecteplase compared to alteplase in thrombolysis for patients with IS. **Methods:** For this systematic review, the descriptors «tenecteplase (OR) tissue plasminogen activator» combined (AND) with «alteplase» and (AND) «ischemic stroke» were used in the PUBMED and BVS databases. The filters «last 10 years» and «clinical trial" were used. After removing duplicates and thoroughly reading 27 randomized clinical trials, 13 were selected for this article. Exclusion criteria were: addressed individuals under 18 years old; included patients outside the 4.5-hour window for thrombolysis; were not freely available. **Results:** Data from 16,699 individuals were evaluated, among whom 65.57% were treated with rtPA and 34.43% with TNK. The minimum dose of TNK evaluated was 0.1 mg/kg, and the maximum was 0.4 mg/kg, the 0.25 mg/kg bolus dose was evaluated in all the analyzed studies. The rtPA maintained the standard dose of 0.9 mg/kg. 12 of the 13 studies involved individuals over 18 years old, and one study focused on individuals over 80 years old. The main outcomes were a score of 0-1 on the Modified Rankin Scale (mRs) within 90 days or a reduction of 4 or more points on the NIHSS within 24 to 72 hours, in addition to safety outcomes such as symptomatic intracranial hemorrhage (ICH) and 90-day mortality. The neurological improvement observed with TNK use slightly surpassed that obtained with rtPA in all studies that used the 0.25 mg/kg dose. Symptomatic ICH within 48 hours followed this trend, being lower with TNK than with rtPA in 44.4% of the cases, as well as 90-day mortality. **Conclusion:** The efficacy of TNK was similar to that of rtPA regarding the primary outcomes, with a statistically insignificant difference in acute IS within the 4.5-hour window from symptom onset. There were no statistically significant differences in the proportions of ICH within 90 days after symptom onset or in mortality rates within the 3 months following therapy. Thus, the results support the implementation of TNK 0.25 mg/kg as an alternative thrombolytic agent to the standard treatment with rtPA 0.9 mg/kg.

Ten-year neurological IgG4-related disorder: a case report presenting with mild seizures evolving with late inflammatory brain tumor

Polyana Favero Ferreira Caetano[1], João Henrique Fregadolli Ferreira[1], Lívia Almeida Dutra[1]

[1]Instituto do Cérebro, São Paulo SP, Brazil.

Correspondence: Polyana Favero Ferreira Caetano; Email: polyanafaveroc@hotmail.com.

Case presentation: A 43-year-old woman had focal motor seizures for the past 10 years, characterized by tonic movements in the right arm, progressing to bilateral tonic-clonic seizures. Initial brain MRI and EEG were normal. Despite treatment with valproate, she continued to have occasional mild seizures. In 2022, she started with focal seizures involving the right leg. A new MRI showed a Gd+ mass lesion in the left precentral gyrus and brain biopsy showed perivascular lymphoplasmacytic infiltrate with storiform fibrosis. Immunohistochemistry was negative for CD1a, and positive for S100 with IgG4+ plasmocytes < 40 and IgG4/IgG > 40%. Whole body CT scans revealed pulmonary involvement with ground glass infiltrates. After 4 months, she developed amenorrhea and reduced FSH and LH levels, normal hypophysis on MRI. She was treated with azathioprine, steroids, levetiracetam, topiramate and clobazam. After 12 months, she developed abnormal movements in the right foot, and was admitted for further investigation. Physical examination revealed mild weakness and sensory loss in the right inferior foot with hyperreflexia. Brain MRI showed enlargement of the initial lesion, indicating a recurrence of IgG4-related disease. VEEG was normal and ENMG showed upper motor neuron discharges. She received IV methylprednisolone for 5 days and was started on rituximab. **Discussion:** IgG4-related disease (IgG4-RD) is a systemic immune-mediated fibroinflammatory disease with variable clinical manifestations, depending on the affected organ. Most common neurological manifestations are hypertrophic pachymeningitis and hypophysitis. In this case neurological manifestations had a chronic course of ten years, with slowly progressive symptoms and an initial normal brain imaging, resembling epilepsy with unprovoked seizures. Although brain MRI is subject to specificities of equipment and imaging acquisition, this case indicate that some IgG4-RD patients may present functional neurological impairment rather than structural abnormalities. The clinical pituitary involvement without sella turcica abnormalities also exemplifies this hypothesis. Moreover, this report indicates that the disease may remain silent for a long period and present with a late severe flare. Another important goal learning of this case is the interpretation of brain biopsy results. The findings of perivascular lymphoplasmacytic infiltrate with fibrosis should prompt a focused immunohistochemical study for immune cells as well as IgG4. **Final comments:** This case illustrates the potential challenges of IgG4-related disease neurological manifestations. Patients may present with initial normal brain MRI, the slow progression of the disease may delay the diagnosis and the disease may remain silent for a long period of time. Neurologists should be able to correct interpret brain biopsy results and to ask for complimentary investigation when needed.

Thalamic deep brain stimulation for treatment of refractory epilepsy: a systematic review and meta analysis

Emanuela Freire Caetano Davi[1], Leonardo José Rodrigues de Araújo Melo[1], João Pedro de Oliveira Gouveia Marcotti[1], Alan Duarte Braz[1], Wagner Patrik Sousa Silva[1], Rodrigo Fagundes da Rosa[1], Caio Levi Mendes Costa[1], Leonardo Elias Araujo dos Santos[1], Francisco Duque de Paiva Giudice Junior[1], Mariana Borges Falcão Costa[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Emanuela Freire Caetano Davi; Email: emanueladavi@alu.ufc.br.

Background: Among the target areas for treatment of refractory epilepsy with Deep Brain Stimulation (DBS), the thalamus was shown to have great importance in propagation of seizure activity in experimental evidence, raising the necessity to review its impacts in clinical context. **Objective:** To evaluate the efficacy of DBS in the thalamus of patients with refractory epilepsy on the decrease of seizure frequency (SF) in the existing literature. **Methods:** This systematic review was executed according to the PRISMA 4 checklist. The search on the databases PUBMED, Scielo and EMBASE with "Deep Brain Stimulation" AND "epilepsy" AND "Thalamus", with 41 results. Inclusion criteria were controlled trials in English and Portuguese that evaluated the efficacy of thalamic DBS on the decrease of SF on human patients. The RoB2 guidelines were used to assess risk of bias, and the GRADE tool to assess certainty of evidence. The effect measures analyzed for outcome were the median percentage of SF decrease from baseline, responder's rate and value p, evaluated in meta analysis with Jamovi. The software Rayyan was used to automate exclusion and 12 studies were selected for assessment and 3 were discarded due to data duplicity or high risk of bias. **Results:** Across the 9 studies reviewed, data of 356 patients, mean age 32.4, was analyzed in follow-up periods varying between 3-84 months. The change of monthly SF from baseline while on active stimulation was evaluated using seizure diaries registered by patients or caretakers. FIAS was the most common type of seizure in this population, and the temporal lobe was the most common location of seizure origin. In studies that compared location subgroups, temporal lobe seizures had the highest decrease on SF of 70%. The decrease of SF was achieved and statistically significant by the population in follow-up studies, with the median percentage of decrease varying between 33% to 75% and overall mean of 53.9% of decrease (CI, 63, 44.7), with reported rates of 69% (CI, 43, 96.5) reduction in 5 years. 48% of the total population reached the responder rate of ≥ 50% SF reduction in comparison to baseline. Patients with intellectual disabilities (42 patients, 11.7%) present less efficacy in decrease of SF, ranging across 25% on studies with this population, though this group presented higher baseline SF. Notably, 4 trials reported subjects with improvement of SF after surgery but previous to stimulation. **Conclusion:** This systematic review indicates that the stimulation of the thalamus for the treatment of refractory epilepsy is an effective treatment in support of antiepileptic medication with objective decrease of SF in most populations. On study limitations, it's noted the use of Antiepileptic drugs are a possible confounding, divergence in inclusion criteria for participants, increasing standard deviation, and the sample was limited in the current literature. Due to this, the GRADE level of certainty was assessed as III.

https://doi.org/10.5327/CBN241596

The 'rosetta' sign: a peculiar gyral conformation of type II focal cortical dysplasia

Rafael Paglioli[1], Eliseu Paglioli[1], Francine Hehn[1], William Martins[1], Ricardo Paganin[1], Victoria Bizzi Schvartzman[1], André Gus[1], Natalie Donida[1], Bibiana Thome[1], André Palmini[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Victoria Bizzi Schvartzman; Email:Bizzivictoria@gmail.com

Focal cortical dysplasia (FCD) is a frequent pathology underlying an epileptic focus. The lesions can be subtle and despite much better imaging, clinical studies with 3T magnetic resonance imaging (MRI) still report a significant number of patients with histologically proven FCD that are 'MRI-negative'. Here, we report a series of patients with histology-proven type II FCD with a distinct, peculiar, 3D pattern of cortical gyration resembling what in botany is called a rosetta. M: Were evaluated 20 patients operated for refractory seizures due neocortical epilepsies over two years, in whom pathology revealed type II FCD. All had daily or weekly socially disabling attacks and presurgical evaluation, including clinical epileptological investigation, video-EEG scalp recordings, 3T MRI and neuropsychological testing. Following visual analysis of the 2-D MRI data by two neuroradiologists, a Visual Manipulation Toolkit for NeuroImages (VMTN) software was used to provide 3-D images of the sulci and gyri, at sequential sections, starting at the outermost cortical surface. After integration of presurgical data and delineation of the epileptogenic zone, patients underwent stepwise resective surgery, fine-tuned by electrocorticographic recordings with 16 individual electrodes that allowed acute probing of electrical activity from the surface, lateral banks and depths of gyri in sequential fashion during resection. Resected tissue was stained with hematoxylin-eosin and immunostained with neuronal nuclear antigen (NeuN), vimentin, GFAP and Olig2. FCD II was diagnosed by dyslamination on NeuN and the presence of large, dysmorphic neurons, accompanied or not by balloon cells. R: In 10 patients (50%), reformatted 3D images using VMTN software showed that gyri had a roughly circular arrangement radiating from a deep sulcus - a depressed, void center (the '3D image of the dimple') - the whole set akin to a rosetta of leaves. In all, dysplastic cortex was found in the gyral banks surrounding the depressed center and highly epileptogenic electrocorticographic discharge patterns were recorded acutely from variable portions of the gyri emanating from the depressed center. In 5 of these patients, conventional 2D-images showed discrete dysplastic lesions, variably characterized by thickened cortex, increased signal and blurring of the cortical-subcortical transition. In the other 5, images were initially read as normal and finding the rosetta pattern was crucial to confirm localization, supplemented by VEEG and semiological data. The 10 patients in whom the rosetta pattern was not seen had visible, large dysplastic lesions. C: The rosetta sign showed to be a reliable indicator of dysplastic epileptogenic cortex often not otherwise identified in many patients. Using the software and paying attention to the rosetta pattern are important assets to surgical decision in many patients with refractory neocortical seizures, obviating the need for costly and invasive studies.

The advances in monoclonal antibody research and its influence on Alzheimer's early prognosis

Nathan Chinelato Afonso[1], Victoria Lima Marques[1], Carlos Eduardo Fernandes Poppi[1], Júlia Carolina Fernandes Poppi[1], Otávio Antigo Orlandini[1], Amanda Piveta Nicodemo[1]

[1]Centro Universitário Ingá, Maringá PR, Brazil.

Correspondence: Nathan Chinelato Afonso; Email: nathan.afonsoch@gmail.com.

Background: Alzheimer's disease (AD) is characterized as chronic neurodegenerative complex and multifactorial pathology; being know for it's progressive loss of memory, cognitive functions, as well as synaptic dysfunction. Statistical data predicts an increase in the number of AD patients in America, surpassing 13.8 million cases by 2050. In addition, the observed pathological characteristics are, high levels of amyloid-β (Aβ) proteins composing plaques and hyperphosphorylated tau (p-tau), aggregated intracellularly. Recently findings review positive results with therapies with monoclonal antibodies, which act on the reduction of beta-amyloid Plaques. **Objective:** To demonstrate the efficiency of specific antibodies in the reduction of cerebral amyloid plaques accompanied by a reduction in clinical decline, taking into account that it brings promising expectations in the delay of the disease. **Methods:** This is an integrated review by means of a literature review in the PubMed and SciELO databases. The established descriptors were "lecanemab", "alzheimer" and "monoclonal antibody" connected by the Boolean operator and, published in English, during the last 5 years (2019-2024). A total of 140 articles were found, excluding those that did not involve the proposed theme, repeated in the databases, or addressed only one aspect or specific population, and 14 were initially chosen to be part of the research. **Results:** The studies show that patients affected by Alzheimer's disease present cognitive impairment and dementia at an early stage, due to mainly the neurodegeneration created by the amyloidogenic pathway, being a product of the successive cleavage of the amyloid precursor protein, which is extracellularly deposited in the parenchyma and cerebral vasculature. Monoclonal antibodies (mAbs), such as lecanemab, represent an approach based on high-affinity ligands in Aß plaques, such action promotes removal of aggregates by phagocytosis, mediated by receptors, altering the course of the disease. Concomitantly, randomized controlled trials using mAbs have shown that reduction of β-amyloid protein can be achieved in 3 months of treatment, with clinical efficacy in 6 months. According to the tests carried out, one of the most common side effects presented by this therapy occur in ARIA-E and ARIA-H, edema and hemorrhage, respectively, affecting only 12.6% of patients. At the same time, research has shown relevant improvements in biomarkers of the Tau protein (a potentially fundamental molecule in the pathogenesis of neurodegenerative diseases). **Conclusion:** In summary, the data obtained by clinical tests represent an effective way to improve the manifestations of symptoms, delay or even interrupt the progress of AD. Essentially, the therapeutic approach of monoclonal antibodies in pathology should be further explored.

Background: The potential impact of statin therapy on cognitive function and the risk of developing dementia has been a topic of considerable debate. Primarily prescribed for their lipid-lowering effects and cardiovascular benefits, statins have been hypothesized to exert neuroprotective effects due to their anti-inflammatory and antioxidant properties, as well as their ability to modulate cholesterol metabolism in the brain. Observational studies have often reported a lower incidence of dementia among statin users compared to non-users. However, the results from randomized clinical trials have been less consistent, with some studies failing to demonstrate a significant benefit of statins on cognitive outcomes. **Objective:** To provide a current and thorough review of the association between statin use and the incidence of dementia. **Methods:** MEDLINE, Embase and Cochrane databases were systematically searched until May 20, 2024. Observational studies that evaluated the association of statins and the development of dementia were included. We computed the Hazard Ratios (HR) of developing dementia in the statin group, while the reference was the non-statin group.

Additionally, subgroups' HRs were collected for further analysis. Data were analyzed using the Mantel-Haenszel method and 95% confidence intervals (CI). Heterogeneity was assessed using I^2 statistics. Standard Error and logHR were calculated through Review Manager 5.4.1 and statistical analysis was performed using R, version 4.3.2. **Results:** This meta-analysis included 34 observational studies evaluating the effect of statin use on the risk of developing dementia. The overall analysis demonstrated a statistically significant reduction in dementia risk among statin users compared to non-users (HR 0.87; 95% CI 0.83 to 0.90; I^2=86%; P<0.001). Among the analysed subgroups, statistically significant reduction was identified in the Lipophilic (HR 0.84; 95% CI 0.78 to 0.91; I^2=83%; P<0.001), but not in the Hydrophilic group. Atorvastatin and Rosuvastatin were the only specific statins that showed statiscally relevant reduction in dementia risk (HR 0.88; CI 0.83 to 0.94; I^2=86%; P<0.001 and HR 0.71; CI 0.61 to 0.83; I^2=91%; P<0.001, respectively). Furthermore, statins reduced the risk among Diabetes Mellitus patients (HR 0.87; CI 0.85 to 0.89; I^2=38%; P<0.001). **Conclusion:** In this comprehensive systematic review and meta-analysis, statin use is associated with a significantly reduced risk of developing dementia. Subgroup analysis revealed that rosuvastatin is the most effective in reducing this outcome. These findings support the potential neuroprotective role of statins, highlighting their importance in dementia prevention strategies.

Background: The dengue fever is an arbovirosis with the major number of infections in Brazil, defining a public health problem in the country. We can estimate around 390 million infections occurring annually. Of those, between 1-5% show some compromise with the nervous system like encephalitis, an inflammatory condition of the brain generated by an infection of the central nervous system (CNS). **Objective:** Analyze the quantitative relation between the outbreaks of dengue fever with the increase the amount of cases of viral encephalitis in Brazil. **Methods:** Studies with ecological design, data extracted from the Departamento de Informática do Sistema Único de Saúde (DATASUS), in which were analyzed the number of hospitalizations by encephalitis in the months with the major incidence of hospitalization by dengue fever in Brazil in the year of 2023. The data were analyzed by descriptive statistics. **Results:** In Brazil, there were 432,423 hospitalizations by dengue fever between the years 2013 and 2023, being around 239,632 (55.4%) in the months of march, april, may and june. In this same period, 21,643 hospitalizations by encephalitis were notified, being 6,680 (30.8%) in the months of major incidence of hospitalizations by dengue fever. There was an increase of 30% in the cases of encephalitis in comparison with the months of low incidence of the disease. Furthermore, the age range that was affected the most during the outbreaks of dengue fever was between 20 to 40 years old, representing 45% of the cases in this period. **Conclusion:** Lastly, the results of this study suggest a significant correlation between the outbreaks of dengue fever and an notable increase in the cases of encephalitis, especially between young adults. This highlights the necessity of executing preventive measures and strengthening the epidemiological vigilance for a better understanding and control of these diseases in a more efficient way in the Brazilian territory.

Background: Alzheimer's disease is the most common type of dementia in the elderly, being characterized by slow and gradual impairment of mental function. It is a progressive neurodegenerative disorder that manifests itself as damage to cognition, memory, judgment, thinking and motor skills. Being aware of the already known benefits of physical activity in the elderly, this practice needs to be considered as a possible strategy for improvement of prognosis in this disease. Considering the increase in the number of cases due to population aging, the potential benefits of combined physical training are of great importance and need to be further elucidated. **Objective:** Therefore, this study aims to identify the possible benefits of physical training on cognitive performance, physical performance, quality of life and activities of daily living in patients with Alzheimer's. **Methods:** The bibliographic research was conducted according to the guidelines outlined in PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis). The following electronic databases were used: PubMed, Web of Science and Embase. The systematic search was performed without date and language restrictions. The research used the following descriptors as a search strategy: Alzheimer's disease, exercise, aerobic training, strength training, multimodal training, cognitive function, functional independence and neuropsychiatric symptoms. After the selection process, 113 studies were included in the systematic review and 26 studies (82 trials and 2231 individuals) were included in the meta-analysis. The studies were grouped according to the impacted Alzheimer's axis and the duration of combined physical training: cognitive performance, physical performance, quality of life and activities of daily living up to 3 months and up to 6 months of training. **Results:** The practice of combined physical training for up to 3 months had a moderate effect on cognitive performance, by Mini Mental State Examination (SMD: 0.34; 95% CI: 0.07-0.61; p=0.016), physical performance (SMD: 0.75; 95% CI: 0.43-1.06; p=0.000) and quality of life (SMD: 0.40; 95% CI: 0.17-0.63 ; p=0.567) of the patient. However, activities of daily living remained stable (SMD: -0.10; 95% CI: -0.31-0.12; p=0.621). The combined physical training lasting from 4 to 6 months did not alter cognitive performance (SMD: 0.01; 95% CI: -0.22, 0.24; p=0.397) or activities of daily living (SMD: 0.00; 95% CI: - 0.12, 0.12; p=0.444), but there was a moderate effect on physical performance (SMD: 0.51; 95% CI: 0.23-0.79; p=0.000). **Conclusion:** The practice of physical exercise for up to 3 months generates positive impacts on the cognitive performance, physical performance and quality of life of individuals with Alzheimer's, with longstanding improvements in physical capacity.

The challenger thalamic anatomy and clinical spectrum of posterior circulation stroke: a anteromedial bitalamic ischemic presentation by artery of percheron infarct

Renato Dumbá Monteiro de Castro[1], Taís Luise Denicol[1], Fernanda Nicoli Broch[1], Alexandre Laisson Prado Taschetto[1], Juan Sebastian Sanchez Léon[1], Amanda Cipriano Torquato[2], Carolina Matté Dagostini[1], Julian Gomez Gonzalez[1], Diogenes Guimaraes Zan[1], Marlise de Castro Ribeiro[1]

[1]Santa Casa de Porto Alegre, Porto Alegre RS, Brazil.
[2]Universidade Vale do Rio Doce, Governador Valadares MG, Brazil.

Correspondence: Renato Dumbá Monteiro de Castro; Email: renato.castro@ufcspa.edu.br.

Case presentation: A 68-year-old man, metabolic syndrome (hypertension, dyslipidemia, obesity) unsatisfactory medication control, admitted to the emergency department after 5 hours of sudden behavioral change and partial depression of consciousness, impaired verbal response, confusing but understandable words, temporal and spatial disorientation followed by hypersomnia, doesn't remain alert with eyes open for more than 10 seconds even with vigorous stimulation. There was response to commands with difficulty, overcoming gravity and supporting the four limbs with preserved strength, despite impairment of executive functions and attention, scoring 10 according to the Glasgow Coma Scale (GCS), National Institutes of Health Stroke Scale (NIHSS) = 2 and Head Impulse Test (HINTS) non suggestive for central nervous system damage. Other focal neurological deficits were not identified and cranial nerve examination was normal. Laboratory tests and liquor analysis ruled out infections and systemic metabolic changes. The initial cranial and neck CT angiography showed microangiopathies, diffuse atheromatous stenosis minor 50% with parietal irregularities, worse in the right vertebral artery and 0.8 cm subdural hematoma(SDH) on left cerebellar tentorium. Furthermore, complementary magnetic resonance showed a well-defined area suggestive of recent bitalamic anteromedial ischemia. Conservative therapy was followed for SHD and ischemic stroke. Etiological screening identified heart failure with a slightly reduced fraction, 46% with diffuse hypokinesia, serological tests and prothrombotic factors with negative results. Initially classified as an embolic stroke of undetermined source (ESUS). Control neuroimaging after 10 days showed SDH resolution. According to clinical stability, he was discharged home on multidisciplinary support in partial improvement, dysexecutive rehabilitation and secondary prophylaxis. **Discussion:** Although less prevalent, posterior circulation stroke has atypical presentation that can mimic other neurological conditions. Thalamus disorders are true semiological challenges that can involve from purely language syndromes to motor, cerebellar, memory and behavioral associations. The medial and intralaminar thalamic nuclei are the most affected by vascular lesions, prefrontal cortex connection territories and the center of wakefulness through ascending activating fibers (SARA), respectively. Bilateral thalamic involvement suggests vascular supply through a single trunk of the paramedian arteries, the proximal branch of the posterior cerebral artery. This anatomical variation occurs in 4-12% of the population known to have Percheron's artery. **Final comments:** Recognizing the presentation of stroke is crucial for early diagnosis and therapeutic planning according to the time window for indications. Therefore, it is important to describe and publicize less prevalent cases among health professionals and the scientific community.

The challenges of diagnosing chronic inflammatory demyelinating polyneuropathy. The experience of Hospital Universitário Pedro Ernesto

André Rodrigues Poton[1], Rafael Oliveira Vidon[2], Salim Lázaro Balassiano[1], Eduardo Rodrigues Davidovich[1], Robson Teixeira Vital[1], Clarissa Neves Spitz[1], Larissa Bittencourt de Carvalho Chaffin[1], Marcia Rodrigues Jardim[1]

[1]Hospital Universitário Pedro Ernesto, Rio de Janeiro RJ, Brazil.
[2]Hospital Universitário Gaffrée e Guinle, Rio de Janeiro RJ, Brazil.

Correspondence: André Rodrigues Poton; Email: andrepoton@gmail.com.

Background: Chronic inflammatory demyelinating polyneuropathy (CIDP) affects both proximal and distal nerve segments, characterized primarily by muscle weakness and various types of sensory impairment. It presents in multiple forms and is an immune-mediated disease with a pathophysiology that is not fully understood. Despite being treatable, CIDP is often misdiagnosed, especially its variants, prompting the development and revision of diagnostic criteria. The 2021 revised clinical and electrophysiological criteria by the European Academy of Neurology/Peripheral Nerve Society (EFNS/PNS) are the most widely accepted. **Objective:** To analyze CIDP and its variants among patients in our hospital's Neurology service, focusing on the clinical and electrophysiological 2021 EFNS/PNS Consensus criteria. **Methods:** Retrospective study analyzing data from patients admitted with the initial diagnostic hypothesis of CIDP, seen at our Peripheral Neuropathies outpatient clinic between 2004 and 2024. Patients diagnosed with CIDP were included if sufficient medical records for evaluating 2021 EFNS/PNS Consensus clinical and corresponding electromyography data were found. Those with alternative diagnosis, insufficient medical data, or unavailable electromyography were excluded. **Results:** Among 1681 clinic patients, 68 (4%) were admitted with suspicion of CIDP. Among these, 21 (30.9%) were selected for analysis of the EFNS/PNS criteria. Five (7.3%) were excluded due to alternative diagnoses, and 42 (61.8%) due to inadequate data or unavailable electromyography. Of the 21 analyzed, 7 (33.4%) met typical CIDP criteria, while 13 (61.9%) met variant criteria: 10 (47.7%) Distal, 2 (9.5%) Motor, and 1 (4.7%) Sensory; 1 (4.7%) did not meet clinical criteria. Sixteen (76.2%) out of 21 met EFNS/PNS electrodiagnostic criteria. There were 12 (57.2%) men and 9 (42.8%) women, with an average age at symptom onset of 53.3 years (17-74), and an average time from symptom onset to electromyography of 27.9 months (1-180). **Conclusion:** Diagnosing CIDP is a challenge even in large neuromuscular disease centers. The diagnosis is primarily based on neurophysiological findings. There are various diagnostic criteria proposed across different centers, with the EFNS/PNS criteria currently being widely accepted. However, due to the diverse clinical presentations of CIDP, diagnostic complexities persist. It is important to discuss the criteria used for diagnosing CIDP to reduce both false positive and, especially, false negative diagnoses, as these prevent the treatment of a potentially disabling disease.

The correlation between long-term sleep deprivation and the development of Alzheimer's disease: a systematic literature review

Flávia Brady de Carvalho Gauziski Figuerêdo[1], Carolina Louise Costa de Faria[1], Fernanda Pais Mainiere[1], Fernando Tarcsay Marques Neto[1], Giovanna Prudente Buccino[1], Larissa Enes Cota[1], Leonardo Figueira Magno[1], Letícia de Castro Carvalho Oliveira de Faria[1], Letícia Jabor Veiga[1], Matheus Rocha Clemente[1]

[1]Faculdades Souza Marques, Rio de Janeiro RJ, Brazil.

Correspondence: Flávia Brady de Carvalho Gauziski Figueredo; Email: flaviabrady@outlook.com.

Background: Sleep deprivation refers to a reduction in sleeping time below individual's basal needs. Inefficient sleep is a risk for human development of acute and chronic pathologies. Long-term sleep deprivation is responsible for beta-amyloid protein deposition in the brain, forming neuroinflammatory plaques and hyperphosphorylation of Tau resulting in neurofibrillary tangles, damaging the functions of neurons and synapses. These represent risk factors for the pathogenesis and progression of AD, a neurodegenerative disorder which consists in progressive cognitive decline, causing behavioral, personality and functional capacity changes in the patient. Therefore, investigating the effects of sleep deprivation on Alzheimer's disease is relevant for a scientific foundation on prevention and treatment of this pathology. **Objective:** Systematic review of articles that expose the correlation existent between long-term sleep deprivation and the progression of Alzheimer's in patients in different approaches so that the knowledge of this topic is unified and critically analyzed. **Methods:** Systematic review of articles from 2012 to 2023 selected from Ministério da Saúde, PubMed and Scielo database with the following keywords: "Alzheimer's Disease", "sleep deprivation" and "memory". Each database was screened independently by all the authors of this review. **Results:** All the 6 studies analyzed showed a degree of relation between sleep and the increase in beta-amyloid levels in the brain. A bidirectional relation was demonstrated, in which sleep alterations present themselves both as a symptom of AD and as an aggravating factor, since they favor the early onset and faster progression of the disease. There is a specific relationship between interruptions in slow-wave sleep (SWS) and Alzheimer's pathophysiology, highlighting that SWS is essential for memory-related functions and exhibits a causal and bidirectional relationship with beta-amyloid accumulation. It was observed that the preferred locations for beta-amyloid accumulation are cortical regions, due to higher expression of the HOMER1 gene in these areas, contrasting with other studies that demonstrated a higher affinity of beta-amyloid for hippocampal regions. During NREM slow-wave sleep, neuronal hyperpolarization and reduced neuronal firing decrease beta-amyloid production. Self-reported sleep problems in cognitively normal individuals correlate with AD biomarkers, such as lower Aß42 levels and higher Tau protein levels in cerebral-spinal fluid. Sleep deprivation and circadian rhythm dysfunction can lead to dysfunctional tau protein metabolism, contributing to dementia even without Aß alterations. **Conclusion:** In brief, the intricate relationship that exists between sleep deprivation and AD can either be a symptom or an aggravating factor for its quickest advance. Furthermore, this insight is crucial for prevention and treatment of this disease.

The correlation between manual dexterity, executive function, and grip strength in individuals with Parkinson's disease

Julia Vitória Bento[1], Maria Eduarda Chaves da Silva[1], Hayslenne Andressa Gonçalves de Oliveira Araújo[1], Renan Alexandre Mregalote[1], Sara Garcia Amaro dos Reis[1], Francis Camila de Oliveira[1], Larissa Laskovski[1], Suhaila Mahmoud Smaili[1]

[1]Universidade Estadual de Londrina, Londrina PR, Brazil.

Correspondence: Maria Eduarda Chaves da Silva; Email: maria.eduarda.chaves@uel.br.

Background: The clinical spectrum of Parkinson's disease (PD) is broad and is characterized by motor and non-motor symptoms, as well as impairments in manual dexterity and grip strength. Equally important, the prevalence of non-motor symptoms such as depression and cognitive decline greatly impact the functionality and quality of life of individuals who suffer from it. These changes, combined with motor disturbances, impair the executive functions responsible for efficient motor planning. Since these outcomes play an important role in the independence of individuals with PD, their evaluation needs to be routine, detailed, and individualized, as well as their interrelationships understood. **Objective:** To analyze the correlation between manual dexterity, executive function, and grip strength in individuals with PD. **Methods:** This cross-sectional study involved individuals diagnosed with PD who were receiving care at a specialized neurofunctional physiotherapy outpatient clinic at the State University of Londrina, encompassing both sexes. All individuals were evaluated during the "on" phase of their medication. Initially, the Mini-Mental State Examination (MMSE), modified Hoehn & Yahr scale (HY), and Movement Disorder Society Unified Parkinson's Disease Rating Scale (MDS-UPDRS) were all used to characterize the sample. For the evaluation of manual dexterity, executive function, and grip strength, the Squares Test, Trail Making Test - parts A and B (TMT A and B), and manual dynamometry were all used respectively. Clinical and demographic data was described in median and interquartile range, and the correlation between manual dexterity, executive function, and dynamometry data was analyzed using Spearman's correlation test, adopting a significance level of < 0.05. The study was approved by the Research Ethics Committee under opinion number (CAAE: 23272819.8.0000.5231). **Results:** 27 individuals were analyzed, with a median age of 68 [56.0-74.0], between mild to moderate stages of PD, with a diagnosis time of 6 [4.0-10.0] years. In the analysis between manual dexterity and the executive function tests, moderate correlations were observed between the Squares Test on the right and left with TMT A (r = -0.69 and r = -0.68, respectively) and TMT B (r = -0.53 and r = -0.52, respectively). However, there was no significant correlation between manual dexterity and executive function tests with grip strength. **Conclusion:** In this study, manual dexterity correlated with better performance in executive function tests, which did not occur with grip strength. This result aids therapeutic planning in clinical practice, indicating a greater interconnection between executive function activities and manual dexterity compared to grip strength. Training these skills is important for activities of daily living and can improve the autonomy of people with PD.

The critical role of accurate diagnosis in trigeminal autonomic cephalalgias: a case study

Rhaná Carolina Santos[1], Aline Oliveira dos Santos Meneses[1], Giovanna Polo[1,2], Carlos Eduardo Mantese[1]

[1]Universidade do Vale do Rio dos Sinos, São Leopoldo RS, Brazil.
[2]Hospital Mãe de Deus, Porto Alegre RS, Brazil.

Correspondence: Rhaná Carolina Santos; Email: santoscrhana@gmail.com.

Case presentation: A 31-year-old female patient, previously healthy, has been diagnosed with cluster headache for four years. She started treatment with verapamil 480mg/day and occipital block with lidocaine. Despite treatment, the patient reported intense attacks of right periorbital headache, with pain intensity of 10/10 on the visual analog scale. Episodes were associated with trigemino-autonomic phenomena such as ptosis, hyperemia and rhinorrhea, occurring up to six times a day and lasting 15-20 minutes. A good response to high-flow

oxygen was observed. The episodes occurred in cycles of 1-2 months, each cycle lasting 40 days. Treatment with topiramate was initiated but no response. Subsequently, the use of indomethacin began, with a positive response at a full dose of 100mg/day. Considering the response to indomethacin, the diagnosis of paroxysmal hemicrania was confirmed. **Discussion:** This case illustrates overlapping characteristics between cluster headache and paroxysmal hemicrania, including a good response to oxygen therapy, an important confounding factor in this example. The patient demonstrated an excellent response to "Indotest", which is the diagnostic test for detecting headaches responsive to oral indomethacin. Although paroxysmal hemicrania is less common, the clinical overlap and excellent response to indomethacin highlight the importance of precise differential diagnosis. Paroxysmal hemicrania (PH) is characterized by severe, strictly unilateral head pain attacks, localized to orbital, supraorbital, or temporal areas, accompanied by one or more ipsilateral cranial autonomic features. For a diagnosis of PH according to The International Classification of Headache Disorders (ICHD-3), a minimum of 20 attacks is required, with the frequency exceeding five per day for more than half of the time. The duration of attacks typically ranges between 2 to 30 minutes, although duration can vary widely. Usually, PH attacks are spontaneous, but they can be triggered by various stimuli. The primary treatment for preventing paroxysmal hemicrania attacks is indomethacin. An absolute response to indomethacin is one of the diagnostic criteria; however, achieving this response may require very high doses. Paroxysmal hemicrania can be very similar to cluster headache, but PH usually presents with more frequent and shorter attacks and less predilection for nocturnal occurrence. The key factor distinguishing between these two conditions for diagnosis lies in the response to indomethacin. **Final comments:** Cluster headache management is complex, often taking years to properly diagnose. The need to consider Indotest in cases of diagnosis or refractoriness to conventional treatment is reinforced. Differential diagnosis is essential, since trigeminal-autonomic headaches significantly impact the quality of life of those affected. Accurate identification and appropriate management can prevent years of avoidable suffering.

The effect of GLP-1 analogs on the motor function of patients with Parkinson's disease: a systematic review and meta-analysis

Luís Fernando Ferreira Cavalcante[1], Giovanna Costa[1], Sophia Massafelli Battistuta[1], Pedro Faria Makabe[1], Isadora Silva Fanucci Bueno[1], Bruno Yuamoto[1], Felipe Endrigo Gonçalves Vilela[1], Diogo Haddad Santos[1]

[1]Santa Casa de São Paulo, Faculdade de Ciências Médicas, São Paulo SP, Brazil.

Correspondence: Luís Fernando Ferreira Cavalcante; Email: luiscavalcante.med@gmail.com.

Background: Parkinson's disease (PD) stands as the second most prevalent neurodegenerative disorder. Presently, symptomatic management through medication is standard practice, yet effective disease-modifying therapies remain elusive in routine clinical care. The imperative now lies in advancing treatments to preempt and mitigate disabilities such as balance issues, cognitive decline, speech impairments, and swallowing difficulties among PD patients. Recent literature underscores the pivotal role of microglia in perpetuating chronic neuroinflammation characteristic of this condition. Against this backdrop, emerging research is spotlighting glucagon-like peptide-1 (GLP-1) analogs for their potential to restore dopamine levels, curtail dopaminergic loss, mitigate neuronal degeneration, and alleviate both motor and non-motor symptoms of PD. Originally developed for diabetes management, GLP-1 analogs have since revealed additional anti-inflammatory and neuroprotective properties, notably in suppressing microglial activation. To elucidate the possible effect on the motor function of patients with PD, we present a comprehensive meta-analysis and literature review encompassing four randomized controlled trials evaluating GLP-1 analogs versus placebo. **Objective:** To assess the effect of GLP-1 analogs on the motor function of patients with PD. **Methods:** We performed a systematic review and random effects meta-analysis of randomized control trials comparing GLP-1 analogs to placebo in patients with PD through the change from baseline of Part III of the Movement Disorder Society - Unified Parkinson's Disease Rating Scale (MDS-UPDRS). **Results:** The standard mean difference (SMD) of the change in MDS-UPDRS Part III from baseline of patients with PD was not statistically significant (SMD -0.41; 95% CI -0.93 - 0.10; I2=89%; p =0.11). **Conclusion:** Although there is a trend toward improvement, the role of GLP-1 analogs in the improvement of the motor function of patients with PD remains unclear.

https://doi.org/10.5327/CBN241607

The effectiveness of dual task training when combined with exercise on cognition in individuals with Parkinson's disease: a randomized clinical trial

Rogério José de Souza[1], Alessandra Cattaneo Estrada Melanda[1], Guilherme Lopes Barbosa da Silva[1], Andressa Leticia Miri[1], Patrícia Gonçalves Broto[1], Victor Hugo Kenzo Ishii[1], Ana Raquel Lindquist[2], Adriana Costa-Ribeiro[3], Suellen Mary Marinho dos Santos Andrade[3], Suhaila Mahmoud Smaili[1]

[1]Universidade Estadual de Londrina, Londrina PR, Brazil.

Correspondence: Guilherme Lopes Barbosa da Silva; Email: guilhermelps_@hotmail.com.

Background: Cognitive decline is among the most frequent non-motor symptoms of Parkinson's disease (PD). This decline affects daily activities, gait, postural control, and the ability to perform dual tasks (DT). Managing PD, especially its non-motor symptoms, is challenging, leading to a growing interest in studies investigating the effectiveness of various treatment protocols, whether isolated or combined. **Objective:** To verify the effectiveness of dual task training when combined with walking on a treadmill as well as anodal transcranial direct current stimulation (tDCS) on cognition in individuals with PD. **Methods:** This study is a randomized, controlled, blinded clinical trial involving 36 individuals with mild to moderate PD without cognitive decline. Participants were divided into two groups: 1) the Experimental Group (EG): underwent dual task training + walking on a treadmill + anodal tDCS and 2) the Control Group (CG): underwent walking on a treadmill + anodal tDCS. There were 12 intervention sessions, that were conducted three times a week. The dual task training protocol consisted of three levels, with six tasks per level, progressively increasing in complexity, and was applied for 18 minutes while walking on a treadmill. The current was applied to the left dorsolateral prefrontal cortex at an intensity level of 2mA, while walking on a treadmill. A cognitive assessment was conducted using the Montreal Cognitive Assessment (MoCA), the Trail Making Test, and the Stroop Test. Evaluations were performed three times at different points: pre-intervention, post-intervention, and after a 4-week follow-up period. Repeated measures ANOVA was used to compare the groups based on intervention, time, and group-time interaction. The study was approved by the Ethics Committee (CAAE: 30668420.7.0000.5188) and registered at Clinical Trials (NCT04581590). **Results:** There was a significant improvement in cognition in the EG (time effect) between pre- and post-intervention, and between pre-intervention and follow-up in the delayed recall domain and the total MoCA score. Additionally, there was improvement from pre-intervention to follow-up in the Stroop Test performance. For the CG, there was improvement between pre- and post-intervention in the Stroop Test performance, and between pre-intervention and follow-up in the delayed recall domain of the MoCA. No differences were observed between groups or in the time vs. group interaction. **Conclusion:** The addition of dual task training to a combined walking on a treadmill and anodal tDCS protocol was not effective in improving cognition in individuals with PD. Cognition is a complex construct, and more studies are needed to advance this investigation and seek an optimal protocol based on the type, number of sessions, frequency, duration, and intensity of the intervention to aid clinical decision-making.

https://doi.org/10.5327/CBN241608

The effects of general anesthesia on pediatric neurodevelopment: a systematic review

Ana Beatriz Landim Ribeiro[1], Lara Barbosa Vale[1], Estela Rodrigues Cardoso Chiappetta[1], Giovana Rodrigues França[1], Thiago Antonino Gonçalves[1], Gabriela de Sousa Carvalho[1], Gilberto Sadala Mendes[1]

[1]Universidade Nove de Julho, São Paulo SP, Brazil.

Correspondence: Ana Beatriz Landim Ribeiro; Email: ablr2016@icloud.com.

Background: General anesthesia is crucial for safe and painless pediatric procedures, but inadequate sedation can result in adverse outcomes. Animal studies suggest that anesthetics like isoflurane, sevoflurane, and ketamine may cause persistent cognitive dysfunctions. Retrospective studies indicate potential neurodevelopmental risks in children exposed to anesthesia, such as anxiety and learning disorders, particularly with repeated or prolonged exposure. **Objective:** To analyze the neurodevelopmental impairments caused by pediatric exposure to general anesthesia. **Methods:** This systematic review used the PICOT strategy to investigate the effects of general anesthesia (GA) on pediatric neurodevelopment. Searches in PubMed and Scielo up to February 2024 yielded 55 studies. Following PRISMA, articles on GA in children up to 4 years old were included, excluding reviews, meta-analyses, and unrelated articles. The quality of evidence was assessed using GRADE, resulting in 14 articles analyzed in this review. **Results:** According to the National Anesthesia Clinical Outcomes Registry, pediatric anesthesia poses greater neurodevelopmental risks with longer exposures. The majority of the preclinical studies showed that anesthetics like ketamine and sevoflurane cause persistent cognitive dysfunctions, especially with longer exposure. These findings were similar to the results of the clinical trials analyzed, which indicated negative neurodevelopmental effects with more frequent and prolonged exposures, especially in the first year of life. Similar results were seen in a study in Singapore with 100 children undergoing surgeries with anesthetic sedation before 1 year, that found a higher risk of learning disorders at 12 years old. A cohort study with 97 infants undergoing prolonged anesthesia was associated with reduced outcomes on the Bayley-III test at 12 months. The Bayley-III test assesses domains such as cognitive, language, motor, social-emotional, and adaptive behavior in children. In more extensive research, a cohort investigating 100,144 births revealed a higher risk of developmental delays with three or more exposures to GA. There were also contradictory results, such as a study with 33 infants who underwent general anesthesia and were assessed using the Griffiths Mental Development Scales (GMDS), showing no developmental impairment. However, these trials have limitations like small sample

sizes and exposure. **Conclusion:** This review indicates that clinical studies show prolonged exposure to GA in humans is associated with neurodevelopmental delays, varying according to age, clinical condition, and duration of drug exposure. In contrast, single and brief exposures do not appear to impact infant neurodevelopment. It is essential to continue investigating with larger and more specific clinical studies to confirm these findings and better understand the risks associated with anesthetics, particularly sevoflurane and ketamine.

Background: Meningitis is a disease that affects the membranes lining the brain and spinal cord. Caused by viruses, bacteria, or other infectious agents, it can lead to serious complications if not promptly treated, and it can be prevented through vaccination. **Objective:** To conduct an epidemiological analysis of patients with meningitis treated as emergency cases in the state of São Paulo between the years 2019 and 2023. **Methods:** This is an ecological study that obtained data collection through the Hospital Information System (SIH/SUS). The studied population consisted of individuals from the state of São Paulo with meningitis who were treated as emergency cases during the period from 2019 to 2023. The analyzed variables included the number of hospitalizations, age group, gender, and race/ethnicity. Data were collected using descriptive statistical analysis techniques. **Results:** In this five-year period studied, 7,514 cases of meningitis were reported, with the year 2019 recording the highest number of cases, at 2,041 (27.29%), and the year 2021 recording only 947 cases (12.60%), representing the lowest result in these periods. The most affected age group is infants under 1 year old, with 1,559 cases reported (20.74%), and the second most affected age group is children aged 1 to 4 years, with 1,267 cases (16.86%). Elderly individuals over 80 years old had only 64 hospitalizations (0.85%) over the last 5 years. The predominance in terms of race/ethnicity occurs in the white population, with 3,837 cases (51.06%), notably in the year 2019, when 1,013 episodes (13.48%) were recorded. The second most affected population is the mixed-race (parda) population, with 2,311 occurrences (30.75%), with the year 2023 having the highest incidence, with 652 cases (8.67%). The male population predominated over the female, with 4,300 (57.22%) notifications, notably in the year 2019, when 1,182 (15.73%) cases were recorded, while females accounted for 3,214 (42.77%), also with emphasis in 2019, with 859 hospitalizations (11.43%). According to the analysis of the profile of affected patients seeking emergency care, a significant increase in cases was observed in 2019, especially among children under one year old, white individuals, and males, which is consistent with previous studies. It was found that the elderly population was less affected, accounting for only 0.85% of emergency care over the last 5 years. **Conclusion:** Meningitis poses a major challenge to public health. According to these data, there is a predominant distribution in the pediatric population, thus necessitating the implementation of sanitary, educational, and adequate medical care measures to reduce and control meningococcal disease in the study area. Additionally, it underscores the importance of public actions regarding prophylaxis against such pathology, such as extensive vaccination campaigns against influenza and pneumococcus.

The first experience with the use of deutetrabenazine in a young patient diagnosed with tardive dyskinesia in the Brazilian Amazon: a case report

Maria Esther Lima Rios Evangelista[1], Emanuelle Campos Amaral[2], Fernanda Almeida Carvalho[2], Danilo Lemes Reis[2], Manuela Brandão Ferreira Teles[2], David França Ferreira Cruz[2], Victor Hugo Soares dos Santos[2], Jonathas Taumaturgo Soares[2], Marcus Vinicius Della Coletta[2]

[1]Universidade Federal do Amazonas, Manaus AM, Brazil.
[2]Universidade do Estado do Amazonas, Manaus AM, Brazil.

Correspondence: Maria Esther Lima Rios Evangelista; Email: mariaesther.rios@hotmail.com.

Case presentation: Male patient, 24 years old, diagnosed with tardive dyskinesia in 2019 due to the indiscriminate use of neuroleptics following psychiatric hospitalization for a psychotic episode with acute symptoms. After four years of diagnosis and a significant worsening of his quality of life, he began using deutetrabenazine to treat the severe chorea he presented, under medical supervision and recommendation. **Discussion:** Deutetrabenazine (DTBZ) is a highly selective reversible inhibitor of VMAT2, whose mechanism of action involves the depletion of monoamines in the presynaptic terminals of the CNS. It is metabolized via the hepatic route, producing alpha-dihydrodeutetrabenazine and beta-dihydrodeutetrabenazine as metabolites. In 2023, six years afts is approval by FDA, in the USA, and two years after its approval by ANVISA, in Brazil, the first patient in the state of Amazonas began treatment with this medication, obtained through legal means due to its high cost. Therapy began in September 2023 with one 6 mg pill of DTBZ per day for one week, followed by weekly dosage adjustments until reaching a stable dosage of two pills, 6 mg and 9 mg per day. One month after starting treatment, there was a reduction in chorea in the upper limb extremities and the previously present buccolingual stereotypies. After three months of treatment, a significant change in the patient's routine was noted due to the reduction of motor symptoms, allowing a return to activities that were previously not possible, for example playing soccer and feed himself, and reducing the risks of bronchoaspiration due to food. Currently, he exhibits a progressive improvement in symptoms. **Final comments:** As well as demonstrated in randomized studies conducted abroad, deutetrabenazine showed significant efficacy in the symptomatic treatment of tardive dyskinesia in a young patient in Amazonas, leading to a substantial improvement in his quality of life through the modulation of neurotransmitters by the medication.

The great mimicker strikes again: neurosyphilis mimicking viral and autoimmune limbic encephalitides - a case report

Gabriel Abrahão Stoliar[1], Carolina Mibielli[1], Hélio Afonso Ghizoni Teive[1], Caio César Diniz Disserol[1,2,3]

[1]Universidade Federal do Paraná, Hospital de Clínicas, Curitiba PR, Brazil.
[2]Instituto de Neurologia de Curitiba, Curitiba PR, Brazil.
[3]Hospital Israelita Albert Einstein, São Paulo SP, Brazil.

Correspondence: Gabriel Abrahão Stoliar; Email: gabrielstoliar@gmail.com.

Case presentation: A 47 years old man with a history of smoking and drug abuse (crack) presented with 2 months of behavioral changes, aggressiveness, disorientation and focal evolving to to bilateral tonic-clonic seizures. Upon admission he was febrile and there was no respiratory, gastrointestinal or urinary symptoms. Neurological examination revealed spatial disorientation and psychomotor agitation, without changes in cranial nerves, strength, sensitivity, reflexes, balance, coordination or meningoradicular signs. Brain MRI showed T2/FLAIR hyperintensities affecting the right medial temporal lobes. CSF revealed pleocytosis (20 cells; 98% lymphocytes) and elevated protein levels (98.7); glucose was normal. Due to the high suspicion of herpetic encephalitis, IV acyclovir was started. However, two viral panels were negative for HSV-1, HSV-2, VZV and CMV, and CSF VDRL was positive (1:8). Tissue and cell-based assays for superficial and intracellular neuronal antibodies was negative. The treatment was switched to Crystalline Penicillin 4,000,000 IU every 4 hours for 14 days, and the patient had partial clinical improvement, with residual memory deficit and behaviour changes, but without new seizures or neurological deficits. **Discussion:** infection of the central nervous system by Treponema pallidum is known as neurosyphilis. This is a clinically challenging disease because it affects any part of the CNS, explaining its multifaceted presentations and why is a great mimicker of many disorders. Syphilitic limbic encephalitis mimicking viral or autoimmune encephalitis is rare. Some cases of rapidly progressive neuropsychiatric symptoms with or without seizures and limbic encephalitis on MRI affecting one or both medial temporal lobes have been described. Limbic encephalitis secondary to neurosyphilis still has an uncertain cause. It is possible that intense meningovascular inflammation may cause vasogenic, cytotoxic, and interstitial edema. Furthermore, ischemic changes in small vessels induced by infection can cause gliosis. **Final comments:** This case represents an atypical manifestation of neurosyphilis with limbic system involvement, typical topography of viral and autoimmune etiologies, with partial recovery after antibiotic therapy. Physicians should be aware of this very uncommon presentation of neurosyphilis, which mainly mimics viral and autoimmune encephalitides.

The impact of a stroke unit at Northeastern Brazil on the national institute of health stroke scale and the average rankin: an original study

Maria Luiza Vasconcelos Montenegro[1], Maria Eduarda Vieira de Oliveira[1], Lívia Barbosa Cavalcanti[1], Isaías Henrique Martins de Vasconcelos Norte Bezerra[1], Noelle Ventura Jordão[2], Maria Eduarda Moreira Cardoso[2], Ana Dolores Firmino Santos do Nascimento[2]

[1]Universidade de Pernambuco, Recife PE, Brazil.
[2]Hospital da Restauração, Recife PE, Brazil.

Correspondence: Maria Luiza Vasconcelos Montenegro; Email: marialuizavasc534@gmail.com.

Background: Stroke is a leading cause of death worldwide, accounting for approximately 100,000 deaths annually in Brazil alone. Survivors often experience functional deficits; approximately three-quarters suffer moderate impairments, while 15 to 30% endure severe deficits.

Various scales play crucial roles in stroke assessment, notably the NIH Stroke Scale (NIHSS) for evaluating clinical severity and progression, and the Rankin Scale for assessing patient disability levels. In Brazil, the average cost per stroke patient is $11,300, significantly lower compared to developed countries. Specialized stroke units are pivotal in delivering prompt and effective treatment, thereby enhancing recovery prospects and minimizing long-term sequelae. **Objective:** To evaluate the neurological deficits and functionality of patients admitted to a Stroke Care Unit (SCU), using the NIHSS and RANKIN scales, respectively. **Methods:** This study is a retrospective cohort carried out in a SCU at a reference center, in Pernambuco, Brazil, between January of 2023 and May of 2024, evaluating the NIHSS and the RANKIN scales. The inclusion criteria were patients with stroke of ischemic etiology with age and sex registered, and individuals with at least one of the scales assessed at the time of entry and exit from the hospital. **Results:** 1,224 patients admitted to the SCU were identified, however, 701 were excluded as they did not meet the inclusion criteria, leaving 523 individuals. The study consisted of 276 (52.8%) male, with the average age of the patients being 65.7 years old. Among them, 256 (49%) underwent intravenous administration of thrombolytic agents. The average NIHSS on admission was 12.2. At the time of hospital discharge, the average NIHSS was 9.7 points. About RANKIN, the average value at admission was 0.52, while at hospital discharge there was an increase to 2.6. **Conclusion:** A higher prevalence of ischemic stroke was observed as people aged and in men, with the majority of individuals being treated conservatively. The average NIHSS value was reduced by 20.4% when comparing the moments of hospital admission and discharge, which reveals the importance of stroke units in transforming the patient's prognosis. Despite the increase in RANKIN, the average found in this study was below that reported in another Brazilian study.

The impact of dysphagia on quality life in Parkinson's disease

Vivian Kaori Segawa[1], Arthur Jun Deguti Hata[1], Ana Luiza Fabris Moraes[1], Margarete Jesus Carvalho[1], Alice Estevo Dias[1], Emerson Gisoldi[1]

[1]Faculdade de Medicina do ABC, Santo André SP, Brazil.

Correspondence: Vivian Kaori Segawa; Email: viviankaorisegawa@gmail.com.

Background: Idiopathic Parkinson's disease (IPD) is a neurodegenerative, chronic and slowly evolving pathology that mainly affects the population over the age of 65. Dysphagia is one of the disabling clinical manifestations and affects approximately 80% of patients with IPD. **Objective:** To assess the presence and degree of severity of dysphagia symptoms in patients with ILD. **Methods:** A study was carried out using the Eating Assessment Tool (EAT-10), made up of 10 questions graded from 0 to 4, with 0 corresponding to "no problems" and 4 to "severe problems". The instrument's cut-off point is 3 points, a score equal to or greater than this value indicates a risk of dysphagia. The patients were assessed using the Hoehn & Yahr (H&Y) scale and the Unified Parkinson's Disease Rating Scale (UPDRS) parts I, II, III, IV and V. Pearson's correlation test was used. **Results:** 25 patients with IPD aged between 40 and 80 years were assessed, 14 (56%) of whom were female and 11 (44%) male. The H&Y scale showed that 21 patients (84%) had mild to moderate disability, with answers between 1 and 3, and 4 patients (16%) had severe disability. The UPDRS ranged from 9 to 96. The EAT-10 showed that 4 patients (16%) complained of pain when swallowing; 6 patients (24%) were stressed by swallowing difficulties and had to make efforts to swallow medicines; 7 patients (28%) lost weight due to swallowing problems, reported straining to swallow solids and liquids and reported a reduction in the pleasure of eating; 8 patients (32%) reported that food stuck in their throats; 9 patients (36%) coughed while eating and 12 patients (48%) said they stopped eating out because of swallowing difficulties. There were 12 (48%) scores below 3, representing a low risk of dysphagia, and 13 (52%) scores equal to or greater than 3, with the highest score being 32. There was a weak correlation between H&Y and EAT-10, while the correlation between UPDRS and EAT-10 was moderate. **Conclusion:** This study showed that the EAT-10 was effective in identifying patients' swallowing difficulties and how they affected their quality of life, and could be used during neurological assessment to make a diagnosis. High UPDRS scores denoted severe dysphagia and prompted immediate referral for speech therapy analysis and rehabilitation.

The impact of external attentional focus on prefrontal cortex activity: a preliminary stud

Maria Eduarda Salum Aveiro Henrique[1], Clara Rezende Rocha[1], Pedro Henrique Sousa de Andrade[1], Caroline Rodrigues Osawa[1], Jayne Siqueira Cagliari[1], Marco Túlio Almeida Lenza[1], Luciane Aparecida Pascucci Sande de Souza[1], Gustavo José Luvizutto[1]

[1]Universidade Federal do Triângulo Mineiro, Uberaba MG, Brazil.

Correspondence: Maria Eduarda Salum Aveiro Henrique; Email: aveiromariaeduarda@gmail.com.

Background: Motor control depend on the interaction of the individual with the task and the environment. To develop successful daily tasks, the individual must control movement synchronicity and coordination, which requires prefrontal lobe activity. The frontal lobe is the part of the cortex responsible for executive functions such as planning, organization, and attention targeting. It is possible to optimize coordination during a task to target attention to an external focus. Despite literature proving that an external focus may improve muscular activity during movement, no studies assess the influence of a focus of attention on brain activity. **Objective:** To measure the effect of different foci of attention on prefrontal lobe activity in healthy people during a lower limb task. **Methods:** This is a cross-sectional study with ten neurologically healthy individuals. The prefrontal activity was measured by hemoencephalography (HEG Neurobots®) with sensors allocated at the Fp1 and Fp2 areas during three different activities. Brain activation was assessed by the increase of oxyhemoglobin (oHb) during the realization of each task according to the optical density (OD) presented by the device. Higher levels of oHb increase the OD due to lower absorption of light sent by the device. In the first task, the volunteer had to touch a step 20.3 cm high with the right (RS) and left (LS) legs; the second task demanded touching a plastic cup 8 cm high and 7.5 cm in superior diameter with both legs (RCA/LCA); in the third task, the individual had to perform the same movement as task two but with a plastic cup 4 cm high and 5.3 cm in superior diameter (RCB/LCB). The cups were placed on a platform to measure their height with the step. Each task was performed three times, and the third attempt was analyzed. The OD comparison between tasks and moments of the tasks was analyzed by the ANOVA test of repeated measures and the Tukey test of multiple comparisons. The data was considered statistically significant if $p<0.05$. **Results:** Five women and four men with a mean age of 27.1 years (±5.5) were evaluated. In most tasks, the OD mean registered on HEG was higher at the beginning of the activity than in the other moments (execution and end). There was a statistical difference only in the moments of the RCB ($F=4.0$; $p=0.046$). In the multiple comparison analysis, differences were observed between the beginning and the task ending (MD: 4.3; $p=0.032$). **Conclusion:** Prefrontal lobe activity is highest at the beginning of the task compared to the end when it comes to the RCB activity. This finding suggests that the executive functions related to planning during a task are more significant in its initial phase than in execution and end, especially in tasks requiring more precision.

Background: Sexual dysfunction (SD) is a common non-motor symptom (NMS) in people with Parkinson's disease (PwPD). Sexual health (SH) depends on several biological, mental, and social factors that PD may affect. Despite its prevalence and relevance for quality of life, SD in women with Parkinson's disease (WwPD) is poorly understood, and research in this area is scarce. **Objective:** To investigate the impact of motor, non-motor, and social aspects on the SH of WwPD. **Methods:** We conducted a cross-sectional study of 100 women with confirmed diagnosis of idiopathic PD, (mean age 54.45±8.31), in stages 1-3 of Hoehn and Yahr classification, who reported having an active sex life in the last six months. The following data were collected by remote interview for each participant: (1) Demographic and clinical features; (2) global cognitive capacity; (3) Non-Motor Aspects of Experiences of Daily Living; (4) Motor Aspects of Experiences of Daily Living; (5) Fatigue; (6) Self-esteem; (7) Sleep disorder; (8) Couple relationship quality (CRQ); (9) Depressive signals; (10) Short-term sexual health by Female Sexual Function Index; and (11) Long-term sexual health by Sexual Quotient-Female. **Results:** We found that several motor, non-motor, and social factors were correlated with SH. However, only CRQ and sleep quality were able to predict short and long-term SH in WwPD. We did not find any significant correlations between SH and age, disease onset, post-menopausal period or medication daily dosage. **Conclusion:** Our findings highlight the importance of a multi-professional team approach to provide comprehensive care to improve SH in WwPD.

The impact of PLCG2 gene variants on the pathophysiology of Alzheimer's disease

Savicevic Ortega Silva de Melo[1], Rebeka Mayara Santana Carneiro[1]

[1]Faculdade Pernambucana de Saúde, Recife PE, Brazil.

Correspondence: Savicevic Ortega Silva de Melo; Email: ortegasavicevic@gmail.com.

Background: Alzheimer's disease (AD) is the leading cause of dementia worldwide, characterized by memory loss and progressive cognitive decline. Genome-wide association studies (GWAS) have highlighted the role of microglia in AD pathology, with phospholipase C gamma

2 (PLCγ2) being a gene of particular interest. PLCγ2, expressed in microglia, is involved in immune signaling and cerebral inflammatory response. The P522R variant of the PLCG2 gene has been associated with a reduced risk of AD and other neurodegenerative diseases. This systematic review investigates the impact of PLCG2 gene variants on the pathophysiology of AD, exploring their effects on microglial activity, neuroinflammation, and disease progression, aiming to contribute to the development of new therapies and diagnostic strategies. **Objective:** This study aims to investigate the impact of PLCG2 gene variants on the pathophysiology of AD. We seek to identify specific PLCG2 variants associated with the disease, evaluate their effect on microglial activity, and explore the underlying molecular mechanisms. **Methods:** This is a systematic review based on PRISMA methodological recommendations. The databases used were Lilacs and PubMed. The search descriptors were: "Alzheimer" and "Phospholipase C Gamma". Inclusion criteria were: articles published between 1998 and 2024, in English and Portuguese, specifically investigating the relationship of the PLCG2 gene with AD. We excluded studies in rodents and unavailable texts. **Results:** Of the 44 initially selected articles, 15 were reviewed, providing a detailed view of the central role of PLCγ2 in neurodegenerative diseases, focusing on AD. These studies showed that specific genetic variants, such as P522R, are associated with a reduced risk of AD. The P522R variant was consistently related to the promotion of beta-amyloid clearance and the enhancement of a protective microglial function, characterized by modulated inflammatory responses and increased phagocytic capacity. Conversely, hypermorphic variants such as S707Y were identified as causing exacerbated dysfunctions in microglial cells. These hyperactive PLCγ2 variants demonstrated significant adverse effects, impairing microglial function, potentiating inflammatory processes, and contributing to pathological progression in neurodegenerative disease models. **Conclusion:** The reviewed studies highlighted PLCγ2's crucial role in regulating immune cell processes, including signaling, immune response, and phagocytosis. Optimized fluorogenic substrates enabled advanced methods to assess PLCγ2 activity, facilitating the identification of potential therapeutic activators or inhibitors. These findings enhance our understanding of AD and other neurodegenerative conditions, offering promising avenues for targeted therapies that improve microglial function and reduce the pathological burden in the central nervous system.

The impact of population aging on hospitalizations for Alzheimer's disease: a temporal analysis

Sávio Roberto Roberto Silva[1], Marcos Lude da Silva Ferreira[1], Bruno Kauê Rodrigues Vilhena[1], Danusa Neves Somensi[1], Mariangela Moreno Domingues[1], Emanuel de Jesus Soares de Sousa[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Sávio Roberto Silva Costa; Email: saviorsc20@gmail.com.

Background: From 2010 to 2022, the elderly population in Brazil grew rapidly, increasing by 57.4% to 22.2 million, which represents 10.9% of the Brazilian population. Since aging is considered to be the most significant risk factor for developing Alzheimer's disease (AD), the demographic transition implies an enormous public health challenge. In this context, epidemiological studies on AD in the country are important, in order to provide data to help plan health policies focused on the population studied. **Objective:** To analyze how the aging of the population over two decades has affected hospitalizations for AD in Brazil. **Methods:** This is an ecological, cross-sectional, observational study with a quantitative approach. Secondary data was collected from the Department of Information and Informatics of the Unified Health System (DATASUS), in the hospital morbidity section (SIH/SUS). The data collected refers to the years 2009 to 2023. Variables related to the number of hospitalizations, type of hospitalization, gender, ethnicity, age group, average cost of hospitalization, average length of stay and mortality rate were analyzed. A p-value of less than 0.05 was considered statistically significant for this study; Bioestat 5.3 software was used for the statistical analysis. **Results:** In 10 years, 19,598 hospitalizations for ad were recorded in Brazil. The population aged 65 and over accounted for 92.8% of hospitalizations, while patients with early-onset Alzheimer's (under 65) accounted for 7.2% of the records. In this context, the population aged 80 and over accounted for the majority of hospitalizations, with 57.2% of the total, followed by the 75-79 age group, which accounted for 18% of cases. The age group with the highest relative growth in hospitalizations in the period was 80 years or older (350%), followed by the 60 to 64 age group (334%). In terms of gender, 35% of inpatients were male and 65% female. In addition, 49.7% of patients were identified as white, 20% as brown and only 4% as black. The mortality rate for the period was 4.46, with an average length of stay of 5.4 days. The average cost of hospitalization during the period was R$1,233.92. **Conclusion:** The study revealed that the population most affected is over 65 years old, which highlights the importance of aging. In addition, there was an increase in hospitalizations of patients at an early age for the disease, suggesting the existence of risk factors to be better investigated. In addition, there was a clear predominance of females and whites in hospitalizations, with fewer hospitalizations of the black population. This study can help define public health policies so that they can be more efficient and based on the national reality.

The impact of sex differences on the systemic consequences of diabetes associated with ischemic stroke: a preclinical study

Khiany Mathias[1], Richard Simon Machado[1], Nathalya Camila Cruz Guerra Correa[2], Edgar Pereira[2], Solange Stork[1], Maiara de Aguiar da Costa[2], Victoria Linden de Rezende[2], David dos Santos[2], Gislaine Tezza Rezin[1], Fabricia Petronilho[2]

[1]Universidade do Sul de Santa Catarina, Tubarão SC, Brazil.
[2]Universidade do Extremo Sul Catarinense, Criciúma SC, Brazil.

Correspondence: Khiany Damaris Mathias Maurilio; Email: khianymathiasft@gmail.com.

Background: Diabetes mellitus (DM) is a disease characterized by elevated serum glucose levels, a condition known as hyperglycemia. Hyperglycemia plays a crucial role in the occurrence of complications related to DM, such as ischemic stroke (IS), which results in the interruption or reduction of cerebral blood flow in a focal region of the brain, compromising neurological function. **Objective:** Considering the hypothesis that DM and its hyperglycemic state may not only predispose to IS but also enhance post-ischemic immune and glycemic pathways, the present study aimed to understand the pathophysiological mechanisms of DM in the occurrence and outcome of IS, examining their association with worse outcomes in affected individuals. **Methods:** We randomly assigned male Wistar rats, aged 60 days, into four experimental groups: (1) sham + sham, (2) sham + middle cerebral artery occlusion (MCAO), (3) DM + sham, and (4) DM + MCAO. Animals were experimentally induced into a DM model by a single administration of alloxan 150 mg/kg intraperitoneally, and after 2 days, they underwent the MCAO model to induce IS. Twenty-four hours after painless euthanasia, blood was collected for biochemical analyses, weight evaluation, temperature, neurological score, glycemic, and immunological parameter assessment. **Results:** There was an increase in glucose levels in both sexes on day 2 after alloxan induction compared to day 0, confirming the hyperglycemia model. In both male and female rats, diabetic animals subjected to MCAO showed a significant increase in glucose levels in urine and blood compared to the control group without diabetes. In females, there was a significant decrease in segmented cells in the DM + MCAO group compared to the DM + sham group and a significant increase in lymphocytes in the DM + MCAO and sham + MCAO groups compared to their respective controls, with a decrease in total leukocytes in DM + MCAO females. In males, there was a significant decrease in size in the DM + MCAO group compared to the sham + sham group, possibly explained by the recruitment of immune cells from the spleen. In terms of weight, there was a decrease in spleen weight in DM+MCAO females and males. In females, there was a decrease in the spleen weight/body weight ratio in both the sham + MCAO and DM + MCAO groups. **Conclusion:** The hyperglycemic state, in addition to promoting the occurrence of the disease, is capable of altering the immune response after cerebral ischemia and worsening the outcome of the disease caused by the animal's sex.

[10]Universidade Federal do Acre, Rio Branco AC, Brazil.

Correspondence: Fernando Luiz Westphal Filho; Email: fernandowestphal1@gmail.com.

Background: Statins have attracted attention for their possible effects on brain function and cognition in addition to their cardiovascular benefits. Observational studies suggest that statins may lower the risk of Alzheimer's disease and other types of dementia, but evidence from clinical trials is mixed. Furthermore, the body of evidence lacks thorough evaluations of whether statins are linked to slower cognitive decline. **Objective:** To provide a current and thorough review of the link between statin use and cognitive decline while also pointing out the limitations of the existing evidence. **Methods:** MEDLINE, EMBASE, and Web of Science databases were systematically searched until May 14, 2024. We included observational studies and trials that evaluated the impact of statins in the deterioration of cognitive function in patients with and without dementia through Mini-Mental State Examination (MMSE) score assessment. We computed the MMSE scores at baseline and at the end of follow-up to calculate the mean difference. Data were analyzed using the Mantel-Haenszel method and 95% confidence intervals (CI). Heterogeneity was assessed using I^2 statistics. Statistical analysis was performed using R, version 4.3.2. **Results:** A total of 4 studies were included in this meta-analysis, comprising 3 observational studies and 1 randomized clinical trial, with a combined total of

2,345 patients. Among these, 847 patients were under statin therapy. When compared with the control group, there was no statistically significant difference regarding improvement in the deterioration of cognitive function (MMSE MD 0.70; 95% CI - 0.25 to 1.66; P=0.149; I^2=96%). **Conclusion:** In this comprehensive systematic review and meta-analysis, no statistically significant association was found between statin use and the improvement of cognitive function deterioration, as measured by the MMSE scores. The results highlight a critical gap in the literature: the current evidence, primarily derived from a limited number of observational studies and a single randomized clinical trial, is insufficient to draw definitive conclusions. Therefore, our study underscores the urgent need for more robust and well-designed randomized clinical trials assessing the impact of statin therapy on cognitive function.

https://doi.org/10.5327/CBN241620

The impacts of non-pharmacological therapies on the quality of life of patients with Alzheimer's disease: a systematic review

Priscila Santos Oliveira[1], Emmanuel Santos Trindade[1], Victor Santos Vilares[1], Luídi Neves Nascimento[1], Naila Maria Magalhães da Silva[1], Philip George Glass Andrade[1], Davi Tanajura Costa[1]

[1]Universidade Estadual do Sudoeste da Bahia, Vitória da Conquista BA, Brazil.

Correspondence: Emmanuel Santos Trindade; Email: emmanuelstrindade@gmail.com.

Background: Alzheimer's disease (AD) is a neurodegenerative condition that challenges the physical and mental health of individuals but also affects their Quality of Life (QoL). The concept of QoL transcends mere absence of disease, encompassing multidimensional aspects reflecting physical, psychological, social, and emotional well-being. Addressing the various dimensions of AD, in which the insidious progression of the disease often deprives patients of their autonomy and identity, preservation and promotion of quality of life emerge as essential objectives in caring for these individuals. **Objective:** To conduct a systematic review of the impacts of non-pharmacological therapies on the Quality of Life of patients with Alzheimer's Disease described in the literature in the last 10 years. **Methods:** A systematic literature review was conducted in PubMed and BVS databases on March 18, 2024. The descriptors "Alzheimer's disease", "non-pharmacological treatment", and "quality of life" were used, combined with the boolean operator AND. Systematic reviews and meta-analyses published in the last 10 years in English, Portuguese, and Spanish were included. 48 articles were found, of which 22 were selected after initial reading of the abstracts. After full-text reading, 9 were excluded and 13 were included in this research. **Results:** Among non-pharmacological therapies, music therapy, whether singing or listening to music, appears as one of the main alternative therapies for AD, with improvements in some cognitive domains such as attention and language, and in the patient's QoL. Additionally, dance can be a useful tool in the promotion of wellbeing in patients with AD and Mild Cognitive Impairment well-being, assisting in balance and, primarily, in promoting mental health, which is helpful in depression management. Reminiscence therapy presented positive results in the global cognitive and neuropsychiatric aspects of AD patients, with improvement in depressive symptoms. It is a low-cost technique that improved the QoL of patients after its application. Structured physical activity is also a tool that promotes QoL, assisting in cognitive improvement and sleep. Cognitive stimulation was another approach that proved relevant improvement in QoL and overall cognition, providing benefits even in ADLs. These activities, especially if applied in a multimodal form, can help promote the comfort of these patients. **Conclusion:** It is observed that there is a definitive responsiveness of patients with Alzheimer's Disease (AD) to non-pharmacological treatments. In this sense, despite their apparent simplicity, these activities directly contribute to the positive QoL of individuals with AD and indirectly affect neurocognitive aspects that sometimes reflect consequences of disease progression. Therefore, such non-pharmacological therapies are treatment modalities capable of addressing not only AD but also the associated negative impacts.

The importance of differential diagnosis in acute vestibular syndrome

Daniela Aparecida Lima Viana[1], Amanda Soares Pimenta[1], João Henrique da Matta Clementino[1], Ana Luisa Rufino de Sousa[1], Elisângela Ferraz Pazinat[1], Giovani Zago Borges[1], Alex Eduardo Silva[1]

[1]Universidade Federal do Triângulo Mineiro, Uberaba MG, Brazil.

Correspondence: Daniela Aparecida Lima Viana; Email: danialviana@hotmail.com.

Case presentation: Man, 70 years old, started experiencing dizzying symptoms 15 days ago associated with nausea and vomiting that improved in less than 24 hours and began treatment for labyrinthopathy. He was admitted to the emergency room with vertigo, peripheral facial paralysis on the left, tongue and lip rhyme with deviation to the right, tactile and painful hypoesthesia on the left hemiface, absence of strength deficits and nystagmus. Previously hypertensive and denied smoking. The patient was admitted to the neurological unit in a window for thrombolysis, but with a head tomography showing acute infarction of the left middle cerebellar pendunculus. The investigation was complemented with transthoracic echocardiogram and electrocardiogram without changes that would justify the ischemic event. Arterial CT angiography of cervical and intracranial arteries, small amorphous filling defects in the V1 and V2 (proximal) segments of the left vertebral artery and slight irregularity in the contours of the P2 segment of the left posterior cerebral artery. **Discussion:** Posterior fossa stroke can cause dizzying symptoms, changes in motor and sensory coordination, facial and swallowing impairment. **Final comments:** it is extremely important to carry out the differential diagnosis between peripheral and central vertigo, since the treatment is directed to the cause of the vertigo with the possibility of definitive treatments when possible and rehabilitation.

The importance of multidisciplinary management in Miller Fisher syndrome associated with bickerstaff encephalitis: a case report

Guilherme Antonio Niemeyer Di Mango[1], Bruna de Andrade Hees[2]

[1]Universidade Federal Fluminense, Niterói RJ, Brazil.
[2]Estacio de Sá, Rio de Janeiro RJ, Brazil.

Correspondence: Guilherme Antônio Niemeyer Di Mango; Email: guilherme.dimango@gmail.com.

Background: Miller Fisher syndrome, a benign variant of Guillain-Barré syndrome, characterized by extrinsic ophthalmoplegia, cerebellar ataxia and profound areflexia, may be associated with Bickerstaff encephalitis, constitutes a pathology that requires intensive and multidisciplinary care. **Objective:** To report the clinical and therapeutic evolution of a patient with Miller-Fisher syndrome, Bickerstaff encephalitis and other complications, to discuss its particularities in intensive care, based on the analysis of a case in 2015. **Methods:** This work consists of a case report, with narrative review of articles, whose information and a data contained were obtained through careful reading and review of the medical record, interview with the patient and photographic record of complementary exams, with proper authorizations and signatures on the consent form. **Results:** It is a case report from the year 2015 of an adult female patient who developed Miller Fisher syndrome after Zika virus infection, also presenting Bickerstaff encephalitis. She was treated with venous immunoglobulin in the context of an intensive care unit, supported by a multidisciplinary team trained to manage the case, showing a good response to the therapeutic proposal. **Conclusion:** Treatment for Miller-Fisher syndrome, when indicated, should not be delayed due to the high potential for complications. For an adequate approach to the patient, it is important that there is a multidisciplinary support for the management of the case, in addition to pharmacological or non-pharmacological disease-modifying treatment.

Correspondence: Jocsã David Gomes Santos; Email: jocsadavid.jd@gmail.com.

Background: Stroke is defined as the rapid onset of an episode with symptoms characterized by focal or generalized deficiencies in brain function, vascular motivation, and manifestations lasting at least 24 hours. These symptoms cause changes in the cognitive and motor planning of the affected individual, depending on the location and extent of the lesion. **Objective:** Investigate, through a literature review, the main aspects related to ischemic stroke and possible relationships with changes in cognitive performance. **Methods:** The databases Up To Date, Scielo, Science Direct, and Pubmed were searched with the descriptors "ischemic stroke," "cognitive performance," and "symptoms." Studies of the last 10 years were considered, in addition to English, Portuguese, and Spanish. **Results:** The literature states that approximately 50% of individuals affected by an ischemic stroke manifest cognitive deficits six months after the episode. In addition, stroke has a high incidence, prevalence, and mortality rate, especially in economically less developed countries, and affected elderly individuals are more likely to have impaired cognitive performance after stroke compared to young people. **Conclusion:** Therefore, stroke often leaves sequelae in surviving patients; among these sequelae is the alteration of cognitive performance. To understand the severity, it is necessary to consider the affected area, the extent of the damage, and the structures associated with this brain region.

The influence of the gut microbiome on stroke incidence and recovery: mechanisms and therapeutic interventions

Jocsã David Gomes Santos[1], Maria Clara de Sousa Morais[1], Raquel de Sousa Lima[1], Renata Amélia Léda Moura[1], Luan Kelves Miranda e Souza[1], Lucas Mainardo Rodrigues Bezerra[1], João Felipe Fernandes Brito[1], Maria Tereza Viana Lima[1], Ana Júlia Araújo Fortes[1]

[1]Instituto de Educação Superior do Vale do Parnaíba, Parnaíba PI, Brazil.

Correspondence: Jocsã David Gomes Santos; Email: jocsadavid.jd@gmail.com.

Background: The interaction between the gut microbiome and the cerebrovascular system has been shown to be crucial in determining neurological health. Recent studies have shown that the composition of the gut microbiome can influence both stroke incidence and recovery. This emerging field offers a new perspective on the pathophysiological mechanisms of stroke, as well as suggesting possible therapeutic interventions to improve clinical outcomes. Investigating the gut microbiome opens avenues to understand how alterations in gut flora may affect stroke risk and subsequent recovery. **Objective:** To explore the influence of the gut microbiome on stroke incidence and recovery, elucidating the biological mechanisms involved and evaluating therapeutic interventions based on microbiome modulation. **Methods:** This is an integrative literature review, using descriptors such as "Gut Microbiome" and "Stroke" combined by the Boolean operator AND. The databases consulted were PubMed and Scielo, covering publications in Portuguese, English and Spanish between 2019 and 2024. Original studies, systematic reviews and meta-analyses were included, excluding letters to the editor, editorials and opinion pieces. The analysis focused on studies investigating the composition of the microbiome in stroke patients, mechanisms of interaction between the microbiome and the central nervous system, and therapeutic interventions such as the use of probiotics and prebiotics. **Results:** The review revealed that stroke patients often present with dysbiosis, characterized by a reduction in microbial diversity and a predominance of pro-inflammatory bacteria. In this sense, suggested mechanisms include bacterial translocation and modulation of the gut-brain axis, influencing systemic inflammatory responses and neuroinflammation. Interventions with probiotics, especially with strains of Lactobacillus and Bifidobacterium, have shown potential in restoring the healthy composition of the microbiome, reducing inflammatory markers and improving functional recovery in pre-clinical and clinical models. In addition, diets rich in fiber and prebiotics have shown benefits in modulating the intestinal microbiota and protecting against cerebrovascular lesions. **Conclusion:** Modulation of the gut microbiome is emerging as a promising strategy for stroke prevention and treatment. Understanding the mechanisms by which the microbiome influences cerebrovascular health is key to the development of innovative therapies. Personalized interventions based on the individual microbial profile could optimize clinical outcomes, offering a new approach to post-stroke rehabilitation. This interdisciplinary field has the potential to transform clinical practice and significantly improve the quality of life of patients with cerebrovascular diseases.

The joint increase in deaths and hospitalizations of patients affected by malignant neoplasm of the brain in Northeastern Brazil: analysis of a 12-year epidemiological overview

Marconny Alexandre Oliveira de Medeiros Cavalcante[1], Thiago Luís Marques Lopes[1], Mateus Dutra Balsells[1], Hildel Freire Leite Filho[1], Matheus Lima de Oliveira[1], Oliver Reiks Miyajima[1], Lorenzo Marinho Morais[1], Késia Sindy Alves Ferreira Pereira[1], Chiara Gübel Portugal[1], Daniel Pereira dos Santos[1]

[1]Universidade Estadual do Ceará, Fortaleza CE, Brazil.

Correspondence: Marconny Alexandre Oliveira de Medeiros Cavalcante; Email: alexandremarc1912@gmail.com.

Background: Malignant brain neoplasms (MBN), also known as brain cancers, represent the eighth most prevalent type of tumor in adults over forty years of age, and metastases are closely related to other very prevalent neoplasms, such as breast, skin and lung neoplasms. Due to the limitation of standard therapies, MBN are often endowed with a poor prognosis and the quality of life of patients is greatly affected. Despite this, this is a topic that, in the Brazilian northeast, needs further investigation. Thus, based on the need for a better understanding of this scenario, the justification of this study is given by the intention to better understand this panorama through epidemiology. **Objective:** To analyze the relationship between deaths and hospitalizations caused by MBN in the northeastern region of Brazil, using a twelve-year epidemiological overview. **Methods:** As this is an epidemiological study of secondary data, of the observational, descriptive and analytical type, the "TabNet" platform was accessed, where the axis "Epidemiological and Morbidity" and the topic "Hospital Morbidity of the SUS (SIH/SUS)" were chosen. Next, we selected "General, by place of hospitalization - from 2008 onwards" and "Brazil by Region and Federation Unit". Subsequently, in order to obtain the data for this study, the line "Age group 1", the column "Year of processing" the period "Jan/2012- Dec/2023" and the contents "deaths" and "hospitalizations" were adopted. Finally, from the available selections, "2 Northeast Region" and "Malignant neoplasm of the brain" were chosen in the ICD-10 Region and Morb List, respectively. **Results:** Considering the period from January 2012 to December 2023, there were 4,635 deaths due to MBN in northeastern Brazil, of which the majority, 2,553 (55.1%), were recorded in people aged 50 to 79 years. Dividing this period into four three-year intervals, it is possible to perceive, comparing the 2012-2014 interval (1,037 deaths) with the 2021-2023 interval (1,324 deaths), an increase of 27.7% in the number of deaths. In the case of hospitalizations, during the 12-year period mentioned above, 35,646 occurrences were recorded, of which a considerable portion, 16,659 (46.7%), were associated with people aged 40 to 69 years. Comparing the last three years (10,506 hospitalizations) with the oldest three-year period under analysis (8,165 hospitalizations), an increase of 28.7% is seen. **Conclusion:** Therefore, it is inferred that, together with a higher number of hospitalizations due to MBN treatment, there was a relevant increase in the number of deaths related to this scenario. In addition, the older portion of the adult population and the younger portion of the elderly population were found to be the most affected by the incidence of hospitalizations and deaths associated with this disease. Thus, due to this progressive relevance, more and more studies are needed to improve the management of this scenario of increasing aggravation.

The MCT8 deficiency (Allan-Herndon-Dudley syndrome) from the child neurodevelopment point of view

Marina Ottmann Boff[1], Gabriella Sityá Moojen da Silveira[1], Ana Carolina Baldi Pasqualini[1], Alessandro Batista Soares[1], Eduarda Gandolfi Horst[1], Vanessa Pellenz Soares[1], Ana Lima[1], Luísa Castro Gomes[1], Frederico Orlando Friedrich[1], Magda Lahorgue Nunes[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Marina Ottmann Boff; Email: mottmannboff@gmail.com.

Background: Thyroid hormones (TH) are crucial for the regulation of the metabolism and development, including that of the brain. A mutation in SLC16A2 causes the deficiency of MCT8, a TH transport protein in the brain. It manifests as the Allan-Herndon-Dudley Syndrome (AHDS), which is characterized by severe intellectual and motor deficits resultant from the brain hypothyroidism and by multisystemic sequels secondary to the peripheral hyperthyroidism. A study aiming to identify which outcomes were most valued by the patients' parents showed that the improvement of motor and language abilities occupied 1st place, meaning that the AHDS's neurodevelopmental aspect is responsible for most of the burden in the patients' and their relatives' lives. **Objective:** To gather recent scientific evidence regarding the neurodevelopment in AHDS. **Methods:** This systematic review has been conducted in the Scopus, PubMed and Embase databases with the following Medical Subject Headings (MeSH) terms and boolean operators: "Neurodevelopmental disorder" AND "Monocarboxylate transporter 8 deficiency"; as recommended by the Preferred Reporting Items for Systematic reviews and Meta-Analysis (PRISMA). The inclusion criteria were original articles, open access, published from 2014 to 2024, in english or portuguese, and the exclusion one was non-correspondent text subject. The initial search resulted in 10 distinct articles from which 9 were selected. **Results:** In the nervous system SAHD causes hypomyelination, impairment of the differentiation of GABAergic interneurons and delay in the development of the cerebellum. Global hypotonia, hypertonia due to dystonia and spasticity and persistence of primitive reflexes are present in 90% of the cases and their identification is essential for surveillance and early differential diagnosis. Treatments are based on the administration of THs or their analogues. Triiodothyroacetic acid, an MCT8-independent THs metabolite, inhibits THs production and has low peripheral thyromimetic activity, but it has only been evaluated for neurodevelopment preclinically and exploratorily, presenting to be effective on the neurodevelopmental aspect only if administered early. Sob-AM2, a prodrug of an HT analogue capable of crossing the placental and blood-brain barrier and being specifically metabolized in the brain, is a strong candidate for the prenatal treatment of SAHD, since neurological improvement depends on early treatment. The effectiveness of levodopa, carbidopa and botulinum toxin is quite variable between patients, and may improve spontaneous movements temporarily or not. There was no improvement in the development with diiodothyropropionic acid (recommended treatment), T3 and T4. **Conclusion:** Given the rarity of SAHD, little scientific evidence is produced about it. Even case reports are extremely important for its better characterization. Ongoing trials should better elucidate its treatment from a neurodevelopmental perspective.

The mitigation of "neurophobia" among medical students through the use of active learning methodologies in neuroanatomy

Samuel Natal Rodrigues[1], Eduarda Kei-Lan Tavares Pierre[1], Cristiane Aschidamini[1]

[1]Universidade do Estado do Amazonas, Manaus AM, Brazil.

Correspondence: Samuel Natal Rodrigues; Email: snr.med20@uea.edu.br.

Background: Neurology is a broad medical field that requires great intensity of training and studying to master it. However, there is only a small percentage of professionals who have neurology as their specialty of choice, in contrast with the growing necessity of qualified physicians in the area. The construction of knowledge begins in neuroanatomy, the anatomic field focused on the nervous system, which is an integral portion of the basic sciences curriculum at medical schools. Nonetheless, despite the appreciable value of the subject, neuroanatomy is one of

the most pronounced obstacles for medical students, especially due to difficulties in exposing the material clearly, new technical language for students, and challenges in understanding anatomical elements and linking them to clinical knowledge. These problems lead to a negative perception among scholars regarding neuroanatomy and jeopardize a possible future in neurology. Thus, since 1994, the term "neurophobia" has existed to characterize this immense fear of neurological apprenticeship that a large portion of students can relate to, which is intensified by the first contacts with neuroanatomy. **Objective:** To analyze the efficacy of active learning methods in the teaching of neuroanatomy in order to reduce neurophobia, according to the perspective of first-year students enrolled in a Human Anatomy course at a public medical school in Amazonas, Brazil. **Methods:** A longitudinal, exploratory, descriptive study was conducted with a qualitative-quantitative approach through administration of surveys in a virtual environment. The goal was to evaluate study participants in 3 distinct phases: 1) pre-learning process assessment; 2) process of learning neuroanatomy with active learning methodologies; and 3) post-process assessment of learning. **Results:** Over 50% of study participants, out of 80 in total, had been aware of a "negative reputation" of neuroanatomy, and this knowledge influenced the participant's own perception in 88% of cases; the main factors hindering the study of neuroanatomy were the neuroanatomical terminology and the complexity of the subjects covered by the subject; 75% of participants evaluated the study of neuroanatomy as an important factor in deciding whether or not to delve deeper into future studies in neurology; 95% of participants considered the active methodology in learning neuroanatomy as an important factor in mitigating the symptoms of neurophobia. **Conclusion:** Therefore, it is evident that this study is aligned with the current literature on the topic which states that active learning methodologies in teaching neuroanatomy represent a vital importance in reducing the effects of neurophobia and encourage interest in the future study of neurology among students.

The moral history of seizures: reported causes of seizures in the 19th century

Márcio Pinheiro Lima[1], Adriel Rêgo Barbosa[1], André Felipe Candêas Amorim[1], Gabriel Pinheiro Martins de Almeida e Souza[1], João Victor Cabral Correia Férrer[1], Aline Agatha Lima de Oliveira[1], Rafael Tuzino Leite Neves Maffei[1], Ruan Gambardella Rosalina de Azevedo[1], Victor Cardoso de Faria[1], Fernanda Lustosa Cabral Gomez[1]

[1]Universidade Federal de São Paulo, Escola Paulista de Medicina, São Paulo SP, Brazil.

Correspondence: Márcio Pinheiro Lima; Email: mplima1997@gmail.com.

Background: The first description of epilepsy dates from approximately 2000 BC, from an Akkadian tablet describing a person with "his neck turning left, hands and feet are tense, and his eyes wide open, and from his mouth froth is flowing without him having any consciousness". Nowadays epilepsy is recognized conceptually as "a disorder of the brain characterized by an enduring predisposition to generate epileptic seizures". Seizures were attributed to the different causes throughout history. In the 19th century neurology started organizing as a medical specialty, with many of its great names (such as Charcot, Duchenne and Romberg) acting in this time period. However, in the scientific communications of the time it's often possible to see "unwanted" or "antisocial" daily habits and other characteristics mentioned as causes of seizures, many times with judgmental undertones. **Objective:** Report some of the causes for seizures seen in case reports and statistical tables from 1800-1900 and their relationship to moral concepts at the time. **Methods:** A literature review was made on the PubMed and SciELO databases for works containing the words "epilepsy", "seizure", "epilepsia", "convulsão", convulsión", and "crise epiléptica" from 1800 to 1900. 666 papers were found, all in the English language. Those papers were analyzed for descriptions of the causes of epilepsy, either describing current medical theories or personal opinions of the professionals. **Results:** In the timeframe analyzed it was possible to find various references to "abnormal" behaviors causing epilepsy. Multiple papers ascribed the development of epilepsy in children to mistakes made by the mother during feeding, such as "inadequate attention". The idea that different kinds of personality would be imprinted on the children was also seen, with several papers describing that children of "nervous" or "hysterical" mothers would be predisposed to epilepsy. There were also descriptions about the possibility of cure if the parents raise the children correctly. Sexual behavior was also thought to be correlated with epilepsy, with multiple sources correlating masturbation with seizures - with one source explicitly describing masturbation as evil, and several papers describing the excitation of the genital organs as the origin of reflex epilepsy. The behavior of women was scrutinized, with a report attributing seizures to the use of heavy dresses with the consequent pressing down of the ovaries. Women were also described as more emotional, and therefore more prone to epilepsy, especially after puberty. **Conclusion:** Even though the 19th century was a time of scientific experimentation for neurology - then a budding specialty – it's possible to notice multiple examples of how the moral thought of the European/North American society of the time influenced the thought about epilepsy. This serves as a reminder of the influence of the notions of the wider society in medicine.

The negative impact of anxiety-depression symptons on cognition after mild COVID-19: analyses of 151 individuals without past history

Beatriz Amorim da Costa[1], Leila Camila Santos Silva[1], Mateus Nogueira[1], Marjorie Cornejo Pontelli[1], Ana Paula Beppler Lazaro Lino[1], Lucas Scárdua Silva[1], Italo Karmann Aventurato[1], Fernando Cendes[1], Clarissa Lin Yasuda[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Beatriz Amorim da Costa; Email: b165550@dac.unicamp.br.

Background: Although cognitive impairment has been observed in patients with LONG-COVID, little is known about the negative impact of mood dysfunction on cognition after mild infection. **Objective:** To investigate the impact of symptoms of fatigue, daytime somnolence, anxiety and depression on the neuropsychological performance of patients (without psychiatric history) after mild SARS-CoV-2 infection. **Methods:** We studied 151 post-COVID-19 patients with a median of 85 days after diagnosis (range 18-420). Subjects had a median of 15 years of education and no history of psychiatric events. Individuals responded the BDI (Beck Depression Inventory) and BAI (Beck anxiety inventory) for quantification of symptoms; we then divided the subjects into ASYMPT-Group (no symptoms of depression or anxiety) (69 subjects), DOUBLE-group (combined symptoms of anxiety and depression) (43 subjects), ANX-group (exclusively anxiety symptoms) (30 subjects) and DEPRESS-group (exclusively depressive symptoms) (9 subjects). Daytime somnolence was assessed with the Epworth Sleepiness Scale (ESS) (median 10 points, range 0-21), and fatigue was evaluated with the Chalder Fatigue Scale (CFQ-11) (median 18, range 0-33). We included different cognitive test domains, including language (Verbal Categorical Fluency Test and Phonemic Verbal Fluency Test), verbal episodic memory (Logical Memory), visuoconstruction and visuospatial episodic memory (the Rey Complex Figure Test), manual dexterity (9-hole Peg Test), selective attention (FDT-Choice), inhibitory control (FDT-Inhibition), alternate attention and cognitive flexibility (FDT-Alternation and Flexibility), and sustained attention, perceptual tracking and motor skills (the Color Trail Test [CTT]-parts A and B). Subjects were balanced for diagnosis interval (p=0.24), sex (p=0.90) and age (p=0.86). We performed Mann-Whitney tests to compare continuous variables among groups and Spearman tests for correlations. **Results:** The DOUBLE-group presented higher scores of somnolence (ESS) and fatigue (CFQ) compared to the ASYMPT-group (p<0.005) and ANX-group. Overall, the cognitive performance was worse than expected for most of the patients, according to their age and education. Performance of language, verbal memory, mental flexibility/inhibition and FDT were more affected in the DOUBLE-group compared to the ASYMPT-group (p<0.05). Manual dexterity z-scores (bilaterally) were similarly low for all groups. **Conclusion:** Our results suggest that any individual can present some degree of cognitive dysfunction after a mild infection. The impairment seems worse in individuals with symptoms of anxiety and depression (who also showed more symptoms of fatigue and somnolence). Neuropsychiatric and cognitive dysfunction in long-covid are part of a complex phenomenon and require multidisciplinary attention for effective resolution.

The nobel prize awarded to Torsten Wiesel and David H. Hubel: progress in visual neuroscience and its connection to neuroesthetics

Maria Clara Jackson de Carvalho Sousa[1], Luiz Henrique Mattos da Silva Santos[1], João Ignacio Ferrara Neto[1], Maria Isabella Osório Cavalcanti de Jardim Sayão[1], Roberto Pereira Santos[1], Marleide da Mota Gomes[1]

[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Maria Clara Jackson de Carvalho Sousa; Email: mariaclarasousa93@gmail.com.

Background: Torsten Wiesel, the Swedish neurophysiologist, worked in visual neuroscience, in collaboration with David H. Hubel (1926-2013), which has significantly advanced our comprehension of how the brain processes visual stimuli. As we honor the birth anniversary of Wiesel, it is imperative to recognize his contributions to the field of neurophysiology. Wiesel and Hubel were co-recipients of the Nobel Prize in Physiology or Medicine in 1981 for their research on the complexities of visual information processing. Their partnership marked an advance in visual neuroscience, illuminating the brain's interpretation and response to visual stimuli and laying the groundwork for the neuroesthetics. **Objective:** This paper aims to delve into the contributions of Torsten Wiesel and David H. Hubel to the field of visual neuroscience. Additionally, the paper seeks to explore the concept of neuroesthetics and its role in uncovering the neural mechanisms underlying aesthetic experiences. **Methods:** To accomplish the objective, a comprehensive review of the seminal research conducted by Wiesel and Hubel on the visual system will be conducted. By analyzing their experiments and findings, the key advancements in our understanding of how the brain processes visual information will be elucidated. Additionally, the emergence of neuroesthetics as a discipline will be explored. **Results:** The research conducted sheds light on the achievements of Torsten Wiesel and David H. Hubel in visual neuroscience, emphasizing their significant findings on orientation selectivity in visual cortex neurons and the columnar organization of the visual cortex. Additionally, the exploration of neuroesthetics demonstrates the discipline's potential to bridge art and science, offering fresh perspectives on aesthetic experiences. **Conclusion:** The contributions of Torsten Wiesel and David H. Hubel in visual neuroscience have provided

new insights into brain functioning. The emergence of neuroesthetics presents exciting possibilities for delving into the neural basis of aesthetic experiences and their implications for various fields. By combining the findings of Wiesel and Hubel with the principles of neuroesthetics, new avenues for research and collaboration at the intersection of art and science can be unlocked.

[4]Hospital Alemão Oswaldo Cruz, São Paulo SP, Brazil.

Correspondence: Gabriella Chinaglia Zanin; Email: gabriella.zanin@aluno.fcmsantacasasp.edu.br.

Pain is commonly reported by patients with Alzheimer's disease, and daily pain rates could be as high as 70% of nursing home patients. Consequently, analgesic medications are some of the most prescribed drugs for patients with Alzheimer's disease, and yet current literature shows that undertreatment of pain is common in context of dementia, as it is a referred symptom and dementia patients progressively loose communication ability, concurrent with a progressive increase in nociception disturbances. Thus, the present study's aim was to analyze the use of analgesic medications prescribed to patients with Alzheimer in the last 5 years in reference neurology center in São Paulo, while comparing it to the general Brazilian usage of analgesic in Alzheimer patients. An electronic medical record aggregator called TriNetX was used to anonymously obtain the patient data used in the study, using exclusively hospital related records. The Brazilian cohort was built using a database that coalesces patient records of several institutions throughout national territory, via selecting patient with Alzheimer diagnosis who were at least 50 years old when they received the diagnosis. The reference center cohort was built using the same criteria as the Brazilian but pulled data only from the database of a reference neurology center in São Paulo. Analgesic use event was defined as the first prescription of the drug, regardless of time of use or subsequent administrations. Test results revealed a Brazilian cohort of N=5,944, of whom 42% had been prescribed any type of analgesic at some point. Opioids where the most common at 34%, distributed between Tramadol at 22%, Morphine at 18%, Fentanyl at 9% and Remifentanil at >1%. Non-opioids usage totaled 24% of patients, with acetaminophen at 12% and metamizole at 11%. The reference center cohort had N=250 patients, whom 48% had been prescribed any type of analgesic. Opioids where the most common at 40%, distributed between Tramadol at 28%, Morphine at 28%, Fentanyl and 16% and Remifentanil at 12%. Non-opioids usage totaled 24% of patients, with acetaminophen at 16% and metamizole at 16%. While prevalence of chronic pain in community dwelling patients with Alzheimer is close to 40%, in nursing homes the prevalence increases to between 60 to 70%. Based on the obtained results, this may point to both an undertreatment, as even in the reference center only 48% of patients were prescribed any analgesic, possibly pointing to a difficulty of identifying pain in these patients, as well as an overtreatment, due to the preference for opioids, an option with unclear consequences as some studies suggest no negative impact of use, while others associated it with increased mortality. Thus, it can be concluded that pain management remains an important, complex and easily overlooked aspect of Alzheimer's disease treatment.

The path of a young patient with a lower motor neuron syndrome: a case report

Filipe Tupinambá Di Pace[1], Frederico Mennucci de Haidar Jorge[1], Nicolas Ruan dos Santos Cavalcante[1], André Macedo Serafim Silva[1], Rodrigo de Holanda Mendonça[1], Mariana Hiromi Manoel Oku[1], Gabriella Corrêa Dousseua[1], Gabriel Saboia de Araújo Torres[1], Dagoberto Callegaro[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Filipe Tupinambá Di Pace; Email: filipedipace@gmail.com.

Lower motor neuron syndromes encompass diseases affecting the anterior horn cell, the motor axon, and/or its surrounding myelin, sometimes clinically indistinguishable from neuromuscular junction disorders. Here, we present a case of a young man with progressive motor neuron degeneration. **Case presentation:** A 15-year-old right-handed male with no significant medical history started complaining about weakness in the abduction of the fifth digit of his right hand. Over several months, this weakness extended to his entire hand, accompanied by significant muscle wasting, leading to writing impairment. Eighteen months later, similar symptoms manifested in his left hand. After multiple investigations, including neurophysiological studies, the diagnosis was classified as motor neuron disease localized to the cervical spine with no clear etiology. Initial treatment included corticosteroids and physical rehabilitation. The patient's condition continued to progress slowly, with increased weakness and muscle wasting in both hands. Four years after the onset of the symptoms, he was referred to our service, now with right forearm weakness and wasting. The electromyography showed signs of active denervation (fibrillations) at rest and a chronic reinnervation pattern in voluntary muscle activation in C7-T1 myotomes bilaterally (predominance on the right). A dynamic cervical MRI revealed a "snake eye" sign and mild spinal atrophy from C5 to C6, along with posterior epidural enlargement during neck flexion. These findings confirmed the diagnosis of Hirayama disease. Following spinal surgery, the patient's disease progression halted, and he experienced some improvement in both hands, now able to write with adaptations. **Discussion:** Hirayama disease is a rare motor neuron disorder predominantly affecting unilateral or asymmetrical bilateral upper extremities, more common in juvenile Asian males. It is typically benign and self-limiting course but can occasionally lead to significant disability and progressive symptoms over time. The optimal treatment strategy remains debated, including long-term neck brace use or surgical intervention. Our decision to proceed with surgery was influenced by the patient's rapid initial progression, the four-year duration of unstable disease, and the patient's informed preference after discussing the available options. **Final comments:** This case exemplifies a classical presentation of Hirayama disease, which, despite extensive investigation, took four years to be diagnosed, resulting in irreversible damage. Awareness of rare but classic diseases, coupled with an integrated healthcare system facilitating specialist referrals, is crucial to prevent permanent disability in similar patients.

Correspondence: Carolina Ferreira Tessler; Email: carolinatessler@gmail.com.

Neuropsychological assessment has emerged as an indispensable instrument in the comprehensive care of individuals with mesial temporal lobe epilepsy (MTLE). This approach plays a fundamental role in enhancing the accuracy of diagnosis, tailoring effective treatment strategies, and refining prognostic considerations for MTLE patients. The significance of neuropsychological evaluation becomes particularly evident when distinguishing performance patterns among MTLE patients with or without hippocampal sclerosis (HS) and side of the lesion. Therefore, we aimed to differentiate the cognitive performances associated with MTLE. We selected 167 individuals with MTLE, divided according to the presence of HS on the MRI: 23 MRI-negative, 54 had right-HS, 80 had left-HS, and 10 had bilateral-HS. The neuropsychological assessment utilized the following tests: Wechsler Memory Scale - Revised; Wechsler Adult Intelligence Scale - Revised; Phonemic and Semantic Verbal Fluency Tests; and the Boston Naming Test. To test differences in epilepsy duration and cognition, we employed univariate ANOVA or ANCOVA and partial correlation controlling for education. The duration of epilepsy was similar among groups, except between MRI-negative and left-HS ($p=0.022$), with longer duration in the second group. We found differences in the performance of the cognitive domains of verbal memory, general memory, delayed memory, and semantic verbal fluency between MRI-negative and right-HS (all $p\leq0.009$), MRI-negative and left-HS (all $p\leq0.01$), and MRI-negative and bilateral-HS (all $p\leq0.004$), with all the HS groups showing poorer performance when compared to MRI-negative. Therefore, MRI-negative MTLE patients had better performance when compared to patients with right, left, and bilateral HS in the cognitive domains related to verbal, general, and delayed memory, as well as language, suggesting that the presence of HS, regardless of side, influence the cognitive impairment in MTLE. In this series, we found no difference in verbal and visual memory between patients with right and left HS.

The potential of cannabidiol as a novel adjuvant therapy for myotonic dystrophy type 1 (Steinert's disease): a case report

Fernanda Valeriano Zamora[1], Andres Villca Zamora[2], Ana Clara F. F. Santos[3], Lorhayne Kerley Capuchinho Scalioni Galvao[2], Nicole S. Pimenta[1], João Pedro C.E. A. Salles[1], Afshan Nizami[4], Camila M. Yamada[2], Deivyd Vieira Silva Cavalcante[5], Dayana Dourado de Oliveira Costa[6]

[1]Universidade Estadual do Rio de Janeiro
[2]Universidade Federal de Minas Gerais
[3]Universidade Cidade de São Paulo, São Paulo SP, Brazil.
[4]Apollo Institute of Medical Sciences and Research, Telangana, India.
[5]Universidade Federal do Maranhão, São Luís MA, Brazil.
[6]Universidade Ceuma, São Luís MA, Brazil.

Correspondence: Fernanda Valeriano Zamora; Email: dra.fernandavaleriano@gmail.com.

Case presentation: Male patient, 17 years old, diagnosed with Steinert's disease at age 14, presents with significant language delay, impairments in communication and social interaction, as well as restricted and repetitive patterns of behavior, interests, or activities. He also experiences progressive muscle weakness, myotonia, muscle fatigue, and sleep-related respiratory difficulties, along with painful muscle spasms. The patient has undergone

various prior treatments, including Carbamazepine, sodium valproate, baclofen, and topiramate, as well as sessions of occupational therapy, speech therapy, psychology, and neuropsychopedagogy. While there is no specific treatment to reverse the effects of Myotonic Dystrophy Type 1, treatments can help improve quality of life and manage associated complications. It is crucial that the treatment plan be personalized for each patient, considering the severity of symptoms and the stage of the disease. However, the patient has experienced significant impairment in quality of life despite symptomatic treatment and multidisciplinary care. Given the patient's family history of schizophrenia in his father, it was decided to initiate therapy with Broad Spectrum Cannabidiol (CBD) at a dosage of 200mg/ml, 5 mg/kg/day, starting at low doses and gradually increasing. The patient showed improvement in overall condition, behavior, social interaction, and patterns of interest. He also reported reduced muscle fatigue and muscle spasms. There were no observed side effects from the medication. Liver transaminases showed a slight increase during treatment but stabilized after 3 months of follow-up. **Discussion:** CBD is already used to treat spasticity and muscle pain in chronic conditions such as multiple sclerosis, cerebral palsy, among others. Its potential use in Steinert's disease is attributed to its action on the endocannabinoid receptors CB1 and CB2, which promote muscle relaxation, neuroprotection, and anti-inflammatory effects. Its application has led to an improvement in these symptoms in this patient. It is also known that the presence of various cannabinoids in Broad Spectrum CBD allows for the use of lower doses to achieve its therapeutic potential, thanks to the entourage effect. This justifies the reported improvement of the patient with a low dosage of CBD. **Final comments:** CBD demonstrated potential in improving overall condition, behavior, social interaction, and alleviating muscle symptoms without adverse effects, suggesting it could be a beneficial adjunctive treatment for managing symptoms of Steinert's disease. Further research is warranted to confirm these findings and investigate CBD's long-term efficacy and safety in similar patient populations.

The potential peripheral effects of long COVID: critical neuropathy after COVID-19 infection: a case report

Antonia Cardoso Silva[1], Olagide Wagner Castro[1], Ênio José Bassi[1], Amanda Pacheco[1], Abelardo Silva Júnior[1], Fernanda Souza[1], Alanna Michella Oliveira de Albuquerque da Silva[1], Gabriel de Oliveira Souza[1], Sarah Antunes Figueiredo[1], Mariana Reis Prado[1]

[1]Universidade Federal de Alagoas, Maceió AL, Brazil.

Correspondence: Antonia Cardoso Silva; Email: antonia.silva@famed.ufal.br.

Case presentation: Patient, male, 32 years old, with grade 1 obesity, diagnosed with COVID-19 in November 2020. He progressed to acute respiratory failure, requiring orotracheal intubation (OTI) for 35 days, followed by a tracheostomy. He developed pneumonia, laryngotracheal injury, and laryngotracheobronchospasm, leading to the decision for endoscopic gastrostomy and removal of the nasoenteric tube. He developed peritonitis, necessitating an exploratory laparotomy, which revealed gastric injury. He presented with wound dehiscence, incisional hernia, and femoral head osteonecrosis. After 87 days of hospitalization, he had reduced mobility, requiring a wheelchair and rehabilitation sessions. In August 2023, with grade 2 obesity and after a mild case of COVID-19 reinfection, he developed long COVID (LC) symptoms. Clinical evaluation revealed current symptoms of fatigue, arrhythmia, dyslipidemia, anxiety, memory impairment, mild to moderate depression, insomnia, constipation, and hip pain. He also presented with paresis in all four limbs, more pronounced in the lower limbs, right foot drop and steppage gait, painful, thermal, and tactile hypoesthesia in the right lower limb with a similar pattern in the upper limbs. Electroneuromyography indicated peripheral sensorimotor axonal polyneuropathy with mild secondary demyelination, predominantly distal. There was significant involvement of the right fibular nerve, with an axonal pattern throughout its extent, and moderate involvement of the left tibial nerve, with an axonal pattern in the middle and lower third of the left leg. **Discussion:** Long COVID (CL) arises following acute infection with SARS-CoV-2 and is generally associated with severe cases of the infection, occurring across all degrees of severity. The syndrome encompasses physical, mental, and cognitive symptoms, with muscular and neuromuscular effects being among the most prevalent and persistent. CL is associated with muscular conditions characterized by the presence of peripheral and/or central demyelination. Additionally, neuromuscular alterations in CL may be linked to axonal neuropathies in peripheral and even cranial nerves. COVID-19 has been strongly linked to the condition of critical illness polyneuropathy (CIP), predominantly observed in severely ill patients subjected to prolonged intensive care. It is characterized by sensory and motor axonal neuropathic alterations. Causes include sepsis, systemic inflammatory response syndrome, microcirculation damage, and increased cytokine secretion, conditions that are possible in COVID-19 and CL. The mechanisms linking COVID-19 to axonal pathologies and the relationship between CL and CIP are not clearly elucidated. This reported case presents electroneuromyographic characteristics consistent with axonal sensory-motor peripheral neuropathy. **Final comments:** This case highlights the severe impacts of COVID-19 and CL, emphasizing the complexity of recovery and the importance of comprehensive care.

The prevalence of delirium in hospitalized patients of a tertiary hospital in Curitiba.

Mariana de Oliveira Trintinalha[1], Giulia Schaidt[1], Juan Carlos Pacheco[1], Bruna Segaspini Felber[1], Letícia Graniska Salanti[1], Carlos Alexandre Twardowschy[1]

[1]Pontifícia Universidade Católica do Paraná, Hospital Universitário Cajuru, Curitiba PR, Brazil.

Correspondence: Mariana de Oliveira Trintinalha; Email: marianaatrintinalha@hotmail.com.

Background: Delirium is a confusional state characterized by fluctuating symptoms, primarily affecting the elderly, which can lead to a series of detrimental events to the patient. The development of such a condition depends on multiple factors–modifiable or not–and the clinical presentation is often variable and fluctuant, making the diagnosis mostly based on clinical evaluation. Therefore, delirium is generally highly underdiagnosed. **Objective:** This study aimed to assess the prevalence of delirium in patients admitted to a tertiary hospital. **Methods:** A cross-sectional observational study was conducted between October 2022 and March 2023 on hospitalized patients over 18 years. Epidemiological data (age, current and previous health status, presence of metabolic, neurological, and infectious factors) were collected and the diagnosis of delirium was using the Confusion Assessment Method (CAM). The results obtained were analyzed, according to the type of variable considered, using the Chi-square test or Fisher's exact test, where applicable; the non-parametric Mann-Whitney test; and the Wald test. The confidence interval used was 95%, with p-values < 0.05 indicating statistical significance. **Results:** Among the patients included (n=100), 76% did not have a neurological cause for hospitalization and 83% did not require mechanical restraint. The analysis showed that 20% of the sample experienced delirium during the interview, with metabolic factors being the most common in the population. The risk factor most associated with the occurrence of the phenomenon was the use of mechanical restraint during hospitalization. **Conclusion:** Delirium has a high prevalence even in patients without neurological causes or comorbidities, thus healthcare professionals need to broaden their knowledge on the topic to identify and prevent it, reducing its occurrence during hospitalizations. The routine use of mechanical restraint should be avoided, as it represents the main precipitating factor of delirium. Clinical observation of hospitalized patients with risk factors is essential for diagnosis.

The prevalence of migraine in Brazil from 2013 to 2023

Rebeca Alessi Tedeschi Pachega[1], Daniele Pelegrini Coral[1], Guilherme Henrique Dalaqua Grande[1], Leandra Ernst Kerche[1]

[1]Universidade do Oeste Paulista, Presidente Prudente SP, Brazil.

Correspondence: Rebeca Alessi Tedeschi Pachega; Email: rebeca.alessi@hotmail.com.

Migraine is a prevalent global health issue and the most common neurological disorder worldwide, significantly impacting public health. It predominantly affects females more than males, with a ratio of 3:1 respectively, and ranks as a leading cause of years lived with disability among adult women. The condition affects approximately 15% of the global population, exceeding one billion individuals. Prevalence is highest in the working-age population, particularly between 25 and 55 years, resulting in an annual economic burden of 27 million dollars due to debilitating migraine episodes. In Brazil, the annual prevalence is 15.8%, affecting 22% of women and 9% of men aged between 30 and 50 years old. This ecological research is crucial for optimizing public policies aimed at the migraine-affected population. To analyze migraine hospitalization rates in Brazil from 2013 to 2023, focusing on gender, age groups, and years of disability (YLDs). This ecological research utilized databases from the Hospital Information System of Brazil (HIS/SUS) and the Burden of Diseases database for 2021. Prevalence rates per 100,000 inhabitants were analyzed for hospital admissions related to migraines and other headache syndromes (ICD-10-G43) from 2013 to 2023 in Brazil. The analysis included age groups, gender distribution, public healthcare costs, and disability duration (YLDs) caused by migraine. The study investigated migraine-related hospitalizations in Brazil from 2013 to 2023, revealing a higher prevalence among females than males, with an approximate ratio of 2:1. A significant peak occurred in 2019, with prevalence rates of 4.21:7.26 (men:women), resulting in 7,796 female hospitalizations. The main affected age group was 20-59 years old, accounting for 69.4% of total hospitalizations. In these cases, 69% were women, more than twice the number of men admitted. During this period, hospital services incurred total costs of 26,712,306.73 Brazilian reais funded by SUS. According to the Burden of Diseases in 2021, women accumulated nearly 27 million years of disability due to migraine (YLDs), which is 30% higher than men. In Brazil, in the same year, over one million days were lost due to migraine, double the number observed in men.Migraine represents a significant public health concern, profoundly affecting quality of life and national economies due to productivity losses and healthcare expenditures. The analysis of migraine hospitalizations in Brazil in this article emphasizes a consistent trend of higher prevalence among economically active women. Furthermore, there is a need for additional research to refine treatment strategies and enhance understanding across diverse demographics. These initiatives aim to reduce hospital admissions, lower healthcare expenditures, and improve the quality of life for individuals living with chronic migraines.

Background: Multiple sclerosis (MS) is a chronic autoimmune disease of the central nervous system characterized by the development of autoantibodies against the myelin sheath of neuronal axons. This results in inflammatory sites and oxidative stress, leading to neurodegeneration and demyelination of affected neurons. MS is a global disease with incidence varying by geography, age, ethnicity, and sex. It is one of the leading causes of neurological symptoms in young adults, with no known cure, primarily affecting individuals between 20 and 40 years old. The main symptoms include fatigue, paresis, spasticity, weakness, mood alterations, apathy, euphoria, anxiety, depression, and issues with physical and cognitive functions. **Objective:** To evaluate the profile of hospitalizations for Multiple Sclerosis in Brazil from 2019 to 2023. **Methods:** Data collection was performed using publicly available information from the Hospital Information System of the Brazilian Unified Health System (SIH/SUS) on Tabnet/DATASUS between January 15 and May 15, 2024. This retrospective longitudinal study employed a quantitative descriptive design. Data were grouped by Brazilian macro-regions, service classification, sex, age group, and race/ethnicity. Statistical inference was conducted using BioEstat 5.3 software, with paired t-tests for related samples to compare groups and data presentation using descriptive statistics, central tendency, and dispersion measures. **Results:** Between 2019 and 2023, there were 27,586 hospitalizations for Multiple Sclerosis in Brazil. The majority (69.10%, n=19,062) were among females (p=0.0023), and 56.59% (n=15,612) were among white individuals (p=0.0071). The age group most affected was 30 to 39 years, accounting for 28.05% (n=7,738; p<0.0001) of the hospitalizations. The Southeast region had the highest concentration of cases (n=20,790), representing 75.36% (p=0.0010) of the total, with an average annual cost of R$3,183,762.06 for treatments. Deaths were more frequent in the Southeast, with 43.53% (n=74) of the total (p=0.0056) and an average mortality rate of 6.65 (p=0.2311). The highest number of hospitalizations occurred in 2022, comprising 26.46% (n=7,299) of the total, compared to only 14.40% (n=3,972) in 2020. Most hospitalizations were for urgent care, accounting for 52.33% (n=14,436; p=0.2964) of the cases. **Conclusion:** Hospitalizations for Multiple Sclerosis are predominantly concentrated in the Southeast region of Brazil, with the highest proportionality of deaths and healthcare costs. Many cases occur among white females aged 30 to 39, with urgent care being the most common type of service required.

https://doi.org/10.5327/CBN241639

The relationship between deaths and hospitalizations by age group caused by epilepsy in Brazil: analysis of a 12-year epidemiological overview

Chiara Gübel Portugal[1], Lorenzo Marinho Morais[1], Thiago Luís Marques Lopes[1]

[1]Universidade Estadual do Ceará, Fortaleza CE, Brazil.

Correspondence: Chiara Gübel Portugal; Email: chiaraportugal@gmail.com.

Background: Epilepsy is defined as a brain disorder characterized by a chronic predisposition to generate epileptic seizures. These seizures are transient occurrences of signs and/or symptoms due to abnormal, excessive, or synchronous neuronal activity in the brain, alongside the neurobiological, cognitive, psychological, and social consequences of this condition. Epilepsy has a high prevalence, affecting approximately 50 million people worldwide and 2% of the Brazilian population. It is also one of the most common neurological disorders in childhood, challenging in terms of diagnosis and treatment, which vary depending on classification, type, and age group. **Objective:** Given the need for a better understanding of this scenario, this study is justified to analyze the epidemiological profile of patients and their respective therapeutic responses. **Methods:** This is an epidemiological study using secondary data, of observational, descriptive, and analytical nature. Data were accessed through the "TabNet" platform, focusing on the "Epidemiological and Morbidities" axis and selecting the topic "Hospital Morbidity of SUS (SIH/SUS)". The subtopic "General by Place of Hospitalization from 2008" was chosen. The study period covered "2012-2023", examining "Hospitalizations per Year processed by Age Group 1", "Deaths per Year processed by Age Group 1", and "Morbidity List CID-10: Epilepsy". **Results:** From 2012 to 2023, there were a total of 639,924 hospitalizations and 15,539 deaths due to epilepsy. Of all hospitalizations, 47,433 (7.4%) occurred in children under one year old and 106,832 (16.7%) in the age group of 1 to 4 years, which had the highest number of hospitalizations, followed by a 54% decrease in hospitalizations in the 5 to 9 years age group. In terms of deaths, 461 (3%) occurred in infants under 1 year old and 502 (3.2%) in children between 1 and 4 years old, followed by a 50% decrease in the 5 to 9 years age group. Based on these data, the mortality rate among hospitalized patients was 0.97% for children under 1 year old and 0.47% for those aged 1 to 4 years. **Conclusion:** Therefore, there is a controversy in the age group of children under 1 year old, as despite having fewer hospitalizations, they proportionally have twice the number of deaths compared to children aged 1 to 4 years. This suggests lower therapeutic efficacy and a higher likelihood of lethal outcomes in infants under 1 year old. The decrease in hospitalizations and deaths among children aged 1 to 4 years indicates that appropriate diagnosis and treatment of epileptic syndromes reduce the recurrence of seizures, emphasizing the importance of studies that continually improve the management of this condition.

https://doi.org/10.5327/CBN241640

The relationship between response to antiseizure medication and temporo-limbic atrophy in patients with mesial temporal lobe epilepsy and hippocampal sclerosis

Pamela Regina Henning[1], Aline de Fátima Dias[1], William Souza Martins Ferreira[1], Lucas Scárdua Silva[1], Luciana Ramalho Pimentel da Silva[1], Marina Koutsodontis Machado Alvim[1], Clarissa Lin Yasuda[1], Fernandos Cendes[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Pamela Regina Henning; Email: pamrhenning@gmail.com.

Background: Mesial temporal lobe epilepsy (mTLE) associated with hippocampal sclerosis (HS) is the most common type of focal refractory epilepsy in adults. Quantitative MRI studies have shown evidence for progressive atrophy in these patients; however, the relationship between patterns of response to antiseizure medication (ASM) and the degree and distribution of gray matter atrophy is not yet clear. **Objective:** To correlate response to ASM with cortical surface area (CSA), cortical thickness and subcortical volumes (SV) in patients with mesial temporal lobe epilepsy with hippocampal sclerosis (mTLE-HS). **Methods:** 224 patients with mTLE-HS who did not undergo surgery because they refused it, had contraindications, or had good seizure control with ASM (mean follow-up of 17 years) were categorized in three groups: pharmacoresponsive (seizure-free in the last two years or more), fluctuating-response (seizure-freedom periods of one year or longer) and pharmacoresistant (never had a seizure-free period of more than one year). T1-weighted MRIs (1x1x1mm) were processed with Freesurfer. We analyzed the following regions of interest for CSA: inferior, middle and superior temporal gyrus, parahippocampal gyrus and insula. Volumes of thalamus, hippocampus and amygdala, along with the CSA from each ASM response-groups were compared with 223 controls. No violations of models' assumptions were found. **Results:** The 224 patients were balanced for sex, and side of HS. 58 were, pharmacoresponsive, 61 had a fluctuating-response to ASM and 105 were pharmacoresistant. Age of onset was earlier ($p<0.05$) in the pharmacoresistant group than the others. Compared to controls, there was significant volume reduction for ipsilateral hipoccampus and amygdala for the three groups and bilateral thalamus also in the three groups (all $p<0.002$). Significant reduced cortical thicknesses were found in ipsilateral limbic regions in all three groups (all $p<0.02$) and only contralateral parahippocampal region was reduced in pharmacoresponsive and pharmacoresistant groups ($p<0.005$). Regarding CSA, contralateral areas of limbic regions were significantly reduced ($p<0.04$) but not the ipsilateral CSA. Interestingly, for these ipsilateral regions, we found that age significantly adjusted the model, with weak to moderate effect sizes. Meaning that an effect of aging might be more sensitive to these changes than the clinical outcome. **Conclusion:** Contrary to our initial hypothesis, the findings of reduced CSA, cortical thickness and volume of limbic structures and subcortical regions did not differ among pharmacological responses in these patients. Factors other than the degree and distribution of gray matter damage should explain the differences in response to ASM in mTLE-HS.

The relationship between the chronic use of benzodiazepines and the risk of developing Alzheimer's disease

Raquel Fakhouri Cardoso[1], Evelyn Victória Braselino[1], Marina Maiolino de Carvalho[1], Isabelle Campos Campi[1], Sarah Mística Simplício Silva[1], Mariana Lima de Moura[1], Jennifer Carvalho Garcez Obeid[1], Emanueli Vicente da Silva Honorato[1], Pedro Henrique Cabral Vilhena[1], Matheus Alves da Silva[1]

[1]Universidade Anhembi Morumbi, São Paulo SP, Brazil.

Correspondence: Raquel Fakhouri Cardoso; Email: raquelfakhouri@gmail.com.

Background: Alzheimer's disease (AD) is a chronic neurodegenerative disorder that manifests itself through cognition deterioration and compromise of daily life activities. AD occurs due to deposits of abnormal proteins in the central nervous system (CNS), creating neurotoxic protein fragments that induce a progressive neural loss in areas of the brain such as the hippocampus. In this context, recent evidence suggests that the chronic use of benzodiazepines (BZDs) is one of the risk factors for the development of AD. BZDs are psychotropic drugs whose mechanism of action consists of the depression of the CNS and can treat psychiatric diseases. However, its chronic use can lead to complications, as well as aggravation of pre-existing pathologies. **Objective:** To explore the relation between the effects of the chronic use of BZDs and

the development of AD. **Methods:** A PubMed Central database search was made in April 2024. The DeCS/MeSH descriptors "Alzheimer's Disease", "Benzodiazepines" and "Risk Factors" were used and filtered for publications from the last 5 years written in English. This resulted in 18 articles, 6 of which met the selection criteria of being free of charge and correlating with the topic studied. **Results:** BZDs are potentially inappropriate medications (PIMs) for the elderly, but are commonly used. Studies suggest that the prolonged use of BZDs promotes cognitive disorders in older persons and can predispose to the genesis and progression of AD, mild cognitive impairment, and dementia. Therefore, many hypothetical mechanisms aim to elucidate this relationship, such as the role of BZDs in the reduction in the number of chloride channels in the GABA A receptors; the alterations in synaptic plasticity and memory; as well as acting as intensifiers in the aggregation of hyperphosphorylated tau, enhancing the cytotoxicity and neurodegeneration in AD. Moreover, there are ponderations as to the neurotoxicity induced by the chronic use of BZDs being drug and dose-dependent, and occur mainly in females, however, while some studies highlight short and intermediate-acting BZDs as the major inducers of dementia, others delegate this importance to long-acting BZDs. Nonetheless, the association of the binomial BZD-AD is controversial, considering some studies have reported that BZDs do not compromise cognition or the progression of AD long-term, and even if it does happen, there are no significant disparities between genders. **Conclusion:** There is a questionable association between the chronic use of BZDs and AD, because not all studies highlight the potential impact of these drugs on the progression of cognitive deterioration in elderly, through the drug and dose-dependent neurotoxicity. Since there are disparities between studies on the association of chronic BZD use and DA, more investigations on this subject are needed to define these implications.

https://doi.org/10.5327/CBN241642

The relationship between the increase in deaths from Alzheimer's disease and the heterogeneity of macro regions in Brazil: analysis of a 12-year epidemiological overview

Chiara Gübel Portugal[1], Lorenzo Marinho Morais[1], Thiago Luis Marques Lopes[1]

[1]Universidade Estadual do Ceará, Fortaleza CE, Brazil.

Correspondence: Chiara Gübel Portugal; Email: chiaraportugal@gmail.com.

Background: Alzheimer's disease (AD) is currently the leading type of dementia. This condition is neurodegenerative, leading to cognitive and functional decline, making it a major source of morbidity and mortality among the elderly population. The estimated prevalence of AD is 50 million cases worldwide and 1.6 million in Brazil, with projections suggesting a tripling of cases by 2050. Despite many advances in research, the disease's pathophysiology is not fully understood. Therefore, this study aims to better analyze the progression trend and evaluate the patient population profiles, focusing on mortality data. **Objective:** To analyze the epidemiological profile of deaths by region in Brazil over a 12-year period. **Methods:** This is an epidemiological study using secondary data, of an observational, descriptive, and analytical type. Data were accessed through the "TabNet" platform, selecting the "Epidemiological and Morbidities" axis and the topic "Hospital Morbidity of SUS (SIH/SUS)". The subtopics "General by Place of Hospitalization from 2008" and "Brazil by Region and State" were then selected. The period analyzed was "2012-2023", focusing on "Alzheimer's Disease", "Deaths by Age Group", and "Deaths by Region". **Results:** Between 2012 and 2023, there were 3,524 recorded deaths from AD, 98.6% of which were among the elderly (3,474). Dividing this period into three four-year intervals (2012-2015, 2016-2019, and 2020-2023), there were 765, 1,240, and 1,519 deaths, respectively. In percentage terms, there was a 62% increase between the first two intervals and a 22.5% increase between the last two, totaling an overall increase of approximately 99%, which aligns with the global trend. However, when breaking down the deaths by region, significant regional discrepancies are evident. The Southeast region had the highest number of deaths (2,167), with a 72% increase, while the North, Northeast, South, and Central-West regions showed increases of 136%, 172%, 87%, and 721%, respectively. **Conclusion:** The increase in deaths from AD was significant, but this increase did not follow a uniform pattern across Brazil's five macroregions, a higher number was expected in the Southeast, as it is the most populous region, but it obtained a lower percentage increase. This reinforces the idea that, in addition to the aging population, other modifiable risk factors that vary by region–such as education, hypertension, smoking, depression, and air pollution–also significantly influence the development of the disease, contributing to these interregional disparities in death rates.

The role of cutaneous silent period in sensory ganglionopathies avaliaton: a case series and review

Hendrick Henrique Fernandes Gramasco[1], Maria Clara Foloni[1], Marcos Antônio de Lemos Júnior[1], Cristina Saade Jaques[1], Márcio Luiz Escórcio Bezerra[1], Karlo Faria Nunes[1]

[1]Universidade Federal de São Paulo, Escola Paulista de Medicina, São Paulo SP, Brazil.

Correspondence: Hendrick Henrique Fernandes Gramasco; Email: gramasco.hendrick@gmail.com.

Background: Sensory ganglionopathies consist of conditions characterized by involvement of the dorsal root ganglion, leading to a pure sensory deficit syndrome, not length-dependent, with involvement of the face, trunk and upper limbs before involvement of the lower limbs, in general. Most ganglionopathies affect primarily the large fibers, leading to symptoms such as sensory ataxia. Less commonly, ganglionopathy can affect only the small sensory fibers, leading to burning pain, tingling, shock pain and dysautonomia. In general, routine neurophysiological assessment does not evaluate the small sensory fibers, requiring specific tests, such as the cutaneous silent period, to access them. **Objective:** We present a series of cases of sensory ganglionopathy at different stages of evolution, from initial to chronic conditions, followed in a referenced center, in which we perform a cutaneous silent period test protocol. Our objectives were to use this information to differentiate cases of ganglionopathy from cases of asymmetric peripheral polyneuropathy, evaluate the involvement of small sensory fibers and the evolution of this involvement according to the course of the ganglionopathy. **Methods:** We selected cases already monitored as ganglionopathy or included patients diagnosed by our group based on standard electroneuromyography to carry out a protocol to evaluate the cutaneous silent period and the autonomic nervous system using Ewing tests, in addition to a targeted questionnaire and clinical examination. **Results:** Until the moment this work was sent, it was possible to observe that there is preservation of the cutaneous silent period and Ewing tests in cases recently diagnosed as ganglionopathy, while in later cases, we observed changes in the tests. It is possible that there is an association between the underlying disease and the involvement of fine fibers and the autonomic nervous system. **Conclusion:** This pilot study allows us to establish a low-cost standardized evaluation protocol to evaluate the involvement of small sensory fibers in cases of ganglionopathy, to assist in the differential diagnosis and in an attempt to establish a prognostic assessment and relationship between the underlying cause and the type of compromised fiber, thus assisting in the etiological investigation.

The role of etiologic subtypes in predicting functional impairment after stroke: a longitudinal study

Maria Vitória do Nascimento Silva[1], Maria Laura Lima da Silva[1], Jéssica dos Santos Coelho[1], Joan Lins Serafim[1], Thiago Bezerra dos Anjos[1], Ana Luiza Sampaio Lopes[1], Américo Danúzio Pereira de Oliveira[1], Rita Di Cassia Oliveira Angelo[2]

[1]Universidade de Pernambuco, Serra Talhada PE, Brazil.
[2]Universidade de Pernambuco, Garanhuns PE, Brazil.

Correspondence: Maria Vitória do Nascimento Silva; Email: vitoria.nsilva@upe.br.

Background: Stroke is the second leading cause of mortality and disability worldwide, arising from various causes and resulting in differing levels of neurological impairment and disability. Identifying the etiological subtypes of ischemic stroke (IS) is crucial for personalized patient management, guiding subtype-specific treatments, and delineating distinct disease patterns across populations. **Objective:** To investigate potential associations between etiological subtypes of IS and levels of functional impairment among patients treated at a public hospital in Serra Talhada, Pernambuco, Brazil. **Methods:** A longitudinal study was conducted involving IS patients treated at a public healthcare in Pernambuco between 2021 and 2023. The analysis employed the Trial of Org 10.172 in Acute Stroke Treatment (TOAST) classification and the Modified Barthel Index (MBI), administered at hospital discharge. **Results:** The sample included 157 patients, predominantly male (n=89; 56.7%), self-identified as Black (n=115; 73.3%), aged 61-80 years (n=86; 54.8%), and diagnosed with arterial hypertension (n=127; 80.9%). Etiological classification revealed a higher prevalence of stroke of undetermined cause (SUC) (n=94; 59.9%), followed by large artery atherosclerosis (LAA) (n=29; 18.5%) and small vessel occlusion (SVO) (n=20; 12.7%). The median MBI score at discharge was 24 [14-38], indicating severe functional dependence. Thus, the majority of patients exhibited some degree of functional dependence in their post-stroke activities of daily living (n=147; 93.6%). After excluding patients with undetermined etiology (i.e., SUC), a statistically significant association was observed between SVO and lower functional dependence (p=0.015). **Conclusion:** The findings of this study suggest that individuals over 60, males, Black individuals, and those diagnosed with arterial hypertension are at higher risk of experiencing a stroke. The high prevalence of SUC may be due to challenges in determining IS etiology within healthcare facilities. Patients in the SVO subgroup appeared to exhibit lower functional dependence compared to those with other etiologies. Identifying the underlying cause of IS seems to significantly influence functional dependence, highlighting the importance of etiological identification for prognosis and treatment. Furthermore, the prevalence of severe functional dependence underscores the need for improved access to recanalization therapies and post-stroke rehabilitation programs.

The role of tonic motor activation (TOMAC) for restless legs syndrome: a systematic review and single-arm meta-analysis

Daniela Lopes Vieira, Ana Beatriz da Cruz Pessoa[1], Stephanie Senna Cotta Queiroz de Oliveira[1], Wanessa Almeida Luna[1], Daniele Fernandes Holanda[2]

[1]Universidade Federal de Minas Gerais
[2]Universidade Federal do Amazonas

Correspondence: Daniela Lopes Vieira; Email: daniela.medufmg@gmail.com.

Background: Restless legs syndrome (RLS) is a neurological condition characterized by a distressing need to move the legs, especially during periods of immobility, resulting in chronic conditions that worsen the patient's health and quality of life. Conventional pharmacological treatment for RLS has limitations, including the worsening of symptoms and adverse effects, with many patients developing refractory RLS as a common scenario. In light of this situation, Tonic Motor Activation Therapy (TOMAC) emerges as a non-invasive intervention alternative, consisting of peripheral nerve stimulation of the fibular nerve using a wearable device bilaterally on the lower legs. **Methods:** PubMed, Embase and Cochrane databases were searched to compose our systematic review and single-arm meta-analysis of randomized clinical trials (RCTs) to evaluate TOMAC's efficiency in treating RLS. We pooled outcomes for treatment responder rate and for change in the severity of symptoms. Subgroup analyses were performed for (1) medication-resistant and (2) medication-naïve participants. Mean differences (MD) were pooled with 95% confidence intervals (95%CIs) for continuous outcomes using a random-effects model. We used OpenMeta-Analyst for statistical analyses. **Results:** 5 RCTs and 270 patients were included in the meta-analysis. The mean time of follow-up was 5,2 weeks. Statistically, there was no significant improvement on psychopathology (3 RCTs; 55.8%; n=106; 95%CI 0.379 to 0.737; p=0.06; I2=64.49%), assessed with the Clinical Global Impressions-Improvement scale (CGI-I). TOMAC resulted no reduction for severity of RLS symptoms (5 RCTs; n=167; MD -7.034; 95%CI -8.110 to -5.957; p=0.610; I2=0%), evaluated with the International RLS Rating Scale. Subgroup analysis indicated that medication-resistant (3 RCTs; n=102; MD -7.351; 95%CI -8.613 to -6.088; p=0.880 I2=0%) and medication-naïve participants (3 RCTs; n=49; MD -7.177; 95%CI -10.136 to -4.217; p=0.284 I2=20.5%) both exhibited similarly responses. **Conclusion:** This is a single-arm meta-analysis due to the scarce scientific production in the field. Despite no statistically observed benefit for RLS psychopathology, TOMAC potential for medication-refractory RLS treatment should be measured by further studies with larger numbers of participants, better study design and longer follow-ups.

The spectrum of IL6 signaling-related genetic variants in a cohort of AQP4+ and AQP4- NMOSD: towards for personalized anti-IL6R therapy in NMOSD

Elielson Veloso da Silva[1], Renan Amphilophio Fernandes[1,2], Andreza Lemos Salvio[1], Jessica Raposo Vedovi[1], Larissa Araujo Duarte[1,2], Helena França Alcaraz Ferreira[1,2], Anna Beatriz Scherer Vanzan[1], Elisa Gouvea Gutman[1,2], Valéria Coelho Santa Rita Pereira[2], Soniza Vieira Alves-Leon[1,2]

[1]Universidade Federal do Estado do Rio de Janeiro, Instituto Biomédico, Laboratório de Neurociências Translacional, Rio de Janeiro RJ, Brazil.
[2]Universidade Federal do Rio de Janeiro, Hospital Universitário Clementino Fraga Filho, Centro de Referência em Doenças Inflamatórias Desmielinizantes, Rio de Janeiro RJ, Brazil.

Correspondence: Elielson Veloso da Silva; Email: elielsonveloso@hotmail.com.

Background: Interleukin-6 (IL-6) plays a pivotal role in the pathogenesis of NMOSD, prompting the development of anti-IL-6R biologics such as tocilizumab and satralizumab as treatment options. However, treatment response variability between AQP4+ and AQP4- patients underscores the necessity of investigating genetic factors influencing therapeutic efficacy. Currently, the mechanisms behind treatment response differences in these serostatus groups are still poorly understood. Exome sequencing in polygenic and multifactorial disorders like NMOSD offers a powerful tool to identify biological pathways contributing not only to our understanding of disease mechanisms but also to the identification of genetic variants associated with treatment failure or suboptimal response. **Objective:** Our aim was to identify genetic variants in IL-6 signaling-related genes in a cohort of 41 NMOSD patients, stratified by AQP4 serostatus, and to uncover a novel spectrum of genetic variants that warrant further investigation for predicting treatment response in clinical trials of anti-IL6R biologics for NMOSD. **Methods:** For that, we analyzed exome sequencing data from 41 NMOSD patients (27 AQP4+ and 14 AQP4-) to identify genetic variants within genes associated with IL-6 signaling (IL6R, FCGRT, ADAM10, and ADAM17). Fisher's exact test assessed the significance of differences in variant frequency between the two groups. Expression Quantitative Trait Loci (eQTL) data for the most significant variants were examined using the FIVEx and GTEx databases and relevant scientific literature. **Results:** The variants rs3810194 and rs2878342 (FCGRT), rs7179724 (ADAM10), and rs2228145 (IL6R) showed the most significant differences in frequency between the groups. Notably, variants rs3810194 and rs2878342 within the FCGRT gene, encoding the IgG transport receptor FcRn, demonstrated statistically significant differences (p=0.0303) with higher frequency in the AQP4- group. Furthermore, eQTL databases suggest these variants may decrease FCGRT gene expression. Since FcRn plays a crucial role in satralizumab recycling, reduced expression of FCGRT could potentially impact its efficacy in AQP4- NMOSD. **Conclusion:** This study identified genetic variants in IL-6 signaling-related genes that may contribute to the variability in treatment response among AQP4+ and AQP4- NMOSD patients. Notably, variants rs3810194 and rs2878342, potentially associated with reduced FCGRT gene expression and observed at higher frequencies in AQP4- patients, suggest a potential mechanism influencing the efficacy of satralizumab. It's important to note that variants rs2228145 in IL6R and rs7179724 in ADAM10, although not statistically significant in our cohort, warrant further investigation in cohorts treated with anti-IL6R biologics or larger NMOSD cohorts. These findings emphasize the need for genetic profiling in clinical trials to optimize the use of anti-IL6R therapies, paving the way for personalized medicine in NMOSD management.

The storm within: unmasking thunderclap headache and reversible cerebral vasoconstriction (RCVS) in pheochromocytoma: a case report

Ingrid Lorena da Silva Gomes[1], Tainá Fátima Ramos Gonçalves[1], Giovanni Caniçali Simões[1], Guilherme Lago Miranda[1], Pedro Almeida Martins Pontes[1], Henrique de Moraes Bernal[1], Eduardo Takashi Takehara[1], Roberta Arb Saba Rodrigues Pinto[1], Marcele Schettini de Almeida[1], Sônia Maria César de Azevedo[1]

[1]Instituto de Assistência Médica ao Servidor Público Estadual, Hospital do Servidor Público Estadual, São Paulo SP, Brazil.
[2]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Ingrid Lorena da Silva Gomes; Email: ilsgomes@yahoo.com.

Case presentation: A 43-year-old female teacher presented with a history of thunderclap headaches (TCH) starting 15 days prior to admission. She reported recurrent episodes occurring more than three times daily, accompanied by cardiac palpitations, high blood pressure episodes, and a sensation of impending head explosion. Symptoms typically resolved spontaneously within 5 minutes, yet residual headache often persisted. Eleven days after the initial TCH, the patient developed sudden blurred vision and complete disproportionate left hemiparesis, prompting emergency admission to a secondary unit under suspicion of stroke. After a normal brain CT scan, she was discharged within 24 hours due to the complete resolution of symptoms. Due to recurrent headache episodes, she visited several emergency units before presenting to our service on the 16th day from the initial symptom onset. She denied using any vasoconstrictors or illicit drugs. Upon thorough evaluation, we found that the patient had been experiencing recurrent acute symptoms of sweating, high blood pressure and fainting lasting less than one minute, typically occurring after large meals several times daily for at least 3 years. Despite initiating antihypertensive medication prescribed by a general practitioner, her symptoms did not improve. The neurological examination was unremarkable, prompting further investigation. Imaging included CT angiography of the brain and cervical arteries, followed by MRI of the brain and cerebral angiography, revealing multiple segmental stenoses in the bilateral anterior cerebral arteries and branches of the middle cerebral arteries. After hypothesizing TCH secondary to RCVS with no identifiable trigger, we explored the possibility of an adrenergic crisis due to pheochromocytoma based on the patient's prior symptoms. Abdominal MRI revealed two exophytic nodular lesions in the left adrenal gland and kidney, with elevated urinary catecholamine levels. Symptomatic treatment for RCVS and preoperative alpha-blocker therapy to prevent an adrenergic crisis were initiated. After resolution of headache symptoms, the patient was discharged. Three months later, scheduled left adrenalectomy and nephrectomy confirmed histological and immunohistochemical findings consistent with pheochromocytoma. **Discussion:** Various factors contribute to the development of RCVS, and its management depends on addressing the underlying cause. Although rare, catecholamine-secreting tumors are significant contributors to RCVS. Accurate history-taking and appropriate diagnostic tools are crucial for reaching a definitive diagnosis. **Final comments:** Pheochromocytoma represents a significant yet frequently overlooked cause of RCVS. A multidisciplinary approach is crucial for effective patient management. Clinicians must maintain a high index of suspicion for this diagnosis, particularly in patients experiencing recurrent episodes of thunderclap headache without an identifiable trigger.

The use of anti-Tau therapy in patients with Alzheimer: a systematic review

Raquel de Sousa Lima[1], Maria Clara de Sousa Moraes[1], Ingred Lauane Balbino Alves[2], Myrella Evelyn Nunes Turbano[1]

[1]Instituto de Educação do Vale da Parnaíba, Parnaíba PI, Brazil.
[2]Universidade do Estado do Rio Grande do Norte, Mossoró RN, Brazil.

Correspondence: Raquel de Sousa Lima; Email: rl1918042020@gmail.com.

Background: Alzheimer's disease (AD) is a neurodegenerative condition. The accumulation of the Tau protein in this disease accompanies cognitive decline and plays a subsequent role in its progression. Therefore, therapies such as anti-Tau monoclonal antibodies aimed at slowing or stopping this accumulation are of utmost importance. However, there are persistent controversies regarding the efficacy of these drugs in treating the pathology. **Objective:** To analyze the efficacy of antibody therapy targeting the Tau protein AD. **Methods:** This scientific production is a systematic review based on randomized studies of an adult and elderly population with AD and high Tau load, who used anti-Tau monoclonal therapy and showed improvement. Furthermore, the databases used were: PubMed, Cochrane Library, and Scopus. The research was conducted based on the PRISMA strategy

(Preferred Reporting Items for Systematic Reviews and Meta-Analyses). The inclusion criteria for the analyzed studies were: randomized studies, without temporal restriction, focused on the topic. **Results:** Based on the strategies and criteria, 5 articles were selected for data collection. The use of anti-Tau monoclonal antibodies, such as: SEMORINEMAB, GOSURANEMAB, TILAVONEMAB, and ABBV-8E12, proved to be safe and well-tolerated by patients who used them, capable of reducing the ADAS-Cog11 score (11-item version of the Alzheimer's Disease Assessment Scale - Cognitive Subscale) compared to the placebo group. Additionally, it was noted that the Tau protein load is reduced in cerebrospinal fluid when compared to baseline value when exposed to antibodies at low doses. **Conclusion:** Therefore, it was evidenced that anti-Tau therapy with monoclonal antibodies in patients with Alzheimer's associated with high Tau protein load caused significant reductions in non-bound N-terminal Tau levels in cerebrospinal fluid compared to placebo. This encourages the continuation of studies to ensure greater treatment effectiveness.

The use of decompressive craniectomy in young patients with ischemic stroke: a case report

Yuri Victor Barbosa Silva[1], Carolina Diniz Furtado[1], José Nilo Ribeiro Neto[1], Márcio Luís Soares Ferreira[1], Roseliny de Moraes Martins Batista[1], Sanzylly Soares França Ferreira[2], João Guilherme de Brito Rodrigues[1], Lael Mendonça Moraes[1]

[1]Centro Universitário UNDB, São Luís MA, Brazil.
[2]Universidade Estadual do Maranhão, São Luís MA, Brazil.

Correspondence: Yuri Victor Barbosa Silva; Email: yurifisiocenter@hotmail.com.

Case presentation: Patient, 16 years old, female, was admitted to the regional hospital in the city of Bacabal-MA, presenting with syncope 6 hours after admission. Patient denies Sys-temic Arterial Hypertension (SAH), Diabetes Mellitus (DM) and other pathologies. Laboratory tests, electrocardiogram and head tomography were requested. Skull to-mography with signs of hypodensity in the territory of the middle cerebral artery on the left with slight deviation of the midline structures. Laboratory tests and electrocardio-gram were unremarkable. The patient subsequently underwent decompressive craniectomy with bone flap stor-age in the abdomen. After surgery, the pupils were isochoric and photoreactive, and the patient re-mained sedated in an intensive care unit bed. Sedation was weaned after 72 hours. The cranioplasty was scheduled within six months, with no complications oc-curring during the procedure. **Discussion:** Ischemic stroke (IS) is defined as partial or total occlusion of a cerebral blood vessel by an atherosclerotic plaque or clot (David et al, 2024). IS has a high mortality rate and, above all, functional disability, causing a major impact on the lives of indi-viduals and their families. The prevalence rate is higher than that of hemorrhagic stroke, averaging around 80% to 85% of cases (Feitosa et al, 2022). Ischemic brain injury results from a cascade of events, from energy depletion to cell death, some intermediate factors include excess of extracellular excitatory amino acids, formation of free radicals and inflammatory processes (Leite, 2020). Rios et al (2021) mentions that manifestations of ischemia are caused by biochemical sequenc-es that lead to the destruction of the brain parenchyma and follow three main path-ways: in the neuron, in the glia and in the microcirculation, called ischemic cascades.Several treatment approaches are carried out for patients with ischemic stroke, both conservative and surgical, based on the level of consciousness and imaging tests performed every 48 hours for monitoring in cases of clinical signs of neurological disease (Neufeuld et al, 2020). According to Wang et al (2021), decompressive craniectomy is the removal of a segment of the skull large enough to minimize refractory intracranial pressure and maintain brain compliance with the aim of preventing injury to other structures and neurological deterioration. According to Leite (2020), the purpose of the surgery is to promote decompression above the swollen cerebellum to open space. **Final comments:** As the updated studies state, it is notable that the causes of stroke must be in-vestigated mainly and especially in cases of young patients. Decompressive craniec-tomy is an appropriate surgical intervention in cases of extensive mass effect, since conservative treatment is not very effective or when the subject presents considerable changes in consciousness levels, thus obtaining a greater probability of survival.

The use of fibroblasts culture to evaluate treatment for mitochondrial diseases

Celia Harumi Tengan[1], Paloma Ramos de Macedo[1], Aryane Coutinho[1], Vinicius Gomes da Silva[1], Jomênica de Bortoli Livramento[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Celia Harumi Tengan; Email: chtengan@unifesp.br.

Background: Mitochondrial diseases are characterized by oxidative phosphorylation (OXPHOS) deficiencies and are caused by mutations in the nuclear or mitochondrial DNA. Despite significant advances in discovering the genetic causes, no proven effective treatments are available for patients with these diseases. The large number of genes associated with mitochondrial diseases, the rarity and the highly variable phenotypes hinder the study of potential therapies in clinical trials. **Objective:** To evaluate the effect of potential therapies for mitochondrial diseases using fibroblast culture. **Methods:** Cultured fibroblasts were obtained from skin biopsies of patients (n=4) with mitochondrial diseases. Fibroblasts with no abnormalities in OXPHOS were used as controls (n=2). We evaluated the effects of two antioxidants (N-acetyl cysteine, NAC, and mitoquinone, MitoQ) and the precursor of nitric oxide synthesis, L-Arginine (L-ARG). Treatments were performed for 12 days with the following concentrations: 1 mM and 5 mM NAC; 10 nM and 100 nM MitoQ; and 1 mM L-ARG. Fibroblasts were cultured in two different media: (1) with high concentrations of glucose and (2) in a restrictive condition where glucose was replaced by galactose, not favoring the growth of mitochondrial-deficient cells. The effect of treatment was evaluated by measuring cell growth (or cell proliferation) in both conditions and at different time points. We expected that improving mitochondrial function would result in better cell proliferation in the restrictive medium. **Results:** Controls exhibited an exponential growth in cell number in both glucose and restrictive media, whereas patient cultures showed a good exponential growth only in the glucose medium, except one culture (P-1), which also had good cell proliferation in the restrictive medium. Treatment with MitoQ, NAC and L-ARG did not affect control samples. MitoQ (10 nM) led to a higher number of cells in P-2 fibroblasts at day 12 (4188±277 cells vs 6125±554 cells, p=0.02), with this tendency starting at day 8. Treatment with 1 mM L-ARG improved cellular growth in the restrictive medium in P-4, with a statistically significant difference in cell number starting from day 8. The increases in cell number were 151% (day 8), 307% (day 10) and 790% (day 12) compared to untreated cells. This increment reached 10625±946 cells with L-ARG versus 1344±157 cells with no treatment at day 12 (p=0.03). The other treatments with 100 nM MitoQ and NAC (1 mM and 5 mM) did not modify cellular growth in a restrictive medium. **Conclusion:** These preliminary results demonstrate that this assay can detect improvements in cell growth with MitoQ and L-ARG treatment. Variable results may indicate individual variability, highlighting the importance of personalized study on drug responses. Further studies are still necessary to confirm the beneficial effects of these treatments.

https://doi.org/10.5327/CBN241651

The use of neural networks to predict stroke diagnosis: a systematic review

Vanessa de Oliveira e Silva[1], Luciana Cartaxo[1], João Victor Loiola[1], Kael Costa Santana[1], João Wilson de Luna Freire Neto[1], Matheus Oliveira Lira[1], Marcela Vasconcelos Montenegro[2], Maria Luiza Vasconcelos Montenegro[2], Maria Clara Formiga de Mello[1], Maria das Graças Loureiro das Chagas Campêlo[1]

[1]Universidade Federal de Campina Grande, Campina Grande PB, Brazil.
[2]Universidade de Pernambuco, Recife PE, Brazil.

Correspondence: Luciana Cartaxo; Email: lucianaestudos1000@gmail.com.

Background: Stroke is a syndrome of acute neurological deficit attributed to vascular damage to the Nervous System (NS). The Artificial Intelligence (AI) techniques in Medicine – such as Artificial Neural Networks algorithms (ANNs) – have helped in making clinical decisions for this condition. **Objective:** To evaluate how Artificial neural networks are being used to predict the diagnosis of stroke. **Methods:** This is a systematic review of articles indexed in databases PubMed, BVS, SciELO, Cochrane and SpringerLink, between January and February of 2022. The inclusion criteria and filters for this study were: articles related to the topic, randomized studies, cohort and clinical trials, studies with humans, carried out in the last 5 years, only in Portuguese, English and Spanish and with the full text available free of charge. The parameters of exclusion were: duplicated articles, off-topic studies, review articles and papers that did not meet all inclusion criteria. The Kappa coefficient was calculated and it was obtained a value equal to 0.795 (substantial agreement). Furthermore, the review has a protocol registered on the International Prospective Register of Systematic Reviews (PROSPERO) website with registration number CRD42021290522. **Results:** ANNs are being used mainly to evaluate areas of ischemic and hemorrhagic injury by segmentation methods and the most used exams for modeling the programs have been Magnetic Resonance Imaging (MRI) and Computed Tomography (CT). In addition to CT and MRI, magnetic resonance angiography and CT angiography are also being used for algorithm modeling and they are useful because they have greater sensitivity for detecting infarcts. **Conclusion:** Segmentation and classification algorithms applied to ANNs are part of personalized medicine and serve as a basis for doctors in clinical practice.

https://doi.org/10.5327/CBN241652

The use of physical exercise as a treatment for Alzheimer's disease: a systematic review

Júlia de Castro Couto Santos[1], Helena Oliveira Farage[1], Letícia Dalton Moreira dos Santos[1], Lucas Vieira Nogueira[1], Raquel Toledo Martins de Almeida[1], Roberta de Oliveira Lima Duarte[1], Sofia Oliveira Duarte[1]

[1]Faculdade de Ciências Médicas e da Saúde de Juiz de Fora, Juiz de Fora MG, Brazil.

Correspondence: Júlia de Castro Couto Santos; Email: juliacastroccs@yahoo.com.

Background: Alzheimer's dementia (AD) is a hypocholinergic disease, in which beta amyloid deposition and tau protein hyperphosphorylation occur, resulting in the loss of neurons and, consequently, synapses in brain regions, compromising cognitive function and the consolidation of new memories. **Objective:** To analyze the influence of physical exercise in the treatment of patients diagnosed with AD. **Methods:** Controlled and randomized clinical trials originally published in English, from the last ten

years, on humans were analyzed, using the National Library of Medicine (MedLine) database as a reference. The search for descriptors and terms used was carried out by consulting the Medical Subject Headings (MeSH), through the U.S. National Library of Medicine (NLM) portal and the descriptors used were: Alzheimer Disease, Physical Exercises, Treatment. Studies with a sample of individuals over 50 years of age and a clinical diagnosis of probable mild to moderate AD were included. Articles that evaluated individuals without evidence of cognitive impairment and studies lasting less than 16 weeks were excluded. The PRISMA scale was used to systematize the reporting of this review. **Results:** Initially, 7 studies were found and, after selecting inclusion and exclusion criteria, only 4 articles were part of the scope and final analysis. When analyzing cerebral blood flow, no benefits were observed over 16 weeks of moderate to high intensity aerobic exercise, and a limitation noted in this study was the duration of the intervention. However, in a study lasting 6 months, the angiogenic process, in response to the increased energy demand promoted by physical exercise, during this period of time contributed to significant functional changes and improvements in cerebral blood flow, which are factors affected by AD. Furthermore, it is known that, through biomarker analysis, physical exercise contributes to increased levels of neuroprotective proteins and can positively affect cognition in individuals with AD. Furthermore, training in activities of daily living is a viable and effective intervention in improving other issues affected by the disease, such as physical resistance and depressed mood in nursing home residents. **Conclusion:** Physical exercise proved to be significantly effective, especially in periods longer than 16 weeks in the treatment of patients with AD.

https://doi.org/10.5327/CBN241653

The use of Wobble Chair to assess trunk postural control in individuals with Parkinson's disease: a reliability study

Hayslenne Andressa Gonçalves de Oliveira Araújo[1], Patrícia Gonçalves Broto[1], Luzia Aparecida Trinca[2], Alessandra Cattaneo Estrada Melanda[1], Marcelle Brandão Terra[1], Suhaila Mahmoud Smaili[1]

[1]Universidade Estadual de Londrina, Londrina PR, Brazil.
[2]Universidade Estadual Paulista, Botucatu SP, Brazil.

Correspondence: Patrícia Gonçalves Broto da Silva; Email: pbroto@hotmail.com.

Background: Postural instability is a relevant symptom that can occur from the early stages of Parkinson's disease (PD), resulting in loss of functionality and independence. Trunk control represents a large portion of body mass and plays an essential role in maintaining postural control. However, there is still a lack of specific instruments to assess trunk control in PD. **Methods:** A cross-sectional study with 44 individuals with mild to moderate idiopathic PD, according to UK Brain Bank criteria, recruited from an outpatient of specialized physiotherapy (GPFIN), with no cognitive impairment, and walking independently. Trunk control was assessed using the Wobble Chair, (which is an instrument based on force platform and composed by a pivot and springs structure, aiming to provide instability during seated evaluation). Participants were assessed under three conditions: 1) eyes open (EO); 2) eyes closed (EC); and 3) no feet support (NS). The outcome variables included: center of pressure (COP) area (cm^2), AP/ML amplitude (cm), AP/ML mean frequency (Hz) and AP/ML velocity (cm/s). The test and retest were performed within a 7-day interval and compared using a paired t-test. The instrument reliability was quantified using an intraclass correlation coefficient (ICC), 95% confidence intervals (CI), and Bland Altman plot. Statistical Package for the Social Sciences 29 (SPSS 29) and GraphPad Prism 10.0 were used for the analysis, and we considered a statistical significance of $p< 0.05$. CAAE: 31775420.8.0000.0108. **Results:** The ICC ranged from 0.51 to 0.86 in the different analyzed tasks, and overall, the EO, EC, and NS conditions showed similar results, since the CI measurements overlapped. The EO condition showed excellent reliability for AP and ML velocity (ICC=0.82, for both) and ML mean frequency (ICC=0.75), as well as good reliability for the other analyzed parameters (area, amplitudes, and AP mean frequency). The EC condition showed excellent reliability for AP and ML velocities, and ML mean frequency (ICC=0.75, ICC=0.82, and ICC=0.75, respectively) and good reliability for COP area, amplitudes, and AP mean frequency. Finally, the NS condition showed excellent reliability for the COP area (ICC=0.75), AP velocity (ICC=0.82), AP and ML mean frequencies (ICC=0.75 and ICC=0.79, respectively), as well as good reliability for amplitudes and ML velocity. Considering the variables analyzed, velocity showed the most consistent reliability, with ICCs ranging from 0.74 to 0.86. **Conclusion:** The Wobble Chair is a reliable and accurate instrument to assess trunk postural control in individuals with PD, especially considering the velocity and EO situations (with and without feet support). Further studies are suggested to explore different conditions, populations, and assessment protocols.

https://doi.org/10.5327/CBN241654

The utilization of telemedicine and computed tomography in the management of stroke in Brazil: a focus on emergency referral in 14 secondary care hospitals

Guilherme Nobre Nogueira[1], Rafaela Fernandes Gonçalves[2], Adrielle Holler Pykocz[2], Guilherme Batista do Nascimento[3], Gustavo Rassier Isolan[2]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.
[2]Faculdade Evangélica Mackenzie do Paraná, Curitiba PR, Brazil.
[3]Centro Universitário de Adamantina, Adamantina SP, Brazil.

Correspondence: Guilherme Nobre Nogueira; Email: guiermenobre@gmail.com.

Background: The recognition of stroke (AVC) and its symptoms is a topic that significantly impacts the treatment time for suspected strokes, mainly due to delays in reaching medical care. In this context, telemedicine provides specialized support promptly for neurological emergencies. **Objective:** To demonstrate the experience of using telemedicine in managing cases of suspected stroke, investigating the average time of care and the type of stroke. **Methods:** This study is a descriptive, cross-sectional, and retrospective study involving 587 patients from 14 hospitals in the states of Rio Grande do Sul and São Paulo, from April 2019 to October 2022. All patients signed a consent form for the research, respecting the general data protection law. **Results:**A total of 587 patients were evaluated. The age ranged from 0 to 98 years, with an average of 63.1 (standard deviation - SD ±18.7) and a median of 65. There was a slight majority of men, accounting for 51.2%. The distribution of patients by age group showed that 10.56% of individuals were between 1 and 40 years old, 28.28% were in the age group of 41 to 60 years, 44.12% were between 61 and 80 years, and 17.04% were between 81 and 100 years old. Regarding medical history, headache was reported by 46.68% of patients, progressive neurological symptoms were mentioned by 23.68%, and sudden neurological symptoms were recorded in 29.64% of the analyzed individuals. Out of the 587 patients, 40.37% had hemorrhagic stroke, 23.68% had old ischemic stroke, 29.64% had new ischemic stroke, and 6.30% had Aneurysmal Subarachnoid Hemorrhage. In terms of response time, it was observed that all patients had telemedicine initiated within 30 minutes. Considering the start of care, CT evaluation, treatment recommendation, and referral, the average time was 93.4 minutes (SD = 120.4). There was a significant association between tomographic changes and emergency referral. The chi-square test results showed a value of 130.05 with 3 degrees of freedom and a P-value < 0.001. These results suggest a statistically significant association between the variables under study. The effect size (φ) was 0.47 between the variables, indicating that the emergency referral variable has a strong and significant influence on the tomographic change variable. **Conclusion:** Since emergency referral was recommended after telemedicine consultation, we can infer that it influenced the management of these conditions. Telemedicine is relevant in caring for patients with suspected stroke, particularly due to its prompt service in a country with continental dimensions like Brazil. These results provide valuable information about the clinical and tomographic profile of patients, emphasizing the importance of effective strategies for stroke through real-time specialist opinions.

The weight of genotype on clinical presentation of COQ7 related hereditary motor neuropathy: case series and literature review

Laura Alonso Matheus Montouro[1], Amanda Selvátici dos Santos Dias[1], Maria da Penha Ananias Morita[1], Érica Nogueira Coelho[1], João Aris Kouyoumdjian[1], Carla Renata Graça[1], Fábio Nazaré Oliveira[1], Charles Lourenço Marques[1], Eduardo de Paula Estephan[1,2]

[1]Faculdade de Medicina de São José do Rio Preto, São José do Rio Preto SP, Brazil.
[2]Universidade de São Paulo, Faculdade de Medicina, São Paulo SP, Brazil.

Correspondence: Laura Alonso Matheus Montouro; Email: lauramontouro@hotmail.com.

Background: The mitochondrial enzyme 5-demethoxyubiquinone hydroxylase, encoded by COQ7, is involved in CoQ10 biosynthesis. Mutations in the COQ7 gene result in primary CoQ10 deficiency-8. First case was published in 2015, presenting as a multisystemic form (MF). Subsequently, other phenotypes described: spastic paraparesis (SP), polyneuropathy, and motor neuron disease and distal hereditary motor neuropathy (dHMN). Since 2022, dHMN related to p.1met? variant, mostly in Brazil. A founder effect evidence of this variant in Brazil was published recently. **Objective:** To report five Brazilian patients from three unrelated families with p.1met? variant and dHMN. Also perform narrative review of COQ7 disorders and analyze possible correlations between the variants and phenotypes/clinical sign and also between p.1met? and other dHMN from Brazil. Reinforce the notion of founder effect and the phenotype probably related to this mutation. **Methods:** Descriptive study of our cases. Our case series clinical features were compared with all COQ7-patients reported and Brazilian dHMN cohorts in literature so far. Categorical variables were expressed as absolute frequencies and compared using Fisher's test (two-tailed) and Odds Ratio (OR), with confidence interval 95% (CI). **Results:** Patient 1 presented dHMN plus with cerebellar (CS) and pyramidal syndrome (PS). Patient 2 had pure dHMN. Patients 3 and 4, siblings, both had a dHMN plus (PS) and patient 5 had dHMN plus with cognitive impairment. Our search identified 20 studies with 47 patients with COQ7 related disorders, with origin from 10 countries. Comparing the phenotypes among the presence of variants, the p.1met? was significantly more frequent in patients with dHMN (21 out 30, $p<0.001$). Brazilian origin was also significantly related to p.1met? variant compared to other regions ($p<0.001$, OR: 10.5, CI: 2.6-40.8). Brazilian origin is also related to the dHMN phenotype ($p=0.009$, OR: 8.6, CI: 1.6-45.8). All patients with CS were from Brazil, and this relation was also statistically significant ($p=0.0063$). Compared to 170 cases of dHMN from Brazil, PS ($p<0.001$; OR: 7,2273, CI: 2.42-21.5) and CS ($p<0.001$) associated with dHMN had a strong relation with p.1met?. SPG-COQ7 is related

to p.Leu111Pro with statistical significance (p=0.00181, OR:34, CI:3.3-427.9). This variant had a strong association with Iran (p<0.001). The p.Arg54Gln was statistically associated with SPG (p:0.029, OR:11.1 95%, CI: 1.4-83.5). **Conclusion:** Specific variants in COQ7 can be associated with specific phenotypes. The variant p.1met? has a strong association with dHMN, Brazil and cerebellar syndrome. Among Brazilian patients with dHMN with CS and/or PS suggests a higher chance of COQ7 disease. The finding of CS only in Brazilian patients raises the hypothesis of environmental influence in disease expression.

Therapeutic effects of human dental pulp stem cell derived exosomes in transgenic mice SOD1G93A

João Pedro Nunes Gonçalves[1], Rodrigo Pinheiro Araldi[2], Cristiane Valverde Wenceslau[3], Irina Kerkis[4], Marcondes Cavalcante França Junior[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.
[2]BioDecision Analytics Ltda., São Paulo SP, Brazil.
[3] Cellavita Pesquisas Científicas Ltda., Valinhos SP, Brazil.
[4]Instituto Butantã, São Paulo SP, Brazil.

Correspondence: João Pedro Nunes Gonçalves; Email: j227991@dac.unicamp.br.

Background: Amyotrophic lateral sclerosis (ALS) is a devastating condition for which treatment still represents an unmet need. Exosomes derived from human dental pulp stem cell (hDPSCs) secrete neurotrophic factors and have shown positive therapeutic results in some neurodegenerative disease models, but not yet properly explored in ALS. **Objective:** To evaluate the potential therapeutic effect of hDPSC-derived exosomes in the ALS SOD1G93A transgenic mice model. **Methods:** Seventy-day-old transgenic mice were treated intravenously either with exosomes (n=5) or saline (n=5) for 5 weeks and were sacrificed at the age of 15 weeks. A 3rd third group of wild type mice was also used for comparison. We then proceeded quantified motor neurons in the ventral horns of lumbar spinal cord using Nissl staining. Between-group comparisons were accomplished with ANOVA followed by post-hoc Tukey test. **Results:** At 15 weeks, neuronal survival was significantly different across experimental groups. Neuronal loss was significantly higher in non-treated SOD1 G93A mice compared to the other two groups (p<0.0001, CI:95% for both groups). In contrast, neuronal survivability was similar in treated and wild type animals (p=0.025, CI:95%). **Conclusion:** While still in the early stages, our findings show that spinal cord motor neuron survival in this ALS mouse model is preserved by repeated IV injections of hDPSC-derived exosomes, though they still vary from wild-type animals. Further studies are needed to understand the mechanisms underlying such therapeutic effects.

Therapeutic plasma exchange in steroid-refractory attacks of myelin oligodendrocyte glycoprotein antibody-associated disease: a systematic review and meta-analysis

Roger Santana de Araujo[1], Thiago Trajano da Silva[1], Guilherme Diogo Silva[1], Samira Luisa dos Apóstolos Pereira[1], Dagoberto Callegaro[1]

[1]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Roger Santana de Araujo; Email: rogersantana.araujo@gmail.com.

Background: Therapeutic plasma exchange (TPE) has been extensively studied for its role in disability recovery during attacks of demyelinating diseases like Multiple Sclerosis and Neuromyelitis Optica Spectrum Disorder. However, its efficacy in Myelin Oligodendrocyte Glycoprotein Antibody-Associated Disease (MOGAD) remains uncertain. While MOGAD attacks typically respond well to glucocorticoids, the effectiveness of TPE in steroid-refractory cases is still debated and under investigation. **Objective:** To evaluate the response to TPE in steroid-refractory MOGAD attacks. **Methods:** We conducted a systematic review and meta-analysis, searching PubMed/MEDLINE, Embase, and Scopus for manuscripts published up to March 21, 2024, using synonyms for "plasma exchange" and "MOGAD." We included cohorts, case reports, and case series of patients with MOGAD attacks who underwent TPE. Two evaluators selected studies and extracted data, resolving disagreements by consensus. We collected information on age, sex, and core clinical demyelinating events. The primary outcome was the clinical response to TPE in MOGAD attacks at the last follow-up, categorized as complete response, partial response, or no response. We performed a meta-proportion analysis using R software with a random-effects model. **Results:** We included 40 studies, comprising 36 case reports and 4 cohorts, totaling 278 attacks (mean age 34 years, 46% male). Core clinical demyelinating events included optic neuritis (49%), transverse myelitis (28%), acute demyelinating encephalomyelitis (3%), cerebral with focal deficits (9%), brainstem or cerebellar deficits (7%), and cortical encephalitis (4%). Complete recovery was observed in 36% (95% CI 26%; 48%) of cases, while 13% (95% CI 6%; 25%) showed no response. **Conclusion:** TPE may improve neurological recovery in steroid-refractory MOGAD attacks. This study is ongoing.

Therapeutic window for thrombolysis at a stroke center in Northeast Brazil: current overview and future perspectives

Raphael Pinheiro Camurugy da Hora[1], Ana Dolores Firmino Santos do Nascimento[1], Manuela Magalhães Dardenne Tenório[1]

[1]Secretaria de Saúde de Pernambuco, Hospital da Restauração, Recife PE, Brazil.

Correspondence: Raphael Pinheiro Camurugy da Hora; Email: raphaeldahora@hotmail.com.

Background: Stroke is a complex, multifactorial disease with a high social impact. Its most prevalent subtype, ischemic stroke, has undergone a radical therapeutic revolution in the last thirty years with the advent of intravenous thrombolysis and thrombectomy. Even so, the outcome of patients with stroke in Brazil is still suboptimal, with a small percentage of patients receiving thrombolytic treatment. **Objective:** To evaluate the conversion rate to thrombolysis and the reasons why patients admitted to Hospital da Restauração (HR) in the therapeutic window for intravenous thrombolysis had the procedure contraindicated. **Methods:** This study is classified as observational, cross-sectional, retrospective and analytical. Data were collected through review of medical records, tabulated and analyzed in IBM SPSS Statistics®. **Results:** 3,140 medical records were reviewed over a period of nine months in the neurological emergency department of HR. Of these, 14.1% (445) were flagged as possible stroke within a therapeutic window of up to 270 minutes. The conversion rate to intravenous thrombolysis was 42.6% (190) and considering only patients diagnosed with ischemic stroke (352), this percentage was 53.98% (190). When analyzing the prevalence of contraindications to the use of thrombolytics, we observed an ASPECTS scale <7 (13.5%), AVCH (11.9%), AIT (6.3%), more than one reason (5.8 %), minimal deficit or NIHSS <5 (4%), gastrointestinal or genitourinary hemorrhage <21 days (2.2%), use of anticoagulant drugs (1.3%) and others with less statistical significance. Secondly, 57 ASPECTS contraindications were reviewed by the neuroradiology team, revealing a 35.7% agreement rate. **Conclusion:** Analysis of the results revealed a very satisfactory therapeutic index within our reality. Furthermore, the implementation of vessel studies and extended protocols across all shifts could increase this rate, as well as the active presence of radiology in the acute ischemic stroke protocol.

Background: Multiple sclerosis (MS) is an autoimmune disorder that affects the central nervous system, often showing suboptimal responses to traditional treatments. This has prompted significant interest in alternative symptom management approaches. Non-invasive brain stimulation (NIBS), particularly theta burst stimulation (TBS), has emerged as a promising method to mitigate the disease's morbidity. TBS delivers rapid impulses to enhance neural activity, fostering beneficial neuroplasticity. We conducted a meta-analysis comparing outcomes in patients receiving theta-burst stimulation versus placebo, aiming to evaluate its efficacy in managing MS symptoms. **Objective:** To assess the efficacy of theta-burst stimulation for the treatment of patients with Multiple Sclerosis spasticity. **Methods:** MEDLINE, Embase, and Cochrane databases were systematically searched for randomized placebo-controlled trials (RCT) that tested theta-burst stimulation in multiple sclerosis patients. Data were examined using the Mantel-Haenszel method and 95% confidence intervals (CIs). Heterogeneity was assessed using I^2 statistics. This meta-analysis was performed to evaluate measures of spasticity through the Modified Ashworth Scale (MAS). Statistical analysis was conducted using R, version 4.4.0. **Results:** The initial search identified 619 results. After removing duplicate records and screening the studies based on title and abstract, 412 studies were eligible for full-text review according to predefined criteria. Among these, three randomized placebo-controlled trials (RCT) were included, with a total number of 59 patients, of whom 32 (54.2%) received TBS and 27 (45.7%) received sham stimulation. Mean age ranged from 38.4 to 49.8 years, with a majority of female patients. Our pooled analysis showed that, compared with the placebo group, TBS was associated with a significant reduction in MAS score (Mean Difference -0.82; 95% CI -1.11-0.53; p<0.000001; I^2=0%), indicating an improvement in muscle spasticity. **Conclusion:** This systematic review and meta-analysis highlights the effectiveness of theta-burst stimulation in improving spasticity among patients with MS, as evidenced by significant improvement on the Modified Ashworth Scale.

Three-territory sign in acute ischemic stroke as a manifestation of ovarian tumor: a case presentation

Ana Luísa Castelo Branco Gomes[1], Davi Telécio Firmino[2], Gilmar Leite Pessoa Filho[1], Luciano Gonçalves do Nascimento Júnior[1], Felipe Nunes de Araújo[1], Diego Almeida de Souza[1], Rafael de Souza Andrade[1], Francisco Anderson de Sá Carvalho[1], Paulo Antonio Farias Lucena[1], Juliana Magalhães Leite[1]

[1]Hospital Metropolitano Dom José Maria Pires, João Pessoa PB, Brazil.
[2]Universidade Federal da Paraíba, João Pessoa PB, Brazil.

Correspondence: Ana Luísa Castelo Branco Gomes; Email: analuisa_gomes@hotmail.com.

Case presentation: I.F., 75 years old, female, smoker, hypertensive, history of acute vertigo for 2 months, associated with headache and disorientation. Three days after admission, she presented a new acute event of drowsiness, emetic episodes and worsening vertigo. Neurological examination revealed dysarthria, right facial palsy and right hemiparesis. During the investigation, brain MRI showed an area of diffusion restriction in the parietal lobes, right cerebellar hemisphere and right posterolateral region of the medulla oblongata, as well as late subacute intraparenchymal hematomas in the left temporal lobe. An etiological investigation was carried out with EKG, TTE, TEE and cervical and intracranial arterial AngioMRI without abnormalities. Laboratory investigation for systemic lupus erythematosus and antiphospholipid syndrome were negative. Once the possibility of stroke due to hypercoagulability was raised, neoplastic investigation was initiated. Pelvic MRI showed a nodule in the right ovary with hyposignal on T1 and T2 without gadolinium enhancement. The patient was referred for neoplastic investigation and anticoagulation was started. **Discussion:** Trousseau syndrome(TS) is a hypercoagulative state associated with cancer that leads to venous or arterial thromboembolic events. The three-territory sign is a radiographic marker of TS, which is described as an ischemic stroke involving three vascular territories, including involvement of the bilateral anterior and posterior circulations. The primary approach to treating TS is to eliminate, if possible, the causative tumor, as well as anticoagulation, with heparin being the treatment of choice. **Final comments:** In the present case, the lesions in three different vascular territories raise the possibility of a hypercoagulable state, after excluding possible causes of stroke, mainly cardioembolic causes. Therefore, this case report is relevant in the etiological study of patients with stroke, leading to early diagnosis of neoplastic diseases based on cerebrovascular conditions.

Thrombectomy in SUS: a new perspective to the AIS treatments

Vítor de Oliveira Cei[1], Jéssica Helena Gomes Ferreira[1], Gabrielly Gomes de Oliveira[1], Leticia Fernandes de Freitas[1], Priscila Maria de Oliveira[1], João Gabriel Alves Coimbra Chaves[1], Caroline Chaves Bittencourt[1]

[1]Universidade Nove de Julho, Guarulhos SP, Brazil.

Correspondence: Leticia Fernandes de Freitas; Email: lecaff1984@gmail.com.

Background: Recently, the Brazilian Ministry of Health instituted Ordinance: GM/MS No. 1996 of 11/24/2023, regarding the implementation of Mechanical Thrombectomy (MT) in the SUS, guaranteeing this treatment option in applicable cases of Acute Ischemic Stroke (AIS) with a symptomatic signals between 8 and 24 hours. MT consists of removing the obstructive content that impedes blood flow to the brain, resulting in acute ischemia and neurological deficit. According to DATASUS, between 2022-2023, AIS caused 55 thousand deaths. Therefore, with this possibility, there are expectations of reducing the number of deaths and alleviating serious functional disabilities. **Objective:** To evaluate the effectiveness of treating AIS with mechanical thrombectomy and outline prospective parameters for Brazil with the implementation of GM/MS regulation nº1996 of 11/24/2023. **Methods:** Records were collected on the PubMed platform with the descriptors: Thrombectomy, Acute Ischemic Stroke. Randomized clinical trial studies were selected that highlight the advantages and disadvantages of thrombectomy. **Results:** Studies have shown a positive prognosis with MT. Sarraj (2023), in a randomized and controlled clinical trial on AIS covering the United States, Canada, Europe, Australia and New Zealand, compared 178 patients who underwent MT in 24 hours with 174 who received only medical care with local protocols, the median ischemic volumes 74ml vs 77ml, both with a median of 4 on the ASPECTS (Alberta Stroke Early Score) and a median of 19 on the NIHSS (National Institutes of Health Stroke Scale) score. In the MT group, 142 (79.8%) had successful reperfusion, with 20.3% showing functional independence at 90 days (Modified Rankin Scale [mRS] from 0 to 2) and 37.9% with independent ambulation at 90 days (mRS from 0 to 3). Furthermore, 11.5% showed early neurological improvement (decreasing 8 points in the NIHSS), however 24.7% showed worsening of the neurological condition related to a larger ischemic area when compared to the group without neurological worsening. The hospital death rate was 23.6%. In the medical care group at 90 days, the median MRS was 5; functional independence at 90 days 7% (mRS 0-2); independent ambulation at 90 days 18.7% (mRS 0-3); deaths at 90 days 41.5% and neurological worsening 15.5%. Comparatively, MT obtained better results compared to the group that received only clinical care. **Conclusion:** The regulation of GM/MS No. 1996/24/11/2023 to accomplish thrombectomy in the SUS indicate a promising future, given the high effectiveness of the procedure and a better prognosis in reperfusion and the patient's clinical condition 90 days after management, especially the decrease in the death rate. Therefore, the 12 institutions accredited for the procedure in Brazil can minimize national morbidity and mortality, with the need for further Brazilian comparative studies to assess the status before and after its implementation.

https://doi.org/10.5327/CBN241662

Thrombolysis in primary brain tumor: anaplastic meningioma simulating recurrent ischemic stroke

Caroline Schiochet Verza[1], Glauco Kody Nagata[1], Victor Alfonso Garcia Ortiz[1], Carolina Heck Haubrich[1], William Alves Martins[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Hospital São Lucas, Porto Alegre RS, Brazil.

Correspondence: Caroline Schiochet Verza; Email: carolinesverza@gmail.com.

Case presentation: A 55-year-old woman presented to the emergency room with acute aphasia that began one hour earlier. Her medical history was notable only for mild, treated hypertension. Upon arrival, her National Institute of Health Stroke Score (NIHSS) was 4. A CT scan showed no signs of bleeding or early stroke, and there were no contraindications to administering tissue plasminogen activator (tPA). Thirty minutes into the tPA infusion, she regained her language function but began to experience a severe headache. The tPA infusion was stopped, and an emergency CT scan revealed a small hemorrhage in the left parietal lobe. She remained asymptomatic during her hospital stay, and an MRI showed an area of diffusion restriction along with hypointense images on gradient echo, attributed to the tPA-induced hemorrhage. Subsequent stroke investigations revealed no specific etiology, and she was discharged 20 days later on aspirin and simvastatin. Three months later, she returned due to acute right-side weakness. This lasted about one hour and was not accompanied by changes in consciousness. A new CT scan showed a significant area of brain edema in the left parietal lobe. She was admitted and started on dexamethasone. MRI revealed a 4 cm mass in the temporo-parietal region with heterogeneous gadolinium enhancement. Extensive surgery was performed, successfully resecting the entire lesion. Histopathological examination confirmed an anaplastic meningioma (WHO grade III). The patient is now undergoing radiochemotherapy and remains free of permanent neurological deficits. **Discussion:** Thrombolysis in patients with brain tumors is rarely reported in the literature, resulting in the systematic exclusion of these patients from such therapy. Differentiating small, undiagnosed brain tumors from stroke can be challenging. A small percentage of patients treated with thrombolysis are later found to have stroke mimics rather than true strokes. In a systematic review, seizures were identified as the most common cause of stroke mimics. Our patient had a reversible deficit following a seizure caused by an anaplastic meningioma, a rare, malignant, and rapidly growing tumor. Since patients with brain tumors were excluded from thrombolysis trials, the risk of intracranial bleeding can only be inferred from case reports. Etgen and colleagues reviewed the use of thrombolysis in patients with brain tumors, concluding that it is potentially safe in cases of extra-axial lesions without significant mass effect. Some studies highlight the difficulty in differentiating ischemic stroke from seizures, suggesting that CT perfusion may assist. Thrombolysis minimizes morbidity and represents the current state of the art in treating acute ischemic stroke. Understanding conditions that mimic stroke and the associated risks of brain hemorrhage with thrombolytic therapy is crucial for expanding inclusion criteria and translating clinical trial results to real-life situations.

Thrombolytic treatment to isolated brachiocephalic dissection related stroke: case report

Rodrigo Targa Martins[1], Cristiane de Oliveira[1], Kelin Cristiane Martin Hackenhaar[1], Ana Carolina Rodrigues Farias[1]

[1]Grupo Hospitalar Conceição, Porto Alegre RS, Brazil.

Correspondence: Cristiane de Oliveira; Email: c.deoliveirasm@gmail.com.

Ischemic stroke (IS) sums 62% of all strokes in the world, its cause includes frequently large vessel atheromatosis, cardioembolic event, small vessel occlusion and less often arterial dissections. In young arterial dissection plays a major role in IS etiology with carotid and vertebral most frequently involved. Dissections involving extracranial portions of these arteries are routinely treated with intravenous thrombolysis (IVT) in the acute phase. In contrast, aorta dissection represents a contraindication to IVT and demands surgical to early brain hypoperfusion correction. The occurrence of IS related to isolated brachiocephalic trunk dissection (IBD) is rare with even fewer known results of IVT treatment to this condition (n=1 to our knowledge). **Case presentation:** We describe a 63 y/o woman hypertensive with acute onset of left hemiplegia including face, neglect, dysarthria, right ocular deviation admitted 90 minutes after symptoms onset and stroke severity scale (NIHSS) 17. She denied recent trauma, arm hyperextension or chest pain - but had light pain in the back of the neck. She had a symmetrical radial pulse and admission blood pressure was 110/90mmHg. Brain CT without contrast didn't show hyperdense artery or early hypodensity. She underwent IVT with 131 minutes of onset with improvement of symptoms finishing infusion with NIHSS 4. Because of worsening of neck pain now radiating to the right shoulder and appearing difference in BP between arms right 90x62mmHg, left 103x71mmHg she underwent and cervical CT-angio that showed BC dissection with 20 mm of maximal diameter, extending to right carotid artery and sparing aortic arch. She maintained improvement of neurologic symptoms attaining

NIHSS 0 in the first 24 hours, was urgently evaluated by cardiovascular surgery that defined conservative management based on resolution of neurologic symptoms and no critical arm hypoperfusion. Was maintained with anticoagulation with false lumen reduction and no new neurologic symptoms. **Discussion:** Our report involves uncommon stroke syndrome IS attributed to arterial dissection involving isolated IBD treated with IVT and improvement of neurologic deficits without worsening of arm perfusion or aortic involvement. The only case treated with IVT suggest succession of stroke mechanisms to explain early response and latter deficits reappearing. Similarly, as the cases described by Sansoni, ours didn't involve the base of BCT and in our cases atherosclerosis was notably absent in the arterial tree. **Final comments:** We conclude only with reliable estimates of main complications of IVT in this condition it will be possible to decide when to proceed to thrombolytic treatment vs surgical/endovascular approaches or if one would be generally advisable in neurologic presenting cases. So, this case does not ensure safety by absence of enough data but intends to contribute to this peculiar acute stroke etiology.

https://doi.org/10.5327/CBN241664

Thunderclap headache in a puerperal patient

Luma Santos de Oliveira[1], Emanuelly Victoria Andrade Fonseca[1], Igor Flavio Gonçalves do Vale[1], Daniel Mariani Favalessa[1], Bruno Batitucci Castrillo[1]

[1]Universidade Federal do Espírito Santo, Vitória ES, Brazil.

Correspondence: Luma Santos de Oliveira; Email: luma.oliveira@edu.ufes.br.

Case presentation: A 35-year-old woman presented with Thunderclap headache during the immediate puerperium briefly after administration of metaraminol hemitartrate due to convulsive syncope. The headache was in the frontal region, of strong intensity, pulsatile, improving after 30 minutes. She had other 4 episodes of thunderclap headache over the next 10 days, interrupting her sleep. She denied visual symptoms, paresthesias and focal deficits. She had a history of vasovagal syncope with manifestation of convulsive syncope for years. She also reported a diagnosis of primary headache since the age of 18. She was taking sertraline and denied use of ilycit drugs. On examination, she had only pain on palpation of the occipital nerves and cervical muscles. Magnetic resonance angiography (MRA) was normal 3 days after the initial symptom. Patient preferred not to use any medication because she was afraid of lactating meanwhile using any pills. She had more episodes of thunderclap headache during the next days and a new MRA showed vascular narrowings and confirmed reversible cerebral vasoconstriction syndrome (RCVS). Verapamil was started and patient had an excellent response. **Discussion:** RCVS is understood as a thunderclap headache, with sudden onset and reversible multifocal narrowing of the cerebral arteries, lasting around three months with or without focal neurological symptoms. It comes on rapidly, peaking in less than a minute, and can be unilateral or bilateral, followed by diffuse, short-lasting pain. Its pathophysiology is partially understood, involving multiple mechanisms, such as dysregulation of cerebral vascular tone and genetic predisposition. In the case mentioned, the combined use of sympathomimetics after vasovagal syncope and serotonergic agents in a puerperal woman with a history of primary headache contributed to the development of CRVCS. It should also be noted that SSRIs can play a vasoconstrictive role in larger cerebral arteries, due to the increase in serotonin in the CNS, and that the puerperium also contributes to an increase in blood pressure and loss of cerebral autoregulation. Diagnosis is based on tests that prove diffuse cerebral vasoconstriction. Angiography can reveal alternating smooth and elongated narrowings and dilations, which can resemble a string of pearls. It should be borne in mind that the initial CT scan or MRI may be normal, and will have to be repeated a few days later if the suspicion is high. Treatment is carried out by removing possible causal agents, using calcium channel blockers as a prophylactic action, but there is still little scientific evidence to prove that the course of the disease has changed. **Final comments:** This highlights the intricate relationship between CRVCS, the use of medication and the postpartum period in women with a history of headache. It is of the utmost importance to better understand CRVCS, including its pathophysiological mechanisms and treatment strategies.

https://doi.org/10.5327/CBN241665

Thyrotoxic hypokalemic periodic paralysis in a Brazilian male: a case report

Victor Hugo Soares dos Santos[1], Eduarda Kei-Lan Tavares Pierre[1], Emanuelle Campos Amaral[1], Fernanda Almeida Carvalho[1], Fernando Luiz Westphal Filho[2], Jonathas Taumaturgo Soares[1], Manuela Brandão Ferreira Teles[1], Vanise Campos Gomes Amaral[1]

[1]Universidade do Estado do Amazonas, Manaus AM, Brazil.
[2]Universidade Federal do Amazonas, Manaus AM, Brazil.

Correspondence: Victor Hugo Soares dos Santos; Email: vhsds.med21@uea.edu.br.

Case presentation: A 49-year-old Brazilian male was referred for neurological evaluation due to the worsening of paresthesias in the calves and feet, muscle weakness, myalgia, and tremors in the lower limbs with periods of fluctuation over the past three months. Upon admission, the patient reported a recent flu-like illness with fever, nasal congestion, dry cough, and headache. Additionally, he had been diagnosed with hyperthyroidism two months prior and, despite treatment with methimazole, continued to experience insomnia, anxiety, fatigue, retro-orbital pain, exophthalmos, resting tremor in the upper limbs, hair loss, night sweats, cervical swelling, and a weight loss of 15 kg over five months. The patient was admitted to the medical ward, where he continued to experience episodes of flaccid paralysis in the lower limbs despite therapeutic intervention. On physical examination at hospital admission, the patient was in good general condition, alert, and oriented. Vital signs included a heart rate of 115 bpm. He exhibited asymmetric resting tremors in the upper limbs, cervical swelling, bilateral and asymmetric resting tremors in the upper limbs, and proximal paraparesis in the lower limbs graded as 2/5, and distal paraparesis graded as 3/5 bilaterally. Laboratory tests showed normal magnesium and phosphorus levels, with a serum potassium level of 3.0 mEq/L. **Discussion:** Thyrotoxic hypokalemic periodic paralysis (THPP) is frequently underdiagnosed due to its nonspecific clinical presentation and symptoms common to various pathologies. Differential diagnoses for ascending muscle weakness include Guillain-Barré syndrome; however, in this patient, cerebrospinal fluid analysis did not show cytoalbuminologic dissociation. The hypothesis of THPP is supported by the clinical presentation and low potassium levels, with the condition being more prevalent in males at a ratio of 20:1. **Final comments:** THPP should be considered in any patient presenting with muscle weakness associated with low serum potassium levels. Potassium replacement must be done cautiously due to its intracellular presence.

Background: Dual antiplatelet therapy (DAPT) with aspirin plus clopidogrel is the first-line antithrombotic regimen for unruptured intracranial aneurysms. However, in recent years, ticagrelor has been increasingly investigated to replace clopidogrel for this purpose since it has a faster effect and a more intense platelet inhibition. **Objective:** To perform a systematic review and meta-analysis comparing ticagrelor versus clopidogrel dual antiplatelet therapy in patients with unruptured intracranial aneurysms. **Methods:** PubMed, Scopus and Web of Science databases were searched for randomized controlled trials that compared ticagrelor to clopidogrel dual antiplatelet therapy for unruptured intracranial aneurysms and reported the outcomes of (1) Thromboembolic complications; (2) Mortality, and (3) Major Bleeding. Mean differences (MDs) with 95% confidence intervals (CIs) were calculated using a random-effects model. Heterogeneity was examined with I^2 statistics. Pvalues of ≤0.05 were considered statistically significant. Statistical analyses were performed using RStudio, version 4.2.3. **Results:** Three studies and 534 patients were included, of whom 252 (47%) received ticagrelor. The follow-up ranged from 3 to 12 months and the mean age was 57,15. Incidence of thrombo-embolic complications [7.49% ticagrelor vs. 8.60% clopidogrel RR 1.14 95%CI 0.56, 2.32 p=0.71; I^2=28%], major bleeding [8.88%ticagrelor vs. 6.52% clopidogrel RR 0.69 95%CI 0.38, 1.25 p=0.22; I^2=0%] and mortality [0.96% ticagrelor vs. 1.34% clopidogrel; RR 1.20 95%CI 0.26, 5.55 p=0.80; I^2=0%] did not reach a statistically significant difference between groups. **Conclusion:** Although most of the recent data indicate that ticagrelor appears to be safe and effective in replacing clopidogrel in DAPT settings for unruptured aneurysms, our results show no significant difference between the clopidogrel and the ticagrelor dual antiplatelet therapy arm.

Time series analysis in pediatric stroke: investigating the differences in stroke trends and patterns according to age groups

Alisson Rafael de Oliveira Pereira[1], Lucas Abreu Dias[1], Pedro Henrique de Vilhena[1], Rodrigo Ferreira de Moura[1]

[1]Universidade Federal de Lavras, Lavras MG, Brazil.

Correspondence: Alisson Rafael de Oliveira Pereira; Email: alissonropereira@gmail.com.

Background: Stroke, the leading cause of death in Brazil since 2022, does not affect age groups uniformly, with a predominance in adults and the elderly, affecting less the pediatric group. The biggest difference between these groups was related to etiology. In adults, the main related factors are hypertension, smoking, and arrhythmias. In

the pediatric population, the deficit is caused by arteriovenous malformations (AVMs), coagulation dysfunction, and other congenital alterations. Although the possibility of recovery from neurological deficits in children is greater than that in adults due to neuroplasticity, it is important to understand the trends in the occurrence of the syndrome to anticipate interventions generating better prognosis. **Objective:** To evaluate trends in hospitalizations and deaths due to stroke in the pediatric age group as well as their types in the same age group. **Methods:** A retrospective study was conducted by tabulating the data recorded in SIH by DATASUS. Data on hospitalizations and deaths from ischemic, hemorrhagic, and unspecified strokes were collected. The data was grouped according to the WHO definitions of age group as childhood, adolescence and "pediatric" (sum of the groups). The data was analyzed using regression models. **Results:** During the study period, there was a global trend of increase in the rate of hospitalization for all types of stroke in the pediatric age group (AAPC= 1.5; 95%CI: 0.6 to 2.0; p<0.01), maintaining a stationary trend most of the time, with a joinpoint followed by a significant increase in 2021 (APC: 10.3, p<0.001). However, the overall trend of death decreased in the total period (AAPC= -2.3; 95%CI: -3.2 to -1.6; p<0.01). The analysis of the subgroups according to the type of stroke revealed that the trend of hospitalization for ischemic stroke did not change, maintaining a significant increase throughout the study period (APC= 2.4; p=0.01), while the hemorrhagic stroke group had a reducing effect (AAPC= -1.2, p<0.01). The unspecified stroke group showed a significant increase (AAPC= 5.4, p<0.01). The correlation between the three subgroups was evaluated according to covariances in an ARIMA model (0,1,0), seeking to identify whether the decrease in hospitalization due to hemorrhagic stroke would be compensated by the increase in unspecified cases; however, no significance was identified in the estimated effect (B= -0.17; SE= 0.3; t= -0.5; p=0.6). **Conclusion:** In the pediatric age group the trend of increase in the rate of hospitalizations due to stroke occurred at the same time that there was a decrease in deaths from the same disease. As for the types of stroke, cerebral infarctions have maintained their initial upward trend, and there is insufficient evidence to suggest that the decrease in hospitalization for intracerebral hemorrhage is related to the increase in unspecified stroke cases.

Time to diagnosis of dmd patients with or without development delay

Marco Antônio Veloso de Albuquerque[1], Karlla Danielle Ferreira Lima[1], Fernando Kok[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Karlla Danielle Ferreira Lima; Email: karlla.dfl@gmail.com.

Background: Duchenne muscular dystrophy (DMD), the most common inherited childhood neuromuscular disease, typically starts around 3-5 years with progressive weakness, but a group of boys presents symptoms in early childhood with delayed development milestone, including walking and language delay. Despite the availability of genetic tests, the age of diagnosis has remained unchanged in the last decade. **Objective:** To analyze the age of diagnosis in a cohort of 127 DMD boys, comparing the time to diagnosis between patients with normal development milestones (group 1) and those with a delay of walking and / or speech acquisition (group 2). **Results:** The mean age of diagnosis in the cohort was 6.9 years (range: 2-16 years), with the meantime interval until genetic diagnosis of 3.6 years (range: 1-13 years). From the total, 89/127 (70%) showed an initial motor symptom with normal development. In this group, the mean age at presentation was 3.8 years (range: 1 to 7 years), and the age of genetic diagnosis was 7.5 years, (range: 2-16 years). On the other hand, 20% of patients (29/127) showed some development delay (group 2). In this group, the initial symptom was noted in a mean age of 1.4 years (ranged 0.5 - 2 years), with a delay of 3.4 years until diagnosis; 2.7 years earlier than group 1. **Conclusion:** Although patients with DMD and developmental delay presented earlier manifestations and diagnosis, the time to diagnosis did not differ much from those without delay in motor development. The importance of considering the diagnosis of DMD in patients with delayed motor development and elevated serum CK levels is highlighted.

Multiple sclerosis is a central nervous system affecting, chronic demyelinating disease, mediated via inflammatory mechanisms. It can result in progressive and permanent disabilities in both the physical and cognitive spectrum, the degree of impairment associated with time to initial treatment. Recent data challenges the previous status quo of initiating treatment with low-efficacy treatments and escalating to High-Efficacy disease modifying drugs based on relapse, due to reduced annualized relapse rate and reduced disability progression associated with early High-Efficacy treatment. Thus the study's objective is to evaluate the time to introduction of High-Efficacy drugs within 5 years of newly diagnosed Multiple Sclerosis in a Brazilian population. An electronic medical record aggregator called TriNetX was used to anonymously obtain the patient data used in the study, using exclusively hospital related records. The cohort was built using a Brazilian-only database via selecting patients who received the Multiple Sclerosis diagnosis in the last 10 years time frame, had never received an MCI or Multiple Sclerosis diagnosis before, and were at least 18 years at the time of the diagnosis. The Multiple Sclerosis diagnosis was considered the index event, while the outcome was the introduction of the high-efficacy medications available within 5 years of the index event. The high-efficacy drugs investigated in the study were natalizumab, fingolimod, alemtuzumab, cladribine, rituximab, ofatumumab and ocrelizumab. The resulting cohort had N=3,181 patients, with 2,747 patients who did not used High-Efficacy therapies as first line treatment. The remaining 434 patients had a median follow-up of 490 days. In this group, quickest therapy to introduce was Fingolimod, used by 25 patients, with a median time to treatment of 32 days, followed by Natalizumab, used by 228 patients, with a median time to treatment of 39 days. Rituximab was next, used by 34 patients, and with a median time to treatment of 76 days, followed by Ocrelizumab, used by 76 patients, with a median time to treatment of 79 days. The longest time to treatment was found with Alemtuzumab, used by 6 patients with a median time to treatment of 591 days. No patients used ofatumumab or cladribine as first line therapy. Established literature demonstrates benefit associated with introduction of High-Efficacy therapy within the first 6 months (approximately 180 days) of diagnosis. Based on the gathered results, apart from Alemtuzumab, the investigated therapies have been administered in adequate time. An unforeseen result obtained was the 86% of the initial cohort with Multiple Sclerosis who were not under High-Efficacy therapies, likely pointing to a lack of accessibility to these therapies. This is possibly a reflection of the high price associated these therapies or insurance policies restricted by specific clinical presentations of the disease.

Very early-onset Alzheimer's disease in a 29-year-old patient from the interior of Bahia

Sheila Ferreira Pessoa[1], Sonia Maria Dozzi Brucki[1], Cristiane Araújo Martins Moreno[1], João Luiz de Carvalho Santos[2], Vitor Guimarães Corrêa[1], Raphael Ribeiro Spera[1]

[1]Universidade de São Paulo, São Paulo SP, Brazil.
[2]Universidade Federal da Bahia, Vitória da Conquista BA, Brazil.

Correspondence: Sheila Ferreira Pessoa; Email: sheilaferreirapessoa@hotmail.com.

Case presentation: A 29-year-old woman with no history of previous comorbidities began experiencing progressive amnestic impairment and executive function decline at the age of 25. Over four years, this progressed to rigid-akinetic parkinsonism, myoclonus, and severe language impairment. Her paternal family history was unknown, and her maternal family history did not reveal any similar conditions. She tested negative for potentially reversible causes. CSF analysis was within normal limits but showed a biological signature for Alzheimer's disease (AD) with elevated P-tau: 176 pg/mL (normal range < 61); beta-amyloid 1598.00 ng/L (normal range < 550 pg/mL), and an AB42/AB40 ratio of 0.100 (normal range ≤ 0.10). MRI revealed global volumetric reduction. Given the clinical and biological findings, and the complexity of the case, including the early onset of symptoms, molecular analysis via DNA sequencing was performed. This identified a pathogenic mutation in the PSEN1 gene in heterozygosity (c.617G> T, p.Gly206Val) and an APOE genotype of E3/E4 in heterozygosity. **Discussion:** AD is the most common progressive neurodegenerative condition and is associated with aging. However, it is also the leading cause of pre-senile dementia. Very early-onset forms can present with atypical initial symptoms and are more strongly related to genetic factors. About 10% of cases are caused by mutations in three genes: presenilin 1 (PSEN1), presenilin 2 (PSEN2), and amyloid precursor protein (APP). Mutations in the PSEN1 gene present phenotypic heterogeneity, including amnestic presentations, executive function impairment, attention deficits, and also epileptic seizures, myoclonus, spastic paraparesis, and parkinsonism. Several mutations in the PSEN1 gene are associated with very early-onset AD (< 35 years of age). The patient's described variant (p.Gly206Val) has been previously reported to be associated with symptom onset before the age of 30, an extremely rare condition. Additionally, our patient has the E4 allele in heterozygosity, which may have accelerated the appearance of symptoms. **Final comments:** Given its severity and the particularities in terms of diagnosis and treatment, early-onset AD represents a crucial field of research. Identifying genetic biomarkers and elucidating underlying molecular mechanisms are essential steps for advancing early diagnosis, monitoring disease progression, and developing more effective therapies. Better understanding the genetic bases and pathological processes of early-onset Alzheimer's will not only help manage this specific condition but may also offer valuable insights into the more common late-onset form of the disease.

Multiple sclerosis (MS) is an autoimmune, degenerative and demyelinating disease that affects the central nervous system (CNS) and represents the leading cause of neurological disability in young adults. Natalizumab (NTZ) is recognized as a safe and effective monoclonal antibody (mAb) in the treatment of MS as it suppresses the migration of immune cells to the CNS mitigating inflammation. Genetic factors can significantly influence the therapeutic outcomes of MS treatment, however, there are few pharmacogenetic predictors of therapeutic outcomes in the treatment of MS patient. Therefore, this study aims to analyze the feasibility of TLR4 (rs10759931 and rs2737190) and FCGR2A (rs1801274) polymorphisms as a potential pharmacogenetic predictor of therapeutic failure.Were collected 104 blood samples from patients admitted to two university hospitals in Rio de Janeiro (CAAE 64171122.7.0000.5259 / 69411517.2.0000.5258). A detailed analysis of each patient was conducted, including an extensive clinical history (demographics, age of onset, disease duration, Expanded Disability Status Scale (EDSS) score and treatment history) and brain magnetic resonance images. The sample was categorized into two groups according to their response to NTZ treatment (responders and non-responders). Genomic DNA was extracted from leukocytes for subsequent genotyping by allelic discrimination using the TaqMan® PCR assay. TLR4 rs10759931 functional assay was conducted on peripheral blood mononuclear cells (PBMCs) of healthy volunteers. This was followed by stimulation with 1μg of LPS for 24h and subsequent assessment of mRNA expression. Among the patients, 9 confirmed therapeutic failure to NTZ treatment. The genotypic distributions were in Hardy-Weinberg equilibrium, there was no linkage disequilibrium (LD) between the two TLR4 SNPs (D >0.9). Statistical analysis identified significant association between the GG genotype of FCGR2A (p=0.0004, OR=0.3530) and therapeutic failure. Furthermore, a higher frequency of the AG genotype was observed in patients who did not experience treatment failure (p=0.0002, OR=3.144). Individuals carrying the TLR4 (rs10759931) AA genotype were observed in the good response group (p> 0.0002) associated with decreased expression of TLR4 mRNA. Our prior results for the TLR4 (rs2737190) also support the AA genotype as a good response group (p>0.0001), corroborating a possible protective role. Given the genetic diversity of the Brazilian population due to admixture, our preliminary findings suggest the need to investigate the role of FCGR2A rs1801274, TLR4 rs10759931 and rs2737190 as a potential pharmacogenetic predictor for MS patients' response to NTZ.

Tocilizumab as second line treatment option to refractory anti-NMDAR encephalitis with severe clinical complications

Renato Pierre Lima[1], João Henrique Fregadolli Ferreira[1], Marcos Vinícius Tadao Fujino[1], Ana Luíza Vieira de Araújo[1], Lívia Almeida Dutra[1]

[1]Hospital Israelita Albert Einstein, São Paulo SP, Brazil.

Correspondence: Renato Pierre Lima; Email: rpierrelima@gmail.com.

Case presentation: A prior healthy 30-year-old female patient presented nausea and vomiting for 4 days. She evolved with aphasia and two episodes of tonic-clonic seizures. Brain MRI and CSF had normal results. After a week she developed psychosis and catatonia and was admitted to a psychiatric ward. During the next 14 days, she seizures frequency increased, she developed orofacial dyskinesias, and was admitted to the ICU. Antineuronal antibodies panel in CSF and serum confirmed anti-NMDAR encephalitis (anti-NMDARE). She was started on IVIG and steroids 35 days after firs symptoms with no improvement, and evolved with refractory status epilepticus, acute renal injury requiring hemodialysis, segmental pulmonary thromboembolism, and sepsis due to Pseudomonas with gluteus abscess. Upon admission to the ICU, the patient was under sedation, on mechanical ventilation, with RASS -3, receiving propofol and fentanyl. Pupils were isofotoreactive. The patient exhibited orofacial-limb dyskinesias and appendicular rigidity. Clinical evaluation at this point revealed mRs 5 and CASE of 22. Laboratory exams showed Hb of 6.4g/dL, platelets 46.000/ml, Cr 2.52mg/dL, normal serum immunoglobulins, negative TB Gold, and anti-HBs and IgG anti-HBc positive. EEG showed extreme delta brush. Due to the multiple clinical complications and severe infection, along with the risk of hepatitis B virus reactivation, she was started on tocilizumab 8mg/kg and tenofovir 300mg/day. She evolved with slowly clinical and neurological improvement in the following 30 days, did not have additional clinical complications, was weaned from mechanical ventilation and became seizure-free. Rituximab was started after a washout period of 30 days from the last tocilizumab dose. **Discussion:** We report a patient that received tocilizumab as second line option for anti-NMDARE, due to many clinical complications and formal contraindication to rituximab. Tocilizumab effects start 5 days after infusion and lasts for 30 days, which is suitable for unstable patients with severe complications in the ICU, as opposed to rituximab, which may take 15-30 days for initial effect. Although no controlled trial evaluated the efficacy of tocilizumab versus rituximab in anti-NMDARE, this case illustrates how patients in the ICU may benefit from other therapies, as time to treatment is a variable with prognostic value. **Final comments:** Tocilizumab may be considered as second-line treatment to patients with severe complications in ICU.

https://doi.org/10.5327/CBN241673

Tocilizumab for cryptogenic fires with hemofagocytic syndrome: a case report

Anna Maria Gomes[1], João Henrique Fregadolli Ferreira[1], Rejane de Souza Macedo Campos[1], Carol Ladeia-Frota[1], Victor Rebelo Procaci[1], Livia Almeida Dutra[1]

[1]Hospital Israelita Albert Einstein, São Paulo SP, Brazil.

Correspondence: Anna Maria Gomes; Email: g.annamgomes@gmail.com.

Case presentation: A previously healthy 11-year-old boy presented with fever, rash and vomiting. Five days later, he developed bilateral tonic-clonic seizures, and status epilepticus. He had experienced childhood infections associated with disproportionate febrile reactions and migratory arthritis, but no previous autoimmune diseases diagnosis. Family history was unremarkable. Lab results showed mild leukocytosis 14120 and anemia 10.3g/dl. Brain MRI was normal. CSF analysis demonstrated 1 cell, 24 mg/dL protein, 13.5mg/dl lactate, 62 mg/dL glucose, OBC were absent, antineuronal and antiglial antibodies were negative. He evolved with super-refractory status epilepticus, despite the use of eight different antiseizure medications. He was diagnosed with Febrile Infection-Related Epilepsy Syndrome (FIRES) and was started on methylprednisolone and plasmapheresis (4 cycles) two weeks after the initial symptoms followed by anakinra. After twelve days, anakinra was discontinued due to posterior reversible encephalopathy syndrome. CSF cytokine profiling showed significantly increased IL-6 (31.2 pg/mL) and IL-1 (<6.5 pg/ml). Forty-four days after the onset of seizures, tocilizumab was administered and repeated biweekly. Seizures improved, nonetheless the patient developed persistent fever, increased ferritin, bicytopenia, hypertriglyceridemia and elevated transaminases, indicating hemophagocytic lymphohistiocytosis (HLH), for which intrathecal dexamethasone and etoposide were introduced (5 cycles). One dose of cyclophosphamide was administered the day after dexamethasone, resulting in improvement of the EEG and systemic inflammation. The patient neurological condition gradually improved, and he was discharged home, ambulatory with mild cognitive impairment, with tocilizumab and antiseizure medication. Exoma was normal. **Discussion:** FIRES is rare type of New-Onset Refractory Status Epilepticus (NORSE), and it is characterized by the sudden onset of a febrile infection between 24 hours and 2 weeks before the onset of refractory status epilepticus, with or without fever at the onset of RSE. This case illustrates that cytokine profile can help in switching medications, and also shows that brain inflammation can trigger systemic inflammation leading to HLH. Moreover it shows how FIRES requires intensive immunossupressive treatment and association of depleting agents as well as cytokine blockage. **Final comments:** Cryptogenic FIRES is a challenging disease, which can evolve with multiple complications, including HLH.

Todd's paralysis as a differential diagnosis for stroke

Emanuelly Valentim Oliveira[1], Maria Luiza Rodrigues Defante[1], Diogo de Souza Vargas[1], Henrique Rosa Henriques[2]

[1]UniRedentor, Itaperuna RJ, Brazil.
[1]Universidade Iguaçu, Itaperuna RJ, Brazil.

Correspondence: Emanuelly Valentim Oliveira; Email: valentimanu@outlook.com.

Case presentation: A 42-year-old male patient with no previous comorbidities presented for blood donation. During the procedure, he experienced a tonic-clonic seizure and was taken to the local emergency department, where he had another seizure episode. Around 2 PM that day, he exhibited sudden onset focal neurological deficit, presenting with sensory aphasia and complete brachiocrural hemiplegia disproportionately affecting the right side with brachial predominance. Initial suspicions included Todd's Paralysis (TP) and acute ischemic stroke (AIS). A cranial CT scan showed no bleeding, leading to a conservative approach with acetylsalicylic acid, lamotrigine, clopidogrel, and simvastatin. The patient was admitted for further investigation and transferred to the Intensive Care Unit. Electroencephalography ruled out epileptogenic activity. A follow-up CT scan after 24 hours revealed ischemic lesions, confirming the diagnosis of AIS. **Discussion:** AIS, the most common cerebrovascular disease, refers to ischemia resulting from obstruction, vasospasm, or narrowing of cerebral arteries. Clinical manifestations depend on the occluded artery's location. The middle cerebral artery is most commonly involved, presenting with hemiparesis, aphasia, hypoesthesia, central facial paralysis, and hemineglect. TP, on the other hand, is a postictal state following tonic-clonic and absence seizures, manifesting as hemiparesis, aphasia, hemineglect, and visual disturbances, lasting from minutes to up to 36 hours. Differentiating TP from AIS can be challenging, particularly due to the focal impairments in the postictal state. Diagnosing TP requires investigating the patient's medical history to identify possible AIS risk factors and previous seizure occurrences, as well as knowing the medications being used. A CT scan, showing ischemic lesions 24 hours post-event, and an EEG, which ruled out epileptogenic activity, are crucial in this differentiation. **Final comments:** Differentiating between

TP and AIS is vital. While TP does not require medical intervention, AIS management depends on blood pressure and vascular control, utilizing medications that affect blood viscosity along with fibrinolytic administration. Thus, understanding the differential diagnosis is essential to guide appropriate clinical management, avoiding potential iatrogenesis in TP cases and/or delays in AIS treatment.

Tongue tremor as a presentation of focal seizure: a rare case report

Ana Letícia Amorim de Albuquerque[1], Cândida Driemeyer[2], Carolina Oldoni[3], Rhaná Carolina Santos[1], Rafaela Jucá Lindner[1], Amanda da Silva Araújo[1], Natália Toebe Giudice da Costa[1]

[1]Universidade do Vale do Rio dos Sinos, São Leopoldo RS, Brazil.
[2]Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre RS, Brazil.
[3]Hospital de Clínicas de Porto Alegre, Porto Alegre RS, Brazil.

Correspondence: Cândida Driemeyer; Email: candidaplena@gmail.com.

Case presentation: A 43-year-old female patient, with unknown comorbidities, was brought to the emergency room with involuntary episodes of tongue tremors, associated with sialorrhea and dysphagia, occurring over the past 24 hours. The episodes last about 2 minutes, are involuntary, and are associated with twitching of the second and third fingers of the right hand and dysarthria during the episodes. In the preceding week, she reported a mild headache without alarm signs, which was relieved by dipyrone. There were no focal deficits on physical examination and no laboratory abnormalities. A cranial MRI with contrast revealed a recent intraparenchymal hemorrhage in the left inferior frontal gyrus measuring 1.8 cm, associated with a vascular structure extending towards the subependymal region of the left lateral ventricle, suggestive of a developmental venous anomaly. A contrast-enhanced CT angiography confirmed the presence of an arteriovenous malformation (AVM). Given the semiology of the movements and the imaging findings, the possibility of focal seizures was considered. Administration of diazepam during an episode resulted in the cessation of movements, supporting this impression. Consequently, the patient was treated with phenytoin without further recurrence of seizures. **Discussion:** AVMs are congenital anomalies of intracranial vessels, characterized by a cluster of abnormal arteries and veins, resulting in abnormal and high cerebral blood flow. AVMs tend to present clinically around the age of 30, with intracranial hemorrhage, progressive neurological deficit, and/or seizures. Focal epilepsy presenting as isolated tongue tremor is a rare condition, highlighting the diversity in the presentation of epileptic seizures. This condition is particularly relevant in the context of an AVM, as the vascular anomaly can create an environment suitable to epileptic activity due to altered blood flow and brain structure. Thus, seizures may manifest in less common cerebral areas, such as the tongue. **Final comments:** Although previously reported in other studies, focal epilepsy of the tongue area is a rare manifestation with diverse causes. We present a case where the epileptic focus is related to a structural origin of abnormal cerebral blood vessels. Medical follow-up is essential for monitoring the condition to prevent further seizures and, in the case of AVMs, new hemorrhages. Therefore, we highlight the importance of considering AVMs in the differential diagnosis of similar cases, especially in atypical presentations in young patients. The diagnostic and therapeutic approach should be comprehensive and multidisciplinary, aiming at both seizure control and the correction of the underlying vascular anomaly when deemed possible.

Tongue ultrasound assessment in patients with nemaline myopathy

Ana Lucila Moreira[1], Cristiane Araujo Martins Moreno[2], Clara Gontijo Camelo[2], Edmar Zanoteli[2]

[1]CENEC Neurofisiologia Clínica, Campinas SP, Brazil.
[2]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Ana Lucila Moreira; Email: ana.lucila.moreira@gmail.com.

Background: Dysphagia in Nemaline Myopathy (NM) is commonly associated with altered orofacial structure, but tongue function may be a key feature in the evaluation of these patients. **Objective:** To describe the changes found on ultrasound of the tongue muscles in patients with NM. **Methods:** Fifteen patients with NM underwent ultrasound using muscle-specific setup with fixed gain (GE Logic E) with a 4 to 12 MHz transducer, evaluating the muscles of the tongue in coronal section with B-mode and M-mode, the latter being used with a plane on the digastric muscle to evaluate the number of movements performed during saliva swallowing. The muscles were graded using the modified Heckmatt scale (Grade 1 - normal muscle; Grade 2 - probably abnormal; Grade 3 - abnormal). **Results:** Nine patients were male, aged between 1 and 54 years (median 16 years). Five patients had severe dysphagia with exclusive use of gastrostomy, six had mild dysphagia and four had normal swallowing. All patients showed involvement of the genioglossus muscle on ultrasound. The geniohyoid was the least commonly affected muscle on ultrasound, being altered in only seven patients, five of which had tongue atrophy. The number of movements performed for swallowing was evaluated in eleven patients and was greater in patients with involvement of more than one muscle evaluated. **Conclusion:** Ultrasound of tongue muscles is capable of detecting changes in patients with NM even before the development of atrophy or dysphagia. Early recognition of these changes is important for therapeutic guidance.

Toxoplasmic encephalitis in a patient with multiple myeloma: a case report

Josenice Gomes Trindade Seidel[1], Ahmad Kassem El Zein[1], Joana Laura Aihara Barbosa[1], Matheus Rodrigues Nogueira[1], Lucas Henrique de Moura Rogerio Garcia[1], Romulo Loss Mattedi[1], Julia Martins Brunelli[1], Lúcio Huebra Pimentel Filho[1], Bruno Fukelmann Guedes[1], Tarso Adoni[1]

[1]Hospital Sírio Libanês, São Paulo SP, Brazil.

Correspondence: Josenice Gomes Trindade Seidel; Email: josegomes15@hotmail.com.

Case presentation: An 83-year-old woman previously diagnosed with IgG Kappa multiple myeloma (MM) currently in remission was admitted to the emergency department due to a 10-hour history of mental confusion and impaired speech. The previous oncological approach was induction therapy with lenalidomide and dexamethasone followed by maintenance treatment with lenalidomide, and the patient was considered ineligible for an autologous hematopoietic stem-cell transplantation (AHSCT). On neurological evaluation, the patient presented global aphasia, psychomotor agitation, and right-hand paresis. Brain magnetic resonance imaging (MRI) identified a ring-enhancing oval cortical and subcortical lesion in the left temporoparietal region. An 18F-FDG PET/CT scan showed increased metabolic expression in the same region. IgM antibodies for toxoplasmosis were negative, but IgG antibodies were positive. Serology tests for HIV, hepatitis B and C, syphilis and tuberculosis were negative. Cerebrospinal fluid analysis revealed increased protein with lymphocytic pleocytosis and normal glucose levels, negative bacterioscopy and cultures, as well as negative for syphilis and toxoplasmosis. Proton MRS and perfusion MRI showed eccentric target sign and scattered nodular foci of enhancement in both cerebral hemispheres. Increased blood volume in the left hemisphere and reduced neuronal viability were noted. The possibility of brain metastases was considered. Given the neurological worsening with seizures and diagnostic uncertainty, a brain biopsy was performed and demonstrated inflammatory infiltrate with extensive coagulative necrosis and the presence of grouped parasites in the form of pseudocysts, as well as free in the parenchyma, suggestive of Toxoplasma gondii bradyzoites and tachyzoites. Both polymerase chain reaction and immunohistochemistry were positive for toxoplasma in the brain tissue. Treatment with trimethoprim/sulfamethoxazole was promptly initiated, resulting in a significant improvement in the patient's clinical condition. **Discussion:** Toxoplasmosis is the most common opportunistic infection of the central nervous system in patients with HIV, but patients with MM also have an increased risk of infections due to dysfunctional adaptive immunity. Furthermore, the use of chemotherapy and immunomodulatory therapy has increased typical and atypical neurological infections. Rare cases of cerebral toxoplasmosis in HIV seronegative patients with MM, were described in the literature, most of them in patients undergoing AHSCT or using multiple chemotherapy drugs. We report a rare case of toxoplasmosis reactivation, manifested as acute encephalitis, in a patient with MM in remission, considered ineligible for an AHSCT, HIV seronegative, and using lenalidomide only. **Final comments:** Toxoplasmic encephalitis should be considered as a differential diagnosis in patients with MM, regardless of disease status and therapy.

Tracing the legacy of arnold pick on his death centennial: insight into frontotemporal dementia

João Ignacio Ferrara Neto[1]

[1]Universidade Federal do Rio de Janeiro, Faculdade de Medicina, Rio de Janeiro RJ, Brazil.

Correspondence: João Ignacio Ferrara Neto; Email: joaoignacioferrara@gmail.com.

Background: Arnold Pick (1851-1924), born in Velké Mezi í í, Moravia, graduated from Vienna's medical school in 1875. He completed an elective at Vienna's Landesirrenanstalt and served as a student assistant to Theodor Meynert from 1872 to 1874, focusing on neuroanatomy. Pick, alongside Carl Wernicke, distinguished himself as a Czech psychiatrist and neurologist, advancing behavioral neurology. In 1892, Pick described what is now known as Pick's disease or frontotemporal dementia (FTD). He outlined distinct clinical symptoms and identified two types of agrammatism: temporal, characterized by defective syntax, rapid speech, and incorrect inflections; and frontal, marked by substantive word juxtaposition without syntactical elements. Pick's findings on brain atrophy in the frontal and temporal lobes significantly advanced the understanding of presenile dementia, solidifying his legacy in neurological research. **Objective:** This historical report aims to investigate Arnold Pick's pioneering work during the late 19th and early 20th centuries, focusing on his discovery and characterization of frontotemporal dementia (FTD), later termed Pick's disease. **Methods:** This historical analysis of Arnold Pick's work and legacy entails an extensive literature review of primary and secondary sources, encompassing medical journals and biographies. Key documents and case studies authored by Pick will be scrutinized to elucidate his contributions to neurology. Furthermore, a comparative analysis with contemporaries such as Alois Alzheimer will be conducted. **Results:** Arnold Pick's early articles lacked

histological descriptions of FTD until Alois Alzheimer's 1911 discovery of Pick Bodies–silver-staining globular inclusions. Today, Pick's disease is recognized by pathology featuring Pick bodies, Pick cells, and circumscribed brain atrophy. FTD is classified into three categories: behavioral variant, semantic variant primary progressive aphasia, and non-fluent variant primary progressive aphasia, all based on symptoms identified by Pick. Thus, Pick pioneered research on these topics and neuroanatomy and left a lasting legacy in the field. **Conclusion:** In conclusion, Arnold Pick's groundbreaking contributions to the understanding of frontotemporal dementia have profoundly influenced the field of neurology. His meticulous observations and pioneering descriptions continue to shape our understanding of neurodegenerative diseases, underscoring the enduring legacy of his work in modern medicine.

Tract-specific spinal damage in SCA2, SCA3 and SCA6

Fabrício Catro de Borba[1], Joyce Macedo Sanches Fernandes[1], Thiago Junqueira Ribeiro de Menezes[1], Carelis González-Salazar[1], Lucas de Melo Teixeira Branco[1], Paulo Schneider Wolmer[1], José Luiz Pedroso[2], Orlando Graziani Povoas Barsottini[2], Marcondes Cavalcante França Junior[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.
[2]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Fabrício Castro de Borba; Email: fabriciocborba@gmail.com.

Background: Spinocerebellar ataxias (SCAs) are a group of neurodegenerative disorders characterized by progressive ataxia. **Objective:** To characterize spinal cord abnormalities in patients with SCA2, SCA3, and SCA6 and identify their phenotypic correlates. **Methods:** A multimodal spinal neuroimaging study was conducted on 26 SCA3, 16 SCA2, and 14 SCA6 patients, along with matched healthy controls. MRI scanning was performed using a 3 Tesla device, and the Spinal Cord Toolbox (SCT) was employed for morphometric and diffusivity analyses of the cervical spinal cord. **Results:** Significant spinal cord atrophy and altered white matter microstructural metrics were observed in SCA3 and SCA2 patients compared to controls, with no abnormalities in SCA6. A strong negative correlation was found between cross-sectional cord area and disease duration in SCA2, suggesting its potential as a biomarker for disease progression. **Conclusion:** This study highlights the importance of spinal cord imaging in understanding the pathophysiology of SCAs and demonstrates the utility of MRI-based metrics in identifying structural deviations and their clinical correlates. Further longitudinal studies are needed to validate these findings and explore their implications for clinical trials and therapeutic interventions.

Correspondence: Marcos Vinícius do Nascimento da Silva; Email: ufrj.marcosnascimento@gmail.com.

Background: Epilepsy is a neurological disorder characterized by recurrent, unprovoked seizures. A significant part of people affected by this disease has a condition called refractory epilepsy, which does not respond adequately to anti-seizure drugs. Therefore, transcranial direct-current stimulation (TDCS) is a neuromodulation technique and a promising treatment for those with this condition, given its ease of use and non-invasive nature. However, its benefits for this purpose remain unclear. **Objective:** To clarify the safety and efficacy of TDCS in reducing seizure frequency in patients with refractory epilepsy. **Methods:** We searched MEDLINE, Scopus, and Web of Science databases for randomized clinical trials (RCT) and observational studies that assessed transcranial direct current stimulation in refractory epilepsy patients. A random-effects model was used to calculate the mean differences (MDs) with 95% confidence intervals (CIs). Heterogeneity was assessed using I^2 statistics. R, version 4.3.2, was used for statistical analysis. **Results:** A total of four studies comprising 88 patients with epilepsy were included. For seizure frequency, TDCS demonstrated a statistically significant reduction compared with sham treatment, with a mean difference (MD) of -4.19 (95% CI -6.54 to -1.83, p=0.0005; I^2=62%).In contrast, for interictal epileptiform discharge (IED) frequency, TDCS showed no statistically significant difference compared with sham treatment (MD -3.69; 95% CI -8.20 to 0.81; p=0.11; I^2=64%). **Conclusion:** In this meta-analysis, consistent results suggest that while TDCS may significantly reduce seizure frequency, its effect on IED frequency remains inconclusive. Therefore, to evaluate the benefits of TDCS in IED, further studies are needed.

Transcranial doppler assessment as an ancillary tool in the diagnosis of convulsive syncope with disrupted cerebral autoregulation in a pregnant woman

Vinícius Canhestro Roedel[1], Rodrigo Santiago Gomez[1], Mirian Fabiola Studart Gurgel Mendes[1], Aretha Miranda Silva[1], Bárbara Cristina Silveira de Oliveira[1], Rachel Laguardia Rego[1], Larissa Cruvinel Leite[1], Samuel Inácio Oliveira Araújo[1], Verônica Moreira Belo[1]

[1]Hospital Madre Teresa, Belo Horizonte MG, Brazil.

Correspondence: Vinícius Canhestro Roedel; Email: roedelvinicius@gmail.com.

Case presentation: A 22-year-old woman with depression and attention deficit hyperactivity disorder experienced an unplanned pregnancy and began having recurrent episodes of loss of consciousness. These episodes started around the twenty-sixth week of pregnancy, gradually increasing in frequency to several times a day, significantly impairing her daily life. The loss of consciousness was preceded by subjective sensations of "everything turning white" and "pressure in the ears," lasted a few seconds, and was notably triggered by standing up. During these episodes, the patient exhibited eye deviation and flexion posturing of hands and fingers, raising concerns about an epileptic origin of her symptoms. Investigations included magnetic resonance imaging, which was normal, and a video electroencephalogram (EEG), during which four events were recorded. These events were characterized by a drop in blood pressure and severe, generalized slowing of EEG waves. The patient was then evaluated using transcranial Doppler (TCD) for 35 minutes in a sitting position. Paroxysmal periods of tachycardia were observed, and during one of these periods, another episode of loss of consciousness occurred. This episode was marked by interrupted diastolic flow in the left middle cerebral artery, reduced systolic flow velocity, and a significant increase in the pulsatility index. **Discussion:** This case underscores the importance of a well-established differential diagnosis between epileptic seizures and convulsive syncopes. It also highlights the utility of TCD monitoring during an event to demonstrate a hemodynamic disorder as the cause. The patient and her family were oriented, avoiding unnecessary use of anticonvulsant drugs, which could be problematic during pregnancy. Furthermore, the TCD findings indicated increased cerebrovascular resistance due to vasoconstriction in the middle cerebral artery, consistent with findings from other studies using TCD during tilt-tests. This cerebral vasoconstriction in response to systemic hypotension is paradoxical, as the expected response would be vasodilation, suggesting a link to the pathophysiology of syncope. However, this case does not fit the classic neurocardiogenic syncope profile, as there was a tachycardia response instead of bradycardia, nor does it align with postural orthostatic tachycardia syndrome, since systemic hypotension was recorded. The pathophysiology might be related to the decreased venous return typical of pregnancy, resembling a hypovolemic shock and triggering an exaggerated adrenergic response that causes tachycardia and cerebral vasoconstriction. **Final comments:** TCD use in assessing episodes of loss of consciousness is not routine, but it can aid in diagnosis and provide new insights into cerebral circulation autoregulation. To our knowledge, this is the first documented case of using TCD assessment combined with EEG for episodes of loss of consciousness in a pregnant woman.

Transcranial sonography in diseases with hippocampal atrophy

Rita de Cássia Leite Fernandes[1]

[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Rita de Cassia Leite Fernandes; Email: rilefe2016@gmail.com.

Background: Neurological sonography is a cost-effective and safe neuroimaging method. In many scenarios it may help to quickly establish a diagnosis, sometimes at the bedside, in patients with limited or delayed access to routine neuroimaging. The indications of Neurosonology are rapidly expanding outside the field of cerebrovascular diseases. Transcranial sonography (TCS) may assist in the differential diagnosis of movement disorders and a good correlation to MRI imaging in Alzheimer's dementia (AD) was found. Our **Objective:** To check the ability of TCS to visualize medial temporal lobe structures (MTLs). **Methods:** Preliminary proof-of-the-concept study to evaluate MTLs in patients of a universitary hospital. TCS was performed through the temporal bone window bilaterally with HD11XE (Philips) equipment using a sectorial 1-5MHz transducer. Axial and coronal insonation planes were used. A group with patients diagnosed with ILAE criteria for MTL epilepsy and MRI showing unilateral hippocampal sclerosis (MTL-HS) had the following structures analyzed and compared by both methods: choroidal fissure height (CF), temporal pole ventricle width (TP) and hippocampal height. The MTL atrophy index was calculated for both methods (MTLA=CF+TP). A second group was divided in AD patients with a > 2y diagnosis of a probable AD and a healthy control no dementia group. Hippocampi were evaluated and compared; the following measures were obtained: (A) lateral temporal pole, (B) MTL height, (C) MTL width, (D) ambiens cistern width and (E) choroidal fissure height. **Results:** Visualization of MTL structures by TCS was easy and feasible in all 23 participants. Only 1 patient had no bone window on one side. MTLE-HS group (n=4) had 3 men and ages 24-50y. Comparison between measures obtained by TCS and MRI showed a good correlation, specially the MTLA index, with a 74% agreement. The worst measures were the TP, with only 43% agreement. The laterality definition of HS by TCS

and MRI was 100%. In the other group we examined 4 DA patients and 15 controls, similar age. There was significant difference in MTL width between the groups (1.54+0.11 cm vs 1,91+0,33 cm; p=0.0027). The ratio B/E was the best to identify the dementia patients (2.23+0.22 vs 3.17+0.47; p=0.0001). **Conclusion:** TCS depicts MTL structures easily for an experienced operator. We compared measures obtained by TCS with MRI in a small group of HS patients and found them quite similar with identical laterality identification. Also, AD patients showed a ratio between MTL height and choroidal fissure height (B/E) significantly different from controls. Although the number of patients is small, this work points to a possible usefulness of TCS in evaluating MTL structures and, therefore, in diagnosing diseases with hippocampal atrophy. Studies with larger participant groups are highly desirable to prove TCS accuracy in clinical neurological practice as a neuroimaging modality in these diseases.

Transient ischemic attack in a young patient with rete mirabilis circulation pattern in the middle cerebral artery: a case report

Hélio Aquaroni Farão Gomes[1], Itamar Meireles Andrade Santos[1], Dominick Esthephanny Monteiro Silva[1], Ana Beatriz Marangoni Baston[1], Pedro Machry Pozzobon[1], Caroline de Barros Viegas[1], Eduardo Abrão Spinola Rezk[1], Gabriela Rossini Dantas[1], José Eduardo Tentim Longo[1], Gabriel Pinheiro Modolo[1]

[1]Universidade Estadual Paulista, Botucatu SP, Brazil.

Correspondence: Hélio Aquaroni Farão Gomes; Email: heliofarao@hotmail.com.

Case presentation: GFO, 31 years old, in February 2024 presented with sudden onset of complete and proportionate right hemiparesis and dysarthria lasting around 25 minutes, denies head trauma, denies headache, in evaluation patient admitted asymptomatic, kept in neurological observation in stroke unit for 48 hours without clinical recurrence of deficits. He was investigated with a CT scan of the brain with an ASPECTS of 10 and no acute ischemic lesion or even indirect signs of ischemia. On CT angiography, he appeared to having a stop in M1 to the left, with heterogeneous and posterior hyperdensity in M2 which may correspond to an atypical circulation pattern; laboratory investigation has not found alterations in rheumatological or coagulation tests, or metabolic tests. MRI angiography and arteriography were then requested to complete the diagnosis and the study of the two exams revealed a network of exuberant insular perforating branches and slowed distal filling of the left middle cerebral territory, disconnecting the distal M1 portion with M2, corresponding to the rete mirabilis/Twin like pattern. Once the investigation was concluded, the patient was followed up as an outpatient with secondary prophylaxis with double antiaggregation for 21 days followed by monoaggregation and there has been no recurrence of the condition. **Discussion:** The rete mirabilis pattern is more common in other animal species, its formation does not occur during the fetal period and is usually formed by a network of physiological collaterals after a situation of vascular agenesis, whether of branches of the carotid or vertebral portion, shown on imaging exams with a hypoplastic vessel and circulatory compensation has a network shape maintaining circulation. Patients with a rede mirabilis circulation pattern are usually discovered in the event of an ischemic stroke, subarachnoid hemorrhage, intraparenchymal hemorrhage and carotid-cavernous fistula, showing the association with various vascular abnormalities, as was also the case with the patient presented in this case, with vascular hypoplasia noted in the middle cerebral artery. Suspicion of the condition is consistent when vascular hypoplasia/agenesis is seen in association with a network of small vessels in close proximity to the preserved subsequent circulation, with arteriography being the definitive diagnostic method for the condition. The best prophylaxis for the condition has not yet been defined in the bibliography, so the choice of prophylaxis was based on the prophylaxis normally used in transient ischemic attacks in this case. **Final comments:** with the development of new imaging methods, circulation variants are increasingly recognized and may be important causes of cerebrovascular alterations. Their recognition and increased presentation will motivate further research for better monitoring, prophylaxis and surgical approaches to avoid consequences for patients.

Transverse myelitis following arbovirus infection (dengue): a case report

Rodrigo Batista Irikura[1], Isabella Brasileiro Quintella Migueis[1], Anouar Sacca Colognesi[1], Guilherme Leonel Gomes da Cunha[1], Talles Camin Rajab[1], Sarah de Souza Chinelato[1], Bruna Santos Silva Guzzardi[1], Gustavo Carvalho Viveiros[1]

[1]Faculdade de Medicina de Marília, Marília SP, Brazil.

Correspondence: Isabella Brasileiro Quintella Migueis; Email: isabellabrm2@gmail.com.

Case presentation: A 33-year-old male patient presented to the Emergency Department with a history suggestive of dengue fever starting around May 27, 2024, characterized by fever (not measured), myalgia, and petechiae throughout the body. On June 5, 2024, around 10 PM, he experienced sudden onset of lower limb weakness resulting in a fall, and the following day (June 6, 2024), he woke up with paraparesis and paresthesia, prompting him to seek emergency evaluation. The patient developed urinary retention, necessitating placement of an indwelling urinary catheter. He denied lower back pain, upper limb weakness or paresthesia, dysphagia, visual changes, or other neurological complaints. He was admitted under the Neurology team for diagnostic investigation, including Brain MRI and cervical and thoracic spine MRI, as well as Dengue serology. The diagnosis of Transverse Myelitis following Arbovirus (Dengue) infection was established. **Discussion:** Transverse myelitis is a neuroimmune disorder affecting the spinal cord, characterized by rapid onset of muscle weakness, bladder dysfunction, and sensory disturbances. It typically follows an infectious illness but can also be associated with neuroinflammatory disorders such as multiple sclerosis. **Final comments:** Transverse myelitis is a rare condition, with an annual incidence of one to nine cases per million people. Therefore, enhanced understanding of the disease is crucial for suspicion and diagnostic investigation, as early treatment initiation may help prevent neurological damage.

https://doi.org/10.5327/CBN241685

Trauma car accident and Miller-Fisher syndrome: a case report

Bárbara Borges de Oliveira[1], Brenda Letícia Lopes Batista[1], Victor Souza Torres de Vasconcelos[1], Yanne Almeida Aguiar[1], Monique Evelyn Mendonça do Nascimento[1], Mariana Holanda Gameleira[1], Ana Carolina Paiva Farias[1], Rosevaldo Alves Junior[1], Maria Lúcia Brito Ferreira[1], Ana Rosa Melo Correa Lima[1]

[1]Hospital da Restauração, Recife PE, Brazil.

Correspondence: Bárbara Borges de Oliveira; Email: barbaraborgesneurologia@gmail.com.

Case presentation: A 25-year-old male patient presented with symptoms of binocular diplopia and imbalance 3 days after being admitted to the hospital. He had been involved in a car accident 4 days prior to the onset of symptoms but did not experience any head trauma or other complications at the time. The patient had no recent history of infection or vaccinations. The neurological examination revealed bilateral mydriasis, semiptosis, ophthalmoparesis, global arreflexia, dysmetria, and Romberg's sign. CSF analysis showed protein-cytological dissociation, and viral serologies were negative. MRI of the brain showed no abnormalities, and ophthalmologic evaluation revealed no issues. The patient was diagnosed with Miller-Fisher syndrome (MFS) possibly related to the trauma and treated with intravenous human immunoglobulin for 5 days. Although there was partial improvement in oculomotricity, the patient still had some symptoms upon discharge, which eventually resolved over the following months. **Discussion:** MFS is considered a rare variant of Guillain-Barré syndrome, an acute inflammatory and immune-mediated demyelinating polyradiculopathy, with an estimated incidence of 1 to 5% of cases in Western countries. It is characterized by the triad of ataxia, arreflexia and ophthalmoplegia. In addition to protein-cytological dissociation in the CSF, the presence of anti-GQ1b antibodies reinforces the diagnosis, as they are positive in more than 90% of MFS cases, although this is not pathognomonic. Although the syndrome is usually triggered by respiratory or gastrointestinal infections, it is known that other factors, although infrequent, can act as precipitants, such as vaccination and even cases of trauma. Regarding trauma, the pathogenesis is thought to involve various biochemical cascade reactions, including the release of catecholamines and cytokines, increased permeability of the blood-brain barrier. This allows macrophages to secrete neurotoxic mediators such as tumor necrosis factor alpha and nitric oxide and thus allowing the inflammatory process with damage to the myelin sheath and axon. **Final comments:** In MFS, it is important to carry out a more thorough clinical examination and ask about the patient's pathological history, especially a history of trauma. The patient had no other clinical event besides the trauma that could be related to the condition, and similar cases have already been described in the literature. Despite the favorable prognosis for MFS, with the possibility of self-limiting remission, treatment with IVIG is typically chosen to expedite recovery and minimize complications.

https://doi.org/10.5327/CBN241686

Traumatic brain injuries in military police: a case series of 11 officers wounded by high-caliber firearms

Raquel Maria Ayres Monteiro[1], Raphaela Coelho Veloso Gomes[1], Uri Adrian Prync Flato[2], Carlos Gilberto Carlotti Júnior[3], Wellingson Silva Paiva[3], Mário Vicente Campos Guimarães[3]

[1]Faculdade Israelita de Ciências da Saúde Albert Einstein, São Paulo SP, Brazil.
[2]Hospital Israelita Albert Einstein, São Paulo SP, Brazil.
[3]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Raquel Maria Ayres Monteiro; Email: raquelmamonteiro@gmail.com.

Background: Traumatic brain injury (TBI) is a major global health issue, with combat TBI, often resulting from armed conflicts, accounting for 2% of cases. Advances in technology and military tactics have altered injury patterns, increasing both fatality and morbidity. Although generally mild, up to 25% of combat TBIs lead to chronic impairments like cognitive, behavioral, and sensory changes, known as post-concussion syndrome. Firearm-related TBIs tend to cause more severe sequelae than blunt traumas. In Brazil military police officers face a higher risk of firearm fatalities than civilians, predominantly outside work hours. These incidents mainly affect men and Black

individuals (97% and 67%, respectively), highlighting the professional risks and the physical, psychological, and social consequences of their duties. **Objective:** This case series analyzes the profile of 11 military police officers from São Paulo State, aiming to compare findings with global and Brazilian statistics. **Methods:** This study included 11 military police officers from the State of São Paulo, who survived gunshot wounds to the skull and were treated between 2014 and 2017. Variables analyzed included sex, age, number of projectiles, entry wound, need for decompressive craniectomy, and cranioplasty, with a descriptive analysis conducted using JASP software. **Results:** Patients in this case series, aged 23 to 35 years with an average age of 26.9, included 10 men and one woman among 11 police officers. The most common injury was a frontotemporal entry wound (54.54%), followed by parietal wounds (18.18%), with occipito-mastoid, frontotemporoparietal, and temporoparietal entry wounds each accounting for 9.09%. Decompressive craniectomy was performed in 9 cases (81.8%), and cranioplasty in 8 (72.7%). The injuries were primarily caused by two types of projectiles, 5.56 and 7.62, with the latter responsible for 90% of the injuries; notably, one patient was struck by projectiles of two different calibers. Neurologically, 5 patients (45.4%) exhibited left hemiparesis, 4 (36.3%) had right hemiparesis–with half of these also presenting with aphasia. Additionally, one case involved diparesis accompanied by aphasia, and another presented with vertigo and right-sided anacusis. **Conclusion:** This study of traumatic brain injuries in São Paulo's military police underscores the severe implications of high-caliber firearm wounds. Extensive surgical interventions were necessary due to the injury severity. The officers experienced significant chronic impairments, affecting their quality of life and necessitating a multidisciplinary medical approach. The findings call for more research and improved safety measures for law enforcement professionals.

Traumatic brain injury and correlations with psychiatric disorders: a systematic review

Rafaela Coelho Rachid[1], Lizen Clare André Moreira[2], Gustavo Joji Yoshida[2], Fernanda Beatriz Venturi Araújo[1], Augusto Neuberger[1], Anita Ferreira Das Neves[1]

[1]Universidade Federal do Rio Grande, Rio Grande RS, Brazil.
[2]Universidade Federal Fluminense, Niterói RJ, Brazil.

Correspondence: Rafaela Coelho Rachid; Email: rafacoelhorachid@hotmail.com.

Background: Traumatic brain injury (TBI) is a neural injury that affects millions of people each year. While physical and cognitive impairments are extensively studied, psychological effects are relatively understudied. Recent studies indicate a significant relationship between TBI and post-traumatic mental disorders, emphasizing the importance of understanding this connection to guide treatments. **Objective:** To identify the main mental disorders following TBI in patients with no psychiatric history. **Methods:** A systematic review was conducted following the PRISMA protocol across three databases: Scopus, Web of Science, and PubMed. Initially, 1232 articles were found based on the PICO criteria, but 1082 were excluded after title and abstract screening. Of the remaining 150 articles, 97 were included after full-text review, with 17 excluded due to lack of access. **Results:** Symptoms analyzed in TBI patients included anxiety, depression, memory and sleep disturbances, irritability, obsession, suicidal ideation, mood disorders, post-traumatic stress disorder (PTSD), and personality disorders. Assessment tools used included the Structured Clinical Interview for DSM-IV, Pittsburgh Sleep Quality Index, and Mini Mental Health State Examination. Udala M found a negative correlation between anxiety and working memory in TBI patients. Katzin identified mood and personality changes in inmates with TBI (66.9% with personality changes). Maguen S noted a higher tendency for mental disorders, PTSD, and depression in blast-related TBIs. Collen J found specific sleep disorders like obstructive sleep apnea related to blunt traumas, with insomnia prevalent in blast-related traumas. Lange RT reported irritability in 30-40% of mild TBIs and 66% in severe cases. Choi Y identified depression as the most common disorder, with an incidence of 34.6 per 1000 persons per year compared to 21.42 in the control group. Yeh TC found a doubled risk of developing disorders in TBI patients compared to non-TBI individuals. Sivolap YP highlighted increased substance abuse, and Talaslahti T noted a 1.9 to 2.5 times higher suicidal tendency in TBI patients. Some studies suggest symptoms worsen over time and with TBI severity, indicating a risk for cognitive decline but not necessarily neurodegenerative diseases. **Conclusion:** TBI is associated with psychiatric disorders. It is evident that a more accurate assessment of individuals' neuropsychiatric state occurs when there is a correlation between neuropsychological domains, neurobehavioral questionnaires, and self-perception. The trauma mechanism was a determining factor in the development of specific neuropsychiatric disorders. Depression, anxiety, sleep disturbances, and suicidal behavior were the most frequent disorders. However, more studies with general populations are needed, as many of those included only inmates or military personnel.

Treatment for 5q spinal muscular atrophy with risdiplam: safety and preliminary efficacy in a Brazilian cohort

Raquel Diógenes Alencar Sindeaux[1], Rodrigo de Holanda Mendonça[1], Graziela Jorge Polido[1], Eduardo Vital de Carvalho[1], Leandro Augusto de Almeida[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Departamento de Neurologia, São Paulo SP, Brazil.

Correspondence: Eduardo Vital de Carvalho; Email: duvital1983@gmail.com.

Background: Risdiplam is approved for the treatment of all types 5q spinal muscular atrophy (5q-SMA) from 16 days of age onwards. Although clinical trials have shown improvements or stabilization in motor and respiratory function, real-world data is still scarce. **Objective:** To describe the experience of a neuromuscular specialized center in Brazil in treating 5q-SMA patients with risdiplam and to analyze clinical aspects during a follow-up period up to 32 months (range 3-32; mean 10,95 months). **Methods:** Eighteen 5q-SMA patients have been followed by a multidisciplinary team since the beginning of treatment with risdiplam from November 2021 to May 2024. These patients have been monitored in a specialized public outpatient clinic and a private clinic in São Paulo-Brazil. At each follow-up visit, subjective global impression of the patient or caregiver and adverse treatment events have been collected. Motor scales and respiratory assessments have also been performed when feasible. **Results:** All patients were treatment-naïve, and they started risdiplam between 17 days and 49 years old (mean 18,62 years). Three patients began treatment in a pre-symptomatic phase. One patient was SMA type 1, eleven were SMA type 2 and three were SMA type 3. Fifteen patients (83.3%) reported improvement or stability with risdiplam. Motor scales were regularly applied only to pre-symptomatic or type 1 SMA children, who demonstrated score gains like those described in clinical trials. All pre-symptomatic patients had 2 copies of SMN2 and achieved maximum score on Children's Hospital of Philadelphia Infant Test of Neuromuscular Disorders (CHOP INTEND) at 4 months old. CHOP INTEND score of type 1 SMA patient increased from 29 to 44 within 3 months of treatment. Among the 14 patients with type 2 or type 3 SMA: nine reported improvement, two stability and three worsening in motor function; one also reported improvement in cough strength and another in vocal power. Three patients with type 2 SMA underwent spirometry before and after 6 months of treatment: two showed stabilities in forced vital capacity and one showed an increase of 6%. Six patients reported adverse effects: one had diarrhea, one constipation, one abdominal pain, one anemia, one headache and one hair loss. **Conclusion:** Risdiplam was well tolerated, and no patient changed or discontinued treatment. Furthermore, most patients experienced clinical improvement or stabilization. This real-world data from risdiplam showed results like those from clinical trials.

Treatment of NEDAMSS syndrome by deep brain stimulation: report of the first successful treatment case in the world

Sophia Keiko Inuzuka[1], Gabriel de Castro Micheli[1], Marcello Reis da Silva[1], Gustavo da Fontoura Galvao[1], Marlos Melo Martins[1], Hanid Fontes Gomes[1], Roberto Santos Pereira[1], Rita de Cássia Leite Fernandes[1]

[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Sophia Keiko Inuzuka; Email: sophia.keiko@gmail.com.

Case presentation: A 9-y-old girl had a confirmed diagnosis of NEDAMSS ("Neurodevelopmental Disorder with Regression, Abnormal Movements, Loss of Speech, and Seizures"), through genetic testing that revealed the pathogenic variant p.(Val76Cysfs*50). The recently described ultra-rare syndrome is a progressive condition caused by mutations of the intronless gene IRF2BPL ("interferon regulatory factor 2 binding protein like"), mapped to 14q24.3. Its relationship with neural development has not yet been fully established, but its mutation is manifested by neurological regression beginning around 3.5 y of age. There is loss of gait and speech accompanied by epilepsy, dysphagia, dysarthria and dystonia. To date, there is no specific treatment. Our patient was born at 32 w with 1.9 kg. She had continued monitoring due to asthma, low weight and slow cognitive development. At the age of 5, she began to show impairment in gait. The diagnosis of the syndrome was not established at the time. Over the next two years, there was a progressive worsening with mother reports of "involuntary muscle contractions" and pain that led to the use of morphine and cannabidiol in high doses, without adequate relief. At that time, genetic testing diagnosed the mutation responsible for NEDAMSS. Treatment with gabapentin, trihexyphenidyl and clonazepam was unsuccessful and generalized dystonia developed with 80 points on the Fahn-Marsden Scale (BFMDRS), associated with loss of speech and gait. Cranial MRI was unremarkable DBS implantation in the Globus Pallidus Internus (GPi) was done using the Vercise Genus P16 implantable pulse generator. Four weeks after bilateral symmetrical stimulation began, guided by three-dimensional reconstruction and set to 1.5 mA pulse, width of 60 µs and frequency of 130 Hz. After a week of stimulation, significant improvement in clinical picture was observed. She was able to sit up without assistance, cooperated with physiotherapy and medication doses reduced by a third. The BFMDRS score decreased to 24, indicating a positive response to DBS treatment. **Discussion:** The effectiveness of DBS in the treatment of generalized dystonias is widely recognized, evidenced by significant reductions in post-procedure BFMDRS scores. Although the only previous report indicated refractoriness of dystonia in a male patient with NEDAMSS undergoing pallidal DBS, our patient showed a remarkable response to DBS. We remain optimistic that the benefits will sustain and improve with subsequent device schedules. **Final comments:** This case represents a significant milestone by demonstrating, for the first time, a positive response to DBS treatment in the GPi in patients with dystonia.

This suggests a therapeutic potential for patients with NEDAMSS refractory to conventional treatment. Further studies are needed to validate these findings and better understand the mechanisms underlying the response to DBS in this ultra-rare syndrome.

Treatment of neurodegenerative diseases: comparative study of the spatio-temporal distribution between Brazilian regions in the years 2019 to 2023

Luan Nascimento Pereira de Amorim[1], Dangilla Ribeiro dos Santos[1], Bruno Kenji Hosoda Mineshita[1], Fernando Lourenzo Rocha Vianna Oliveira[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Luan Nascimento Pereira de Amorim; Email: luanamorim010@gmail.com.

Background: Neurodegenerative diseases are incurable and debilitating conditions, such as Alzheimer's disease and Parkinson's disease. They result from the progressive degeneration of neurons in structures in various anatomical regions of the nervous system and reflect gradual functional alterations, leading to movement and cognitive deficits. Specialized healthcare and expensive treatments are associated with high treatment costs and a high demand for hospitalizations. **Objective:** To characterize the spatio-temporal distribution of treatment for neurodegenerative diseases in Brazil between 2019 and 2023. **Methods:** This is a quantitative, time-series ecological study based on data from the Hospital Information System of the Unified Health System on the treatment of neurodegenerative diseases in Brazil between January 2019 and December 2023. The following variables were used: number of hospitalizations, cost of treatment, average length of stay, character of care, mortality rate and deaths. **Results:** In the period from 2019 to 2023, 25,446 hospitalizations were recorded with an annual average of 5.08±0.97 procedures, with the most in the Southeast region, with 8,849 hospitalizations (34.77%), followed by the South with 8,643 (33.96%), and then the Northeast with 5,536 (21.75%). With regard to the type of care, 88% (N=22,393) were urgent and 12% (N=3,051) elective. During hospitalization, the average length of stay was 13.1 days between the regions, in which the North and Midwest were the only ones to reduce the average from 2019 to 2023, with the Northeast showing an increase of 40.43%, from 9.4 to 13.2 days. Regarding the cost of treatment, the average value per hospitalization was R$1,408.64, the lowest in 2019 (R$1,190.46) and the highest in 2022 (R$1,500.40), an increase of 26.04% between these years and a drop of 4.34% in 2023. The North region had the highest value among the regions (R$2,552.90). Regarding the evolution of the condition, 2,484 deaths were recorded, denoting 9.76% of all hospitalizations, with an annual average of 496.8±121.7, with the Southeast once again in first place in this regard (N=967/38.93%). The Northeast had the highest mortality rate (18.23%), above the national average of 9.76%. **Conclusion:** There has been an increase in the treatment of neurodegenerative diseases, especially emergencies, in the Southeast and South. Expenditure increased over 5 years, especially in the North, possibly due to the impact of the pandemic on labor and input costs. In the Midwest, the diagnosis of death has improved, reflected in the higher annual variation in the mortality rate. This highlights the importance of effective management and preventive strategies to reduce cases of these pathologies.

Treatment of Parkinson's disease in Brazil's public heath system: is there still room for dopaminergic agonists?

André Borges Ferreira Gomes[1], Raynrich Kevin Assis Lima[2], Isabela Cacau Sousa Santos[2], Carolina Helen Soares de Macêdo[2], Flavia de Paiva Santos Rolim[2], Antonia Rosivalda Teixeira Marinho[1], Vivia Linhares Mesquita[1], Manoel Albano Amora Neto[1], Amanda Araujo Braga[1], Fernanda Martins Maia Carvalho[2]

[1]Hospital Geral de Fortaleza, Fortaleza CE, Brazil. [2]Universidade de Fortaleza, Fortaleza CE, Brazil.

Correspondence: Andre Borges Ferreira Gomes; Email: andrebfg@gmail.com.

Background: Parkinson's disease (PD) is a heterogeneous condition in which no agents have been shown to have unequivocal evidence of disease-modifying effects so far. Treatment for motor symptoms involves pharmacologic approaches (typically with levodopa preparations), particularly in regions where access to other therapies are restricted or not available. **Objective:** To determine the clinical and epidemiological profile of patients with PD in a movement disorder outpatient clinic of a public hospital in the state of Ceará. **Methods:** A descriptive, observational, cross-sectional study, with a quantitative approach, was carried out in 2023. A total of 636 patients were screened and were evaluated using specific questionnaire and review of medical records. In this first stage, patients meeting the Movement Disorder Society criteria for the diagnosis of PD were included. A descriptive statistical analysis of epidemiological, clinical and therapeutic data of the patients was obtained. **Results:** A total of 226 PD patients were included. Most patients were male (62%), presenting a mean age was 65 years. The vast majority (92%) were using some form of levodopa, with a mean dosage of 710mg per day. The second most commonly used medication among patients was pramipexole (61.9%), followed by rasagiline (50.8%), amantadine (41.1%) and entacapone (31.4%). The mean duration of the disease was 13 years and the mean result of the Hoehn and Yahr was 3. Dyskinesia and motor fluctuations were referred by 50.4% and 79.6% of the patients, respectively. When any psychiatric symptom was investigated, it was evidenced in 54.8% of the patients. **Conclusion:** Although levodopa therapy is the most effective and recommended therapy for PD, pramipexol is maintained in most patients in this tertiary public health care clinic in the Northeast of Brazil, in a higher proportion than rasagiline and entacapone. Even though dopaminergic agents are progressively becoming less prescribed worldwide, the limited access to surgical and infusion therapies for advanced PD may be a reason for maintaining such therapies. Despite the side effects described in the literature and restriction of use in some regions of the world, more studies are needed to understand the role of dopamine agonists in the treatment of PD in low-income regions.

Treatment of Parkinson's disease in Brazil from 2019 to 2023: a comparative analysis between regions

Luan Nascimento Pereira de Amorim[1], Fernando Lourenzo Rocha Vianna Oliveira[1], Dangilla Ribeiro dos Santos[1], Bruno Kenji Hosoda Mineshita[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Luan Nascimento Pereira de Amorim; Email: luanamorim010@gmail.com.

Background: Parkinson's disease is a neurodegenerative syndrome characterized by the involvement mainly of the neurons of the substantia nigra pars compacta, which can lead to bradykinesia, resting tremors and rigidity. The WHO estimates that around 1% of the world's population over the age of 65 has the disease, which means that as the population ages, the number of cases is expected to rise. Therefore, continued treatment is essential for the patient's survival, quality of life and well-being. **Objective:** To analyze the distribution of Parkinson's disease treatment in Brazil from 2019 to 2023. **Methods:** This is a descriptive, cross-sectional and quantitative study, based on data from the Hospital Information System tabulated by the Department of Informatics of the Unified Health System (SIH/DATASUS), recorded from 2019 to 2023, in Brazil. Data was collected for ICD-10: Parkinson's Disease. The variables used for analysis were the average value per hospital admission authorization, approved hospitalizations, average length of stay and mortality rate, which, due to the lack of a population estimate for the year 2023, absolute data were used. Microsoft Excel 2021 software was used for the calculations and analysis. **Results:** During the period analyzed from 2019 to 2023, a total of 2640 hospital care authorizations (AIH) were found, with an average of 528 AIH per year, with the Region with the highest number being the Southeast with 1016 (38.4%), followed by the South, 870 (32.9%) the North appears in last place with 168 (6.3%), As for the average value per AIH, The regions with the highest values were the Midwest (R$1017.9) and the Northeast (R$804.61). When analyzing the average length of stay variable, it can be seen that the two regions mentioned have the longest with 9.9 and 10.1 days respectively, while the value per AIH and the average time in the North are among the lowest (R$796.93 and 8 days). With regard to the annual mortality rate, the North (10.12) leads this variable and exceeds the national rate (7.8), while the Midwest (6.04) has the lowest rate. **Conclusion:** It can therefore be seen that the lack of greater investment in the North Region in the treatment of Parkinson's Disease, with fewer AIHs approved, the lower average length of stay and average values per AIH contribute to it having the highest mortality rate in the country, but the opposite is observed in the Midwest Region, which has a lower rate than the country. Therefore, attention to the dichotomies between regions can help to understand the dynamics of negative or positive outcomes and the relationship with the promotion of treatment for the disease.

Treatment of Parkinson's disease with botulinum toxin: a systematic literature review

Flávia Brady de Carvalho Gauziski Figuerêdo[1], Bruna Meschesi Dantas[1], Enzo Pelajo Mosca[1], Fabrícia Elysio Linhares dos Santos[1], Gabrielle Brandão Vasconcelos[1], Giovana Mattos Delgado[1], Maria Carolina Luiz Rodrigues Meireles[1], Pedro Vieira Ahouagi Cunha[1], Reynaldo Yuji Souza Tanaka[1], Natalia Conti Lessa Pereira[1]

[1]Faculdades Souza Marques, Rio de Janeiro RJ, Brazil.

Correspondence: Flávia Brady de Carvalho Gauziski Figueredo; Email: flaviabrady@outlook.com.

Background: Botulinum toxin (BoNT) is considered a promising alternative for treating various symptoms of Parkinson's disease (PD). This neurodegenerative condition, in addition to its characteristic motor symptoms such as tremor, bradykinesia, and rigidity, also includes non-motor symptoms that significantly affect patients' life quality. Among these, sialorrhea often occurs, causing difficulties such as infections, swallowing problems, and social impact. The treatment of sialorrhea with BoNT injections into the salivary glands, often guided by ultrasonography, has been studied and suggested as an effective and safe approach. Additionally, BoNT has shown utility in managing spasticity, which is an increase in muscle tone due to central nervous system impairment, offering a therapeutic alternative for various disabling aspects of PD. **Objective:** Systematic review of methodological practices in the treatment of PD through the use of botulinum toxin in the literature, taking into account recent work and the analysis of changes in the practice of this treatment. **Methods:** Systematic review of articles from 2012 to 2023 selected from Ministério da Saúde, PubMed and Scielo database with the following keywords: "Parkinson's Disease", "botulinum toxin" and "neurodegenerative".

Each database was screened independently by all the authors of this review. **Results:** Five articles were included in the final review, all of which identified BoNT injections as a promising treatment for symptoms linked to PD, including sialorrhea, dystonia and tremor. Two of the articles reinforced the positive effects on the reduction of sialorrhea, mainly in volume of salivation, in PD patients regarding the weekly use of local toxin injections for up to 96 weeks. However, three articles emphasized the need of additional studies to fully elucidate BoNT's role in managing various motor disorders correlated to PD, such as at rest tremors and dystonias. Furthermore, four articles reported adverse effects associated with the BoNT injections, such as muscle weakness, fatigue, dry mouth, neck pain, dysphagia, diarrhea, worsened gait, and dysarthria. These adverse effects were more prevalent in the use of BoNT for motor disorders, which were described as having a more challenging approach in the administration of the drug due to the number of muscles and articulations in arms and legs of the patients that needed to be properly medicated. **Conclusion:** BoNT injections are a promising therapeutic alternative for the symptomatic treatment of PD, due to the subjective and objective improvement in the condition and life quality of these patients, especially those with sialorrhea, despite the possible side effects. However, further studies are still needed to prove the safety and efficacy of this potential therapeutic intervention.

Treatment of perioral dystonia with botulinum toxin in case of Meige's syndrome

Thais Lins Gemir[1], Silvana Sobreira Santos[1], Bárbara Matos Almeida Queiroz[1], Alberico Albanês Oliveira Bernardo[1], Natalia Saraiva Ramos e Cruz[1], Denise Carvalho de Albuquerque[1], Mauricea Novaes Costa Pereira[1]

[1]Rede D'Or.

Correspondence: Thaís Lins Gemir; Email: tatalg_30@hotmail.com.

Case presentation: A 37-year-old woman with a history of recurrent facial paralysis for 2 years and perioral dystonia . She also had difficulty opening her eye several times a day. The patient was hospitalized for investigation and electroneuromyography compatible with bifacial dystonia and blepharospasm component in the left eye. Normal skull MRI. She started epileptic seizures. She didn't show dystonia and can be associated with complex movement of lower fany improvement with diazepam, haloperidol, levodopa or baclofen, and the application of botulinum toxin was indicated with excellent results. **Discussion:** "Meige's syndrome" is a type of cranial dystonia characterized by blepharospasm and oromandibularacial muscles, mouth, jaw, tongue, pharyngeal and cervical muscles. Frequently, blepharospasm is the earliest clinical manifestation, which spreads over a period of time to involve other cranial and extra-cranial muscles. Common characteristics of this syndrome are well known, but their variety is wide. In the majority of the patients Meige's syndrome is primary or idiopathic, where the cause of spasm is not known, however secondary cases can occur following prolonged use of neuroleptics or secondary to underlying brain disorders. Most of the patients are successfully treated with injection of botulinum toxin, however deep brain stimulation has emerged as a good therapeutic option in intractable patients. The result of the intramuscular botulinum toxin A injections was characterized by the patients as "much improved"; correspondingly, dystonia was significantly reduced in visual analog scale scores, on examiner-based assessments, and in recordings of EMG. **Final comments:** Meige's syndrome is a type of cranial dystonia characterized by a combination of blepharospasm and orofacial-cervical dystonia. Most of the cases are primary or idiopathic, however secondary cases also occur usually due to chronic neuroleptics exposure or focal brain lesions. Neurophysiological studies have demonstrated abnormal excitability of the sensorimotor cortex and brainstem inter-neuronal pathways. Incapacitating perioral dystonia in Meige's syndrome may be safely controlled by recurrent EMG-guided botulinum toxin A injections in the orbicularis oris muscle, in combination with general medication

Treatment of trigeminal autonomic cephalalgia: a case report

Gabriella Mara Arcie[1], Eduarda Menin da Silva[2], Valentina Lima Cartaxo da Silva[2], Victor Frandoloso[3]

[1]Faculdade Evangélica Mackenzie do Paraná, Curitiba PR, Brazil.
[2]Universidade Positivo, Curitiba PR, Brazil.
[3]Instituto de Neurologia de Curitiba, Curitiba PR, Brazil.

Correspondence: Eduarda Menin da Silva; Email: eduardamenindasilva@gmail.com.

Case presentation: A 69-year-old male patient was diagnosed with trigeminal autonomic cephalalgia, SUNCT syndrome, in 2021. The patient presented with intense, intermittent pain in the left periorbital region, lasting for seconds, associated with conjunctival hyperemia, ptosis, and ipsilateral tearing. He reported that the pain was triggered by daily activities such as talking, drinking water, and brushing his teeth. His medical history included hypertension and dyslipidemia. He was taking Carbamazepine 200 mg; Pregabalin 75 mg; Micardis; and Rosuvastatin 10 mg. Neurological examination was unremarkable. In 2021, the patient underwent conventional and pulsed radiofrequency procedures of the left sphenopalatine ganglion. **Discussion:** SUNCT syndrome is a trigeminal autonomic cephalalgia characterized by short episodes of unilateral pain associated with autonomic symptoms such as conjunctival hyperemia and tearing. The patient in this case presents with typical symptoms of the syndrome, including intense paroxysmal pain in the left periorbital region and ipsilateral autonomic symptoms. SUNCT is a challenging condition to treat, often requiring a multifaceted approach. Initial pharmacological treatment with anticonvulsants aims to reduce the frequency and intensity of pain attacks, although efficacy may be limited. Conventional radiofrequency (CRF) creates thermal lesions on target nerves, interrupting pain signal transmission and providing long-lasting pain relief. Pulsed radiofrequency (PRF), on the other hand, uses intermittent energy pulses, modulating neural function without causing significant thermal lesions. In this patient's case, the combination of CRF and PRF performed in 2021 on the sphenopalatine ganglion proved to be an appropriate approach. PRF, in particular, has a favorable safety profile and can be repeated if necessary. **Final comments:** Managing the syndrome can be challenging due to the intensity and frequency of pain episodes. Therefore, SUNCT treatment must be personalized, taking into account individual response to treatments and safety profile. Combining pharmacological treatments with radiofrequency interventions, such as CRF and PRF, can offer significant relief, improving patients' quality of life.

Treatment of uncontrolled epileptic seizures in Brazil: an epidemiological analysis over the last 5 years

Matheus Prado dos Santos[1], Rafael Hendrick Freitas de Paula[1], Luan Nascimento Pereira de Amorim[1], Fernando Silva Galvão[2], Daniel Lucas Araujo Ramos[2], Paola Carolina Santos Foinkinos[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.
[2]Universidade Federal do Pará, Belém PA, Brazil.

Correspondence: Matheus Prado dos Santos; Email: imatheusprado@gmail.com.

Background: An epileptic seizure is caused by an abnormal electrical discharge that occurs in the gray matter of the brain, disrupting brain function. Typically, an epileptic seizure results in an altered level of consciousness, abnormal sensations, focal involuntary movements, or motor crises. Understanding the efficacy of treatment and its specific action concerning the epidemiological variations among the regions of Brazil is crucial for formulating strategies to control epileptic seizures in our country. **Objective:** To analyze the epidemiological profile of uncontrolled epileptic seizures in Brazil from 2019 to 2023. **Methods:** This is an ecological, cross-sectional, descriptive, and analytical study with a quantitative approach, conducted by collecting secondary data from the Department of Informatics of the Unified Health System (DATASUS) from 2019 to 2023. The following variables were analyzed: number of hospital admissions, average cost per admission, average length of stay, mortality rate, and the nature of the care provided for approved admissions. **Results:** Between 2019 and 2023, there were 228,181 hospitalizations for uncontrolled epileptic seizures in Brazil, with an approximate annual average of 45,636 hospitalizations. According to region, during this period there were 14,730 hospitalizations in the North (6.4%), 61,208 in the Northeast (26.8%), 94,777 in the Southeast (41.5%), 37,195 in the South (16.3%), and 20,271 in the Midwest (8.8%). As for the number of hospitalizations per year, there were 44,012 in 2019 (19.2%), 40,073 in 2020 (17.5%), 44,156 in 2021 (19.3%), 51,700 in 2022 (22.6%), and 48,240 in 2023 (21.1%). Regarding the cost per hospitalization, the average was 565.75 reais in the North, 784.71 reais in the Northeast, 988.05 reais in the Southeast, 903.4 reais in the South, and 806.6 reais in the Midwest. The mortality rate was 3.02 in the North, 3.24 in the Northeast, 3.52 in the Southeast, 2.09 in the South, and 2.19 in the Midwest. Concerning the type of care, 8,600 hospitalizations were elective (3.7%) and 219,576 were emergencies (96.3%). Additionally, the average length of stay per year was 5.8 days in the period studied: 5.3 days in the North, 6.1 days in the Northeast, 5.9 days in the Southeast, 5.3 days in the South, and 5.1 days in the Midwest. **Conclusion:** The Southeast region had the highest number of hospitalizations, the highest average cost per hospitalization, the highest mortality rate, and the highest absolute number of deaths in the period studied. Therefore, there is a need to improve health services in the Southeast of Brazil, which, despite having the highest cost of hospitalization, has high mortality rates. Finally, there is a need for further studies to understand the factors influencing the current scenario in the Southeast and Northeast regions of the country.

https://doi.org/10.5327/CBN241697

Trends in door-to-needle and door-to-puncture times in ischemic stroke: a quality improvement study

Caio Pinheiro Santos Souza[1], Murilo Santos de Souza[2], Luiz Eduardo Fonteles Ritt[2], Eduardo Sahade Darzé[2], Alexandre Drayton[2], Gabriel Xavier[2], Humberto Castro-Lima[2], Matheus do Rosário[2], Barbara Costa[2]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.
[2]Instituto D'or de Pesquisa e Ensino, Hospital Cardio Pulmonar, Salvador BA, Brazil.

Correspondence: Caio Pinheiro Santos Souza; Email: caiopsouza21.2@bahiana.edu.br.

Background: Stroke will affect one in four adults over their lifetime, causing the destruction of billions of synapses every minute. Furthermore, delays from the onset

of symptoms to reperfusion therapy progressively reduce its effectiveness. The protocol implemented in our institution stipulated: 1) Early identification of patients with signs of stroke and direct referral to CT by nursing staff; 2) Early assessment by a neurologist, with an expected interval of <20 minutes between contact and the arrival of the on-call neurologist; 3) Stroke training and simulations; 4) Real-time feedback to the emergency room team. **Objective:** Therefore, our single-center observational study aimed to evaluate the effect of a treatment protocol designed to reduce delays in treatment. **Methods:** This retrospective cohort study included all patients eligible for Chemical Thrombolysis or Mechanical Thrombectomy from 2011 to 2023. The impacts of the protocol were evaluated by calculating the absolute frequencies and the annual median of door-to-needle time (DNT) and door-to-puncture time (DPT), with interquartile range. Given that the data did not follow a normal distribution, the Kruskal-Wallis test was used to analyze differences between times. Temporal trends were assessed using the Mann-Kendall test. **Results:** Between January 2011 and December 2023, 1014 patients were admitted under the stroke protocol. The median age was 74 years (63-83) and the NIHSS was 3 (1-9). Reperfusion therapy was offered to 174 patients; in this group, the median age was 74 years (61-84), and the NIHSS was 8.5 (4-18). We observed a significant increase in the thrombolysis rate from 7.9% to 15% (P<0.001) and in the thrombectomy rate from 1.1% to 7.6% (P<0.001) when comparing the periods 2012-2014 and 2015-2023. The DNT during the studied years showed a statistically significant difference (P=0.008), with a reduction in this time from 89 minutes (84-116) in 2012 to 31 minutes (18-51) in 2015, and later to 28 minutes (17-43) in 2019. When analyzing the pre-pandemic period, a moderate to strong statistically significant decreasing temporal trend was identified in median values over time (tau = -0.64, P =0.02). Despite the trend disruption due to the COVID-19 pandemic, the DNT did not exceed 45 minutes during the period, ultimately reaching 34 minutes (18-48) in 2023. There was no difference in mortality (P=0.89) or the rate of hemorrhagic transformation (P=0.33) between the years in patients undergoing reperfusion therapy. **Conclusion:** During the protocol implementation period, which included validated strategies, there was a considerable reduction in treatment delays and a significant downward trend in times. An increase in reperfusion rates was also observed, without an increase in mortality or complications. Thus, the study demonstrates that the implementation of robust protocols in healthcare institutions can positively impact stroke care.

[5]Universidade Federal da Paraíba, Departamento de Medicina Interna, Serviço de Neurologia, João Pessoa PB, Brazil.

Correspondence: Tiago César Costa da Silva; Email: tiagocesarcs@hotmail.com.

Case presentation: A 34-year-old male patient presented with paroxysmal shock-like pain in the right V2 and V3 branches, persisting for approximately 12 years. Neuroimaging revealed basilar invagination and neurovascular conflict of the trigeminal nerve. The patient was refractory to treatments with duloxetine (120 mg/day), carbamazepine (1,200 mg/day), valproate (1,500 mg/day), lamotrigine (200 mg/day), and cannabidiol. Surgical intervention was deemed inappropriate. Physical examination revealed a short neck, allodynia, hyperalgesia in the right V2 and V3 branches, and signs of poor self-care. Treatment was initiated with type A botulinum toxin (Botox®) (BoNT/A), 30 units distributed subcutaneously in the V2 and V3 territories, with 2 cm between application points. An 80% improvement in pain (visual scale from 10/10 to 2/10) and frequency (from constant to few attacks per day) was observed after the first dose. Quality of life increased from 0 to 10 (assessed by the Quality Of Life Scale from the American Chronic Pain Association), sleep and mood improved (according to the Beck Depression Inventory from 36 to 2), remitting his suicidal ideation and resumption of his employment. Results were observed from the 3rd day, without adverse effects, and remained consistent over successive applications. **Discussion:** Resistance or adverse effects to conventional therapies often necessitate alternatives when treating patients with trigeminal neuralgia (TN). In this case, optimized pharmacotherapy did not control the pain, highlighting the refractory nature of some TN cases. BoNT/A demonstrated excellent efficacy, substantially alleviating pain and improving the patient's well-being, quality of life, and mood, emphasizing the importance of non-conventional approaches when standard treatments fail. Recent studies indicate that BoNT/A reduces pain in more than 50% of patients with TN at 1- and 3-months follow-up. Surgical interventions can lead to severe and intractable complications. The mechanisms of pain modulation by BoNT/A include inhibition of neurotransmitters (substance P, glutamate, calcitonin gene-related peptide), interference with synaptic vesicle fusion, modulation of neurons in the dorsal root ganglia and spinal cord, and indirect effects on the central nervous system. Interaction with glial cells suggests an additional analgesic mechanism. **Final comments:** This case underscores the efficacy of BoNT/A in managing complex and refractory pain syndromes associated with trigeminal neuralgia secondary to structural anomalies, offering a promising therapeutic avenue for patients resistant to conventional treatments.

Case presentation: A 2 year old female patient, born at full term via vaginal delivery (APGAR 9/10). During the gestation, the mother, besides taking fluoxetine and diazepam, presented with urinary tract infection during the first trimester and hypertension during the third. At 1 month of age, the patient suffered a traumatic brain injury (TBI), undergoing a cranial tomography (CCT) that revealed an occipital aligned fracture on the left and subgaleal hematoma. She had a positive clinical recovery. At 5 months, it was detected in a new CCT corporal assimetry with hemihypertrophy on the right side and cervical inclination on the left. At 10 months, besides having a hypoplasic left kidney detected by ultrasound, the patient was diagnosed with thyroglossal duct cyst and Waldeyer's ring hypertrophy after b3ing submitted to a craniocervical magnetic ressonance. The Karyotype revealed trysomy on gene 14 with low grade mosaicism (2% of cells). At 16 months, she exhibited hypocromic linear macular lesions throughout the whole body, apendicular hypotonia, difficulty with chewing, shuddering attacks, aggressive behavior and motor stereotypes. At 22 months, she showed dysfunctional play, hearing hypersensitivity and difficulty to communicate. At 2 years, she began to walk without support, while continuing with significant delay in speech, hyperfixations, food selectivity, agitated sleep, difficulty to comprehend simple commands and to sustain attention, irritated behavior. Currently, the patient persists with developmental delay (DD), but has been improving non-verbal communication, attention and social interactions. **Discussion:** This case describes manifestations related to Trisomy 14 in mosaic, a rare chromossomic disorder caused by anomalous cell division on a certain amount of cells, being incompatible with life in most cases. This genetic condition predisposed the presence of body assimetry, genitourinary abnormalities, pigmented skin lesions, intelectual disability, hypotonia and DD, symptoms that were detected on the presented patient. It is also relevant that the DD secondary to this condition is also supported by the TBI suffered by the patient and the gestational complications, that may have altered intrauterine environment and, as a result, this child's neurodevelopment. **Final comments:** In front of the complications that carriers of this Trisomy face, it is necessary for this chromossomal disorder to be more studied by the scientific community and detected early, once this alteration substancially affects the neurodevelopment. Furthermore, it is important for the individuals that carry this Trisomy to have access to a multidisciplinary care, since it is a genetic condition that affects multiple systems, with the goal of improving the patient's and their family's quality of life.

TTN gene and proximal myopathy: a case report

Ivo Gabriel Ribeiro Carvalho[1], Guilherme Marques Nunes Mamede[1], Fabio Victor Vieira Rocha[1], Renann Nunes Pirola[1], Daniel José Siqueira Tosi[1]

[1]Universidade Federal do Espírito Santo, Vitória ES, Brazil.

Correspondence: Ivo Gabriel Ribeiro Carvalho; Email: ivo.carvalho@edu.ufes.br.

Case presentation: A 44-year-old female with tremors during intense exercise and difficulty walking since childhood. She has been using a wheelchair since the age of 40 following hospitalization for dengue fever. The patient reports inability to fully extend her arms, but without distal motor deficits. Neurological examination revealed symmetric proximal tetraparesis with absent reflexes, elbow contractures limiting extension, preserved facial mimicry, and speech. Electroneuromyography showed neurophysiological findings suggestive of chronic myopathy affecting all four limbs. Muscle biopsy displayed dystrophic pattern and nuclear centralization. Genetic testing conducted in 2023 revealed a homozygous mutation in the titin gene, indicating suspicion of TTN-related myopathy. **Discussion:** Titin, encoded by the TTN gene, is a giant sarcomeric protein that maintains myofibrillar structure, positioning filaments within the sarcomere and providing elasticity and stability during muscle contraction. Mutations in the TTN gene can cause cardiac and muscular disorders, including limb-girdle muscular dystrophy type 2J (LGMD2J). This autosomal recessive disorder typically begins in adulthood or childhood with progressive weakness and proximal muscle atrophy,

predominantly affecting the shoulder and pelvic girdles. Cardiac involvement is common and can significantly impact life expectancy. Physical examination in this case revealed proximal tetraparesis, areflexia, distal muscle atrophy in the lower limbs, and preservation of the extensor digitorum brevis (EDB). In titinopathy, patients may exhibit atrophy of the anterior compartment of the leg (tibialis anterior) while preserving EDB function, distinguishing it from neuropathic patterns. Genetic testing identified a homozygous mutation in the TTN gene (2q31.2), resulting in truncated titin isoforms in skeletal and cardiac muscles. Electroneuromyography demonstrated a myopathic pattern with loss of functional fibers in all limbs. Muscle biopsy findings showed dystrophic pattern with nuclear centralization. Regular cardiac monitoring is crucial to prevent morbidity and sudden death due to the high frequency of cardiomyopathy and arrhythmias associated with TTN mutations. **Final comments:** Unlike neuropathies, titinopathy is characterized by distal muscle hypotrophy with preserved EDB function, underscoring the importance of evaluating the pattern of distal muscle involvement. The disease exhibits a wide age range and phenotypic diversity, posing diagnostic challenges. This case highlights the importance of detailed clinical evaluation, muscle biopsy, and genetic analysis for accurate diagnosis.

Tumefactive demyelination: atypical presentation of multiple sclerosis?

Bruno Paulo Teles Chaves[1], Vanessa Cristina Fragoso Cassiano Alencar[1], Marcilio Oliveira Filho[1], Nathalia Saraiva Ramos e Cruz[1], Mauricéa Novaes Costa Pereira[1], Lidiane Alves de Macedo Souza[1], Maria Iris Moraes Machado[1], Maria Lucia Brito Ferreira[1]

[1]Hospital da Restauração, Recife PE, Brazil.

Correspondence: Bruno Paulo Teles Chaves; Email: brunopaulo.c@gmail.com.

Background: Atypical demyelinations exhibit pathological characteristics similar to those observed in multiple sclerosis (MS), although their clinical manifestations and radiological patterns differ from those of classic MS. The relationship between MS and its demyelination variants is still unclear, making it difficult to identify patients at risk of developing MS. Tumefactive Demyelination associated with MS is a rare and understudied variant due to the lack of large patient cohorts. The estimated incidence is 1-2 per 1000 MS cases, although other authors suggest a prevalence of 1.4 to 8%. The most common clinical manifestations include hemiparesis or hemiplegia, and headache, aphasia, cognitive, visual, and sensory disturbances, as well as epilepsy, may also be identified. Several important aspects stand out in this aggressive form of demyelination, characterized by tumor-like lesions that are equal to or greater than 2 cm in size. These lesions can occur as single or multiple, and a biopsy may be indicated if the imaging is inconclusive. These lesions may be present in patients with diagnosed MS in 30% of cases or may present as the first episode. **Objective:** To analyze the cases attended with tumefactive demyelination, following up on these cases and subsequently defining the diagnosis of MS. **Methods:** Patients included in the database of the referral service for MS patients care between 1997 and 2019 at the Hospital da Restauração (Recife, Pernambuco) were analyzed. The inclusion criterion was the presence of clinical and imaging findings compatible with tumefactive lesions and the possibility of a final MS diagnosis. **Results:** Seven cases were analyzed, including six female and one male patient, with ages ranging from 11 to 42 years. The predominant signs and symptoms were headache, low visual acuity, motor deficit, seizures, and altered sensorium. MRI revealed multiple pseudotumoral lesions. Three patients underwent biopsy due to suspected primary brain tumor. All patients received pulse therapy with methylprednisolone (MTP), one underwent plasmapheresis (PLEX), three used beta-interferon, one used glatiramer acetate (GA), and two used natalizumab as a second option. The EDSS ranged from 0 to 4 at the onset and from 0 to 7 at the last evaluation, with one death recorded. **Conclusion:** Variants of MS have demonstrated tumefactive lesions and distinct immunological signatures. Tumefactive demyelinating lesions (TDLs) can also occur in patients with other atypical demyelinating syndromes, such as ADEM, NMOSD seropositive for AQ4 IgG or seronegative, as well as MOGAD and other neuroinflammatory diseases (neurosarcoidosis and Behçet's disease), posing a constant challenge, especially in these cases.

Tumor severity of diffuse gliomas and immunohistochemical markers (S100, GFAP, ATRX, IDH1, synaptophysin, P53): a retrospective study from a tertiary center

Guilherme Nobre Nogueira[1], Pedro Yago Lima de Mesquita[1], Osvaldo Mariano Viana Neto[1], Cauan Miranda Mateus[1], Iasmin Maria Rodrigues Saldanha[1], Vivian Helen Alves Bezerra[1], Lourdes Maria Silva de Assis[1], Maria Jânia Teixeira[1], Gunter Gerson[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Guilherme Nobre Nogueira; Email: guiermenobre@gmail.com.

Background: The prognosis of gliomas is directly related to the tumor grade. The molecular profile allows specific characterization of gliomas, enabling the customization of therapeutic plans to improve prognosis and treatment efficacy. In this context, immunohistochemical analysis stands out as a good alternative for the early identification of tumor severity and consequently the management to improve patient prognosis. **Objective:** To associate the main immunohistochemical alterations with the tumor grade in patients undergoing glioma resection at a tertiary referral hospital. **Methods:** A descriptive, cross-sectional, and retrospective study was conducted with patients who underwent brain tumor resection at a tertiary referral hospital in the state of Ceará between 2013 and 2023. A total of 158 patients were analyzed, with the appropriate authorization from the ethics committee. **Results:** Regarding the characterization of the included patients, the mean age was 48 years, ranging from 17 to 85 years, with a median age of 50 years. Of these patients, 56% were male, and 44% were female. Concerning the diagnosis of brain tumor severity, no patients with grade 1 gliomas were identified. Seventy-four patients were diagnosed with grade 2 gliomas, of which, in terms of immunohistochemistry, 23 (31%) were positive for synaptophysin, 37 (50%) showed P53 alteration, 47 (63%) had IDH1 mutation, 38 (51%) had preserved ATRX, 50 (65%) were positive for GFAP, and 32 (43%) for S100. Eighteen patients were diagnosed with grade 3 gliomas, with 5 (28%) positive for synaptophysin, 9 (50%) showing P53 alteration, 12 (67%) had IDH1 mutation, 8 (44%) had preserved ATRX, 14 (78%) were positive for GFAP, and 6 (33%) for S100. Sixty-six patients were diagnosed with grade 4 gliomas, with 11 (17%) positive for synaptophysin, 40 (60%) showing P53 alteration, 46 (70%) had IDH1 mutation, 36 (54%) had preserved ATRX, 54 (81%) were positive for GFAP, and 39 (59%) for S100. **Conclusion:** The high positivity of GFAP in all three types of gliomas suggests it could be considered a diagnostic marker for brain tumors. Prognostically, ATRX was primarily identified in low-grade gliomas, while S100 was more present in glioblastomas. The IDH1 mutation is associated with worse prognoses in patients with gliomas, as observed in this study, consistent with the literature. Thus, the importance of immunohistochemical analysis for the diagnosis and prognosis of brain tumors is evident, highlighting the need for further studies to demonstrate the correlation between severity and altered markers.

Two-year longitudinal evaluation of brain structural changes and ataxia severity in RFC1-related disorder

Camila Caroso Lobo[1], Thiago Junqueira Ribeiro Rezende[1], Gustavo Moreira Jarola[1], Fabrício Diniz Lima[1], Paula Camila Alves de Assis Pereira Matos[2], Alberto Rolim Muro Martinez[1], José Luiz Pedroso[2], Orlando Graziani Povoas Barsottini[2], Wilson Marques Jr[3], Marcondes Cavalcante França Jr[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.
[2]Universidade Federal de São Paulo, São Paulo SP, Brazil.
[3]Universidade de São Paulo, Faculdade de Medicina de Ribeirão Preto, Ribeirão Preto SP, Brazil.

Correspondence: Camila Caroso Lobo; Email: camilaloboc@gmail.com.

Background: The structural characteristics of the brain in RFC1-related ataxia are well-documented; however, the progression of brain damage over time remains poorly understood. **Objective:** To delineate the evolutionary patterns of brain changes in RFC1-related ataxia through longitudinal neuroimaging assessments and to compare these findings with clinical evaluations of ataxia severity using the SARA scale. **Methods:** A cohort comprising ten patients diagnosed with RFC1-related ataxia and ten age- and sex-matched healthy controls underwent 3T MRI scans at two-year intervals. Gray matter volumes were analyzed using FreeSurfer, cerebellar structures were assessed with CerebNet, white matter integrity was evaluated via DTI multiatlas analysis, and spinal cord morphology was examined using the Spinal Cord Toolbox. Longitudinal changes between the groups were investigated using covariance analysis, with effect sizes (ES) calculated for significant findings. **Results:** Compared to healthy controls, patients with RFC1-related ataxia exhibited more pronounced progressive atrophy in the brainstem (ES=2.18), left hippocampus (ES=1.21), and right thalamus (ES=1.24). Additionally, there was a reduction in cross-sectional area at C1 of the spinal cord (ES=1.09) and an increase in axial diffusivity of the middle cerebellar peduncle (ES=1.44) over the study period. Concurrently, mean SARA scores increased from 15.2±5.1 to 19.4±7.9 (ES=0.62). **Conclusion:** Quantitative neuroimaging methods effectively capture the progressive nature of RFC1-related ataxia, demonstrating greater sensitivity compared to clinical evaluation based on SARA scores. These findings underscore the utility of longitudinal MRI assessments in understanding the evolving brain changes associated with RFC1-related ataxia and their potential as a sensitive biomarker.

Ultra-high-field brain imaging at 7 Tesla magnetic resonance in LAMA2-RD patients

Clara Gontijo Camelo[1], Maria da Graça Morais Martin[1], Khallil Taverna Chaim[1], Leandro Tavares Lucato[1], Suely Fazio Ferraciolli[1], Claudia da Costa Leite[1], Umbertina Conti Reed[1], Paulo Ribeiro Nóbrega[2], Edmar Zanoteli[1]

[1]Universidade de São Paulo, São Paulo SP, Brazil.
[2]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Clara Gontijo Camelo; Email: claragc@gmail.com.

Background: LAMA2-related muscular dystrophy (LAMA2-RD) is an autosomal recessive disorder that causes muscle weakness in a broad spectrum of phenotypic severity. The disease affects muscle strength and causes brain abnormalities, such as high signal intensity in the white matter on T2 and FLAIR, and in rarer cases, cortical malformations. The correlation between motor severity and CNS abnormalities is not well understood, and few studies have detailed the brain MRI alterations in these patients. Ultra-high-field MRI [≥7 Tesla (7T)] has improved the capability to depict and characterize brain structures efficiently, with better signal-to-noise ratio and spatial resolution. **Objective:** To compare the brain imaging findings at 7T magnetic resonance with the images obtained with 3 Tesla magnetic resonance techniques in patients with LAMA2-RD. **Methods:** Patients with LAMA2-RD who had previously 3T brain MRI were selected, and were submitted to a 7T brain MRI protocol. The patients included both the congenital muscular dystrophy (CMD) form of the disease (unable to walk) and the limb-girdle muscular dystrophy form (LGMD). Patients under 16 years old who could not tolerate the exam without anesthesia were excluded, as well as those who had previously undergone spine surgery. **Results:** Four patients were submitted to the 7T brain MRI by now, aged between 26 and 40 years. Two patients had the phenotype of CMD, and two had LGMD. Three patients had epilepsy. The images revealed generalized white matter alterations with both field strengths, although the 7T better depicted a tigroid pattern, that could represent some perivascular preserved fibers. The subcortical area was preserved in certain regions among patients with the LGMD phenotype. All three patients with epilepsy showed cortical malformations, specifically polymicrogyria / cobblestone lissencephaly. These malformations were predominantly located in the occipital region and were not widespread across the cortex. Although the 7T MRI provided better resolution, it did not reveal additional cortical malformations compared to the 3T MRI. Also, due to 7T technical limitations, the occipital cortex was of limited identification, mainly in patient with accentuated kyphosis. **Conclusion:** Both patients with CMD and LGMD related to the LAMA2 gene exhibit CNS abnormalities. The 7T MRI provides better resolution, but did not identify more cortical malformations than previously identified with 3T.

Ultrasonographic characteristics in prevalent myopathies: a systematic review

Lucas Frigo[1], Matheus Henrique Brustolim Marcucci[1], Ana Luiza Souza Santos[1], Leslie Mateus de Sousa Nunes[1], Leonardo Elias Araujo[1], Letícia da Costa Rios[1], Letícia Gadelha Caldas[1], Júlia Viana de Castro[1], Leonardo José Rodrigues de Araújo Melo[1], David Augusto Batista Sá Araújo[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Lucas Frigo; Email: lucas.frigo2@gmail.com.

Background: Ultrasonography has emerged as a valuable tool in the assessment of prevalent myopathies, offering real-time, detailed visualization of skeletal muscle tissue. Advanced ultrasound modalities including shear wave elastography have expanded diagnostic capabilities, providing insights into muscle morphology, edema, atrophy, and lipid infiltration. **Objective:** To summarize and analyze the ultrasonographic characteristics of prevalent myopathies, aiming to enhance diagnostic precision and therapeutic strategies. **Methods:** A systematic search of literature was conducted on PubMed, following PRISMA protocol, using DeCS/MeSH descriptors ("idiopathic inflammatory myopathies" OR "inflammatory myopathies" OR "myositis") AND ("muscle ultrasound" OR "neuromuscular ultrasound" OR "ultrasound").The inclusion criteria were cohorts or clinical trials published in English from 2019-2024. Reviews, case reports or animal studies were excluded. Initially, 140 articles were found, of which 9 studies met the inclusion criteria. **Results:** The systematic review of ultrasonographic findings in prevalent myopathies highlighted significant insights. In healthy controls aged 50 years and older, shear wave speed (SWS) in the deltoid muscle during passive stretch was notably lower compared to younger controls (2.80 vs. 2.47m/s). Echogenicity and power Doppler values varied widely across muscles examined, ranging from 1 - 3 and 0 - 4, respectively. Age, sex, and BMI significantly influenced muscle metrics. Age inversely correlated with SWS in the deltoid (Rs:-0.40) and positively with echogenicity in the flexor digitorum profundus (Rs:0.38). Higher BMI was associated with lower SWS (Rs:-0.45, p=0.018) and higher echogenicity (Rs:0.69) in the deltoid. Comparative analyses between healthy controls and patients with inclusion body myositis (IBM) and necrotising autoimmune myopathy (NAM) revealed specific differences. In IBM, the flexor digitorum profundus exhibited increased echogenicity and reduced muscle thickness compared to controls and patients with polymyositis/dermatomyositis. These findings underscore ultrasound's utility in differentiating myopathies, providing valuable quantitative data for clinical assessment and monitoring of muscle pathologies. **Conclusion:** This review examined ultrasonographic characteristics in prevalent myopathies, revealing significant insights into diagnostic and monitoring capabilities. The findings underscored age, sex, and BMI as critical factors influencing muscle metrics such as shear wave speed and echogenicity. Moreover, comparisons between healthy controls and patients with specific myopathies like inclusion body myositis highlighted distinctive ultrasound markers such as increased echogenicity and reduced muscle thickness. These quantitative findings enhance our understanding of muscle pathology and emphasize ultrasound's potential as a non-invasive tool for precise diagnosis and therapeutic monitoring in clinical practice.

https://doi.org/10.5327/CBN241706

Ultrasound in the diagnosis of hereditary sensory neuronopathies: report of two cases

Vitor Santos de Souza[1], Rodrigo Santiago Gomez[1]

[1]Universidade Federal de Minas Gerais, Hospital das Clínicas, Belo Horizonte MG, Brazil.

Correspondence: Vitor Santos de Souza; Email: vitorsantosdesouza@outlook.com.

Case presentation: Patient 1, 67 years old, parents were cousins. Progressive course started 10 years ago, with main complaints of imbalance and chronic dry cough. Clinical examination revealed bilateral and symmetrical foot paresis, mild paresis of thigh adductors, myotatic areflexia in upper and lower limbs. Bilateral extensor plantar cutaneous reflex. Reduced superficial and deep sensation up to the iliac spine. Ocular motricity showed difficulty with pursuit eye movements and absence of vestibulo-ocular reflex. Mild gait ataxia. Patient 2, 65 years old, parents were cousins. Progressive course started 4 years ago, with main complaint of gait disturbance and chronic dry cough. Clinical examination showed reduced superficial and deep sensation in lower limbs, myopathic areflexia, absence of oculocephalic reflex, and Romberg test with non-specific side preference. Ultrasonographic evaluation of both patients revealed significant reduction in cross-sectional area of various peripheral nerves in upper and lower limbs. Genetic testing for cerebellar ataxia, neuropathy, and vestibular areflexia syndrome (CANVAS) was requested, showing biallelic expansion compatible with the diagnosis. **Discussion:** CANVAS affects middle-aged individuals. Diagnosis is made by identifying biallelic expansions of AAGGG in the replication factor C complex 1 (RFC1). Despite primarily sensory features, the phenotype of RFC1-related disease is expanding, including reports of motor neuron involvement, leading to a broad and sometimes challenging differential diagnosis. In the two cases described above, the presence of reduced cross-sectional area of peripheral nerves was crucial in suspecting CANVAS. Most sensory neuronopathies exhibit this reduction. Recently, ultrasound has gained prominence for its utility in recognizing and screening tests for predominantly sensory neuronopathies or late-onset ataxias of unknown cause. This is feasible due to ultrasound characteristics that can predict a hereditary or acquired origin. Recent studies show that acquired sensory neuronopathies have normal or enlarged nerves, whereas hereditary ones have abnormally small nerves. In the aforementioned case reports, besides clinical phenomenology, finding reduced average nerve diameters was fundamental for diagnostic reasoning and for recommending intronic biallelic expansion study in the RFC1 gene. **Final comments:** The use of ultrasound played a pivotal role in diagnosing the above-mentioned cases, due to its ability to aid in the identification of hereditary sensory neuronopathies. This underscores the advantages of using this tool in neuromuscular studies due to its practicality, low cost, detailed imaging capabilities, and minimal potential for harm.

Underreporting of meningitis cases in the Northeast region of Brazil during the COVID-19 pandemic: an epidemiological overview

Guilherme Carvalho de Souza[1], Analuiza Silva Tenório Luna Sarmento[1], Alícia Eduarda Rios Soares[1], André de Oliveira Paiva[1], Antonia Cardoso Silva[1], Cecilia Maria Monteiro Barbosa[1], Gabriela Barbosa de Sá Rocha[1], João Victor Vasconcelos Tavares Maximiliano[1], Julio César Soares Barros[1], Larissa da Silva Almeida[1]

[1]Universidade Federal de Alagoas, Faculdade de Medicina, Maceió AL, Brazil.

Correspondence: Guilherme Carvalho de Souza; Email: guicadesouza@gmail.com.

Background: Meningitis is the inflammatory process of the membranes surrounding the brain and spinal cord, which can be of infectious or non-infectious origin. Due to its clinical and epidemiological significance, it is a compulsory notification condition. However, the onset of the COVID-19 pandemic in 2020 significantly impacted healthcare systems, affecting the epidemiological scenario and the reporting of conditions such as meningitis. **Objective:** To evaluate the underreporting of meningitis cases in the Northeast region of Brazil compared to the rest of the country during the COVID-19 pandemic. **Methods:** This is a quantitative, cross-sectional analytical study of meningitis notifications in the Northeast region of Brazil compared to the rest of the country from 2015 to 2021, using data from the Notifiable Diseases Information System (SINAN/DATASUS) for the variables of year of diagnosis and region of notification. **Results:** Between 2020 and 2021, the average number of meningitis notifications in the Northeast region of the country was 1139.5 cases, compared to an average of 2352.6 cases between 2015 and 2019, representing a decline of approximately 51.5%. This pattern was also observed in the national epidemiological analysis, which showed a reduction of approximately 56.9% in notifications during the same period. **Conclusion:** During the pandemic period of 2020 and 2021, there was a significant decrease in meningitis notifications both in the Northeast region of Brazil and nationally, which may be correlated with the coronavirus pandemic. Possible contributing factors to this epidemiological scenario include reduced access to healthcare services for individuals with meningitis, as well as difficulties in patient monitoring and updating health surveillance information due to the overload associated with the high rate of COVID-19 hospitalizations. Additionally, the adoption of social distancing, self protection and hygiene measures during this period may have contributed to the decline in the incidence of infectious meningitis.

Understanding the impact of neuropsychiatric symptoms of dementia on caregiver burden: a systematic review

Ana Maria Porto Cortines Laxe Martins da Silva[1], Leonardo Sena de Souza[1], Luisa Lara Calazans[1], Marianna Leite[1], Carolina Braga Moura[1], Raquel Quimas Molina da Costa[1]

[1]Universidade Federal Fluminense, Niterói RJ, Brazil.

Correspondence: Ana Maria Porto Cortines Laxe Martins da Silva; Email: analaxe@id.uff.br.

Background: Behavioral and Psychological Symptoms in Dementia (BSPD) can significantly contribute to caregiver burden, leading to physical, psychological, social, and financial strains on caregivers. The impact is particularly observed on family members, often women, who experience higher burden levels than men. These symptoms can also contribute to institutionalization, escalating care costs. Recognizing and managing these symptoms is crucial for enhancing the patient's and caregiver's quality of life. **Objective:** To explore the relationship between BPSD in people living with dementia, as assessed by the Neuropsychiatric Inventory (NPI), and caregiver burden scales. **Methods:** A systematic review was conducted, searching PubMed, LILACS, Scielo and Embase databases for articles in English, Spanish, and Portuguese without time restrictions. Articles focusing on dementia and utilizing the NPI for symptom measurement were included. Screening and data extraction were performed independently by three reviewers, with disagreements resolved through discussion. **Results:** Of the 368 articles identified, 16 met the inclusion criteria. Various types of dementia were included. Cognitive decline was assessed mainly by the Mini Mental State Examination, Barthel Index, and Global Deterioration Scale, while the caregiver's burden was measured by Zarit Burden Interview(ZBI) and Neuropsychiatric Inventory caregiver Distress (NPI-D) Neuropsychiatric symptoms such as Apathy/indifference and Agitation/aggression were significantly associated with caregiver burden, being the former the most prevalent. **Conclusion:** Specific BPSD are linked to caregiver burden, urging early identification and management to prevent caregiver overload and preserve the quality of life for both patients and caregivers. Efforts should be made to address these symptoms effectively to improve the overall care experience for all involved parties.

https://doi.org/10.5327/CBN241709

Unexpected presentation: case report of inflammatory cerebral amyloid angiopathy in a young adult with Down syndrome

Mateus Gustavo Favaro[1], Thales Pardini Fagundes[1], Gustavo Maximiano Alves[1], Joyce Yuri Silvestre Yamamoto[1], Jorge Alberto Martins Pentiado Junior[1]

[1]Hospital São Lucas, Ribeirão Preto SP, Brazil.

Correspondence: Mateus Gustavo Favaro; Email: mateusgustavofavaro@gmail.com.

Case presentation: A 32-year-old female patient with Down syndrome was admitted to our hospital with a multisystemic disease, characterized by fever, vomiting, diarrhea, and dyspnea. Basic laboratory tests presented elevated serum inflammatory markers (C-reactive protein of 30mg/L and a erythrocyte sedimentation rate of 135 mm/h), and thoracic imaging revealed pleural and pericardial effusions. After one week of hospital admission, the patient developed neurological symptoms, characterized by dysarthria, right hemiparesis, and an altered mental status with seizures. On the brain MRI it was found an asymmetric leptomeningitis leptomeningitis, predominantly in the left hemisphere, along with T2/FLAIR cortical/subcortical hyperintensities on the precentral gyrus, and multiple cortical microbleeds on SWI sequence. The cerebrospinal fluid (CSF) analysis showed high inflammatory activity (CSF protein of 363mg/dL and 365 white blood cells/mm^3, with a lymphocytes predominance). No microorganismswere isolated on CSF cultures. The combination of these findings leads to the diagnosis of Inflammatory Cerebral Amyloid Angiopathy (CAA-RI). Initially, the patient received an intravenous pulse of methylprednisolone (1g/day for 5 days) followed by oral prednisone for maintenance, which resulted in partial improvement. However, a few months later, she was readmitted with exertional dyspnea and moderate pericardial effusion. A follow-up brain MRI showed improvement but persistent inflammation. CSF analysis and the absence of clinical response suggested refractoriness to corticosteroids. At this point additional immunosuppression was required. Rituximab was chosen for its efficacy and favorable safety profile. **Discussion:** The patient exhibited a spectrum of symptoms including cognitive decline, seizures, and focal neurological deficits, consistent with CAA-RI. The pathophysiology of CAA involves beta-amyloid deposition in leptomeningeal arteries, sharing mechanisms with Alzheimer's disease. In Down syndrome, triplication of chromosome 21, which includes the APP gene, leads to augmented APP expression and beta-amyloid accumulation, contributing to early Alzheimer's neuropathology. This may explain the presentation at such a young age. Initial treatment with methylprednisolone pulse therapy followed by prednisone maintenance showed partial improvement, but relapse necessitated additional immunosuppression.. Rituximab was chosen for its efficacy and lower risk of adverse effects. **Final comments:** Immunomodulatory treatment can significantly improve clinical and radiographic outcomes in CAA-RI patients, reducing recurrence probability. However, studies on CAA-RI lack robust data due to limited cases and lack of large-scale randomized trials. More rigorous research is needed to elucidate underlying mechanisms, optimize treatment strategies, and improve clinical outcomes.

https://doi.org/10.5327/CBN241710

Unilateral protruding ear as a novel clue for Fragile-X-associated tremor ataxia (FXTAS)

Luis Eduardo Borges de Macedo Zubko[1], Renata Cristine Alves[1], Francisco Manoel Branco Germiniani[1], Hélio Afonso Ghizoni Teive[1]

[1]Universidade Federal do Paraná, Complexo Hospital de Clínicas, Curitiba PR, Brazil.

Correspondence: Luis Eduardo Borges de Macedo Zubko; Email: luis.zubko@gmail.com.

Case presentation: A 51-year-old woman presented with a history of a troubled gait associated with imbalance and falls. Although initially, she reported having no relevant past medical history, during follow-up her family mentioned that the patient had global developmental delay and significant learning difficulties during childhood. Family history was also noteworthy, with 2/7 brothers, having formerly been diagnosed with cerebral palsy, with no previous history of perinatal complications. Additionally, 1 brother and 5 cousins had similar abnormal gait and possible intellectual complaints. Her maternal grandparents were first-degree cousins. Her gait deteriorated until she was wheelchair-bound within 2 years since symptom's onset. During that time, she also had a significant cognitive and functional decline, leading her to become completely dependent for self-care activities. Physical examination was unremarkable, except for an asymmetrical protruding right ear. Neurological exam showed severe executive dysfunction with frontal release signs, severe ataxic and hypophonic dysarthria, moderate bilateral dysmetria and dysdiadochokinesia, mild bilateral bradykinesia, bilateral hypertonia due to rigidity and paratonia, and wide-based stance with severe postural instability requiring either constant bilateral support or wheelchair. Brain MRI disclosed moderate global cortical atrophy and severe cerebellar atrophy with a vermis predominance. Laboratory work-up showed only signs of ovarian insufficiency and no other cause of ataxia. Final diagnosis was achieved with specific sequencing of the FMR1 gene with 114 repeats in one allele and 30 repeats in the other allele (Premutation 55-200), thus confirming the diagnosis of Fragile-X-Associated Tremor Ataxia (FXTAS). She has been treated with levodopa, buspirone and trehalose with mild improvement in her overall quality of life. **Discussion:** Fragile-X-associated tremor ataxia (FXTAS) is a hereditary X-linked ataxia characterized by increased CGG repeats in the FMR1 gene in the premutation range between 55-200. It presents clinically between 50-70 years of age with progressive gait ataxia, intention tremor, and mild parkinsonism. Constitutional abnormalities may include protruding ears in 20% of cases, similar to the complete phenotype seen in fragile X syndrome. Asymmetry in constitutional findings is rare in FXTAS, with only one previously reported case with unilateral macroorchidism. Cognitive decline with compromise of memory and executive function, mood lability, and/or anxiety varies amongst cases. MRI findings may include global brain atrophy and a specific focal increased signal in the middle cerebellar peduncles on T2-weighted images. **Final comments:** FXTAS is the most common hereditary ataxia with a X-link pattern of inheritance. Clinical clues for its diagnosis include protruding ears, personal, or family history of intellectual disability, or early ovarian failure.

[2]Harvard Medical School, Brigham and Women's Hospital, Boston, MA, USA.

Correspondence: Carolina Rodrigues Dal Bo; Email: carolinardalbo@gmail.com.

Case presentation: A 33-year-old man presented with left elbow pain radiating into the forearm and the left fifth digit, occurring 1-2 times weekly, often triggered by specific positions. Physical exam revealed tenderness at posterior medial epicondyle of humerus (Tinel's sign), positive elbow flexion test, sensory deficits in fingers 4 and 5, consistent with McGowan Grade 1 ulnar neuropathy. Electromyography (EMG) and nerve conduction studies (NCS) were normal. Neuromuscular ultrasound and MRI identified an accessory anconeus epitrochlearis muscle overlying the ulnar nerve, which was compressing the ulnar nerve. **Discussion:** The anconeus epitrochlearis is a rare anatomical variant muscle that extends from the medial epicondyle of the humerus to the olecranon of the ulna. Although often asymptomatic, it can sometimes compress the ulnar nerve, leading to an ulnar neuropathy, mimicking a cubital tunnel syndrome. Traditional diagnostic tools such as EMG and NCS can be normal. Neurodiagnostic imaging, specifically neuromuscular ultrasound and MRI, played a pivotal role in identifying the accessory anconeus epitrochlearis muscle as the underlying cause. This underscores the importance of incorporating advanced imaging techniques when initial diagnostic tests are inconclusive but clinical suspicion remains high. **Final comments:** In cases of normal EMG/NCS, neurodiagnostic imaging (Neuromuscular ultrasound +/- MRI) is crucial for investigating ulnar neuropathy, especially in younger patients with activity-related symptoms even in absence of palpable mass. Excision of this muscle and anterior ulnar nerve transposition can be effective surgical treatments.

Unmasking the great masquerader: neuroimaging of general paresis in neurosyphilis

Samir Andres Ramirez Ojeda[1], William Alves Martins[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Samir Andres Ramirez Ojeda; Email: samir.ramirez@edu.pucrs.br.

Case presentation: A 38-year-old female presented with a 3-month history of behavioral changes, initially attributed to a psychiatric disorder. Neurological examination showed cognitive impairment, sensory ataxia, pyramidal tetraparesis with exaggerated deep tendon reflexes. Serum VDRL was found to be reactive (1/64). Both reactive VDRL test (1/32) and positive FTA-Abs on cerebrospinal fluid confirmed the diagnosis of neurosyphilis. HIV testing was negative. Brain MRI demonstrated diffuse atrophy associated to frontotemporal hyperintensities. Serological and CSF studies confirmed syphilitic meningoencephalitis. She was treated with intravenous crystalline penicillin and presented negative follow up VDRL on CSF and serum. Her symptoms stabilized and she presented slight improvement in motor function. She remained severely compromised with disinhibition and a frontal lobe syndrome. **Discussion:** Syphilis is a multisystem chronic infection caused by treponema pallidum support. Although there is a decrease in the number of cases of syphilis with the introduction of penicillin into use, it is still an important cause of the sexually transmitted diseases in developing countries because of the increase of incidence of AIDS and HIV seropositivity in the world. Syphilis progresses into four stages if untreated as primary, secondary, latent and tertiary stages. Tertiary syphilis is seen 1-30 years after primary infection. This inflammatory disease progresses slowly as neurosyphilis or gummatous syphilis. Neurosyphilis is classified as early and late syphilis. Cerebrospinal fluid (CSF), meninges and vascular structures are involved in the early stages of neurosyphilis, while in the late stage; cerebral tissue and spinal cord parenchyma are affected. Therefore, neurosyphilis can manifest with many different symptoms. In this article, we present a case of neurosyphilis with progressive cognitive changes and intractable behavioral and psychiatric problems whose primary and secondary phases were not detected. **Final comments:** Neurosyphilis affects the brain, meninges and/or spinal cord, varying from asymptomatic to several specific syndromes. Initial misdiagnosis of a psychiatric disorder is not an uncommon presentation of general paresis. Although MRI is variable, severe atrophy associated to patchy hyperintensities in frontotemporal regions should raise suspicion, helping to unmask this 'great masquerader'. Neurosyphilis has been a rarely seen clinical entity within the last decade. It can be encountered in almost all psychiatric disorders including dementia, personality changes, mania, depression, psychosis and delirium.

[3]Universidade do Estado da Bahia, Salvador BA, Brazil.

Correspondence: Arthur Caribé Sena; Email: arthurcaribe.17@hotmail.com.

Case presentation: Patient, 9-month-old, only child of non-consanguineous couple, followed up due to motor delay associated with malformation of the central nervous system and renal agenesis. Physical examination revealed axial hypotonia, spasticity in the extremities, bitemporal narrowing, ocular hypotelorism, upward slanted palpebral fissures, prematurely closed fontanel, prominent ears, deep philtrum and PC of 41.5cm (p3). Cranial MRI revealed agenesis of the corpus callosum, monoventricle, interventricular fusion in the midline - alterations in the formation of the supratentorial brain suggestive of semilobar HPE, in addition to delay in the formation of cerebral sulci and cisterns, and incomplete myelination of the white matter. Whole Exome Sequencing detected a probably pathogenic heterozygous variant in the ZIC2 gene, associated with AD holoprosencephaly (p.Val197Trpfs*21). 46, XY karyotype. Unaltered CGH-array. BERA revealed moderate/severe bilateral hearing loss. Urinary tract USG revealed renal agenesis on the right and mild hydronephrosis on the left. Thus, the diagnostic hypothesis of HPE5 was strengthened. **Discussion:** Holoprosencephaly occurs due to incomplete cleavage of the prosencephalon between the 18th and 28th day of gestation, affecting both the forebrain and the face and resulting in neurological manifestations and facial anomalies of variable severity. Mutations in the ZIC2 gene are the second most common heterozygous variants detected in patients with HPE, accounting for 4.8%-5.2% of patients with semilobar holoprosencephaly. The variant (p.Val197Trpfs*21) in ZIC2 described in this case is novel in the literature. Patients with ZIC2 mutations often have neurologic impairment, and renal/urinary anomalies may be more common than those with pathogenic variants in other genes. **Final comments:** The reported case represents the first description of the p.Val197Trpfs*21 variant in ZIC2 associated with HPE5. Neurological involvement is frequent in patients with HPE, and renal/urinary anomalies may be more common than those with pathogenic variants in genes other than ZIC2. This is a genetic condition, therefore chronic and without cure, and treatment should focus on symptoms and follow-ups. Early diagnosis and management, with the support of a multidisciplinary team, are important for treatment and prevention of complications related to this condition. The risk of recurrence for the couple's offspring is low because it is a non-inherited condition.

Unraveling acquired hepatocerebral degeneration: a case study

Rhaná Carolina Santos[1], Aline Oliveira dos Santos Meneses[1], Laura Porto Nunes[1], Ana Letícia Amorim de Albuquerque[1], Carolina Oldoni[2]

[1]Universidade do Vale do Rio dos Sinos, São Leopoldo RS, Brazil.
[2]Hospital de Clínicas de Porto Alegre, Porto Alegre RS, Brazil.

Correspondence: Rhaná Carolina Santos; Email: santoscrhana@gmail.com.

Case presentation: 74-year-old female with type 2 diabetes mellitus, systemic arterial hypertension, hypothyroidism, previous hepatitis A, and hepatic steatosis as comorbidities. Using the following medications: metformin, metoprolol, rosuvastatin, ezetimibe, levothyroxine, duloxetine, mirtazapine, primidone. She reported the onset of tremors in the upper limbs (UL) 10 years ago, without specifying whether they occurred at rest or during movement, with symptom progression. She currently reports bradykinesia and constipation but denies hyposmia or sleep disturbances. Physical examination showed facial hypomimia, right eyelid ptosis, jaw tremor, Moderate bradykinesia, Resting tremor more evident in the right upper limb, postural tremor in both upper limbs, cogwheel rigidity worse on the left side, gait characterized by small and shuffling steps. Laboratory investigation was carried out with blood count, renal function and vitamins without changes, and serologies (HIV, hepatitis B and C and syphilis) were non-reactive. Investigation for Wilson's disease was negative. Other results indicated altered liver function: TGO 78, TGP 61, GGT 451, FA 138, INR 1.54. Abdominal MRI showed chronic liver disease. Brain TRODAT scintigraphy revealed symmetrical uptake and preserved neurotransmitter activity, suggesting integrity of the dopaminergic system. Brain MRI showed microangiopathy and T1 hyperintense areas in the basal ganglia, suggesting Acquired Hepatocerebral Degeneration (AHD). **Discussion:** AHD is characterized by extrapyramidal and neuropsychiatric symptoms, including lethargy, somnolence, emotional lability, hallucinations, and movement disorders such as parkinsonism, ataxia, and myelopathy. It is a chronic and rare condition that manifests in patients with advanced hepatobiliary diseases, such as cirrhosis. Although the pathogenesis of AHD is not fully elucidated, it is known to be associated with manganese (Mn) accumulation in the basal ganglia. This accumulation can be detected by MRI, evidenced by T1 hyperintensities. Due to the morbidity associated with AHD and its limited response to pharmacological treatment, early diagnosis is crucial. Liver transplantation is a therapeutic option, with improvement in the progression of AHD observed post-procedure. **Final comments:** In the presented case, the integrity of the dopaminergic system and the metabolic alterations secondary to chronic liver disease observed in MRI support the diagnosis. This example underscores the importance of multidisciplinary assessment and continuous monitoring in patients with chronic liver diseases, given their prevalence, for the early identification and proper management of neurological complications, which, although rare, ad significant morbidity. Therapeutic intervention should focus on optimizing the control of the underlying liver disease and managing the imposed neurological symptoms to improve patient's quality of life.

Background: Genetic heterogeneity is a hallmark of hereditary spastic paraplegias (HSPs) with more than 90 associated genes reported so far. Despite that, few studies attempted to characterize the genetic epidemiology of HSPs and none of them in the highly admixed Latin American population. **Objective:** To describe the genetic profile of HSP in a large multicentric Brazilian HSP cohort recruited through an ongoing collaborative effort involving ten groups from five states (São Paulo, Rio Grande do Sul, Minas Gerais, Paraná and Paraíba) and to evaluate the diagnostic yield of next-generation sequencing (NGS) for suspected HSP. **Results:** The present cohort is composed of 668 patients (358 men and 310 women) from 490 families. Declared consanguinity was reported in 102/490 families, not present in 316/490 and unknown/not available in 72/490. Considering all families, 236 were inconclusive or not genetically tested yet. From those index-cases who underwent NGS, 192/490 (39,18%) had non-diagnostic results whereas 298/490 (60,82%) had diagnostic results. The top five most frequent genotypes were: SPG4 [SPAST] 61/490 (12,45%), SPG11 50/490 (10,20%), SPG7 22/490 (4,49%), SPG76 [CAPN1] 19/490 (3,88%) and SPG5A [CYP7B1] 15/490 (3,06%). Apart from the 'known' HSP genes, we also uncovered newly recognized genes associated with the HSP phenotype: COQ7 gene variants were present in 6 patients from 5 families - the p.Met1? variant appearing in 4 patients either in homozygous state or combined with p.Arg54Gln or Arg107Trp, and in 2 patients with p.Arg54Gln in homozygous state; RNASEH2B p.[Ala177Thr];[Ala177Thr] is present in two HSP sisters, SNAPC4 p.[Trp404Ter];[Ala415Val] present in two siblings and SPTAN1 (SPG91) last gene related with HSP appearing in 2 relatives with the described variant p.[Arg19Trp]. **Conclusion:** The study emphasizes the heterogeneity of HSP and the importance of NGS methods for genetic testing also the need for further genetic analyses for the inconclusive cases.

Correspondence: Luiz Eduardo Novis de Faria; Email:luizeduardonovis@hotmail.com

Background: Hereditary ataxias (HAs) encompass a diverse and genetically intricate group of rare neurodegenerative disorders, presenting diagnostic challenges. Whole-exome sequencing (WES) has significantly improved diagnostic success. **Objective:** To elucidate genetic causes of cerebellar ataxia within a diverse Brazilian cohort. **Methods:** Biological samples were collected from individuals with sporadic or familial cerebellar ataxia, spanning various ages and phenotypes, excluding common SCAs and Friedreich ataxia. RFC1 biallelic AAGGG repeat expansion was screened in all patients. For AAGGG-negative cases, WES targeting 441 ataxia-related genes was performed, followed by ExpansionHunter analysis for repeat expansions, including the recently described GGCZFHX3. Variant classification adhered to ClinGen guidelines, yielding definitive or probable diagnoses. **Results:** The study involved 76 diverse Brazilian families. 16 % received definitive diagnoses, and another 16 % received probable ones. RFC1-related ataxia was predominant, with two definitive cases, followed by KIF1A (one definitive and one probable) and SYNE-1 (two probable). Early-onset cases exhibited higher diagnostic rates. ExpansionHunter improved diagnosis by 4 %.We did not detected GGC-ZFHX3 repeat expansion in this cohort. **Conclusion:** This study highlights diagnostic complexities in cerebellar ataxia, even with advanced genetic methods. RFC1, KIF1A, and SYNE1 emerged as prevalent mutations. ZFHX3 repeat expansion seem to be rare in Brazilian population. Early-onset cases showed higher diagnostic success. WES coupled with ExpansionHunter holds promise as a primary diagnostic tool, emphasizing the need for broader NGS accessibility in Brazil.

https://doi.org/10.5327/CBN241717

Unraveling toxic-metabolic encephalopathy: the decisive role of EEG in hyperemesis-related seizures

Luís Guilherme Pacheco de Almeida[1], Luiza Gonçalves Fraga[1], Patrícia Coral[1], Marlon Wycliff Caeira[1], Carlos Eduardo Soares Silvado[1], Luciano de Paola[1], Mayara de Rezende Machado[1]

[1]Universidade Federal do Paraná, Complexo Hospital de Clínicas, Curitiba PR, Brazil.

Correspondence: Luiza Gonçalves Fraga; Email: luizaag.fraga@gmail.com.

Case presentation: A 24-year-old pregnant woman at 15 weeks of gestation, with no significant medical history, presented with her first epileptic event in the context of severe hyperemesis gravidarum. The episode was followed by persistent altered consciousness. An electroencephalogram (EEG) revealed diffuse cerebral dysfunction with occasional multifocal epileptiform activity, predominantly bifrontal. The diffuse cerebral dysfunction observed on EEG, in association with the patient's altered level of consciousness, suggested an encephalopathic state overlaid by an acute symptomatic seizure. Given the clinical context, Wernicke's encephalopathy was suspected and later confirmed by MRI findings. Following thiamine administration, the patient showed progressive electroclinical improvement, with resolution of epileptiform activity and recovery of consciousness, and was discharged without further antiseizure medication. **Discussion:** Wernicke's encephalopathy (WE) is caused by thiamine deficiency, commonly associated with alcohol abuse, malabsorption, malnutrition, increased metabolism, or hemodialysis. A brief literature review was conducted to examine the relationship between thiamine deficiency and epileptic manifestations. In series of patients with WE or Korsakoff's psychosis, epileptic seizures are frequently mentioned, often attributed to alcohol withdrawal. In a group of 50 adult patients, 16 with neurological manifestations demonstrated epileptiform activity on their EEGs. Thiamine deficiency interferes with cerebral electrogenesis through several mechanisms. It impacts the biosynthesis of neurotransmitters such as acetylcholine and gamma-aminobutyric acid affects membrane stability and conduction along the neurilemma, provokes osmotic imbalance with perineural edema and neuronal swelling, and causes periventricular lesions due to high metabolic rates dependent on vitamin B1. These factors seem to contribute to transient epileptogenicity, which can be reversed with treatment before severe damage permanently affects neuronal circuitry. **Final comments:** This case illustrates the important role of EEG in diagnosing and managing encephalopathy in hyperemesis gravidarum. Although EEG findings are not specific, they offer significant diagnostic insights when combined with clinical history, aiding in the rapid identification of WE. Early thiamine treatment led to marked improvement, preventing irreversible neurological damage. This highlights the necessity of early recognition and intervention, particularly in pregnant women with severe hyperemesis gravidarum, to prevent long-term neurological sequelae.

https://doi.org/10.5327/CBN241718

Unsteadiness of gait in terminal renal failure: Miller Fisher syndrome triggered by haemodialysis

Natália Contini[1], William Alves Martins[1], Lucas Porcello Schilling[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Natália Contini; Email: nataliacontini4@gmail.com.

Case presentation: A 79-year-old man presented acutely with dizziness, unsteadiness of gait and falls during a session of hemodialysis, which had started two months earlier due to hypertensive nephropathy. Brain MRI ruled out structural or acute ischemiclesions. Neurological examination showed downbeat nystagmus, right facial paresis and sixth nerve palsies bilaterally. Muscle strength remained normal, but deep tendon reflexes were absent diffusely. He showed an unstable and wide-based gait, with a tendency to fall in all directions. Cerebrospinal fluid analysis showed high protein (79mg/dl) with a normal cell count (<5cell/mm3). Nerve conduction studies disclosed absent sensory conduction, along with motor conduction slowing and absent H-reflex. Miller Fisher syndrome (MFS) was diagnosed under clinical and neurophysiological features. Intravenous immunoglobulin was introduced, followed by slowly recovery of balance and cranial nerves palsies. Haemodialysis continued three times per week, without recurrence. **Discussion:** Chronic renal insufficiency leads to a myriad of neurological complications, of which one of the most common is peripheral neuropathy. Usually, gradual onset of a distal axonal neuropathy is the clinical picture. Haemodialysis and continuous peritoneal dialysis are thought to arrest progression or even recede uremic neuropathy. This view is, conversely, challenged by a few reports of acute or subacute demyelinating polyradiculoneuropathy associated to dialysis. Neurological involvement as a complication of dialysis has a scarce literature. It mainly manifests as Wernicke's encephalopathy, aluminum poisoning or electrolytes imbalance. A Guillain-Barré-like (GBS) illness after initiation of peritoneal dialysis has been eventually described since 1993. Small osmotic changes between interstitial tissue and nerve sheaths may predispose either to direct myelin injury or expose nerve tissues to immune vigilance. The clinical triad of ophthalmoplegia, ataxia and arreflexia

the hallmark of MFS, a variant of GBS described in 1956. Pathophysiological mechanisms involve the targeting of antibodies to peripheral nerves' gangliosides. Despite many reports of unusual triggers in MFS, association to haemodialysis had been reported only once. Similar to our patient, initial assessment led to misguided diagnosis focused on vascular complications of renal insufficiency. Sometimes forgotten clinical signs, such as deep tendon reflexes and gait exam, unveil directly the diagnosis. Despite positivity of anti-gangliosides in 83% of patients, diagnosis can be made on clinical grounds, as in our patient. **Final comments:** In conclusion, sudden onset of ataxic symptoms in patients in haemodialysis should not be overlooked and MFS should enter in the differential diagnosis.

https://doi.org/10.5327/CBN241719

Unusual aseptic meningitis and cognitive syndrome in a patient under anti-TNF therapy for rheumatoid arthritis: a case report

Guilherme Lago Miranda[1], Isabela de Almeida Stella[1], Ingrid Lorena da Silva Gomes[1], Giovanni Caniçali Simões[1], Henrique de Moraes Bernal[1], Pedro Almeida Martins Pontes[1], Tainá Fátima Ramos Gonçalves[1], Marcele Schettini de Almeida[1], Herval Ribeiro Soares Neto[1], Sonia Maria Cesar de Azevedo Silva Moura Magalhães Gomes[1]

[1]Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo SP, Brazil.

Correspondence: Guilherme Lago Miranda; Email: lagomiranda.g@gmail.com.

Case presentation: A 66-year-old female retired lawyer, with a past medical history of rheumatoid arthritis (RA) treated with Golimumab for the last 10 months, with behavioral change in the past two months, after a single dose of intra-articular corticosteroid due to articular pain. Her family claims that she became progressively agitated, easily irritated and euphoric, and made excessive expenses. She was taken to a psychiatrist and started on olanzapine and valproic acid. Subsequently, her humor became depressed, with a feeling of anguish and loss of interest in her usual activities. Due to progression, she was taken to the emergency department. Her neurological exam was only remarkable for a cognitive impairment, scoring 21 out of 30 points in the Montreal Cognitive Assessment (MoCA), with losses in visuospatial function, attention, delayed recall and orientation. Her CSF showed a mild increase in cellularity of 7 and proteins of 58, and a brain MRI showed aseptic meningitis (AM). Considering her immunosuppressed status, she was started on empirical acyclovir, ceftriaxone and ampicillin, without improvement. A CSF metagenomic was negative. Paraneoplastic investigation was also unremarkable. As an alternative diagnosis, we considered the possibility of Golimumab being the trigger for the AM; therefore, the medication was stopped and she received a course of IVIg followed by IV methylprednisolone. Upon discharge, brain MRI and MoCa improved, and on outpatient follow-up, she no longer had remarkable findings on neuroimaging and her MoCA evaluation was 28/30. **Discussion:** RA can cause meningitis, but its treatment can also be linked to AM by direct effect or leading to infectious meningitis due to the immunosuppressive effect. 23 cases of RA patients developing AM due to the use of anti-TNF medications were found by Yıldırım, R. et al., with half of them within the first year of exposure. There are no specific findings that differentiate rheumatoid AM from anti-TNF-induced AM, but the development of the condition after starting treatment suggests the later. Since anti-TNF agents cannot cross the blood-brain barrier, it is thought that the inhibition of tumor necrosis factor (TNF) results in paradoxical increase in its concentration within the CNS. Additionally, it can lead to immune dysregulation by inhibiting the apoptosis of self-reactive T cells. There is no consensus on treatment, but discontinuation of the precipitating drug and high-dose corticosteroids are the most common initial choices. **Final comments:** AM gives rise to a series of possible differential diagnoses, so a thorough investigation is mandatory. Special attention was paid to infectious etiologies, and we only pursued immunotherapy after a negative study of her CSF. It's a known fact that medications can cause AM, and anti-TNF, already linked to a series of other neurological diseases, has to be on the list of causes when evaluating a patient.

https://doi.org/10.5327/CBN241720

Unusual kleptomania in a Parkinson's disease patient treated with pramipexole: a case report

Maria Eduarda Vieira de Oliveira[1], Carlos Frederico Lima[2], Maria Clara Arcoverde[2], Maria Thayana Barros Bandeira[3], Maria Luiza Vasconcelos Montenegro[1], Laís Diniz Pessoa de Santana[1]

[1]Universidade de Pernambuco, Recife PE, Brazil.
[2]Hospital Universitário Oswaldo Cruz, Recife PE, Brazil.
[3]Faculdade de Medicina de Olinda, Olinda PE, Brazil.

Correspondence: Maria Eduarda Vieira de Oliveira; Email: eduardaoliveira0194@gmail.com.

Case presentation: A 49-year-old male with Parkinson's Disease (PD), diagnosed in 2017, initially presented with rigidity in the left upper limb, progressing to resting tremor in the same limb, later affecting the right upper limb and both lower limbs. He also reports chronic constipation, agitated sleep, festinating gait, difficulty swallowing, dysarthria, and various bodily pains. The patient was using Pramipexole 0.125 mg, Fluoxetine 20 mg, Clonazepam 2 mg, and Levodopa 800 mg daily. Initially, he was taking Pramipexole 0.125 mg three times a day. Due to nocturnal freezing and the short duration of Levodopa's effect, the dose of Pramipexole was increased to 1 mg three times a day. Later, he reported taking 1.5 mg of Pramipexole three times a day, resulting in significant improvement in motor symptoms. At the most recent consultation, he was advised to reduce Pramipexole to 1.5 mg per day due to significant dyskinesias and compulsive behaviors. Other medications remained unchanged. During the evaluation, the patient reported compulsive behaviors related to Pramipexole. He mentioned an uncontrollable urge to take items from supermarkets, a behavior never exhibited before, causing concern for his wife. He reported taking multiple small items from the market that he did not need, just to satisfy this urge. He has no diagnosis of conduct disorder, bipolar disorder, or antisocial personality disorder. **Discussion:** Kleptomania is characterized by a recurrent failure to resist the impulse to steal objects not needed for personal use or monetary value, with tension before the act and pleasure or relief during the theft (DSM-IV TR). Dopamine agonists like pramipexole are effective in treating PD motor symptoms but can induce impulse control disorders (ICDs) such as pathological gambling, hypersexuality, and compulsive shopping. The pathogenesis of ICDs involves hyperactivation of the mesolimbic dopaminergic system associated with reward behavior and impulse control. Pramipexole, by excessively stimulating D3 dopamine receptors, can dysregulate these circuits, leading to compulsive behaviors. In this case, the patient developed an uncontrollable compulsion to take items from the market, leading to a reduction in the pramipexole dose. Studies show that ICDs induced by dopamine agonists are relatively common, with prevalence ranging from 6.1% to 14% in PD patients. However, kleptomania as a side effect of pramipexole use has been reported only three times in the international literature. **Final comments:** This case illustrates the complexity of managing Parkinson's Disease, especially when medication side effects compromise the patient's quality of life. Identifying kleptomania as a rare side effect of pramipexole is crucial for appropriate therapeutic adjustment. Continuous studies on the adverse effects of dopamine agonists and regular patient monitoring are essential to improve outcomes and quality of life for these individuals.

https://doi.org/10.5327/CBN241721

Unusual manifestation due to infection with viruses from the herpesviridae family: Guillain Barré syndrome associated with herpes simplex – a case report

Daniel Lacerda da Costa[1], Beatriz Carneiro Gondim Silva[1], Angelina Maria Martins Lino[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Daniel Lacerda da Costa; Email: dlacerdadacosta@gmail.com.

Case presentation: E.L.S, 72 years old, male, has a history of short-term paraparesis in 2021, pulmonary tuberculosis treated 8 years ago and benign prostatic hyperplasia. In April 2022, the patient developed non-specific flu-like symptoms, and after 20 days he developed signs of ascending weakness. He was admitted to our institution with significant limitations in his ability to walk. On neurological examination, the patient presented with flaccid tetraparesis, areflexia, in addition to appendicular ataxia of the upper limbs and facial diparesis. Upon admission, cerebrospinal fluid was collected, which resulted in: 90 cells, with a predominance of monocytes (45%) and lymphocytes (42%), proteinorrhaquia of 143 mg/dl and glucose 43 mg/dl. Herpes simplex I/II was identified in the viral panel. Electroneuromyographic examination demonstrated marked multifocal demyelinating neuropathy, fulfilling criteria for Guillain-Barré syndrome (GBS) in its AIDP form. Human immunoglobulin was initially administered at a dose of 2g/kg over 5 days with progressive worsening of the clinical condition. After the third day of hospitalization, with the results of the viral panel, IV acyclovir was added (dose of 10 mg/kg every 8 hours for 14 days), with significant improvement. The patient was discharged on May 16th to continue rehabilitation with the physiatry and multidisciplinary team. **Discussion:** The involvement of the nervous system by the herpes simplex virus is a common condition and can be serious if not identified early. Forms such as meningoencephalitis, Mollaret's meningitis, myeloradiculitis, Bell's palsy are extensively reported. Herpes virus-associated acute polyradiculoneuritis (PRN) is an uncommon manifestation. There are few reports in the literature related to the herpes family such as HSV-1, HSV-2, VZV, EBV and CMV and their association with GBS. The first report of the condition dates back to 1975, of a case that developed flaccid tetraparesis and areflexia due to HSV infection. Despite the use of corticosteroids and physiotherapy, the patient evolved well. There are reports of cases in which immunoglobulin and acyclovir were administered with good evolution. The patient in this case showed significant worsening in the first three days after starting immunoglobulin, with significant improvement after the introduction of acyclovir 10mg/kg/dose every 8 hours per day for 14 days, showing excellent evolution. **Final comments:** The recognition of unusual forms of common diseases is important, even more so in diseases that may compromise functionality and risk death, such as GBS. Increased cellularity in Guillain syndrome is one of the warning signs, and should list the possibility of differential diagnosis or associated disease, as in this case, the association with Herpes Simplex.

Correspondence: Bruno Henrique Carneiro Costa Filho; Email: brunohccosta97@gmail.com.

Case presentation: An 85-year-old patient with Parkinson's disease for 16 years began to exhibit vocal tremor in the last six years. A videolaryngoscopy was performed to better characterize the tremor and explore the option of treatment with botulinum toxin (BT) in the vocal cords. Meanwhile, considering the possibility that the oropharyngeal tremor could be due to comorbid essential tremor (ET), treatment with topiramate and primidone was attempted, but there was no benefit, leading to the discontinuation of these drugs. Videolaryngoscopy revealed the presence of resting tremor in the larynx, pharynx, base of the tongue and adjacent facial structures, consistent with the diagnosis of PD. It was decided not to administer BT due to the videolaryngoscopic findings, which suggested that the vocal simptons were mostly secondary to the pharyngeal and facial muscles tremor. Instead, the optimization of the dopaminergic therapy dose was chosen, along with continuing the speech therapy that the patient was already undergoing. **Discussion:** Resting tremor is one of the core motor symptoms of PD, but vocal tremor is less frequently observed and can significantly impair speech ability. It is usually due to laryngeal tremor, but palate, pharyngeal, and tongue tremor can also occur. Due to the uncommonness of this symptom, there are no treatment guidelines specifically for vocal tremor in PD, though optimization of antiparkinsonian medications are usually the first line of therapy. Anticonvulsants, benzodiazepines, and beta-blockers can also be tried, if comorbid ET is suspected. Specific cases may be managed with BT or deep brain stimulation. **Final comments:** We present a case of an elderly female with Parkinson's disease with an uncommon presentation of laryngeal, pharyngeal, tongue and facial resting tremor, resulting in significant speech difficulties. The case underscores the heterogeneous and progressive nature of the disease, as patients may develop additional symptoms and complications over time. There is a need for a personalized approach to effectively address these different presentations, as there is insufficient data to indicate the best treatment modalities for this specific symptom.

Correspondence: Ingrid Lorena da Silva Gomes; Email: ilsgomes@yahoo.com.

Case presentation: An 82-year-old male patient presented with a 4-month history of gait disturbances leading up to an inability to stand or walk unassisted. Several episodes of forgetfulness, coupled with progressive and rapid changes in behavior and mood were also remarkable, prompting his family to seek specialized evaluation. His medical history included a thyroidectomy for thyroid malignancy at age 62, for which he was on levothyroxine. The neurological examination revealed a dysexecutive patient, with reduced fluency and a Mini-Mental State Examination (MMSE) score of 10/30, which deteriorated progressively, rendering further testing unfeasible. An investigation for rapidly progressive dementia was initiated. Serum levels of Vitamin B12, thyroid function, serology for HIV, hepatitis, and syphilis were normal. CSF analysis and neoplastic investigation also showed no abnormalities. Subsequent testing of an anti-neuronal autoantibodies panel (including cell surface and onconeural antibodies) yielded negative results prior to initiation of any immunotherapeutic treatment. Brain MRI evidenced symmetric signal alteration affecting the cortical/subcortical region of the insulae, thalami, and some central areas of the pons, with high signal intensity on T2/FLAIR and EEG was abnormal. Based on our primary suspicion of an autoimmune encephalitis, a course of IV methylprednisolone was started, with improvements in motor tasks and on his MMSE score of 17/30. Nevertheless, during steroid tapering, he started to deteriorate again. As he was responsive to immunotherapy, we requested a 5-day course of plasmapheresis (PLEX), which further established his progressive improvement: in learning abilities, a better performance on the clock test, and he achieved an MMSE score of 25/30. He also resumed playing the guitar, an activity he could no longer engage in, being back to his baseline. However, 4 months after complete cessation of prednisone, he experienced symptom recurrence, necessitating readmission and a new course of pulsed therapy, with subsequent improvement. We chose to maintain him on a minimal regimen of prednisone and started rituximab. **Discussion:** Seronegative autoimmune encephalitis comprises a group of encephalitides lacking identifiable specific antibodies, presenting a diagnostic challenge in neurological practice. Clinical presentation guides treatment decisions, as neuroimaging findings may not always be definitive. Initial therapies include high-dose corticosteroids, intravenous immunoglobulin, and PLEX. Long-term immunosuppressive therapy may be necessary in select cases. **Final comments:** Rapidly progressive cognitive decline requires thorough evaluation. Despite inconclusive complementary exams, acute immunotherapy should be considered for patients with progressive neurological impairment in the absence of suggestive degenerative signs. Treatment should be individualized and maintenance immunosuppression after a second relapse is essential.

Unveiling the relationship between poliovirus vaccination rates and acute flaccid paralysis incidence: a data-driven analysis

Ariana Leal Borges da Cruz[1], Ana Flávia Novaes[1], Qesya Rodrigues Ferreira[1], Júlia Spínola Ávila[1], Davi Tanajura Costa[1]

[1]Universidade Federal da Bahia, Vitória da Conquista BA, Brazil.

Correspondence: Ariana Leal Borges da Cruz; Email: arianacruz@ufba.br.

Background: Poliovirus is a pathogen capable of causing poliomyelitis, commonly known as infantile paralysis. It has three serotypes, with type 1 most associated with paralysis development. Approximately 1% of infected individuals are estimated to develop acute flaccid paralysis (AFP). Brazil provides a cost-free vaccination schedule against the disease for all children. As a result of vaccination efforts, the country was certified free from wild poliovirus circulation in 1994. However, vaccine coverage has significantly declined over the past decade, re-emerging as a critical public health issue. **Objective:** In this sense, this study aims to analyze the incidence of Acute Flaccid Paralysis associated with vaccination coverage in Brazil. **Methods:** This study employs a quantitative cross-sectional approach. Data were sourced from the Department of Informatics of the Unified Health System (DATASUS), a division of the Ministry of Health of Brazil. Data from the Notifiable Diseases Information System (SINAN) are publicly accessible. The study analyzed vaccination coverage from 2011 to 2023 and incidence of Acute Flaccid Paralysis (AFP) among Brazilians up to 15 years old from 2011 to 2021, with 2021 being the latest year for which data are available in the system. **Results:** Between 2011 and 2021, there were 4663 reported cases of AFP, with 4662 occurring in individuals up to 15 years old. The year 2018 recorded the highest number of cases (520), with the Northeast region reporting the highest total notifications during this period (1761). Regarding ethnicity, 49.92% of cases occurred in individuals of brown skin color. Additionally, 55.75% of cases occurred in males. No cases were classified as "wild poliovirus", although three cases were characterized as "poliomyelitis-compatible" during the study period (one case each in 2011, 2018, and 2019). Moreover, 3935 cases of AFP were classified as "discarded poliomyelitis", six as "vaccine-associated", 99 as "inconclusive", and 620 as "ignored/blank". Confirmation criteria included 447 cases recorded as "ignored/blank", 353 as "clinical-epidemiological", 15 as "loss to follow-up", 27 as "death", 570 as "evolution", and 3252 as "laboratory". National vaccination coverage data indicated a rate of 101.33% in 2011, while the 2023 epidemiological bulletin reported coverage at 84.7%, marking a decline of 16.63%. The lowest vaccination rate occurred in 2021 (71.04%). **Conclusion:** There is no demonstrable association between cases of Acute Flaccid Paralysis and Poliomyelitis. However, the decline in vaccination coverage remains a significant concern in the country. Additionally, there is a pressing need for more detailed data regarding the final classification of AFP cases, particularly in light of the substantial number reported as "ignored/blank".

Unveriling the intersection: cerebral venonus thrombosis in the context of ulcerative colitis

Gabriel Abrahão Stoliar[1], Catarina Dantas Corrêa[1], Valéria Cristina Scavasine[1], Juliano André Muzzio[1], Viviane Hiroki Flumignan Zetola[1], Marcos Christiano Lange[1]

[1]Universidade Federal do Paraná, Hospital de Clínicas, Curitiba PR, Brazil.

Correspondence: Gabriel Abrahão Stoliar; Email: gabrielstoliar@gmail.com.

AACB, male, 47 years, no comorbidities. Presented with sudden onset of severe periorbital and temporal headache. About four days later noticed blurred vision and speech impairment, while maintaining the headache pattern. The patient denied taking medication, smoking, alcohol or illicit drugs abuse. Systemic enquire revealed hematochezia for the last three months with episodes of mucus diarrheal stools. Neurological examination showed reduced comprehension, fluency, naming, repetition and reading associated with intelligible dysarthria, right homonymous hemianopsia and right nasolabial fold erasure. There were no other deficits. The patient was submitted to a CT scan that revealed intraparenchymal hemorrhage in the left temporal lobe with adjacent edema. Subsequently, CT angiography showed thrombosis of the sigmoid, transverse, straight venous sinuses and the left internal jugular. During hospital, stay AACB was diagnosed with active ulcerative colitis which was related to the prothrombotic status that caused the extend cerebral venous thrombosis with venous infarct complication. Anticoagulation with dabigatran was prescribed to treat CVT and mesalazine to colitis ulcerative's control. Inflammatory Bowel Disease (IBD) accounts for less than 2% of Cerebral Venous Thrombosis cases, with Ulcerative Colitis (UC)

being slightly more common than Crohn's disease (CD) among those cases. In these autoimmune diseases, the risk of developing thrombosis increases proportionally to disease activity. Systemic inflammation leads to excessive platelet and coagulation cascade activation and endothelial dysfunction, which culminates in an enhanced thrombosis tendency. Nevertheless, inflammatory diseases are not the only risk factors. Other predisposing factors, such as anemia, thrombocytosis, thrombophilia, deep venous thrombosis, oral contraceptives, infections and recent surgeries should also be considered. Clinical presentation of CVT related do IBD is similar to others CVT with headache present in 80% of the cases. Seizure, vomiting, hemi/tetraplegia, altered awareness, vision deficits and papilledema are also common. The involvement of several venous sinuses simultaneously is frequent, occurring in 50% of patients. The most affected sinus is the superior sagittal followed by straight sinus. The presence of venous infarct caused by CVT is also common. Treating CVT related to IBD is identical to CTV by other causes. Anticoagulation must be started as soon as possible, even in the presence of GI bleeding, unless it may be life-threatening. It is recommended that all the patients with IBD receive prophylactic anticoagulation when hospitalized due to its prothrombotic state. The use of steroidal anti-inflammatory drugs may be helpful reducing the hypercoagulable state and so the risk of thrombotic event. This case highlights the importance of a detailed medical history, with a thorough review of systems, in diagnosing the cause of cerebral venous thrombosis.

Update on new pharmacological treatments for motor symptoms of Parkinson's disease: a systematic review

érica Otoni Pereira Miranda[1], Lukas Santos Freire[1], Priscila Santos Oliveira[1], Davi Tanajura Costa[1], Philip George Glass Andrade[1], Emmanuel Santos Trindade[1], Giovana Andrade de Oliveira[1]

[1]Universidade Estadual do Sudoeste da Bahia, Vitória da Conquista BA, Brazil.

Correspondence: Érica Otoni Pereira Miranda; Email: ericaotoni15@gmail.com.

Background: Parkinson's disease (PD) is a neurodegenerative disorder caused by the loss of dopaminergic neurons in the substantia nigra and the presence of misfolded α-synuclein in Lewy bodies. This disorder is present in at least 1% of the population over 60 years of age and is characterized by bradykinesia and at least one other symptom of rigidity and resting tremor, so that the manifestations are progressive and significantly affect quality of life. Currently available treatments aim to control motor symptoms, but do not affect the natural course of the disease. **Objective:** To provide an update on new pharmacological treatments for motor symptoms of Parkinson's Disease. **Methods:** This is a systematic literature review carried out in PubMed and BVS databases, using the descriptors "Pharmacological treatment" and "Parkinson's disease". Randomized controlled trials and meta-analyses published between 2020 and 2024, in English, Portuguese and Spanish were considered. The studies included were those addressing new drug treatments for motor symptoms of PD, with free access to the full text. Duplicates or those that did not correspond to these criteria were excluded. **Results:** Of the 708 articles initially found, 42 were included in this review. In general, those studies evaluate drugs according to PD scales and ON/OFF periods. Among the scales, the most used is the Unified Parkinson's Disease Rating Scale (UPDRS), a classification tool in 4 parts, with Part III - motor subscale - being the most relevant in this study. The ON and OFF states depict periods in which the drug has an adequate motor response or not, respectively. The most consolidated adjuvant drugs to levodopa for the motor treatment of PD were: apomorphine, pramipexole, selegiline, safinamide and opicapone, the last two being quite elucidated and effective in reducing OFF periods time and motor fluctuations, with improvement in UPDRS Part III. Safinamide (a modulator of dopaminergic and glutamatergic systems) was effective, in the medium to late stages of the disease, in doses of 50-100mg, and opicapone (a catechol-O-methyltransferase inhibitor), in doses of 25-50mg. Other drugs lack robust evidence or are controversial, such as isradipine (a dihydropyridine calcium channel blocker), effective, in one trial, at a dose of 10mg, but ineffective in the motor sphere in another, at the same dose. Also controversial, nilotinib (a tyrosine kinase inhibitor) - despite being beneficial in several studies, in doses of 150-300mg - was symptomatically ineffective and worsened motor function in the arms, in one trial, with the same dose. **Conclusion:** Few drugs have shown benefits in controlling the motor symptoms of Parkinson's disease, particularly when associated with levodopa. There is a lack of evidence for the use of these drugs as monotherapy in the management of the disease. Therefore, robust randomized controlled trials are needed to evaluate the real effectiveness of these new drugs.

Urban mobility through the special assistance service (Atende) for people with autism in the city of São Paulo

Andréia Maria Souza Cardoso[1], Gabriela Vitória da Costa Barbosa[1], Lissandra Andrea Nadalini Mauá[1], Paula Santos Justino[1], Soraia Micaela Silva[1], Alessandra Cristina Guedes Pellini[1], Isaac Lucas Camargo Arruda[1], João Carlos Pina Faria[2], Éric Edmur Camargo Arruda[1]

[1]Universidade Nove de Julho, São Paulo SP, Brazil. [2]Faculdade de Medicina do ABC, Santo André SP, Brazil.

Correspondence: Andréia Maria Souza Cardoso; Email: andreiamaria@uni9.edu.br.

Background: The Special Assistance Service - Atende, was created through decree No. 36,071 of May 9, 1996 and is currently governed by Municipal Law No. 16,337, of December 30, 2015. It is a type of free, door-to-door transportation, with its own regulations, offered by the City of São Paulo, managed by São Paulo Transporte S.A. and operated by public transport companies in the city of São Paulo and accessible taxi cooperatives. **Objective:** It is aimed at people with autism, deafblindness or physical disabilities with a high degree of severity and dependence, from 7am to 8pm, from Monday to Sunday, excluding holidays. **Methods:** Data were obtained using an electronic form sent to the Electronic Citizen Information System (e-SIC) (https://esic.prefeitura.sp.gov.br/) at the São Paulo City Hall Public Transparency Portal, requested on 08/31/2023, identified with protocol 076111 and forwarded to SP TRANS (São Paulo Transporte S/A) requesting information on the quantity, age, region and neighborhood of the autistic users of the Special Attention Service (ATENDE) residing in the city of São Paulo. **Results:** By August 2023, 2761 autistic users were contemplated through ATENDE, of which 2138 were male, 566 were female, 1 was the other and 56 were not registered with their gender, 906 users reside in the east zone, 588 reside in the west zone, 650 reside in the north zone and 617 reside in the south zone of the city of São Paulo. In the city of São Paulo in the ATENDE service, ages 2 to 10 represent 76.74% of users, the minimum age was 2 years and the maximum of 84 years, the average age is 9.82 years and standard deviation of 6.93, the east zone has an average age of users of 8.87 years and standard deviation of 7.37 years, the west zone has an average of users' age of 8.31 years and standard deviation of 5.80, the north zone has an average age of users of 8.50 years and standard deviation of 6.40 and the south zone has an average age of users of 9 .56 years and standard deviation of 7.70. The neighborhoods with the most users are Americanopolis (south zone), Jardim Peri (north zone), Itaquera (east zone), Conjunto Residencial Jose Bonifácio (east zone), Parque Paulistano (east zone), Cidade Líder (east zone) and Jardim São Luiz (West Zone). **Conclusion:** The Special Care Service - Atende assists 2761 autistic people in the city of São Paulo by taking them to consultations and treatments. More studies on this population are necessary so that primary care can map and guarantee universal and equitable care for all.

https://doi.org/10.5327/CBN241728

Use of antisense oligonucleotides as a therapeutic approach for Huntington's disease: a systematic review

Matheus Jarek[1], Anna Caroline Ulson da Costa[1], Eduarda Nakoula[1], Mohamad Ali Hussein[2]

[1]Universidade Positivo, Curitiba PR, Brazil. [2]Instituto de Neurologia de Curitiba, Curitiba PR, Brazil.

Correspondence: Matheus Jarek; Email: matheusjarek.up@gmail.com.

Background: Huntington's disease (HD) is a neurodegenerative disorder caused by the expansion of the CAG trinucleotide repeat in the HTT gene, which leads to the coding of mutant huntingtin (mHTT). Therapies for HD are still restricted to treating the symptoms. Recent clinical trials have evaluated the use of antisense oligonucleotides (ASOs) to reduce mHTT levels. ASOs are small single-stranded nucleic acid sequences that bind via Watson-Crick hybridization to the target RNA; regulating gene expression especially by acting on messenger RNA (mRNA) through cleavage and degradation of the ASO-mRNA complex mediated by RNase H. **Objective:** Evaluate the evidence on the efficacy of using ASOs as a therapeutic approach for HD. **Methods:** A systematic review was carried out according to the PRISMA protocol. PubMed, Embase, and ClinicalTrials.gov databases were used, and studies were selected up to January 2024. Inclusion criteria were defined based on study design, language, intervention performed, and outcomes of interest. Animal studies, in vitro studies, and literature reviews were excluded. **Results:** From 143 studies identified, 4 were included after the selection and eligibility stages, which totaled 986 participants in clinical trials evaluating the use of ASOs in HD. Three ASOs were identified: Tominersen, WVE-120101, and WVE-120102. Tominersen was associated with significant reductions in mHTT concentration levels in cerebrospinal fluid (CSF) (reductions of more than 40% were observed in patients on a 120 mg dose); however, there was a worse performance on the Composite Unified Huntington's Disease Rating Scale (cUHDRS) compared to placebo in patients who received tominersen intrathecally every 8 weeks. In addition, transient increases in CSF neurofilament light chain (NfL) levels, increases in ventricular volume, and the occurrence of serious adverse effects were observed; including 3 cases of hydrocephalus. As for WVE-120101 and WVE-120102, both are allele-selective ASOs, selectively decreasing mHTT and preserving HTT expression through targeting based on the single nucleotide polymorphisms (SNPs) rs362307 (SNP1) and rs362331 (SNP2), respectively. Patients on a 16 mg dose of WVE-120101 showed an average reduction of 11.6% in the concentration of mHTT in the CSF, while those treated with a 32 mg dose of WVE-120102 had an average decrease of 9.9%. No significant changes in CSF NfL levels were observed in either ASO. As for adverse effects, most were mild to moderate in intensity, but there was an increase in the number of serious adverse effects, such as ataxia, meningitis, and delirium, in patients taking the 32 mg dose of WVE-120102. **Conclusion:** Despite being a promising therapeutic approach for HD, ASOs are not yet completely effective for treating the disease. Promoting a substantial reduction in mHTT levels as well as reducing the occurrence of adverse effects represent challenges to be overcome in the development of effective ASOs for HD.

https://doi.org/10.5327/CBN241729

Use of anxiolytics and antidepressants in medical students

Clara Alves Caram[1], Lucas Seri Iijima[1], Mércia Tancredo[1]

[1]Pontifícia Universidade Católica de São Paulo, Sorocaba SP, Brazil.

Correspondence: Clara Alves Caram; Email: claracaram@outlook.com.

Background: Medical students are constantly subjected to an intense routine from the beginning of their degree, with many activities and demands, which can lead to emotional and physical exhaustion. Consequently, the feeling of incapacity, which favors symptoms of anxiety and depression. Emotional signs and symptoms include depressive mood, apathy, pessimism, highlighting the delay in thinking and action, which has a direct impact on students' academic performance. Anxiety disorders and depression affect university students in general and this rate is even higher in medical students, due to the high study workload and the emotional stress faced by these students. **Objective:** To identify the prevalence of anxiety and depression among medical students and the presence of anxiolytics and/or antidepressants. **Methods:** After approval by the Ethics and Research Committee and acceptance of the Free and Informed Consent Form, medical students responded to a semi-structured, self-administered questionnaire developed for this research, created using Google Forms. **Results:** Of the 102 students surveyed, the majority (55.9%) used medication for depression or anxiety. When segmenting for clinical indication, most participants (82.5%) cited anxiety, followed by depression (47.4%), insomnia (17.5%), premenstrual tension (5.3%), obsessive compulsive disorder (3.5%) and one bipolar disorder student (1.8%). Among users of antidepressants and anxiolytics, they use the medications as prescribed by psychiatrists (84.3%), followed by neurologists (11.8%). It is important to highlight that 49.1% have been using it for more than 2 years. **Conclusion:** The vast majority of medical students reported a diagnosis of anxiety and/or depression and the continuous use of anxiolytics and antidepressants for more than two years, demonstrating that even when using these psychotropic drugs continuously, the signs/symptoms of anxiety and depression remain, characterizing the chronicity and resistance of this pathology, which highlights the need for reassessment of treatment methods.

https://doi.org/10.5327/CBN241730

Use of artificial intelligence for brain mapping and surgical planning

Julio Cerqueira Sampaio[1], Bruna Rios Beserra[1], Lara de Oliveira Boaventura[1]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.

Correspondence: Bruna Rios Beserra; Email: brunabeserra23.1@bahiana.edu.br.

Case presentation: In 2022, a 44-year-old female patient from Salvador, Bahia, with a pre-diagnosed tumor in the posteromedial region of the left cerebral lobe, was admitted to the hospital due to a significant worsening of the neurological condition, in which the patient presented aphasia, low level of consciousness, intense headache, emesis, paresthesia in the right hemibody and difficulty processing working memory. At the time, the patient tested positive for COVID-19, which led to the neurological symptoms being associated with a viral infection. However, a new computed tomography scan showed significant tumor growth, with signs of degeneration suggestive of high-grade glioma. **Discussion:** Given the situation exposed, the surgical procedure to remove the tumor was performed, so a mapping of brain networks was used using magnetic resonance imaging with Omniscient Neurotechnology technology, the Quicktome. This resource assisted in surgical planning provided a clear visualization of brain areas affected by the tumor and brain areas that were at risk of being injured during resection, such as the limbic/paralympic system and the medial temporal system. **Final comments:** At this time, brain mapping carried out using Quicktome, based on studies from the Human Connectome Project, emerged as the safest method for performing the surgery, as it was this resource that provided a safe corticectomy without significant sequelae for the young patient. Therefore, the present work aims to highlight the importance of knowing individual brain tracts, as well as the importance of using software such as Omniscient Technology, which can bring greater safety to the procedure and a better prognosis for the patient.

Use of audiovisual resources in the teaching of the photomotor reflex

Akson Isaac Oliveira de Souza[1], Giovana de Sousa Ferro Barbosa[1], Giulia Veloso Matias Santos[1], Luciana dos Santos Viana[1], Carlos Eugênio Rangel Vieira[1], Caio Vinicius Seixas Freitas[1], Helena Vieira Goudard[1], Jussara Mathias Netto Khouri[1]

[1]Universidade Federal do Rio de Janeiro, Macaé RJ, Brazil.

Correspondence: Akson Isaac Oliveira de Souza; Email: aksonisaac5@gmail.com.

The photomotor reflex, or pupillary light reflex, is characterized by the contraction of the pupils in response to a light stimulus that penetrates the eye. This mechanism involves connections between the retina and brainstem neurons, mediated by cranial nerves. Assessment of this reflex is a crucial step during the neurological examination, both in alert and comatose patients (Bear et al., 2017). Information and Communication Technologies (ICT) inserted in the educational environment offer teachers different ways of streamlining classes, in addition to stimulating new learning skills. Such resources are facilitating tools in the teaching of neurology, whose physiological and anatomical bases are often challenging and real barriers for medical students, due to their complexity (Schon et al., 2002). Didactic videos, for example, allow students a practical visualization of the topic, helping to avoid these unknown knowledge gaps during graduation (Nascimento et al., 2022). This work aims to create an animation as a teaching tool to demonstrate the neural pathway of the pupillary light reflex and its clinical importance. The animation will address the anatomical, physiological and clinical aspects of the photomotor reflex arc exam in a dynamic way, improving the learning process. It is concluded that knowledge of the afferent and efferent pathways of the photomotor reflex is fundamental for the physician, given its clinical relevance in the evaluation, diagnosis and monitoring of neurological patients.

https://doi.org/10.5327/CBN241732

Use of benzodiazepines in sleep disorders in the elderly population: a systematic review

Kerolayne Lisa Thimoteo da Costa[1], Daniel Lima Varela[1]

[1]Atitus, Passo Fundo RS, Brazil.

Correspondence: Kerolayne Lisa Thimoteo da Costa; Email: kerolayne_thimoteo32@outlook.com.

Objective: This study sought to investigate in a generalized and rigorous way, through a systematic review, the use of benzodiazepines in the treatment of insomnia in the elderly, verifying their efficacy, effectiveness, possible benefits, and potential risks with chronic use. **Methods:** In this study, we considered high-qua- lity scientific works published in journals with a high impact factor, and that discussed the use of benzodiazepines in the elderly population as a method of treatment for insomnia. This research includes experimental, randomized clinical trials, preferably double-blind and with a control group, as well- conducted prospective observational studies on the proposed subject matter, and published between January 2013 and January 2022. Studies carried out on animals, adul- ts, and elderly people who are not taking benzodiazepines were not included in the analysis. Case studies and reports, literature reviews, systematic reviews, and meta- analyses were also excluded from this study. This process of elaborating and conducting the systematic review was guided by the guidelines of the PRISMA protocol. **Results:** The use of benzodiazepines in old age is controversial, as these drugs can cause a series of side effects, including congnitive impairment, excessive sedation, and the risk of falls. Tolerance and dependence on these drugs must also be taken into account. Therefore, the use of benzodiazepines should be monitored safely and restricted to a certain time period. Considering the risks and side effects associated with the use of benzodiazepines, it is crucial to consider alternative therapeutic measures, such as Sleep Hygiene and Cognitive Behavioral Therapy. **Conclusion:** This review provides key insights into the impact of the use of benzodiazepines in the elderly population for the treatment of insomnia, consolidating significant evidence that highlights the importance of sleep in health during aging. This work highlights the importance of a holistic approach in the treatment of insomnia in the elderly. Considering clinical, psychosocial and behavioral aspects, it is possible to develop care plans that improve the quality of life of the elderly, promoting healthy sleep and, consequently, healthy aging.

https://doi.org/10.5327/CBN241733

Use of cannabidiol in refractory epilepsy with positive outcome: case report

Karen Arissa Iwase[1], Rafael Gustavo de Mello Couto[1], Barbara Franco Martins[1], Anna Claudia Lavoratti[1], Livia Ceolin Valério[2], Maria Julia de Souza Padulla[1], Laura Regovichi[2], Bianca Gomes Suckel[1], Carolina Brun Ferrarini[1]

[1]Centro Universitário Fundação Assis Gurgacz, Cascavel PR, Brazil.
[2]Unicesumar.

Correspondence: Karen Arissa Iwase; Email: karen.arissa@outlook.com.

Case presentation: Patient R.S, a 24-year-old female, was referred to a Reference Center in the West of Paraná for investigation of refractory epilepsy in 2018 following a status epilepticus (SE), during which she experienced recurring convulsive seizures without regaining consciousness between them. She reports suffering from generalized tonic-clonic and absence seizures, as well as focal seizures, for the past 10 years. Her first convulsive seizure occurred at the age of 8, and since then, she has not achieved adequate control of this pathological condition with medication, fitting the diagnosis of difficult-to-control refractory epilepsy. **Discussion:** In 2018, during the patient's first consultation at the Reference Center, she was already on several medications, including topiramate, lamotrigine, valproic acid, and carbamazepine. Subsequent consultations involved dose increases of these medications, yet the patient continued to experience frequent generalized seizures. Levetiracetam was added progressively to the regimen, along with increased doses of the other anticonvulsants, reaching maximum doses. However, the patient still experienced frequent seizures. In 2023, progressive doses of cannabidiol were introduced (current dose 200mg every 12 hours), and since then, the control has been very

satisfactory. As a result, the patient reports brief absence seizures, approximately 4 per month, and has not experienced any further episodes of generalized tonic-clonic seizures or the need for hospitalization. There has been a significant improvement in the quality of life perceived by the patient and her family. Currently, there has been a reduction in the dose of the current anticonvulsant regimen, with the patient currently taking Levetiracetam 750mg, two tablets every 12 hours; lamotrigine 100mg every 12 hours; Valproic acid 500mg every 12 hours, in addition to cannabidiol 200mg/ml, 1 ml every 12 hours. **Final comments:** Epilepsy is one of the major neurological diseases affecting young adults worldwide, and treatment with anticonvulsants fails to control seizures satisfactorily in over 30% of the population, directly impacting patients' quality of life, autonomy, and self-esteem. There is a need to explore alternative treatments, such as Cannabis derivatives, in which one of the main active components is cannabidiol (CBD), responsible for its anticonvulsant properties and the absence of typical psychoactive effects of Δ-9-tetrahydrocannabinol (THC). Furthermore, this derivative has been shown to be safe over a wide dosage range and has not produced significant adverse effects.

Use of FilmArray® ME in the diagnosis of suspected central nervous system infections: experience in 2,502 cases

Renan Domingues[1], Irineu Massaia[1], Daiane Salomão[1], Márcio Vega[1], Myrna Monteiro[1], Camila Spinelli[1], Lais Guerra[1], Carlos Senne[1]

[1]Senne Liquor Diagnóstico, São Paulo SP, Brazil.

Correspondence: Renan Barros Domingues; Email: contato@renandomingues.med.br.

Background: The FilmArray® meningitis/encephalitis is a real time multiplex PCR for identifying 14 CNS infection agents, including bacteria, Cryptococcus and viruses. **Objective:** In this study, we retrospectively evaluated the clinical utility of using this method, in cerebrospinal fluid (CSF), in samples from patients with suspected neuroinfection. **Methods:** We retrospectively evaluated data from 2,502 CSF samples from patients with suspected CNS infection in whom CSF was submitted to the FilmArray®. The diagnostic utility of this panel was evaluated. **Results:** 888 tested CSF samples (35.5%) were positive with FilmArray®. Enterovirus was the most common agent, being present in 539 (60.7%) of the positive samples. 86 samples (9.7%) were positive for bacteria. Streptococcus pneumoniae was the most common bacterial agent identified by FilmArray, in 35 of the 86 CSF samples positive for bacterial infection (40.7%). In 21 out of the 2502 samples (21.4%) the etiological agent was identified by a microbiological method other than FilmArray, including bacterioscopy and culture. Of the 1614 FilmArray negative samples, an infectious agent was identified by conventional microbiology method in 4 cases, namely: Micrococcus sp, Escherichia coli, Streptococcus intermedius and Pseudomonas aeruginosa. Three out of these 4 samples were diagnosed as meningitis based on cytological and biochemical analysis of the CSF. **Conclusion:** FilmArray® was able to identify the etiology of neuroinfection in 867 cases where other etiological identification methods did not reveal the causative agent. In only 3 cases of meningitis, FilmArray was negative while a conventional microbiological test was positive. Therefore, FilmArray considerably increases the likelihood of an etiological diagnosis in cases of neuroinfection.

Use of fingolimod in patients at a reference center for demyelinating diseases of Recife-PE: epidemiological characteristics and association with HLA-G

Bruno Paulo Teles Chaves[1], Vanessa Cristina Fragoso Cassiano Alencar[1], Marcílio José de Oliveira Filho[1], Mauricéa Novaes Costa Pereira[1], Lidiane Alves de Macedo Souza[1], Nathalia Saraiva Ramos e Cruz[1], Maria Iris Moraes Machado[1], Álvaro J P Silva Moreira[1], Norma Lucena Silva[1], Maria Lucia Brito Ferreira[1]

[1]Hospital da Restauração, Recife PE, Brazil.

Correspondence: Bruno Paulo Teles Chaves; Email: brunopaulo.c@gmail.com.

Background: Multiple sclerosis (MS) is an inflammatory disease with associated neurodegeneration affecting the central nervous system (CNS). In the preclinical and clinical studies performed to date in MS, fingolimod has been proven to exert different protective effects, including inhibition of lymphocyte egress, inhibition of microglial and astroglial activation, reduction of neuronal death, restoration of lost synapsis, and reduction of dendritic spine loss, among others. HLA-G is an immunological checkpoint molecule, which is immunoprotective in some physiological situations, such as pregnancy. he role of the HLA-G molecule in multiple sclerosis has been studied considering the specific characteristic of immune mediation, related to reactivation of T lymphocytes, presence of meningeal inflammatory cell niches B and Th17 lymphocyte populations. The expression of HLA-G or sHLA-G has been associated with poor survival, poor prognosis, therapeutic response, clinical and outcomes in various malignancies. **Objective:** To evaluate the profile of patients using fingolimod in a health center reference in demyelinating diseases in Recife-PE. Assess whether there is any variable that determines better or worse outcome related to the use of fingolimod, establishing sHLA-G levels in individuals who used the treatment. **Methods:** Ninety patients who underwent treatment with fingolimod at some stage of treatment were selected in an institutions database. **Results:** Seventy-one patients were female (78.8%). Fingolimod was initiated as first-line treatment in 14 patients (15.6%), 61 as second line (67.8%), 13 as third line (14.4%) and 2 as fourth line (2.2%). Of the patients who started fingolimod as second-line treatment, eight were using glatiramer acetate (13.1%) and 53 were using interferon (86.9%). Therapeutic failure ocurred in 44 patients (72.1%), with radiological worsening in 35 patients (57.4%). Of the patients who used fingolimod as second-line treatment, eight patients experienced therapeutic failure (13.1%), requiring a change to third-line medication. Therapeutic failure ocurred in 3 patients (23%) who used fingolimod as third-line treatment. The analysis of sHLA-G levels was carried out in 17 patients using fingolimod (N=2) and interferon (N=15) as first-line treatment. Patients using interferon had the highest levels of sHLA-G and resistance to the drug, being eligible for the use of fingolimod as a treatment for second (N=11) and third (N=4) lines. **Conclusion:** It's possible to observe that the majority of patients use fingolimod as second-line therapy, with a low rate of therapeutic failure. To clarify a possible connection between the use of fingolimod and low sHLA-G levels and better clinical response, it's necessary measuring sHLA-G levels after switching interferon treatment protocol for fingolimod and expanding the number of tests.

Use of fingolimod in pediatric multiple sclerosis: assessment of patients from a specialized center

Mariana de Oliveira Trintinalha[1], Danielle Karla Feitosa Alves Feitosa[1], Alfredo Damasceno[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Mariana de Oliveira Trintinalha; Email: marianaatrintinalha@hotmail.com.

Background: Multiple sclerosis (MS) is a chronic inflammatory disease of the central nervous system, which mainly affects young women, however 2-5% of cases occur in children under 18 years of age, pediatric MS. Due to the greater risk of progression at this stage, the choice of treatment is very important. Two main strategies: scaling and high effectiveness. Among the highly effective medications is Fingolimod (non-specific sphingosine 1 phosphate receptor agonist), the first medication studied and released in pediatric MS. There is a scarcity of data in this population. **Objective:** To evaluate the characteristics of patients using Fingolimod in the outpatient clinic. **Methods:** Retrospective observational study with medical record analysis. Included patients diagnosed with pediatric MS, under 18 years of age at diagnosis, using BRANDO (ColaBoRative LAtin AmericaN Database for Multipe SclerOsis). **Results:** 7 patients in the pediatric age group using Fingolimod. The average age was 17 years old, 86% girls and 14% boys. All had RRMS. EDSS at diagnosis: 4 patients with unknown prior EDSS, three with EDSS of 1, 1.5, and 4. EDSS currently: 1 patient with EDSS of 1, 3 patients with EDSS 1.5, 2 with EDSS 2.5, and 1 with EDSS 0. The history of outbreaks before Fingolimod: 28.57% had 6 outbreaks and 14.29% had 1, 3 and 4 outbreaks. None had clinical flare-ups after fingolimod at the time of evaluation. Children are closer to the biological onset of the disease, so treatment at this stage determines long-term results. An important factor is the immaturity of the immune system, which can increase susceptibility to autoimmune diseases. There are several therapies for adults, however the safety of many has not been evaluated in children. Interferons and Glatiramer are started more frequently, approximately one third of these patients fail early and change treatment within the first 6 months. The PARADIGMS study demonstrated that Fingolimod was superior to Interferon β-1a in patients with RRMS aged 10 to 17 years, with lower rates of attacks and lesions on Magnetic Resonance Imaging (MRI). Immovilli et al., 2022 described a 13-year-old patient, after 2 years of using Interferon β-1a, he presented new lesions and was switched to Natalizumab, interrupted due to adverse effects, opting for Fingolimod, after 2.5 years, which patient was in NEDA 3 (absence of flare-ups, active lesions and no worsening in EDSS). The results from our study are consistent with the literature, 7 patients have shown no activity or progression of the disease to date. **Conclusion:** Fingolimod can be a suitable option, with a good tolerability and disease control profile, demonstrated in our patients and in the literature.

Use of immunophenotyping and cytomorphology in cerebrospinal fluid (CSF) samples for diagnosis of neurological involvement in patients with leukemia

Renan Barros Domingues[1], Irineu Massaia[1], Myrna Monteiro[1], Márcio Vega[1], Camila Spinelli[1], Lais Guerra[1], Daiane Salomão[1], Carlos Senne[1]

[1]Senne Liquor Diagnóstico, São Paulo SP, Brazil.

Correspondence: Renan Barros Domingues; Email: contato@renandomingues.med.br.

Background: Lymphoid and myeloid leukemias are hematological neoplasms with the highest risk of central nervous system infiltration. The presence of neurological involvement in these conditions has very important therapeutic consequences. The diagnosis of this infiltration can be made through cytomorphology and immunophenotyping in CSF samples. **Objective:** To evaluated the results obtained with both methods in CSF samples obtained from patients with acute and chronic, lymphoid and myeloid leukemias, investigating the diagnostic performance of both methods. **Methods:** We retrospectively evaluated immunophenotyping and cytology data of CSF samples, assessed by two examiners, from 797 CSF samples from

patients with acute lymphoid leukemia (ALL), 19 cases of chronic lymphoid leukemia (CLL), 120 samples from patients with acute myeloid leukemia (AML), and 15 with chronic myeloid leukemia (CML). We also recorded the total cell count in the CSF of these patients and the percentage of samples with pleocytosis among those with confirmed neurological involvement. **Results:** Positivity with at least one method was obtained in:

- 163 cases of ALL (20.5%), with 79 (48.5%) positive with both methods, 6 (3.4%) positive only with cytology, and 78 (47.8%) positive only with immunophenotyping.
- 6 out of the 19 cases of CLL were positive with both methods and 8 were positive only with immunophenotyping.
- Forty cases of AML (33.3%), with 28 (70%) positive with both methods, 7 (17.5%) only with cytology, and 5 cases (12.5%) positive only with immunophenotyping.
- Nine out of 15 cases of CML (60%) were positive, with 7 being positive with both methods (77.8%), 1 case (11.1%) positive only with immunophenotyping, and 1 case positive only with cytology. Increased CSF cellularity among patients with CNS infiltration was found in:
- 42 (25.8%) cases of lymphoid leukemias
- 20 (50%) cases of AML, and all 9 cases of CML.

Conclusion: Immunophenotyping significantly increased diagnostic sensitivity for CNS infiltration, particularly in lymphoid leukemias. Immunophenotyping and cytology had similar diagnostic sensitivity in cases of CNS infiltration by AML and CML. The results confirm the importance of paired testing with both examinations. Only one in four cases of lymphoid leukemias and only half of the cases of myeloid leukemias with meningeal neoplastic infiltration showed increased CSF cellularity, highlighting the need for specific tests to increase the chances of detecting an infiltrative process.

Use of telemedicine as a tool in the evaluation of traumatic tomographic changes for emergency referrals in secondary care hospitals in Rio Grande do Sul

Guilherme Nobre Nogueira[1], Rafaela Fernandes Gonçalves[2], Gustavo Rassier Isolan[2]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.
[2]Faculdade Evangélica Mackenzie do Paraná, Curitiba PR, Brazil.

Correspondence: Guilherme Nobre Nogueira; Email: guiermenobre@gmail.com.

Background: Neurotrauma represents a significant medical emergency, with the proper management of these patients being a major concern for healthcare professionals. In this context, telemedicine emerges as a significant advancement in the rapid diagnosis and treatment of individuals who have suffered neurological trauma. Delayed management of cranioencephalic and spinal cord injuries can result in a worsening prognosis for patients. **Objective:** Tto evaluate the use of telemedicine in assisting with traumatic tomographic changes, based on the different clinical histories of each patient. **Methods:** This is a cross-sectional, retrospective study involving 355 patients from 14 hospitals in the states of Rio Grande do Sul and São Paulo, conducted from April 2019 to October 2022. All patients signed an informed consent form for this research, and the data collection adhered to the General Data Protection Law. **Results:** The association between tomographic changes and the clinical history of the patients (categorized as follows: spinal cord injury (SCI) due to fall, SCI due to assault, traumatic brain injury (TBI) due to fall, TBI due to assault, TBI due to motor vehicle accident, progressive neurological symptoms, headache, and sudden neurological symptoms) was analyzed for the 355 patients. Of these, 23 (6.48%) suffered SCI due to fall, 23 (6.48%) suffered SCI due to assault, 88 (24.79%) suffered TBI due to fall, 46 (12.96%) suffered TBI due to assault, 46 (12.96%) suffered TBI due to motor vehicle accident, 90 (25.35%) presented with progressive neurological symptoms, 38 (10.7%) with headache, and 1 (0.28%) with sudden neurological symptoms. The analysis of the relative frequency underscores the clinical importance of each cause and aids in prioritizing care and resource allocation in emergency services. These data are crucial for guiding appropriate medical approaches in emergency cases and implementing effective prevention strategies to reduce the incidence of traumatic injuries. **Conclusion:** Telemedicine effectively addresses traumatic tomographic changes due to the increased likelihood of treatment within short care windows. Thus, telemedicine emerges as a significant approach to improving the survival and quality of life of post-traumatic individuals.

Use of the erasmus GBS respiratory in sufficiency score in predicting mechanical ventilation: a study of Brazilian patients with Guillain-Barré syndrome

Miguel Inácio Silva Gomes[1], Fátima de Menezes Dantas[1], José Víctor Carvalho Dantas Gualberto[1], Heric Weverton dos Santos[1], Mário Emílio Teixeira Dourado Júnior[1], Selma Maria Bezerra Jerônimo[1]

[1]Universidade Federal do Rio Grande do Norte, Natal RN, Brazil.

Correspondence: Miguel Inácio Silva Gomes; Email: miguel.inaciosg@gmail.com.

Background: mEGRIS is a score that predicts the risk of a patient with Guillain-Barré Syndrome requiring mechanical ventilation during the first week of hospitalization. This score is a simplified version of the EGRIS score, but it has not yet been validated in Brazil. **Objective:** To evaluate the effectiveness of mEGRIS in predicting the risk of mechanical ventilation after 1 week of hospital admission in Brazilian patients with Guillain-Barré syndrome. **Methods:** A retrospective study was conducted, in which the medical records of 50 Brazilian patients diagnosed with Guillain-Barré syndrome between 2017 and 2024 were evaluated. The following data were collected to calculate mEGRIS: time from onset of weakness to hospital admission (in days), bulbar weakness (yes or no), cervical weakness (MRC 0 to 5) and bilateral psoas weakness (0 to 10). Each patient's classification on the Hughes Disability Scale was also recorded after 1 week of onset of motor symptoms. A Mann-Whitney U test was used to compare the mEGRIS of patients who underwent mechanical ventilation (Hughes 5) with those who did not (Hughes < 5). The variables were correlated using a Spearman test. The study was approved by the Local Ethics Committee (CAAE: 75882923.7.0000.5292) and all participants signed an informed consent form. **Results:** The median mEGRIS of patients undergoing mechanical ventilation was 25.0 (18.5 - 27.0), while that of those not undergoing mechanical ventilation was 4.0 (1.0 - 7.0), p<0.0001. As none of the patients died in the 1st week, there were no cases of Hughes 6, which would be a possible confounding factor in the analysis. The median time from disease onset to hospital admission was 4 days for patients undergoing mechanical ventilation (2 - 7 days), whereas those not undergoing mechanical ventilation had a median of 6 days (4 - 10 days), p= 0.231. The mEGRIS and Hughes variables showed a strong positive correlation (r=0.7857). **Conclusion:** Final analysis suggests that mEGRIS is effective in predicting the risk of mechanical ventilation after 7 days of hospitalization in Brazilian patients diagnosed with Guillain-Barré syndrome. Since it has similar accuracy to EGRIS, even with the assessment of a smaller number of muscle groups, mEGRIS is a valuable tool for emergency contexts. General practitioners can be trained to apply it, in order to identify patients at risk of developing respiratory failure at an early stage. To confirm our results, prospective studies with larger cohorts need to be carried out.

https://doi.org/10.5327/CBN241740

Use of the palliative care screening tool for patients admitted for ischemic stroke

Luciana de Oliveira Neves[1,2], Igor Bessa Santiago[1], Vitor Silva Abreu[1], Lara Carvalho de Oliveira[1], Carmem Rachel Alves de Paula Flôr[1], Benevides José Silva Santos[1], Clarissa Rocha Montenegro[1], João Renato Figueiredo Souza[1], Karla Maria Carneiro Rolim[2], Paulo Goberlânio[3]

[1]Hospital São Carlos, Fortaleza CE, Brazil.
[2]Unichristus, Fortaleza CE, Brazil.
[3]Universidade de Fortaleza, Fortaleza CE, Brazil.

Correspondence: Luciana de Oliveira Neves; Email: dra.luciananeves@gmail.com.

Background: Stroke is an important cause of morbidity and mortality in Brazil and worldwide and one of the main pathologies to consider Palliative Care. Many advances have been made over the years, and there is no doubt about the importance of effective acute care for therapies such as thrombolysis and thrombectomy in acute ischemic stroke. The Palliative Care Screening Tool (PCST) is a tool that can be useful for screening patients to be referred to Palliative Care. **Objective:** To evaluate the usefulness of the PCST for patients admitted in the acute phase of stroke, undergoing thrombolysis and/or thrombectomy in a high complexity hospital during 2021. **Methods:** This is an observational, retrospective study, with data obtained through the analysis of medical records of patients hospitalized for acute ischemic stroke and undergoing thrombolysis and/or thrombectomy, in 2021. The study is part of the project approved by the Ethics and Research Committee of hospital itself. Two neurologist researchers evaluated the admission note and two others, the last evolution of hospitalization, using Google Forms. The following variables were evaluated: age, sex, NIH Scale (National Institutes of Health Stroke Scale) and Rankin on admission and discharge, outcome and whether Palliative Care was addressed. Upon admission, the PCST scale was applied, with its score categorized as up to 2 points: no indication of Palliative Care; up to 3 points: clinical observation; ≥4 points: consider Palliative Care. Data analysis was carried out using the SPSS program, obtaining the frequencies and means of the variables and the kappa index between the evaluators. **Results:** 14 medical records were evaluated. 57.14% of patients were male and the average age was 74.71 years. 71.4% underwent intravenous thrombolysis, 21.42% thrombolysis and mechanical thrombectomy and 7.14% thrombectomy alone. The average NIH admission among the researchers was 12 and 11 and the Rankin was 0 and 2. When using the PCST, for one researcher, 14.28% and for another 21.42% of patients should be referred to Palliative Care. Regarding the outcome, the average NIH of patients who were discharged was 5 and 3 and the average Rankin was 2.71 for both. Three patients (21.14%) died during hospitalization, one of which was mentioned Palliative Care in the medical record. The PCST Kappa index among the researchers who evaluated the admission was 0.759, with a significance of 0.003. **Conclusion:** The study demonstrated that the PCST has a good agreement between evaluators and could have been useful in detecting patients with a profile for a palliative approach. The use of assessment instruments can help with more assertive and person-centered decision-making. A characteristic of the place studied is that the Palliative Care team was only active at the end of the 2nd semester. As an improvement, the authors suggest a new prospective study with a larger number of participants.

https://doi.org/10.5327/CBN241741

Use of the Wobble Chair to evaluate trunk postural control in individuals with Parkison's disease

Thayná Lye Ishii[1], Hayslenne Andressa Gonçalves de Oliveira Araújo[1], Sarah Possetti Godoi[1], Natália Mariano Barboza[1], Andressa Leticia Miri[1], Renata Pasquarelli Volpe[1], Suhaila Mahmoud Smaili[1]

[1]Universidade Estadual de Londrina, Londrina PR, Brazil.

Correspondence: Sarah Possetti Godoi; Email: sarahpossetti@gmail.com.

Background: Trunk postural control is crucial for our transfers and is an essential part of providing postural stability, especially in individuals with Parkinson's disease (PD). **Objective:** To evaluate trunk postural control in individuals with PD in the seated position using a Wobble Chair and to analyze the influence of cognitive and motor demands on their postural stability. **Methods:** A cross-sectional study with a sample of 15 individuals with idiopathic PD in mild to moderate stages. The Mini-Mental State Examination was used for cognitive assessment, and the modified Hoehn & Yahr and the Unified Parkinson's Disease Rating Scales were used to assess disease staging and progression, respectively. Trunk mobility and functional independence were measured using the Trunk Mobility Scale, and the Schwab and England Activities of Daily Living Scale. Postural control was assessed using the Wobble Chair, an instrument based on a force platform with a pivot and spring system that creates an unstable base for evaluating trunk control while in the seated position. Participants underwent four different conditions: a) eyes open (EO) - control position; b) eyes closed (EC); c) dual-task cognitive (DT); and d) no foot support (NF). The conditions were randomized, repeated twice for 30 seconds each, with a 30-second interval between each of them. The outcome measures collected were center of pressure (COP) sway area, anteroposterior (AP) and mediolateral (ML) amplitudes, as well as AP and ML velocities. Friedman's test was used for comparison between test conditions, considering $p<0.05$. Ethical approval is under opinion 31775420.8.0000.0108. **Results:** A larger COP area, amplitudes, and velocities were observed in the DT condition compared to the EO condition. The DT condition also showed greater AP amplitude and higher AP and ML velocities compared to the NF condition. Furthermore, the DT condition exhibited higher postural control values compared to the EC condition for the variables of AP and ML velocity. Thus, the DT condition was the most challenging position with increased activity of postural control indicators. There was no significant correlation between any trunk postural control variables and trunk mobility and functional independence assessments. **Conclusion:** The evaluation of trunk control while in the seated position in individuals with PD showed greater postural instability in more challenging positions, specifically when adding dual-task cognitive demands and removing visual stimuli, in all balance variables measured using the Wobble Chair, especially AP and ML velocities. Assessing postural control in the seated position under different conditions can aid in understanding neuromuscular strategies and treating postural control in individuals with PD, as most studies are conducted on individuals in the standing position.

Use of transcranial doppler and optic nerve sheath diameter ultrasonography in acute idiopathic intracranial hypertension: a case report

Thamires Marx da Silva Santos[1], Rodrigo Santiago Gomez[1], Sabrina Gesteira Souza[1], André Luis de Oliveira Silveira[1], Italo Pena Guimarães[1], Nathália Luísa Carlos Ferreira[1], Gustavo Carvalho Oliveira Gonçalves Machado[1], Maria Luiza Nóbrega Lima de Albuquerque[1], Bernardo Gomes Muffato[1]

[1]Universidade Federal de Minas Gerais, Hospital das Clínicas, Belo Horizonte MG, Brazil.

Correspondence: Thamires Marx da Silva Santos; Email: marxthamires@gmail.com.

Case presentation: We report the case of an 18-year-old female patient admitted with a 25-day history of headache and visual blurring with progressive worsening. She was obese, having gained 25 kg in the last 4 months, without other comorbidities. Upon admission, she had a perception of movement in the right eye, with restriction of ocular movement in all directions, and in the left eye, she could count fingers at 10 cm and had restricted abduction. Bilateral papilledema was noted on fundoscopic examination. Cranial tomography revealed intraocular protrusion of the optic discs, thickened optic nerves bilaterally, and a partially empty sella turcica. A lumbar puncture was performed, with cerebrospinal fluid analysis within normal limits and an opening pressure of 85 cmH2O, determining, according to the International Headache Society criteria, the diagnosis of idiopathic intracranial hypertension (IIH). In the initial transcranial Doppler (TCD) study, signs of intracranial hypertension were observed with a mild to moderate increase in the pulsatility index (PI) in the middle cerebral artery bilaterally and the right vertebral artery, and an increase in mean velocity (MV) in these vessels. The ultrasonography of the optic nerve sheath diameter (ONSD) showed a significant bilateral increase, also indicating intracranial hypertension. A lumboperitoneal shunt was chosen, along with treatment with acetazolamide, topiramate, and five days of pulse therapy with methylprednisolone. The patient showed significant improvement in headache and partial improvement in visual acuity in both eyes (20/200 on the Rosenbaum chart), improvement in right eye ophthalmoparesis, with persistent left eye abduction restriction. The TCD performed after therapeutic measures showed normalization of MV and PI in the studied arterial segments, indicating improvement after intracranial pressure (ICP) reduction. **Discussion:** IIH is a disease of unknown etiology, presenting with signs and symptoms of elevated ICP in the absence of structural lesions or other identifiable causes. One of the main risk factors is obesity, and with the current global obesity epidemic, the incidence of IIH has increased considerably, making diagnostic, treatment, and follow-up measures increasingly important. Currently, ICP measurement is performed via lumbar puncture, an invasive and uncomfortable procedure for the patient. Non-invasive methods such as TCD and ONSD ultrasonography are being studied for indirect ICP assessment in these cases. Literature shows that increased ICP significantly affects cerebral blood flow, altering parameters evaluated by TCD, such as MV and PI, which tend to normalize after adequate treatment and ICP reduction, and that ONSD measurements have a positive correlation with ICP. **Final comments:** TCD and ONSD ultrasonography are useful, non-invasive, and low-cost tools that can potentially be implemented for the diagnosis, monitoring, and clinical management of patients with IIH.

Use of virtual reality as a treatment for motor functions in patients with Parkinson's disease: a systematic review and meta-analysis

Luiz Carlos Figueiredo Filho[1], Walter Oliveira Verissimo[2], Ricardo Massoud Ormanes[1], Rafael Augusto Silva Cabeça[1], Ingrid Jade Muniz Wanderley[1], Alexandre Marques da Rocha[1], Luanna de Melo Pereira Fernandades[1], Leonardo Yuji Nihira Alencar[2]

[1]Universidade do Estado do Pará, Belém PA, Brazil.
[2]Universidade Federal do Pará, Belém PA, Brazil.

Correspondence: Leonardo Yuji Nihira Alencar; Email: leo1820.alencar@gmail.com.

Background: Parkinson's disease (PD) is degenerative, causes tremors, bradykinesia and muscle rigidity, and affects almost 1% of the world's population. Diagnosis is clinical, but accuracy is challenging due to overlapping symptoms and lack of a specific cause. In this sense, virtual reality (VR) can improve the treatment of the disease, complementing physiotherapy and developing physical, mental and emotional skills. **Objective:** To evaluate the use of virtual reality in rehabilitating Parkinson's patients, focusing on motor prognosis, balance, gait, coordination and quality of life. **Methods:** This is a systematic review with meta-analysis, defined using the PICOS strategy, where (P) patients with Parkinson's disease; (I) virtual reality; (C) conventional treatment; (O) improvement in motor symptoms, gait, balance and daily activities. The Preferred Reporting in Systematic Reviews and Meta-Analyses (PRISMA) guidelines were used. Scientific articles from randomized clinical trials (RCTs) and quasi-randomized clinical trials (QRCTs) were included. The articles were collected from the PUBMED/MEDLINE, VHL, Embase, Cochrane Database, Web of Science and Clinical Trial.gov databases. The results were arranged in tables using the Microsoft Excel 2016 program, according to the variables: author, year, age of participants, gender, type of intervention, evaluation protocol, outcomes analyzed and supervision by professionals during the test application. The meta-analysis was carried out using Review Manager 5.4 software. Heterogeneity between studies was assessed using the Chocran Q test and I2 statistic and interpreted following the Cochrane Handbook for Systematic Reviews of Interventions. **Results:** We identified 492 articles in the databases. After removing duplicates, 323 were selected, 119 full articles were assessed for eligibility, and 25 were included in the final synthesis of the review. It was observed that VR induced beneficial changes in balance when using the BBS scale MD=2.22 (95%CI 1.58-3.63, $p< 0.00001$) and improved motor function using the UPDRSIII index MD=-4.4 (95%CI -7.97; -1.71, $p=0.002$) when compared to conventional treatment. However, no substantial difference was found between the physiotherapy and VR groups regarding gait, balance, activities of daily living and motor function, indicating that the interventions are partially effective. The funnel plot showed a symmetrical dispersion in the analysis of clinical heterogeneity and publication bias. **Conclusion:** VR can improve the treatment of PD, it showed comparable efficacy to traditional physiotherapy in balance and motor functions, however, it does not improve all aspects of treatment. Further studies are needed to evaluate the complete integration of VR exercises to overcome the limitations of the few studies available for precise analysis and to definitively establish improvements in the treatment of PD.

Correspondence: Marta Maria da Silva Lira Batista; Email: fonointensivista@gmail.com.

Background: Apraxia of speech is a neurological disorder that affects a person's ability to sequence and coordinate the voluntary movements necessary for the production of

speech sounds, while preserving the cognitive linguistic level. The unpredictability and inconsistency of speech errors are a major challenge for rehabilitation. **Objective:** To identify the most efficient and effective computer model for speech recognition in people with acquired apraxia of speech (AOS). **Methods:** Cross-sectional, prospective, quantitative study. Ten people with apraxia were asked to read a list of words (from monosyllables to polysyllables). The audios were evaluated by 11 speech therapists. The final score per audio considered the phonetic and phonological accuracy of the target word, giving a score between 0 and 100. The data was processed by averaging the scores obtained from the form based on the differences between the averages obtained in the descriptive statistics. The 5 main similarity algorithms for speech recognition (Levenshtein; Jaccard; Jaro-Winkler; Hamming; Caracter Error Rate (CER)) have different characteristics for obtaining similarity between two strings. To evaluate the models, the audio and its correct transcription (string) were used; each model used its own algorithm to translate the audio and obtain its correlated result. Statistical correlation (student's t-test) was used to compare the means obtained by the AOS with the expected means. The study was approved by the CEP under report no. 5111083. **Results:** The average of the judges' results was 80%. The average word analysis of the results evaluated by each algorithm was: Hamming (39.1%); CER (41.1%); Jaccard (53.7%); Levenshtein (60.6%): Jaro-Winkler (75.8%). When analyzing the performance of each algorithm separately, it was possible to determine that the least assertive was CER (660.27 variance), which was considered the least accurate and reliable in the analysis of apaxic speech. CER is widely used in automatic speech recognition systems and therefore does not take into account the general intelligibility of the string, which is highly impaired in AOS. However, the Jaro-Winkler algorithm showed the greatest stability, the lowest variance (n=114.90) and the highest accuracy, capturing well the similarity between strings with small transpositions of characters. In the Person correlation test, Jaccard showed a negative correlation when compared to the judges' averages; this can be explained by the phonological changes that occurred between the speakers, and is a limitation of the algorithm (ineffective in analyzing word sequence order; phonological changes). **Conclusion:** Once an efficient model of apraxic speech has been determined, it will be possible to develop more effective applications aimed at speech rehabilitation for this audience.

Vaccination against polio in Brazilian federal regions from 2014 to 2024: causes, consequences and goals

Luana Cristina de Oliveira Lima[1], Arthur Vinícius Feitosa Santos[1], Vagner Costa da Cunha Júnior[1], Sabrina Sthéphanie Ataíde Martins[1], Maria Cecília Leal Menezes[1]

[1]Universidade Tiradentes, Aracaju SE, Brazil.

Correspondence: Luana Cristina de Oliveira Lima; Email: luana.cristina0410@gmail.com.

Background: Poliomyelitis is an acute contagious disease that can infect children and adults, through direct contact with feces or secretions eliminated through the mouth of sick people and can cause paralysis in the lower limbs in severe cases. Due to declining vaccination coverage over the past 10 years, the Brazil has been classified as very high risk (2022) and high risk (2023) for the reintroduction of wild poliovirus and the emergence of vaccine-derived poliovirus. **Objective:** To describe the drop in vaccinations over a 10-year period, its possible causes, consequences and new national goals. **Methods:** Cross-sectional ecological study, with secondary data from the IT Department of the Unified Health System (DATASUS), the National Vaccination Program (SI-PNI),the SUS Hospital Information System (SIH/SUS) and the Brazilian Institute of Geography and Statistics (IBGE). The variables analyzed are region, Vaccination Coverage (VC) and the human development index (HDI). **Results:** In 2014, national VC reached 96.76%, however the North region was already below the target established by the PNI (95%),with coverage at 90.05%. From 2015 to 2021, the five regions had a decrease in VC, reaching the mark of 71.04%, with the North having the lowest index (62.29%) and the South having the highest (79.98%). Moreover, in the following years, there was a slight increase in vaccination, reaching a coverage of 84.7% in 2023, despite the North, Southeast and Central-West regions maintaining the worst immunization rates, respectively. Regarding the human development index (HDI), of the 10 Brazilian federative units with the highest rates, 7 belong to the regions with the lowest vaccination coverage in 2023, while the Northeast - second highest vaccination coverage index - has the states with the lowest human development indices. **Conclusion:** Therefore,it is noted that,from 2015-2021, vaccination targets were not achieved in any region, a period marked by COVID-19, the reduction of some preventive health services and anti-vaccination movements. From 2022 onwards, the VC increased,however, the targets have not yet been achieved, as the confidence of segments of the population has been affected by the vast circulation of health misinformation on social media. Moreover, on the other hand, it was observed that the regions with the highest HDI had a low VC, which may be related to the strong adherence to the denialist and anti-vaccine movement experienced in recent years, especially in these locations. Regarding regions with lower HDI (North and Northeast), it can be pointed out that there is a correlation between poor immunization and difficulty in accessing public health services. Therefore, it is necessary to raise awareness among the people about the effectiveness and safety of vaccination,informing them about its schedule and the consequences of non-compliance with it, in order to prevent previously eradicated diseases from returning and bringing consequences to the well-being of the society.

[3]Universidade de Pavia, Pavia, Italy.

Correspondence: Jonas Alex Morales Saute; Email: jsaute@hcpa.edu.br.

Background: Hereditary Spastic Paraplegias (HSP) are a group of neurogenetic diseases. The main symptoms are characterized by hyperreflexia, muscle spasticity and weakness that compromises the walking ability. The heterogeneity of these diseases complicates the identification of progression biomarkers; however, spatiotemporal gait parameters are crucial for understanding both normal and pathological gait, making them potential progression biomarkers. Furthermore, Inertial Measurement Units (IMUs), with their portability and ease of use, offer a promising motion capture technology that could aid in identifying the best parameters as progression biomarkers. **Objective:** To evaluate the reliability of an inertial system and a mobile application, compared to a reference motion capture system to capture spatiotemporal parameters in patients with HSP. **Methods:** Twelve patients with PEH were evaluated, 11 of them with SPG4 and 7 with gait independent of assistive devices. Each patient´s gait was assessed using simultaneously a system composed of seven IMUs, a mobile application, and the optoelectronic reference system thought of the timed up and go test at a distance of 5 meters. Each participant performed two trials at self-selected and maximum walking speed. The agreement between systems was assessed using the Bland-Altman statistical method. The parameters were stratified by right and left leg steps, and the effect of using walking aids was analyzed with three groups: general group, patients with independent walking and patients requiring walking aids. **Results:** The system with seven IMUs compared with the optoelectronic reference system showed statistically significant agreement for the overall group when analyzing steps from both right and left sides together on the spatiotemporal parameters. However, when a separate analysis of right and left steps on the spatiotemporal parameters for the overall group was conducted, the inertial systems showed statistically significant agreement only for patients who were independently ambulant. The systems did not agree on the step length parameter for patients needing walking aids. The mobile application was not reliable for evaluating spatiotemporal gait parameters in patients with HSP. **Conclusion:** The inertial system utilized in this study effectively measured spatiotemporal gait parameters in independently ambulant patients with HSP. This portable device has the potential to be used in future clinical trials for evaluating gait in patients with the disease.

Vascular Parkinsonism due to cerebral cavernomatosis associated with a heterozygous mutation in the KRT1 gene: a case report from a healthcare unit in Amazonas

Emanuelle Campos Amaral[1], Maria Esther Lima Rios Evangelista[2], David França Ferreira Cruz[1], Danilo Lemes Reis[1], Fernanda Almeida Carvalho[1], Manuela Brandão Ferreira Teles[1], Júlia Ágata Cardoso Barbosa[2], Frederico de Sousa Marinho Mendes Filho[2], Paulo Roberto Moss Lopes[2], Marcus Vinícius Della Coletta[1]

[1]Universidade do Estado do Amazonas, Manaus AM, Brazil.
[2]Universidade Federal do Amazonas, Manaus AM, Brazil.

Correspondence: Emanuelle Campos Amaral; Email: eca.med22@uea.edu.br.

Case presentation: Female patient, 70 years old, previously diagnosed with idiopathic Parkinson's disease, with a slow progression of symptoms for about 2 years and intestinal constipation, with a history of sleep disorders for 8 years. On physical examination, the patient presented with bilateral bradykinesia, with a slight predominance on the right, mild bilateral postural tremor, action tremor during line and spiral tests, and mild rigidity on the left and moderate on the right. The first MRI analysis showed multiple low-signal foci on the gradient sequence, with suspected microhemorrhages related to amyloid angiopathy. Upon repeating the MRI for a more recent analysis, multiple and countless supratentorial and infratentorial cavernous angiomas were found bilaterally, as well as in the brainstem, suggesting familial multiple cavernomatosis syndrome as the main diagnostic hypothesis (KRT1 gene mutation). **Discussion:** Cerebral vascular malformations refer to a group of conditions characterized by abnormal vascular configurations occurring within the brain (and spinal cord). Familial CM cases have an autosomal dominant inheritance pattern and are estimated to account for approximately 20 percent of all cases of CMs. Most familial cases have multiple CMs. Pathogenic variants are known to cause familial CMs, with KRIT1 being the variant identified in the examination of the patient described here.Supratentorial CMs commonly present with hemorrhage, seizures, and progressive neurologic deficits. Seizures and progressive neurologic deficits may result from mass effect and secondary compromise of the microcirculation or from microhemorrhages with local hemosiderin deposition irritating cortical or subcortical

tissue. Infratentorial CMs commonly present with hemorrhage and progressive neurologic deficits. Lesions in the brainstem present with cranial neuropathies and long-tract signs that cause progressive neurologic decline due to the high volume of critical nuclei and fiber tracts in this area. Notwithstanding these common symptoms, the patient in this case presented the evolution of the main complaint with a classic picture of idiopathic Parkinson's syndrome. With the typical exome of cerebral cavernomatosis due to an alteration in the KRIT1 gene, the patient demonstrates an atypical clinical picture rarely found in the literature regarding the correlation of this pathology with Parkinsonian syndrome, highlighting the rarity and relevance of the case. **Final comments:** As demonstrated in Neurology, there are clinical cases that can present with atypical manifestations. It is important not to limit oneself and to seek differential diagnoses, highlighting the importance of complementary examinations such as magnetic resonance imaging and, especially in this case, genetic testing. Despite the limitations within the state of Amazonas, it was possible to report an atypical manifestation of parkinsonism of vascular origin due to cerebral cavernomatosis.

VCP gene mutation: muscle disorder or nerve disorder?

Luma Santos de Oliveira[1], Fabio Victor Vieira Rocha[1], Emanuelly Victoria Andrade Fonseca[1], Igor Flavio Gonçalves do Vale[1], Daniel Mariani Favalessa[1], Bruno Batitucci Castrillo[1], Renann Nunes Pirola[1]

[1]Universidade Federal do Espírito Santo, Vitória ES, Brazil.

Correspondence: Luma Santos de Oliveira; Email: luma.oliveira@edu.ufes.br.

Case presentation: A 64-year-old male patient with a decade-long history of progressive and asymmetric proximal and distal crural paraparesis, along with foot paresthesias and significant lower back pain, without any cognitive complaints. Neurological examination showed muscle strength (D/E) of II/I for hip flexion, IV/III for knee extension and flexion, and IV/III for ankle dorsiflexion. Achilles reflexes were absent, with painful hypoesthesia and hypopallesthesia in a glove-and-stocking pattern. Lab results indicated a CPK of 293 and alkaline phosphatase of 259. Electroneuromyography revealed severe, length-dependent axonal sensory-motor polyneuropathy. The patient declined a muscle biopsy. MRI and CT of the lumbar spine showed vertebral cortical and trabecular thickening with uptake. Bone scintigraphy indicated increased bone uptake with high osteoblastic activity. Genetic testing confirmed a mutation in the VCP gene (R93C), compatible with Charcot-Marie-Tooth disease type 2Y (CMT2Y). **Discussion:** Autosomal dominant mutations in the VCP gene lead to a multisystem proteinopathy that can present with inclusion body myositis, Paget's disease of bone, and frontotemporal dementia. Ubiquitin-positive protein aggregates are a key pathological characteristic. In rare cases, mutations in this gene are also linked to CMT2Y. The patient shows confirmed polyneuropathy and Paget's disease of bone. Although myopathy hasn't been definitively confirmed, the clinical presentation of initial proximal weakness and slightly elevated CPK levels suggests a possible overlapping myopathy. The genotype-phenotype correlation shows significant clinical variability, even among family members with the same mutation. Until now, CMT2Y has been linked only to the E185K mutation, while this patient has the R93C mutation. **Final comments:** This case illustrates the complex genotype-phenotype relationships in VCP gene mutations. The patient's progressive crural paraparesis, polyneuropathy, and Paget's disease of bone are consistent with VCP-related conditions. This emphasizes the need for comprehensive genetic testing and clinical assessment in patients with diverse multisystem symptoms to fully understand the range of VCP-related disorders

Velpeau's Law in practice: consecutive diagnoses of inclusion body myositis on the same day

Igor Flavio Gonçalves do Vale[1], Fernanda Bulhões Pagotto Pádua[1], Lucas Brumatti Setubal[1], Renann Nunes Pirola[1]

[1]Universidade Federal do Espírito Santo, Vitória ES, Brazil.

Correspondence: Igor Flavio Gonçalves do Vale; Email: igor.f.vale@edu.ufes.br.

Case presentation: Velpeau's Law, described by Alfred Velpeau, posits that rare diseases tend to manifest two or more times in a short interval. This observation was corroborated by the evaluation of two female patients, with an average age of 52 years, who presented with progressive asymmetric weakness in the proximal muscles of the lower limbs (LL), worse on the left, and varying degrees of bulbar involvement, progressing for more than five years, who were seen on the same day. They also reported distal weakness in the upper limbs (UL), with an emphasis on the deep flexors of the fingers (DFPs), associated with atrophy of the flexor muscles of the forearm. Magnetic resonance imaging (MRI) of the LL revealed predominant hypotrophy and fatty replacement in the bilateral quadriceps femoris in the first patient, while the second showed muscle atrophy with adipose degeneration in the posterior compartment of the thigh.Creatine kinase (CK) levels were 449 U/L and 3220 U/L, respectively. Neuromuscular ultrasound (NMUS) revealed a hyperechoic pattern in the quadriceps femoris muscles in both patients, indicating atrophy and fatty replacement in this region, sparing the rectus femoris. **Discussion:** Inclusion body myositis (IBM), with a prevalence of 24.8 to 46 cases per million inhabitants and a male predominance (2:1) after age 45, is a subtype of idiopathic inflammatory myopathy characterized by asymmetric and progressive weakness of the appendicular muscles. The weakness is predominantly proximal in the LL, primarily affecting the quadriceps femoris muscle, and distal in the UL, especially the deep flexors of the fingers (DFPs) and flexor pollicis longus (FPL). Additionally, there is the presence of bulbar dysfunction, which progresses to dysphagia in 70% of cases. Due to the insidious and progressive nature of the disease, the diagnosis, which is based on clinical presentation, elevated CK levels, less than 12 times the reference value, and histopathological findings such as rimmed vacuoles and p62 aggregates, or MRI findings of muscle atrophy and fatty replacement of the quadriceps femoris, usually takes three to five years to establish. However, NMUS has emerged as a promising diagnostic tool, with 98% specificity and 82% sensitivity. It allows the detection of severely affected muscles, such as the gastrocnemius and, primarily, the DFP, which is the most discriminative muscle for IBM diagnosis. This technique also shows relative preservation of the adjacent flexor carpi ulnaris muscle, enabling a useful comparison in a single image, minimizing the need for invasive and high-cost procedures. **Final comments:** In the context of a rare disease with a long diagnostic window, NMUS has the potential to become an extension of the bedside physical examination, strengthening clinical reasoning and enabling a faster diagnosis. In line with Velpeau's Law, two women were consecutively seen and diagnosed with inclusion body myositis, facilitated by NMUS.

Venlafaxine versus amitriptyline in the prophylactic treatment of migraine: an updated systematic review

Pedro Vitor Ferreira Rodrigues[1], Leonardo José Rodrigues de Araújo Melo[1], Francisco Luciano Honório Barreto Cavalcante[1], Paulo Victor de Santiago Gonçalves[1], Cássia Caroline Aguiar da Ponte[1], Pedro Lucas Grangeiro de Sá Barreto Lima[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Pedro Vitor Ferreira Rodrigues; Email: pedrovitorf7@gmail.com.

Background: The current migraine pharmacological prophylaxis consists mainly in the use of beta-blockers, tricyclics antidepressants and anticonvulsants as first-class drugs for the reduction in the number and severity of headache events. However, many physicians had used Venlafaxine (VLF), a selective serotonin and norepinephrine reuptake inhibitors, as option in the treatment of this headache type without a relevant quantity of data about the benefit of this medication compared with the traditional treatment. **Objective:** To evaluate and compilate the data about the efficacy of Venlafaxine versus Amitriptyline (AMT) in migraine prophylaxis treatment. **Methods:** This study was conducted using the Preferred Reporting Items for Systematic Review and Meta-analyses (PRISMA) guidelines. The search was conducted in the PUBMED/MEDLINE, EMBASE and COCHRANE databases. Only articles comparing directly Venlafaxine with amitriptyline were included. Any papers in languages other than English were excluded. The screening was done by 2 independent authors, which selected the articles for this study based on the PICO process (Migraine; Venlafaxine; Amitriptyline; Frequency, Severity, Pain and Adverse effects) in which 1083 articles were selected for screening, with 289 of them being excluded as duplicates and 790 for not meeting the eligibility criteria defined in the formulation of the study. At the end, 3 articles were selected for compose this systematic-review. **Results:** A total of 284 patients were included in this review, with 142 in the venlafaxine group. The follow-up time ranged from 8 to 24 weeks. The mean dose of venlafaxine was of 75mg, and 25mg of Amitriptyline was used as comparison. Only 2 articles showed a statistical significance in the difference between the two drugs, with a mean reduction of 5,4 attacks per month ($p< 0.0001$) for reduction of migraine frequency in the venlafaxine group. There was no statistical difference between the drugs in the headache duration ($p> 0.05$). One study showed a remarkable reduction in the pain by the Visual Analog Scale in the VLF group. Two studies had no difference between the severity decrease in the drugs comparison. Most of the adverse effects cases were of patients using venlafaxine, with sleep disturbances being the principal side effect related. A meta-analysis was not done by the heterogenicity of the data. **Conclusion:** In our analysis there was no real difference ($p>0.05$) between the two drugs in the duration and severity of the migraine attacks, showing no likely vantage in the choice of one drug instead of the other in terms of efficacy. However, the benefit expressed by one of the articles in the reduction of pain by venlafaxine and the high incidence of adverse effects, shows the necessity of more studies comparing the two pharmacological therapies for a better analysis and efficacy study.

Ventricular papilloma in a pregnant patient: case report

Lianna da Silva Facco[1], Luidia Giacomini[2], Milena Moraes[1], Ana Flávia Orlandini[1], Israel Farias Silva[1], Giovanni Cândido Volino[1], Guilherme Weimer Vilanova Audino[1], Laura Martens Fischer[1], Matheus Felipe Kuhn Urnau[1], Charles André Carazzo[2]

[1]Universidade de Passo Fundo, Passo Fundo RS, Brazil.
[2]Hospital São Vicente de Paulo, Passo Fundo RS, Brazil.

Correspondence: Lianna da Silva Facco; Email: lianna.facco@gmail.com.

Case presentation: A 28-year-old woman, 38 weeks pregnant and with a history of migraines without attacks for 2 years, was transferred to our institution complaining of a severe occipital headache that started the day before. She reported intense unilateral pain in the occipital region, which started suddenly in the early hours of the day of admission, accompanied by vomiting and prostration. The patient had photophobia and blurred vision. The pain worsened with movement and improved with pressure applied to the back of the neck. There have been reports of seizures at the hospital of origin. On physical examination, the patient was alert but prostrate, with no signs of fever, preserved pupillary reflexes, a positive bilateral Hoffmann reflex, and pain on palpation in the cervical region. Owing to the warning signs (sudden and intense headaches in pregnant women), magnetic resonance imaging (MRI) with TOF sequence was requested for investigation. The following day, the test results showed an expansive lesion in the fourth ventricle, with signs of acute bleeding and increased dimensions compared with previous tests. A cesarean section was performed on the same day due to concerns about the initial signs of cranial hypertension, with a contraindication to spinal anesthesia. On the days following her hospitalization, the patient was diagnosed with ventricular papilloma and underwent surgery to resect the tumor of the fourth ventricle with intratumoral hemorrhage. After the procedure, the patient showed progressive improvement without recurrence of headaches or other symptoms. Subsequent exams confirmed tumor removal and a reduction in intratumoral bleeding. The patient was discharged 12 days after hospitalization, with outpatient follow-up instructions. **Discussion:** Ventricular papillomas are a rare condition, being more common in children, representing 1-4% of all pediatric brain tumors, even though they can appear at any age. In children, they normally affect the internal regions of the lateral ventricles. In adults, there is a preference for the fourth ventricle. They are divided into choroid plexus papilloma (CPP), atypical choroid plexus papillomas (APP), and choroid plexus carcinoma (CPC). The presence of simian virus 40 in the coding regions of some genes appears to produce a tumor antigen (TAG) that can interact with tumor suppressors, p53 and pRb, forming a complex, which appears to be an important factor in the formation of these types of tumors. **Final comments:** This case illustrates the complexity of the differential diagnosis of headaches in pregnant women, emphasizing the importance of thorough investigation in the face of serious symptoms, such as sudden and intense headaches. Early identification of warning signs and prompt intervention are crucial to avoid serious complications for both the mother and the fetus.

https://doi.org/10.5327/CBN241752

Verheij syndrome: a case report of a differential diagnosis of autism

Rachel Leirner Argelazi[1], Gabriel Salmen Lobo Gonçalves[2], Santhiago Calvelo Graça[1], Marcella Gonçalves Ferreira[2], Hugo Raphael Resende Cruz[2], Gabriela Ribeiro do Val[2], Yasmim Mendes Silva[2], Raquel Monico Cavedo[2], Hugo José de Carvalho Garcia dos Santos[2], Laís Russo Carneiro Peruzzi[2]

[1]Santa Casa de São Paulo, Faculdade de Ciências Médicas, São Paulo SP, Brazil.
[2]Irmandade da Santa Casa de Misericórdia de São Paulo, São Paulo SP, Brazil.

Correspondence: Rachel Leirner Argelazi; Email: racheleirner@gmail.com.

Case presentation: HBS, a 4-year-old, attended his first pediatric neurology consultation in May 2024 at Hospital Santa Casa de Misericórdia in São Paulo for neuropsychomotor development delay. He is the only child of a healthy, non-consanguineous couple with no prenatal complications. At birth, he had dysphagia and laryngomalacia, requiring speech therapy. Milestones included head control at 3 months, sitting with support at 9 months, walking at 1 year and 6 months, and speaking first words at 2 years. Despite delays, he has attended school for a year and a half, participates in physical activities, sleeps well, and maintains good family relationships. Mild autism was suspected. During evaluation, he was alert, cooperative, age-appropriate cognitively, oriented, and had coherent speech. His gait was atypical, and muscle strength, coordination, balance, tone, and trophism were adequate, with no involuntary movements or neurological issues. He had dysmorphic facial features, including large ears, a thin face, and almond-shaped eyes, leading to consideration of a genetic syndrome. Exome sequencing revealed a PUF60 gene alteration, diagnosing Verheij Syndrome, a new mutation with a mild presentation. **Discussion:** Verheij syndrome, or PUF60-related developmental disorder, is a rare genetic condition caused by mutations in the PUF60 gene, identified through genetic testing like whole exome sequencing. This gene is crucial for proper mRNA processing and protein synthesis. The syndrome is usually linked to de novo heterozygous loss-of-function mutations in the PUF60 gene. In our study, the patient had the c.245_246del; p.(Val82Alafs*57) variant found in heterozygosity, which causes a premature stop codon and likely results in protein degradation by the Nonsense Mediated Decay (NMD) pathway. Verheij syndrome is characterized by a range of congenital anomalies and developmental issues, including ophthalmic coloboma, short stature, skeletal abnormalities, congenital abnormalities, developmental delay, palatal abnormalities, congenital heart and kidney defects and facial dysmorphims. There is significant variability in the presentation of Verheij syndrome. Some individuals may have milder forms with fewer features, while others have more severe manifestations. The reported patient presents a mild form of the syndrome. Despite developmental delay and typical phenotype, the child is able to develop and engage in school, sports, and social activities. **Final comments:** This is one of the first cases of Verheij syndrome in the state of São Paulo, and it is even rarer due to its mild presentation. The differential diagnosis of genetic syndromes in suspected autism cases is essential for proper diagnosis and management.

Vertebral artery dissection as an etiology of intense headache in the post-operative surgery of elective plastic surgery: a case report

Pedro Igor Lustosa Roriz[1], Gabriela Sebastiana Barbosa Sá[1], Eloismaile Leite Ferraz[1], Ádrya Aryelle Ferreira[2], Cleilson Barbosa de Freitas[2], Victor Ribeiro Neves[2]

[1]Instituto de Educação Médica, Juazeiro BA, Brazil.
[2]Universidade de Pernambuco, Petrolina PE, Brazil.

Correspondence: Pedro Igor Lustosa Roriz; Email: pedroilroriz@gmail.com.

Case presentation: Female patient, 32 years old, with no history of previous chronic illness or continuous use of medication. No history of smoking or alcohol consumption. On the first day after elective aesthetic plastic surgery on her abdomen and breasts, shortly after being discharged from the hospital, she developed a severe headache, which reached its peak after about 15 minutes. The headache was bilateral, pulsating, intense and worsened with any effort. In addition, she presented photophobia, phonophobia, nausea and mild and persistent neck pain. The headache was even more exacerbated in the supine position and there was a slight improvement in orthostasis. The patient was hospitalized again to control her symptoms. Initially, a head tomography was requested, which showed no changes and was treated only with symptomatic medication when a migraine was suspected. The next day, she was evaluated by the hospital's neurology team for persistent headaches and diplopia. The neurological examination revealed only abduction deficit in the right eye, suggesting possible involvement of the right sixth cranial nerve. The examination did not highlight neck stiffness, fundus changes, or other cranial nerve involvement. Although the brain resonance showed no changes that would justify the pain (also without an area of restriction to water diffusion), the angioresonance showed an image suggestive of dissection in the right vertebral artery. **Discussion:** The importance of remembering the warning signs in the evaluation of headaches must be highlighted to exclude differential diagnoses of more severe syndromes that may pose more serious risks to patients. At the beginning of the case, the patient had no previous history of headache refractory and high-intensity pain as warning signs. **Final comments:** In this case, the surgeon performed the aesthetic procedure away from the cervical region (breast and abdomen). It is possible to relate the appearance of cervical vascular injury to patient manipulation in bed or to the spontaneous occurrence of the disease. However, it cannot be ruled out that the surgical procedure contributed to the emergence of the problem.

Vertigo induced by unilateral hippocampal infarction: a case report

Maria Eduarda Andreatta[1], André Luiz Pereira Martins[1], Joana Laurindo da Silva[1], Olga Cassol Silva[1], Carolina Aparecida Donofrio Santos Costa[1], Mariana Costa Borges[1], Cristine Koehler[1], Rafael Marques Mendes[1], Gabriela da Silva Cremonese[1], Gladys Lentz Martins[1]

[1]Hospital Governador Celso Ramos, Florianópolis SC, Brazil.

Correspondence: André Luiz Pereira Martins; Email: martinsandrelp@gmail.com.

Case presentation: A 64-year-old female presented to the emergency department with sudden-onset vertigo. There were no previous similar episodes, nor any history of weakness, speech changes, tinnitus or hearing loss. She denied recent head or neck trauma. Her medical history included systemic arterial hypertension. On examination, she displayed horizontal nystagmus with a rightward fast phase induced by rightward gaze, asymmetric between both eyes, non-fatigable and with no latency, upbeat vertical nystagmus and dysmetric rightward saccades. Positive skew deviation and a negative head impulse test were noted. Also, she had a positive Romberg test and cerebellar ataxic gait. An angiotomography revealed an old ischemic lacuna in the right cerebellar hemisphere and ruled out occlusion and stenosis. A follow-up magnetic resonance showed two foci of diffusion restriction in the right hippocampus, confirming a subacute ischemic event. Treatment included aspirin, clopidogrel and metoclopramide, leading to symptomatic improvement. Transthoracic echocardiogram and electrocardiogram were unremarkable. Laboratory findings showed dyslipidemia. The patient was discharged for outpatient follow-up with further investigations for secondary prevention. **Discussion:** Acute vestibular syndrome is characterized by the rapid onset of vertigo accompanied by nausea, gait unsteadiness, and nystagmus lasting a day or more. Its primary cause is usually peripheral vestibulopathy, such as vestibular neuritis. Nonetheless, vertigo can manifest as early symptoms of acute stroke, often involving the posterior circulation. In the central nervous system, lesions typically responsible for vertigo are often found in the brainstem. Conversely, there is limited research on whether lesions in the supratentorial hemispheres can lead to vertigo. Brain studies in humans have revealed several vestibular cortex areas that includes the insular area, the superior temporal gyrus, the precuneus, the anterior cingulate gyrus and the hipoccampus. Although not uncommon, literature on hippocampal infarction remains sparse. Increasing

evidence supports the existence of a lateralized vestibular cortex, suggesting that cortical strokes in the right hemisphere are more likely to cause vestibular symptoms compared to the left hemisphere. Hippocampal infarctions can lead to persistent anterograde and retrograde amnesia, mental status changes and, more rarely, vertigo. Treatment options differ; anticoagulants or antiplatelet agents are prescribed for secondary prevention of hippocampal infarctions, based on the underlying cause. **Final comments:** It is essential to remember that acute central vestibular syndrome can arise from not only the brainstem but also supratentorial structures. We present a rare case of a woman who developed an acute central vertiginous syndrome due to a hippocampal infarction. To our knowledge, this is the first reported case of a hippocampal stroke presenting with vertigo.

Correspondence: Lara Santos Machado; Email: laramachado231@gmail.com.

Case presentation: A 73-year-old woman sought care for vision loss in the right eye, which progressed to the left eye in one day. She presented at the same time with paresthesia and progressive weakness of her legs, becoming unable to walk in 15 days, associated with urinary incontinence and constipation. At presentation, she had right RAPD, had a visual acuity of hand movement in the right eye, and could count fingers at 10 meters with the left eye. She had weakness of both legs, hypoesthesia with sensory level at T4, and diffuse pathologically brisk reflexes, with bilateral Babinski sign. She had been diagnosed with chronic lymphocytic leukemia (CLL) without treatment 5 years before. T2 FLAIR brain and spinal cord MRI showed a subcortical hyperintense signal in the right parietal lobe and the cervicothoracic region, with gadolinium enhancement and a cerebellar lesion. The cerebrospinal fluid analysis presented 7.3 white blood cells/μL with 95% lymphocytes and an increased protein concentration of 51 mg/ dL. Oligoclonal bands and immunophenotyping were not available. Infectious, rheumatology and a paraneoplastic investigation were negative. She tested negative for anti-AQP-4 and positive for anti-MOG antibodies. The patient was treated with intravenous methylprednisolone, followed by intravenous immunoglobulin and high daily doses of corticosteroids, with partial improvement of symptoms. The patient presented a recurrence of symptoms after weaning from corticosteroid therapy. Azathioprine, rituximab, and venetoclax treatment were started due to the possibility of autoimmune complications of CLL. **Discussion:** A very late-onset inflammatory demyelinating event (VLO-IDE) of the central nervous system is an onset after age 70. Degenerative, neoplastic, paraneoplastic, granulomatous, rheumatologic, and infectious lesions must be excluded. Given the possibility of an inflammatory etiology, the institution of immunotherapy treatment should not be delayed. Demyelinating diseases include very late-onset clinically isolated syndrome (VLO-CIS), multiple sclerosis (VLO-MS), neuromyelitis optica (VLO-NMO), or myelin oligodendrocyte glycoprotein antibody-associated disease (VLO-MOGAD). MOGAD can present with optic neuritis, transverse myelitis, acute disseminated encephalomyelitis, cortical encephalitis, brainstem encephalitis, seizures, and meningitis. Elderly patients present subacute evolution and decreased risk of recurrence. There is no report of MOGAD associated with CLL, but an NMO-like presentation as a CNS complication of CLL has been described. **Final comments:** A clinical inflammatory demyelinating event in elderly patients is rare and must be extensively investigated. Neoplastic, paraneoplastic, and infectious etiologies must be discarded. With population aging, attention must be paid to the possibility of VLO-IDE, including MS, NMO, and MOGAD.

Very long-chain acyl-CoA dehydrogenase deficiency: an illustrative case of late manifestation inborn error of metabolism

Helena Fussiger[1], Giuseppe Dick Bonato[1], William Alves Martins[1], Marina Scop Medeiros[1], Rodrigo Rezende Arantes, Lilia Farret Refosco, Bibiana Mello Oliveira

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Hospital São Lucas, Porto Alegre RS, Brazil.

Correspondence: Giuseppe Dick Bonato; Email: g.d.bonato@hotmail.com.

Case presentation: A 28-year-old female with a history of recurrent nausea and vomiting since childhood exacerbated by physical exertion, temperature changes, and prolonged fasting, notably worsened over the past year. At age 27, she experienced three episodes spaced approximately 20 days apart, preceded by fasting, characterized by vomiting, lethargy, and acute epileptic encephalopathy necessitating ICU admission. Episodes also featured hypoglycemia, muscle weakness, deteriorating renal function, metabolic acidosis, elevated transaminases, hyperCKemia, and hyperammonemia. The unusual clinical presentation led to consideration of psychiatric diagnoses, including suicidal attempts, prompting outpatient psychiatric evaluation. There was no parental consanguinity, but a maternal and paternal cousin died at 22 years old from gastroenteritis and fulminant hepatic failure. Physical examination revealed proximal muscle weakness and predominantly distal hyporeflexia. During the third episode of acute encephalopathy, investigations revealed cardiomyopathy, metabolic acidosis, hyperlactatemia, hypoglycemia, elevated CPK, ammonia, transaminases, and bilirubin. Liver biopsy indicated cirrhosis with a cholestatic pattern; EMG suggested axonal sensory-motor neuropathy. Brain MRI and cardiovascular assessment were normal. Acylcarnitine profiling showed deficiencies in C0 and elevated organic acids, specifically 4-OH-phenylacetic and 4-OH-phenylpyruvic acids. Molecular analysis using a treatable diseases panel identified likely pathogenic variants p.Lys382Serfs*11/p.Glu285Gln in the ACADVL gene, confirming VLCAD deficiency. Treatment recommendations included avoiding prolonged fasting, limiting long-chain lipids, consuming complex carbohydrates, and initiating L-carnitine supplementation along with triheptanoin. These interventions led to clinical improvement with no acute episode recurrence within 4 months post-treatment initiation. An emergency management plan for clinical incidents was established, and family investigation continues. **Discussion:** Inborn errors of metabolism (IEM) are rare genetic disorders typically appearing in childhood due to enzymatic or transport deficiencies affecting specific metabolic pathways. Very long-chain acyl-CoA dehydrogenase deficiency (VLCAD) is a disorder within fatty acid beta-oxidation, impairing the conversion of very long-chain fatty acids into energy. This condition predisposes individuals to encephalopathy, cardiomyopathy, hepatopathy, and hypoglycemia, inherited in an autosomal recessive manner. **Final comments:** This case underscores the severe manifestation of IEM in adulthood, presenting significant diagnostic and therapeutic challenges. The definitive diagnosis followed a prolonged investigative journey, enabling targeted therapies aimed at reducing disease-related morbidity and mortality.

Vestibular paroxysmia: a case report

Bibiana Mayer[1], Chadi Emil Adamo[2]

[1]Universidade de Ribeirão Preto, Ribeirão Preto SP, Brazil.
[2]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Bibiana Mayer; Email: bibiana_mayer@hotmail.com.

V.T.D., male, 50 years old, electrical engineer. He reported acute pain in the cervical region followed by episodic, non-positional subjective vertigo lasting about 30 seconds over 2 weeks. He underwent an otolaryngological examination, which did not detect any peripheral causes. He received antivertigo medication without improvement. Neurological examination revealed no cranial nerve abnormalities except for a Weber test lateralized to the left with a positive Rinne test. The head impulse test was negative. The Fukuda test showed lateralization to the left and slight asymmetry of reflexes, with the left reflex stronger than the right. Deep tendon reflexes were normal, with no posterior cord abnormalities. Cerebellar, motor, and sensory tests were preserved. During hyperventilation maneuvers, the vertigo episode was reproduced after about 45 seconds. He underwent cranio-cervical MRI and vascular studies, which showed no areas of ischemia and ruled out vertebral artery dissection and abnormalities in the cranio-cervical junction (i.e., foraminal stenosis). The investigation was complemented with an MRI using FIESTA sequences and a mastoid MRI. During this period, he experienced additional episodes of paroxysmal vertigo and worsening of unilateral pulsatile tinnitus, not synchronous on the right. Upon re-evaluation, tortuosity of the V4 segment of the left vertebral artery was observed, conflicting with the emergence of the eighth cranial nerve on the same side, compressing the superolateral portion of the pons on the left. The right vertebral artery was hypoplastic (2.2 mm in diameter) and joined the basilar artery (4.45 mm in diameter), projecting axially to the right. The mastoid MRI showed dehiscence of the right superior semicircular canal. The patient was treated with carbamazepine, optimized to a dose of 400 mg/day, leading to symptom resolution. Antivertigo medications were discontinued. Given the above situation, the patient met the criteria for a condition known as Vestibular Paroxysmia, in this case, secondary to compression of the vestibulocochlear nerve by dolichoectasia of the basilar arterial system. The neurophysiopathology of this disease is attributed to neurovascular compression, similar to trigeminal neuralgia; ephaptic transmission has also been proposed as a mechanism. Dedicated MRI of the internal auditory canal may reveal unilateral cross-compression of the anterior inferior cerebellar artery (AICA) or its branch and the eighth cranial nerve complex, but clinical and radiological correlation is not always evident. Certain characteristics define the syndrome, such as: short, very frequent, and intense attacks of rotational or to-and-fro vertigo lasting seconds, sometimes milliseconds; attacks often triggered by specific head positions; permanent hearing loss or hearing loss during an attack (often associated with "typewriter tinnitus"); audiovestibular deficits on testing; and exclusion of a central cause.

vHIT: a new method for vestibular function testing

Carolina Oldoni[1], Marcelo Tohoru Nakamura[1], Fernando Henrique Magri Alves[1], Emanuelle Roberta da Silva Aquino[1], Cristiana Borges Pereira[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Carolina Oldoni; Email: carololdoni15@gmail.com.

Case presentation: The video Head Impulse Test (vHIT) began to gain popularity around 2009 as a possible method to evaluate the function of each semicircular canal (SCC) individually (in pairs, right and left sides) non-invasively, and it is increasingly being used for the assessment of peripheral vestibular disorders. Prior to this, the expensive, complex, ingenious, and semi-invasive scleral search-coil systems were used. In many places, the vHIT has become the preferred initial test over caloric testing for patients suspected of having peripheral vestibular lesions, considering that caloric testing is quite uncomfortable for the patient and its results can vary depending on the examiner and the technique used (air versus water). The vHIT, on the other hand, is a quick, non-invasive test where the patient is subjected to rapid, passive, unpredictable head movements (about 15º, 100º/s) while looking at a fixed target. A device attached to the patient's head measures the head movements performed in the planes corresponding to the SCC action planes and the associated eye movement through a laser directed at the pupil's center of mass. These devices, linked to the supplier's software, generate graphs showing SCC function (by measuring the "gain") and the presence or absence of compensatory saccades, with the added advantage of recording covert saccades, i.e., eye movements that are not visually noticeable as they occur during head movement but are captured by the eye movement sensor. These covert saccades provide additional information, especially about the recovery of vestibular function. **Discussion:** This case aims to illustrate the use of a new complementary examination method for vestibular disorders, the vHIT. Here we describe the application of this test in patient A.M.R., a 50-year-old man diagnosed with superior branch right vestibular neuritis, with a vHIT showing reduced gain in the right anterior and lateral canals and the presence of both covert and overt compensatory saccades (test performed about 40 days after the ictus). Additionally, patient M.C.T., a 60-year-old woman diagnosed with a right posterior medullary stroke (likely involving the inferior vestibular nucleus), had a normal vHIT. The vHIT plays a primary (but not exclusive) role in differentiating peripheral from central vestibular diseases (when there are no other neurological examination findings aiding clinically in this differentiation), in conditions such as vestibular neuritis. **Final comments:** The vHIT emerges as another option for complementary vestibular function testing, this time in a non-invasive, portable manner, with minimal discomfort for the patient. There is still much to be understood about the alteration patterns presented in the vHIT, not only for diagnosis but also for prognosis and evaluation of vestibular function recovery.

Vibratory stimulation system for reducing diabetic neuropathy associated sequelae

Laura Caroline Felipe de Freitas[1], Sérgio Ricardo de Jesus Oliveira[1], Mariana de Oliveira[1], Samuel de Oliveira Lino[1], Leonardo Bongiovani Batista de Souza Figueiredo[1], Felipe Rodrigues Moreira dos Santos[1], Daniel Botelho Silveira[1], João Vitor Silva[1], Pedro Luís Mendonça Silva[1]

[1]Universidade Federal de Uberlândia, Uberlândia MG, Brazil.

Correspondence: Laura Caroline Felipe de Freitas; Email: lauracffreitas03@gmail.com.

Background: Diabetic neuropathy is a Diabetes Mellitus complication associated with disorders of the nervous system, which can affect motor, sensory and autonomic functions. As a result of sensory loss in the foot region, people with diabetic neuropathy are at greater risk for developing ulcerative lesions. The impairment of tactile feedback associated with the increased vulnerability of people with diabetes to infectious processes suggests the need for strategies capable of helping the patient to perceive the lesions, so diligent treatment can be scheduled. **Objective:** To test a system composed of tactile insoles, which will be used to monitor the level of pressure on the plantar surface of the feet in volunteers with diabetic neuropathy. In conjunction with the insole, a mechanical vibration stimulator will convert the signals received from the tactile sensors into a pattern of vibratory stimuli. The intensity and location of the stimuli will be defined depending on the location and severity of pre-existing injuries. **Methods:** This study is a clinical trial and will longitudinally and prospectively follow an experimental and a control group. Both will be defined based on the following inclusion criteria: being 25 years old or over, having diabetic neuropathy and presenting symptoms compatible with the syndromic condition of diabetic foot. Volunteers who are absent from experimental sessions and who do not use the device consistently enough will be excluded from the study. The follow-up rate for each participant will be 10 days and data collection will be carried out every 5 days. The data obtained from the collections will be useful in evaluating the history of pressure values at specific points on the insole, in order to observe whether the stimulation system can be effective in preventing the worsening of previously existing injuries due to mechanical improvements. The normality of the data obtained for each group will be verified using the Kolmogorov-Smirnov test. Appropriate parametric or non-parametric statistical tests will be used according to the normality of the variables, considering a significance level of 5%. **Results:** This is an ongoing study. It is speculated that increasing the perception of stimuli through the use of the device during the time of segments of the volunteers in the experimental group could be effective in n reducing pressure values over ulcerative lesions, enhancing the healing process and predisposing to an optimization of the time required for resolution. **Conclusion:** From this study, we hope to find an alternative to improve, in a non-invasive way, diabetic neuropathy carriers quality of life. Thus, it would be possible to contribute to reducing the morbidity associated with the disease and its complications.

Correspondence: Larissa Bianca Borsone; Email: larissa.borsone@hotmail.com.

Background: Viral encephalitis is an inflammatory process of the brain parenchyma associated with clinically manifested neurological dysfunction. Viral encephalitis generally occurs following hematogenous viral dissemination into the central nervous system. The most common causative agents are herpes viruses, non-polio enteroviruses, and arboviruses. Although relatively rare, it is a clinical condition with high morbidity and mortality rates. Symptoms and signs of viral encephalitis can range from fever, headache, cerebrospinal fluid pleocytosis, and abnormal MRI findings to altered mental status, severe encephalopathy, seizures, and permanent neurological deficits. **Objective:** To evaluate the profile of hospitalizations due to viral encephalitis in Brazil between the years 2019 and 2023. **Methods:** Data collection was conducted using publicly available information from the Hospital Information System of the Brazilian Unified Health System (SIH/SUS) in the Tabnet/DATASUS database between January 15 and May 15, 2024. This study employed a retrospective longitudinal design with a quantitative descriptive approach. Data were grouped by Brazilian macro-regions, type of care, sex, age group, and race/ethnicity. Statistical inference was performed using BioEstat 5.3 software, utilizing paired T-tests for related samples to compare groups, and descriptive statistics, measures of central tendency, and dispersion were used to present the data. **Results:** Between 2019 and 2023, there were 9,486 hospitalizations for viral encephalitis in Brazil. The majority, 53.61% (n=5,085), were male (p<0.0038), and 51.03% (n=4,841) were of mixed race (p=0.0039). The age group most affected was 1-4 years, accounting for 17.37% (n=1,648; p<0.0001) of the cases. The Northeast region had the highest concentration of cases (n=3,890), corresponding to 40.99% (p=0.0004), with an average annual treatment cost of R$ 7,658,211.31. Mortality was most prevalent in the Northeast, with 38.13% (n=188) of deaths (p=0.0016), and a mortality rate of 10.16 (p=0.2311) in the South region. The number of hospitalizations peaked in 2019, accounting for 25.68% (n=2,436) of the total, compared to only 21.79% (n=2,067) in 2023. The majority of hospitalizations, 51.03% (n=4,841; p<0.0039), were classified as urgent. **Conclusion:** Hospitalizations due to viral encephalitis are predominantly concentrated in the Northeast region of Brazil, with a higher proportion of deaths and treatment costs during the study period. Most cases occurred among children aged 1-4 years who were male and of mixed race, with urgent care being the most common type of hospitalization.

Virtual reality for improving social skills in children and adolescents with autism spectrum disorder: a systematic review and meta-analysis

Mayara Bottentuit Nogueira[1], Arthur Duarte de Sousa[1], Murilo Freitas e Silva Filho[1], Lanna Marry Silva de Morais[1], Patrícia Mendes Viana[2]

[1]Universidade Federal do Maranhão, São Luís MA, Brazil.
[2]Universidade do Extremo Sul Catarinense, Criciúma SC, Brazil.

Correspondence: Arthur Duarte de Sousa; Email: arthurddesousa@gmail.com.

Background: Although Autism Spectrum Disorder (ASD) is characterized by its persistent social deficits, the emotional processing abilities of individuals with ASD can improve over time with training. Virtual Reality (VR) technology is often reported as a tool that might help children and adolescents with ASD develop various social and emotional skills. However, despite several randomized controlled trials (RCTs) addressing its use, its efficacy in social and communication skills remains to be seen and will therefore be further investigated in this meta-analysis. **Objective:** To conduct a systematic review and meta-analysis to compare the effectiveness of virtual reality on social skills improvement compared to non-VR treatment in patients with ASD. **Methods:** We systematically searched Medline, Cochrane, and EMBASE databases for randomized controlled trials (RCTs) published until May 16th, 2024. Outcomes of interest were changes in social and communication skills, measured by changes from baseline in the validated scores: Autism Behavior Checklist (ABC), Psychoeducational Profile (PEP-3) and Vineland Adaptive Behavior Scale (VABS). All analyses were performed using Review Manager Software (v5.4). The effect sizes across studies were combined using the fixed-effect model, and the standardized mean difference (SMD) was used to combine the continuous outcomes. **Results:** Three RCTs were included in the meta-analysis, with a total of 167 patients, aged 3 to 12 years, of whom 77,2% were male and 54,5% underwent VR, which had a duration range of 3 to 5 months. Compared with the control groups (conventional therapy), the intervention group (adjunctive VR therapy) showed significant improvements

in social skills (SMD 0.57, 95% CI 0.24 to 0.89, p= 0,0006). The studies did not report any major side effects. In the qualitative assessment, four studies were included, and they suggested that adjunctive virtual reality therapy in children and adolescents with ASD is associated with significant improvement in social communication skills, but not with imitation, social interaction, language, or primary emotion recognition skills. **Conclusion:** Our study suggests that adjunctive VR therapy improves social skills when compared to conventional therapy. Due to the limited sample size, further research should be considered to strengthen the best available options for improving social skills in children and adolescents with ASD.

https://doi.org/10.5327/CBN241762

Visual and hearing loss in a patient after electric shock: Cogan syndrome and differential diagnosis

Giovani Zago Borges[1], Daniela Aparecida Lima Viana[1], Ana Luisa Rufino de Sousa[1], João Henrique da Matta Clementino[1], Elisangela Ferraz Pazinato[1], Amanda Soares Pimenta[1], Alex Eduardo da Silva[1]

[1]Universidade Federal do Triângulo Mineiro, Uberaba MG, Brazil.

Correspondence: Giovani Zago Borges; Email: gzagob@gmail.com.

Case presentation: Male, 46 years old, admitted to the emergency room due to sudden low visual acuity, tearing, pain in the right eye and holocranial headache with rapid evolution of symptoms 1 day after an accident at work with an electric shock (220V) in right upper limb, with no history of local trauma or other previous neurological complications. Upon admission, laboratory tests were carried out and toxic-metabolic-infectious causes that could justify the condition were ruled out, in addition to showing no changes on Magnetic Resonance Imaging (MRI) of the brain and orbits or on Optical Coherence Tomography (OCT), with visual field examination confirming low visual acuity of the affected eye, without other ophthalmological changes. It was decided to start pulse therapy with methylprednisolone for 5 days without satisfactory response. In an outpatient follow-up consultation, after 3 months, his condition worsened, with bilateral progressive hearing loss worse on the right, profound and moderately severe on the left, confirmed by audiometry and evoked potentials of optic nerves indicating reproducible, asymmetric, central responses. with prolonged absolute latencies and reduced amplitudes on the right side. A new investigation was carried out during hospitalization, with no changes in the cerebrospinal fluid examination, with a new normal MRI and OCT, a hypothesis was raised based on clinical and exclusion criteria of Cogan syndrome, immunoglobulin was administered followed by pulse therapy, both for 5 days, prednisolone and methotrexate were prescribed at discharge. with stabilization of the evolution of symptoms 4 months later. **Discussion:** Cogan syndrome is a rare autoimmune disease that affects the eyes and inner ear, resulting in eye inflammation (interstitial keratitis) and hearing problems (vertigo, tinnitus and hearing loss). The prevalence is unknown, but it is considered very rare. The typical form presents interstitial keratitis and auditory vestibule symptoms. The atypical form includes other ocular and systemic manifestations. The diagnosis is clinical, based on symptoms and exclusion of other conditions, such as SUSAC syndrome, stroke and other central nervous system vasculitis. Treatment involves corticosteroids and immunosuppressants to control inflammation, and, in severe cases, biological therapy may be necessary. **Final comments:** Understanding Cogan syndrome is crucial for early diagnosis and effective treatment of an autoimmune disease, which, despite being very rare and underdiagnosed, can cause permanent hearing loss and severe visual complications. Correct identification of characteristic symptoms, such as interstitial keratitis and auditory vestibule problems, allows immediate medical interventions, reducing disease progression and improving patients' quality of life. Furthermore, knowledge about this syndrome helps to exclude other conditions with similar symptoms, ensuring adequate clinical management.

Visual evoked potentials in spinocerebellar ataxias type 3 and 10

Otto Jesus Hernandez Fustes[1], Francisco Branco Germiniani[1], Cláudia Suemi Kamoi Kay[1], Paulo José Lorenzoni[1], Renata Dal-Prá Ducci[1], Paula Raquel do Vale Pascoal Rodrigues[1], Leo Coutinho[1], Rosana Herminia Scola[1], Hélio Afonso Ghizoni Teive[1]

[1]Universidade Federal do Paraná, Curitiba PR, Brazil.

Correspondence: Otto Jesus Hernandez Fustes; Email: otto.fustes@hc.ufpr.br.

Background: Visual evoked potentials (VEP) is a neurophysiological test that evaluates the function of the visual system, including the optic nerve, brain stem and cerebral cortex, through the electrical response to visual stimulation. Spinocerebellar ataxias (SCA) are heterogeneous diseases, with more than 50 types described, they present with different phenotypes, varying speeds of progression and clinical manifestations of different severity. Considering the presence of neuropathy, myelopathy, epilepsy and oculomotor changes among the SCAs, several studies have used electrophysiological methods to better characterize such manifestations. **Objective:** To report the electrophysiological findings presented in VEP in a cohort of patients with spinocerebellar ataxias type 3 and 10, comparing them. **Methods:** This was a cross-sectional study, in which we evaluated the VEP in a cohort of patients with SCA 3 (n=15) and SCA 10 (n=9). The patients underwent clinical evaluation in which demographic and clinical data, such as sex, age, duration of disease, and SARA scores, were collected. The VEP exam followed the guidelines from the American Clinical Neurophysiology Society. Both amplitudes and latency for the P100 potential were recorded and analysed. For statistical analysis we used a t-test and Wilcoxon test to compare normally and non-normally distributed numerical data respectively, whereas Spearman's correlation test was used to search for correlations between duration of disease/SARA scores and VEP abnormality. **Results:** 25 patients were enrolled in our study, 16 with SCA 3 and 9 with SCA 10. The clinical and demographic data did not present any statistically significant difference between the two groups. SARA scores and age of onset were similar between both groups. Conversely, VEP abnormalities differed between the two groups, as increased P100 latency and amplitude decrease were the most frequent change in the SCA 3 group (n=4). However, the occurrence of VEP abnormalities did not have a statistically significant correlation to either duration of disease, or SARA scores. **Conclusion:** Our data indicate that patients with SCA 3 have greater impairment of the visual pathway than those with SCA 10. More data are needed to confirm these findings, as well as to determine differences in the electrophysiological profile between Brazilian patients and other populations of patients with SCA 10. VEP can be a useful test in the monitoring of SCAs, as VEP can be used to detect changes in visual function that may be a sign of disease progression.

https://doi.org/10.5327/CBN241764

Visual loss: beyond demyelinating diseases

Fernanda Nicoli Broch[1], Cândida Driemeyer[1], Laís Elizabete Favaretto[1], Alexandre Laisson Prado Taschetto[1], Marlise de Castro Ribeiro[1], Liselotte Menke Barea[1]

[1]Universidade Federal de Ciências da Saúde de Porto Alegre, Hospital Santa Casa de Misericórdia de Porto Alegre, Porto Alegre RS, Brazil.

Correspondence: Fernanda Nicoli Broch; Email: fernandanbroch@gmail.com.

Case presentation: A 32-year-old female patient was referred to the emergency department by the ophthalmologist due to the complaint of low visual acuity in the left eye. The patient reported progressive blurred vision in the left eye which had begun one year ago. Two months ago she noticed significant worsening of the symptoms leading to unilateral amaurosis. She was then hospitalized in another institution, where it was performed a skull computed tomography, which showed infiltration of the optic nerve. She then received a presumed diagnosis of neuromyelitis optica (NMO). It was prescribed pulse therapy and the patient was discharged with prednisone 80 mg/day. One month later, she was evaluated in our hospital presenting a persistent headache, pain when moving the left eye and blurred vision in the right eye. An investigation was carried out, and evidenced pachymeningitis on skull MRI and normal rheumatological tests, except for ANA, which was 1:640. Lumbar puncture had no abnormalities. Because of these findings, it was suspected of a granulomatosis disease and it was necessary to perform a meningeal biopsy. The immunohistochemical analysis confirmed pachymeningitis for IgG4-related disease (IgG4-RD). **Discussion:** IgG4-RD is an inflammatory disorder, immune mediated and it can affect multiple organs and systems, which can lead to fibrosis and tissue destruction. Any organ might be involved, but pancreas, biliary tract and lacrimal glands are most often affected. Neurologically, the disease is relevant due to the possibility of affecting the orbits, pituitary gland, meninges, peripheral nerves and even the brain. It usually affects individuals between 50-80 years old. Autoimmune pancreatitis affects both man and women in a proportion of 4:1. IgG4-RD is usually indolent, although acute and subacute manifestations are common when there is vascular involvement. In this case, significant involvement of the pachymeninges was observed with infiltration at the level of the optic foramen bilaterally, more evidently on the left, in addition to the orbital apex on the left and the retropharyngeal space. Infectious hypotheses were ruled out, serum IgG4 level was normal. CSF IgG4 level was not available. In the biopsy, lymphoplasmacytic predominance was noted with an IgG4:IgG ratio > 60%. Treatment with corticosteroids was started and continued with a biannual infusion of Rituximab. **Final comments:** Early consideration of IgG4-RD in differential diagnosis is crucial, as prompt diagnosis improves response to corticosteroid treatment. Delayed diagnosis can lead to irreversible fibrotic changes and permanent disabilities. Our patient spent over a year from the onset of symptoms until diagnosis. Despite the use of anti-CD20 therapy, the patient continues to show disease progression, highlighting concerns regarding limited therapeutic options and evidence.

Weight loss at the time of diagnosis is associated with a shorter survival in ALS

Laura Carvalheira Dourado[1], Emanuela Coriolano Fidelix[1], Lucia Leite Lais[1], Mario Emílio Teixeira Dourado[1]

[1]Universidade Federal do Rio Grande do Norte, Natal RN, Brazil.

Correspondence: Mario Emilio Teixeira Dourado Junior; Email: medourado03@gmail.com.

Background: Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disease, and the nutritional status of ALS patients is associated with survival. **Objective:** We retrospectively analyzed the effect of weight

loss (≥ 10%) at diagnosis and its association on patient survival. **Methods:** We reviewed a cohort of 132 ALS patients in our outpatient clinic at the hospital between January 2008 and March 2022. Clinical and demographic data were compiled. To assess predictors of survival, we analyzed weight loss ≥ 10% at time of diagnosis. Survival was defined as the time, in months, from the onset of symptoms to death or tracheostomy. **Results:** 54 (40.9%) patients had weight loss ≥ 10% at time of diagnosis. This weight loss was associated with a shorter survival time, comparing 24.0 months (95% CI: 19.2 - 28.8) vs. 34 months (95% CI: 30.9-37.1), p<0.010. In addition, 61 (46.3%) patients had significant weight loss at diagnosis without suffering from dysphagia. **Conclusion:** Weight loss at diagnosis is a significant concern in ALS and cannot always be attributed solely to dysphagia. Treatment for weight loss, including a high-calorie diet, oral nutritional supplements, and/or percutaneous endoscopic gastrostomy, should be discussed and considered during the patient's follow up.

Case presentation: A 77 years-old woman was admitted to the emergency presenting sudden onset of vertigo, diplopia, strabismus, ataxic gait, profuse vomiting, dysarthria. She was independent for daily activities and had a history of arterial hypertension, atrial fibrillation and a previous stroke without sequelae. Physical examination: right ptosis with ipsilateral eye exotropia, ophthalmoparesis, preserving just abduction movement of right eye, left eye has a neutral position, adduction and lower gaze preserved with abduction, conjugate vertical gaze palsy, bilateral appendicular ataxia, right body lateropulsion. MRI with high-signal T2/FLAIR lesions with real diffusion restriction (DWI/ADC map) in the right thalamus, mesial portion of the right temporal lobe and right paramedian midbrain. Hypoplasia of left vertebral and occlusion of right P2 on MR Angiography. On electrocardiogram, no visible P waves and an irregularly irregular QRS complex. On Echocardiogram, left atrial enlargement. Rivaroxaban prescribed for cardioembolic stroke prevention. **Discussion:** Midbrain infarctions are unusual, 0.9% of strokes, which is explained by the complex arterial blood supply of midbrain, supplied by posterior cerebral artery, upper basilar artery and the superior cerebellar artery. First described in 1958 by Lhermitte, the Wernekink Commissure syndrome (WCS) is very rare (69 cases), caused by an infarction of the paramedian midbrain, affecting wernekink commissure (brachium conjunctivum), medial longitudinal fasciculus, oculomotor nucleus and nerve, reticular formation, red nucleus. Clinical signs are bilateral cerebelar syndrome, variable eye movement anomalies and can also have variable movement disorders. This case has ipsilateral III nerve palsy, bilateral cerebelar syndrome, vertical gaze palsy and a contralateral reverse internuclear ophthalmoplegia, also called pseudo abducens palsy or pseudo-sixth phenomenon, a uncommon condition. This is the first report of a Brazilian patient with clinical and radiological WCS. **Final comments:** The midbrain has a complex arterial supply, which explains the rarity of WCS, and neuroanatomy, which can cause challenger neurological examination.

What do we know about posterior reversible encephalopathy syndrome and burns? A systematic review

João Felipe Pissolito[1], Wilson Falco Neto[1], Beatrice David de Freitas[1], Felipe Bergamo Silva[1], Eliana Meire Melhado[1], Laura Alonso Matheus Montouro[1,2]

[1]Centro Universitário Padre Albino, Faculdade de Medicina de Catanduva, Catanduva SP, Brazil. [2]Faculdade de Medicina de São José do Rio Preto, São José do Rio Preto SP, Brazil.

Correspondence: João Felipe Pissolito; Email: felipe.pissolito@gmail.com.

Background: Reversible Posterior Encephalopathy syndrome (PRES) is an acute neurological condition characterized by a combination of clinical symptoms and radiological findings. It can occur in various clinical situations, but the incidence and characteristics of this syndrome in burn victims are unknown. **Objective:** Although no systematic review of this theme was previously conducted, the following study carried out a systematic search of the literature in order to clarify the clinical presentation of the syndrome. **Methods:** the following study consists of a systematic review following the PRISMA protocol. The search was carried out in three databases: Pubmed, Embase and BVS Saúde. In addition, the selected studies had their references checked in order to obtain new articles. The strategy was "Burned Patients" (Population) and "Posterior Reversible Encephalopathy Syndrome" (Outcome), however no terms referring to the population were used in order to obtain more articles. A search strategy was devised for each of the databases and the data from each was exported to the Rayyan platform for screening, which was carried out independently (blinded) by two researchers (FBS and BDF). Articles describing patients with PRESS after burns were included, regardless of the type of study or type of publication and language. Articles were excluded if they were not full-text or if they reported a case of the same patient. Data extraction was carried out by two researchers (WFN and JFP) and synthesis was carried out using the Google Sheets tool, obtaining information on demographics, diagnosis and clinical management. The quality of the articles included was assessed using the Joanna Briggs Institute Critical Appraisal tools' 8-item "Checklist for Case Reports" by two independent assessors (WFN and JFP). **Results:** once the databases had been searched, 14118 articles were found, of which 3276 were duplicates, totalling 10842 articles, which were scanned by reading the title and abstract. In the end, after reading the full text, a total of 5 articles were found, totalling 5 patients. Regarding clinical findings, the main findings were fever (n=3), visual alteration (n=2), convulsion (n=3), and hypertension (n=2), other findings include weakness and increased inflammatory response. With regard to imaging tests, the patients underwent CT and MRI of the skull, and bilateral vasogenic edema was found involving the white matter, predominantly in the temporal and occipital lobes.. In addition, two of the patients underwent EEG, showing generalized slowing, but no epileptiform activity. The findings converge with the classic characteristics of PRES. **Conclusion:** Even using a systematic search, only one case was located in relation to the last literature review. The low number of cases may be associated with the rarity of the condition and poor diagnosis. Neurological assessment of burn patients is essential for rapid identification and appropriate management.

What is the influence of fatigue, global function, cognitive state, and pain in individuals with amyotrophic lateral sclerosis? A cross-sectional study

Tatiana Souza Ribeiro[1], Stephano Tomaz da Silva[1], Diogo Neres Aires[1], Aline Alves de Souza[1], Luciana Protásio de Melo[1], Saionara Maria Aires da Câmara[1], Ricardo Alexsandro de Medeiros Valentim[1], Ana Raquel Rodrigues Lindquist[1], Giane Amorim Ribeiro Samora[1]

[1]Universidade Federal do Rio Grande do Norte, Natal RN, Brazil.

Correspondence: Tatiana Souza Ribeiro; Email: tatiana.ribeiro@ufrn.br.

Background: Fatigue is still an incompletely understood symptom in individuals with Amyotrophic Lateral Sclerosis (ALS), and little is known about its relationship with other symptoms such as global function, pain, and cognition. **Objective:** To identify the levels of fatigue, pain, global function, and cognition in a Brazilian group of individuals with ALS, in order to investigate potential influences between the aforementioned symptoms and fatigue. **Methods:** This is a cross-sectional study derived from a longitudinal (cohort) study. Individuals with ALS were recruited intentionally and non-probabilistically. After agreeing to participate in the research, the individuals were assessed using a custom evaluation form, collecting data regarding the level of fatigue (independent variable), global function, pain, and cognition (dependent variables). To assess fatigue, we used the Fatigue Severity Scale. For the dependent variables, we used the Amyotrophic Lateral Sclerosis Functional Rating Scale - Revised, the Visual Analogue Scale along with a body diagram, and the Amyotrophic Lateral Sclerosis Cognitive Behavioral Screen to measure global function, pain, and cognition, respectively. The covariates considered were sex, disease duration, type of symptom onset, age, and education level. Data were analysed by categorising fatigue (with and without fatigue) and considering the covariates. Comparisons, bivariate analyses, and multiple linear regression analyses were then performed. **Results:** We collected data from 72 individuals with ALS. Inferential statistics indicated differences between the fatigue categories in terms of global function, pain, and cognition. Bivariate analyses showed correlations between the independent variable and all dependent variables, as well as correlations between the covariates (except for type of symptom onset) and some of the dependent variables (P<0.20). Multiple linear regression analyses indicated a relationship between fatigue and the dependent variables. **Conclusion:** Fatigue is associated with lower levels of global function, poorer cognitive status, and higher levels of pain in a Brazilian sample of ALS patients. Additionally, age, sex, education level, and disease duration were identified as potential factors for the occurrence of fatigue, with a higher frequency observed in women compared to men with the condition.

What is the role of telerehabilitation in motor symptoms, gait and balance of individuals with Parkinson's disease? A systematic review and meta-analysis

Liliane Santos de Vasconcelos[1], Lorenna Raquel Dantas de Macêdo Borges[1], Raíssa Souza Taveira[1], Larissa Araújo Gomes[1], Maria Amanda Ferreira Quirino[1], Larissa Coutinho de Lucena[2] , Lorenna Marques de Melo Santiago[2], Tatiana Souza Ribeiro[1]

[1]Universidade Federal do Rio Grande do Norte, Natal RN, Brazil. [2]Instituto Santos Dumont, Macaíba RN, Brazil.

Correspondence: Larissa Coutinho de Lucena; Email: larissa.lucena@isd.org.br.

Background: Parkinson's disease (PD) is a common neurological condition characterized by motor symptoms affecting mobility, social interaction, and mental health. In this context, Telerehabilitation (TR) uses information

and communication technologies to support continuity of care, reduce costs, and improve accessibility for this kind of patients. While studies indicate the feasibility and efficacy of TR in PD, extensive research is still ongoing post-pandemic, and existing reviews are not yet conclusive. **Objective:** To observe the effects of telerehabilitation in individuals with PD. **Methods:** This systematic review with meta-analysis follows PRISMA guidelines and included randomized and quasi-randomized controlled trials, and crossover studies with separed data for each phase. These studies involved individuals with PD at any stage of disease and aged over 18 years old, and the considered intervention was TR through physiotherapy. The primary outcomes were considered motor function (Movement Disorders Society - Unified Parkinson's disease Rating Scale: MDS-UPDRS); gait speed (10 Meter Walk Test - 10 MWT); gait stability (Dynamic Gait Index - DGI or by the Functional Gait Assessment - FGA); and postural balance (Berg Balance Scale - BBS or by the Mini-BESTest). For continuous outcomes with consistent instruments and units, the weighted mean difference was used. When instruments and units varied, the standardized mean difference was applied, along with 95% confidence intervals. For dichotomous outcomes, such as adverse events, the odds ratio and 95% confidence intervals were used. A random-effects model was adopted for the meta-analyses, and a narrative synthesis was conducted when meta-analysis was not feasible. **Results:** A total of eight randomized clinical trials were selected, conducted between 2016 and 2021, encompassing 486 individuals (average age of 68.59 years). The therapeutic modalities applied included resistance exercises (muscle strengthening), stretching, postural balance exercises, walking, and fall prevention strategies through TR. The studies varied in session duration from 15 to 60 minutes, and in frequency from 1 to 3 times per week, and for 3 consecutive days. A meta-analysis was conducted, and TR did not have a greater effect than control group on motor function (standardized mean difference = - 1.85, 95% CI -19.08 to 15.38; p=0.03; I^2=56%), on gait speed (standardized mean difference = -0.00 95% CI -0.31 to 0.31; p=0.75; I^2=0%), on gait stability (standardized mean difference = -0.01 95% CI -0.31 to 0.33; p=0.95; I^2=0%) and postural balance (standardized mean difference=0.09; 95% CI=-0.27 to 0.45; p=0.12; I^2=48%). **Conclusion:** TR did not demonstrate to be an effective physical therapy intervention to promote improvement in the outcomes analyzed in the population of individuals with PD in this study.

Whole exome sequencing identifies SIN3A variant in a atypical Witteveen-Kolk syndrome patient: a case report

Lucas Scárdua Silva[1], Luciana Cardoso Bonadia[1], Alberto Rolim Muro Martinez[1], Clarissa Lin Yasuda[1], Iscia Lopes-cendes[1], Fernando Cendes[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Lucas Scárdua Silva; Email: scardua@unicamp.br.

Background: The Witteveen-Kolk syndrome is usually characterized by growth or feeding difficulties and possible brain malformation with developmental delay or intellectual disability. Epilepsy, psychiatric illnesses and dysmorphic facial features may accompany it, like a tall, broad forehead, down-slanting palpebral fissures, triangular face, pointed chin, and thin upper lip. Witteveen-Kolk is typically associated with variants of the SIN3A gene. **Objective:** To present a case of an adult male patient with an atypical Witteveen-Kolk syndrome, diagnosed with clinical and molecular methods. **Methods:** We performed whole exome sequencing (WES) in the patient's DNA extracted from peripheral blood. Variants of interest were selected and classified according to the ACMG recommendation. **Results:** The patient presented temporal lobe epilepsy, without brain malformation, associated with scapular, pectoralis major and sural bilateral muscular atrophy and weakness. He also presented some genetic marks as down-slanting palpebral fissures, a broad forehead and a triangular chin. Two maternal uncles presented with epilepsy, although his siblings and parents did not have epilepsy. He presented an electroneuromyography from 2008, which yielded a possible metabolic or muscular pattern. We identified a variant in the molecular analysis, c.1609C>T, p.R537* (NM_001145358.2) in SIN3A gene after analysis of the patient´s WES data. The variant was classified as pathogenic according to ACMG criteria: PM2- absent in population databases; PVS1-Null variant in a gene where the loss of function is a known disease mechanism and PS4- the prevalence of the variant in affected individuals is significantly increased compared to the prevalence in controls, Sanger sequencing confirmed the presence of the variant in a heterozygous state. No other pathogenic or likely pathogenic variants that could explain the phenotype were found. **Conclusion:** We report here a patient with a pathogenic variant in the SIN3A gene. The SIN3A gene encodes a transcriptional regulatory protein and has been definitely associated with intellectual disability syndrome. The Witteveen-Kolk syndrome has few muscular dystrophy-associated cases in the literature; future cases may help to better describe this additional phenotype.

https://doi.org/10.5327/CBN241771

Wilson's disease mimicking essential tremor: a case report

Rafael Bastos Delgado[1], Maria Julia dos Santos[2], Regina Maria Papais Alvarenga[1], Marina Papais Alvarenga[1]

[1]Universidade de Vassouras, Vassouras RJ, Brazil. [2]Faculdade de Medicina de Catanduva, Catanduva SP, Brazil.

Correspondence: Rafael Bastos Delgado; Email: 16rafaelbastos@gmail.com.

Case presentation: A 43-year-old mixed-race woman from Rio de Janeiro was referred to the demyelinating diseases center in January 2024 with suspected multiple sclerosis. She reported starting a depressed mood in 2020, which she attributed to her husband's death from COVID-19. Simultaneously, she noticed hand tremors, weakness in all four limbs, and dizziness. She consulted an orthopedist who ordered electromyography (normal). In 2021, she was evaluated by a neurologist who first requested brain magnetic resonance imaging (MRI), showing scattered T2 and FLAIR hypersignal focus in the white matter adjacent to the lateral ventricles, with a nonspecific appearance. Additionally, there was T2 hypersignal without venous contrast enhancement or signs of diffusion restriction along the corticospinal tract extending from the thalamus through the midbrain to the pons bilaterally, also with a nonspecific appearance. Subsequent MRI scans in 2022 and 2023 showed the same images, suggesting metabolic changes such as copper accumulation disease. The patient denied prior neurological or systemic diseases, family history, and parental consanguinity. Neurological examination revealed postural and action tremors in the upper limbs, asymmetrically more pronounced in the left upper limb. Head tremors were also observed in denial. Tone, strength, reflexes, cranial nerves, and sensation were normal. The patient was lucid and oriented in time and space. Given the patient's extrapyramidal syndrome and MRI findings with a "panda face sign", Wilson's disease was suspected. Test results indicated reduced ceruloplasmin (13.3 mg/dL; normal range = 20-60 mg/dL), elevated urinary copper (209.1 mcg/L; normal range = up to 80 mcg/L), normal serum copper (91 mcg/dL; normal range = 76-152 mcg/dL), and presence of Kayser-Fleischer rings. Total abdominal ultrasound and liver function tests were normal. **Discussion:** We report a rare case of late-onset Wilson's disease with exclusive neurological presentation and essential tremor phenotype. The average age of onset in Brazil is 19 years, with onset after 40 years being rare. The patient presented with action and postural tremors typically associated with essential tremor, highlighting the importance of MRI in apparently benign cases. The absence of hepatic manifestations is uncommon, as most patients initially have liver involvement. **Final comments:** This case illustrates the phenotypic variability of Wilson's disease and the importance of differential diagnosis, especially in late-onset neurological presentations without a family history. Given that effective treatment exists for this disease, delays in diagnosis in atypical clinical presentations can be detrimental to quality of life and lead to severe neurological and hepatic complications.

Wolfram syndrome: a rare multisystemic autosomal recessive disease case report

Lucas Araujo Limongi Horta[1], Breno Sousa Paiva[1], Mackeyle Siqueira de Souza[1], Sávio Cesar Rodrigues Pestana[1], Lucas Grobério Moulim de Moraes[1]

[1]Universidade Federal do Espírito Santo, Vitória ES, Brazil.

Correspondence: Sávio Cesar Rodrigues Pestana; Email: saviocesar05@gmail.com.

Case presentation: A 51-year-old Caucasian male with persistent dysglycemia was diagnosed with insulin-dependent diabetes mellitus at age six. During adolescence, he experienced a progressive decline in visual acuity over months to years, resulting in bilateral blindness. Ophthalmologic evaluation revealed bilateral optic nerve atrophy. In his second decade of life, the patient developed gradual, asymmetric sensorineural hearing loss of neurodegenerative origin. At age 20, a severe hypoglycemic event caused by inadvertent exogenous insulin administration led to hypoglycemic encephalopathy, resulting in transient coma. Due to a family history of Wolfram Syndrome (two siblings), this diagnosis was considered and confirmed through genetic testing. In his fourth decade, he reported neurological complaints, notably forgetfulness related to daily activities, and displayed progressive ambulatory difficulties, including impaired balance and a wide-based gait, requiring wheelchair use by age 45. In subsequent years, following an acute ischemic stroke, the patient developed dysphagia, REM sleep behavior disorder, urinary incontinence, and constipation. Additionally, he experienced focal seizures with secondary generalization, with presumed structural origin. **Discussion:** Wolfram syndrome (WFS) or DIDMOAD (Diabetes Insipidus, Diabetes Mellitus, Optic Atrophy, and Deafness), is a rare genetic disorder with these primary features. It can also involve neurological and psychiatric disorders and progressive neurodegeneration. The disease's severe neurological progression often leads to premature death, typically due to respiratory failure. WFS is an autosomal recessive condition associated with mutations in two genes, defining its subtypes: Wolfram syndrome-1 (WFS1) and Wolfram syndrome-2 (WFS2). WFS1, the classical form, is caused by mutations in the WFS1 gene, encoding the wolframin protein. WFS2, caused by mutations in the CISD2 gene, differs from WFS1 by presenting with bleeding, upper intestinal ulcers, defective platelet aggregation, and the absence of diabetes insipidus and psychiatric disorders. In the presented case, typical of WFS1, the initial symptom was diabetes mellitus, followed by visual acuity loss. By the first half of the second decade of life, the patient developed optic nerve atrophy progressing to blindness, consistent with most case reports. During this period, hearing loss unrelated to diabetes mellitus and diabetes insipidus may occur, potentially leading to hydronephrosis and atony of the bladder and ureter. Eventually, neurological symptoms such as reduced or abolished reflexes, dysphagia, and seizures may appear. **Final comments:** Despite limited understanding of WFS, advancements have been made in understanding the variability in onset and progression.

WFS should be suspected in cases of optic nerve atrophy following a diagnosis of diabetes mellitus in children and adolescents, with genetic testing used for confirmation.

Worsening in attentional performance during presentation of medium-speed visual stimuli after a dialysis session

Carolina Corrêa Abramovicz[1], Gabriel da Silva Senges[1], Mario Meyer Rodrigues Fernandes[1], Ana Luiza Caldas Coutinho[1], Sergio Luiz Schmidt[1]

[1]Universidade Federal do Estado do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Carolina Corrêa Abramovicz; Email: carolinaca0226@gmail.com.

Background: The Continuous visual attention test (CVAT) is a 15-minute Go/No-go task. Previously, we demonstrated that attentional deficit in patients with End-stage kidney disease (ESKD) is restricted to high-speed presentation of stimuli [Interstimulus time intervals (ISI)] of 1 second and their RTs do not increase as tests progress (68 hours without dialysis). **Objective:** To evaluate the distribution of the RTs across the 15-minute test after a dialytic session. **Methods:** 109 ESKD and 109 controls participated in the study. The CVAT is divided into three blocks (5 minutes each). Each block presents two different target frequencies [low, 20% and high, 80% (LF and HF)] and three Interstimulus time intervals (1, 2, and 4 seconds). We conducted repeated-measures MANCOVA. Within-subject factors: Target frequency (TF) - 2 levels; ISI - 3 levels; Block - 6 levels; Time-length - 3 levels; Test/Retest - 2 levels. Between-subject factor: Group (ESKD and controls). In case of a significant interaction between the Group and one of the within-subjects factors, subsequent ANCOVAs were performed. **Results:** After a dialysis session, the patients' RTs showed a statistically and clinically significant increase during ISI = 2 s (F=7.541, df=1.524, P=0.002). This result did not depend on the TF. Additionally, their RTs increased throughout the 15-min CVAT. **Conclusion:** ESKD patients' RTs remained impaired during ISI = 1 s (high-speed) and worsened during ISI = 2 s (middle-speed). These findings suggest a fatigue effect caused by the dialysis session.

https://doi.org/10.5327/CBN241774

Years lived with migraine disability in the fourth decade of life in Brazil: a five-year analysis

Hálisson Ferreira Freitas Filho[1], Felipe José Silva e Silva[1], Nathália Coimbra Coêlho[1], Izabella Carolline Menescal Ferreira[1], Luan Víctor Silva Ribeiro[2], João Victor Souza de Barros[1], Igor Moreira Miguez Godoy[3], Kaliana Kennedy Oliveira Calixto[1], Antônio Marcos da Silva Henriques[1], Larissa Suzan Basilio e Silva[1]

[1]Universidade Federal do Pará, Belém PA, Brazil.
[2]Afya Faculdade de Ciências Médicas, Cabedelo PB, Brazil.
[3]Centro Universitário Metropolitano da Amazônia, Belém PA, Brazil.

Correspondence: Hálisson Ferreira Freitas Filho; Email: halisson.filho@ics.ufpa.br.

Background: Migraine is a neurological disease characterized by repeated attacks of pain with a very variable frequency, usually associated with nausea, vomiting and sensitivity to light. With the growth of the 30-39 year-old population in Brazil, which represented 15.9% of the population in 2022, the high prevalence and great impairment in the quality of life of this comorbidity is reducing the healthy life expectancy in this age group, which can be characterized as the average number of years a person can expect to live in good health, without difficulties in carrying out certain functional activities. **Objective:** To evaluate the evolution of the rate of years lived with disability (YLDs) due to migraine in the fourth decade of life in Brazil from 2017 to 2021, identifying trends and differences in order to subsidize effective public policies. **Methods:** This is an observational, descriptive epidemiological study in which data on YLDs due to migraine from 2017 to 2021 were obtained from the Institute for Health Metrics and Evaluation (IHME) platform, in the Global Burden of Disease (GBD) section. Information on neurological diseases was selected and migraine data was filtered annually. The YLDs were calculated by multiplying the prevalence of the disease by the corresponding degree of disability. In order to carry out the appropriate correlation with the years of the fourth decade of life and the calculation of the rate per 100,000 inhabitants, the age groups, of both sexes, 30 to 34 years and 35 to 39 years, classified respectively as age group 1 and age group 2, were selected. **Results:** In the first year of analysis, 2017, for males, the highest rate was 626.34, in age group 1, and the lowest was 596.61, in age group 2. In 2018, the highest rate was in age group 1 (632.46) and the lowest in age group 2 (602.33). In 2019, the highest rate was 635.10 (age group 1) and the lowest 605.52 (age group 2). In 2020, the highest rate was 627.35 (age group 1) and the lowest 601.84 (age group 2). In 2021, the highest rate was 632.73 (age group 1) and the lowest 610.48 (age group 2). In the first year of analysis, 2017, with regard to females only, the highest rate was 1,106.94, corresponding to age group 2, and the lowest rate was 1,106.75, in age group 1. In 2018, the highest rate was found in age group 2 (1,111.08), and the lowest rate was in age group 1 (1,108.79). In 2019, the highest rate was 1,112.57, in age group 2. In 2020, the highest rate was 1,111.63 (age group 2), and the lowest rate was 1,103.17 (age group 1). In 2021, the highest rate was 1,122.01, continuing for age group 2. In age group 1, the rate was 1,109.24. **Conclusion:** In men, age group 1 had the highest rates in the five years analyzed, with an increase of 1.02% in the highest rates and 2.32% in the lowest rates from 2017 to 2021. In women, age group 2 had the highest rates, with an increase of 1.36% in the highest rates and 0.22% in the lowest rates over the same period.

https://doi.org/10.5327/CBN241775

Young patient with third cranial nerve palsy due to midbrain stroke: a case report

Giuliana Moro[1], Caio de Lima Ferreira[1], Mayara Tszesnioski Maçaneiro[1], Beatriz Heloisa Born[1], Maria Eduarda Dobner e Silva[1], Letícia Sonza Brun[1], Aléxia Zattar[2], Felipe Ibiapina dos Reis[1]

[1]Universidade da Região de Joinville, Joinville SC, Brazil.
[2]Hospital Municipal São José, Joinville SC, Brazil.

Correspondence: Giuliana Moro; Email: gmgiulianamoro@gmail.com.

Case presentation: A female patient, 34 years old, was admitted in a hospital with changes in left ocular motility and left hemiparesthesia in the last 24 hours, suggesting partial paralysis of the third pair of cranial nerve. Patient had a history of stroke 3 years ago, but was unable to detail the condition. Neurological examination revealed the patient to be lucid and oriented in time and space, with mRankin and previous NIHSS of 0, paralysis of the left third nerve with pupillary involvement and partial eyelid drooping. A brain Computed Tomography (CT) was performed, which only revealed the presence of arachnoid cysts in the left frontal region. The magnetic resonance imaging showed a lesion with restricted diffusion in the midbrain, suggesting an Ischemic Stroke (IS). The transthoracic echocardiogram showed microbubbles on the left side of the heart after the fourth heartbeat following the saline injection, suggestive of extracardiac shunt. Finally, the Venous Doppler ultrasound of the lower limbs showed no signs of venous thrombosis and the CT of the chest with contrast also showed no significant changes. After 8 days of admission, an IS was determined in the territory of midbrain perforators, suggestive of Patent Foramen Ovale (PFO), with no indication for further investigation or invasive procedures and no other conditions associated. According to the results, there was no cardiological indication for anticoagulation, but it suggests the possibility of complementing the diagnosis with Cardiac catheterization. The follow-up treatment and complete investigation was based in advising the patient about warning signs and symptoms, prescription of antiplatelet aggregation and analgesia and return to the monitoring results of cerebral and cervical angiography. **Discussion:** Isolated paralysis of the third cranial nerve is an uncommon condition with various differential diagnoses, such as infectious, vascular, or inflammatory diseases. The oculomotor nerve is responsible for the innervation and movement of ocular muscles and its nuclei are located in the upper midbrain region. The occurrence of an IS in the midbrain region can cause isolated paralysis of the oculomotor nerve and consequently lead to diplopia, ptosis, and mydriasis. IS can have different causes, the most common being cardioembolic. Patients with a PFO may suffer IS of cardioembolic origin and, in rarer cases, affect the circulation of the midbrain. **Final comments:** In conclusion, our case underscores the diagnostic challenges posed by the presentation of third cranial nerve palsy. The identification of a PFO in this patient shows the importance of comprehensive evaluation in cases of cryptogenic stroke. The rare association of PFO with midbrain ischemia causing third cranial nerve palsy underscores the need for comprehensive evaluation and multidisciplinary care, including cardiac catheterization, for optimal management.

Z-drugs effects for the treatment of sleep disorders

Letícia Fernandes de Freitas[1], Paulo Souza Oliveira[1], Júlia Oliveira Caldas[1], Sophia Carnavale Maciel de Lima[1], Yuri Ogi de Lima Barbosa[1], Caroline Chaves Bittencourt[1]

[1]Universidade Nove de Julho, Guarulhos SP, Brazil.

Correspondence: Leticia Fernandes de Freitas; Email: lecaff1984@gmail.com.

Background: It is known that sleep disorders are exponentially prevalent throughout the world, ranging from 37.2% to 69.4% in adults, which is the majority affected population. Many studies have been carried out to investigate the etiology and adequate treatment of these disorders, but it has only been found that their origin is multifactorial and, currently, the most prescribed treatment is the Z drugs, represented by zolpidem, zopiclone and zaleplon. However, the effects of these medications in the treatment of sleep disorders must be analyzed, considering their benefits, but also their dangers for neurophysiology in the long term, compared with other medications, such as benzodiazepines. **Objective:** This research is up to analyze the effectiveness of Z drugs in the treatment of sleep disorders. Furthermore, the mechanisms of action of Z drugs on the central nervous system and their impact on sleep patterns should be investigated. **Methods:** The research was made through databases on sites such as BMC Medicine, Springer Links and PubMed/MEDLINE about the effects of Z drugs in the treatment of sleep disorders, following the Guidelines of Preferential Report Items for Systematic Reviews and Meta- Analysis [PRISMA], as proposed by Moher et al. (2009) and Higgins and Green (2011). **Results:** When carrying out the study, it was observed that prescriptions for Z drugs were greater than prescriptions for other

hypnotics, such as benzodiazepines, for the treatment of insomnia. These drugs were mostly prescribed by non-psychiatric doctors and for a longer period than recommended, as many patients were advised to continue the medication for a month or more. From this perspective, harmful effects were observed in patients using these drugs, who reported at least one side effect,. Thus, although Z drugs are currently considered the best choice for treating insomnia, caution and better knowledge on the part of health professionals about their effects are still necessary. **Conclusion:** Based on the analyzed information for insomnia treatment, it is deemed necessary to consider the risks and benefits of the medications used. For older adults, controlled-release melatonin and doxepin are recommended as first-line agents, while Z-drugs should be reserved for use if first-line agents are ineffective. It is important to avoid the use of benzodiazepines in insomnia treatment due to factors such as high tolerance and dependence rates, potential cognitive side effects, lack of long-term efficacy, and the availability of safer options for patients. Individuals with sleep apnea or chronic lung disease are advised to seek evaluation by a sleep specialist before taking sedative medications. These guidelines aim to ensure effective and safe treatment for patients with insomnia while emphasizing the importance of considering patients' experiences and preferences when prescribing hypnotic medications for insomnia.

Case presentation: A 53-year-old man with previous history of hypertension and diabetes started with a moderate-severe throbbing headache in October 2022. The pain was located in frontal head and worsened immediately after standing up and after Valsalva maneuver, accompanied by nausea, visual blurring, diplopia, gait ataxia and tinnitus. No trauma history. The patient presented to an emergency neurological care in February 2023 and cranial and spinal magnetic resonance imaging (MRI) showed indirect signs of cerebrospinal fluid (CSF) hypotension, including reduced mammillopontine distance and the descent of cerebellar tonsils through the foramen magnum. Cranial arterial and venous magnetic resonance angiography and CSF analysis revealed no abnormalities. Conservative treatment was unsuccessful. In April 2023, a blind epidural blood patch was performed and was also refractory. The patient continued to have significant orthostatic headaches and a cisternal scintigraphy in August 2023 showed leakage of radioactive material in the lumbar region. A targeted epidural blood patch was performed at the location of the lumbar CSF fistula, resulting in a good response and stability since then. **Discussion:** Spontaneous intracranial hypotension is a disorder caused by spinal CSF leakage and it typically occurs in patients in their midthirties to midfifties. The classic presentation is acute orthostatic headache, usually bilateral, which can present with migrainelike features, such as nausea and photophobia. The headache presents with moderate to severe intensity and can worse with the Valsalva maneuver. Other symptoms may include vestibulocochlear manifestations such as hypoacusis, dizziness and tinnitus, gait disturbances and cranial nerve palsies. According to the International Classification of Headache Disorders, Third Edition (ICHD-3), a diagnosis of spontaneous intracranial hypotension requires the presence of a headache that developed in temporal relation to low CSF pressure (<60mm) and/or evidence of CSF leak on imaging, in the absence of procedures or trauma. The most common complication is subdural hematoma. Several neuroimaging modalities can aid in diagnosis. Brain MRI may reveal typical findings, but CT-myelography or cisternal scintigraphy can be necessary to locate the CSF leakage. The treatment consists of conservative management such as strict bed rest, hydration and caffeine, epidural blood patches and, in refractory cases, surgical repair of spinal fistula. **Final comments:** Spontaneous CSF hypotension is rare but debilitating and should be promptly recognized. It typically presents with acute orthostatic headache but can have another associated symptoms. Currently, the epidural blood patch is the treatment of choice, especially when targeted to the exact location of the CSF leakage, resulting in good pain control and improved quality of life.

Correspondence: Laura Mariana Araújo do Amaral; Email: laurithia@hotmail.com.

Case presentation: A 51-year-old man, R.C.L.J, smoker, drinker, without comorbidities, a porter, and gardener. He was admitted to the hospital with a holocranial headache lasting for 02 months, with no precedents and gait alteration/difficulty; admission due to loss of strength in the left half of the body. Cranial nerve alterations with paresis and deviation of the tongue to the right, exophthalmos, ptosis, Babinski and Chaddock signs on the left, and signs of upper motor neuron syndrome on physical examination. Whole-body CT revealed lung lesions and a left occipitoparietal nodular lesion, both with characteristics suggestive of neoplasms or infection.Additionally, cranial CT showed multiple expansive lesions in the brain parenchyma and brainstem, with ring enhancement after contrast injection.Histopathology showed lymph nodes with architectural subversion and the presence of several granulomas with areas of necrosis compatible with the fungus causing PCM.Finally, brain MRI revealed cortical granulomas in both hemispheres, a lesion in the brainstem affecting the medulla, pons, and midbrain, a larger temporo-occipital lesion, and a left frontal lesion. The association of histological findings, previously presented symptoms with similar involvement of the CNS and lungs led to the diagnosis of NP.A 4-week treatment with intravenous amphotericin B was performed with subsequent clinical improvement, followed by maintenance itraconazole (200 mg oral tablet once daily) proposed for 12 months. **Discussion:** Paracoccidioidomycosis (PCM) is a systemic disease of fungal etiology caused by thermally dimorphic microorganisms of the genus Paracoccidioides, and its prevalence is significant in Latin America, especially in Brazil, with over 70% of cases.One of the main predictors of infection is middle-aged men and farmers, given that the fungus is saprophytic in soil.A systematic review demonstrated that the most affected site is the lungs, although cutaneous, lymph node, adrenal, and even central nervous system (CNS) lesions can also occur, characterizing neuroparacoccidioidomycosis (NP).The latter can present with intense headache, seizures, sensory, motor, cognitive, and cerebellar changes.The definitive diagnosis of PCM is achieved by isolating the fungus through biopsy or necropsy, but the complexity and applicability of these methods converge on a diagnosis based on evidence of involvement of other organs associated with symptoms and neurological imaging such as CT and/or MRI.In this context, a case report is presented aiming to clarify concrete and effective diagnostic methods, given the difficulty in managing patients with NP. **Final comments:** PCM is a systemic disease with relatively low CNS prevalence; thus, NP, despite low mortality, presents high morbidity with long-term sequelae, generating health burden. Therefore, the relevance of understanding the pathology and the importance of diagnostic efficacy for appropriate management are perceived.

Immunotherapy in the treatment of Alzheimer's disease: a systematic review

Danilo Golfeto Dourado[1], Laura Dellagnesi Depieri[1], Felipe Iankelevich Baracat[1], Igor Nobre Cruz[1],

Correspondence: Igor Nobre Cruz; Email: igornobrecruz@gmail.com.

Background: Alzheimer's disease (AD) is a progressive and irreversible neurodegenerative disorder characterized by multiple cognitive deficits. It is marked by the accumulation of neuritic plaques and neurofibrillary tangles in the brain, primarily due to the build-up of beta-amyloid peptide (Aβ42) and tau protein (p-tau). AD affects millions of people and is a leading cause of disability and morbidity in the elderly population. Immunotherapy involves monoclonal antibodies, which are proteins that bind to Aβ42 to facilitate its removal from the brains of patients with AD. Current studies on immunotherapy are promising; however, there is no consensus on its therapeutic potential. Therefore, this review aims to elucidate the effects of this intervention on modifying therapies for Alzheimer's Disease. **Objective:** To compare the efficacy of monoclonal antibody immunotherapy versus placebo in the treatment of patients with AD through randomized clinical trials. **Methods:** The systematic review protocol was conducted according to the recommendations of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA). Searches were conducted in the PubMed and Embase databases. Randomized clinical trials comparing the efficacy of monoclonal antibody immunotherapy and placebo in the treatment of AD patients were included. The outcomes evaluated were changes in the Clinical Dementia Rating Scale Sum of Boxes (CDR-SB) and Alzheimer's Disease Assessment Scale–Cognitive Subscale (ADAS-Cog13). Two independent reviewers performed study selection, data extraction, and risk of bias assessment, with a third reviewer resolving any discrepancies. The JADAD scale was applied to assess the methodological quality and risk of bias of the studies. **Results:** The search identified 2738 studies, of which 2709 were excluded based on title and abstract evaluation, while 29 were read in full. The main exclusion criteria were study design, thematic inadequacy, duplicates, and the absence of a comparison between monoclonal antibody use and placebo. To date, 22 clinical trials have been included in this review. Among these, 6 studies demonstrated a reduction in p-tau levels associated with immunotherapy, and 2 of them also showed a slower clinical decline compared to placebo; 2 studies independently associated monoclonal antibodies with a better composite score for cognition. Fourteen other studies did not present significant differences. However, interpretation should be cautious, as these results are partial. **Conclusion:** To date, the effects of immunotherapy in the treatment of AD, derived from the results, suggest a positive but limited impact compared to placebo. Nonetheless, even modest improvements justify further exploration of immunotherapy for AD.

Neurosyphilis tumefactive lesions mimicking a tumor: a case report

Ana Clara Vlakov Isper[1], Letícia Isper[1], Guilherme Bussola Carazzatto[1], Igor Nobre Cruz[1], Ana Júlia Machado Parente[2], Maria Teresa Fernandes Castilho Garcia[1], Guilherme Menezes Mescolotte[1]

[1]Universidade do Oeste Paulista, Presidente Prudente SP, Brazil.
[2]Hospital Regional de Presidente Prudente, Presidente Prudente SP, Brazil.

Correspondence: Igor Nobre Cruz; Email: igornobrecruz@gmail.com.

Case presentation: Male, 50 years old, smoker, was transferred to our emergency service after initiated, 10 days ago, a progressive and asymmetric paraparesis. After 30 days of evolution the patient had loss of sensation at T6 level, with no upper motor neuron signs, only areflexy and hypotonic finds. The patient denied recent infectious history. Cranial and spinal MRI was performed revealing bilateral solidocystic expansive injuries in the temporal lobes with significant vasogenic edema. Extensive transverse myelitis affecting from cervical to medullary cone, including a well-circumscribed intramedullary nodular formation at the T6 level. Both with contrast enhancement. Cerebrospinal fluid (CSF) analysis demonstrated high cellularity with 228/ mm^3 lymphomononuclear cells, as well as hyperproteinorrhaquia with (150mg/dL) and VDRL titers above 1/16 in CSF. Bacterial and fungal cultures of the CSF were negative, as well as the viral panel. Following confirmation of Neurosyphilis, treatment with Crystalline Penicillin was launched. Screening for Paraneoplastic Syndrome was performed with Esophagogastroduodenoscopy, Colonoscopy, CT scans of the Abdomen, Pelvis, and Chest, revealing only mediastinal and retroperitoneal lymphadenopathy. Given the mazed diagnostic, a biopsy of the temporal lesion was performed, and the tissue showed leukocytic proliferation with heterogeneous density involving intra and extra-axial compartments and a polymorphic infiltrate, predominantly lymphomononuclear. Additionally, areas of non-suppurative necrosis with peripheral granulomatous outline were found. **Discussion:** Neurosyphilis can manifest at any point in the natural history of the onset, with the most severe forms appearing in the tertiary period. This involvement was more common in HIV-positive patients, however, this evidence could not be observed in the presented case. Histologically, there is evidence of chronic inflammatory process, predominantly lymphocytes and plasma cells. Gummas formation may be observed, mimicking expansive lesionsor syphilitic lesions forming masses, which in CT or MRI images may trick primary or metastatic malignant tumors. In the reported case, arranged with clinical record, laboratory and radiological findings, and foreclosure of other possible diagnoses, it is confirmed Neurosyphilis. **Final comments:** We thus demonstrate that syphilis may pose a diagnostic challenge, due to it's wide range of manifestations and it's potential imitator. Furthermore, the clinical findings associated to it's complex management finds out to be rarer than the others, adding medical knowledge.
